# Endocrine Abstracts (www.endocrine-abstracts.org)

*Endocrine Abstracts* (ISSN 1470-3947) is published by BioScientifica, Euro House, 22 Apex Court, Woodlands, Bradley Stoke, Bristol BS32 4JT, UK.
Tel: +44 (0)1454-642240; Fax: +44 (0)1454-642201;
E-mail: editorial@endocrinology.org;
Web: www.bioscientifica.com.

Subscriptions and requests for back issues should be addressed to *Endocrine Abstracts*, Portland Press, PO Box 32, Commerce Way, Whitehall Industrial Estate, Colchester CO2 8HP, UK. Tel: +44 (0)1206-796351; Fax: +44 (0)1206-799331.

**Subscription rates 2012**

| | *Annual* | *Single part* |
|---|---|---|
| North & South America | $382 | $127 |
| Rest of the World | £191/€287 | £64/€96 |

There are two regular issues per year plus occasional additional issues. Each issue is a separate volume.

**Claims and communications**
All claims or communications regarding issues lost or damaged in transit should be addressed to Portland Press in Colchester (see above for address). This applies to both institutional and personal subscribers. No claims can be entertained if they are later than 3 months after the date of despatch.

**Disclaimer**
The material contained in each issue of the journal has been prepared and written by named authors. Accordingly, neither the conference, BioScientifica Ltd nor their officers, employees or agents are responsible for the accuracy or otherwise of any abstracts or other articles and shall have no liability for any claims, damages or losses howsoever arising from the contents or any use to which they may be put by any person. It is not possible to guarantee that the abstracts printed in this issue will be presented at the conference.

Cover design by Rumba Graphic Design Ltd, Bristol, UK.

Typeset by OKS Prepress Services, Chennai, India.
Printed by Latimer Trend & Company Ltd, Plymouth, UK.

Printed on acid-free paper.

**Advertisements**
Applications for advertisement space should be sent to Advertisement Department, BioScientifica Ltd, Euro House, 22 Apex Court, Woodlands, Bradley Stoke, Bristol-BS32 4JT, UK. Tel: +44 (0) 1454-642269; Fax: +44 (0)1454-642201;
E-mail: advertising@endocrinology.org. Copy is required 6 weeks before publication date. Rates are available on request.

**USA Postmaster:** send address corrections to *Endocrine Abstracts*, c/o Mercury International, 365 Blair Road, Avenel, New Jersey 07001. Periodicals postage is paid at Rahway New Jersey and at additional mailing offices.

All despatches outside the UK are sent by air-speeded service.

**Citing *Endocrine Abstracts***
When citing abstracts from this publication please include the names of the authors, year of publication, abstract title, name of this publication i.e. *Endocrine Abstracts*, volume and abstract number: e.g. Stewart P 2001 A tale of two enzymes. *Endocrine Abstracts* **2** SP2.

# CONTENTS

## *15th International & 14th European Congress of Endocrinology (ICE-ECE 2012)*

### PRIZE LECTURES AND BIOGRAPHICAL NOTES

The European Journal of Endocrinology Prize Lecture . . . . . EJE1
The Geoffrey Harris Prize Lecture . . . . . GH1
The IPSEN Foundation Prize Lecture . . . . . IFPL1

### PLENARY LECTURES

Red wine Endocrinology . . . . . PL1
Testosterone more than sex . . . . . PL2
Mating, sex and the immune system in humans and fish . . . . . PL3
. . . . . PL4
Why your bones break - from childhood to old age . . . . . PL5
Maternal nutrition, metabolism and fetal programming . . . . . PL6
Diabetes as a gut disease . . . . . PL7
Novel molecular link between the circadian clock and hypertension . . . . . PL8

### SYMPOSIA

Molecular mechanisms of differentiated thyroid cancer . . . . . S1.1–S1.3
40 years of male hormonal contraception research and no product . . . . . S2.1–S2.3
Absolute fracture risk assessment with FRAX . . . . . S3.1–S3.3
The gut nutrient sensing in energy metabolism . . . . . S4.1–S4.3
Transition from paediatric to adult care - do we have progress? . . . . . S5.1–S5.3
Subclinical adrenal diseases . . . . . S6.1–S6.3
Hormones, metabolism and cancer: more than coincidences? . . . . . S7.1–S7.3
Global phenotypes of endocrine disease . . . . . S8.1–S8.3
The risk and benefits of tight glycaemic control . . . . . S9.1–S9.3
Thyroid: From fetal life to adulthood . . . . . S10.1–S10.3
Novel genetic and endocrine insights in the Klinefelter's syndrome . . . . . S11.1–S11.3
Determinants of peak bone mass . . . . . S12.1–S12.3
Novel therapies for protecting beta cell function at diagnosis of type 1 diabetes . . . . . S13.1–S13.3
Wnt/Beta-catenin in pituitary development and disease . . . . . S14.1–S14.3
Adrenal cancer . . . . . S15.1–S15.3
Understanding growth . . . . . S16.1–S16.3
Hormonal control of pregnancy . . . . . S17.1–S17.3
Molecular mechanisms in autoimmune thyroid disease . . . . . S18.1–S18.3
Controversies in testosterone replacement . . . . . S19.1–S19.3
Signalling to and from osteoclast . . . . . S20.1–S20.3
Obesity and reproduction . . . . . S21.1–S21.3
Pituitary tumorigenesis . . . . . S22.1–S22.3
Advances in regulation of aldosterone synthesis . . . . . S23.1–S23.3
ManagemDiabetes in children . . . . . S24.1–S24.3
Reproductive hormone action . . . . . S25.1–S25.3
TSH Receptor . . . . . S26.1–S26.3
Are endogenous testosterone levels predictors of cardiovascular events? . . . . . S27.1–S27.3
Osteoporosis treatment in 2012 and beyond . . . . . S28.1–S28.3
Are we ready for novel therapies in obesity? . . . . . S29.1–S29.3
New developments in pituitary adenomas . . . . . S30.1–S30.3
Progress in treatment in primary aldosteronism . . . . . S31.1–S31.3
Disorders of sex development (DSD) . . . . . S32.1–S32.3
Pollution Related Acromegaly . . . . . S33.1–S33.3

Effects of thyroid hormone derivatives . . . S34.1–S34.3
Endocrinology and the Olympics: Will hormones help to win? . . . S35.1–S35.3
Bone and metabolism . . . S36.1–S36.3
Diabetes and cancer . . . S37.1–S37.3
Craniopharyngioma: Hypothalamic complications . . . S38.1–S38.3
Adrenal insufficiency . . . S39.1–S39.3
New familial endocrine cancer syndromes: pathophysiology and counselling . . . S40.1–S40.3
The endocrinology of adipose tissue . . . S41.1–S41.3
Novel insights into regulation of puberty . . . S42.1–S42.3
Graves' orbitopathy (GO) . . . S43.1–S43.3
Genome wide studies in reproduction . . . S44.1–S44.3
Bone quallity and bone strength . . . S45.1–S45.3
Chronic inflammation and insulin resistance . . . S46.1–S46.3
Cushing's syndrome . . . S47.1–S47.3
Pathogenesis of primary aldosteronism . . . S48.1–S48.3
Genetic breakthroughs in reproductive pathology and physiology . . . S49.1–S49.3
Circadian regulation of metabolism . . . S50.1–S50.3
Recent management of pheochromocytoma / paraganglioma syndrome . . . S51.1–S51.3
Thyroid & Pregnancy . . . S52.1–S52.3
Genetic polymorphism in reproduction . . . S53.1–S53.3
Vitamin D . . . S54.1–S54.3
The fatty liver as an endocrine disease . . . S55.1–S55.3
Pituitary development transcription factors: stem cells and beyond . . . S56.1–S56.3
What's new in congenital adrenal hyperplasia (CAH)? . . . S57.1–S57.3
Best Clinical Practice . . . S58.1–S58.3
Obesity and thyroid function . . . S59.1–S59.3
Performance enhancing hormones in sports . . . S60.1–S60.3
New insights in thyroid cancer diagnosis . . . S61.1–S61.3
Early Development and Treatment of PCOS . . . S62.1–S62.3
Emerging ideas about phosphate metabolism . . . S63.1–S63.3
Endoplasmic Reticulum Stress, Obesity and Metabolic Homeostasis . . . S64.1–S64.3
Somatostatin receptors in pituitary . . . S65.1–S65.3
HPA axis, stress metabolism and adaptation . . . S66.1–S66.3
Central regulation of energy homeostasis . . . S67.1–S67.3
European network for the study of adrenal tumours (ENSAT) . . . S68.1–S69.3
Current progress in the management of thyroid cancer . . . S69.1–S69.3
Young Active Researchers Symposium (YAR) . . . S70.1–S70.5

**ENDOCRINE NURSE SYMPOSIUM** . . . 1.1–3.2

**JOE/JME PRIZE PRESENTATION Sponsored by *Journal of Endocrinology*** . . . JP1

**MEET THE EXPERT SESSIONS** . . . MTE1–MTE32

**ORAL COMMUNICATIONS**

Pituitary Clinical I . . . OC1.1–OC1.6
Thyroid Clinical I . . . OC2.1–OC2.6
Diabetes Clinical . . . OC3.1–OC3.6
Pituitary Basic . . . OC4.1–OC4.6
Obesity Basic . . . OC5.1–OC5.6
Female Reproduction Basic . . . OC6.1–OC6.6
Adrenal Clinical . . . OC7.1–OC7.6
Bone . . . OC8.1–OC8.6
Endocrine Tumours & Translation . . . OC9.1–OC9.6
Pituitary Clinical 2 . . . OC10.1–OC10.6

# European Society of Endocrinology

*the European hormone society*

**The European Society of Endocrinology promotes research, education and clinical practice in endocrinology. It aims to strengthen endocrinology by enabling scientists and doctors across Europe to work together more successfully by providing high-quality education and communication opportunities. The European Society of Endocrinology is a charity and a company limited by guarantee.**

- ESE represents and incorporates the full breadth of endocrinology throughout its activities, which includes not only the core endocrine diseases but also diabetes, metabolism & obesity, bone & calcium, reproduction, and oncology; and through balancing the coverage of common and rare endocrine diseases.
- ESE is the natural home for researchers, clinicians, students, nurses and pharmaceutical companies working in the field of endocrinology and hormonal systems, supporting them through its activities such as education and grants.
- ESE is a community which provides the 'voice of endocrinology', promoting ESE and the understanding of endocrinology to endocrinologists, to European legislative and funding bodies and by providing the public with information on endocrinology, and by supporting endocrine nurses and patient advocacy groups.

### ESE Vision Statement

The European Society of Endocrinology exists to support research, education and patient care in endocrinology and it will continue to achieve this by promoting excellence in endocrine science and medicine and by providing public information on endocrinology.

ESE has a distinctive European flavour, creating an inclusive community that takes advantage of the diversity found within Europe. It will be an innovative society that responds rapidly to the changing needs of clinicians and researchers. It will also provide authoritative and independent information to the public.

## Major activities

Major activities include the annual European Congress of Endocrinology and training courses which provide outstanding updates for basic scientists and clinicians. The Society also runs regular postgraduate educational courses aimed at both basic scientists and clinicians.

## Save the Dates!

**12th ESE Postgraduate Course in Clinical Endocrinology**

Antalya, Turkey
18-21 October 2012

**Summer School on Endocrinology**

Bregenz, Austria
5-9 August 2012

## Membership

### Ordinary Membership

Open to researchers, clinicians and students with an interest in the field of endocrinology and hormonal systems. In particular, the Society welcomes early-career endocrinologists, endocrine nurses and basic scientists.

**Benefits of ordinary membership include:**

- **Free online access to all five official ESE journals:** *European Journal of Endocrinology, Journal of Endocrinology, Journal of Molecular Endocrinology, Endocrine-Related Cancer* and *Endocrine Connections*, an interdisciplinary Open Access journal, launched in 2012
- Reduced rate print subscription to the *European Journal of Endocrinology, Journal of Endocrinology, Journal of Molecular Endocrinology* and *Endocrine-Related Cancer*
- Reduced rate registration to the European Congress of Endocrinology and any other ESE events
- Access to ESE Prizes, Grants and Awards
- Access to a Members' only section with access to a web-based directory of European endocrinologists
- Tri-annual newsletter and regular email alerts advising of news and grants
- Grants forum
- Voting rights and attendance at general meetings

### Affiliated Society Membership

ESE values its links with the 43 national endocrine societies and 10 specialist societies that are currently members.

Membership is open to national endocrine societies in Europe and in countries bordering the Mediterranean sea as well as pan-European and international sub-specialist endocrine societies.

### Corporate Membership

Corporate membership is open to companies working in the field of endocrinology. Thank you to all our Corporate Members for their generous and continued support of ESE and activities:

- Amgen
- CMM Global
- Eli Lilly
- Ipsen
- Laboratoire HRA Pharma
- Merck Serono
- Novartis
- Novo Nordisk
- Otsuka Pharmaceuticals Europe Limited
- Pfizer
- Roche
- Sandoz International Gmbh
- ViroPharma SPRL

# Grants

## ESE Meeting Grant

ESE offer 50 ESE Meeting Grants per year, worth up to €400 each, for ESE members to attend an ESE meeting. The grant is made as a contribution towards the total cost of attending either the annual European Congress of Endocrinology (ECE) or an ESE Training Course in accordance with the eligibility criteria.

## ESE Basic Science Meeting Grant

ESE is making every effort to bring basic scientists to its annual meeting by the introduction of the ESE Basic Science Meeting Grant. ESE offer 100 ESE Basic Science Meeting Grants per year worth up to €450 each for ESE members who are basic scientists to attend the annual European Congress of Endocrinology (ECE) in accordance with the eligibility criteria.

# Journals

The Society has five official journals; between them they cover the full spectrum of endocrinology and help to raise the profile of European endocrinology.

## *European Journal of Endocrinology*

The official clinical journal of the European Society of Endocrinology. The journal publishes original research papers, reviews, short communications and case reports within clinical endocrinology. Invited commentaries also feature regularly. 'Highlights' are concise summaries of new breakthroughs. ESE members receive free online access to the journal.
**IMPACT FACTOR: 3.482** *(as at 2010)*

## *Journal of Endocrinology*

*Journal of Endocrinology* provides a wide coverage of research in all aspects of endocrinology. It is in the top ranks of global endocrine journals and publishes high quality, leading-edge research from all over the world.
**IMPACT FACTOR: 3.099** *(as at 2010)*

## *Journal of Molecular Endocrinology*

*Journal of Molecular Endocrinology* provides a forum for papers devoted to describing molecular mechanisms by which hormones and related compounds regulate physiological and pathological processes. JME publishes high quality, leading-edge research from all over the world and its readership is worldwide.
**IMPACT FACTOR: 3.628** *(as at 2010)*

## *Endocrine-Related Cancer*

*Endocrine-Related Cancer* offers a global forum for basic, clinical and experimental investigations which concern endocrine-related cancer in human and animal subjects. **IMPACT FACTOR: 4.432** *(as at 2010)*

## *NEW for 2012*

## *Endocrine Connections*

A new Open Access journal which offers authors the highest possible visibility for their work and stimulating cross-discipline collaboration.

The European Society of Endocrinology is collaborating with the UK Society for Endocrinology to launch *Endocrine Connections* a new, interdisciplinary, Open Access journal in Spring 2012. The journal focuses on articles that have relevance across the many disciplines that intersect with endocrinology. The broad scope encompasses metabolism, obesity, diabetes, hormones, reproduction and bone disorders.

# Executive Committee

ESE is governed by an Executive Committee, members of which have been elected by members of the ESE, thus representing a broad range of endocrine interests and a wide geographical area of Europe and ensuring fair representation. The ESE Officers are:

*President*
**Phillipe Bouchard**, France, 2011-2015

*Vice President*
**Paolo Beck-Peccoz**, Italy, 2009-2013

*Treasurer*
**Aart J van der Lely**, The Netherlands, 2008-2012

*Secretary*
**Barbara Jarzab**, Poland, 2010-2014

*Acting Secretary*
**Justo Castaño**, Spain, 2010-2014

## ESE Committees

In addition to the Executive Committee there are 9 specialist committees.

Clinical Committee, currently chaired by **Pia Burman**

Congress Committee, currently chaired by **Martin Reincke**

Corporate Liaison Committee, currently chaired by **Jens Christiansen**

Education Committee, currently chaired by **Peter Trainer**

International Liaison Committee, currently chaired by **Philippe Bouchard**

Nominations Committee, currently chaired by **Andrea Giustina**

Publications Committee, currently chaired by **Paolo Beck-Peccoz**

Science Committee, currently chaired by **Ilpo Huhtaniemi**

European Young Endocrine Scientists (EYES) Committee, currently chaired by **Jens Mittag** (until May 2012) and then **Dominik Schulte** (until May 2014)

A full list of Executive Committee and Committee members is available on the ESE website.

**Further information about ESE can be found at www.ese-hormones.org or by contacting the ESE Secretariat at info@euro-endo.org.**

Registered Office: European Society of Endocrinology, Euro House, 22 Apex Court, Woodlands, Bradley Stoke, Bristol BS32 4JT, UK. The European Society of Endocrinology is a charity and a company limited by guarantee.

Registered Charity No. 1123492

# Prize Lectures and Biographical Notes

# The *European Journal of Endocrinology* Prize Winner

Professor Sadaf Farooqi, PhD, FRCP

Sadaf Farooqi qualified with Honours in Medicine from the University of Birmingham, being awarded the gold medal. After hospital posts in Birmingham and Oxford she moved to Cambridge to undertake a PhD. She identified the first single gene defect to cause human obesity in patients with a mutation in the leptin gene (Nature 1997) and described their dramatic response to leptin therapy, establishing leptin's role in the regulation of eating behaviour, puberty and immune function (NEJM 1999; SCIENCE 2007). As a Wellcome Trust Senior Clinical Fellow at the Institute of Metabolic Science in Cambridge, Professor Farooqi co-ordinates a programme of research into the genetic, molecular and physiological basis of human obesity. She has been invited to speak at numerous international meetings, is on several Editorial Boards and has been the recipient of a number of awards in recognition of her work including the RD Lawrence Award (Diabetes UK 2007), Andre Mayer Award (International Association for the Study of Obesity 2006) and the Society for Endocrinology Medal 2012.

The *European Journal of Endocrinology* Prize Lecture

# Tackling obesity: lessons from genetics

S Farooqi, Wellcome Trust Senior Clinical Fellow and Professor of Metabolism and Medicine, University of Cambridge Metabolic Research Laboratories, and NIHR Cambridge Biomedical Research Centre, Institute of Metabolic Science, Addenbrooke's Hospital, Cambridge, UK

Whilst the rise in the prevalence of obesity has been driven by environmental factors, there is considerable evidence that body weight and fat mass are highly heritable traits. Differences in susceptibility to obesity between individuals have strong genetic determinants.

Our strategy has been based on studies of patients with severe obesity where we hypothesised that major highly penetrant genetic variants were likely to be playing an important role.

The identification of patients with mutations in the gene encoding the hormone leptin, and their successful treatment with recombinant human leptin, have provided insights into the role of leptin responsive pathways in the regulation of eating behaviour, the onset of puberty and T-cell mediated immunity. Leptin acts by regulating a complex network of brain responses that can be studied using functional imaging, to co-ordinate changes in nutritional state with changes in food intake and the liking of food. A downstream target of leptin action, the melanocortin 4 receptor (MC4R), plays a key role in modulating sympathetic nervous system mediated changes in blood pressure.

Recently, genome wide approaches are proving to be an increasingly important tool in understanding the genetic heterogeneity associated with obesity. The discovery of how genetic variation at an individual and at a population level contributes to weight gain will drive further understanding of the molecular and physiological pathways involved in weight regulation.

# The Geoffrey Harris Prize Winner

Professor Jonathan R Seckl, Moncrieff-Arnott Professor of Molecular Medicine and Executive Dean, College of Medicine and Veterinary Medicine, Endocrinology Unit, Centre for Cardiovascular Science, The Queen's Medical Research Institute, University of Edinburgh, Edinburgh, UK

Jonathan Seckl is both medically and scientifically qualified (MBBS at UCL, PhD at ICL). A clinical endocrinologist and former Wellcome Trust Senior Clinical Research Fellow, Seckl's research (funded by successive programme grants from the Wellcome Trust, and additional programme awards from MRC, Wellcome and HFSP) focuses on glucocorticoid biology from 'cloning to clinic'. His main themes are the importance of local tissue regeneration of glucocorticoids by 11β-hydroxysteroid dehydrogenases as a cause of and therapeutic target for age-related memory impairments and the metabolic syndrome-diabetes-obesity continuum. His group advanced and supported the glucocorticoid hypothesis of fetal 'programming' and has elucidatedmolecular and epigenetic mechanisms by which this leads to subsequent disorders in adult life. Seckl has authored ~300 peer-reviewed papers (career citations >22,000; h=78), has given ~200 invited lectures at international meetings, has talked to schools, teachers groups, lay audiences and in public fora. Thirty-eight of his students have gained PhDs, several are now Professors around the globe. He has been on committees for the MRC, Wellcome Trust, RSE, RS, UK charities, the EU, the Scottish Government, and the Councils of the Academy of Medical Sciences and the Society for Endocrinology.

The Geoffrey Harris Prize Lecture

# Glucocorticoid metabolism and the brain, from fetal programming to senescence

Jonathan R Seckl, Endocrinology Unit, Centre for Cardiovascular Sciences, University of Edinburgh, Queens Medical Research Institute, Edinburgh EH16 4TJ, UK.

Chronic elevation of glucocorticoids adversely impacts on cognition and the integrity of hippocampal cells. Moreover, inter-individual differences in memory with ageing correlate directly with blood glucocorticoid levels in rodents and humans. Beyond plasma steroid levels, glucocorticoid action on target tissues is determined by the density of nuclear receptors and by intracellular metabolism by 11β-hydroxysteroid dehydrogenases (11β-HSDs) which catalyse interconversion of active cortisol (corticosterone in rodents) and inert cortisone (11-dehydrocorticosterone). In the fetal CNS and placenta 11β-HSD2 predominates. This isozyme catalyses the rapid inactivation of glucocorticoids and acts as a 'barrier' to steroid access to receptors. Inhibition, knockout, bypass or down-regulation (maternal stress, inflammation or malnutrition) of feto-placental 11β-HSD2 allows excess glucocorticoid action on the fetus which 'programmes' many organs, notably the brain. The offspring show affective and cognitive deficits throughout life. Similar effects are seen in the offspring of women who consume liquorice-based 11β-HSD inhibitors in gestation.

In the adult brain 11β-HSD type 1 predominates. This catalyses the reverse reaction, regenerating active steroids and thus amplifying intracellular glucocorticoid action. 11β-HSD1 inhibition protects hippocampal cells from neurotoxic challenge in vitro. 11β-HSD1 is elevated in aged rat hippocampus and correlates with the degree of cognitive decline suggesting an aetiological role. Importantly, 11β-HSD1 null mice resist glucocorticoid-associated cognitive impairments with ageing. Indeed the 11β-HSD inhibitor carbenoxolone improves cognitive performance in elderly humans. Early results suggest selective 11β-HSD1 inhibitors improve memory in aged rodents and even modify pathogenesis in models of Alzheimer's disease. 11β-HSD1 inhibition appears a promising target for therapy of age-related cognitive disorders.

Paolo Sassone-Corsi

Paolo Sassone-Corsi is Donald Bren Professor at the University of California, Irvine, where he is Director of the Center for Epigenetics and Metabolism. He is also External Member of the Max-Planck Institute, Germany. Paolo Sassone-Corsi is an internationally recognized leader in the field of genetics and cell biology. After his PhD in Italy, he has spent time in France and at the Salk Institute (San Diego, CA). He started his research group in Strasbourg, France, where he was Director of Research, before moving back to California in 2006. Early in his career he became fascinated by the world of DNA and gene expression, a field that was beginning to be unraveled at the time, and that he felt had to embody all fundamental facets of cellular and organismal physiology. His research on the regulation of gene expression has been essential to elucidate a remarkable variety of molecular mechanisms, all highly relevant to the fields of endocrinology, neuroscience, metabolism and cancer. All organisms adapt to the environment by readjusting their physiology and metabolism. This plasticity includes chromatin remodeling and epigenetic reprogramming and leads to changes in the activity of genes. Epigenetic processes demonstrate that there is much more to the genome than DNA sequence, permitting plasticity beyond the double helix. The work by Paolo Sassone-Corsi during the past 20 years has been influential and trend-setting, leading to many awards, including the EMBO Gold Medal, the highest recognition for a European molecular biologist. He has been also awarded the Charles-Leopold Meyer Prize of the Academie des Sciences (Paris), the Edwin Astwood Award and the Roy O. Greep Award of the Endocrine Society (USA), the CNRS Medal (France), the Grand Prix Bettencourt for Medical Research and the Endocrine Prize of the Ipsen Foundation.

The IPSEN Foundation Prize Lecture

# Common Threads: Epigenetics, Metabolism and the Clock

Paolo Sassone-Corsi, Center for Epigenetics and Metabolism, University of California, Irvine, California 92697, USA. psc@uci.edu,

Circadian rhythms govern a number of fundamental physiological functions in almost all organisms, from prokaryotes to humans. The circadian clocks are intrinsic time-tracking systems with which organisms can anticipate environmental changes and adapt to the appropriate time of day. Disruption of these rhythms can have a profound influence to human health and has been linked to depression, insomnia, jet lag, coronary heart disease, neurodegenerative disorders and cancer. At the heart of circadian regulatory pathways is the clock machinery, a remarkably coordinated transcription-translation system that utilizes also dynamic changes in chromatin transitions and epigenetic control. Recent findings indicate that regulation goes also the other way, since specific elements of the clock are able to sense changes in the cellular metabolism. Understanding in full detail the intimate links between cellular metabolism and the circadian clock machinery will provide not only critical insights into system physiology and endocrinology, but also novel avenues for pharmacological intervention towards metabolic disorders.

## Testosterone – more than sex

### PL2

**Testosterone: more than sex**

M. Maggi
Sexual Medicine and Andrology, Florence, Italy.

Testosterone is the main male hormone controlling sexual and reproductive functions. Testosterone deficiency is associated with male hypogonadism, a syndromic condition that encompasses the well-recognised sexual and reproductive failure. Male hypogonadism has been, in fact, recently associated to an increased cardiovascular and metabolic risk (metabolic syndrome), most probably because testosterone deficiency is a stigmata of visceral adiposity. A stepwise reduction in testosterone has been described in human and animal models of increased abdominal adiposity. The biological significance of obesity-induced testosterone deficiency is still a matter of debate, because it can have a detrimental effect, further increasing visceral fat accumulation, or a protective role, by limiting reproductive potential, or it can represent only a marker of a decreased wellness. Nonetheless, meta-analysis of intervention trials on hypogonadism in metabolic syndrome indicate that testosterone supplementation can increase insulin sensitivity and decrease visceral adiposity. Although it is generally assumed that a decreased androgen signalling will restrain prostate overgrowth, having therefore a therapeutic potential for benign prostate hyperplasia (BPH), recent data indicate that both metabolic syndrome and obesity-induced hypogonadism might have a causative role on BPH-associated lower urinary tract symptoms (LUTS). In an animal model of high fat diet-induced metabolic syndrome and hypogonadism, we found that the prostate, as well as the liver, was affected by fibrosis, hypoxia and inflammation. Similar changes, although of a more limited extent, was observed in the bladder. Testosterone supplementation was able to revert hypoxia and fibrosis and to decrease prostate and bladder inflammation. It is therefore conceivable that testosterone supplementation in pathological conditions, such as metabolic syndrome, might have favourable effects not only in increasing insulin sensitivity and decreasing visceral adiposity, but also in ameliorating prostate function and LUTS.

**New insights into the roles of sirtuins in metabolic decline and disease of aging**

David A. Sinclair
Genetics Department, Paul F. Glenn Laboratories, Harvard Medical School, Boston, Massachusetts 02115, USA.

Sirtuins are $NAD^+$-dependent deacetylases that are implicated in mediating health benefits of calorie restriction and possibly exercise. We will report on novel roles of SIRT1-3 in diseases of aging and recent progress in using small molecules to activate SIRT1. Small molecule activators of SIRT1 (STACs), such as resveratrol and SRT1720, improve multiple health parameters in mice including protection from type II diabetes and hepatic steatosis. We developed an system that permits whole-body deletion of SIRT1 in adult mice and have tested whether the effects of resveratrol and SRT1720 on mitochondrial function are SIRT1-dependent. We have also developed novel substrate-agnostic sirtuin assay to discover that SIRT1 activation is facilitated by specific hydrophobic amino acids in native SIRT1 substrates such as PGC-1$\alpha$ and FOXO3$\alpha$, thus explaining substrate specificity. A structured N-terminal domain is critical for the direct activation of SIRT1 by all known STACs and we find that cells with alterations in this domain are insensitive to the effects of STACs. Together, these data point to a common mechanism for allosteric activation of SIRT1 by small molecules.

## Why your bones break - from childhood to old age

### PL5

**Why your bones break: from childhood to old age**

E. Seeman
University of Melbourne, Heidelberg, Victoria, Australia.

Bone's ability to tolerate loading is determined by its material composition and structural design. During growth, growth plate trabeculae condense by appositional growth forming the metaphyseal cortices ('corticalization'). Rapid distal radial longitudinal growth in early puberty outpaces trabecular condensation producing transitory intracortical porosity predisposing to fractures.
In adulthood, remodeling removes and replaces damaged bone. Around midlife in women, the volume of bone formed decreases and the volume resorbed increases producing a negative bone balance which produces structural decay, especially after menopause when remodeling intensity increases. Remodeling is always initiated upon an internal surface of bone. Remodeling upon haversian canal surfaces enlarges the canal focally producing intracortical porosity (in cross section) which fragments ('trabecularizes') the cortex thinning it from 'within'. Pores coalesce increasing the surface area; remodeling becomes self-perpetuating; more bone is lost from a decreasing cortical bone volume so bone loss accelerates. Remodeling upon trabeculae removes them so trabecular remodeling is self-limiting. Resorption upon the endocortical surface adjacent to marrow also thins the cortex. The porous structure loses its ability to resist cracking predisposing to fractures. Most bone loss is cortical, most occurs after 65 years and most fractures are appendicular, not vertebral.
Antiresorptives reduce remodeling intensity slowing structural decay. Structure is partly restored as refilling of resorptive cavities present at the start of treatment proceeds with the concurrent appearance of fewer new remodeling cavities. Osteons formed months earlier mineralize more completely instead of being replaced with younger less fully mineralized bone matrix. More homogenous and fully mineralized bone is more brittle – it cannot absorb energy by deforming. Thus, protracted remodeling suppression reduces structural decay but may compromise bone's material composition. Understanding why and how bone's break requires the study of bone's material composition and structure its 'qualities'. Bone densitometry was a good beginning.

## Diabetes as a gut disease

### PL7

**Diabetes as a gut disease**

Michael A. Nauck

Gastric inhibitory polypeptide (GIP) is a physiologically important incretin hormone secreted from K cell of the upper small intestine. Glucagon-like peptide 1 (GLP-1) is secreted from L cells in the lower small and large intestine. Both hormones are released after nutrient (especially carbohydrate and fat) ingestion and glucose-dependently augment insulin secretion. An involvement of either incretin hormone in the pathogenesis of diabetes may, in principle, be related to abnormalities of either secretion or action. While some studies suggest reduced GLP-1 secretion after oral glucose or meal ingestion in patients with type 2 diabetes, more recent data do not support any systematic difference to healthy subjects. There is, however, a large inter-individual variation. GIP secretion is also not impaired in type 2 diabetic versus healthy subjects. Nevertheless, type 2 diabetes is associated with a reduced incretin effect. This means that oral glucose has only little more stimulatory effect on insulin secretion than has an isoglycaemic intravenous glucose infusion (i.e. at the same glycaemic profile). In healthy subjects, marked differences are typical, with two thirds of the secretory response being due to factors other than hyperglycaemia, pointing to mechanisms related to the absorption of nutrients from the gut. Insulinotropic GIP effects, in contrast to unchanged secretion, are markedly reduced in patients with type 2 diabetes compared to healthy subjects. Therefore, defective GIP action on β-cells explains impaired insulin secretory responses in patients with type 2 diabetes. This may be pathophysiologically relevant in the case of nurtrient-stimulated insulin secretion, i.e. after meals. A similarly reduced insulinotropic activity of GIP has been described with a variety of other forms of diabetes, whenever there is fasting hyperglycemia. Whether or not such defects are central to the pathophysiology of type 2 diabetes is still unclear. Two hypothesis have been derived: i) there is a specific insensitivity to GIP in type 2 diabetes, so that the type 2-diabetic endocrine pancreas is particularly insensitive to endogenous and exogenous GIP, more than, for example, in response to glucose or other insulinotropic stimuli. The alternative explanation is that ii) there is a generalized functional defect in the endocrine pancreas of patients with type 2 diabetes, which pertains for glucose- as well as GIP-stimulated insulin secretion to a similar degree. Current evidence supports the latter hypothesis. In contrast to markedly reduced insulinotropic GIP effects in type 2 diabetes, GLP-1 actions are much less impaired. If not at physiological concentrations, at pharmacological GLP-1 concentrations, a normalization of plasma glucose can be achieved in most type 2 diabetic patients examined so far. In conclusion, the major abnormality with respect to incretin (GIP and GLP-1) secretion and action in type 2 diabetes is a reduced responsiveness of β cells to GIP. This may partly explain impaired insulin secretion in type 2 diabetes. On the other hand, GLP-1 retains its insulinotropic activity even in advanced type 2 diabetes, why it has become the parent compound for incretin-based medications like GLP-1 receptor agonists and inhibitors of dipeptidyl peptidase-4 (DPP-4).

## Novel molecular link between the circadian clock and hypertension

### PL8

**Novel molecular link between the circadian clock and hypertension**

H. Okamura
Kyoto University, Kyoto, Japan.

Rhythmic change of the internal milieu is a fundamental principle in all living organisms. A variety of physiological events show daily rhythms, such as blood pressure, hormonal secretion, cell cycle, and migration of stem cells from the bone marrow to the systemic circulation. This timing is determined by the endogenous oscillatory system called the circadian clock. Within the last ten years, the molecular dissection of circadian clock has progressed dramatically, and it is now known that circadian time is generated by clock genes interlocked in an autoregulatory transcription-(post)translational feedback loop operating in most cells of the body. However, the fundamental timing system evolved in a rhythmic environment is now threatened by recent life-style changes: steady day-night (light-dark) cycles are disrupted by shift-works and long working hours, which increases in the risk of life-style related diseases such as hypertension, metabolic syndrome and cancer, caused by such lifestyles. To clearly demonstrate the importance of the biologic clock for health, we used completely arrhythmic mice with deleted Cry1 and Cry2 clock genes (Cry-null mice). Phenotype survey of these animals revealed Cry-null mice rapidly develop salt-sensitive hypertension. By adrenal transcriptome, we identified a new type of 3-β-hydroxysteroid dehydrogenase/Δ-5-4 isomerase (3-β-HSD) that was dramatically over-expressed in Cry-null mice. This enzyme, Hsd3b6, expressed in the zona glomerulosa (ZG), is regulated by the circadian clock. The lack of a functional circadian clock in Cry-null mice leads to Hsd3b6 over-expression, hyperaldosteronism and, ultimately, salt-sensitive hypertension. We further identified HSD3B1 as the human homologue of mouse HSD3B6, and prevalence of this enzyme in a group of human primary aldosteronism, which represents new possibilities in the treatment of hypertension that are being investigated.

## Molecular mechanisms of differentiated thyroid cancer

### S1.1

**Molecular consequences of deregulated RNA genes in papillary thyroid carcinoma**

A. de la Chapelle[1,2]
[1]Ohio State University, Columbus, Ohio, USA; [2]The Ohio State University Comprehensive Cancer Center, Columbus, Ohio, USA.

Early miR expression analyses in papillary thyroid carcinoma (PTC) disclosed profound differences in the expression of several, microRNAs in thyroid tumor compared with unaffected thyroid tissue. For instance, miR146 and miR221 were 19- and 11-fold upregulated in PTC. These and other miRs target the thyroid hormone receptor THRB gene. Transfection of cell lines with miR146a and other miRs *in vitro* resulted in down-regulation of THRB transcript and protein. Promoter luciferase reporter experiments as well as *in vivo* measurements were concordant. These findings are reflected *in vivo* in thyroid tumor tissue (miRs are up, THRB is down). Thus miRs up-regulated in PTC tumors directly inhibit the expression of THRB, an important tumor suppressor gene.
Examples from other cancers suggest that many more miRs are probably involved in PTC pathogenesis. Indeed the early studies targeted only a fraction ($n=460$) of all miRs known today ($n>1500$). All miRs in the genome can presently be assessed by RNA sequencing. Such studies are in progress and may reveal roles for miR-mediated perturbations in key PTC pathways but definitive data are not presently available.
Recent advances fueled by second-generation deep sequencing implicate long intergenic noncoding RNAs (lincRNAs) in the pathogenesis of cancer. Examples in thyroid pathology include the NAMA gene in 9q22. NAMA is a noncoding RNA associated with the MAP kinase pathway and growth arrest. The PTCSC1 gene in 8q24 is embedded in the introns of two protein-coding genes, thyroglobulin (TG) and Src-like adaptor (SLA). The PTCSC3 gene in 14q13 is a highly thyroid-specific spliced gene that is strongly downregulated in PTC tumors. By functional assays it acts as a tumor suppressor. Some unpublished data on lincRNA genes will be discussed.

**Correlation between the BRAF V600E mutation, TGFβ pathway and tumour invasiveness in papillary thyroid carcinomas**

G. Riesco-Eizaguirre[1] & P. Santisteban[2]
[1]Hospital La Paz Biomedical Research Institute (IDIPAZ), Madrid, Spain; [2]Biomedical Research Institute, CSIC-UAM, Madrid, Spain.

The V600E mutation of BRAF oncogene is one of the most frequent genetic events in thyroid cancer, particularly in papillary thyroid carcinomas (PTC) and in some anaplastic carcinomas that derive from preexisting PTC. It has been associated with advanced clinical stages, extrathyroidal extension, and a high risk of recurrences, particularly those that have lost the ability to accumulate iodide, a property mediated by the sodium iodide symporter (NIS).
Our previous data have shown that BRAFV600E promotes NIS functional repression in thyroid cells and that BRAF-positive tumors exhibit a significantly reduced NIS expression. In addition this oncogene promotes cell migration and invasion. Its mechanism of action is mediated by the MEK-ERK pathway, although MEK inhibition does not fully rescue BRAF-induced NIS repression. We have shown that the mechanism through which BRAF induces NIS repression and promotes epithelial to mesenchimal transition and invasion is based on the operation of an autocrine TGFβ loop.
The role of TGBβ as oncogenic factor is gaining increasing importance. We have analyzed its role in a panel of thyroid cancer cells lines harbouring the main genetic mutations described so far in thyroid cancer. Thyroid cancer cells were classified in two groups depending on whether TGFβ had an oncogenic response or not. In addition preliminary results show that a high TGFβ-Smad pathway activity is present in the most aggressive forms of human thyroid cancer, including well- differentiated carcinomas with radioiodide-refractory metastatic disease, poorly differentiated and anaplastic carcinomas. We suggest that TGFβ is an oncogenic factor in advanced thyroid cancer.

## 40 years of male hormonal contraception research and no product

### S2.1

Abstract unavailable.

### S2.2

**Clinical trials in male hormonal contraception to date**

M. Meriggiola, S. Cerpolini & A. Costantino
Gynecology and Physiopathology of Reproduction, Bologna, Italy.

Over the last 50 years, different studies have been carried out in the field of male hormonal contraception. Two multicenter efficacy studies supported by WHO in which the prototype testosterone-alone regimen was used, have demonstrated the validity of the principle of male hormonal contraception. Contraceptive protection is dependent on the degree of sperm suppression. Azoospermia is certainly the gold standard for this type of contraceptive since no pregnancies were reported among azoospermic men. However, the pregnancy rate among azoospermic and severely oligospermic (sperm count $<1$ million/ml) men was 0.8 per 100 person/year (95% CI 0.1–2.7; 2 pregnancies in 269.5 years of exposure). Therefore, the threshold of 1 million/ml for sperm suppression after hormone administration seems to be an acceptable interim goal for a hormonal male contraceptive. Further clinical studies have shown that testosterone must be combined with a progestin in order to consistently induce profound sperm suppression. Different androgen-progestin regimens have been tested in small pilot trials suggesting that these regimens can effectively suppress sperm counts without inducing major adverse effects. Two efficacy trials testing two different androgen-progestin combinations have recently been performed confirming the high effectiveness of these combinations in terms of sperm suppression and pregnancy rate. Further studies will be needed to confirm the efficacy of these combinations and to select the safest androgen-progestin combination for market entry.

### S2.3

**Acceptability of male hormonal contraception by the pharmaceutical industry and by the consumer**

F. Saad[1,2]
[1]Bayer Pharma AG, Berlin, Germany; [2]Gulf Medical University School of Medicine, Ajman, United Arab Emirates.

Introduction
Following extensive research activity to develop an effective hormonal approach to control male fertility, little is known concerning attitudes of men and women

towards male contraception in different countries. Although several pharmaceutical companies have conducted studies in male contraception, a full clinical development programme to obtain approval for one of the hormonal methods has never been initiated.
Methods
Several studies and surveys have been performed in different parts of the world. Major surveys have been funded by Schering (now Bayer Pharma), one in 2002 in 9000 men aged 18–50 years, and a second one in 2006/2007 in 20 000 men in the same age group. An internet survey was conducted in 2000 women in Germany in 2010. In addition, published data are reviewed.
Results
In all surveys, male contraception is seen as an option to share responsibility for contraception in stable relationships. 70% say that the method of contraception is taken in a joint decision. In all surveys, 50% of men and women express a positive attitude towards male contraception. In the two large international surveys, acceptance rates are particularly high in Latin American countries and somewhat lowest in Asia. The majority of men would seek advice on hormonal MFC from a physician.
The two companies with an interest in male contraception have been taken over by two of the largest companies in pharmaceutical industry whose strategic goals are in different areas. Moreover, the premature termination of the WHO study has substantially increased the hurdles for those still willing to consider the development of male contraceptives.
Conclusion
The overall acceptance of male hormonal contraception is broad across both genders and various cultures. However, in the current situation, it is unlikely that pharmaceutical industry will see an opportunity for male hormonal contraception for many years to come.
Declaration of interest
The author declares that there is a conflict of interest.

## Absolute fracture risk assessment with FRAX

### S3.1

Abstract unavailable.

### S3.2

**Use of FRAX in Asian populations**
L. Koh
Gleneagles Medical Centre, Singapore, Singapore.

Asia occupies 30% of the world's landmass and contains 60% of the world's population encompassing a wide diversity of people and demographics. It has been estimated that by 2050, half of all hip fractures in women >65 years of age will occur in Asia. Hip fracture incidence rates among women vary widely in Asian populations, from as low as 100 up to 500 per 100 000. Within the space of 1 to 3 decades in several countries, hip fracture incidence rates have risen dramatically, constituting an increasing health problem. As in the rest of the world, osteoporosis is under-diagnosed and under-treated in Asia.
FRAX is a computer-based tool which estimates the 10-year probability of major and hip fractures using easily obtained clinical risk factors, with an option to input femoral neck bone mineral density to enhance fracture risk prediction. The recent data that relates high fracture probability with FRAX to densitometric osteoporosis may have important clinical implications in Asia where, except in a few countries, access to bone densitometers is limited.
The FRAX model has been calibrated based on fracture and mortality data for China, Hong Kong, Japan, Philippines, Singapore, South Korea, Sri Lanka, Taiwan, Jordan and Lebanon, and is a work in progress. Unfortunately, there is a lack of epidemiological data from other Asian countries to enable wider calibration. Although using available FRAX models in countries without fracture data may not be suitable, it may be possible to extrapolate fracture risk in neighbouring countries with similar ethnicities and levels of development. Country-specific threshold risk levels for intervention have yet to be established in Asia as health care systems, reimbursement and wealth differ between countries and from the West.
Despite such limitations, with increasing connectivity and easy accessibility, FRAX may prove a useful tool in addressing osteoporosis in Asia.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

### S3.3

**Beyond FRAXÒ**
John A. Eisman
Professor of Medicine (Conjoint), University of New South Wales; Staff Endocrinologist, St Vincent's Hospital; and Director, Clinical Translation and Advanced Education, Garvan Institute of Medical Research, Sydney, New South Wales 2010, Australia.

The FRAXÒ algorithm represented a major step forward in absolute fracture risk assessment. It took advantage of globally derived information to predict fracture risk that used that as the basis for rational treatment recommendations for a large proportion of the international community. The extrapolation of FRAXÒ to different regional and geographic criteria has been based on two sets of data that can be obtained with relatively high accuracy; these being regional age-adjusted hip fracture and mortality rates. Other fracture risk calculators that have been proposed and validated in other cohorts, including the Garvan FractureRiskCalculator that we developed from the Dubbo Osteoporosis Epidemiology Study data. This differs from FRAXÒ in that it predicts hip fractures and a range of other fragility fractures as outcomes and includes falls risk as an important fracture risk factor. However it does not include other clinical risks that are included in the FRAXÒ algorithm, including diet, smoking and glucocorticoid use amongst others. Since fragility fractures are associated with premature mortality, our work has been focussing on considering the combined risk of initial or recurrent fracture and premature mortality together. As only individuals who are at risk of fracture or other adverse events can benefit from any intervention, identifying individuals at high risk of such 'adverse outcomes' will underpin rational decisions for intervention. Another other major step forward that is yet to take place is randomised controlled interventional studies of novel agents being based on selection of individuals at high absolute risk. This next stage of the validation of treatments based on absolute fracture risk assessment is critical. The future involves more accurate prediction of risk and then selection amongst treatments, validated in specific studies based on such risk selection. This would provide a rational basis for cost-effective osteoporosis risk management.

## The gut nutrient sensing in energy metabolism

### S4.1

**Bile acid metabolism for the control of metabolic disease**
M. Watanabe
School of Medicine, Keio University, Tokyo, Japan.

Over the 5 years, the field of bile acid (BA) research has undergone a considerable evolution. Besides their well-established roles in dietary lipid absorption and cholesterol homeostasis, it has recently become clear that BAs are also biological signaling molecules. For instance, BAs were shown to be natural ligands that activate FXR, which controls both the synthesis and enterohepatic recycling of BAs. We have shown that the FXR-mediated SHP induction attenuates the capacity of LXR and LRH-1 to induce the expression of SREBP-1c, explaining the inhibition of hepatic fatty acid and triglyceride biosynthesis and VLDL production by BA administration.
BAs may also signal in peripheral tissues through a newly-identified pathway involving the binding and activation of GPCR, TGR5. The subsequent activation of type 2 iodothyronine deiodinase (D2), the enzyme that converts inactive thyroxine into active 3,5,3′-triiodothyronine and hence determines thyroid hormone receptor saturation in cells, and of PGC-1 then stimulates energy expenditure in brown adipose tissue (BAT) and skeletal muscle. Thus, activation of this pathway explains how administration of BAs to mouse models of 'diabesity' induces weight loss and insulin sensitization. These observations build a strong case that BAs have effects beyond the strict control of BA homeostasis and function as general metabolic integrators.
Bile acid-binding resins (BABRs) are effective drugs for lowering LDL-cholesterol and the primary prevention of coronary heart disease. BABRs absorb BAs in the intestine thereby preventing their uptake in the ileum and interrupting their enterohepatic cycling. We characterize in detail the molecular and functional impact of BABR on metabolic homeostasis in mouse and hamster models and

human subjects with the metabolic syndrome. Interestingly, BABR are not only shown to reduce cholesterol levels but also to decrease body weight and to improve glucose tolerance, qualifying them as ideal agents to treat the metabolic syndrome.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## S4.2

**Taste receptors in gut regulate endocrine function**
R. Margolskee
Monell Chemical Senses Center, Philadelphia, Pennsylvania, USA.

We have found that many of the receptors and downstream signalling elements involved in taste detection and transduction are expressed also in intestinal hormone producing (endocrine) cells where they underlie key chemosensory functions of the gut. In one example of gastrointestinal chemosensation it is known that glucose given orally, but not systemically, induces secretion of the 'incretin' hormone glucagon like peptide-1 (GLP-1), which in turn regulates insulin secretion and glucose homeostasis. We have found that intestinal endocrine cells express sweet taste receptors, the taste G-protein gustducin, and several other taste transduction elements. Knockout mice lacking gustducin or the sweet taste receptor subunit T1R3 have deficiencies in secretion of GLP-1 and in the regulation of plasma levels of insulin and glucose. We have studied intestinal cell lines that express gustducin, taste receptors and other taste signaling elements to identify the roles of these taste proteins in regulating GLP-1 hormone release. In another example of gastrointestinal chemosensation we have found that endocrine cells of the pancreas express multiple taste proteins that are involved in regulating insulin release. Furthermore, taste cells of the oral cavity express GLP-1, other 'gut' hormones and the insulin receptor. Most recently, we have identified intestinal-type glucose transporters and pancreatic-type ATP-gated K+ channels (K-ATP metabolic sensors) as being present in taste cells and potentially functioning in the detection of the sweet taste of sugars. In sum these studies point out similarities in gustation and gut chemosensation and indicate the importance of 'taste cells of the gut' and 'endocrine cells of the tongue' in coordinating the body's hormone responses to regulate glucose homeostasis.

## S4.3

**Gut microbiome and energy metabolism: the concept of MicrObesity**
P. Cani
Universite catholique de Louvain, Brussels, Belgium.

Obesity, type-2 diabetes and low-grade inflammation are becoming worldwide epidemic. We and others have provided evidence that the gut microbiota contribute to the control of energy homeostasis. Therefore, we have defined a novel concept, that we called the 'MicrObesity' (microbes and obesity), devoted to decipher the specific role dysbiosis and its impact on host metabolism and energy storage.
Over the last 15 years, our work has been devoted to examine the way by which the bacteria present in the gut interact with nutrients and host biology to control obesity and associated disorders, including diabetes, inflammation and liver diseases. Recently, we discovered that the gut microbiota contribute to the development of the insulin resistance and the low grade inflammation characterizing obesity. We described the concept of metabolic endotoxemia (increase in plasma LPS levels) as triggering factor in the development of the metabolic alterations associated with obesity.
Following this discovery, we found that the major factor involved in the development of metabolic endotoxemia observed upon obesity is related to the gut barrier function. For instance, we found that both nutritional and genetic obesity are associated with an increased gut permeability leading to the leakage of LPS and possibly other microbiota derived factors. Although the clear mechanisms involved in the bacteria-host interactions are still under investigation, we found that the gut microbiota control enteroendocrine functions such as L-cells (producing GLP-1 and GLP-2) number and differentiation, the endocannabinoid system tone but also leptin sensitivity.
We found that selective changes in the gut microbiota composition by using prebiotics reduce metabolic endotoxemia and gut permeability via different mechanisms (e.g. GLP-2, endocannabinoid system).
Taken together, the compelling data currently published suggest that specific changes in the gut microbiota could be promoted to counteract fat mass development, diabetes and the low levels of inflammation associated with obesity.

# Transition from paediatric to adult care - do we have progress?

## S5.1

**GH use in Prader–Willi syndrome (PWS): an evidence-based approach to a clinical practice guideline (CPG), on behalf of the GH Research Society (GRS) and Workshop Participants**
C. Deal
Canada.

GH therapy in children with PWS was approved in the US in 2000, based on short term growth data, and in Europe in 2006, based on growth and body composition data. GH therapy in PWS has been used by the medical community and advocated by parental support groups since this time. The advent of GH therapy for individuals with PWS represents a unique therapeutic challenge with its intersection of GH treatment for individuals with cognitive disability, varied therapeutic goals that are not focused only on increased height, and potential association with life-threatening adverse events. Given the availability of new results regarding efficacy and safety in infants, children, and adults with PWS from randomised controlled trials as well as from a recent Cochrane review, a CPG Workshop sponsored by the GRS systematically reviewed the literature, graded the available evidence and provided concise recommendations for the use of GH in this context. Forty-three experts (pediatric and adult endocrinologists, clinical and basic geneticists, epidemiologists, a nutrition specialist, an orthopaedic surgeon, a psychiatrist, health technology assessment specialists, a bioethicist, health economist, and a patient advocate) participated. The 4-day workshop followed the CPG development recommendations outlined by the AGREE Collaboration (www.agreetrust.org/). Strength of evidence was graded using the EVIDEM Quality Assessment instrument, using questions organized into 8 domains including study population, intervention and comparators, outcomes measures, design, adverse events ascertainment, time horizon, types of analyses and results validity and relevance (www.evidem.org/praderwilli). For clinical evidence in the pediatric population, randomized controlled trials (RCTs), comparative observational studies and long term studies ($>3.5$ years) were included. Adult studies included RCTs of GH treatment for $\geq 6$ months and uncontrolled trials, since data was more limited. Safety data was obtained from pharmaceutical registries (Phase 4) and clinical trials (Phase 3). Data on disease, therapeutic context, and economic, ethical and societal aspects were assessed to reflect the international context. This presentation will review the data discussed in the Workshop and present recommendations for GH treatment of individuals with PWS. We will also address a process for obtaining informed consent/assent of patients with PWS and/or their families.

## S5.2

**Fertility options for adults with panhypopituitarism**
Margaret E. Wierman
Professor in Medicine, University of Colorado, Director of Pituitary Program, Chief of Endocrinology, Denver VAMC, Denver, Colorado, USA.

Hypopituitarism and impaired fertility in adulthood may result from congenital genetic defects detected during childhood or acquired pituitary dysfunction after apoplexy or resection of a pituitary tumor or following radiation therapy. This lecture will review the fertility options for hypopituitary patients, success rates and predictors of outcome for conception and live births. In those with normal pituitary function planning surgery and/or radiation to the hypothalamic-pituitary axis, banking of sperm, oocytes or embryos are newer options to preserve future fertility options. In those with partial or complete pituitary hormonal deficiencies, optimization of thyroid, adrenal and perhaps growth hormone function must be obtained before fertility options are discussed. In men, induction of spermatogenesis is usually achieved with intermittent human chorionic gonadotropin (hCG) alone, or in combination with recombinant follicle stimulating hormone (FSH), or

human menopausal gonadotropins. Size of the testes at baseline predicts success, as therapy must restore or recapitulate the pubertal process to achieve normal spermatogenesis. In women with partial gonadotropin deficiency, induction of ovulation with clomiphene citrate may be an option. For most hypopit women with hypogonadotropic hypogonadism, therapeutic options include recombinant FSH with hCG alone or in combination with intrauterine insemination, or *in vitro* fertilization. Despite the expansion of treatment options, decreased response to ovulation induction, decreased live births, increased small for gestational age infants and peripartum complications have been reported in women with hypopituitarism. Further research is needed to plan future options for fertility in those pituitary patients undergoing treatment that will impair reproductive function, and to optimize the treatment options and success rates for patients with hypopituitarism desiring fertility.

## S5.3

**Sex steroid replacement in young males and females**

G. Conway
University College London, London, UK.

Once induction of puberty has been completed the options for sex steroid hormone replacement change to take in to account long term health outcomes and the issues of transition from pediatric to adult care. With regard to the late stages of development, some thought has to be given to the fact that bone mass continues to increase to reach a peak at about the age of 25. It may not be until the age of 18 that meaningful bone density results can be obtained. For those who are slow to reach peak bone mass there might be a benefit to running generous dosing levels for some years.

For many young adults, compliance with treatment can be a problem with some passing through a time of rejection of medical care. The health care team should be alert to the problems of transition and the high rate of drop out from clinic for young adults. With regard to sex steroid replacement, regimes can be adjusted to find one that is most acceptable for the individual. Involving the patient in the process of choice with education may require extending clinic time and a good relationship with nursing staff.

As young adults hypogonadal patients will take stock of their success or otherwise of pubertal development and many express concern about some aspect of physical development or self-confidence in relationships. If these points are not volunteered then skills in eliciting a frank exploration of these psychological issues will often be required. Males in particular may feel that their hypogonadism makes the common sexual insecurities of this age group much more profound.

# Subclinical adrenal diseases

## S6.1

**Diagnosis and treatment of subclinical Cushing's syndrome (SCS)**

T. Yanase
School of Medicine, Fukuoka University, Fukuoka City, Japan.

SCS is defined as an adrenal tumor (usually adenoma) with autonomous cortisol secretion and no overt symptoms of Cushing's syndrome. SCS has attracted much attention because it often is masked by lifestyle-related diseases such as diabetes mellitus (DM), metabolic syndrome (MS) and hypertension. Because of the broad variation in autonomous cortisol secretion among patients, diagnostic criteria for SCS have not been fully established. Furthermore, the cut-off values of the dexamethasone suppression test (DST) differ among current criteria. Diagnostic problems also arise because of differences in sensitivity among assay kits for the measurement of low serum cortisol levels. We have tried to establish diagnostic criteria for SCS based on the 1-mg DST cut-off value of serum cortisol of $>1.8$ μg/dl by analyzing 118 patients with adrenal incidentaloma. For the diagnosis of SCS, we finally selected two additional values (basal adrenocorticotropic hormone (ACTH) $<10$ pg/ml and serum cortisol $\geq 5$ μg/dl at 23:00 h) from several parameters, because these values showed stronger associations with the results of the 1-mg DST than the other parameters. In some exceptional cases with basal ACTH $\geq 10$ pg/ml, the poor response of ACTH to corticotropin-releasing hormone was equally important for accurate diagnosis. Patients who met these criteria had a significantly higher frequency of IGT/DM than did patients who did not meet these criteria. Improvements in metabolic parameters have been reported after removing the adrenal tumor in patients with SCS. However, it is sometimes a challenge to select operation for individuals with SCS, particularly for asymptomatic individuals showing no significant objective abnormalities. To overcome this problem, some reports have investigated the hormonal conditions of patients with SCS who showed improvements in metabolic profiles following the removal of the adrenal tumor.

## S6.3

**Subclinical Addison's disease**

A. Falorni
University of Perugia, Perugia, Italy.

Autoimmune Addison's disease (AAD) occurs in approximately 1:8000 individuals. Its autoimmune pathogenesis is made evident by the presence of circulating 21-hydroxylase autoantibodies. A recent international program aimed at standardizing adrenal autoantibody measure to optimize both the etiological classification of the disease and the identification of at-risk subjects. Approximately 1% of subjects with autoimmune endocrine diseases and 5% of women with primary ovarian insufficiency are positive for 21OHAb, not necessarily in association with clinical symptoms of adrenal insufficiency. Detection of adrenal autoantibodies in subjects with no clinical signs of adrenal insufficiency defines the so-called subclinical AAD. The overall risk for future development of AAD in 21OHAb-positive individuals is as high as 40% at 10 years. The risk can be stratified on the basis of hormonal parameters, such as basal aldosterone, plasmatic renin activity, basal and ACTH-stimulated serum cortisol and basal plasma ACTH. A subnormal response to the Synacthen test and an increased plasma ACTH mark the irreversible phase of the disease, that evolves towards clinical AAD in over 90% of cases. On the other hand, only a minorityy of cases with normal ACTH levels and normal cortisol increase after the ACTH test progresses towards clinical AAD. Additional risk factors are male gender and high autoantibody titer, while available genetic markers are poor predictors of progression towards the clinical form of the disease. During the last years, studies have addressed the problem of the optimization of the Synacthen test, as the classical stimulation with 250 μg co-syntropin is largely supraphysiological. The low-dose test, performed with 1 μg of synthetic ACTH, is able to accurately discriminate subjects with subnormal cortisol response. An ongoing European study is testing the predictive value of a very low-dose test, performed using 0.5 μg of synthetic ACTH.

# Hormones, metabolism and cancer: more than coincidences?

## S7.1

**An epigenetic switch linking inflammation to cancer and the use of metformin as an anti-cancer drug**

K. Struhl
Harvard Medical School, Boston, Massachusetts, USA.

Transient activation of Src oncoprotein can mediate an epigenetic switch from immortalized breast cells to a stably transformed line that forms self-renewing mammospheres that contain cancer stem cells (CSCs). Src activation triggers an

inflammatory response mediated by NF-kB that directly activates Lin28 transcription and rapidly reduces the level of let-7 microRNAs. Let-7 inhibits IL6 expression, and IL6 activates STAT3. Importantly, IL6 activates NF-kB, thereby completing a positive feedback loop. Furthermore, STAT3 activates transcription of the miR-21 and miR-181b microRNAs, and each of these is sufficient to activate the epigenetic switch. This positive feedback loop is enhanced in CSCs as compared to non-stem cancer cells in the same population. Thus, inflammation activates a positive feedback loop that involves NF-kB, Lin28, Let-7, IL6, STAT3, miR-21, and miR-181b that maintains the epigenetic transformed state for many generations in the absence of the inducing signal.
The cancer stem cell (CSC) hypothesis suggests that, unlike most cells within a tumor, CSCs resist chemotherapeutic drugs and can regenerate the various cell types in the tumor, thereby causing relapse of the disease. Relatively low doses of metformin, a standard diabetes drug, inhibits transformation and selectively kills breast CSCs. The combination of metformin and doxorubicin kills both CSCs and non-stem cancer cells in culture, and it prevents relapse much more effectively than either drug alone in mouse xenografts. Metformin is equally effective combined with other chemotherapeutic agents, and with a 4-fold reduced dose of doxorubicin. The combination of metformin and doxorubicin prevents relapse in xenografts involving cancer cell lines from several, but not all, developmental lineages. Metformin appears to inhibit the inflammatory pathway. These results support the CSC hypothesis, and they provide a rationale and experimental basis for using the combination of metformin and chemotherapeutic drugs to improve treatment of patients with breast (and possibly other) cancers.

## S7.2

### The insulin-like growth factor system and cancer: what are the implications?

D. LeRoith
Mount Sinai School of Medicine, New York, New York, USA.

Insulin and the IGFs, the IGFBPs and the insulin and IGF-1 receptors play an important role in cancer progression. Higher levels of circulating total IGF-1 is often associated with an increased risk of developing cancer. Furthermore, the IGF-1 receptor (IGF-1R) is often overexpressed in tumor tissues. This overexpression has been shown to be due to mutations in tumor suppressor genes such as p53, WT1 and BRCA genes. Inhibition of the IGF-1R in culture and preclinical studies led to the development of humanized antibodies and tyrosine kinase inhibitors for human trials as adjunct therapy for chemotherapy. Thus far human trials have been less impressive than anticipated and suggest compensation by other tyrosine kinase receptors including the IR.
Obesity, metabolic syndrome and early type 2 diabetics have hyperinsulinemia that is associated with increased cancer risk and cancer-related mortality and studies both in mouse models and humans have suggested that hyperinsulinemia via the IR-A receptor on breast cancer is mitogenic, and suggests other therapeutic options.

## S7.3

### Obesity and cancer

A. Renehan
University of Manchester, Manchester, UK.

By 2008, we[1] and others had established that excess body mass index (BMI), as an approximation of general body adiposity and excess calorie intake, is associated with increased risk of several cancer types. These associations exist for both common (colon, endometrial, post-menopausal breast cancers, oesophageal adenocarcinoma) and less common malignancies (thyroid cancer, non-Hodgkin lymphoma). Given the plausibility of the biological explanations (including insulin/IGF-I; sex steroids; and adipokines/inflammatory cytokines), the consistency of associations, the sufficiently long latency times between BMI measurement and cancer occurrence, and the recent demonstrations of risk reversibility in morbidly obese cohorts undergoing bariatric surgery, many of these associations are probably causal. Approximately 124 000 new cancer cases may be attributable to excess BMI in Europe (2008). Since 2008, it has become clear that associations between BMI and cancer risk may be modified in the presence of other risk factors. For example, in users of hormonal replacement therapy, the associations between BMI and endometrial and post-menopausal breast cancers are attenuated. In turn, these observations point to a strong influence of oestrogen as an intermediary between obesity and cancer development in these cancer groups. Two areas of recent research will be highlighted: (i) it is hypothesised that approximations of central adiposity, such as waist circumference (WC), may better describe associations between adiposity and increased cancer risk, but updated standardised analyses do not fully support this, suggesting a refinement to the proposed mechanistic role of insulin resistance in carcinogenesis; and (ii) studies of the impact of BMI on cancer-specific mortality in patients with a diagnosis of an obesity-related cancer do not necessarily mirror relationships seen for incident risk. These observations suggest that obesity may act through pathways, which in turn, are prognostic pathways for certain cancers. Better understanding of these associations will facilitate refinements of approaches to prevent obesity-related cancers.

# Global phenotypes of endocrine disease

## S8.1

Abstract unavailable.

## S8.2

### Ethnic specific PCOS

C. Wijeyaratne
Faculty of Medicine, Colombo, Sri Lanka.

PCOS is the commonest endocrine disorder of young women. It has appreciable impact on wellbeing and quality of life, fertility and reproduction, and long term metabolic and cancer risks. Acknowledged a 'condition of our times', there was no data from Asia until recently. South Asians have early manifestation with more severe symptoms than white Europeans. Young affected Asians have significantly greater insulin resistance than older white Europeans; with approximately a third having the metabolic syndrome. Central obesity, hypertension and abnormal lipids bear greater significance than BMI; a new dimension to the South Asian phenotype. This highlights their propensity to central fat accumulation. Advancing age impacts significantly on metabolic problems, while gestational diabetes is closely interwoven. Studies in China and Thailand also demonstrate ethnic variation with less overt hirsutism.
Country specific epidemiological data reveals substantial intra-regional variation in the Asian phenotype, particularly the BMI and degree of hyperandrogenism. There is also a notable 'culture of silence' among young pre-marital rural Asian women with PCOS; with diminution of quality of life linked to hirsutism rather than obesity that differs from western women. This highlights socio-cultural determinants in differing ethnic groups. The metabolic problems also reveal the need for a life cycle approach. Screening for diabetes pre-conception, weight maintenance through health promotion are simple low cost interventions that require adoption in low income countries.
To study ethnic variations requires evaluation of epidemiological data based on the geographic location of affected women. This warrants a systematic review of population based data or of large clinic databases to ascertain racial and cultural determinants of manifestations of PCOS. In view of its heterogeneous phenotype, an appraisal of possible link(s) between Androgenic, Reproductive, Metabolic phenotypes among different ethnic groups is also required. The 3rd ESHRE/ARSM consensus statement on PCOS (2011) addresses ethnic variation of PCOS.

**Obesity and diabetes in Asian Indians**

V. Mohan
Dr Mohan's Diabetes Specialitie Centre, WHO Collaborating Centre for NonCommunicable Disease Prevention and Control; IDF Centre of Education and Director and President, Madras Diabetes Research Foundation, Chennai, India.

According to the recent Diabetes Atlas published by the international diabetes federation, globally there are 366 million people with diabetes. The number projected for India was 61.3 million people with diabetes. The recent Indian Council of Medical Research-India Diabetes (ICMR-INDIAB) study which is one the first of its kind to provide accurate and comprehensive state and national level data on diabetes prevalence in India, confirmed that there are 62.4 million people with diabetes in India. Moreover, the study showed that there are 77.2 million people with pre-diabetes, an earlier stage of diabetes, a large percentage of whom will convert to diabetes in the near future.

Obesity is a global health problem and India is facing a rising epidemic of obesity. The prevalence of generalized obesity (as defined by BMI $\geq$25 kg/m$^2$) and abdominal obesity (as defined by waist circumference $\geq$90 cm in men and $\geq$80 cm in women) in the INDIAB study were 21% and 24.8% respectively. Combined obesity (generalized plus abdominal) was present in 28.6% of the population, which translates to 199 million people with obesity in India. The combined diabetes and obesity epidemic is referred to as 'diabesity'. Diabesity in Indians are increased insulin resistance, stronger genetic factors and environmental factors particularly associated with epidemiological transition due to rapid urbanization, industrialization and demographic transition leading to increasing income levels and all of which resulted in altered lifestyle today. Appropriate nutrition measures will help in reducing the risk of not only diabetes and obesity, but also hypertension, dyslipidaemia and hyperinsulinaemia. Thus, effective preventive programmes need to be urgently implemented to tackle the diabesity epidemic threatening the country.

# The risk and benefits of tight glycaemic control

## S9.1

**What do type 2 diabetes outcome trials tell us about the CV risks and benefits of intensive glycaemic control**

Hertzel C. Gerstein

Diabetes is a strong risk factor for cardiovascular (CV) events, and large epidemiologic studies have repeatedly shown that higher fasting or post-load glucose levels predict a higher incidence of CV events regardless of whether or not diabetes is present. In the UKPDS, targeting near-normal fasting glucose levels in newly diagnosed diabetes with a strategy starting with basal insulin or sulfonylurea reduced the 20-year risk of myocardial infarction and mortality by 15% and 13%, respectively. However, this strategy did not maintain stable glucose levels, possibly because it was reactive in nature.

In more recent large clinical trials of different degrees of glucose-lowering in people with advanced type 2 diabetes, stable glucose levels were achieved using a proactive strategy but with more mixed effects on CV outcomes. Indeed, a recent meta-analysis of the major CV outcomes trials in 27 049 people with type 2 diabetes including 5-year data from the UKPDS, the ACCORD trial, VA Diabetes Trial and the ADVANCE trial reported that a strategy of intensive control (which was largely based on insulin therapy) vs conventional glycaemic control reduced the composite CV outcome of myocardial infarction, stroke or cardiovascular death by 9% (95% CI 1–16%), with most of the effect attributable to a 15% reduction in myocardial infarction and no effect on CV death or stroke[1]. However, there was evidence of a mixed effect on mortality with higher deaths in the ACCORD trial.

In addition to these trials of glucose-lowering degrees (i.e. more vs less) several other trials of different glucose-lowering strategies have also been reported or are underway[2]. These include the recently published BARI 2D trial showed that in patients receiving medical therapy for documented coronary artery disease, a strategy of glucose lowering based on insulin-providing therapies had CV effects that were similar to those observed with a strategy based on insulin-sensitizing therapies[3]. To date no clearly effective strategy has been identified however other trials are underway[4].

## S9.3

**Time course of the glucose legacy effect**

R. Holman
University of Oxford, Oxford, UK.

During the 10-year UK Prospective Diabetes Study (UKPDS) post-trial monitoring period, sustained reductions were seen in the risks of diabetic complications, despite the previously randomised conventional and intensive treatment groups becoming identical with respect to median HbA1c values and glucose-lowering therapies. This continuing benefit of an earlier intervention in people with type 2 diabetes has been termed the 'legacy effect'. A similar phenomenon seen in people with type 1 diabetes has been termed the 'metabolic memory'. At the present time, neither the precise mechanism which produces the legacy effect nor the time course over which it operates have been established.

Analyses have been conducted to examine the degree to which the UKPDS glucose legacy effect can be attributed to prolonged benefits of HbA1c levels achieved in each of the previous years since diagnosis of diabetes. The impact of each annual HbA1c value on the future risk of death or myocardial infarction has been estimated, assuming the risk at every moment depended on the contributions from all previous moments.

Major effects of improved glycaemic control are seen 5–10 years later, explaining in part the sustained reductions in risk of death and myocardial infarction seen in the UKPDS post-trial monitoring period.

# Thyroid: From fetal life to adulthood

## S10.1

**Placental transport of thyroid hormone**

J. Franklyn, S. Chan, E. Vasilopolou & M. Kilby
University of Birmingham, Birmingham, UK.

The transplacental passage of thyroid hormones (TH) from the maternal to fetal circulations is important for normal fetal development, particularly the fetal central nervous system. This is particularly so before the onset of endogenous fetal TH production from the second trimester of pregnancy. The human hemochorial placenta regulates the quantity of TH passing through and the complement of the different forms of TH to ensure requisite levels are present in the fetus for each stage of development. Transplacental TH supply to the fetus is modulated by several factors including plasma membrane TH transporters which regulate the passage of TH in and out of cells, the metabolism of TH by iodothyronine deiodinases, as well as TH binding to several different proteins within placental cells themselves. In pathological situations of either maternal or fetal TH deficiency during pregnancy, the placenta appears to lack the full compensatory mechanisms required to optimize maternal-fetal transfer of TH to achieve normal fetal TH levels, and this may contribute to the development of neurodevelopmental delay associated with such conditions. Thus, maintaining normal maternal TH status is likely to be the primary factor in ensuring adequate transplacental TH passage and iodide supply to the fetus.

## S10.3

**Thyroid hormones and fetal neurological development**

M. Li
The University of Sydney, Sydney, New South Wales, Australia.

The importance of thyroid hormones in neurological development has been well documented in both animals and humans. Thyroid hormones deficit during fetal development can have irreversible adverse effects on an individual's neurological function; including mental retardation, deafness, and spasticity. The only source of thyroid hormones for the developing brain in early pregnancy is from the mother. There is a growing body of epidemiological and experimental evidence to suggest that even mild maternal hypothyroxinemia may lead to abnormalities in fetal neurological development. The fetal thyroid gland reaches maturity by about week 10–12 gestation and begins to produce thyroid hormones at around the 16th week of gestation. Fetal production of thyroid hormones becomes increasingly important in the second half of pregnancy. The molecular and cellular mechanisms by which thyroid hormones affect fetal neurological development are still not well understood. Evidence of the interaction between thyroid hormones and brain development so far has primarily come from animal experiments. Thyroid hormones play an important role in regulating gene expression of myelination and cell differentiation in rats. Severe iodine deficiency (median urinary iodine concentration $<20$ μg/l), which causes both maternal and fetal hypothyroidism, is the most common cause of mental retardation. Moderate iodine deficiency (median urinary iodine concentration 20–49 μg/l) may also be associated with increased risk of impaired fetal neurological development. Future studies are needed to improve the understanding of human iodine nutrition during pregnancy, maternal and fetal thyroid function and mechanisms of fetal neurological development.

# Novel genetic and endocrine insights in the Klinefelter's syndrome

## S11.1

**Klinefelter mouse (41XXY): model for human Klinefelter syndrome**

R. Swerdloff[1], Y. Lue[1], P. Liu[2], I. Munir[1], K. Erkilla[3] & C. Wang[1]
[1]LABiomed at Harbor-UCLA Medical Center, Torrance, California, USA; [2]Woolcock Research Institute University of Sydney, Sydney, New South Wales, Australia; [3]Hospital for Children and Adolescents University of Helskini, Helskini, Finland.

Klinefelter syndrome (47XXY male) (KS) is the most common sex chromosome disorder in men. The phenotype is diverse including: infertility, hypogonadism, impaired cognition, behavior disorders, increased autoimmunity and osteopenia. We have studied osteopenia, learning dysfunction, germ cell loss, and testosterone deficiency in 41 XXY mice bred by two separate methods. We have characterized the germ cell loss by apoptosis and germ cell migration as the mice progress from day 1 to 10 days of age and subsequently into adulthood. These studies confirm the phenotypic similarities of XXY mice to human KS. Mice have low testicular venous and peripheral blood levels of testosterone (with elevated LH and FSH levels) yet have normal to elevated intratesticular testosterone levels. This suggests a testosterone sequestration effect within the testes. The ability of the testes to synthesize testosterone is present and augmented by response to LH in Leydig cells and in whole testis in culture. Germ cell transplants from XY mice to XXY mice shows seeding of the GFP labeled XY donor germ cells into 41XXY immature and adult recipients with progression to spermatocyte or spermatid germ cells. While overexpression of non-X inactivated genes is believed to be a likely molecular basis for the disorder, the reasons for phenotypic heterogeneity are only partially understood.

## S11.2

**Endocrine changes in KS and the effects on growth, bone and body composition**

L. Aksglaede, N. Skakkebæk & A. Juul
Rigshospitalet, Copenhagen, Denmark.

Klinefelter syndrome (KS; 47,XXY) is the most common sex chromosome disorder in man, affecting approximately 1:660 men, and is a common cause of infertility. Patients with KS are characterized by tall stature and progressive testicular failure. This results in azoospermia and androgen deficiency with an accompanying risk of developing several phenotypic characteristics in adulthood, e.g., osteopenia or even frank osteoporosis, and metabolic syndrome.

Recent studies on Klinefelter infants during the so-called minipuberty have indicated that serum testosterone (T) concentrations are low or low- normal. Many adults with Klinefelter syndrome have subnormal serum concentrations of total T and the majority of patients have T in the lower half of the normal range, as well as elevated LH. A bivariate LH-T comparison reveals an abnormal LH-T setpoint suggestive of abnormal Leydig cell function.

Sertoli cell function is not impaired in KS patients until puberty, as reflected by normal AMH and inhibin B concentrations in KS boys during infancy and childhood. However, in mid- to late puberty, Sertoli cell function deteriorates progressively, resulting in extremely low or undetectable AMH and inhibin B concentrations, very high FSH levels and small testicular volumes.

Accordingly, patients with Klinefelter syndrome are at increased risk of developing osteopenia or osteoporosis already in young adulthood, whereas normal bone mineralization during childhood and adolescence has been reported. Recent studies showed an increased incidence of an unfavourable change in body composition; with accumulation of body fat and decreased muscle mass already in prepubertal boys with KS. In addition, adult patients have an increased risk of diabetes with decreased insulin sensitivity. It is not known to which degree these symptoms are the result of additional copies of non-inactivated genes on the supernumerary X chromosomes, lifestyle factors, or whether they are partly (or completely) the result of an impaired pituitary-gonadal function.

Special efforts to detect this under-diagnosed chromosome disorder are necessary in order to initiate early androgen therapy, and to prevent the development of a deleterious body composition with the risk of metabolic syndrome.

## S11.3

**The Muenster EXAKT project: epigenetic regulation of the supernumerary X chromosome and its escapee genes**

J. Gromoll, R. Bongers, S. Werler, S. Kliesch, M. Zitzmann & F. Tuettelmann
University Clinics, Muenster, Germany.

Klinefelter syndrome (47,XXY; KS) is a very common chromosomal disorder, affecting 1:500 men and leading to hypergonadotropic hypogonadism as well as an increased incidence of metabolic syndrome. However, our knowledge on the functional role of the supernumerary X chromosome itself and to which extent its origin contributes to the observed pathophysiology is still very limited. Recently we started the EXAKT (Epigenetics, X-Chromosomal features and clinical Applications in Klinefelter syndrome Trial) project which is a Muenster-based prospective study involving Klinefelter patients ($n=130$), and their parents assessing a wide area of biochemical, physiological and genetic parameters in comparison to age-matched healthy male and female controls ($2\times n=50$).

The aim of the genetic and epigenetic part of the EXAKT project is to obtain information on the paternal or maternal origin and the meiotic disjunction events leading to the presence of a supernumerary X chromosome, the inactivation of the second X-chromosome by the non-coding RNA XIST and the expression of X-linked genes which escape X inactivation.

Determination of the origin of the X chromosome by microsatellite analysis in KS and their parents revealed a nearly equal distribution between the paternal (56%)

and maternal (44%) origin of the second X chromosome. Methylation analysis of the XIST promoter displayed a significant higher methylation pattern in KS patients (75%) when compared to women (65%). Moreover analysis of escape genes such as KDM6a in blood RNA samples of KS revealed expression levels comparable to levels detected in women.
The first genetic and epigenetic analyses of KS within the EXAKT project revealed a significantly altered inactivation status and an expression of escapee genes reminiscent of women, indicating a pathophysiological role of the supernumerary X chromosome.

## Determinants of peak bone mass

### S12.1

**Epidemiology of peak bone mass, structure and strength in males as assessed by high resolution peripheral quantitative CT (HR-pQCT). A cross-sectional study**

K. Brixen & S. Hansen
University of Southern Denmark, Odense, Denmark.

In males, peak bone mass as evaluated by DXA is reached at the age of 20–22 years and may be important for the risk of fracture later in life. DXA, however, only provides two-dimensional images and does not allow assessment of bone structure. We used HR-pQCT to assess trabecular and cortical volumetric BMD (vBMD) and bone microarchitecture at the distal radius and tibia in a population based study including healthy male volunteers. Moreover, bone strength was estimated using finite element analysis. Subjects treated with drugs or diagnosed with conditions affecting bone metabolism were excluded. A total of 247 men aged 20–80 years were included. DXA at the lumbar spine and total hip (Hologic Discovery, US) and HR-pQCT at the non-dominant distal radius and tibia (Scanco Medical, Switzerland) were performed.
Assessed by DXA, areal BMD at the lumbar spine was highest at the age of 35 and had peaked by the age of 20 years at the total hip. Trabecular vBMD in radius and tibia peaked around the age of 30 and 25 years, respectively. Trabecular number in radius had peaked by the age of 20 and peaked around the age of 30 years in tibia. Trabecular thickness in both radius and tibia had peaked by the age of 20 years. Cortical thickness in radius and tibia peaked before the age of 20 and around the age of 40 years, respectively. From the time of peak (or age 20) to the age of 80, pronounced changes in both radius and tibia were seen in trabecular thickness ($-1.4$ and $-1.6$ S.D., respectively) and cortical thickness ($-0.6$ and $-0.9$ S.D., respectively). Data on estimated bone strength will be presented.
In conclusion, bone mass, structure and strength peak at different ages. With age detrimental effects on microarchitecture were most pronounced for trabecular thickness and cortical thickness.

### S12.2

**The contribution of genetic factors to bone mass**

W. Van Hul
University of Antwerp, Antwerp, Belgium.

An large number of clinical entities are associated with abnormal bone mineral density. On one end of the spectrum, the sclerosing bone dysplasias are characterized by an excess of bone tissue. These conditions are, in most cases, monogenic diseases with involvement of one gene resulting in a clear mode of inheritance. Molecular genetic studies over the last decennia revealed the underlying genetic causes for many of them. The pathogenic mechanism can either be a decreased bone resorption, as in different forms of osteopetrosis, or an increased bone formation. The latter cases were for example very instrumental in illustrating the essential role of canonical Wnt signaling in the process of bone formation.
On the other end of the spectrum osteoporosis is the best known example of a condition with decreased bone mass resulting in an increased risk for low trauma fractures in the elderly. The risk for osteoporosis is influenced by both environmental and genetic factors and is determined both by the peak bone mass reached at young age and by the subsequent bone loss later on in life. Especially genome wide association studies in the last years have been very useful for dissecting the genetic basis for the regulation of bone mineral density. However, despite extremely large scale studies by very extended consortia, the obtained results so far can explain only a small percentage of the assumed genetic variability and further studies are needed. But these genome wide association studies definitely contributed to our current understanding of bone homeostasis by the identification of novel genes of relevance, as was the case by the study of monogenic sclerosing bone dysplasias.

### S12.3

**Estrogens as regulators of bone growth and bone mass**

C. Ohlsson[1,2], S. Windahl[1,2], M. Lagerquist[1,2], L. Vandenput[1,2] & A. Börjesson[1,2]
[1]Gothenburg University, Gothenburg, Sweden; [2]Medicine, Sahgrenska Academy, Gothenburg, Sweden.

Estrogens regulate bone growth and bone mass mainly via estrogen receptor-α (ERα). In addition, the anabolic effect of mechanical loading on cortical bone requires ERα. This lecture summarizes some recent findings characterizing the primary target cells and the crucial ERα domains for the mediation of these estrogenic effects on the skeleton.
Mice with complete inactivation of ERα continue to grow throughout life associated with increased growth plate height, resembling the longitudinal bone growth phenotype of patients with inactivating mutations in ERα or aromatase. It is unknown whether the effects of estrogens on skeletal growth are mediated directly via ERs in growth plate cartilage. Using a mouse model with cartilage-specific inactivation of ERα, we found that during early sexual maturation, ERα in growth plate cartilage is not important for skeletal growth. In contrast, it is essential for high-dose estradiol to reduce the growth plate height in adult mice and for reduction of longitudinal bone growth in elderly mice.
ERα stimulates target gene transcription through two activation functions (AFs), AF-1 in the N-terminal and AF-2 in the ligand binding domain. Using domain-specific ER-inactivated mouse models, we demonstrated that ERα AF-2 is required for the estrogenic effects on all parameters evaluated, whereas the role of ERα AF-1 is tissue-specific, with a crucial role in uterus but not cortical bone, suggesting that selective ER modulators stimulating ERα with minimal activation of ERα AF-1 could retain beneficial actions in cortical bone while minimizing effects on reproductive organs. We recently demonstrated that ERα amplifies the osteogenic response to mechanical loading in a ligand-independent manner involving its AF-1 but not AF-2. Thus AF-2 but not AF-1 is required for the estradiol effect in cortical bone while ERα AF-1 but not AF-2 is required for the osteogenic loading response.

# Wnt/Beta-catenin in pituitary development and disease

## S14.1

### β-catenin deficiency disrupts patterning of the ventral diencephalon, causing adenohypophysis over growth and dysmorphology

S. Camper, A. Mortensen & S. Davis
University of Michigan, Ann Arbor, Michigan, USA.

β-catenin is thought to play an important, intrinsic role in early pituitary development by regulating adenohypophysis (anterior pituitary) transcription factor activity. Expression of β-catenin is detected in the adenohypophysis, rostral mesenchyme, and neural ectoderm, including the area that develops into the infundibulum and neurohypophysis, and nearby regions. The importance of β-catenin expression in the neural ectoderm and mesenchyme has not been addressed, and the precise role of β-catenin expression in the anterior pituitary is controversial. We tested the function of β-catenin using a panel of cre alleles to inactivate the gene in specific regions. Wnt1-cre knocks out β-catenin in the midbrain and migratory neural crest during head development, eliminating expression in the neural ectoderm and rostral mesenchyme. This results in dramatic expansion and dysmorphology of the adenohypophysis with no obvious effect on specification or differentiation of hormone producing cells. The organ overgrowth is attributable to induction of an abnormally large area of the oral ectoderm to become Rathke's pouch, marked by ISL1 and LHX3. Elimination of β-catenin in the neural crest shifts the expression of SIX6 and the regions of BMP and FGF signaling that emanate from the infundibulum. Lineage tracing experiments show that P0-cre is active in neural-crest derived mesenchyme and the adenohypophysis. In contrast to Wnt1-cre, P0-cre mediated deletion of β-catenin has no obvious effects on the adenohypophysis. This is surprising given the idea that β-catenin has an intrinsic role in adenohypophysis development. Our results imply that β-catenin is necessary for patterning the ventral diencephalon and underscore the significance of establishing a proper organizing center there for normal pituitary development.

## S14.2

### Wnt/beta-catenin signalling in craniopharyngioma

J. Martinez-Barbera
University College London, London, UK.

Adamantinomatous craniopharyngioma (ACP) is an epithelial intracranial lesion arising from Rathke's pouch with a median age at diagnosis of 8 years. ACP is the third most common paediatric brain tumour, accounting for approximately 5–13% of brain tumours, and the commonest pituitary tumour among children. Although histologically benign, ACP often behaves aggressively with invasion of the hypothalamus and visual pathways. Consequences associated with both the tumour and its treatment (surgery and/or radiotherapy) include obesity and subsequent Type 2 diabetes mellitus (up to two thirds of patients), learning difficulties (psychological and educational problems), visual impairment, severe multiple pituitary hormone deficiencies and irreversible diabetes insipidus in up to 95% of patients. This high morbidity bears a vast burden to patients and families as well as considerable financial costs to health services. In a significant percentage of patients, complications may result in death.
Activating mutations in the gene encoding β-catenin have been identified in ACP and recently, using a novel mouse model, we have demonstrated a causative role for mutated β-catenin and the subsequent over-activated Wnt/ β-catenin pathway in ACP tumorigenesis. We have utilised this new genetic tool further understand the aetiology and pathogenesis of human ACP, as well as to test the efficacy of small-molecule inhibitors for treatment of these tumours. Our research has revealed that pituitary progenitors/stem cells are likely to play an important role in the oncogenic process by acting as signalling centres promoting cell proliferation and survival. In addition, we have identified several genes/pathways expressed in mouse and human ACP, thus providing novel biomarkers for studying genotype/phenotype correlations. Finally, we show that inhibiting some of these pathways may deliver targeted therapies for the treatment of these devastating childhood tumours.

## S14.3

### Wnt signalling in oestrogen-induced lactotroph proliferation

J. Davis & G. Brabant
University of Manchester, Manchester, UK.

The anterior pituitary gland displays considerable plasticity with a proliferative response to oestrogen in a number of different situations including pregnancy. The nature of pituitary remodelling to this physiological demand is not clear.
Using microarray analysis we found that oestrogen treatment of the rat *in vivo* increased expression of Wnt4 mRNA in adult rat pituitary tissue. Dual immunofluorescence analysis showed that this Wnt4 expression was not confined to lactotrophs but was expressed in all anterior pituitary cell types. Reporter gene assays for canonical Wnt signalling action on transcription showed no effect of Wnt4 or other activators in pituitary lactotrophic GH3 cells, suggesting that an alternative pathway might be in operation. No nuclear localisation of beta-catenin was detected under any conditions in either GH3 cells or normal rat anterior pituitary cells. On the other hand Wnt4 did inhibit calcium oscillations in GH3 cells, indicating that a non-canonical pathway may be activated in the mature lactotrophic cell. Immunocytochemical studies showed that Wnt4 was particularly strongly expressed in the marginal zone, a region of the pituitary containing progenitor cells expressing Sox9. Studies in normal human pituitary tissue showed higher expression of Wnt4 staining in the lateral aspects of the pituitary but no counterpart to this marginal zone expression was clearly identifiable. Wnt4 immunostaining was seen in all types of pituitary adenoma including prolactinomas and somatotroph adenomas, and was weakest in corticotroph adenomas.
In summary Wnt4, a known developmental regulator in the fetal pituitary, is increased during oestrogen-induced pituitary proliferation. It acts through non-canonical signalling pathways in the mature pituitary lactotroph. Wnt4 is expressed in a variety of different human pituitary adenomas, though its role in their pathogenesis remains unclear.

# Adrenal cancer

## S15.1

### Molecular pathogenesis of adrenocortical cancer

E. Lalli
[1]CNRS, Valbonne, France; [2]Université de Nice – Sophia Antipolis, Valbonne, France.

Adrenocortical carcinoma is a rare heterogeneous neoplasm with a poor prognosis. Most patients present with symptoms related to steroid hormone excess or presence of an abdominal mass, while less frequently they are diagnosed incidentally during clinical exploration for other causes. In children, adrenocortical tumors are most commonly found associated with mutations of the TP53 tumor suppressor gene and have the highest incidence in southern Brazil. Several clinical and pathological features distinguish children from adult adrenocortical tumors.
Much progress has been made recently in our understanding of the pathogenesis of adrenocortical cancer, with an important contribution from genomic studies. A relevant role is played by loss of heterozygosity of the 11p15 chromosomal region, with consequent deregulation of the expression of the IGF2 growth factor and other genes. Clinical studies and mouse models also demonstrated the important role for overexpression of the SF-1 transcription factor and beta-catenin activation in triggering tumorigenesis. mRNA expression profiling of adult adrenocortical tumors allowed their molecular classification and the identification of predictors of malignancy and survival, while reliable markers of clinical outcome are still lacking for childhood tumors. Expression of a distinct set of miRNAs, affecting the function of crucial intracellular signalling pathways, is also deregulated in adrenocortical tumors and may be exploited in the future to

identify circulating markers of malignancy. Furthermore, studies of tumor genomes have shown the presence of recurrent chromosomal alterations and suggested that distinct oncogenic routes may exist in adrenocortical tumors. Finally, preclinical studies have shown the efficacy of drugs targeting the most important signaling pathways deregulated in adrenocortical tumors to slow down tumor cell proliferation *in vitro* and *in vivo*. Those drugs represent promising novel therapeutic tools to be associated to current chemotherapeutic protocols.

## S15.2

**Imaging of adrenocortical cancer**
I. Ilias
Elena Venizelou Hospital, Athens, Greece.

Adrenocortical cancer (ACC) is a rare and challenging malignancy for clinicians. The cornerstone of imaging for the diagnosis of ACC or re-evaluation of known ACC is thin-collimation computed tomography (CT) without contrast and after early and late washout of contrast medium. Although size and shape of adrenal lesions must be taken into consideration to differentiate adenomas from other adrenal lesions, it is pre- and post-contrast adrenal lesion density, measured in Hounsefield units, which is the key parameter not to be omitted; histogram analysis is also useful (sensitivities of 67–98% and specificity of 100% have been reported for both modalities). Chest CT is useful for staging while CT angiography gives important information on tumor extension. Multiplanar magnetic resonance imaging (MRI) is helpful, particularly in delineating tumor vascular extension. MRI refinements such as chemical shift add to its diagnostic potential (with sensitivity of 79–100% and specificity of 94–100%). Approximately one third of adrenal lesions cannot initially be categorized with CT/MRI. Functional (i.e. nuclear medicine) modalities are used to further evaluate patients. 131I-iodonorcholesterol (NP-59) imaging is an adrenal-cortex-specific modality, with sensitivity of 79%, but its availability is limited. Positron-emission tomography (PET) with 11C-metomidate is a recent adrenal-cortex-specific modality giving good results but its availability is also limited due to the very short half-life of 11C (newer relevant clinical studies are being undertaken with radionuclides that have a longer half-life). PET with 18F-fluorodeoxyglucose (FDG) may be non-specific for the adrenal cortex but its wide availability (and the combination of PET/CT) has yielded extensive and useful information on the evaluation of adrenal and extra-adrenal lesions. Bone scintigraphy can detect osseous disease extension. The use of CT plus FDG PET/CT may be time-saving, if not cost-effective, in the evaluation of ACC (with sensitivity of 97% and specificity of 91%).

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## S15.3

**Genetics of micronodular hyperplasias (associated with Cushing syndrome)**
C. Stratakis
NIH, Bethesda, Maryland, USA.

The overwhelming majority of benign lesions of the adrenal cortex (AC) leading to Cushing syndrome (CS) are linked to one or another abnormality of the cAMP signaling pathway. Benign adrenocortical causes of CS include the common and sporadic cortisol-producing adenoma (CPA) and a spectrum of corticotropin (ACTH)-independent, and almost always bilateral, hyperplasias. Macro-hyperplasias are more common among older patients, whereas micro-hyperplasias are frequent among children and young adults. Massive macronodular adrenocortical disease (MMAD) or ACTH-independent macronodular adrenocortical hyperplasia (AIMAH) describes a heterogeneous group of disorders that are associated with aberrant G-protein-coupled receptor (GPCR) expression (E). Abnormal GPCR-E has been found in CPAs; a small number of both MMADs and CPAs harbor somatic GNAS (Gsa) mutations. AIMAH can also be found in the context of McCune-Albright syndrome. Micro-hyperplasias are either pigmented (the classic form being that of primary pigmented nodular adrenocortical disease or PPNAD) or non-pigmented (NP-MAH) and isolated (i) or in the context of other syndromes (Carney complex – CNC). CNC and iPPNAD are caused by germline PRKAR1A mutations; somatic mutations of this gene that regulates cAMP-dependent protein kinase (PKA) are also found in 10–20% of all CPAs and abnormalities of PKA are present in MMADs. NP-MAH forms of adrenal hyperplasia and some CPAs are associated with phopshodiesterase (PDE)-11A and PDE-8B defects. Mouse models of PRKAR1A deficiency also show that increased cAMP signaling leads to tumors in AC and other tissues. Micro-RNA studies identified the Wnt-signaling pathway as a possible culprit. We also investigated Prkar1a (±) mice when bred within the Rb1 (±) or Trp53 (±) backgrounds. These studies identified Wnt signaling as the main pathway activated by abnormal cAMP signaling. Prkar1a haploinsufficiency is a relatively weak tumorigenic signal that can act synergistically with other defects to induce tumors, mostly through Wnt-signaling activation and cell cycle dysregulation.

# Understanding growth

## S16.1

**From Galton to GWAS (and beyond): what we have learned about the genetics of human height?**
P. Visscher
University of Queensland, St Lucia, Queensland, Australia.

Variation in quantitative traits such as human height is caused by a combination of multiple genes and environmental effects. Traditionally, since Galton in the late 1800s, the genetics of such traits has been studied using concepts that refer to the combined effect of all genes (e.g., heritability). Estimation of heritability for adult height are ~0.8, so that 80% of differences between people is due to genetic factors. Genome-wide association studies (GWAS) facilitate the dissection of heritability into individual locus effect. They have been successful in finding many SNPs associated with height and have greatly increased the number of genes involved in height variation. To date, hundreds of loci have been identified that explain in total about 10–15% of heritability. Estimation of heritability explained by all common SNPs together (not just the significant ones) are ~50%, spread over all chromosomes in proportion to their length, implying that there are many more variants with effects sizes too small to be detected with sample sizes employed to date. Many SNPs are in loci that are in meaningful biological pathways (e.g., skeletal growth) and/or in genes for which major (Mendelian) mutations were already known, and there is evidence at a number of genes for multiple segregating variants. The effect sizes of individual detected SNP variants are very small, about 1 to 4 mm per allele, which means that very large sample sizes are needed to detect more variants. The International GIANT (Genetic Investigation of ANthropometric Traits) consortium is analyzing GWAS data on ~250 000 people and is likely to identify hundreds more loci that are associated with adult height. The emerging genetic architecture of human height from DNA evidence is one of many hundreds to thousands of loci scattered throughout the human genome with tiny effect sizes. The identification of hundreds of associated variants facilitates the study of biology and function, in particular when genetic data is combined with data on gene expression.

## S16.2

**Genes and the investigation of idiopathic short stature (ISS): are we ready for prime time?**
J. Wit
Leiden University Medical Center, Leiden, The Netherlands.

Strictly speaking, the diagnosis of idiopathic short stature (ISS) can only be made after exclusion of all known causes of growth failure, but for pragmatic and financial reasons there are limits to the investigations that can be carried out. Clinical algorithms can assist decisions on genetic testing. Testing for SHOX is indicated if there are signs of Leri-Weill syndrome, including Madelung deformity, short forearm and lower legs. Short upper arms and legs should lead to testing for FGFR3 (hypochondroplasia). In both disorders sitting height/height ratio is high, and arm span/height ratio low. If serum IGF-I is $< -2$ SDS while

the GH peak in a provocation tests is normal or high, the differential diagnosis includes 3 conditions with normal GH sensitivity (bioinactive GH; neurosecretory dysfunction; GHSR defect) and 4 conditions with low GH sensitivity (GHR, STAT5b, IGFALS and IGF1 defects). The likelihood of such defects can be assessed by measuring GHBP, IGFBP-3, prolactin, and ALS, and performing an IGF-I generation test. While all cases with homozygous IGF1 mutations are born small for gestational age (SGA) and microcephalic, heterozygous carriers can present as ISS, particularly in short families. Children with heterozygous IGF1R defects, usually characterized by a serum IGF-I$>0$ SDS, SGA and low head circumference, but in some cases birth weight and length are $>-2$ SDS (thus 'ISS'). In cases with dysmorphic features, consulting a clinical geneticist is indicated. If a known genetic disorder is suspected, the candidate gene approach may lead to the diagnosis. If not, particularly if there are additional clinical features, a whole genome SNP analysis can be performed to detect copy number variants or uniparental disomy. With nextgen whole exome sequencing novel gene defects can be discovered, particularly if more than one family member is affected, or when various patients with a similar clinical syndrome are studied.

# Hormonal control of pregnancy

## S17.1

**Hormone signalling between mother and fetus**

R. Reynolds
University of Edinburgh, Edinburgh, UK.

The developing fetus adapts to an adverse in utero environment, and is 'programmed' to an increased risk of developing disease in later life. Fetal growth is regulated via a complex interplay between mother, placenta and fetus. Maternal nutrients, transported via the placenta, are essential for fetal growth. Conversely, the placenta may also respond to fetal endocrine signals to regulate maternal metabolism. The placenta also regulates fetal growth via production and metabolism of key hormones involved in growth and glucocorticoid metabolism. For example, the enzyme 11 beta hydroxysteroid dehydrogenase type 2 interconverts active cortisol into cortisone, thus protecting the developing fetus from the adverse effects of excess glucocorticoids. Over-exposure to glucocorticoids leads to low birthweight and programmes long term risk of development of diabetes, cardiovascular risk and behavioural problems. While most studies have focused on maternal undernutrition and long-term adverse effects for fetal growth, there is now evidence that overnutrition of the fetus may have similar adverse effects. This is pertinent given the rising prevalence of obesity as currently 1:5 women are obese at the time of pregnancy. We are exploring the factors that influence fetal growth in a cohort of severely obese (BMI$>40$) pregnant women. Ultimately it is hoped that understanding of the mechanisms regulating fetal growth will have long-term benefits for later health.

## S17.2

**What controls labour in humans?**

R. Smith
John Hunter Hospital, Newcastle, New South Wales, Australia.

In most mammals the onset of labour is regulated by an abrupt fall in circulating progesterone concentrations or a rise in circulating oestrogens. In humans, however, no dramatic change is observed in circulating steroid concentrations prior to labour and the mechanisms regulating the onset of labour have remained obscure. In a series of studies we have shown that placental production of the peptide hormone CRH increases exponentially across gestation peaking at the time of labour. We have also shown that CRH can exert direct actions on the fetal adrenal to stimulate production of DHEA which is 16 hydroxylated in the fetal adrenal and then converted to estriol in the placenta. The exponential increase in CRH drives a rise in estriol production in late gestation leading to a progressive increase in the ratio of estriol to estradiol (which is derived largely from maternal precursors). The increase in ratio of estriol to estradiol leads to activation of estrogen responsive genes and the onset of labour. Recently it has become apparent that the increase in placental CRH production is the result of expression of endogenous retroviruses in the placenta. The retrovirus gene product Syncytin promotes cytotrophoblast fusion and CRH expression. Data also indicates that CRH can directly increase placental estrogen synthesis and inhibit progesterone synthesis. Thus CRH plays a central role in modifying the placental endocrine environment to promote labour. It is not yet clear how this links to the expression of the myometrial proteins that regulate myometrial contraction including the progesterone receptors, connexin 43 and the changes in ion channels that regulate myometrial excitability. It may be that prostaglandins are stimulated by CRH and then regulate progesterone isoforms expression by changing the epigenetic marks on the promoters of the progesterone receptor promoters.

## S17.3

**Placental hormones as putative markers of gestational diseases**

C. Voltolini, M. Torricelli, C. Bocchi, M. De Bonis, F. Severi & F. Petraglia
University of Siena, Siena, Italy.

Preterm delivery (PTD) and preeclampsia (PE) are 'obstetric syndromes', characterized by complex pathogenesis and representing major causes of perinatal mortality and morbidity. Although therapeutical treatment have been developed, their incidence is not reducing. Prevention aims to preclude development of disease by eliminating/reducing risk in women with known risk factors.

The feto-placental unit produces hormonal/neuronal/immune factors, crucial in maintaining feto-placental homeostasis, that are abnormally secreted in gestational diseases as part of pathogenetic mechanisms and/or feto-maternal adaptive response. Corticotrophin releasing hormone (CRH) and inhibin/activin, expressed by trophoblast, locally modulate hormone secretion, blood vessel tone, myometrial contractility, inflammatory events. Their measurement in biological fluids has been investigated to find putative biochemical markers for early diagnosis/prediction of these conditions.

PE is characterized by poor placentation due to impeded transformation of spiral arteries into low resistance vessels. Uterine artery Doppler at mid gestation allows to screen high-risk population through early detection of abnormally high resistance uteroplacental blood flow. Maternal serum activin A and inhibin A are high at 12 and 24 weeks in patients later developing PE. sFLT-1, soluble VEGF receptor neutralizing angiogenic actions of VEGF and PlGF, is elevated in women developing PE.

Spontaneous PTD is characterized by pathological and premature onset of labor and the ultrasound measurement of cervical length and, more recently, fetal membrane thickness are useful predictors of PTD. High maternal plasma CRH can predict delivery within 48 hours in symptomatic and within 34 weeks in asymptomatic women. High plasma urocortin levels predict delivery within 34 weeks in women with threatened PTD. High salivary estriol levels predict PTD with good accuracy and plasma estriol/estradiol ratio is altered before the onset of preterm labor.

Given the complex pathogenesis of PTD and PE, a multiple approach through the combination of biophysical and biochemical parameters may add significant prognostic information in women at risk.

## Molecular mechanisms in autoimmune thyroid disease

### S18.1

**Predictors of relapse of Graves' disease after antithyroid drug withdrawal**

P. Wang[1], I. Chen[1], S. Juo[2], E. Hsi[2], R. Liu[1] & C. Hsieh[1]
[1]Kaohsiung Chang Gung Memorial Hospital, Chang Gung University College of Medicine, Kaohsiung, Taiwan; [2]Kaohsiung Medical University Hospital, and Graduate Institute of Medical Genetics, Kaohsiung Medical University, Kaohsiung, Taiwan.

For patients with Graves' disease (GD), the primary goal of antithyroid drug therapy is to temporarily restore the patient to the euthyroid state and wait for a subsequent remission of the disease. This study sought to identify the predictive markers for the relapse of disease.
To do this, we studied 262 GD patients with long enough follow-up after drug withdrawal to determine treatment outcome. The patients were divided into three groups by time of relapse: early relapse group ($n=91$) had an early relapse within 9 months, late relapse group ($n=65$) had a relapse between 10–36 months, and long-term remission group ($n=105$) were either still in remission after at least 3 years or relapsed after 3 years of drug withdrawal. We assessed the treatment outcome of 23 SNPs of costimulatory genes, phenotype and smoking habits. We used permutation to obtain P values for each SNP as an adjustment for multiple testing. Cox proportional hazards models was performed to assess the strength of association between the treatment outcome and clinical and laboratory variables. Four SNPs were significantly associated with disease relapse: rs231775 (OR, 1.96, 95% CI, 1.18–3.26) at CTLA-4 and rs745307 (OR, 7.97, 95% CI, 1.01–62.7), rs11569309 (OR, 8.09, 95% CI, 1.03–63.7), and rs3765457 (OR, 2.60, 95% CI, 1.08–6.28) at CD40. Combining risk alleles at CTLA-4 and CD40 improved the predictability of relapse. Using 3 years as the cutoff point for multivariate analysis, we found several independent predictors of disease relapse: number of risk alleles (HR, 1.30; 95% CI, 1.09–1.56), a large goiter size at the end of the treatment (HR, 1.30; 95% CI, 1.05–1.61), persistent TSH-binding inhibitory Ig (HR, 1.64; 95% CI, 1.15–2.35), and smoking habit (HR, 1.60; 95% CI, 1.05–2.42).
In conclusion, genetic polymorphism of costimulatory genes, smoking status, persistent goiter, and TSH-binding inhibitory Ig predict disease relapse.

### S18.2

**Genotype-phenotype correlations in GD**

T. Bednarczuk[1,2]
[1]Medical University of Warsaw, Warsaw, Poland; [2]Mossakowski Medical Research Centre Polish Academy of Sciences, Warsaw, Poland.

Graves' disease (GD) is a heterogeneous disorder affecting with varying degrees of severity the thyroid and eyes. This variety may suggest that complex interactions between genetic, environmental and endogenous factors influence the clinical course of GD. Although the genetic predisposition to GD is well established, the significance of genotype-phenotype correlations remains controversial. Moreover, the lack of complete phenotypic concordance in twin studies suggested that environmental and/endogenous factors are of great importance. The major environmental factor influencing the clinical course of GD is cigarette smoking.
Most evidence for genotype-phenotype correlations in GD is based now on case-control association studies with candidate genes. The following loci have been proposed to influence susceptibility to orbitopathy, age of onset of GD and/or severity of hyperthyroidism: HLA, PTPN22, CTLA4, CD40, TSHR, TG, TNF, ICAM-1, IFN-γ, IL-23R, NFKB1. Unfortunately the results of these studies have to be judged very carefully. The vast majority of studies are small and underpowered; replication studies are lacking or were unable to confirm the initial finding; the studied groups were often not characterized in detail. At present, while some genetic differences between subgroups of GD patients have been identified, none of the polymorphisms justifies genetic testing to guide therapy or preventive strategies. Genotype-phenotype correlations in GD remain to be elucidated in future, well designed and appropriately powered studies.

### S18.3

**Regulatory cells, Th17 lymphocytes, and dendritic cells in autoimmune thyroid disease**

M. Marazuela
Hospital de la Princesa, Madrid, Spain.

Human autoimmune thyroid diseases (AITD), mainly including Hashimoto's thyroiditis (HT) and Graves' disease (GD), are characterized by reactivity to self-thyroid antigens. Regulatory T cells have an important role in immune tolerance to self-antigens. We have reported that different regulatory T cell subsets are abundant in the peripheral blood and in inflamed thyroid tissue in AITD and are able to synthesize the immunoregulatory cytokines IL-10 and TGF-beta. However, they are apparently unable to downmodulate the autoimmune response and the tissue damage seen in AITD.
Since there is a reciprocal negative regulation between Treg and Th17 lymphocytes, we hypothesized that the defect in T regulatory cells could be related to an expansion of Th17 cells. Accordingly, we found a higher proportion of Th17 cells and raised levels of Th17 cytokines in the peripheral blood and thyroid gland from patients with AITD, mainly those with HT. Thus, our data suggest that Th17 may have a relevant role in the inflammatory phenomenon and tissue destruction seen in HT.
Dendritic cells (DCs) bear the great responsibility of discerning whether a particular antigen must be interpreted as harmful or innocuous; whether specific T cells must develop to self-reactive T cells or to regulatory T cells. In humans, two subtypes of DCs: myeloid (mDCs) and plasmacytoid (PDCs) have been reported, each one with different phenotype and function. We have studied the phenotype and function of both DCs (mDCs and PDCs) including the expression and function of inhibitory receptors. We have found phenotypic and functional abnormalities in DCs from peripheral blood and the thyroid gland in patients with AITD that point to a role in the amplification and/or perpetuation of the immune process. These findings add additional elements to the complex pathogenesis of AITD.

## Controversies in testosterone replacement

### S19.1

Abstract unavailable.

### S19.2

**Late onset hypogonadism: who should receive testosterone?**

J. Svartberg
University Hospital of North-Norway, Tromsø, Norway.

The search for eternal youth has created a market for treatments that might affect the process of aging, and testosterone (T) is one of the hormones that have been in focus. It is well accepted that T levels decline with increasing age, although the individual variation is large. Male hypogonadism is characterised by a low serum T level in combination with a diversity of symptoms and signs such as reduced libido and vitality, decreased muscle mass, increased fat mass and depression. Similar symptoms in combination with subnormal T levels are seen in some elderly men, and several attempts have been made to identify symptoms and corresponding T levels that would define late-onset hypogonadism as a syndrome. However, symptoms of T deficiency in elderly men are nonspecific and are difficult to discriminate from symptoms of other conditions and diseases common in older men. Despite this uncertainty, the sale of T has increased tremendously over the last few years.
In observational studies low T levels tends to predict the development of metabolic syndrome and type 2 diabetes, and have been associated with all-cause mortality and cardiovascular disease mortality. Results from small intervention studies, however, are diverging but have mainly shown that T treatment in older men increase fat-free mass and decrease overall body fat while the effect on glucose and lipid metabolism have been slight. Weight reduction, on the other

hand, in obese men with low T levels has been shown to normalize T levels as well as significantly improve both lipid and glucose levels. Thus, low T levels may be seen as a marker of general health, and the primary treatment should probably be lifestyle changes. T treatment should not routinely be initiated in elderly men with subnormal T levels until benefits and safety are confirmed in well performed studies.

## S19.3

**Testosterone for women: why when and how?**

S. Davis
Monash University, Melbourne, Victoria, Australia.

Testosterone is a vital hormone in women, circulating in nanomolar concentrations. Not only is testosterone a precursor for estradiol biosynthesis in the ovaries and extragonadal tissues, but testosterone acts directly via androgen receptors throughout the body. Levels decline with age in women with the greatest fall in total and free testosterone occurring before the menopause. Large RCTs involving naturally and surgically postmenopausal women presenting with hypoactive sexual desire disorder (HSDD) demonstrate that testosterone therapy, with/without concurrent estrogen therapy, improves the quality of the sexual experience. More recent studies demonstrate the use of testosterone therapy improves sexual wellbeing in premenopausal women with HSDD. The effects appear not to be mediated by aromatization of testosterone to estrogen. The other potential benefits of testosterone in women include favorable effects on bone density, muscle mass, vascular endothelial function and cognitive function.

Data from observational studies mostly show an inverse relationship between testosterone and CVD risk. Published RCTs indicate that non oral testosterone therapy does not adversely affect plasma lipids or other CVD risk markers. The relationship between endogenous testosterone production and breast cancer risk remains contentious, with recent studies indicating no relationship. There does not appear to be an association between testosterone and endometrial cancer, or other malignancies.

Testosterone use has not been approved other than for surgically menopausal women on estrogen therapy in Europe. Despite this, the use of testosterone by women is widespread, with vast numbers of women using testosterone preparations developed and marketed for men, testosterone preparations compounded on individual prescriptions as oral lozenges and creams, and testosterone implants. Hence there is a clear need for a testosterone therapy delivering an appropriate female dose to be approved, so that women have the option of using a product formulated for women.

# Signalling to and from osteoclast

## S20.1

**Efferent signalling by osteoclasts**

K. Matsuo
School of Medicine, Keio University, Tokyo, Japan.

The 'coupling' concept of bone resorption and formation was developed at both the whole-body and microscopic levels in the 1960's. At the whole-body level, 'coupling' served to explain a positive correlation observed between whole body rates of bone resorption and formation, as determined by radiocalcium kinetics. At the microscopic level, 'coupling' describes sequential bone remodeling at each basic multicellular unit (BMU), in which bone resorption is followed by an equivalent amount of bone formation. 'Coupling factors' have been defined as osteoclast-derived molecules that facilitate the transition from bone resorption to formation at the BMU level by either recruiting or promoting differentiation and activation of osteoprogenitors and osteoblasts. Factors derived from osteoblasts and osteocytes have generally been excluded from coupling factors to avoid confusion. Coupling factors are either released from the extracellular matrix, such as TGF-beta and IGFs, secreted from osteoclasts, like sphingosine-1-phosphate, or are membrane-bound.

The transmembrane ligand ephrinB2 is one such membrane-bound factor expressed on osteoclasts, while its receptor EphB4 is expressed on osteoprogenitors and osteoblasts. Significantly, ephrinB2/EphB4 signaling is bidirectional. Forward signaling into EphB4-expressing progenitors enhances osteoblast differentiation, while ephrin-expressing osteoclasts receive 'reverse signaling' upon ephrinB2/EphB4 interaction, suppressing osteoclast differentiation and function. It is increasingly clear that osteoclast-derived factors also negatively regulate osteoblasts. Such negative regulators may be GPI-anchored ephrinA2, which is produced by osteoclasts. Our data suggest that its receptor EphA2 expressed on osteoblasts inhibited mineralization. We propose that ephrinA2 and other osteoclast-efferent negative factors should be designated 'coupling inhibitors'.

## S20.2

**Immune signaling in osoteoclasts**

Hiroshi Takayanagi
Tokyo Medical and Dental University, Erato, Tokyo, Japan.

In addition to cellular interactions via cytokines, the immune and skeletal systems share various molecules, including transcription factors, signaling molecules and membrane receptors[1]. RANKL stimulates osteoclastogenesis through NFATc1 in cooperation with immunoglobulin-like receptors, using the immunomodulatory molecules for signalling[2]. Here I will discuss emerging topics in osteoimmunology including the mechanisms underlying bone cell communication: osteocyte RANKL[3], regulation of bone formation by osteoclast-derived Sema4D[4], and osteoprotection by osteoblast-derived Sema3A[5].

## S20.3

**Coupling of bone resorption and formation**

Xu Cao
Department of Orthopedics Surgery, Johns Hopkins University, Baltimore, Maryland, USA.

Coupling of bone formation subsequent to bone resorption is a fundamental mechanism for sustaining bone density in adults. We have demonstrated that TGFβ1 released from the bone matrix during osteoclastic bone resorption induces the migration of bone marrow mesenchymal stem cells (MSCs). We also found that IGF1 released from bone matrix responsible osteoblast differentiation of MSCs recruited by TGFβ1 during bone remodeling. TGFβ1 released from the bone matrix during osteoclastic bone resorption induces the migration of MSCs, whereas IGF1, also released from the bone matrix stimulates osteoblast differentiation of MSCs for new bone formation.

# Obesity and reproduction

## S21.1

**Integrating hypothalamic regulation of energy homeostasis and reproduction**

C. Elias
University of Texas Southwestern Medical Center, Dallas, Texas, USA.

Nutrition is a crucial regulatory component of the reproductive physiology. Conditions of negative energy balance or low energy store often causes a

disruption of the neuroendocrine reproductive axis and arrest of sexual maturation. On the other hand, excess energy, as observed in obesity, also negatively impacts the reproductive physiology. For example, high adiposity may induce or aggravate polycystic ovarian syndrome, ovulatory dysfunction and hypothalamic amenorrhea. In obese men, fertility is usually decreased due to altered activity of the hypothalamus-pituitary axis and defective steroidogenesis. Thus, changing levels of key metabolic cues constitutes a fundamental signal for the coordinated control of the reproductive physiology. Of particular importance is the adipocyte-derived hormone leptin. In humans and mice, inactivating mutations of the leptin or leptin receptor genes induce hyperphagic obesity, diabetes and infertility. These individuals exhibit low gonadotropins levels, deficient gonadal development and lack of sexual maturation. Leptin replacement to leptin-deficient subjects restores gonadotropins levels and the reproductive function. Leptin may also contribute to the obesity-associated decrease in fertility as the reproductive deficits observed in obese subjects may be in part caused by excess leptin and leptin resistance at the cellular (receptor/signaling) level. In this Symposium, I will discuss the recent advances in the identification of populations of hypothalamic neurons relaying leptin's action in the integration of metabolism and reproduction. Special attention will be given to glutamatergic neurons located in the ventral premammilary nucleus and kisspeptin neurons of the arcuate nucleus. We will also discuss the use of mouse genetics and Cre/loxP technology to assess the role of specific neuronal populations in the metabolic control of the reproductive function.

## S21.2

**Impact of obesity on male reproduction**

A. Martini
Instituto de Fisiología, Córdoba, Argentina.

The incidence of obesity has dramatically increased, not only in industrialized societies but also in developing countries. Since male fertility shows a parallel decrease, obesity should be considered as possible etiology of male subfertility. Studies exploring this possible association report that obesity may affect fertility by different mechanisms that include: abnormal reproductive hormonal milieu, increased release of adipokines and adipose-derived hormones (mainly leptin and resistin), in addition to other problems such as increased scrotal temperature, obstructive sleep apnea and accumulation of environmental toxins (endocrine disruptors) in adipose tissue. All these factors could provoke erectile dysfunction and/or decline in sperm quality.

Obese reproductive hormonal profile is characterized by reduced levels of total and free testosterone concentration, gonadotrophins, SHBG and/or inhibin B (marker of Sertoli cells function) and excess of estrogens (explained by the aromatase overactivity ascribed to adipose tissue increase).

The enhance in leptin levels could be responsible for at least some of the alterations on the hypothalamic-pituitary-testicular axis (reducing hypothalamic Kiss 1 expression) and could also exert direct deleterious effects on Leydig cells physiology, spermatogenesis and sperm function.

Adipokines (proinflammatory agents), higher scrotal temperature and toxins accumulation are responsible for the increase in testes oxidative stress, and sleep apnea suppresses the nocturnal testosterone rise necessary for normal spermatogenesis.

Finally, although controversial, hormonal misbalance and leptin increase might comprise gametes quality. Some reports indicate that obesity may decrease seminal sperm density/motility and increase sperm DNA fragmentation, probably disturbing spermatogenesis and/or epididymal function. Nonetheless, these alterations are mild.

In summary, although obesity may impair male fertility by some/all of the described mechanisms, the fact is that only a small proportion of obese men are infertile; probably those genetically predisposed or morbidly obese. Nevertheless, since the incidence of obesity is increasing, the number of men with reduced fertility will rise as well.

## S21.3

**Lifestyle modification and fertility**

R. Norman
University of Adelaide, North adelaide, South Australia, Australia.

With an increasing prevalence of overweight and obesity, there is abundant evidence linking these conditions with sub- and infertility in women. The evidence in men is less well developed but is emerging gradually. Even when fertility is achieved in women, there are many conditions of pregnancy that are increased including diabetes mellitus, hypertension, congenital abnormalities and peripartum problems. Children born also have an increased long-term problem of obesity and associated disorders. In males, there is evidence for a non-genomic transfer of metabolic disease to the offspring. Use of assisted reproduction is more comon and compromised by weight disorders.

Abnormalities of eggs, sperm, embryos and endometrium have been documented in overweight conditions in animals and humans.

Lifestyle modification to improve fertility is well documented but not accompanied by a strong literature of randomised trials or evidence-based interventions. It is alledged that $>5\%$ weight loss is effective at inducing pregnancy in overweight women. The respective roles of exercise, diet and pharmacology is yet to be determined.

The role of diet has not shown any benefit of any particular composition with most of the effect being due to the amount of calories consumed. It would seem logical to use a low calorie diet with a Mediterranean type composition. Exercise can be arranged to suit the ability of the person to participate and associated medical conditions. There is little evidence for benefit of medications, particularly metformin. A full metabolic profile should be doen prior to pregnancy, especially with respect to glucose.

Much needs to be done to determine, the epidemiology of weight disorders and infertility and outcomes of offspring. Randomised trials are essential to determine the most effective interventions. A better understanding of the pathophysiology of weight and metabolic disorders and fertility is urgently required.

# Pituitary tumorigenesis

## S22.1

**Molecular mechanisms: the genes involved in pituitary tumorigenesis**

S. Melmed
Cedars Sinai Medical Center, Los Angeles, California, USA.

Pituiatry tumors account for about 15% of all intracranial neoplasms. They arise from pituitary cell types due to both cell cycle trophic dysruptions leading to adenomatous growth, as well as a coupling of specific hormone gene over-expression. Thus, both tumor growth characteristics, as well as hormonal excess are the hallmarks of these invariably benign tumors. They may lead to both central compressive features due to mass expansion or invasion, as well as to specific clinical hormone hypersecretory syndromes. Although several familial syndromes have recently been characterized for specific gene mutations, the etiology of spontaneous non-familial tumorigenesis has remained largely elusive. This talk will emphasize findings for spontaneous pituitary tumorigenesis. Transgenic murine and zebrafish models will be described which recapitulate phenotypic human pituitary adenomas, and genetic mechanisms derived from these models will be translated to human clinical observations. Limited information derived directly from human tumor specimens will also be discussed, inasmuch as they relate directly to cause rather than effect of specific pituiatry adenoma subtypes. An overview of known genetic changes which underly pathogenesis of these tumors include dysrupted cell cycle proteins, including CDKs and CDK inhibitors and the RB-related cascade will be provided. Disordered genetic regulation of HMG proteins, PTTG, tumor supressor genes and cAMP-related genes will also be reviewed. Epigenetic and chromatin-associated changes leading to altered specific transcriptional patterns for cell cycle or hormone-related gene expression, may also contribute to the observed genetic changes. Given that these tumors are predominantly benign, and rarely progress to malignancy, genetic mechanisms underlying premature proliferative arrest and oncogene-induced senescence will also be reviewed. Overall, the myriad of genetic information will be integrated into a unifying hypothesis which determines the etiology of these tumors responsible for considerable patient morbidity and mortality. These insights provide direction for future subcellular approaches to therapy, and examples of such available pharmacologic agents will be presented. Thus,understanding genetic alterations in these tumors will lead to enhanced disease prognostic

marker prediciton, as well as development of novel therapies.
Declaration of interest

## S22.2

**Tracing back a Gene's influence**
M. Korbonits
Barts and the London School of Medicine, London, UK.

In the late 1700s, a 22 y patient suffering from pituitary gigantism died and his skeleton was deposited in a medical museum. A contemporary etching showed him standing alongside a set of giant twin brothers who were believed to be his cousins. The existence of such a rare disorder within closely related family members indicates to modern science a genetic dimension to their disease. In 1909 Cushing opened the skull and he found a greatly enlarged pituitary fossa. We identified a mutation in the AIP gene (aryl hydrocarbon receptor interacting protein, a gene known to predispose the young-onset pituitary adenomas) from a tooth of the patient indicating the genetic basis of his gigantism. In addition, several families, originating from the vicinity of the giant's birthplace were also identified with familial isolated pituitary adenoma and exactly the same AIP mutation (c.901C>T/p.R304X). Whilst the geographical location of these families suggests a common ancestral origin, the possibility of a mutational hotspot also had to be considered, as this C>T change occurred at a CpG-site and such sites typically have higher mutation rates. The hotspot theory was supported by the fact that the same mutation has been identified in several patients from various countries around the world. Microsatellites demonstrated that the 18th-century giant and the families inherited this allele from a common ancestor, while other patients with the same mutation from elsewhere do not share this common ancestor. The age of this founder mutation and forward simulations allowed us to estimate the number of carriers alive today.
Genetic screening from this geographical area identified further carriers. Clinical screening of carriers provides earlier diagnosis with an anticipated improved clinical outcome. Our case study provides an interesting example of how medical history combined with molecular genetics has resulted in direct benefit to patients and their families.

# Advances in regulation of aldosterone synthesis

## S23.1

**Regulation of aldosterone synthase expression in normal adrenal and primary aldosteronism**
W. Rainey
Georgia Health Sciences University, Augusta, Georgia, USA.

The human adrenal cortex can be divided into distinct zones that have both morphologic and biochemical differences. The production of aldosterone in the zona glomerulosa can be traced to the zone-specific expression of the enzymes involved in steroid biosynthesis. This is particularly true for its expression of the enzyme aldosterone synthase (CYP11B2). For aldosterone biosynthesis, CYP11B2 expression has often been called the 'late rate-limiting' step. We and others have shown that the expression of CYP11B2 is controlled at the level of its gene transcription, which is normally under tight control of the renin angiotensin system (RAS). Detailed analysis of the mechanisms regulating transcription of CYP11B2 has demonstrated a key role for the NGFI-B and the CREB/ATF families of transcription factors. In addition, we have extended the molecular studies to human disease and have shown that the recently described mutations in KCNJ5 increase adrenal cell expression of both CYP11B2 and NURR1. Thus, APA expression of KCNJ5 somatic mutations leads to renin-independent aldosterone production. A disruption in the normal regulation of NURR1 and CYP11B2 expression appears to be an important part of the disease process leading to primary aldosteronism. The ongoing studies are providing a detailed understanding of the molecular mechanisms regulating aldosterone and cortisol production within the normal adrenal and should provide insight into diseases of adrenal steroid excess.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## S23.2

**Extra-adrenal aldosterone biosynthesis**
C. Gomez-Sanchez[1,2]
[1]University of Mississippi, Jackson, Mississippi, USA; [2]G.V. Montgomery VA Medical Center, Jackson, Mississippi, USA.

Aldosterone (aldo) concentrations in the brain and heart are slightly lower, but parallel those in the plasma. Plasma, heart and urine aldosterone continue to be detected in very small amounts in adrenalectomized (ADX) rats, however the concentrations of aldosterone in the brain, though very low, are higher than plasma levels in ADX rats. StAR protein and all of the steroidogenic enzymes necessary for the synthesis of aldosterone are expressed in the central nervous system (CNS) of rats and humans. Brain tissue from ADX rats synthesizes aldo from endogenous substrate and converts 3H-deoxycorticosterone into 3H-aldosterone *in vitro*. Inappropriately high aldo levels are associated with increased sympathetic drive and hypertension of central origin. Aldo synthesized in the brain appears to play a role in the development of hypertension in the Dahl salt-sensitive rat. Aldo concentration in the hypothalamus of Dahl SS rats is higher than in Sprague-Dawley controls and inhibition of enzymes within the aldosterone biosynthetic pathway, including trilostane, a 3-hydroxysteroid dehydrogenase, and aldosterone synthase, decreases the BP in the Dahl SS rat. Rats in which the aldosterone synthase enzyme cDNA is over-expressed in neurons also have hypertension.
Though most of the aldo in the brain is sequestered from circulating aldo synthesized by the adrenal gland, a small proportion is locally synthesized in the normal rat. As the amount is exceedingly low and number of cells that produce aldo in the brain few, aldo produced in the brain, if relevant, would be expected to have autocrine or paracrine functions. Aldo synthesized in the CNS might have a role in those forms of hypertension and autonomic dysfunction in which circulating aldo is not elevated, but which respond nonetheless to mineralocorticoid receptor antagonists.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## S23.3

**Role of N-type calcium channel blockers in aldosterone biosynthesis**
M. Yoshimura
The Jikei University School of Medicine, Tokyo, Japan.

The inhibition of aldosterone activity is a significant approach for preventing the progression of cardiovascular diseases in hypertensive patients. We hypothesized that N-type calcium channels might regulate aldosterone biosynthesis and firstly examined *in vivo* studies using rats. We investigated the effects of cilnidipine, an L-/N-type calcium channel blocker (CCB), and nifedipine, an L-type CCB, on aldosterone levels and found that only cilinidipine significantly reduced

aldosterone levels. We secondly examined the direct relationship between N-type calcium channels and aldosterone production in human adrenocortical cells. In this study, the analysis of quantitative reverse transcription-PCR, western blotting, and immunocytological staining indicated the possible presence of N-type calcium channels in human H295R cell line. Patch clamp analysis indicated that omega-conotoxin GVIA (CnTX), an N-type calcium channel inhibitor, suppressed voltage-dependent barium currents. CnTX significantly reduced the transient calcium signaling induced by angiotensin II (Ang II) and partially prevented Ang II-induced aldosterone formation. Knockdown of $\alpha$1B calcium channel subunits significantly decreased Ang II-induced aldosterone formation with increments in CYP11B2 mRNA expression. We investigated the inhibitory activities of cilnidipine and showed a dose-dependent inhibition effect on Ang II-induced aldosterone production. These results suggest that N-type calcium channels have a significant role in transducing the Ang II signal for aldosterone biosynthesis in humans.

## ManagemDiabetes in children

### S24.1

Abstract unavailable.

### S24.2

**Hypotheses explaining the increase in type 1 diabetes**

M. Knip

[1]University of Helsinki, Helsinki, Finland; [2]Folkhälsan Research Center, Helsinki, Finland.

The incidence of type 1 diabetes (T1D) has increased markedly after World War II among children and adolescents, and in parallel the mean age at diagnosis has decreased. These trends support a critical role of exogenous factors in the development of T1D, since genetic factors alone can hardly explain the rapid increase. The hygiene hypothesis postulating a relationship between allergic diseases and a childhood environment characterized by a decreased pathogen exposure has recently been expanded to explain the rising incidence of autoimmune diseases such as T1D. It is conceivable that a decreased microbial load in early life may have a major impact on the programming of the immune system. Enterovirus infections have been implicated as potential triggers of the disease process leading to T1D. The frequency of enterovirus infections has, however, lately decreased among the general population in developed countries at the same time as the T1D incidence has increased. This seeming contradiction can be explained by the so called polio hypothesis, according to which the decreasing infection rate in the general population results in a situation where infants have an impaired protection against acute enterovirus infections early in life. This may then result in more invasive enterovirus infections, some of which might lead to the induction of the diabetic disease process as a complication. Bovine insulin have been proposed to function as a driving exogenous antigen in T1D. One can speculate that the increasing processing of milk products may have some impact on the immunogenicity of bovine insulin in commercial milk products. Children grow linearly and gain weight faster now than some decades ago. Rapid growth and weight gain induces beta-cell stress and could thereby lead to an earlier presentation of clinical T1D and also an increasing incidence by expanding the proportion of susceptible individuals progressing to overt disease.

Declaration of interest

The author declares that there is a conflict of interest.

## Reproductive hormone action

### S25.1

**GnRH receptor signalling**

Ursula B. Kaiser

Brigham and Women's Hospital and Harvard Medical School, 221 Longwood Avenue, Boston, Massachusetts, USA 02115.

The hypothalamic decapeptide, gonadotropin-releasing hormone (GnRH), is the key neuroendocrine regulator of mammalian reproductive development and function. GnRH binds to its target, the GnRH receptor (GnRHR), on pituitary gonadotropes to stimulate the synthesis and intermittent release of the gonadotropins, luteinizing hormone (LH) and follicle-stimulating hormone (FSH), which in turn stimulate gametogenesis and gonadal hormone synthesis. Thus GnRH, via the GnRHR, plays a pivotal role in the coordination of reproductive events, and dysregulation of GnRH signaling underlies many reproductive disorders, such as polycystic ovarian syndrome (PCOS), hypothalamic amenorrhea, disorders of pubertal maturation, and infertility. GnRH is released in a pulsatile manner, with the frequency and amplitude of GnRH pulses varying temporally and developmentally, for example during different phases of the menstrual or estrous cycle. These patterns of pulsatile GnRH release activate distinct signal transduction cascades to contribute to frequency decoding of GnRH pulsatility by gonaodtropes, resulting in differential LH and FSH synthesis and secretion. The identification and studies of mutations in the GnRHR in patients with disorders of reproductive maturation and function have further highlighted the importance of GnRHR signalling in regulation of gonadotropin synthesis and secretion.

### S25.2

**Light on the structural communication in gonadotropin hormone receptors: implications in genetic diseases**

F. Fanelli

[1]University of Modena and Reggio Emilia, Modena, Italy; [2]Dulbecco Telethon Institute, Modena, Italy.

The network paradigm is being increasingly used to describe the topology and dynamics of complex systems. The representation of protein structures as networks of interacting amino acids has in fact been used to investigate and elucidate complex phenomena such as protein folding and unfolding, protein stability, the role of structurally and functionally important residues, protein-protein and protein-DNA interactions and intra- and inter-protein communication and allosterism.

The graph theory was combined with fluctuation dynamics in the framework of Protein Structure Network (PSN) analysis to investigate the structural communication in the inactive and active states of the Gonadotropin Hormone Receptors (GHRs). The analysis of wild type and spontaneously occurring GHR mutants served to identify key amino acids that are part of the regulatory network responsible for propagating communication between the extracellular and intracellular poles of the receptors. Highly conserved amino acids in the rhodopsin family of G Protein Coupled Receptors (GPCRs) participate in the protein structural stability as highly connected nodes in the network (i.e. hubs) in both the inactive and active states. Moreover, they behave as the most frequent nodes in the communication paths between the extracellular and intracellular sides.

Hub distribution reflects the existence of a diffuse intramolecular communication inside and between the two poles of the helix bundle, which makes pathogenic mutations share similar phenotypes irrespective of topological and physico-chemical differences between them. Spontaneously occurring gain-of-function and loss-of-function mutations induce perturbations in the structure network that characterize the wild type form. In this framework, the computational models are useful tools for structure-based identification of ligands able to correct the genetic defect by restoring the essential features of the native structure network.

## S25.3

**Extragonadal FSH action- facts and dreams**
N. Ghinea
Inserm, Paris, France.

Early detection is essential for curative cancer therapy and for achieving a decrease in cancer mortality. Markers for incipient stages of every type of cancer constitute therefore all oncologists' dream. We have recently uncovered a new tumor marker, the FSH receptor (FSHR). Compared with the available markers, FSHR is found in a wide array of cancers, including eleven of the most frequent types. We have shown by various methods that FSHR is expressed in $>1300$ human tumors, in all tumor types examined (colon, prostate, breast, lung, ovary, testis, kidney and others), for all tumor grades and stages examined (Radu *et al. N Engl J Med* 2010 **363** 1621–30). FSHR (as protein and mRNA) is present only in the tumor's endothelial cells, most frequently at the periphery of the tumors. No expression has been noticed at the level of blood vessels in healthy tissues from cancer patients, with the exception of the reproductive organs where it is present in much lower concentrations than in tumors. A mouse tumor model showed that the FSHR is present on the luminal surface of the endothelium in tumors and can internalize ligands delivered in the vasculature.
Based on these results, FSHR appears to be very promising for various applications such as cancer diagnosis, imaging, and therapy. It is also possible that the level of the endothelial FSHR expression could have predictive power regarding the progression of the disease and the efficacy of various therapies, especially those aimed at tumor vasculature. The latter possibility is supported by our recent publication (Siraj *et al. J Cell Mol Med* 2011. doi:10.1111/j.1582-4934.2011.01495.x.) in which we reported that the level of FSHR expression in the primary kidney tumors could predict the response to subsequent therapy with sunitinib, a drug that it is thought to act by inhibiting tumor angiogenesis.

# TSH Receptor

## S26.1

**Low molecular weight antagonists of the TSH receptor**
M. Gershengorn & S. Neumann
NIH, Bethesda, Maryland, USA.

Over the last several years, we have generated low molecular weight (LMW) antagonists of the TSH receptor (TSHR) that have the potential to be developed as drugs to treat patients with Graves' hyperthyroidism (GD)/Graves' ophthalmopathy (GO) and thyroid cancer. As GD is caused by persistent, unregulated activation of TSHRs by thyroid-stimulating antibodies (TSAbs) on thyrocytes and GO may be caused by activation of TSHRs on retro-orbital fibroblasts, a LMW TSHR antagonist could be used to treat GD and GO. Some antagonists, termed inverse agonists, in addition to inhibiting receptor stimulation by agonists like TSH and TSAbs, inhibit basal receptor signaling. As TSHR exhibits basal signaling, inverse agonists could be used to inhibit basal TSHR signaling on thyroid cancer cells and thereby further suppress activation of residual thyroid cancer. In this presentation, we will describe the data we have developed concerning the effects of these LMW antagonists in model cell systems over-expressing TSHRs, in primary cultures of human thyrocytes, and in primary cultures of fibroblasts from the retro-orbital space of patients with GO.

## S26.2

**Learning from how antibodies interact with the TSH receptor**
Terry F. Davies, Syed. Morshed & Rauf. Latif
Thyroid Research Unit, Mount Sinai School of Medicine, James J Peters VA Medical Center, New York, New York, USA.

Successful crystallization of TSHR residues 21–260 has been reported (Sanders *et al. Thyroid* 2007 **17** 395) using a partial ectodomain (ECD) bound to the Fab fragment of a human stimulating TSHR monoclonal antibody (M22) and its conformational epitopes delineated. We have now studied antibody binding to the entire ECD (residues 1–412) using epitope protection. In this approach, we first protected a highly purified ectodomain fragment with a variety of TSHR antibodies prior to enzyme digestion and the protected peptides were then delineated by mass spectrometry. There were 7 protected linear peptides spanning the TSHR-ECD. Five of these regions corresponded to peptides in leucine rich domains (LRD) but in addition, monoclonal thyroid stimulating antibodies contacted a region on the amino terminal of the TSHR and a protected epitope on the hinge region (residues 263–293) which encompasses a highly conserved motif (SHCCAF) previously implicated in activation of the receptor. These data demonstrate that stimulating TSHR-Abs have epitopes not confined to the LRD but also incorporate epitopes not revealed in the available crystal structure and indicate the potential for such antibodies to activate the receptor by direct contact with the non-LRD regions of the TSHR. Only TSHR-Abs which bound to the LRD were able to activate $G\alpha s$ and $G\alpha q$ pathways and induce thyroid cell proliferation and activation. In contrast, neutral TSHR-Abs which bound only to the hinge region of the ectodomain activated only $G\alpha q$ and in the absence of PKA activation induced thyroid cell apoptosis. These results indicate that the binding sites of TSHR-Abs determine the pattern of signal activation and the resulting transduction pathways involved in thyroid cell responses.

## S26.3

**Structure and function of TSH receptor**
H. Biebermann, G. Kleinau, A. Grüters & H. Krude
Charité Universitätsmedizin Berlin, Berlin, Germany.

The Thyrotropin receptor (TSHR) is known as the important key-player for regulation of thyroid growth and function. As a G-protein coupled receptor (GPCR) TSHR predominantly activates the Gs/adenylyl cyclase and the Gq/11 phospholipase C signaling pathways, that finally regulate thyroid hormone production. Aberrant thyroid hormone production can be caused by activating TSHR mutations in case of toxic thyroid nodules or non-autoimmune hyperthyroidism or via inactivating mutations identified in patients suffering from hyperthyrotropinemia, TSH resistance or congenital hypothyroidism. Careful functional characterization of naturally occurring TSHR mutations and huge efforts from side-directed mutagenesis studies combined with fragmental structural information have widened our knowledge of signaling related processes at the TSHR significantly. In addition, it is recognized that the TSHR functions as a dimer or oligomer, which is of importance to understand specificities of patient phenotypes caused by heterozygous inactivating TSHR mutations. Strikingly, the available information is a prerequisite for understanding the role of TSHR under different physiological and pathophysiological conditions, which is also important for the development of artificial ligands that modulate controlled TSHR functions. However, several details of the TSHR are still unknown like the assembly of the entire receptor protein and the interplay between receptor components during signal transduction. For that reason, even after nearly twenty years of TSHR mutational screening, naturally occurring mutations are still helpful to reveal new insights into such missing information. Recently identified mutations for example prompted to details of the sixth transmenbrane helix during receptor activation and inactivation, or to a potential relationship between activating mutations and a TSHR oligomer constellation. Under these perspectives latest insights into pathogenic malfunctions are still of enormous importance also to complete the understanding of the TSHR regulation mechanisms and related physiological processes.

## Are endogenous testosterone levels predictors of cardiovascular events?

### S27.1

**Androgen action on the cardiovascular system**

K. Channer
Royal Hallamshire Hospital, Sheffield, UK.

The most important cause of death as men age is cardiovascular disease and as men age so their androgen status declines. Studies have shown that lowering of endogenous androgen by deprivation therapy as treatment for prostate cancer increases the risk of cardiovascular death. In long term studies, low blood testosterone is associated with accelerated atherosclerosis as manifest in coronary, aortic and carotid vascular territories.

Animal models of hypogonadism with cholesterol feeding have also shown accelerated atherosclerosis, which replacement therapy (TRT) ameliorates. The mechanism is not understood but low testosterone in men, is associated with an adverse lipid profile, increased inflammatory activation, weight gain, insulin resistance and impaired glucose tolerance which is improved by TRT as proven in randomised controlled trials.

Testosterone has also been shown to be an arterial vasodilator, an effect mediated by blocking the L-type calcium channels in the vascular smooth muscle membrane. This may be the mechanism whereby it improves exercise capacity in men with low blood testosterone who also have angina or heart failure.

The disadvantage of a low blood testosterone level is not just related to accelerated atherosclerosis. There have been at least 4 epidemiological studies showing that a low serum testosterone is associated with an excess mortality, in populations of normal men without overt vascular disease. We recently reported a follow up study of 930 men with coronary disease confirmed at angiography which showed that men with low levels of bioavailable testosterone had a highly significant increase in mortality (x2) compared with those with a normal bioavailable testosterone over a follow-up period of 7 years.

It is not known whether TRT to normal physiological levels will prolong life or reduce cardiovascular events, but there is no doubt that TRT improves symptoms, functional capacity and well being.

### S27.3

**Endogenous androgens, diabetes, and cardiovascular disease in women: the Rancho Bernardo study**

E. Barrett-Connor
Unviersity of California San Diego, La Jolla, California, USA.

For $>50$ years female cardioprotection was attributed to premenopausal endogenous estrogen levels. We describe here how cardioprotection is greatly reduced in the presence of diabetes and endogenous testosterone levels.

Forty years ago we measured total and bioavailable testosterone (bioT), total and bioavailable estradiol, and SHBG in community-dwelling older men and women from the Rancho Bernardo Study, using organic solvent extraction and celite column chromatography prior to radioimmunoassay (SSC Yen). Participants were followed to the present. SHBG was used to directly measure bioavailable sex hormones in this cohort; it was not associated with the 19-year risk of heart disease or CVD mortality in men or women.

During menopause, total testosterone levels decrease 35%, later increasing to levels near the lower range in intact women. After bilateral oophorectomy and loss of ovarian stromal cells, women had 38% lower testosterone levels; after hysterectomy without oophorectomy women still had somewhat lower testosterone levels.

In women without diabetes, FPG was positively associated with bioT levels, but not with estrone or total estradiol. Women in the highest quartile of bioT had a 2.9-fold increased risk of developing diabetes (by OGTT criteria). Older women with IGT or diabetes had higher bioT levels than normoglycemic women.

Total testosterone was positively associated with HDL and inversely with triglycerides in both sexes. In contrast, bioT was positively associated with body mass index, waist girth, and cholesterol in women but not in men. Women with higher bioT levels had more metabolic syndrome (MetS) components, while men with lower total T had more MetS components. Women with lower total T had a poorer 20-year cumulative CHD-event-free survival. In contrast, both extremes of bio-T levels predicted the poorest survival in women. Endogenous testosterone appears to be a critical component of diabetes-related sex differences in cardiovascular disease.

## Osteoporosis treatment in 2012 and beyond

### S28.1

**Controversial issues with bisphosphonate treatment**

S. Papapoulos
Leiden University Medical Center, Leiden, The Netherlands.

Bisphosphonates, because of their efficacy, safety and ease of administration, are accepted as first-line therapy for osteoporosis worldwide. They decrease the rate of bone resorption but have also distinct pharmacological properties including preferential uptake in the skeleton, primarily at sites with increased bone remodeling, and long-term retention in bone. There are differences among bisphosphonates both in their affinity for bone as well as in their antiresorptive potencies and the whole molecule is responsible for their inhibitory effect of bone resorption. Available potent bisphosphonates can be given to patients by different dosing schedules that range from daily oral administration to yearly intravenous infusions. While at the bone surface bisphosphonates decrease the rate of bone resorption and turnover, maintain or improve structural and material properties of bone, increase areal mineral density and thereby decrease the risk of fractures. Bisphosphonates are generally safe provided that recommendations and indications for their use are followed. Selection of a bisphosphonate for the treatment of an individual patient should be based on review of efficacy data, risk profile of the bisphosphonate and values and preferences of the patient. However, despite progress in our understanding of the basic and clinical pharmacology of bisphosphonates there are still controversial issues in the use of bisphosphonates in the management of osteoporosis that remain to be addressed. The most important of these issues is the length of treatment and, consequently, its potential role in the development of the rare, but serious clinical events of osteonecrosis of the jaw and atypical fractures of the femur. In addition, potential, clinically relevant differences among individual bisphosphonates, optimal selection of patients for treatment, use in combination with bone forming agents as well as their action in reducing all-cause mortality in treated patients need to be clarified.

### S28.2

**Sclerostin: a key bone regulatory molecule**

M. Robinson
UCB Pharma, Slough, UK.

Sclerostin is an osteocyte-expressed, extracellular cystine-knot protein that is lacking in patients with sclerosteosis, a rare condition characterized by excessive bone formation. Sclerosteosis patients exhibit very high bone mass (lumbar spine Z scores up to $+14$) and are anecdotally resistant to bone fracture. Homozygous patients commonly develop symptoms associated with cranial nerve entrapment from excessive bone formation but do not show signs of heterotopic bone formation or metabolic abnormalities. Carriers demonstrate moderately elevated bone mass without associated untoward symptoms of excessive bone formation. Sclerostin knockout mice recapitulate many of the features of the excessive bone

formation seen in sclerosteosis patients. Sclerostin acts by down modulating signaling through two osteogenic pathways (the Wnt and BMP pathways) and is consequently believed to negatively regulate the anabolic output from cells in the osteoblast lineage Treatment of rodents with monoclonal antibodies that block the function of sclerostin results in significant increases in bone formation, bone mass and bone strength. Further, antibodies to sclerostin can reverse the bone loss in rodents associated with ovariectomy, chronic inflammatory conditions and steroids. In primates, sclerostin antibodies cause a dose-dependent increase in circulating markers of bone formation as well as increasing bone mineral density and bone strength in both trabecular and cortical bone.
Sclerostin antibodies also accelerate bone repair in both rodent and primate fracture repair models. Mechanistic studies have shown that primarily acts to stimulate bone formation through a modeling rather than a remodeling pathway. A Phase 1 clinical study demonstrated that a humanized antibody to sclerostin increased markers of bone formation and also inhibited a marker of bone resorption in a dose-dependent manner. Sclerostin inhibition provides an opportunity to evaluate therapies to increase bone mass to reduce fracture and accelerate fracture healing.

## S28.3

### Other emerging therapies

P. Ebeling[1,2]
[1]University of Melbourne, St. Albans, Victoria, Australia; [2]Western Health, St. Albans, VIC, Victoria, Australia.

Current osteoporosis therapy is predominantly 'anti-resorptive'. Oestrogen antagonises the action of RANK-Ligand, a potent cytokine for osteoclast differentiation. Amino-bisphosphonates inhibit the HMG CoA reductase pathway, reducing osteoclast activity and viability, while denosumab is a human monoclonal antibody that binds to RANKL. Denosumab treatment reduces fractures. In a study of 7868 women with postmenopausal osteoporosis, denosumab reduced new radiographic vertebral fracture risk (HR, 0.32; 95% CI, 0.26 to 0.41; $P<0.001$); hip fracture risk (HR, 0.60; 95% CI, 0.37 to 0.97), and nonvertebral fracture risk (HR, 0.80; 95% CI, 0.67 to 0.95). Importantly, there was no increase in the risk of cancer, infection (apart from cellulitis), cardiovascular disease, delayed fracture healing, or hypocalcemia, and no cases of osteonecrosis of the jaw. However, two subsequent cases have been reported. Denosumab increases BMD after alendronate therapy, and increased BMD more than alendronate in a head-to-head study. In elderly men on androgen deprivation for prostate cancer, denosumab reduced vertebral fractures by 62%, compared with placebo, after 3 years. Cathepsin-K is a collagenolytic enzyme, relatively specific for bone. It is an 'uncoupling' anti-resorptive that reduces osteoclast activity, but not viability. The cathepsin-K inhibitor, odanacatib, increases BMD and reduces bone resorption markers in a dose-dependent manner. Importantly, bone formation is only modestly and transiently reduced. Fracture data are awaited. A further cathepsin-K inhibitor, ONO-5334, is being assessed. A new drug family inhibits endogenous inhibitors of Wnt-dependent anabolic bone pathways e.g. anti-sclerostin and anti-dikkopf (Dkk-1) antibodies. Anti-sclerostin antibodies increased BMD, bone formation and doubled skeletal strength after only 2 months in primates. A phase-1 study in older women and men showed a single injection of anti-sclerostin antibodies resulted in large increases in bone formation and smaller decreases in bone resorption, resulting in increases in BMD after only 85 days, and may represent a paradigm shift in osteoporosis therapy.

# Are we ready for novel therapies in obesity?

## S29.1

Abstract unavailable.

## S29.2

### Growth hormone replacement and metabolic syndrome in GH deficient adults

D. Clemmons
University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, USA.

There is an increased prevalence of metabolic syndrome in patients with severe GH deficiency. Prior studies used different criteria to define metabolic syndrome but in spite of this limitation, several studies indicate that GH therapy improves many of these parameters. The variable that shows the greatest improvement is waist circumference. Some studies show improvement in both systolic and diastolic blood pressure and in HDL cholesterol. Definitive evidence of decreased levels of triglycerides has not been forthcoming. GH results in minimal changes in adiponectin, leptin and resistin. The changes that occur in glucose metabolism are clearly dependent on GH dose. A low dose, e.g. 0.1 mg/day, improves glucose utilization but in studies wherein the entire range of GH doses was utilized, fasting glucose increased in initially 23% and then returned toward normal in all but 11% of patients. Only 6% of patients developed evidence of diabetes mellitus and this also tended to improve over time. Although GH administration clearly increases insulin resistances, most patients do not develop impaired fasting glucose or diabetes. In summary, the prevalence of the characteristic features of the metabolic syndrome is increased in GH deficiency. Institution of GH therapy is likely to improve waist circumference and in many patients it increases HDL. The effects on triglycerides and blood pressure are variable. Some lack of consistency may be due to patient selection and GH dosage. The effects on glucose metabolism are complex and involve increasing insulin resistance and decreasing visceral adiposity. The combined effect of these two changes results in maintenance of glucose homeostasis in most patients although a small subset may develop impaired fasting glucose or overt diabetes which requires modification of dosage. Whether changes in these parameters of metabolic syndrome will result in a benefit in terms of altering cardiovascular mortality has not been definitively determined.

## S29.3

### GLP-1 and analogues in obesity

A. Astrup
Faculty of Science, University of Copenhagen, Frederiksberg, Denmark.

A wealth of evidence has substantiated GLP-1's role in regulating appetite and energy intake in humans. Meta-analyses confirm that i.v. infusion of native GLP-1 reduces energy intake in lean and overweight subjects[1]. A high-protein diet is known to increase satiety and this effect appears to be at least partly mediated by GLP-1. Increased post-prandial GLP-1 levels have been measured in healthy subjects following high-protein meals compared with medium- and low-protein meals, which correlated to increased satiety in the high-protein group[2].
Agonists of the GLP-1 receptor, such as exenatide and liraglutide, have been demonstrated to cause weight reduction and decreased food intake in animal models and in patients with type 2 diabetes. Trials are underway to assess efficacy and tolerability in obese patients.
Liraglutide has been shown to cause weight loss in obese patients. Liraglutide 1.2–3.0 mg was compared with placebo or orlistat over 104 weeks in 564 non-diabetic obese individuals[3,4]. After 52 weeks weight loss was greater with liraglutide 3.0 mg (7.8 kg) vs placebo (2.0 kg) or orlistat (3.9 kg; both $P\leq0.0001$). Nausea and vomiting occurred more often with liraglutide, but adverse events were mainly transient and mild. In another study liraglutide 3.0 mg ($n=207$) maintained weight lost through diet and exercise for 52 weeks in 81% of subjects compared to 49% of subjects on placebo ($n=206$; $P<0.0001$)[5]. In summary, GLP-1 is an endogenous satiety hormone involved in appetite regulation and GLP-1 receptor agonists are being investigated for the management of obesity.

## New developments in pituitary adenomas

### S30.1

**Symposium 30: new developments in pituitary adenoma cytokines and other new genes in pituitary adenomas**

E. Arzt
IBioBA-CONICET-MPSP, Ciudad de Buenos Aires, Argentina.

With the aim of identifying genes involved in the development of pituitary tumors, we used the mRNA differential display technique comparing tumor and normal pituitary cells. Two genes have been identified to be involved in pathogenesis process: in prolactinomas obtained from Dopamine D2R knockout female mice, we have found differential expression of the cytokine BPMP-4 and in clones of the tumoral lactosomatroph cell line GH3 cell line overexpressing the cytokine IL6 signal transducer gp130, which have enhanced tumorigenecity in nude mice, we found the expression of a novel gene RSUME.
BMP-4 has a dual role in lactotrophas and corticotrophs: it is augmented (and its antagonist noggin decreased) during prolactinoma development stimulating this cell proliferation, while, on the contrary, in corticotrophinomas BMP-4 has an inhibitory action. In both cases the action is different of that of TGF β and involves a cross talk of smad-4 with steroid receptors. RSUME expression is induced under hypoxic conditions, increases VEGF and HIF expression, which correlates with increased angiogenic potential of the lactosomatotrophic gp130 clones, and has a potential role during vascularization. Its mechanism of action involves the stabilization of these proteins through sumoylation. RSUME is overexpressed in human pituitary adenomas, particularly in necrotic areas. These proteins provide new interesting targets for inhibiting differente steps involved in the development of pituitary adenomas.

### S30.2

**'Dopastatin': an evolving story**

T. Brue[1,2]
[1]Assistance Publique-Hôpitaux de Marseille, Marseille, France; [2]Aix-Marseille Université, Marseille, France.

Somatostatin receptors (sstr1–5) and dopamine receptor 2 (D2DR) are expressed and co-localized in several endocrine tumors including pituitary adenomas that express both D2DR and various subtypes of somatostatin receptors, depending on the original cell type. Treatment of pituitary adenomas using somatostatin or dopamine analogs targets only one receptor (octreotide/lanreotide mainly sst2, cabergoline D2DR). Association of octreotide and cabergoline showed limited additive effects in GH adenomas both *in vivo* and *in vitro*. Sst5 agonists showed *in vitro* the capacity to suppress hormonal secretion in pituitary adenomas, and pasireotide, targeting both sst5 and sst2, showed efficacy in controlling GH and ACTH hypersecretion.
Both sst2 and sst5 are able to form heterodimers with D2DR, which modifies ligand binding and signal transduction in a cooperative manner. Sst2-D2DR cooperation may be more efficiently triggered through so-called 'dopastatins' i.e. hybrid dopamine and somatostatin agonists. In GH tumoral cells *in vitro*, characterized by a balanced sst2/D2DR expression, dopastatins showed a synergic effect on cell secretion and proliferation by acting through both sst2 and D2DR receptors. *In vivo* phase IIA single dose study of BIM-23A760 dopastatin showed encouraging efficacy and safety profile. However, in a phase IIb repeat dosing clinical trial, a strong dopaminergic activity was observed, but little evidence of somatostatinergic activity with weak inhibition of both GH and IGF1. In other types of pituitary adenomas presenting lower sst2 expression, dopastatin showed *in vitro* an antisecretory and antiproliferative effects similar to D2DR agonists. In prolactinomas resistant to D2DR agonist treatment, sst2 overexpression induced a sst2/D2DR balance similar to that of GH adenomas. However inhibition of PRL secretion induced by dopastatin remained similar to that obtained by the reference D2DR agonist.
Gastro-entero pancreatic neuroendocrine tumors (GEPNET) and other neuroendocrine tumors, like pheochromocytomas and paragangliomas, express both sstr and D2DR, opening the way for potential sst2–D2DR cooperation in these tumors. Further studies are underway to validate the interest of chimeric agonists in pituitary adenomas and other neuroendocrine tumors.

### S30.3

**The use of temozolomide in pituitary tumours**

A. McCormack[1,2] & R. Clifton-Bligh[2]
[1]Garvan Institute of Medical Research, Sydney, New South Wales, Australia; [2]Kolling Institute of Medical Research, Sydney, New South Wales, Australia.

The management of aggressive pituitary tumours is challenging. These tumours are typically resistant to standard medical therapy and progressive tumour growth occurs despite multiple operations and radiotherapy. Chemotherapy has been reserved as salvage therapy, although historically results are often disappointing. However temozolomide, an oral alkylating agent, has recently demonstrated significant activity against these tumours. Over the past 6 years, growing international experience with the use of temozolomide in aggressive pituitary tumours is reflected in more than 40 published cases. A review of these cases demonstrates a 60% response rate overall to temozolomide, with prolactinomas and ACTH-secreting tumours more likely to respond compared with non-functioning pituitary tumours[1]. A degree of publication bias towards reporting of successful outcomes may be overstating the effectiveness of temozolomide in the management of aggressive pituitary tumours.
O-6-Methylguanine-DNA methyltransferase (MGMT), a DNA repair protein, directly removes the alkylating lesion induced by temozolomide. MGMT expression, as determined by immunohistochemistry, shows promise as a biomarker of response to temozolomide, although there is concern about its clinical utility[1]. In addition, low MGMT expression has been reported with increased frequency amongst more aggressive pituitary tumours[2]. This suggests that MGMT may play a role in pituitary tumorigenesis. Indeed, we have recently found a difference in the gene expression profiles between pituitary tumours with low and high MGMT expression.
Temozolomide is the first chemotherapeutic agent to show promising efficacy in the treatment of aggressive pituitary tumours, and clinical trials are needed. Pituitary tumour MGMT expression may serve both as a biomarker of response to temozolomide and a prognostic marker.

**Genetics of disorders of sex development**

T. Ogata[1,2]
[1]Hamamatsu University School of Medicine, Hamamatsu, Japan; [2]National Research Institute for Child Health and Development, Tokyo, Japan.

Recent progress in molecular genetics has successfully identified multiple causative genes for DSD. Such advance is primarily based on the detection of pathologic mutations on coding sequences. However, genetic disorders can be caused by other mechanisms. Here, I will review such mechanisms that have been identified recently.
Aromatase excess syndrome (AEXS) as a model for genomic disorder
AEXS is a rare autosomal dominant disorder characterized by gynecomastia in which no causative mutation has been identified on the coding region of CYP19A1. Here, I will explain three genomic rearrangements leading to AEXS because of CYP19A1overexpression: i) a tandem duplication involving seven of 11 non-coding CYP19A1 exons 1 associated with tissue-specific promoters; ii) two types of deletions at the upstream region of CYP19A1 that have produced a chimeric mRNA between CYP19A1 coding exons and a promoter-associated DMXL2 exon 1; and iii) four types of inversions involving the upstream region of CYP19A1 that have yielded chimeric mRNAs between CYP19A1 coding exons and promoter-associated exon 1 of CGN1, MAPK6, TMOD3, and TLN2. This represents novel mechanisms leading to gain-of-function of CYP19A1.
SOX9-related DSD as a model for a regulatory region disorder
SOX9 is a causative gene for DSD and campomelic dysplasia. Recent studies have indicated that heterozygous deletions of the $5'$ region of SOX9 can lead to 46,XY DSD with gonadal dysgenesis (I will introduce a hitherto unreported patient with this condition), and that heterozygous duplications involving similar regions can result in 46,XX DSD with variable degree of testis development. In addition, larger duplications involving the commonly duplicated segment in 46,XX DSD patients permit normal male sex development. These findings imply that the contrastive DSD phenotypes may be caused by loss or duplication of a testis-specific enhancer(s), or by alteration of a chromatin structure affecting SOX9 expression.

### S32.2

**Psychosocial and psychosexual outcome in DSD**

P. Cohen-Kettenis
VU University Medical Center, Amsterdam, The Netherlands.

The 2006 DSD consensus statement states that all newborns should receive a gender assignment. Gender assignment decisions are typically guided by a combination of diagnosis and long-term, adult follow-up studies that focus on gender identity stability and other psychosexual outcomes. One relevant question in gender assignment is whether, in newborns, gender identity can be predicted, and if so, whether adult gender identity is related to prenatal brain exposure to testosterone. Sexuality is another area that is closely related to quality of life. It may be hampered by psychological factors, such as uncertainties about one's sexual orientation, fertility, or appearance, but also to medical interventions such as early surgery. From various reviews is appears that gender identity is not closely related to prenatal brain exposure to testosterone. It also seems that adolescent girls with DSD reach psychological milestones somewhat later than their peers and that sexual problems are more common in women with DSD than in control women. Outcomes, however, differ largely between conditions, gender of rearing and treatment centers. This reflects the need for large scale multi-clinic collaboration.

## Pollution Related Acromegaly

### S33.1

**Pollution mediated acromegaly**

S. Cannavo
University of Messina, Messina, Italy.

Acromegaly is a disease due, almost in all cases, to a pituitary adenoma (PA) characterized by GH hypersecretion. Its prevalence seems widely variable among different geographic areas, ranging 36–151 cases $\times 106$ of inhabitants (c.p.m.). Apart from the possible underestimation due to misdiagnosis, reliable epidemiological studies showed that the prevalence of acromegaly could be 4–5 times higher in some geographic areas than in other ones, independently by presumable geographic clustering due to a very rare genetic predisposition. In 2010, we showed that prevalence of acromegaly in the province of Messina (654.601 inhabitants) was 97 c.p.m., similar to that reported in other studies performed in other European country, but it was dramatically higher in a high-risk zone for environmental crisis (RR 2.36, 95% CI 1.20–4.64, $P=0.01$). In this zone the prevalence was 210 c.p.m. and increased to 238 c.p.m. when four neighboring small towns, identified on the basis of increased air pollutants distribution, were enclosed into the high-risk zone. In this wider area, laryngeal, bone, and connectival tumors, among men, and all kind of tumors, among women, were more prevalent than in the population residing in surrounding towns in a 15 km radius area. On the basis of studies performed from 2002, daily atmospheric concentrations of non methanic hydrocarbons (NMHC), and volatile organic compounds (VOC) are dramatically increased in the high-risk zone. The risk to develop PAs after exposition to environmental toxics was evaluated also in Seveso populations, after accidental dioxine exposure, demonstrating that the relative risk of developing PAs was increased, despite not significantly. The effect of several endocrine disruptors in the proliferative promotion and in hormone secretion of pituitary cells (CH3, MtT/E-2, HeLa, etc.) is well known, but their role on pituitary tumorigenesis have been poorly investigated until now.

**Exposure to endocrine disrupting chemicals may interfere with reproductive development in humans and affect timing of puberty**

K. Main
Rigshospitalet, Copenhagen, Denmark.

Man-made chemicals in our environment may be harmful, in particular for the developing child with potential irreversible effects into adulthood. Considering the rapid increase in use and distribution of such chemicals over the past decades, it is tempting to speculate whether these changes contribute to the increase in some health problems.

The prevalence of hypospadias and cryptorchidism in boys has increased in some countries, parallel to adult testicular cancer and impaired semen quality. Many countries report an earlier onset of puberty, in particular in girls. In addition, there is evidence that some environmental chemicals contribute to postnatal obesity.

Our data from prospective cohort studies show associations of early pre- and perinatal chemical exposure with reproductive outcomes in both sexes, body composition and puberty.

Exposure to persistent chemicals such as polybrominated diphenyl ethers (flame retardants) and polychlorinated pesticides increased the risk of giving birth to a son with cryptorchidism. Exposure to phthalate monoesters (plastic emollients) was negatively correlated with infant serum testosterone levels and anogenital distance (AGD). AGD is a measure of androgen effect in the newborn, which is positively associated with semen quality in adulthood. Childhood exposure to phthalates additionally lowered thyroid hormone and IGF1 levels and affected growth patterns.

Early prenatal exposure to modern pesticides was associated with earlier onset of breast development in girls, smaller genital size in boys and an increase in body fat percentage. The latter effect was enhanced if the mother also smoked during pregnancy and the child was carrier of a specific genetic polymorphism, underlining the importance of interaction between life style, genetic susceptibility and exposure scenarios.

Thus, current evidence suggests that growth and reproductive development in both sexes may be susceptible to endocrine disrupting chemicals.

## S33.3

**Effect of iodine intake on thyroid diseases in China**

W. Teng[1,2]
[1]Institute of Endocrinology and Department of Endocrinology and Metabolism, The First Hospital of China Medical University, Shenyang, China; [2]Key Laboratory of Endocrine Diseases, Sheyang, Liaoning Province, China.

It has been 14 years since universal salt iodization was conducted legislatively throughout China in 1996, and the residents experienced the period of excessive iodine intake (MUI > 300 μg/l) for 6 years and more than adequate iodine intake (MUI 240 μg/l) for 8 years, and now the status of iodine is normally adequate (MUI 180 μg/l).

During this period, we completed several epidemiological studies on the relationship between iodine intake and thyroid diseases. (1) A 5-year follow-up study ($n = 3761$) conducted in three regions with different levels of iodine intake (MUI 84, 243 and 651 μg/l respectively) showed that the incidence of subclinical hypothyroidism increased by 11.3 and 12.6 times in the communities with more than adequate iodine intake and excessive intake, respectively. The incidence of autoimmune thyroiditis increased by 4.4 and 5.5 times respectively. A shift in iodine intake from mildly deficient to more than adequate was a risk factor for the development of subclinical hypothyroidism to overt hypothyroidism. the incidence of papillary thyroid carcinoma significantly increased in the community with excessive intake of iodine (MUI 651 μg/l). (2) A cross-sectional study ($n = 3813$) conducted in two communities with different levels of iodine intake (MUI 261 and 145 μg/l, respectively) showed that the prevalence of subclinical hypothyroidism and autoimmune thyroiditis were significantly higher in subjects from the region with more than adequate iodine intake than with adequate iodine intake. (3) A follow-up study conducted in pregnant women ($n = 610$) showed that the prevalence of post-partum thyroiditis significantly increased in the subjects with more than adequate and excessive iodine intake. (4) A cross-sectional epidemiologic study of ten cities ($n = 15\,008$) showed that the prevalence of overt hypothyroidism, subclinical hypothyroidism, positive TPOAb and TgAb in the region with more than adequate iodine intake (MUI 240 μg/l) were significantly higher than adequate iodine intake (MUI 189 μg/l).The serum TSH level significantly increased with the increase of iodine intake.

In conclusions, supplementation of iodine should be maintained at a safe range with MUI 100–200 μg/l in order to ensure the thyroid health of susceptible populations (more than 10% of the general population).It is necessary to establish the region iodine-specific reference interval of TSH to avoid the influence of iodine status.

# Effects of thyroid hormone derivatives

## S34.1

**Pathways of thyroid hormone (TH) metabolism**

J. Koehrle
Charité Universitätsmedizin Berlin, Berlin, Germany.

TH are derived from the iodinated amino acid tyrosine and coupled to their typical diphenylether structure. Metabolic modifications of TH lead to activation, inactivation or novel quality not exerted by the parent molecule L-$T_4$. Phenolic-5′-(outer) and tyrosyl-3′-(inner ring) deiodination are well known metabolic pathways. Activating 5′deiodination of $T_4$ to $T_3$ is catalysed by two distinct DIO1 and DIO2 selenoproteins, with distinct biological characteristics, developmental profiles, tissue distribution and regulation. DIO2 significantly contributes to local $T_3$ production while DIO1, highly expressed in hepatic, renal and thyroid tissue, mainly generates $T_3$ for systemic circulation. DIO3 represents the key enzyme for $T_4$ and $T_3$ inactivation in various tissues, diseases and during development. Inappropriate function of DIO3 during development alters the HPT set point and over-expression in juvenile hemangioma leads to 'consumptive hypothyroidism'. TH metabolism at the alanine side chain generates Tetrac and Triac, both found in the blood. Tetrac antagonizes $T_4$ and $T_3$ activation of the cell membrane $\alpha_v\beta_3$ integrin receptor, possibly involved in tumour proliferation and angiogenesis. Triac, a potent TR ligand, is clinically used in TH resistance without producing concomitant $T_3$-typic cardiac effects. Recently, 3T1AM has been 're-discovered' as a potent 'cooling' thyroid TH metabolite. Aromatic amino acid decarboxylase had been proposed as the enzyme catalysing decarboxylation of the TH alanin side chain to thyronamines, but this hypothesis has recently been refuted. Oxidative diphenylether-ring cleavage inactivates TH generating DIT, found in septic serum and probably generated by activated macrophages and leucocytes. Conjugation of the 4′ phenolic OH group with sulphate or glucuronide inactivates TH and leads to their biliary excretion and enterohepatic recycling.

Several major and minor pathways of TH metabolism have been characterized during the last decades, but still detection of novel, relevant TH metabolites such as 3T1AM brings surprises for thyroid community. Supported by DFG and BMBF grants.

## S34.2

**Thyroid hormone mimetic compounds**

G. Chiellini
University of Pisa, Pisa, Italy.

Thyroid hormones $T_4$ and $T_3$ regulate many different physiological processes in different tissues in vertebrates. Most of the actions of thyroid hormones are mediated by the thyroid hormone receptor (TR), which is a member of the nuclear receptor superfamily of ligand-activated transcription regulators. There are two different genes that encode two different TRs, TR alpha and TR beta, and these two TRs are often co-expressed at different levels in different tissues. TRα is the major TR in the heart, and is crucial for heart rate and for cardiac contractility and

relaxation, whereas TRβ is the predominant TR isoform in the liver and is important for lipid metabolism. Compounds that selectively modulate thyroid hormone action by functioning as isoform-selective agonists or antagonists of the TRs might be useful for medical therapy. We present here the design, synthesis and biopharmacological profile of a series of halogen free TH analogs, either agonists or antagonists, structurally related to our TRbeta selective lead compound GC-1, also known as QRX-431 and Sobetirome, which recently completed Phase I clinical studies as a cholesterol-lowering agent. Selective thyroid hormone modulators provide useful experimental probes to better define thyroid hormone actions, and most importantly some of them have the potential to become novel therapeutic agents.

# Endocrinology and the Olympics: Will hormones help to win?

## S35.1

### Does the high performance athlete need hormone replacement?

L. Di Luigi
University of Rome 'Foro Italico', Rome, Italy.

Endogenous hormones (e.g. catecholamines, glucocorticoids, growth hormones, androgens, growth factors) may affect the characteristics of physical capacity and performance in athletes by influencing, throughout long-term and short term effects, morphological and functional qualities of neuromuscular, cardiovascular, metabolic and adaptive systems. Exercise per se is associated to the release of different hormones: acute exercise stimulates an acute hormones secretion (e.g. catecholamines, growth hormone, CRH-ACTH-cortisol, testosterone) while chronic exercise (training) is able to modify hormones secretion at rest and their activation during acute exercise. A physiological quantitative/qualitative hormone release at rest (e.g. for long-term effects) and an adequate hormones activation during exercise (e.g. for short-term effects) are essential to reduce specific health risks and to guarantee optimal performances in athletes. Consequently, in athletes with reduced/altered hormonal secretion a correct and specifically adapted replacement therapy is necessary. In fact, at least in theory, for health-protective concerns and to guarantee optimal/maximal physiological performances the hormone replacement in athletes should assure the physiological amount of the reduced hormone and to reproduce, as much as possible, its physiological profile/rhythm and specific activation during exercise. In this sense, besides symptomatic classical diseases or conditions that may reduce/alter the qualitative/quantitative hormones secretion, serious clinical concerns exist for asymptomatic endocrine hypo-function (e.g. sub-clinical hypogonadism, growth hormone deficit and hypothyroidism), particularly in adult athletes. For example, in master athletes we observed an high prevalence of undiagnosed severe (12%) and mild (18%) hypo-testosteronemia frequently in the absence of clinical symptoms. In our opinion, a testosterone replacement therapy should be considered in all athletes with true hypogonadism (e.g. no related to anabolic androgens abuse) independently from the presence of classic symptoms of hypogonadism and if no contraindications exist. Unfortunately, few studies evaluated the prevalence of reduced hormones secretion in athletes and the concept of adapted hormone replacement in high competitive athletes.

## S35.2

### Can an endocrine patient participate in high performance sports?

R. Auchus[1], J. Brenna[2], H. Tobias[2] & Y. Zhang[2]
University of Michigan, Ann Arbor, MI; Cornell University, Ithaca, New York, USA.

The question posed by this title encompasses three issues. First, certain endocrine diseases present physiologic challenges to high-intensity or endurance activities, including type 1 diabetes mellitus and adrenal insufficiency. Using carefully adjusted insulin regimens evolved in concert with training sessions, several athletes with type 1 diabetes have succeeded in elite competitions, but the endocrinologist must 'train with the athlete' and craft regimens that continuously deliver both insulin and glucose. Patients with adrenal insufficiency might require additional hydrocortisone for training in extreme circumstances of heat and intensity, even when fluid and electrolyte replacement appears adequate. Second, specific endocrine disorders require treatment with hormones, which are banned performance-enhancing substances. Men with hypogonadism require testosterone replacement, and type 1 diabetics require insulin therapy. For these athletes, a process called Therapeutic Use Exemption (TUE) has been developed, and this process will be reviewed. Third, certain endocrine disorders and genetic variations might confound testing for doping with androgens and lead to false-positive or false-negative test results. For example, women with 21-hydroxylase deficiency excrete higher amounts of androgens and their metabolites than unaffected women, and depending on the testing method, might be flagged for testosterone doping. A common deletion in the UGT2B17 gene impairs the capacity of some testing methods to detect testosterone doping by lowering the excretion of testosterone glucuronide but not epitestosterone glucuronide. Efforts to improve the accuracy of testing for doping with testosterone or other endogenous androgens will be discussed.

Declaration of interest
The authors declare that there is a conflict of interest.

## S35.3

### Hormone abuse in sports: the knowns and unknowns

M. Thevis
German Sport University Cologne, Cologne, Germany.

Sports drug testing laboratories are facing multifaceted challenges including the misuse of naturally/endogenously occurring substances, non-approved/discontinued drug candidates, urine manipulation, etc. In order to enable the differentiation of licit drug use and/or the natural variation of hormone concentrations (due to e.g. legal interventions) from doping offences, best-possible analytical performance is required. Therefore, modern doping control analytical assays commonly employ mass spectrometry-based and immunological approaches to detect prohibited substances and methods of doping exploiting the respective advantages.

With the constantly increasing analytical requirements concerning the number of target compounds, the complexity of analytes (e.g. peptides and proteins) as well as the desire to accelerate analyses and obtain information allowing also for retrospective data mining, high resolution/high accuracy mass spectrometry has gained much attention recently. This methodology is successfully complemented and seconded by selected immunoassays targeting in particular peptide hormones such as human growth hormone (hGH) and erythropoietin (EPO). In the course of the presentation, advances and limitations of current methods in sports drug testing will be outlined by means of selected examples demonstrating the complexity of measuring mostly known and partly unknown substances from a limited volume of serum or urine.

## Bone and metabolism

### S36.1

**Leptin and bone signaling**

S. Takeda
Keio University, Tokyo, Japan.

Osteoporosis is caused by a failure of bone homeostasis. The precise molecular mechanism controlling bone homeostasis is largely unknown. Increasing evidences that neurons and neurotransmitters are intimately involved in bone remodeling shed light on a novel regulatory mechanism for bone homeostasis. Namely, like all other homeostatic functions, bone remodeling is under the control of hypothalamus. We have uncovered that leptin, an adipocyte-derived anorexigenic hormone, regulates bone mass through its receptor located in the central nervous system. Subsequent analysis revealed that leptin uses sympathetic nervous system to inhibit bone formation and stimulate bone resorption. Furthermore, serotonin has emerged as an indispensable molecule linking leptin, bone and energy metabolism. We also found that NMU, another anorexigenic neuropeptide, is a novel central mediator of leptin-dependent regulation of bone mass. In addition, many epidemiological studies confirmed the effect of beta blockers on bone mass and fracture. We are currently analyzing the bone abnormality in mice lacking other neuropeptides. I will summarize the advance of this brain-bone-adipo axis research field.

### S36.2

**Insulin-bone axis**

Thomas. L Clemens
Department of Orthopaedic Surgery, Johns Hopkins Maryland, USA.

Energy homeostasis in mammals is controlled by the actions of circulating hormones, which coordinate fuel production and utilization between metabolically active tissues. Mounting evidence implicates the osteoblast as an important player in the coordination of global energy utilization through its hormonal interactions with other tissues. Leptin produced by adipocytes controls postnatal bone acquisition by activating sympathetic nerves whose efferent outputs target $\beta_2$-adrenergic receptor on osteoblasts to regulate their proliferation and differentiation. Insulin stimulates osteocalcin production by the osteoblast, which in turn stimulates insulin secretion by the pancreas. These observations suggest that skeletal cells such as the osteoblast, whose cellular ancestry is common to fat and muscle, evolved pathways to participate in global energy homeostasis. New basic questions arising from these findings will probe the precise nature of the fuel sensing and processing mechanisms in the osteoblast and their relative contribution to overall glucose disposal and utilization. The answers to these questions should improve our ability to diagnose and manage patients with metabolic diseases.

### S36.3

**Functions and mode of action of osteocalcin**

G. Karsenty
Columbia University, New York, New York, USA.

We have proposed twelve years ago that bone mass accrual, energy metabolism and reproduction must be coordinately regulated by hormones that would appear during evolution with bone. This hypothesis has been tested and verified in several ways one of them being to show that osteocalcin, the most osteoblast-specific secreted protein, is a hormone that regulates insulin secretion, glucose homeostasis, energy expenditure and male fertility. The metabolic function of osteocalcin has been confirmed, through correlative studies, in humans. Work in our laboratory has begun to unravel the signaling pathway used by osteocalcin to fulfill some of its actions. We will present at the meeting the current state of knowledge signaling the functions and mode of action of this hormone.

### S37.3

**Goiter throughout the pediatric ages**

M. Polak
[1]Hôpital Necker, AP-HP, Univesrsité Paris Descartes, INSERM U845, Paris, France.

Goiter may be present before birth in utero, at birth or detected at any age thereafter. The goiter may be caused by increased thyrotropin (TSH) secretion resulting from hypothyroidism; antibodies that activate TSH receptors (Graves' disease) with increased thyroid hormone secretion; or TSH-independent processes, such as inflammation associated with autoimmune thyroiditis, benign and malignant tumors, and infiltrative disease.

The causes of goiter in fetuses, infants, children, and adults are similar, but their relative frequency varies substantially. In the United States and in Europe, for example, most children with a goiter have chronic autoimmune thyroiditis; whereas, among adults, nontoxic nodular goiters predominate. Goiter in neonates and infants will be more often due to dyshormogenesis whereas in older children and fetuses the major causes will be autoimmune disorders.

We will not cover all the etiologies but rather will focus on less known forms of goiter such as in fetuses where the therapeutic options may appear controversial. In pregnant women with past or current Graves' disease, ultrasonography of the foetal thyroid gland by an experienced ultrasonographer is an excellent diagnostic tool that will inform of potential fetal thyroid dysfunction if a goiter is noticed; close teamwork among internists, endocrinologists and obstetricians, echographists and paediatrician, can ensure normal foetal and neonatal thyroid function. Some rare studies have confirmed the feasibility and safety of intrauterine L-thyroxine treatment for nonimmune fetal goitrous hypothyroidism when detected. Whether it allows goiter size reduction in the majority of cases, the effectiveness to reach euthyroidism at birth remains inadequate; monitoring of fetal thyroid function by amniocentesis was not adequate. In the latter situation, the risks to the foetus and the psychological burden on the parents should be factored into the risk to benefit evaluation.

The possibility of delayed detection of goiter due to congenital dyshormonogenesis rather than autoimmune goiter will also be pinpointed.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## Craniopharyngioma: Hypothalamic complications

### S38.1

**Childhood Craniopharyngioma**

H. Müller
Klinikum Oldenburg, Oldenburg, Germany.

Craniopharyngiomas are embryogenic tumorous malformations of the sellar region, presumably derived from Rathke cleft epithelium. With an overall

incidence of 0.5–2 new cases per million population per year, approximately 30–50% of all cases represent childhood craniopharyngioma. Typical manifestations at primary diagnosis are headache, visual impairment, polyuria/polydypsia, growth retardation, and weight gain.
Therapy of choice in patients with favorable tumor localization is total resection with the intention to maintain optical nerve and hypothalamic-pituitary functions. In patients with unfavorable tumor localization (hypothalamic tumor involvement), a limited resection followed by local irradiation is recommended.
Survival rates are ranging from 91 to 98%. Recurrences after complete resection and progressions of residual tumor after incomplete resection are anticipated subsequent events after primary surgery. Accordingly, the appropriate time point of irradiation after incomplete resection is currently under investigation in a randomized trial (KRANIOPHARYNGEOM 2007).
Quality of survival is frequently impaired due to the proximity to optical, pituitary and hypothalamic structures. Long-term sequelae substantially reduce the quality of life of ~50% of long-term survivors, notably extreme obesity owing to hypothalamic involvement and/or surgical- or radiation-induced lesions especially of posterior hypothalamic structures.
Initial hypothalamic tumour involvement, especially when both, anterior and posterior areas are involved, has an apriori effect on the clinical course. Therefore, the recommendations are based on recognizing childhood craniopharyngioma as a chronic disease requiring commensurate monitoring and medical resources for treatment and follow-up in order to provide the best lifetime quality of life for the patient.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## S38.2

**Hypothalamic disorders in Clinical practice; relevance to clinical practice**

C J Thompson
Beaumont Hospital, Dublin, Ireland.

Craniopharyngioma (CP) is associated with considerably higher mortality and morbidity than pituitary adenomas. The tumours are rare, but present a considerable management challenge. In addition to the endocrine and mass effects which are common to all tumours arising from the region of the pituitary fossa, the site, size, and sometimes the treatment of CP, dictate that the endocrinologist must also manage hypothalamic complications. Endocrinologists are aware of the high frequency of diabetes insipidus in CP, which, in contrast to pituitary adenomas, may be present prior to surgical intervention. However diabetes insipidus may be complicated in craniopharyngioma by thirst disturbances. These include adipsia/hypodipsia, which predisposes to hypernatraemia, particularly during intercurrent illness, and polydipsia, which may lead to hyponatraemia when the patient is treated with desmopressin for DI. Obesity is very common in CP patients and is most likely multifactorial; some patients have polyphagia and are sometimes referred to as having hypothalamic obesity, whereas others have somnolence and low exercise levels. The contribution of hormonal disturbances to obesity remains to be fully explained. A number of groups have shown disturbances of sleep, including obstructive sleep apnoea, in CP, and daytime somnolence in the absence of sleep disorders has also been reported. The heterogenous nature of somnolence in CP indicates that patients should be fully evaluated as a number of therapeutic interventions are available which can improve quality life. Many authorities have hypothesised that hypothalamic complications of CP may be related to the effects of destructive neurosurgery and recommendations for less extensive surgery with post operative radiotherapy is partly predicated on aspirations to minimise high morbidity hypothalamic complications in CP patients.

## S38.3

**Management of hypothalamic obesity in patients with craniopharyngioma**

G. Wittert
Univ Adelaide, Adelaide, South Australia, Australia.

The presence of a craniopharyngioma, and/or treatment related damage to centres in the hypothalamus that regulate energy balance often results in severe obesity and abnormal eating behaviours. This may be exacerbated by hormonal deficits from coexistent hypopituitarism.
Decreased activity of sympathoadrenal activity, deregulated parasympathetic activity, marked hyperinsulinaemia and elevated leptin disproportionate to fat mass are evident. Plasma levels of alpha-melanocyte stimulating hormone are reduced. Delayed suppression of ghrelin after food intake, and in part the hyperinsulinaemia, along with hyper-responsiveness of GLP1 release to glucose may reflect dysregulation of vagal neural circuits mediating gastro-intestinal function. Intentional and non-exercise associated physical activity decreases. Disruption of the co-ordination of circadian rhythms including the sleep wake cycle and the presence of obstructive sleep apnoea may also be contributory.
Efforts to optimise diet and levels of physical activity and pituitary hormone replacement, including the minimisation of hydrocortisone dose, adequate sex steroid replacement, and use of growth hormone and CPAP may improve overall health and well-being, but have minimal effect on weight and eating behaviour. The long acting somatostatin analogue octreotide lowers insulin levels, but does not produce significant weight loss, nor does low dose dexamphetamine, although they may help to stabilise weight. Dexamphetamine or modafinil may be helpful when daytime somnolence is problematic. Metformin improves metabolic state and may also help to ameliorate weight gain.
Bariatric surgery, in particular the Roux-en-Y gastric bypass (RYGB), has been shown to be a safe and highly effective treatment modality; an illustrative case and review of the evidence will be provided.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

# Adrenal insufficiency

## S39.1

Abstract unavailable.

## S39.2

**Molecular pathomechanisms of steroidogenetic adrenal disorders**

F. Riepe
University Hospital Schleswig-Holstein, Kiel, Germany.

Adrenal steroid hormones are vitally important. Deficient adrenal steroid biosynthesis causing a lack of glucocorticoid and / or mineralocorticoid hormones leads to hypoglycaemia, hypotension, salt loss and death. Concomitant changes in adrenal androgen biosynthesis are responsible for virilisation in females or undervirilisation in males. Because of the importance of adrenal steroids for overall survival and reproduction, defects in steroidogenesis and steroid action are rare and have serious consequences. The steroidogenic enzymes belong to the cytochrome P450 enzymes and hydroxysteroid dehydrogenases. Cytochrome P450 enzymes can be subdivided into mitochondrial type 1 enzymes and endoplasmic type 2 proteins. The hydroxysteroid dehydrogenase are either aldo-keto reductases or short-chain dehydrogenases. Expression of the genes that mediate steroidogenesis is tightly controlled by numerous transcription factors such as NR5A and GATA family members. The enzymatic activity is further affected by posttranslational modifications or protein-protein interaction with cofactors, e.g. responsible for electron transfer. Naturally occurring sequence variations in steroidogenic enzymes are responsible for various forms of isolated or complex adrenal insufficiency. By studying the molecular genetics of these rare defects *in vitro* and in silico, the underlying molecular mechanisms can be described. Hereby, protein residues involved in heme positioning and binding, substrate access and product release, electron transfer and cofactor binding as well as regions inhibiting proteolysis have been detected. These analyses give further insights in the structure-function relationships of steroidogenic enzymes what is of fundamental importance for the understanding of adrenal diseases, disorders of sexual differentiation or reproduction.

## S39.3

### New developments in the immunology of Addison's disease

E. Husebye, E. Bratland & R. Hellesen
University of Bergen, Bergen, Norway.

Autoimmune Addison's disease (AAD) is an endocrine disease resulting from the immune system's destruction of hormone producing cells in the adrenal cortex. Autoantibodies against the steroidogenic enzyme 21-hydroxylase (21OH) is the hallmark of this form, and found in about 85 percent of patients in European populations. Risk factors are both genetic and presumably environmental. Genes associated with AAD are MHC class II especially the DR locus, MHC class I and MIC-A, but other immune genes such as PTPN22 and CTLA-4 also contribute. Recently, T cells reactivities against 21OH have been observed in patients with AAD, all of which had autoantibodies against 21OH. Moreover, the high-risk genotype DR3/DR4(0404) was frequently observed among those showing T cell proliferation. Autoantibodies potentiated the proliferative response and epitope mapping revealed that the peptide 21OH(342–361) was responsible for much of the reactivity. The adrenocortical cell itself may participate in the autoimmune destruction by expressing toll-like receptors and producing chemokines such as interferon inducible protein 10 thereby attracting lymphocytes to the adrenal cortex.
We hypothesized that the hormone producing cells in the adrenal cortex under proinflammatory conditions, such as viral infections, play a critical part in the induction of autoimmune Addison's disease in genetically susceptible individuals.

### DICER1 mutations characterize a novel syndrome with endocrine features

M. Wu[1,2], J. Priest[5], N. Hamel[1,3], N. Sabbaghian[1,2], B. Xu[1,9], M. Tischkowitz[1,2,4], C. Choong[6,7], C. Deal[8], S. Albrecht[1,9], A. Charles[6], P. Goodyer[1] & W. Foulkes[1,2]
[1]McGill University, Montreal, Quebec, Canada; [2]Lady Davis Institute, Montreal, Quebec, Canada; [3]Research Institute, McGill University Health Centre, Montreal, Quebec, Canada; [4]University of Cambridge, Cambridge, UK; [5]Minneapolis, MN; [6]University of Western Australia, Perth, Western Australia, Australia; [7]Princess Margaret Hospital for Children, Perth, Western Australia, Australia; [8]Université de Montréal, Montreal, Quebec, Canada; [9]Montreal Children's Hospital, Montreal, Quebec, Canada.

DICER1 is a microRNA processing-RNase III-type endoribonuclease and is crucial for embryogenesis and early development. Nearly 50 different heterozygous germ-line DICER1 mutations have been reported world-wide in individuals who developed, as children or young adults, pleuropulmonary blastoma, cystic nephroma, ovarian sex cord stromal tumors (especially Sertoli–Leydig cell tumor), multi-nodular goiter, embryonal rhabdomyosarcoma (of cervix and other typical sites), Wilms Tumor (WT) and other rare phenotypes, including pituitary blastoma. The latter is a very rare tumor with an apparently specific presentation: infants less than age 24 months with Cushing's syndrome or diabetes insipidus; the three investigated to date all carry DICER1 mutations.
In addition, single cases of primitive neuroectodermal tumor, pulmonary sequestration, juvenile intestinal polyps, adult-onset pleomorphic sarcoma, ciliary-body medulloepithelioma and pineoblastoma have been reported in DICER1 mutation carriers.
More recently, somatic mutations in DICER1 have been identified in nearly 30% of non-epithelial ovarian tumor, notably 60% in Sertoli–Leydig cell tumors, including 4/4 from individuals with germline DICER1 mutations. Somatic mutations involved codons encoding metal-binding sites within the RNase IIIb catalytic centers, critical for microRNA interaction and cleavage. Mutations were also found in non-seminomatous testicular germ-cell tumor (1/14), embryonal rhabdomyosarcomas (2/5), and ovarian/endometrial carcinoma (1/266). The mutant DICER1 proteins showed reduced RNase IIIb activity but retained RNase IIIa activity.
In an extension of this work, we have recently identified somatic DICER1 mutations, both within and outside the RNaseIIIb domain, in a small percentage of apparently sporadic WT. Notably, all three WT with germ-line DICER1 mutations possessed likely pathogenic somatic mutations. Since these mutations do not obliterate DICER1 function but alter it in specific cell types, the traditional two-hit model of carcinogenesis does not seem to apply.
The prevalence of endocrine presentations (goitre, androgenisation in young women and infants with pituitary dysfunction, especially Cushing syndrome) indicates that endocrinologists should consider germ-line DICER1 mutations when evaluating children and adolescents with these distinctive clinical presentations.

## S40.2

### The paediatric patient with paraganglioma syndrome

M. Robledo
Spanish National Cancer Center, Madrid, Spain.

Pheochromocytomas and paragangliomas (PCC/PGL) are rare tumours of the adrenal gland or derived from sympathetic and parasympathetic paraganglia occurring sporadically or as part of a familial cancer syndrome. Up to 20% of them are diagnosed in children, and they are not genetically well characterized. As most are functional tumors, children more often present with signs and symptoms related to hypertension. In fact, sustained hypertension is found in more than 60–90% of paediatric pheochromocytoma cases, whereas it is reported in only 50% of adult cases.
Originally, it was suggested that 10% of PCCs are hereditary, but current advances in molecular genetics have shown that germline mutations occur in up to 30–40% of PCC/PGLs. There are several features to take into account to suspect a hereditary tumor syndrome. Among them, the family history, the presence of multiple tumours or the age of onset are important clues to estimate the risk of a hereditary tumor syndrome. In this regards, 40% to 59% of PCCs patients younger than 18 years have germline mutations in some of the PCC/PGL susceptibility genes, and this proportion increases to 70% for those presenting before 10 years of age. According to data available, VHL is the most commonly (42%) mutated gene, followed by SDHB, SDHD, RET, and NF1. In some cases PCC/PGL presenting during childhood represents an early manifestation of an adult disease caused by predisposing germline mutations. Therefore, genetic testing should be performed in every child with PCC/PGL, because a proper characterization of the underlying mutation is a key factor in estimating the risk for development of malignant disease and contralateral tumour, which may also guide the follow-up and clinical management.

## S40.3

### Li-Fraumeni Syndrome: A paradigm of genetic testing to clinical surveillance for pediatric endocrine tumors

D. Malkin
The Hospital for Sick Children, Toronto, Ontario, Canada.

Li Fraumeni syndrome (LFS) is a prototypic cancer predisposition syndrome, characterized by multiple, early-onset malignant tumours including breast cancer, bone and soft tissue sarcomas, brain tumors and adrenocortical carcinoma (ACC). LFS is most commonly attributed to germline mutations in the TP53 tumor-suppressor gene. p53 activity is tightly regulated by multiple post-translational

mechanisms, disruption of which may lead to tumorigenesis. ACC occurs at disproportionately high rates among p53-mutation carriers, suggesting tissue-specific manifestations of p53 deficiency. Additionally, p53-associated ACC demonstrates a strong predominance in infants and children. Several of the p53 alleles associated with pediatric ACC retain significant wild-type activity and demonstrate incomplete penetrance, a finding distinct from other LFS-component tumors. This presentation will evaluate current knowledge of the relationship between p53 and adrenocortical carcinogenesis, with specific focus on disease-specific alleles, tumorigenesis in the context of adrenal development and potential therapeutic approaches to p53-associated ACC. In addition, evaluation of the implementation of a clinical surveillance protocol for early tumor detection will be discussed. The example of LFS as a paradigm of translation from molecular testing to clinical intervention will be highlighted in this session.

## The endocrinology of adipose tissue

### S41.1

**Physiological and neuronal determinants of brown adipose tissue-mediated thermogenesis in small mammals and humans**
D. Richard
Quebec Heart and Lung Institute, Quebec, Quebec, Canada.

Brown adipose tissue (BAT) is a thermogenic organ. Its tremendous thermogenic potential is conferred by uncoupling protein 1 (UCP1), which dissociates ATP synthesis from energy substrate oxidation and thereby insures heat production. BAT represents a key thermogenic effector implicated in thermoregulatory thermogenesis. The physiological control of BAT activity and capacity is ensured by the sympathetic nervous system (SNS), which densely innervates brown adipocytes. SNS-mediated BAT thermogenesis is essentially governed by hypothalamic and brainstem neurons. BAT is not only controlled by brain thermoregulatory circuits but also by brain energy balance pathways including the brain melanocortin pathway, whose major role in energy balance tends to support a genuine involvement of SNS-mediated BAT thermogenesis in energy homeostasis. BAT could be involved as a thermogenic effector not only in small mammals but also in humans. The use of molecular imaging procedures such as positron emission tomography / computed tomography (PET/CT) scanning have revealed noticeable BAT depots in the cervical, clavicular, paraspinal areas in adult humans. Moreover, there is recent evidence pointing to the presence of brown adipocytes in the human epicardial adipose tissue. The detection/prevalence of these depots was reported to increase with exposure to low temperature, to be higher in women than in men, and to decrease with age and body fat mass. The purpose of this short article is to provide an overview of the recent advances made in our understanding of the physiological and neuronal determinants of BAT thermogenesis in laboratory rodents and adult humans.

### S41.2

**'Obesity and insulin resistance: the cross-talk macrophage-adipocyte view'**
J. Fernandez-Real
H Girona, Girona, Spain.

Background
Adipocytes and macrophages resident in adipose tissue produce and secrete a variety of biologically active mediators (adipokines) that contribute to the development of insulin resistance, type 2 diabetes mellitus and cardiovascular disease. Malfunction of adipocytes may play an important role in the development of low-grade inflammatory state associated with obesity.
Objectives
Describe alternative ways to adipokines with potential impact on the development of this inflammatory state associated with obesity.
Methods
Review of recent contributions in the field.
Results
There are new circulating markers that can help identify the development of inflammation and insulin resistance in obese subjects. The study of some components of the immune system and of the complement system helps to better understand their relationship with carbohydrate metabolism. Examination of the bacterial flora composition sheds new ways in this regard as well as the shortening of telomere length in cells from adipose tissue. Finally, a detailed study of microRNAs present in adipose tissue is a relatively unexplored field of knowledge.
Conclusions
The exploration of these tools could provide new therapeutic approaches in insulin resistance associated with inflammation.
Discussion
The balance between different inflammatory factors and anti-inflammatory systemic level should be further explored to better understand the different eukaryote and prokaryote biological processes involved in a complex phenotype such as insulin resistance.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## Novel insights into regulation of puberty

### S42.1

**Central networks controlling the timing of puberty**
A. Lomniczi, J. Castellano, A. Loche, K. Somnez, H. Wright & S. Ojeda
ONPRC-OHSU, Beaverton, Oregon, USA.

Attainment of mammalian reproductive capacity depends on an increased pulsatile release of gonadotropin releasing hormone (GnRH) from hypothalamus neurons. After reaching the pituitary gland GnRH stimulates the synthesis and release of gonadotropins, which in turn promote gonadal function. The pubertal activation of GnRH secretion is brought about by coordinated changes in transsynaptic and glial-neuronal communication, which involve an increase in neuronal and glial excitatory inputs to the GnRH neuronal network and a decrease in transsynaptic inhibitory influences. Coordination of this regulatory neuronal-glial network appears to require gene networks hierarchically arranged. One level of coordination is provided by subordinate genes encoding proteins required for dynamic cell–cell communication. A second level is provided by subordinate genes engaged in intracellular signaling. A third and higher level of control involves the transcriptional regulation of these genes by a handful of genes that acting as 'central nodes' sustain the functional integration of the network. The existence of functionally connected genes controlling the pubertal process is consistent with the concept that puberty is under genetic control, and that the genetic underpinnings of both normal and deranged puberty are polygenic rather than specified by a single gene. It is unclear, however, how such inherited, permanent changes in DNA sequence can dynamically coordinate the expression of gene sets controlling the pubertal process. Using high-throughput approaches and computational methods for global analysis of DNA methylation and chromatin modifications, as well as quantification of mRNA and protein expression, we have obtained evidence suggesting that the activity of gene networks controlling puberty is coordinated by an epigenetic mechanism of transcriptional repression, which prevent the premature unfolding of the pubertal process.

**Re-wiring the hypothalamus with new peptides to control puberty**

V. Navarro[1,2]
[1]Universty of Cordoba, Cordoba, Spain; [2]Harvard Medical School, Brigham and Women's Hospital, Boston, Massachusetts, USA.

Puberty is a tightly regulated process by which an individual attains reproductive capability. An intricate network of central and peripheral factors has been described to play a role in this process; however, the mechanism triggering puberty onset remains largely unknown. Recently, the neuropeptides kisspeptin (encoded by Kiss1) and Neurokinin B-NKB- (encoded by TAC3 in humans and Tac2 in rodents) have been placed as essential gatekeepers of puberty onset. Studies in humans and rodents have revealed that loss-of-function mutations in the genes encoding either Kiss1/NKB or their receptors, Kiss1r/neurokinin 3 receptor (NK3R), lead to the absence of sexual maturation and infertility. Kisspeptin, NKB and dynorphin A are co-expressed in neurons of the arcuate nucleus (Arc), so called KNDy neurons. Importantly, these neurons also co-express NK3R. Compelling evidence suggests a stimulatory role of NKB (or the NK3R agonist senktide) on LH release in a number of species and exogenous administration of senktide is able to rescue puberty onset in undernourished female rats. This effect is likely mediated by autosynaptic inputs of NKB on KNDy neurons to induce the secretion of GnRH in a kisspeptin-dependent manner with the coordinated action of other neuroendocrine factors such as dynorphin, glutamate or GABA. Thus, we have proposed a model in which NKB feeds back to the kiss1 neuron to shape the pulsatile release of kisspeptin, and hence GnRH, in a mechanism also dependent on the sex steroid level. Investigating how the GnRH pulse generator activates during puberty onset and remains functional in adulthood is a primary goal in recent neuroendocrinology of reproduction.

## S42.3

**Novel insights into regulation of puberty: lessons from human genetics**

B. Mendonca & A. Latronico
University of Sao Paulo, Sao Paulo, Brazil.

The human pubertal development is a very complex biological process that can be influenced by multiple factors including the genetic ones. A growing list of genes has been implicated in the pathogenesis of the congenital isolated hypogonadotropin hypogonadism (IHH) pointing to the complexity of the genetic basis of this condition. These genes encode peptides, which are involved in the development and migration of GnRH neurons or in regulation of synthesis, secretion and action of GnRH. Among several distinct genes associated with IHH, two neuropeptides are the main regulators of the GnRH secretion: Kisspeptin and its receptor KISS1R and neurokinin B (TAC3) and its cognate receptor TACR3. Inactivating mutations have been identified in KAL1, GNRHR, FGFR1, KISS1 and KISS1R, PROK2 and PROK2R and more recently in TAC3 and TACR3 genes in patients with congenital IHH.

Central precocious puberty (CPP) has a striking predominance among girls, and in most cases is considered idiopathic. However, a familial history of early sexual maturation in girls with idiopathic CPP suggests a genetic basis for this condition. We hypothesized that gain-of-function mutations of KISS1 or of KISS1R genes might be associated with CPP. The new heterozygous mutation R386P in the GPR54 gene was identified in a Brazilian girl with CPP, the first evidence of non-constitutively dominant activating mutation of GPR54 related to the development of precocious puberty in humans. Functional study of this unique GPR54 mutation demonstrated a prolonged activation of intracellular GPR54 signaling pathways in response to kisspeptin. We also investigated the presence of potential variants in KISS1 gene and the new heterozygous P74S mutation was found in a boy with CPP. The capacity to stimulate signal transduction was significantly greater for P74S compared to the wild type after pre incubation of wild type and mutant kisspeptins with human serum, indicating that the mutant was more resistance to degradation.

Most of the identification of the molecular defects came from well characterized human phenotypes. The several emerging next-generation sequencing technologies for whole genome analyses surely will allow the identification of new genes responsible for congenital pubertal disorders.

# Graves' orbitopathy (GO)

## S43.1

**Immunopathogenesis of Graves' orbitopathy**

R. Bahn
Mayo Clinic, Rochester, Minnesota, USA.

Graves' orbitopathy (GO) is an inflammatory autoimmune disorder of the orbit. The close clinical and temporal relationships between Graves' hyperthyroidism and GO suggest that both conditions derive from a single systemic process and share the thyrotropin receptor (TSHR) as autoantigen. Autoimmunity directed against the TSHR on orbital fibroblasts sets in motion connective tissue remodeling within the orbit that leads to the various clinical expressions of the disease. Hyaluronic acid (HA) accumulation, expansion of orbital adipose tissues and the presence of inflammatory cells and pro-inflammatory cytokines appear to be the salient histologic features of the disease. Orbital fibroblasts express functional TSHR and are considered to be the target cells. Several laboratories have explored the impact of TSHR activation in these cells on signaling and cellular functions relevant to the orbital tissue changes. Both HA synthesis and new fat cell development are enhanced by activation of orbital fibroblast TSHR, whether effected through ligation of the receptor by TSH or monoclonal antibodies directed against the receptor (TRAb), or by the introduction of an activating mutant TSHR. The phosphoinositide 3-kinase/Akt signaling cascade appears to be an important effector pathway in this process, with input from adenylyl cyclase/cAMP and other signaling pathways. Circulating TRAb in patients with Graves' hyperthyroidism are heterogeneous and have differing potency and affinities. Stimulatory TRAb activate various TSHR signaling cascades in thyrocytes, resulting in the over-production of thyroid hormones. It appears likely that they similarly activate orbital fibroblast TSHR to modulate HA synthesis and adipogenesis. While IGF1 and other growth factors may act in an autocrine or paracrine fashion to impact TSHR signaling, little evidence supports a role in GO for circulating autoantibodies directed against IGF1R. Future therapies may involve the inhibition of TSHR signaling in orbital fibroblasts, perhaps using small molecular ligands that antagonize TSHR effector pathways.

## S43.2

**How to restore euthyroidism in the presence of Graves' orbitopathy? Is there a best way?**

L. Hegedüs
Odense University Hospital, Odense, Denmark.

Around 50% of patients with Graves' disease (GD) have Graves' orbitopathy (GO). However, only 5–10% have overt active disease which merits more than symptomatic treatment. Clearly, the best treatment is prophylaxis related to avoiding tobacco smoking and to obtain and maintain euthyroidism.

Whether antithyroid drugs (ATDs), radioiodine (RAI), or thyroidectomy should be chosen for therapy of GD, whether or not there is presence of active GO, is a matter of debate and randomized controlled trials (RCTs) are scarce. Thus, much is based on 'expert' opinion. ATDs, independent of whether the titration or the block-repacement regimen is used, and thyroidectomy (as long as euthyroidism is maintained) do not influence the natural history of GO. RAI can cause progression or de novo GO in around 15% of GD patients, smokers being particularly at risk. This can at large be prevented by prophylactic glucocorticoid therapy.

In patients with mild or inactive GO, the choice of therapy for GD is independent of GO. In patients with active GO the choice of therapy is mainly based on 'expert' opinion modified by the wishes of the patient and not based on RCTs. Questionnaire surveys indicate that RAI, in this situation, is only used by a small minority of 'experts'. Preliminary data suggest that biological therapy with rituximab (monoclonal anti-CD20 antibodies), aiming at B cell depletion may be advantageous for both GD and GO and thereby offer a shift in paradigm.The recently investigated low-cost administration of the trace-element selenium, also

holds promise. Importantly, a too strong focus on the risk of GO may unintentionally overrule taking availability of therapy options, co-morbidity, perceived risk of overall side-effects, cost-benefit, and the wish of the patient into consideration.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## S43.3

### Progress in immunosuppressive treatment of GO (selenium, steroid dosage, rituximab)

L. Bartalena

University of Insubria, Varese, Italy.

Management of Graves' orbitopathy (GO) is a challenge, and 30–50% of patients are eventually dissatisfied with medical treatment outcome. GO natural history is poorly understood, but some patients experience a progression of GO over time. Thus, prevention of development/progression by abolishing risk factors (e.g. smoking, thyroid dysfunction) is important. The recent results of a randomized clinical trial (RCT) carried out by the EUGOGO group showed that selenium (sodium selenite for 6 months) prevented progression of mild GO to more severe GO. Selenium, probably acting through antioxidative and immunoregulatory pathways, also caused a significant improvement of preexisting GO compared to placebo. Thus, selenium is a useful tool for prevention of progression and for management of mild GO. Accordingly, a 6-month course of selenium is advisable for patients with mild GO.

Glucocorticoids, preferentially given intravenously, represent the first-line treatment for moderate-to-severe and active GO. The most common regimen employs a cumulative dose of 4.5 g methylprednisolone, subdivided in 12 weekly intravenous infusions. However, evidence concerning the optimal dose in terms of efficacy and side effects is missing. The EUGOGO group has just completed an RCT comparing three different cumulative doses (2.5, 5.0, 7.5 g). Preliminary analysis suggests that the highest dose is more effective (particularly on eye motility) but associated with more major side effects. Thus, for the time being, it is reasonable to say that the dose should be tailored in each patients based on the activity and severity of GO, evaluating potential benefits and risks.

The frequently unsatisfactory response to glucocorticoids underscores the need for novel and more pathogenic treatments. Given the role played by B lymphocytes in GO pathogenesis, rituximab, an agent that depletes CD20-positive B lymphocytes, might be such a drug. Results in the field of GO are preliminary, based on small, uncontrolled studies. But they are promising by showing beneficial effects, mostly in GO patients resistant to conventional glucocorticoid treatment. Two ongoing RCTs (rituximab vs glucocorticoids, rituximab vs placebo) should hopefully provide useful information on the efficacy and safety of this expensive drug.

### Genome-wide association study of endometriosis identifies a locus at 7p15.2 with pleiotropic effects

K. Zondervan[1], J. Painter[2], N. Rahmioglu[1], D. Nyholt[2], C. Anderson[3], S. MacGregor[2], H. Lee[2], P. Visscher[2], P. Kraft[4], N. Martin[2], A. Morris[1], S. Treloar[3], S. Kennedy[2], C. Lindgren[1], S. Missmer[4,5] & G. Montgomery[3]

[1]University of Oxford, Oxford, UK; [2]Queensland Institute of Medical Research, Brisbane, Queensland's , Australia; [3]The Wellcome Trust Sanger Institute, Hinxton, UK; [4]Harvard School of Public Health, Boston, Massachusetts, USA; [5]Brigham and Women's Hospital and Harvard Medical School, Boston, Massachusetts, USA.

Endometriosis is a common gynaecological disease associated with severe pelvic pain and sub-fertility. We conducted a genome-wide association (GWA) study in 3,194 surgically confirmed endometriosis cases and 7060 controls of European ancestry from Australia and the UK using 540,000 genetic markers (SNPs). Polygenic predictive modelling showed significantly increased genetic loading among the 1364 (43%) cases with moderate-severe (rAFS III/IV) endometriosis. The strongest association signal was observed on chromosome 7p15.2 for SNP rs12700667 for all endometriosis ($P = 2.6 \times 10^{-7}$, OR = 1.22 (1.13–1.32)) and for moderate-severe disease, ($P = 1.5 \times 10^{-9}$ (OR = 1.38 (1.24–1.53)). We replicated rs12700667 in an independent US cohort of 2392 self-reported surgically confirmed endometriosis cases and 2271 controls ($P = 1.2 \times 10^{-3}$, OR = 1.17 (1.06–1.28)), resulting in a genome-wide significant $P$ value of $1.4 \times 10^{-9}$ (OR = 1.20 (1.13–1.27)) for all endometriosis in our combined datasets.

Rs12700667 is located in a 48 kb genomic segment of high LD, and marked one of 13 loci associated with waist-hip ratio adjusted for BMI (WHRadjBMI) in an independent GWA dataset of 77,167 individuals using ~2.8 million genotyped and imputed SNPs (top SNP rs1055144: $P = 1.49 \times 10^{-8}$). $P$-values for 5/12 other WHRadjBMI-associated SNPs varied from 0.01 to 0.81 for all endometriosis and from 0.05 to 0.77 for rAFS III/IV cases. The probability of finding a common genetic locus associated with two traits by chance at the given significance levels was, allowing for multiple testing of 6 SNPs, very small: $P = 2.2 \times 10 - 4$. Alleles of SNPs at 7p15.2 which are associated with increased risk of moderate-severe endometriosis are associated with decreased WHRadjBMI ('pear-shape'), consistent with hypotheses of hormonal regulation for both, suggesting that the locus has pleiotropic effects on the two phenotypes. Further results will be discussed.

## S44.2

### Cytogenetic analysis and genome-wide association study (GWAS) in chinese women with premature ovarian failure (POF)

Z. Chen[1,2,3]

[1]Provincial Hospital Affiliated to Shandong University, Jinan, China; [2]National Research Center for Assisted Reproductive Technology and Reproductive Genetics, Jinan, China; [3]The Key laboratory for Reproductive Endocrinology of Ministry of Education, Jinan, China.

Premature ovarian failure (POF) is defined as cessation of menstruation before the expected age of menopause. The disorder is considerable heterogeneous with a wide spectrum of causes- genetic, autoimmune, metabolic, infectious, and iatrogenic. However, etiology remains to be elucidated in most cases.

Chromosomal abnormalities have long been recognized as frequent causes of POF. However, few large cohorts have been studied. Ethnic background is usually not well characterized. We investigated 472 Chinese females with POF to determine the prevalence of cytogenetic anomalies in this ethnic group.

Chromosomal abnormalities were detected in 11.2% (53/472). 94.3% involved the X chromosome; 1 involved autosomes (t(13q;14q)), and 2 were 46,XY and 45,X/46,XY. We detected 15 X terminal deletions; 8 isochromosomes; 1 ring X and 1 inv X; 1 non-mosaic isodicentric, and 1 complex X arrangement. Eight X-autosome translocations were detected. Aneuploidy was found in 15 cases. Our result confirms a major role for X chromosome abnormalities in POF, highlighting the importance of routinely assessing for chromosomal abnormalities.

We sought to identify additional genetic loci associated with POF by performing the first large-scale GWAS. GWAS using Affymetrix SNP 6.0 chip was conducted in an initial discovery set of 391 Chinese POF patients, compared to 895 unrelated Chinese female controls. A replication study was then performed in an independent set of 400 cases and 800 controls. Suggestive significant associations were observed at 8q22.3. Replication of eight SNPs was confirmed. No specific candidate gene was found in the immediate region of 8q22.3. This GWAS, involving by far the largest sample of POF cases accumulated to date, revealed heretofore unrecognized association between POF and a novel genetic locus or region of unknown nature on 8q22.3. We speculate existence of a long-distance regulatory region that has relevance to the control of ovarian differentiation or oogenesis.

**Genetics of (In)fertility**

J. Laven, L. Stolk & A. Uitterllinden
Erasmus Medical Centre, Rotterdam, The Netherlands.

Since menarche is the landmark for the beginning of fertility and menopause marks the end of a women's reproductive lifespan genetics of fertility as well as infertility will be discussed taking recent GWAS data on both menarche and menopause into account.
Recently, 30 new loci for age at menarche were identified in a meta-analysis of 32 genome-wide association studies (GWAS) in women of European descent. In addition to two known loci the new loci included four genes previously associated with body mass index, three in or near other genes implicated in energy homeostasis and three in or near genes implicated in hormonal regulation of the ovary. Similarly, in a recent meta-analysis of 22 GWAS 13 newly genetic loci involved in the occurrence of natural menopause were identified. Candidate genes located at these newly associated loci include genes implicated in DNA repair and immune function. The finding that the innate immune response can be upregulated in response to DNA damage suggests that interplay between the two main pathways we identified (DNA repair and inflammation) may contribute to variation in age at natural menopause. Surprisingly there were only very few genes identified which might be involved in folliculogenesis. Three of the 17 regions can be linked to hormonal regulation, an additional route to follicle pool exhaustion.
In summary, our findings demonstrate a pivotal role of genes that regulate DNA repair and immune function in regulating age at menopause, indicating that the process of ageing is involved in both somatic and germ line aging. During this lecture the old dogma that regarding the cause of menopause will be challenged and evidence will be provided to support the theory that ageing of the soma initiates the cessation of ovarian function rather than the ovary itself.

**Finite element analysis in osteology**

P. Zysset
University of Bern, Bern, Switzerland.

Osteoporosis is a metabolic bone disease characterized by low bone mass leading to fractures that are associated with high mortality, morbidity and growing health care costs. Diagnosis of osteoporosis relies on dual energy X-ray absorptiometry (DEXA) to measure bone areal density, which is constantly reported as a poor surrogate of bone fracture risk.
Bone tissue is a composite of collagen, mineral and water, which multi-scale organization is increasingly well understood with the help of X-ray computer tomography. Its mechanical properties are assessed with various techniques at various levels and are altered by aging and disease.
Finite element analysis (FEA) is a widely applied engineering method to compute the strength of mechanical structures such as airplanes, bridges or cellular phones subjected to various loading scenarios. The increasing resolution of X-ray computer tomography opens new perspectives for finite element analysis of human bones from the constituent up to the organ level.
In the laboratory, desktop micro-computed tomography systems allow evaluation of trabecular architecture using micro finite element models of bone samples by converting directly each image voxel into a finite element. These microFE models bring new insight in bone mechanics, but often require high performance computing.
In a clinical environment, high resolution peripheral computed tomography provides detailed anatomy of bones such as the distal radius and permits to extract cortical thickness, volume fraction, orientation of trabecular bone in order to generate accurate patient-specific finite element models. Quantitative computed tomography delivers bone mineral density distributions and can also be exploited as a template for simplistic patient-specific finite element models. These models are carefully validated by experiments, require a standard PC for computation and can be used to make patient-specific predictions of bone strength that are significantly more accurate than DEXA.

**AIMing at metabolic syndrome: towards development of novel therapies for modern metabolic diseases via macrophage-derived AIM**

T. Miyazaki
The University of Tokyo, Tokyo, Japan.

Metabolic syndrome is a cascade of metabolic diseases starting with obesity and progressing to atherosclerosis and is often fatal because of serious cardiovascular problems such as heart/brain infarction and hemorrhage. Accumulating evidence has revealed a critical involvement of inflammatory responses triggered by lesional macrophages in its pathogenesis. Importantly, we found that macrophages are associated with the progression of these diseases not only in the induction of inflammation but also in the production of apoptosis inhibitor of macrophage (AIM), which we initially identified as a soluble factor expressed by macrophages[1]. At atherosclerotic plaques, AIM is highly expressed by foam macrophages and inhibits apoptosis of these cells. This results in the accumulation of macrophages, causing inflammatory responses within the lesion, and ultimately disease progression[2]. In adipose tissue, macrophage-derived AIM is incorporated into adipocytes through CD36-mediated endocytosis, thereby reducing the activity of cytosolic fatty acid synthase. This unique response stimulates lipolysis, resulting in a decrease in adipocyte size, which is physiologically relevant to the prevention of obesity[3]. The lipolytic response also stimulates inflammation of adipocytes in association with the induction of metabolic disorders subsequent to obesity[4]. Thus, AIM is involved in the progression of metabolic syndrome in both advancing and inhibitory fashions. Regulation of AIM could therefore be therapeutically applicable for metabolic syndrome.

## S46.2

**Macrophage regulation of adipocyte biology**

P. Scherer
UT Southwestern Medical Center, Texas, USA.

During the progression from the lean to the obese state, adipose tissue undergoes hyperplasia as well as hypertrophy in an attempt to cope with the increased demand for triglyceride storage. This requires a high degree of plasticity at both

the cellular and at the tissue level. Even though adipose tissue as a whole seems to be a relatively static tissue containing many adipocytes that turn over relatively slowly, these cells are embedded in an environment that can rapidly adapt to the needs of expanding and newly differentiating adipocytes.
Subclinical inflammation is frequently associated with obesity. We want to better define the acute inflammatory response during fasting. Representatives of immune-related proteins in circulation and in tissues were analyzed as potential markers for adipose tissue inflammation and modulation of the immune system. Lipopolysaccharide treatment or high fat diet leads to an increase in circulating serum amyloid (SAA) and α1-acid glycoprotein (AGP), while adipsin levels are reduced. Mouse models that are protected against diet-induced challenges, such as adiponectin overexpressing animals or mice treated with PPARgamma agonists, displayed lower SAA levels and higher adipsin levels. An oral lipid gavage increased circulating SAA concurrent with the elevation of FFA levels. Moreover, prolonged fasting increased circulating SAA and was associated with an increased number of Mac2 positive, crown-like structures and an increase in the capillary permeability in adipose tissue. This fasting-induced inflammatory response in adipose tissue was associated with increased VEGF expression and an increase in several M2-type macrophage markers. This fasting-induced switch to M2 type macrophages is impaired in metabolically challenged animals. Therefore, one of the underlying reasons for the 'metabolic inflexibility' observed under those conditions is the prevailing lack of 'immunological fitness' of adipose tissue.

## S46.3

**The inflammatory-adipokine hypothesis and stem cell abnormalities**
R. Vettor
University of Padua Clinica Medica 3, Padua, Italy.

Increased body weight and adipose tissue accumulation amplifies the risk of developing various age-related diseases, such as cardiovascular disease, type 2 diabetes mellitus, musculoskeletal disorders. Adipose tissue-derived secreted pro-inflammatory adipokines generate a chronic low-grade inflammation which contributes to the pathogenesis of obesity-linked complications. Recent advancements in tissue-resident adult stem/progenitor cell research have revealed that inflammation, enhanced telomere shortening, oxidative stress, may occur in these immature and regenerative cells during chronological aging. Particularly, the alterations in key signaling components controlling their self-renewal capacity may result in their dysfunctions, growth arrest and senescence or apoptotic death during the aging process. These molecular events may culminate in a progressive decline in the regenerative functions and the number of tissue-resident adult stem/progenitor cells, and age-related disease development. In the microenvironment, inflammation may favor adipose derived stem cell (ASC) differentiation into endothelial cells while inhibiting their differentiation into adipocytes. On the other hand it has been shown that ASCs possess anti-inflammatory properties and promote endothelial cell differentiation and microvascular regeneration.
The chronic low-grade inflammation and oxidative stress cold lead to muscle-to-fat conversion of muscle satellite cells (SCs), thus explaining the increase in intermuscular adipose tissue depots that occurs under some pathological conditions (i.e. primary myodystrophies, obesity, hyperglycaemia, high plasma free fatty acids, hypoxia, age-related sarcopenia, etc.) or simply because of a sedentary lifestyle or during aging. Several pathways and factors (PPARs, WNT growth factors, myokines, GEF-GAP-Rho, p66shc, mitochondrial ROS production, PKCβ) could be implicated in the adipogenic conversion of SCs.

## S47.3

**Learnings from ERCUSYN: the first 500 patients**
E. Valassi
Hospital Sant Pau, Barcelona, Spain.

The European Registry on Cushing's syndrome (ERCUSYN) is a project aimed at gathering data at EU level on clinical features, diagnostic procedures and therapeutic strategies in CS patients. The creation of this large European database is expected to provide comprehensive information on all stages of the disease from the first diagnosis to long-term follow-up. This ultimately should result in earlier recognition of CS and all its co-morbidities, and assist clinicians in considering and treating all possible manifestations of the disease, thus improving long-term prognosis.
The ERCUSYN database currently comprises data on 630 patients from 50 participating centres in 28 European countries. An initial analysis of baseline demographic and clinical data in 481 patients has been recently published. It showed differences in clinical presentation depending on gender and etiology, confirmed a long delay between onset of symptoms and diagnosis of CS, with a high number of specialists consulted who often missed the correct diagnosis. Furthermore, morbidity at diagnosis resulted high, with low bone mass, especially in men. Quality of life was impaired and less than half the cohort was actively working at the time of diagnosis of CS. Thus, there is great potential for improvements in reducing the time to diagnosis, which would have obvious consequences for patients and for the health care systems. In this presentation, updated results from the ERCUSYN database will be shown and future perspectives will be discussed.
In conclusion, ERCUSYN represents the largest collaboration of endocrine centres in Europe and has potentials to provide new insights into the diagnostic and therapeutic challenges of CS and to improve the care of patients with CS.
Acknowledgements
ERCUSYN was initially funded by the EU PHP 800200 and by the European Society of Endocrinology.

# Pathogenesis of primary aldosteronism

## S48.1

**Genomic profile in primary aldosteronism**
P. Hellman
Department of Surgical Sciences, Uppsala, Sweden.

Primary aldosteronism has recently been found as a common cause for essential or secondary hypertension. As much as 1/10 may be explained by this disease. Diagnosis is crucial, since a adrenalectomy may cure the patient.
The underlying cause in the majority of sporadic cases have been unknown until recently, while classically three forms of familial hyperadlosteronism (FH) exist: familial hypertension type I, II and III.
FHI, which occurs in childhood, is caused by a chimeric gene product combining the promotor of the 11-β-hydroxylase gene with the coding region of the aldosterone synthetase gene. This derangement is glucocorticoid sensitive.
In FHII there is no phenotypical difference towards classical sporadic PA, and genetic linkage exist to chromosome 7p22, as well as close to the MEN1 gene locus on 11q13.
FHIII is found in families with severe hypertension in early childhood, resistant to aggressive antihypertensive therapy. Although several genes have been proposed in FHIII, no one has been identified as the cause. A possible candidate is the recently identified mutation in the potassium channel KCNJ5, possibly explaining up to 40% of sporadic cases of PA. Interestingly, a family with early onset hypertension and bilateral hyperplasia and a mutation on KCNJ5 adds to the list of hereditary forms of PA.
Mutations in KNCJ5 (G151R or L168R) were found in 40% of aldosterone-producing adenomas which were associated with hyperplasia.

The talk comprise an overview of these genetic deragnements associated with PA.

## S48.2

**Integrating genetics and genomics in primary aldosteronism**

M. Zennaro[1,2,3]
[1]INSERM, Paris, France; [2]Université Paris Descartes, Sorbonne Paris Cité, Paris, France; [3]Assistance Publique-Hôpitaux de Paris, Paris, France.

Primary aldosteronism (PA) is the most common form of endocrine hypertension. The two main causes of PA are aldosterone producing adenoma (APA) and bilateral adrenal hyperplasia (BAH). Efficient and timely screening for PA is of major importance, given the severe cardiovascular outcome of aldosterone excess that is independent of blood pressure levels. Yet, the pathogenic mechanisms leading to aldosterone hypersecretion and cell proliferation are largely unknown. Several studies have addressed the molecular changes underlying APA formation. Transcriptome analyses have highlighted the contribution of different signaling pathways converging upon increased expression of CYP11B2, coding for aldosterone synthase. Less is known with regard to the mechanisms underlying nodulation. Recent evidence indicates a link between APA formation and peritumoral tissue remodelling and ZG hyperplasia, which are major features of adrenals with APA. Both APA and adjacent ZG present characteristics of stem/precursor cells; the re-expression of genes involved in foetal adrenal development could underlie excessive cell proliferation and APA formation.
Recently, a few recurrent somatic mutations of the KCNJ5 gene, coding for the potassium channel Kir3.4, have been implicated as a cause of APA, while inherited mutations of the same gene were identified in familial hyperaldosteronism type 3. Somatic KCNJ5 mutations are found in ~34% of unselected patients with APA; germline KCNJ5 mutations, however, are not similarly causative for BAH. Mutations all lie near or within the selectivity filter of the Kir3.4 channel; they result in a loss of channel selectivity, with increased sodium conductance leading to membrane depolarization. This leads to opening of membrane voltage-dependent calcium channels which is followed by activation of the calcium signaling pathway. While it has been formally established that this cascade of events leads to increased aldosterone production, it remains still unclear whether and how KCNJ5 mutations are responsible for increased cell proliferation.

## S48.3

**Potassium channels in primary aldosteronism**

R. Warth[1], S. Bandulik[1], D. Penton[1], P. Tauber[1], M. Zennaro[2], P. Mulatero[3], F. Beuschlein[4] & J. Barhanin[5]
[1]University of Regensburg, Regensburg, Germany; [2]INSERM, Paris Cardiovascular Research Center, Paris, France; [3]AOU S.Giovanni Battista, Torino, Italy; [4]Klinikum der Universität München, München, Germany; [5]CNRS, and Université de Nice Sophia Antipolis, Nice, France.

Potassium channels regulate the membrane voltage of aldosterone-producing glomerulosa cells in the adrenal glands. They are required for the unique $K^+$ sensitivity of these cells and are targets of angiotensin II signaling. Several $K^+$ channels show high levels of expression in the adrenal cortex and are believed to be important for the control of hormone secretion, e.g. KCNJ5, TASK1, TASK3, KCNMA1, and KCNQ1.
In a pioneering study, Lifton and co-workers have described somatic mutations of the $K^+$ channel KCNJ5 in aldosterone producing adenoma. Recent follow-up studies have confirmed the concept that pore-region mutations turn KCNJ5 into a $Na^+$-permeable channel. Interestingly, such mutations can be found in more than 30% of aldosterone producing adenomas.
For TASK1 and TASK3, no human phenotype has been described so far. However, knockout mice for TASK1 and TASK3 have highlighted the functional relevance of these channels: Before puberty, inactivation of the TASK1 gene resulted in autonomous aldosterone production and caused an aberrant expression of aldosterone synthase in zona fasciculata cells that normally produce only glucocorticoids. After puberty, male mice were able to compensate for the defect of TASK1 and their aldosterone synthase regained regular localization in glomerulosa cells. In female TASK1 knockout mice, dyszonation of the aldosterone synthase and hyperaldosteronism persisted after puberty.
In TASK3 knockout mice, plasma renin activity was suppressed and the aldosterone/renin ratio, an indicator of autonomous aldosterone production, was elevated. TASK3 knockout animals were unable to adapt aldosterone production to dietary salt intake in a normal way. The inappropriately high aldosterone levels under high dietary salt resulted in arterial hypertension.
These novel data corroborate the concept that $K^+$ channels play a critical role in adrenocortical cells. Dysfunction of adrenal $K^+$ channels can lead to developmental deficits, hyperaldosteronism and adenoma formation and maladaptation of aldosterone secretion to dietary salt intake.

**RANK ligand mediates hormone induced mammary epithelial proliferation and carcinogenesis**

E. Gonzalez Suarez[1,2], A. Jacob[1], J. Jones[1], R. Miller[1], M. Roudier[1], R. Erwert[1], J. Pinkas[1,3], D. Branstetter[1] & W. Dougall[1]
[1]Amgen, Inc., Barcelona, Spain; [2]IDIBELL, Barcelona, Spain; [3]ImmunoGen, Inc., Boston, Massachusetts, USA.

RANK and RANKL are essential for mammary gland development in mice. We demonstrated that RANK signalling promotes proliferation and impairs mammary epithelial differentiation in mice. RANK and RANKL expression is detected in breast cancer cells. MMTV-RANK acini show hallmarks of transformation in a RANKL dependent manner. After multiple pregnancies MMTV-RANK females spontaneously develop adenocarcinomas, and after DMBA (dimethylbenz(a)anthracene) and MPA (medroxiprogesterone) treatments show a shorter latency and a higher incidence of preneoplastic lesions and adenocarcinomas as compared to wild-type (WT) mice. Reciprocally, selective pharmacologic inhibition of RANKL after progesterone and carcinogen treatment attenuates mammary tumor formation in MMTV-RANK mice and prevents mammary tumor formation in WT mice. Anti RANKL treatment also decreases tumor formation and lung metastasis in MMTV-neu mice. The reduction in tumorigenesis upon RANKL inhibition was preceded by a reduction in preneoplasias and correlated with rapid and sustained reductions in hormone induced mammary epithelial proliferation. These results show that increased RANKL signalling promotes breast cancer initiation in mice and that RANKL is the main mediator of the protumorigenic effects of progesterone. Importantly, these results suggest that increased RANKL signaling may be a risk factor for mammary tumor development and that RANKL inhibitors may be effective for breast cancer treatment.

## Circadian regulation of metabolism

### S50.1

**Basic mechanisms of circadian regulation in the brain**

H. Oster[1,2]
[1]Max Planck Institute for Biophysical Chemistry, Göttingen, Germany; [2]University of Lübeck, Lübeck, Germany.

Circadian clocks regulate the adaptation of the organism to the rotation of the earth around its axis. In mammals the circadian timing system is comprised of numerous cellular oscillators throughout the brain and the body. In the hypothalamic suprachiasmatic nucleus a circadian pacemaker is synchronized to the external light/dark cycle via direct innervation along the retinohypothalamic tract. From the SCN, peripheral clocks are synchronized by neuronal, endocrine and behavioral means. Close interaction between different tissue oscillators in brain and periphery is essential for maintaining plasticity of circadian regulation under different environmental conditions. For example, SCN and adrenocortical clocks together regulate the entrainment of glucocorticoid secretion to the light/dark cycle.
In this talk I will summarize the knowledge on the regulation of molecular and endocrine rhythms by different tissue oscillators and present some of our recent approaches to unravel the communication pathways within the mammalian circadian timing system.

**Circadian rhythms in adipose tissue**

J. Gimble[1], A. Ptitsyn[2] & Z. Floyd[1]
[1]Pennington Biomedical Research Center, Baton Rouge, Louisiana, USA; [2]University of Florida, St. Augustine, Florida, USA.

Circadian mechanisms regulate metabolism in adipose tissues. The genes encoding the circadian regulatory proteins oscillate over a 24 h period in human and murine adipose tissue depots,. This expression profile is entrained by photic stimuli, temporally restricted food access, and/or nuclear hormone receptor ligands, such as glucocorticoids. In mice, deletion or mutation of the circadian regulatory genes, clock and PPAR gamma coactivator 1 (PGC1), is associated with increased risk of obesity and/or abnormal glucose metabolic function. Bioinformatic analyses of transcriptomic data indicate that $>20\%$ of the adipose-tissue expressed genes exhibit pronounced circadian or diurnal rhythmicity. These *in vivo* findings can be observed in *in vitro* models. For example, dexamethasone exposure synchronizes the expression profile of circadian protein encoding genes in primary cultures of undifferentiated and adipocyte-differentiated human adipose-derived stem cells. Similar observations regarding the synchronization of circadian regulatory genes have been reported in murine 3T3-L1 pre-adipocyte cultures. In addition, multiple circadian regulators directly modulate both adipogenic and osteogenic differentiation in these *in vitro* models. The expression profiles of the circadian regulatory genes correlate directly with those of adipogenic markers in human adipose tissue mRNAs. Furthermore, polymorphisms in circadian regulatory genes have been correlated directly with obesity risk in human subjects. There is a growing body of endocrine and epidemiological evidence linking circadian dysregulation to the incidence of obesity, hypertension, cardiac disease, and the metabolic syndrome. Consequently, there will be a potential role for targeting circadian mechanisms in the treatment of clinical endocrine and metabolic disorders of adipose tissue using behavioral and/or pharmacological interventions.

## Recent management of pheochromocytoma/paraganglioma syndrome

### S51.1

**Recent progress in biochemical testing for pheochromocytoma**

S. Petersenn
ENDOC Center for Endocrine Tumors, Hamburg, Germany.

Background
Since signs and symptoms of pheochromocytomas are unspecific, diagnosis is crucially dependent on biochemical evidence of excessive catecholamine production. Diagnostic workup was previously based on measurement of urinary catecholamines. Subsequently it was shown that pheochromocytomas contain high amounts of catechol-*O*-methyltransferase (COMT), the enzyme that converts epinephrine to metanephrine and norepinephrine to normetanephrine. This metabolism occurs in a continuous fashion within tumour cells and independently of variations of catecholamine release, providing diagnostic advantages to measuring the metanephrines over the parent catecholamines.
Role of metanephrines: Determination of plasma free metanephrines by liquid chromatography–tandem mass spectrometry (LC–MS/MS) is now regarded as gold standard. Due to the cost- and time-intensive technique the method is limited to specialized centers. Immunoassays may be an alternative process. The diagnostic value of plasma free and urinary metanephrines measured by either RIA or enzyme immunoassays (EIA) was recently demonstrated by us and others. In our study, urinary fractionated metanephrines demonstrated a slightly lower sensitivity and specificity than their plasma counterparts. Urinary metanephrines largely reflect sulfate-conjugated metabolites, which are formed in gastrointestinal tissue. Thus, they are not related only to pheochromocytoma.
Influence of confounding variables: Non-selective alpha-blockers may be associated with higher levels of norepinephrine and normetanephrine. Beta-blockers, to a much lower extent, may be responsible for elevated levels of metanephrines. We found, that coffee elevated normetanephrine. Furthermore, physical exercise led to relevant changes of metanephrine and normetanephrine and should therefore be avoided prior to sampling. Although effects of age, sex and BMI were small, these variables should be considered when interpreting biochemical results. In contrast, supine rest significantly decreased both metanephrine and normetanephrine when compared to standing rest. Metanephrine and normetanephrine were not significantly influenced by time of day, menstrual cycle or venepuncture. Of note, adjusted thresholds may be required for patients with hereditary syndromes.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### S51.2

**Prevalence of SDH gene mutations in pheochromocytoma**

G. Opocher[1,2]
[1]University of Padova, Padova, Italy; [2]Veneto Institute of Oncology, Padova, Italy.

Hereditary pheochromocytoma/paraganglioma (PHEO/PGL) syndrome is a rare disease. It has been demonstrated that about 25% of the apparently sporadic PHEO/PGL are due to a germ line mutation in one of the susceptibility genes, such as, VHL, RET, NF1, TMEM127, MAX and the genes encoding the four

subunits of the mitochondrial enzyme succinate dehydrogenase (SDH) as well as the gene encoding one SDH assembly factor, SDHAF2. SDH is located in the inner mitochondrial membrane and is formed by four subunits: SDHA–B–C–D. It is an enzyme involved in the tricarboxylic acid cycle and in the mitochondrial electron transport chain.

Beside the pivotal role played by mitochondria in modulating programmed cell death and other fundamental processes within cells, the first incontestable examples of causality between mitochondrial dysfunction and tumorigenesis were only discovered when mutations in SDH were found to be the initiating events of familial PHEO/PGL.

Germ line mutations in SDHD, SDHAF2, SDHC and SDHB genes are responsible for the occurrence of different syndromes named PGL1, PGL2, PGL3 and PGL4 respectively. Also mutations of SDHA can predispose to functioning PHEO/PGL (PGL5 ?). PGL1 presents benign, non-secreting, multiple head and neck PGLs (HN-PGL) not frequently associated with PHEOs and/or abdominal secreting PGLs. PGL2 presents only HN-PGLs. PGL3 is mainly characterized by single HN-PGL but recently abdominal secreting PGL has also been reported. PGL4 presents PHEO or abdominal/thoracic PGL, which, at variance with tumors developed in PGL1 and PGL3, are malignant in up to 30% of cases, leading to metastatic disease. PGL1 and PGL2 are parent of origin diseases and only carriers of the mutation in the paternal allele can develop tumors of the paraganglia. Overall, SDH mutations accounts for 3–5% of PHEO/PGL presenting as apparently sporadic.

## S51.3

**Treatment of malignant pheochromocytoma**

A. Tanabe
Institute of Clinical Endocrinology and Hypertension, Tokyo Women's Medical University, Tokyo, Japan.

Effective treatments of malignant pheochromocytoma have not been established. Although 131-I-MIBG radiotherapy, chemotherapy with a combination of cyclophosphamide, vincristine and dacarbazine (CVD), and molecular target therapies have been used for unresectable tumors, those are usually palliative and rarely curative. However, excessive catecholamine impairs the activities of daily living by causing various symptoms (e.g. palpitation, paroxysmal hypertension and hypotension and severe constipation) and even more fatal arrhythmia and heart failure. Therefore, controlling chronic overproduction of catecholamine is one of the most important therapeutic targets to maintain hemodynamics stable and to improve performance status of the patients. Although molecular target therapies such as tyrosine kinase inhibitors and the mammalian target of rapamycin (mTOR) inhibitor are promising and under clinical trial in the EU and North America, CVD is the most representative therapy available in Japan and only a limited numbers of case series have been reported. In our 14 patients treated with CVD, no patients showed complete biochemical and tumor responses. However, partial biochemical and/or tumor response was achieved in five patients (35.7%). No significant biochemical or tumor response was seen in four patients (28.6%), while deterioration in biochemical and tumor responses was seen in five patients (35.7%). These effects were demonstrated 1–5 months after CVD (average: 3 + 2 months) and lasted for 12–60 months (average: 32 + 21 months). The patients with biochemical response were associated with an improvement in diabetes mellitus and hypertension and were free from various symptoms and cardiac complications associated with catecholamine excess. In addition, adverse effects associated with CVD were transient and mild. Our results suggest that CVD still could be a beneficial treatment in relieving excessive catecholamine and related complications as well as in reducing tumor volume although the effects are limited in its magnitude and duration.

# Thyroid & Pregnancy

## S52.1

**Outcome of the controlled antenatal thyroid screening study**

J. Lazarus
Cardiff University, Cardiff, UK.

Fetal brain development depends on thyroid hormone and children born to mothers with low thyroid hormone levels have decreased cognitive function. Nineteen per cent of children born to mothers known to have a high TSH during gestation had an IQ $<80$ compared to 5% of children born to mothers known to have normal TSH levels in pregnancy ($P<0.001$; Haddow *et al*. 1999).

We conducted a randomized trial of antenatal hypothyroidism screening with selective treatment and assessment of childhood cognitive function.

Pregnant women were randomized at about 12 weeks' gestation into a screen or control group. Blood was collected for thyroid stimulating hormone (TSH) and free thyroxine ($FT_4$) measurements before 16 weeks. In the screen group measurements were made immediately; control group serum was stored and measurements made shortly after delivery. Women with TSH levels $>97.5$th centile and/or $FT_4$ levels $<2.5$th centile were designated positive and women in the screen group were prescribed levo-thyroxine. IQ measurements were performed on children of women with positive results aged three by psychologists unaware of whether the women were in the screen or control group.

Out of 21 846 women tested, 390 in the screen group and 404 in the control group tested positive. Nineteen percent of women required levo-thyroxine dose adjustment. The mean IQ's in the screen and control positive groups were 99.2 and 100.0; a difference of 0.8 (95% CI $-1.1$ to 2.6, $P=0.403$, intention-to-treat analysis) respectively, and the proportions with IQ $<85$ were 12.1 and 14.1% respectively; a difference of 2.1% (95% CI $-2.6$ to 6.7%, $P=0.39$). An on-treatment analysis showed no significant difference.

Antenatal screening and treatment for hypothyroidism from about 12 weeks of pregnancy showed no benefit in childhood cognitive function assessed at age three. (Funded by The Wellcome Trust UK and Compagnia di San Paulo Turin).

Declaration of interest

## S52.2

**The case for thyroid screen in pregnancy**

R. Negro
Division of Endocrinology, 'V. Fazzi' Hospital, Lecce, Italy.

Screening is defined as 'the presumptive identification of unrecognized disease or defect by the application of tests, examinations, or other procedures which can be applied rapidly. Screening tests sort out apparently well persons who probably have a disease from those who probably do not'. Ideally all the following criteria should be met: The Condition should be an important health problem; well known epidemiology and natural history of the condition. The test should be a simple, safe, precise and validated with agreed reference range. The treatment should be effective, there should be agreed evidence based policies covering which subjects need treatment and the appropriate treatment to be offered. The Screening Programme is effective in reducing mortality or morbidity (evidence from high quality Randomised Controlled Trials); is clinically, socially and ethically acceptable to health professionals and the public. The benefit from the screening programme should outweigh the physical and psychological harm (caused by the test, diagnostic procedures and treatment). The opportunity cost of the screening programme should be economically balanced in relation to expenditure on medical care as a whole (cost benefit and/or cost effectiveness analyses). In the case for thyroid screening in pregnancy, most of the above mentioned points are satisfied. In particular, everyone agrees that overt thyroid dysfunctions need to be treated, and a cost-effective analysis demonstrated that universal screening is cost-effective even assuming that only overt hypothyroidism has adverse obstetrical outcomes. The problem is still represented by the halo of uncertainty that surrounds clinical entities such as subclinical hypothyroidism and isolated hypothyroxinemia. The lack of high quality Randomized Controlled Trials in these two conditions, does not allow, by now, to universally endorse a screening for thyroid disease in pregnancy.

## S52.3

**Treatment of hyperthyroidism in pregnancy**

Fereidoun. Azizi
Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran.

Graves' disease is the most common cause of autoimmune hyperthyroidism in pregnancy accounting for 0.1 to 1% (0.4% clinical and 0.6% subclinical) of all pregnancies. It may be diagnosed for the first time in pregnancy, may present as a recurrent episode in a woman with past history of hyperthyroidism, or in a women on antithyroid drugs (ATD). Less common non autoimmune causes include multinodular goiter, toxic adenoma, and factitious hyperthyroidism. More frequent than Graves' disease as the cause of hyperthyroidism is the syndrome of gestational hyperthyroidism defined as 'transient hyperthyroidism, limited to the first half of pregnancy characterized by elevated $FT_4$ or adjusted $TT_4$ and suppressed or undetectable serum TSH, in the absence of serum markers of thyroid autoimmunity'.

Poor control of thyrotoxicosis is associated with miscarriages, PIH, prematurity, low birth weight, intrauterine growth restriction, stillbirth, thyroid storm and maternal congestive heart failure. Antithyroid drugs are the mainstay of treatment for hyperthyroidism during pregnancy. Side effects occur in a 3–5%, of patients taking thionamide drugs, mostly allergic reactions such as skin rash. The greatest concern in the use of ATD in pregnancy is related to teratogenic effects. Exposure to MMI may produce several congenital malformations, mainly aplasia cutis and the syndrome of 'methimazole embryopathy' that includes choanal or esophageal atresia, and dysmorphic faces. Although very rare complications, they have not been reported with the use of PTU. Report from the Adverse Event Reporting System of the Food and Drug Administration (FDA) has called attention to the risk of hepatotoxicity in patients exposed to PTU and an advisory committee recommended to limit the use of PTU to the first trimester of pregnancy. Hepatotoxicity may occur at any time during PTU treatment, without warning; however it may be appropriate to monitor liver function tests regularly while PTU is administered. In women with hyperthyroidism due to Graves' disease or a toxic nodule goiter, ATDs are initiated, or adjusted in those women on treatment, at conception. PTU is preferred in the first trimester. Following the first trimester, PTU should be switched to methimazole.

The combination of ATD plus levothyroxine is not recommended in the management of hyperthyroidism in pregnancy. Adrenergic β blocking agents, such as propranolol 20–40 mg every 6–8 h may be used for controlling hypermetabolic symptoms. In the vast majority of cases the drug could be discontinued in 2 to 6 weeks. Long term treatment with propranolol has been associated with intrauterine growth restriction, fetal bradycardia and neonatal hypoglycemia. Thyroidectomy should be considered in cases of allergies to both ATDs, women requiring large doses of ATDs and the occasional patient who is not adherent to drug therapy. If surgery is indicated, second trimester is the optimal time. A determination of serum TRAb titers is mandatory at the time of surgery in order to assess the potential risk of fetal hyperthyroidism. Preparation with β-blocking agents and a short course of potassium iodine solution (50–100 mg a day) are recommended.

# Genetic polymorphism in reproduction

## S53.1

**Genetic variation of the androgen receptor: from gene regulation to prostate cancer**

M. Zitzmann
University Clinics Muenster, Muenster, Germany.

In addition to symptoms of androgen deficiency induced by low serum testosterone concentrations (i.e. classical hypogonadism), also variable phenotypes of androgen insensitivity exist in humans, mainly owing to defective, mutated androgen receptors. A more subtle modulation of androgen effects has been related to the CAG repeat polymorphism (CAGn) in exon 1 of the androgen receptor gene: *in vitro*, transcription of androgen-dependent target genes is attenuated with increasing length of triplets. As a clinical entity, the CAG repeat polymorphism is, in healthy males, compensated for by an increased release of LH and, hence, testosterone. In men with an affected hypothalamic–pituitary–gonadal signal chain, however, it can relate to variations of androgenicity in (apparantly) eugonadal men in various tissues and psychological traits: the longer the CAGn, the less prominent is the androgen effect when individuals with similar testosterone concentrations are compared. A strictly defined threshold to hypogonadism might then be replaced by a continuum originating fom genetics, hormone concentrations as well as symptom specificity. In addition, effects of externally applied testosterone can be markedly influenced by the CAGn and respective pharmacogenetic implications are likely influence indications as well as modalities of testosterone treatment of hypogonadal men.

Abstract unavailable.

## S53.3

**Genetic complexity of FSH receptor function**

M. Simoni
University of Modena and Reggio Emilia, Modena, Italy.

FSH acts via binding to its specific receptors, the FSHR, possessing a large number of SNPs. The FSHR SNPs at nucleotide position 919 and 2039 in exon 10 are very common (heterozygosity: 0.469) and result in the aminoacid transition Thr/Ala at codon 307 and Asn/Ser at codon 680 respectively. In addition a G/A SNP is found in the promoter region at position −29, with the G allele covering 75% and the A allele 25% of the alleles in Caucasians. In turn, the FSHB gene, encoding the α subunit of the gonadotropin, possesses an interesting SNP in the promoter region (SNP, rs10835638; G/T) 211 bp upstream from the FSHB mRNA transcription start-site, located within a highly conserved region among placental mammals.

Several studies demonstrated that the FSHR SNPs affect ovarian response to FSH in women undergoing assisted reproduction techniques (ART). The FSHR Ser680 genotype is less sensitive to the FSH action *in vivo*, compared to the FSHR Asn680 genotype. A recent meta-analysis including data available from different ethnic group have confirmed that the marker Ser680 is associated with a poor response during ART, concluding that FSHR genotyping could provide important information to customize the dose of FSH during controlled ovarian hyperstimulation and reinforcing the critical role of FSHR SNPs in assisted reproduction treatment. The FSHR polymorphism G/A at position −29 could modulate ovarian response to FSH as well, since it controls the transcription rate of the mRNA. Data in fertile and infertile men are less clear-cut. Studies *in vitro* were so far unable to demonstrate the molecular and cellular effects of the SNPs in the FSHR.

Concerning, the FSHB gene studies in males demonstrated that the SNP in the promoter is significantly associated with serum FSH and testosterone levels and that the -221T allele has an increased prevalence in infertile men.

# Vitamin D

## S54.1

**Vitamin D is a multifunctional hormone Roger Bouillon Clinic and laboratory of experimental medicine and endocrinology**

R. Bouillon
KULeuven, Leuven, Belgium.

The vitamin D endocrine system (D-endo) is essential for calcium and bone homeostasis. Absence of a functional VDR or CYP27B1 creates a severe rachitic bone and growth plate phenotype in humans and mice as in severe vitamin D deficiency. The intestine is the key target for VDR as a high calcium intake or selective VDR rescue in the intestine restores a normal bone and growth plate phenotype. Selective absence of VDR in osteoblasts does not create a bone phenotype when calcium intake is normal.

VDR is ubiquitously expressed and about 3% of the mouse or human genome is regulated by D-endo. The native immune defense system is activated by D-endo but VDR or vitamin D deficiency leads to increased sensitivity to autoimmune diseases such as inflammatory bowel disease or autoimmune diabetes after exposure to predisposing factors. VDR deficient mice do not have a spontaneous increase in cancer but are more prone to oncogen, chemocarcinogen or UV-B induced tumors. A wealth of observational studies in men also links a poor vitamin D nutritional status to increased risk of all major cancers. D-endo is also related to the cardiovascular system as VDR or CYP27B1 KO mice develop high renin hypertension, cardiac hypertrophy and increased thrombogenicity. Observational studies in men also link poor vitamin D status to all aspects of the metabolic syndrome and increased risk of cardiovascular diseases. The muscle development of VDR KO mice is delayed and their fertility is impaired.
Whether the same spectrum of activity is also operational in humans is not yet established but vitamin D deficiency is frequently associated with an increased prevalence of diseases expected on the basis of the VDR KO phenotype. Prospective and intervention studies will be presented as to define the spectrum of activities and the optimal vitamin D status for global health.

## S54.2

**Vitamin D and primary hyperparathyroidism**

L. Mosekilde[1,2]
[1]Aarhus University Hospital, Aarhus C, Denmark; [2]University of Aarhus, Aarhus, Denmark.

The occurrence of vitamin D (vitD) insufficiency (plasma 25OHD < 50 nmol/l) and deficiency (25OHD < 25 nmol/l) in primary hyperparathyroidism (PHPT) varies worldwide in prevalence, severity and symptoms. Epidemiological studies support that the clinical presentation of PHPT is more severe in patients with coexisting vitD deficiency. Most PHPT patients in Europe only have slightly decreased plasma 25OHD levels compared with gender-, age- and season matched controls, and severe symptomatic vitamin D deficiency is rare. However, in the patients low plasma 25OHD appear to be associated with higher levels of PTH, calcium and bone turnover and lower femoral neck and forearm BMD. Low 25OHD has also been associated with higher left ventricular mass index.
The decrease in plasma 25OHD in PHPT has been explained by i) a stimulated renal 1α-hydroxylation of 25OHD to 1,25(OH)2D induced by PTH and hypophosphatemia, ii) an increased 24-hydroxylase activity with hydroxylation of 25OHD and 1,25(OH)2D to more polar metabolites, iii) increased body weight in PHPT patients, and iv) development of secondary and later tertiary hyperparathyroidism because of long standing severe vitD deficiency.
In cases where the combination of both PHPT and hypovitaminosis D is diagnosed vitamin D repletion is an option. However, only limited evidence exists for this treatment. In case series and cohort studies vitD treatment lowers preoperative PTH levels and may reduce bone turnover in some cases. Furthermore, high vitD status may decrease the risk of postoperative hypocalcaemia and secondary hyperparathyroidism. However, there are no randomised controlled studies to prove any beneficial effects on calcium and bone metabolism or on muscle function, CNS symptoms or quality of life. Furthermore, serum and urinary calcium may increase in some patients. It is unknown, whether routine vitD supplementation should be offered preoperatively to all PHPT patients or as part of long term medical follow-up.

# The fatty liver as an endocrine disease

## S55.1

**Pathogenesis of fatty liver disease**

C. Postic
Institut Cochin Inserm U1016, Paris, France.

Non-alcoholic fatty liver disease (NAFLD) is gaining increasing recognition as a component of the epidemic of obesity worldwide. The spectrum of NAFLD ranges from simple fatty liver with benign prognosis, to a potentially progressive form, non-alcoholic steatohepatitis (NASH), which may lead to liver fibrosis and cirrhosis, resulting in increased morbidity and mortality. All features of the metabolic syndrome, including obesity, type 2 diabetes, arterial hypertension, and hyperlipidemia are associated with NAFLD/NASH. Despite being potentially severe, little is known about the natural history or prognostic significance of NAFLD. Excessive accumulation of triglycerides in hepatocytes is the hallmark of NAFLD. Despite the existing correlation between fatty liver and insulin resistance it remains unclear whether insulin resistance causes the excessive accumulation of TG in liver or whether the increase in TG or of metabolic intermediates may play a causal role in the development of hepatic or systemic insulin resistance. Studies have reported that the accumulation of intra-hepatic lipids precedes the state of insulin resistance while others showed that hepatic TG themselves are not toxic and may in fact protect the liver from lipotoxicity by buffering the accumulation of deleterious fatty acids. Such findings suggest that hepatic steatosis is not necessarily associated to insulin resistance. In agreement with this concept, some identified population of obese humans can stay free of insulin resistance and are metabolically healthy despite morbid obesity. These findings suggest that not all lipids are detrimental for insulin sensitivity and that specific lipid species, when present in the proper location and time, may trigger signals that modulate adaptation to stress. In the recent years, we have determined the metabolic impact of modulating liver *de novo* fatty acid synthesis (lipogenesis) via the transcription factor ChREBP on the outcome of hepatic steatosis and/or insulin resistance in mice and humans with NAFLD.

## S55.3

**Fatty liver disease in childhood**

Valerio. Nobili
Chief of Hepatometabolic Diseases, Bambino Gesu Hospital, Rome, Italy.

Nonalcoholic fatty liver disease (NAFLD) is a multifactorial condition, ranging from simple steatosis to nonalcoholic steatohepatitis (NASH) with or without fibrosis. NAFLD affects both adults and children who present with particular risk factors, including obesity, sedentary lifestyle and/or a predisposing genetic background. The escalation of the prevalence of NAFLD in children worldwide is a worrying phenomenon because this disease is closely associated with the development of both cirrhosis and cardiometabolic syndrome in adulthood. The etiopathogenesis of primary NAFLD in children is unknown; however, considerable knowledge about the mechanisms of liver damage that occur during disease progression has been gathered over the past 30 years. Understanding the pathogenetic mechanisms, together with the histological pattern, provide the basis to characterize potential early predictors of the disease, suitable noninvasive diagnostic tools and design novel specific treatments and possible management strategies. Despite a few clinical trials on the use of antioxidants combined with lifestyle intervention for NAFLD that showed encouraging results, to date, no treatment guidelines exist for children with NAFLD.

## Pituitary development transcription factors: stem cells and beyond

### S56.1

**The GPS niche of stem cells in the pituitary**

M. Garcia-Lavandeira[1], E. Diaz-Rodriguez[1], T. Vila[1], C. Saez[2], M. Japon[2], C. Dieguez[1] & C.V. Alvarez[1]
[1]IDIS-CIMUS, Department of Physiology, School of Medicine, University of Santiago de Compostela (USC), Santiago de Compostela, Spain;
[2]Hospital Virgen del Rocio Seville, University of Santiago de Compostela (USC), Santiago de Compostela, Spain.

The pituitary is an anatomically well protected endocrine gland in permanent contact with the central nervous system. Although it was known that pituitary has plasticity in response to the physiological demands of the body, there were few clear data about the post-natal mechanisms in charge of this plasticity. The discovery of a group of cells expressing stem cell markers precisely organized in the outer zone of the adenopituitary open up new possibilities to explain the constant pituitary renewal. Moreover, the organization and location of these cells is conserved from rodents (mouse and rat) to human pituitary suggesting an essential role of this structure called the GPS niche. The GPS cells express the tyrosine-kinase receptor RET together with two of its co-receptors GFRa2 and GFRa3 (***G***). But also they retain expression of PROP1 (***P***) a key transcription factor during pituitary embryonic development, while they co-express markers of pluripotency such as SOX2, OCT4 and KLF4 (***S***). Opposite GPS cells do not express any pituitary hormone or transcription factors associated to differentiation as for example Pit-1. The data obtained so far indicate that more than one type of cells can exist around the GPS. The precise characterization of markers together with functional studies suggest a true niche of stem cells. The GPS niche could be implicated in disease as data obtained in human cranyopharingiomas suggest.
But if new cells are being recruited from the niche to the adenopituitary to replace those which are old or non-functional, we should explain how unfit cells are isolated and marked for removal. Our recent data in rodent somatotrophs indicate that the RET receptor, when is not activated by the ligand through another co-receptor GFRa1, is intracellularly processed by Caspase 3 triggering a mechanism of arrest and cell death. Thus, RET over-activates the Pit-1 promoter, Pit-1 excess directly activates the ARF promoter increasing ARF expression which in turn stabilizes p53 leading to cell death. New data in somatotroph adenoma cultures indicate that the pathway is conserved in humans.
In summary, the data gathered at present highlight the importance of GPS cells in pituitary cell renewal and further our understanding on the mechanisms leading to pituitary hyperplasia, pituitary adenomas, and related tumors such as craniopharyngiomas.

### S56.2

**LHX3: an insightful model of pituitary hormone deficiency**

S. Rhodes[1,2], R. Malik[2], S. Park[2] & K. Prince[2]
[1]Indiana University Indianapolis, Indianapolis, Indiana, USA; [2]Indiana University School of Medicine, Indianapolis, Indiana, USA.

Our goal is to better understand the molecular and cellular nature of paediatric combined pituitary hormone deficiency diseases in order to facilitate improved diagnosis, treatment, and family counselling. LIM-homeodomain transcription factors regulate many aspects of development and mutations in the genes that encode these regulatory proteins are associated with several diseases. The LHX3 LIM-homeodomain protein is critical for pituitary gland organogenesis and some nervous system development. Loss of function of the LHX3 gene can cause complex paediatric syndromes involving combined pituitary hormone deficiency, limited neck rotation, hearing loss, and other symptoms. In recent studies, we have described patients with mutations in the LHX3 gene and we have investigated the aberrant mechanisms underlying loss of function of the gene or protein. Using gene knock-in technology to alter the mouse genome to mimic a human mutation in the LHX3 gene, we have generated a mouse model of paediatric combined hormone deficiency disease. This resource is allowing analyses of the developmental aspects of the disease using cellular and proteomic approaches and has also permitted studies of the influences of genetic background on the varied phenotypic outcomes of human transcription factor gene mutations. To understand the mechanism by which the human LHX3 gene is itself regulated, we have used transgenic approaches to characterise genomic promoter and enhancer elements that guide temporal and spatial expression of the gene in the endocrine and nervous systems. We are also investigating the mechanism by which LHX3 proteins interact with chromatin-associated regulatory complexes to modulate anterior pituitary gene expression. Supported by NIH HD42024 to SJR.

### S56.3

**Transcriptional and epigenetic mechanisms for cell fate choice in pituitary**

J. Drouin
Institut de recherches cliniques de Montréal (IRCM), Montréal, Quebec, Canada.

All secretory cells of the anterior and intermediate pituitary derive from the oral ectoderm that forms Rathke's pouch. Pituitary progenitors present in the pouch as well as similar progenitor/stem cells that remain along the cleft of the adult gland, are marked by expression of Sox2. Sox2-positive progenitors can self-replicate or enter differentiation. Before any differentiation marker is expressed, progenitors first exit the cell cycle under the control of the cell cycle inhibitor p57kip2; this mechanism appears to be restricted to progenitors and the related p27kip1 prevents cell cycle re-entry of differentiated cells. Initial events involved in differentiation and determination of cell fate are still poorly understood but transcriptional regulators driving terminal differentiation of pituitary lineages have been identified. Thus, Pit1 is required for terminal differentiation of somatotropes, lactotropes and thyrotropes whereas SF1 is required to complete differentiation of gonadotropes. Similarly, we identified Tpit as the transcriptional regulator for terminal differentiation of both POMC-expressing lineages, the corticotropes and melanotropes. The requirement on the same factor Tpit for terminal differentiation of both lineages does not explain the cell fate choice between these lineages. The combinatorial action of other transcription factors together with Tpit is one model that may direct unique cell fate choices. Interestingly, we have identified a factor that is expressed slightly before Tpit, only in melanotropes and that behaves as a cell fate switch and selector gene since its knockout results in a switch from melanotrope to corticotrope identify. Current evidence suggests that epigenetic changes including chromatin remodeling are required in order to change the outcome of Tpit-driven gene expression and cell identity. Genome-wide alteration of chromatin organization thus sets the stage for transcriptionnally driven terminal differentiation.

## What's new in congenital adrenal hyperplasia (CAH)?

### S57.1

**Congenital adrenal hyperplasia: counselling from birth to the next generation**

N. Krone
University of Birmingham, Birmingham, UK.

Congenital adrenal hyperplasia (CAH) is a group of autosomal recessive disorders causing deficient cortisol synthesis. The commonest cause, 21-hydroxylase deficiency, accounts for about 90–95% of cases. Other entities such as deficiencies of 11β-hydroxylase, 17α-hydroxylase, 3β-hydroxysteroid dehydrogenase type 2, and P450 oxidoreductase are considerably rarer. The differential diagnosis has to be established as different forms of CAH will require different therapeutic approaches and have different health risks. For over a decade, CAH newborn screening is clinical practice in an increasing number of countries. It is beneficial to reduce morbidity; however the impact on mortality is a matter of

debate. Newborns detected early enough can be commenced on medication and generally avoid hospitalisation. Improved steroid analysis employing rapid and comprehensive mass spectrometry profiling as first or second tier test reduces false positive rates. Such improvements have also simplified the differential diagnosis of CAH other than 21-hydroxylase deficiency. The drug of choice for glucocorticoid replacement in paediatric life is hydrocortisone. This therapy aims to replace cortisol, to normalise androgens into age and sex-specific ranges and to avoid normalisation of 17-hydroxyprogesterone concentrations. No supporting evidence exists on superiority on different timings of glucocorticoid application. Glucocorticoids should be minimised to avoid iatrogenic side-effects and adjusted to requirement during infancy, childhood and adolescence. This is often only achieved if mineralocorticoid and salt replacement are meticulously monitored. Additional growth promoting and puberty suppressing treatment are not routine therapy. Co-morbidities in CAH have been described in adults and to some degree in children. However, comprehensive data on the general health status during childhood and adolescence do not exists. These are warranted to identify the onset of co-morbidities and develop paediatric preventive health care provision strategies in CAH to improve prevention of long-term co-morbidities. This presentation will discuss diagnostic strategies, therapeutic management and onset of long-term problems in CAH.

## S57.2

**CAH and adulthood**

R. Ross
University of Sheffield, Sheffield, UK.

CAH is the commonest inborn endocrine disorder and associated with significant morbidity. The health status of CAH adult patients has recently been reported by the United Kingdom Congenital Adrenal Hyperplasia Adult Study Executive, CaHASE (Arlt *et al. JCEM* 2010 **95** 5110–21). Compared to the health survey for England, metabolic abnormalities were common in adult patients with CAH: obesity (41%), hypercholesterolemia (46%), insulin resistance (29%), osteopenia (40%), and osteoporosis (7%). HR-QOL (SF-36) showed significant impairment similar to scores in heart failure. The CAH patients were taking different glucocorticoid therapies at various doses ($n=196$): hydrocortisone ($n=25$M, 26W), prednisolone ($n=21$M, 67W), dexamethasone ($n=15$M, 22W), or combination therapy ($n=4$M, 16W). The CaHASE group have hypothesised that steroid dose mediates some adverse metabolic outcomes. ANOVA and univariate regression analysis only showed weak correlations ($r<0.2$) between prednisolone equivalent dose and SBP and DBP, HDL-cholesterol and HOMA-IR. However, using principal component analysis (PCA), it was identified that disease control factors, BP and mutation severity are associated with both the choice and total dose of glucocorticoid prescribed. Studies, independent of CaHASE, have examined the development of a modified release formulation of hydrocortisone, Chronocort, for the treatment of adults with CAH. Chronocort, in dexamethasone suppressed normal individuals, is capable of recreating the physiological rise in overnight cortisol levels and in adult patients with CAH improved control of morning 17-hydroxyprogesterone compared to immediate release hydrocortisone. In conclusion, health status in adults with CAH is significantly impaired and Chronocort represents a foundation for future drug development in the pursuit of physiological cortisol replacement.

CaHASE is grateful to the Society for Endocrinology for management of the project and The Clinical Endocrinology Trust for financial support

# Best Clinical Practice

## S58.1

**Towards a European Guideline for the treatment of hyponatremia**

B. Allolio
University Hospital Wuerzburg, Wuerzburg, Germany.

The growing complexity of medical practice has increased the demand for well conceived guidelines. Such guidance is also urgently needed in endocrinology, but difficult, as well-conducted trials are scarce. As a first step towards the systematic development of 'Best Practice in European Endocrinology' a guideline for diagnosis and treatment of hyponatremia was initiated.
Hyponatremia is the most frequent electrolyte disorder and of prognostic significance. Furthermore, with the availability of V2-receptor antagonists a new treatment option has become available which poses a challenge to optimal diagnosis and targeted treatment.
The European Society of Endocrinology together with the Europeans Society of Intensive Care Medicine and the European Renal Best Practice Initiative of ERA-EDTA has, therefore, jointly initiated this guideline. A key technique is the PICOM methodology for selecting the relevant papers by defining the patient population (P), the intervention/exposure (I), the adequate comparator (C) and the relevant outcome (O) respectively. Furthermore the methodology of the respective studies needs to be carefully addressed (M). Careful development of the PICOM questions is key in the guideline development, as it is at the basis of the literature search. After defining the PICOM questions a comprehensive literature search was completed with a first screening based on titles and abstracts, followed by a second screening to eliminate editorials letters and comments without primary data. In the next screening phase the working group members of the guideline committee performed comprehensive data extraction of the relevant papers using a standardized data extraction form. This allows a summary of all findings in tables and a grading of the evidence applying GRADE methodology.
It is expected that at the time of presentation a first summary of the evidence can be presented. This effort represents an important first exercise to implement structures for the continuous development of 'Best Practice in European Endocrinology'.

# Obesity and thyroid function

## S59.1

**Obesity and thyroid function**

T. Reinehr
Vestische Kinderklinik, University of Witten/Herdecke, Datteln, Germany.

While it is well known that hyperthyroidism leads to weight loss, and hypothyroidism is associated with weight gain, there has been an increasing focus on the relationship between thyroid function and body weight in recent years. A moderate elevation of TSH concentrations, which is associated with triiodothyronine ($T_3$) values in or slightly above the upper normal range, is frequently found in obese humans. These thyroid hormone alterations in obesity seem rather a consequence than a cause of obesity since weight loss leads to a normalization of elevated thyroid hormone levels. The underlying pathways are not fully understood. White adipose tissue, the largest energy store in the body,

actively produces various hormones, cytokines, and chemokines, which together exert important roles in homeostasis and also in thyroid hormone regulation. The adipokine leptin seems to be the most promising link between body weight and TSH levels since leptin stimulates the hypothalamic–pituitary–thyroid axis.
High serum $T_3$ levels in obesity and overfeeding suggest a role for $T_3$ in metabolic adaptation to these situations: increased basal metabolic rate and thermogenesis in obesity and as a consequence the availability of accumulated energy for conversion into fat is diminished. Since rapid weight loss is associated with a decrease of TSH and $T_3$, the resulting decrease in REE may contribute towards the difficulties maintaining weight loss.

## S59.3

**Type 2 deiodinase in muscle during health and disease**
A. Boelen
Academic Medical Center, Amsterdam, The Netherlands.

One of the major routes for metabolism of thyroid hormones is by deiodination through the iodothyronine deiodinases, an enzyme family consisting of three members, types 1 (D1), 2 (D2) and type 3 (D3). The outer ring of thyroxin ($T_4$) can be deiodinated by D2, leading to the formation of active hormone, triiodothyronine ($T_3$). D2 is expressed predominantly in the brain and pituitary, but also in brown adipose tissue and muscle. Within the cell, D2 is localized in the endoplasmic reticulum and it is negatively regulated by thyroid hormone both pre- and post-transcriptionally.
Human skeletal muscle D2 was believed to be involved not only in local $T_3$ production but also in systemic production of $T_3$ in the basal condition. However, this concept was recently challenged as skeletal muscle D2 is expressed only at very low levels under euthyroid conditions in healthy persons. In addition, muscle D2 mRNA expression was reported to be modulated by fasting and by insulin suggesting that muscle D2 is involved in energy metabolism. Finally, recent studies have reported alterations in muscle D2 expression during inflammation. Both acute and chronic inflammation increase D2 mRNA expression in skeletal muscle while bacterial sepsis is associated with decreased D2 expression. Septic patients often develop muscle dysfunction which is probably due to decreased mitochondrial activity and content. This may point to a role for D2 in muscle dysfunction during sepsis as thyroid hormones are involved in mitochondrial function and biogenesis. In summary, D2 expression varies in skeletal muscle according to the type of inflammation. The changes in deiodinase expression are likely to result in altered local $T_3$ availability which may affect muscle function. Our future studies will focus on the question whether the observed changes in thyroid hormone metabolism in muscle during inflammation are clinically relevant in terms of muscle (dys)function.

# Performance enhancing hormones in sports

## S60.1

**The spectrum of hormones in sports doping**
F. Lanfranco
University of Torino, Torino, Italy.

Physical activity exerts an important influence on the endocrine system, modulating synthesis and secretion of several hormones. On the other hand, several hormones are able to influence physical performance and body composition. Thus, a two-way relationship between exercise and hormones exists. The use of performance-enhancing compounds dates back to the initial Olympiad in ancient Greece where herbal remedies and animal extracts were used by the athletes before competition. In the past decades, hormone abuse has become a widespread habit among professional and - most of all and more frequently – recreational athletes. Anabolic androgenic steroids (AAS), GH and erythropoietin (EPO) are the most frequently abused hormonal substances in sports. The use of AAS as performance enhancing drugs dates back at the 1936 Olympic Games in Berlin, shortly after testosterone was first isolated and synthesized. GH was introduced to the world of sport by the Underground Steroid Handbook, a leaflet published in 1982 and used in the 1988 Olympic Games. Recombinant human EPO has been imputed to be abused by athletes in aerobic sports early after its marketing as an erythropoiesis-stimulating drug.
AAS are chemically modified analogs of testosterone which act on the skeletal muscle as a primary target tissue. The anabolic effect of testosterone is dose dependent, and significant increases in muscle size and strength occur only with supra-physiological doses. GH is used as a drug of abuse in sports, although there are no proper scientific studies demonstrating GH to be performance enhancing in normal subjects. EPO stimulates an increase in hemoglobin thus increasing the oxygen-carrying capacity of the blood.
The adverse effects of hormone abuse are numerous and affect several organs and body systems leading to increased mortality. Thus, hormone abuse among athletes and specific subsets of the general population represents a major public health issue which requires further research in sports endocrinology and widespread educational programs.

## S60.2

**GH and testosterone: do they work?**
V. Birzniece[1,2]
[1]Garvan Institute of Medical Research, Sydney, New South Wales, Australia; [2]St Vincent's Hospital, Sydney, New South Wales, Australia.

Perceived anabolic benefits of androgens and GH have fueled their abuse among both competitive and recreational athletes. While both hormones increase muscle mass, whether they enhance exercise capacity in healthy adults is less clear. The yearning to boost performance however continues to bolster their inappropriate use in sports, despite many adverse effects. These include acne, excessive hair growth, prostate hypertrophy, behavioural, psychiatric, cardiovascular side effects, hepatic and sexual dysfunction for androgen use and oedema, carpal tunnel syndrome, arthralgias, as well as a state mimicking acromegaly with increased risk for diabetes, cardiomyopathy and malignancy, in the case of GH. As GH and testosterone interact to promote anabolic effects, many athletes abuse both of these hormones. Testosterone significantly and dose-dependently increases muscle mass and strength in healthy adults. The effect of testosterone on aerobic exercise capacity is less clear. GH increases lean body mass, although fluid retention contributes to this effect. Our recent data indicate that GH does not enhance muscle strength, power, or aerobic exercise capacity, but improves anaerobic exercise capacity. When GH and testosterone abused together, there is not only potentiation of their effects on muscle mass and function, but also increased risk to develop side effects. As both these hormones are effective in improving body composition and certain aspects of performance, they are tempting targets for abuse among athletes. Whether they live up to the expected, that's another question.

## S60.3

**Erythropoietin and its derivatives**
M. Saugy
Swiss Laboratory for doping analses, Epalinges, Switzerland.

Erythropoietin (EPO) is a glycoprotein hormone endogenously produced by the kidney, whose main physiological role is the stimulation of red blood cells

production. Since the beginning of the nineties, recombinant human EPO (rhEPO) has been manufactured by pharmaceutical companies and was immediately misused by athletes to increase their muscle oxygenation process, enhancing then tremendously their endurance performances. It is why EPO has been put on the list of the forbidden substances of the International Olympic Committee (IOC), and then of the World Anti-doping Agency (WADA). Nowadays, not only EPO, but all the erythropoiesis-stimulating agents are part of the forbidden peptide hormones from the WADA list. The darbepoietin alpha (NESP for Novel Erythropoiesis Stimulating Protein), the methoxy polyethylene glycol-epoetin beta (CERA for Continuous Erythropoietin Receptor Activator) and the pegninesatide (Hematide) are also cited as example of forbidden compounds when practicing sports competitions. There are nowadays also many biosimilar epoietins on the market, mainly derived from epoietin alpha, widely used by the cheating athletes.

The analytical differentiation of endogenously produced erythropoietin from its recombinant form by using isoelectric focusing (IEF) and double blotting is one of the most efficient tool in the detection of doping with rhEPO. However, because of the use of these various analogous products, it is not always easy to detect them by the standard IEF-method. The different modes of application, by using for example micro doses of EPO biosimilars, make the detection window thinner and the efficiency of any method less robust than expected. Because of the lack of sensitivity of the direct detection of the doping substance, the new individual and longitudinal follow up of the athletes, called the biological passport, will certainly provide the proper answers to question of the abuse of EPO in top level sport.

## New insights in thyroid cancer diagnosis

### S61.1

**BRAF(T1799A) can be detected in the blood of papillary thyroid carcinoma patients and correlates with disease status**

M. Zatelli
University of Ferrara, Ferrara, Italy.

The worldwide incidence of thyroid cancer has been increasing during the last years and is a public health concern because treatment of thyroid cancer implies high health costs and may raise overtreatment issues. On the other hand, effective medical treatment for advanced disease escaping radiometabolic treatment and not amenable for surgical approach is still lacking. Current methods of detection, decision making, prognostic indications, and monitoring rely on clinical, morphologic, and histopathologic characteristics. Therefore, precocious diagnosis is still a mainstay for thyroid cancer treatment in the early stages.

The activating BRAF(T1799A) mutation occurs in 45–80% of papillary thyroid cancers and is believed to cause the malignant transformation of the follicular cell. Detection of this mutation has been used to increase the diagnostic sensitivity of fine-needle aspiration biopsies of thyroid nodules suspected for malignancy and to provide a better staging, allowing detection of minimal disease metastatic to locoregional lymphnodes. In addition, BRAF(T1799A) mutation has been associated with unfavourable outcomes in retrospective studies.

Previous studies on melanoma have shown that circulating BRAFT1799A is indeed detectable and could potentially be used as a marker of prognosis and/or a surrogate for assessment of clinical response. The mutation has been more frequently found in metastatic tissue than in primary tumors. Therefore,the serum assay may be used in monitoring for disease progression. Accordingly, recent studies showed that detection of circulating BRAFT1799A might allow diagnosis of PTC with a blood test, identifying patients with minimal residual disease to be addressed to radioiodine remnant ablation, radioactive iodine therapy, or other adjuvant treatment measures. On the other hand, BRAFT1799A positivity in blood did not correlate with disease status/stage at the time of presentation and did not predict out come. Large-scale prospective studies are needed before circulating BRAFT1799A detection can become an accepted clinical tool for thyroid cancer screening and management.

## Early Development and Treatment of PCOS

### S62.1

**Early hormonal abnormalities in children born to women with PCOS**

T. Sir-Petermann
University of Chile, Santiago, Chile.

Polycystic ovary syndrome (PCOS) is a common endocrine-metabolic condition with a strong familial component suggesting a genetic susceptibility. During pregnancy, PCOS mothers offer an altered intrauterine environment which may also be implicated in the origin of this syndrome, and could determine endocrine/metabolic disturbances in their offspring (boys and girls) that may persist later in life. We have evaluated this possibility studying sons and daughters of PCOS mothers from early infancy to early adulthood. In daughters of women with PCOS (PCOSd), we have observed higher serum AMH concentrations and increased ovarian volumes during early infancy and adolescence compared to daughters of control mothers. In addition, these girls exhibit higher postprandial insulin serum concentrations and lower serum adiponectin levels compared to carefully matched controls, even before the onset of puberty. During puberty, we have studied PCOSd using the GnRH analog test, showing increased basal and peak testosterone concentrations and higher peak LH and 17-OHP levels, at a time when some early clinical signs of hyperandrogenism are mildly evident. During this period, 45% of PCOSd in Tanner IV and 60% in Tanner V have biochemical hyperandrogenism compared to control girls. However, it is not known how many PCOSd ultimately develop PCOS in the early reproductive period. After menarche (1–3 years) using the AES criteria, hyperandrogenism is the main diagnostic feature for PCOS present in these girls, while menstrual irregularity, PCO morphology and AMH levels are secondary elements that may aid in the diagnosis of this syndrome. In sons of women with PCOS, we have also observed increased serum AMH concentrations and higher BMIs, well before the onset of puberty. During adulthood, they remain overweight and show higher postprandial insulin concentrations and lower insulin sensitivity (adjusted for BMI) compared to controls. In summary, our studies have addressed the timing and sequence of the onset of metabolic and reproductive perturbations in the offspring of PCOS patients. Considering the early onset and the nature of these alterations, PCOS sons and daughters constitute a high-risk group for metabolic and reproductive disease.

### S62.2

**Early development and pubertal prevention of polycystic ovary syndrome**

F. de Zegher[1] & L. Ibanez[2]
[1]University of Leuven, Leuven, Belgium; [2]University of Barcelona, Barcelona, Spain.

PCOS (defined by NIH, Rotterdam or AES criteria) is traditionally viewed as an ovarian disorder that appears in adolescence and may lead to metabolic

complications in adulthood. Emerging evidence, however, indicates that PCOS is primarily a disorder of adipose-tissue hyperexpansion that may originate in early life, develop across childhood and puberty, and advance into end-stage disease (including ovulatory dysfunction and ovarian androgen excess) by adolescence. Prepubertal markers pointing to PCOS risk include a viscerally adipose body composition, high levels of circulating triglycerides, insulin, IGF1, DHEAS and leptin, and low levels of adiponectin and SHBG.
The novel concept on the ontogeny of PCOS does not only harbour the most common (obese and non-obese) phenotypes of PCOS, but implies also a potential to prevent PCOS by preventing the hyperexpansion of adipose tissue in childhood and puberty. This potential has now been tested in a subgroup of non-obese girls that can be identified early as being at high risk for PCOS, namely low-birthweight girls with precocious pubarche. Treatment with metformin across late prepuberty and puberty was associated with postpubertal reductions in visceral, hepatic and total-body adiposity and also with a reduction in the prevalence of PCOS (5 vs 47% by NIH or AES criteria, after 8 year of study). Welcome epiphenomena of such early metformin intervention were an increment of adult stature (by ∼4 cm towards normal) and a delay of menarche (by ∼1 year towards normal).
Another implication of the novel concept is that intervention in adolescent girls with PCOS should not aim primarily at silencing the ovaries (with an oral contraceptive) but rather aim at reducing adipose-tissue hyperexpansion and low-grade inflammation (for example, with a low-dose combination of metformin, flutamide and pioglitazone) thereby allowing for spontaneous resumption of ovulation and also for waning of androgen excess.

## S62.3

**Hyperandrogenism in obese girls: what is the significance?**
C. McCartney
University of Virginia, Charlottesville, Virginia, USA.

Polycystic ovary syndrome (PCOS) is marked by (primarily ovarian) hyperandrogenemia and ovarian dysfunction. In many cases, PCOS first manifests during adolescence, and both peripubertal hyperandrogenemia and obesity are considered risk factors for the development of PCOS. Many, but not all, pubertal girls with obesity – including those in early puberty – exhibit relative hyperandrogenemia. However, the causes of peripubertal obesity-associated hyperandrogenemia, and mechanisms by which hyperandrogenemia could support progression to PCOS, are unknown.
Early data suggest that adrenal androgen responsiveness to ACTH is exaggerated in overweight peripubertal girls; this may partly reflect the effects of hyperinsulinemia. However, LH is the proximate stimulus for ovarian androgen production, and LH appears to be a better predictor of free testosterone than insulin in obese girls. Studies in adults with PCOS and in animal models suggest that excess androgens decrease GnRH pulse generator sensitivity to sex steroid negative feedback, augmenting GnRH pulsatility. These relationships – LH stimulating androgen production and androgens increasing GnRH (and LH) secretion – may constitute a vicious cycle that links peripubertal hyperandrogenemia and the development of full-blown PCOS.
How obesity and hyperandrogenemia affect the normal pubertal sequence of GnRH secretion is unclear. Early puberty is characterized by sleep-associated increases of LH (and by inference GnRH) pulse frequency, while LH pulse frequency decreases during sleep in late puberty. Early data suggest that these wake-sleep changes may partly reflect differential sensitivity of the GnRH pulse generator to negative feedback suppression depending on sleep status. We have proposed a working model in which relative hyperandrogenemia during puberty – as may occur in obesity – disrupts these relationships. Indeed, both early and late pubertal girls with obesity – especially those with hyperandrogenemia – exhibit blunted wake-sleep changes of LH pulsatility. Such alterations may increase LH release and limit FSH production, worsening hyperandrogenemia and promoting progression toward PCOS.

# Emerging ideas about phosphate metabolism

## S63.1

Abstract unavailable.

## S63.2

**FGF23 and tumor-induced osteomalacia**
S. Fukumoto
University of Tokyo Hospital, Tokyo, Japan.

Tumor-induced osteomalacia (TIO) is a paraneoplastic syndrome characterized by hypophosphatemia associated with renal phosphate wasting and low to low normal serum level of 1,25-dihydroxyvitamin D (1,25(OH)2D). FGF23 was identified as a causative factor for TIO which inhibits proximal tubular phosphate reabsorption and decreases serum 1,25(OH)2D by modifying the expression levels of vitamin D-metabolizing enzymes. This disease is cured by complete resection of responsible tumors. However, it had been clinically often difficult to diagnose and treat patients with TIO. After the identification of FGF23, it was shown that FGF23 levels are elevated in virtually all patients with TIO and rapidly decrease after complete removal of responsible tumors. Therefore, measurement of FGF23 levels seems to be useful in the diagnosis and follow up of patients with TIO. The causative tumors for TIO are often small and difficult to find. Several imaging studies including as magnetic resonance imaging, positron emission tomography and octreotide scintigraphy have been used for the search of responsible tumors for TIO. However, none of these imaging studies indicate that the detected tumors are producing FGF23 and responsible for TIO. We have conducted systemic venous sampling for FGF23 in several patients with suspected TIO and reported that this maneuver is useful for the detection of responsible tumors at least in some patients. Furthermore, it is possible that the inhibition of FGF23 activity could be a new therapy for patients with TIO whose tumors cannot be found or removed by technical reasons. In this symposium, I would like to discuss about the diagnosis and treatment of TIO with special emphasis on FGF23.

## S63.3

**FGF23 in chronic renal failure**
J. Silver
Hadassah Hospital, Jerusalem, Israel.

FGF23 secretion is increased in response to 1,25(OH)2 vitaminD3 (1,25D) and an oral phosphorus (P) load. Patients with chronic kidney disease (CKD) are unable to excrete their dietary P which contributes to an increased secretion of the two major phosphaturic hormones, PTH and FGF23. The increased FGF23 would normally bind to its receptor, klotho-FGFR1 in the renal tubules to increase P clearance and decrease the synthesis of 1,25D. Increased FGF23, P and PTH levels are all associated with an increased mortality in CKD. Physiologically, FGF23 acts on its receptor klotho-FGFR1 in the parathyroid to decrease PTH expression and parathyroid cell proliferation but in advanced CKD there is a decrease in the expression of klotho-FGFR1 both in the parathyroid in the kidney. This is associated with high levels of both FGF23 and PTH. In turn, the high levels of PTH act on bone cells to increase FGF23. We recently showed that PTH acts directly on osteoblast like cells to increase FGF23 expression. Remarkably, parathyroidectomy in rats both prevents and corrects the high FGF23 due to short-term experimental uremia. In patients a decrease in PTH leads to a decrease in serum FGF23. Therefore, in CKD, the high levels of PTH are necessary to maintain the high levels of FGF23. Experimental CKD is associated with low renal klotho levels and the administration of klotho has been shown to bind to TGFβ1 and improve renal function. Dialysis patients' course is often complicated by left ventricular hypertrophy (LVH) and cardiac failure. FGF23 acts directly on cardiomyocytes to cause LVH and the progression to LVH in CKD correlates with the high levels of FGF23. Moreover, administration of an FGFR blocker attenuated LVH in experimental CKD. Therefore, FGF23 expression is increased by P, 1,25D and PTH and it has important actions on the kidney, parathyroid and heart.

## Somatostatin receptors in pituitary

### S65.1

**Imaging somatostatin activity in live pituitary**
S. Schulz
Jena University, Jena, Germany.

Fluorescence resonance energy transfer (FRET) using genetically encoded biosensors has proven to be a powerful technique to monitor the spatiotemporal dynamics of cAMP signals stimulated by Gs-coupled receptors in living cells. In contrast, real-time imaging of Gi-mediated cAMP signals under native conditions remains challenging. Here, we describe the use of transgenic mice ubiquitously expressing the highly sensitive cAMP sensor Epac1-camps for cAMP imaging in living pituitary slices and primary pituitary cells. This technique can be widely used to assess the contribution of various pituitary receptors, including individual Gi protein-coupled somatostatin receptors, to the regulation of cAMP levels under physiologically relevant settings.

### S65.2

**Is somatostatin receptor expression in adenomas related to pharmacological response?**
S. Fougner
St. Olavs Hospital, Trondheim University Hospital, Trondheim, Norway.

The clinical response to somatostatin analogue (SMS) treatment in acromegaly is highly variable. In unselected, previously untreated patients, biochemical control is achieved in 20–50% of patients, and mean overall tumour shrinkage has been reported to 25–40%.
The somatostatin analogues exert their effects through binding to the somatostatin receptor (SSTR) localized in the cell membrane. The available analogues bind with high affinity to SSTR2, less to SSTR5 and lower to SSTR3. It can therefore be expected that the adenoma expression of SSTR2 is important for the SMS response. Indeed, the first studies of SSTR2 mRNA from adenoma extracts demonstrated a correlation to *in vivo* octreotide response either in an acute test or long-term treatment. This has later been confirmed in studies of SSTR2a protein expression and long-term SMS treatment. Two studies of 18/20 patients have shown that the percentage GH or IGF1 reduction during treatment is larger in adenomas with a high proportion of SSTR2a positive cells in adenoma immunohistochemistry. Another study found that patients with $<50\%$ GH reduction during preoperative treatment did not express SSTR2a in immunohistochemistry, in contrast to octreotide responders. However, the studies also demonstrated patients with low SSTR2a positivity and good octreotide response, and patients with high SSTR2a positivity and very poor octreotide efficacy. This suggests that not only adenoma SSTR2 expression determines the clinical efficacy of SMS. One could expect an impact of SSTR5, but the research of SSTR5 expression and SMS response has not been conclusive. However, the densely granulated somaototroph adenomas respond significantly better to SMS treatment compared to sparsely granulated adenomas, but they also display lower SSTR2a protein expression. Despite a lower SSTR2a protein expression in gsp positive adenomas, they do not respond better to long-term SMS treatment. This can imply additional mechanisms important for SMS response in these adenomas.

### S65.3

**Somatostatin receptors and filamin: a developing story**
S. Najib[1,2], N. Saint-Laurent[1], D. Fourmy[2], S. Schulz[4], R. Luque[5], J. Castano[5], M. Delisle[1,3], S. Pyronnet[1,2], C. Susini[1,2] & C. Bousquet[1,2]
[1]INSERM U1037, Toulouse cedex 4, France; [2]Université Toulouse 3 Paul Sabatier, Toulouse, France; [3]Toulouse Hospital, Toulouse, France; [4]Jena University Hospital, Jena, Germany; [5]Instituto Maimónides de Investigación Biomédica de Córdoba, Cordoba, Spain.

The G protein-coupled (GPCR) somatostatin receptor sst2 transduces the majority of somatostatin actions, including inhibition of hormone and growth factor secretion, cell survival and angiogenesis. Sst2 agonists such as octreotide are widely used for the treatment and diagnostic of human neuroendocrine tumors that frequently over-express sst2. To initiate its inhibitory signalling pathways, sst2 engages, in addition to G protein subunits, different protein partners such as phosphatases and kinases. We have reported an original mechanism for sst2 to restrain the phosphoinositide 3-kinase (PI3K) activity, involving a ligand-regulated direct interaction between sst2 with the PI3K regulatory p85 subunit. We also identified the scaffolding protein filamin-A (FLNA) as a critical player regulating the dynamic of this complex. A pre-existing sst2–p85 complex, which was shown to account for a significant basal PI3K activity in the absence of ligand, is disrupted upon sst2 activation. FLNA was identified as a competitor of p85 for direct binding to two juxtaposed sites on sst2. Switch of sst2 binding preference from p85 towards FLNA is determined by changes in tyrosine phosphorylation of p85- and FLNA-binding sites on sst2 upon activation. It results in disruption of the sst2–p85 complex and subsequent inhibition of PI3K. Knocking-down FLNA expression, or abrogating FLNA recruitment to sst2, reversed inhibition of PI3K and of tumor growth induced by sst2. FLNA is an actin-binding and scaffolding protein for numerous cytosolic and transmembrane signalling proteins including GPCRs. Our results demonstrate that FLNA is critical to maintain the stability of sst2 at the membrane in close proximity with its signalling effectors including actors of the lipid PI3K family. Strikingly, in GH-secreting pituitary adenomas expressing sst2, resistance to octreotide correlates with decreased expression of FLNA, further emphasizing the critical role of FLNA in sst2 functions.

## HPA axis, stress metabolism and adaptation

### S66.1

**Neuroendocrine and (epi)genetic impact on HPA function**

E. de Kloet
Leiden University Medical Center, Leiden, The Netherlands.

The HPA axis facilitates adaptation to stress and is essential for metabolism and health, but dysregulation of the HPA axis compromises resilience and promotes vulnerability to stress-related diseases. This includes diseases of the brain where an aberrant stress hormone action targeting susceptibility pathways causes emotional and cognitive disturbances, and affects the onset and progression of neurodegenerative processes, while impairing recovery and neurogenesis. This action exerted by the hormone involves genes, but also epigenetic modulations triggered by early life experience may permanently alter behaviour and HPA axis activity. The focus is on the action of the HPA axis endproduct cortisol and its dual high- and low affinity receptor systems: mineralocorticoid (MR) and glucocorticoid receptors (GR). Both receptor types are co-expressed in abundance in limbic brain regions and serve together as a master switch in the control of neural network responses that underly activation and suppression of HPA axis activity. Imbalance in MR:GR driven pathways caused either by genetic receptor variants or by experience-related factors compromises processing of stressful information and dysregulates the HPA axis. Therapies are therefore envisioned to rebalance the HPA axis for protection or repair from damaging signaling pathways. Here I will discuss indepth our recent data on i) functional implications of genetic receptor variants as presented recently by MD Klok and RH de Rijk (Translational Psychiatry (2011) 1, e62), and ii) the work of NP Daskalakis (Thesis Leiden University, 2011) regarding the role of genetic predisposition in the programming effects of adverse early life/adolescent experiences on the HPA axis.

### S66.3

**Modulation of cortisol action**

M. Jangani, A. Berry, L. Matthews, S. Farrow, R. Donn & D. Ray
University of Manchester, Manchester, UK.

Variation in glucocorticoid (Gc) sensitivity underlies metabolic disease, and affects therapeutic response in inflammation. Using an in-vitro screening approach we identify two new mechanisms capable of regulating Gc sensitivity. The first involves interferon induced factor 16 (IFI16). IFI16 potentiated both transactivation, and Gc repression of NFκB. IFI16 did not affect glucocorticoid receptor (GR) expression, ligand dependent repression of GR expression, or the ligand dependent induction of GR phosphorylation. Co-immunoprecipitation revealed an interaction, suggesting IFI16 modulation of GR function is mediated by protein cross-talk. Transfection analysis with GR mutants showed that the ligand binding domain of GR binds IFI16, and is the target domain for IFI16 regulation.

The second mechanism involves Merm1, a histone methyltransferase, which potentiates GR transactivation through its SAM and methyltransferase domains. Merm1 is required for maintenance of an active chromatin methyl mark (H3K79me2) at the GREs and facilitates GR binding. Activated GR promotes H3K4me3, and represses H3K79me2 marks at GREs, in a Merm1 dependent manner, suggesting coordinated histone modification whereby one change influences the other. Inflammation causes glucocorticoid resistance, which is replicated in-vitro by the combined action of inflammatory cytokines TNFα, and IFNγ. These cytokines suppress Merm1 protein, impair GR recruitment to GREs, and inhibit acquisition of the H3K4me3 mark. Glucocorticoid sensitivity was rescued by restoring Merm1 expression.

In conclusion, IFI16 is a novel modulator of GR function, acting through the GR ligand binding domain, and Merm1 regulates chromatin structure so affecting GR recruitment, GR function, and mediates cytokine-induced cellular glucocorticoid resistance.

## Central regulation of energy homeostasis

### S67.1

**CNS control of energy and glucose metabolism**

C. Könner
Institute for Genetics, Cologne, Germany.

The tight coordinated regulation of food intake and energy expenditure represents the prerequisite for stable body weight control. Dysregulation of energy homeostasis, i.e. obesity represents a major and steadily growing health burden to western societies. The CN coordinates both the control of energy homeostasis, i.e. the balance of food intake and energy expenditure as well as peripheral fuel metabolism. Anatomical lesion experiments, pharmacological inhibition of signaling pathways and, more recently, the analysis of conditional mouse mutants with modifications of hormone and nutrient signaling in defined neuronal populations have broadened our understanding of how these complex neurocircuits interact and how their activity is regulated. The hypothalamus receives information from the periphery of the body about the fuel sources available either via hormonal signals such as leptin and insulin as well as directly by nutrient components such as amino acids, glucose and fatty acids. The presentation will focus on the genetic analysis of interacting neurocircuits involved in these processes.

### S67.2

**Gut hormones: history, physiology and therapeutic opportunities**

Dr Keval Chandarana

In recent decades, a great deal of investigation has been focused on the role of gut hormones in energy homeostasis. The gastrointestinal tract is the largest endocrine organ in the body producing hormones that have important sensing and signalling roles in regulating body weight and energy expenditure. Dietary modifications are the first-line treatment for obesity however dieting results in only moderate weight-loss and maintenance of weight-loss is poor. Compensatory gut hormone changes appear to contribute to the failure of weight-loss through dietary means. In contrast, bariatric surgery is an efficacious treatment modality for obesity, resulting in durable weight loss and amelioration of obesity-associated co-morbidities, particularly type 2 diabetes mellitus. Moreover, the metabolic benefits of bariatric surgery occur independently of weight loss. An increasing body of evidence suggests that alterations in circulating gut hormones mediate the weight-loss and metabolic benefits of bariatric surgery. Logically, strategies aimed at modulating circulating gut hormone concentrations or targeting their receptors are being developed as potential pharmacotherapies for obesity.

## European network for the study of adrenal tumours (ENSAT)

### S68.1

**Genetics for pheochromocytoma and paraganglioma in 2012**

M. Robledo
Spanish National Cancer Center, Madrid, Spain.

Pheochromocytomas (PCCs) and paragangliomas (PGLs) are rare tumours of neural crest origin, previously referred to as 'the 10 percent' tumor due in part to the frequency of inherited forms. During the last decade the scientific community has been witness to a fast increase of knowledge of the genetics of these tumours. In this regards, the use of different strategies and new platforms has allowed to identify up to date thirteen PCC/PGLs susceptibility genes. Currently the proportion of familial PCC/PGLs may exceed 40%, which renders PCC/PGL as one of the most inherited tumor entities.

There is no doubt about the importance of detecting a mutation in any of the known genes related to the disease, not only for the affected patient but also for the relatives. Keeping in mind the genetic heterogeneity we face, it is critical the consideration of clinical, biochemical and immunohistochemical features to set up efficient algorithms able to guide a rational genetic screening in each patient. It is worth highlighting that at least 10% of patients, negative for the genetic study of the so far disease-related genes, are actually good candidates to be carriers of mutations in other susceptibility loci not yet identified.

Despite the powerful tools currently available, the identification of new susceptibility genes is not a straightforward issue. Only after a thorough patient's selection, either due to the phenotypic features or other OMIC data, the discover of new genes will be feasible. The participation of International Consortium is mandatory to this end.

## Current progress in the management of thyroid cancer

### S69.1

**TSH suppression in differentiated thyroid cancer: how low should we go?**

D. Cooper
The Johns Hopkins University School of Medicine, Baltimore, Maryland, USA.

Suppression of serum thyrotropin (TSH) is a cornerstone of thyroid cancer treatment, due to the tropic effects of TSH on thyroid cells. However, when deciding on the degree of TSH suppression during initial and long-term management, it is necessary to consider the aggressiveness of the cancer, as well as the potential for adverse effects induced by iatrogenic subclinical or overt hyperthyroidism. More aggressive TSH suppression is indicated in patients with high-risk disease or recurrent tumor, whereas less aggressive TSH suppression is reasonable in low-risk patients. In patients with high-risk differentiated thyroid cancer and an equally high risk of adverse effects (e.g. osteoporosis, cardiovascular disease), long-term treatment with levothyroxine therapy should be individualized and balanced against the potential for adverse effects.

**New mechanisms underlying the role of the mTORC1 pathway in the hypothalamic control of energy balance**

D. Cota
INSERM, Bordeaux, France.

Similar to individual cells, hypothalamic neural circuits profit from intracellular pathways known to work as fuel sensors to maintain energy balance.

The mammalian target of rapamycin complex 1 (mTORC1) signaling cascade is among the latest intracellular fuel-sensing pathways to be implicated in the hypothalamic regulation of energy balance.

mTORC1 activity is found in both NPY/AgRP- and POMC-producing neurons of the arcuate nucleus. Activation of mTORC1 and phosphorylation of its downstream targets are critical intracellular steps mediating the anorectic actions of both nutrients, such as amino acids, and hormonal signals like leptin. Interestingly, mTORC1 activity in the mediobasal hypothalamus varies as a function of the cell type and of the particular stimulus employed, as opposed to responding in a uniform manner to nutritional and hormonal changes. Furthermore, a link exists between intracellular fatty acid metabolism and mTORC1 and recent studies have shown that high-fat feeding and diet-induced obesity are conditions leading to the impairment of mTORC1 activity in the hypothalamus.

Here we will give an overview of the known functions of this pathway in the context of energy balance regulation and we will further present downstream mechanisms that we have recently identified to be engaged by mTORC1 for the control of food intake and body weight.

Taken together, these findings lead to conclude that mTORC1 is a highly conserved fuel sensor, which integrates signals from both stored and immediately available fuels and whose activity in the hypothalamus triggers adaptive feeding responses.

**DNA methylation of the body weight-regulating proopiomelanocortin gene: functional and ontogenetic aspects**

M. Mischke, P. Kuehnen, A. Grueters & H. Krude
Charité Berlin, Berlin, Germany.

Obesity is a polymorphic chronic disease with epidemic prevalence. Furthermore, heritability of the weight phenotype is high. However, within the catabolic leptin–melanocortin signalling pathway, which is pivotal for body weight regulation, gene mutations are rare. This indicates that other, non-genetic heritable factors might play a role in the development of obesity, such as epigenetic mechanisms. In a candidate gene approach, we analyzed the functional relevance and ontogenesis of the DNA methylation of the proopiomelanocortin (POMC) gene, which has a key role in hypothalamic body weight regulation. In vitro luciferase reporter gene analyses revealed DNA methylation-dependent promoter activity of both CpG islands (CGIs) of POMC. Regarding the ontogenesis, postnatally stable POMC DNA methylation patterns with interindividual conservation and non-tissue specificity were detected for both CGIs in mice, applying bisulfite sequencing. In addition, it was observed that the POMC DNA methylation patterns develop prenatally between the blastocystal stage and the early organogenesis.
Overall, these results indicate that stochastic variances arising in the course of the POMC DNA methylation development might influence the POMC activity and consequently alter the risk to develop obesity.

**Mineralocorticoid receptor antagonism counters metabolic dysfunctions induced by high fat diet in mice**

F. Cinti[1], M. Young[2], G. Cranston[2], E. Fletcher[2], V. Marzolla[1], A. Armani[1], A. Antelmi[1], A. Fabbri[3] & M. Caprio[1]
[1]IRCCS San Raffaele Pisana, Roma, Italy; [2]Prince Henry's Institute of Medical Research, Clayton, Victoria, Australia; [3]Unit of Endocrinology, S. Eugenio and CTO A. Alesini Hospitals, University of Rome 'Tor Vergata', Roma, Italy.

Drospirenone (DRSP) is a potent antimineralocorticoid with progestative and moderate antiandrogenic properties. We have previously shown that DRSP exerts a potent antiadipogenic activity in murine and human preadipocytes through specific antagonism of the MR. In the present study responses to DRSP were investigated in a model of diet-induced obesity for 12 weeks. Female 10-week-old C57bl6 mice were fed with normal chow or a high fat diet (HF, containing 45% fat by calories). Mice were concomitantly treated for 12 weeks with either vehicle, DRSP (3 and 30 mg/kg per day) or the MR antagonist Potassium Canrenoate (kCan 20 mg/kg per day). Glucose tolerance tests were performed after 3 and 12 weeks of treatment. High levels of MR mRNA were detected in all examined depots of adipose tissue. Mice fed HF showed significantly increased body weight and fat mass, increased expression of MCP-1 and adipogenic markers and a reduced glucose tolerance. DRSP (3 mg/kg per day) significantly improved glucose tolerance and reduced gonadal, renal and subcutaneous fat mass in mice fed HF; similar responses were observed with KCan, though to a lesser extent. Importantly, DRSP reversed HF-induced up-regulation of leptin, LPL, AcetilCoA and MCP-1 mRNA expression. HF diet-induced increase in adipocyte size was also completely reversed by DRSP, and to a lesser extent by kCan. Finally, DRSP induced the appearance of paucilocular UCP1 positive adipocytes in gonadal and subcutaneous adipose tissue of mice fed HF.
In conclusion, we show that DRSP can reverse adipocyte dysfunction induced by HF in an MR-dependent manner. Finally, DRSP treatment caused a dramatic morphological switch of white to brown adipocytes. This could explain the improvement in the metabolic profile of treated mice, suggesting a novel role for MR in controlling fat metabolism and white to brown transdifferentiation. MR blockade therefore has promise as a novel therapeutic option for the prevention of metabolic syndrome.

## S70.5

**A four-week fat overfeeding study in constitutional thin women: a human model of weight gain resistance**

N Germain[1], B Galusca[1], L Feasson[2], D Grouselle[2], J Epelbaum[2], J Minnion[3], M Laville[3], H Vidal[4], Y Boirie[5] & B Estour[1]
[1]University Hospital, Saint-Etienne, Saint-Etienne, France; [2]University Paris Descartes, Paris, France; [3]Imperial College, London UK, London, UK; [4]University Lyon 2, Lyon, France; [5]University Clermont-Ferrand, Clermont-Ferrand, France.

Introduction
Constitutional thinness (CT) is a rare condition of natural low body weight, with normal menstruation, no fear of weight gain and no hormonal abnormalities except for an anorexigenic hormonal profile. CT can be considered as the opposite of obesity and its resistance to weight loss. Therefore, we hypothesised they would have a resistance to weight gain.
Methods
10 female Controls (BMI 18.5–25 kg/m$^2$) and 10 CT women (BMI $<$ 17.5 kg/m$^2$) underwent a 4-week fat overfeeding (700 kcal) intervention. Body weight, food intake, body composition, energy expenditure and the profile of appetite regulatory hormones after test meals were monitored prior to and after dietary intervention.
Results
After one month of fat overfeeding, the mean body weight remained the same in the CT group ($-0.300$ kg, $P=0.258$ vs baseline) showing a resistance to weight gain, whereas it normally significantly increased in the control group ($+1.3$ kg, $P=0.0248$). After one month ad libitum food intake, the CT group body weight significantly dropped down ($-0.850$ kg, $P=0.0245$ vs the end of the overfeeding period), showing a rapid escape of the body weight gain, whereas the control group maintained its body weight gain ($+1.5$ kg, $P=0.02$ vs baseline). Resting energy expenditure significantly increased in the CT group only ($P=0.0307$). In the CT group, post meal PYY plasma levels ($P=0.008$) and post meal exposure time to GLP-1 significantly increased ($P=0.04$), emphasising the baseline anorexigenic profile. Conversely, in the control group, total and acylated ghrelin plasma levels increased significantly ($P=0.016$ and $P=0.028$ respectively) in an orexigenic profile.
Conclusion
This data is the first to demonstrate a resistance to weight gain in constitutional thinness population in response to 4-week fat overfeeding, associated with an increase in resting energy expenditure and an emphasised anorexigenic hormonal profile.

# Endocrine Nurse Symposium

## EN1.1

**Puberty induction in males and females**

Caroline Brain
Paediatric Endocrinology, GOSH/UCLH London UK.

Induction of puberty is indicated in children with primary or secondary gonadal failure, and where there is pubertal arrest or delay for whatever reason.
Timing of induction will vary depending upon age at presentation/diagnosis, but as far as possible this should coincide with expected pubertal changes within the normal population range.
Optimization of final height, breast and uterine development, and fertility are important outcome considerations and are dependent upon the underlying diagnosis (e.g.Turner syndrome, Klinefelter's Syndrome, survivors of childhood cancer).
Indications for pubertal induction in both sexes fall into two main diagnostic categories;

- Hypogonadotrophic hypogonadism
  Hypopituitarism (primary & Secondary)
- Hypergonadotrophic hypogonadism
  Primary Gonadal failure (dysgenic/syndromic/autoimmune/toxicity)

Specific genetic diagnoses may require disclosure and counciling prior to pubertal induction and ideally require a multidisciplinary team approach.
Protocols for induction of puberty must be individualized as response to sex hormone replacement is very variable and may depend upon the underlying diagnosis.
Puberty may be induced using preparations given by oral, transdermal or intramuscular (Male) routes. Titration of dose is made depending upon individual clinical response with emphasis on mirroring normal pubertal development.
Appropriate monitoring and transition to adult service as appropriate, is an integral part of the induction process.
*The role of the Endocrine clinical nurse specialist is crucial to this process and for optimum transition to long term adult follow-up.*

## EN1.2

**The role of the endocrine nurse in puberty induction**

Meg Keil

The adolescent/young adult who requires pubertal induction presents unique challenges to the health care team. Nurses serve as a key resource for patients and their families during the process of pubertal induction. Health promotion is the keystone of nursing practice and a developmental model is an appropriate framework to tailor nursing assessment and intervention to the adolescent/young adult's developmental level. The nurse's role in health promotion during pubertal induction may include: psychosocial and physical assessment, advocacy, case management, counseling, and patient education. Perhaps the most important component of the initial assessment prior to initiation of pubertal induction is for the nurse to address the patient and/or family member's anxiety or fears in order to identify potential barriers to initiation of and/or compliance with treatment. Typical patient/family concerns include: body image, short stature, final height, social interaction, physical and emotional changes, what to expect during treatment, possible side effects, fertility, and selection and cost of treatment. The endocrine nurse also provides education and advice to patients and their families regarding: normal puberty, effects of pubertal delay, diagnostic testing, goals and expectations of treatment, options for sex steroid replacement, possible side effects of treatment, clinical monitoring of treatment, and sexuality. In addition, the role of the endocrine nurse includes providing reinforcement of medical information discussed with endocrine health care team and facilitation of communication with the primary health-care provider, school nurse, and insurance provider. Part of counseling the patient/family includes referral to appropriate resources such as patient support groups, social work, genetic counseling, and patient education literature/web sites. Future studies are needed to identify effective intervention models for health promotion that include outcome measures such as quality of life, patient satisfaction, and cost effectiveness.

## EN1.4

**Choosing the right sex steroid replacement option for patients: the role of the endocrine nurse**

Shashana Shalet (Endocrine Advanced Nurse Practitioner)

In the UK the expansion of nurses' autonomy and scope of practice over recent years means that the clinical nurse specialist (CNS) can effectively provide a quality service to endocrine patients. The role of the endocrine CNS in enabling patients to choose the right sex steroid replacement option does not differ much from the Doctor's role. The CNS does, however, often have more time to provide the necessary education to the patient required to make an informed choice and thereby potentially increasing compliance with their chosen therapy. The CNS is able to review the patient and their medications on a more frequent basis which again can support compliance with treatment.
A sound knowledge base of the available treatment options and the ability to focus those options down to meet the exact needs of the individual patient is a key element in providing this service. By understanding the benefits and risks of individual medications, being knowledgeable around the necessary precautions as well as creating a trusting relationship with the patient through clear communication the role of the endocrine CNS is to support the informed choice process. It is important that there are clear and structured clinical guidelines that support this process and ensure the safety of both the patient and the CNS.

## EN2.1

**Diagnosis and management of Cushing's syndrome**

Richard Feelders
Erasmus Medical Center, Rotterdam, The Netherlands.

Cushing's syndrome (CS) is characterized by chronic overproduction of cortisol resulting in significant morbidity and, when untreated, an increased mortality. CS is divided into adrenocorticotropin (ACTH)-dependent CS and ACTH-independent CS. ACTH-dependent CS, the majority of cases, can be caused by a corticotroph pituitary adenoma and, more rarely, by ectopic ACTH production. ACTH-independent CS is usually caused by an unilateral adrenal adenoma and less frequent by an adrenal carcinoma and bilateral adrenal hyperplasia.
The diagnosis CS is biochemically established by demonstration of increased urinary cortisol excretion, insufficient cortisol suppression by dexamethasone and absence of the cortisol diurnal rhythm. In case of ACTH-dependent CS and a negative MRI of the sellar region, bilateral inferior petrosal sinus sampling (BIPSS) is performed to differentiate between a non-visible pituitary adenoma and ectopic ACTH production. If BIPSS shows no central to peripheral ACTH gradient the ectopic cause can often be visualized with CT and somatostatin receptor scintigraphy. In patients with ACTH-independent CS, CT or MRI of the abdomen is performed to detect an adrenal neoplasia.
Surgery is the primary treatment for all causes of CS. The remission rate in patients with pituitary-dependent CS varies between 60 and 80% after transsphenoidal adenomectomy. Patients with persistent or recurrent pituitary-dependent CS can be treated with radiotherapy and/or medical therapy with neuromodulatory drugs (dopamine agonists, somatostatin analogs), adrenal blocking drugs (ketoconazole, metyrapone) or glucocorticoid receptor antagonists (mifepristone). Ectopic ACTH production is frequently accompanied by severe hypercortisolism which may necessitate bilateral adrenalectomy.

## EN2.2

**The role of the endocrine nurse in the diagnosis and management of the patient with Cushing's syndrome**

W Geilvoet

Cushing's syndrome is a rare disease and difficult to diagnose. A number of different physical and psychological signs and symptoms can be present. Lots of patients have symptoms many years before diagnosis. Endocrine nurses can play an important role for these patients during diagnosis, medical or surgical treatment and in the postoperative phase.
During the diagnostic phase, nurses need to know why patients must undergo certain endocrine function tests, which diagnostic medication needs to be administrated and how to inform the patient. During the operative phase, the endocrine nurse will inform the patient about the pre-operative work up, the surgery and post-operative observations. But it is also important to pay attention

to the psychological disturbances patient may suffer from like depression, anxiety and even psychoses.
After surgery, psychological en physical recovery may take a long time. Even after long-term remission of Cushing's syndrome, patients report more negative illness perceptions compared with patients with other acute or chronic conditions. There are some patients who will need a rehabilitation program to work on a better physical condition and to get psychological support during reducing the glucocorticoid replacement therapy to a 'normal level'. In this phase, the endocrine nurse gives education about the recovery process, helps the patient with coping strategies, adherence to medication and self-management. The self-management aspects that come with glucocorticoid replacement therapy, like dose adaptation during medical emergencies, recognising and preventing life threatening situations, like an acute adrenal crisis needs to be highlighted repeatedly.
Not only information and instructions given by nurses to the patient and his family are important, but also education for nurses in the ward or outpatient clinic is recommended. Endocrine nurses can make the difference for these patients.

## EN2.3

**Diagnosis and management of prolactinoma**

M Andersen
Odense University Hospital, Odense C, Denmark.

Prolactinomas are the most prevalent pituitary adenomas. The incidence of prolactinomas varies with age and sex. The ratio between women and men has been estimated to 10:1 before the age of 50 years. Hypogonadism and infertility are important clinical problems associated with prolactinomas. There may be mass effects including visual field defects in a patient with a macroadenoma.
Hyperprolactinaemia is a relatively frequent finding in women. It is important to consider medication and primary myxoedema that may cause hyperprolactinaemia and, when appropriate, a pregnancy test must be performed. There are pitfalls regarding the biochemical diagnosis of hyperprolactinaemia. However, if hyperprolactinaemia is unequivocal, an MR-scan of the pituitary is indicated.
Prolactin is the most important acute blood sample in a patient with a pituitary adenoma and visual field defects. Because, generally, dopamine-agonists are first-line therapy for prolactinomas. Cabergoline, bromocriptine and quinagolide are the dopamine-agonists, we use. We want to normalize prolactin levels to obtain eugonadism and we aim at reducing tumour size. Surgery and radiotherapy may be used for the few resistant prolactinomas.
When fertility is an issue, the woman has to be informed about the possible risks of prolactinoma growth during pregnancy and we have to consider which dopamine-agonist should be chosen. In all patients the safety of dopamine-agonists is important. During the last 5 years, there have been reports on cabergoline and the risk of valvular heart disease. The authorities have requested that patients on cabergoline are referred to echocardiography follow-up. There are ongoing studies trying to elucidate the risk of heart disease in patients with prolactinomas. Dopamine-agonist withdrawal may be considered in patients who achieve normoprolactinemia and complete tumour disappearance. Patients with prolactinomas and hypopituitarism should receive standard hormone replacement therapy. However, gonadal replacement should be delayed. An assessment of the bone mineral density (BMD) is generally indicated.

**The role of nurse prescribing in the care of endocrine patients**

Shashana Shalet (Endocrine Advanced Nurse Practitioner)

In the UK, the number of nurses able to legally prescribe medicines is rapidly increasing. The skills of nurse independent prescribing (NIP) offer an effective way for the Clinical Nurse Specialist (CNS) to be more responsive to the changing, and unpredictable, needs of patients by enabling timely and appropriate symptom control in a single, seamless consultation. The structure of the Nurse-led clinic often allows for a longer consultation time enabling the CNS to provide a greater depth of information to the patient around the different medication options, the potential side effects and benefits of that medication. The NIP role promotes expansion and innovations in practice that can meet the changing needs, and costs, of effective service delivery.
The endocrine CNS is able to develop a therapeutic relationship with the patient that encourages informed decisions about which medical therapy is most suitable and the consultation is completed by prescribing the correct medication to the correct patient at the correct time. It enables the timely dose titration of medications with the NIP qualification providing validation for these changes with other members of the multi-disciplinary team. A final factor in the role of the NIP in endocrinology is the amount of time saved when the CNS does not have to seek out a medical prescriber's signature, this time can then be better spent providing direct care to patients. Each NIP's work is closely monitored by both National and local guidelines that dictate prescribing must only be within their area of expertise.

### Melanocortin receptor accessory proteins (MRAPs) in adrenal gland physiology and beyond

LF Chan
Centre for Endocrinology, William Harvey Research Institute, Queen Mary University of London, Barts and The London School of Medicine and Dentistry, London.

The melanocortin receptor (MCR) family consists of five G protein-coupled receptors (MC1R-MC5R) with diverse physiological roles. MC1R controls pigmentation, MC2R is a critical component of the hypothalamic-pituitary-adrenal axis, whilst MC3R and MC4R have a vital role in energy homeostasis and MC5R is involved in exocrine function.

The melanocortin receptor accessory proteins, MRAP and its paralogue MRAP2, are small single-pass transmembrane proteins that have been shown to regulate MCR expression and function.

In the adrenal gland, MRAP is an essential accessory factor for the functional expression of the MC2R/ACTH receptor. The importance of MRAP in adrenal gland physiology is demonstrated by the clinical condition familial glucocorticoid deficiency, where inactivating MRAP mutations account for approximately 20% of cases. MRAP is highly expressed in both the zona fasciculata, and the undifferentiated zone. Expression in the undifferentiated zone suggests that MRAP could also be important in adrenal cell differentiation and/or maintenance. In contrast, the role of adrenal MRAP2, which is highly expressed in the fetal gland, is unclear.

The expression of MRAPs outside the adrenal gland is suggestive of a wider physiological purpose, beyond MC2R mediated adrenal steriodogenesis. In vitro, MRAPs have been shown to reduce surface expression and signaling of all the other melanocortin receptors (MC1,3,4,5R). MRAP2 is predominantly expressed in the hypothalamus, a site that also expresses a high level of MC3R and MC4R. This raises the intriguing possibility of a central nervous system role for the MRAPs.

**Adrenal incidentaloma and subclinical Cushing's syndrome**

P. Stewart
University of Birmingham, Birmingham, UK.

The widespread use of abdominal CT/ MRI has resulted in a new and common diagnosis for the clinical endocrinologist – the management of patients with adrenal incidentalomas. Defined as an adrenal mass discovered incidentally in the work-up or treatment of clinical conditions not related to suspicion of adrenal disease, incidentalomas cover a spectrum of underlying adrenal pathologies with a common pathway of discovery. Because of the risk of malignancy, they raise uncertainty, confusion and concern in doctors and patients alike and consume significant resource. We will define the scale of the problem, discuss diagnostic challenges as they relate to functionality of the tumours and ascertaining whether the lesions are benign or malignant. The natural history and suggested follow-up and treatment of patients based on published NIH clinical guidelines will be addressed; such guidelines perhaps over-inflate the real risk of malignancy and a more 'risk-averse' approach to management is now required. Our new biomarker research based on analyzing the urinary steroid metabolome may improve the diagnosis and follow-up of such cases. One particular area of contention is the term 'sub-clinical' Cushing's reported in up to 15% of all cases; the suggestion being that this may account for underlying obesity, low BMD and cardiovascular morbidity. However diagnostic criteria vary considerably, have usually failed to comply with Endocrine Society guidelines with false positive results generating considerable uncertainty. In the absence of any test with 100% sensitivity and specificity, the issue is likely to be one of diagnosing mild Cushing's syndrome where there is a limited evidence base that reversal of the condition significantly alters clinical features.

**Approach to the patient with Cushing's disease after pituitary surgery failure**

M. Tóth
Semmelweis University, Budapest, Hungary.

The treatment of choice for ACTH-producing pituitary adenoma is selective transsphenoidal adenomectomy. The remission rate after transsphenidal surgical intervention for Cushing's disease ranges from 69 to 98% (average 83%). If the first pituitary surgical intervention fails, the following questions should be answered: i) Is the localization diagnosis correct without doubt (pituitary or ectopic source of ACTH- overproduction)? ii) Is it reasonable to recommend repeat pituitary surgery? The answers to these questions depend on the results of inferior petrosal sinus sampling (IPSS) and histology.

If the diagnosis of ACTH-producing pituitary adenoma is without doubt, in cases of microadenomas (both visible and invisible on MRI) repeat pituitary surgical intervention seems to be the best choice. In the best hands, remission after repeat surgery may occur in 50–60% of patients contrary to the 75–90% remission rate of the first surgery. Regarding the extent of repeat pituitary surgery, selective adenomectomy, hemihypophysectomy or total hypophysectomy may be performed. Scarce literature data suggest that IPSS performed before reoperation has much inferior diagnostic information than the sampling performed before the first intervention. This observation may probably be explained by altered anatomic situation and venous drainage caused by the initial surgery.

If repeat pituitary surgery does not achieve remission, then radiosurgery or stereotactic radiotherapy, bilateral adrenalectomy, and/or medical therapy are the therapeutic options. Medical therapy for the treatment of Cushing's disease may target the ACTH secretion of the pituitary tumor (cabergoline, pasireotide) or block the steroid biosynthesis of the adrenals (ketoconazole, metyrapone, mitotane).

Bilateral laparoscopic adrenalectomy may be a therapeutic option in most severely hypercortisolemic patients. Nelson's syndrome is potentially the most severe complication of bilateral adrenalectomy developing in 20–30% of adrenalectomized patients. The newest series of Nelson's syndrome represent that the modern 'Nelson's syndrome' is different from the entity originally described.

**Challenges of transsphenoidal pituitary surgery**

P. Cappabianca
Universita' degli Studi di Napoli Federico II, Naples, Italy.

The endoscopic endonasal approach, initially reserved only for sellar lesions, is a continuous evolving speciality of modern neurosurgery, which requires precise anatomical knowledge, technical skills and integrated appreciation of the pathology dealt with. Nowadays, it represents a minimally invasive approach to deal with several diseases interesting mostly the entire skull base – namely the suprasellar, retrosellar and parasellar spaces – obviating brain retraction. The endoscopic endonasal approach offers some advantages arising from the use of the endoscope itself: a superior close-up view of the relevant anatomy and an enlarged working angle with an increased panoramic vision inside the surgical area.

Most pituitary adenomas can be managed and removed through a standard transsphenoidal approach either microscopic or endoscopic. Nevertheless, several cases, present some features such as dumbbell shape or para/suprasellar extension and/or fibrous or rubbery consistency – high likely in case of recurrence tumors –, that somehow hinder such route. More recently, the introduction of the endoscope in the extended endoscopic endonasal approach has definitely afforded its widespread so that, nowadays this technique can be considered suitable for removal of lesions extending beyond the sellar area such as parasellar, suprasellar and/or retrosellar spaces.

We have been employing the endoscopic endonasal technique since 1997 on more than 1000 patients aiming to remove first sellar and, recently, skull base lesions applying the so-called extended endonasal approach. Namely, in the management of invasive pituitary adenomas this technique allowed us to use two surgical corridors the conventional endosellar extra-arachnoidal and a suprasellar trans-arachnoidal.

We, though, report our experience throughout a step-by-step depiction of the surgical techniques to access the different compartments, detailing the anatomy as seen from the endonasal perspective, focusing on the 'dangerous landmarks', describing possible complications and the techniques to manage this kind of lesions.

## MTE5

**Meet the expert: discussion of common but difficult thyroid cancer cases**

L. Wartofsky[1,2]
[1]Washington Hospital Center, Washington, District of Columbia, USA;
[2]University School of Medicine, Washington, District of Columbia, USA.

Endocrinologists today face an ever increasing variety of presentations of thyroid cancer related to the well documented increasing frequency of thyroid cancer patients worldwide. The overwhelming majority of these tumors are small microcarcinomas with excellent prognosis for which management is quite straightforward. But many patients are seen for whom optimal steps for

management are unclear, constituting therapeutic dilemmas that are typically not well addressed in current guidelines of our professional societies. This session will discuss several patient scenarios, ranging from the misleadingly innocent microcarcinoma to the more aggressive thyroid cancer that requires more innovative management. For the microcarcinoma, because there are potential adverse effects of overly aggressive management, questions arise such as whether more conservative approaches are sufficient such as: (i) subtotal rather than total thyroidectomy; (ii) if central compartment dissection is really necessary; (iii) if radioiodine ablation can be avoided; and (iv) how much TSH suppression is required? Yet, management cannot be overly cavalier because a significant percent of patients with microcarcinomata already have lymph node metastases at presentation that imply future recurrences, and a small number may have, or will develop, distant metastases. Other cases will be discussed that require more aggressive surgery, local or regional ablation interventions, and higher dose radioiodine therapy such as that given by dosimetry. It will be proposed that these varied potential clinical presentations call for a risk-stratified approach to management that would minimize harm to the patient and yet optimize outcomes. Clinical parameters such as age, sex, tumor size, multifocality, vascular or capsular invasion, extrathyroidal extension, lymph node metastases, histologic variants of PTC, or the presence of mutational markers that might require more aggressive management will be discussed, to place them into a risk-adapted algorithmic approach intended to achieve minimal morbidity and optimal outcomes at less cost to the patient and society.

## MTE6

**Clinical management of adrenocortical carcinoma**

M. Terzolo
S. Luigi Hospital, University of Turin, Orbassano, Italy.

A thorough pre-operative hormonal workup is advised following the recommendations of the European Network for the Study of Adrenal Tumors. Demonstration of endocrine activity may serve to the following purposes: i) prove adrenocortical origin of the mass; ii) suggest malignancy, in the event of androgen hypersecretion; iii) provide tumor markers whose assessment may be exploited during follow-up to detect tumor residual or recurrence after surgery; iv) avoid life-threatening post-operative adrenal insufficiency. Hypercortisolism may indeed escape clinical detection, thus preventing use of post-operative steroid replacement. Assessment of tumor dignity and visualization of potential metastases needs an adequate imaging study. Computerized tomography (CT) is the technique of choice but magnetic resonance imaging may be equally effective. CT characteristics suggesting malignancy are: a) large mass size, usually $>4$ cm; b) elevated mass density ($>10$ Hounsfield Units) on unenhanced scan; c) rapid washout of contrast medium on enhanced scan. Recent data demonstrate that 18F-FDG PET helps to differentiate suspicious CT scan lesions.

As to treatment, recent studies challenged the dogma that there is no role for laparoscopy, although data on the comparison between open and laparoscopic adrenalectomy remain conflicting. The crucial issue is to select an experienced surgeon. Adiuvant therapy with mitotane has recently received increased interest after publication of a multicentric study on a large series of ACC patients that showed a significant reduction in the risk of recurrence and death for the mitotane treated patients. However, controversy still exists on the value of post-operative mitotane and a randomized controlled trial is currently ongoing. Results of medical treatment of advanced disease with the available regimens are overall disappointing and also the first experiences with targeted therapies are not encouraging, but new trials are ongoing and hopefully will allow definition of a more personalized treatment.

Declaration of interest

The author declares that there is a conflict of interest.

## MTE7

**Pregnancy and pituitary disorders**

Z. Karaca
Erciyes University Medical School, Kayseri, Turkey.

The pituitary gland is altered by both anatomical and physiological changes during pregnancy. The most striking finding is the physiological enlargement of the pituitary gland as a result of lactotroph hyperplasia. Hormonal evaluation of pregnant women requires special consideration due to the emergence of the placenta as a new source of hormone production, changes in binding globulin levels and resistance to hormones such as glucocorticoids.

Pituitary adenomas may adversely affect pregnancy by their hormone production and pose a potential risk of tumour growth. Prolactinomas are the most common pituitary adenomas encountered during pregnancy since the disease is common among women of reproductive age and fertility can be achieved easily after medical treatment. Acromegaly is the second most common pituitary adenoma seen in relation to gestation after prolactinomas. Medical therapy can be ceased safely after confirmation of pregnancy in both GH and PRL secreting pituitary adenomas. The risk of tumour growth during gestation is low in most cases of acromegaly and prolactinomas. Cushing's disease is rare and most cases with Cushing's syndrome are caused by adrenal adenomas, unlike in non-pregnant women. Cushing's disease adversely affects pregnancy, therefore prompt diagnosis and treatment according to gestational period are essential. Other hormonal and non-functional tumours are rarer and have been presented as case reports.

Sheehan's syndrome and lymphocytic hypophysitis are other pituitary disorders associated with pregnancy. They lead to hypopituitarism, sometimes with delays in diagnosis and difficulties in differential diagnosis. Pregnancy is not common among patients with hypopituitarism or pituitary adenomas due to altered gonadotroph functions. Ovulation induction is essential for fertility achievement, but the replacement of other deficient pituitary hormones, including GH, also plays an important role in the preparation of the uterus for implantation. Due to increased fecundity by improved assisted reproductive technologies and treatment methods, the number of pregnant women with pituitary disorders seen in clinical practice is increasing which necessitates special attention.

**Diagnosis and management of SIADH**

C. J. Thompson
Beaumont Hospital/RCSI Medical School, Dublin, Ireland.

Hyponatraemia is the commonest electrolyte abnormality in clinical practice; epidemiological data would suggest that SIAD is the commonest cause of hyponatraemia, and it is particularly important in patients undergoing neurosurgery, in whom SIAD is common. Recent data has shown that even mild hyponatraemia (plasma sodium 125–135 mmol/l) is associated with gait instability, falls, fractures, osteoporosis and increased mortality. This has led to the recognition that correct diagnosis and treatment of hyponatraemia may offer the opportunity to reduce morbidity an mortality and to reduce hospital stay. SIAD must be differentiated from other causes of hyponatraemia and the key diagnostic criteria are plasma osmolality $<275$ mOsm/kg, urine osmolality $>100$ mOsm/kg, euvolaemia, urine sodium $>30$ mmol/l and exclusion of hypothyroidism, glucocorticoid deficiency and diuretic use. It is particularly important to exclude acute ACTH/cortisol deficiency in patient with subarachnoid haemorrhage or traumatic brain injury. Fluid restriction is the traditional treatment for SIAD and still has a role, particularly in hospital patients with transient hyponatraemia, but there is a lack of an evidence base, and it is difficult

for patients to maintain without close supervision. Randomised controlled trials have shown that the vasopressin receptor antagonists (vaptans) are superior to placebo in the management of hyponatraemia dur to SIAD and other causes; they cause an aquaresis, but in contrast to loop diuretics, no natriuresis. Tolvaptan is now available in oral form in Europe though cost remains a prescribing consideration, particularly in long term hyponatraemia

## MTE10

**Elastosonography in the evaluation of thyroid and parathyroid lesions**

M. Erdogan
Ankara üniversitesi, Ankara, Turkey.

Finding of a firm nodule during palpation of the thyroid gland is one of the clues for malignancy. In addition to palpation, as a new imaging technique, tissue stiffness can be evaluated by ultrasound elastography (USE); thereby helping us further to detect firm thyroid nodules, even the non-palpable ones. Tissue stiffness is detected by USE through measuring the amount of distortion that occurs when the lesions is subjected to external pressure. The power of USE in detecting malignant thyroid nodules was also reported in several studie, in which a high power for this new technique was reported. A recent meta-analysis evaluating most of these reports revealed high sensitivity and specificity for USE.
Studies conducted with USE could mainly be divided into two groups. The first group included thyroid nodules only undergoing surgery and having histopathological diagnoses. The second group included nodules having cytological diagnoses as well as those with histopathological diagnoses. However, all of those studies carry two major limiting factors: (i) small sample size and/or (ii) selection bias. As a result, like initial historical studies evaluating the power of each new ultrasound technique, these preliminary USE studies might overshoot the real sensitivity and specificity. Therefore, we planned to discuss the diagnostic power of USE in detecting malignant thyroid nodules in this MTE session.
Parathyroid adenomas were demonstrated to be elastographically stiff lesions. In contrast, almost half of the parathyroid hyperplasias were soft in elastographic evaluations in our hands. USE seems to be a valuable new assisting technique that might enhance the power of the preoperative localization studies of parathyroid lesions. Moreover, the USE image of a parathyroid lesion may further assist in determining the type of operation that is going to be applied. However, this issue should further be studied to investigate whether parathyroid elastography can also improve postoperative outcomes. We will try to discuss the ultrasound elastographic features of parathyroid lesions as well in this session.

**Diagnosis and treatment considerations in autoimmune polyendocrine syndrome type 1**

O. Kampe
Uppsala University, Uppsala, Sweden.

Autoimmune polyendocrine syndrome type I (APS-1) is a rare autosomal recessive disorder which starts in early childhood, typically associated with chronic mucocutaneous Candidiasis. Patients with APS-1 later develop autoimmunity against endocrine tissues such as the adrenal cortex and the ovaries, and non-endocrine tissues such as the liver and melanocytes. The disease is caused by mutations in the autoimmune regulator (AIRE) gene that encodes a 54 kDa protein expressed in thymic medullary epithelial cells and in certain peripheral lymphoid cells.
APS-1 patients display autoantibodies directed against proteins in the affected tissues. These autoantibodies are often predictive for the development of organ failures such as adrenal insufficiency or premature ovarian failure where autoantibodies reactive to 21-hydroxylase and side-chain cleavage enzyme, respectively, can be detected. Recently, the discovery of autoantibodies against IL-22 may provide an explanation to the mucocutaneous Candidiasis, another autoimmune component of the syndrome.
Due to its rarity the diagnosis of APS-1 can easily be missed. Methods to diagnose, the clinical usefulness of autoantibody analyses, the recommended follow-up of these patients and the management of complications will be discussed.

**Graves' ophthalmopathy**

W. Wiersinga
Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands.

Management of Graves' ophthalmopathy (GO) requires knowledge of smoking behaviour, thyroid function and antibodies, and activity and severity of the ophthalmopathy.
Smokers should be strongly adviced to stop smoking because outcome of Graves' disease is less favourable in smokers compared to nonsmokers.
High serum concentrations of TSH receptor antibodies (TBII) are associated with a more severe and protracted course of GO. Restoration and maintenance of euthyroidism is relevant for the eyes, but how hyperthyroidism should be treated in GO patients remains controversial. Antithyroid drugs and near-total thyroidectomy are apparently neutral with respect to the course of GO, but 131I therapy carries a risk of about 15% for devleoping and/or worsening of GO. The risk can almost be neutralized by a prophylactic course of steroids, but its timing, dose and duration are ill-defined. Steroid prophylaxis should be restricted to patients who are at high risk, i.e. patients who smoke, have active GO, or high TBII.
Mild GO usually requires no treatment, but a recent randomized clinical trial demonstrated improvement of eye changes and prevention of progression to more severe GO upon treatment with selenium (100 microgram sodium selenite twice daily for 6 months). Moderate-to-severe GO if active should be treated preferably with intravenous methylprednisolone pulses (e.g. 0.5 g weekly for 6 weeks, followed by 0.25 g weekly for another 6 weeks), which are more effective and have less side effects than oral prednisone. However, intravenous methylprednisolone pulses exceeding a cumulative dose $>8$ gram have been associated with liver failure and cardiovascular events. In case of steroid failure, the combination of low dose oral prednisone (20 mg daily) with either cyclosporin or retrobulbar irradiation can be tried. Rituximab –although still experimental- might be applied in desperate cases. Very severe GO (dysthyroid optic neuropathy) requires high-dose intravenous methylprednisolone pulses (e.g. 6 pulses of 1.0 g each, administered on alternate days); if visual functions do not improve within two weeks, an urgent surgical orbital decompression is indicated. Complete restoration of appearance and visual functions is obtained in many patients only after various surgical procedures (decompression, squint surgery, blepharoplasty), which should be done in the inactive phase of the disease.

## MTE14

**Hirsutism**

K. Unluhizarci
Erciyes University Medical School, Kayseri, Turkey.

Hirsutism, affects 5–8% of the whole female population, results either from an increase in circulating androgen concentrations, an increase in the sensitivity of the pilosebaceous unit to normal androgen concentrations or a combination of these factors. Polycystic ovary syndrome (PCOS) is the underlying cause in vast majority of the patients with hirsutism. PCOS can only be diagnosed after exclusion of some other diseases such as non-classical congenital adrenal hyperplasia (NCAH), idiopathic hyperandrogenemia, Cushing's syndrome, hyperprolactinemia and acromegaly. In approximately 1–8% of the women with hirsutism, NCAH due to 21-hydroxylase deficiency may be diagnosed. Basal or ACTH stimulated 17-OHP concentration greater than 10 ng/ml was considered as the hormonal criteria for 21-OH deficiency. Some hirsute patients do not have evidence of detectable androgen excess or endocrine imbalance, as in women with 'idiopathic hirsutism'. A number of patients have hyperandrogenemia with normal ovarian morphology and regular cycles and called as idiopathic hyperandrogenemia. A correct etiological diagnosis is essential in order to exclude life threatening conditions such as androgen secreting tumors or the life long consequences of some disorders associated with hirsutism such as PCOS and NCAH. Thus certain tests must be conducted to ascertain properly the etiology of hirsutism. However, there is no universal consensus regarding the least required tests for the differential diagnosis of hirsutism. Specific causes of hirsutism such as Cushing's syndrome, adrenal/ovarian tumors should be treated by surgical excision of the tumor. In the other patients pharmacological approach is the mainstay of the therapy. The options are anti-androgens, combined oral contraceptive pill with or without anti-androgen agents, gonadotrophin-releasing hormone agonists and rarely insulin sensitizers. Patients should be aware that most of the drugs used in the management of hirsutism are contraindicated in women desiring pregnancy and simultaneous treatment of infertility and hirsutism is difficult.

## MTE15

**Pituitary tumours in adolescents and adults**

M. Andersen
Odense University Hospital, Odense C, Denmark.

Pituitary tumours are usually benign, but aggressive local growth may occur. Malignancy with demonstrable extracranial metastases is rarely seen. Tumour formation is probably the result of genetic changes involving tumour suppressor gene inactivation and oncogene activation. Pituitary adenomas that occur in a familial setting account for 4–5% of the tumours, they can be part of endocrine-related tumour syndromes. In 2006, Vierimaa *et al.*[1] reported the results of a comprehensive genetic study that identified mutations in the aryl hydrocarbon receptor-interacting protein (AIP) gene as being associated with the familial presentation of somatotropinomas and prolactinomas. Prolactinomas are the most frequent pituitary adenomas in adolescents as well as adults. It is important to consider possible macroprolactinaemia, when prolactin measurements are performed. Usually macroprolactin consists of a monomer of prolactin and IgG, macroprolactin is not bioactive. The impact of failure to recognize macroprolactinaemia is significant. There can be no doubt that the diagnosis of acromegaly is often delayed and even overlooked. GH-hypersecretion may, however, rarely be found in patients with known pituitary adenomas, clinically silent or in prolactinomas.

Temozolomide is the first chemotherapeutic agent to show substantial response rates in aggressive pituitary tumours. Temozolomide is an alcylating agent with great ability to cross the blood–brain barrier, it was first used for malignant gliomas. The lesion at *O*6-guanine is the critical methyl adduct produced by temozolomide and responsible for the greatest cytotoxicity. This lesion is repaired in the presence of *O*6-methylguanine-DNA methyltransferase (MGMT). Future studies will evaluate the role of temozolomide in the management of benign aggressive pituitary adenomas.

## MTE16

**Management of non-functioning pituitary adenomas**

N. Karavitaki
Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford, UK.

Non-functioning pituitary adenomas (NFAs) are benign pituitary neoplasms arising from the adenohypophyseal cells. They are not associated with clinical evidence of hormonal hypersecretion and have a prevalence of 22 cases per 100,000 people. At presentation, the majority is macroadenomas and their clinical manifestations are the result of pressure effects to surrounding structures.

Management options include observation, surgical removal combined or not with external irradiation, radiotherapy alone or medical treatment.

Studies assessing the natural history of presumed NFAs, have shown probability of enlargement 19% for microadenomas and 44% for macroadenomas at 48 months. Surgery remains the treatment of choice in patients with macroadenomas and achieves improvement of vision in around 80% of the cases. Hypopituitarism (partial or complete) is present in a significant number of patients post-operatively (30–83%) and its rate increases following radiotherapy. Regrowth rates in subjects treated solely by surgery range between 6–46% (the risk is higher if there is large tumour remnant) and in those managed by surgery and adjuvant radiotherapy between 0–36%. Up to 20% of the relapses have been detected 10 years post-operatively necessitating long-term surveillance. Reliable markers of tumour relapse at a pathological and/or molecular level are lacking.

The management of patients presenting with pituitary apoplexy (conservative or surgical) is dictated by the presence of pressure effects and careful monitoring for recurrence is required post-operatively (11.1% at a mean follow up of 6.6 years). The value of medical treatments (dopamine agonists, somatostatin analogues) remains to be assessed.

Recent data from the Oxford series suggest that the quality of life of patients with NFAs following treatment (surgery combined or not with radiotherapy) is not compromised to a significant extent.

Finally, the impact of NFAs on the long-term mortality is not as yet, clear.

## MTE17

**Multiple endocrine neoplasia type 2**

F. Raue
Molecular Laboratory, Heidelberg, Germany.

Multiple endocrine neoplasia type 2 (MEN 2) is an autosomal dominant hereditary cancer syndrome caused by missense gain-of-function mutations of the RET proto-oncogene, encoding a receptor tyrosine kinase, on chromosome 10. It has a strong penetrance of medullary thyroid carcinoma (MTC) and can be associated with bilateral pheochromocytoma and primary hyperparathyroidism. MEN 2 is divided into three varieties depending on clinical features: MEN 2A, MEN2B and FMTC (familial MTC). The specific RET mutation may suggest a predilection toward a particular phenotype (MEN 2A, MEN 2B and FMTC) and clinical course of the MTC, with strong genotype–phenotype correlations. Offering RET testing is best practice for the clinical management of patients at-risk of MEN 2, and MEN 2 has become a classic model for the integration of molecular medicine into patient care. Recommendations on the timing of prophylactic thyroidectomy and extent of surgery are based on classification of RET mutations into risk levels according to genotype–phenotype correlations. By earlier identification of patients with hereditary MTC, the presentation changed from clinical tumours to preclinical disease resulting in a high cure rate of affected patients with much better prognosis.

**Normocalcemic primary hyperparathyroidism**

Claudio. Marcocci
Department of Endocrinology and Metabolism, University of Pisa, Pisa, Italy.

Normocalcemic primary hyperparathyroidism (NC-PHPT) is a condition characterized by normal albumin-adjusted total serum calcium or ionized calcium and persistently elevated serum PTH. Therefore, to recognize this entity it is necessary to measure PTH in normocalcemic individuals. The question arises why would someone measure PTH in a normocalcemic subject? A pro-active approach to women evaluated in their early postmenopausal years for parameters of skeletal health as well as the attitude of measuring PTH in all subject undergoing evaluation for low bone mineral density may at least partially answer this question. In the diagnostic workup vitamin D status should be firstly evaluated. Indeed vitamin D insufficiency (25OHD levels below 30 ng/ml) is a rather common condition and often account for elevated PTH levels. Patients with low 25OHD should be replaced with vitamin D and reevaluated. Occasionally these patients will become hypercalcemic, thus unmasking the more typical hypercalcemic PHPT. If PTH remains elevated following vitamin D repletion, all other causes of secondary hyperparathyroidism, such as liver disease, renal disease, significant hypercalciuria (urinary calcium $>350$ mg/24 h), and gastrointestinal disease associated with malabsorption, or other metabolic bone disease that could affect PTH levels (e.g. Paget's disease) should been considered and ruled out. Patients taking drugs which might affect PTH levels (lithium carbonate, thiazide diuretics) or calcium metabolism (estrogens, loop diuretics, bisphosphonates, and anticonvulsants) should be reevaluated after drug withdrawal. The natural history of NC-PHPT is unknown, but observational studies provided evidence that some individuals may develop hypercalcemia or evidence of disease progression with development of kidney stones, decline of bone mineral density, fractures, marked hypercalciuria. The current evidence indicates that NC-PHPT is a real clinical entity, which has been recognized at the 3rd International Workshop on the Management of Asymptomatic PHPT as a variant of PHPT.

**The diagnosis and treatment of secondary osteoporosis in children**

L. Ward
University of Ottawa, Ottawa, Ontario, Canada.

There is increasing awareness that children with chronic illnesses, particularly those with glucocorticoid use and neuromuscular disorders, have the potential to develop significant bone fragility due to osteoporosis. In such cases, osteoporosis manifests as low-trauma extremity fractures, with vertebral fractures an under-recognized consequence of reduced bone strength. We have studied the Genant semi-quantitative classification for characterizing vertebral fractures in children with chronic illness, and have shown that the strongest predictor of vertebral fractures in children with leukemia at 12 months was the presence of vertebral fractures around the time of diagnosis. We have further shown that even mild (Grade I) vertebral fractures were associated with increased odds for future spine fracture. These observations assign biological relevance to the Genant classification in children.

The use of clearly-defined, DXA-based bone mineral density (BMD) cut-offs for the diagnosis of osteoporosis in children with chronic illness has been challenging to date, in part due to the paucity of data on the relationship between BMD and fractures in children with underlying disorders. We have shown that such children can sustain vertebral fractures with spine BMD Z-scores well within 2 standard deviations (SD) below the mean, an observation which calls into question the use of – 2 SD as a definitive cut-off to define osteoporosis in the pediatric chronic illness setting.

The treatment of secondary osteoporosis in children presents unique issues due to the potential for spontaneous restitution of bone mass deficits and reshaping of vertebral bodies through bone growth, particularly when bone health threats are transient. As such, the identification of candidates for intervention involves not only confirmation of osteoporosis but assessment of the potential for spontaneous recovery. Bisphosphonates have been the most frequently used agents to treat secondary osteoporosis in children; a number of promising novel treatments on the horizon will also be discussed.

## MTE21

**Autoimmune hyperthyroidism: initiation and duration of thionamide therapy**

P. Laurberg
Aalborg Hospital, Aalborg, Denmark.

Graves' disease is a common autoimmune disorder with autoimmunity against the TSH-receptor being a central pathogenetic element. The disease may present with a number of clinical manifestations, among which hyperthyroidism caused by TSH-receptor stimulating antibodies is the most prevalent. The disease is common in all adult ages and affects women 4–5 times more often than men.

In many countries the preferred initial therapy of the hyperthyroidism is thionomide drugs (TD) that will in most patients lead to euthyroidism and be followed by a gradual remission of the underlying autoimmune abnormality with disapperance of TSH-receptor autoantibodies from blood

The three major problems with TD therapy are:

1. Side-effects to the drugs.
2. A frequent relapse of hyperthyroidism after drug withdrawal
3. Insufficient response to TD in a minority of patients

The choice of drug in specific situations, the initial dosing, and evidence for and against prolonged TD therapy will be discussed.

Interim data from the RISG study (Remission Induction and Sustenance in Graves' hyperthyroidism) investigating prolonged use of TD in a prospective randomized design will be discussed, as will data related to the use of Propylthiouracil for initial therapy of patients with impending thyrotoxic crisis and patients not responding to conventional TD therapy.

## MTE22

**Clinical management in transgender sex hormone treatment**

G. T'Sjoen
Ghent University Hospital, Gent, Belgium.

Gender Identity Disorder (GID) is a condition in which a person experiences discongruency between their assigned sex and what they feel their genderidentity is. A person with gender dysphoria experiences persistently uncomfortable feelings about their birth gender (Diagnostic and Statistical Manual of Mental Disorders, Fourth edition (DSM-IV) (American Psychiatric Association, 1994). During the 'real life experience' hormonal treatment starts and applicants are required to live socially in the desired gender role before irreversible surgical

reassignment is considered. Cross sex hormonal treatment is desired by transsexual persons to help them successfully live as a member of their identified gender. It is clear that both in adults and adolescents the decision for starting hormonal treatment in transsexualism is not to be made by the endocrinologist. The mental health professionals (psychiatrists and/or psychologists), by preference working in a multidisciplinary Gender team, will guide these persons to make an informed decision about hormonal treatment. Eligibility criteria and readiness as described by WPATH's Standards of Care for GID-7th version, should be evaluated. The goal of treatment in female-to-male transsexual persons is to induce virilization and to stop menses. The prinicipal hormone treatment is a testosterone preparation. In male-to-female transsexual persons oestrogen and anti-androgen treatment is provided. Treatment regimens are currently not standardised and include various forms of oestrogens, progestins, and/or (anti-) androgens as reported by different clinical centres. So far, no randomized intervention trials are available so treatment is largely experience-based.
Appropriate care for transgender persons will lead to better outcome and should avoid unnecessary psychological pain, health risks (e.g. secondary psychiatric conditions or suicide), or self medication with inherent greater risk of complications.
Declaration of interest
The author declares that there is a conflict of interest.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## MTE23

**Subclinical hypothyroidism**

B. Biondi
Federico II University, Naples, Italy.

Subclinical hypothyroidism (SHypo) is characterized by elevated serum TSH and thyroid hormone levels at the lower limit but within their respective reference range.
It is necessary to distinguish between patients with mildly increased serum TSH levels (5–9 mU/L) and patients with more severely increased serum TSH levels (10 mU/l or higher). About 75% of all SHypo patients have mild disease.
The high prevalence (between 4 and 20% of the adult population) and the various implications of SHypo require the need to establish a correct diagnosis, clinical assessment and treatment of this disorder.
The evaluation of transient and false causes of mild increases in TSH should be excluded before treating SHypo.
Subclinical hypothyroidism may be progressive or reversible. The annual rate of progression to overt disease is particularly increased (4.3%) in women with elevated serum TSH and anti-thyroid antibodies.
Important cardiovascular and metabolic effects may develop in long-term untreated SHypo.
Elderly Subjects with a TSH level of 7 mU/L or greater have a higher risk of heart failure events than euthyroid subjects.
There are some discrepancies in epidemiological data with reference to the risk of coronary heart disease (CHD) in patients with SHypo. A recent meta-analysis analyzed the individual data of 55 287 participants from 11 prospective cohorts. This analysis confirms that the risk of both CHD and mortality due to CHD were significantly increased in participants with TSH levels of 10 mU/L or greater. These results strongly support the association between CHD and SHypo in patients with TSH of 10 mU/L or greater.
Treatment of SHypo is recommended for all patients with SHypo with serum TSH levels of 10 mU/L or greater because these patients may have a significantly increased risk of progression to overt hypothyroidism, are more frequently symptomatic and may have a higher chance of dyslipidemia and cardiovascular dysfunction with an increased risk of CHD events, CHD mortality and CHF.
No consensus exists on the clinical significance and treatment of the mild form of thyroid failure. The available data suggest that treatment of mild SHypo should be personalized. Clinicians should consider the degree of TSH increase, the patients' age, the risk of progression to overt disease, the quality of life, the cognitive, metabolic and cardiovascular risk factors and the presence of associated co morbidities.
Declaration of interest
The author declares that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## MTE24

**Approach to the management of the infertile couple**

A. Lenzi
Sapienza University of Rome, Rome, Italy.

Infertility is defined by the World Health Organization (WHO) as the inability of a couple to achieve conception or bring a pregnancy to term after 1 year or more of regular, unprotected sexual intercourse. It remains a major clinical and social problem, affecting 13–15% of couples worldwide. Evaluation usually starts after 12 months, although it might be indicated earlier. The most common causes of infertility are divided into: male factor, related to sperm abnormalities, female factor, such as ovulatory dysfunction and tubal pathology, combined male and female factor or unexplained infertility, where no obvious cause is found. We reviewed randomized studies, meta-analyses and scientific societies recommendations to propose a simplified approach for the management of the infertile couple.
Full history-taking (obstetric, developmental, menstrual, contraceptive, sexual, familial, past/present history) is a necessary tool to identify most of underlying problem.
To exclude male and/or female factor, clinical examination, semen analysis (with the WHO reference values), detection of testicular function (hormonal assay, scrotal ultrasonography), ovarian function (early follicular FSH and LH levels, mid-luteal progesterone, transvaginal ultrasonography), and evaluation of tubal patency by hysterosalpingography should be performed. Chromosomal karyotyping and genetic screening are indicated in selected cases (suspected genetic disorders, sex chromosomal aneuploidy, cystic fibrosis, deletion of Y-chromosome).
The therapeutic strategies can be classified as etiological or empirical, whether or not a causative factor is found; fertility treatments are classified into: medical (including hormones for ovulation/spermatogenesis induction, nutraceutical supplementation); surgical (such as hysteroscopy, varicocelectomy and treatment of obstructive disorders); assisted reproduction techniques (ART). The need for ART, however, should not preclude the search for etiological treatments, any surgical or medical therapy appropriate for improving the fertility potential. Finally, the approach to diagnosis and management of infertility should be balanced taking into account several aspects that include efficacy, timing, costs, compliance and side effects.

## MTE25

**Pituitary incidentalomas**

S. Tsagarakis
Evangelismos Hospital, Athens, Greece.

During the past several years the wide application of sensitive brain imaging techniques (CT, MRI) has led to an increasing recognition of asymptomatic lesions in the pituitary. Although their etiology covers a wide range of pathologies, most incidentally discovered pituitary lesions are benign adenomas, ranging in size from micro- ($<10$ mm) to macro- ($>10$ mm) adenomas. Micro-incidentalomas are very common, with a reported incidence in normal individuals of 4–20%. Although the identification of such lesions raises the theoretical risk of hormonal hypersecretion further screening confers minimal benefit and may not be cost-effective. Although, in the absence of clinical stigmata of Cushing's disease or acromegaly, only the measurement of prolactin represents a cost-effective strategy, recent guidelines suggest that a broader hormonal investigation may be more widely recommended. MRI follow-up of micro-incidentalomas is expensive. Since the majority of micro-incidentalomas do not increase in size during follow-up, the suggested need for routine application of repeat scans needs careful evaluation. At variance with pituitary micro-incidentalomas, the incidental discovery of a macro-lesion requires extensive investigation. Most, but not all, macro-incidentalomas demonstrate radiological features consistent of pituitary adenomas. If the lesion causes hypersecretion of prolactin, GH or ACTH, specific therapy is required. If the lesion compresses the optic chiasm, and there is no evidence of prolactin hypersecereti on, surgical removal is obviously indicated. If no hormonal hypersecretion is found, and if the lesion is in some distance from the optic chiasm, routine surgical removal may not be necessary. Indeed, not all tumors demonstrate a significant increase in size requiring surgical

excision. Thus expectant management is a safe option for many patients, given that regular MRI surveillance is recommended. Evaluation for anterior pituitary hormone deficiencies is required in all patients with macro-lesions and, hormone replacement therapy should be offered as required.

**Differential diagnosis of Cushing's syndrome**

J. Salvador
University Clinic of Navarra, Pamplona, Spain.

The characteristics of Cushing's syndrome (CS) pathophysiology, the heterogeneity of its clinical presentation and the different patterns of ACTH and cortisol secretion independently of the cause make the diagnosis of ACTH-dependent CS a difficult task in some cases. Clinical symptoms are not always specific enough to establish the diagnosis. 1 mg DEX suppression is one of the most used tests for CS screening. Nocturnal salivary cortisol may be used, but its accuracy has to be validated in each laboratory and can be elevated in other diseases. Urinary free cortisol and nocturnal plasma cortisol are used to confirm the diagnosis. Stress, liver or renal disease, and interferences due to several drugs should be excluded. Severe mental disease and other clinical disturbances may also induce functional hypercortisolaemia, also called seudoCushing's syndrome, confounding the real diagnosis. Differentiation of seudoCushing's from mild ACTH-dependent CS is difficult. Combination DEX-CRH and, more recently, DDAVP stimulation, have been proposed, but these tests are not free of pitfalls. Episodic and cyclical disease can complicate the diagnosis, especially in quiescent secretory phases. To establish the origin of ACTH-dependent Cushing could represent a real challenge, since ACTH-secreting pituitary microadenomas can be small enough to be seen in MR studies, and, on the other hand, bronchial carcinoids may functionally behave as pituitary adenomas usually do. IPSS has to be considered before confirming an etiological diagnosis in those cases. PRL measurements can be useful to improve the performance of the procedure. Diagnosis of ACTH-independent CS is based upon consistent cortisol hypersecretion with low or undetectable ACTH levels. When patients present with bilateral or multiple adrenal masses associated to CS, a possible ACTH-independent macronodular hyperplasia with aberrant expression of adrenal receptors may be suspected. A correct diagnosis is essential for an effective therapeutic intervention.

**Management of bone loss induced by cancer treatment in early breast and prostate cancer**

J. Body
CHU Brugmann, Brussels, Belgium.

Patients with endocrine-related cancers are notably at increased risk for developing osteoporosis as a complication from their adjuvant anticancer treatment, especially aromatase inhibitors (AIs) in early breast cancer (EBC) and androgen deprivation therapy (ADT) in early prostate cancer (EPC). AI-induced bone loss (AIIBL) occurs at a rate at least 2-fold higher than bone loss seen in healthy, age-matched postmenopausal women and they have a more than 30% higher risk of fractures. Recently considered fracture risk factors in EBC are AI therapy, T-score $< -1.5$, age $> 65$ years, family history of hip fracture, history of fragility fracture after age 50, oral corticosteroid use $> 6$mo, smoking, and BMI $< 20\ kg/m^2$. The WHO-FRAX algorithm does not address AIIBL and may underestimate EBC fracture risk. General advice includes exercise, calcium/vitamin D supplements, and baseline BMD monitoring. Bisphosphonates and denosumab can preserve BMD during AI therapy for EBC. Poor compliance may reduce oral bisphosphonate benefits. Overall, bisphosphonate evidence is strongest for zoledronic acid (ZOL; 4 mg q6mo). Potential anticancer activity of ZOL might provide benefits beyond preserving bone mass. Patients initiating AI with T-score $< -2.0$ or $\geq 2$ risk factors should receive appropriate antiresorptive therapy. Bone loss that occurs with ADT is also more rapid and severe than that associated with normal age-related bone loss. ADT also increases fracture risk and the hazard ratios appear to be comparable to the ones reported for AIs in breast cancer. There are a few randomized studies in patients with prostate cancer demonstrating that bisphosphonates, notably ZOL, can prevent bone loss under ADT. The effects of denosumab (60 mg sc q6mo) on bone loss and incidental vertebral fractures have been demonstrated in a large-scale placebo-controlled trial in the setting of ADT-induced bone loss. Specific guidelines are lacking for the treatment and the prevention of ADT-induced bone loss.

**Treatment of vitamin D deficiency**

Nikhil Tandon
Department of Endocrinology and Metabolism, All India Institute of Medical Sciences, New Delhi, India.

The need for treating vitamin D deficiency arises either when patients present with musculoskeletal symptoms attributable to hypovitaminosis D or when screening of individuals at high risk reveals the presence of vitamin D deficiency, as defined by serum 25(OH)D levels $< 20$ ng/ml. The recommended dietary intakes of vitamin D vary with age and physiological state. The recommended daily intake ranges from 400 IU in infants, 600 IU in children and adults and 800 IU in those over 70 years of age, though higher doses varying from 1000 IU per day in infants and children to 1500–200 IU per day in adults and the elderly being required to raise 25(OH)D levels to 30 ng/ml (the level of sufficiency). The recommended dose increases 2- to 3-fold when the individual is on anti-convulsant drugs, glucocortiocids, anti fungal agents and anti-retroviral therapy. Correction of vitamin D deficiency requires higher daily doses of vitamin D, ranging from 2000 IU for those $< 1$ year of age, 4000 IU for children between 1–18 years of age, and 10,000 units for adults. These doses can either be delivered on a daily basis or an equivalent dose calculated and provided on weekly basis. For infants and children, both the daily dose (2000 IU /day) or a weekly calculated dose (50,000 IU per week for 6 weeks followed by 1500–200 units per day) are acceptable. In adults, the commonest strategy is to give 50,000 units per week for 8 weeks followed by 2000 IU per day or an equivalent weekly or monthly dose. In the elderly additional anticipated benefits include fall prevention and fracture risk reduction. vitamin D therapy targeting serum 25(OH)D levels $\geqq 60$ nmol/l is associated with fall prevention, while levels between 66–74 nmol/l appear to be required to reduce the risk of non-vertebral and hip fractures.

## MTE31

**Cryptorchidism**

J. Toppari
University of Turku, Turku, Finland.

Normal position of the testes at term birth is on the bottom of the scrotum. In 2–9% of newborn boys, the testes have failed to descend normally (cryptorchidism), and at the age of three months, 1–3% of all boys remain cryptorchid. Thereafter spontaneous descent occurs rarely, whereas testicular ascent starts to appear and acquired cryptorchidism becomes a problem almost as often as congenital disorder. Cryptorchidism is associated with an increased risk of testicular cancer and subfertility. Germ cell loss in a cryptorchid testis appears already during the second year, and therefore early orchidopexy is generally recommended for treatment. Early operation (before 1 year) has been reported to improve testicular growth as compared with later operation (at 3 years). Hormonal treatment with either human chorionic gonadotropin (hCG) or gonadotropin releasing hormone agonist is still used in some countries, although the efficacy is rather poor (approximately 20%) and some short-term and long-term potential side effects have been reported after hCG (interstitial bleeding, inflammation, increased apoptosis, reduced adult testicular size). The benefit is the avoidance of surgery. In most cases the reason for cryptorchidism remains elusive, although several rare genetic mutations disturbing hormonal regulation of testicular descent are known. Normal function of hypothalamo-pituitary-testicular axis is necessary, and disorders of synthesis/action of androgens and/or insulin-like peptide 3 can cause cryptorchidism. Environmental endocrine disrupters affecting these systems are suspected to be involved in etiology. Links to impaired semen quality, increased risk of testicular cancer and hypospadias suggest that cryptorchidism can be a part of testicular dysgenesis syndrome (TDS) where fetal maldevelopment of the testis can result in one or several signs depending on the timing and nature of the disrupting agent/event.

**Management of GEP-NET tumors**

K. Oberg[1,2]
[1]Uppsala University Hospital, Uppsala, Sweden; [2]Uppsala University, Uppsala, Sweden.

Neuroendocrine gastro-enteropancreatic tumors constitute a diverse group of malignant neoplasms with a common feature of hormone production and release. The incidence and prevalence have constantly increased over the last decades with an incidence of about 6/100 000 and a prevalence of 35/100 000 inhabitants. The majority of patients present a metastatic disease at diagnosis. The most common subtypes of GEP-NETs are small intestinal NETs (carcinoids) followed by pancreatic and rectal NETs. The diagnosis is based on histopathology verification of neuroendocrine features such as positive immunohistochemical staining for CgA, synaptophysin and NSE. The proliferation is determined by the antibody MIB-1 (Ki-67). The biochemical workup includes a general tumor marker such as CgA, which is complemented by peptides and amines related to clinical symptoms (i.e. u-5HIAA, gastrin, glucagon). Localisation procedure include standard radiology, such as CT/MRI, US and endoscopic US. The majority of GEP-NETs express somatostatin type 2 receptors, whereby staging and localisation can be performed by somatostatin receptor scintigraphy with 111Indium-DTPA-Octreotide as well as PET-scanning with 68Ga-DOTATATE. The treatment of neuroendocrine GEP tumors includes surgery as well as debulking procedures such as RFA, embolization (plain or radio-embolization). Peptide receptor radiotherapy is more and more applied using radioactive 177Lutetium-DOTATATE or 90Yttrium-DOTATOC. The medical treatment includes biotherapy such as somatostatin analogs, interferons but also cytotoxic agents, including streptozotocin, 5FU, cisplatinum, etoposide, temozolomide + capecitabine. Most recently pancreatic NETs have been successfully treated with tyrosine kinase inhibitors, sunitinib, as well as the mTOR inhibitor, everolimus (Afinitor). The treatment is based on tumor type, stage and grade. In the future a more personalized treatment will be developed, based on information from molecular genetics and tumor biology.

Declaration of interest

The author declares that there is a conflict of interest.

**Pasireotide LAR is significantly more effective than octreotide LAR at inducing biochemical control in patients with acromegaly: results of a 12-month randomized, double-blind, multicenter, Phase III study**

A. Colao[1], M. Bronstein[2], P. Freda[3], F. Gu[4], C. Shen[5], M. Gadelha[6], M. Fleseriu[7], K. Hermosillo Reséndiz[8], M. Ruffin[9], Y. Chen[8] & M. Sheppard[10]
[1]University of Naples 'Federico II', Naples, Italy; [2]University of São Paulo Medical School, São Paulo, Brazil; [3]Columbia University, College of Physicians and Surgeons, New York, New York; [4]Ministry of Health, Peking Union Medical College Hospital, Beijing, China; [5]National Yang-Ming University, Taipei, Taiwan; [6]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; [7]Oregon Health and Science University, Portland, Oregon, USA; [8]Novartis Pharmaceuticals Corporation, Florham Park, New Jersey, USA; [9]Novartis Pharma AG, Basel, Switzerland; [10]University of Birmingham, Edgbaston, Birmingham, UK.

Introduction
Using the criterion of GH $<2.5$ μg/l and normalized IGF1, response rates to currently available somatostatin analogues in medically-naïve patients with acromegaly are 20–25% after 12 m. The broader somatostatin receptor binding profile of pasireotide may potentially improve response rates. This randomized, double-blind 12-m study compared pasireotide LAR with octreotide LAR.
Methods
Patients with acromegaly (GH $>5$ μg/l or GH nadir $\geq 1$ μg/l post-OGTT, and IGF1 $>$ ULN) who were *de novo* with a visible adenoma on MRI or medically-naïve (no previous medical therapy but prior pituitary surgery) received pasireotide LAR 40 mg/28d ($n=176$) or octreotide LAR 20 mg/28 d ($n=182$) for 12 m. At 3 and 7 m, dose titration to pasireotide LAR 60 mg or octreotide LAR 30 mg for suboptimal biochemical response was permitted, but not mandatory. Primary objective: comparison of the proportion of patients in each arm with GH $<2.5$ μg/l and normal IGF1 at 12 m. GH was measured as a 5-point mean (2 h curve).
Results
At baseline, mean GH was 21.9 and 18.8 μg/l in the pasireotide LAR and octreotide LAR arms, respectively; mean IGF1 was 2.6×ULN and 2.8×ULN. 80.1 and 85.7% of pasireotide LAR and octreotide LAR recipients completed 12 m. Dose uptitration was performed in 50.6 and 67.6% of pasireotide LAR and octreotide LAR recipients. Mean GH and IGF1 decreased by 3 m and remained suppressed. The primary endpoint was achieved by 31.3 and 19.2% of pasireotide LAR and octreotide LAR recipients ($P=0.007$); 48.3 and 51.6% had mean GH $<2.5$ μg/l ($P=0.536$); 38.6 and 23.6% had normal IGF1 ($P=0.002$). Pasireotide LAR recipients were 63% more likely to achieve full biochemical control than octreotide LAR recipients. Symptom improvement and tumor volume reduction were similar in both groups. The most common AEs with pasireotide LAR vs octreotide LAR were diarrhea (39.3 vs 45.0%), cholelithiasis (25.8 vs 35.6%), headache (18.5 vs 26.1%) and hyperglycemia (28.7 vs 8.3%). Most AEs were mild or moderate.
Conclusions
In the largest randomized study of a medical therapy in patients with acromegaly, pasireotide LAR was significantly more effective at inducing full biochemical control, as well as normal IGF1, than the current standard medical therapy octreotide LAR, with an acceptable safety profile.

**Patients with Cushing's disease achieve normal urinary cortisol with LCI699, a potent 11β-hydroxylase inhibitor: preliminary results from a multicenter, proof-of-concept study**

X. Bertagna[1,2], R. Pivonello[3], M. Fleseriu[4], Y. Zhang[5], P. Robinson[6], A. Taylor[7], C. Watson[7], M. Maldonado[8], A. Hamrahian[9], M. Boscaro[10] & B. Biller[11]
[1]Cochin Hospital, Paris, France; [2]Université Paris 5, Paris, France; [3]University of Naples 'Federico II', Naples, Italy; [4]Northwest Pituitary Center, Oregon Health and Science University, Portland, Oregon, USA; [5]Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, USA; [6]Novartis Pharmaceuticals UK Limited, Horsham, UK; [7]Novartis Institutes for BioMedical Research, Cambridge, Massachusetts, USA; [8]Novartis Pharma AG, Basel, Switzerland; [9]Cleveland Clinic Foundation, Cleveland, Ohio, USA; [10]Polytechnic University of Marche, Ancona, Italy; [11]Massachusetts General Hospital, Boston, Massachusetts, USA.

Introduction
The clinical features and complications of Cushing's syndrome result from chronic excess of circulating cortisol, typically quantified by 24-h urinary free cortisol (UFC). LCI699 is a potent inhibitor of 11β-hydroxylase. Since 11β-hydroxylase catalyzes the final step of cortisol synthesis, LCI699 is a potential new treatment for all forms of Cushing's syndrome.
Methods
Adult patients with mild-to-severe Cushing's disease (UFC $>1.5\times$ the upper limit of normal (ULN), mean of three collections in 14 days) received oral LCI699 for 10 weeks in an open-label study. LCI699 was initiated at 2 mg bid. Dose escalation was planned every 2 weeks to 5, 10, 20 and 50 mg bid until UFC normalized, in which case the dose was maintained until day 70, when treatment stopped. Dose reduction for tolerability was permitted. UFC was assessed on the penultimate day of each 2-week period. Patients were monitored until day 84. The primary endpoint was UFC $\leq$ ULN or a $\geq 50\%$ decrease from baseline at day 70 using the mean of 3 UFC samples collected during the week before day 70.
Results
Eleven patients (aged 25–55 years; four men) have been enrolled and nine have completed the study to date. Nine patients had prior surgery. Baseline UFC range was 1.6–17.0×ULN. UFC levels were normal on at least one assessment in 11 of 11 patients during the study. The primary endpoint was achieved by all nine patients who have completed the active treatment phase, eight of whom had normal UFC levels on day 70. After treatment discontinuation, UFC was $>$ ULN in six patients with measurements at day 84. The median dose of LCI699 associated with UFC normalization was between 5 and 10 mg bid. At day 70, mean SBP decreased by 13.1 mmHg from baseline. LCI699 was generally well tolerated; the most frequently reported adverse events were fatigue (5/11), nausea (4/11) and headache (3/11). Five patients experienced ACTH levels $>2\times$baseline. Four patients experienced study drug-related hypokalemia ($K^+ <3.5$ mmol/l; min 3.1 mmol/l). There were no serious AEs of suspected drug relationship.
Conclusion
LCI699 demonstrated efficacy with a satisfactory safety profile in this proof-of-concept study in patients with Cushing's disease.
Declaration of interest
The authors declare that there is a conflict of interest.

**Efficacy and safety of long-term treatment with pegvisomant in acromegaly: Italian pegvisomant observational study (ACROSTUDY)**

A. Bianchi[1], S. Grottoli[2], F. Bogazzi[3], A. Colao[4], N. Sicolo[5], S. Cannavò[6], E. Ghigo[2], L. De Marinis[1] & Italian Acrostudy Group[7]
[1]Catholic University, Rome, Italy; [2]University of Turin, Turin, Italy; [3]University of Pisa, Pisa, Italy; [4]University 'Federico', Naples, Italy; [5]University of Padova, Padova, Italy; [6]University of Messina, Messina, Italy; [7]Acrostudy Centers, Italy, Italy.

ACROSTUDY is an international observational study to evaluate efficacy and safety of long-term treatment with pegvisomant (PEGA) in acromegaly. ACROSTUDY Italy was started in 2007 and we report data from the first 185 patients (93M, 92F, mean age, range, 49.9 y; 17–83.8 y) treated with PEGA (mean duration, range, 3.2 y, 0.1–8.5 y), from 24 centers, until 01/2010. Before and during PEGA, IGF1, GH-Ab, liver enzymes, metabolic parameters and pituitary MRI were assessed. Before PEGA, 70 patients had undergone surgery, 15 radiation therapy, 161 had received SSA ± DA and in 24 subjects no previous medical treatment of acromegaly was documented. At the start of treatment, 43.2% of patients received PEGA alone, 49.9% in association with SSA and 10% SSA + DA. During treatment, a progressive increase in the subjects receiving PEGA alone was observed. In 87% of cases PEGA was used in daily administration. The mean dose of PEGA received alone (mean starting dose 12.2 mg/day, at 5 y 18.5 mg/day) was not significantly different ($P=$NS) from that used in association with SSA ± DA (mean starting dose 12.4 mg/day, at 5 y 19.3 mg/day). In 74.4 and 75.5% of patients, IGF1 levels were normalized after 1 and after 5 y of therapy respectively. During PEGA, an increase in tumor lesion in 11 cases and a reduction in 16 cases was observed, but the centralized blinded reassessment confirmed the increase in three cases and a reduction in one case. In no case a significant and sustained transaminases elevation was reported. Discontinuation of treatment for serious adverse events was required in two cases. In conclusion, our data confirm that long-term PEGA therapy is highly effective in acromegalic patients resistant to other treatment and shows an excellent safety profile.
Declaration of interest

## OC1.4

**A multi-centre audit of the prevalence of cardiac valvulopathy in patients treated with dopamine agonists for hyperprolactinaemia**

W. Drake[1], C. Stiles[1], J. Bevan[2] & R. Steeds[3]
[1]St Bartholomew's Hospital, London, UK; [2]Aberdeen Royal Infirmary, Aberdeen, UK; [3]Queen Elizabeth Hospital, Birmingham, UK.

Bromocriptine (BC) and cabergoline (CAB) are ergot-derived dopamine agonists (DAs) used for the treatment of hyperprolactinaemia. Recently, concern has been raised about a possible association between long-term DA use and cardiac valvular abnormalities. These concerns are largely derived from studies in patients with Parkinson's disease receiving higher doses (typically CAB 3 mg/day vs 0.5–1 mg/week for hyperprolactinaemic patients). Studies in hyperprolactinaemic patients are generally reassuring but limited by their small size. We report the preliminary results of a UK-wide cross-sectional survey of echocardiographic findings in patients treated with BC/CAB for hyperprolactinaemia. The project was supported by the Clinical Endocrinology Trust and an unrestricted grant from Pfizer, UK. IRB permission was obtained at each centre. Anonymised data from 520 patients (163 male, median age 43, range 16–89) in 17 centres were collected. Studies were performed to British Society of Echocardiography standards. Patients were divided into two groups: completely normal ($n=192$); and those with any valvular abnormality of any severity (leaflet thickening, regurgitation, stenosis, reduced mobility or calcification, $n=328$). The two groups were then subdivided into BC- and CAB-treated. A two-tailed unpaired *t*-test was performed on the CAB-treated normal vs CAB-treated abnormal echocardiogram groups; and on the BC-treated normal vs BC-treated abnormal echocardiogram groups. There were no 'severe' and seven 'moderate' valve defects (two aortic valve thickening; two tricuspid regurgitation; one reduced aortic valve mobility; one aortic stenosis; one aortic regurgitation). Each patient's cumulative exposure to DA was calculated. There was no statistically significant difference in the cumulative dosage of either BC ($P=0.48$) or CAB ($P=0.13$) between those with normal vs abnormal echocardiograms. There was a trend towards a higher cumulative dose of DA in the groups with normal echocardiograms. This cross-sectional survey finds no evidence of an increased prevalence of valvulopathy in patients being treated with BC or CAB for hyperprolactinaemia.

## OC1.5

**Initial hypothalamic involvement is the major risk factor for impaired prognosis and quality of life in childhood craniopharyngioma regardless of chosen treatment strategies: results of KRANIOPHARYNGEOM 2000**

H. Müller[1], U. Gebhardt[1], M. Warmuth-Metz[2], R. Kortmann[3], A. Faldum[4], T. Pietsch[5], C. Gabriele[6] & N. Sörensen[7]
[1]Klinikum Oldenburg, Oldenburg, Germany; [2]University Hospital Würzburg, Würzburg, Germany; [3]University Hospital Leipzig, Leipzig, Germany; [4]University Mainz, Mainz, Germany; [5]University Hospital Bonn, Bonn, Germany; [6]University Hospital Münster, Münster, Germany; [7]Evangelisches Krankenhaus Oldenburg, Oldenburg, Germany.

Hypothalamic obesity has major impact on prognosis and quality of life (QoL) in childhood craniopharyngioma (CP). The pathogenic relevance of initial hypothalamic involvement versus treatment-related hypothalamic lesions is a matter of controversy.

One hundred and twenty patients were recruited prospectively during 2001 and 2007 and evaluated after 3 years of follow-up. Body mass index (BMI) and QoL at diagnosis and 36 mo after diagnosis were analyzed based on reference assessment of tumour localization and post-surgical hypothalamic lesions using a standardized grading system (no, anterior, posterior involvement/lesion). Treatment was analyzed regarding neurosurgical strategy of 50 participating neurosurgical centres and the centre sizes. Based on patient load during the 6-year recruitment period, participating centres were categorized as small (1 pt/6 years), middle (2–5 pts/6 years) or large-sized centres (>5 pts/6 years).

BMI SDS at diagnosis was similar in patients with or without hypothalamic involvement. Surgical lesions of anterior and posterior hypothalamic areas were associated with higher increases in BMI SDS during 36 mo post-diagnosis compared to patients without or only anterior lesion ($+1.8$ BMISD, $P=0.033$, $+2.1$ BMISD; $P=0.011$), negatively impacting QoL in patients with posterior hypothalamic lesions. Surgical strategies varied between the 50 neurosurgical centres (3 large, 24 middle, 23 small centres). Patients treated in small centres presented with a higher rate of hypothalamic involvement compared to middle and large-sized centres. Treatment in large centres was less radical, the rates of complete resection and hypothalamic surgical lesions lower than those of middle-sized and small centres. However, a multivariable analysis showed that pre-operative hypothalamic involvement was the only independent risk factor for severe obesity ($P=0.002$).

Radical strategies leading to posterior hypothalamic lesions are not recommended due to potential to exacerbate hypothalamic obesity and impaired QoL. Because our results show that initial hypothalamic involvement has an *a priori* effect on the clinical course, our recommendations are based on recognizing CP as a chronic disease.

**Normal weight adult patients with Prader–Willi syndrome are not protected from insulin resistance during treatment with GH: results from a 12 month prospective study**

A. Jørgensen[1], T. Ueland[1], R. Sode-Carlsen[2], T. Schreiner[1], K. Rabben[5], S. Farholt[2], C. Høybye[3], J. Christiansen[4] & J. Bollerslev[1]
[1]Oslo University Hospital, Rikshospitalet, Oslo, Norway; [2]Aarhus University Hospital, Skejby, Aarhus, Denmark; [3]Karolinska University Hospital, Stockholm, Sweden; [4]Aarhus University Hospital, Aarhus, Denmark; [5]Frambu, Siggerud, Norway.

Background

Diabetes mellitus is prevalent in adults with Prader–Willi syndrome (PWS), and GH therapy may deteriorate glucose balance.

Design

We prospectively investigated effects of 12 months of GH treatment on body composition and insulin resistance in relation to BMI in forty-two adults, mean($\pm$s.d.) age $28.5\pm6.7$ years with genetically verified PWS. Three patients with known diabetes were excluded. Data from baseline and 12 months of GH treatment in 35 patients, who completed the study are presented. The number of patients in each BMI-group (kg/cm$^2$) were 14(<25), 10(25–30) and 11(>30). Fat mass (FM) and lean mass (LM) were assessed by DEXA. Fasting blood samples and 2 h p-glucose after oral glucose tolerance test (OGTT) were made at baseline and after 12 months. Insulin resistance was estimated by homeostasis model assessment (HOMA-IR).

Results

With a mean final GH dose of $0.6\pm0.25$ mg we observed an increase in Insulin-like growth factor 1 (IGF1) from $115\pm35$ to $171\pm52$ µg/l, $P<0.001$, LM $39.9\pm8.1$ to $42.2\pm8.8$ kg, $P<0.001$, 2 h p-glucose $7.4\pm2.5$ to $8.1\pm2.5$, $P<0.05$, HOMA-IR $1.9\pm0.8$ to $2.3\pm0.7$, $P<0.01$ and a decrease in FM $29.4\pm12.5$ to $27.5\pm13.4$, $P<0.02$.

At baseline, IGF1 was lower with BMI (25–30) as compared to the other two groups, $95\pm27$ vs $124\pm33$ µg/l, $P<0.01$ and HOMA-IR was higher with BMI >30, $1.7\pm0.7$ vs $2.4\pm0.8$. Age and LM did not differ between the groups and variations in BMI were due to different FM. Final mean GH dose and IGF1 level did not differ between the groups. A reduction in FM was seen only with BMI (25–30), $29.1\pm3.0$ to $24.3\pm5.0$ kg, $P<0.01$ and HOMA-IR increased in the lowest BMI-group only, $1.6\pm0.6$ to $2.3\pm0.8$, $P<0.05$.

Conclusions

GH treatment in PWS patients results in the expected increase in insulin resistance irrespective of fat mass.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Overt hyperthyroidism is associated with increased mortality: a nationwide register-based study of disease discordant Danish twins**

F. Brandt[1], D. Almind[2], K. Christensen[1,2], A. Green[3], L. Hegedüs[1] & T. Brix[1]
[1]Odense University Hospital, Odense, Denmark; [2]University of Southern Denmark, Odense, Denmark; [3]University of Southern Denmark and Center for National Clinical Databases, South, Odense University Hospital, Odense, Denmark.

Introduction
Overt hyperthyroidism (OH) is associated with potentially lethal conditions such as atrial fibrillation, pulmonary embolism, stroke and coagulopathy. OH has also been connected with an increased mortality. However, this could be the result of common genetic and environmental factors affecting both OH and mortality.
Objective
To investigate if OH is associated with an increased mortality and to what degree the relation might be explained from genetic and/or environmental confounding.
Setting
Denmark.
Design
Register-based cohort study.
Participants
Twins ($n=96\,064$) and singletons from a 5% sample of the Danish population ($n=281\,549$) born from 1870 until 1990.
Methods
Unpaired and intrapair Cox regression analyses were compared. From the discordant twin pair design early environmental and genetic confounding was controlled by design. All participants were followed until December 31, 2008.
Results
Out of all participants, 4850 singletons and 1492 twins were identified as cases (OH). In the unpaired analyses, there was a significant higher mortality in individuals diagnosed with OH both in singletons (HR = 1.33, 95% CI 1.27–1.40) and in twins (HR = 1.31, 95% CI 1.18–1.46). In the intrapair analyses stratification for zygosity yield similar results for dizygotic twins (HR = 1.80, 95% CI 1.27–2.55), whereas the effect of OH attenuated in the monozygotic twins (HR = 0.95, 95% CI 0.60–1.50).
Conclusion
The findings of a raised mortality in singletons and within dizygotic twins pairs, but not within monozygotic twins, support a genuine relation between OH and mortality, which to some degree is influenced by shared genetic determinants.

**Identification and functional analysis of DUOX2 variants: biallelic mutations are associated with permanent congenital hypothyroidism**

M. Muzza[1], I. Zamproni[2], L. Persani[3], F. Cortinovis[2], M. Vigone[2], S. Rabbiosi[2], L. Beccaria[4], T. Visser[5], J. Moreno[6], G. Weber[2] & L. Fugazzola[1]
[1]University of Milan, Milan, Italy; [2]San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy; [3]University of Milan and Istituto Auxologico Italiano, Milan, Italy; [4]A Manzoni Hospital, Lecco, Italy; [5]Erasmus Medical Center, Rotterdam, The Netherlands; [6]INGEMM-Institute for Medical and Molecular Genetics, La Paz University Hospital, Madrid, Spain.

Since the first identification of DUOX2 as an actor in the pathogenesis of congenital hypothyroidism (CH), several mutations have been associated with transient or permanent CH, with a high intra- and interfamilial phenotypic variability. In the present study, we report clinical and molecular studies of 7 unrelated children and 2 couple of siblings affected with CH and partial iodide organification defect (PIOD).
We identified nine novel and five previously reported DUOX2 mutations (seven missense, six stop codon – three nonsense and three frameshift – and one splice site mutations) using specific PCR primers able to distinguish the two highly homologous DUOX1 and DUOX2 sequences. The missense mutations involve conserved residues located in critical regions for protein function. Functional analysis of these variants indicated a significant impairment of $H_2O_2$ generation. Moreover, the nonsense mutants are shown to totally abolish the DUOX2 activity by different mechanisms: nonsense-mediated RNA decay, exon skipping and protein truncation.
Six out of eight cases with compound heterozygous variations had permanent hypothyroidism, but without evident correlations between the type of mutation and the phenotype in terms of TSH levels and discharge rates. However, two siblings showed biallelic mutations and transient CH. On the other hand, among the three patients harboring monoallelic mutations, one had transient and two permanent CH.
In conclusion, in our cohort most biallelic pathogenic DUOX2 variants were associated with permanent CH. The existence of other $H_2O_2$ generating systems and differences in age, ethnicity and iodine intake may account for the discrepant biallelic transient cases while the monoallelic cases with permanent CH could be explained by cryptic DUOX2 variations or alterations involving other thyroid mechanisms.

### OC2.3

**Thyroid hormone levels in euthyroid young men are associated with body composition and metabolic parameters**

G. Roef, Y. Taes, B. Lapauw, K. Wierckx & J. Kaufman
Universitary Hospital of Ghent, Ghent, Belgium.

Introduction
Thyroid disorders affect metabolism and body composition; however, literature data have been conflicting on whether this is also the case for thyroid hormone levels within the euthyroid range. Therefore, we have investigated the relationship between indices of thyroid status and both body composition and metabolic parameters in a population of healthy euthyroid men.
Methods
Healthy male siblings ($n=941$, 25–45 years, median BMI 24.6) were recruited in a cross-sectional, population-based study; a history or treatment of thyroid disease and positive thyroid auto-immunity were exclusion criteria. Body composition and muscle cross-sectional area were assessed by dual-energy X-ray absorptiometry (DXA) and peripheral quantitative computed tomography (pQCT). Total ($TT_3$, $TT_4$) and free thyroid hormones ($FT_3$, $FT_4$), TSH, Thyroxin Binding globulin (TBG) and reverse $T_3$ ($rT_3$) were determined using immunoassays.
Results
$FT_3$, $TT_3$ and TBG were positively associated with BMI, fat mass and serum leptin (all $P$ values between 0.02 and 0.0001), whereas $FT_4$ and $TT_4$ were solely associated with fat mass and serum leptin ((+); $P$ values $<0.005$). Inverse associations between lean mass ($P<0.005$) and other muscular parameters and thyroid hormones were observed. Higher levels of (F) $T_3$ and TBG were associated with lower insulin sensitivity, as assessed by HOMA-IR ($P=0.0001$). No associations between TSH and body composition or metabolic parameters were seen.
Conclusion
Thyroid hormone levels were positively associated with fat mass and leptin and inversely with indices of muscle mass and insulin sensitivity in this population of healthy young men with well characterized euthyroidism. Direction and

## OC2.4

**The thyroid hormone receptor-coactivator interface mediates negative feedback regulation of the human pituitary–thyroid axis**

C. Moran[1], M. Agostini[1], E. Schoenmakers[1], C. Mitchell[1], J. Gregory[2], M. Gurnell[1] & K. Chatterjee[1]
[1]University of Cambridge, Cambridge, UK; [2]University Hospital of Wales, Cardiff, UK.

Corepressors and coactivators mediate thyroid hormone receptor-dependent repression and transactivation of positively-regulated target genes respectively, but their role in negative regulation is not understood.
A 4 years old boy was born at 31 weeks. He was jittery at birth, with neonatal respiratory distress. Childhood features included poor weight gain, heat intolerance, tachycardia and hyperactivity. Ongoing problems are low frequency hearing loss, poor sight, impaired coordination and learning disability. His circulating free thyroid hormones are consistently elevated ($FT_4$ 47.1 pmol/l (RR 9.8–23.1), $FT_3$ 13.7 pmol/l (RR 3.5–6.5) together with non-suppressed TSH (8.0 mU/l (RR 0.35–5.50)) levels; parental thyroid function is normal.
The proband is heterozygous for a novel mutation (E457Q) in the TRβ gene, involving a highly conserved residue located in its carboxyterminal transactivation domain; the mutation occurs *de novo*, with wild type parental TRβ sequence, consistent with their normal thyroid function. Although the mutant receptor binds T3 normally (WT $Ka = 1.29 \times 10^{10}\ M^{-1}$; E457Q $Ka = 1.26 \times 10^{10}\ M^{-1}$) hormone-dependent negative regulation (hTSHα) by E457Q TRβ is markedly impaired; in addition, when coexpressed, E457Q TRβ is a strong dominant negative inhibitor of WT receptor function. In protein-protein interaction assays, E457Q TRβ binds and dissociates from corepressors (NCoR, SMRT) normally; however, the mutant receptor fails to recruit coactivators (TRAP 220, SRC-1, RIPI40, LCoR). Crystallographic modelling indicates that substitution of glutamine for the negatively-charged glutamic acid at codon 457 abrogates electrostatic receptor-coactivator interactions.
Elevated thyroid hormones with non-suppressed TSH in the proband indicate impaired negative feedback in the pituitary–thyroid axis *in vivo*. consistent with impaired negative regulation of the TSHα promoter by E457Q TRβ seen *in vitro*. Together these observations suggest that proteins recruited to the thyroid receptor-coactivator interface mediate negative transcriptional regulation of target genes in the human pituitary–thyroid axis.
*Please note C Moran and M Agostini contributed equally to this work.

## OC2.5

**Thyroid spongiform nodules are the best candidates for percutaneous laser ablation. A 5 year follow-up study in 72 patients**

R. Valcavi, G. Stecconi Bortolani, F. Riganti & C. Pacella
IRCCS Santa Maria Nuova, Reggio Emilia, Italy.

Background
Percutaneous laser ablation (LA) is a therapeutic procedure used for the reduction of benign thyroid nodules. After LA a 50% nodule reduction was observed by most authors. However, eligibility criteria for LA based on long term efficacy have not been established.
Methods
Seventy-two patients (51 women and 21 men) with benign cold thyroid solitary nodules or a dominant nodule within a normo-functioning multinodular goiter underwent thermal Nd:YAG LA of thyroid nodular tissue by 1–4 optical fibers positioned into the tissue by 21-G needles under ultrasound real-time assistance. Mean ± SD nodule volume was 28.1 ± 29.3 ml. Energy delivered was 8842 ± 6086 Joules with an output power of 2–4 Watts.
According to internal content, nodules were classified as follows: a) compact: iso/hypoechoic, homogeneous, ≤10% of cystic content; b) mixed: solid, inhomogeneous, with a 20–50% cystic content; c) spongiform: aggregation of multiple microcystic components in more than 50% of the nodule. Cystic nodules (fluid content ≥50%) were excluded from this series.
Results
Five years after LA, nodule volume decreased to 14.5 ± 17.6 ml, with a reduction of −49.6% from pretreatment in the whole group of 72 patients. In 25 spongiform nodules, volume decreased from 24.8 ± 25.9 to 7.7 ± 7.5 ml, with a reduction of −58.7%. In 14 mixed nodules, volume decreased from 41.1 ± 47.3 to 16.1 ± 17.4 ml, with a reduction of −48.3%. In 33 solid nodules, volume decreased from 26.4 ± 24.5 ml to 17.9 ± 22.0 ml, with a reduction of −26.8%.
LA was more effective in patients with spongiform nodules as compared to mixed ($P \leq 0.01$) and compact ($P \leq 0.001$) nodules.
Conclusions
After 5 years, percutaneous LA achieved the expected 50% shrinkage in a variety of benign cold thyroid nodules. However, our data demonstrate that LA procedure was more successful and durable in patients with spongiform nodules. These patients are therefore the best candidates for percutaneous LA procedure.

## OC2.6

**Concurrent presence of nonendocrine autoimmune diseases with Hashimoto's thyroiditis: a systematic assessment on more than 5000 consecutive patients**

M. Centanni[1,2], M. Santaguida[1], S Del Duca[1], M. Cellini[1,2], L. Gargano[2], N. Brusca[1,2] & C. Virili[1]
[1]'Sapienza' University of Rome, Latina, Italy; [2]AUSL Latina, Latina, Italy.

Systematic studies on the association of autoimmune thyroiditis (AIT), as pivotal disease and nonendocrine autoimmune diseases (NEAD) are scarce and mostly based only on the presence of circulating autoantibodies. In a large cohort of consecutive outpatients, AIT was diagnosed in 1541 (28.2%) and whenever additional autoimmune disorders were suspected, they underwent further screening. Diagnostic criteria were according with the Consensus Conferences for each suspected autoimmune disease. The association AIT + NEAD was detected in 250/1541 (16.2%) patients (227 W and 23 M; W/M 10:1; median age = 39 years). Of these, 64 patients (25.6%) had more than one autoimmune disease associated with AIT. The most frequent associated disease was chronic atrophic gastritis (CAG) (34.8%), followed by nonsegmental vitiligo (22.3%), celiac disease (11.0%), anti-phospholipids syndrome and multiple sclerosis (7.6%). Although most of patients with multiple autoimmune disorders were adult to old, 9.9% of them had a second autoimmune disease before the age of 30 years. In this group the most frequent diseases associated with thyroiditis were vitiligo (39%) and celiac disease (26%), while CAG was less observed (13%). Peculiar

characteristics of patients with AIT+NEAD were thyroxine malabsorption, chronic unexplained anemia and recurrent pregnancy loss (RPL). Thyroxine malabsorption was indeed higher than in patients with isolated thyroid diseases (31 vs 12.3%; $P<0.0001$; OR=3.60). RPL was observed in 6.9% of patients with AIT+NEAD as compared with 1.7% found in patients with isolated thyroid diseases ($P<0.0001$; OR=4.06). Unexplained anemia was found in 2.2% of patients with isolated thyroid diseases and in 18.3% of patients with AIT+NEAD ($P<0.0001$; OR=8.23). In conclusion: i) 1 patient out of 6 has NEAD associated with AIT and 1/10 of them is younger than 30 years; ii) atrophic gastritis, vitiligo and celiac diseases are the most frequent autoimmune disorders associated with AIT, being their prevalence age-related; iii) the presence of thyroxine malabsorption, chronic unexplained anemia and recurrent pregnancy loss in patients with AIT should induce to look for other autoimmune diseases.

## Diabetes Clinical

### OC3.1

**Common variants of monogenic diabetes genes may affect β cell functional mass in patients with newly diagnosed type 2 diabetes**

S. Bonetti[1,2], M. Trombetta[1,2], B. Linda[1,2], M. Dauriz[1,2], G. Malerba[1], E. Trabetti[1], P. Pignatti[1], E. Bonora[1,2] & R. Bonadonna[1,2]

[1]University of Verona School fo Medicine, Verona, Italy; [2]Azienda Ospedaliera Universitaria Integrata of Verona, Verona, Italy.

We tested the hypothesis that common genetic variability of β cell mass and/or function genes may influence β cell functional mass in type 2 diabetes (T2DM). We studied 590 drug-naive GAD-negative patients with newly diagnosed T2DM (age: median=60.0 yrs; I.Q. range: 52–66; BMI: 29.3 kg/m$^2$; 26.5–32.9). β cell functional mass was assessed by state-of-art mathematical modeling of glucose/C-peptide curves during a 240' frequently sampled OGTT, to provide the β cell responses to the rate of increase of glucose (derivative control: DC) and to glucose concentration (proportional control, PC). Insulin sensitivity, measured by the insulin clamp technique, acted as an internal control for the number of false positive hits. Forty-five SNPs, selected to cover over 90% of common genetic variability, were genotyped in 8 MODY (HNF4A, GCK, HNF1A, PDX1, HNF1B, NEUROD1, KLF11, CEL) and 2 neonatal diabetes mellitus (NDM) (KCNJ11, ABCC8) genes. Allelic variants of 4 SNPs (rs1303722 and rs882019 of GCK, rs7310409 of HNF1A and rs5219 of KCNJ11, the latter being a known type 2 diabetes risk variant) were significantly associated to changes in DC of β cell function ($P=0.007-0.03$). Allelic variants of 5 other SNPs (rs2869084 and rs6031544 of HNF4A, rs10774580 of HNF1A, rs1801262 of NEUROD1, and rs7129639 of ABCC8) were found to influence significantly PC of β cell function ($P=0.001-0.04$). Only 1 (rs6721191 of KLF11) out of 45 SNPs was associated to insulin sensitivity ($P=0.047$). In multivariate regression models, combining GCK, HNF1A and KCNJ11 SNPs accounted for ~2.5% of DC of β-cell function, whereas combining HNF4A, HNF1A, NEUROD1 and ABCC8 SNPs accounted for ~3.6% of PC of β cell function. Thus, common variability of MODY and NDM genes is significantly associated to β cell functional mass in patients with type 2 diabetes, thereby potentially playing a role in the pathophysiology of the disease and in its metabolic prognosis.

### OC3.2

**Weight-loss independent metabolic benefits of gastric bypass surgery? Experiences from the Swedish obese subjects (SOS) study**

M. Peltonen[1], E. Sjöström[2], K. Sjöholm[2] & L. Carlsson[2]

[1]National Institute for Health and Welfare, Helsinki, Finland; [2]University of Gothenburg, Gothenburg, Sweden.

Objective

Bariatric surgery has a marked effect on diabetes risk in the obese. The aim of this study was to evaluate weight-loss independent effects of gastric bypass on glucose and insulin levels over 10-years of follow-up.

Research design and methods

A total of 2010 obese individuals received bariatric surgery in the Swedish Obese Subjects (SOS) study (376 patients underwent non-adjustable or adjustable banding, 1369 underwent vertical banded gastroplasty (VBG), and 265 underwent gastric bypass (GBP)). Health examinations with anthropometric measurements and laboratory analyses were conducted at baseline and at 2- and 10-year follow-up. Follow-up rates were 92% and 74% at 2- and 10-years, respectively. Diabetes was defined by fasting venous whole blood glucose 6.1 mmol/litre or more, and/or self-reported diabetes medication. Weight loss was categorized in four groups: <30 kg; 30 to 25 kg; 25 to 20 kg; 20 to 15 kg. Changes in blood glucose and serum insulin levels were compared between the three surgical groups accounting for the degree of weight loss. Data was analysed separately for persons with and without diabetes at baseline.

Results

The average 10-year weight losses were 18 kg, 20 kg and 29 kg in the banding, VBG and GBP groups, respectively ($P<0.001$). Changes in fasting glucose and insulin were related to the degree of weight loss. There were no significant differences in changes in glucose and insulin between the three surgical groups, when patients within same weight loss categories were compared. This was observed for patients with and without diabetes at baseline. As expected, changes in glucose and insulin levels were more marked in patients with diabetes at baseline as compared to persons without.

Conclusions

Given same degree of weight loss over 10-years following bariatric surgery, there was no support for weight-loss independent benefits of GBP over banding and VBG on fasting glucose and insulin levels.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### OC3.3

**Diabetic ketoacidosis at diagnosis influences complete remission after treatment of hematopoietic stem cell transplantation in adolescents with type 1 diabetes**

W. Gu[1], J. Hu[1], D. Zhu[2], W. Tang[1], L. Li[2], W. Cui[2], J. Hong[1], Y. Zhang[1], W. Wang[1] & G. Ning[1]

[1]Shanghai Ruijin Hospital Affiliated to Shanghai JiaoTong University, Shanghai, China; [2]Nanjing Drum Tower Hospital affiliated to Nanjing University Medical School, Nanjing, China.

**Abstract**

Objective

To determine if autologous nonmyeloablative hematopoietic stem cell transplantation (AHSCT) was worthwhile to do in type 1 diabetes adolescents with diabetic ketoacidosis at diagnosis.

Research Design and Methods

We enrolled 28 type 1 diabetes patients aged 14–30 years in a prospective AHSCT phase II clinical trial. Hematopoietic stem cells were harvested from the peripheral blood following a pretreatment consisting of a combination of cyclophosphamide and antithymocyte globulin. Changes of exogenous insulin requirement were observed and serum levels of hemoglobin A1c, C-peptide secretion during the oral glucose tolerance test (OGTT) and anti-glutamic acid decarboxylase antibody (GAD) were measured before and after AHSCT.

Results

After transplantation, complete remission (CR) defined as insulin independence was observed in 15 (53.6%, 15/28) patients for a mean period of 19.3 months over a follow-up ranging 4–42 months. The non-DKA patients achieved greater CR rate than the DKA ones (70.6%, 12/17 in non-DKA vs 27.3%, 3/11 in DKA, $P=0.051$). In non-DKA group, levels of fasting C-peptide, Cmax(peak value during OGTT) and AUCC(area under C-peptide release curve during OGTT) were enhanced significantly one month after transplantation and remained high during 24 months follow-up (all $P<0.05$). In DKA group, significant elevation of fasting C-peptide level and Cmax level were only observed at 18-month and 6-month respectively. There was no mortality.

Conclusions

We have performed AHSCT in 28 cases of type 1 diabetes. The data demonstrate AHSCT to be an effective long-term treatment of insulin dependence with greater efficacy achieved in patients without ketoacidosis at diagnosis.

Trial Registration clinicaltrials.gov Identifier: NCT00807651

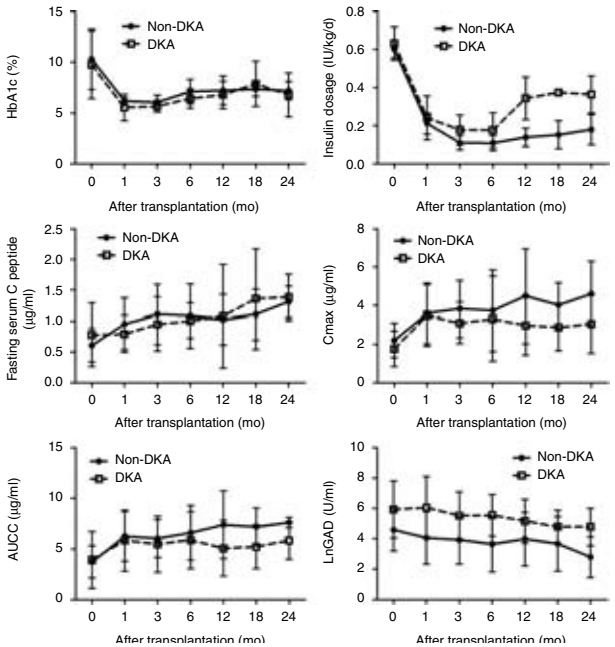

Fig1. Time course of HbA1c, Insulin dose, fasting C-peptide, Cmax, AUCC and LnGAD level in non-DKA group and DKA group respectively Note: Cmax, peak value of C-peptide during OGTT; AUCC (area under C-peptide release curve during OGTT); LnGAD, log form of GAD because of the uneven data distribution. Solid line, non-DKA group; Dotted line, DKA group.

## OC3.4

### Glucose lowering therapies and cancer specific mortality in adult insulin-treated diabetes

S. Ioacara[1], C. Guja[1], C. Ionescu-Tirgoviste[1], S. Fica[2], S. Martin[2], S. Sabau[3] & C. Tiu[4]
[1]'I Pavel' Outpatient Clinic, Bucharest, Romania; [2]'Elias' Hospital, Bucharest, Romania; [3]'Tokai' University, Sapporo, Japan; [4]'University' Hospital, Bucharest, Romania.

**Abstract**
Aim
Following the general concern regarding the association between various diabetes treatments and cancer risk, the present study evaluated the cancer specific mortality in adult insulin-treated diabetes patients.
Materials and methods
All diabetes patients residing in a major urban area, aged over 40 years and receiving insulin treatment were included at the moment of their first diabetes outpatient visit from 01/01/2001 to 12/31/2008. A total of 11366 subjects (46.5% males) were followed-up for death of any cause until 12/31/2010 by crosslinking with the National Institute of Statistics mortality database, with a virtually 100% cover-up. Mortality data for the general population was obtained from the same source. Death related data was based on death certificate. Antidiabetic prescriptions were available from local pharmacies or prescribing institutions. Subjects with $<6$ months of follow-up were excluded (avoiding protopathic bias). Age and sex adjusted time-dependent Cox proportional hazard analysis (1 month update of treatment modalities) was performed.
Results
Mean age at baseline was $59.8 \pm 10.7$ years, mean follow-up period $6.75 \pm 2.98$ years (76697.9 person-years). Overall, unadjusted all-cause mortality was 49.7/1000 person-years (3811 deaths); cancer mortality was 6.9/1000 person-years (531 deaths). The major types of cancers were: pulmonary ($n=94$, 17.7%), pancreatic ($n=67$, 12.6%), liver ($n=64$, 12.1%), colorectal ($n=60$, 11.3%), breast ($n=55$, 10.4%) and stomach ($n=25$, 4.7%). Adjusted hazard ratios for cancer mortality (CI95%) were: biguanides 0.49 (0.35–0.68, $P<0.001$), sulfonylurea 0.9 (0.64–1.26, $P=0.54$), human rapid insulin 1.17 (0.96–1.41, $P=0.11$), rapid analogs 0.74 (0.46–1.22, $P=0.24$), human premixed insulin 0.85 (0.59–1.24, $P<0.4$), premixed analogs 0.91 (0.59–1.38, $P<0.64$), human intermediate insulin 0.82 (0.53–1.26, $P=0.36$), glargine 1.05 (0.64–1.74, $P=0.84$), and detemir 1.54 (0.75–3.15, $P=0.24$).
Conclusions
Biguanides are the only diabetes treatment choice associated with an independent, statistical significant (protective) effect on cancer mortality. Of interest, exposure to long acting analogues was not associated with increased cancer mortality in insulin treated subjects.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## OC3.5

### Study of toll like receptor 2 and 4 expression in monocytes in type 1 diabetes mellitus with and without micro-vascular complications

S. Sedek, W. Ahmed, S. Shelbaya, R Abd El Baki & M. Abass
Shams University hospitals, Cairo, Egypt.

Background
Toll-like receptors (TLRS) are a class of proteins that play a key role in the innate immune system. They are single, membrane, non catalytic receptors which are expressed in multiple tissues predominantly cells of the innate immune system especially monocytes. So, they play a critical role in the regulation of immune function and inflammation.
Aim of our work
To study the expression of toll-like receptor 2 and 4 on monocytes in T1DM patients and its relation to microvascular complications.
Subjects and methods
This cross sectional study was conducted on 80 subjects above age of 18 years divided into Group I: 20 T1DM patients without diabetic complications. Group IIa: 9 T1DM patients with nonproliferative diabetic retinopathy (NPDR), Group IIb: 11 T1DM patients with proliferative diabetic retinopathy (PDR), Group IIIa: 7 T1DM patients with micro-albuminuria, GroupIIIb: 13 T1DM patients with macroalbuminuria, Group IV: 20 healthy subjects. They were subjected to full clinical history, thorough clinical examination, fundus examination, fasting plasma glucose level, (HbAIc), level albumin/creatinine ratio in random urine sample, measurement of TLR 2 and 4 using flowcytometry.
Results
There was highly significant difference between the studied groups as regards TLR2 and TLR4 percent ($P$ value $<0.01$) being higher in T1DM with microvascular complications than in T1DM without microvascular complications than in healthy control subjects. There was also highly statistical significant positive correlation ($P$-value $<0.01$) between TLR2 and age, duration of diabetes, SBP, DBP, FPG, HbA1c and albuminuria as well as highly statistical significant positive correlation ($P$ value $<0.01$) between TLR4 and age, duration of diabetes, SBP, DBP, FPG, HbA1c and albuminuria.
Conclusion
These results postulate that TLR2 and TLR4 may have a role in the microvascular complications of type 1 diabetic patients.

**Glucose disorders exert a detrimental effect on total brain volume in the elderly: a 2-year prospective MRI study**

K. Samaras[1,2], H. Lutgers[1], W. Wen[3,4], L. Campbell[1,2], B. Baune[5], H. Brodaty[3], J. Trollor[3] & P. Sachdev[3,4]
[1]Garvan Institute of Medical Research, Darlinghurst, Sydney, NSW, Australia; [2]St. Vincent's Hospital, Darlinghurst, Sydney, NSW, Australia; [3]University of New South Wales, Randwick, NSW, Australia; [4]Prince of Wales Hospital, Randwick, NSW, Australia; [5]University of Adelaide, Adelaide, SA, Australia.

Introduction
Long-standing type 2 diabetes (DM) is associated with brain atrophy. In this prospective study we examined the impact of glycaemic status on total brain volume in an elderly cohort.
Methods/Design
Two-year follow-up study of a population-derived cohort of non-demented community-dwelling adults aged 70–90 years (Sydney Memory and Aging Study). Prospective MRI and metabolic data were available in 312 of the 542 participants who had a MRI at baseline. At follow-up, participants were categorized in 4 groups: stable normoglycemia (NG at both time points, $n=102$), stable IFG (IFG at both time points, $n=120$), progression of glucose status (from NG to IFG/DM or from IFG to DM at follow-up, $n=57$), and, diagnosed DM at baseline ($n=33$). Total brain volume (TBV) was defined as the sum of grey and white matter ($cm^3$).
Results
$n=312$, mean age 78 ($\pm 4.4$) years; 54% Male, 41% had IFG and 13% had diagnosed DM at baseline. Compared to delta TBV in stable NG ($-18.4\ cm^3$), the decrease in TBV was 1.4-fold greater in stable IFG ($-26.6\ cm^3$, $P=0.2$), 2.3-fold greater compared to subjects with progression of glucose status ($-41.7\ cm^3$, $P<0.05$) and 2.3-fold greater in subjects with DM at baseline ($-42.3\ cm^3$, $P<0.05$). In a model that examined predictors of the decrease in TBV, glucose status at 2 years significantly predicted a decline, after adjusting for covariates (age, sex, TBV at baseline, history of hypertension, history of hyperlipidemia, use of lipid-lowering drugs), $\beta=-9.8$, $P<0.01$. Whilst 75% of the total variance in TBV at follow-up was explained by baseline TBV, 16% of the residual variance was explained by glucose status at follow-up.
Conclusion
This study in community-dwelling elderly people found that diagnosed DM as well as transition in glucose status to IFG or DM has an early and detrimental effect on brain volume assessed by MRI.

**Obestatin plays an opposite role in the regulation of pituitary somatotrope and corticotrope function in primates and mice**

R. Luque[1], J. Córdoba-Chacón[1,2], C. Grande[3], I. Gesmundo[3], M. Gahete[1,2], D. Gallo[3], A. Pozo-Salas[1], E. Ghigo[3], R. Granata[3], R. Kineman[2] & J. Castaño[1]
[1]University of Cordoba, Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), and CIBER Fisiopatología de la Obesidad y Nutrición, Córdoba, Spain; [2]University of Illinois at Chicago and Jesse Brown Veterans Affairs Medical Center, Research and Development Division, Chicago, IL; [3]University of Turin, Turin, Italy.

Obestatin is a 23-amino acid amidated peptide that is encoded by the ghrelin gene and was therefore presumed to have regulatory effects on pituitary. However, the limited set of studies performed hitherto suggests that obestatin has no major effect on hormone secretion, *in vivo* or *in vitro*, from rodent pituitary, whereas no comparable data is still available on primates. Here, primary pituitary cell cultures from a non-human primate (baboon; Papio anubis) served to test the effects of obestatin (100 nM; 24 h) on the function of all pituitary cell types. Results revealed that obestatin did not alter expression or release of prolactin, LH, FSH or TSH. Conversely, obestatin treatment stimulated proopiomelanocortin (POMC) expression and ACTH release, while, surprisingly, it inhibited GH expression and release. Interestingly, these in vitro effects of obestatin on primate pituitary cultures were completely mimicked in mice treated in vivo with obestatin, suggesting that the effects of obestatin on pituitary cell function are conserved across species. Furthermore, obestatin treatment downregulated Pit-1 in both primate and mice pituitary cells, as well as mouse hypothalamic GHRH expression, which might contribute to the inhibitory effect of obestatin on GH expression and release observed in both species. Conversely, obestatin up-regulated expression of pituitary CRF-R1 in both models, and increased pituitary In2-ghrelin variant in mice, which may contribute to its stimulatory effects on POMC expression and ACTH release in both experimental models. Obestatin also down-regulated expression of somatostatin receptors 1 and 2 in both models, and also inhibited hypothalamic cortistatin in mice, thus reinforcing the evidence for its regulatory role on the GH and ACTH axes. Taken together, our results provide the first comprehensive experimental evidence to support a potential role of obestatin in the direct and opposite control of pituitary somatotrope and corticotrope function in mice and, most importantly, in a primate model.

**Transcriptional regulation of prolactin by oestrogen *in vivo***

A. Patist[1], K. Featherstone[1], D. Spiller[1], S. Semprini[2], J. McNeilly[2], A. McNeilly[2], J. Mullins[2], M. White[1] & J. Davis[1]
[1]University of Manchester, Manchester, UK; [2]University of Edinburgh, Edinburgh, UK.

Circulating levels of prolactin are subject to acute and long-term regulation by many factors including oestrogen and dopamine. We have studied the regulation of prolactin promoter activity in living pituitary cells using transgenic Fischer rats in which reporter gene expression is regulated by the human prolactin gene locus (hPRL-d2EGFP). We have previously identified pulsatile prolactin transcription patterns in living lactotroph cells in fetal tissue, that became stabilised during neonatal development. In order to assess how transcription patterns are affected during physiological and supraphysiological prolactin upregulation in the adult, we have evaluated the expression of the hPRL-d2eGFP transgene during the oestrous cycle and in males with long-term oestradiol releasing implants, respectively.
Rats, injected with LHRH to synchronise oestrous cycles, were culled and pituitary glands harvested at proestrus, oestrus and diestrus. Flow cytometry indicated a 1.8-fold increase in the number of cells expressing detectable levels of the d2EGFP reporter at oestrus ($n=7$) as opposed to diestrus ($n=5$). Mean fluorescence per cell increased by 10.6-fold. Validation by qPCR, confirmed a 4.1-fold increase in the expression of d2EGFP mRNA and a 3.7-fold increase in the endogenous rat PRL mRNA. Immunofluorescence confirmed induction of EGFP and prolactin protein expression in tissue sections. These data indicate a major increase in transcription rate in individual cells, which is likely to be necessary to sustain the high level secretory output during proestrus and oestrus. Supraphysiological oestrogen stimulation in males caused a 2.5-fold increase in pituitary weight and transgene expression was shown to be upregulated by flow cytometry and qPCR.
Using live cell imaging of tissue slice preparations from oestrous animals, fluctuating gene expression was detectable in a proportion of cells. The spatio-temporal nature of these transcription patterns is currently being subjected to mathematical analysis to determine how they are modified by relative cell positions in the tissue.

## OC4.3

**miR-26a targets PRKCD in ACTH pituitary adenoma**

E. Gentilin, F. Tagliati, E. degli Uberti & M. Zatelli
University of Ferrara, Ferrara, Italy.

MicroRNAs (miRNAs) have several physiological functions, but have been also implicated in human neoplastic initiation and progression. We previously demonstrated that 30 miRNAs are differentially expressed in normal human pituitary as compared to pituitary adenomas. However, the most of miRNAs target genes remain unknown, hindering the understanding of the miRNAs contribute to pituitary tumorigenesis.

The aims of this study were to: (i) validate a murine ACTH-secreting pituitary adenoma cell line as a possible model to study pituitary miRNA deregulation; (ii) validate and investigate the role of potential targets of differentially expressed miRNAs. We analysed the murine AtT-20/D16v-F2 cell line, deriving from a murine ACTH-secreting pituitary adenoma, and normal mouse pituitary for the expression pattern of 11 miRNA, which expression was found to be different in human pituitary adenomas vs normal pituitary. Our results showed a partial agreement (50%) between expression trend of these miRNAs in human and mouse. In particular, we found that miR-26a has overlapping expression patterns in humans and mice, being up-regulated in adenomas vs. normal pituitary. Our results confirm that the 3′ untranslated region of PRKCD, a miR-26a putative target gene, is a functional target of this miRNA and provide evidence, by Real Time PCR, that this target is translationally suppressed. PRKCD, a member of the PKC subfamily, is dynamically involved in cell apoptosis in a specific stimulus manner. We observed that miR-26a inhibition led to a decrease in cell viability without increasing caspase 3/7 activity. These results indicate that miR-26a is overexpressed in human ACTH pituitary adenoma and can control cell viability in AtT-20/D16v-F2 cell line, by reducing the PRKCD expression, playing an important role in pituitary adenoma development. Our study provides new insights into potential contribution of these RNAs to pituitary neoplastic transformation and suggests that miR-26a might be a possible target for therapeutic strategies.

## OC4.4

**Identification of coupling specificity between somatostatin receptor 5 (SST5) and G proteins by a bioluminescence resonance energy transfer (BRET) technique: the role of GoA protein**

E. Peverelli[1], G. Mantovani[1], E. Vitali[1], M. Busnelli[2], B. Chini[2], A. Lania[1,3], P. Beck-Peccoz[1] & A. Spada[1]
[1]University of Milan, IRCCS Ospedale Policlinico, Milan, Italy; [2]CNR Institute of Neuroscience, Milan, Italy; [3]Istituto Clinico Humanitas IRCCS, Rozzano, Italy.

In this study we employed a novel bioluminescence resonance energy transfer (BRET) biosensor to study the coupling specificity of somatostatin receptor 5 (SST5) and its naturally occurring mutant R240W in living cells. Our previous data demonstrated that SST5 carrying the R240W mutation as well as other mutations in the third intracellular loop maintained the ability to inhibit intracellular cAMP levels similarly to the wild-type but failed to mediate the inhibition of intracellular calcium levels, GH release and cell proliferation, suggesting that different regions of SST5 are required for the activation of different signaling pathways. The BRET biosensor may monitor the activation of G proteins in response to SST5 activation by specific agonist BIM23206. The energy transfer occurs within two subunits of the heterotrimeric G protein complex, the energy donor (G alpha-Renilla Luciferase) and the acceptor (G gamma2-GFP10). G protein activation induces a structural rearrangement that increases the distance between the donor and the acceptor with a consequent decrease in the energy transfer. To detect specific G protein activation in living cells, we expressed in HEK293 cells wild-type or mutant SST5 together with different G protein (i1, i2, i3, oA, oB or q). We demonstrated that wild-type SST5 activated Gi (1, 2 and 3) and Go (A and B), whereas R240W SST5 maintained the ability to activate all Gi and GoB, but not GoA. As expected, neither the wild-type nor mutant receptors activated Gq. To investigate the role of GoA in SST5-mediated signal transduction in a pituitary cell model, we cotransfected cultured cells from GH-secreting adenomas with SST5 and a pertussis toxin (PTX)-resistant GoA protein. In PTX-treated cells, GoA restored the ability of BIM23206 to inhibit ERK1/2 phosphorylation and GH secretion. In conclusion, our data first demonstrated the coupling specificity of SST5 and revealed a crucial role for GoA in SST5 signaling in GH-secreting adenomas.

## OC4.5

**Targeting the IGF-IR system in pituitary tumors *in vitro*: antiproliferative action & pitfalls**

M. Theodoropoulou[1], M. Tichomirowa[2], V. Cerovac[1], J. Monteserin[1], H. Rubinfeld[3] & G. Stalla[1]
[1]Max Planck Institute of Psychiatry, Munich, Germany; [2]Medical Clinic, University of Mainz, Mainz, Germany; [3]Rabin Medical Center, Petach Tikva, Israel.

IGF-I receptors (IGF-IR) and their aberrant signaling cascade contribute to the pathogenesis of several solid cancers. Pituitary adenomas express IGF-IR and present with overactivation of the IGF-IR pathway. The aim of the study was to identify the potential antiproliferative action of the small molecule IGF-IR inhibitor NVP-TAE226 on acromegalic ($n=11$) and nonfunctioning pituitary adenomas (NFPA; $n=15$) in primary cell culture. Changes in cell viability were determined by thymidine incorporation and a nonradioactive colorimetric assay. The compound at the 100 nM concentration suppressed cell viability by more than 20% in 9 out of 15 NFPA (mean growth suppression as % of vehicle control: $30\pm15$) and in 10 acromegalic tumors ($29\pm7$), while at 10 nM it was efficacious in 8 NFPA ($24\pm10$) and 4 acromegalic tumors ($28\pm14$). Inhibiting the PI3K pathway in the same tumors using BEZ235 suppressed cell viability at 10 nM concentration in all NFPA ($48\pm20$) and in two acromegalic tumors ($31\pm15$). In contrast, mTOR inhibition with everolimus was efficacious in 4 out of 15 NFPA ($25\pm10$) and in all but one acromegalic cases ($48\pm17$). Put together, these data indicate a tumor specific dependency to the different IGF-IR signaling branches, with NFPA being sensitive to PI3K inhibition and acromegalic tumors to the mTOR inhibition.

IGF-IR inhibition in acromegalic tumors *in vitro* was accompanied by increased GH secretion (GH normalized to cell viability assay counts; mean suppression as % of vehicle control: $46\pm10$). Similar GH increase was observed after mTOR but not in the same extend after PI3K inhibition ($42\pm31$ vs $20\pm14$; $P=0.043$), indicating a role for the mTOR pathway on GH synthesis.

Altogether, IGF-IR inhibitors have a potential as antiproliferative agents for the treatment of NFPA. In contrast their potent antiproliferative action in acromegalic tumors is compromised by the concomitant increase in GH secretion.

## OC4.6

**Cell cycle G2/M transition is modulated by microRNAs in pituitary adenomas**

H. Butz[1], I. Likó[2], S. Czirják[3], M. Korbonits[4], K. Rácz[1] & A. Patócs[1,5]
[1]Faculty of Medicine, Semmelweis University, Budapest, Hungary; [2]Gedeon Richter Plc, Budapest, Hungary; [3]National Institute of Neurosurgery, Budapest, Hungary; [4]Barts and the London School of Medicine, Queen Mary University of London, London, UK; [5]Hungarian Academy of Sciences, Budapest, Hungary.

Background

Although pituitary adenomas are common endocrine neoplasms, the background of their pathogenesis has not clearly revealed. G1/S checkpoint alterations of the cell cycle have already been described in these tumours. MicroRNAs (miRs) which are small, non-coding RNA molecules, and posttranscriptionally regulate protein expression have also identified as potential pathogenic factors in certain cases. Our aim was to determine miR expression profile in pituitary adenomas, and validate targets of miRs that differentially expressed between normal and adenomatous pituitary.

Materials and methods
57 pituitary tissue samples were analyzed. MiR expression profiles were determined by TaqMan Low Density Arrays, selected miRs and genes were validated by real-time PCR. Multiple in silico target prediction algorithms were applied for identification of miR–mRNA interactions. Protein changes were detected using immunhistochemistry and Western blot. mRNA–miR interactions were proved using *in vitro* luciferase reporter system.
Results
162 differentially expressed miRs and those which were correlated with tumour size were determined in pituitary adenomas compared to normal tissues. Using target prediction we identified the downregulation of the Wee1 kinase protein by three overexpressed miRs targeting Wee1 proved by luciferase reporter gene experiment. 6 of 24 genes involved in G2/M transition were differentially expressed in adenoma tissues compared to normal tissue. Among CDC25 family that has opposite function to Wee1 Cdc25A and CDC25C were found to be overexpressed and its targeting miRs were underxpressed in pituitary adenomas.
Conclusion
Wee1 and CDC25 have opposite regulator effect on Cyclin B–CDK1 complex that controls G2/M transition of cell cycle. Our results show that in pituitary adenomas G2/M transition is complexly regulated by RNA interference through Wee1 and CDC25. Therapeutical approaches targeting miRs and members of G2/M transition are under development and based on our results these may have therapeutical significance in treatment of pituitary adenomas.

**GH ameliorates impaired glucose tolerance in obese mice by modifying the visceral fat condition through adiponectin**

Y Okamoto, M Fukushima, S Ishii, M Okamoto, H Katsumata & S Minami
Nippon Medical School, Kawasaki, Japan.

Objectives
Secretion of GH, a pituitary and anabolic hormone that reduces visceral fat, is diminished in obese or elderly subjects. The reduced GH may induce visceral fat accumulation and subsequently accelerate metabolic syndrome in these population. In the present study, we sought the effect of chronic GH supplement on visceral fat and glucose metabolism in diet-induced obese (DIO) mice.
Methods and results
Male obese mice (C57BL/6, 12 weeks old) under high fat/high sucrose (HF/HS) diet were treated with daily injection of GH (5 μg/g body weight, $n=6$) or PBS (control, $n=6$) for 6 weeks. GH markedly reduced the mass of epididymal fat (Epi; PBS: $1.68\pm0.14$ vs GH: $1.13\pm0.04$ g, $P<0.0001$) and increased that of skeletal (gastrocnemius) muscle (PBS: $0.31\pm0.01$ vs GH: $0.36\pm0.02$ g, $P<0.0001$). Intra-peritoneal glucose tolerance test (IPGTT) demonstrated that GH dramatically ameliorated the impaired glucose tolerance (IGT) in the DIO mice. Real-time quantitative PCR analyses with Epi showed that GH significantly increased the expressions of adiponectin (40.8%, $P<0.05$), anti-inflammatory M2 macrophage markers (IL10: 66.4%, $P<0.05$; CD206: 41.4%, $P<0.01$), anti-oxidant enzyme (glutathione peroxidase: 36.6%, $P<0.05$) compared with control. Moreover, GH lowered the plasma levels of thiobarbituric acid reactive substance (TBARS), an oxidative stress marker, by 22.1% (PBS: $4.48\pm0.23$ vs GH: $3.49\pm0.17$ μM, $P<0.05$), in the DIO mice. However, in adipoectin-deficient mice under HF/HS diet, GH supplement neither changed the mass of Epi and skeletal muscle, nor modified IGT.
Conclusion
Chronic GH supplement mitigates IGT in DIO mice by modifying visceral fat mass, inflammation and oxidative stress likely through adiponectin.

### OC5.2

**Production of galectin-1, -3, -9 and -12 in adipose tissue of lean and obese mice**

D. Rhodes[1], M. Pini[1], T. Montero-Melendez[2], D. Cooper[2], M. Perretti[2] & G. Fantuzzi[1]
[1]University of Illinois at Chicago, Chicago, Illinois, USA; [2]Barts and the London School of Medicine, Queen Mary University of London, London, UK.

Introduction
Obesity is characterized by an expanded and chronically inflamed adipose tissue (AT). The galectin (Gal) family of proteins exerts a variety of activities, including regulation of inflammation and adipogenesis.
Methods
We used RT-PCR, ELISA and flow cytometry to evaluate regulation of expression and production of 4 members of the Gal family – Gal1, Gal3, Gal9 and Gal12 – in visceral (VAT) and subcutaneous (SAT) adipose tissue of male C57BL6 mice fed a low (LFD) or high fat diet (HFD) for 5, 9, 13, 17 and 24 weeks.
Results
Feeding a HFD induced a progressive elevation in body weight and circulating leptin levels that was accompanied by a significant increase in serum levels of Gal1 and Gal3. Expression of each of the 4 Gal did not significantly change over time in either VAT or SAT of LFD mice. In mice fed a HFD there was a progressive and significant increase in expression of the anti-inflammatory Gal1 and Gal9 selectively in SAT, whereas expression of the pro-inflammatory Gal3 significantly increased in both VAT and SAT of HFD-fed mice. Expression of Gal12, which modulates adipogenesis, significantly declined over time in VAT, but not SAT, of HFD mice, following a trend comparable to adiponectin. Evaluation of cellular expression indicated that both adipocytes and the stromovascular fraction (SVF) produced Gal1 and Gal3, while Gal9 was predominantly produced by the SVF and Gal12 almost exclusively by adipocytes. Flow cytometry analysis demonstrated increased production of Gal3 and Gal9, but not Gal1, in both CD11c− and CD11c+ macrophages obtained from VAT, but not SAT, of HFD versus LFD mice.Conclusions: Our data indicate that feeding a HFD leads to differential modulation of Gal1, Gal3, Gal9 and Gal12 in macrophages and adipocytes in VAT and SAT, suggesting that Gal proteins may actively participate in regulating inflammation and adipogenesis in obesity.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### OC5.3 The Young Investigator Winner

**Insulin action in brown adipose tissue is compromised during diet-induced obesity**

C. Quarta[1], R. Mazza[1], P. Iozzo[3], S. Obici[2], R. Pasquali[1] & U. Pagotto[1]
[1]S.Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy; [2]University of Cincinnati, Cincinnati, Ohio, USA; [3]National Research Council, Pisa, Italy.

Increasing evidences indicate that brown adipose tissue (BAT) functional activity is reduced during obesity. The nature of this deficit in BAT function, however, is still poorly understood. To analyze whether insulin function in the BAT is altered during obesity, we studied the in vivo metabolic activity of BAT by PET/CT imaging and euglycaemic hyperinsulinemic clamp in lean and diet-induced obese mice. Three groups of mice were analyzed after administration of different diet regimens leading to progressive obesity levels: standard chow diet (SD), high fat diet (HFD, 40% fat), super high fat diet (SHFD, 60% fat). Glucose uptake in the BAT was assessed analyzing 18F-FDG accumulation (a PET tracer glucose analogue) on PET/CT images. Insulin strongly increased PET signal in BAT of SD mice, whereas insulin induced 18F-FDG uptake was lower in HFD group, and completely absent in SHFD group. To analyze whether insulin exerts a role on BAT thermogenesis, we recorded BAT temperature during euglycaemic hyperinsulinemic clamp studies by the means of telemetric probes surgically implanted in the tissue. Insulin was able to reduce BAT thermogenesis in lean mice, whereas obese mice were not able to respond to insulin-induced modifications in BAT activity. To analyze the effect of insulin on glucose storage; glycogen accumulation into the BAT was studied analyzing glycogen content in the tissue at the end of the clamp procedure. Insulin-induced glycogen accumulation was impaired in BAT of obese mice. QT-PCR and Western blot analysis of the protein PTG (protein targeting to glycogen) confirmed the presence of a compromised glycogen metabolism in the BAT of obese mice.

These data show that during diet-induced obesity, BAT is not able to correctly respond to insulin with respect to glucose uptake, glycogen accumulation and thermogenesis modifications thus indicating that obesity leads to metabolic inflexibility in BAT.

## OC5.4

**Bile acid binding resin shows anti-obese effect through the modifications of intestinal microbiota**

Y. Kusumoto[1], J. Irie[1], H. Tagawa[1], A. Itoh[1], M. Kato[1], N. Kobayashi[1], K. Tanaka[1], S. Yamada[2], T. Kawai[1] & H. Itoh[1]

[1]Keio University School of Medicine, Shinjuku, Japan; [2]Kitasato University Kitasato Institute Hospital, Minato, Japan.

The growing epidemic of obesity has led health professionals to understand the pathophysiology of obesity and its complications. Gut microbiota are of special interest, since some kinds of microbiota such as Bacteroides are less in obese persons and some microbiota induce obesity in animals by effective fat storage through microbiota-mediated intestinal Fiaf (Fasting-induced adipose factor) suppressions. Recently, bile acid-binding resins (BARs), non-absorbable drug for dyslipidemia, were reported to prevent obesity in rodents and humans, but the precise mechanisms and the effects to microbiota are unclear. Here we report the impact of BAR to gut microbiota and environments.

Six-week-old male BALB-c mice were fed standard diet, high-fat diet or high-fat diet with 1.5% of BAR (colestimide). Body compositions and gene expression were analyzed after 12-week treatment. The compositions of gut microbiota were studied by 16S rDNA analysis of cecal contents. The same procedures were performed under the germ-free conditions.

The administration of BAR significantly reduced the body weight and intra-abdominal fat gain ($P<0.01$). The decrease of gut Bacteroides and the increase of Clostridium in high-fat group were observed compared with normal diet, and the administration of BAR induced the increase of Bacteroides and the decrease of Clostridium ($P<0.05$). The intestinal fiaf expression decreased significantly with high-fat diet and increased significantly by BAR. These anti-obese effects of BAR disappeared under germ free conditions and the germ-free mice conventionalized with standard flora showed reduced body weight gain as shown in normal BAR-treated mice.

In conclusion, BAR has anti-obese effects through the changes of gut microbiota and environments. The modulation of gut microbiota by changing intestinal bile acid flux would be the novel therapeutic target for obesity.

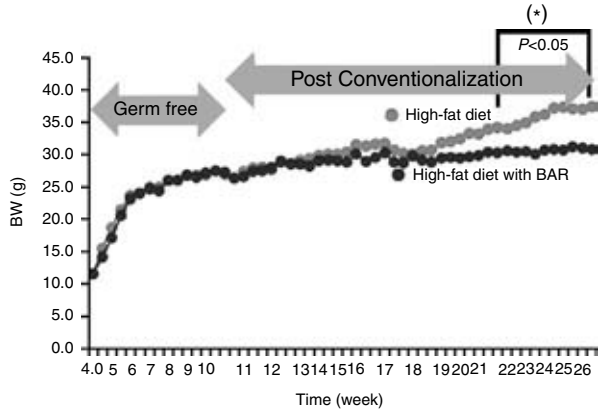

**Fig 1** BAR shows anti-obese effects through gut microbiota

## OC5.5

**Development of leptin deficient *Lep$^{mkyo}$/Lep$^{mkyo}$* rat-evidence for its superiority over *Lep$^{ob}$/Lep$^{ob}$* mouse as a model for human obesity**

M. Aizawa-Abe[1,2], K. Ebihara[1,2], C. Ebihara[1], T. Kusakabe[1], D. Aotani[1,2], V. Gumbili[1], T. Mashimo[1], T. Serikawa[1] & K. Nakao[1]

[1]Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Kyoto University Hospital, Kyoto, Japan.

Introduction

It is critical to consider species differences in translating the findings of obesity-model animals into human pathophysiology. Leptin plays an important role in regulating energy homeostasis. Although much has been learned from genetically obese leptin deficient *Lep$^{ob}$/Lep$^{ob}$* mice, some flaws were noted in mice as animal models for human diabetes.

Methods

To develop a rat leptin-deficient model, we use N-ethyl-N-nitrosourea (ENU) mutagenesis followed by high-efficient screening system. To compare the effect of thiazolidinediones (TZDs) on fatty liver between mouse and rat, we treated 12-week-old male leptin-deficient mice and rats with pioglitazone or rosiglitazone. Parameters of glucose and lipid metabolism, adiposity and PPARγ gene expression in the liver were examined.

Results

We found a leptin-deficient rat strain, Lepmkyo/Lepmkyo, which had a nonsense mutation (Q92X) within the leptin gene. *Lep$^{mkyo}$/Lep$^{mkyo}$* rats showed morbid obesity, glucose intolerance, hypertriglyceridemia and fatty liver, which are comparable to *Lep$^{ob}$/Lep$^{ob}$* mice. In a striking contrast, treatments with TZDs disclosed marked deterioration of steatohepatitis in obese *Lep$^{ob}$/Lep$^{ob}$* mice, while they improved steatohepatitis in obese *Lep$^{mkyo}$/Lep$^{mkyo}$* rats as in obese individual. TZDs differentially regulated hepatic peroxisome proliferator-activated receptor gamma (PPARγ) mRNA expression and body fat distribution between *Lep$^{ob}$/Lep$^{ob}$* mice and *Lep$^{mkyo}$/Lep$^{mkyo}$* rats. The present study demonstrates the superiority of *Lep$^{mkyo}$/Lep$^{mkyo}$* rats over *Lep$^{ob}$/Lep$^{ob}$* mice as animal models of obesity.

Conclusion

The present study provides an evidence of the superiority of *Lep$^{mkyo}$/Lep$^{mkyo}$* rats over *Lep$^{ob}$/Lep$^{ob}$* mice as a model for human obesity.

Context

Alterations in white adipose tissue (WAT) function, including changes in extracellular matrix (ECM) composition, play an important role in conditions of both weight gain and loss.

Objective

We set out to identify novel genes regulated by obesity and cancer cachexia in human scWAT with potential roles for adipocyte function and/or tissue remodelling.

Design Candidate genes were selected by overlapping previously published global gene expression profiles in human WAT ($n=X$) with functional RNAi screens assessing lipid droplet morphology in Drosophila S2-cells. *In vitro* experiments were performed in primary cultures of human preadipocytes/adipocytes.

Results

33 genes regulated by obesity/cachexia had orthologues in Drosophila and of these two affected lipid droplet morphology in the RNAi screen. One of the two,

semaphorin 3C (SEMA3C), encodes a secreted factor not previously studied in human adipocytes. SEMA3C mRNA expression was increased in obesity and decreased in cancer cachexia. In addition, SEMA3C was predominantly expressed/secreted by mature adipocytes. Incubating human adipocytes with recombinant SEMA3C had no effect on differentiation, lipolysis, glucose transport or the expression of lipid oxidation genes which could be explained by the significant down-regulation of the SEMA3C receptors/co-receptors during adipocyte differentiation. In contrast, incubation of human pre-adipocytes with SEMA3C increased the production of the ECM-related factors fibronectin 1 and connective tissue growth factor in a concentration-dependent manner without any effects on differentiation.
Conclusions
SEMA3C is a novel adipokine altered by weight changes that regulates the expression of ECM genes in preadipocytes. SEMA3C may therefore play a role in tissue plasticity and remodelling.

**GnRH release failure in hyperprolactinemia is caused by a Kisspeptin deficiency**

C. Sonigo[1], J. Bouilly[1], N. Carré[1], V. Tolle[2], P. Zizzari[2], A. Caraty[3], J. Tello[4], F. Simony[4], R. Millar[4,5], J. Young[1,6] & N. Binart[1]
[1]Univ Paris-Sud, Faculté de Médecine Paris-Sud, Le Kremlin-Bicêtre, France; [2]Centre de Psychiatrie et Neurosciences, Univ Paris Descartes, Paris, France; [3]Univ. de Tours, Nouzilly, France; [4]University of Edinburgh, Edinburgh, EH8 9XD, UK; [5]University of Cape Town, Pretoria, South Africa; [6]Hôpital du Kremlin Bicêtre, Le Kremlin Bicêtre, France.

Hyperprolactinemia is the most common cause of hypogonadotropic anovulation in women. It is related to an alteration of pulsatile GnRH secretion. This gonadotropic deficiency has been proposed to result from direct suppression of prolactin (PRL) on GnRH release but its mechanism remains unknown. Because GnRH neurons do not express unequivocally the PRL receptor, and are stimulated by kisspeptin (Kp) neurons which do express PRL receptors, we hypothesized that GnRH deficiency in this condition could be due to a decrease in Kp secretion. To test this we developed and characterized a hyperprolactinemic female mouse model mimicking the human pathology and analyzed the ability of Kp10 i.p. administration to restore gonadotropin secretion and cyclicity
We demonstrated that 28 days administration of PRL by micropumps, significantly inhibited mouse ovarian cyclicity evaluated by vaginal smears, and decrease corpora lutea (CL) number, reflecting ovulation rate impairment. This anovulation was related to a significant downregulation of pituitary *LHβ* and *FSHβ* transcripts indicating a gonadotropin deficiency in this model. Hypothalamic *GnRH* expression was not altered while there was, a significant decrease of Kp mRNA and peptide (hypothalamic staining) suggesting a role of *Kp* decrease in GnRH release alteration in hyperprolactinemic female mice. We then demonstrated that Kp-10 administration restored cyclicity, ovulation and pituitary gonadotropin expression in hyperprolactinemic mice. Using hypothalamic explants, we also demonstrated that *in vitro* decrease of GnRH release induced by PRL was rescued by Kp-10 administration.
Together with the recent demonstration that Kp neurons express high levels of PRL receptor, our data suggest that PRL excess acts directly on Kp neurons to suppress Kp secretion and downstream GnRH secretion. Kp neurons appear, therefore, to be the missing link between hyperprolactinemia and GnRH deficiency in mammals.

**Ghrelin modulates fertilization, early embryo development and implantation**

E. Luque, L. Vincenti, G. Stutz, M. Santillán, R. Ruiz, M. Fiol de Cuneo & A. Martini
Instituto de Fisiología, Córdoba, Argentina.

Ghrelin (Ghr) acts as a link between energy balance and reproduction; hence, hyperghrelinemia reduces reproductive success. In addition, this hormone has an evident physiological role on reproduction, since Ghr and/or its receptor are synthesized by gametes/embryos and several reproductive tissues (including decidua/placenta); in addition, Ghr plasma concentration rises during gestation. The objectives of our study were to evaluate the effects of ghrelin administration (4 nmol/animal/day; sc) or endogenous ghrelin inhibition (by 6 nmol/animal/day of (D-Lys3)GHRP-6; sc) on mice fertilization, embryo development and implantation. We carried out three experiments treating female mice with Ghr and/or its antagonist: i) from one week previous to 12 hours after copula, sacrificing mice at Day 18 of pregnancy; ii) from ovulation induction to 80 hours after ovulation, when we retrieved embryos from uterus and iii) from Day 3 to Day 7 of pregnancy (peri-implantation period), sacrificing mice at Day 18.
Experiment 1: the antagonist increased the percentage of females with one/more atrophied fetuses (antagonist: 75.0% vs control: 11.1%; $n=8$–11 females/group; $P<0.0134$). Experiment 2: the antagonist significantly diminished induced ovulation and fertilization and both, Ghr and the antagonist, delayed embryo development (embryos in blastocyte stage: Ghr 40.8%, Ghr+antagonist 28.9% and antagonist 36.8% vs control 66.3%; $n=76$–136 embryos/treatment, $P<0.0001$). In experiment 3, Ghr and the antagonist significantly diminished fetuses weight and dams weight gain during gestation. Moreover, Ghr augmented the percentage of embryo loss (TM$\pm$SEM; Ghr: $17.3\pm6.58$ and Ghr+antagonist: $13.3\pm3.7$ vs control: $3.9\pm4.8$ and antagonist: $6.7\pm4.0$; $n=9$–12 females/treatment; $P=0.045$) and again, Ghr and the antagonist increased fetuses atrophy (Ghr: 71.4%, Ghr+antagonist: 44.4% and antagonist 62.5% vs control: 0%; $n=7$–10 females/group; $P<0.01$).
Our results suggest that hyperghrelinemia and/or endogenous ghrelin inhibition exerted immediate and long lasting effects on oocyte/embryo quality, implantation and embryo/fetal development, supporting the hypothesis that ghrelin has modulatory actions on these reproductive processes.

**LH and hCG produce different responses in human granulosa lutein cells *in vitro***

L. Casarini[1], E. Pignatti[1], A. La Marca[2], T. Marsella[2], D. Tagliasacchi[2], F. Adversi[2], M. Lispi[3], S. Longobardi[3] & M. Simoni[1]
[1]University of Modena and Reggio Emilia, Modena, Italy; [2]University Hospital of Modena, Modena, Italy; [3]Merck KGaA, Rome, Italy.

Introduction
LH and hCG act on the same receptor (LHCGR), but it is not known whether they elicit the same cellular and molecular response. This study aims at comparing the activation of cell-signalling pathways and gene expression in response to LH and hCG.
Design
We evaluated the activation of cAMP, ERK and AKT-pathways and progesterone production by ELISA and Western blotting in human primary granulosa cells (hGLC) stimulated for up to 36 hours with equipotent doses of LH or hCG. The expression of target genes was measured by real-time PCR after 12-hours of stimulation with either gonadotropin, using specific ERK or AKT-pathways inhibitors (U0126 and LY294002) to differentiate their effects on gene expression.
Results
Continuous exposure of hGLC to equipotent doses of LH or hCG for 36 hours revealed that the intracellular cAMP production is pulsatile with a frequency of about 3–4 hours, with significantly higher stimulation by hCG vs LH (t-test; $P<0.05$; $n=3$), despite no differences in progesterone production, which increased progressively. Conversely, phospho-ERK and -AKT activation was more potent and sustained by LH vs hCG over 1 hour (t-test; $P<0.05$; $n=4$).

hCG was almost inactive on AKT. Finally, LH significantly increased the expression of NRG-1 and CYP19A1 genes after ERK inhibition, while hCG decreased the expression of AREG after AKT inhibition (t-test; $P<0.05$; $n=3$).
Conclusions
In terms of cAMP production, hGLC respond to equipotent, constant LH or hCG stimulation in a pulsatile fashion. Acutely, hCG is more potent on cAMP production, while LH is more potent on the ERK and AKT activation. The early inhibition of ERK and AKT results in the differential induction of expression of target genes depending on ligand, indicating that the LHCGR is able to differentiate the activity of LH and hCG.

## OC6.4

**Female fertility and activin-stimulated Fshb expression do not require SMAD2/3 in murine gonadotropes**

J. Fortin & D. Bernard
McGill University, Montreal, Quebec, Canada.

In mammals, follicle-stimulating hormone (FSH), produced by pituitary gonadotropes, is required for proper gonadal function and female fertility. The TGFβ superfamily members, activins, are critical regulators of FSH synthesis. Activins signal through heteromeric type I/type II receptor complexes and the effector proteins SMADs 2 and 3 to regulate gene transcription. Numerous studies in gonadotrope-like cell lines suggest that activin-stimulated FSH β subunit (Fshb) transcription is mediated by SMAD2/3. To test the hypothesis that SMAD2/3 are required in gonadotropes for proper FSH synthesis and reproductive axis activity *in vivo*, we generated mice with gonadotrope-specific deletion of Smad2/3 (hereafter Smad2/3KO) by crossing Gnrhr-IRES-Cre (GRIC) mice with those carrying conditional (floxed) Smad2 and Smad3 alleles. Female Smad2/3KO mice had diminished estrous cycle frequency and spent more time in estrus than control females as assessed by daily inspection of vaginal cytology. However, in metestrus/diestrus, Smad2/3KO ovarian and uterine weights were comparable to those of control mice. Importantly, the frequency and size of litters produced over a six month period by Smad2/3KO females paired with wild-type males were indistinguishable from controls. Smad2/3KO males had slightly reduced testes weights but were fertile. Surprisingly, pituitary Fshb expression was normal in both male and female Smad2/3KO mice. In light of these results, we examined whether SMAD2/3 are required for activin A-regulated Fshb expression in gonadotropes ex vivo. Primary pituitary cells from mice carrying floxed Smad2/3 alleles were infected with control or Cre-expressing adenovirus. Despite >95% depletion of Smad2/3 mRNA in Cre infected cultures, inhibitory effects on basalFshb and activin A-induced Fshb expression were modest. Together, our data challenge the current model that FSH synthesis depends on SMAD2/3-mediated signaling.

**Dihydrotestosterone treatment in mice induces a persistent polycystic ovary syndrome phenotype**

E. van Houten, P. Kramer, B. Karels, A. McLuskey, A. Themmen & J. Visser
Erasmus MC, Rotterdam, Netherlands.

Polycystic ovary syndrome (PCOS), the most common endocrine disorder in women in their reproductive years, is defined by two out of the following three criteria: hyperandrogenism, oligo/anovulation, and polycystic ovaries. Affected women are often obese and insulin-resistant. Recently, we developed a mouse PCOS-model through chronic exposure to dihydrotestosterone (DHT). Here, we studied whether the PCOS-phenotype remains after withdrawal of DHT treatment, which would more closely resemble PCOS in women.
Prepubertal mice were treated with a 90-days continuous release DHT or placebo pellet. After treatment (90 days) mice were sacrificed (chronic group, $n=17$) or allowed a 30-day wash-out period before sacrifice (sustained group, $n=17$). Before sacrifice mice vaginal smears were taken and an Intraperitoneal Glucose Tolerance Test (IPGTT) ($n=8$–9 per group) or an Insulin Tolerance Test (ITT) ($n=8$–9 per group) was performed.
After 90 days, DHT-treated mice were acyclic, their ovaries contained antral follicles with a cyst-like structure and an increased number of atretic follicles, bodyweights were higher, and chronically DHT-treated mice were glucose intolerant.
Mice of the sustained group remained anovulatory, their ovaries still contained cyst-like follicles and an increased number of atretic follicles. In contrast to the chronically DHT-treated mice, DHT-treated mice of the sustained group had an increased number of healthy follicles compared to placebo-treated mice. Bodyweight and weights of fat depots remained significantly increased in the sustained group and mice remained glucose intolerant. Insulin sensitivity did not appear to be affected in the DHT-treated mice, although the counter regulatory mechanisms after insulin administration were impaired in both the chronically and sustained DHT-treated mice.
We confirmed that chronic DHT-treatment induces a PCOS-like phenotype in mice. A 30-day wash-out period did not improve the ovarian and metabolic phenotypes. This suggests that in mice after a 90-day DHT treatment period, a sustained PCOS phenotype is induced.

**Kit ligand-c-kit interaction regulates estradiol production by rat granulosa cells via oocyte factors**

T. Miyoshi, F. Otsuka, E. Nakamura, K. Inagaki & H. Makino
Okayama University Graduate School, Okayama, Japan.

Kit ligand (KL)-c-kit interaction is critical for oogenesis and folliculogenesis in the ovary. However, the significance of KL-c-kit loop in ovarian steroidogenesis has yet to be elucidated. We here investigated the impact of KL-c-kit interaction in regulation of steroidogenesis using rat primary granulosa cells co-cultured with oocytes. Treatment with soluble KL suppressed FSH-induced estradiol production and aromatase mRNA expression without changing FSH-induced progesterone production. Blocking the KL-c-kit interaction by its neutralizing antibody increased FSH-induced estrogen production by granulosa cells, suggesting that endogenous KL is functionally involved in suppression of estrogen production by granulosa cells through the interaction between KL and its receptor c-kit on oocytes. The cAMP-PKA pathway activity was not involved in the KL and c-kit actions on estrogen regulation in granulosa cells. To explore the possible oocyte factors induced by KL-c-kit interaction, changes in the expression levels of major oocyte factors including BMP-15, GDF-9 and FGF-8 were investigated. It was of note that KL increased the expression levels of oocyte-derived FGF-8 and GDF-9, while it reduced the expression levels of oocyte-derived BMP-15 in the oocyte-granulosa co-culture. Based on the findings that FGF-8, but not BMP-15 or GDF-9, suppressed FSH-induced estrogen production by granulosa cells, oocyte-derived FGF-8 is possibly involved in suppression of FSH-induced estrogen production through the KL-c-kit interaction. Furthermore, the KL suppression of FSH-induced estrogen production in the co-culture was reversed by the FGFR inhibitor SU5402, which was additionally reversed by the combined treatment with extracellular-domain protein of BMPRII that antagonizes BMP-15 and GDF-9. These data suggest that endogenous oocyte factors including FGF-8 and BMP-15/GDF-9 are likely to be involved in the KL activity that inhibits FSH-induced estradiol production. Thus, KL-c-kit interaction plays a regulatory role in estrogen production through oocyte-granulosa communication.

**Progression-free survival without treatment of malignant pheochromocytoma and paraganglioma at one year**

S. Hescot[1], S. Leboulleux[1], L. Amar[2], I. Borget[1], D. Vezzosi[9], R. Libé[3], P. Niccoli[5], F. Borson-Chazot[7], C. Do Cao[6], A. Tabarin[4], C. de la Fouchardiere[10], I. Raingeard[11], C. Chougnet[1], A. Gimenez-Roqueplo[2], J. Young[8], J. Bertherat[5], J. Wémeau[6], X. Bertagna[3], M. Schlumberger[1], P. Plouin[2] & E. Baudin[1]
[1]Institut Gustave Roussy, Villejuif, France; [2]Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Paris, France; [3]Assistance Publique Hôpitaux de Paris, Hôpital Cochin, Paris, France; [4]Hôpital Haut Lévêque, Centre Hospitalier Universitaire de Bordeaux, Bordeaux, France; [5]CHU Timone, Marseille, France; [6]Hôpital Claude Huriez, CHU Lille, Lille, France; [7]groupement hospitalier Lyon-Est, Bron, France; [8]Assistance Publique Hôpitaux de Paris, Hôpital Bicêtre, Le Kremlin-Bicetre, France; [9]Centre Hospitalier Universitaire Larrey, Toulouse, France; [10]Leon-Berard Cancer Center, Lyon, France; [11]Hôpital Lapeyronie, Montpellier, France.

Pheochromocytoma and paraganglioma are defined as malignant by the occurence of metastasis in extra paraganglionic sites. The natural evolution of these tumors remains unknown.
The aim of our retrospective study was to define the progression-free survival (PFS) of untreated Malignant Pheochromocytoma and Paraganglioma (MPP) at 12 months (12 m-PFS) and to look for prognostic markers of 12 m-PFS. We analyzed clinical parameters of patients followed within 8 centers of the INCa-COMETE and GTE-RENATEN French networks. Patients were included whether they had a diagnosis of metastasis between 01/01/2001 and 01/01/2011. Progression was defined according to RECIST 1.1 for morphologic imaging and by the appearance of new lesions on scintigraphic imaging.
Ninety-three files were reviewed on site. Among them, 57 untreated patients for whom a follow-up strategy was first proposed, were included (34 males, 23 females), with a median age of 51 years (17–80). Median time since initial diagnosis was 17 months (0–341). Primary tumors were 47% pheochromocytomas ($n=27$), 40% abdominal paragangliomas ($n=23$) and 13% head and neck paragangliomas ($n=7$). A pheochromocytoma/paraganglioma genetic test was performed in 54 patients. None mutation was identified in 27 of the patients (50%) whereas 20 patients (37%) carried a SDHB mutation, one patient had neurofibromatosis type 1, one von Hippel-Lindau disease, two a SDHD- and two a SDHC-hereditary paraganglioma. Median follow-up was 2.4 years, (range = 0.4–5.7). 12 m-PFS without treatment was assessed to 46% (33–59). No significant prognostic markers of 12m-PFS were found. Untreated patients presented more frequent peritoneal metastases and less frequent bone metastases than directly-treated patients ($P<0.05$).
Forty-six percent of MPP have a stable disease without treatment at 1 year. If patients are asymptomatic, we recommend a first imaging work-up at 3 months, a wait-and-see policy and/or local treatments in the absence of progression on imaging.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### OC7.2

**Activation of the PKA pathway triggers formation of an illicit serotonergic regulatory loop in primary pigmented nodular adrenal disease (PPNAD) tissues associated with Cushing's syndrome**

Z. Bram[1], S. Renouf[1], C. Duparc[1], B. Ragazzon[2], R. Libe[2], A. Martinez[3], C. Stratakis[4], J. Bertherat[2], E. Louiset[1] & H. Lefebvre[1,5]
[1]Institute for Biomedical Research and Innovation, University of Rouen, Rouen, France; [2]University Paris V, Cochin Institute, Paris, France; [3]Clermont University, Aubiere, France; [4]NIH, Bethesda, Maryland, USA; [5]Institute for Biomedical Research and Innovation, University Hospital of Rouen, Rouen, France.

In the normal adrenal gland, serotonin (5-HT) stimulates cortisol secretion through activation of 5-HT4 receptors whereas, in some macronodular adrenal hyperplasia tissues, the corticotropic effect of 5-HT is mediated by ectopic 5-HT7 receptors. The aim of the present study was to investigate the role of 5-HT in the control of cortisol secretion in PPNAD tissues from 12 patients by using molecular, immunohistochemical and pharmacological approaches. RT-PCR studies revealed overexpression of the genes encoding tryptophan hydroxylase, the key enzyme of 5-HT synthesis, and the 5-HT4 and 5-HT7 receptors, in comparison with normal adrenals. Tryptophan hydroxylase was detected in hyperplastic nodules by immunohistochemistry. 5-HT dose-dependently increased cortisol production by PPNAD cells derived from 6 patients. The potency and efficacy of 5-HT to stimulate cortisol were higher in PPNAD than in normal adrenocortical cells. 5-HT was also able to increase expression of the CYP11B1 gene, which encodes the steroidogenic enzyme 11alpha-hydroxylase, in the PPNAD immortalized cell line LT2. Both the 5-HT4 receptor antagonist GR113808 and the 5-HT7 receptor antagonist SB269970 significantly inhibited the stimulatory effect of 5-HT on cortisol by reducing the potency and efficacy of the indolamine. These data indicate that, in PPNAD cells, the stimulatory action of 5-HT on cortisol release is mediated by both the eutopic 5-HT4 receptor and an ectopic 5-HT7 receptor. In most patients, PPNAD results from inactivating mutations of the PRKAR1A gene which cause enhancement of the PKA pathway. In the adrenocortical cell line H295R, inhibition of PRKAR1A gene expression markedly stimulated expression of tryptophan hydroxylase, 5-HT4 and 5-HT7 receptor mRNAs. Taken together, our results show that activation of the PKA pathway triggers formation of an illicit serotonergic regulatory loop in PPNAD tissues associated with Cushing's syndrome. **Ribonucleotide reductase large subunit (RRM1) gene expression predicts efficacy of adjuvant mitotane in adrenocortical cancer**

M. Volante[1], M. Terzolo[1], M. Fassnacht[2], I. Rapa[1], A. Germano[1], S. Sbiera[2], F. Daffara[1], P. Sperone[1], G. Scagliotti[1], B. Allolio[2], M. Papotti[1] & A. Berruti[1]
[1]University of Turin, Turin, Italy; [2]University Hospital Wurzburg, Wurzburg, Germany.

Purpose
Mitotane is the reference systemic therapy for adrenocortical carcinoma (ACC), but its mechanism of action and possible predictors of treatment response remain poorly defined. Our aim was to evaluate the gene expression of ribonucleotide reductase large subunit 1 (RRM1) and excision repair cross-complementation group 1 (ERCC1) in ACC as potential biomarkers for clinical outcome and response to mitotane.
Experimental design
Forty-five and 47 tissue samples from two cohorts (Orbassano, Italy; Wurzburg, Germany) of completely resected ACC were centrally analyzed using Real Time PCR for RRM1 and ERCC1 expression. Fifty-four patients received surgery alone and 38 received adjuvant mitotane after surgery. Clinical and pathological features were highly comparable in the two series. H295R and SW-13 ACC cell lines were also used for pharmacological tests.
Results
ERCC1 gene expression was not associated to clinical outcome. In contrast, high RRM1 gene expression was associated to shorter disease-free and overall survival at both univariate and multivariate analysis. In patients with low RRM1 gene expression adjuvant mitotane was associated with improved disease free survival, whereas this effect was lost in cases expressing high RRM1. *In vitro* mitotane induced strong up-regulation of RRM1 transcription (up to 25-fold increase) in mitotane-insensitive SW-13 cells but not in mitotane-sensitive H295R cells.
Conclusion
Our *in vitro* and *in vivo* data indicate that RRM1 gene expression is functionally associated to mitotane sensitivity and represents the first biomarker in ACC predicting response to adjuvant mitotane.

## OC7.4

**Differential diagnosis of primary aldosteronism by peripheral plasma levels of 18-oxo-cortisol: a noninvasive method with a high specificity**

F. Satoh, R. Morimoto, M. Kudo, Y. Iwakura, Y. Ono, K. Takase, Y. Nakamura, H. Sasano & S. Ito
Tohoku University Hospital, Sendai, Japan.

18-Oxocortisol (18-oxoF) is a derivative of cortisol (F) that is produced by aldosterone synthase (CYP11B2), and its clinical usefulness has not been clarified. We prospectively measured 18-oxoF, using highly sensitive liquid chromatography-tandem mass spectrometry (LC/MS/MS), in peripheral plasma of patients with primary aldosteronism (PA) who underwent adrenal venous sampling (AVS) to differentiate aldosterone producing adenoma (APA) from bilateral hyperplasia. The study was performed in 116 patients with surgically-proven APA and 121 patients with bilateral hyperplasia diagnosed by AVS which was successfully performed. The levels of 18-oxoF were significantly higher in the peripheral plasma from the patients with APA than that from the patients with bilateral hyperplasia (bilateral hyperaldosteronism (BHA) diagnosed by AVS and surgically-proven idiopathic hyperaldosteronism (IHA) were shown in Fig. 1). The cutoff value (4.7 ng/dl) of 18-oxoF levels was calculated by ROC analysis with sensitivity of 0.64 and specificity of 0.97. In the cases with CT-positive unilateral adrenal masses, the cutoff value (4.6 ng/dl) of 18-oxoF levels was calculated by ROC analysis with sensitivity of 0.73 and specificity of 0.97. In these cases, the 18-oxoF levels in 60 cases (80%) with APA were higher than 4.6 ng/dl, and while, those in 29 cases (97%) with bilateral hyperplasia and those in eight cases (89%) with contralateral CT-negative micro-APA were lower than 4.6 ng/dl. Thus, according to peripheral blood levels of 18-oxo-cortisol, 80% of APA patients with unilateral masses might be able to undergo ipsilateral adrenalectomy without AVS.18-oxoF levels can be a clinically useful biomarker for differentiating APA from bilateral hyperplasia.

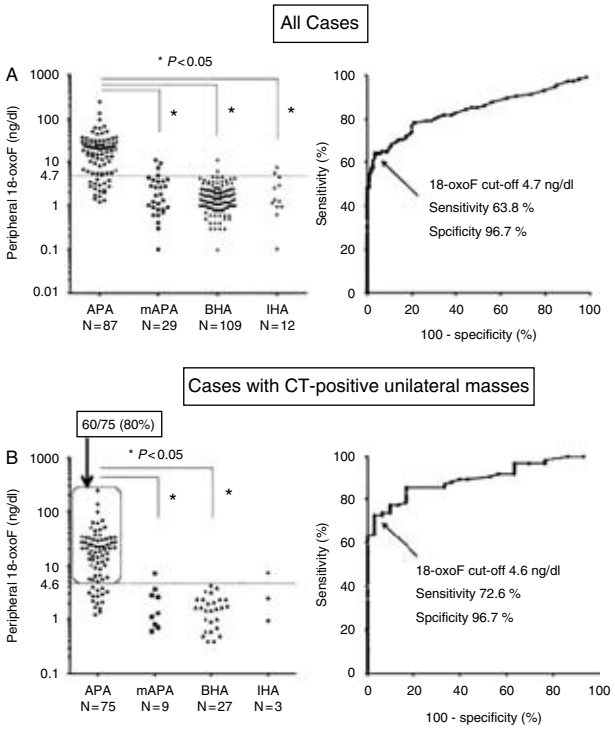

**Figure 1** ROC of 18oxoF plasma levels for the identification of APA versus bilateral hyperplasia in all cases (A) and cases with CT-positive unilateral adrenal masses (B): APA; cases with surgically-proven ipsilateral aldosterone producing CT-positive adenoma (A, B): mAPA (A); cases with CT-negative aldosterone producing adenoma: mAPA (B); cases with CT-positive non-functioning adenoma and contralateral CT-negative aldosterone producing adenoma: BHA; bilateral hyperaldosteronism diagnosed by AVS: IHA; surgically-proven idiopathic hyperaldosteronism.

## OC7.5

**Continuous subcutaneous hydrocortisone infusion (CSHI) as replacement therapy in Addison's disease (AD)**

M. Øksnes[1,4], S. Bjørnsdottir[2], P. Methlie[1,4], E. Bratland[4], M. Isaksson[3], O. Kämpe[3], A. Hulting[2], S. Bensing[2], E. Husebye[1,4] & K. Løvås[1,4]
[1]Haukeland University Hospital, Bergen, Norway; [2]Karolinska Institutet, Stockholm, Sweden; [3]Uppsala University Hospital, Uppsala, Sweden; [4]University of Bergen, Bergen, Norway.

Background
Conventional glucocorticoid replacement therapy is unphysiological, and does not restore quality-of-life in AD. Here we evaluated the dosing regimens and glucocorticoid metabolism in 10 patients undergoing 24 h sampling during oral replacement therapy and CSHI.
Design, Subjects, Measurements
We set up a cross-over randomised multi-centre clinical trial to evaluate dosage and effects of CSHI in 40 Scandinavian AD patients, comparing 3 months of thrice daily oral hydrocortisone with 3 months on CSHI (NCT 01063569). Doses were adjusted according to serum cortisol 4 h after the morning dose (weight-adjusted oral treatment), and salivary cortisol (body-surface-area(BSA)-adjusted CSHI). Ten of the patients were admitted for 24 h blood sampling to determine whether circadian cortisol rhythm was restored, and to analyse the effects on ACTH levels.
Results
Oral treatment doses (median 0.24 mg/kg/day, range 0.2–0.5; median 10.4 mg/BSA/d, range 7.9–19.3) were slightly lower than CSHI doses (median 0.31 mg/kg/24 h, 0.26–0.5; median 13.1 mg/BSA/24 h, range 10.1–20.1).
Oral treatment yielded high post-dose serum cortisol peaks, whereas CSHI created a smooth circadian cortisol curve with median serum cortisol 472 nmol/L (interquartile range 467–589; 08 h), 336 nmol/L (291–415; 14 h), 141 nmol/L (126–212; 20 h) and 60 nmol/L (42.5–78.2; 02 h). The cortisone rhythm resembled the cortisol rhythm; the principal difference between the treatments was non-detectable levels during night-time on oral treatment, as opposed to a rise in the levels from 02 h on CSHI. Compared with oral treatment CSHI resulted in significantly lower ACTH levels from 06 h (median 49.1 pmol/L (interquartile range 9.0–271) vs 4.0 (1.0–28.6), $P=0.011$) to 12 h (21.5 pmol/L (2.1–91.6), vs 1.8 (1.0–5.9), $P=0.008$). Three patients on CSHI had morning ACTH values below the reference range.
Conclusion
CSHI safely established circadian cortisol rhythm in AD patients, which resulted in more normal ACTH levels. We suggest that with physiological replacement therapy ACTH is the appropriate effect parameter for individualisation of dose.

**Progressively increased patterns of subclinical cortisol hypersecretion in adrenal incidentalomas differently predict major metabolic and cardiovascular outcomes: a large cross-sectional study**

G. Di Dalmazi, V. Vicennati, E. Rinaldi, A. Morselli-Labate, E. Giampalma, C. Mosconi, U. Pagotto & R. Pasquali
S Orsola Malpighi Hospital, Bologna, Italy.

Background
Subclinical Cushing's syndrome (SCS) is defined as alterations in hypothalamic–pituitary–adrenal axis without classic signs or symptoms of glucocorticoid excess. It is still controversial whether SCS leads to metabolic and cardiovascular diseases, and if the degree of subclinical hypercortisolism may predict these clinical outcomes.
Aim
To evaluate the prevalence of hypertension, type-2 diabetes (T2D), coronary heart disease (CHD), ischemic stroke, osteoporosis, and osteoporotic fractures, and the relationship of these outcomes to increasing patterns of subclinical

hypercortisolism, in patients with adrenal adenomas classified as non-secreting (NSA) and SCS.
Methods
Using the 1-mg dexamethasone suppression test (DST) as primary diagnostic tool, 348 patients were classified as above: 203 were defined NSA and 19 SCS, using the most stringent cut-off values ($<50$ and $>138$ nmol/l respectively). Patients with cortisol post-DST between 50 and 138 nmol/l were considered intermediate phenotypes and classified as minor ($n=71$) and major ($n=55$) using plasma ACTH and/or urinary free cortisol as additional diagnostic tools.
Results
SCS patients showed higher prevalence of T2D, CHD, osteoporosis, and osteoporotic fractures, respect to NSA. Intermediate phenotypes showed also higher prevalence of CHD and T2D, respect to NSA. The prevalence of all clinical outcomes was not different between intermediate phenotype patients, which were therefore considered as a single group (IP) for multivariate logistic regression analysis. This analysis was performed to evaluate the relationships between potential risk factors (including the cortisol secreting pattern) and the adverse clinical outcomes: both IP and SCS secreting patterns showed a significant association with CHD (odds ratio – OR 4.09; 95% CI 1.47–11.38 and OR 6.10; 95% CI 1.41–26.49 respectively), independently of other potential risk factors. SCS was also independently associated with osteoporosis (OR 5.94; 95% CI 1.79–19.68).
Conclusion
Patterns of increasing subclinical hypercortisolism in adrenal adenomas are associated with increased prevalence of adverse metabolic and cardiovascular outcomes, independently of other potential risk factors.

### Hypophosphatasia: enzyme replacement therapy (ENB-0040) decreases TNSALP substrate accumulation and improves functional outcome in affected adolescents and adults

P. Kishnani[1], C. Rockman-Greenberg[2], M. Whyte[3], T. Weber[1], A. Mhanni[2], K. Madson[3], A. Reeves[3], K. Mack[3], H. Plotkin[4], N. Kreher[4] & H. Landy[4]
[1]Duke University, Durham, North Carolina, USA; [2]University of Manitoba, Winnipeg, Manitoba, Canada; [3]Shriners Hospital for Children, St. Louis, Missouri, USA; [4]Enobia Pharma, Cambridge, Massachusetts, USA.

Hypophosphatasia (HPP), a heritable metabolic bone disease, results from low alkaline phosphatase (TNSALP) activity. Inorganic pyrophosphate (PPi), an inhibitor of mineralization, and pyridoxal 5′-phosphate (PLP), are substrates that accumulate in HPP. There is no approved therapy. ENB-0040, a bone-targeted, recombinant, human TNSALP improves skeletal mineralization in affected infants and children with HPP.
Objective
Evaluate substrate levels and six-minute walk test (6MWT) following 24 weeks of treatment.
Methods
Six adolescents and 13 adults with HPP (mean age 42 years (14–68)) were randomized in an open-label, multicenter, concurrent control study of the safety and efficacy of ENB-0040. Patients received no treatment, 2.1 or 3.5 mg/kg per week via daily SUBCUTANEOUS injections of ENB-0040.
Results
Statistically significant decreases in PPi and PLP ($P=0.002$ and $P=0.009$, respectively) occurred in the treated groups (2.1 and 3.5 mg/kg per week) vs non-treated group. Serum PPi levels decreased from baseline levels of 5.5 to 3.5 μM at week 24 (2.1 mg/kg per week) and from 5 μM at baseline to 2.8 μM at week 24 (3.5 mg/kg per week). Serum PLP levels decreased from 324 ng/ml at baseline to 69 ng/ml at week 24 (2.1 mg/kg per week) and from 603 to 38 ng/ml at week 24 (3.5 mg/kg per week).
At baseline, patients averaged 349 m (6 – 620 m) during the 6MWT, with 10/19 requiring assistive devices during testing. At week 24, treated patients improved $+26$ m vs no improvement ($-14$ m change) for controls. Of 12 patients with functional impairment (BL 6MWT was 25%–75% of normal), nine improved (8/9 treated, 1/3 no treatment). The mean improvements for the 2.1 and 3.5 mg/kg per week groups were $+35.4$ m (n=5) and $+43.5$ m ($n=4$) respectively.
Injection site reactions occurred in seven patients, but did not cause discontinuation of treatment. Six serious adverse events (SAEs) were reported among 3 patients, two control (no treatment) patients had four of the SAEs. No SAEs were associated with ENB-0040.
Conclusion
ENB-0040 significantly decreases TNSALP substrates and improves function in adolescents and adults with HPP.
Declaration of interest
The authors declare that there is a conflict of interest.

## OC8.2

### Comparison of high protein and normal protein weight loss diets on bone density in overweight post-menopausal women

D. Jesudason[1,2] & P. Clifton[1,2]
[1]Commonwealth Scientific and Industrial Research Organisation, Adelaide, SA, Australia; [2]University of Adelaide, Adelaide, SA, Australia.

Introduction
The role of dietary protein in maintaining bone health is controversial. Traditionally the acidifying effect of high dietary protein (HP) has been thought to promote calcium loss from bone and hence hypercalciuria and so was considered harmful compared to a normal protein (NP) diet. However more recently the anabolic effect of increased dietary protein and its effect in increasing calcium absorption have been appreciated. There are no long term prospective clinical trials comparing high and normal protein diets in maintaining bone health.
Methods
We randomized 323 overweight (BMI $>$ 27 kg/m$^2$) post-menopausal women aged 40-70 to an isocaloric HP (approximately 100 g/day) or NP (approximately 67 g/day) weight loss diet for 2 years. We had excluded subjects with impaired bone health eg primary hyperparathyroidism, vitamin D insufficiency, previous low impact fracture, hip t score $<-2.0$ or using medications such as hormone replacements or steroids.
Results
Subjects were equally matched for age, weight, serum parathyroid hormone, vitamin D, cross-laps and osteocalcin at baseline. 69 of 164 HP subjects and 68 of 159 NP subjects completed the 2 year study. As expected there was matched weight loss across both groups with the HP group losing $9.6\pm1.6$ kg vs NP $10.3\pm1.9$ kg (NS). There was no significant difference in bone loss after 2 years at either hip, forearm or spine between groups (Table 1). ANCOVA analysis showed baseline bone density at any site and to a lesser extent baseline Vitamin D was the only significant predictors of bone density at that site at 2 years. Baseline weight, parathyroid hormone, cross-laps and 24 hour urea were not significant predictors.
Conclusion
The amount of dietary protein does not significantly affect bone health in post-menopausal women.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This work was supported, however funding details are unavailable.

**Table 1** Comparison of bone loss after 2 years of HP or NP diet at different sites

| Bone Loss at 24 months | L2-4 | Forearm | Hip |
|---|---|---|---|
| HP | $-0.7\pm0.6\%$ | $-1.2\pm0.4\%$ | $-1.2\pm0.3\%$ |
| NP | $-1.8\pm0.5\%$ | $-1.0\pm0.3\%$ | $-1.5\pm0.3\%$ |
| Significance | NS | NS | NS |

### Profiling insulin like factor 3 (INSL3) signaling in human osteoblasts

A. Ferlin, L. Perilli, L. Gianesello, G. Taglialavoro & C. Foresta
University of Padova, Padova, Italy.

Insulin-like factor 3 (INSL3) is a testis-specific, Leydig cell derived hormone, which we recently demonstrated to play a role in bone metabolism. Young men with mutations in the gene for the INSL3 receptor (Relaxin family peptide 2, RXFP2) are at risk of reduced bone mass and osteoporosis. Consistent with the human phenotype, bone analyses of Rxfp2$^{-/-}$ mice showed decreased bone

volume, alterations of the trabecular bone, reduced mineralizing surface, bone formation, and osteoclast surface. The aim of this study was to elucidate the INSL3/RXFP2 signaling pathways and targets in human osteoblasts, by studying the effects of INSL3 on different molecular, cellular, and genetic mechanisms.
We analyzed the effects on alkaline phosphatase (ALP) production, protein phosphorylation, intracellular calcium, gene expression, and mineralization. INSL3 induced a significant increase in ALP production, and Western blot and ELISA analyses of multiple intracellular signaling pathway molecules and their phosphorylation status revealed that the MAPK was the major pathway influenced by INSL3, whereas it does not modify intracellular calcium concentration. Quantitative Real Time PCR and western blotting showed that INSL3 regulates the expression of different osteoblast markers. Alizarin red-S staining confirmed that INSL3-stimulated osteoblasts are fully differentiated and able to mineralize the extracellular matrix.
Together with previous findings, this study demonstrates that INSL3 is involved in bone metabolism by acting on the MAPK cascade and stimulating transcription of important genes of osteoblast maturation/differentiation, matrix deposition and osteoclastogenesis, and it stimulates mineralization.

## OC8.4

**Radiological vertebral fractures in hospitalized elderly patients with heart failure**

G. Mazziotti[1,2], M. Baracca[2], M. Doga[1], T. Porcelli[1], P. Vescovi[2] & A. Giustina[1]
[1]University of Brescia, Brescia, Italy; [2]Azienda Ospedaliera Carlo Poma, Mantova, Italy.

Heart failure (HF) has been associated with bone loss and an increased risk of fragility fractures. Indeed, most of literature data on fractures were based on an historical and clinical approach focused on the identification of peripheral fractures, whereas the risk of vertebral fractures in this clinical setting is still unclear. In this study, we aimed at evaluating the prevalence of radiological vertebral fractures in 791 consecutive elderly and hospitalized patients (372 females and 419 males; median age: 75 years.; 190 patients with HF). The research focused on fractures of the thoracic spine, which were identified using chest X-ray routinely performed in the diagnostic work-up of HF. Exclusion criteria were: i) neoplastic diseases in progression; ii) systemic autoimmune diseases; iii) chronic therapy (>3 months) with oral and parenteral glucocorticoids; iv) chronic immobilization; v) trauma; vi) previous clinical history of HF without specific symptoms at the time of enrollment. Vertebral fractures were found in 170 patients (21.5%), the prevalence being significantly higher in patients with HF as compared to those without HF (38.9 vs 16.0%; $P<0.001$). The association between HF and vertebral fractures remained statistically significant (odds ratio 2.20, 95% C.I. 1.34–3.83) even after adjustment for age, sex, loop diuretic therapy, anticoagulant therapy, proton pump therapy, coexistent chronic obstructive pulmonary disease, diabetes mellitus and chronic liver diseases. In patients with HF, vertebral fractures were significantly correlated with duration of HF (odds ratio 1.09, 95% C.I. 1.06–1.10; $P<0.001$), female sex (odds ratio 5.85, 95% C.I. 1.90–17.4; $P=0.01$), ischemic heart disease (odds ratio 2.55, 95% C.I. 1.03–6.29; $P=0.04$) and treatment with anti-osteoporotic drugs (odds ratio 2.87, 95% C.I. 1.09–7.55; $P=0.03$).
Our study shows for the first time that patients suffering from HF are at higher risk of developing vertebral fractures as compared to age/sex matched subjects selected in the same clinical environment.

**Pathogenetic chromosomal rearrangements in a large series of patients with pseudohypoparathyroidism type I**

F. Elli[1], L. de Santis[2], M. Filopanti[1], P. Beck-Peccoz[1], A. Spada[1] & G. Mantovani[1]
[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy; [2]Regina Margherita Children's Hospital, Turin, Italy.

Pseudohypoparathyroidism (PHP) type I includes two major subtypes, Ia and Ib. About 70% of Ia patients, characterized by Albright hereditary osteodystrophy and multihormone resistance (PTH/TSH/GHRH/gonadotropins), carry point mutations in GNAS exons encoding Gsα. About 60% of Ib patients, with hormone resistance limited to PTH and TSH, have methylation defects within GNAS locus (sporadic or genetic-based). Recently, methylation defects were detected in pts with Ia phenotype, suggesting a molecular overlap between the two forms. Despite advances in the determination of molecular mechanisms underlying PHP, 30–40% of patients lack a molecular diagnosis. Moreover, it is unclear whether apparently sporadic imprinting defects are rather secondary to genetic defects. In order to simultaneously investigate for GNAS and STX16 deletions/duplications and for GNAS imprinting status (A/B-AS-NESP-XL DMRs), we performed methylation specific multiplex ligation-dependent probe amplification (MS-MLPA) in 96 patients (Ia=48/Ib=48), all negative for Gsα mutations. In 15 patients we detected rearrangements at GNAS and/or STX16 genes (known to be implicated in autosomal dominant Ib). In particular: i) of 8 PHP-Ia patients: two patients with apparent methylation defects carry a deletion of the entire GNAS locus, 1 had A/B loss of methylation (LoM) caused by STX16 deletions, five had deletions encompassing Gsα exon 1; ii) of 7 PHP-Ib patients: five had A/B LoM associated with STX16 deletions and two showed both extensive methylation defects and deletions within the AS region. In conclusion: a) MLPA proved to be a reliable method to detect genetic abnormalities associated with PHP-I, both known and novel to the literature; b) PHP-Ia and Ib may be caused by GNAS submicroscopic structural mutations; iii) All PHP-I patients negative for Gsα gene mutations should be considered for further molecular investigations to optimize genetic counselling. Ongoing studies are aimed to characterize the newly detected deletions and to investigate the function of the involved regions.

**Simultaneous gain and loss of methylation at imprinted loci in a subset of patients with pseudohypoparathyroidism type 1b and GNAS epimutations**

S. Maupetit-Méhouas[1], S. Azzi[3], V. Steunou[3], C. Reynes[6], C. Silve[1], A. Barlier[5], I. Netchine[3,4] & A. Linglart[1,2]
[1]INSERM, Kremlin-Bicetre, France, [2]APHP, Kremlin-Bicetre, France; [3]INSERM, Paris, France; [4]APHP, Paris, France; [5]CNRS, Marseille, France; [6]Université Paris Diderot, Paris, France.

The majority of patients affected with pseudohypoparathyroidism type 1b (PHP-1b) display loss of imprinting (LOI) encompassing the GNAS locus responsible for decreased Gsa expression in target tissues and PTH resistance. In other imprinting disorders like Silver-Russell, Wiedemann-Beckwith syndromes or transient neonatal diabetes mellitus due to LOI of the imprinted 11p15 and 6q24 regions respectively, we and others have shown that the LOI may spread over to other imprinted loci in some patients. These findings suggested that multilocus imprinted disorders may result from dysfunction(s) of transacting factors.

Therefore, we hypothesized that similar mechanisms may underlie PHP-1b.

We have investigated, in 63 patients affected with PHP-1b, the methylation pattern of six human imprinted loci –in addition to GNAS- ZAC1, PEG1/MEST, ICR1 and ICR2 at 11p15, SNRPN and DLK1/GTL2 IG-DMR.

We found for the first time multilocus imprinting defects in five patients affected with PHP-1b and broad epigenetic changes at the GNAS locus. We observed both gain of methylation at the maternally PEG1/MEST ($n=3$) and at the paternally DLK1/GTL2 IG-DMR ($n=1$) methylated loci and loss of methylation at the PEG1/MEST locus ($n=1$). We propose that the mechanism causing the multilocus imprinting defects in PHP-1b differs from that of other imprinting disorders harboring exclusively loss of methylation in patients with multilocus defects.

Thereby, the epidominance assumption claiming that phenotypes are ruled by the most severely affected imprinted locus seems confirmed by our study, as we did not find clinical differences between patients affected with PHP-1b with or without multilocus defects.

## OC9.1 The Young Investigator Winner

**Temozolomide therapy for progressive metastatic paraganglioma/ pheochromocytoma: SDHB mutation as a prognosis biomarker for efficacy**

J. Hadoux[1], S. Leboulleux[1], A. Al Ghuzlan[1], I. Borget[1], C. Caramella[1], C. Chougnet[1], J. Young[2], F. Dumont[1], F. Deschamps[1], M. Schlumberger[1] & E. Baudin[1]
[1]Insitut Gustave Roussy, Villejuif, France; [2]APHP Bicêtre, Kremlin Bicêtre, France.

Malignant pheochromocytoma and paraganglioma (PPGLs) are rare diseases with a heterogeneous behaviour. 131I-MIBG therapy and the cyclophosphamide-dacarbazine-vincristine chemotherapy regimen (CVD) constitute the most popular options in the metastatic setting. We have investigated the antitumor effect of temozolomide (TMZ), in patients with metastatic PPGLs. Efficacy was primary endpoint, safety and identification for prognosis factors of response were secondary endpoints.

Fifteen consecutive patients with progressive ($n=14$) or symptomatic ($n=1$) metastatic PPGLs received TMZ therapy. There were 12 men (80%); median age was 43 years. Germline mutations were screened: 10 patients harbored SDH B mutation and 5 patients had no mutation. Median number of cycle was 7, mean dose intensity for each cycle was 171 mg/m$^2$ per day (95% CI 160.7–181) for five days of a 28-days cycle.

The most frequent all grade toxicities included asthenia, nausea and anemia. Grade three toxicities were lymphopenia ($n=2$) and hypertension ($n=1$). According to RECIST 1.1 criteria or F18-FDG-PET evaluation, there was 5 (33%) partial responses, 8 (54%) stable diseases and 2 (13%) progressive diseases. With a median follow up of 29 months (range 6.4–37.9), median overall survival was not reached and median progression free survival (PFS) was 9.6 months.

Partial responses were observed in 4 out of 10 SDHB mutated patients but in no sporadic case. Patients with SDH B mutations or with no mutation had a median PFS of 16.7 and 2.6 months, respectively (log-rank, $P=0.013$); Patients with SDH B mutations or with no mutation had a 12-month PFS of 60 or 0% respectively. Methyl guanine methyl transferase (MGMT) expression was analyzed in four patients, including 3 responders and, was found negative.

This study demonstrates for the first time the antitumor efficacy of TMZ in a large series of metastatic PPGLs as well as the potential role for SDH B mutation as a prognosis biomarker of response.

## OC9.2

**GH protects breast cancer cells from chemotherapy by blocking cytotoxic-induced apoptosis in estrogen receptor negative breast cancer cells**

M. Minoia, E. Gentilin, D. Molè, F. Tagliati, M. Ambrosio, E. degli Uberti & M. Zatelli
University of Ferrara, Ferrara, Italy.

Context

GH and insulin-like growth factor (IGF1) play important roles in breast cancer (BC) development. IGF1 has been shown to importantly influence estrogen effects on BC, suggesting that estrogen receptors (ER) may mediate also GH effects. We previously demonstrated that GH and IGF1 protect the ER positive BC-derived MCF7 cell line towards the cytotoxic effects of doxorubicin (D), independently of IGF1.

Aim of the study

Evaluate whether this holds true also in the ER negative BC-derived MDA-MB-231 cell line and in the normal MCF-12A breast cell line. In addition, we investigated the possible mechanisms implicated in the protective action of GH towards the cytotoxic effects of D.

Results

GH protects MDA-MB-231 cells from the cytotoxic effects of D but does not influence MCF-12A cell viability. The GH receptor antagonist Pegvisomant (Peg) reduces GH-induced DNA synthesis also in MDA-MB-231 cells. In addition, in both MDA-MB-231 and MCF7 cells GH does not revert D-induced G2/M accumulation, but significantly reduces basal and D-induced apoptosis, an effect blocked by Peg. GST activity is not implicated in the protective effects of GH, while D-induced apoptosis depends on JNK activation and GH reduces both basal and D-stimulated JNK transcriptional activity and phosphorylation.

Conclusions

In human BC cell lines GH directly promotes resistance to apoptosis induced by chemotherapic drugs independently of ER expression by modulating JNK, further supporting the hypothesis that GH excess might hamper cytotoxic BC treatment and that GH receptor antagonism may represent a new therapeutic pathway also in ER negative BC.

**The central role of estrogen receptor α in IGF2 dependent adrenocortical carcinoma (ACC) cell proliferation suggests the use of selective estrogen receptor modulators (SERMs) for the treatment of ACC**

R. Sirianni[1], A. Chimento[1], A. De Luca[1], L. Cerquetti[4], G. Carpinelli[5], F. Fallo[2], C. Pilon[2], G. Arnaldi[3], A. Stigliano[4] & V. Pezzi[1]
[1]University of Calabria, Rende, Italy; [2]University of Padova, Padova, Italy; [3]University of Ancona, Ancona, Italy; [4]University of Roma Sapienza, Roma, Italy; [5]Istituto Superiore di Sanità, Roma, Italy.

Adrenocortical Cancer (ACC) is characterized by an increased production of insulin-like growth factor 2 (IGF2) and by estrogen receptor (ER) α

up-regulation. Aim of this study was to define IGF2 and estrogen signaling interactions in ACC, in order to give new indications for a better therapy. To this aim we used H295R cells and human ACC tissues which display common features: IGF2 activation of downstream effector pathways and over-expression of estrogen-related genes including ERα and aromatase, the enzyme required for estrogen production. We demonstrated that IGF2 controls expression of steroidogenic factor 1 (SF-1), that in turn increases aromatase transcription. 17β-estradiol ($E_2$) bound to ERα up-regulated IGF1R expression as a consequence of increased pCREB binding to IGF1R promoter. On the other hand, $E_2$ and PPT (a selective ERα agonist) stimulated IGF1R phosphorylation and caused ERK1/2 and AKT activation. In the $E_2$-dependent IGF1R transactivation we found the involvement of the scaffold protein PELP1/MNAR which acted as an adaptor protein for connecting ERα-IGF1R-Src-ERK1/2-AKT. These data suggest the ability for estrogens to activate IGF1R-downstream pathways even in the absence of IGF2. Furthermore, ERα regulated $E_2$- and IGF2-induced cyclin D1 expression, a gene controlling cell cycle progression overexpressed in ACC. Silencing ERα significantly blocked the ability of $E_2$ and IGF2 to induce cell proliferation more effectively than an anti-IGF1R monoclonal antibody, as used in phase I clinical trials. We also utilized H295R cells to generate xenografts in athymic nude mice to demonstrate the ability of SERMs such as tamoxifen to control ACC growth in vivo. Tamoxifen therapy significantly inhibited tumor growth further indicating that ERα contributes to the pathogenesis of ACC. These findings establish a critical role for ERα in IGF2-dependent ACC proliferation and provide rationale for targeting ERα (or PELP1) to control the proliferation of adrenocortical carcinoma.

**Functional characterization of mutations in the multiple endocrine neoplasia type 1 (MEN1) gene suggest therapeutic strategies**

L. Canaff & G. Hendy

McGill University, Montreal, Quebec, Canada.

Menin is the product of the multiple endocrine neoplasia type 1 (MEN1) gene which when inactivated causes an autosomal dominant disorder characterized by tumors of the parathyroids, endocrine pancreas and anterior pituitary.

We identified an MEN1 splice-site mutation leading to a menin Δ(184–218) mutant having an in-frame deletion of 35 amino acids, but otherwise of wild-type sequence. The transfected mutant was well expressed, and like wild-type menin, interacted directly with the transcriptional regulators JunD and NF-κB and inhibited their activities. However, the mutant had lost the normal interaction with Smad3 and was defective in mediating TGF-β-stimulated Smad3 transcriptional activity, stimulation of the cyclin dependent kinase inhibitors (CDKIs), p15 and p21, and cytostatic activity. Thus the mutant was stable, had selective loss of TGF-β signaling and growth inhibition and, importantly, identified the menin/Smad3 interacting region on a homology model of the human menin structure. These studies suggest the menin/Smad3 interface as a potential therapeutic target.

We functionally characterized a panel of 16 menin missense mutants, including W423R and S443Y identified in new MEN1 families and that are poorly expressed. Proteasome inhibitors, MG132 and PS-341, and inhibition of the chaperone, heat shock protein 70 (Hsp70), or the ubiquitin ligase, COOH-terminus of Hsp70-interacting protein (CHIP), by specific siRNAs, restored the levels of the mutants whereas that of wild-type menin was unaffected. Inhibition of CHIP restored the ability of mutants to mediate normal functions of menin – TGF-β upregulation of p15 and p21, as well as TGF-β inhibition of cell proliferation. Potentially, targeting specific components of the proteasome chaperone pathway could be beneficial in treating a subset of MEN1 cases.

**Glucagon-like peptide 1 receptor (GLP-1R) imaging for the preoperative localization of benign insulinomas in 30 patients**

E. Christ[1], F. Forrer[2], D. Wild[2], T. Clerici[3], M. Braendle[3], H. Maecke[2], P. Ell[4], M. Caplin[5], B. Gloor[1] & J. Reubi[6]

[1]University Hospital of Bern, Inselspital, Bern, Switzerland; [2]University Hospital of Basel, Basel, Switzerland; [3]Kantonsspital St. Gallen, St. Gallen, Switzerland; [4]University College Hospital, London, UK; [5]Royal Free Hospital, London, UK; [6]University of Bern, Bern, Switzerland.

Background

Although biochemical diagnosis of endogenous hyperinsulinemic hypoglycemia is straightforward, surgical removal of an insulinoma is hampered by difficulties to localize it using conventional radiological procedures (endosonography, MRI, CT-imaging techniques).

*In vitro* data suggest that human insulinoma cells exhibit a high density of GLP-1R. 111In-exendin-4 is a 111In labeled GLP-1R agonist that binds with high affinity to GLP-1R and may be helpful in localizing benign insulinomas.

Aim

To localize benign insulinomas using 111In-exendin-4 in patients with proven endogenous hyperinsulinemic hypoglycemia but no or only one suspicious lesion on conventional imaging.

Material and methods

111In-exendin-4 was administered i.v. at a dose of (≈90 MBq; 30 μg peptide) over 5 min to 30 patients (18 females, 12 males, age ± 52.6 ± 14.8 years, mean ± S.D). Whole body planar images and SPECT/CT images (single photon emission computed tomography) of the abdomen were performed at 0.5 h, 4 h, 23 h, 96 h up to 168 h post injection. Diagnosis was confirmed by histology after surgical removal.

Results

Conventional imaging (MRI, CT, endosonography) was positive in 17 patients. $^{111}$In-exendin-4 SPECT/CT detected 23 true positive benign insulinomas and five additional positive lesions (one malignant insulinoma; two islets hyperplasia; two uncharacterized lesions). True negative tests were detected in two patients (one malignant insulinoma; one islets hyperplasia). There was no false negative result. The positive predictive value was 85% the negative predictive value 100%.

Conclusion

These data suggest that *in vivo* GLP-1R imaging defines a new non-invasive diagnostic approach to successfully localize small insulinomas.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**First *in vitro* study of human gastroenteropancreatic-neuroendocrine tumors: comparative effect of octreotide and pasireotide**

A. Mohamed[1], M. Blanchard[1], M. Albertelli[2], P. Niccoli[3], G. Monges[3], S. Garcia[4], V. Moutardier[4], J. Delpero[3], A. Enjalbert[1], T. Florio[2], D. Ferone[2], A. Saveanu[1] & A. Barlier[1]

[1]UMR7286-CRN2M, Marseille, France; [2]Laboratory of pharmacology, Genova, Italy; [3]Institut Paoli Calmettes, Marseille, France; [4]CHU - Hopital Nord, Marseille, France.

Somatostatin analogs (SSAs) such as octreotide (OCT) are currently effective in controlling most hypersecretion associated symptoms of Gastoenteropancreatic-neuroendocrinetumors (GEP-NETs). The results of the phase IIIb PROMID trial showed that OCT doubled time to progression for patients with metastatic neuroendocrine midgut tumors compared with placebo. SSAs act on different intracellular pathways through different somatostatin receptor (Sst) subtypes. While OCT is mainly an Sst2 agonist, Pasireotide (PAS) is a new universal ligand, binding to all Sst (except Sst4). Our aim was to compare on primary culture of human GEP-NETs the effect of OCT and PAS on cell viability, hormonal secretion and transduction pathways.

Methodology

This study was performed on 12 human GEP-NETs *in vitro*. The expression of SST subtypes mRNAs was evaluated and the trafficking of SST2 in presence of SSAs was followed by confocal microscopy.

Results

1 Sst2 > Sst1 > Sst5 are expressed in all analysed GEP-NETs; 2/ Oct and PAS induced different Sst2 internalization patterns; 3/ OCT and PAS suppress cell

viability at similar levels in all analysed tumors (range 20–90%) through caspase dependant apoptosis process. 5/ Chromogranin A secretion is suppressed by both PAS and OCT in a dose dependant manner, close to the suppression observed in viability experiments. Conclusion: it is the first *in vitro* study on human GEP-NETs. PAS has a similar effect to OCT on cell viability and secretion of human GEP-NETs *in vitro*, despite a clear difference in Sst2 trafficking.

**Predictors of morbidity and mortality in acromegaly: an Italian survey on behalf of the Italian study group of acromegaly**

M. Arosio[1,2], G. Reimondo[3,4], P. Berchialla[3], E. Malchiodi[1,5], L. Montefusco[1,2] & M. Terzolo[3,4]
[1]University of Milan, Milan, Italy; [2]San Giuseppe Hospital, Mulimedica Group, Milan, Italy; [3]University of Turin, Turin, Italy; [4]San Luigi Hospital, Orbassano (Turin), Italy; [5]Foundation IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy.

This study presents epidemiological data of 1512 Italian acromegalic patients who had been diagnosed from 1980 to 2002 and followed-up for more than 10 years, retrospectively collected by 24 tertiary referral centers. Data on co-morbidities and mortality were compared to those of the general Italian population obtained by the Italian National Institute of Statistic. At diagnosis median age of patients (41% M, 59% F) was 46 years, GH (mean ± S.D.) 31 ± 37 mcg/l, IGF1 744 ± 318 ng/ml (median SDS 8.53, IQR 5.82–12.34). Diabetes mellitus was reported in 16% of cases, hypertension in 33%. Older age and higher IGF1 but not GH levels at diagnosis were significant predictors of diabetes and hypertension. The patients were treated by surgery (80%), pharmacotherapy (75%), radiotherapy (18%), radiosurgery (6%) alone or in combination. The prevalence of neoplastic diseases (all causes) was significantly higher than in the general population. Older patients who had a greater delay of diagnosis and previous radiotherapy were also at higher risk to develop a neoplasm. Diabetes was a significant risk factor for neoplasm in the univariate analysis, only. At last follow-up 65% of patients had a controlled disease, with 55% off medical treatment. Multivariate analysis showed that male gender, extrasellar adenoma and high GH at diagnosis were predictors of disease persistence. Observed deaths were 61, with a standardized mortality ratio (SMR) of 1.13 (95% CI: 0.87–1.46). Mortality was significantly higher in the patients with persistently active disease (SMR 1.93; 95% CI: 1.34–2.70). Main causes of deaths were vascular diseases and malignancies with similar prevalence. Older age, higher GH at last follow-up, higher IGF1 levels at diagnosis, malignancies and radiotherapy were independent predictors of mortality.
In conclusion: basal IGF1 levels are important predictors of morbidity and mortality in acromegaly. The delay of diagnosis increases the risk to develop a neoplasm. The full hormonal control of the disease, nowadays reached in the majority of the patients, reverses the increased mortality.

### OC10.2

**Food intake regulating hormones in adult craniopharyngioma patients**

J. Roemmler[1], V. Geigenberger[1], B. Otto[1], M. Bidlingmaier[1], C. Dimopoulou[1,2], G. Stalla[2] & J. Schopohl[1]
[1]Medizinische Klinik Campus Innenostadt, LM-Universität München, München, Germany; [2]Endocrinologie, Max-Planck-Institute, München, Germany.

Introduction
Patients with craniopharyngeoma often have disturbances of the hypothalamic–pituitary axis and serious comorbidities as obesity. We hypothesized, that the pattern of hormones regulating the nutritional status is worsened in adult patients with craniopharyngioma (CP) compared to adult patients with non-functioning pituitary adenoma (NFPA).
Methods
We included 33 patients with CP ($m=16$, $f=17$, median age: 48 years (26–77)) and 33 patients with NFPA ($m=24$, $f=9$, median age: 66 years (44–80)) in the study. The prevalence of hormonal pituitary insufficiencies of adenohypophysis did not differ significantly between groups. We measured fasting glucose, insulin, leptin, serum total ghrelin, PYY and CCK. Furthermore, total body fat mass (= FM) was determined by dual-X-ray-absorptiometry.
Results
Significantly more patients with CP had diabetes mellitus ($n=7$ vs $n=1$, $P=0.027$). Patients with CP had significantly higher FM than patients with NFPA (38.48% (20.90–54.90) vs 32.48% (17.90–53.70), $P=0.017$). Moreover, glucose levels (82.5 mg/dl (68–120) vs 73.5 mg/dl (54–112), $P=0.004$) and leptin levels (15.9 µg/l (1.7–139.5) vs 9.3 µg/l (0.7–45.5), $P=0.007$) were significantly higher in CP than in NFPA. But insulin, ghrelin, PYY and CCK did not differ significantly between the two groups. When groups were divided by gender, ghrelin levels were significantly lower in female CP (132 ng/l (69–807) vs 287 ng/l (103–488), $P=0.003$).
Conclusion
Patients with craniopharyngioma have more metabolic complications including higher leptin levels and lower ghrelin levels in females than patients with NFPA. This might be caused by hypothalamic damage and not by pituitary insuffciency. Interestingly, the pattern of other food intake regulating hormones seems not be disturbed.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### OC10.3

**Pathophysiology of renal calcium handling in acromegaly revisited**

P. Kamenicky[1,2,3], A. Blanchard[4], C. Gauci[4], S. Salenave[1,2], A. Letierce[1], M. Lombès[2,3], M. Azizi[4], D. Prié[5], J. Souberbielle[5] & P. Chanson[1,2,3]
[1]Assistance Publique-Hôpitaux de Paris, Hôpital de Bicêtre, Le Kremlin Bicêtre, France; [2]Univ Paris-Sud, Le Kremlin Bicêtre, France; [3]INSERM, Le Kremlin Bicêtre, France; [4]Assistance Publique-Hôpitaux de Paris, Hôpital Européen George Pompidou, Paris, France; [5]Assistance Publique-Hôpitaux de Paris, Hôpital Necker Enfants Malades, Paris, France.

Background
Hypercalciuria is frequent in patients with acromegaly, but it is unclear how GH/insulin-like growth factor 1 (IGF1) regulate renal calcium handling. Elevated fasting plasma calcium levels despite increased glomerular filtration suggest enhanced renal calcium reabsorption.
Objective
To investigate the impact of acromegaly on phosphocalcium metabolism.
Design
Prospective sequential study (ClinicalTrials.gov Identifier: NCT00531908).
Setting
Tertiary referral medical center and clinical investigation center.
Intervention
16 consecutive patients (5F/11M) with acromegaly received a single IV infusion of 25 mg of furosemide to induce an acute increase in calcium and magnesium delivery to distal tubular segments during a high-sodium diet with stable dietary calcium, magnesium and phosphate intake.
Measurements
Baseline plasma and urine electrolytes, plasma calcitropic hormones, and furosemide-induced changes in the fractional excretion (FE) of Ca and Mg were measured before and 6 months (range: 1–12) after effective treatment of acromegaly.
Results
Serum IGF1 concentrations normalized in all the patients after acromegaly treatment. Compared with controlled acromegaly, active acromegaly was associated with significantly higher fasting plasma ($P=0.0002$) and urinary calcium ($P=0.0003$) levels, lower PTH levels ($P=0.0075$), higher calcitriol

levels ($P=0.0137$); higher phosphatemia ($P<0.0001$) and tubular phosphate reabsorption ($P=0.0002$); similar FGF23 concentrations; and a lower calciuric ($P=0.0327$) but not magnesiuric response to furosemide.
Conclusion
The IGF1-mediated and PTH-independent increase in calcitriol synthesis in acromegaly is responsible for both absorptive hypercalciuria and increased fasting plasma calcium linked to enhanced distal tubular calcium reabsorption, as shown by the selectively diminished calciuric response to furosemide, that may counteract the effect of increased glomerular filtration and prevent major urinary calcium losses. Physiologically, this calcium-retaining tubular effect of GH/IGF1 would limit calcium excretion during childhood, thus contributing to the positive calcium balance required for juvenile growth.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## OC10.4

**Higher glucocorticoid supplementation doses are associated with increased overall mortality in patients with non-functioning pituitary adenoma**

T. Zueger[1], P. Kirchner[1], C. Herren[1], S. Allemann[1,2], S. Fischli[3], M. Zwahlen[2], E. Christ[1] & C. Stettler[1]
[1]Inselspital, Bern University Hospital, and University of Bern, Bern, Switzerland; [2]University of Bern, Bern, Switzerland; [3]Kantonsspital Lucerne, Lucerne, Switzerland.

Introduction
Current treatment guidelines for patients with insufficiency of the hypothalamic pituitary adrenal (HPA) axis recommend weight adjusted glucocorticoid supplementation doses to minimize risk of negative side effects (e.g. osteoporosis etc).
However, little is known on a potential dose-dependent effect of glucocorticoid supplementation on overall mortality in patients with pituitary disease. Non-functioning pituitary adenoma (NFPA) is one of the most frequent sellar pathologies. Therefore, the present study aimed at assessing whether higher glucocorticoid supplementation doses were associated with increased mortality in individuals with NFPA and HPA insufficiency.
Methods/Design
We included 105 patients (29 female, 76 male) referred to our tertiary Endocrine referral center after pituitary surgery due to NFPA and with glucocorticoid supplementation due to HPA insufficiency; 101 individuals with NFPA but without HPA insufficiency were included as comparators. Status (alive/death) and date of death were assessed per end of 2010. Mortality was assessed using Kaplan Meier methodology as well as Cox regression analysis with adjustments for age, body-weight and gender.
Results
Average age at inclusion was $57.6\pm15.0$ years, mean follow-up was $10.8\pm8.2$ years, mean hydrocortisone (HC) equivalent dose at follow-up was $22\pm13.1$ mg. Kaplan Meier survival probabilities differed significantly when comparing individuals with differing absolute HC dose (none, 5–19, 20–29, $\geq30$ mg, $P=0.011$) as well as using weight-adjusted doses ($P=0.047$). This result persisted when analyses were adjusted for age, weight, and gender with hazard ratios increasing from 1 (5–19 mg) to 1.36 (20–29 mg), and to 2.67 ($\geq30$ mg, $P$ for trend 0.036).
Conclusions
Higher glucocorticoid supplementation doses are associated with increased overall mortality in patients with NFPA and insufficiency of HPA axis. This further substantiates the importance of a balanced and adjusted glucocorticoid replacement therapy in these patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## OC10.5

**Once-weekly, CTP-modified hGH (MOD-4023) is effective in growth hormone deficient adults: a phase II, dose and frequency finding study**

V. Popovic[1,2], M. Goth[3], P. Vanuga[4], J. Payer[5], M. Pfeifer[6], M. Bidlingmaier[7] & E. Fima[8]
[1]University Clinical Center, Belgrade, Serbia; [2]University of Belgrade, Belgrade, Serbia; [3]Military Hospital, Budapest, Hungary; [4]National Institute of Endocrinology and Diabetology, Lubochna, Slovakia; [5]University Hospital, Comenius University, Bratislava, Slovakia; [6]University Medical Centre Ljubljana, Ljubljana, Slovenia; [7]Medizinische Klinik Campus Innenstadt, Munich, Germany; [8]Prolor-Biotech, Ltd, Nes Ziona, Israel.

Objective
GH replacement therapy currently requires daily injections, which may cause poor compliance and distress for patients. CTP-modified hGH (MOD-4023) is being developed for once-weekly administration in GH Deficient adults and children. The present study evaluated the safety, pharmacokinetics (PK) and pharmacodynamics (PD) of MOD-4023 in GHD adults.
Design and methods
39 normalized GHDA patients currently treated with daily GH were randomized and switched to 3 dose levels of once-weekly MOD-4023 (30%, 45% or 100% of each patient's cumulative weekly hGH dose) to evaluate safety and PK/PD profile. The study was comprised of two stages. Stage I included an optimization period and 4 weeks of once-weekly subcutaneously administered MOD-4023. Stage II is an optional 16 week extension period of once weekly MOD-4023 administration to collect further safety information and confirm the results obtained in Stage I. Here we present the results of Stage I.
Results
MOD-4023 was well-tolerated and a dose dependent response of IGF1 concentration was demonstrated. In most patients, IGF1 levels were maintained within $\pm2$ SDS during the 4 weeks, without exceeding $+2$ SDS at peak levels. In two cohorts (45% and 100%) the mean IGF1 values were comparable to those obtained with daily hGH at steady state. The adverse effects reported were consistent with known hGH related side-effects, and were mostly mild. MOD-4023 was not immunogenic.
Conclusions
Once-weekly, repeated doses of long-acting MOD-4023 were safe and well tolerated in adult GHD patients. IGF1 levels were maintained within the normal range in most MOD-4023 treated patients for the entire 4 weeks of treatment.
Based on the positive results of Stage I, an estimated target dose range for a Phase III study has been established and the 16-week extension study was initiated to further confirm the estimated dose range and to provide additional safety information.
Declaration of interest
The authors declare that there is a conflict of interest.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## OC10.6

**Second neoplasms in childhood cancer survivors with growth hormone deficiency treated or not treated with GH**

F. Felicetti[1], D. Di Cuonzo[1], R. Manicone[2], F. Lazzarato[1], E. Biasin[2], P. Chiabotto[2], G. Boccuzzi[1] & E. Brignardello[3]
[1]University of Turin, Turin, Italy; [2]Regina Margherita Children's Hospital, Turin, Italy; [3]San Giovanni Battista Hospital, Turin, Italy.

Introduction
The relation between GH treatment and cancer is still matter of debate. Childhood cancer survivors (CCS) have a high risk to develop second benign and malignant neoplasms (SNs), mainly as a consequence of radiation therapy. Thus, in patients with GH deficiency it is difficult to discriminate the oncological risk due to GH treatment from that caused by anticancer therapy and by individual susceptibility.
Methods
We studied the prevalence of SNs in 49 CCS who developed GDH during childhood, after cancer therapy. 32 patient had a previous diagnosis of central nervous system tumor, 17 were cured for hematologic malignancies. 44 patients (90%) received radiation therapy involving the head, at doses ranging between 12 and 70 Gy. Patients were divided in two groups: GHD-treated patients ($n=25$, 18 males, 7 females) who received GH therapy during childhood for at least 12 month (mean $\pm$ S.D. $=3.9\pm1.9$ years), and GHD not-treated patients ($n=24$,

12 males, 12 females) who did not receive any GH replacement. Statistical analysis was performed using Chi-square and Student's t tests.
Results
Mean age at the time of the study was similar in the two groups (25.5±4.9; 28.3±6.7 years). Mean follow-up time was 16.7±7.0 years. In GHD-treated group, 8 patients (32%) developed 10 SNs (Table 1). In GHD not-treated group 6 patients (25%) developed 8 SNs (Table 1). None of the 5 GHD patients who did not received radiotherapy developed a second malignancy.
Conclusions
Data show that CCS with GHD are at high risk to develop SNs, mainly meningiomas. It is likely due to the very high percentage of GHD patients previously treated with radiation therapy, which is a risk factor for both GHD and SNs. Also if the difference between SNs in treated and not-trated patients is not statistically significant, these data should be considered when prescribing GH to CCS, especially in adulthood.

**Table 1** SNs in cancer survivors with GHD

| | GDH treated ($n$ = 25) | GDH not-treated ($n$ = 24) |
|---|---|---|
| Meningioma | 5 | 4 |
| Non Melanoma Skin Cancer | 3 | 3 |
| Thyroid Cancer | 1 | |
| Neurinoma | 1 | |
| Melanoma | | 1 |

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## Thyroid clinical 2

### OC11.1

**Growth retardation and severe constipation due to the first human, dominant negative thyroid hormone receptor alpha mutation**

N. Schoenmakers[1], E. Bochukova[1], M. Agostini[1], E. Schoenmakers[1], O. Rajanayagam[1], J. Keogh[1], E. Henning[2], J. Reinemund[1], E. Gevers[2], M. Sarri[2], K. Downes[3], A. Offiah[4], A. Albanese[5], D. Halsall[1], J. Schwabe[6], M. Bain[5], K. Lindley[2], F. Muntoni[7], F. Vargha-Khadem[2], M. Dattani[2], S. Farooqi[1], M. Gurnell[1] & K. Chatterjee[1]
[1]Addenbrooke's Hospital, Cambridge, UK; [2]Great Ormond Street Hospital for Children, London, UK; [3]Cambridge Institute for Medical Research, Cambridge, UK; [4]University of Sheffield, Sheffield, UK; [5]St George's Hospital, London, UK; [6]University of Leicester, Leicester, UK; [7]Institute of Child Health, London, UK.

Introduction
Thyroid hormones act via receptors encoded by different genes (THRA and THRB) generating receptor subtypes (TRα1, TRβ1, TRβ2) with differing, tissue-specific expression. Resistance to Thyroid Hormone due to THRB defects is well recognised, but no THRA mutations have yet been reported. We describe the first case of human TRα-mediated thyroid hormone resistance due to a dominant negative THRA mutation.
Results
A 6-year-old female presented with lower segmental growth retardation (height < 10th centile), skeletal dysplasia (delayed bone age, femoral epiphyseal dysgenesis, delayed fusion of cranial sutures) and severe constipation. Thyroid function tests showed low/low-normal free T4 (fT4), high/high-normal free T3 (fT3), low reverse T3 (rT3) and normal TSH resulting in a markedly subnormal fT4/fT3 ratio. Heart rate, blood pressure (BP) and basal metabolic rate (BMR) were subnormal, but serum sex hormone binding globulin concentrations (SHBG), a hepatic marker of thyroid hormone action, were elevated.
Whole exome sequencing identified a heterozygous nonsense mutation (E403X) in THRA, generating a carboxyterminally truncated receptor protein which binds corepressors aberrantly and inhibits wild type receptor action in a dominant-negative manner. Thyroxine treatment suppressed TSH and normalised BMR with a further rise in SHBG; but heart rate, BP, growth retardation and intestinal dysmotility remained refractory.
Conclusions
This patient exhibits tissue-specific hypothyroidism paradoxically associated with only borderline abnormal thyroid hormone levels, synonymous with findings in TRα mutant mice. Some parameters (TSH, SHBG) responded to thyroxine treatment, but cardiac, gastrointestinal and skeletal tissues remained refractory. Such differential tissue sensitivity to thyroid hormone action, reflects preserved hormone responsiveness in TRβ-expressing tissues (e.g. hypothalamus, pituitary and liver) but resistance in TRα-expressing tissues (skeleton, gastrointestinal tract and myocardium). Recognition of hypothyroid features, but associated with a distinctive biochemical profile (subnormal fT4/fT3 ratio, low rT3), may enable future identification of additional cases.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

[1]University Hospital Gentofte, Hellerup, Denmark; [2]University Hospital Herlev, Herlev, Denmark; [3]University Hospital Roskilde, Roskilde, Denmark; [4]Copenhagen General Practitioners Laboratory, Copenhagen, Denmark.

Background
It is still uncertain if subclinical thyroid disease or 'high-normal' thyroid function are risk-factors for atrial fibrillation (AF).
Objectives
To examine the risk of AF in relation to thyroid function.
Methods
Patients consulting their general practitioner from 2000–2009 in Copenhagen, Denmark, who underwent thyroid blood tests, were identified by individual-level linkage of nationwide registries. Patients with a history of thyroid disease, AF or related medication were excluded. Risk of AF was analyzed using cumulative incidence plots and Poisson regression models to gain Incidence Rate Ratios (IRR).
Results
Of 525,100 individuals in the study population (mean age 51.7 years [s.d. ±18.0]; 39.5% males) 504,113 (96.0%) were euthyroid, 1474 (0.3%) had clinical hypothyroidism, 10,679 (2.0%) subclinical hypothyroidism, 3421 (0.7%) clinical hyperthyroidism and 5414 (1.0%) subclinical hyperthyroidism. A 'dose-dependent' increased risk of AF was found in two levels of subclinical hyperthyroidism (TSH <0.1, 0.1–0.2 mU/l): IRR 1.8 [95% CI: 1.5–2.2], IRR 1.5 [1.2–2.0] and in 'high-normal' levels of euthyroidism (TSH 0.2–0.4 mU/l): IRR 1,3 [1.2–1.5]. Both clinical and subclinical hypothyroidism was associated with a lower risk of AF.
Conclusions
Subclinical hyperthyroidism and 'high-normal' thyroid function is a significant risk-factor for AF, whereas hypothyroidism is associated with decreased risk of AF.

**Is overt hypothyroidism associated with increased mortality? A nationwide register-based study of disease discordant Danish twins**

M. Thvilum[1], F. Brandt[1], D. Almind[2], K. Christensen[1,2], T. Brix[1] & L. Hegedüs[1]
[1]Odense University Hospital, Odense C, Denmark; [2]University of Southern Denmark, Odense C, Denmark.

Background
Overt hypothyroidism (OH) has repeatedly been associated with a number of potential lethal conditions. However, it is still debated whether OH is linked with increased mortality. Moreover, a link between OH and mortality could be the result of common genetic and environmental factors affecting both OH and mortality. Investigating twin pairs discordant for OH can minimize this potential confounding. Our objective was to investigate, at a nationwide level, whether OH influence mortality.
Study populations
A random 5% sample of the Danish population ($n = 281\,549$) and all Danish twins ($n = 96\,064$) born between 1870 and 1990.
Methods
Unpaired and intrapair Cox regression analyses were compared. From the discordant twin pair design, early environmental and genetic confounding was controlled by design. The participants were followed until December 31, 2008.
Results
In the 5% sample of the Danish population, mortality was increased by 20% in subjects with OH (Hazard ratio, HR = 1.20, 95% CI, 1.14–1.27). The impact of OH on mortality remained significant after adjusting for the degree of comorbidity (HR = 1.16, 95% CI, 1.10–1.23). OH was not associated with an increased mortality in the analyses of twins discordant for OH (HR = 1.03, 95% CI, 0.75–1.42). Stratifying for zygosity yield essential similar results in monozygotic (HR = 1.00, 95% CI, 0.54–1.83) and dizygotic same sex pairs (HR = 1.04, 95% CI, 0.71–1.52).
Conclusion
Our findings of lack of association between OH and mortality within DZ and MZ twin pairs discordant for OH, implies, that the association found in the singletons may be due to genetic and environmental confounding.

**Prevalence of TSH receptor mutation and clinical characteristics among 84 patients with hyperthyroidism with diffuse goiter and negative TBII**

E. Nishihara[1], S. Fukata[2], Y. Nagayama[3], A. Hishinuma[4], N. Amino[1] & A. Miyauchi[1]
[1]Kuma Hospital, Kobe, Japan; [2]Tajiri Clinic, Kumamoto, Japan; [3]Nagasaki University, Nagasaki, Japan; [4]Dokkyo University of Medicine, Mibumachi, Japan.

Introduction
Hyperthyroidism with diffuse goiter and negative TBII includes Graves' disease in the early stage or near remission and nonautoimmune hyperthyroidism (NAH) caused by constitutively activating germline mutations of TSH receptor. To verify the NAH in this situation, we examined TSH receptor mutation and followed-up the clinical course.
Patients and methods
From 2003 through 2011, 84 patients had hyperthyroidism with negative TBII and diffuse radioiodine uptake in the thyroid. Genomic DNA sequencing analysis of the TSH receptor gene was performed for these patients (11 men and 73 women; median, 36 years).
Results
Four families with novel heterozygous point mutations (L512Q,E575K,-D617Y,L267F) consisted of 11 members were detected. Subsequent *in vitro* functional assays except for L267F showed their constitutive activity. There was a family history of hyperthyroidism in 90.9% of the group with TSH receptor mutation and in 32.9% of the group without mutation. There were no significant difference of sex, age and thyroid volume at first visit between the two groups. Among 11 patients of the mutated group, 5 had consistently subclinical hyperthyroidism without therapy, 3 were treated with anti-thyroid drug or inorganic iodine (ATD/KI), and 3 underwent ablative therapy (surgery or radioiodine) during 1 to 8 years of follow-up. Meanwhile, among 57 patients of non-mutated group, 14 obtained remission, 15 had consistently subclinical hyperthyroidism without therapy, 8 were treated with ATD/KI, 3 underwent ablative therapy, 5 were suspicious for toxic multi-nodular goiter, and 12 had positive TBII during more than 1 year of follow-up.
Conclusion
The genetic analysis of TSH receptor shows the frequency of NAH family is about 5% among all subjects. Approximately half of non-mutated patients are considered as Graves' disease in the early stage or near remission.

Objective
The role of thyroid hormones in the control of erectile functioning has been only marginally investigated. The aim of this study is to investigate the association between thyroid and erectile function in a general population sample (European Male Aging study, EMAS study) and in patients seeking medical care for sexual dysfunction (University of Florence Study, UNIFI study).
Participants
Two different cohorts of subjects were evaluated. The first one derives from EMAS study, a multicenter survey performed on a sample of 3370 community dwelling men aged 40–79 years (mean $60 \pm 11$ years). The second cohort is a consecutive series of 3203 heterosexual male patients (mean age $51.8 \pm 13.0$ years) attending our Andrology and Sexual Medicine Outpatient Clinic for sexual dysfunction at the University of Florence (UNIFI study). In the EMAS study all subjects were tested for thyroid-stimulating hormone (TSH) and free thyroxin

(FT4). Similarly, TSH levels were checked in all patients in the UNIFI study, while FT4 only when TSH resulted outside the reference range.
Results
Overt hyperthyroidism (reduced TSH and elevated FT4, according to the reference range) was found in 0.3 and 0.2% of EMAS and UNIFI study, respectively. In the EMAS and UNIFI samples, TSH levels were inversely related with erectile dysfunction (ED). Overt hyperthyroidism was associated with an increased risk of severe erectile dysfunction (ED, hazard ratio = 14 and 16 in the EMAS and UNIFI study, respectively; both $P<0.05$), after adjusting for confounding factors. These associations were conformed in nested case-control analyses, comparing subjects with overt hyperthyroidism to age, BMI, smoking status and testosterone-matched controls. Conversely, no association between hypothyroidism and ED was observed.
Conclusions
Erectile function should be evaluated in all individuals with hyperthyroidism. Conversely, assessment of thyroid function cannot be recommended as routine practice in all ED patients.

## OC11.6

### Is age a risk factor for hypothyroidism in pregnancy? An analysis of 5223 pregnant women

E. Potlukova[1], O. Potluka[2], J. Jiskra[1], Z. Limanova[1], Z. Telicka[1], J. Bartakova[1] & D. Springer[1]
[1]General University Hospital and 1st Faculty of Medicine, Charles University, Prague, Czech Republic; [2]Faculty of Business Administration, University of Economics, Prague, Czech Republic.

Introduction
The guidelines of American Thyroid Association from 2011 include age over 30 as one of the risk factors for hypothyroidism in pregnancy. The aim of our study was to verify whether age increases the risk of autoimmune thyroid diseases (AITD) in pregnant women.
Methods
We performed a cross-sectional study in 5223 unselected consecutive pregnant women in the 9th–12th gestational weeks. In a single laboratory, we measured serum concentrations of thyroid-stimulating hormone (TSH) and antibodies against thyroperoxidase (TPOAb). Reference interval for TSH was 0.06–3.67 mU/l; the upper cut-off value for TPOAb was 143 kU/l.
Results
Overall, 857 (16.4%) women were positively screened. Of these, 294 (5.63%) had TSH elevation; 146 (2.79%) TSH suppression; 561 (10.74%) were TPOAb+ and 417 (7.98%) were euthyroid and TPOAb+. The average age was 31.1 years with 65.1% of women being $\geq$30 years of age. Of the 294 hypothyroid women, 189 (64.3%) were $\geq$30 years. Using logistic regression model, we did not find any significant association between age and neither serum TSH suppression, TSH elevation and TPOAb positivity ($P=0.553$. $P=0.680$ and $P=0.056$, respectively), nor between age and TSH elevation with TPOAb positivity combined ($P=0.967$). In a subgroup analysis of risk factors for hypothyroidism in 132 hypothyroid women, addition of age $\geq$30 increased the proportion of women identified in a case-finding screening according to ATA from 55.3 to 85.6%.
Conclusions
Prevalence of AITD does not increase with age in pregnant women; however, addition of age $\geq$30 to the case-finding screening strategy may substantially improve its efficacy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## OC12.1

### Circulating endocannabinoids are associated to cardiometabolic alterations independently from adiposity

F. Fanelli, M. Mezzullo, I. Belluomo, V. Di Lallo, M. Colavita, M. Baccini, E. Casadio, D. Ibarra Gasparini, V. Vicennati, R. Pasquali & U. Pagotto
S.Orsola Hospital - University of Bologna, Bologna, Italy.

Obesity is characterized by an increase of endocannabinoid circulating levels as anandamide (AEA) and 2-arachidonoyl-glycerol (2AG). Whether these lipids represent a biomarker of dysmetabolism or merely reflect the fat mass spill-over is still unclear. After generating rigorous, gender specific, plasma reference intervals by 2D-liquid chromatography-tandem mass spectrometry, we defined the 97.5thcentile of endocannabinoid distribution in the normal population as the cut-off above which they are considered pathological: 2AG = 4.23 and 3.12 pmol/ml; AEA = 1.66 and 1.59 pmol/ml, in males (M) and females (F), respectively. By using the cut-off we analyzed the endocannabinoid levels in a 348M and 439F population (106 and 160 normal weight (NW), BMI $\leq$ 24.9 kg/m$^2$; 242 and 279 overweight/obese subjects, BMI $\geq$ 25.0 kg/m$^2$) aged 18–90 y. 3.8%M ($n=4$) and 9.4%F ($n=15$) of NW and 8.7%M ($n=21$) and 17.2%F ($n=48$) of overweight/obese showed elevated 2AG, while 3.8%M ($n=4$) and 9.4%F ($n=15$) of NW and 9.5%M ($n=23$) and 29.4%F ($n=82$) of overweight/obese displayed increased AEA, respectively, indicating that obese/overweight F have more frequently pathologically plasmatic AEA levels. Within overweight/obese group, metabolic features were compared between subjects having normal or elevated 2AG and AEA levels. Males with elevated 2AG showed similar BMI but higher diastolic and systolic blood pressure (DBP and SBP, $P=0.018$ and $P=0.006$, respectively) and triglycerides ($P=0.036$) compared to those having 2AG in the normal range. Females with higher 2AG showed increased BMI ($P=0.012$), glycaemia ($P=0.020$) and triglycerides ($P<0.0001$), the latter maintaining the statistical significance after correction for BMI ($P=0.0005$). Both males and females with elevated AEA exhibited higher BMI and waist circumference compared to those with AEA in the normal range ($P=0.025$ and $P<0.0001$; $P=0.014$ and $P=0.001$, respectively). Females showing higher AEA had increased DBP, SBP and insulin even after correction for BMI ($P=0.006$, $P=0.016$ and $P=0.032$, respectively). In conclusion, circulating endocannabinoids are associated in a gender-specific fashion to cardiometabolic alterations independently from adiposity.

## OC12.2

**Lipid-induced insulin resistance is associated with a reduction of IGF1 bioactivity independent of changes in IGFBP-1 and -2 in humans**

A. Arafat[1,2], S.v.G. Homssi[1], M. Weickert[3,4], J. Kraatz[1], J. Spranger[1,5,6], J. Frystyk[6], A. Pfeiffer[1,2] & M. Mohlig[1,2]
[1]Charité-University Medicine Berlin, Campus Benjamin Franklin, Berlin, Germany; [2]German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, Germany; [3]University Hospitals Coventry and Warwickshire NHS Trust, Coventry, UK; [4]Warwick Medical School, University of Warwick, Coventry, UK; [5]Charité-University Medicine Berlin and Max-Delbrück Centre Berlin-Buch, Berlin, Germany; [6]Charité-University Medicine Berlin, Berlin, Germany; [7]Faculty of Health Sciences, Aarhus University, Aarhus, Denmark.

Objectives
Insulin interacts with the GH – insulin-like growth factor (IGF) system by a reciprocal regulation of IGF-binding proteins (IGFBPs) and GH, which in turn interact to regulate insulin sensitivity (IS). We previously showed that IGFBP-2 is involved in the insulin-induced reduction in IGF1 bioactivity. We here address the modulation of IGF1 bioactivity during acute lipid-induced insulin resistance.
Methods
18 healthy men ($30.8 \pm 2.6$ years; BMI $23.6 \pm 0.5$ kg/m$^2$) were studied in a controlled, randomized crossover trial using lipid-heparin infusion at a dose inducing physiological elevations of free fatty acids (FFAs), vs saline-heparin infusion as control. IS was quantified by subsequent hyperinsulinemic euglycemic clamps. IGF1 bioactivity was estimated using an IGF1 kinase receptor activation assay (KIRA). Total IGF1, IGFBP-1 and IGFBP-2 were also measured under fasting conditions, during lipid or saline infusions and during the steady state of the subsequent clamps.
Results:
Lipid-infusion significantly reduced IGF1 bioactivity [$3.3 \pm 0.3$ µg/l (baseline) vs $2.5 \pm 0.2$ (180 min); $P<0.01$], total IGF1 [$135.2 \pm 10.8$ µg/l (baseline) vs $121.9 \pm 9.7$ (180 min); $P<0.01$] and IGFBP-1 [$27.1 \pm 4$ µg/l (baseline) vs $15.2 \pm 2.4$ (180 min); $P<0.01$]. This was associated with significant reduction in peripheral glucose-uptake [GIR.kg-1BW: $4.3 \pm 0.4$ (lipid) vs $6.1 \pm 0.5$ (saline); $P<0.01$]. No changes were detected after saline-infusion ($P>0.05$).
Subsequently, euglycemic hyperinsulinemia induced further reductions in IGF1 bioactivity and in IGFBP-1 levels ($P<0.01$) in both intervention arms, but did not change total IGF1 levels ($P>0.05$).
IGFBP-2 levels did not change neither after lipid- nor saline-infusions ($P>0.05$) but significantly increased during steady state ($P<0.05$).
Conclusions
We here show that lipid-induced reduction of insulin sensitivity was associated with reduction in IGF1 bioactivity. The impact of elevated free fatty acids/triglycerides on IGF1 bioactivity was not mediated by changes in IGFBPs, but may relate to the concomitant suppression of total IGF1.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## OC12.3 The Young Investigator Winner

**Transient increase of beta-cell first phase secretion after smoking cessation: a possible contributor to carbohydrate craving and body weight gain?**

M. Stadler[1,6], L. Toman[1], A. Storka[2], M. Wolzt[2], S. Peric[1], C. Bieglmayer[2], O. Wagner[2], G. Pacini[3], H. Brath[4], P. Bech[5], R. Prager[1] & M. Korbonits[6]
[1]Hietzing Hospital Vienna, Vienna, Austria; [2]Medical University Vienna, Vienna, Austria; [3]Institute of Biomedical Engineering, National Research Council, Padova, Italy; [4]Health Care Center Vienna South, Vienna, Austria; [5]Hammersmith Hospital, Imperial College London, London, UK; [6]Barts and the London School of Medicine, London, UK.

Despite the known health hazards of cigarette smoking, many smokers fail to quit smoking, mainly due to nicotine's addictiveness, but also because of fear from gaining weight. However, the mechanism of weight gain after smoking cessation is not fully elucidated yet.
Healthy long-term smokers ($28 \pm 2$ years, 10F/20M, $23.4 \pm 1.3$ kg/m$^2$) participating in a smoking cessation programme underwent 3-hour oral glucose tolerance tests (oGTT) and body composition measurements while still smoking (Visit A; $n=27$) and after a minimum of 3 (3 m; $n=14$) and 6 months (6 m; $n=8$) of non-smoking. Fasting (QUICKI) and dynamic insulin sensitivity (OGIS) were calculated. First phase beta-cell secretion was calculated as the ratio of C-peptide and glucose areas under the curve in the first 40 min of oGTT (IGI40). Appetite was quantified with a free-choice-buffet. Fasting plasma concentrations of neuropeptide-Y (NPY), peptide-YY (PYY), glucagon-like-peptide-1 (GLP-1), leptin, ghrelin and visfatin were measured.
Body weight and fat mass increased after 3 m (+4% and +22% respectively) and after 6 m non-smoking (+5% and +35% respectively, $P<0.05$ vs baseline).

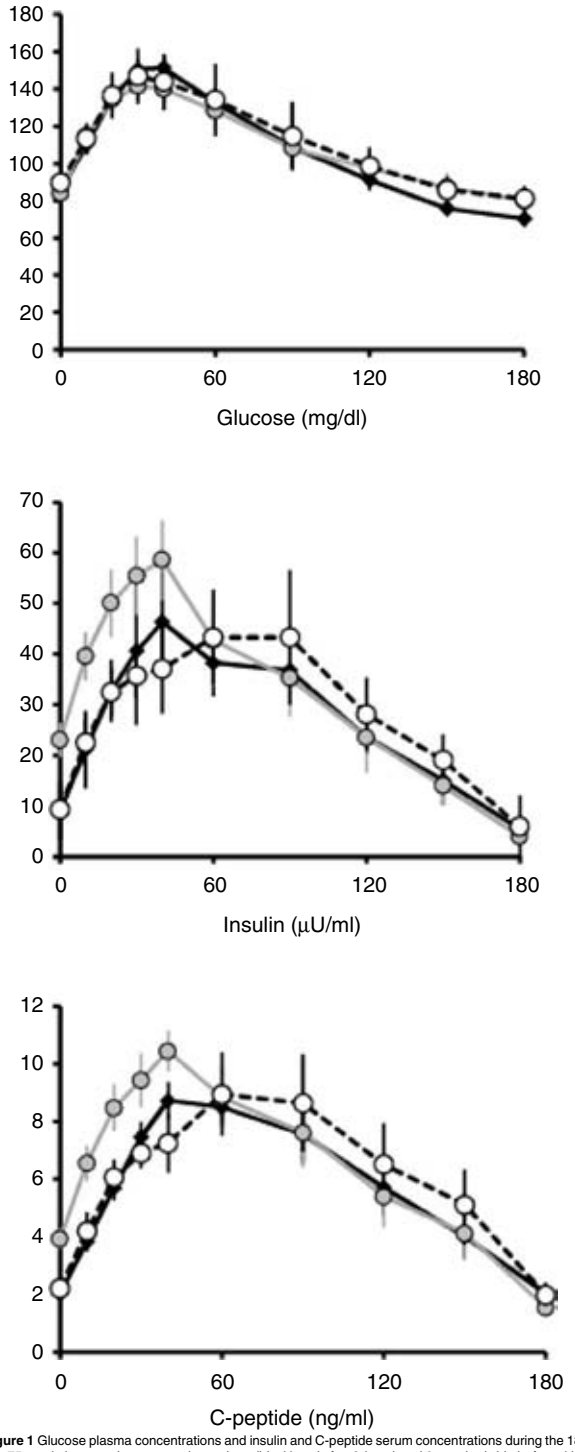

**Figure 1** Glucose plasma concentrations and insulin and C-peptide serum concentrations during the 180 min 75g oral glucose tolerance test in smokers (black) and after 3 (grey) and 6 months (white) of smoking cessation.

Participants showed significant fasting insulin resistance (QUICKI: 3 m:0.37 ± 0.02 vs baseline:0.41 ± 0.2; $P < 0.05$) at 3 m, but not at 6 m, while OGIS remained unchanged throughout. IGI40 increased by 31% after 3 m (baseline:0.299 ± 0.11 vs 3 m:0.391 ± 0.11, $P < 0.01$), but reversed to normal after 6 m (0.265 ± 5). Accordingly, carbohydrate ingestion was significantly increased after 3 m (3 m:500 ± 39 kcal vs baseline:396 ± 45 kcal; $P < 0.05$), but not after 6 m. Fasting NPY was increased at 3 m (3 m: 0.41 ± 0.03 ng/ml vs baseline:0.26 ± 0.04 ng/ml; $P < 0.05$), but not at 6 m. Interestingly, increased beta-cell-secretion at 3 m was less pronounced in participants finally succeeding to quit smoking for at least 6 m, as opposed to those relapsing after 3 m ($P < 0.05$).

Smoking cessation leads to a transient increase of first phase beta-cell secretion in response to glucose, fasting insulin resistance and NPY plasma levels. These alterations could contribute to increased carbohydrate craving and consequent body weight gain after smoking cessation (Fig. 1).

### Genetic susceptibility, birth weight and obesity risk in young chinese

J. Shi[1], J. Hong[1], L. Qi[3], B. Cui[2], W. Gu[1], Y. Zhang[1], L. Li[1], M. Xu[1], L. Wang[1], Y. Zhai[1], L. Miao[1], R. Wang[1], Y. Bi[1], W. Wang[1] & G. Ning[1]
[1]Ruijin Hospital, Shanghai, China; [2]Institute of Health Sciences, Shanghai, China; [3]Harvard School of Public Health, Boston, Massachusetts, USA.

Thus far, approximately 30 loci influencing body mass index (BMI) and the risk of obesity have been identified. In this study, we aimed to examine the individual and joint associations of 23 BMI-associated loci identified from recent genome-wide association studies in Caucasians with obesity risk in young Chinese. Birth weight reflects prenatal metabolic adaption and has been related to later-life obesity risk. We particularly assessed whether these genetic variants interacted with birth weight in relation to obesity risk. We recruited 540 young (14–30 years) and obese patients (BMI $\geq$ 30 kg/m$^2$), and 500 age- and sex-matched normal-weight healthy individuals (BMI $<$ 23 kg/m$^2$).We genotyped genetic variants in those 23 BMI-associated loci. Six loci, including SEC16B, GNPDA2, BDNF, FTO, MC4R and TMEM160, were significantly associated with obesity risk, with odds ratio from 1.314 to 1.701. These risk loci accounted for 4.84% of the genetic variance in obesity. We created a genetic risk score (GRS) by summing the risk alleles of these associated genetic variants. Prediction of obesity was significantly improved ($P <$ 0.001) when the GRS was added to a model with age and gender, with improvement of discrimination for obesity by 2.7%. In addition, we found that the GRS interacted with birth weight in relation to obesity ($P$ interaction $<$ 0.001). The genetic effect appeared to be more pronounced in individuals with normal range of birth weight (25–75%) than those with either low ($<$25%) or high ($>$75%) birth weight. In conclusion, we showed that the combined genetic risk of variants identified from European populations might significantly improve the identification of high-risk group of obesity in young Chinese. For the first time, we demonstrated birth weight might interact with genetic susceptibility in relation to obesity risk in later life, which deserves consideration in future efforts to prevent obesity.

## OC12.5

### Brown adipose tissue activation is inversely related with central obesity and metabolic parameters in adult human

W. Wang[1], Q. Wang[1], M. Zhang[2], M. Xu[1], W. Gu[1], L. Qi[3], B. Li[2] & G. Ning[1]
[1]Division of Endocrinology and Metabolism of The E-Institute of Shanghai Universities, Shanghai, China; [2]Ruijin Hospital, Shanghai, China; [3]Harvard School of Public Health, Boston, Massachusetts, USA.

Background

Recent studies have shown that adult human possess active brown adipose tissue (BAT), which might be important in affecting obesity and related metabolic risk. However, the supporting evidence in large population based studies is sparse.

Methods

We studied 4011 (2688 males and 1323 females) tumor-free Chinese adults aged 18–89 for BAT activities, visceral/subcutaneous fat areas and metabolic parameters. *In vivo* 18F-fluorodeoxyglucose (18F-FDG) uptake into adipose tissue and abdominal fat distribution were measured by whole body FDG-positron-emission tomography and computed tomography (PET/CT) and CT scans at umbilicus level.

Results

We found that the prevalence of BAT was around 2.7% in our study participants, with a significant sexual difference (5.5% in the females vs 1.3% in the males; $P < 0.0001$). BAT detection was increased in low temperature and declined in elderly subjects. The BAT positive subjects had lower BMI ($P < 0.0001$), less subcutaneous fat areas ($P < 0.01$), visceral fat areas ($P < 0.0001$), waist circumferences ($P < 0.0001$), lower fasting glucose and triglyceride levels (both $P < 0.01$) and increased HDL cholesterol concentrations ($P < 0.0001$), compared with the BAT negative subjects. Robust logistic regression revealed that after adjustment for covariates (including age, sex, BMI, visceral and subcutaneous fat areas and waist circumferences), age and BMI in the males (OR 0.92 and 0.84, both $P < 0.008$) while age and visceral fat areas in the females (OR 0.87 and 0.98, respectively, $P < 0.05$) were independently associated with detectable BAT.

Conclusion

We found the amount of active BAT is inversely related with central adiposity and metabolic parameters in adult humans, suggesting a potential role of BAT in the control of body weight and metabolic status.

**Eating speed and the risk of type 2 diabetes mellitus: a case-control study**

L. Radzeviciene & R. Ostrauskas
Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction
Diabetes mellitus is one of the main public health issues. It is becoming a world pandemic. Type 2 diabetes appears to involve interaction between susceptible genetic backgrounds and environmental factors. It's important to identify modifiable risk factors that may help reduce the risk of type 2 diabetes. For the meantime no data in scientific literature or eating speed could influence on the risk of developing type 2 diabetes mellitus. Therefore the aim of the study was to assess the relationship between eating speed and the risk of type 2 diabetes mellitus.
Subjects and methods
A case-control study included 234 cases with newly confirmed diagnoses of type 2 diabetes mellitus and 468 controls those who were free of the disease. Cases and controls (ratio 1:2) were matched by gender and age (+5 years). A specifically designed questionnaire was used to collect information on possible risk factors of type 2 diabetes mellitus. Anthropometrical measurements were made according to WHO recommendations. The odds ratios (OR), and 95% confidence intervals (CI) for type 2 diabetes mellitus were calculated by a conditional logistic regression.
Results
The cases had higher body mass index and significantly lower education level, compared to the controls.
Variables such as a family history on diabetes, education, morning exercise, body mass index, waist circumference, cigarette smoking and plasma triglycerides level were retained in multivariate logistic regression models as confounders because their inclusion changed the value of the OR by more than 5% in any exposure category. After adjustment for possible confounders more than two-fold increased risk of type 2 diabetes mellitus was determined for subjects eating faster (OR = 2.52; 95% CI 1.56–4.06) vs subjects eating slower.
Conclusions
Our data support a possible relationship between faster eating speed and the increased risk of type 2 diabetes mellitus.

**Targeting multiple signalling pathways showed high anti-tumour potential in two mouse phaeochromocytoma cell lines**

S. Nölting[1], E. Garcia[1], G. Alusi[1], M. Korbonits[1] & A. Grossman[1,2]
[1]William Harvey Research Institute, Barts and The London School of Medicine, Queen Mary Universtity of London, London, UK; [2]Oxford Centre for Diabetes, Churchill Hospital, University of Oxford, Oxford, UK.

Introduction
Since there is no completely effective therapy available for malignant phaeochromocytomas (PCCs) and paragangliomas, we have been investigating novel targeted therapies utilising one more benign (MPC) and one more malignant (MTT) PCC cell line. We have previously shown that the IGF1-receptor-inhibitor NVP-AEW541 led to compensatory ERK and mTORC1 up-regulation at suboptimal doses and that the dual PI3K/mTORC1-inhibitor NVP-BEZ235 also resulted in compensatory ERK activation at low doses. Therefore we speculated that the efficacy of NVP-BEZ235 may be enhanced by combination with the established agent lovastatin which inhibits ERK-signalling.
Methods/Design
Both cell lines, generated from heterozygous Neurofibromin-1 knock-out-mice, were treated with varying concentrations of lovastatin, NVP-BEZ235, or the combination of both drugs, for different time periods. Metabolic viability was assessed by cell proliferation assay (MTS). Protein levels of phospho-(p) and total AKT, ERK and p70S6K were investigated by Western blotting in MPC cells. Apoptosis was measured by a caspase assay (Caspase-Glo®3/7) in MPC and MTT cells.
Results
Lovastatin significantly dose- and time-dependently decreased MPC and MTT cell viability and diminished pAKT and pERK, but increased pp70S6K. Pre-treatment for 24 h with 10 uM lovastatin followed by addition of 50nM NVP-BEZ235 for 48 h showed a marked additive effect in both cell lines. Combination treatment decreased both pAKT and pp70S6K without ERK up-regulation. Single treatment with NVP-BEZ235 did not induce apoptosis. However, lovastatin significantly enhanced apoptosis compared to the vehicle. Combination treatment increased apoptosis compared to single NVP-BEZ235 treatment but decreased apoptosis compared to single lovastatin treatment.
Conclusions
Targeting PI3K/AKT-, mTORC1/p70S6K- and ERK-signalling simultaneously suggests a novel therapeutic approach for malignant PCCs. Targeting only one or two of these pathways results in compensatory activation of the remaining ones. ERK inhibition appears to specifically increase apoptosis.

## OC13.2

**VSNL1 is upregulated in aldosterone producing adenomas with KCNJ5 mutations and protects from calcium-induced apoptosis**

S. Monticone[1], V. Crudo[1], J. Burrello[1], M. Galmozzi[1], R. Warth[2], F. Veglio[1], P. Mulatero[1] & T. Williams[1]
[1]University of Torino, Torino, Italy; [2]University of Regensburg, Regensburg, Germany.

Visinin-like 1 (VSNL1) is upregulated in aldosterone-producing adenomas (APA) compared to normal adrenals. We demonstrate that VSNL1 over-expression in adrenocortical carcinoma cells (NCI H295R) upregulates basal and angiotensin II (Ang II)-stimulated CYP11B2 gene expression 3.2- and 1.5-fold, respectively. Conversely, silencing VSNL1 by RNA interference decreases Ang II-stimulated CYP11B2 expression and aldosterone secretion by 41 and 34.5%, respectively. Mutations in the potassium channel KCNJ5 have been identified in APA that result in sodium influx, membrane depolarization and are postulated to result in calcium influx in adrenal glomerulosa cells. VSNL1 and CYP11B2 are 8.1- and 6.0-fold more highly expressed, respectively, in APA harbouring KCNJ5 mutations compared to those without, and the upregulation of VSNL1 in these APA accounts for the overexpression of VSNL1 in the total APA sample set compared to normal adrenals. Silencing VSNL1 in H295R cells renders them sensitive to ionomycin-induced apoptosis indicating that VSNL1 protects these cells against calcium-induced cell death. Concomitant expression of mutated KCNJ5 (G151R) and silencing VSNL1 results in apoptosis of H295R cells, an effect that is blocked by nifedipine and is absent using a control siRNA or when wild-type KCNJ5 is expressed and VSNL1 is silenced. These data demonstrate that VSNL1 plays a dual function in vitro in the regulation of CYP11B2 gene expression and in the inhibition of calcium-induced apoptosis. Additionally, VSNL1 may play a role in the pathophysiology of APA harbouring mutations in the potassium channel KCNJ5 via its anti-apoptotic function in response to calcium cytotoxicity and its effect on aldosterone production.

**Cortisol secretion is dependent on intraadrenal production of ACTH in macronodular bilateral adrenal hyperplasia causing Cushing's syndrome**

E. Louiset[1], C. Duparc[1], J. Young[2], I. Boutelet[1], S. Renouf[1], Z. Bram[1], L. Groussin[3], P. Caron[4], A. Tabarin[5], F. Grunenberger[6], S. Christin-Maitre[7], J. Kuhn[1,8], Y. Anouar[1], J. Bertherat[3] & H. Lefebvre[1,8]
[1]Institute for Biomedical Research and Innovation, University of Rouen, Rouen, France; [2]Kremlin-Bicêtre University Hospital, APHP, Bicêtre, France; [3]Cochin University Hospital, APHP, Paris, France; [4]CHU de Toulouse - Hôpital Larrey, Toulouse, France; [5]CHU de Bordeaux - Hôpital du Haut Lévêque, Pessac, France; [6]Hôpital de Hautepierre, CHU de Strasbourg, Strasbourg, France; [7]Hôpital Saint-Antoine, APHP, Paris, France; [8]Rouen University Hospital, Institute for Biomedical Research and Innovation, Bois Guillaume, France.

Illicit expression of membrane receptors for circulating regulatory factors, such as gastric inhibitory polypeptide (GIP), luteinizing hormone (LH) and serotonin (5-HT) receptors, has been well documented in ACTH-independent macronodular adrenal hyperplasias (AIMAHs) causing Cushing's syndrome. In addition, we have observed an abnormal expression of ACTH in some steroidogenic cells in two AIMAH tissues. The aim of the present study was to investigate the role of local production of ACTH in the control of steroidogenesis in a series of 30 AIMAH tissues. Expression of pro-opiomelanocortin (POMC) mRNA and ACTH-like immunostaining were detected in all tissues studied. ACTH co-localized with 17-hydroxylase, the HDL-cholesterol receptor SR-B1, prohormone convertase 1 and secretogranin II immunoreactivities in clusters of cells disseminated throughout hyperplasia tissues. Perifusion experiments demonstrated that adrenal slices spontaneously released detectable amounts of ACTH in a pulsatile fashion. ACTH secretion was significantly increased *in vitro* by GIP, hCG and 5-HT in tissues previously sensitive *in vivo* to the stimulatory action of food intake, hCG and 5-HT4 receptor agonists. In addition, measurement of ACTH concentrations in plasma obtained from two AIMAH patients during adrenal vein sampling showed a significant ACTH gradient versus periphery indicating that AIMAH tissues actually secrete ACTH *in vivo*. The ACTH receptor antagonists corticostatin and ACTH(7–38) reduced basal as well as GIP-induced cortisol production from perifused hyperplasia tissues. These data indicate that, in AIMAH tissues, ACTH released by a subpopulation of steroidogenic cells exerts an intraadrenal stimulatory tone on cortisol secretion. They also suggest that macronodular bilateral adrenal hyperplasia may be regarded as a cause of ACTH-dependent Cushing's syndrome due to ectopic expression of corticotropin within the adrenal cortex. This work was supported by grants from INSERM, University of Rouen, Assistance Publique des Hôpitaux de Paris, the COMETE network, the Société Française d'Endocrinologie and Novo Nordisk Laboratory.

Introduction

DNA methylation is a mechanism for gene expression dysregulation in cancer. Little is known about methylation in adrenocortical tumors (ACT). Previous transcriptome studies proposed an original classification of ACT, first discriminating carcinomas from adenomas, then separating the carcinomas in two groups with different prognosis (C1A and C1B), the poor outcome group (C1A) being divided in three subgroups: p53 inactivation sub-group (C1Ap53), β-catenin activation sub-group (C1Aβcatenin), and a third with no known molecular alteration (C1Ax). Here we studied the genes promoter methylation, and the relation between methylation and gene expression in ACT, especially with the transcriptome classification of ACT.

Patients and methods

Genome-wide methylation patterns of 84 adenomas and 51 carcinomas were studied by the Infinium HumanMethylation27 Beadchip (Illumina). Gene expression data were available for 87 tumors, including 34 carcinomas (HG-U133Plus2.0 AffymetrixGeneChip, Affymetrix).

Results

Overall, the carcinomas are more methylated than the adenomas (Wilcoxon-test, $P = 7e\text{-}07$). Methylation varies among transcriptome-based subgroups of carcinomas: two subgroups of poor outcome harbor a high level of methylation (C1Ap53 and C1Ax), one of poor outcome a low level of methylation (C1Aβcatenin), and one of better outcome an intermediate level of methylation (C1B).

A few genes are recurrently hypermethylated in carcinomas whatever the group (ex: H19), other genes having subgroup-specific methylation. The transcriptome/methylation correlation shows 1741 genes (out of 12 250) negatively correlated; among the top genes are the expected H19 and several tumor suppressors (PLAGL-1, G0S2, NDRG2).

Methylation and expression also show regional patterns, among which are the regions 1q22, 8p21.3, 11p15 and 17p13.1.

Conclusions

This first ACT genome-wide methylation study shows that specific methylation profiles characterize the transcriptome-identified subgroups of carcinomas. It identifies tumor suppressor genes with recurrent methylation aberrations, related to gene expression deregulation.

## OC13.5

**KCNJ5 mutations in Japanese patients with aldosterone-producing adenomas**

M. Yamada, R. Taguchi, Y. Nakajima, T. Satoh, K. Hashimoto, N. Shibusawa, A. Ozawa, T. Tomaru, S. Okada, N. Rokutanda, D. Takata, Y. Koibuchi, J. Horiguchi, T. Oyama, I. Takeyoshi & M. Mori
Gunma University Graduate School of Medicine, Maebashi, Japan.

Background

Primary aldosteronism (PA) has been reported to affect about 10% of patients with essential hypertension. In Western countries, about one third of them have aldosterone-producing adenomas (APA), and mutations of the KCNJ5 gene have recently been identified in approximately 30% of APAs. In contrast, most Japanese (~80%) with PA have APA. Therefore, Japanese PA may have different characteristics from patients in Western countries, and those with mutations of the KCNJ5 gene may have different features from those without.

Design

We sequenced KCNJ5 cDNAs in 25 tumors from patients with APA operated on at Gunma University Hospital and compared their clinicopathological features between patients with and without mutations. In addition, we investigated levels of KCNJ5 mRNA in the two groups and compared to those in cortisol-producing adenomas (Cushing's syndrome) and pheochromocytomas.

Results

Of the 25 patients with APA, 16 (64%) had two recurrent somatic mutations of the KCNJ5 gene: 12 cases of p.G151R (8 with c.451G > A, and 4 with c.451G > C) and 4 cases of p.L168R (c.503T > G). Levels of KCNJ5 mRNA were significantly higher in the APAs with mutations than those without. Immunohistochemistry also showed a stronger staining of KCNJ5 on the cell membrane in the tumor with a mutation. The level of KCNJ5 mRNA in cortisol-producing adenomas was approximately 30% of that in APAs, and almost no expression was observed in pheochromocytomas. In addition, the patients with mutations were statistically younger and showed higher plasma aldosterone concentrations and lower serum potassium levels.

Conclusions

i) We identified a high prevalence of mutations of the KCNJ5 gene in Japanese patients with APA, ii) KCNJ5 mRNA levels were higher in the APAs with KCNJ5 mutations, and iii) the expression of KCNJ5 mRNA was significantly higher in APAs than cortisol-producing adenomas and pheochromocytomas, and iv) patients with APAs associated with somatic mutations of the KCNJ5 gene may exhibit early onset and high serum aldosterone level.

### OC13.6

**GATA-4 overexpression induces adrenocortical tumorigenesis and ectopic expression of luteinizing hormone receptor in C57Bl/6J mice**

M. Chrusciel[1,2], S. Vuorenoja[1], B. Mohanty[1], A. Rivero-Müller[1], Z. Lei[3], J. Toppari[1], X. Li[4], I. Huhtaniemi[1,5] & N. Rahman[1,6]
[1]University of Turku, Turku, Finland; [2]Polish Academy of Science, Olsztyn, Poland; [3]University of Louisville, Louisville, Kentucky, USA; [4]China Agriculture University, Beijing, China; [5]Imperial College London, London, UK; [6]Florida International University College of Medicine, Miami, Florida, USA.

We have earlier shown a reciprocal feed-forward amplification link between expression of transcription factor GATA-4 and luteinizing hormone receptor (LHR) during adrenocortical tumorigenesis, and also that chronically elevated LH levels may induce LHR in mice, but not GATA-4. Hereby, our goal was to analyze the consequences of ectopically expressed GATA-4 on murine adrenal cortex in the presence and absence of gonadectomy (GDX) induced elevated LH levels. For this purpose, we established a transgenic (TG) murine model overexpressing ectopically GATA-4 under the adrenal specific 21-hydroxylase (21-OH) promoter (21-OH-GATA-4) in C57Bl/6J genetic background. In intact 21-OH-GATA-4 females, but not in males, a gradual age-dependent increase of adrenal Gata-4 expression was followed by slowly progressing hyperplasia of non-steroidogenic spindle-shaped cells (A cells) in the subcapsular cortex. This phenotype was markedly enhanced by GDX in both sexes. Additionally, adrenocortical hyperplastic areas of GDX 21-OH-GATA-4 mice, besides A cells, were also composed with large lipid-laden cells (B cells). Long exposure on elevated LH levels resulted with adrenocortical adenoma in 21-OH-GATA-4 females. Intact and GDX 21-OH-GATA-4 adrenals displayed high Fog-2 but downregulated Gata-6 expression. In contrast to WT adrenal cortex and neoplastic B cells, areas with spindle-shaped A cells in intact and GDX 21-OH-GATA-4 mice were SF-1, DAX-1 and CYP11A1a negative. Both normal and neoplastic adrenocortical cells were StAR positive. 21-OH-GATA-4 mice of both sexes expressed ectopic LHR already by the age of 2 mo. LHR was localized in morphologically normal adrenocortical cells and large lipid-laden B cells of intact and GDX 21-OH-GATA-4 adrenals. Our findings provide the molecular pathways into the induction of adrenocortical tumorigenesis and expression of LHR as a consequence of ectopic adrenocortical expression of GATA-4.

## Male reproduction

### OC14.1

**X chromosome-linked copy number variations in male infertility**

C. Krausz[1], C. Giachini[1], D. Lo Giacco[2,3], F. Daguin[1], E. Ars[3], E. Ruiz-Castane[2], G. Forti[1,4] & E. Rossi[4]
[1]University of Florence, Florence, Italy; [2]Fundació Puigvert, Barcelona, Spain; [3]Fundació Puigvert, Universitat Autònoma de Barcelona, Barcelona, Spain; [4]University of Pavia, Pavia, Italy.

The role of CNVs in male infertility is poorly defined, and only those linked to the Y chromosome have been the object of extensive research. Although it has been predicted that the X chromosome is also enriched in spermatogenesis genes, no clinically relevant gene mutations have been identified so far. In order to advance our understanding of the role of X-linked genetic factors in male infertility, we applied high resolution X chromosome specific array-CGH in 199 men with different sperm count followed by the analysis of selected, patient-specific CNVs in large groups of cases and controls. We identified 73 CNVs, among which 48 are novel, providing the largest collection of X-linked CNVs in relation to spermatogenesis. We found 21 patient-specific CNVs with potential clinical implication. Cancer Testis Antigen gene family members were the most frequently affected genes, and represent new genetic targets in relationship with altered spermatogenesis. The most relevant finding of our study is the significantly higher global burden of CNVs in patients than controls due to an excessive rate of deletions/person and to a higher mean sequence loss/person. Our observation adds 'CNV burden' to the list of those genetic anomalies which may link spermatogenic failure with genomic instability. The implications of this finding may not be restricted to infertility and should be taken into consideration in the era of assisted reproductive techniques, which allow infertile men to conceive their own biological children.

### OC14.2

**Deficient expression of genes involved in the endogenous defense system against transposons in cryptorchid boys with impaired mini-puberty**

F. Hadziselimovic, N. Hadziselimovic, P. Demougin & E. Oakeley
Kindertagesklinik Liestal, Liestal, Switzerland.

Mini-puberty is the period between 30 and 80 days after birth when testosterone and gonadotropin surges occur in male infants to induce the transformation of gonocytes into Ad (adult/dark) spermatogonia. Cryptorchid boys with impaired mini-puberty develop infertility despite timely and successful surgical treatment. The decreased germ cell count found in this group of boys could be the result of uncontrolled transposon activity inducing genomic instability and germ cell death. A genome-wide analysis of 18 cryptorchid and 4 control testes was performed with Affymetrix chips. We found that 6 of 8 genes that are important for transposon silencing were not expressed in the high azoospermia risk (HAZR) group of cryptorchid boys but were expressed in the low azoospermia risk (LAZR) and control groups. Two genes, CBX3 and DNMT1, were equally expressed in all 3 groups. Impaired expression of the DDX4, MAEL, MOV10L1, PIWIL2, PIWIL4, and TDRD9 genes in the group of cryptorchid boys at high risk of infertility indicates that gene instability induced by impaired expression of transposon silencing genes contribute to the development of azoospermia. Intact mini-puberty appears to be essential for the development of the endogenous defense system mediated by transposon silencing.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

### OC14.3

**Comparison of serum testosterone and estradiol levels in 3174 European men as measured by a platform immunoassay and mass spectrometry; relevance for the diagnostics in aging men**

I. Huhtaniemi[1], A. Tajar[2] & F. Wu[2]
[1]Imperial College London, London, UK; [2]The University of Manchester, Manchester, UK.

Testosterone (T) and estradiol (E2) are the two most important sex steroids in men and women, respectively, and their accurate determination in serum is of crucial importance in assessing gonadal function both in clinical management and research. The limitations of serum T and E2 measurements using non-extraction platform immunoassays (IA) are widely recognized. Switching to more specific mass spectrometry (MS)-based methods has been advocated but directly comparative data on the two methods are scarce. We compared here serum T and E2 measurements in a large sample of middle-aged/elderly men using a common platform IA and a gas chromatography (GC)-MS method, in order to assess their limitations and advantages, and to diagnose male hypogonadism, in subjects of the European Male Aging Study ($n=3174$; age 40–79 years). Peripheral serum T and E2 were analyzed using established commerical platform IAs (Roche Diagnostics E170) and in-house GC-MS methods. Over a broad concentration range, serum T levels measured by IA and MS showed high correlation ($R=0.93$, $P<0.001$), which was weaker in the hypogonadal range ($<11$ nmol/l; $R=0.72$, $P<0.001$). The IA/MS correlation was less robust for E2 levels ($R=0.32$, $P<0.001$, at E2 $<40.8$ pmol/L, and $R=0.74$, $P<0.001$, at E2 $>$ 40.8 pmol/L). Using MS as 'gold standard', IA ascertained low T compatible with hypogonadism ($<11$ nmol/L) with 75% sensitivity and 96.3% specificity. The same parameters with IA for detection of low E2 ($<40.7$ pmol/L) were 13.3%

and 99.3%, and for high E2 (>120 pmol/L) 88.4% and 88.6%. In conclusion, validated platform IA is sufficient to detect subnormal T levels in the diagnosis of male hypogonadism. The IA used for E2 measurements showed poor correlation with MS and may only be suitable for the detection of high E2 in men.

## OC14.4

**The prevalence of hypogonadism in men on methadone maintenance**

A. McGowan[1], S. Keating[2], J. O'Connor[2], A. Nestor[2] & M. Healy[1]
[1]St. James's Hospital, Dublin 8, Ireland; [2]Pearse Street, Dublin 2, Ireland.

Opioid analgesia impairs gonadal function in healthy men and women. Methadone, a synthetic opioid is used in opioid addicts to prevent relapse due its longer-lasting effects and is known to cause hypogonadism. Little data exists on the prevalence of this and the mechanism through which this occurs.
Men ($n=147$), mean age 36.2 years (S.D 7.2) attending a drug-treatment rehabilitation centre for methadone maintenance therapy had early morning gonadotrophins, prolactin, thyroid hormones and sex-hormone binding-globulin (SHBG) levels measured.
35.4% ($n=52$) of men had total testosterone (TT) below the reference range (8.6–29 nmol/L). The mean TT in the hypogonadal group was 5.18 nmol/L (S.D. 2.28) compared to 18.1 nmol/L (S.D. 7.65) in the eugonadal group ($P<0.001$). SHBG concentrations were increased in the whole group, 62.5 U/l (S.D. 28.9) compared to the normal reference range (14.5–48.4 U/l). SHBG concentrations were significantly lower in the hypogonadal group compared to the eugonadal group, 49.7 U/l (S.D. 22.0) versus 69.3 U/l (S.D. 29.9) respectively ($P<0.001$).
There was no significant difference in methadone dose, antidepressant, benzodiazepine or anti-psychotic use between groups. Prolactin levels were normal and not significantly different in the low TT compared to the normal TT group, 223.5 mU/l and 250.6 mU/l respectively.
LH levels were significantly lower in the hypogonadal group, 4.10 U/l (S.D. 3.46) compared to the eugonadal men, 5.87 U/l (S.D. 2.97) ($P<0.005$). There was no difference in FSH levels. TSH was significantly greater in the hypogonadal group 5.82 mU/l (S.D. 14.92) compared to the eugonadal group 1.96 mU/l (S.D. 1.51) ($P<0.05$), with normal free T4 levels in both groups.
In summary, there is a high prevalence of hypogonadism in male methadone users. The whole group have high SHBG levels. However, compared to eugonadal users, hypogonadal users have significantly lower SHBG and LH levels and higher TSH levels. The clinical implications of this are not known.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## OC14.5

**The muenster EXAKT project: X-inactivation in klinefelter patients**

S. Werler[1], R. Bongers[1], F. Tuettelmann[2], M. Zitzmann[1], S. Kliesch[1] & J. Gromoll[1]
[1]Centre of Reproductive Medicine and Andrology, Muenster, Germany; [2]Institute of Human Genetics, Muenster, Germany.

Introduction
Klinefelter Syndrome (KS; 47,XXY) is the most common sex chromosome disorder in men, characterized by hypergonadotropic hypogonadism. EXAKT (Epigenetics, X-chromosomal features and clinical Applications in Klinefelter syndrome Trial) is a Muenster-based prospective project involving Klinefelter patients and their parents assessing a wide area of cardiovascular, inflammatory and metabolic factors as well as a broad range of genetic and epigenetic investigations especially regarding X-inactivation that could be disturbed due to the aberrant sex chromosomal constitution. Therefore, we have examined the methylation profile of XIST, which drives X-inactivation, in KS blood samples taking into account the X-chromosomal origin.
Material & methods
Klinefelter blood samples ($n=130$), male ($n=50$) and female ($n=50$) controls; Pyrosequencing; Microsatellite analysis.
Results
X-origin was determined in 80 KS patients: 56% of patients had a paternal origin of the supernumerary X-chromosome, whereas 24% showed a maternal MII origin and 20% MI origin of the extra X. In men, XIST methylation levels reached nearly 100% while in women on average 65% were found, indicating the correct silencing of one of the two X-chromosomes. XIST methylation level in 130 KS patients was 75% on average. The XIST methylation pattern of KS patients with paternal origin of the X-chromosome (74%) resembled that of KS patients with MI origin (73%) and both significantly differed from the methylation pattern of patients with MII X-origin (80%).
Conclusion
In contrast to previous studies, we detected hypermethylation of XIST in KS. The role of the altered XIST methylation pattern remains to be further studied. The higher XIST methylation in KS patients with MII origin points to a disturbed X-inactivation depending on the parental inheritance.

**Erectile dysfunction after liver transplantation**

O. Levalle[1], L. Chavez[2], V. Descalzi[2], F. Gruz[2], E. Mormandi[1], N. Kogovsek[1], S. Aszpis[1] & P. Otero[1]
[1]Hospital Durand, Buenos Aires, Argentina; [2]Hospital Universitario Favaloro, Buenos Aires, Argentina.

Despite it's believed that sexual function may improve after liver transplantation (LT), many patients complain about unsatisfactory sexual life. There are few longitudinal data on the endocrine changes which occur after liver transplantation.
Aim
To evaluate erectile sexual dysfunction (ESD) prevalence and factors associated with its development, especially with relation to the status of sex steroids. Patients and Methods: 54 post-LT male patients were invited to answer a five-item International Index of Erectile Function (IIEF-5) and Hamilton Depression Rating Scale (HS). ESD was defined as a IIEF-5 $\leq 21$ points and depression as a HS $\geq 8$ points. Patients were tested for serum levels of testosterone (T), bioavailable T (bioT), androstane-3alpha,17beta-diol (3-DIOL-G) (glucuronide metabolite of dihydrotestosterone), SHBG, glucose and insulin.
Results
Main aetiologies of cirrhosis were HCV, HBV, alcohol, cryptogenic and NASH, showing a prevalence of 30, 22, 17, 11, and 11% respectively; median age was 60 (20–78) years old and follow up was 6 to 168 months. 85% were on calcineurin inhibitors as immunossupressors. 49 patients answered the questionnaires: 5 patients (10.2%) had more than 21 points in IIFE-5 (normal erectile function) while 21 (42,9%) had $<8$ points (no depression), $P<0.003$. No correlation was found between age/ESD – age/HS – ESD/HS. An inverse correlation between age and T ($P<0,02$) and bioT ($P<0,003$), and a direct correlation between IIFE-5 and T ($P<0,04$), bioT ($P<0,03$) and 3-diol ($P<0,03$) were established.
Conclusions
i) A surprisingly high prevalence of ESD was found in our series, and it seems not to be related to psychological status, ii) Hypogonadism does not seem to improve after LT, perhaps because of pre-existing gonadal alterations (toxic-metabolic damage) and immunosuppressive pharmacological side effects, iii) Further studies are needed to find out other reasons for the relationship between hypogonadism and LT outcome, and to explore the possibility of post transplant androgen therapy.

***PATZ1* is a new candidate tumour-suppressor gene in thyroid cancer**

G. Chiappetta[2], T. Valentino[1], M. Vitiello[1], R. Pasquinelli[2], M. Monaco[2], G. Palma[2], C. Arra[2], A. Fusco[1] & M. Fedele[1]
[1]Istituto di Endocrinologia e Oncologia Sperimentale del CNR, Napoli, Italy; [2]Istituto dei Tumori di Napoli Fondazione G. Pascale, Napoli, Italy.

Thyroid carcinoma arising from the thyroid follicular epithelium represents the most frequent endocrine malignancy and is mainly associated with gene rearrangements generating RET/PTC and TRK oncogenes, as well as BRAFV600E and RASV12 activating point mutations. Except for p53, which appears to be involved only in poorly differentiated and aggressive histotypes, a role of tumor-suppressor genes in the pathogenesis of thyroid cancer is still poorly known.
We found that the POZ/AT-hook/kruppel Zinc finger 1 (PATZ1) gene is down-regulated, with an inverse correlation to the degree of malignancy and differentiation, in the vast majority of thyroid tumours compared to normal thyroid, suggesting a tumour-suppressor role mainly involved in the late stages of thyroid carcinogenesis.
To explore this possibility, we performed functional studies in the papillary thyroid cancer (PTC)-derived TPC1 and the anaplastic thyroid cancer (ATC)-derived FRO cell lines, in which the expression of *PATZ1* is strongly down-regulated with respect to normal thyroid cells. Restoration of *PATZ1* expression, by stable DNA transfection, had no effect on the growth rate of both cell lines. Conversely, it led FRO cells to death and highly reduced migratory and invasive capabilities of both cell lines. Finally, we examined the transformed phenotype of the FRO cell transfectants expressing *PATZ1*, by analyzing their ability to grow in soft agar and to induce tumours in athymic mice. Differently from the parental cell line expressing the empty vector, these transfectants did not form colonies in soft agar and had reduced transforming ability *in vivo* compared to their controls. These data indicate that the loss of *PATZ1* expression exerts a functional role in the pathogenesis of thyroid cancer, and they are consistent with a specific role of PATZ1 in the signaling pathways involved in cell survival and metastatic progression.

**Ligand bound-thyroid hormone receptor contributes to reprogramming of pancreatic exocrine cells to insulin-producing cells via induction of Ngn3 and MafA**

F. Furuya, H. Shimura, T. Endo & T. Kobayashi
University of Yamanashi, Chuo, Japan.

Introduction
One goal of diabetic regenerative medicine is to instructively convert mature pancreatic exocrine cells into insulin-producing cells. We recently reported that liganded thyroid hormone receptor α (TRα) plays a critical role in expansion of the β-cell mass during postnatal development.
Materials and Methods
AdTRα is a recombinant adenoviral vector that expresses human TRα1 under the control of the cytomegalovirus promoter. To analyze whether TRα gene transfer induces reprogramming of pancreatic exocrine cells to insulin-producing cells, AdTRα were injected into the pancreas of immunodeficient mice. Rat pancreatic AR42J cells that possess exocrine and neuroendocrine properties were infected with AdTRα. The expression of transcription factors that are involved in the differentiation of pancreatic endocrine cells was then analyzed by quantitative RT-PCR, western blot or immunocytochemistry. To explore whether liganded-TRα-induced reprogramming of pancreatic exocrine cells is direct or indirect effect, AdTRα-infected AR42J cells were concomitantly transfected with siRNA of Ngn3 or MafA.
Results
Small scattered clusters of insulin-producing cells, which also expressed lipase, were observed in AdTRα-infected mice. T3-treatment of AR42J cells that were infected with AdTRα and pretreated with activin A increased the mRNA and protein expression levels of Ngn3 and MafA, compared to no T3-treatment. Overexpression of TRα together with T3-treatment also induced insulin expression in activin A-treated AR42J cells. The siRNA-induced inhibition of expression of Ngn3 or MafA significantly inhibited AdTRα-induced reprogramming of AR42J cells into insulin-producing cells.
Conclusions
These results suggested that combination of liganded-TRα and activin A leads to reprogramming pancreatic exocrine cells to insulin-producing cells via induction of Ngn3 and MafA. Our findings also support the hypothesis that liganded-TRα plays a critical role in β-cell regeneration during postnatal development.

### OC15.3

**Radioiodine therapy of non-thyroidal cancer following systemic sodium iodide symporter (NIS) gene transfer using Transferrin-receptor (Tfr) targeted non-viral gene delivery vectors**

K. Klutz[1], G. Grünwald[1], M. Willhauck[1], N. Schwenk[1], A. Vetter[2], W. Rödl[2], M. Hacker[2], C. Zach[2], R. Senekowitsch-Schmidtke[3], E. Wagner[2], B. Göke[1], M. Ogris[2] & C. Spitzweg[1]
[1]Campus Grosshadern, University Hospital of Munich, Munich, Germany; [2]Ludwig-Maximilians-University, Munich, Germany; [3]University Hospital Klinikum rechts der Isar, Munich, Germany.

We have recently demonstrated the high potential of non-viral polyplexes for tumor-specific delivery of the sodium iodide symporter (NIS) after systemic application. In the current study we used novel polymers based on linear polyethylenimine (LPEI), shielded by polyethylene glycol (PEG), and coupled with the synthetic peptide B6 (LPEI-PEG-B6) as a transferrin (Tf)-receptor specific ligand to achieve active tumor targeting to human hepatocellular cancer (HuH7) cells after systemic delivery of NIS DNA.
We complexed LPEI-PEG-B6 with a NIS-expressing plasmid and analyzed levels of functional NIS expression after transfection of HuH7 (high Tf-receptor expression level) as compared to control cancer cells with low Tf-receptor expression level (colon cancer, RKO) *in vitro* and *in vivo*.
*In vitro* incubation of HuH7 cells with LPEI-PEG-B6/NIS resulted in a 9-fold increase in iodide uptake activity as compared to RKO cells. After establishment of subcutaneous HuH7 and RKO tumors in nude mice, NIS-conjugated nanoparticles or control vectors were injected i.v. followed by analysis of radioiodine biodistribution using I-123 scintigraphy. After injection of LPEI-PEG-B6/NIS, a significant perchlorate-sensitive iodide accumulation (8.5–10.9% ID/g I-123; eff. half-life of 5 h) was observed in HuH7 tumors resulting in a tumor absorbed dose of 50 mGy/MBq I-131 after systemic NIS gene transfer using LPEI-PEG-B6/NIS polyplexes. Tumoral iodide uptake activity and NIS mRNA expression were significantly lower in RKO cells confirming the specificity of Tf-receptor targeted nanoparticle vectors. After four cycles of polymer application followed by therapeutic application of I-131 (55.5 MBq), tumor growth was significantly reduced as compared to control groups.
These results clearly demonstrate that systemic *in vivo* NIS gene transfer using nanoparticle vectors coupled with a Tf-receptor targeting ligand is capable of inducing tumor-specific radioiodide uptake, which represents a promising innovative strategy for the NIS gene therapy approach in metastatic cancer.

### OC15.4

**The DNA methylation as a predisposition factor in the pathogenesis of congenital hypothyroidism in premature infants**

F. Marelli[1,4], D. Gentilini[1], G. Weber[2], M. Vigone[2], G. Radetti[3] & L. Persani[1,4]
[1]IRCCS Istituto Auxologico Italiano, Cusano Milanino, Italy; [2]HSR Istutito Salute e Vita San Raffaele, Milan, Italy; [3]Compensorio sanitario di Bolzano, Bolzan, Italy; [4]University of Milan, Milan, Italy.

Introduction
Epidemiological data indicate that children born prematurely have a risk 3–5 fold higher of congenital hypothyroidism (CH). In addition premature infants born small for gestational age (SGA) have a risk of 12% higher to develop IC compared to prematures with appropriate development (AGA). The mechanisms that justify the increased risk of IC are still unknown. Some studies report a

pattern of aberrant methylation associated with prematurity, intrauterine fetal development and the onset of some diseases. This project is focused on the study of DNA methylation, as predisposing factor of thyroid diseases.
Methods
Using the Illumina Infinium-HumanMethylation27 technology we analyzed the global DNA methylation patterns (AVGβ) and selected the differentially methylated genes (DMGs) between 31 CH-cases born premature, AGA or SGA, and 31 term or preterm controls. The following groups were selected according to the gestational age at birth: 12 CH-with severe prematurity (CH-SP < 32 weeks) and 19 CH-premature infants (CH-P 32–37 weeks); Controls: 9-CPS, 6-CP, 12-term birth (CT > 37 weeks). The same subjects were then analyzed according to intrauterine growth (20 CH-SGA, 11 CH-AGA than 6 C-SGA and 20 C-AGA) or the degree of CH: 19 with overt CH (CH-O, TSH > 10 μU/l) and 12 with mild CH (CHM, TSH < 10 μU/l) than 16 CP and 12 CT.
Results and Conclusions
The global and gene-specific methylation analysis showed that infants born prematurely and SGA have a significant hypomethylation than term-controls. The 95% of the DMGs are hypomethylated and the 70% are represented by CpG sites located in DNA non-coding regions. The gene ontology analysis revealed that DMGs involved in fetal growth and thyroid hormone metabolism were deregulated. In conclusion, these data suggests that genomic instability caused by global hypomethylation maybe related to premature birth and fetal growth delay. Thyroid defects could be caused by an increased expression of predisposing-genes, rather than a reduced expression of protective-genes.

## OC15.5 The Young Investigator Winner

**Lymphatic endothelial markers podoplanin and Prox1 in differentiated thyroid tumors**

J. Janik[1], I. Strzyzewska-Jowko[1], M. Rudzinska[1], J. Czerwinska[1], M. Kiedrowski[2], W. Olszewski[2], B. Gornicka[3], J. Sowinski[4] & B. Czarnocka[1]
[1]Medical Center of Postgraduate Education, Warsaw, Poland; [2]Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, Poland; [3]Medical University of Warsaw, Warsaw, Poland; [4]Poznan University of Medical Sciences, Poznan, Poland.

It is believed that differentiated thyroid tumors (DTC) metastasize via different pathways: papillary carcinoma (PTC) usually via lymphatic spread whereas follicular cancers (FTC) mainly hematogenously. However, the mechanism/s contributing to these tumors invasion is not fully understood.
We examined the expression of lymphatic endothelial markers: Podoplanin (type-1 transmembrane mucin-like glycoprotein) and Prox1 (Prospero homeobox protein 1) in the PTC and FTC derived cell lines and series of DTC using quantitative Real-Time PCR (Q-RT-PCR), Western blot and immunochemical (IHC, IF) methods.
Podoplanin (PDPN) was highly expressed on both transcript and protein levels in papillary cell lines BcPAP and TPC1 whereas follicular cell lines: FTC-133, CGTH-W-1 and ML-1 were negative. Papillary tumor cells showed PDPN mostly restricted to and distributed in the cytoplasm. Cell lines with podoplanin expression showed low or undetectable Prox1 transcript level. By contrast PDPN negative FTC cell lines highly expressed Prox1 mRNA. There was no correlation between Prox1 protein and transcript. In all examined cell lines Prox1 protein was present at similar level exhibiting diffuse nucleocytoplasmic pattern.
The majority (72/120) of PTC and all FTC tissues were PDPN negative. However, in 48/120 (40%) of PTC cases podoplanin was expressed in cytoplasm of tumor cells with heterogonous intensity. This cytoplasmic neoexpression was correlated with patients age. Normal thyroid (NT) and peritumoral tissue (PT) cells were totally negative. In these tissues antibody labeled solely lymphatic vessels used as internal positive control. Prox1 protein was strongly expressed in the cytoplasm, weakly in some nuclei of PDPN positive PTC and clearly in the nuclei of NT.
Our study is the first to demonstrate the difference in the expression of lymphatic specific markers podoplanin and nuclear transcription factor Prox1 in DTCs. This might suggest different spreading pathways of PTC and FTC. Further on-going studies will define this mechanism/s and its potential implications.

## OC15.6

**Thyroglobulin induces thyroid cell growth through suppression of miR-16 and miR-195**

T. Akama, T. Hara, D. Yan, A. Kawashima, A. Yoshihara, M. Sue, K. Tanigawa, H. Wu, Y. Ishido, N. Ishii & K. Suzuki
National Institute of Infectious Diseases, Higashimurayama-shi, Japan.

Introduction
Thyroglobulin (Tg) is stored in the follicular lumen of the thyroid and serves as a substrate of thyroid hormone biosynthesis. However, it was shown that Tg significantly induces thyrocyte cell growth and suppresses expression of thyroid-functional genes. Despite having such functions, molecular mechanisms of Tg action are largely unclear. We have recently demonstrated that TSH-induced thyroid cell growth is partly mediated by a downregulation of microRNAs (miRNA) and induction of their target genes required for cell growth. In this study, we examined possible role of such miRNAs on Tg-induced thyroid cell growth.
Methods
Rat thyroid FRTL-5 cells maintained without TSH, insulin, and with 0.2% rather than 5% serum were treated with physiological concentrations of Tg. Total RNA was extracted and expression of miRNAs was determined using miRNA microarray and real-time PCR. The effect of miRNAs on cell growth and the expression of their target genes were assessed by bromodeoxyuridine (BrdU) incorporation, cell count, and real-time PCR using specific miRNA agonists.
Results
We have identified 21 miRNAs whose expression was downregulated by Tg. Those included miR-16 and miR-195, which were previously shown as important mediators of TSH action. Overexpression of miR-16 and miR-195 resulted in suppression of Tg-induced BrdU incorporation and cell growth. In that condition, induction of their target genes essential for cell growth, Mapk8, Ccne1 and Cdc6, were attenuated.
Conclusion
Our results indicate that Tg induces thyroid cell growth through suppression of miR-16 and miR-195 and induction of their target genes, which is similar to the mechanism of TSH action. miR-16 and miR-195 might be essential miRNAs for the regulation of thyroid cell growth.

**The association between birth weight and PCOS in adult life. A register-based study on 523, 757 Danish women born 1973–1991**

H. Mumm[1], M. Kamper-Jørgensen[2], A. Nybo Andersen[2], D. Glintborg[1] & M. Andersen[1]
[1]Odense University Hospital, Odense, Denmark; [2]University of Copenhagen, Copenhagen, Denmark.

Introduction
PCOS is characterized by insulin resistance and an increased risk of type 2 diabetes.
Objective
To study the association between birth weight and risk of polycystic ovary syndrome (PCOS) in adult life in Danish women born 1973–1991.
Methods
Female offspring born in Denmark during 1973–1991 of Danish mothers ($n = 523,757$) were included and followed for a total of 4, 739, 547 person-years at risk. Information on birth weight was extracted from the Danish Medical Birth Register. The cohort was followed-up for the diagnoses hirsutism or PCOS from age 15 years until the end of 2006 in the Danish National Patient Register (NPR). Information on maternal diabetes diagnoses was also extracted from the NPR. Incidence Rate Ratios (IRR) were estimated from Poisson regression models with

95% confidence intervals (CI). All analyses were adjusted for attained age and period.
Results
The risk of PCOS was significantly increased in women with birth weight > 4500 grams (IRR =1.57 (95% CI 1.21–2.03)) compared to women with birth weight 3000–3499 grams. The risk of PCOS was independent of size for gestational age. Offspring of women with diabetes diagnoses had an increased risk of PCOS. In this population low birth weight was associated with increased risk of PCOS.
Conclusions
Our data suggest that the risk of PCOS was increased in girls with birth weight >4,500 grams. Girls born of diabetic mothers had increased risk of PCOS, but in this population low birth weight was associated with increased risk of PCOS.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## OC16.2

**The first missense mutation of BMP15 mature domain identified in a Chinese family with primary ovarian insufficiency causes defective production of the bioactive protein**

R. Rossetti[1,2], E. Beccaria[1,2] & L. Persani[1,2]
[1]Università Statale di Milano, Milano, Italy; [2]Istituto Auxologico Italiano IRCCS, Milano, Italy.

Primary Ovarian Insufficiency (POI) is an ovarian defect characterized by the premature depletion of ovarian follicles before 40 years and represents one major cause of female infertility. POI is a heterogeneous disease but, despite its idiopathic origin in most of patients, there is a strong genetic evidence, in particular for X chromosome-linked defects. BMP15 gene maps to Xp11.2 within a Turner locus critical for ovarian function and mutations in this gene have been found in the heterozygous state in association with both primary and secondary amenorrhea in several POI cohorts. All the variations are located in the proregion of the protein, except for the R329C substitution, identified very recently in the Chinese population, co-segragating with POI in mother and daughter, and is the first reported located in the mature peptide. Involving an Arg to Cys change, the mutation was predicted in silico to be possibly damaging by impairing the correct folding of the protein. To verify the in silico prediction, we further in vitro studied the mutation. By western blot analysis, we observed a reduced production of both precursor and mature peptide, moreover the mutant form showed a significant reduction of the BMP signalling pathway activity compared to the wild-type by a luciferase reporter assay in COV434 granulosa cells. We demontrated that the first mutation discovered in the BMP15 mature domain is responsible for an impairment of either the maturation process or the precursor stability, resulting in a defective secretion of the bioactive protein. This results suggest that the BMP15 haploinsufficiency could have caused the onset of POI in the Chinese family harbouring the R329C mutation. In conclusion, our analysis confirm the importance of the screening of BMP15 for the prediction of POI risk and the importance to evaluate functionally possible disease-linked mutations to be distinguished from rare polymorphisms.

## OC16.3

**Anti-müllerian hormone as a predictor of ovarian response to weight loss in overweight women with polycystic ovary syndrome**

P. Popova[1,2], L. Ivanova[3] & E. Grineva[1,2]
[1]Almazov Federal Heart, Blood and Endocrinology Centre, Saint-Petersburg, Russian Federation; [2]Saint Petersburg Pavlov State Medical University, Saint-Petersburg, Russian Federation; [3]Kirov Military Medical Academy, Saint-Petersburg, Russian Federation.

Introduction
Weight loss is a key initial treatment strategy in obese women with polycistic ovary syndrome (PCOS) and improves insulin sensitivity and metabolic risk factors. In some women with PCOS it may reduce hyperandrogenism and restore menstrual function, ovulation and fertility. The aim of this study was to reveal clinical predictors of menstrual response to weight loss in overweight women with PCOS.
Design
overweight unovulatory women with PCOS (age 25.7±5.9 yr, body mass index (BMI) 32.3+5.3 kg/m$^2$) followed a 6-month weight loss program. We estimated ovulation induction (by ultrasound scanning), change in menstrual cycle, anthropometric measurements, endocrine parameters and insulin sensitivity.
Results
Mean reductions in weight by 9.0±5.9 kg ($P<0.001$) and BMI by 3.3±2.1 kg/m$^2$ ($P<0,001$) occurred for the subjects over the study duration. That was followed by reduction in fasting insulin (from 20.8±17.4 to 11.1±7.8 mU/liter, $P=0.002$), glucose (from 5.7±0.6 to 5.3±0.5 mmol/L, $P=0.01$) and the homeostasis model assessment of insulin sensitivity (HOMA) (from 5.2±4.2 to 2.7±1.9, $P=0.06$). Of 30 subjects, 15 (50%) responded to the intervention with improvements in menstrual cyclicity (responders). Compared to nonresponders, responders had lower baseline anti-mullerian hormone (AMH) levels (6.3±3.3 vs 9.8±4.2 ng/ml; $P=0.015$) and higher BMI (34.8±5.6 vs 30.4±4.2 kg/m$^2$, $P=0.026$). Using ROC-curves we calculated that the value of AMH less than 6.5 ng/ml can predict improvement of menses (sensitivity 73%, specificity 67%) by weight loss in overweight women with PCOS.
Conclusions
AMH measurement can be useful in the pretreatment identification of women with PCOS who will benefit from lifestyle intervention by menstrual improvements.

## OC16.4

**Epidemiological survey on the prevalence of hyperandrogenic states in adolescent and young women**

A. Gambineri, O. Prontera, F. Fanelli, A. Repaci, G. Di Dalmazi, U. Pagotto & R. Pasquali
Orsola-Malpighi Hospital, Bologna, Italy.

The aim of this epidemiologic study, performed in a wide population of high-school students in Northern Italy, was to obtain an unbiased estimate of the prevalence of hyperandrogenic states in adolescents and young females.
2052 female students, aged 15–19 years, were consecutively contacted. 939/2052 (45.8%) refused to participate in the study, but 431 of the 939 non-participants (45.9%) agreed to fill out a brief questionnaire aimed to broadly assess clinical hyperandrogenism. 1113/2052 (54.2%) participated in the study (group A) that included a medical visit and a nutritional interview. Hirsutism was scored through the modified Ferriman-Galley score and androgenic alopecia through the Ludwig scale. Number of menses in the previous year was recorded and used to define menstrual dysfunction. 570/1113 participants (group B) also agreed to give a blood sample for the measurement of testosterone by isotopic dilution-liquid chromatography-tandem mass spectrometry (ID-LC-MS/MS); the reference interval was established in-house using a subgroup of 149 healthy, normal-weight and untreated students. 203 students were subsequently excluded from group A because of oral contraceptive pills (OCPs); 105 students were subsequently excluded from group B because of OCPs and 20 students because of thyroid dysfunction or hyperprolactinemia. Within group A we found: 109 students (12.0%) with isolated menstrual dysfunction; 134 students (14.7%) with isolated clinical hyperandrogenism (hirsutism and/or androgenic alopecia); 32 students (3.5%) with the association between menstrual dysfunction and clinical hyperandrogenism. Within group B we found: 40 students (9.0%) with isolated menstrual dysfunction; 66 (14.8%) with isolated clinical hyperandrogenism; 17 (3.8%) with Polycystic Ovary Syndrome (menstrual dysfunction, clinical hyperandrogenism and high testosterone levels); 26 (5.8%) with isolated hypertestosteronemia; 5 (1.1%) with the association of clinical hyperandogenism and high testosterone levels, but with regular menses. These data show that hyperandrogenic states are common in adolescent and young women, thereby supporting the need for specific diagnostic criteria.

## OC16.5

**Urinary glucocorticoid metabolite excretion is associated with insulin resistance independent of body mass index (BMI) in patients with polycystic ovary syndrome**

M. O'Reilly, J. Hazlehurst, M. Lebbe, B. Hughes, P. Stewart, J. Tomlinson & W. Arlt
University of Birmingham, Birmingham, UK.

Polycystic ovary syndrome (PCOS) is a triad of insulin resistance, hyperandrogenism and anovulation. PCOS is associated with increased adrenocortical drive, which may have adverse metabolic consequences. Here we analysed the relationship of urinary androgen and glucocorticoid metabolite excretion with insulin resistance in a large PCOS cohort.

We compared results from 127 PCOS patients (Rotterdam criteria) with 100 BMI-matched controls. All subjects underwent anthropometric assessment including BMI, and metabolic testing with oral glucose tolerance test (OGTT) and homeostatic model assessment of insulin resistance (HOMA-IR). 24-h urine samples from patients and controls were analysed by gas chromatography/mass spectrometry for total androgen (androsterone + etiocholanolone) and total glucocorticoid metabolite excretion (μg/24 h). HOMA-IR values were log-transformed to normalise their distribution. Linear regression was used to measure the impact of urinary steroid metabolite excretion on HOMA-IR.

OGTT results were abnormal in 26 PCOS patients (21%). Dysglycaemic PCOS women did not differ by age from normoglycaemic patients but had a significantly higher BMI (35.6 ± 6.2 vs 30.5 ± 6.7 kg/m$^2$, $P=0.001$). Of those PCOS patients with a BMI > 30, 33% (22/67) had dysglycaemia on OGTT, compared to 7% (4/53) of those with BMI < 30. Total glucocorticoid excretion was significantly higher in PCOS patients compared to controls (9612 ± 4194 vs 8067 ± 4165, $P=0.013$). After adjustment for age and BMI, total glucocorticoid excretion was highly predictive of HOMA-IR levels, with HOMA-IR values increasing by 7% (95% CI, 2–11%, $P=0.003$) for each increase of 1000 μg/24 h in glucocorticoid metabolites (Table 1). Total urinary androgen metabolites were not predictive of HOMA-IR, $P=0.068$.

In PCOS, total glucocorticoid metabolite excretion is strongly correlated with markers of insulin resistance. Increased adrenocortical drive in PCOS may have adverse metabolic consequences.

**Kisspeptin-10 stimulation of gonadotropin secretion in women is modulated by sex steroid feedback**

J. George[1], R. Anderson[1] & R. Millar[1,2,3]
[1]University of Edinburgh, Edinburgh, UK; [2]University of Cape Town, Cape Town, South Africa; [3]University of Pretoria, Pretoria, South Africa.

Background

Sex-steroid feedback regulates gonadotropin (LH and FSH) secretion. Kisspeptin, a novel hypothalamic neuropeptide, stimulates gonadotropin secretion by stimulating GnRH secretion, and has been shown in animal models to play a central role in mediating sex steroid feedback.

Hypothesis

As estrogen feedback occurs at both the hypothalamus and the pituitary in women, we hypothesized that the stimulatory effect of kisspeptin-10 would be dependent on prevailing sex-steroid milieu.

Methods

Responses to intravenous kisspeptin-10 (0.3 μg/kg) in women in the follicular phase ($n=10$) were compared with a low sex steroid/high gonadotropin condition (post-menopause, $n=6$) and with a high sex steroid/low gonadotropin condition (combined contraceptive pill, $n=4$; progestogen contraceptive implants, $n=4$). 60-min AUC of gonadotropin secretion before and after kisspeptin-10 were compared using paired *t*-tests. By deducting 60-min mean baseline value from observed gonadotropin concentrations, inter-individual variability in baseline secretion was controlled for.

Results

Kisspeptin-10 stimulated LH secretion in follicular phase (ΔAUC 2.3 ± 0.8 IU/l × h, $P=0.009$), post-menopausal (5.3 ± 0.9 IU/l × h, $P=0.002$) and progestogen implant (2.6 ± 0.8 IU/l × h, $P=0.05$) groups but not in women taking the combined pill (0.9 ± 0.4 IU/l × h, $P=0.13$).

FSH secretion was significantly increased only in post-menopausal women (ΔAUC 2.6 ± 0.8 IU/l × h, $P=0.03$) with changes of <0.5 IU/l × h observed in the other three groups.

Gonadotropin responses in post-menopausal women were significantly larger than the other groups (one-way ANOVA analysis of ΔAUC; LH ($P=0.012$) and FSH ($P=0.001$)) without significant differences between the other groups.

Conclusions

Gonadotropin responses to kisspeptin-10 in women are enhanced in sex-steroid deficient post-menopausal women and suppressed in women taking pharmacological doses of exogenous estrogen and progestogen. Moreover, in keeping with other studies of kisspeptins, kisspeptin-10 preferentially stimulates LH over FSH.

These results are consistent with the notion that the pituitary gonadotrope is a functionally important locus of estrogen feedback in women and also inform potential translational applications of kisspeptin in reproductive endocrine disorders.

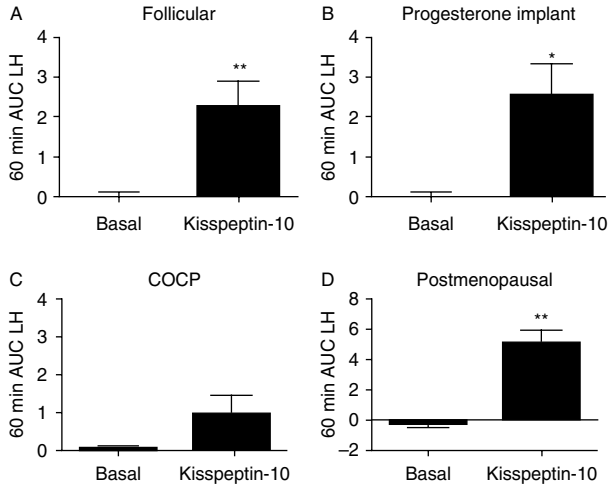

**Figure 1** 60-min AUC of LH before and after i.v. administration of 0.3 μg/kg kisspeptin-10 to healthy women. A, women in follicular phase ($n=10$); B, women using progesterone implants for contraception ($n=4$); C, women taking combined oral contraceptives ($n=4$); D, postmenopausal women ($n=6$).

**Pdk1/Foxo1 pathway regulates macrophage migration, polarization, and insulin sensitivity**

Y. Kawano, J. Nakae & H. Itoh
Keio University School of Medicine, Tokyo, Japan.

Chronic inflammation in adipose tissue contributes to obesity-related insulin resistance. The 3-Phosphoinositide-dependent Protein Kinase 1 (Pdk1)/forkhead transcription factor (Foxo1) pathway is important in regulating glucose and energy homeostasis, but little is known about this pathway in adipose tissue macrophages (ATMs). To investigate this, we generated transgenic mice that

carried macrophage/granulocyte-specific mutations, including a Pdk1 knockout (LysMPdk1-/-), a Pdk1 knockout with transactivation-defective Foxo1 (Δ256LysMPdk1-/-), a constitutively active nuclear (CN) Foxo1 (CNFoxo1-LysM), or a transactivation-defective Foxo1 (Δ256Foxo1LysM). The LysMPdk1-/- mice exhibited elevated M1 macrophages in adipose tissue and insulin resistance. Insulin-stimulated IRS1 or IRS2 and Akt phosphorylation were significantly decreased in epididymal fat and liver of LysMPdk1-/- compared to control mice. F4/80+ Kupffer cells in liver were significantly decreased. Furthermore, expression levels of Il4 and Il10 were significantly decreased and bone marrow derived Cd11b+ cells were significantly increased in liver of LysMPdk1-/-. LysMPdk1-/- exhibit increased Ccr2 expression in stromal vascular fraction (SVF) and peritoneal macrophage. Transwell migration assays revealed that Pdk1-deficient bone marrow derived macrophages (BMDM) exhibited significantly increased capacity of migration compared to BMDM from control. Overexpression of transactivation-defective Foxo1 rescued these phenotypes. CNFoxo1LysM promoted transcription of the C-C motif chemokine receptor 2 (Ccr2) in ATMs and increased M1 macrophages in adipose tissue. On a high fat diet, CNFoxo1LysM mice exhibited insulin resistance. Furthermore, Pdk1 deletion or Foxo1 activation in bone marrow-derived macrophages abolished insulin- and interleukin-4-induction of genes involved in alternative macrophage activation. These data suggested that Pdk1-Foxo1 pathway regulates migration and polarization of macrophage and plays an important role in the regulation of insulin sensitivity *in vivo*.

### Placental restriction co-ordinately alters hepatic expression of micro-RNAs and targets related to non alcoholic fatty liver disease, in adult male sheep

H. Harryanto, M. De Blasio, P. Grant, K. Gatford & J. Owens
University of Adelaide, Adelaide, SA, Australia.

Placental restriction (PR) of fetal growth impairs insulin action and metabolic control in postnatal life. MicroRNAs (miRNAs) are important post-transcriptional regulators, down regulating mRNA abundance or translation. We therefore determined if PR in the sheep alters miR expression in liver, skeletal muscle and adipose tissue of adult offspring and if this associates with altered abundance of their predicted molecular targets.

PR was induced by pre-pregnancy removal of most uterine implantation sites. Control (8 male, 8 female) and PR (6 male, 8 female) sheep had insulin sensitivity and metabolism measured at 12 months, then tissues collected for RNA extraction. MiRNA expression was measured by Exiqon miRarray (v8.1) (R, with adjustment for multiple comparisons) and RTPCR, as was expression of predicted targets (identified by algorithms, then networks and pathways by IPA). Effects of PR and sex were assessed by ANOVA, associations by Pearson's correlation, with statistical significance at $P<0.05$.

PR mostly increased microRNA expression in insulin sensitive tissues of adult sheep. In males, PR increased hepatic expression of eight miRNAs by ~1.5-3.5-fold, with differential expression of four independently confirmed (miR 1, 21, 142-3p and 144), each predicted to target molecules involved in insulin signalling, metabolism and hepatic disease. The latter include p85α, Pparα, Igf1, Foxo3 and Acox1, all exhibiting reduced hepatic expression (~ 2.3-4.0 fold) following PR in males, with the abundance of miR-1, 142-3p and -144 correlating negatively with Acox1 expression.

These findings show for the first time that PR co-ordinately alters hepatic expression of miRs and predicted targets related to non-alcoholic fatty liver disease (NAFLD), in adult male offspring. Reduced hepatic expression of Pparα (regulates lipid catabolism), and Acox1 (peroxisomal fatty acid β-oxidation) characterise or promote development of NAFLD, increasingly common following fetal growth restriction in humans, and microRNAs may partly mediate this prenatal programming of NAFLD.

### Caerulin precursor fragment (CPF-AM1): a novel insulinotropic peptide from the skin secretion of the clawed frog, Xenopus amieti

O. Ojo[1], J. Conlon[2], P. Flatt[1] & Y. Abdel-Wahab[1]
[1]University of Ulster, Coleraine, UK; [2]United Arab Emirates University, Al-Ain, United Arab Emirates.

We reported the isolation and structural characterization of CPF-AM1 and other peptides from the skin secretion of Xenopus amieti. This study investigated the insulin-releasing activities of synthetic CPF-AM1 using clonal pancreatic cell line, BRIN-BD11 and Swiss TO mice with diet-induced insulin resistance.

Acute insulin-release studies were performed in Krebs Ringer bicarbonate buffer supplemented with 5.6 mM or 16.7 mM glucose, purified synthetic peptide (0–3 mM) and known modulators of insulin secretion. Insulin-release was measured by radioimmunoassay. Membrane potential and intracellular calcium ([Ca2+]i) were measured by flourometric assay using FLEXstationTM. Degradation of CPF-AM1 by plasma enzymes was investigated using reversed-phase HPLC and MALDI-TOF spectrometer.

At 5.6 mM glucose, CPF-AM1 significantly stimulated insulin-release over concentration range of 30 nM (1.4-fold, $P<0.05$) to 3 μM (3.4-fold, $P<0.001$) without beta-cell cytotoxicity. Without extracellular calcium, the stimulation was reduced by 25.3%. CPF-AM1(1 μM)-induced stimulatory effects were inhibited by co-incubation with 50 μM verapamil (57.4%, $P<0.001$) and 300 μM diazoxide (51.8%, $P<0.001$). Insulin-secretion increased by 3.3-fold with KCl (30 mM, 16.7 mM glucose) and CPF-AM1 (1 μM). At 5.6 mM glucose and 1 μM CPF-AM1, co-incubation with 200 μM IBMX and 200 μM tolbutamide caused 1.2-fold and 1.1-fold increase in insulin-release respectively. The peptide induced membrane depolarization (2.6-fold) and increased [Ca2+]i (2.0-fold) at 5.6 mM glucose. *In vivo*, intraperitoneal administration of CPF-AM1 (75 nmol/kg bw) with 18 mmol/ kg glucose significantly enhanced insulin-release (1.5-fold) and improved glucose tolerance by 28% ($n=6$, $P<0.05$). CPF-AM1 is resistant to degradation by plasma proteolytic enzymes up to 8 hr.

The study showed that CPF-AM1 is a novel peptide with potential for development into a new antidiabetic drug.

### Syntaxin-3 regulates recruitment and exocytosis of newcomer insulin granules and granule-granule fusion during biphasic glucose-stimulated insulin secretion in pancreatic β-cells

D. Zhu[1], E. Koo[1], E. Kwan[1], Y. Kang[1], S. Park[1,2], H. Xie[1], S. Sugita[1,2] & H. Gaisano[1]
[1]University of Toronto, Toronto, ON, Canada; [2]University Health Network, Toronto, ON, Canada.

Introduction

The molecular basis of exocytosis of secretory insulin-containing granules (SGs) during biphasic glucose-stimulated insulin secretion (GSIS) of pancreatic β-cells remains unclear. Syntaxins (Syns) Syn-1A and Syn-4 are t-SNARE proteins situated on the plasma membrane that have been well studied to mediate insulin exocytosis. However, Syn-3, peculiarly more abundant in insulin SGs, has unclear function in GSIS.

Methods/Designs

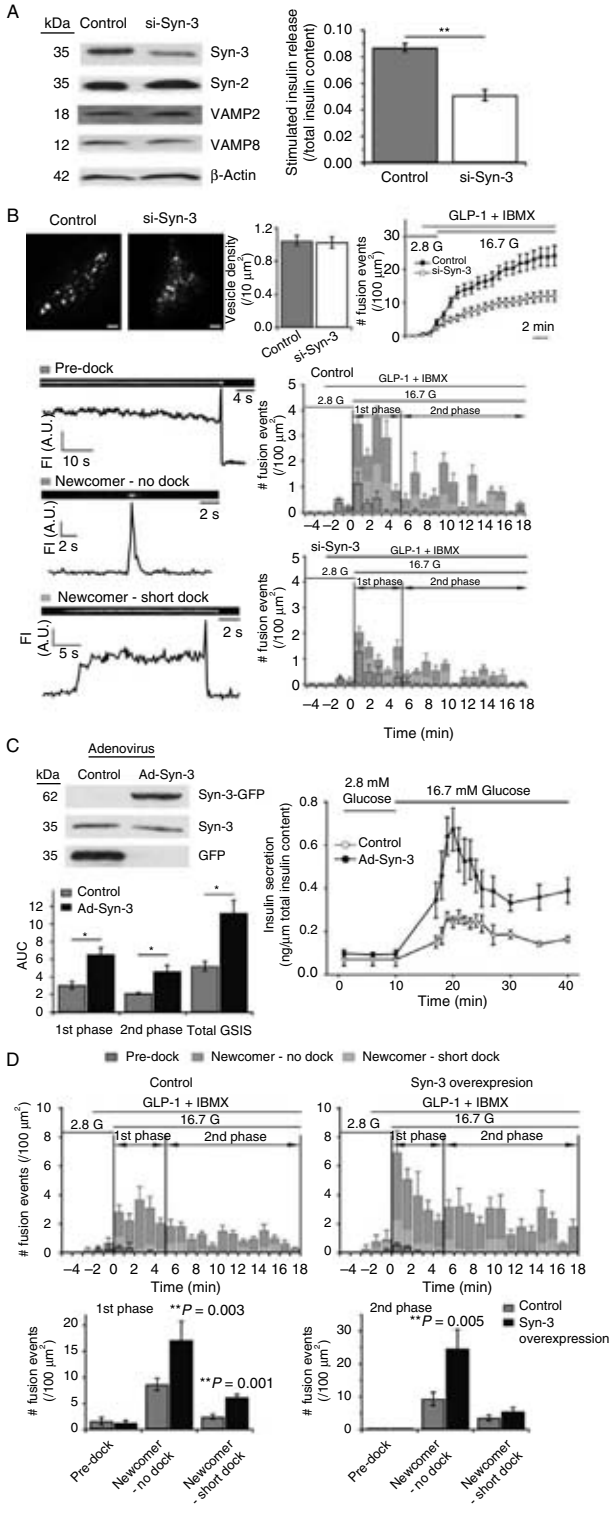
Confocal microscopy confirmed the localization of Syn-3 to insulin SGs in insulin secretory cells. Syn-3 function was assessed by loss of endogenous function by siRNA downregulation of Syn-3 expression, and gain of function by Syn-3 overexpression in INS-1 cell line and rat islet β-cells. Readouts included electron microscopy (EM), insulin secretion by RIA, and visualizing single insulin SG behavior by total reflection fluorescence microscopy (TIRFM).

Results

Depletion of endogenous Syn-3 in INS-1 cells inhibited GSIS by 42%. Time-lapse TIRFM showed no change in the number and fusion competence of docked SGs, and instead, a marked reduction in the recruitment of newcomer SGs to plasma membrane and subsequent slowing of their exocytotic fusion kinetics per se in both fist and second phases encompassing biphasic GSIS. Conversely, overexpression of Syn-3 into mouse islets and INS-1 cells caused enhancement of first and second phases of GLP-1-potentiated GSIS by 2-fold, accounted for by an increase in newcomer SGs, and remarkably, also by increased SG-SG/compound fusion events, the latter confirmed by EM.

Conclusions

Syn-3 in insulin SGs functions to mediate SG-SG fusion and mobilization of newcomer SGs to the plasma membrane, contributing to both first and second phases of GSIS in pancreatic β-cells.



A) Reduction of endogenous Syntaxin-3 levels impairs glucose-stimulated insulin secretion (GSIS). B) Reduction of endogenous Syntaxin 3 levels inhibits recruitment and exocytosis of newcomer insulin granules but with no effect on docked granules. C) Overexpression of Syntaxin 3 enhances GSIS. D) Enhancement of biphasic GSIS by Syntaxin 3 overexpression is due to recruitment and fusion of newcomer insulin granules with plasma membrane.

### Glucocorticoid receptor α expression is downregulated in gluteal subcutaneous adipose tissue of black South African women and associates with increased metabolic risk

J. Goedecke[1,2], R. Stimson[3], D. Livingstone[3], P. Hayes[1], K. Adams[1], J. Dave[1], D. Keswell[1], J. Evans[1], H. Victor[1], E. Lambert[1], N. Levitt[1], S. Kahn[5] & T. Olsson[4]

[1]University of Cape Town, Cape Town, South Africa; [2]Medical Research Council, Cape Town, South Africa; [3]University of Edinburgh, Edinburgh, UK; [4]Umeå University, Umeå, Sweden; [5]VA Puget Sound Health Care System and University of Washington, Seattle, Washington, USA.

Introduction

Increased capacity for glucocorticoid regeneration in subcutaneous adipose tissue (SAT) by 11β-hydroxysteroid dehydrogenase-1 (11HSD1) is associated with obesity and associated risk factors. We hypothesised that down-regulation of SAT 11HSD1 and/or glucocorticoid receptor-α (GRα) may explain differences in body fat distribution and metabolic risk between black and white women. The study aimed to compare the expression of 11HSD1 and glucocorticoid receptor-α (GRα), and glucocorticoid-responsive genes in gluteal SAT depots, and determine their relationships with body composition and metabolic risk factors in South African women.

Methods

Body fatness (DXA) and distribution (computerized tomography), insulin sensitivity (SI, intravenous glucose tolerance test) and the expression of 11HSD1, GRα, PPARγ, adiponectin, CD68 and TNFα were measured in gluteal SAT of 56 normal-weight and obese black and white premenopausal South African women.

Results

11HSD1 expression was increased with obesity in both black and white women ($P<0.001$), but did not differ by ethnicity. In contrast, GRα mRNA levels were significantly lower in both normal weight and obese black compared to white women ($0.86\pm0.25$ vs $1.31\pm0.65$ AU and $0.52\pm0.21$ vs $0.91\pm0.26$ AU, respectively, $P<0.01$). Lower GRα expression in black women was associated with increased CD68 ($r=-0.64$, $P<0.001$) and TNFα ($r=-0.39$, $P<0.01$), reduced PPARγ ($r=0.84$, $P<0.001$) and adiponectin mRNA levels ($r=0.47$, $P<0.001$), as well as increased fat mass ($r=-0.61$, $P=0.001$) and serum triglycerides ($r=-0.43$, $P=0.022$), and reduced HDL-cholesterol ($r=0.48$, $P=0.010$) and SI ($r=0.47$, $P=0.016$).

Conclusions

Expression of GRα is downregulated in gluteal SAT of black South African women, and associates with reduced adipogenic capacity and increased metabolic risk factors.

### Meta-analysis of differentially expressed microRNAs in type 1, type 2 and gestational diabetes mellitus

C. Collares, A. Evangelista, D. Xavier, C. Macedo, D. Rassi, M. Foss-Freitas, M. Foss, E. Sakamoto-Hojo, G. Passos & E. Donadi

Faculty of Medicine of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil.

Introduction

MicroRNAs (miRNA) are noncoding RNAs that play a central role in governing a variety of physiological and pathological processes, and there are few studies on

miR involvement in diabetes mellitus. There are three principal types of diabetes, i.e., type 1 (T1DM), type 2 (T2DM) and gestational diabetes mellitus (GDM). In this study we performed a meta-analysis of the miRNA expression profiling of peripheral blood mononuclear cells (PBMC) from T1DM, T2DM and GDM patients by using the microarray technology.
Methods/Design
Agilent human miRNA microarray kits (v3) $8\times15$ K were used to perform hybridizations of samples from T1DM ($n=4$), T2DM ($n=4$) or GDM ($n=5$) patients that were quantified and analyzed using GeneSpring GX11 pack (Agilent). ANOVA ($P<0.05$) with Benjamini-Hochberg FDR multiple testing correction was performed. Finally, miRNAs exhibiting fold change $\geq2.0$ were considered for the study.
Results
Ten miRNA were differentially expressed in the 3 types of diabetes: hsa-miR-328, hsa-miR-181b, hsa-miR-1306, hsa-miR-181c, hsa-miR-1275, hsa-let-7b*, hsa-miR-939, hsa-miR-623, hsa-miR-595, and hsa-miR-1268. None of these miRNAs were previously described in association with any type of diabetes. Interestingly, two members of miR-181 family contribute to T cell tolerance, and this miRNA family has been involved in the inhibition of IL-2 expression.
Conclusion
Considering that autoimmunity is characteristic of T1DM, considering the similarities of mRNA expression profiles between T1DM, T2DM and GDM, and considering that miR-181 family modulates some cytokine expression, these results indicate that miRNA may be used as marker for diabetes. **Mutations in the NR5A1 gene in patients with 46,XY disorders of sex development (DSD): high frequency of familial multi-generational occurrence**

M. Costanzo, G. Guercio, R. Marino, P. Ramirez, J. Galeano, N. Perez Garrido, M. Ciaccio, D. Warman, M. Baquedano, N. Saraco, E. Berensztein, E. Chaler, M. Maceiras, J. Lazzatti, M. Rivarola & A. Belgorosky
Hospital de Pediatria Garrahan, Buenos Aires, Argentina.

The nuclear receptor SF1/NR5A1 regulates transcription of genes involved in reproduction, steroidogenesis and male sexual differentiation. Mutations in humans cause gonadal dysgenesis with or without adrenal failure in both 46,XY and 46,XX individuals. In a cohort of patients with familial 46,XY DSD, we identified 6 heterozygous NR5A1 mutations in 19 subjects from 5 unrelated families (F1-F5). Moreover, a de novo heterozygous mutation in one patient with 46,XY DSD and no affected relatives was also detected. Low ovarian reserve with preserved fertility was detected in females harboring NR5A1 mutations. Extreme within-family variability was found in 46,XY DSD affected patients, with phenotypes ranging from severe fetal undervirilization, prompting female sex of rearing, to spontaneous pubertal development and even preserved fertility. Analyses revealed a W279X heterozygous mutation and an intronic deletion (g3314-3317delTCTC (IVS 4+8) in F1, and a Y183X heterozygous mutation in F2. A novel R313H heterozygous variation was found in F3, and a novel S303R mutation in F4. A novel heterozygous R69H mutation was found in the only 46,XY DSD patient studied in F5, and a de novo G77E mutation in the sporadic case. All new mutations were predicted to affect protein function by prediction models (SIFT, Polyphen and MutationTaster). Mode of inheritance seems to be autosomal dominant with variable penetrance. We emphasize the extreme phenotypic variability, even in siblings with the same mutation. As previously reported, we found spontaneous puberty in 46,XY DSD individuals raised as males, and for the first time we report preserved fertility in one of these affected individuals. Subjects with heterozygous NR5A1 mutations and mild phenotypes, such as isolated hypospadias in 46,XY patients, compensated ovarian dysfunction and early menopause in 46,XX subjects, might easily go undetected. A careful family screening of 46,XY as well as 46,XX individuals is recommended whenever an index case is detected.

**Clinical profile, gender choice and long term follow up of subjects with 5 alpha-steroid reductase 2 deficiency**

I. Shabir, M. Khurana, M. Eunice, B. Kulshreshtha, R. Khadgawat, N. Gupta, A. Ammini & D. Gupta
All India Institute of Medical sciences, New Delhi, India.

Introduction
5 alpha-steroid reductase deficiency (5α SRD) is a rare autosomal recessive disorder. Presented here is the clinical profile and long term outcomes of subjects with 5α SRD examined in our hospital during the last 30 yrs.
Methods
Records of patients registered in the endocrine clinic of our hospital and new patients with diagnosis of 5α SRD were compiled. Details of history,physical examination,chromosomal analysis, hormonal studies, psychological assessment, nature of surgery and follow up were recorded.
Electrochemiluminiscence method was used for the estimation of LH,FSH and T. DHT was done by Radioimmunoassay (RIA)[kit based method (Immunotech, Prague)]after Celite chromatography.
Results
There were 30 patients, age 2 to 28 yrs ($13.01\pm7.4$) (from 27 families) were diagnosed to have 5α SRD during the last 31 years. One family had 4 boys, all with 5α RD. The mean age at which medical attention was sought was 5.6 yrs. 23 patients were assigned female sex while 7 patients were assigned male sex at birth. Among the 23 who were assigned female sex,11 sought medical attention peripubertally,10 opted for male gender re-assignment while 1 opted to continue her female gender status. Eleven patients received medical attention during infancy to early childhood, 9 had male gender assignment and 2 had female gender assignment on medical advice. One of them,11 years, reared as female is under evaluation. The 2 patients who had feminizing genitoplasty during infancy presented with gender dysphoria at age 8 and 11 years. One of them had gender reassignment after 2 years of follow up. Gender dysphoria was not observed among any of the children initially assigned male gender. Two patients are married, wife of one of them was pregnant at the last follow up. The second patient had normal LH, FSH and Testosterone at the initial evaluation. Semen analysis at age 16 revealed sperm count of 16 million/ml. He married at age 24, semen analysis at age 26 revealed azoospermia, elevated LH and FSH and subnormal testosterone.
Almost all patients who grew up as females without medical attention had opted for male gender assignment peripubertally. No gender dysphoria was observed among those reared as boys.

**Effects of vitamin D insufficiency and its correction on insulin sensitivity and serum osteocalcin concentration in obese children**

P. Nantarakchaikul, P. Poomthavorn, P. Mahochoklertwattana, P. Khlairit & L. Chailurkit
Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.

Background
Vitamin D insufficiency (VDI) was reported to be associated with decreased insulin sensitivity (IS). Individuals with higher osteocalcin (OC) were shown to have better IS. Vitamin D regulates OC synthesis. Obese children carry an abnormal glucose homeostasis risk. Whether correction of VDI improves IS in obese children and mediates such effect via OC are unclear. We, therefore, studied glucose homeostasis, IS, vitamin D status and serum OC concentration in 230 obese children and examined vitamin D treatment effect on those parameters in 42 obese children with VDI.
Methods
Serum 25-hydroxyvitamin D (25-OHD) and OC levels were measured. An oral glucose tolerance test (OGTT) was performed. IS indices including HOMA-IR, Matsuda index and QUICKI and β-cell function, insulinogenic index (IGI) were calculated. Patients with VDI (25-OHD $<30$ ng/ml) were treated with 560 000 units of vitamin D2 and underwent the second OGTT after treatment completion.

Results
Of 230 patients, 58 (25%) had impaired glucose tolerance, impaired FPG and diabetes. One hundred and fifty-nine (69%) had VDI (25-OHD 22.3 (4.5) ng/ml), while the remaining 69 patients had adequate 25-OHD level of 34.6 (2.9) ng/ml. Comparing between patients with vitamin D sufficiency and insufficiency, there were no differences in BMI Z-score, OC, IS and β-cell function. However, 42 VDI patients who had 25-OHD increased to 55.5 (14.8) ng/ml after treatment completion had Matsuda index and QUICKI significantly increased from the pre-treatment values. Furthermore, the percentage of patients with abnormal OGTT was reduced from 33 to 19%. There were no changes in IGI and OC. OC was positively correlated with IGI ($r=0.218$, $P=0.001$) but not with IS.
Conclusion
Correction of VDI in obese children could enhance IS but not β-cell function. Critical level of 25-OHD may be needed to augment IS. IS enhancement seems not to be mediated by OC.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## OC18.4

### Mortality in GH-treated (Tx) patients (pts) enrolled in the global genetics and neuroendocrinology of short stature international study (GeNeSIS)

C. Child[1], A. Zimmermann[2], C. Quigley[2], R. Rosenfeld[3], L. Robison[4] & W. Blum[5]
[1]Eli Lilly and Company, Windlesham, UK; [2]Eli Lilly and Company, Indianapolis, Illinois, USA; [3]Oregon Health & Science University, Portland, Oregon, USA; [4]St Jude Children's Research Hospital, Memphis, Tennessee, USA; [5]Eli Lilly and Company, Bad Homburg, Germany.

Preliminary data from the French SAGhE study of 6928 pts with isolated idiopathic GH deficiency (IsIGHD), idiopathic short stature (ISS) or born small for gestational age (SGA) who started GH treatment during childhood (1985–1996) & were followed up in 2009, suggested increased mortality vs the French general population (pop; standardized mortality ratio (SMR): 1.3, 95% confidence interval (CI): 1.1–1.6; 116 403 person-years (PY))[1].
To assess mortality in a global pediatric observational study, deaths in GeNeSIS pts (all diagnoses, incl. organic & syndromic) were identified; for reference to SAGhE data, mortality rates were calculated for GH-Tx pts with IsIGHD, ISS & SGA. SMR/95% CI were calculated using age- & sex-specific pop rates from CDC (USA) & WHO (other countries).
Among 18 147 pts (all diagnoses) 33 deaths were reported (30/17 692 GH-Tx, 3/455 non-GH-Tx) during median (Q1, Q3) follow-up of 2.0 (0.9, 3.8) years. Deaths were due to acute illness (16), recurrence of pre-existing intracranial neoplasms (8, incl. the 3 non-GH-Tx pts), second cancers (2, both irradiated), accidents (3), underlying conditions (2) & unknown causes (2). 5 deaths were in pts with IsIGHD, ISS & SGA (Table).
The total death rate in GH-Tx pts with IsIGHD, ISS & SGA in GeNeSIS was similar to the 2007 US age adjusted mortality rate for children aged 5–14 years (rate: 15.3/100 000 PY)[2]. SMRs for each diagnosis individually & combined were not elevated.
There was no evidence of increased mortality in the GH-Tx IsIGHD, ISS or SGA pts in GeNeSIS. However, our analysis in pts during GH treatment is not directly comparable with SAGhE. Other limitations include comparison with general pop data (lacking untreated controls) & limited follow-up time.

## OC18.5

### Earlier reactivation of the hypothalamo-pituitary-gonadal axis and advancement of puberty in boys under labour stress

A. Khan[1], A. Kanwal[1], S. Naureen[1], A. Naseem[1], S. Aslam[2], M. Irfan[1], F. Tahir[3], M. Qayyum[1], R. Mansoor[4], S. Murtaza[5] & S. Rizvi[1,6]
[1]PMAS Arid Agriculture University, Rawalpindi, Pakistan; [2]Government College University, Lahore, Pakistan; [3]National Institute of Health, Islamabad, Pakistan; [4]Rawalpindi Medical College, Rawalpindi, Pakistan; [5]Nuclear Oncology and Radiotherapy Institute, Islamabad, Pakistan; [6]Pakistan Science Foundation, Islamabad, Pakistan.

The reawakening of the hypothalamo-pituitary-gonadal (HPG) leading to attainment of sexual maturation and reproductive capacity is influenced by several internal and external factors. Amongst external factors, adverse physical or psychological conditions may alter the timing of onset of puberty. The present study examined the effect of persistent and severe physical stress on timing of onset of puberty. The study included non-working school/college going and working boys of 10–20 years of age ($n=594$). Blood samples were obtained, plasma was separated and concentrations of (LH), (FSH), testosterone (T), inhibin B and cortisol were measured using specific ELISA systems. Data were analyzed using student's T test and ANOVA. In non-working boys, concentrations of LH and T gradually increased, attaining first peak at 15 and a second peak at 18 years, whereas concentrations of FSH and inhibin B progressively increased and peaked at 14 years. The concentrations of FSH were maintained thereafter, whereas levels of inhibin B slowly declined to low levels. In working boys, concentrations of LH, which were several fold higher at 10 and 11 years compared to school going boys, increased progressively and reached first peak at 14 and a second peak at 17 years. The levels of FSH steadily increased and attained a plateau at 13 years. The concentrations of T were higher at 11 and 12 years and attained first peak at 13 and a second peak at 17 years. The concentrations of inhibin B gradually reached maximum concentrations at 13 years, declining thereafter to low concentrations at 20 years. The concentrations of cortisol were significantly higher in working boys of all age groups. In conclusion, the present study demonstrates that boys under labor stress experience an earlier reawakening of HPG axis and an advancement of puberty by a year or so.

## OC18.6 The Young Investigator Winner

### Functional characterization of a new mutation in the NKX2.1 in patients with thyroid–lung–brain syndrome

I. Nettore[1], P. Mirra[3], A. Ferrara[1], A. Sibilio[1], C. Kamoi Kay[2], P. Lorenzoni[2], L. Werneck[2], I. Bruck[2], F. Bequinot[3], P. Ungaro[3], G. Fenzi[1], R. Scola[2] & P. Macchia[1]
[1]University of Naples 'Federico II', Naples, Italy; [2]Clinical Hospital, Parana Federal University, Curitiba, Brazil; [3]University 'Federico II', Naples, Italy.

TTF1/NKX2.1 is a transcription factor expressed in thyroid, lung and brain. Several heterozygous mutations have been described in patients with primary congenital hypothyroidism, respiratory distress and benign hereditary chorea, typical aspects of the 'thyroid–lung–brain syndrome'.
We recently studied a family affected by some of these features, and the direct sequencing of the NKX2.1 gene demonstrated an heterozygous deletion of a cytosine at position 665 that causes a frameshift with the formation of a truncated protein.
Aim of our study was to better characterize the molecular effects determined by the C665del mutation.
The transcriptional properties of both WT and C665del NKX2.1 were investigated by cotransfection assays. As expected, the C665del mutant is unable to transactivate the Tg, the artificial C5 and the SP-C promoters. Interestingly, we demonstrated a dose-dependent dominant negative effect of the C665del on the WT NKX2.1 on Tg or C5 promoters. This dominant negative effect is absent on

the SP-C promoter. To further understand the dominant-negative action, we performed cotransfection experiments with PAX8, observing that the mutant is unable to modify the PAX8 basal activity. Moreover a dominant negative effect is also present when both WT and mutant are cotransfected with PAX8. Same results can be observed in presence of known NKX2-1 coactivators such as P300 or WWTR1.
Then, we evaluated the binding of NKX2.1 to DNA in the presence of NKX2.1 C665del by electrophoretic mobility shift assay (EMSA). This binding remains unaltered but the C665del, alone, is unable to bind to DNA. These data suggest that the mutated NKX2.1 protein produces dominant-negative effects on the wt NKX2.1 in promoter-specific manner and it interferes with the activity of wt, but not with its binding to DNA.
In conclusion, these experiments allow to understand the functional relevance of the different domains in the NKX2.1 protein and show the high variability between genotype-fenotype in patients with TLB syndrome. On the basis of our data it seems reasonable to consider that the pathogenetic mechanisms underlying the effect of the mutations are very complex, and tissue-specific.

## Cardiovascular Endocrinology

### OC19.1

**Both EPA/AA ratio and absolute AA levels constitute an independent risk factor for coronary atherosclerosis in type 2 diabetic patients**

T. Nakamua[1] & H. Maegawa[2]
[1]Omihachiman Community Medical Center, Omihachiman, Japan; [2]Shiga University of Medical Science, Otsu, Japan.

Background
N-3 polyunsaturated fatty acids (PUFA), such as α linolenic acid (ALA), eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), have been shown to modify several key risk factors for cardiovascular disease, although n-6 PUFA arachidonic acid (AA) has important roles in inflammation. However, it is not clear whether the apparent protection of n-3 PUFA against cardiovascular disease has been found in diabetic patients.
Methods
To clarify the effects of PUFA, firstly we calculated fasting serum PUFA, LDL-cholesterol, HDL cholesterol and triglyceride (TG) levels three times in type 2 diabetic patients. Those patients had been never treated with EPA drugs. Next we have followed the patients, focusing on newly onset of acute coronary syndrome, which have been undergoing elective coronary intervention for three years. Then, we divided diabetic patients into two groups in which acute coronary syndrome (ACS, PCI-group, $n=42$) was observed or not (DM-group, $n=44$), whereas 36 normal glucose tolerance subjects (Nor-group) were studied as control. Finally, we analyzed EPA/AA ratio and absolute EPA, AA levels among three groups. These values were analyzed using an ANOVA model.
Results
EPA/AA ratio in PCI-group (0.37) were significantly lower than in DM (0.47, $P<0.05$) and in Nor-group (0.52, $P<0.01$), although absolute AA ratio in PCI-group (207.2 mol%) was statistically higher than in DM (173.9, $P<0.05$) and in Nor-group (162.3, $P<0.01$). Moreover, absolute EPA levels were statistically lower in PCI-group compared to DM and Nor-group ($P<0.05$, $P<0.05$), whereas the average levels of LDL, HDL-cholesterol and HbA1c were not significantly changed among three groups.
Conclusion
A negative correlation was noted between the event of coronary artery disease and both EPA/AA ratio and absolute EPA values in diabetic patients. In addition, constantly high AA levels in PCI-group may contribute the incidence of acute coronary syndrome. We also suggest that both EPA/AA ratio and absolute EPA levels constitute an independent risk factor for coronary atherosclerosis.

### OC19.2

**Increased arterial stiffness is independently associated with cerebral infarctions and white matter lesions in patients with type 2 diabetes despite good blood pressure and lipid control**

E. Laugesen[1], P. Høyem[1], B. Grøn[2], A. Mikkelsen[2], W. Kim[2], S. Thrysøe[2], M. Erlandsen[4], J. Christiansen[1], S. Knudsen[1], K. Hansen[3], T. Hansen[1] & P. Poulsen[1]
[1]Aarhus University Hospital, Aarhus, Denmark; [2]Aarhus University Hospital Skejby, Aarhus, Denmark; [3]Regional Hospital Silkeborg, Silkeborg, Denmark; [4]Aarhus University, Aarhus, Denmark..

Aim
Patients with type 2 diabetes (T2DM) have increased risk of cardiovascular disease (CVD) including stroke. The risk of CVD is traditionally assessed using office blood pressure (BP) and lipid profile. Increased arterial stiffness predicts cardiovascular events in the general population. We investigated if arterial stiffness was associated with cerebrovascular disease in patients with T2DM and sex- and age-matched controls indepentl y of classical risk factors.
Methods
patients with newly diagnosed T2DM and Ninety sex- and age- matched controls were examined. Arterial stiffness was assessed by aortic pulse wave velocity (PWV), and cerebrovascular disease by cerebral infarctions and severity of white matter lesions (WMLs) on MRI scans of cerebrum. A blinded reviewer rated WMLs a.m. Breteler (no/slight changes = 0, moderate = 1, severe = 2).
Results
Antihypertensive treatment and lipid lowering treatment was more frequent in diabetic patients, who consequently had lower office BP (126 +/− 12 vs 131 +/− 14 mmHg systolic, $P=0.01$) and lower lipid levels. Despite this, diabetic patients had significantly higher PWV compared to controls, (9.2 +/− 2.0 vs 8.0 +/− 1.6 m/s, $P<0.0001$). PWV was higher in patients with cerebral infarctions (9.9 vs 8.5 m/s, $P=0.002$) and PWV increased across Breteler categories (8.2 +/− 1.7 vs 9.3 +/− 2.0 vs 9.4 +/− 2.1 m/s, $P<0.001$ for trend). PWV remained independently associated with severity of WMLs ($P<0.01$) and cerebral infarctions, ($P<0.02$) after adjustment for the following covariates: age, sex, diabetes, mean arterial pressure, smoking, statins and BMI in multivariate regression.
Conclusion
Despite good BP and lipid control, PWV was substantially higher in T2DM patients. PWV is independently associated with WMLs and cerebral infarctions. PWV may represent a clinically relevant parameter in the evaluation of CVD risk in T2DM.

### OC19.3

**Copeptin and adrenomedullin in a large cohort of patients with coronary heart disease and newly diagnosed glucose intolerance ('Silent diabetes study')**

S. Kusche[1], R. Doerr[1], O. Hartmann[2], N. Morgenthaler[4], O. Schnell[3] & T. Lohmann[1]
[1]Hospital of Dresden-Neustadt, Dresden, Germany; [2]Thermo Fisher Scientific GmbH, Hennigsdorf, Germany; [3]Research Laboratories, Munich-Neuherberg, Germany; [4]Charite University Berlin, Berlin, Germany.

Background
Copeptin is used as a diagnostic marker for acute myocardial infarction, adrenomedullin as a prognostic marker for congestive heart failure. Both hormones may be involved in pathophysiology of metabolic syndrome.
Methods
We have used sera of the 'Silent diabetes study' (1). Sera of 920 patients were eligible for this analysis. All patients underwent an oral glucose tolerance test, patients with previously known diabetes were excluded. In coronary angiography, 59 patients had no coronary disease (no CHD), 152 patients had only stenosis <50% (beginning CHD), 164 had 1-vessel disease (1-VD), 172 had 2-vessel (2-VD) and 230 had 3-vessel disease (3-VD). In oGTT 393 patients had normal glucose tolerance (NGT), 279 had impaired glucose tolerance (IGT) and 105 had diabetes mellitus (DM). Copeptin and MR-pro-adrenomedullin (MR-proADM) were measured in the BRAHMS Kryptor assay (Thermo Fisher Scientific). Statistical analysis was performed by ANOVA and Kruskal–Wallis methods.

Results
Patients with no CHD had significantly lower copeptin levels (4.4 + 2.02 pmol/l) compared to patients with beginning CHD (6.94 + 6.29, $P = 0.023$), 1-VD (6.91 + 6.84, $P = 0.03$), 2-VD (6.64 + 5.57, $P = 0.012$) or 3-VD (8.93 + 10.20, $P < 0.0001$), differences between patient groups were not significant. Patients with 3-VD (0.71 + 0.27 nmol/l, $P = 0.0002$) and beginning CHD (0.68 + 0.24, $P = 0.009$) had higher MR-proADM levels compared to no CHD patients (0.57 + 0.13). Both patients with DM (9.8 + 10.15 pmol/l, $P < 0.0001$) and IGT (8.11 + 9.17, $P = 0.0003$) had higher copeptin levels compared to patients with NGT (6.1 + 5.91). There was no significant difference between patients with DM and IGT. Patients with NGT had lower MR-proADM levels (0.63 + 0.17 nmol/l) compared to patients with IGT (0.71 + 0.29, $P < 0.0001$) or patients with DM (0.71 + 0.22, $P = 0.005$).
Discussion
Copeptin is elevated in patients with CHD compared to those with no CHD but there is no grading to the severity of CHD. MR-proADM is elevated in patients with advanced CHD (3-VD) and in beginning CHD compared to no CHD patients. Both marker are elevated in patients with IGT and previously unknown DM. The early elevation of both hormones may argue for an early involvement in the development of the metabolic-vascular syndrome.

## OC19.4

**Oxytocin is cardioprotective hormone**
J. Gutkowska & M. Jankowski
CR-CHUM, University of Montreal, Montreal, QC, Canada.

We have uncovered the entire functional oxytocin (OT) system in the rat and human heart. In the experimentally-induced myocardial infarction (MI) in rats, the continuous OT delivery improves the cardiac work, reduces inflammation, and stimulates angiogenesis. We hypothesized that these actions of OT are mediated by increase in glucose uptake in cardiomyocytes (CM). Indeed OT (10 nM) increased basal glucose uptake in CM to 4.0 ± 0.2 fmol/mg protein in comparison to 2.2 fmol/mg in control cells ($P < 0.001$). OT had a moderate synergistic effect with 0.1 mM 2, 4-dinitrophenol (a hypoxia-inducing agent, DNP), augmenting basal glucose uptake to 5.5 ± 0.5 fmol/mg. Wortmannin (0.1 μM), an inhibitor of phosphatidylinositol-3-kinase (PI3K), significantly suppressed OT and insulin (10 nM) ($P < 0.001$) effects on glucose uptake, indicating a common pathway. The activation of PI3K pathway suggested beneficial effects of OT in prevention of CM hypertrophy. Analysis of the cells treated with OT revealed accumulation of ANP in perinuclear region and its co-localization with mitochondria without changes of cell size. Further study demonstrated that OT inhibits CM hypertrophy induced by GqPCR agonists such as endothelin-1, inhibits CM apoptosis and decreases oxydative stress after exposure to ischemia-reoxygenation, the conditions, mimicking the myocardial infarction. The pre-treatment of cells with OT (10 nM) completely inhibited the hypertrophic effect induced by ET-1 both in the newborn and adult rat CM. The OT receptor antagonist and cGMP inhibition abrogated the anti-hypertrophic effect of OT. Furthermore, Western blot analysis indicated that OT treatment modulates phosphorylation of proteins downstream of PI3K such as PKB/Akt. In summary, these findings suggest that OT cardioprotective action is due at least in part to stimulation of PI3K signaling pathway and ANP accumulation in CM. Therefore, in pathological conditions, OT plays a cardioprotective role, and improves vascular and metabolic functions, thus OT presents potential for therapeutic use.

## OC19.5

**Circulating adrenomedulin levels are associated with atrial natriuretic peptide and brain natriuretic peptide levels in heart failure patients**
P. Holmager[1], M. Schou[2], M. Egstrup[3], I. Gustafsson[4], J. Goetze[5], F. Gustafsson[5], P. Hildebrandt[3], J. Faber[1] & C. Kistorp[1]
[1]Herlev Hospital, Herlev, Denmark; [2]Hillerod Hospital, Hillerod, Denmark; [3]Frederiksberg Hospital, Herlev, Denmark; [4]Gentofte Hospital, Gentofte, Denmark; [5]Rigshospitalet, Copenhagen, Denmark;.

Introduction
Heart failure is characterised by an up-regulation of neurohoromones, and brain natriuretic peptide (BNP) and atrial natriuretic peptide (ANP) are well-established diagnostic biomarkers with substancial prognostic value. Adrenomedullin is a vasoactive peptide and a potential biomarker of vascular injury in patients with cardiovascular disease (CVD) The aims of the present study were to investigate whether mid-regional pro adrenomedullin (MR-proADM) is predictive of outcome in heart failure (CHF) patients and if MR-proADM is associated with MR-proANP or NT-proBNP.
Materials and methods
Prospective, observational study of 360 unselected CHF patients included at baseline (30% female, mean age 71 years). 63% had CVD. Patients were followed for a median of 17 months with respect to mortality. 184 patients died and 229 were hospitalised.
Results
Mean (S.D.) MR-proADM levels were 0.75 (0.42) nmol/l, mediann (interquartile range) MR-proANP levels were 238 (149–362) nmol/l and NT-proBNP levels were 1138 (469-2636) pg/ml. MR-pro ADM was associated with age ($r = 0.28$, $P < 0.001$), s-creatinine ($r = 0.32$, $P < 0.001$), NT-proBNP ($r = 0.29$, $P < 0.001$) and MR-proANP ($r = 0.42$, $P < 0.001$). Using Cox proportional hazard analysis increasing logarithmic levels of MR-proADM were predictive of mortality HR being 1.32 (1.29–1.35, $P = 0.007$) and MR-proANP were predictive of mortality HR being 1.36 (1.33–1.39, $P = 0.013$) after adjusting for age, gender, CVD, NYHA, systolic blood presure, LVEF and treatment with β-blocker or aldosteron antagonist. When adding NT-proBNP to the model HR of mortality was 1.21 ($P = 0.09$) for MR-proADM and 1.13 ($P = 0.42$) for MR-proANP.
Conclusion
MR-proADM levels were associated with both NT-proBNP and ANP. MR-proADM was predictive of mortality after adjustment for well known risk factors in CHF. Neither MR-proADM or MR-proANP was independently related with outcome after including NT-proBNP in the multivariate model.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## OC19.6

**Endothelial progenitor cells in acromegaly are reduced and responsive to treatment with somatostatin analogues**
I. Albano, G. Fadini, F. Dassie, C. Martini, C. Agostini, A. Avogaro, N. Sicolo, R. Vettor & P. Maffei
Padua University Hospital, Padua, Italy.

Introduction
Acromegaly is characterized by high cardiovascular morbidity and mortality possibly due to increased prevalence of main traditional cardiovascular risk factors. It is not clear though whether the incidence of atherosclerosis is truly enhanced. Moreover recent *in vitro* studies show a protective role of (GH) and IGF1 (insulin-like growth factor-1) on the endothelium. As expression of endothelial regenerative reserve, endothelial progenitor cells (EPCs) could clarify the complex balance between pro- and anti-atherogenic factors in acromegaly. We therefore aimed to study the distribution of EPCs within a sample of acromegalic patients.
Materials and methods
42 acromegalic patients (female/male ratio = 1.5; mean age = 51 ± 12.75 ys) underwent a clinical evaluation and a blood test including count and typization of peripheral EPCs using monoclonal antibodies CD34+ or CD133+ or KDR+ specific. Data were compared to fourty two control subjects matched by age, gender and class of glucose tolerance. In a group of 9 patients with active disease (normalized IGF1 > 1) the whole evaluation was repeated after 24 weeks of treatment with somatostatin analogues (SSA).

Results

Acromegalic patients show a significantly lower number of CD34+/KDR+ cells than controls ($P=0{,}005$) while CD34+/CD133+/KDR+ cells are reduced in active patients compared to the inactive group ($P=0.00001$) and increase after SSA treatment ($P=0.03$). In acromegalic patients, the number of CD34+/CD133+/KDR+ cells correlates with IGF1 levels ($R=-0.56$, $P=0.0001$), fasting plasma glucose ($R=-0.46$, $P=0.002$), plasma insulin ($R=-0.33$, $P=0.03$) and HOMA index ($R=-0.37$, $P=0.02$), IGF1 showing to be the most important covariate in a multivariate analysis ($\beta=-0.35$, $P=0.03$). In acromegalic and controls the CD34+/KDR+ variability is mainly explained by diastolic blood pressure ($\beta=-0.26$, $P=0.03$).

Conclusions

Acromegalic patients seem to have a reduced endothelial regenerative capacity and an increased cardiovascular risk probably related to IGF-1 levels, glucose metabolism alterations and hypertension. Treatment with SSA could ameliorate EPC peripheral pattern.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Clinical practice guideline on linear growth measurement of children**

Jan M Foote[1,2]
[1]Blank Children's Endocrinology Clinic, Blank Children's Hospital, Des Moines, Iowa, USA; [2]The University of Iowa College of Nursing, Iowa City, Iowa, USA.

Introduction
Growth is an important and sensitive indicator of child health. Abnormal growth is a common consequence of many conditions, therefore its identification acts as a useful warning of possible pathology. Effective growth monitoring requires precise linear growth measurements; however, measurements are often inaccurate and unreliable. Measurement error influences the interpretation of growth patterns resulting in failure to identify underlying pathology or apparent growth divergence in normally growing children.
Purpose
The purpose of this project was to develop a clinical practice guideline to assist professionals in applying evidence-based knowledge in measuring children using standardized instruments and techniques to facilitate accurate and reliable growth assessments.
Methods
Systematic methods were used to identify evidence to answer focused clinical questions about linear growth measurement. A multidisciplinary team of health professionals critically appraised and synthesized the evidence to develop explicit clinical practice recommendations using an evidence-based practice rating scheme. The guideline was prospectively evaluated through internal reviews, external expert reviews, and a pilot study.
Results
Data analyses were used to improve guideline clarity, applicability, and feasibility, while demonstrating validity and intraexaminer and interexaminer reliability ($P<0.0001$). The guideline provides clinical practice recommendations for measurement techniques, measurement instruments, use of less expensive instruments, calibration of instruments, diurnal height variation, measuring height versus length, replicate measurements, and special considerations. Each recommendation is linked with scientific rationale and supporting references. Tools are available to facilitate guideline implementation.
Conclusions
The clinical practice guideline on linear growth measurement is based on the best available evidence and was developed using rigorous methods. Health professionals and parents need accurate and reliable growth information. Guideline use will improve timely recognition, diagnosis, and treatment of growth disorders, while reducing unnecessary and costly evaluations in normally growing children. Widespread dissemination and adoption of the guideline can significantly impact child health around the globe.
Keywords: linear growth, children, evidence-based, clinical practice guideline.

**The nurse's role in establishing modern testosterone replacement therapy in an endocrine clinic**

T Yarndley, H M Conaglen, R Paul, M S Elston & J V Conaglen
Endocrine Unit, Waikato Hospital, Hamilton, New Zealand.

Our nurse-led testosterone replacement clinic in the Waikato Endocrine Service was the only clinic in New Zealand where specialised endocrine nurses established the use of and administered subcutaneous implants using testosterone pellets for hypogonadal men. Information gained through networking with nursing colleagues at the Annual Endocrine Nurses Society of Australasia (ENSA) symposia regarding the introduction of the depot injection Testosterone Undecanoate (Reandron™) has enabled the implants to be superseded by this more modern and patient-friendly therapy. We report on the development of our testosterone replacement programme in which we are currently treating 250 hypogonadal men using intramuscular Reandron™. The results and side-effects of treatment for this large cohort of patients for up to 2 years will be presented. The endocrine nurses have extended the programme to involve the patient's primary health care team, which whilst maintaining good therapeutic practice has improved convenience and access for patients. This presentation demonstrates that sharing best practice and evidence-based research at conferences such as the ENSA symposia can lead to significant changes in nursing practice and improved patient care.

**Interdisciplinary risk assessment and patient discharge management: combining biomarker & clinical scores, medical & nursing aspects**

Antoinette Conca [1], Ursula Schild [1], Katharina Regez [1], Rita Bossart[1], Petra Tobias[1], Gabriela Wallimann[1], Ruth Schweingruber[1], Barbara Reutlinger[1], Werner Albrich[2], Kristina Rüegger[2], Frank Dusemund[2], Philipp Schütz [2], Andreas Huber[3], Ulrich Bürgi[4] & Beat Müller[2]
[1]Nursing Department, Kantonsspital Aarau, CH-5001 Aarau, Switzerland; [2]Medical University Department, Kantonsspital Aarau, CH-5001 Aarau, Switzerland; [3]Department of Laboratory Medicine, Kantonsspital Aarau, CH-5001 Aarau, Switzerland; [4]Emergency Department, Kantonsspital Aarau, CH-5001 Aarau, Switzerland.

Introduction
Current medical and nursing scores have limited efficiency and safety profiles to assign the most appropriate treatment site to patients with lower respiratory tract infections (LRTIs). We assessed the potential of a combined score of CURB65 with proadrenomedullin (ProADM) levels and the adapted post-acute discharge score (PACD) for triage and discharge management decisions. We aimed to identify the proportions of patients who would be best cared for at different levels of care ranging from home with or without home-health care (Spitex), health ressort, nurse-led unit (NLU), and rehabilitation to acute-care hospitals.
Methods
Consecutive patients with LRTIs presenting to our emergency department were prospectively followed and retrospectively classified according to CURB65 and ProADM levels (CURB65-A) and biopsychosocial risk (PACD). We compared proportions of patients virtually allocated to triage sites with actual triage decisions and assessed the added impact of ProADM and the accuracy of the PACD.
Results
Overall, 93% of 146 patients were hospitalised. Among the 138 patients with available CURB65-A, 17.4% had a low medical risk indicating possible treatment in an outpatient or non-acute medical setting; 34.1% had an intermediate medical risk (short-hospitalisation); and 48.6% had a high medical risk (hospitalisation). Reasons for staying in the acute care setting after resolving medical problems (mean 3.6 days) were predominantly organisational (e.g. waiting for a post-acute care facility, 43 (69%) of the 62 nursing overruling reasons). The PACD identified in 55% ($n=202$) of the LRTI patients a risk for post-acute care needs (sensitivity 82%; specificity 55%).
Conclusion
Current rates of hospitalization are high in patients with LRTI and length of stay frequently extended beyond time of medical stabilization. This suggests a substantial potential of an interdisciplinary and biomarker-enhanced triage. The PACD was able to predict post-acute care needs and qualifies for screening purposes to facilitate early interdisciplinary discharge management.
Keywords: interdisciplinary risk assessment, post-acute care needs, triage, discharge management.

**Effect of metformin in teenagers with metabolic syndrome**

G N Rakhimova, Sh Sh Azimova & A Aliyeva
Republican Specialized Scientific-Practical Medical Centre of Endocrinology under the Ministry of Health of the Republic of Uzbekistan, Chair of Endocrinology of Tashkent Institute of Postgraduate Medical Education, Tashkent, Uzbekistan.

Research objective
To estimate efficiency of metformin use in children and teenagers with metabolic syndrome (MetS).
Materials and methods
Eighty children and teenagers aged 10–16 with exogenous-constitutional obesity (ECO) were observed. From them in 19 (23.8%) MetS was diagnosed according to diagnostic criteria of IDF (2007); 15 of them (78.9% – seven boys and eight girls) were prescribed metformin (Siofor, Berlin Chemie) in dose from 1000 to 1500 mg a day on the background of life style change (hypo-calorie diet and physical activity). Middle age was $12.5\pm0.58$ years (Me-12). Duration of treatment and observation was 6 months.
Results and their discussion
In 6 months after treatment in observed group the component of MetS – waist circumference (WC) significantly decreased from $93.7\pm2.82$ to $85.8\pm2.47$ sm ($P=0.04$). Also we observed non-significant reduction of weight from $69.8\pm5.01$ to $66.7\pm4.78$ kg ($P=0.66$), and BMI from $30.1\pm1.37$ to $28.7\pm1.27$ kg/m$^2$ ($P=0.47$).

On the background of the therapy statistically significant decrease in level of TG from 2.62±0.23 mmol/l (95%CI 2.16–3.07) to 1.83±0.20 mmol/l (95%CI 1.45–2.51) ($P=0.02$) was found. Along with it the tendency to significant increase of level of HDL Cholesterol (from 1.14±0.10 to 1.96±0.18 mmol/l, $P=0.0001$) was found.
Level of fasting glycemia (from 4.43±0.19 to 4.14±0.15 mmol/l, $P=0.24$) and HbAlc (from 5.56±0.20 to 5.05±0.22%, $P=0.24$) decreased accordingly by 6.5 and 9.2%. Hemodynamic indicators decreased non-significantly, as they initially were within normal range.
Conclusion
On the background of metformin treatment in six (31.6% – three boys and three girls) of observed diagnosis of MetS was withdrawn; there were no side-effects during metformin use revealed.

## N5

**Translation and cultural adaptation of the Brazilian version of patient assessment of chronic illness care: Pacic-Brazil**

Camila Aparecida Pinheiro Landim[1], Fabio Araujo De Almeida[2], Antonia Tayana Da Franca Xavier[3], Thiago Antonio Moretti De Andrade[4], Maria Lucia Zanetti[5], Maria Manuela Martins[6], Constança Paul[7] & Carla Regina De Souza Teixeira[8]
[1]RN, PhD Student, School of Nursing of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil; [2]MSW, PhD, Assistant Professor, Translational Obesity Research Program, College of Agriculture and Life Sciences, Blacksburg, Virgnia, USA; [3]RN, School of Nursing of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil; [4]PhD Student, Department of Internal Medicine, School of Medicine of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil; [5]RN, PhD, Associate Professor, School of Nursing of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil; [6]RN, PhD, Coordinator Professor, Higher School of Nursing of Porto, Porto, Portugal; [7]RN, PhD, Professor, Institute for Biomedical Sciences Abel Salazar, Porto University, Porto, Portugal; [8]RN, PhD, Associate Professor, School of Nursing of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil.

Background
The Chronic Care Model (CCM), developed by Wagner *et al.*, at MacColl Institute for Heathcare Innovation at Group Health Research Institute, Seattle, Washington, United States, is one approach to improving chronic illness care, including diabetes *mellitus* (DM), that is being used increasingly to assess and improve care. The CCM is based on evidence-based practices and reviews of the literature on effective care. The Patient Assessment of Chronic Illness Care (PACIC) is a 20-item questionnaire assessing the implementation of the CCM from the patient perspective that focuses on the receipt of patient-centered care and self-management behaviors.
Objective
To translate and conduct the cultural adaptation of the Brazilian version of the PACIC in Brazilian patients with DM.
Methods
Methodological study, whose adaptation process cultural included: forward translation, expert committee, back-translation and cognitive interview. The study addresses a sample of 50 Brazilian patients with DM in a Basic Health District Unit in Ribeirao Preto, Sao Paulo, Brazil in 2010.
Results
The former revealed good acceptance of the translated version of the instrument, which participants considered having items of easy understanding. After analysis of the psychometric properties and completion of the validation process, the instrument will become available to Brazilian researchers, enabling its comparison with other cultures.
Conclusion
It is concluded that a culturally adapted instrument in the Brazilian context with a focus on quality of care can provide support for health staff and managers in the planning the health care of patients with chronic illness, especially DM.
Comments/keywords
Comments for the Nurse Abstracts Markers: a culturally adapted instrument in the Brazilian context with a focus on quality of care for patients with DM can ensure continuity of health services and clinical practice of nursing.
Keywords: Chronic Disease, Diabetes Mellitus, Validation Studies, Nursing.

**Perception of quality of care in patients with pituitary disorders**

Dahlgren Christina[1], Hollman Frisman Gunilla[2] & Björkquist Eva[1]
[1]Department of Endocrinology, University Hospital, 581 85 Linköping, Sweden; [2]Division of Nursing Sciences, Department of Medical and Health, Faculty of Health Sciences, Linköping University, 581 85 Linköping, Sweden.

Background
In order to support patients with lifelong chronic illness, such as pituitary disorders, it is a challenge to continuously offer high quality of care.
Aim
The aim of this study was to examine how patients with pituitary disorders of different causes perceive quality of care in contact with a specialized endocrinology reception.
Methods and materials
Randomly selected, patients with chronic pituitary disorders ($n=100$) were asked to participate. Seventy-seven patients (females, $n=44$), 22–82 years of age responded and participated in the study. The questionnaire Quality from the Patient's Perspective (QPP; modified short version) was used to measure patient's perception of quality of care (considered from four dimensions: physical-technical, medical-technical, identity- orientation and socio-cultural atmosphere). Each question was calculated using an action index of each investigated area. Impaired quality of care in specific dimensions above 15% indicates need of improvement. In addition two open-ended questions were asked.
Results
Most of the respondents, 97%, expressed that necessary physical-technical equipment was available while in the medical-technical dimension 26% reported impaired quality of care. In the identity-orientation dimension, impaired quality of care was reported by 25% mainly due to non-participation in care- and treatment decisions as well as concerning information about results of treatments and self-care activities. In the socio-cultural dimension impaired quality of care was reported in 25%. In addition, the patients asked for extended telephone receptions at the clinic and improved information about pituitary disorders.
Conclusion
The patients were satisfied with the technical part of the medical care, but less satisfied with participation in care decisions and information about self-care. In our setting improvements are needed regarding patient information and access to care.
Comments/keywords
Keywords: pituitary disorders, quality of care, participation, patient satisfaction.

## N7

**Neutralization of Flightless I (Flii) using Flii-specific monoclonal antibodies accelerates impaired healing in diabetic wounds through improved cell proliferation**

Nadira Ruzehaji[1,2], Hillary Wallace[4], Michael Stacey[4], Robert Fitridge[3] & Allison Cowin[1,3]
[1]Women's and Children's Health Research Institute, 72 King William Road, North Adelaide, South Australia, Australia; [2]Discipline of Paediatrics, University of Adelaide, Adelaide, South Australia, Australia; [3]The University of Adelaide, Discipline of Surgery, The Queen Elizabeth Hospital, Woodville South, South Australia, Australia; [4]School of Surgery, University of Western Australia, Perth, Western Australia, Australia.

Ulceration is a common and severe complication of diabetes affecting 15% of the 200 million patients with diabetes worldwide. A significant proportion of these chronic wounds fail to respond to conventional treatment, hence major amputation is a feared outcome of diabetes. More than 60% of non-traumatic amputations in the western world are performed in the diabetic population. There exists a growing need for effective therapeutic agents to improve healing in these wounds.
The manipulation of actin-remodelling protein Flightless I revealed its important role as a negative regulator of wound healing. Reductions in Flightless produce improvements, whereas elevated expression impairs wound outcomes. We have studied the biopsy tissue recovered from patients with diabetic ulcers. Immunohistochemistry showed increased expression of Flightless in diabetic wounds compared to unwounded skin samples.
Both diabetic wound fluid and Flightless have previously been shown to inhibit cell proliferation and migration. Therefore to determine if the inhibitory effect of wound fluid could be due in part to Flightless, chronic fluids were preincubated

with Flightless neutralizing antibodies (FliiAb) and the effect on fibroblast proliferation determined. FliiAb treated chronic wound fluid ablated the inhibitory effect of chronic wound fluid with fibroblast proliferation being restored to untreated control levels.
It is hypothesized that reduction of Flightless expression in the skin will create permissive environment for improved diabetic wound healing. Using in vivo wound healing models, wounds were created on the back of Type 1 diabetic and non diabetic mice. Diabetic mouse wounds healed faster when Flightless gene expression was reduced. Indeed neutralization of Flightless activity by Flightless specific monoclonal antibodies in WT diabetic wounds lead to higher rate of re-epithelialisation and acceleration of diabetes-impaired wound healing. These results suggest that reducing the activity of Flightless improves diabetic wound healing, which is promising for future development of new therapies for diabetic ulcers.
Comments/keywords
I am a podiatrist with 5 years of experience of working with both Type 1 and Type 2 diabetes patients. I am especially interested in the treatment of non healing diabetic wounds. I am currently undertaking a PhD by research at the University of Adelaide, South Australia. I am in my last year of PhD and I expect to submit my thesis in 3 months. I would be honoured to present the findings of my research results as part of the 'nurse session' of the 15th International Congress of Endocrinology.

**Diabetes nurse leadership group: a forum for improving diabetes care in Brooklyn, NY**

Linda Cohen, Sandy Hirsch, Dawn Hagerty & Maria Yomtov
State University of New York (SUNY) Downstate Medical Center, University Hospital of Brooklyn, Brooklyn, New York, USA.

We created a forum to meet on a regular basis to join forces to facilitate providing optimal diabetes care and education for the members of the hospital, academic and communities of Brooklyn.
Learning Objectives:
1. To identify the opportunities where CDE's can have an impact on the education, management and prevention in and out of the hospital and academic setting.
2. To illustrate the use of CDE's in an urban academic medical center to optimize the education of nurses, patients and the community in diabetes management and prevention.
3. To describe the process of using CDE's in diabetes improvement initiatives and education in an academic urban hospital and in the Brooklyn community.
Content Outline
1. CDE Opportunities in an Urban Academic Medical Center
   a. Inpatient
   b. Outpatient
   c. Education of staff
   d. Education of students
   e. Community Health Forums
   f. Research
2. Utilizing CDE's in an Urban Academic Medical Center
   a. In-servicing staff
   b. Precepting students
   c. Conducting Workshops
   d. Representation on Hospital Wide Clinical Committees
   e. Research Activities
   f. Implementing new policies/procedures
   g. Evaluating new policies/procedures
3. The Process of Utilizing CDE's
   A CDE's involvement in:
   a. Community Activities
   b. Patient Clubs
   c. Regulatory Affairs
   d. Nursing Education
   e. Physician Education
   f. Medical Resident/Physician Education in-servicing
   g. Preceptorship of Nurses

**Childhood osteoporosis: screening, prevention, treatment and safe handling practices in a tertiary care pediatric hospital**

Nicole Kirouac[1], Leslie Galloway[1], Joanna Gies[4], Raili Macleod[1], Paige McCullough[1], Anna Mendoza[1], Kathy Miller[1], Gina Rempel[1,4], Arlene Stocki[1], Shayne Taback[2,3], Sandy Taylor[1,3] & Brandy Wicklow[1,2]
[1]Health Sciences Centre, Winnipeg Children's Hospital, Winnipeg, Manitoba, Canada; [2]University of Manitoba, Winnipeg, Manitoba, Canada; [3]The Manitoba Institute of Child Health, Winnipeg, Manitoba, Canada; [4]Rehabilitation Centre for Children, Winnipeg, Manitoba, Canada.

Osteoporosis is a challenge facing children of all ages with a variety of health conditions and physical abilities. The reality of this challenge spurred the development of the child health program's interdisciplinary bone health project team in a tertiary care in-patient pediatric hospital. The team's goal was to develop protocols and tools to identify 'at risk' children and ultimately prevent fragility fractures in this group of children. The use of standardized evidence-based diagnosis, treatment, and prevention protocols empowers all care providers to make bone health a priority for their patients. An interdisciplinary approach to bone health and fracture prevention is the key to successful outcomes for all children at risk for osteoporosis. Strategies included the development and implementation of 1) an evidence-based screening tool to allow primary caregivers to quickly recognize the child who is most at risk for osteoporosis, 2) a 'Fragile: Handle with Care' protocol for 'at risk' children along with identifiable signage that alerts caregivers and others who handle the child of the need to do so safely, 3) a bone health algorithm for hospital staff to guide them from screening through diagnosis, prevention or treatment protocols, and 4) a resource for families and caregivers that includes the definition of pediatric osteoporosis, diagnostic criteria, prevention strategies, nutrition and lifestyle recommendations related to activities of daily living, safe handling practices, and tips to prevent injury. Critical success factors and challenges of spreading this hospital wide screening and intervention program will be reviewed. Statistics of the percentage of children admitted to the centre who meet the osteoporosis risk category through this screening will be presented. The team's current focus includes identifying children with osteoporosis in the community by expanding the screening and fracture prevention protocols through the education of pediatric outpatient treatment areas, community care providers and families.

**Endocrine and exocrine function changes in acute pancreatitis**

Floreta Kurti[1,2], Tatjana Çina[1], Alketa Dervishi[1] & Klodiana Poshi[1,3]
[1]University of Tirana, Faculty of Nursing, Tirana, Albania; [2]Department of Gastroeneterology UHC, Tirana, Albania; [3]Department of Endocrinology, UHC, Tirana, Albania.

Introduction
Acute pancreatitis may cause endocrine and exocrine dysfunction, but in the early phase of acute pancreatitis these changes are poorly documented.
Aim
The aim of this study was to asses the endocrine and exocrine impairment in the early phase of AP and to establish the need for
Patients and methods
We have collected data from 116 patients with AP, with different aetiologies and degrees of severity of the disease. We had 93 male pts (80.17%) and 23 female pts (19.82%). Mean age $45.74 \pm 13.05$ years old (range 20–76 years).
Pancreatic endocrine function was evaluated by fasting blood glucose (FBG), glycosylated haemoglobin. Factors that could influence the endocrine function as obesity, hiperlipidemia were also investigated. Pancreatic exocrine function was evaluated by faecal elastase.
Results
Nine pts (7.76%) had the confirmed diagnosis of diabetes already prior to acute pancreatitis. 42 pts (36.20%) had hyperglycaemia and 65 pts (56.03%) had normal blood glucose level.
The blood glucose levels did not correlate with the severity of the disease. During the hospital stay 9 pts were already in insulin therapy and needed to modify doses, while 17 pts out of them initial hyperglycaemia had to start the insulin therapy recently.
Pancreatic exocrine insufficiency was seen in 21 pts (18.1%).
Conclusions
Endocrine functional impairment was found in pts with AP. Obesity, hyperlipidemia, and diabetes related symptoms increased the likelihood of developing functional impairment after AP.

Hyperglycemia may present in pts with AP, even during the first days of the disease onset, but usually normalizes as the inflammatory process subsides. Blood glucose may fluctuate, and insulin should be administered cautiously.

### A prospective study of growth and development of children recently adopted from orphanage care

Margaret F Keil[1], Sharon Singh[2], Jennifer Graf[3], Maddalena Ugolini[1], Roma Gandhi[1], Patrick Mason[4], Penny Glass[2] & Constantine A Stratakis[1]
[1]Section on Endocrinology and Genetics, Program in Developmental Endocrinology and Genetics, *Eunice Kennedy Shriver* National Institute of Child Health and Human Development (NICHD), National Institutes of Health, Bethesda, Maryland 20892, USA; [2]Children's National Medical Center, Washington, District of Columbia , USA, [3]Clinical Center Nutrition Department, NIH, Bethesda, Maryland, USA; [4]International Adoption Center, Inova Fairfax Hospital for Children, Fairfax, Virginia, USA.

Background and aims
Over 200 000 international adoptions by US families occurred between 1999–2010. Prior studies suggest that the effects of institutionalized care on growth and development may not be fully reversible. The exact mechanisms through which early life stress affect biobehavioral outcomes have yet to be determined, but environmental influences could regulate both biobehavoral outcomes through an effect on the hypothalamic-pituitary-adrenal (HPA) axis.
Methods
Prospective study of 10 recently adopted children with an average time spent in orphanage care of $23.6 \pm 9$ months. Eligible participants had no history of significant medical, developmental, or behavioral problems. Anthropometric measurements, HPA axis tests, bone age, neurocognitive testing, and behavioral questionnaires were evaluated.
Results
Shortly after adoption by a U.S. family ($1.8 \pm 1$ mos.), height standard deviation unit (Ht SDU) was $-1.6 \pm 0.8$; weight SDU was (Wt SDU) $-0.9 \pm 1.2$; and head circumference SDU (HC SDU) was $-1.8 \pm 1$ Bone age was consistent with chronological age in four, advanced in three, and delayed in three children. Time in orphanage care was positively associated with serum cortisol ($r=0.64$; $P<0.06$) and negatively associated with HT SDU ($r=-0.63$; $P<0.05$). Neurocognitive testing (Bayley-III) showed significant delays in all scores. HC SDU was positively associated with cognitive and receptive language subscales on the Bayley III ($r=0.62$, 0.69; respectively). Response on the Behavior Rating Inventory of Executive Function endorsed clinically significant inhibitory control in half the children, and subscale scores for behavioral regulation were positively associated with HC SDU ($r=0.9$; $P<0.05$).
Conclusion
Prenatal factors and time in orphanage care were associated with negative effects on linear growth, serum cortisol, cognitive, and behavioral outcomes.
Clinical implications
Careful assessment of prenatal and environmental risk factors will help to identify children at risk for untoward effects on biobehavioral outcomes and target early interventions.
Comments/keywords
Keywords: Biobehavioral, Cortisol, Growth, Cognitive, Hypothalamic pituitary adrenal axis.

## N12

### Improving the efficiency and safety of managing children with diabetic keto-acidosis

Joan Luce[1] & David Turkewitz[1,2]
[1]Pediatrics at York Hospital, York, Pennsylvania, USA; [2]Immediate Past President of Pennsylvania Chapter of the American Academy of Pediatrics, York, Pennsylvania, USA.

Background
The nursing management of DKA in children is labor intensive. The traditional management of DKA involves numerous physician ordered changes of parenteral fluids. This is time consuming for the nurse; challenging for the pharmacy and can lead to delays in proper fluid administration.
Aims
The purpose of this pilot study was to investigate whether a streamlined process using a three-bag-system for treating children with DKA would improve efficiency for nurses, length of hospitalization, cost, and blood glucose levels.
Methods
Standardized orders for fluid solutions and rates of infusion were developed using a three-bag-system.
(1): ¾NSS with 20 mEq/L KCL and 20 mEq/L K-Phosphate
(2): D10% ¾ NSS with 20 mEq KCL/L and 20 mEq/L K-Phosphate.
(3): 250 units regular insulin/250 ml NSS.
Nurses manage IV fluids based on standardized orders with physician communication only as needed for uncovered contingencies. A comparative non-experimental design was used to evaluate the outcomes of children hospitalized with DKA before and after initiation of the three-bag-system. Thirty medical records were reviewed with 16 patients not using three-bag-system (control group) and 14 patients using three-bag-system (study group).
Results
Independent samples *t*-test and $\chi^2$ were used to determine significance. No difference found in glucose between groups. Length of stay, number of IV bags, and cost were reduced in the study group. This change was insignificant. Verbal orders decreased in study group (14%; $P<0.008$) vs control group (68%).
Conclusions
Using the three-bag-system, there was a reduction in IV bags, cost, and length of stay; however, the sample size was too small to demonstrate significance. The reduction in verbal orders was statistically significant.
Clinical implications
Using a three-bag-system within standardized DKA orders creates a streamlined process reducing frequency of verbal orders, creating efficient care. Further studies using larger sample sizes are warranted verifying additional benefits using a three-bag-system.

### Socio-demographic factors associated with pediatric diabetic ketoacidosis admissions in Southern West Virginia

Kevin R Lewis[1], Sachin V Bendre[1], Crystal Clark[2] & Debbie Wiley[3]
[1]Pediatrics, West Virginia University, Charleston, West Virginia, USA; [2]School of Nursing, Mountain State University, Beckley, West Virginia, USA; [3]Pediatric Intensive Care Unit, Charleston Area Medical Center, Charleston, West Virginia, USA.

Background
Diabetic Ketoacidosis (DKA) is a well known complication in children with Type 1 Diabetes (T1DM) with a mortality rate estimated at 2%. Sparse data is available from the literature describing socio-demographic factors associated with DKA admissions in children. A previous study identified that children of non-Caucasian race and Medicaid, with T1DM, had increased incidence of DKA admissions.
Aims
To identify the socio-demographic factors associated with DKA admissions including type of insurance coverage, income by county, race, gender and HbA1c in West Virginia, a rural part of Appalachia.
Methods
A retrospective chart review of patients with known type 1 diabetes ages 1 to 18 years admitted to the Pediatric ICU with DKA in Charleston WV from January 2007 to December 2010 in comparison to our general type 1 diabetes population. The data collection tool included multiple socio-demographic factors and HbA1c.
Results
We reviewed a total of 167 patients with an admitting diagnosis of DKA; 63 charts were excluded because they did not meet either DKA criteria, age criteria, had new onset diabetes or lived outside of WV. 57% were female, 43% male. Average age was 13.6 years (SD $\pm$ 2.81) 56% were covered by Medicaid or Chips insurance and 44% by commercial payers. 11.5% were African American and 88.5% were Caucasian. The average HbA1c was 10.85%. (SD $\pm$ 2.364).
Conclusions
Salient findings include higher HbA1c, higher rates in African American patients and in those covered by Medicaid.

Clinical implications
This study identifies socio-demographic factors associated with children admitted for DKA in WV. Patients identified at higher risk for DKA include those with elevated HbA1c, African American race and those covered by Medicaid/CHIPS. Findings can be utilized to identify patients at higher risks for DKA and implementation of prevention strategies.

## N14

**Failure to thrive due to inherited congenital isolated growth hormone deficiency**

Lisa Michele Pincham & Paul Kaplowitz
Children's National Medical Center, Washington, Districts of Colombia, USA.

Patient Demographics
22-month-old female, severe failure to thrive.
Past History
Birth weight 5 lb 11 oz at term, grew well for 4 months and then deviating progressively below the curve in height and weight.
Physical exam: Length 66 cm (−5.1 SD), weight 6.6 kg (−6.7 SD). Prominent forehead and midfacial hypoplasia noted. Muscle mass decreased.
Family history: Mother's height of 5 ft 3 inches with menarche at age 13. Father, – 4 SD, diagnosed with isolated growth hormone deficiency at 7 years of age, and treated (5 ft 4 inches). Siblings included a 6-year-old brother who was very small at age 22 months during an endocrine evaluation and a 3-year-old sister with height and weight at both −4 SD below the mean.
Evaluation (studies/assessment)
Free T4 1.28 ng/dL (normal 1.1−1.7), TSH 1.8 uU/mL. IGF-1 <25 ng/mL (44–174) and IGFBP-3 <0.5 ug/mL (1.3–3.5) were both very low. Growth hormone stimulation testing peak 1.1 ng/mL. DNA sequencing of the GH-1 gene found a heterozygous sequence variance.
Interventions (physiologic or psychosocial)
Growth hormone therapy started at 0.27 mg/kg/week and headaches began 5 days later, likely due to increased intracranial pressure, GH stopped and dose reduced by 1/3 which was tolerated. She has grown about 12 cm (first 10 months) but is still −3.5 SD.
Discussion/recommendations
Failure to thrive in the first 2 years of life rarely has an endocrine etiology. In this case, recognizing the importance of the family history and better compliance with follow-up care of the older siblings might have resulted in earlier diagnosis and treatment of these patients. In addition, the headaches likely due to benign intracranial hypertension in the first case suggests that this rare complication of GH therapy might be more common in children with this rare and severe form of GH deficiency, so starting GH at lower doses than usual would be prudent.

## N15

**Diabetic foot in jordan: a qualitative content analysis of self-treated problems**

Ma'en Zaid Abu-Qamar[1] & Anne Wilson[2]
[1]Department of Adult Health Nursing, Faculty of Nursing, Mu'tah University, Mu'tah, Jordan; [2]School of Nursing, The University of Adelaide, Adelaide, South Australia, Australia.

Diabetes is a chronic condition that predisposes to a wide range of foot problems that potentially end with ulcer formation. The purpose of this manuscript is to report 68 participants' diabetic foot problems self-treated with complementary therapies. Participants were recruited from nine healthcare facilities in Jordan and interviewed via survey. Their responses to an individual question seeking information about complementary therapy usage was analysed using content analysis. The content analysis identified a wide range of foot problems that included: fungus, ulcers, corns, foot pain and other problems. The identified problems are common among sufferers of diabetes, and potentially may develop into ulcers. Accordingly, health education programs need to consider common foot problems among those with diabetes, and lifelong management need to be tailored to reduce the possibility of developing ulcers.
Comments/keywords
Content analysis, complementary therapy, diabetic foot, Jordan, foot problems, prevention, neuropathy.

**Planning for the future: preparing the endocrine specialist nurse of tomorrow**

Maggie N Carson
Nursing Studies, The University of Edinburgh and OPD 2 (Endocrine Unit), Edinburgh Royal Infirmary, Scotland, UK.

We have come a long way in the UK over the past ten years towards our goal of meeting the educational needs of nurses specialising in adult endocrinology. Endocrine nurses are now able to access annual training updates and attend specific nurse-led sessions at scientific meetings thanks to the ongoing work undertaken by the Society for Endocrinology's nurse committee.
It is therefore time to turn our attention to how we can encourage nurses to want to specialise in endocrinology and to start to prepare them for such a role before rather than after they find themselves working in this field. One way to do this is to ignite their interest in endocrinology while they are still students. With this aim in mind the first undergraduate course in adult endocrine nursing in the UK was developed and introduced as part of the Bachelor of Nursing (Hons) programme at Edinburgh University for the 2011/12 academic session. The course, which runs over ten weeks, is available as an Honours option to students in their third and fourth years and is delivered as a series of lectures and tutorials. The content covers specific endocrine conditions and alongside these critically explores issues such as compliance with prescribed treatment, quality of life, patient support and patient self-management, the role of the specialist nurse and nurse-led clinics. It is taught primarily by an endocrine nurse/lecturer with some specific input from visiting speakers. In addition to the formal taught aspects students are encouraged to attend endocrine out-patient clinics, observe pituitary surgery and attend local patient support group meetings as well as national patient conferences.
Fifteen students have now successfully completed the course. Course evaluation has been extremely positive. Of the seven final year students, two are now proactively seeking endocrine nursing positions to apply for on graduation.

**The Swedish pituitary registry**

Maria Forsgren[1], Elisabeth Olsson[1], Christina Dahlgren[2], Olof Ehn[3], Margareta Lindgren[4], Ann-Sofie Nilsson[5], Caroline Westholm[6] & Maria Wärn[7]
[1]Uppsala University Hospital, Uppsala, Sweden; [2]University Hospital in Linköping, Linköping, Sweden; [3]Sahlgrenska University Hospital, Gothenburg, Sweden; [4]Norrland University Hospital, Umea, Sweden; [5]Skåne University Hospital, Malmö, Sweden; [6]Örebro University Hospital, Örebro, Sweden; [7]Karolinska University Hospital, Solna, Sweden.

Background
The Swedish Pituitary Registry is a national quality registry founded in 1991 by the Swedish Pituitary Group.
A total of 89 such national quality registries exist in Sweden (2011) that provide important data in the continuous quality assessment and improvement work within the Swedish health care system.
In 2011, a nurse network was started for nurses working with the registry.
Purpose
The purpose of the Swedish Pituitary Registry is to guarantee that all patients with pituitary diseases get equivalent evaluation and treatment, as well as to evaluate given therapy.
Methods
Data from 3955 patients (1893 men/2062 women), median age 52 years (range 0–97), with pituitary diseases were registered 1991–2011.
Data registered in the registry consist of diagnosis, abnormal production of pituitary hormones, impact on vision, tumour extension and given treatment. Follow-ups were done after 1, 5 and 10 years. Since 2011 quality of life (EQ5D) and work ability are included.
Results
Among the pituitary tumours 1744 were non-functioning, 813 produced prolactin, 658 produced GH, 275 produced ACTH, 28 produced TSH and 15 produced FSH/LH.
102 patients had craniopharyngiomas and 320 had other pituitary diseases (including empty sella and Rathke's cleft cyst).
The incidence 1991–2011 for the pituitary tumours overall was 19 cases/million/year. The incidence was 9.3 for non-functioning pituitary tumours, 4.3 for prolactinomas and for the most complete groups in the registry, GH and ACTH, the incidence was 3.5 and 1.5 respectively.

Most of the patients were treated with surgery, radiotherapy or medical treatment, alone or in combination.
Conclusion
The registry gives us possibilities to evaluate given treatments, and to get an indication if there are regional variations in the treatment results. It is also a unique source of acquired knowledge and gained experience for these unusual diseases.

**Molecular genetics in turner syndrome**
Kelly Mullholand Behm

The basics of molecular genetics are reviewed with emphasis on introducing terminology frequently encountered in genetic lab results and in lectures focusing on the genetic origins of disease. Mutations thought to be associated with various phenotypical features of Turner syndrome are identified. Specific examples of genetic test results revealing Turner syndrome are reviewed. The new molecular testing available for diagnosing Turner syndrome is presented. Applications to the role of the endocrine nurse are provided.
Objectives
After attending this presentation, attendees will be able to:
1. Describe the possible molecular mechanisms responsible for the TS karyotype.
2. Identify mutations thought to be associated with physical features of TS.
3. Discuss diagnostic testing options for TS.
4. Differentiate between the role of a genetic counselor and a genetics/endocrine nurse in caring for a patient with TS.

## N19

**An Internet based protocol for examining transitional experiences of 16–26 year olds with Turner syndrome (TS)**
Kelly Mullholand Behm[1,2]
[1]Rush University College of Nursing, Chicago, Illinois, USA; [2]Pediatric Endocrinology Nursing Society, Ann Arbor, Michigan, USA.

Problem
Programs for adolescents with Turner syndrome (TS) are currently based on evidence derived from medical surveillance or parental and teacher perceptions. Little is known about how personal perceptions in this population influence behavior and psychosocial outcomes. Facing issues associated with puberty and young adulthood, such as body image, relationships, and careers, can be more challenging when living with TS.
Framework
Unlike frameworks for chronically ill adolescents that focus on medical aspects of care for co-morbidities, the Meleis Transitions Theory integrates concepts, change processes, and multifaceted contexts that permit broader analysis of perceptions of life experiences. The theory encompasses the nature of transition, its facilitators and inhibitors, and process and outcome indicators.
Methodology
This study utilizes a descriptive, qualitative, cross-sectional design with a theory driven thematic analysis. Recruitment is via the internet and referral from health care providers and support groups. Consent occurs through an interactive electronic document. Data are extracted from interviews conducted through sequential e-mails with participants.
Subjects
The sample includes 20 females with TS, ages 16–26. TS results from an arrangement of chromosomes demonstrating complete or partial absence of one X-chromosome.
Anticipated analysis
Coding and thematic analysis of interview data are ongoing using NVivo9 and Excel.
Results
In preliminary analysis, participants describe their individual experiences, conditions surrounding life changes, and patterns of personal response. 'Normal' vs 'not normal' is an overriding theme. Multiple transitions occur simultaneously. There is marked frustration with lack of public awareness of TS. Primary supports are family, friends, and religion rather than health care providers.
Implications
Nurses working with young women with TS need a better understanding of the variables of transition facing this population, as well as factors that enhance or inhibit positive psychosocial outcomes. Strategies for addressing unmet psychosocial and cognitive needs must be developed with the input of affected individuals.

**Self care practice among diabetic patients attending metropolyclinic, Kathmandu**
Radha Acharya & Pratikchaa Chapagain
Department of Nursing, Dhulikhel Hospital, Kathmandu University Hospital, Dhulikhel, Nepal.

Introduction
Diabetes is expected to rise from 177 million today to 370 million in 2030. Self care is a crucial to keep the disease under control. Appropriate self care practice can keep the disease under control.
Objective
The aim of the study was to find out the self care practice among diabetic patients.
Methods
This is a simple descriptive cross-sectional study. A total of 50 respondents, who met eligible criteria were purposively sampled and directly interviewed. Chi-square test was used to see the association. Self care practice of the respondents of this study population was examined using the SPSS version 16.0.
Result
Self care practice among the respondents was not satisfactory. Unsatisfactory self care practice was more than half (56.75%) among adequate knowledge respondents. Among respondents having inadequate knowledge, majority (92.31%) had unsatisfactory practice. Majority (74%) had adequate knowledge and satisfactory self care practice was done by only 34%.
Conclusion
Thus it is concluded that satisfactory self care practice was inadequate. There was significant relationship between self care practice and knowledge regarding diabetes among respondents. Thus the study also concluded that adequate knowledge on Diabetes should be provided to the patients for satisfactory self care practice.
Comments/keywords: self care practice, knowledge, diabetes.

**Eat, Pray, Love…Yourself**
Shari Liesch

Eat, Pray, Love ….Yourself; the title is modeled after a book (made into a movie) on life exploration and change. As health care providers, we spend a lot of time helping others; but how do we care for our self? We have been challenged to lead by example in our ever changing healthcare climate. To do this, we must nurture the physical, emotional, and relationship parts of our life. Insight into the risks of employment in health care will be used to direct conversations in managing these risks to achieve positive outcomes in longevity of employment and our own lives. In this talk, we will use the tenets of self determination theory (competence, autonomy and relatedness) as we explore personal and professional strategies to increase life satisfaction.

In preparation for this general session, (given at PENS conference, April 2012), Pediatric Endocrine Nurse Society (PENS) nurses were surveyed to determine perceived autonomy, relatedness and competence in their job using Self Determination Theory Work Satisfaction Questionnaire. In addition to this assessment of job satisfaction, it was important to assess their overall Quality of Life. For this, the short version of Quality of Life Enjoyment and Satisfaction Questionnaire (Q-LES-Q) was used. This was done to identify correlations between overall quality of life and perceived work satisfaction. Results of the surveys, as well as demographics will be used for the talk. This session will attempt to connect past and present perceptions of workplace and personal factors that impact job and life satisfaction. Through storytelling and exploration we will discuss how nurses can remain healthy as they care for others. Assessment of individual perceptions can direct future research to positively impact group competence, thus impacting nurse roles.

**Dance for health: implementation of a dance program to improve physical activity of children**

Terri H Lipman[1], Gillian Bazelon[2], Kali Rhodes[1], Carrie Preston[1], Sarah Ratcliffe[3] & Janet A Deatrick[1]
[1]University of Pennsylvania, School of Nursing, Philadelphia, Pennsylvania, USA; [2]Sayre Health Center, Philadelphia, Pennsylvania, USA; [3]University of Pennsylvania, Center for Biostatistics and Epidemiology, Philadelphia, Pennsylvania, USA.

Background
Sedentary lifestyle, decreased physical activity and poor diet contribute to the increasing problem of childhood obesity and risk for type 2 diabetes.
Aims
The purpose of this study was compare the effect of dance, with unstructured playtime, on the physical activity level of an underserved, urban population of children.
Methods
In this longitudinal study, height, weight and body mass index (BMI) were measured during the first week of the four week program. Every week, heart rates (HR) and pedometer readings (PR) were recorded. Pre activity heart rates were obtained and a dance class was taught for 30 minutes, once a week. Resting HR and PR were measured after the dancing. During the non-dancing days, PR were taken to gauge physical activity during usual activity.
Results
38 children (16 F, 22 M; 4.7–12.9 yr) participated in the study. Average BMI was 18.3 ($\pm$5.5); 20% were $>85^{th}$% for age and sex. Overall, the average PR measurement for dancing days was 1760 ($\pm$945) vs 851 ($+$619) on non-dancing days. The number of steps in dancing days was approximately double those in non-dancing weeks ($P<0.001$). Children 8–10 yr had more steps than younger and older age groups. Age had a quadratic association with PR ($P<0.001$). Males had 37.2% more steps than females ($P=0.026$); BMI was not found to be associated. Resting HR was significantly higher than baseline ($P<0.001$).
Conclusions/clinical implications
Children in this population were not physically fit as evidenced by their elevated resting heart rates after exercise. Implementing dancing increased steps and activity of the children. Dance is a culturally relevant, enjoyable, free and easily accessible method of activity. It is crucial for nurses in pediatric endocrinology to address the obesity epidemic with culturally appropriate interventions and to partner with the community to tackle this public health crisis.

**Self-care competence in the case of Brazilian patients with diabetes mellitus in a multiprofessional educational programme**

Camila Aparecida Pinheiro Landim[1], Maria Lucia Zanetti[2], Manoel Antonio Dos Santos[3], Thiago Antonio Moretti De Andrade[4], Tania Alves Canata Becker[5], Ellen Cristina Barbosa Dos Santos[5], Gabriel Guidorizzi Zanetti[6], Beatriz Cardoso Lobato[7], Rosana Cristina Franco[7] & Carla Regina De Souza Teixeira[8]
[1]RN, PhD Student, School of Nursing of Ribeirao Preto, University of Sao Paulo, Sao Paulo, Brazil; [2]RN, Associate Professor, School of Nursing of Ribeirao Preto, University of Sao Paulo, Sao Paulo, Brazil; [3]Associate Professor, Faculty of Philosophy, Sciences and Letters, University of Sao Paulo, Sao Paulo, Brazil; [4]PhD Student, Department of Internal Medicine, School of Medicine of Ribeirao Preto, University of Sao Paulo, Sao Paulo, Brazil; [5]RN, PhD Student, School of Nursing of Ribeirao Preto, University of Sao Paulo, Sao Paulo, Brazil; [6]MSc Student, School of Nursing of Ribeirao Preto, University of Sao Paulo, Sao Paulo, Brazil; [7]RN, PhD Student, School of Nursing of Ribeirao Preto, University of Sao Paulo, Sao Paulo, Brazil; [8]RN, Associate Professor, School of Nursing of Ribeirao Preto, University of Sao Paulo, Sao Paulo, Brazil.

Background
Diabetes mellitus is mainly characterized by a dysfunction of glucose metabolism. The growth of diabetes mellitus as a chronic condition requires continuous management and requires health services to implement care strategies. Diabetes education and self-care competence have been recognized over the last few decades as essential for patients with diabetes mellitus to achieve positive treatment results.
Objective
To compare self-care competencies in the physical, cognitive and emotional and motivational dimensions of patients with diabetes mellitus before and after participation in an educational programme.
Design
A prospective, comparative study was used.
Methods
A total of patients with 43 diabetes mellitus participated in this study, before and after a four-month educational programme on diabetes held in Ribeirao Preto, SP, Brazil in 2009. Data were collected through the Scale to Identify diabetes mellitus Patients' Self-Care Competence (Escala para Identificação da Competência do Portador de diabetes mellitus para o Autocuidado) at two points in time: at the beginning (T1) and at the end (T2) of the programme. Linear mixed effects models were used ($P < 0.05$) in the analysis.
Results
Statistically significant differences were not found in relation to physical competence in the comparison between T1 and T2. Statistically significant differences were found in the comparison of cognitive and emotional and motivational competencies, respectively, between T1 and T2.
Conclusion
The scores related to cognitive and emotional and motivational competencies for self-care presented statistically significant differences between T1 and T2.
Relevance to clinical practice: The educational activities implemented in the educational programme favored improved cognitive, emotional and motivational competence for the incorporation of positive self-care actions.
Comments/keywords
Comments for the Nurse Abstracts Markers: health professionals, nurses, psychologists, nutritionists and physical educators, should therefore encourage patients with DM to participate in educational activities, with a view to the incorporation of positive self-care actions.
Keywords: Diabetes Mellitus, Health Education, Nurses, Nursing, Patient Education, Self-Care.

**Primary hyperparathyroidism, vitamin D deficiency and quality of life**

Åberg Wiveca, S. Norenstedt, A. Eriksson, Y. Pernow, M. Sääf, J. Nordenström, J. Zedenius & I.-L. Nilsson
Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

Background
The study aimed to evaluate quality-of-life (QoL) aspects and impact of vitamin D deficiency in primary hyperparathyroidism (pHPT).
Method
150 consecutive patients (119 women) with pHPT (mean age 60$\pm$11 years; BMI 27$\pm$5 kg/m$^2$; ionized calcium 1.44$\pm$0.08 mmol/l; PTH 130$\pm$69 ng/l) were included. Six weeks postoperatively, the pHPT patients were reexamined and randomized (double-blind) to daily substitution with calcium carbonate (1g), with or without cholecalciferol (1600 IE). Self-estimation questionnaires (SF-36) were completed at baseline and repeatedly during follow-up. A gender- and age-matched reference group ($n=459$) was randomly selected from the Swedish SF-36 norm database.
Results
Vitamin D deficiency, defined as 25-hydroxyvitamin D $<$ 50 nmol/l, was present preoperatively in 59% of the patients. The 25-hydroxyvitamin D level increased postoperatively (mean 49$\pm$18 vs 52$\pm$17 nmol/L, $P=0.019$). The calcium level normalized after parathyroidectomy in all patients, while the PTH level decreased but was not normalized in 45% of the cases. Compared to the reference population

baseline, the patients scored significantly lower on all eight domains of the SF-36. Postoperatively, patients improved significantly but reached the level of the reference population in only two domains: GH (general health perceptions) and BP (bodily pain). No correlation was found between the SF-36 scores and the calcium, PTH or vitamin D levels at baseline. The baseline scores were inversely correlated to body mass index (BMI; $r=-0.226$–$r=-0.386$; $P<0.01$). The study will be deblinded on January 15 2012 and further follow-up data will be presented.
Conclusions
Patients with pHPT had worse QoL scores than the reference population on all eight domains of the SF-36. The outcome after parathyroid surgery was not predictable from preoperative calcium, PTH- or vitamin D status. The effects of vitamin D supplementation are yet to be evaluated.

## N26

**Evaluation of self management and diabetes education newly diagnosed with Type 2 diabetic patients in Mongolia**

Enkhjargal Ya[1], D Tserendagva[1], Kh Altaisaikhan[2], D Davaalkham[3] & S Sergelenchimeg[1,2,3]
[1]School of Health Technology, Health Sciences University of Mongolia, Mongolia; [2]University of FIJI, FIJI; [3]School of Public Health, Health Sciences University of Mongolia, Mongolia.

Introduction
Educating patients about diabetes plays a pivotal role in encouraging people to changing lifestyle and supporting them to improve the quality of life, and actively responsibile for self control of their condition.
Objective
To evaluate self management after receiving diabetes education for newly diagnosed Type 2 diabetes in Mongolia.
Methods
The cross-sectional survey was conducted from May and October 2011. At Diabetes centers and Level II hospitals in Ulaanbaatar. 150 participants with type 2 diabetes was referred within, from May to August as newly diagnos and included only the ones who met inclusion criteria and agreed with informed consent. Each patient's knowledge and psychosocial status were assessed be the internationally accepted questionnaire and collected anthropometric and metabolic indicators according to the protocol. Statistical analysis was performed with the SPSS16 software.
Results
The study involved newly diagnosed Type 2 diabetes 23–64 years were men 43,6% (65),women 56,7% (85). Educated groups participants attended a structured education programme within 0–2 weeks of diagnosis. The diabetes knowledge anthropometric and metabolic indicators were indifferent between groups educated and without diabetes education. However psychosocial status which includes satisfaction of health care service, anxiety of their disease depression related blood glucose reactions eating family and regular self management was significantly different between educated and without education groups.
Conclusion
Psychosocial status which includes satisfaction of health care service, anxiety of their disease, depression related blood glucose reactions eating family and regular self management were significantly different between both groups.
Keywords: Newly diagnosed type 2 diabetes, patient's self management education

**Individuals with Addison's disease and their experiences of onset and self-care: new knowledge?**

Ylva Wessman

Aim
The aim of the study was to elucidate the experiences of onset and self-care among individuals with Addison's disease.
Background
Addison's disease, primary adrenal insufficiency, is a rare endocrine disorder where the production of glucocorticoids and mineralcorticoids are insufficient. The disease could be difficult to diagnose and the lifelong treatment involves hydrocortisone administration daily. Individuals with Addison's disease have a chronic disease where the different kinds of symptoms and the changing in pharmaceutical treatment affect their condition in daily life.
Design
A qualitative content analysis was used.
Methods
13 individuals were interviewed during 2009.
Results
Two categories emerged from the interviews:' to handle life with the disease related to one's surrounding' and 'to handle life with the disease related to oneself'. The categories are linked to a main theme 'dependent vs independent' which reflects the limitations and strategies to manage the limitations.
Conclusion
The findings show that the individuals could have a long lasting and sometimes even dramatically experiences of onset. They contribute experiences by showing difficulties in managing the hydrocortisone medication in daily life. Their strategies of self-care are mostly based upon an autodidact approach. The individuals express need for more information concerning the adjusting of hydrocortisone medication and of self-care. They also request supplementary knowledge of Addison's disease among health professionals.
Relevance to clinical practice
The study may add new knowledge for health care providers to identifying areas of improvement in the given information to the individuals and to understand the importance of awareness of the symptoms of this rare, and sometimes even life-threatening, disease.
Keywords
Addison's disease, experiences, nursing, onset, qualitative study, self-care.

## N28

**A survey of knowledge related to cystic fibrosis related diabetes**

Erin Booth
Virginia Commonwealth University, Richmond, Virginia, USA.

Background
Cystic fibrosis (CF) is the most common life threatening autosomal recessive genetic disease in the United States. Cystic fibrosis related diabetes (CFRD) is the most common co-morbidity of CF, and, as patients age, the likelihood of developing diabetes increases. CFRD leads to decreased lung function, poor nutritional status, and decreased survival rates. Symptoms can be subtle and may be overlooked. The extent to which individuals with CF know about CFRD is unknown.
Aims
1. To assess knowledge of CFRD in adults with CF.
2. Describe where information related to their disease is obtained.
3. Examine relationships between measures.
Methods
A cross sectional descriptive design was used. Adults ($>18$ yrs) with CF were recruited during an outpatient CF visit and asked to complete a 15-item CFRD Knowledge Survey. The survey included 10 items on knowledge of CFRD, 2 items on obtaining information about CF, and 3 items on experience with diabetes.
Results
Twenty-six individuals with CF participated, 70% were male, mean (SD) age was 27.73 (10.23). Regarding knowledge, 92% had heard of CFRD, 65% knew symptoms of CFRD, and 58% knew how the diagnosis was made. A majority (65%) reported they seek information related to CF only when necessary. The three most common sources for obtaining information were internet, physician, and clinic. The total knowledge score was significantly correlated with the experience score ($r=0.50$, $P=0.009$), and understanding the importance of knowing that you have CFRD ($r=0.80$, $P<0.001$). The experience score was also significantly correlated with understanding importance of knowing if you have CFRD ($r=0.60$, $P=0.001$). Understanding the importance of knowing if you have CFRD was also significantly correlated with being diagnosed ($r=0.43$, $P=0.028$).
Clinical implications
As the number of patients diagnosed with CFRD continues to increase, both pediatric and adult endocrine nurses need to be educated and equipped to successfully manage this patient population.

**Targeting mutated β-catenin *in vitro* and *in vivo* inhibits cell proliferation and stimulates apoptosis: a promising therapeutic target in adrenocortical carcinoma**

B. Ragazzon[1], S. Gaujoux[1], C. Hantel[2], F. Tissier[1], M. Rizk-Rabin[1], F. Beuschlein[2] & J. Bertherat[1]
[1]Institut Cochin, Université Paris Descartes, Paris, France; [2]Medizinische Klinik-Innenstadt, Ludwig-Maximilians-University, Munich, Germany.

Adrenocortical carcinoma (ACC) is a rare and highly aggressive endocrine neoplasm, with limited therapeutic option. Activating β-catenin somatic mutations are observed in ACC and associated with a poor outcome. Activation of the Wnt/β-catenin signaling pathway seems to play a major role in ACC aggressiveness, and might be a promising therapeutic target. The H295 cell line derived from an ACC harbors an activating β-catenin mutation. We herein assess the *in vitro* and *in vivo* effect of β-catenin inactivation using doxycyclin (dox) inducible sh-RNA plasmid in H295R adrenocortical cancer cells line (clones named H295R-shβ).
*In vitro*: a dramatic reduction in β-catenin expression was detectable in H295R-shβ after dox treatment compared to control clones (−82%, $P<0.005$). Accordingly, we observed a transcriptional Wnt/β-catenin-dependent luciferase reporter activity decrease (−62%, $P<0.05$) as well as a decreased expression of an ubiquitous target gene, AXIN2 (−76%, $P<0.0001$). β-catenin silencing led to a decreased cell proliferation (−46%, $P<0.05$) and cell cycle alterations with cell accumulation in the G1 phase (+10%, $P<0.05$) and increased apoptosis (+67%, $P<0.05$).
*In vivo*: after subcutaneous induction of tumor xenografts in athymic nude mice, 9 days dox administration was associated with a significant decrease in intra-tumoral β-catenin (−89%, $P=0.007$) and AXIN2 (−87% $P<0.005$) expression in H295R-shβ grafted mice while mice grafted with control H295R clone remained unaffected. Long-term dox administration, starting 3 days after tumor cell inoculation, was associated with a total absence of tumor growth in the H295R-shβ group while tumors were present in all the mice of the control group (median tumor weight after sacrifice 67.4 mg vs 0 mg, $P<0.001$).
In summary, these experiments provide evidences that Wnt/β-catenin pathway inhibition in ACC is a promising therapeutic target.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### P2

**Pathophysiological significance of CYP11B2 immunohistochemical staining in primary aldosteronism**

K. Nanba[1], M. Tsuiki[1], K. Sawai[1], K. Mukai[2], K. Nakao[1], T. Tamanaha[1], T. Usui[1], T. Tagami[1], H. Okuno[1], T. Yamamoto[1], A. Shimatsu[1] & M. Naruse[1]
[1]National Hospital Organization Kyoto Medical Center, Kyoto, Japan; [2]School of Medicine, Keio University, Tokyo, Japan.

Background
Although primary aldosteronism (PA) is the common cause of hypertension subjected to surgery, methods of pathological confirmation of aldosterone overproduction have not been established. Aim of the study was to investigate immunohistochemically the expression of CYP11B2 in the adrenal tissue of PA.
Methods
Twenty five patients with PA including 20 patients with aldosterone-producing adenoma (APA) and 5 patients without APA (non-APA) were studied. Immunohistochemical staining was performed with anti-CYP11B2 on paraffin-embedded sections. We analyzed the expression of CYP11B2 semi-quantitatively by scoring the staining intensity from (− or ±) to (2+).
Results
Eighty five % of the patients with APA showed positive immunostaining for CYP11B2 in the adrenal tumor. Tumor volume estimated from the diameter was negatively correlated with CYP11B2 score ($P<0.001$) and positively correlated with basal aldosterone to renin ratio (ARR) ($P<0.001$). CYP11B2 score adjusted by the tumor volume was correlated positively with ARR ($P<0.01$) and negatively with serum potassium ($P<0.05$). In addition to the immunostaining in the tumor, there existed cell clusters of positive immunostaining of CYP11B2 (APCC) in the adjacent tissues. Although the APCC was seen in the adjacent tissue of APA, the number of APCC was significantly larger in patients with non-APA than those with APA ($P<0.001$). Serum potassium was significantly lower ($P=0.01$) and number of anti-hypertensive drug ($P<0.05$), prevalence of hypokalemia (P=0.001), plasma aldosterone concentration ($P=0.001$), and ARR ($P<0.01$) were significantly higher in patients with APA than those with non-APA.
Conclusions
The present study clearly demonstrated that CYP11B2 immunostaining is useful for the histopathological confirmation of aldosterone production and that both CYP11B2 expression and tumor volume could contribute to the extent of hyperaldosteronism in APA. In addition, increased number of APCC in the non-tumorous adrenocortical tissues could cause aldosterone excess in patients with non-APA.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

### P3

**The role of salivary cortisol measured by liquid chromatography-tandem mass spectrometry (LC-MS/MS) in the diagnosis of subclinical hypercortisolism (SH) in patients with adrenal incidentaloma (AI).**

S. Palmieri, V. Morelli, E. Cairoli, E. Polledri, S. Fustinoni, I. Chiodini & P. Beck-Peccoz
Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico, Milan, Italy.

Introduction
For defining SH in AI patients at least 2 altered criteria among serum cortisol after 1 mg dexamethasone test (1 mgDST), ACTH levels, 24 h urinary free cortisol (UFC) and midnight serum cortisol levels are generally required. Midnight salivary cortisol (MSC), a sensitive and easy-to-perform marker of overt hypercortisolism, appears to be of limited utility in these patients. Data on the role of salivary cortisol using LC-MS/MS, the gold standard procedure for steroids measurement, are lacking.
Methods/design
In 50 AI patients (F/M 27/23) we evaluated morning salivary cortisol (CS8, normal values. 1.5–15 nmol/L), salivary cortisol after 1mg-DST (Sa-DST, cut-off $<1.2$ nmol/L), MSC (cut off $<2.8$ nmol/L) using LC-MS/MS, serum cortisol after 1 mgDST (Se-DST), UFC and ACTH levels. We defined SH in the presence of at least 2 out of: Se-DST $>83$ nmol/L, ACTH $<10$ pg/ml, UFC $>193$ nmol/24 h. In all patients, the presence of diabetes, hypertension and dyslipidemia was detected as an indirect marker of SH.
Results
MSC levels were higher in patients with SH ($8.8\pm9.1$ nmol/L) than in those without ($4.5\pm3.3$ nmol/L, p=0.03). CS8 and Sa-DST were comparable between patients with and without SH ($22.9\pm23.2$ vs $18.2\pm14.3$ nmol/L, $P=0.4$; $6.6\pm7.2$ vs $4.6\pm3.9$ nmol/L, $P=0.06$; respectively). The CS8 and MSC levels were associated with Se-DST ($R=0.4$ and 0.5, respectively, $P<0.01$). The presence of chronic complications was related to Se-DST ($R=0.3$, $P=0.03$) but not to any salivary parameter. Using the MSC cut-off of 2.8 nmol/L the sensitivity (Se) and the specificity (Sp) for diagnosing SH was 25% and 81% respectively. MSC values $<1.0$ nmol/L excluded the presence of SH (Sp 38%), while MSC $>8.0$ nmol/L had the 100% Sp (Se 13%).
Conclusion
In AI patients, CS8 and Sa-DST are of limited utility, while MSC, even measured by LC-MS/MS, cannot be used for the SH screening, though may be useful as a confirmative test.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

### P4

**Semen parameters in men with congenital adrenal hyperplasia (CAH) due to 21-hydroxilase deficiency (21-HD)**

P. Vitale, A. Cozzolino, C. Simeoli, F. Cariati, D. Iacuaniello, M. Galdiero, F. Lo Calzo, G. Lombardi, A. Colao & R. Pivonello
University of Naples Federico II, Naples, Italy.

CAH has been described to be associated to infertility and semen abnormalities in 40–70% of adult male patients, because of hypogonodotropic hypogonadism, consequent to the increased levels of sex steroids, but mostly because of the

frequent presence of testicular adrenal rest tumors. The aim of the current study was to evaluate semen parameters and hormonal setting in a subset of men with CAH. Fourteen patients with classical CAH due to 21-HD (six with simple virilizing, and eight with salt-wasting CAH) and 28 controls entered the study. All patients were under treatment with glucocorticoids and, if necessary, mineralcorticoids at the moment of the study; every patients but one were well-controlled by medical therapy. Semen analysis and hormone assessment were performed in the totality of patients and controls. A significant decrease in sperm concentration ($P=0.002$), total motility ($P=0.002$), progressive motility ($P=0.001$) and sperm morphology ($P<0.001$) was found in patients compared with controls. Serum testosterone, LH and DHEA-S levels were directly correlated with sperm morphology ($P=0.002$) whereas serum 17-OH progesterone, testosterone, LH and androstenedione levels were inversely correlated with either total or progressive motility ($P=0.04$). In conclusion, the results of the current study confirmed the evidence of an impairment of semen parameters in men with CAH despite the appropriate treatment for the adrenal disease and seem to suggest that an uncontrolled disease might affect total and progressive sperm motility while an excessive glucocorticoid treatment might impair sperm morphology.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P5

**Non-radioactive strategies on the diagnosis of congenital adrenal hyperplasia due to 21 hydroxylase deficiency (CAH - 21OHD).**

F. Coeli, W. Turatti, P. Elias, C. Martinelli Jr, A. Moreira, S. Antonini & M. Castro

University of Sao Paulo, Ribeirao Preto, Brazil.

Introduction

Defects in the pseudogene, CYP21A1P, can be transferred to the functional CYP21A2 gene by recombination and account for approximately 95% of CYP21A2 mutations, leading to CAH-21OHD. We conducted a comprehensive genetic analysis to assess whether Multiplex Ligation dependent Probes Amplification (MLPA) could substitute southern blotting with radioactive probes without compromising reliability of the diagnosis.

Patients and Methods

We studied 90 families/99 patients presenting salt-wasting (SW; $n=32$), simple-virilizing (SV; $n=29$), and non-classical (NC; $n=29$) phenotypes. Molecular analysis was sequentially performed by detecting the 8 most frequent point mutations by allele specific oligonucleotide polymerase chain reaction (ASO-PCR), large deletions and conversions by MLPA (KIT-P050-B2-CAH), and rare mutations by direct sequencing. Parental segregation was evaluated.

Results

Mutated alleles were elucidated by ASO-PCR in 92.2%, by MLPA in 5.0% and by direct sequencing in 2.8%. In SW group, the most frequent mutations detected by ASO-PCR were IVS2-13A/C>G (43.7%), p.R356W (12.5%), and p.Q318X (11.0%), large conversions in 12.5% by MLPA, and the 1762_1763InsT (1.6%) by direct sequencing. In SV patients, the most frequent mutations detected by ASO-PCR were p.I172N (55.2%), p.R356W (10.3%) and IVS2-13A/C>G (6.9%), large conversion in one single allele (1.7%) by MLPA, and the p.G424S mutation was found in 1.7% by direct sequencing. In NC patients, the most frequent mutations detected by ASO-PCR were p.V281L (72.4%), p.I172N (5.2%), IVS2-13A/C>G (5.2%). Direct sequencing revealed rare mutations (p.P453S, p.R408C, and p.A265V) in one allele each (5.2%). No large conversions were found in this group.

Conclusion

Although MLPA false positive results could arise due to mutations/polymorphisms close to the probe binding regions and due to probe hybridization and ligation, these problems can be overcome by the association of MLPA with ASO-PCR and parental segregation. Using these approaches, we can successfully substitute southern blotting in a cost-effective laboratory routine.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Diagnostic value of urinary steroid profiling in the evaluation of adrenal incidentaloma.**

T. Kerkhofs[1], M. Kerstens[2], I. Kema[2], I. Hermsen[1] & H. Haak[1]

[1]Máxima Medical Center, Eindhoven, The Netherlands; [2]University Medical Center Groningen, Groningen, The Netherlands.

Objective

An adrenal incidentaloma is discovered in about 3–4% of patients undergoing radiological examination (CT/MRI) of the abdominal region. Current diagnostic algorithms for differentiating between benign and malignant lesions largely depend on imaging studies, which lack in specificity. This often leads to extended radiological follow-up of benign lesions, which is time-consuming, expensive and carries a health risk. It was recently suggested that urinary steroid profiling using gas-chromatography/mass-spectrometry (GC/MS) might be a valuable diagnostic test regarding this clinical problem. We present a large clinical series to test this hypothesis.

Methods

Urinary steroid profiles from patients with adrenal enlargement evaluated between 01-01-2000 and 01-11-2011 were collected. The concentrations of 22 metabolites were measured using GC/MS in 24-hour urine samples. Patient's records were studied and information was collected regarding symptoms and signs, laboratory measurements, imaging studies, treatment, pathology reports and clinical outcome. Steroid profiles were analyzed by calculating receiver operating characteristics (ROC) for every individual metabolite.

Results

In our population of 155 patients, we found significantly higher concentrations of eighteen metabolites in patients with ACC ($n=18$) compared to patients with other adrenal conditions. Tetra-hydro-deoxycortisol (THS) distinguishes ACC from other adrenal disorders with 100% sensitivity and specificity at a cut-off value of 2.95 μmol/24 h.

Conclusion

Our results confirm earlier findings, which suggest that measuring urinary excretion of THS can be useful in differentiating adrenocortical carcinoma from other adrenal tumors. The technique of GC/MS is reliable, non-invasive and less expensive than repeated imaging studies. The next step is prospective validation of this diagnostic tool.

**The combined use of nocturnal salivary cortisol and urinary cortisol to creatinine ratio in the evaluation of cycling in patients with Cushing's syndrome**

U. Graham, S. Hunter, M. McDonnell, K. Mullan & B. Atkinson

Royal Victoria Hospital, Belfast, UK.

Cyclical Cushing's syndrome is typically detected by collecting sequential daily early morning urine (EMU) samples for cortisol to creatinine ratio over a 28 day period. More recently nocturnal salivary cortisol (NSC) measurement has been shown to be a sensitive means of screening for Cushing's syndrome. The Endocrine Society have suggested that NSC may be used to assess patients for cyclical Cushing's however there is limited evidence that it correlates with the present standard of EMU testing or that it demonstrates a cyclical pattern over 28 days. In this study we sought to correlate NSC with EMU results collected the following morning and to determine whether NSC could be used to detect cycles in patients with cyclical Cushing's syndrome.

A sequential 28 day collection of NSC and EMU was performed on 11 occasions in ten patients with confirmed or suspected Cushing's syndrome. One patient with cyclical Cushing's completed the collection both before and after cabergoline therapy. Seven collections were from patients with active Cushing's disease (3 with cyclical form), three were from patients in remission (1 with cyclical Cushing's and 2 with clinical features suspicious of recurrence) and one was from a patient eventually shown not to have hypercortisolism.

In total there were 270 matched salivary and urinary results. The Spearman's rank correlation coefficient was 0.79 ($P=<0.001$). In two patients with cyclical

Cushing's, EMU and NSC followed a similar cyclical pattern. In one patient with recurrent cyclical Cushing's, cortisol was elevated in both saliva and urine but with more prominent cycles in saliva.
We found that NSC correlated reasonably well with EMU collected the following morning. NSC detected all three cases of cyclical Cushing's. If these results are replicated in larger numbers NSC may prove to be an additional option or replacement for EMU in detecting cyclical Cushing's syndrome.

### Defining 17α-hydroxylase in zebrafish: expression pattern of two paralog genes (*zCyp17a1*; *zCyp17a2*) and comparative *in vitro* and *in silico* analysis

S. Parajes[1], A. Griffin[1], I. Miguel Escalada[1], I. Rose[1], A. Taylor[1], L. Sacco[1], J. Grötzinger[2], W. Arlt[1], F. Müeller[1] & N. Krone[1]
[1]University of Birmingham, Birmingham, UK; [2]Christian-Albrechts Universität, Kiel, Germany.

Background
Zebrafish is emerging as a comprehensive model system in endocrinology. Zebrafish synthesise steroid hormones in the interrenal (counterpart of the mammalian adrenal), gonad and brain. Data on steroidogenic pathways is patchy and steroidogenic enzymes in zebrafish have not been well characterised. Human 17α-hydroxylase (hCYP17A1) facilitates two conversion steps, 17α-hydroxylase and 17,20-lyase reactions in the adrenal and gonad. Two zCyp17a (zCyp17a1; zCyp17a2) enzymes exist in zebrafish.
Aim
To characterise the expression pattern and the catalytic activity of zebrafish Cyp17a enzymes.
Methods
*zCyp17a* expression was determined by RT-PCR from whole embryos and adult tissues. Functional assays were performed using transiently transfected COS7 cells expressing *zCyp17a* or *hCYP17A1*. 17α-hydroxylase activity was assessed by the conversion of pregnenolone into 17-hydroxypregenenolone and progesterone into 17α-hydroxyprogesterone. The 17,20-lyase activity was measured by the conversion of 17α-hydroxypregenenolone into DHEA and 17α-hydroxyprogesterone into androstenedione.
Results
*zCyp17a1* and *zCyp17a2* expression was observed from fecundation. In adult fish, both enzymes are expressed in the interrenal, gonad and brain. zCyp17a1 and zCyp17a2 17α-hydroxylated substrates 1.5–3 and 6–11 times more efficiently than human CYP17A1. Furthermore, zCyp17a1 showed a preference for the Δ4-pathway, while zCyp17a2 converted Δ5-steroids more efficiently. In contrast to hCYP17A1, zCyp17a1 efficiently synthesised both, DHEA and androstenedione. zCyp17a2 completely lacks 17,20-lyase activity. We conducted comparative *in silico* analysis between two newly developed three-dimensional zCyp17a models and our human CYP17A1 model. Residue divergence within the substrate and redox interaction domains may explain our *in vitro* findings.
Conclusions
Herein, we demonstrated that both zCyp17a enzymes facilitate 17α-hydroxylation more efficiently than hCYP17A1. Catalytic efficiency is substrate specific. zCyp17a2 cannot synthesise androgen precursors. Expression data suggest a role of zCyp17a enzymes already during early embryologic development. Importantly, our data provides novel insights into zebrafish steroidogenesis and will help to establish a novel cutting edge tool for *in vivo* studies of steroidogenic disorders.

## P9

### Progressive adrenal insufficiency in a patient with 46,XY DSD caused by two novel mutations in the cytochrome P450 side-chain cleavage (*CYP11A1*) gene

S. Parajes[1], B. But[2], A. Chan[2], I. Rose[1], A. Taylor[1], A. Griffin[1], V. Dhir[1], W. Arlt[1] & N. Krone[1]
[1]University of Birmingham, Birmingham, UK; [2]Queen Elizabeth Hospital, Hong Kong, China.

Background
Cytochrome P450 side-chain cleavage enzyme (CYP11A1) catalyses the first and rate-limiting step of steroidogenesis. CYP11A1 firstly converts cholesterol into 22R-hydroxycholesterol, which relies on mitochondrial steroidogenic acute regulatory protein (StAR)-mediated cholesterol import. Two further StAR-independent CYP11A1 reactions facilitate pregnenolone biosynthesis. CYP11A1 deficiency is rare and manifests with adrenal insufficiency (AI), and, in 46,XY individuals, with normal male genital development or disorder of sex development (DSD).
Patient
We describe a 46,XY patient born with hyperpigmentation, micropenis and penoscrotal hypospadias. At birth, biochemical and hormonal findings were normal except for low testosterone concentrations. Development was unremarkable apart from an episode labelled as sepsis (day 15 of life) with documented hyponatraemia and hyperkalaemia. Finally, AI was diagnosed at the age 2.8 yr with raised ACTH and renin, low aldosterone and normal baseline cortisol, not responding to ACTH-stimulation. Ultrasound showed normal-sized adrenals and testicular microlithiasis.
Results
Molecular genetic analysis showed mutations neither in the *SF1* nor *StAR* gene. However, two novel *CYP11A1* mutations (p.Arg360Trp (g.27921C>T); p.Arg405X (g.28327C>T)) were found. Segregation analysis confirmed compound heterozygosity. Functional *in vitro* analysis was performed in COS7 cells transfected with wild-type or mutant *CYP11A1* cDNA, with or without wild-type *StAR* cDNA. Transfected cells were incubated with either cholesterol or 22R-hydroxycholesterol. Pregnenolone was quantified by liquid chromatography/tandem mass spectrometry. Our *in vitro* assays showed that p.Arg360Trp retains by 30–40% of wild-type activity. Our *in silico* analysis confirmed these findings and suggest that p.Arg405X completely abolishes CYP11A1 activity.
Conclusions
Our data demonstrates that *CYP11A1* mutations can differently impact on adrenal and gonadal sterodoidogenesis, which is exemplified by progressive AI during infancy but impaired gonadal function already during prenatal life. The delayed onset of adrenal insufficiency may hinder early diagnosis of CYP11A1 deficiency. Thus, a short synacthen test should be performed in patients with DSD to assess adrenal function and prevent life-threatening adrenal crisis.

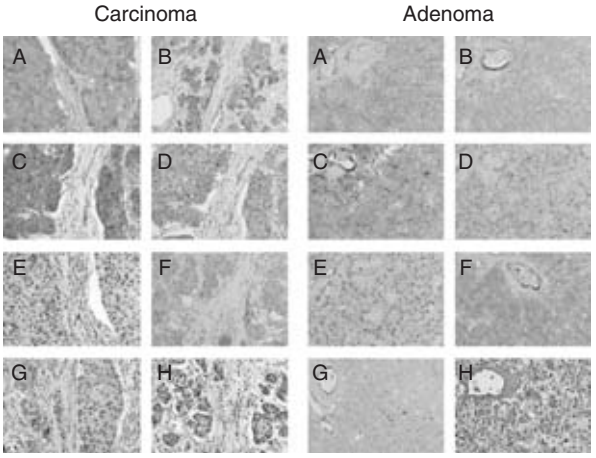
## P10

### The mTOR-pathway in normal and tumoral human adrenocortical tissues

M. De Martino[1,2], P. van Koetsveld[1], R. Feelders[1], D. Sprij-Mooij[1], M. Waaijers[1], S. Lamberts[1], W. de Herder[1], A. Colao[2], R. de Krijger[1], R. Pivonello[2] & L. Hofland[1]
[1]Erasmus MC, Rottedam, Netherlands; [2]"Federico II" University, Naples, Italy.

Background
Novel treatment options are required for patients with adrenocortical carcinomas (ACCs). mTOR-inhibitors are anti-neoplastic drugs that target the mTOR-pathway.
Aim
To describe the expression of the mTOR-pathway in normal and pathological adrenocortical tissues.
Methods
We evaluated mRNA expression levels of mTOR, S6K and 4EBP1 in 10 normal adrenals (NA), 11 adrenal hyperplasias (AH), 19 adrenal adenomas (ACA) and 26 ACCs (24 adults, 2 children) by qRT-PCR and determined protein expression of total/phospho-mTOR; total-S6K/phospho-S6K and total/phospho-4EBP1 in 3

NAs, 3 AHs, 6 ACAs and 17 ACCs (15 adults, 2 children) by immunohistochemistry (IHC).
Results
The expression levels of mTOR and 4EBP-1 mRNA were not significantly different in the different tissues evaluated. The S6K mRNA levels were significantly lower in ACCs compared to the other groups (ACC: $0.10 \pm 0.08$; ACA: $0.20 \pm 0.11$; AH: $0.29 \pm 0.07$; NA: $0.23 \pm 0.08$; median $\pm$ SD; $P < 0.01$). In the NA and AH a stronger IHC staining of the evaluated proteins was observed in the glomerulosa and reticularis layers. The majority of ACCs and ACAs presented a significant IHC staining of total-mTOR (59%; 83%); total-4EBP1 (88%; 100%); phospho-4EBP1 (59%; 83%) and phospho-S6K (59%; 83%). A significant staining of phospho-mTOR and total-S6K were observed in 6% and 24% of ACCs and in 33% and 66% of ACAs, respectively.
Compressively a significant staining of both phospho-S6K and phospho-4EBP1 was observed in 41% ACCs and 84% ACAs. A significant expression of at least one of these proteins was observed in 13/17 ACCs (76%).
In ACCs, none of the evaluated mTOR-pathway components was correlated with the Weiss's score or the hormonal status.
Conclusion
This study demonstrates a layer-specific expression of the major components of the mTOR-pathways in NA and the presence of an activated mTOR-pathway in the majority of adrenal tumors. These results support a potential role of mTOR-inhibitors in the treatment of selected patients with ACCs.



Immunocytochemical detection of total-mTOR (A), phospho-mTOR (B), total-4EBP1 (C), phospho-4EBP1 (D), total-S6K (E) and phospho-S6K (F) in a case of human adrenocortical carcinoma (ACC [left panel]) and a case of human adrenocortical adenoma (ACA [right panel]). Pictures "G" shows the absence of staining in the negative controls, and picture "H" the HE staining in both panels Magnification, X100.

**Measurement of cortisol in scalp hair can be a new tool in the diagnosis and follow-up of patients with Addison's Disease and (cyclic) Cushing's Syndrome**

L. Manenschijn[1], J. Koper[1], E. van den Akker[1], L. de Heide[2], F. de Jong[1], R. Feelders[1], S. Lamberts[1] & E. van Rossum[1]
[1]Erasmus MC, Rotterdam, The Netherlands; [2]Medical Center Leeuwarden, Leeuwarden, The Netherlands.

Introduction
The diagnosis of Cushing's Syndrome (CS) and in particular cyclic CS can be complicated. Standard screening tests for CS are the measurement of cortisol in 24-hours urine collections and in midnight saliva. In case of cyclic CS, results of these tests can be normal in between periods of hypercortisolism. The development of a method to measure cortisol in scalp hair provides the opportunity to investigate historical cortisol levels of months to years ago, with each cm of hair corresponding to a period of one month. This method has been well validated in healthy individuals and might contribute enormously in the diagnosis and follow up of patients with (cyclic) CS. Furthermore, in patients with Addison's Disease (AD), the measurement of historical cortisol levels could provide useful information concerning the disease course and effect of hydrocortisone replacement therapy. Our aim was to study whether hair cortisol levels correspond with clinical course in patients with (cyclic) CS and AD.
Methods
Hair samples were collected from 16 CS patients, 5 cyclic CS patients and 3 AD patients. Cortisol was extracted from these samples with methanol and cortisol levels were measured using an ELISA. A group of 195 healthy individuals were used as control group.
Results
Cortisol levels were significantly elevated in CS patients ($P < 0.0001$) and decreased in patients with AD ($P = 0.002$) compared to healthy individuals. Hair cortisol timelines of patients with CS, cyclic CS and AD corresponded with clinical course.
Conclusion
Scalp hair can be used to evaluate the clinical course in patients with CS and AD and provides valuable information about previous cortisol exposure. This can contribute significantly in the diagnosis of cyclic CS.

**Pattern of adrenal hormonal secretion in patients with adrenal adenomas: the relevance of aldosterone in arterial hypertension**

T. Pappa[1], L. Papanastasiou[1], G. Kaltsas[2], A. Markou[1], P. Tsounas[1], V. Tsiavos[1], A. Dasou[1], V. Tsiama[1], G. Zografos[1] & G. Piaditis[1]
[1]'G. Gennimatas' General Hospital, Athens, Greece; [2]Laikon Hospital, National University of Athens, Athens, Greece.

Introduction
Autonomous aldosterone secretion (AAS) is present in approximately 10% of hypertensives. Adrenal incidentalomas (AI) can be found in up to 19% of hypertensive individuals. However, data on the incidence of AAS in hypertensive patients with AI is scarce. Our aim was to evaluate the adrenal aldosterone secretory profile in patients with adrenal adenomas with and without arterial hypertension.

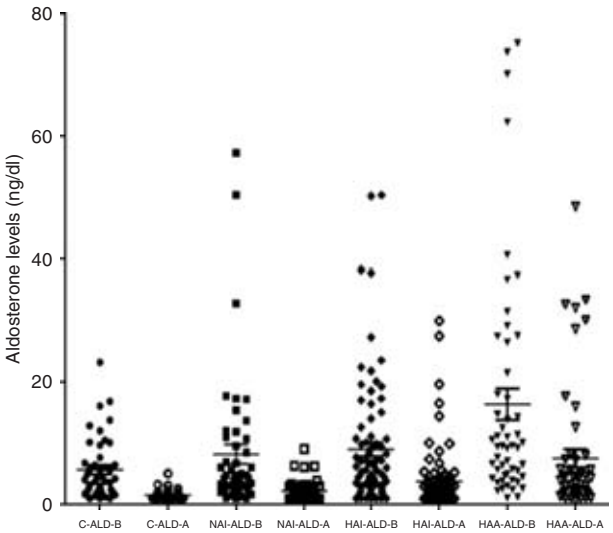

**Figure 1** Comparison of aldosterone levels among the control and the three patients' groups. ALD-B: basal aldosterone levels. ALD-A: aldosterone levels following the modified saline infusion test. C: control group. NAI: normotensive patients with adrenal incidentalomas. HAI: hypertensive patients with adrenal incidentalomas. HAA: hypertensive patients with adrenal adenomas identified during investigation for arterial hypertension.

Patients and methods
We investigated 72 normotensive subjects with normal adrenal morphology and 191 subjects divided in three groups: 46 normotensive individuals with an AI (NAI), 89 hypertensive patients with an AI (HAI) and 56 hypertensive patients with an adrenal adenoma identified after investigation for arterial hypertension (HAA). All patients underwent a low dose dexamethasone suppression test to assess the presence of autonomous cortisol secretion. The diagnosis of autonomous aldosterone secretion was based on a modified saline infusion test (MSI), i.e. following overnight dexamethasone administration to suppress ACTH-induced aldosterone secretion.
Results
To evaluate the prevalence of AAS, we applied the following cut-offs: post MSI aldosterone (ALD) levels: 2.41 ng/dl and the aldosterone/renin (ALD/REN) ratio: 0.35 ng/dl/μU/ml). Based on these cut-offs, 12% of NAI, 36.4% of HAI and 54.2% of HAA patients had AAS. The prevalence of autonomous cortisol secretion did not differ among the three groups. Post MSI aldosterone levels and the aldosterone/renin ratios were significantly elevated in HAI and HAA patients compared to NAI subjects (Figure 1).
Conclusions
Using the MSI test, we found a remarkably increased prevalence of AAS in hypertensive patients with adrenal adenomas, even when the latter present an incidental finding.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P13

**Influence of unilateral adrenalectomy on set point of Hypothalamic-pituitary-adrenal-axis in long-term survivors of childhood nephroblastoma and neuroblastoma**

M. van Waas, R. Pieters, M. Van Noesel, A. Van der Lely, F. De Jong, M. van den Heuvel & S. Neggers
Erasmus University Medical Center, Rotterdam, The Netherlands.

Introduction
Adrenal insufficiency, or relative insufficiency, might partly explain increased mortality rates in nephroblastoma and neuroblastoma survivors after unilateral adrenalectomy. Aim of this study was to assess adrenal function and its metabolic effects after unilateral adrenalectomy.
Patients and Methods
Cross-sectional study with a socio-demographically similar control group, conducted between October 2009-March 2011 at the Erasmus University Medical Centre, the Netherlands. Sixty-seven adult long-term survivors of nephroblastoma, 36 survivors of neuroblastoma and 49 control subjects were included in this study. Adrenal function was assessed by a 1 μg short Synacthen-test. Cortisol, adrenocorticotrophic hormone (ACTH), low (LDL-C) and high-density lipoprotein-cholesterol (HDL-C), triglycerides, apolipoprotein-B, glucose and insulin levels were assessed in blood samples taken at baseline. In addition, cortisol levels were assessed after 30 ($t=30$) and 60 minutes. Homeostatic Model Assessment (HOMA) was calculated.
Results
Adrenal insufficiency was not present in survivors. Interestingly, baseline serum cortisol levels were higher in survivors after unilateral adrenalectomy (mean 503 nmol/l) ($N=46$) than in survivors with both adrenals intact (mean 393 nmol/l, $P=0.002$) ($N=52$), and than in controls (mean 399 nmol/l, $P=0.013$) ($N=49$). After correcting for age, sex, and use of oral estrogens, unilateral adrenalectomy was independently associated with elevated baseline cortisol and ACTH levels. Baseline cortisol levels were positively associated with triglycerides ($P<0.001$), LDL-C ($P=0.004$), apolipoprotein-B ($P<0.001$) and HOMA ($P=0.008$).
Conclusions
No adrenal insufficiency was observed in survivors of nephroblastoma and neuroblastoma. Survivors treated with unilateral adrenalectomy had relatively high basal cortisol and ACTH levels, indicating a higher central setpoint of the hypothalamic-pituitary-adrenal axis. This higher setpoint was associated with lipid concentrations and insulin resistance.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P14

**PET-tracers for differential diagnosis in primary hyperaldosteronism – *in vitro* studies**

B. Heinze, K. Mathe, S. Gabor, K. Lang, M. Zink, B. Allolio, A. Schirbel & S. Hahner
University Hospital of Wuerzburg, 97080, Germany.

Objective
The major diagnostic problem in primary aldosteronism is the differentiation between bilateral hyperplasia and aldosterone producing adenoma which is essential for further treatment. Adrenal vein sampling is regarded as the current gold standard, however it is an invasive, highly examiner-dependent method. Molecular imaging targeting the aldosterone synthase (CYP11B2) which is expressed specifically in aldosterone producing adrenal tissue may be an useful alternative. CYP11B2 is highly homologous to 11β-hydroxylase (CYP11B1) (93%). We, therefore, aimed to develop a PET tracer which binds to CYP11B2 with both high affinity and high selectivity.
Methods
We have synthesized more than 90 new compounds so far mostly containing a fluorine atom which enables radiolabelling with 18F for PET imaging. Compounds were tested for inhibition of aldosterone/cortisol (corticosterone) in NCI-H295 cells, murine Y1 cells expressing human CYP11B1/CYP11B2 and in V79 chinese hamster fibroblasts expressing rat CYP11B1/CYP11B2.
Results
After structural optimization, 7 fluorinated CYP11B2 inhibitors could be identified (IC50 values for inhibition of aldosterone synthesis up to 5.5 nM, selectivity factors for inhibition of aldosterone vs cortisol synthesis in murine Y1 cells mostly $>100$).
Conclusion
We developed several fluorinated inhibitors of CYP11B2 exhibiting high affinity and selectivity binding to the target enzyme. These compounds may be suitable for specific molecular imaging in primary hyperaldosteronism. Establishment of radiosynthesis and in vivo evaluation is subject of ongoing studies.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P15

**Role of Endogenous Somatostatin and Cortistatin in Regulating Adrenal Gland Function**

A. Moreno-Herrera[1], J. Córdoba-Chacón[1,2], M. Gahete[1,2], A. Pozo-Salas[1], L. de Lecea[3], R. Kineman[2], J. Castaño[1] & R. Luque[1]
[1]University of Cordoba, Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), and CIBER Fisiopatología de la Obesidad y Nutrición, Córdoba, Spain; [2]University of Illinois at Chicago and Jesse Brown Veterans Affairs Medical Center, Research and Development Division, Chicago, IL, USA; [3]Stanford University, Stanford, CA, USA.

Neuroendocrine balance of the hypothalamo-pituitary-adrenal axis (HPA) is a critical component in the control of metabolic homeostasis, and its dysregulation can contribute to severe pathologies, like obesity, where the HPA is significantly altered at the central and systemic levels. Somatostatin and cortistatin have been shown to reduce circulating ACTH and glucocorticoid-levels in rodents and humans in vivo. However, to date, no studies have thoroughly investigated and compared the precise actions and potential physiological relevance of somatostatin/cortistatin at the adrenal gland level. Accordingly, here we studied the specific roles of endogenous somatostatin/cortistatin on the regulation of the adrenal gland by using somatostatin-knockout (KO) and cortistatin-KO mice and their wildtype-littermate controls, both under normal or obesity-conditions. Results revealed that circulating corticosterone levels were elevated in male/female somatostatin/cortistatin-KO as compared to normal controls. Similar results were observed in obesity conditions, although male plasma corticosterone levels were lower in obese cortistatin-KO. Interestingly, at the adrenal level, major gender- and genotype-dependent differences were found in the expression of key components potentially involved in glucocorticoid regulation. Specifically, MCR2 (main ACTH-receptor in adrenal gland) was not altered in cortistatin-KO while it was decreased in female somatostatin-KO under normal conditions, and increased in obese somatostatin-KO male mice. Interestingly, expression of 11β-hydroxysteroid-dehydrogenase and tyrosine-hydroxylase, two key markers associated with glucocorticoid synthesis were reduced in male somatostatin/cortistatin-KO mice under normal conditions, but were increased in female

cortistatin-KO under normal conditions and in obese somatostatin-KO mice. These results, together with data showing major differences in somatostatin-, CRF-, IGFI- and leptin-receptors in the adrenal gland, reveal that endogenous somatostatin and cortistatin exert unique, gender-dependent actions in the control of adrenal function, which are tightly regulated in extreme metabolic-conditions (obesity), thereby inviting to investigate further the hitherto poorly explored relevance of both peptides in the (patho)physiological regulation of HPA axis.

**Cyclical Cushing's syndrome masquerading as Polycystic Ovarian Syndrome – pitfalls in diagnosis**

J. Bukowczan, P. Kane & S. Nag
James Cook University Hospital, Middlesbrough, UK.

Introduction
We present a case of probable cyclical Cushing's syndrome (CS) masquerading as polycystic ovarian syndrome (PCOS) which went undetected for almost a decade. Our case highlights the subtleties and complexities of interpreting diagnostic tests in patients with cyclical endogenous hypercorticolism.
Case
A 33-year old female with presumed PCOS presented with a seven year history of persistent hirsutism and acne. However there was no menstrual disturbance and she had two spontaneous pregnancies. She worked as an advisor for a Slimming Company and reported that both weight and hirsutism fluctuated significantly in a cyclical fashion despite a healthy lifestyle.
Investigations
On presentation BMI was 28 kg/m$^2$ without marked truncal obesity. Blood pressure was 132/90 mmHg and there were no other clinical stigmata of hypercortisolaemia. The diagnosis of PCOS was revisited and CS was queried in view of the absence of menstrual disturbance and fluctuating weight-gain. 17-OHP and serum testosterone was normal. 24-hour urinary free cortisol excretion was raised at 221 (normal $<$200 nmol/24 h). 48 hr low dose Dexamethasone suppression test (DST)showed non suppression of cortisol (Baseline 430 nmol/l; 48 hr 156 nmol/l) confirming endogenous hypercortisolaemia. There was also disruption of diurnal cortisol variation(Midnight cortisol 538 nmol/l). High dose DST suppressed cortisol to 51 nmol/l confirming ACTH dependent CS(ACTH 28 ng/L; normal 0.1 to 47.0). Pituitary MRI demonstrated an 18$\times$10 mm adenoma with cystic degeneration. Transphenoidal pituitary surgery was undertaken without complications and was curative.
Conclusion
Cyclical CS is a rare entity and often misdiagnosed. Cyclical manifestation of the pathognomonic signs and symptoms of hypercortisolism are suggestive of the diagnosis and endocrine testing during symptoms may aid the diagnosis. PCOS shares common symptoms with CS like hyperandrogenism and weight gain and is often over diagnosed by non-specialists. A high index of suspicion remains the cornerstone of diagnosis.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P17

**Prolonged zona glomerulosa insufficiency causing hyperkalemia in primary aldosteronism following adrenalectomy**

E. Fischer, A. Pallauf, C. Degenhart, F. Beuschlein, M. Bidlingmaier, U. Linsenmaier, T. Mussack, R. Ladurner, K. Hallfeldt & M. Reincke
LMU Medizinische Klinik Innenstadt, Munich, Germany.

Context
Unilateral adrenalectomy is the therapy of first choice in aldosterone producing adenoma (APA). Improvement of blood pressure (BP) and hypokalemia is achieved in the majority of patients. Because of hypoaldosteronism, hyperkalemia can develop in the postoperative course. Our aim was to analyze the frequency of hyperkalemia, to determine the cause of hypoaldosteronism and to assess the influence of preoperative mineralocorticoid antagonist (MRA) therapy at our center.
Patients
We analyzed retrospectively data from 69 patients with APA after adrenalectomy. Hyperkalemia was defined as potassium $>$5.0 mmol/L. Patients were seen at the out-patient clinic. BP, aldosterone, renin, serum potassium, creatinine, microalbuminuria and the number of antihypertensive medications were recorded. Dosage and duration of preoperative treatment with MRA were assessed.
Results
We observed postoperative hyperkalemia in 16 patients (23.2%). In 12 of these patients, hyperkalemia was mild without need for further treatment. In 4 patients, the hyperkalemia persisted for 15, 13, 11 and 10 months. The maximum serum potassium observed was 7.1 mmol/L. These patients needed dietary advice, treatment with fludrocortisone (0.1–0.3 µg/day), forced diuresis and bicarbonate administration. They suffered from secondary hypoaldosteronism as plasma renin concentrations remained postoperatively suppressed. In univariate analysis, postoperative hyperkalemia was significantly associated with higher age at diagnosis (57.5+3.2 vs. 49.7+1.5 years, $P$=0.021) and with a worse renal function postoperatively (creatinine 1.29+0.11 vs. 0.98+0.04 mg/dl, $P$=0.025). Although 49 patients received spironolactone in a dose of 51.6+3.0 mg (treatment time 2.3+0.3 months) and 5 patients eplerenone in a dose of 30.0+5 mg (5.0+3.3 months) prior surgery, this did not have a significant impact on postoperative hyperkalemia.
Conclusion
Clinically meaningful postoperative hyperkalemia occurs in 5.8% of adrenalectomized PA patients, caused by prolonged secondary zona glomerulosa insufficiency. Potassium levels after adrenalectomy must be monitored to avoid life-threatening hyperkalemia. Pre-treatment with MRA does not appear to be effective in preventing hyperkalemia.

**Use of the 250 mcg short synacthen test in the diagnosis of primary aldosteronism**

U. Graham, S. Hunter, D. McCance, B. Atkinson & K. Mullan
Royal Victoria Hospital, Belfast, UK.

Aberrant and upregulated eutopic receptors have been identified *in vitro* in patients with primary aldosteronism (PA). We previously identified an exaggerated aldosterone response to synacthen in patients with PA versus healthy controls. In this study we aimed to evaluate whether the synacthen test differentiates between patients with PA and essential hypertension (EH).
The 250mcg intramuscular synacthen test was performed after 30 minutes recumbency in the morning and off interfering medications in ten patients with PA (7 aldosterone producing adenoma (APA), 3 bilateral adrenal hyperplasia (BAH)), 14 with EH (normal aldosterone to renin ratio) and 14 normotensives. PA was confirmed with saline suppression testing and classified using CT imaging and adrenal venous sampling. Serum aldosterone and cortisol were measured at 0, 30 and 60 minutes. Differences were compared using one way analysis of variance.
Aldosterone was significantly higher in the PA group compared to the EH and normotensive groups at all three time points ($P\leq$0.001 at 0, 30 and 60 minutes). The area under the curve (AUC) on receiver operating curve analysis was greatest at T=60 minutes (AUC: 0.96, $P\leq$0.001). There was also maximal separation between groups at this time point. There was no difference in cortisol response between groups and no difference in response between APA and BAH patients.
This study demonstrated an exaggerated aldosterone response to ACTH in patients with PA compared to those with essential hypertension and normotensive controls. This was a small study however if confirmed in larger numbers and in patients taking anti-hypertensive medications, the synacthen test may prove to be a useful diagnostic tool for PA.

**Evaluation of sexual function and psychological attitudes in adult women with congenital adrenal hyperplasia (CAH) due to 21-hydroxylase Deficiency (21-HD)**

A. Cozzolino[1], C. Simeoli[1], P. Vitale[1], L. Vignozzi[2], D. Iacuaniello[1], L. Grasso[1], M. Maggi[2], A. Colao[1] & R. Pivonello[1]
[1]Federico II University, Naples, Italy; [2]Univeristy of Florence, Florence, Italy.

Women with CAH have decreased fertility and sexual activity because of psychological aspects and genital status. The aim of this study was to evaluate sexual function and psychological attitudes in 18 women with CAH due to 21-HD (12 with non-classical, four with salt-wasting and two with simple virilizing CAH; 20–48 yrs) under standard treatment, and 18 age-matched healthy women. Sexual function was evaluated by a validated Female Sexual Function Index (FSFI) questionnaire for the assessment of six domains of female sexual function (desire, arousal, lubrication, orgasm, satisfaction, and pain) as well as an experimental questionnaire (SIEDY), evaluating the same FSFI domains together with three more domains including body image, relationship with partner and masturbation. Psychological attitudes were investigated through the validated Middlesex Hospital Questionnaire (MHQ), evaluating six domains (anxiety, phobia, obsession, somatisation, depression, hysteria). A significantly lower FSFI score, particularly in lubrication and pain domains, was found in patients than controls ($P<0.05$). This evidence was confirmed by SIEDY questionnaire, which demonstrated a significant difference also in body image and relationship with partner domains ($P<0.05$). A significantly higher score ($P<0.05$) was also found in all MHQ domains except for hysteria domain. Serum testosterone, 17-OH progesterone and androstenedione levels were directly correlated with anxiety, phobia, obsession, somatisation, depression ($P<0.05$) and inversely correlated with desire, arousal, lubrication, orgasm, satisfaction, and pain ($P<0.05$). Conversely, DHEA-S was not correlated with MHQ domains, but inversely correlated with arousal, lubrication, orgasm and satisfaction ($P<0.05$).
In conclusion, this study demonstrated that women with CAH are affected not only by disturbed psychological balance but also to a pathological sexual function, as demonstrated by both a standard and an experimental questionnaire, despite an appropriate treatment.

## P20

**Role of adrenal vein sampling in primary aldosteronism. Impact of different diagnostic criteria on subtype diagnosis**

M. Cicala, A. Patalano, M. Salvà, D. Miotto, B. Rubin, R. Pezzani, B. Mariniello & F. Mantero
University of Padua, Padua, Italy.

In patients with primary aldosteronism (PA), adrenal vein sampling (AVS) is considered the gold standard to distinguish between unilateral and bilateral disease, while diagnostic imaging tests (CT/MRI) are often inconclusive for the diagnosis of PA. To date agreement is lacking on the best criteria indicating successful cannulation and lateralization. Aim of the study was to evaluate the impact of different diagnostic criteria for the successful cannulation and lateralization on subtype diagnosis and to compare the difference of the findings between adrenal CT scan and AVS. 67 patients with confirmed PA underwent AVS. The different diagnosis of PA subtype reached using AVS data assessed by more permissive (type 1) and strict (type 2) criteria were compared. All patients performed CT scan and imaging results were compared with results of AVSs. Using Type 1 criteria AVSs were successful in 86% of patients;using type 2 criteria only 64.5%. Type 1 criteria led to a higher rate of diagnosis of unilateral PA (85% of successful procedures) than type 2 (75%). There was considerable disparity in the diagnosis reached using the 2 different criteria, with a concordance in only 45% of patients. In conclusion more permissive criteria for successful cannulation and lateralization on AVS can lead to incorrect diagnosis and accordingly to inappropriate treatment options. In the selected group of patients with successful AVS, CT findings correlated with AVSs findings and correctly identified unilateral or bilateral disease in 58,5% of patients using type 1 criteria and in 47.5% using type 2 criteria. Finale diagnosis was based on histological results in 32 patients (48%) which underwent adrenalectomy based on AVSs findings. On the basis of CT findings alone 17% of patients from the first group and 32,5% of patients of the second group probably would have been incorrectly bypassed as candidates for adrenalectomy. CT scanning lacks sensitivity and specificity and should, therefore, be followed by AVS, which is the only reliable means of differentiating unilateral from bilateral PA and lateralizing APAs preoperatively. However, there are still controversies to be solved by large prospective studies on the criteria to adopt for defining the most appropriate cut off for correct cannulation and lateralization.

**Predicting factors of the post-surgical decline in renal function in patients with primary aldosteronism**

K. Nakao, K. Nanba, T. Tamanaha, M. Tsuki, T. Tagami, T. Usui, A. Shimatsu & M. Naruse
National Hospital Organization Kyoto Medical Center, Kyoto, Japan.

Primary aldosteronism (PA) is the most common cause of secondary hypertension. Although decline in renal function especially that experienced after adrenalectomy (ADX) has been demonstrated, details of the mechanism remain to be elucidated. Aim of the study was to investigate the factors predicting renal outcome after ADX in PA. Twenty patients with PA and four patients with non-functioning adrenal tumor (NFT) as control were studied. eGFR, serum potassium, plasma aldosterone concentration (PAC), and plasma renin activity (PRA) before and 1 month after ADX were analyzed. The study was approved by the institutional ethical committee. Baseline characteristics ($M\pm SD$, PA vs. NFT) were as follows: age; $51\pm9$ vs. $65\pm9$ yrs, blood pressure; $138\pm13$ (estimated duration of hypertension $10.3\pm9.1$ yrs) vs. $114\pm10$ (mmHg), eGFR; $79.2\pm18.4$ vs. $75.3\pm19.2$ (ml/min/1.73 $m^2$), serum potassium; $3.1\pm0.9$ vs. $4.4\pm0.3$ (mEq/L), PRA; $0.3\pm0.3$ vs. $1.0\pm0.6$ (ng/ml/h), PAC; $336\pm238$ vs. $87\pm35$ (pg/mL), and ARR; $2089\pm2728$ vs. $131\pm102$. Eighty % of PA patients (16/20) showed decline in eGFR after ADX ($79.2\pm18.4$ to $72.2\pm21.5$, $P=0.002$). Post-ADX eGFR was correlated positively to baseline eGFR ($r=0.82$) and ΔPAC ($r=0.46$) and negatively to ΔK ($r=0.44$) and estimated duration of hypertension ($r=0.63$). Of the 13 patients with PA with hypokalemia before ADX, twelve patients showed normokalemia and 1 patient showed hyperkalemia (5.6 mEq/L) after ADX. Post-ADX serum potassium was correlated positively to baseline PAC ($r=0.70$) and ARR ($r=0.75$) and negatively to ΔPAC ($r=0.63$) and ΔARR ($r=0.76$). By contrast to the changes in PA, there were no changes in eGFR and serum potassium in NFT after ADX. These results suggest that duration of hypertension and PAC is the predicting factors for a significant decline in eGFR and hyperkalemia after ADX. Early diagnosis with correction of hypertension and hyperaldosteronism is essential for a better renal outcome in PA.

**Specialized surgery for adrenocortical carcinoma in The Netherlands: analysis of national cancer registry data**

T. Kerkhofs[1], R. Verhoeven[2], I. Hermsen[1], L. van de Poll-Franse[2] & H. Haak[1]
[1]Máxima Medical Center, Eindhoven, The Netherlands; [2]Comprehensive Cancer Center South, Eindhoven, The Netherlands.

Introduction
Carcinoma of the adrenal cortex (ACC) is a rare disease with an estimated incidence of 1–2 per 1 million population. Optimal treatment of ACC is multidisciplinary and has complex aspects such as adrenal surgery, adjuvant therapy with mitotane and cytotoxic chemotherapy in advanced stages. The Dutch Adrenal Network (DAN), a collaboration between all university centers and Máxima Medical Center, was founded with the objective of improving patient care and stimulating scientific research regarding ACC. Currently, not all patients

with ACC are treated in such a specialized DAN-center. The objective of our current investigation is to determine whether there are differences in survival between patients operated on in DAN-centers and non-DAN hospitals.
Methods
Data on all adult ACC patients diagnosed between 1999 and 2009 were obtained from The Netherlands Cancer Registry (NCR). Overall survival was calculated and a comparison was made between DAN- and non-DAN hospitals.
Results
The registry contained data on 191 patients, ACC was histologically confirmed in 185 patients (97%). Median survival was significantly different between patients with ENS@T disease stage I-III operated on in a DAN hospital ($n=40$) compared to patients operated on in a non-DAN hospital ($n=33$, median survival not reached versus 45 months (95% CI 16–74 months), $P=0.026$). This difference remained significant when corrected for gender, age, year of diagnosis, chemotherapy and stage of disease in multivariate analysis ($P=0.026$, hazard ratio 0.44 (95% CI 0.21–0.90)).
Conclusion
The results display that surgery in a DAN-center yields a survival benefit for patients with local or locally advanced adrenocortical carcinoma. These findings should be carefully considered in the strive for further centralization of ACC-treatment in The Netherlands.

## P23

**Long term follow-up of patients with adrenal incidentalomas – a prospective study**

F. Adamidou, P. Anagnostis, C. Zouli, M. Poulasouchidou & M. Kita
Hippokration Hospital of Thessaloniki, Thessaloniki, Greece.

Introduction
Adrenal incidentalomas (AIs) are increasingly detected due to the widespread use of abdominal imaging for diagnostic purposes. AIs are usually benign non-functioning adenomas but few prospective studies exist regarding their evolution. The aim of this study was to investigate the morphological and hormonal changes of AIs in a cohort of patients with long-term follow-up.
Materials and methods
This was a prospective observational study conducted at the department of Endocrinology in Hippokration General Hospital (Thessaloniki, Greece) from 2008. The following tests were performed: serum cortisol at 08:00 and 23:00, 24h-urinary free cortisol, 1-mg dexamethasone-suppression-test, plasma adreno-corticotrophic hormone (ACTH), serum aldosterone (ALDO), plasma renin activity (PRA), ALDO/PRA ratio and 24 h-urinary total metanephrines and catecholamines. Radiological assessment was repeated at 6–12 months and yearly thereafter.
Results
Forty patients (12 males and 28 females; mean age $58.9 \pm 11.6$ years), with 51 AIs and follow-up of $19.8 \pm 18.3$ months (range 0–48) were evaluated. The mean diameter was $27.5 \pm 11.5$ mm, being unilateral in 29 [15 (37.5%) in the right and 14 (35%) in the left gland] and bilateral in 11 patients (27.5%). Two patients underwent adrenalectomy, revealing one benign cortical adenoma and one pheochromocytoma. Three patients (7.5%) had subclinical Cushing's syndrome (SCS), 1 (2.5%) pheochromocytoma and 2 (5%) aldosteronoma. The remainder had non-secretory masses. One patient with SCS who underwent adrenalectomy experienced imrovement of dyslipidemia and normalization of blood pressure. Although 6 AIs were $>40$ mm, there were no malignancies detected.
Mass enlargement (5–10 mm) was observed in 6 AIs (15%) (from the first year of follow-up in 5), while mass shrinkage (27 mm) in 1 (2.5%). No hormonal evolution was noticed.
Conclusions
The vast majority of AIs involved benign, non-secretory lesions. Increase in size occurred early on follow-up and was more frequent than previously reported. Adrenalectomy led to amelioration of cardiovascular risk factors in SCS.

## P24

**Effects of sugar cane extract (SCE) supplementation on steroidogenesis of the adrenal cortex in male rats**

S. Mobram[1,2], K. Nagaoka[1,2], M. Mizu[3], J. Kashimura[3], G. Watanabe[1,2] & K. Taya[1,2]
[1]Gifu University, Gifu, Japan; [2]Laboratory Veterinary Physiology, Fuchu, Japan; [3]Mitsui Sugar Co, Ltd, Kanagawa, Japan.

Effects of sugar cane extract (SCE) on the adrenal corticosterone and progesterone secretion in male rats were investigated using an *in vitro* cell culture system. Three-week old male rats were fed SCE free diet or 2.16% SCE diet for 7 weeks. After 7 weeks of treatment, animals were decapitated, and adrenal cells were cultured in the absence or presence of rat ACTH (10–15 to 10-10 M) for 4 hours. Body and adrenal gland weight, plasma concentration of ACTH, corticosterone, progesterone, testosterone and basal mRNAs levels of StAR, 5 steroidogenic enzymes (P450Scc, 3β-HSD, P450c21, P450c11, 17βHSD) and ACTH receptor (MC-2) in adrenal gland were measured. There were no differences in body and adrenal gland weight between two groups. The plasma concentrations of ACTH, corticosterone progesterone were significantly high in the SCE supplemented group as compared with the control group. Adrenal cells in the SCE supplemented rat exhibited significantly higher basal level of corticosterone and progesterone than the control rat. The response of ACTH on corticosterone and progesterone release from adrenal cells was significantly higher in the SCE supplemented rat than the control rat. Basal level of P450c21 mRNA in adrenal glands was significantly higher in the SCE supplemented rats than the control rats, whereas the basal mRNAs levels of StAR, P450Scc and P450c11 in the SCE supplemented rat were significantly low as compared with the control rat. The level of 3β-HSD was non-significantly higher in the SCE supplemented rat than the control rat. In addition, the level of MC-2 mRNA was significantly high as compared with the control rat. These results clearly demonstrated that SCE supplementation stimulates basal and ACTH stimulated secretion of corticosterone and progesterone from adrenal cells in male rats. These results also suggest that stimulatory effect of SCE on adrenal steroidogenesis may result in resistance against stress.
Declaration of interest

## P25

**Evaluation of renal function of primary aldosteronism between pre- and post-treatment**

A. Yoshihara, M. Sue, K. Oda, Y. Oka, S. Usui, Y. Ando, M. Ishikawa, N. Hiroi & G. Yoshino
Toho University School of Medicine, Tokyo, Japan.

Objective
The prevalence of primary aldosteronism (PA) occures in approximately 5–10% of patients with hypertension. Aldosterone induces fluid retention and a variety of angiopathy. We investigated the course of hypertension and renal function in the post-treatment period.
Methods
Nine patients with PA were performed adrenalectomy and 21 patients were administered medications including mineralocorticoid receptor brocker. Blood pressure, serum potassium, aldosterone, plasma rennin-activity (PRA), the aldosterone/renin ratio (ARR), and renal function were evaluated between pre- and post-treatment.
Results
Systolic blood pressure and ARR were significantly decreased and serum potassium level was significantly increased in both groups. However, eGFR was decreased 1 year after treatment in both groups. Drug utilization for hypertension was increased in the group of medication, whereas was not in the group of operation.
Conclusion
Blood pressure was significantly decreased both the treatment of operation and medication. However, renal function was decreased despite the treatment of operation or medication. Fluid retention and vascular distance caused by hypersecretion of aldosterone induced hypertension. The treatments would induce efferent arteriole dilatation and decreased renal blood flow by reduction of blood pressure. The renal dysfunction is considered to be influenced by renal blood flow. Careful long-term follow-up was necessary, because differences of the PA duration and the treatment may affect the course of renal function.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P26

**Follow-up of nonsurgical nonfunctioning adrenal adenomas at five years**

A. Ramos-Prol, R. Cámara-Gómez, B. León-de Zayas, K. García-Malpartida, V. Campos-Alborg, M. del Olmo-García & J. Merino-Torres
Hospital La Fe Universitario y Politécnico La Fe, Valencia, Spain.

The management of nonfunctioning adrenal masses is controversial. The size is usually the only criterion for surgical treatment. The objective was to study the progression of the tumor size and the follow-up of several cardiovascular risk parameters in patients with nonsurgical nonfunctioning adrenal masses.
Retrospective longitudinal observational study of 24 patients (54.2% men) with nonfunctioning adenomas followed for five years without surgical treatment. Age, sex, size and location of tumor, blood pressure (BP), body mass index (BMI), lipids, fasting glucose, ions (Na and K), cortisol levels, 24 hours cortisoluria, ACTH, S-DHEAS, aldosterone, urine catecholamines and metanephrines, were analyzed at the time of diagnosis and after five years. LDL and TG were classified according to ATP -III criteria, and diabetes or prediabetes were diagnosed according to the ADA criteria. Adrenal CT was performed every 6 months. Data are presented as mean (standard deviation) and percentage.
At baseline, mean age was 55.5 (11.8) years, BMI 30.1 (5.3) kg/m$^2$. The adenoma's size was 2.1 (0.9) cm. There was hypertension in 50% of patients, hypercholesterolemia in 29.2%, hypertriglyceridemia in 8.3%, mixed dyslipidemia in 12.5%, prediabetes in 29.2% and diabetes in 4.2%.
The mean tumor growth at 5 years was 0.4 (0.5) cm. 45.8% of patients showed a deterioration on the LDL levels, 37.5% worsened the TG levels, and 37.5% aggravated their carbohydrate metabolism. 29.2% of patients required to increase the antihypertensive treatment and 12.5% of nonhypertensive patients developed hypertension ($P < 0.01$). Only one of the adenomas became functioning (hipercortisoluria, lack of cortisol suppression with dexamethasone), confirmed by biopsy after surgery.
In our serie, the growth of nonfunctioning adrenal adenomas is stable after 5 years since diagnosis. However, there is a tendency to a deterioration of BP, carbohydrate metabolism and lipid profile.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Importance of the genetic study in fertile women with nonclassical congenital adrenal hyperplasia**

M. Rubio-Almanza, S. Navas-de Solis, S. Tenés-Rodrigo, R. Querol Ripoll, A. Pérez-Lázaro, M. del Olmo-García & J. Merino-Torres
Hospital Universitario y Politécnico La Fe, Valencia, Spain.

The Nonclassical Congenital Adrenal Hyperplasia (NCCAH) is an autosomal recessive disorder. The importance of the diagnosis in fertile women relies in its therapeutic implications, genetic counseling and antenatal care during pregnancy. Diagnosis is established by the presence of basal 17-OH-progesterone (17-OHP) levels $\geqq 6$ ng/ml or stimulated after ACTH test $\geqq 15$ ng/ml. Basal values between 2-6 ng/ml or stimulated between 10–15 ng/ml would require further confirmation. To study the correlation between the result of basal and/or stimulated 17-OHP and the presence and type of mutation in the 21-hydroxylase's gene.
Descriptive study of the genetics of 11 women diagnosed analytically of NCCAH with basal 17-OHP$\geqq 6$ ng/ml or stimulated $\geqq 10$ ng/ml. Molecular genetic study of 21-hidroxilase gene was requested. Patients were divided into 2 groups. A: those with basal 17-OHP $\geqq 6$ ng/ml and/or stimulated $\geqq 15$ ng/ml (highly suggestive of diagnosis of NCCAH). B: those with basal 17-OHP $< 6$ ng/ml and/or stimulated 10–15 ng/ml (uncertain diagnosis).
Results are shown on table.
- In our serie with an uncertain analytical diagnosis of NCCAH, the genetic study did not confirm the disease and it revealed three carriers of a mutated allele (mild mutation).
- A patient with basal 17-OHP of 7.5 ng/mL had a severe mutation.
- The genetic study is necessary to identify those pregnant women who would benefit from antenatal treatment.

| Number of participants N = 11 | Group A | Group B |
|---|---|---|
| Basal 17-OH-P ng/mL (mean ± SD) n = 11 | 7.9 ± 8.3 | 2.3 ± 1.1 |
| S timulated 17-OH-P ng/mL (mean ± SD) n = 9 | 50.8 ± 22.7 | 12.1 ± 1.0 |
| Genetics | | |
| Normal | 0 | 3 |
| 1 mutated allele | 1 | 0 |
| 2 mild mutants alleles | 3 | 0 |
| 1 mild mutant allele and 1 severe mutant allele | 1 | 0 |

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P28

**Aldosterone-producing cells regenerated from mesenchymal stem cells**

T. Tanaka, T. Kawanami, T. Nomiyama, Y. Akehi & T. Yanase
Fukuoka University, Fukuoka, Japan.

Introduction
Mesenchymal bone marrow cells (BMCs) contain pluripotent progenitor cells, which differentiate into multiple lineages. In a previous study, we reported that adenovirus-mediated forced expression of steroidogenic factor-1/adrenal 4 binding protein (SF-1/Ad4BP), an essential nuclear receptor for steroidogenesis, could transform human BMCs into steroidogenic cells, suggesting a possibility of cell transplantation therapy in patients with steroid deficiency. In this study, we focused on the capability of the cells to produce aldosterone and characterized the mode of production.
Methods
Primary cultured human BMCs were infected with lentivirus containing human SF-1 cDNA and the steroid production was examined in various conditions.
Results
In human BMCs, endogenous expression of AII receptor type 1 was detected. Introduction of SF-1 into human BMCs caused dramatic inductions of most steroidogenic enzymes including CYP11B1 as well as ACTH receptor. CYP11B2 was barely detectable by SF-1 introduction. However, under the condition of SF-1 introduction, it was dramatically induced by AII treatment, thus leading to a good responsiveness of the cells to ACTH and AII, respectively and final production of corticosterone, aldosterone and cortisol. AII blocker, Losartan canceled the increase of those steroids secretion by AII treatment.
Conclusion
These data suggest that SF-1 can transform BMCs into aldosterone-producing cells which can be regulated by AII-AII receptor system.

## P29

**The ACTH-independent macronodular adrenal hyperplasia gene hunt: from candidate genes to a pangenomic strategy**

G. Assié[1,2], R. Libé[1,2,3], A. Guimier[1], S. Espiard[1], F. René-Corail[1], K. Perlemoine[1], F. Letourneur[1], X. Bertagna[1,2,3], L. Groussin[1,2] & J. Bertherat[1,2,3]
[1]Institut Cochin, Paris, France; [2]Hôpital Cochin, Assistance Publique Hôpitaux de Paris, Paris, France; [3]Rare Adrenal Diseases, Assistance Publique Hôpitaux de Paris, Rare Adrenal Cancer Network COMETE-INCA, Paris, France.

ACTH-independent macronodular hyperplasia (AIMAH) affects both adrenals, and familial forms are reported, suggesting a genetic origin. Rare mutations have been reported in several genes, including Gs alpha (GNAS), Phosphodiesterase 11A (PDE11A), Fumarate Hydratase (FH), and the Glucocorticoids receptor (GR).
Objective
To assess the prevalence known genes mutations, and identify new candidate genes in AIMAH.
Design and methods
Germline and/or tumor DNA of 62 AIMAH patients was studied by direct sequencing of candidate genes (GNAS, PDE11A, FH and GR), and by pangenomic genotyping using Affymetrix SNP6 arrays in search for chromosomal alterations in germline and in AIMAH nodules.
Results
Missense PDE11A mutations were more common in patients (18/62, 29%) than in controls (7% in 279 controls). Mutations in FH were found in 4/49 patients (8%). No germline GR mutation, and no somatic GNAS mutation were found.
Chromosomal gains and losses are uncommon in AIMAH nodules; a recurrent gain was found in 1q (2/29); recurrent losses included chromosomes 1p (3/29), 3, 17 and 18q (2/29). No large recurrent gain or loss was found in germline; one loss in 6q, and in 16p, and one gain in 9q were found. Copy neutral loss of heterozygosity in chromosome 16p was found in 10 nodules from 6 out of 29 patients studied.
Conclusions
Candidate genes and pangenomic approaches are complementary methods to decipher the complexity of AIMAH genetics. PDE11A mutations seem to predispose to AIMAH. Copy neutral loss of heterozygosity in chromosome 16p is the most common alteration in AIMAH nodules, suggesting the implication of gene(s) in this region.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

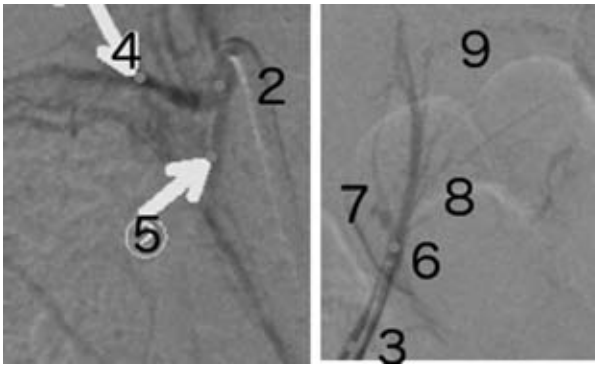
## P30

**Superselective adrenal venous sampling for intra-adrenal localization of aldosterone hypersecretion.**

K. Takase, K. Seiji, F. Satoh, R. Morimoto, S. Ito & S. Takahashi
Tohoku University School of Medicine, Sendai, Japan.

Introduction
Unilateral aldosterone hypersecretion can be adequately treated based on the localization by adrenal venous sampling. However, bilateral aldosterone producing adenoma or primary aldosteronism with preclinical Cushing syndrome cannot be treated with simple unilateral adrenalectomy. Diagnosis of intra-adrenal localization of aldosterone hypersecretion is necessary for surgical treatment of these types of primary aldosteronism.
Method
From 2009 to 2011, we performed superselective adrenal sampling of 68 patients with primary aldosteronism. A 6.5-Fr catheter was inserted from the left femoral vein to select the orifice of the left adrenal vein. Then a 6.5-Fr catheter designed for various types of right adrenal vein ("Adselect series", Hanako medical, Tokyo, Japan) was inserted from the right femoral vein into the right adrenal vein. MDCT information was used as a reference of catheter manipulations. Simultaneous venous sampling was repeated 15 minutes after intravenous one-shot injection of the 0.25 mg of ACTH. Then superselective adrenal venous sampling was performed by catheterization into each 3 tributaries of bilateral adrenal vein using high-fro-type microcatheter.
Results
In all cases, superselecive adrenal venous sampling was successfully perfrmed. In 27 cases, unilateral aldosterone hypersecretion was diagnosed, followed by unilateral adrenalectomy. Superselective sampling provides very high absolute concentration of aldosterone in at least one adrenal venous tributary of unilateral adrenal gland, confirming the diagnosis of aldosterone producing adenoma. In 4 cases, bilateral aldosterone hypersecretion with normal aldosterone level in at least one tributary was diagnosed showing bilateral aldosterone producing adenoma, which enabled surgical treatment of unilateral total adrenarectomy combined with contrarateral partial adrenarectomy. In the remaining 37 cases, blood sample from all the tributaries of bilateral adrenal vein showed high aldosterone concentration showing idiopathic hyperaldosteronism, followed by medical treatment.
Conclusion
Superselective adrenal venous sampling allows primary aldosteronism with bilateral aldosterone producing adenoma treated by surgery.



Bilateral superselective adrenal venous sampling. Blood were sampled from 9 points shown in the figure. Intra-adrenal localization of aldosterone hypersecretion could be diagnosed: bilateral aldosterone hypersecretion with normal aldosterone content in one of the tributaries. This patient could be treated by unilateral total adrenarectomy combined with contralateral partial adrenarectomy.

**Analysis of the glucocorticoid receptors polymorphism in patients with adrenal incidentaloma and patients with Cushing's syndrome.**

G. Reimondo[1], D. Giachino[2], I. Micossi[1], P. Berchialla[3], S. Varacalli[2], B. Allasino[1], A. Pia[1], F. Laino[1], G. Peraga[1], P. Cosio[1], C. Sciolla[1], M. De Marchi[2] & M. Terzolo[1]
[1]Medicina Interna 1 a indirizzo Endocrinologico – AOU San Luigi, Orbassano, Italy; [2]Genetica Medica – AOU San Luigi, Orbassano, Italy; [3]Statistica – AOU San Luigi, Orbassano, Italy.

The effects of glucocorticoids are mediated by the glucocorticoid receptors (GR) and some single nucleotide polymorphisms (SNPs) have been associated to enhanced sensitivity (N363S, BclI) or reduced sensitivity (ER22/23EK) to glucocorticoids.
Aim of the present study was: 1) to assess the frequency of N363S, BclI and ER22/23EK in 46 patients with Cushing's syndrome (CS) and 73 patients with adrenal incidentaloma (AI) compared to 186 healthy subjects; 2) to evaluate a possible correlation between the different SNPs and patient phenotype.
In all patients we evaluated clinical and demographic parameters, urinary free cortisol (UFC) and cortisol after 1 mg dexamethasone suppression test (DST). DNA was extracted from peripheral blood leukocytes using PCR. The PCR product was digested with 1 U of TasI at 65 °C overnight, and the accuracy of genotyping was confirmed by sequencing analysis.
We did not observe any differences between the frequency of N363S, BclI and ER22/23EK in patients and controls. Although not statistically different, we observed a reduced frequency of BclI in patients with AI and cortisol $>5$ mcg/dl after DST. Moreover, 4 out 5 patients with AI carrying the N363S SNP had an overt metabolic syndrome despite normal UFC and cortisol levels after DST.
Our data suggest that the evaluated SNPs are not involved in the pathogenesis of CS or AI. In patients with CS, we did not observe any genotype/phenotype correlation, since the overt hypercortisolism likely masks any modulatory effect

of the SNPs on clinical parameters. In AI patients, who present only a mild hypercortisolism, BclI may affect cortisol suppression after DST, while N363S may be associated to a worsen metabolic profile.

### KCNJ5 Mutations in European Families with Non-Glucocorticoid Remediable Familial Hyperaldosteronism

P. Mulatero[1], P. Tauber[2], M. Zennaro[3], S. Monticone[1], K. Lang[4], F. Beuschlein[5], E. Fischer[5], J. Burrello[1], A. Pallauf[5], M. Galmozzi[1], L. Amar[3], T. Williams[1], T. Strom[6], E. Primary Aldosteronism (PA) is the most frequent cause of endocrine hypertension. Three forms of familial hyperaldosteronism (FH) have been described, named FH-I to -III. Recently, a mutation of KCNJ5 has been shown to be associated with FH-III, whereas the cause of FH-II is still unknown. In this study we searched for mutations in KCNJ5 in 46 patients from 21 families with FH, in which FH-I was excluded. We identified a new germline G151E mutation in two PA affected subjects from an Italian family and three somatic mutations in aldosterone-producing adenomas (APA), T158A previously described as a germline mutation associated with FH-III, and G151R and L168R both described as somatic mutations in APA. The phenotype of the family with the G151E mutation was remarkably milder compared to the previously described American family, in terms of both clinical and biochemical parameters. Furthermore, patients with somatic KCNJ5 mutations displayed a phenotype indistinguishable from that of sporadic PA. The functional characterization of the effects of the G151E mutation in vitro, showed a profound alteration of the channel function, with loss of $K^+$ selectivity, $Na^+$ influx and membrane depolarization. These alterations have been postulated to be responsible for voltage gate $Ca^{2+}$ channel activation, increase in cytosolic calcium and stimulation of aldosterone production and adrenal cells proliferation. In conclusion, we describe herein a new mutation in the KCNJ5 potassium channel associated with FH-III, responsible for marked alterations of channel function but associated with a mild clinical and hormonal phenotype.

### Applicability of the guideline for the diagnosis of primary hyperaldosteronism in patients with hypertension in Japan (PHAS-J2): Prospective multi-center study of national hospital organization

M. Naruse[1], Y. Miyazaki[1,2], T. Tanaka[3], M. Shimizu[4], S. Otani[1,5], S. Hata[6], A. Ogo[1,7], K. Yonezawa[8], K. Yoshida[9], M. Sawamura[10], R. Araki[1,11], M. Tanabe[1,12], M. Tsuiki[1], T. Suzuki[1,13] & T. Shimbo[13]
[1]NHO Kyoto Medical Center, Kyoto, Japan; [2]Misato Kenwa Hospital, Misato, Japan; [3]NHO Mie Chuou Medical Center, Tsu, Japan; [4]NHO Kobe Medical Center, Kobe, Japan; [5]Saitama National Hospital, Wako, Japan; [6]Nagasaki Goto Chuoh Hospital, Goto, Japan; [7]NHO Kyushu Medical Center, Fukuoka, Japan; [8]NHO Hakodate Hospital, Hakodate, Japan; [9]NHO Nagasaki Kawatana Medical Center, Nagasaki, Japan; [10]Nishigunma National Hospital, Shibukawa, Japan; [11]National Mie Hospital, Tsu, Japan; [12]NHO Kokura Medical Center, Kitakyushu, Japan; [13]National Center for Global Health and Medicine, Tokyo, Japan.

Primary aldosteronism (PA) is the most major cause of secondary hypertension, with its prevalence ranging from 3 to 20% of the hypertensive patients. Although guideline for diagnosis of PA has been established by the Endocrine Society, details of its applicability remain to be elucidated. In this study, we investigated the applicability of each step of the guideline in hypertensive patients by the multi-center collaborative study of National Hospital Organization (NHO) in Japan (PHAS-J2). Total 25 NHO hospitals participated into the study. The study was performed in accordance with the Guidelines for Human Research of Japanese Government and approved by the institutional ethical committee. Written informed consent was obtained from each patient. Patients with hypertension ranging from 20 to 75 yrs were enrolled. Plasma aldosterone to renin activity ratio (ARR) with a cutoff of 20 was used for case detection and captopril test was used as a confirmatory testing. Captopril-positive patients were subjected to subtype testing with adrenal CT, 131I-adosterol scintigraphy, and adrenal venous sampling (AVS). Total 1237 patients were enrolled to the study. Case detection was positive in 21% of the patients and captopril test was positive in 58% of the screening-positive patients. Collectively, prevalence of PA was 12.2% of the total patients with hypertension. Adrenal tumor was visualized in 32% on CT. Applicability of each step was 85% in confirmatory testing, 93% in adrenal CT, 14.9% in adrenal scintigraphy, and 39% in AVS. Subtype diagnosis was achieved in 46% in those patients subjected to adrenal scintigraphy and/or AVS. These results suggest that applicability of the PA guideline in its subtype testing is not high enough to make definite diagnosis. Given the high prevalence of PA in hypertension, modification of the PA guideline as well as further advances in subtype testing are mandatory.

### Copy number alterations and loss of heterozygosity in cortisol-secreting adrenocortical adenomas using SNP arrays: evidence of new candidate genes and pathways.

C. Ronchi, E. Leich, S. Sbiera, A. Rosenwald, B. Allolio & M. Fassnacht
University Hospital Wuerzburg, Wuerzburg, Germany.

Introduction
The genetic mechanisms underlying adrenocortical tumor development are still largely unknown. We used high-resolution single nucleotide polymorphism (SNP) microarrays to detect copy number alterations (CNAs) and copy neutral losses of heterozygosity (cnLOH) in cortisol-secreting adrenocortical adenomas (ACAs). We focused on microalterations aiming to discover new candidate genes involved in early tumorigenesis and/or autonomous cortisol secretion.
Methods
15 cortisol-secreting ACAs with matched blood samples were investigated. The SNP arrays were performed by Affymetrix SNP 6.0 and paired data analysis by Partek Genomics Suite software. Gene ontology annotation, pathway, gene and protein network analyses were used to identify candidate genes.
Results
We detected 962 CNAs with a median of 18 CNAs per sample. Half of them involved non-coding chromosomal regions, 89% were $<100$ Kb and 28% were found in at least two samples. Most frequently gained segments were 5p15.33, 6q16.1, 7p22.3-22.2, 8q24.3, 9q34.2-34.3, 11p15.5, 11q11, 12q12, 16q24.3, 20p11.1-20q21.11, and Xq28 ($\geqq$20% of cases), most of them being identified in the same three ACAs. These regions contained among others genes like NOTCH1, CYP11B2, HRAS, and IGF2. Recurrent losses were less common and smaller than gains, being mostly localized at 1p, 6q and 11q. Pathway analysis revealed that Notch signaling was the most frequently altered. We identified 46 recurrent microalterations that each affected a single gene (31 gains and 15 losses), including some genes involved in steroidogenesis (CYP11B1) or tumorigenesis (CTNNB1, EPHA7, SGK1, STIL, FHIT). Finally, 20 small cnLOH in four cases affecting 15 known genes were found.
Conclusion
Our findings provide the first high-resolution genome-wide view of chromosomal changes in cortisol-secreting ACAs and identify novel candidate genes, such as HRAS, EPHA7, and SGK1. Furthermore, they implicate that the Notch1 signaling pathway might be involved in the molecular pathogenesis of adrenocortical tumors.

### Differential DNA methylation of the CYP11B1 and CYP11B2 genes in association with human adrenal zonation

M. Demura[1], F. Wang[1], T. Yoneda[1], M. Kometani[1], T. Sawamura[1], Y. Cheng[1], K. Ono[2], Y. Nakamura[2], H. Sasano[2], K. Saijoh[1] & Y. Takeda[1]
[1]Kanazawa University, Kanazawa, Japan; [2]Tohoku University, Sendai, Japan.

Background
The human adrenal cortex is composed of 3 distinct zones: the zona glomerulosa (ZG), the zona fasciculata (ZF), and the zona reticularis (ZR). Steroidogenic enzymes are expressed in a zone-specific manner. The promoters of CYP11B1 and CYP11B2 possess a number of target sites for DNA methylation that is closely associated with gene silencing.
Methods and Materials
Adrenals from 5 autopsy subjects were assessed for immunohistrochemically defined adrenal zonation, using antibodies for 17alpha-hydroxylase/17,20-lyase (CYP17), 3beta-hydroxysteroid dehydrogenase (HSD3B), and dehydroepiandrosterone (DHEA)-sulfotransferase (SULT2A1). CYP17, HSD3B, and SULT2A1 are entirely expressed in ZF/ZR, ZG/ZF, and ZR, respectively. We used laser capture microscopy to isolate DNA from each zone in adrenal tissues and performed an analysis of DNA methylation. Promoter methylation patterns of CYP11B1 and CYP11B2 in adrenal zones were examined by means of bisulfite sequencing.
Results and Discussions
CYP11B1 was completely hypomethylated in ZF while completely hypermethylated in both ZG and ZR. In contrast, CYP11B2 in ZG was hypomethylated compared with those in ZF and ZR. Inter-individual diversity was observed in DNA methylation of CYP11B2 in ZR. The important differences in DNA methylation were that CYP11B1 and CYP11B2 were hypomethylated in ZF and ZG, respectively compared with other zones and that hypomethylation of CYP11B2 in ZG was incomplete whereas that of CYP11B1 in ZF was complete. 11beta-hydroxylase (CYP11B1) has been reported to be expressed highly in ZF and weakly in ZR while aldosterone synthase (CYP11B2) has been sporadically expressed only in ZG. NR4A receptor family involved in the regulation of CYP11B2 has been shown to be differentially expressed in a zone-specific manner.
Conclusions
Taken together, DNA methylation patterns of the CYP11B1 and CYP11B2 promoters were closely associated with adrenal zonation. The DNA methylation patterns, however, do not fully explain zone-specific expression patterns of 11beta-hydroxylase and aldosterone synthase. DNA methylation is considered important for adrenal zonation in conjunction with zone-specific transcription factors. Since the expression of aldosterone synthase depends on salt intake, incomplete DNA hypomethylation of CYP11B2 in ZG is ascribed to high-sodium diets in contemporary society.

### Super-selective ACTH-stimulated adrenal venous sampling can discriminate the main lesion from the normal tissue for doing partial adrenalectomy in unilateral aldosterone-producing adenoma

M. Omura[1], K. Makita[2], S. Matsui[1], J. Inoue[1], M. Nagata[1], K. Yamaguchi[1], Y. Kakuta[1], Y. Matsuzawa[1], J. Saito[1] & T. Nishikawa[1]
[1]Yokohama Rosai Hospital, Yokohama, Japan; [2]Tokyo-kita Social Insurance Hospital, Tokyo, Japan.

Introduction
Primary aldosteronism (PA) is one of the common diseases, and aldosterone-producing adenoma (APA) is a surgically curable type, which is usually treated by unilateral total adrenalectomy. We had recently developed a new method of supper-selective ACTH-stimulated adrenal venous sampling (SS-ACTH-AVS) for exactly detecting the main lesion(s) of hyperaldosteronemia. Then we attempted to partially remove the unilateral lesion of hyperaldosteronism detected by SS-ACTH-AVS without resecting normal tissues.
Methods
We developed a new micro-catheter to obtain adrenal effluent at intra-adrenal tributary veins. By using that catheter, SS-ACTH-AVS was performed in 50 patients with PA demonstrating unilateral CT-detectable adrenal nodule. Adrenal effluents were sampled at more than 2 intra-adrenal first-degree tributary veins in each adrenal gland after ACTH stimulation. When concentration of aldosterone in effluent sampled at one of the tributary veins connecting to any nodule was $>1400$ ng/dl and the others were $<1400$ ng/dl, the nodule was diagnosed as APA. Then, the patients with APA were treated by laparoscopic unilateral partial resection of the nodule. When aldosterone was $>1400$ ng/dl in all effluents sampled at tributaries of the unilateral adrenal, showing the presence of the nodule and $<1400$ ng/dl in all effluents sampled at each tributary of the opposite adrenal gland, the patients were also diagnosed as unilateral hyperaldosteronism and treated by unilateral total adrenalectomy.
Results
Thirty patients with CT-detectable APA exactly diagnosed by SS-ACTH-AVS were treated by unilateral partial adrenalectomy. Pathological examinations of resected adrenal glands demonstrate that APAs were completely removed without destruction of their capsules. One year after adrenalectomy, concentrations of aldosterone in peripheral blood samples were normalized in 30 patients treated by partial adrenalectomy as well as in 20 treated by total one.
Discussion
SS-ACTH-AVS is promising for choosing how to remove the adrenal lesion inducing hyperaldosteroneima, such as unilateral partial and total adrenalectomy.
Declaration of interest

### Deletion of TASK3 $K^+$ channels leads to hyperaldosteronism in neonatal mice

S. Bandulik[1], P. Tauber[1], D. Penton-Ribas[1], I. Tegtmeier[1], F. Lesage[2], J. Barhanin[3] & R. Warth[1]
[1]University of Regensburg, Regensburg, Germany; [2]Université de Nice Sophia Antipolis, Valbonne, France; [3]Université de Nice Sophia Antipolis, Nice Cedex, France.

Depolarisation of adrenal zona glomerulosa cells is a pivotal event for the secretion of aldosterone. Potassium channels like TASK1 and TASK3 are highly expressed in the adrenal cortex and determine the membrane voltage. Deletion of TASK3 $K^+$ channels in mice caused a severe age-dependent hyperaldosteronism. The aim of this study was to identify the mechanisms underlying this phenotype.
Neonatal TASK3-/- mice (ko) showed higher plasma aldosterone levels compared to wildtype (wt) animals correlating with an increased adrenal mRNA expression level of the aldosterone-synthase. These high aldosterone levels decreased within the first two weeks of life. Plasma concentrations of progesterone and corticosterone showed the same age-dependent dysregulation. These results pointed to a broader adrenal dysfunction in newborn ko mice. A chip-based analysis was performed to measure differential gene expression in adrenals of 1 and 12 day old mice. Interestingly, adrenal renin mRNA was strongly upregulated in newborn ko mice, but decreased to normal wt levels in 12 day old mice. The high renin gene expression was confirmed by realtime PCR and by renin-specific immunofluorescence.
These data suggest that transient activation of the local adrenal renin-angiotensin-system contributes to the hyperaldosteronism of neonatal TASK3-/- mice. Future studies are needed to investigate the signalling pathways resulting in increased adrenal renin production and to identify the compensation mechanisms present in adult mice.

## P38

**Expression of kisspeptin and its receptor in aldosterone-producing adrenal adenomas**

K. Takahashi[1], I. Kato[1], H. Nishiyama[1], K. Ohba[1], K. Kaneko[1], R. Morimoto[1], F. Satoh[1], K. Totsune[2] & O. Murakami[3]
[1]Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Tohoku Fukushi University, Sendai, Japan; [3]Hayasaka Aisei-kai Hospital, Sendai, Japan.

Kisspeptins are the product of the KiSS-1 gene, a metastasis suppressor gene, and play important physiological roles in the hypothalamo-pituitary gonadal axis and reproduction. It was reported that kisspeptin-10 stimulated the aldosterone synthesis in H295R human adrenal cancer cells (Nakamura et al., 2007). However, expression of kisspeptin and its receptor has not been studied in tumor tissues of adrenocortical tumors. The aim of the present study was therefore to clarify expression of kisspeptin and its receptor in tumor tissues of adrenocortical tumors, particularly aldosterone-producing adenomas (APAs). Immunocytochemisty of kisspeptin and kisspeptin receptor was performed by the ABP method in tumor tissues of adrenal tumors obtained at surgery, including 31 APAs. The antiserum against human kisspeptin-10 was raised in a rabbit (Takahashi et al., J Mol Neurosci 41:138;2010). The antibody against kisspeptin receptor (GPR54) was obtained from Santa Cruz Biotechnology, Inc. (sc-48220). Kisspeptin and kisspeptin receptor were immunostained in tumor tissues of all cases of APAs examined. Kisspeptin and kisspeptin receptor were also immunostained in normal adrenal medulla of attached adrenals in all 19 cases examined, and very weakly in normal adrenal cortex of 6 out of 19 cases examined. Furthermore, positive immunostaining of kisspeptin and kisspeptin receptor was observed in other types of adrenal tumors, including cortisol-producing adenomas, non-functioning adenomas and adrenal cancers. Western blot analysis confirmed a band of 43 kDa representing kisspeptin receptor in tumor tissue extracts of the adrenal tumors. The present study has shown expression of kisspeptin and kisspeptin receptor in tumor tissues of adrenal tumors including APAs, raising the possibility that kisspeptins act as autocrine or paracrine regulators for adrenal hormone synthesis and proliferation of adrenal tumor cells.

**Reduction of the 10-year probability of fracture predicted by FRAX® and bone mass recovery in patients with Cushing's Syndrome after 24 months from cure of hypercortisolism**

L. Trementino[1], L. Ceccoli[1], G. Marcelli[1], T. Mancini[2], M. Boscaro[1] & G. Arnaldi[1]
[1]Polytechnic University of Marche, Ancona, Italy; [2]San Marino Hospital, San Marino, Italy.

Introduction

Cushing's Syndrome (CS) has been associated with bone mass abnormalities and with an increased risk of osteoporotic fractures.

Objective

Evaluate the effect of treatment on the 10-year probability of fracture predicted by FRAX® and on the overall bone profile, in patients with CS.

Patients and Methods

We evaluated 36 patients (6 M, 30 F, 12 post-menopausal, mean-age 43.6 ± 13.5), 22 with Cushing's disease (CD), 10 with ACTH-independent CS (ACS) and 4 with ectopic ACTH syndrome. BMD, T-score and Z-score at lumbar spine and left femur and prevalence of vertebral fractures using dual-energy X-ray absorptiometry (DEXA) and the 10-year probability of fracture predicted by FRAX® were assessed at baseline and after a 24 months median follow-up from cure of hypercortisolism. Six patients were on bisphosphonates (BSFs) treatment.

Results

At baseline 60% of patients showed bone mass abnormalities and 22% had vertebral fractures. Bone parameters did not differ between CD, ACS and ectopic CS. Bone mass abnormalities were not related to age, degree and duration of hypercortisolism. After a 24 months median follow-up from cure of hypercortisolism, a significant improvement in BMD, T-score and Z-score was observed with normalization in 7% of patients. There was no difference in percent increase at spine and femur between patients treated and untreated with BSFs. The 10-year probability of hip fracture (FRAX® Hip) and of a major osteoporotic fracture (FRAX® Major) was significantly reduced (respectively of 57% and of 48%) without difference between patients treated and untreated with BSFs. The FRAX® Hip and FRAX® Major percent reduction was related respectively with baseline neck femur and spine Z-score.

Conclusions

In CS patients, the cure of hypercortisolism is associated with recovery of bone mass and with significant reduction of the 10-year probability of osteoporotic fractures evaluated by FRAX®. BSFs seem not to affect bone improvement.

Declaration of interest

**The Wnt/Beta-catenin and Ras/Raf/MEK/ERK signaling pathways alterations in adrenocortical tumors**

B. Rubin, R. Pezzani, S. Barollo, B. Mariniello, M. Salvà, M. Iacobone, A. Fassina & F. Mantero
University of Padua, Padua, Italy.

Adrenocortical tumors (ACT) include benign and malignant tumors. Adrenocortical carcinomas (ACC) are highly malignant neoplasms with a poor prognosis, but their genetic alterations to date identified are limited. Laboratory studies on ACT have revealed a wide variety of signaling pathways involved in these tumors, among these Wnt/β-catenin signaling pathway and Ras/Raf/MEK/ERK pathway resulted often disregulated. Another important factor in many signaling pathways is the epidermal growth factor receptor (EGFR), responsible for proliferation and overexpressed in many adrenocortical tumors.

The objective of our study was to evaluate genetic alterations in key components of Wnt/β-catenin and Ras/Raf/MEK/ERK signaling pathways in order to better understand the pathogenesis of sporadic adrenocortical tumors and provide light onto new possible prognostic factors.

We performed high resolution melting (HRM) analysis for evaluating the presence of activating mutations in EGFR (exons 18, 19, 20, 21), BRAF (exons 11 and 15), H-RAS (exons 1 and 2), N-RAS (exons 1 and 2), K-RAS (exons 1 and 2), CTNNB1 (exon 3), AXIN2 (exon 7). We analyzed a series of 92 sporadic samples: 21 ACC, 38 aldosterone producing adenomas (APA), 29 cortisol producing adenomas (CPA) and 4 normal adrenocortical tissues. Only samples resulted with altered melting curves were direct sequencing.

We found 2 different BRAF mutations in 2 ACC, 4 H-RAS silent mutations in 1 APA, 1 CPA and in 2 ACC, 16 CTNNB1 alterations in 5 APA, 6 CPA and 5 ACC. No alteration in EGFR, N-RAS, K-RAS.

These results suggest that abnormalities in Ras/Raf/MEK/ERK pathway do not represent a frequent pathogenetic mechanism of adrenocortical tumorigenesis, while alterations in Wnt/β-catenin pathway seem to be a more common event. Nevertheless this study identified diverse genetic alterations, whose role in adrenocortical tumors should be further investigated.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P41

**Cancer induces adrenal and pituitary alterations during the development of cachexia-anorexia syndrome**

T. Mazzuco, J. Crespigio, E. Fonseca, M. Macioszek, L. Lazari-Berbel, R. de Freitas & H. Souza
Universidade Estadual de Londrina – UEL, Londrina, Brazil.

Introduction

Tumour cachexia-anorexia syndrome (CAS) is a complex disorder characterized by progressive nutritional and metabolic alterations that lead to loss of muscle and adipose tissue observed in advanced-stage cancer. CAS indicates unfavourable prognosis, regardless of cancer type. Under the influence of permanent aggression, we have evaluated the effects of the cancer cachexia development on the hypothalamic-pituitary-adrenal (HPA) axis.

Methods

Experimental cancer CAS was induced by subcutaneous inoculation of the Walker-256 carcinosarcoma cells in Wistar rats. Histopathology, functional and nutritional parameters were studied in tumour-bearing rats, compared with paired

feeding or free-fed control rats (PBS inoculation). Adrenals and pituitary weights were corrected for body weights.

Results

The onset of the anorexia and body weight reduction was observed from the 5th day in the tumour group (Fig. 1), followed by gradual catabolic changes. Although pair-feeding decreased body weight, it did not affect body mass index; both control groups were similar at necropsy. On days 5 and 12 after tumour inoculation, cachexia index (%) was 10.3(±1.2) and 14.7(±0.9), respectively. In the tumour group, adrenals and pituitary weighed 2.25-fold(±0.15) and 2.17-fold(±0.5) greater than control on day 5, respectively. On day 12, adrenals and pituitary weight significantly decreased to 1.62(±0.09) and 1.45(±0.08) fold change from control, respectively. Adrenal cortex of rats with cancer CAS exhibited hypertrophy of the zona fasciculata; mean cortical width measured 1.22(±0.04) and 1.13(±0.03) mm on days 5 and 12, respectively (control, 0.92±0.02, $P<0.001$). After acute stimulation of tumour-bearing rats (12 days) with supraphysiological doses of exogenous ACTH, plasma corticosterone levels was 146.7±18.3, while the normal response in control rats was 193.3±21.3 ($P<0.01$).

Conclusion

Adrenal and pituitary undergo morphological alterations during the development of cancer CAS indicating the HPA axis activation. Results suggest a biphasic adaptive response to cancer as stressful aggression, which starts before the day 5 of tumour inoculation.

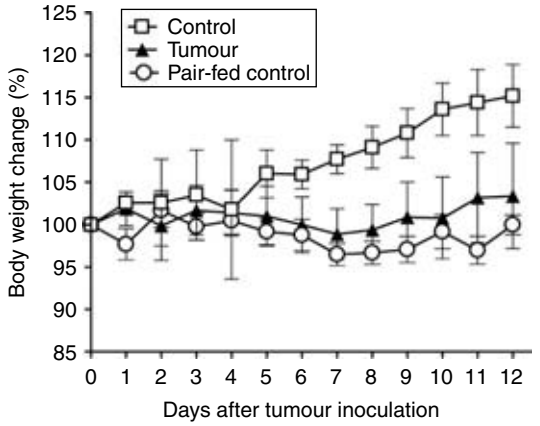

**Figure 1** Weight loss associated with tumour-induced cachexia in control (free-fed), tumour-bearing and pair-fed rats ($n=6$ in each group). $P<0.05$ (ANOVA) and $P<0.001$ for control group compared with each other (Student-Newman-Keuls post-hoc test).

**A revolution in the diagnosis of adrenal disorders: rapid multiplex quantitation of serum steroids by means of tandem mass spectrometry (MSMS)**

N. Lahlou[1,2], A. Canicio[1], J. Guibourdenche[1,2], Y. Rhayem[1,2], C. Gaillard[1], M. Fouré[3], M. Roger[4] & E. Clauser[1,2]

[1]Hôpital Cochin, Paris, France; [2]Université Paris-Descartes, Paris, France [3]PerkinElmer France, Villebon sur Yvette, France [4]IREM, Paris, France.

Context

The biological diagnosis of adrenal disorders is currently based on the quantitation of serum steroids using automated immunoassays. These direct assays often lack the required accuracy and precision and interlaboratory surveys show that performance characteristics of MSMS are far better than those of automated immunoassays.

Method

After liquid chromatography of serum extracts, steroids were quantified on Waters QuattroPremier mass-spectrometer by either targeting several informative steroids for the diagnosis of congenital adrenal hyperplasia (CAH), or by establishing a complete steroid profile using the multisteroid-CHS-kit from PerkinElmer.

Subjects

Group 1: 10 subjects with suspected adrenal tumour (hirsutism and abnormal ultrasound imaging), Group 2: 26 neonates with suspected CAH (positive screening and/or hypoglycemia), Group 3: 10 preterm neonates positive at neonatal screening), Group 4: 10 female neonates with isolated clitoris enlargement.

Results

Group 1: the complete profile including glucocorticoids, mineralocorticoids, and androgens identified in a single run the pathological secretory pattern, with increased levels of DHEA-sulfate, androstenedione and cortisol precursors. Group 2: 19 neonates had normal levels of cortisol and cortisol precursors, precluding the diagnosis of CAH, 6 neonates had excessive 17-hydroxyprogesterone levels, with low cortisol levels, suggesting a 21-hydroxylase defect, 1 neonate had increased 11-deoxycortisol and androstenedione levels, whith low-normal cortisol level, data consistent with 11-hydroxylase blockade. Group 3: the multisteroid assay showed moderately elevated 17-hydroxyprogesterone relative to term neonates, with very high DHEA-sulfate levels and normal cortisol levels. The same subjects had normal steroid profile at 3 months of age. Group 4: the profile of 10 serum steroids was normal, precluding a disorder of sex steroid secretion.

Conclusion

Rapid multisteroid assays in a single run using MSMS allow confirming or rejecting the diagnosis of adrenal tumour or CAH within a few minutes. At the same time, that avoids unnecessary therapy, shortens the delay of treatment starting, and drastically cut the investigational costs.

**Outcome of 232 patients with monolateral adrenal incidentaloma from a single centre**

M. Passeri[1], R. Antonelli[1], E. di Benedetto[1], S. Falcone[1], G. Franconi[1], M. Calanchini[1], M. Caprio[2] & A. Fabbri[1]

[1]Università tor vergata, Rome, Italy; [2]IRCCS san raffaele pisana, Rome, Italy.

Unsuspected adrenal masses, or incidentalomas, are increasingly found with the widespread use of thoracic and abdominal imaging. These masses may be hormonally active or nonfunctional and benign or malignant. Clinicians must determine the nature of the mass to decide what treatment, if any, is needed.

In our 17 year experience, we observed 232 patients (158 females, 74 males aged 22-91, mean age 69) affected with monolateral incidentaloma. 58 of them (25%) underwent adrenal surgery and pathology revealed: 40 cortical adenomas, 12 pheocromocitomas, and 6 primary or metastatic carcinoma. In patients with cortical adenoma, 20 patients presented hormonal findings consistents with Cushing disease, 10 with Conn disease, and 10 presented no hormonal alterations with a size mass >4 cm. In patients with feocromocitoma, only 6 patients presented elevations of cathecolamines/metanephrines. In patients with neoplastic disease, the size of the mass was, in our experience, predictive for malignancy. Among the patients under clinical follow up, 15 of them presented biochemical findings suggestive for subclinical cortisol hypersecretion, but they do not still meet the criteria for surgery, and only 7 patients switched from a silent/subclinical to a hyperfunctional hormonal condition, and/or showed a significant increase of the mass, that required surgery. In 6 of them pathology revealed a cortical adenoma, and in 1 metastasis of an occult lung carcinoma.

Our data suggest that the management of incidental adrenal masses is hampered by the limited studies of their natural history. The low prevalence of adrenal cortical carcinomas and the relatively low incidence of progression to hyperfunction call into question the advisability of current practice of intense, long-term clinical follow-up.

**Female patients with primary aldosteronism are diagnosed earlier and have a better outcome**

A. Pallauf, E. Fischer, S. Endres, M. Bidlingmaier, F. Beuschlein & M. Reincke
Ludwig-Maximilians-University, Munich, Germany.

Introduction
Primary aldosteronism (PA) is the most frequent curable form of hypertension. Hypokalemia is a late symptom of PA. Consequently, PA often is not diagnosed for many years. Our aim was to identify clinical and laboratory parameters in a large cohort of PA patients obtained during their first assessment.
Methods
96 consecutive patients prospectively studied since 2008 at the German Conn's Registry Center in Munich were eligible for this study. Diagnosis of PA was established using the criteria recommended by the Endocrine Society. Clinical data were analysed according to gender. Adrenal vein sampling revealed that 62.5% patients had a unilateral adenoma and 31.1% bilateral hyperplasia.
Results
Mean age at diagnosis was 52 years. Female patients ($n=34$, 35.4%) were diagnosed 10 years earlier than males (44.8 vs. 54.8 years). The time from initial recognition of hypertension to PA diagnosis was 12.8 years, 9.8 in females vs. 14.5 years in males. 33% of the females vs. 16.4% of the males presented with pre-hypertension (120-139/80-89 mmHg).
The prevalence of coronary heart disease was 5.2%, thrombosis 3.1%, stroke 2.1% and peripheral arterial occlusive disease 1%. Combined cardiovascular morbidity was similar in females and males (11.8 vs. 11.3%); women, however, had a higher risk of thrombosis (6% vs. 1.6%).
Specific treatment (adrenalectomy or mineralocorticoid antagonist treatment) reduced mean 24h-blood pressure from 150/94 to 134/83 mmHg ($P<0.01$).
Graded according to the WHO classification, 60% of all patients became normotensive, 67% of the operated patients still requiring antihypertensive medication (50% in females, 73% in males).
Conclusion
Women with PA have a high risk of cardiovascular diseases although they are diagnosed 10 years earlier than men and hypertension is often not as obvious. They have a 50% chance of reaching normotension without antihypertensive medication.

**Influencing factors on quality of life in patients with Addison's disease**

G. Meyer, A. Hackemann, M. Penna-Martinez & K. Badenhoop
J.W.G. University Hospital, Frankfurt, Germany.

Introduction
Several previous studies showed a reduced quality of life (QoL) in patients with Addison's disease, but only few data on the potential influencing factors are available so far.
Methods
We determined current QoL in 200 patients with Addison's disease using AddiQoL-36, a questionnaire developed in collaboration with the European consortium Euradrenal. Furthermore, data about symptoms, diagnosis and medication were collected by questionnaires and serum concentration of vitamin D 25-OH was measured.
Results
With increasing latency between first symptoms and diagnosis of adrenal insufficiency, QoL decreased highly significant ($P=<0.001$). Patients diagnosed in the first month after onset of symptoms had a significantly higher QoL compared to patients with a diagnosis delayed more than 12 months ($P=0.01$). Age at manifestation correlated negatively with QoL ($P=0.01$). Another important influencing factor was the incidence of additional autoimmunopathies. QoL decreased significantly with increasing autoimmune morbidity ($P=0,01$). Coeliac disease ($P=0.05$), atrophic gastritis ($P=0.01$) and especially primary ovarian failure ($P=0.01$) were highly correlated with reduced QoL. Vitamin D 25-OH serum level seemed not to be of influence. QoL did not vary significantly between patients with normal ($>20$ ng/ml), low ($<20$ ng/ml) or extremely low ($<10$ ng/ml) vitamin D concentrations.
Conclusions
Quality of life in patients with Addison's disease is impaired significantly in patients with autoimmune polyglandular syndrome and in those with manifestation at higher ages. Latency between first symptoms and diagnosis revealed as the most important factor influencing the patients quality of life even years after manifestation of the disease. Similar results have been seen in another study recently, emphasizing the relevance of this point.
A higher attention for this rare disease and an earlier diagnosis might lead to a sustained improvement of quality of life in Addison patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Differential methylation signature in benign and malignant cortisol producing adrenocortical tumors**

T. Åkerström, T. Ahmad, P. Hellman & P. Björklund
Uppsala University, Uppsala, Sweden.

Background
Adrenocortical carcinomas (ACC) are rare tumors with an incidence of 1–2 per million. Although rare, it is an aggressive endocrine cancer with poor prognosis. As of today there is no reliable diagnostic biomarker to distinguish benign tumors from malignant tumors. Global changes in DNA methylation and DNA promoter hypermethylation are important events in tumorigenesis. Promoter hypermethylation can cause silencing of tumour suppressor genes or lead to abnormal function of important cellular pathways. The purpose of this study was to investigate the changes in DNA methylation in cortisol producing adrenocortical carcinoma compared to benign cortisol producing adenomas.
Methods
DNA was extracted from 16 adrenocortical tumors and methylataion status was analyzed using the Infinium Human Methylation 450K BeadChip. Total RNA was isolated from 30 tumors, converted to cDNA and mRNA expression was analyzed by q-PCR using SYBR Green and GAPDH as internal control.
Results and discussion
Unsupervised hierarchical clustering showed an altered DNA methylation profile in ACCs compared to adenomas. CYP1B1, OTX1 and RASAL1 were identified as some of the most differentially hypermethylated genes. Aberrant methylation of CYP1B1 has been previously reported in nodular goiter, colorectal cancer and gastric carcinomas. CYP1B1 mRNA expression was significantly reduced in ACCs compared to adenomas. However, no significant difference in mRNA expression was observed for OTX1 and RASAL1. In conclusion, mRNA expression of CYP1B1 was significantly reduced in cortisol producing adrenocortical carcinomas compared to adenomas, expression of CYP1B1 might be used as a biomarker in distinguishing aggressive tumors from benign ones and also provide outlines for choosing the appropriate treatment.

**18-Hydroxycorticosterone, 18-hydroxycortisol and 18-oxocortisol in the diagnosis of primary aldosteronism and its subtypes.**

P. Mulatero[1], S. Morra di Cella[1], S. Monticone[1], J. Burrello[1], M. Galmozzi[1], M. Terzolo[2], C. Fulcheri[1], E. Gomez-Sanchez[3], C. Gomez-Sanchez[3] & F. Veglio[1]
[1]University of Torino, Torino, Italy; [2]University of Torino, Orbassano, Italy; [3]University of Mississippi, Jackson, MS, USA.

Diagnosis of primary aldosteronism (PA) is made by screening, confirmation testing and subtype diagnosis (CT scan and adrenal vein sampling, AVS). However, some tests are costly and unavailable in most hospitals. We evaluated

the role of serum 18-hydroxycorticosterone (s18OHB) and urinary and serum 18-hydroxycortisol (u and s18OHF) and 18-oxocortisol (u and s18oxoF) in the diagnosis of PA and its subtypes, aldosterone-producing adenoma (APA) and bilateral adrenal hyperplasia (BAH). We studied 62 patients with low-renin essential hypertension (EH), 81 PA (20 APA, 61 BAH), 24 patients with glucocorticoid-remediable aldosteronism, 16 patients with adrenal incidentaloma and 30 normotensives. We measured s18OHB, s18OHF and s18oxoF before and after saline load (SLT) and 24hour u18OHF and u18oxoF. PA patients displayed significantly higher levels of s18OHB, u18OHF and u18oxoF compared to EH and normals; APA patients displayed s18OHB, u18OHF and u18oxoF levels significantly higher than BAH patients. Similar results were obtained for s18OHF and s18oxoF. SLT significantly reduced s18OHB, s18OHF and s18oxoF in all groups but steroid reduction was much less for APA patients compared to BAH and EH. The s18OHB/aldosterone ratio after SLT more than doubled in EH, but remained unchanged in APA patients. In conclusions: u18OHF, u18oxoF and s18OHB measurements in patients with a positive ARR correlate with confirmatory tests and AVS in PA patients. If verified, these steroid assays would refine the diagnostic work-up for PA.

**MicroRNA profiling of benign and malignant adrenocortical tumors reveals potential biomarkers of recurrence**

O. Chabre[1], G. Assié[2], R. Libé[2], J. Bertherat[2], J. Feige[3] & N. Cherradi[3]
[1]Service d'Endocrinologie, Grenoble, France; [2]INSERM U567, CNRS UMR8104, Paris, France; [3]INSERM U1036, Grenoble, France.

Objective

To identify miRNAs predictors of poor prognosis in adrenocortical cancer.

Methods

Using microarrays, we evaluated the expression of 728 human miRNAs in six adenomas (ACAs) and twelve carcinomas (ACCs). The ACC group was composed of two subgroups A and B consisting of six recurrent (subgroup A) and six non-recurrent tumors (subgroup B). These two distinct subgroups have been characterized recently (de Reynies et al, 2009) on the basis of distinct gene expression profiles: comparison of global survival revealed a major difference in outcome in these two subtypes of ACC, with a very high rate of relapse and death within two years following surgery in the A subgroup.

Results

Twelve miRNAs were differentially expressed between ACCs and ACAs, 5 of which were down-regulated and 7 up-regulated in ACCs. The best discriminatory miRNAs between ACCs and ACAs were miR-195 and miR-335 which were down-regulated in ACCs. 29 miRNAs were differentially expressed between the two ACC subgroups A and B, with all discriminatory miRNAs more strongly expressed in A than in B carcinoma samples. Among them, miR-139-5p was the most powerful discriminatory miRNA between A and B subtypes with consistent up-regulation in recurrent carcinoma (A). Quantitative RT-PCR revealed that the levels of expression of miR-195 and miR-335 were similar in ACAs and normal adrenal cortex while strongly repressed in ACCs. Overexpression of miR-139-5p was confirmed in ACCs type A. These results were validated in a separate cohort of ten benign and twenty malignant samples (10 ACCs type A and 10 ACCs type B) using quantitative RT-PCR. Target prediction analysis revealed that predicted targets of these miRNAs are involved in biological processes which enhance tumor progression.

Conclusions

Our data suggest that adrenocortical cancer cells progressively switch from a high miR-195 and miR-335 status to a low miR-195 and miR-335 phenotype. miR-139-5P is a potential prognostic biomarker of recurrent ACCs.

**Prevalence and Characteristics of Familial Hyperaldosteronism: the PATOGEN study (Primary Aldosteronism in TOrino - GENetic forms).**

P. Mulatero, D. Tizzani, A. Viola, S. Monticone, T. Williams, J. Burrello, M. Galmozzi, C. Fulcheri, M. Chiarlo & F. Veglio
University of Torino, Torino, Italy.

Primary Aldosteronism (PA) is the most frequent cause of secondary hypertension and patients display an increased prevalence of cardiovascular events compared to essential hypertensives. To date, three familial forms of PA have been described and termed, familial hyperaldosteronism types I, II and III (FH-I to -III). The aim of this study was to investigate the prevalence and clinical characteristics of the three forms of FH in a large population of PA patients. Three hundred consecutive PA patients diagnosed in our unit were tested by long-PCR of the CYP11B1/CYP11B2 hybrid gene that causes FH-I and all available relatives of PA patients were screened to confirm or exclude PA and thus FH-II. Urinary 18-hydroxycortisol and 18-oxocortisol were measured in all familial PA patients. Two patients were diagnosed with FH-I (prevalence 0.66%) as well as 21 of their relatives, and clinical phenotypes of the 2 affected families varied markedly. After exclusion of families who refused testing and those that were not-informative, 199 families were investigated of which 12 were diagnosed with FH-II (6%) and an additional 15 individuals had confirmed PA; clinical and biochemical phenotypes of FH-II families were not significantly different from sporadic PA patients. None of the families displayed a phenotype compatible with FH-III diagnosis. Our study demonstrates that familial forms of hyperaldosteronism are more frequent than previously expected and reinforces the recommendation of the Endocrine Society Guidelines to screen all first-degree hypertensive relatives of PA patients.

**Intercurrent Illness Dose Regimen in Adrenal Insufficiency with a Dual Release Hydrocortisone Formulation Derived from Population Pharmacokinetic Modelling**

U. Simonsson[1], S. Skrtic[2], H. Lennernäs[1] & G. Johannsson[2]
[1]Uppsala University, Uppsala, Sweden; [2]Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden.

Patients with adrenal insufficiency need adjustment of the hydrocortisone (HC) dose during an intercurrent illness. Current recommendation to double the daily HC dose at each occasion does not consider the non-linear dose proportionality in bioavailability i.e. doubling the dose gives less than 100% increase in exposure. We have developed an intercurrent illness dose regimen for a once daily dual release HC tablet using population pharmacokinetic (POPPK) modeling.

Methods

Cortisol serum concentration time profiles were obtained in 62 patients after administraton of oral once daily dual release HC tablets (20–60 mg) on 116 occasions, and in healthy volunteers (after betametasone suppression) after single 5 ($n=14$) and 20 mg ($n=16$) doses. All data was simultaneously modeled using a POPPK modeling approach in NONMEM. Simulations were made in order to investigate optimal intercurrent illness dosing regimens. The safety of the optimal regimen was thereafter studied in a prospective study in patients with Addison's disease.

Results

Simulated data demonstrated that adding an additional dose at $8\pm2$ hours after the morning dose resulted in slightly higher peak concentrations for the second dose and increased cortisol levels during the evening and early night time. Giving three daily doses with 8-hour intervals resulted in no dose accumulation on the day after, but with cortisol levels during the night. The dual release HC b.i.d. or t.i.d. intercurrent illness regimen gives less fluctuations and higher cortisol concentrations in the afternoon compared to immediate release. Prospective collection of data in 173 patient years demonstrated that changing the dosing interval of the dual release tablets from o.d. to b.i.d. (or t.i.d.) during undercurrent illness was safe.

Conclusion

The daily dual release HC dose given twice or thrice daily with $8\pm2$ hours intervals during intercurrent illness increases the 24 h cortisol coverage and has been documented to be safe.

### Cornell product left ventricular hypertrophy in electrocardiogram in patients with primary aldosteronism

K. Takahashi, H. Nishimatsu, M. Akahane, Y. Honma & T. Fujita
University of Tokyo, Graduate School of Medicine, Bunkyo-ku, Japan.

Introduction
Left ventricular hypertrophy (LVH) is associated with increased morbidity and mortality. LVH defined by ECG (ECG-LVH) has been evaluated using standard voltage criteria by Sokolow and Lyon (SL-LVH) and more recently using the Cornell product criteria (CP-LVH). Evaluation of CP-LVH is beneficial in hypertensive patients: however, in patients with primary aldosteronism (PA) whose incidence of cardiovascular events is higher than essential hypertension (EHT), there are no data on CP-LVH. Our aim was to show the higher rate of ECG-LVH, both CP-LVH and SL-LVH, in PA.
Methods
During a 10-year period, the diagnosis of PA was made in 127 patients. During the same period, clinical characteristics and ECG of this group were compared with those of 127 patients with EHT matched for age, gender, and blood pressure.
Results
The prevalence of CP-LVH was 38% for PA, 22% for EHT (odds ratio (OR) = 2.1; 95% CI 1.2 to 3.6), and the prevalence of either CP-LVH or SL-LVH (CP/SL-LVH) was 54 and 34% (OR = 2.2; 95% CI 1.3 to 3.7), respectively. However, the prevalence of SL-LVH was 29 and 23% (OR = 1.3; 95% CI 0.75 to 2.3), respectively. The rate of ECG-LVH (CP-LVH, CP/SL-LVH, but not SL-LVH) increased with decreasing quartile of estimated GFR among PA (Cochran-Armitage $P$ trend = 0.0018, 0.0222), but not for EHT, indicating the strong 'kidney–heart interaction' in PA. In a multivariate logistic regression analysis, the presence of PA was an independent predictor of CP-LVH, CP/SL-LVH, but not for SL-LVH.
Conclusion
Patients with PA exhibit more CP-LVH than did EHT patients independent of blood pressure. CP-LVH clearly reveals the 'kidney-heart interaction' in PA. Thus, screening for CP-LVH to detect higher-risk patients should become a routine part of the evaluation of PA.

### Efficacy of long-term treatment with retinoic acid in patients with Cushing's disease

F. Pecori Giraldi[2,1], A. Ambrogio[2], M. Andrioli[1], F. Sanguin[3], I. Karamouzis[4], S. Corsello[5], C. Scaroni[3], E. Arvat[4], A. Pontecorvi[5] & F. Cavagnini[1]
[1]Istituto Auxologico Italiano, Milan, Italy; [2]University of Milan, Milan, Italy; [3]University of Padua, Padua, Italy; [4]University of Turin, Turin, Italy; [5]Catholic University of Rome, Rome, Italy.

Cushing's disease, i.e. cortisol excess due to an ACTH-secreting pituitary adenoma, is a rare disorder with considerable morbidity and mortality. Current therapeutic strategies include pituitary surgery, radiation, adrenalectomy and medical treatment with steroidogenesis inhibitors, as drugs aimed at the pituitary adenoma are as yet under investigation. Experimental data showed that retinoic acid restrains ACTH secretion by tumoral corticotrophes thus we decided to evaluate the efficacy of retinoic acid treatment in patients with Cushing's disease.
Methods
Seven patients with Cushing's disease (two men, five postmenopausal women) were started on 10 mg retinoic acid daily and dosage increased up to 80 mg/day for 6–12 months. ACTH, UFC and cortisol as well as clinical features of hypercortisolism were evaluated at baseline, during retinoic acid administration and after drug withdrawal.
Results
A marked decrease in UFC levels was observed in five patients: mean UFC levels on retinoic acid were 47–79% of baseline values and normalization in UFC was achieved in four patients. Plasma ACTH decreased by 10–35% in four responsive patients, including patients in whom UFC normalized while levels increased up to 130% of pretreatment values in one patient. Serum cortisol was unchanged during retinoic acid treatment except for a 40% decrease observed in one patient. Blood pressure, glycaemia and symptoms of hypercortisolism, e.g. facial plethora, ameliorated to a variable extent on treatment. Patients reported mild adverse effects, e.g. xerophthalmia, arthralgias.
Conclusions
Prolonged treatment with retinoic acid proved beneficial and well tolerated in five out of seven patients with Cushing's disease. This represents a novel, promising approach to medical treatment with Cushing's disease.
This study was funded by AIFA grant #FARM78F3YR.

## P53

### Relationship of current glucocorticoid dose with metabolic outcomes in CAH: analysis of the United Kingdom congenital adrenal hyperplasia adult study executive (CaHASE) cohort

T. Han[5], R. Stimson[3], A. Rees[6], N. Krone[4], D. Willis[1], S. Wild[4], G. Conway[5], W. Arlt[4], B. Walker[3], R. Ross[2] & X. CaHASE[1]
[1]Society for Endocrinology, Bristol, UK; [2]University of Sheffield, Sheffield, UK; [3]University of Edinburgh, Edinburgh, UK; [4]University of Birmingham, Edinburgh, UK; [5]University College London, London, UK; [6]Cardiff University, Cardiff, UK.

We have previously reported the following metabolic abnormalities were common in 203 adult patients with CAH: obesity (41%), hypercholesterolemia (46%), insulin resistance (29%), osteopenia (40%) and osteoporosis (7%) (Arlt *et al. JCEM* 2010 **95** 5110–21). The CAH patients were taking different glucocorticoid therapies at various doses ($n$ = 196): hydrocortisone ($n$ = 25 M, 26 W), prednisolone ($n$ = 21M,67W), dexamethasone ($n$ = 15M,22W) or combination therapy ($n$ = 4 M, 16 W). To test the hypothesis that glucocorticoid exposure mediates adverse metabolic outcomes, we converted current treatment regimens to prednisolone dose equivalents using three published models: British National Formulary (BNF), Rivkees (*Pediatrics* 2000 **106** 767–73) and Arlt (*JCEM* 2009 **94** 1059–67). The respective ratios for prednisolone:hydrocortisone:dexamethasone were 1:5:0.15, 1:4:0.057, and 1:5:0.125. The relationship of glucocorticoid dose and metabolic parameters was tested by treating dose as a continuous variable using regression analysis and as a categorised variable using ANOVA (with prednisolone dose equivalents in four categories: $<$2.5 mg ($n$ = 4 M, 16 W), 2.5$\leq$5.0 mg ($n$ = 12 M, 27 W), 5.0$\leq$7.5 mg ($n$ = 24 M, 57 W) and $>$7.5 mg ($n$ = 25 M, 31 W)). The mean prednisolone equivalent dose (men: 6.1:7.5:5.7, women: 5.1:6.0:5.0 mg/day) was different for the three models for both sexes ($P < 0.01$). There was no effect of dose in any of the three models as judged by ANOVA or univariate regression analysis on; BMI, waist circumference, triglycerides, HDL-cholesterol, insulin resistance (HOMA-IR) and femoral or lumbar bone mineral density. Partial correlation analysis (age and sex adjustments) showed significant relationships between dose and systolic (BNF: $r$ = 0.188, $P$ = 0.01; Rivkees: $r$ = 0.147, $P$ = 0.04; Arlt: $r$ = 0.189, $P$ = 0.01) and diastolic blood pressure (BNF: $r$ = 0.170, $P$ = 0.02; Arlt: $r$ = 0.154, $P$ = 0.03; except Rivkees: $r$ = 0.070, $P$ = 0.37) and for Rivkees model only, between dose and HDL-cholesterol ($r$ = 0.186, $P$ = 0.02) and HOMA-IR ($r$ = 0.175, $P$ = 0.04). Confounding factors in our analysis may include variable patient compliance with drug and duration of treatment. In conclusion, no published method for comparing glucocorticoid dose equivalence is superior to another. We found little impact of dose on individual metabolic parameters in adults with CAH.

## P54

**Frequency and causes of adrenal crises over life-time in patients with 21-hydroxylase deficiency**

N. Reisch[1], M. Willige[1], D. Kohn[2], H. Schwarz[3], B. Allolio[4], M. Reincke[1], M. Quinkler[4], S. Hahner[4] & F. Beuschlein[1]
[1]Klinikum der Universität München, München, Germany; [2]Ludwig-Maximilians-Universität München, München, Germany; [3]University Hospital Würzburg, Würzburg, Germany; [4]Universitätsmedizin Berlin Charité, Berlin, Germany.

Background
Adrenal crisis (AC) is a life-threatening complication in patients with congenital adrenal hyperplasia due to classical 21-hydroxylase deficiency (21-OHD). AC was defined as an acute state of health impairment which required i.v. glucocorticoid administration and hospital admission. No data on AC over life-time in 21-OHD is available.
Study design
In a retrospective study AC was studied following two approaches: a) questionnaire-based: 122 adult 21-OHD patients (50 men, 72 women, median age 35 years, range 18–69) completed a disease-specific questionnaire, b) patient chart based: charts of 67 21-OHD patients (32 males, 35 females, median age 31 years, range 20–66) were analyzed from diagnosis to last follow-up with regard to frequency and causes of AC since diagnosis.
Results
Evaluation of questionnaires revealed 257 AC in 4456 patient years (frequency 5.8 crises/100 patient years), while patient charts documented 106 AC in 2181 patient years (4.9 crises/100 patient years). The chart-based evaluation showed that gastrointestinal infections (29%) and salt-wasting crisis (18%) were the main causes of AC. In 14% the cause remained uncertain. There was no difference in the overall frequency of AC in males and females. AC mostly occurred during childhood, with more than 70% of AC in the first 10 years of life and one third of AC in the first year of life. Still 20% of cases of AC were observed in adults (>18 years).
Conclusion
Our longitudinal analysis demonstrates a significant risk of AC in patients with 21-OHD over life-time. Specific age-adapted and repeated crisis prevention training may help to reduce morbidity due to AC in 21-OHD.

**Urinary cortisol metabolites in corticotroph and adrenal tumours**

J. Brossaud, D. Ducint, B. Gatta, M. Molimard, A. Tabarin & J. Corcuff
Univ Hospital, Bordeaux, France.

We investigated whether urinary cortisol metabolites could help to diagnose patients with cortisol oversecretion either with benign adrenal or corticotroph tumours.
Liquid chromatography tandem mass spectrometric assay (LC-MSMS) of cortisol (F)m, cortisone, tetra-hydrocortisol (THF), allo-THF, tetra-hydrocortisone (THE), α-cortol, β-cortol, α-cortolone, α-cortolone and internal standard 6-α-methylprednisolone were assayed after deconjugaison and dichloromethane extraction. LC-MSMS was performed with an Acquity UPLC separative module and aTQD detector (Waters, Millport, USA).
In-patients of the endocrine department ($n=253$, 196F, 49 (20–74)years (median (2.5th–97.5th percentile) were control subjects ($n=175$ (N)), patients with active Cushing disease's ($n=35$, (CD)) or with adrenocortical tumours ($n=43$, (AS)). The latter were either secreting or non-secreting tumours (the former were subsequently operated and the latter followed-up). Initial diagnosis was made using routine tools including cortisol assays (Fr) performed by RIA (Diasorin, France).
Analytes excretions of the groups are presented in the table (ng/day). Log-transformed cortisol concentrations determined were significantly linearly correlated with a significant bias (Passing-Bablock regression).
Areas under the ROC curves (AUC) were >0.950 for cortisol, THF, α-cortol for the diagnosis of (CD) with an equal 39% sensitivity at 100% specificity for cortisol and α-cortol. Combined analysis of cortisol and α-cortol improved the sensitivity.
AUC were >0.700 for cortisol and β-cortolone for the diagnosis of whole population of (AS). Based on urinary cortisol, 0800 h ACTH and cortisol in plasma, AS tumours could be non-secreting or secreting (at least two positive criteria). AUC were >0.800 for cortisol, β-cortol and β-cortolone for the diagnosis of secreting (AS).
(F) and β-cortolone and to a minor extent both cortols are useful parameter to investigate benign (AS) and (CD). Whether their combined use can facilitate the diagnosis of these diseases has to be investigated in prospective studies.

**Table 1**

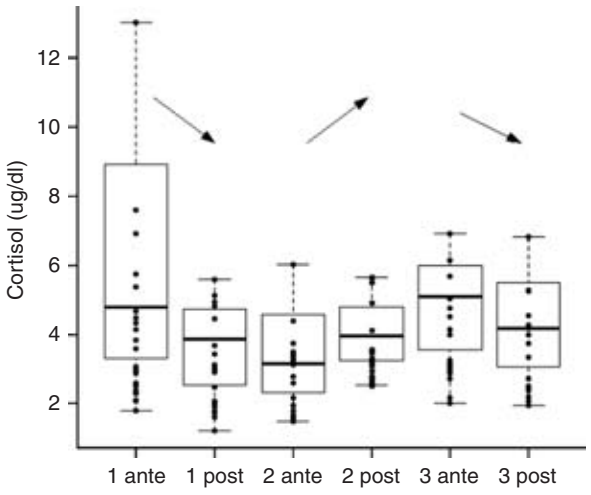
**Soundwave's effect on hematic cortisol level: a pilot study**

C. Olcese[1,2,3], A Fiorin. Damiani[3], R. Dittadi[2], P. Borasio[1] & L. Bartoloni[2,1]
[1]University of Ferrara, Ferrara, Italy; [2]ULSS 12, Venezia, Italy; [3]DENSO, Vittorio Veneto, Italy.

In order to prove that different sound-waves trigger different human hormones release by the way of their vibratile impact on the bodies, we exposed 30 testers (heterogeneous for gender, age and lifestyle) to different frequencies of noisy sound-waves (not melodic and rhythmic music). We organized three sessions in different days and with different waves frequencies: 1st at 40–115 Hz, 2nd at 8200–8500 Hz, 3rd with mixed radio-waves.
Blood cortisol level was measured with the Access Cortisol Kit (Beckman).
An hour of exposure to a low frequency sound (40–115 Hz) diminishes the hematic cortisol concentration in 86% of the testers. On the other hand, high frequencies (8200–8500 Hz). raise cortisol values in 65% of the testers in just 30-40 min.



After each session, testers expressed their opinion on the experience. Appreciation of low frequencies corresponds to lowered cortisol levels. Dislike of high frequencies corresponds to increased cortisol values, while displeasure of mixed radio-waves (low frequencies) is not associated to higher cortisol levels. This finding suggests that the emotional status does not interfere with cortisol release, as much as the physical properties of sound-waves do.
This pilot study gave several interesting clues, to be confirmed in a larger study: i) high frequencies raise cortisol level, while low frequencies diminish it; ii) this change is not correlated to the emotional response to the exposure; iii) older testers seem to respond in a different way.
Each column refers to one sample collection. The black dots represent each individual cortisol value in Ug/dl. The black bar shows the media of the distribution. The lower limit of the box indicates the middle point between the lowest value and the media while the higher limit indicates the middle point between the higher value and the media.

### Reevaluation of the 4 mg intravenous dexamethasone suppression test for differentiation of Cushing's disease from pseudo-Cushing's syndrome

M. Nouvel[1], M. Rabilloud[2], V. Raverot[2], C. Pignard[2], J. Vouillarmet[2], C. Thivolet[2], E. Jouanneau[2], F Borson Chazot[1], M. Pugeat[1] & G. Raverot[1,3]
[1]Hospices Civils de Lyon, Lyon, France; [2]Hospices Civils Lyon, Lyon, France; [3]Faculté de Medecine Lyon-Est, Lyon, France.

Context
Differentiating Cushing's disease (CD) from pseudo-Cushing's syndrome (PCS) is one of the most challenging problems since no biological test is yet perfect. Almost 30 years ago our group demonstrated the interest of 4 mg i.v. dexamethasone suppressing test (DST) to differentiate obese patients to CD.
Objective
To reevaluate the diagnostic accuracy of the 4 mg i.v. DST in carefully selected patients with PCS and CD.
Design
Patients recruited from November 2008 to July 2011 were retrospectively studied. The criteria for PCS were: presence of clinical and biochemical (Urinary Free Cortisol and/or 1 mg DST) features compatible with CS, normal pituitary MRI and at least one year of clinical and biochemical follow-up.
Diagnosis of CD has been confirmed by pathology in 29 patients operated, three patients with abnormal MRI were medically treated.
Patients underwent 4 mg dexamethasone infusion according to Abou-Samra *et al* (*JCEM* 1985). The diagnosis of CD is based on absence of ACTH and cortisol suppression at 8 am on day 2.
Results
68 patients (54F/14M), 32 with CD and 36 with PCS were included. Age and BMI were similar between groups but hirsutism, proximal amyotrophy, and vascular weakness were significantly more frequent in the CD group ($P<0.001$).
Midnight plasma cortisol, 8 am cortisol and ACTH after 4 mg DST were respectively associated with a 95.4% (86.5–99), 90.5% (81.8–96.7) and 98.4% (92.1–99.6) diagnostic accuracy. Cortisol and ACTH threshold used in our endocrine units to affirm the CD (respectively 100 nmol/l and 5 ng/l) yielded more accurate sensibility (93.8%) and specifity (86.1%) than midnight plasma cortisol cut-off of 207 nmol/l retained by the Endocrine and European Societies which was associated with a 96.8% of sensibility and 58.1% of specificity.
Conclusion
4 mg i.v. DST is a very easy and accurate test to distinguish CD from PCS and deserve a place in the CD diagnosis assessment.

## P58

### Treatment with mineralocorticoid receptor antagonists in 'subclinical' cases with adrenal adenomas and autonomous aldosterone secretion

L. Papanastasiou, T. Pappa, P. Tsounas, V. Tsiavos, A. Markou, E. Tseniklidi, M. Anastasakou, S. Fountoulakis, A. Prevoli & G. Piaditis
'G. Gennimatas' General Hospital, Athens, Greece.

Introduction
Patients with adrenal adenomas appear to exhibit an appreciable prevalence of autonomous aldosterone secretion (AAS). Our aim was to evaluate the anti-hypertensive effect of targeted therapy with mineralocorticoid receptor (MR) antagonists in AAS patients.
Patients and methods
We studied 60 hypertensive patients, 21 males and 39 females, harboring an adrenal adenoma with AAS. All patients were receiving combination of anti-hypertensive treatment with inadequate blood pressure (BP) control. Subjects of Conn's syndrome were excluded. The diagnosis of AAS was established using a modified saline infusion test (MSI), i.e. saline infusion after dexamethasone administration. Cut-off levels were developed using 72 normotensive controls with normal adrenal imaging (post MSI aldosterone levels 67 pmol/l). Following hormonal evaluation, patients were switched to receive aldosterone antagonist treatment (spironolactone or eplerenone) and followed up for eight weeks. Self-reported systolic and diastolic BP values were recorded before and after treatment modification.
Results
The mean (S.D.) age of our study population was 54.80 (10.35) years and the body mass index 30.35 (4.33) kg/m$^2$. The serum potassium concentration was 3.8 (0.4) mEq/l and the post MSI aldosterone levels 226.7 (214.1) pmol/l. The use of MSI led to the identification of 30/60 AAS patients that would be undiagnosed using the Endocrine Society guidelines. Treatment with MR antagonists resulted in a marked decrease of maximum BP values (systolic BP: 161.4 (23.6) after vs 126.3 (10.2) mmHg before and diastolic BP: 97.9 (12.5) after vs 79.7 (7.4) mmHg before respectively, $P<0.001$ in both cases; Fig. 1).
Conclusions
We showed a remarkable anti-hypertensive effect of MR antagonists in adrenal adenoma patients with AAS. These patients would have been unrecognized without the use of the recently proposed cut-offs for AAS diagnosis. Our findings await validation with further cohorts. Targeted therapy is expected not only to adequately control BP, but also reduce the adverse aldosterone-mediated cardiovascular actions.

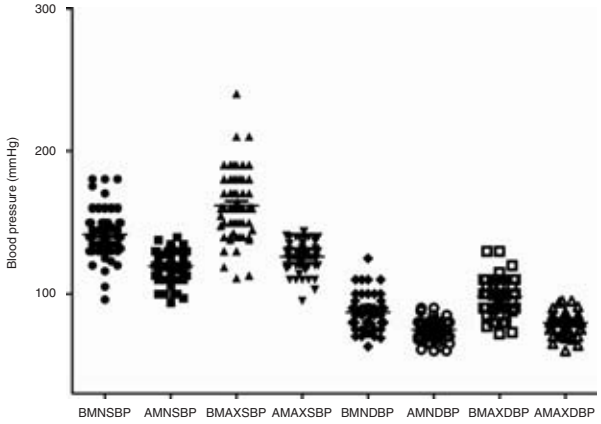

**Figure 1** Minimum (MIN) and maximum (MAX) SBP and DBP values before (B) and on mineralocorticoid receptor antagonist treatment (A) in 60 patients with AAS, $P<0.001$ in all cases. SBP: systolic blood pressure, DBP: diastolic blood pressure.

**The effects of the acute administration of alprazolam, a benzodiazepine, in patients with subclinical Cushing's syndrome**

R. Berardelli, I. Karamouzis, E. Marinazzo, A. Picu, V. D'Angelo, E. Ghigo, E. Arvat & R. Giordano
University of Turin, Turin, Italy.

Subclinical Cushing's syndrome (SCS) is a status of altered hypothalamo-pituitary-adrenal (HPA)-axis secretion in the absence of the classical signs or symptoms of overt cortisol excess. Among the various tests used for the diagnosis of SCS, the 1-mg dexamethasone test (DST) is the most used. Alprazolam (ALP), a benzodiazepine activating GABAergic receptors, possesses clear centrally-mediated inhibitory effects on ACTH and cortisol secretion in normal subjects, while it does not modify ACTH and cortisol hypersecretion in patients with overt hypercortisolism.

Aim of the study was to verify the effect of alprazolam (1 mg p.o. at 23.00 h) on the cortisol response to DST test (1 mg at 24.00 h) in 22 patients with adrenal adenomas (AA) and SCS (14♀ and 8♂, age: 66.3±1.8 years), 11 patients with non-functioning AA (NF, 7♀ and 4♂;55.9±2.9), 10 patients with overt Cushing's syndrome (five of adrenal nature, CS, 4♀ and 1♂,42.0±3.8; 5 with Cushing's disease, CD, 4♀ and 1♂,58.0±5.6). 14 normal subjects (NS, 9♀ and 5♂;55.8±2.2) were enrolled as controls. SCS was defined by a post-DST cortisol level $>1.8$ μg/dl and one of the following: midnight serum cortisol $>7.5$ μg/dl, ACTH $<5$ pg/ml or UFC $>100$ μg/24 h. ALP reduced cortisol secretion after DST in patients with SCS ($P<0.05$), while it was ineffective in CS and CD patients. ALP pre-treatment reduced cortisol values $<1.8$ μg/dl in five patients with SCS but in none CS or CD. All NF and NS showed cortisol levels $<1.8$ μg/dl after DST and ALP+DST.

These data demonstrate that GABAergic activation by ALP still modulates adrenal hyperfunction in patients with subclinical hypercortisolism but not in those with overt disease, suggesting only a partial autonomous adrenal cortisol secretion in SCS. The clinical usefulness of ALP to increase the sensitivity of 1-mg DST in distinguishing functional from organic subclinical hypercortisolism should be confirmed.

**Is isolated secondary adrenal insufficiency more frequent than autoimmune Addison's disease?**

A. Kasperlik-Zaluska[1], B. Czarnocka[1], W. Jeske[1], L. Papierska[1], A. Hulting[2], S. Bensing[2], P. Crock[3] & O. Kampe[4]
[1]The Medical Centre for Postgraduate Education, Warsaw, Poland; [2]Karolinska Institute, Stockholm, Sweden; [3]John Hunter Hospital and Faculty of Health University of Newcastle, Newcastle SW, NSW, Australia; [4]Uppsala University, Uppsala, Sweden.

Similarly as in autoimmune Addison's disease (AAD), diagnosed in about 80% of primary adrenal insufficiency, idiopathic isolated secondary adrenal insufficiency (ISAI) seems to have an autoimmune origin.

Within the last 35 years we have registered in our Department 325 patients with ISAI (F/M ratio 10.9) aged 17–87 years. In comparison, we have in our registry 241 patients with AAD, collected within over 40 years. The diagnosis of ISAI was based on clinical examination and hormonal, immunological and imaging studies. The hormonal investigations: cortisol and plasma ACTH (circadian rhythm), TSH, LH, FSH, PRL, fT4, androgens, E2, testosterone, Synacthen-stimulation test, urinary excretion of cortisol. Immunological studies:antithyroid and pituitary autoantibodies with an immunoblotting assay (with human pituitary cytosol as an autoantigen in 65 patients. A corticotroph-specific transcription factor (Tpit) was investigated as a candidate autoantigen. MRI of the pituitary – in a part of cases.

Results

In all ISAI patients basal cortisol and ACTH levels were found to be below the lower normal limit while Synacthen significantly stimulated cortisol secretion. Various autoimmune disorders were detected in 215 patients, the most frequently thyroid diseases (mainly hypothyroidism), vitiligo, premature ovarian failure, pernicious anemia and T1DM. The thyroid autoantibodies were found in 65%, while pituitary autoantibodies in 34% of patients under study. Tpit was identified as a minor antigen in 10.5% of of the investigated patients. Partially enpty sella was the most frequent imaging finding.

Conclusions

ISAI appeared to be more frequent than AAD. 2/ Association of various autoimmune disorders in 66% of ISAI patients suggests autoimmune origin of the idiopathic isolated secondary adrenal insufficiency.

**Dyslipidemia in patients with adrenal incidentaloma with and without subclinical hypercortisolism and diabetes mellitus.**

B. Masserini, V. Morelli, S. Palmieri, V. Zhukouskaya, E. Cairoli, C. Eller-Vainicher, E. Orsi, PBeck- Peccoz & I. Chiodini
Università degli Studi di Milano, Milan, Italy.

Introduction

Patients with adrenal incidentalomas (AI) and subclinical hypercortisolism (SH) are thought to have increased incidence of cardiovascular risk factors, including diabetes mellitus (DM) and hypertension. Data regarding dyslipidemia are scarce. The aim of this study is to evaluate the possible influence of SH on lipid pattern in relation to the presence/absence of DM.

Methods and design

276 AI patients were enrolled (168 F, 108 M), 55 with diabetes (AIDM+) and 221 without DM (AIDM−). As the presence of dyslipidemia is a common condition associated to DM, 83 age-, BMI- and gender-matched type 2 DM patients (CDM+) and 77 euglycemic subjects (CDM−) served as controls. SH was diagnosed in 49 patients in the presence of at least two out of these three parameters: cortisol levels after 1 mg dexamethasone suppression test $>3$ μg/dl, ACTH levels $<10$ pg/ml, and 24 h urinary free cortisol levels $>70$ μg/24 h. The prevalence of dyslipidemia was evaluated according to ATP III criteria. No subject was taking anti-dyslipidemic drugs.

Results

The prevalence of dyslipidemia tended to be higher, but not statistically significant, in AIDM+ in respect to CDM+ subjects (63.6 vs 54.2%, respectively, $P=0.27$), and was similar between AIDM− and CDM− (23.0 vs 20.8%, respectively, $P=0.68$). No difference was observed between AI patients with and without SH, in both DM and euglycemic groups. Considering the whole group of AI patients, the presence of dyslipidemia was associated with DM (OR 4.88, 95%CI 2.43–9.80, $P=0.0001$) and age (OR 1.03, 95%CI 1.00–1.06, $P=0.047$) and not with BMI (OR 1.02, 95%CI 0.96–1.08, $P=0.55$), and SH (OR 0.83, 95%CI 0.39–1.76, $P=0.62$).

Conclusions

In patients with adrenal incidentaloma, dyslipidemia seems to be associated to diabetes mellitus and not to subclinical hypercortisolism.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P62

**Prevalence of primary aldosteronism in Chinese patients with resistant hypertension**

W. Wang, Y. Jiang, X. Sang, T. Su, B. Cui, J. Ye, J. Cai, J. He, C. Liu & G. Ning
Shanghai Clinical Center for Endocrine and Metabolic Diseases; Laboratory Endocrine and Metabolic Diseases of Institute of Health Science, Shanghai JiaoTong University School of Medicine, Shanghai, China.

Background

Studies across the world have unveiled different prevalence of primary aldosteronism (PA) in distinct geographical areas and human races. However, owing to disparities in methodology and recruitment, the true incidence is still open. Especially information in Asian resistant hypertension is rare, so we determined to investigate the prevalence of PA in this population.

Methods

We launched a large-scale, hospital-based national survey and enrolled 1656 patients with resistant hypertension finally. Serum aldosterone and plasma renin

activity were measured in every subject and ARR (aldosterone-to-renin ratio) was calculated to screen PA. Positive patient ARR > 20 underwent intravenous saline infusion test, and diagnosis of PA was established if post-saline aldosterone was above 8 ng/dl.
Results
Among 1656 patients with resistant hypertension, 494 (29.8%) were screened positive on the basis of ARR > 20 and underwent intravenous saline infusion. The diagnosis of PA was established in 118 (7.1%) subjects according to an unsuppressed post-saline aldosterone (>8 ng/dl). Prevalence of PA decreases with aging and so do aldosterone and renin activity level. Data show no significant gender difference in prevalence, however, women intrinsically have lower PRA level and thus higher ARR, due to which some screening strategies may require further modification.
Conclusion
The prevalence of primary aldosteronism in Chinese patients with resistant hypertension is relatively lower compared with previously reported data from other populations.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P63

**Genetic, anthropometric and metabolic features of adult norwegian patients with 21-hydroxylase deficiency**

I. Nermoen[1,2], I. Bronstad[3], K. Fougner[4], J. Svartberg[5,6], M. Øksnes[3,7], E. Husebye[3,7] & K. Løvås[3,7]
[1]Akershus University Hospital, University of Oslo, Lørenskog, Norway; [2]Akershus University Hospital, Lørenskog, Norway; [3]University of Bergen, Bergen, Norway; [4]St Olavs University Hospital, Trondheim, Norway; [5]University Hospital of North Norway, Tromsø, Norway; [6]University of Tromsø, Tromsø, Norway; [7]Haukeland University Hospital, Bergen, Norway.

Objective
The aim of this study was to determine genetic, anthropometric and metabolic features in an unselected population of adult Norwegian patients with classical 21-hydroxylase deficiency (21OHD).
Patients,
Methods, and design
Sixty-four 21OHD-patients participated (23 men, 41 women; mean age 40.3 (range 19–72) in a cross-sectional study including DNA sequencing of the CYP21A1P-CYP21A2 locus, anthropometric measurements including dual X-ray absorptiometry (DXA) scanning, and biochemical analyses. The results were compared with reference cohorts from the general population.
Results
We identified four novel and plausibly disease-causing CYP21A2 mutations. Gene deletions/conversions (42.1% of alleles), the point mutations I2splice (23.0%) and I172 N (22.2%) were common. The genotype corresponded to clinical phenotype in 89% of the patients. Reduced final height was more pronounced in the men; 168.2 cm (151–186) (mean and range) than in the women 159.1 cm (144–173). The prevalence of osteopenia was 44% in the men and 29% in the women. Both men and women had normal body mass index, but markedly increased fat mass compared with the normal population. Diastolic blood pressure was higher than normal. Only 20% of the women had testosterone levels in the normal range; 13% of the men had testosterone levels below normal.
Conclusion
In this population-based survey of 21OHD we identified four novel mutations and high concordance between genotype and phenotype. The patients had reduced final height, with high frequency of osteopenia in the men, increased fat mass, and increased diastolic blood pressure. These results indicate unfavourable metabolic status and need for improvement of the therapy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P64

**Relationship between plasma dexamethasone level and cortisol in the overnight dexamethasone suppression test**

B. Åsvold[1,2], V. Grill[1,2] & M. Bjørgaas[1,2]
[1]University Hospital, Trondheim, Norway; [2]Norwegian University of Science and Technology Trondheim, Trondheim, Norway.

The 1-mg overnight dexamethasone suppression test (DST) is a screening test for endogenous Cushing's syndrome (CS). The principle is that dexamethasone (D) will suppress ACTH and cortisol (C) secretion in healthy individuals, but not in CS. We have studied the associations between D and C concentrations in patients without CS after 1-mg DST.
Methods
On suspicion of CS, 59 patients received 1-mg D at 23 p.m. and next day at 8 a.m. blood was drawn for C and D. Of 56 subjects with successful measurements, three were diagnosed with CS., C (reference 8 a.m. 142–651 nmol/l) and D were measured with in-house methods. We aimed to investigate if there was a cut-off for plasma D below which C was not suppressed using polynomial regression. Data were analyzed using Stata version 10.1 (StataCorp, etc.). The study was exempted from ethical review by the regional medical ethics committee and approved without need for informed consent.
Results
Median post-test C in the 53 subjects without CS was 48 nmol/l (IQR 28–81) (to convert to μg/l, divide by 2.548). Mean post-test D was 11.7 nmol/l (SD 5.9; range 0.8–25.7). Three subjects had D < 5.0 nmol/l, and in these, C was not suppressed. Among 50 subjects with -D > 5.0 nmol/l, no association of D with C was found. In the regression model, post-test D was associated with C ($P < 0.001$ Figure 1A), and the regression line suggested a strong negative association when D was <5.0 nmol/l, but no association when D was >5.0 nmol/l ($P = 0.55$; Figure 1A).
Conclusions
This study of the 1-mg DST suggests that 8 a.m. plasma dexamethasone <5.0 nmol/l is insufficient to suppress serum cortisol. Among people who achieved 8 a.m. plasma dexamethasone >5 nmol/l, there was no association between post-test dexamethasone and cortisol.

**Mechanisms of gastroprotective action of corticotropin-releasing factor (CRF): involvement of CRF receptor subtypes 1 and 2**

L. Filaretova, T. Bagaeva, O. Morozova & M. Myazina
Pavlov Institute of Physiology, St. Petersburg, Russian Federation.

Exogenous corticotropin-releasing factor (CRF) induces an increase in glucocorticoid production and also may protect the gastric mucosa against stress-induced injury. However, it remained unknown whether glucocorticoids released in response to CRF injection contribute to the gastroprotective effect of CRF. In the present study we investigated whether exogenous CRF may protect

the gastric mucosa against gastric injury through involvement of glucocorticoids and, consequently, through CRF receptor subtype 1. Gastric injury was induced by 3 h cold-restraint stress (at 10 °C) or indomethacin (35 mg/kg) in conscious rats as well as by 3.5 h gastric ischemia-reperfusion in anaesthetized animals. We compared the effects of CRF administration (1.25 and 2.5 μg/kg, i.p.) on the gastric erosion in rats with normal and deficient corticosterone production as well as in rats with normal and occupied glucocorticoid receptors (by RU-38486, 20 mg/kg). Glucocorticoid deficiency was created by metyrapone (30 mg/kg). The selective CRF receptor subtype 2 antagonist, astressin2-B, was also used. Administration of CRF markedly increased plasma corticosterone levels and significantly suppressed the occurrence of gastric erosion induced by each stimulus. Metyrapone injected shortly before CRF administration caused a fast inhibition of CRF-induced corticosterone response and attenuated the protective effect of CRF on the gastric mucosa against the stress- and indomethacin-induced erosion. The gastroprotective effect of CRF was also attenuated by the pretreatment rats with glucocorticoid receptor antagonist RU-38486 in stress and indomethacin ulcerogenic models. Metyrapone and RU-38486 did not influence the protective effect of CRF on the gastric mucosa against ischemia-reperfusion-induced lesion. At the same time the protective effect of CRF on the gastric mucosa against ischemia-reperfusion-induced lesion was prevented by astressin2-B. The results obtained suggest that exogenous CRF may protect the gastric mucosa through involvement of glucocorticoids and, consequently, through CRF receptor subtype 1 as well as through CRF receptor subtype 2.

**Comparison of salivary cortysol by chemiluminensce and mass spectometry in hypercortilosism**

G. Marcelli, C. Concettoni, V. Scocco, M. Brugia, G. Tirabassi, L. Trementino, M. Boscaro & G. Arnaldi
Ospedali Riuniti, Ancona, Italy.

BACKGROUND
The determination of Night Salivary Cortisol (NSC) is a useful survey in the screening for hypercortilosism. Study data about its usefulness, even when different methods of dosage are used, are anyway scarce.
OBJECTIVE
To compare the diagnostic performance in the NSC dosage of the chemiluminescence method (CLIA) and of mass spectrometry (LC-MS/MS).
METHODS
Saliva samples were taken at 11:00 pm in 36 healthy volunteers and in 10 patients with Cushing's syndrome at the diagnosis. Each subject provided 2 saliva samples which were used for the NCS dosage by CLIA and with LC-MS/MS.
RESULTS
The controls had NSC values in LC-MS/MS (0.89l ± 0.37 ng/ml; range 0.10–1.89) significantly lower than the Cushing ones (3.18l ± 1.86 ng/ml; range 0.98–6.19); the same using CLIA: the NCS in the controls (0.40 ± 0.22 mcg/dl; range 0.18–1.05) was significantly lower than the Cushing ones (1.43 ± 0.66 mcg/dl; range 0.02–2.29). The diagnostic performance in LC-MS/MS [AUC 0.94 (0.86–1.02] was a bit higher than that of the CLIA [AUC 0.89 (0.71–1.07)]. The cutoff able to guarantee the highest sensitivity and specificity was calculated through the ROC curve, and it was to 1.2 ng/ml in LC-MS and 0.58 mcg/dl in CLIA. In LC-MS/MS a 90% sensitivity and a 88% specificity were obtained; for CLIA, a 90% sensitivity and a 84.8% specificity; if the cut off provided from the lab was used (0.2 mcg/dl), an unacceptably low performance was obtained. The values in CLIA related significantly to those in LCMS/MS ($r$ 0.9).
CONCLUSIONS
This is the first study which compares a CLIA method with a method such as LC-MS/MS. Our data demonstrate that the cutoffs are highly influenced by the method being used. The analyzed methods can have a similar performance, provided the cutoffs are redefined in the single labs.

**Renin-angiotensin-aldosterone system and inflammation - new aspects of an old system: results from the study of health in pomerania**

A. Grotevendt, H. Wallaschofski, M. Nauck, R. Rettig, W. Hoffmann & A. Hannemann
University Medicine, Ernst-Moritz-Arndt University, Greifswald, Germany.

Objective
The main physiological function of the renin-angiotensin-aldosterone system (RAAS) is the regulation of water and salt homeostasis as well as arterial blood pressure. In addition, the RAAS is proposed to be involved in the pathophysiology of several diseases like hypertension, vascular remodelling, atherosclerosis, insulin resistance and type 2 diabetes mellitus. In a cohort study in north-east Germany, we investigated the association of plasma renin- (PRC) or plasma aldosterone concentrations (PAC) with inflammatory biomarkers.
Design/Measurements
Our study population included 2,892 individuals from the first follow-up of the population-based Study of Health in Pomerania (SHIP-1). The associations of PRC or PAC with the inflammatory biomarkers fibrinogen (FIB), white blood cells (WBC) and high sensitive C-reactive protein (hs-CRP) were determined. Multivariable logistic regression models were calculated.
Results
Subjects with high PAC (>75th percentile) had higher odd ratios (OR) for increased plasma FIB levels (>4.28 g/l, OR 1.55; 95% CI 1.08–2.22) compared to those with low PAC (<25th percentile). Similar results were found for the association of PRC with FIB levels (>4.28 g/l, OR 2.36; 95% CI 1.62–3.45). Furthermore, subjects with high PRC had higher odd ratios for increased WBC counts (>9.1 Gpt/l, OR 2.57; 95% CI 1.79–3.69) and hs-CRP levels (>5.54 mg/l, OR 1.48; 95% CI 1.02–2.13). In a subsample analysis including normotensive individuals who did not take RAAS-altering medication, high PRC (>75th percentile) were associated with higher odd ratios for increased FIB levels (>4.0 g/l, OR 1.92; 95% CI 1.14–3.23) or WBC counts (>9.3 Gpt/l, OR 2.62; 95% CI 1.53–4.47).
Conclusion
High PAC or PRC are associated with inflammatory biomarkers, indicating a link to inflammatory processes within the general population.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P68

**MGMT expression in human adrenocortical carcinoma cell lines and tissues and effects of temozolomide on tumor cell growth.**

P. van Koetsveld, R. Feelders, F. Dogan, R. van den Dungen, W. de Herder & L. Hofland
Erasmus MC, Rotterdam, The Netherlands.

Background
In case of inoperable disease or tumor recurrence, there are only a few medical treatment options for patients with adrenocortical carcinoma (ACC). The oral alkylating drug Temozolomide (TMZ) shows efficacy in a subset of patients with melanoma, glioblastoma or pancreatic neurendocrine tumours. Response to TMZ seems determined by the tumoral expression level of the DNA repair enzyme O(6)-Methylguanine-DNA methyltransferase (MGMT).
Aims
To evaluate the effects of TMZ on human ACC.
Methods
The human ACC cell lines H295, HAC-15 and SW13 were treated with increasing concentrations of TMZ (range: 1–100 μM). Cells were harvested for determination of cell number (after 72 and 144 h of incubation) or for DNA fragmentation (apoptosis; after 72 h). By Colony Forming Assay (CFA) we determined the effect of TMZ on surviving fraction (SF) and colony size (CS). MGMT gene promoter methylation was determined with Cobra technique in the cell lines, 4 normal adrenals (NA) and 16 ACC. Expression of MGMT mRNA was determined by RT-qPCR (mRNA) and by Immunohistochemistry (protein) in the cell lines, 4 NA and 7 ACC.
Results
H295, HAC-15 and SW13 cell lines showed a time- and dose-dependent inhibitory response to TMZ (EC50 17.6 ± 1.0 μM; 17.0 ± 1.1 μM and 41.6 ± 1.1 μM, resp.). In addition, TMZ induced a dose-dependent stimulation of DNA-fragmentation. CFA showed that TMZ decreased SF in H295, HAC15 and SW13 (−85 ± 8%, −82 ± 10% and −57 ± 12%, resp). CS was significantly decreased

in H295 and SW13 (−45±7% and −31±10%, resp.). Partial methylation of the MGMT promoter was found in the 3 cell lines, in 1/4 NA and in 3/16 ACC. MGMT mRNA expression was present in all cell lines, NA and in 6/7 ACC. The cell lines expressed MGMT protein homogeneously, with the strongest staining in the SW13 cells. NA and 3/7 ACC expressed MGMT in a heterogeneous manner.
Conclusions
ACC variably express MGMT mRNA and protein. TMZ, at pharmacological concentrations, is effective in ACC cell lines expressing MGMT, suggesting that other factors determine sensitivity to TMZ as well. However, the cell line with the highest MGMT mRNA and protein level showed the lowest sensitivity to TMZ. One of the effects of TMZ on ACC cell growth is the induction of apoptosis.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**New quick cortisol assay during adrenal vein sampling in patients with primary aldosteronism**

T. Yoneda, S. Karashima, M. Demura, N. Oda, S. Mori, M. Kometani, O. Masashi, A. Hashimoto, T. Sawamura, M. Yamagishi & Y. Takeda
Kanazawa University, Kanazawa, Japan.

Background
Adrenal vein sampling (AVS) is the gold standard test for identification of unilateral primary aldosteronism (PA) which is curable by surgery, but is a difficult procedure with low success rates. Rapid cortisol assays during AVS improved AVS success rates.
Methods
We have developed a gold nanoparticles based immunochromatographic quick cortisol assay (QCA) in which cortisol concentration could be measured both quantitatively and semi-quantitatively within 6 minutes. We performed a prospective randomized controlled study to evaluate the success rate of AVS incorporating our new QCAs at Kanazawa University Hospital. Ninety PA patients were randomly assigned to undergo AVS using quantitative QCA (quantitative QCA group, $n=30$), AVS using semi-quantitative QCA (semi-quantitative QCA group, $n=30$) or AVS without QCA (control group, $n=30$). We next evaluated the usefulness of semi-quantitative QCA at 4 centers: Kanazawa University Hospital and 3 centers with initial low AVS success rates. We randomly assigned 151 PA patients to undergo AVS using semi-quantitative QCA (semi-quantitative QCA group, $n=77$) or AVS without QCA (control group, $n=74$).
Results
AVS success rate in the quantitative QCA group (28 of 30 (93%)) did not differ from that in the semi-quantitative QCA group (28 of 30 (93%)), which were significantly higher than that in the control group (21 of 30 (70%)). The total AVS success rate in the semi- quantitative QCA group at 4 centers was 71 of 77 (92%), significantly higher than that in control group (43 of 74 (58%). Even at 3 centers with initial low AVS success rates, the AVS success rate in the semi-quantitative QCA group was 39 of 43(91%), significantly higher than that in control group (21 of 43 (49%).
Conclusions
Our new quick cortisol assay was very fast, simple, and easy and was proved to improve the AVS success rates.
Declaration of interest
I fully declare a conflict of interest. Details below.

## P70

**Primary aldosteronism is very frequent in resistant hypertension and is associated to early renal vascular damage**

A. Benso[1], B. Lucatello[1], E. Capello[1], L. Marafetti[2], I. Tabaro[1], M Parasiliti Caprino[1], E. Ghigo[1] & M. Maccario[1]
[1]University of Turin, Turin, Italy; [2]ASL Torino 5, Chieri, Italy.

Background
Data on the prevalence of primary aldosteronism (PA) in subjects with resistant hypertension (inadequate pressure control with three full-dose drugs, including a diuretic) are scanty and it is not known if PA is associated with a more severe vascular damage.
Aim
To determine the prevalence of PA in patients with resistant hypertension and define the possible association with early cardiovascular damage.
Methods
Seventy two patients with resistant hypertension consecutively recruited from patients referring to a tertiary care center for hypertension.
Results
Diagnosis of PA (aldosterone (pg/ml)/PRA(ng/ml/h) > 400 AND aldosterone >200 basally AND > 100 after NaCl test, after stopping both interfering drugs and low salt diet), was made in 20 subjects (27.8%); the remaining 52 were considered affected by Essential Hypertension (EH, 72.2%). By CT and adrenal venous sampling 4 patients (20%) were diagnosed to have an aldosterone-producing adenoma and underwent surgical treatment. PA and EH did not differ for age, BMI, smoking habit, glycemia, LDL cholesterol, HDL cholesterol and triglyceride levels, renal function, duration of hypertension and family history of hypertension, or diabetes mellitus, or early cardiovascular disease. Blood systolic pressure levels did not differ in the two groups, but diastolic was significantly higher in PA (104.5±10.9 vs 96.6±13.6 mmHg, $P<0.02$). Potassium was significantly lower in PA (3.5±0.5 vs 4.1±0.5 mEq/l, $P<0.01$).
In PA the rate of intima-media thickness > 0.9 mm was higher (41.2 vs 26.7%), though not significantly but microalbuminuria was significantly more frequent (52.6 vs 26.7%, $P<0.05$). Moreover, PA predicted significantly microalbuminuria (OR =6.54, CI 1.02–19.35, $P<0.05$) in a logistic regression model with glycemia, creatinine, IMT, family history of early cardiovascular disease.
Conclusions
PA is very frequent in hypertensive subjects resistant to pharmacological therapy. Patients with PA show early renal vascular damage more frequently than resistant hypertensive patients with normal mineralcorticoid function.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P71

**Enhanced small dense LDL-subfractions, triglycerides and chemerin as early metabolic alterations in young patients with classic CAH due to 21-hydroxylase deficiency**

A. Zimmermann[1], P. Grigorescu-Sido[2], H. Rossmann[1], C Al Khzouz[2], S. Bucerzan[2], I. Nascu[2], L. Bergholz[1] & M. Weber[1]
[1]Johannes Gutenberg University of Mainz, Mainz, Germany; [2]Iuliu Hatieganu University of Cluj, Cluj-Napoca, Romania.

Background/Aim
Classic 21-hydroxylase deficiency (21HD) presents some traits of the metabolic syndrome.
Aim
To investigate early metabolic alterations in lipid and adipokine profile together with markers of subclinical inflammation in children and young adults with classic 21HD, which could predict early atherogenesis.
Patients und Methods
Thirty nine patients with classic 21HD (4–30 years); 39 age-, sex- and BMI-matched healthy controls. Clinical parameters, hormonal status and genotype were assessed in patients. Total-cholesterin (CL), LDL-CL, triglycerides (TG), HDL-CL were determined in patients/controls. The relative (%) and absolute (mg/dl) small-dense LDL subfractions (sd-LDL) were measured by density gradient ultracentrifugation. Adipokines (leptin, adiponectin, chemerin) and markers of subclinical inflammation (IL-6, PAI-1) were measured by ELISA.
Results
sd-LDL(%) was significantly higher in patients than controls ($P=0.003$). The same applies for absolute sd-LDL (mg/dl) (44.5+/−10.4 vs 38.3+/−7.5, $P=0.033$). TGs were higher in patients (96.1+/−44.7 vs 76.8+/−32.5 mg/dl, $P=0,031$). No significant difference was found in CL, LDL-CL, HDL-CL, leptin, adiponectin, IL-6 and PAI-1. However, chemerin was significantly higher in patients than controls (136.9+/−40.2 vs 111.2+/−41.9 ng/ml, $P=0.007$).
No obvious differences in sd-LDL or chemerin were seen between clinical forms, genotype groups (built according to the predicted residual enzymatic activity of 21-hydroxylase) or the degree of hormonal control, nor were direct correlations observed between the altered metabolic parameters and the total hydrocortisone dose or the duration of treatment.

Conclusion
Children and young adults with 21-hydroxylase deficiency show significantly higher sd-LDL-subfractions, TG and chemerin concentrations compared to age- and sex-matched healthy controls. As we could earlier show, they also exhibit a trend towards insulin resistance with higher IRI values, correlating with the total hydrocortisone dose and the duration of treatment. These alterations represent a risk constellation for early endothelial dysfunction, with potentially increased cardiovascular risk in later life. Supraphysiological hydrocortisone doses should be consequently avoided.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### ACTH and cortisol responses to the combined DEXA-CRH test in patients with adrenal incidentalomas

M. Tzanela[1], V. Tsatlidis[2], E. Margelou[1], Tampourlou[2], N. Mazarakis[3], G. Piaditis[3] & S. Tsagarakis[1]
[1]Evangelismos Hospital, Athens, Greece; [2]Athens' Polyclinic, Athens, Greece; [3]G. Gennimatas Hospital, Athens, Greece.

Adrenal incidentalomas (AI) are a common finding in patients studied by abdominal imaging and approximately 9–17% is found bilaterally. So far, the potential role of hypothalomo-pituitary adrenal (HPA) axis dysregulation in the pathogenesis of AI, especially of those found bilaterally, has not been addressed. The DEXA-CRH test has been previously used to detect dysregulation of the HPA axis; herein, it was used to assess ACTH and cortisol responses in a large group of patients presented with unilateral and bilateral adrenal incidentalomas.
We studied 97 patients (51 with unilateral and 46 with bilateral AI) and 26 normal controls. All subjects underwent a formal low dose dexamethasone suppression test followed by a CRH test (100 ug iv). Patients with AI demonstrated statistically higher ACTH and cortisol responses to the DEXA-CRH test compared to the controls ($P<0.05$). Although ACTH responses did not differ between patients with unilateral and bilateral incidentalomas, cortisol responses were significantly higher in patients with bilateral AI ($P<0.05$). According to ACTH responses patients were divided in 3 groups: group A with ACTH max $<$ 10 pg/ml ($n=48$), group B with ACTH max 10–20 pg/ml ($n=34$) and group C ACTH max $>20$ pg/ml ($n=15$). The proportion of patients with bilateral AI in group C was significantly higher than in group A (66.6% vs 37.5%, $P<0.05$). On the contrary more patients with unilareral AI were found in group A compared to group C (62.5 vs 33.3%, $P<0.05$).
In conclusion patients with AI demonstrate higher ACTH and cortisol responses to the DEXA-CRH test compared to normal subjects. This finding appears to be more common in patients with bilateral AI and, provides some ground for the potential involvement of HPA dysregulation in the pathogenesis, in at least a subgroup, of AI of patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P73

### Idiopathic primary hyperaldosteronism frequently undergoes spontaneous remission: frequence and predictors

B. Lucatello[1], A. Benso[1], I. Tabaro[1], E. Capello[1], L. Marafetti[2], M Parasiliti Caprino[1], D. Rossato[1], S. Oleandri[3], E. Ghigo[1] & M. Maccario[1]
[1]University of Turin, Turin, Italy; [2]ASL TO5, Chieri, Italy; [3]SS Annunziata Hospital, Savigliano, Italy.

Background
Idiopathic primary hyperaldosteronism (IHA) is the subtype of primary aldosteronism (PA) in which lateralization of the mineralocorticoid hypersecretion cannot be demonstrated. Scanty data are available on the clinical history of IHA: a couple of brief reports suggest a remission of aldosterone hypersecretion after years of treatment with mineralocorticoid receptor blocking agents.
Aim of this study was to check the persistence/remission of aldosterone hypersecretion in patients with IHA followed in a tertiary care referral center for endocrine and metabolic diseases, long after the diagnosis, looking for possible associations of persistence/remission with clinical features.
Patients/Methods
Plasma aldosterone to renin acivity ratio (ARR) and plasma aldosterone after saline infusion test, clinical and metabolic features, indices of early target organ damage, adrenal imaging were obtained in 34 patients followed for 8.4 (range 3–15) years after the diagnosis of IHA. All hormonal measurements were carried out after prolonged (30–40 days) withdrawn of both interfering drugs and low salt diet. Criteria for persistence of PA were the same as at the diagnosis: ARR (pg/ml to ng/ml/h) $>400$, plasma aldosterone concentration $>150$ pg/ml basally and $>100$ pg/ml after saline infusion.
Results
In 26/34 patients (76%) PA was not confirmed. At univariate analysis, remission from PA was positively associated with female sex, potassium levels, age over 60, duration of hypertension and duration of follow-up. Absence of unilateral adrenal mass, treatment with mineralocorticoid antagonists and lower aldosterone levels at diagnosis were not associated to remission. At multivariate analysis, age above 60 years was the only independent predictor of remission of PA (OR 64.7, CI 1.1–3758.9, $P=0.044$).
Conclusions
This study suggests that mineralocorticoid function in patients with IHA normalize spontaneously at a high rate. Age is a positive predictor of this evenience.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P74

### Anxiety and depressive symptoms in patients with primary aldosteronism in a longitudinal study

H. Künzel[1], K. Apostolopoulou[1], A. Pallauf[1], G. Hanslik[2], B. Volker[1], F. Evelyn[1], M. Bidlingmaier[1], E. Stephan[1], M. Quinckler[2], F. Beuschlein[1] & M. Reincke[1]
[1]LMU Munich, Munich, Germany; [2]Charite Berlin, Berlin, Germany.

Context
Recent studies showed a high prevalence of anxiety and depressive symptoms in patients with primary hyperaldosteronism (PA). A cross-sectional analysis suggested only minor improvement following adrenalectomy (ADX) and mineralocorticoidreceptor antagonist (MRA) therapy.
Objective
Our aim was to determine the course of anxiety and depression in untreated patients.
Design
We investigated 15 patients with PA at time of diagnosis and 1 year after initiation of specific treatment (ADX: $n=10$; MRA: $n=5$). Blood pressure, aldosterone and renin were recorded in all patients.
Main outcome measures We used GAD-7 and PHQD questionnaires to assess anxiety and depression.
Results
At time of diagnosis patients showed significantly higher mean values for GAD-7 ($6.3\pm4.5$) and PHQ-D ($7.5\pm6.6$) compared to the general population. One year later mean systolic blood pressure ($153\pm20$ vs $128\pm13$), serum potassium ($3.6\pm0.7$ vs $4.4\pm0.3$) and the aldosterone to renin ratio in ADX patients ($64\pm63$ vs $12\pm15$) had significantly improved. In parallel, psychopathology improved to some degree (GAD-7: $4.7\pm3.8$; PHQ-D $4.4\pm5.2$), but still 11 of 15 patients had scores outside the normal range. Gender differences were found. For depression females showed before (b) and after (a) treatment higher scores by trend (b: f $10.71\pm6.15$; m $4.63\pm5.87$ $P=0.72$; a: f $7.0\pm5.94$; m $2.13\pm3.44$ $P=0.07$). For anxiety females and males showed a significant difference after initiation of treatment. (b: f $7.33\pm3.14$; m $5.5\pm5.63$ p$=0.46$; a: f $7.83\pm3.54$; m $2.63\pm2.2$ $P=0.004$).
Conclusion
Patients with PA show a rapid and sustained improvement following intervention for their somatic parameters, but depressive symptoms and anxiety appear to improve more slowly especially in women.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

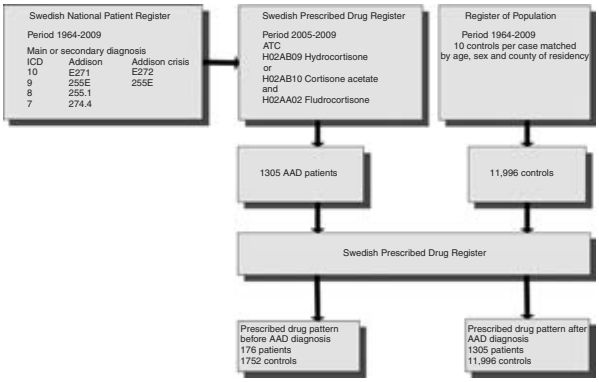
## P75

### Drug prescription pattern in patients with autoimmune addison's disease in Sweden

S. Björnsdottir[1], A. Sundström[1], P. Blomqvist[1], O. Kämpe[2] & S. Bensing[1,2]
[1]Karolinska Institutet, Stockholm, Sweden; [2]Uppsala University, Uppsala, Sweden.

Introduction
There is no published data on dispensed drug pattern in patients with Autoimmune Addison's disease (AAD). Sweden has excellent condition for research in this area, with high-quality population based registers. Among them is the Swedish Prescribed Drug Register (SPDR) that contains information about dispensed prescribed drugs. By linking registry data, we aimed at accurately estimate the prevalence and incidence of AAD, the prevalence of common concomitant autoimmune manifestations and to describe the drug prescription pattern in Swedish patients with AAD.
Methods
Through the Swedish National Patient Register (SNPR) and the SPDR we identified 1305 patients with an AAD diagnosis and combination treatment with hydrocortisone/cortisone acetate and fludrocortisone. Through the Total Population register we identified 11,996 age- and sex- matched controls. Dispensed drug prescription pattern according to the SPDR was analyzed in AAD patients and controls.
Results
The mean age at AAD diagnosis was 42.2 years (standard deviation (S.D.), 16.9) for women and 35.4 years (S.D. 16) for men. 54% were female and 46% male. The prevalence of AAD during the period 2005–2009 was 12.2–13.1 ($P$ for trend 0.062) and the incidence 0.5–0.6 ($P$ for trend 0.131) per 100,000 inhabitants per year. 59.3% of AAD patients had medications indicative of concomitant major autoimmune polyendocrine syndrome manifestations, 46.6% autoimmune thyroid disease, 17.7% B12 deficiency and 14.2% type 1 diabetes mellitus. The mean number of concomitant dispended drugs was 11.6 (S.D. 10.0) in the AAD group and 9.6 (S.D. 8.6) in the control group (Difference in mean 2.1 (95% CI 1.5–2.6), $P<0.0001$). After diagnosis, AAD-patients were dispensed more gastrointestinal medications, vitamins, mineral supplements, osteoporosis drugs, antihypertensive drugs, lipid modifying agents, sex hormones and urological drugs, anabolic steroids, anti-infectives, immunosuppressants, analgesics, hypnotics and sedatives, antidementia drugs, drugs for obstructive airway diseases and opthalmological preparations.
Conclusion
The incidence and prevalence of AAD in Sweden is comparable to the high figures reported from Norway. Patients with AAD have a higher number of dispended drugs compared to controls. The drug prescription pattern is partly expected but also raises concern about the morbidity of patients.



Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Dosing regimens for glucocorticoid replacement therapy - a worldwide patient survey

M. Forss[1], G. Batcheller[1], S. Skrtic[2] & G. Johannsson[2]
[1]Helsingborg, Sweden; [2]Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden.

There is no consensus on the best dosing regimen for glucocorticoid replacement therapy. The general intention is to individualize according to the clinical response and use the lowest possible maintenance dose without risking adrenal crisis.
Aim
To survey patients with adrenal insufficiency (AI) on their glucocorticoid replacement therapy dosing regimen.
Method
Patients (children and adults) were recruited via patient organizations to respond anonymously to a web-based survey. The survey was open from September 12th to December 19th 2008. Data on age and gender was not collected in order to protect individual identity.
Results
There were 1245 responders. 84% with primary AI, 11% with secondary AI and 5% unsure. 64% were from the USA, 20% from Europe and 15% from the ROW. Hydrocortisone (HC) was used by 75%, Prednisone/Prednisolone by 11%, Cortisone Acetate by 6% and Dexametasone by 4% of respondents. The median dose of hydrocortisone was the same (20 mg) for primary and secondary AI when analyzing the whole dose range (2–80 mg). The most commonly used dose was 20 mg for both primary and secondary AI, followed by 30 mg. There were differences in therapy and dosing regimens between countries.
One third of the respondents had their dose adjusted according to body weight or body surface area. These were more often primary AI patients, treated with HC and received more often a TID regimen.
Conclusion
The most commonly used treatment regimen is hydrocortisone 20 mg, with a median dose of 20 mg, which is the same for patients with primary and secondary AI.There is variation in the dosing regimens among countries. The inter-patient differences in dosing regimens highlights the efforts being made to personalize treatment of patients with adrenal insufficiency.
Declaration of interest
I fully declare a conflict of interest. Details below.

## P77

### Significance of ACTH stimulation test in the diagnosis of an aldosterone-producing adenoma

T. Sonoyama, M. Sone, K. Miyashita, N. Tamura, K. Yamahara, K. Park, N. Oyamada, D. Taura, M. Inuzuka, K. Kojima, K. Honda, Y. Fukunaga, N. Kanamoto, M. Miura, A. Yasoda, H. Arai, H. Itoh & K. Nakao
Kyoto University Graduate School of Medicine, Kyoto, Japan.

Primary aldosteronism (PA) is a major cause of secondary hypertension. Among PA, the diagnosis of an aldosterone-producing adenoma (APA) is critical because an APA can be cured surgically. Adrenal venous sampling (AVS) is the golden standard test in the diagnosis of an APA, but is available only in specialized medical centers. Meanwhile, aldosterone secretion of an APA is reported to be more sensitive to ACTH than that of idiopathic hyperaldosteronism (IHA) or essential hypertension. In this study, we evaluated the diagnostic accuracy of ACTH stimulation test with 1 mg dexamethasone suppression (dex-ACTH test) in the diagnosis of an APA among patients with suspected PA. Patients admitted to Kyoto University Hospital on suspicion of PA were included and were classified into three groups; non-PA group ($n=20$), IHA group ($n=16$), and APA group ($n=23$) by captopril challenge test and AVS. In dex-ACTH test, plasma aldosterone concentrations (PACs) were examined every 30 min after ACTH stimulation until 120 min. After ACTH stimulation, PACs increased in all the three groups. PACs in the APA group were significantly higher in patients than those in the non-PA group and the IHA group (Table). Receiver operated characteristics (ROC) curve analysis showed that the diagnostic accuracy of the dex-ACTH test for the diagnosis of the APA group from all the patients included was highest at 90 min after ACTH stimulation, with the optimal cutoff value of PAC $>37.9$ ng/dl, corresponding with sensitivity and specificity of 91.3 and 80.6% (Figure). Our study indicates that the dex-ACTH test is useful in the diagnosis of an APA among patients suspected of PA. Dex-ACTH test, which is available on an outpatient setting and does not require special technique or

devices, can be used to select patients who are highly suspected of an APA and definitely require AVS.

PACs in the three groups before and after ACTH stimulation.

| | **Before** | **30** min | **60** min | **90** min | **120** min |
|---|---|---|---|---|---|
| Non-PA group | 11.1±0.7 | 32.4±2.2 | 34.4±2.4 | 32.2±3.1 | 27.0±2.7 |
| IHA group | 11.6±0.9 | 33.0±2.4 | 34.6±2.8 | 31.9±2.8 | 27.8±2.8 |
| APA group | 17.1±2.9 | 64.7±8.5 | 80.1±13.1 | 75.2±8.8 | 62.6±6.9 |

**An open, multi-centre, phase IIIB, long term follow-up study to assess the safety, tolerability and efficacy of once-daily oral dual-release hydrocortisone in patients with adrenal insufficiency**

G. Johannsson[1], A. Nilsson[1], R. Bergthorsdottir[1], P. Burman[2], P. Dahlqvist[3], B. Ekman[4], B. Edén Engström[5], O. Ragnarsson[1], M. Ryberg[3], J. Wahlberg[4] & S. Skrtic[1]
[1]Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [2]University Hospital MAS, Malmö, Sweden; [3]Umeå University, Umeå, Sweden; [4]Linköping University, Linköpin, Sweden; [5]Uppsala University Hospital, Uppsala University, Uppsala, Sweden.

Introduction
There are limited prospective safety data on glucocorticoid replacement. The aim of this study was to assess the safety and efficacy during long term treatment using a once-daily oral dual-release hydrocortisone in patients with adrenal insufficiency (AI).
Methods
This is an open, multi-centre study in 71 patients with AI. Most patients were recruited from a previous controlled trial ($n=53$) where they had received the dual-release therapy 6–9 months [1] before entering this trial. Every 6 months, clinical and laboratory assessments were performed.
Results
After 18 months 94.6% of patients remained in the study. The median dose was 30 mg (range 20–40 mg) at entry. Nine patients reduced and 6 patients increased their dose during the 18 months. Total serum cholesterol (0.2 mmol/l; $P=0.03$), LDL-cholesterol (0.2 mmol/l; $P=0.03$) and HDL-cholesterol concentrations increased (0.2 mmol/l; $P<0.0001$) while triglycerides decreased (−0.4 mmol/l; $P<0.0001$). In 13 patients with DM HDL-cholesterol increased (0.3 mmol/l; $P=0.004$) triglycerides decreased (−0.2 mmol/l; $P=0.03$) and HbA1c was unchanged.
Systolic blood pressure (−0.4 mm Hg), diastolic blood pressure (0.7 mm Hg) and body weight (−0.8 kg) did not change significantly.
The average number of AEs per patient was 4.5 from 0 to 18 months. Most AEs were classified as "infections and infestations" (40%). The most commonly reported events were nasopharyngitis (20%), fatigue (7%) and gastroenteritis (6%), which is similar to conventional hydrocortisone replacement [1]. The frequency of AEs were similar in the beginning and at the end of the study.
There were 13 non-fatal serious AEs reported; 2 Addison crisis, 6 gastroenteritis, 1 case each of pyelonephritis, gastritis/esophagitis, virosis, colitis and ectopic pregnancy.
Conclusions
No safety concerns were observed in this open prospective study using a new oral dual-release hydrocortisone replacement therapy. Some continuing beneficial metabolic effects could be seen in particular in patients with concomitant DM.

**Malignant adrenal incidentalomas: clinical analysis of 2300 patients with adrenal incidentalomas registered at a single endocrinological center**

A. Kasperlik-Zaluska[1], A. Cichocki[2], M. Otto[3], J. Slowinska-Srzednicka[1], E. Roslonowska[1], W. Jeske[1], O. Gluszak[1], M. Glombica-Czajkowska[1], A. Hajdukiewicz[1] & W. Zgliczynski[1]
[1]Medical Center for Postgraduate Education, Warsaw, Poland; [2]Institute of Oncology, Warsaw, Poland; [3]Warsaw Medical Univewrsity, Warsaw, Poland.

This study aimed at searching for malignancy in a group of 2300 patients with incidentally found adrenal tumours (1688 women and 612 men aged 11-87 years) registered at our Department of Endocrinology. The methods of investigation included clinical and imaging studies, hormonal assays and pathomorphological examinations in the patients treated by surgery. In 168 patients, aged 11 to 81 years, adrenocortical cancer was diagnosed ranging in diameter from 2.5 to 25.0 cm. In 7 patients bilateral carcinomas have been observed. 67% of the detected tumours were at III/IV ENS@T stage. All the patients were treated by surgery and in a significant number of them an additional nephrectomy, splenectomy and/or partial hepatectomy were necessary. Following surgery all the patients have been treated with mitotane.
Metastatic infiltrations of adrenals were found in 57 patients aged 35–79 years (out of 228 ones with malignant disease = 25%). The most frequently the tumours originated from renal, pulmonary or colorectal cancer. Additionally, in 14 other patients some malignant adrenal tumours were found, mainly metastasing pheochromocytomas and lymphomas. In bilateral adrenal tumours (a half of metastatic infiltrations and of lymphomas) Addison's disease or pre-Addison's disease has been observed.
Conclusions
Malignant tumours have been diagnosed in 10% of adrenal incidentalomas; adrenal cancer appeared to be about three times more frequent than metastatic laesions.

**RRM1 Gene expression affects metabolization and activity of mitotane in adrenocortical cancer cell lines.**

A. Germano, I. Rapa, S. De Francia, M. Volante, F. Laino, E. Duregon, A. Berruti, M. Papotti & M. Terzolo
University of Turin, Orbassano, Italy.

Background
Mitotane (o,p'DDD) is the reference therapy for adrenocortical carcinoma (ACC) and should undergo metabolization in o,p'DDE and o,p'DDA to exert its anti-proliferative activity. We have previously shown that there is a link between

RRM1 gene expression and o,p'DDD activity in an adjuvant setting. Aim of this study was to assess whether RRM1 gene expression is correlated to the bioavailability and cytotoxic activity of o,p'DDD and its metabolites in ACC cell lines.
Methods
The ACC cell lines SW-13 and H295R were incubated with o,p'DDD, o,p'DDE, o,p'DDA at therapeutic concentrations, and cell viability (evaluated using the WST-1 method) was correlated with RRM1 gene expression (evaluated using real time-PCR). The intracellular concentrations of o,p'DDD and o,p'DDE were evaluated in cells lysates using HPLC-UV method in both cell lines.
Results
In H295R cells, o,p'DDD, o,p'DDE and o,p'DDA showed a similar cytotoxic effect (IC50 of 32 μM, <1 μM, 292 μM, respectively) and RRM1 gene expression was not influenced by any drug. In SW-13 cells, o,p'DDD and o,p'DDE were effective at high concentrations only (IC50 of 829 μM, 122 μM, respectively), while o,p'DDA showed a greater cytotoxic activity (IC50 292 μM). An up-modulation of RRM1 mRNA was induced by o,p'DDD and o,p'DDE, whose intracellular concentrations were lower in SW-13 than in H295R cells. The higher sensitivity of SW-13 cells to o,p'DDA was associated with the loss of up-modulation of RRM1 mRNA. Moreover, RRM1 gene silencing in SW13 cells increased the intracellular concentrations of o,p'DDD and o,p'DDE, and their cytotoxic activity as well.
Conclusions
The present data suggest that RRM1 gene expression may affect both pharmacokinetic and anti-neoplastic activity of o,p'DDD in SW-13 cells.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### The routine application of the current clinical recommendations for adrenal incidentalomas the management is highly inefficient

M. Villaplana, D. Subías, E. Berlanga, A. Cabo, R. Martos & M. Rigla
Corporació Sanitària i Universitària Parc Taulí, SABADELL, Spain.

Introduction
The improvement in imaging techniques has increased the number of incidentally discovered adrenal lesions. Current clinical recommendations are based on the NIH consensus statement (2002) and include: CT at 6,12 and 24 months plus annual hormone evaluation for 4 years.
The aim of this study was to describe the results of the application of the current guidelines in a cohort of consecutive patients whose initial diagnosis was non-functioning adrenal adenoma
Patients and methods
We reviewed the clinical records of the patients who followed the following inclusion criteria: incidental discovered adrenal mass; no extra-adrenal malignancy; no radiological suspicion of malignancy (apart from size). Annual hormone evaluation consisted in: 1 mg DXT, urine metanephrines and catecholamines, K and Renin/Aldo. Regular CT studies were also performed.
Results
Ninty-nine patients were included (54.5% females, mean age 59.8±11.3 years, BMI 28.8±4.9 kg/m$^2$). Hypertension was present in 49.5% of the patients, dyslipidemia in 41.4%, type 2 DM in 25.3%.
Two patients underwent surgery because of sizeand in both cases the final diagnosis was cortical adenoma. Mean initial size was 21.6±9.5 mm and 14.4% of the patients had bilateral lesions. The median follow-up was 45.5 months.
At the baseline evaluation, hormonally active adenomas were diagnosed in 5 patients (2 hypercortisolism, 3 hyperaldosteronism). All the patients with an initial negative evaluation remained without alterations in the folowing hormonal tests. No significant increase in size (1.7±5.2 mm) was observed through the follow-up period.
Conclusion
The routine application of the current guidelines for the follow-up of adrenal incidentalomas whose initial diagnosis corresponds to non-functioning adenoma does not seem justified.

### The Effect of Glucocorticoid Receptor Polymorphisms on the Sensitivity to Cortisol in Addison's disease

I. Ross[1], N. Levitt[1], D. Blom[1], T. Owen[1], C. Dandara[1] & T. Pillay[2]
[1]University of Cape Town, Cape Town, South Africa; [2]University of Kwazulu Nata, Durban, South Africa.

Background
There is uncertainty as to whether glucocorticoid receptor (GCR) polymorphisms play a role in the development of glucocorticoid-related side-effects in individuals receiving hydrocortisone replacement for Addison's disease.
Method
One-hundred-and-forty-seven Addison's patients were age, gender, ethnicity and body mass index (BMI) matched with 147 control subjects. Genotyping was performed using polymerase chain reaction (PCR) for three single nucleotide polymorphisms, two of which are known to be sensitising BclI and N363S and one polymorphism ER22/23EK is known to induce a degree of cortisol resistance. Associations with metabolic derangements were evaluated.
Results
The prevalence of the BclI polymorphism occurred more frequently in whites than in any of the other ethnic groups, but was not associated with any metabolic derangement. The ER22/23EK polymorphism was associated with an increased BMI in both patients (29.4 vs. 24.7 kg/ m$^2$; $P$ <0.02) and control subjects (26.3 vs. 24.2 kg/ m$^2$; $P$ <0.001) compared with the wild-type. The heterozygous polymorphism was associated with lower low-density lipoprotein (LDL) cholesterol in controls vs. wild-type (3.46 mmol/l vs. 3.93 mmol/l; $P$=0.02). The N363S was not associated with any metabolic derangement.
Conclusion
The overall effect of the GCR polymorphisms was to increase the BMI in healthy control subjects and patients harbouring the ER22/23EK polymorphism, which was in contrast to what was expected. No associations between any of the polymorphisms and hydrocortisone doses were found, albeit that doses are prescribed on an empiric basis.

### Impact of reference values and published thresholds on clinically relevant cut-offs

J. Brossaud, P. Barat, A. Georges & J. Corcuff
University hospital, Bordeaux, France.

The adrenal function of children is investigated similarly to adults' using at rest (basal) and after testing serum cortisol concentration ((F)). di Iorgi et al. (JCEM 95:2132) showed a good diagnostic accuracy of glucagon testing investigating (F) increase. We retrospectively addressed the relevance of using, in children with short stature tested for GH deficiency, 1/ the normal reference range of our assay for basal (F) and 2/ the threshold provided by di Iorgi et al. on (F) response to glucagon-betaxolol testing. This population was not suspect of adrenal insufficiency.
Basal (F)DXi ($N$=140, 10.3 (0.2–15.5) yr (median (2.5th–97.5th percentile)) was 260 (98–604) nmol/l. 26% subjects had lower (F)DXi than the reference range (185–624) nmol/l (Unicel DXi800,Beckman Coulter).
After betaxolol-glucagon testing ($N$=108), GH peak was 34.8 (80–74.4) mUI/l (Liaison analyser, DiaSorin); 29% were low GH responders (peak <20 mUI/l). (F)DXi peak was 502 (117–856) nmol/l. 31% would be considered adrenal insufficient using di Iorgi et al.'s criterion (403 nmol/l: 100% specificity threshold). (F)DXi was compared with results obtained with our prior RIA assay in a subgroup of patients. Basal (F)RIA was 411 (141–1061) nmol/l. 7% subjects had lower (F)RIA than the reference range (200–800) nmol/l. (F)RIA peak was 770 (281–1542) nmol/l. 5% would be considered adrenal insufficient using di Iorgi et al.'s criteria. Passing-Bablock regression showed a significant linear relationship between data from the 2 assays with a significant bias.
This emphasizes again that laboratories have to provide reference values for given populations, (e.g. basal (F) in children with short stature). Clinically relevant thresholds have to be locally defined (e.g. betaxolol-glucagon testing). Data issued from manufacturer's-chosen populations and clinically relevant thresholds established in well-conducted study but with different populations or assays cannot wholly substitute to local references. Failure to do so will elicit false positive or negative results.

**Hormonal and metabolic features in patients with adrenal incidentalomas according to 1 mg overnight dexamethasone suppression test**

S. Vottari, D. Wolosinska, C. Motta, L. Proietti Pannunzi, S. Morgante, S. Caprioli, A. Chiefari, M. Deiana, V. Toscano & S. Monti
Azienda Ospedaliera Sant'Andrea, Rome, Italy.

Adrenal masses are among the most prevalent human tumors and are frequently detected unexpectedly by imaging studies performed for reasons unrelated to suspect of adrenal diseases.
Subclinical hypercortisolism (SH) is the most frequent endocrine dysfunction detected in patients with adrenal incidentalomas (AI), accounting from five to 20% of all cases depending on inclusion criteria. one mg overnight dexamethasone suppression test (one mg DST) should be the first screening test; however there is no consensus on the cutoff values to consider the test as positive.
In this study we investigated hormonal and metabolic aspects of patients with AI according to different cortisol suppression. We included 39 patients with AI and divided them into four groups based on cortisol levels after one mg DST: $<50$ nmol/l (group one, normal suppression) between 50 and 83 nmol/l (group two), between 83 and 138 nmol/l (group three) and $>138$ nmol/l (group four).
Since ACTH levels were $<10$ pg/ ml in 100% of patients in group four, these were considered affected by SH according to literature.
ACTH levels $<10$ pg/ ml were observed in 100% of patients in group three, in 67% of group two and in 31% of group one. ACTH and DHEA-S levels were significantly lower in groups three and four than in group one. Moreover, ACTH response to CRF and/or DDAVP was reduced in patients of groups three and four. Prevalence of diabetes was 15% in group one, 25% in group two, 40% in group three and 33% in group four. Glycemia was higher in groups three and four than in group one. Triglycerides were higher in group three than in group one.
In conclusion, group three showed the same hormonal and metabolic alterations of group four, suggesting that in our patients SH was present in patients with cortisol levels after DST $>83$ nmol/l.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P85

**Therapy with steroidogenesis inhibitors in Cushing's syndrome: a reappraisal**

E. Valassi[1], I. Crespo[1], I. Gich[2], J. Rodríguez[2] & S. Webb[1]
[1]IIB-Sant Pau, Hospital Sant Pau, Universitat Autònoma de Barcelona, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBER-ER 747), Barcelona, Spain; [2]Hospital Sant Pau, Universitat Autònoma de Barcelona, Barcelona, Spain.

Objective
To evaluate the outcome of preoperative therapy with ketoconazole (KTZ) and/or metyrapone (MTP), in previously untreated CS patients who later underwent surgery.
Design and methods
A total of 62 CS patients (85% ACTH-dependent), who have been treated with steroidogenesis inhibitors prior to surgery in our centre between 1983 and 2010, were retrospectively studied. T0 and t1 defined visit at baseline and at the end of medical treatment, respectively.
Results
Outcomes were classified into the following three groups based upon clinical and biochemical (normal UFC) control of hypercortisolism at t1: group CO (controlled) included 20 patients (32%) with eucortisolism and significant clinical improvement as compared with t0; group NC (not controlled) included 30 patients (48%) who had persistent hypercortisolism and lack of clinical control of CS symptoms; and group PC (partially controlled) included 12 patients (19%) who presented eucortisolism but no real clinical improvement. Median duration of treatment was 4 months (range: 1–30.7 months), median cumulative dose of KTZ and MTP was 57g (range: 3.6-240 g) and 120g (range: 7.5–1215g), respectively. No differences in baseline characteristics were observed between groups. Systolic blood pressure at t1 was significantly higher in PC than in NC patients ($P<0.05$). Hypertension persisted more frequently in PC patients than in the other groups ($P<0.05$) after a median post-surgery follow-up of 93 months (range: 2–276 months). UFC at t0 ($r=0.458$; $P<0.0001$) and NC status ($r=-0.315$; $P<0.0001$) predicted the decline in UFC during medical treatment, and remained significant after correcting for baseline characteristics, type and dose of the medications (R2, 0.770).
Conclusions
Preoperative administration of KTZ, MTP or both normalised UFC in 52% of CS patients, although concomitant clinical improvement was not reached in all cases. Future studies are needed to categorise the response to medical therapy and to individualise the treatment in CS patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P86

**Ectopic Cushings and Nocardia series**

A. Rizwan, A. Sarfaraz, A. Jabbar, N. Islam & J. Akhter
Aga Khan University Hospital, Karachi, Pakistan.

Cushing's syndrome results from exposure to excess glucocorticoids. Ectopic Cushings is endogenous ACTH dependant form of Cushing's associated with markedly raised ACTH and cortisol levels. This leads to an impaired immune response, setting the stage for occurrence of opportunistic infections. Nocardia is a gram positive bacterial infection caused by aerobic actinomycetes in genus Nocardia. We report a series of patients diagnosed with ectopic Cushings, with growth of Nocardia asteroides from pulmonary secretions. In one of these cases, the manifestations of Cushing's disappeared with treatment for Nocardia. Two middle aged men presented to the Endocrine clinic in the same year: the first with history of exertional shortness of breath, and weight loss for 1 year, the other with facial swelling, disturbed sleep and lethargy for a month. The third case was a young male who presented with progressive weakness & weight loss for some time. All three had uncontrolled hypertension, high blood sugars & were hypokalemic (K: 2.52, 2.9, 1.5; (normal range 3.6–4.0); 24 hour urine cortisol was elevated at 2000, 27,216 and 9088 (32–243); ACTH 68.5, 159, 255(0–48), respectively. Their MRI pituitary was normal, inferior petrosal sinus sampling revealed no central peripheral gradient. CT chest of these subjects demonstrated cavitatory lung lesions; bronchial washings recovered heavy growth of nocardia. Histopathology revealed no malignancy. Antihypertensives, insulin, potassium replacement, ketoconazole & trimethoprim- sulphamethoxole (TS) were initiated. The patients' symptomatology improved & cavitatory lesions resolved with treatment. The primary source for the ectopic cushings remained unknown. The first case followed a progressively downhill course leading to death. The second case required bilateral adrenalectomy. In the third case, we were able to completely taper off ketoconazole, potassium, insulin & antihypertensives, after starting TS.Opportunistic infections are known to be associated with Cushing's syndrome, as higher levels of glucocorticoid secretion are found in patients with ectopically produced ACTH. Nocardia of lungs is important differential to consider. This series includes the first case reported in which signs and symptoms of cushings subsided after treatment of Nocardia.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P87

**Laparoscopic adrenalectomy for large adrenal tumors**

D. Paun[1,3], N. Totolici[1], R. Petris[1], R. Ganescu[2], S. Paun[2,3] & C. Dumitrache[1,3]
[1]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Emergency Clinical Hospital, Bucharest, Romania; [3]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Background data
Laparoscopic adrenalectomy has became in the last decade "gold standard" for treating of adrenal tumors with diameters smaller than six cm. In addition, one should note than larger tumors or potentially malignant tumors can now also be removed laparoscopically, with virtually no complication.
Objective
The authors evaluate the effectiveness of laparoscopic adrenalectomy for a large adrenal tumors.
Methods
One hundred laparoscopic adrenal procedures over the past five years were reviewed and followed for adequacy of resection.
Results
Indications were: pheochromocytoma ($n=10$), aldosterone-producing adenomas ($n=15$), nonfunctional adenomas ($n=21$), cortisol-producing adenomas ($n=14$), Cushing's disease ($n=32$) and others ($n=8$). Specifically, 32 patients (23 females and nine males) between 20 and 69 (median ages of 46,43 years) had tumors larger than six cm. four of these cases underwent bilateral adrenalectomy by laparoscopic approach; in five cases the surgeons preffered conversion to the open approach. Among the reasons of conversion: bleeding, local invasion (inferior vena cava, liver, diaphragm), unclear landmarks etc. Mean operative time was 114 minutes (from 25 min to 270 min, includind patients with bilateral approach). Mortality among the studied cases was zero and as postoperative complication only a bleeding from spleen (after bilateral adrenalectomy convert to open procedure because of unclear landmarks in a case of Cushing disease) can be mentioned. Patients were discharged anywere between one and 50 days (the complicated case) postoperative (median six days).
Conclusions
Laparoscopic adrenalectomy is a reasonable procedure for selected large adrenal tumors when a complete resection is technically feasible and is no evidence of local invasion.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P88

**Adiponectin gene polymorphisms in primary aldosteronism and their relation to the metabolic syndrome**

I. Jochmanova, V. Habalova, H. Wagnerova & I. Lazurova
[1]Medical faculty University Košice, Košice, Slovakia.

It is well known that primary aldosteronism (PA) is frequently associated with metabolic syndrome. Among possible pathogenic mechanisms, adiponectine gene variants may play a role in the development of metabolic complications especially type two diabetes.
Aim of this study was to assess the presence of two single nucleotide polymorphisms of the adiponectin gene (G276T and T45G) in patients with PA and determine their relation to metabolic parameters.
Subjects and methods
We studied 51 patients with PA and 37 controls with essential hypertension. Twenty three patients had aldosterone producing adenoma (APA) and 28 idiopathic hyperaldosteronism (IHA). Genotypes of the adiponectin gene were determined at positions 45 (exon two) and 276 (intron two) by PCR. BMI, plasma glucose and lipids were measured by routine methods.
Results
The prevalence of G allele of T45G polymorphism in PA was slightly but not significantly higher in comparison to EH (27% vs. 13.7%). Carriers of G allele had significantly higher plasma cholesterol ($P < 0.05$), LDL cholesterol ($P < 0.05$) and slightly but not significantly lower HDL cholesterol. There was no significant difference in the prevalence of G allele between APA and IHA. The prevalence of TT/GT genotypes of the G276T polymorphism was significantly higher in PA as comared with hypertensive controls (54.9% vs. 26%, $P < 0.05$). However patients with T allele did not differ in metabolic parameters from those with G allele only.
Conclusion
Patients with PA have significantly higher prevalence of T allele of the G276T polymorphism than controls with EH. However the presence of T allele was not related to metabolic parameters. On the other side the presence of G allele of the T45G adiponectin gene polymorphism may confer a risk of worse lipid profile in these patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P89

**Primary aldosteronism associated with subclinical Cushing syndrome**

H. Tatsuoka[1], S. Honjo[1], Y. Hamamoto[1], Y. Ohgita[1], K. Mori[1], K. Fujimoto[1], A. Matsuoka[1], H. Ikeda[1], Y. Wada[1], T. Nishikawa[2], H. Sasano[3] & H. Koshiyama[1]
[1]Kitano Hospital, The Tazuke Kofukai Medical Research Institute, Osaka, Japan; [2]Yokohama Rosai Hospital, Yokohama, Japan; [3]Tokoku University Hospital, Sendai, Japan.

Introduction
It has been reported that primary aldosteronism(PA) is often associated with subclinical Cushing syndrome (SCS). In the present study, we investigated the frequency of SCS in subjects with PA.
Method
Subjects included consecutive patients ($n=43$) who were diagnosed as PA between 2003 and 2011 in our institute. They were screened by plasma renin activity (PRA (ng/ml/h)) plasma aldosterone concentration (PAC (pg/mL)) ratio (ARR) above 200. The endocrinological examinations such as furosemide posture test, captopril suppression test and low-dose (1 mg) and high-dose (8 mg) dexamethasone suppression test (DST), were performed. The cases of possible diagnosis of PA underwent adrenal vein sampling (AVS) and the laparoscopic adrenalectomy. The diagnosis of PA was confirmed by the pathological findings.
Result
In 43 subjects who were diagnosed as PA, five (11.6%) showed no suppression in low-dose DST, and four of them were also positive in high-dose DST, indicating the presence of SCS, which was confirmed by pathological examination. One case was associated with overt Cushing syndrome (CS). In all of the five cases 24 h urinary cortisol secretion was abnormally high. However, four of five cases showed normal serum cortisol at morning, and two of five cases maintained normal circadian cortisol variations. Postoperatively, three cases needed replacement therapy of hydrocortisone, while no subjects without SCS needed it.
Conclusion
PA is frequently associated with SCS with prevalence of more than 10% in our study. Since it requires postoperative hydrocortisone replacement therapy, our data suggest the importance of routine screening of SCS with DST in PA cases.

**Primary aldosteronism during 2007–2011 in Iceland**

G. Jónsdóttir[1], J. Gudmundsson[1], G. Birgisson[1] & H. Sigurjónsdóttir[1,2]
[1]Landspitali University Hospital, Reykjavik, Iceland; [2]University of Iceland, Reykjavik, Iceland.

Introduction
Recent publications regarding primary aldosteronism (PA) have challenged the concept of PA being a rare disease. In 2007 a standardized protocol for diagnosing and treating PA was introduced in Iceland for patients suspected of having PA. Data from the Icelandic Heart Association suggests that 35–40% of the adult population (age 46–67) have hypertension. The aim of this study was to gather information about PA as a cause of hypertension at the referral center for endocrine hypertension in Iceland.

Methods
A retrospective chart review was performed of all patients (age 18 and older) diagnosed with PA during 2007–2011 at the Landspitali University Hospital in Iceland, a referral center for the whole country (population of 318.000). All patients were diagnosed using the same standardized methods. Patients were taken off interfering medications 4–6 weeks prior. Screening was considered positive if patients had an increased morning -aldosterone and decreased renin levels and/or an increased 24 h urinary aldosterone secretion. Salt loading and positional tests were used to verify the diagnosis. All patients with verified PA were further examined with a CT scan and adrenal venous sampling (AVS). When AVS indicated unilateral disease, patients were offered a laparoscopic adrenalectomy. Patients with bilateral disease were given specified pharmacological treatment options.
Results
Thirty-three patients were diagnosed with PA, 16 patients had bilateral disease and 16 patients unilateral. The results from AVS in one patient is pending. All 16 patients with unilateral disease had an adrenalectomy, 11 of which had a cortical adenoma and four had adrenal hyperplasia. In one patient the PAD was inconclusive.
Conclusion
This study indicates that PA is an important cause of hypertension in Iceland, and emphasizes the importance of detecting curable causes of hypertension. Interestingly, unilateral hyperplasia was ¼ of unilateral PA.

### Low SLC26A2 expression in adrenal cells is associated with high aldosterone output

T. Bozoglu, A. Spyroglou, M. Reincke & F. Beuschlein
Ludwig-Maximilians-University, Munich, Germany.

A genome-wide association study indicated a correlation between a locus at 5q32 and high aldosterone to renin ratio in subjects from KORA F4 survey. As we considered the genes in this locus for their potential relevance for the etiology of primary aldosteronism, we observed significantly higher expression of one of them, SLC26A2, in mouse adrenal glands, even though the gene's function in the adrenal was not reported in the literature. Using the human adrenocortical cell line NCI H295r and wt mice, effects of aldosterone regulators on SLC26A2 gene expression were evaluated. Consistently, angiotensin II treatment resulted in a decrease in SLC26A2 gene expression *in vitro* and *in vivo*, while potassium resulted in lower expression levels only in the *in vivo* setting. Interestingly, a shRNA-mediated four-fold knockdown of SLC26A2 in H295r cells yielded a significant increase in aldosterone synthase (CYP11B2) expression and aldosterone output of the cells; this effect of knockdown was sustained after incubation with aldosterone stimulators including potassium, angiotensin or forskolin. An increase in the expression of calcium dependent regulators of CYP11B2 expression including CamK1, NR4A1 and NR4A2 was observed. In order to gain insight into *in vivo* functional characteristics of the gene, we analyzed gene expression profiles in adrenal glands from SLC26A2 knock-out mice. These results suggested a tendency towards higher expression for adrenal enzymes with more specific role in aldosterone synthesis and expression in the zona glomerulosa (CYP11B2, HSD3B6), and a tendency towards lower expression for enzymes with a more unspecified expression pattern (STAR, CYP11A1) or a more fasciculata specific distribution (HSD3B1). Further detailed investigation into the functional link between adrenal SLC26A2 expression and aldosterone production is ongoing.

### Three-dimensional contrast-enhanced sonography in the diagnosis of incidentally discovered asymptomatic adrenal masses

T. Gasinska & W. Spychalowicz
Silesian Medical University, Katowice, Poland.

Background
Due to improvements in diagnosis capabilities, there has been a recent increase in adrenal tumors, that are incidentally discovered in patients, who underwent examination by sonography (S), computed tomography (CT) and magnetic resonance imaging (MRI) The aim of this study was to define the usefulness of contrast-enhanced three-dimensional sonography in the diagnosis of nonfunctioning adrenal incidentalomas.
Patients and methods
Sixty-one patients with nonfunctioning adrenal adenomas, 51 women and 10 men, aged 42–78 years ($61 \pm 8$) were subjected to analysis. All were earlier diagnosed by sonography and CT or MRI. All received detailed laboratory testing including hormones profile. Examination with ultrasonography were performed by a single physisians throughout the study. The patients were examined by Acuson Antares (Siemens) with convex transducer of 2.5 MHz, including Duplex, Doppler and three-dimensional sonography followed by a three-dimensional sonography with the Sonovue contrast agent. Shape, structure, size and vascularization of adrenals were assessed according to the RECIST protocol.
Results
After administration of contrast, increase of the size, without the visualization of vascularization within the same tumor, was found in $\sim$ 90% of adrenal incidentalomas.
Conclusions
Contrast-enhanced three-dimensional sonography may be a useful method in the diagnosis of adrenal incidentalomas. It may be a valuable procedure in detecting and follow up of the nonfunctioning adrenal tumors.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Evaluation of uni- and bilateral adrenal incidentalomas with (131I) 6β-iodomethyl-norcholesterol scintigraphy.

L. Papierska[1], J. Cwikla[2], M. Rabijewski[1], E. Roslonowska[1], K. Wernic[1] & M. Otto[3]
[1]The Medical Centre of Postgraduate Education, Warsaw, Poland; [2]Hospital Ministry of Internal Affairs and Administration, Warsaw, Poland; [3]Medical University of Warsaw, Warsaw, Poland.

The growing incidence of adrenal incidentaloma needs new methods of assessment of their function, especially for cases with subclinical hyperfunction. The bilateral adrenal incidentalomas in patients with subclinical Cushing syndrome (SCS) often need only unilateral surgery, but if their diameters and phenotypes are similar, coming to decision about side of adrenalectomy may be difficult. Another problem generate tumors suspected of subclinical aldosterone hypersecretion: the adrenal venous sampling is an invasive method and patients not always agree to it. Border values of cortisolaemia in dexametasone suppression test may also lead to hesitation about usefulness of adrenalectomy. Iodomethyl-norcholesterol is a highly specific tracer for the functional characterization of the adrenal cortex and scintigraphy with it can be a useful additional tool for the treatment decisions in the cases described above.
We present series of Iodomethyl-norcholesterol scintigraphy performed in 25 patients. The indications for scintigraphy were: subclinical hypercortisolaemia in patients with bilateral adrenal tumors (18 cases), primary hyperaldosteronism (three cases) and uncertainty in assessment of cortex function (border results) (four cases). We used two different protocols, depending of assessed adrenal function (without dexametasone if were no doubt about SCS).
Scintigraphy confirmed unilateral adrenal hyperfunction in 12 of 22 patients with suspicion of SCS. In all operated patients in this subgroup, transient postoperative secondary insufficiency of the second adrenal gland was observed, confirming the

diagnosis of SCS and proper choice of operating side. The scintigraphy in three patients with primary hyperaldosteronism confirmed the source of disorder. Two of these patients have already been operated with clinical and biochemical benefits.
Our observations indicated that adrenal scintigraphy may be the valuable method for adrenal tumor function assessment, which helps in decision about surgery in cases of subclinical adrenal hyperfunction and bilateral adrenal lesions.
Declaration of interest

## P94

**The confirmatory Tests of primary aldosteronism should be selected in each countries - the analysis of 83 patients in our hospital**

T. Ichijo, E. Yoshida, K. Yamashita, H. Ouchi & M. Higa
Saiseikai Yokohamashi Tobu Hospital, Yokohama, Japan.

It has been well known the primary aldosteronism (PA) is the most common endocrine hypertension, and it is accounted approximately 10% of all hypertensive patients. It is always challenging for physicians which tests we should select for the confirmatory tests for the patients with aldosterone-renin retio (ARR) positive. We analyzed our 83 PA patients for the sensitivity of each confirmatory test.
We screened those PA suspicious patients by ARR and we considered ARR $\geqq 20$ as positive. We, then, performed the confirmatory tests, such as rapid ACTH stimulating, captopril challenge, upright plus furosemide, and saline infusion tests. When any of those confirmatory tests were positive, the patients undergo an adrenal CT scan. When surgical treatment was practicable and desired, the distinction between unilateral (UHA) and bilateral hyper aldosteronism (BHA) was made by the ACTH-loading adrenal venous sampling (AVS).
The mean age was $55.8 \pm 13.4$ years old including 33 males and 50 females. The sensitivity of those four confirmatory tests among 65 AVS performed cases were 91.5%, 52.6%, 78.8%, and 29.6%, respectively, and the rapid ACTH stimulating test showed the highest sensitivity in UHA. Fifty-five out of 65 AVS performed cases showed plasma aldosterone concentration $\geqq 1{,}400$ ng/dl in either (46.2%) or both (46.2%) side, and 18 cases showed the ratio of PAC/cortisol in higher side to one in lower side $>2.6$, which we consider the laterality positive and performed laparoscopic adrenalectomy.
The reason of the sensitivity of saline infusion test is low may be that our daily salt consumption is higher than most countries and this may push down the sensitivity.
In conclusion, our results confirm the usefulness of the confirmatory tests, and revealed the sensitivity of rapid ACTH test was high and saline infusion test was low. This indicate that each country should confirm which confirmatory tests are useful under its' food culture.

## P95

**ACTH stimulation improves the sensitivity of aldosterone to rennin ratio (ARR) for detecting inappropriate aldosterone secretion**

M. Ishii[1,2], M. Asano[2], Y. Hashimoto[1], Y. Morita[1], M. Isono[1], M. Hukui[2], G. Hasegawa[2] & N. Nakamura[2]
[1]Otus Municipal Hospital, Shiga, Japan; [2]Kyoto Prefectural University of Medicine, Kyoto, Japan.

Background
Aldosterone to renin ratio (ARR) is the gold standard for screening of primary aldosteronism (PA). However, the lower value of ARR cannot rule out the possibility of PA. In this study, we evaluated the change of plasma aldosterone concentration (PAC) in ACTH stimulation among hypertensive patients and explored whether it improved the sensitivity of ARR for detecting PA.
Method
Eighty-five patients with hypertension with plasma renin activity (PRA) $<$ 1.1 ng/ml/hr and PAC $>$ 50 pg/ml were enrolled for the ACTH stimulation test. The stimulation was performed by intravenous injection of 250 μg of ACTH to the patients after 30 min rest in the spine position. The blood sample was collected at 0, 30 and 60 min after the injection. Thirty-seven patients were suspected of PA by ARR $>$ 200 or PAC at 30 or 60 min after ACTH stimulation $>$ 240 pg/ml or having adrenal adenomas. The rest of 48 patients were classified into the non-PA group without confirmation (group A). PA suspected group was followed by confirmatory tests according to the Japanese guideline of PA diagnosis in 2009. Eight patients were excluded and re-categorized into the non-PA group with confirmation (group B) and 29 patients were classified into the PA group (group C).
Results
ΔPAC30 and ΔPAC60 were significantly higher in the group C ($5.6 \pm 2.9$, $3.2 \pm 1.6$) than in the group A ($2.2 \pm 1.0$, $1.1 \pm 0.5$) and group B ($3.5 \pm 1.3$, $2.0 \pm 0.9$) ($P < 0.05$). The ROC curve analysis demonstrated ARR0 of 233 (AUC = 0.92, sensitivity = 83%, specificity = 98%), ARR30 of 392 (AUC = 0.94, sensitivity = 93%, specificity = 89%) and ARR60 of 387 (AUC = 0.96, sensitivity = 93%, specificity = 91%) as the optimum cut-off points.
Conclusion
These results indicated that ACTH amplified inappropriate aldosterone secretion. ARR after ACTH stimulation is more sensitive for detecting PA than that without the stimulation.

**Diagnostics of primary aldosteronism: is obligatory use of confirmatory tests justified?**

J. Mysliwiec, L. Zukowski & M. Gorska
Medical University of Bialystok, Bialystok, Poland.

Introduction
Assessment of the RAAS has been recently granted a much greater role in the evaluation of patients with arterial hypertension (AH). There is no single test efficient in selection of patients for second-step etiological investigation.
Methods
198 consecutive patients- 119 women (60%) and 79 men (40%)- hospitalized in years 2009-2011 at the Clinical Department of Endocrinology UMB as to diagnose PA. In each patient PRA and PAC (basic and after 2l NaCl infusion) were evaluated.
Results
The percentage of patients with PAC $\geq 15$ ng/ml was 53% and percentage of patients with PRA $\leq 0.1$ ng/ml per h was 20%. The percentage of patients screened for PA in which ARR exceeded consecutive cut-offs of 20, 30, 40 and 50 were respectively 57, 45, 34 and 29%. Among 15 patients in which PAC after infusion of two liters of saline was $\geq 6.5$ ng/dl (8.6%) in 13 (6.6%) PA was diagnosed.
Conclusion
obligatory use of tests confirming autonomy of aldosterone secretion in patients screened for PA seems cost-effective in limiting number of patients for further diagnosing.

**Diagnosis of Cushing's syndrome by automatic face classification using frontal and side-view photographs**

R. Kosilek[1], J. Schopohl[1], M. Grünke[2], C. Dimopoulou[1], G. Stalla[3], M. Reincke[1], M. Günther[4], R. Würtz[4] & H. Schneider[1]
[1]Medizinische Klinik Innenstadt, Ludwig-Maximilians University, Munich, Germany; [2]Medizinische Poliklinik, Campus Innenstadt, Ludwig-Maximilians University, Munich, Germany; [3]Max-Planck-Instititut für Psychiatrie, Munich, Germany; [4]Ruhr-Universität, Bochum, Germany.

Background
Cushing's syndrome is a disease that presents with clear symptoms and causes considerable harm to the body if left untreated, yet often remains undiagnosed for prolonged periods of time. Face-classification software might recognize typical changes of the face and thus aid in diagnosing the disease early as we have previously shown in the classification of acromegaly.
Methods
Using a regular compact digital camera, we took frontal and side-view pictures of 21 female patients with Cushing's syndrome (14 endogenous, seven iatrogenic) and of 42 age- and sex-matched controls (2:1 matching).
Nodes were then placed on disease-relevant structures of the face to analyze the pictures using computerized similarity analysis based on Gabor-jets and geometry functions. The leave-one-out cross-validation method was employed to classify subjects by the software.
Results
Using the same combination of Gabor-jets and geometry functions as in our previous publication, 80.1% of patients and 97.6% of controls were correctly classified by the software. This resulted in a total classification accuracy of 92.1%. If only frontal views and only one control person for each patient was included, the classification accuracy was 85.7 and 66.7% in patients and controls, respectively.
Conclusions
In this preliminary analysis we found a good classification accuracy of Cushing's syndrome by face-classification software. By employing 2:1 matching and implementing side-view pictures into the classification process, we could substantially improve classification accuracy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P98

**Cushing disease remission is independent of size tumor. twenty years experience in surgical treatment a Mexican Center**

J. Garduno Garcia, M. Escamilla Ruiz & A. Reza Albarran
Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico.

Background
Cushing disease CD is a rare disorder, caused by an (ACTH) producing tumor. Transsphenoidal pituitary surgery (TSS) remains the treatment of choice for CD. Fewer information is available on the long-term outcome in the group of patients harboring ACTH-secreting adenoma. The aims of this study were to analyze our 20-year experience with surgical treatment in Cushing's disease and to examine whether remission rate is related with size tumors.
Methods
Forty four consecutive patients with proven Cushing's disease who under went to surgical treatment in our center between 1990 and 2010 were analyzed. The diagnosis was made using standard endocrinological criteria. Remission was defined with serum cortisol suppression on oral 1-mg dexamethasone overnight suppression test.
Results
Overall, 41/44 of the patients (80%) were female. The average age was 26.36 ± 7.8. Average urinary cortisol was 566 ± 462.42 μg/24 h and ACTH 61 ± 74 pg/ ml. Microadenoma were present in 32 patients (72%) and macroadenoma in 12 (27%). Total remission was achieved in 34% of the subjects. (11 microadenomas and 3 macro adenomas). In the follow up of the remission patients there were a relapse in three patients. Mean follow up was 43.5 ± 42.28 months in patients with out remission, and 67 ± 59 months in patients with remission. The size of the tumor was not statistically different in the patients with remission (7.3 ± 4.3 mm) compared to the patient with out remission (9.1 ± 7.2 mm) ($P = 0.50$).
Conclusion
The remission confirmed with serum cortisol suppression on oral 1- mg dexamethasone overnight suppression test do not depends on tumor size.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P99

**Cushing's disease – limitations and boundaries**

J. Idriceanu[1], C. Preda[1], C. Galesanu[1], M. Ungureanu[1], V. Scripcariu[2], I. Vasiliu[1], I. Potorac[1], R. Popovici[1], V. Mogos[1] & C. Vulpoi[1]
[1]University of Medicine and Pharmacy 'Gr.T.Popa', Iasi, Romania, [2]University of Medicine and Pharmacy 'Gr.T.Popa' I, Iasi, Romania.

Introduction
Cushing's disease is the most frequent cause of hypercortisolism. Although the classical form is easy to diagnose, nonspecific features raise differential diagnosis problems. Severe forms are associated with high mortality, but subclinical hypercortisolism also has significant morbidity.
Patients and methods
Retrospective study of Cushing's disease evolution in 14 patients, diagnosed between 2000 and 2011 (11 women, 3 men, age at diagnostic 22–48 years).
Results
Clinical: 42.86% patients were overweight and 42.86% obese; 78.58% hypertensive; 92.85% had purple striae, 71.42% muscle weakness and 70% of women secondary amenorrhea. All patients had hypercortisolism (384.81 ng/ml ± 140.04), disturbed nictemeral rhythm and high ACTH (311.61 pg/ml ± 422.45). Diagnosis was supported by inhibition and/or stimulation tests. Over 1/3 had metabolic syndrome and three cases had electrolyte impairment. Pituitary adenoma was identified in nine cases (64.28%, two macroadenomas and seven microadenomas). Only four patients had pituitary adenomectomy (one with complete remission), eight bilateral adrenalectomy, followed in four cases by pituitary radiotherapy, one patient, newly diagnosed, had not yet been treated and one was lost of the view. Steroidogenesis inhibitors were administrated in five patients (preoperative or recurrence) and dopamine receptor analogues in three cases. Therefore, half of patients are in remission, 28.58% relapsed and 21.42% in evolution (recent diagnosed).
Discussions
Although the first line therapy in Cushing's disease is pituitary surgery, it is often difficult to perform it. Given the unpredictable evolution of the disease, combined treatment is often necessary, with better outcomes, but many patients relapse after successful initial treatment (10–20% in specialized centers, > 1/4 in our series).
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P100

**Exogenous corticosteroids: guilty or innocent?**

M. Matos[1,2], P. Freitas[1,2], S. Belo[1,2], J. Frazão[1,2], T. Pimenta[1,2], S. Guimarães[1,2] & D. Carvalho[1,2]
[1]Hospital de São João, Porto, Portugal; [2]Oporto University, Porto, Portugal.

Introduction
The association between autoimmune diseases, including systemic lupus erythematosus (SLE), and endogenous hypercortisolism is rare. The latter is usually misinterpreted as iatrogenic in the case of patients taking exogenous systemic corticosteroid therapy. The excess endogenous glucocorticoids may play an important role in suppressing autoimmune activity. Similarly, the abrupt resolution of endogenous hypercortisolism may lead to a rebound worsening of autoimmunity.
Case report
Twenty-six year-old female, with SLE with renal involvement, diagnosed at the age of 15, since then on systemic corticosteroid therapy. In the past 2 years on

prednisolone 5 mg on alternate days. Hypertension and osteopenia diagnosed in the previous year. Weight gain (6 kg), striae rubrae on the breast and thighs, moon facies, buffalo hump, hair loss, easy bruising, irritability and insomnia were noticed in the previous 4 months. A month after corticosteroid withdrawal, elevated urinary free cortisol [512.9 μg/day (*n*:36–137)] and serum midnight cortisol [40.9 μ/dl ($n$ <7.5)], positive low-dose dexamethasone suppression test [final 8 am cortisol 23.7 μg/dl ($n$ <1.8)] and suppressed ACTH (<1.0 pg /ml) were found. Diagnosis of ACTH independent Cushing's syndrome was made. Abdominal computed tomography showed a 24×24 mm left adrenal nodule with spontaneous density greater than 35 Hounsfield Units. She underwent left adrenalectomy. Pathological analysis of the surgical specimen confirmed an adrenal cortex adenoma. Patient is currently on prednisolone 10 mg id, with appropriate control of renal disease and regression of signs and symptoms of hypercortisolism.

Discussion

The patient's endogenous hypercortisolism has contributed to control her autoimmune disease with low dose exogenous corticotherapy. Abrupt onset of signs and symptoms of hypercortisolism in patients on stable dose of exogenous corticosteroids for a long period of time should raise the possibility of endogenous hypercortisolism.

Declaration of interest

## P101

**Pediatric Cushing disease: case report**

R. Arrais, C. Ramalho, S. Fernandes, P. Albernaz, J. Azevedo & V. Jaime
UFRN – Federal University of Rio Grande do Norte, Natal, Brazil.

Cushing disease is defined by signs and simptoms of hypercortisolism due to augmented ACTH secretion from pituitary origin. It is very rare in pediatric age, with general incidence around 13 cases/1 000 000 persons/year.

Case description

S.G.N, male, 14.5 years old, was brought for medical attention due to weight gain and weakness in the last 4 months. At physical examination, he presented with moon face, cervical acanthosis nigricans, hypertrichosis and acne. Blood pression was 155×110 mmHg.

Initial laboratory profile: glicemia 85 mg/dl, insulin 20.1 mUI/l, total cholesterol 242 mg/dl, HDL 93 mg/dl, LDL 121 mg/dl, tryglicerides 138 mg/dl, cortisol 55.02 μg/dl, 17OHP 4.27 ng/dl, androstenedione 61.40 ng/dl, DHEA 3.4 μg/dl, basal cortisol 57.7 μg/dl, after dexamethasone (8 mg) 32.8 μg/dl.

Petrous sinus catheterism; ACTH test with desmopressin - right petrous sinus: 0′: 110 pg/ml 3′: 124 pg/ml 5′: 119 pg/ml 10′:112 pg/ml. Left petrous sinus: 0′: 813 pg/ml, 3′: 1158 pg/ml, 5′: 834 pg/ml, 10′: 1148 pg/ml. Peripheral blood samples: 0′: 98.4 pg/ml 3′: 99.2 pg/ml 5′: 86.4 pg/ml 10′: 92.6 pg/ml.

Image: abdome and pelvic tomography; adrenal bilateral hyperplasia and a small granuloma found in the left lung. Thorax tomography; thickening of pleura, with atelectasic areas in both lungs. Nuclear magnetic ressonance of sela turcica: slightly hyperplastic hypophysis, without adenomas.

Evolution: treated with ketoconazole, presented with diabetes mellitus, hypertension of difficult control and depression. When the surgical procedure was performed (partial hypophysectomy) medications were gradually suspended. Nowadays, under ambulatory follow-up, displays normal glicemic and arterial pressure values. Interestingly, developed diabetes insipidus, and is taking DDAVP and prednisone.

Conclusions

This case illustrates the importance of physical examination, since Cushing disease is a rare condition, with serious complications and potentially fatal If not adequately treated. The diagnostic and treatment procedures, including central ACTH test, image exams and neurosurgical procedures must be performed in tertiary centers, where these patients must be referred to as soon as possible.

**Proteomic approach to human adrenocortical cancer biology**

G. Poli, E. Ceni, E. Michelucci, L. Canu, V. Piccini, G. Nesi, G. Cantini, G. Moneti, A. Galli, M. Mannelli & M. Luconi
University of Florence, Florence, Italy.

Adrenocortical carcinoma (ACC) is a rare tumor with poor prognosis due to its highly malignant phenotype and lack of effective treatment options.

The etiology of ACC is still unknown. To better understand the pathogenesis of this type of tumor and to determine differentially abundant proteins and candidate biomarkers for adrenal cancer diagnosis and prognosis, we used a novel approach based on two-dimensional differential gel electrophoresis (2D-DIGE). Protein samples were isolated from 10 ACC and 11 normal adrenal tissues (NOR) and subjected to 2D-DIGE analysis. Minimal fluorescent dye labeling was applied and electrophoresis performed with triple samples (normal and tumor; internal control) for each gel. After excision from preparative gels, sixty spots were identified by mass spectrometry. Most of the corresponding proteins associated with spots was significantly up-regulated in tumor compared with normal tissue (fold increase: 2–9.7; cut-off: 1.5). Among them, some were associated with glycolysis and the Warburg effect and others were structural proteins already identified as involved in other tumor types. These data suggest that some of the identified proteins could represent valid diagnostic and prognostic biomarkers also for ACC. Our findings support the application of proteomics not only for elucidating ACC biology but also for its potential transferability to clinics.

Declaration of interest

**GH deficiency in patients with hypoadrenalism**

M. Mendola, G. Beltrami, E. Passeri, A. Tufano, S. Corbetta & B. Ambrosi
IRCCS Policlinico San Donato, University of Milano, San Donato Milanese, Italy.

Introduction

The role of glucocorticoids in the regulation of GH secretion is not well defined. Hypercortisolism inhibits GH secretion, but also hypocortisolism is correlated with impaired GH response to dynamic tests. This study was aimed to evaluate the GH reserve after GHRH+arginine test in patients with Addison's disease (AD) and in operated patients with Cushing's disease (CD).

Design

Twelve AD patients (6M, 6F, aged 52±3.4 years, BMI 24.8±0.9 kg/m$^2$, mean± S.E.M.) were studied. Ten out of 18 CD patients (14F, 4M; 45±1.7 years, BMI 29.2±1.7; all underwent pituitary adenomectomy 2-18 years before) had central hypoadrenalism (group a) and 8 had normal cortisol (group b). Patients were investigated 18 h after steroid withdrawal.

Serum GH peak responses to GHRH+arginine <16.5 and <9 ng/ml were considered as partial (p-GHD) and severe (s-GHD) GH deficiency, respectively. IGF1 levels were evaluated as SDS.

Results

Four of 12 AD patients had s-GHD (peak 4.2±1.1 ng/ml) and 3 had p-GHD (peak 10.7±0.3 ng/ml); IGF1 SDS was <−2 in 7 patients. In CD group a, impaired responses to GHRH+arginine were found in 9 cases (8 had s-GHD, peak 4.7± 1.2 ng/ml and 1 had p-GHD); IGF1 SDS was <−2 in 7 patients. In CD group b, three patients showed a s-GHD (peak 2.7±1.1 ng/ml) and one patient a partial deficiency; IGF1 score was <−2 in all patients with s-GHD.

In AD patients, BMI was negatively correlated with GH peak ($P$=0.01), and a positive correlation between cortisol and GH peak ($P$=0.01) was observed in males. No correlation was found between ACTH, cortisol and GH responses in groups a and b.

Conclusions

This study demonstrates a higher prevalence of GHD in hypoadrenalism than in CD patients with normalized cortisol levels and suggests the need of careful assessment of GH secretion in cured CD.

**The functional assessment and growth rates of adrenal incidentalomas: a single center experience**

S. Avci, S. Zuhur, B. Oguz, S Ucak Basat & Y. Altuntas
Sisli Etfal Research Hospital, Istanbul, Turkey.

Purpose
The aim of this study was to evaluate the functional status and growth rates of adrenal incidentalomas, diagnosed at our center between 2005 through 2010.
Methods
The computer and archive records of 113 patients, diagnosed as adrenal incidentalomas and followed-up at our center, were retrospectively analysed.
Results
A total of 113 patients (133 tumors, 80 women (%70.8) and 33 men (% 29.2), ranged in age between 27 and 77 years old) were included in the study. All patients were evaluated and followed-up by magnetic resonace imaging (MRI) at 6-month intervals. Hormonal evaluation including urinary metanephrine, normetanephrine, free cortisole and serum cortisole (basal and after low dose dexamethasone supression) in all patients, ACTH (in patients with Cushing's sendrome) and plasma renin activity and aldosteron levels (in patients with hypertension) were performed at baseline and then at 6–12-month intervals. According to MRI results, the tumors were located in the right adrenal in 36 (31.8%), in the left adrenal in 57 (50.4%) and in bilateral adrenals in 20 patients (17.7%). A tru-cut biyopsi was performed in 8 patients with suspected tumor appearance on MRI. The clinical diagnosis of patients were presented in Table 1. All patients were followed-up for $15.6 \pm 15.4$ months (min. 6, max. 60 months). During follow up, none of the patients with non-functional adrenal incidentaloma developed hormonal hyperfunction. However, tumor enlargement was determined in ten patients (%7.5), ($<1$ cm in four tumors (%40), between 1 and 2 cm in three tumors (%30) and $>2$ cm in 3 tumors (%30) respectively.
Conclusion
Tumor enlargement may occur in a substantial number of adrenal incidentalomas during follow-up. Since the mass enlargement may be a sign of malignancy, long-term follow-up of these patients with imaging techniques is essential.

**Table 1**

| Diagnoses | Patients ($n=113$) no (%) |
|---|---|
| Non-functional Adenoma Cushing's syndrome Pheochromocytoma Conn's syndrome Congenital Adrenal Hyperplasia Metastasis Malignancy[a] Primary adrenal tuberculosis Adrenomiyelolipoma | 71 (63) 21 (19) 8 (7) 5 (4) 2 (2) 2 (2) 2 (2) 1 (1) 1 (1) |

[a]One non-hodgkin lymphoma and one primary adrenal carcinoma.

**Adrenal venous sampling: local experience in Asian population**

Y. Wan, K. Chan & W. Kan
Pamela Youde Nethersole Eastern Hospital, Hong Kong, Hong Kong.

Primary hyperaldosteronism is a common cause of secondary hypertension. Distinguishing between the two subtypes (unilateral aldosterone-producing adenoma and bilateral idiopathic hyperaldosteronism) is crucial for patient's management. Adrenal venous sampling is an important method for evaluation of the condition, but selective successful right adrenal venous sampling is often reported to be a difficult procedure. A retrospective review of 51 cases suffering from primary hyperaldosteronism with adrenal venous sampling done in the year of 2007 to 2010 in our local hospital in Hong Kong was performed. Biochemical assay of both cortisol and aldosterone levels were done in each sample. Cortisol gradient of 3 between the adrenal sample and a peripheral sample was set as a criterion to indicate successful sampling. Successful catheterizations of the right adrenal vein were noted in 40 cases, while 11 cases failed to meet the cortisol gradient and were excluded. Of the cases fulfilling the cortisol gradient criterion, it was observed that the first sample taken was most useful in analysis of aldosterone–cortisol ratio. Five different patterns of the right adrenal vein were previously described. The right adrenal vein patterns of our patients were as follows: 42.5% with central vein leading to stellate or spidery branches, 27.5% with delta pattern, 10% with glandlike pattern, 7.5% with no discernable adrenal vessels, 2.5% with triangular pattern, and 10% showed vasculatures not typical of these five patterns. Central vein leading to stellate or spidery branches is the commonest pattern, which may differ from those in Caucasians. Identification of these patterns during the interventional procedure may give radiologists a high confidence level that the cannulation is successful, facilitating efficient and precise sampling.

**Comparison of four immunoassays for measurement of cortisol levels**

D. Gruson, T. Lepoutre & L. Galanti
[1]Cliniques Universitaires Saint Luc, Brussels, Belgium, [2]Cliniques Universitaires Mont-Godinne, Yvoir, Belgium.

Background
Measurement of serum cortisol levels can be useful in the diagnosis of conditions of both adrenal insufficiency and excess. Several methods are available for the measurement of the cortisol levels and immunoassays are commonly used in routine laboratories. The aim of our study was therefore to compare four different automated immunoassays for measurement of cortisol in serum.
Methods
Serum samples of seventy two healthy volunteers were used for this comparison of methods. Levels of cortisol were measured with the Architect (Abbott diagnostics), Cobas e411 (Roche diagnostics) DxI (Beckman Coulter) and Liaison (DiaSorin) automated immunoassays.
Results
The four immunoassays were significantly correlated among each other ($P<0.0001$). The mean concentrations (range) were: 326 nM (185–811) for the Architect, 422 nM (200–1142) for the Cobas e411, 343 nM (176–777) for the DxI and 251 nM (113–458 nM) for the Liaison. The mean differences observed with the Bland and Altman plots were $-$ 102 nM (Architect - Cobas e411), $-16$ nM (Architect - DxI), 91 nM (Architect - Liaison), 86 nM (Cobas e411 - DxI), 396 nM (Cobas e411 - Liaison) and 113 nM (DxI - Liaison).
Conclusions
Automated immunoassays for the measurement of cortisol levels are significantly correlated. However, the results are not commutable between the assays and more standardization is still required for cortisol measurement.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Tertiary adrenal insufficiency: case report**

R. Baloescu[1], M. Carsote[2], D. Hortopan[1], A. Gruia[3], R. Miron[4], C. Ene[1] & C. Poiana[1,2]
[1]I.Parhon, Bucharest, Romania; [2]UMPh Davila, Bucharest, Romania; [3]Medlife, Bucharest, Romania; [4]Constanta Hospital, Constanta, Romania.

Introduction
Exogenous Cushing's syndrome is a challenging diagnosis in non-compliant patients or in cases with difficult anamnesis, while the access to self medication is relatively open.
Aim
We present a young female case presenting with tertiary adrenal insufficiency.
Case report
S.C., 40 years old has progressively weight gain of 30 kilos since the last year. The Body Mass Index is 40 kg/m$^2$, with androgen redistribution. The personal and familial medical history is negative. She accuses asthenia, diffuse muscle pain. She presents facial plethora, diffuse hyperemia over the body, multiple red stria at the level of the arm, abdomen, breasts, legs. The menses stopped for several months. She associates high arterial blood pressure, retinal hypertensive angiopathy, dyslipidemia, hyperuricemia, and high levels of the hepatic enzymes. The serum potassium is 3.9 mmol/l. The plasma cortisol is low: 0.11 μg/dl

(normal 11–22). The 24 h free cortisol is 5.04 μg/24 h (normal 30–330). The plasma ACTH is 1 pg/ml (normal 6–65). The computed tomography shows a pituitary microadenoma of 5 by 4.7 mm, that we consider an incidentaloma, and normal adrenals. Central DXA reveales normal bone mineral density for patient's age. An exogenous Cushing's syndrome was suspected, and the anamnesis was resumed. The patient denied any ingestion of some medication, but she did affirm that she was using topic glucocorticoid (Dermovate) for all over her skin for more than a year, recommended at some point by her dermatologist for "dry skin". She no longer used the unguent. Clinical symptoms of adrenal insufficiency were seen. We recommended prednisone 2.5 mg/day for 2 months, then only in case of hypotension or infections, fever. The clinical phenotype persisted for several months with a mild improvement.

Conclusions

In some cases of Cushing's syndrome, the anamnesis is the main clue of diagnosis. The chronic topic use of glucocorticoids is also important in inducing the Cushing's phenotype and the stop of their use might induce tertiary adrenal insufficiency.

### A case of HIV presenting as primary adrenal lymphoma

A. Swiecicka, N. Siddaramaiah, J. Bukowczan, S. Ashwell, R. Mukhtar & V. Arutchelvam

James Cook University Hospital, Middlesbrough, UK.

Introduction

Non-Hodgkin's lymphoma is an AIDS defining malignancy. However, a primary adrenal lymphoma as a presenting feature of HIV infection has not been previously reported.

Case Report

A 66-year-old male presented with a short history of severe fatigue, weight loss, dizziness and nausea. Baseline blood results revealed normal biochemistry with mild normocytic anaemia, neutropaenia with lymphopaenia and the short synacthen test demonstrated intact HPA axis (baseline cortisol 348 nmol/l, 30 min 607 nmol/l, 60 min 632 nmol/l). Upper and lower GI endoscopies as well as CT abdomen showed no significant pathology.

Three months later he presented acutely with extreme fatigue, vomiting, hypotension and hyponatraemia of 123 mmol/l. His short synacthen test was repeated which demonstrated sub-optimal response with baseline cortisol 298 nmol/l, 30 min 353 nmol/l and 60 min 439 nmol/l. Steroid replacement therapy resulted in significant clinical improvement. The CT abdomen was repeated which revealed bilaterally enlarged, well defined homogenous adrenal masses measuring 6 cm each, which were non-secretory on endocrine testing.

Three weeks later, a pre- biopsy imaging showed 70% reduction in adrenal volume, possibly due to steroid therapy. Laparoscopic right adrenelectomy and biopsy confirmed diffuse large B-cell lymphoma. Further investigations confirmed the patient was HIV positive with the CD4 count of 1 per microlitre and the clinical course was complicated by CMV retinitis. Despite the chemotherapy with incorporated HAART, the course of the disease has been complicated by the subsequent development of cerebral lymphoma.

Conclusion

HIV-associated lymphoma is most commonly diagnosed in patients with advanced HIV, a low CD4 count (often $<100/\mu l$), high HIV viral load, and a prior diagnosis of AIDS.

We present this unusual case of primary adrenal lymphoma presenting with adrenal insufficiency which posed a diagnostic challenge.

### Ketoconazole in surgery preparation and follow-up of Cushing's disease - our experience

A. Violante, V. Silva, M. Medeiros & M. Vaisman

Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil.

Cushing's disease is the main cause of endogenous hypercortisolism. Comorbidities increase morbidity and mortality and the treatment is fundamentally surgical. Patients may use drugs to lower hypercortisolism as pre-surgical preparation and post-surgical treatment when cure is not reached.

Objective

Evaluate the benefits and collateral effects of ketoconazole in Cushing's disease.

Methods

In 22 patients with Cushing's disease with mean age of 45.36 years, pre and post-surgical, we compared the group that used ketoconazole ($n=15$) with another that did not use it ($n=07$). Diabetes mellitus control, blood pressure, hyperlipemia, body mass index, plasma levels of potassium and basal cortisol were analysed.

Results

Plasma cortisol was the only parameter with significant reduction ($P<0.01$). There were no collateral or adverse effects in 63.6% of the patients.

Conclusion

The use of ketoconazole permits significant reduction of serum cortisol levels. In order to better evaluate the impact on the control of hypercortisolism and its comorbidities, a higher number of patients must be evaluated for a longer period of time.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Utility of CGM for the determination of optimal glucocorticoid replacement method in patients with adrenal insufficiency

Y. Akehi, T. Fukuda, H. Nagasako, Y. Terawaki, A. Takada, R. Nagaishi, H. Takenoshita, T. Nomiyama & T. Yanase

School of Medicine, Fukuoka University, Fukuoka, Japan.

Introduction

Optimal glucocorticoid (GC) replacement in patients with adrenal insufficiency (AI) is desirable for the prevention of long-term side effects of GC. Both hyperglycemia and hypoglycemia are the risk of atherosclerosis. For the determination of optimal GC replacement method in patients with AI, we tested a utility of continuous glucose monitoring (CGM).

Subjects and methods

Three patients with primary or secondary AI were examined. Case 1, 50 yo female with complete AI because of bilateral adrenalectomy due to bilateral adrenal pheochromocytomas; Case 2, 50 yo male who showed asymptomatic or latent AI due to Rathke's pouch as evidenced by relatively poor response to CRH.; Case 3, 64 yo male of partial panhypopituitarism due to the operation of craniopharyngioma. Under the various regime of hydrocortisone (HC) or dexamethasone (Dex) replacement, the frequency of high (over 110 mg/dl) and low (below 70 mg/dl) blood glucose levels were evaluated by CGM.

Results

In the bilaterally adrenalectomized case 1, regime 1, po HC (20, 0, 10, 0 mg) or regime 2, HC (15, 0, 5, 0 mg) + po Dex 0.25 mg before sleep was tested. While midnight hypoglycemia was more frequent in regime 1, the frequency of daily hyperglycemia and midnight hypoglycemia were dramatically reduced in regime 2. In case 2 of latent AI, even 5 mg HC in the morning increased the frequency of hyperglycemia, leading to the cancellation of the medication. In case 3 of partial AI, regime 1 (15, 5, 10, 0), 2 (15, 10, 5, 0), 3 (15, 0, 10, 0), 4 (10, 5, 5, 0) and 5 (10, 0, 5, 0) were tested. No hypoglycemia was observed in any regimen and the lower the dose of HC, the lower the frequency of hyperglycemia.

Conclusion

CGM is useful for perusing the ideal method of GC replacement in patients with AI.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**A case of subclinical Cushing's syndrome who developed pseudo-aldosteronism caused by green juice**

K. Ohashi[1], T. Hayashi[2], T. Saito[1], H. Yamazaki[1], K. Tojo[2] & K. Utsunomiya[2]
[1]Kawaguchi Municipal Medical Center, Saitama, Japan; [2]The Jikei University School of Medicine, Tokyo, Japan.

Seventy six-year-old man was referred to our hospital for examination of hypertension and hypokalemia. His blood pressure was uncontrolled although he was taking amlodipine besilate, spironolacton and candesartan. In addition, he suffered from atrial fibrillation and chronic heart failure. His serum potassium was low (2.8 mmol/l) and bilateral adrenal glands were found swelling. Hence, we investigated him thoroughly on the suspicion for primary aldosteronism.
Unexpectedly, plasma renin activity (PRA, 0.1 ng/ml per h) and aldosterone concentration (PAC, 10.0 pg/ml) were low. On the other hand, diurnal variation of plasma ACTH and cortisol were lost with suppression of ACTH. At overnight fast, plasma levels of ACTH and cortisol were 4.0 pg/ml (7.2–63.3) and 15.5 μg/dl (4.0–18.2) respectively, and administration of 1 mg nor 8 mg dexamethasone neither suppressed serum cortisol levels. Abdominal CT and MRI revealed bilateral adrenal tumor (right 12×10 mm, left 12×5 mm in diameter). $^{131}$I-adosterol scintigraphy showed bilateral high uptake. On the basis of these findings, we considered possibility of subclinical Cushing's syndrome; however, the causes of hypokalemia and hypertension still remained to be explained.
For differential diagnosis of low-renin, low-aldosterone hypertension, we measured serum DOC and urine THE/THF ratio both of which were within normal range. Liddle syndrome was less likely because of the age of onset.
After admission, his blood pressure returned to be normal without any change in medication. Then, he noticed that he had casually drunk a lot of green juice, which was ceased after admission. Green juice is one of the popular vegetable juices in Japan, and contains licorice. Hence, we concluded that he has pseudo-aldosteronism complicated with subclinical Cushing's syndrome. It could be considered that inhibition of 11βHSD type 2 by licorice in the patient with latent excess of cortisol may develop severe hypokalemia and hypertension through mineralocorticoid receptor.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P112

**Adrenal masses as the first demonstration of non endocrine tumors metastatic disease**

R. Palmeiro, C. Paramo, P. Sanchez, I. Seoane, C. Trigo, Y. Lopez, R. Luna, M. Penin & R. García-Mayor
Complexo Hospitalario Universitario de Vigo, Vigo, Spain.

Introduction
Adrenal lesions occur in more than 10% of the general population. Most are benign, but 2.5% are metastatic disease to the adrenal from tumors such melanoma, renal, breast, colon and lung carcinoma. Adrenal metastatic disease is usually asymptomatic and diagnosed in the extension study or the primary tumor. However it is unusual as a presentation of an endocrine tumor or like the first manifestation of metastatic disease.
We present two patients with adrenal macrolesions like the first manifestation of metastatic disease of non endocrine tumors.
Case study n 1
A 63 year old male with a history of hypertension well controlled and occasional smoker presents with sudden pain in right iliac fosse after physical exertion. Abdominal CT evidence a right adrenal mass (9×11 cm) and two left adrenal nodules (2 and 1.5 cm) reason why he is admitted to our service. Besides the chest radiography and chest CT revealed a nodule of 2 cm in right upper lobe lung.
Urinary catecholamines were slightly elevated and right adrenalectomy was performed with the suspicion of a macropheochromocytoma. The pathological study was consistent with metastatic lung adenocarcinoma. Extension study shown left adrenal and mesentery metastases, and chemotherapy was started.
Case study n 2
A 83 year old male was diagnosed with ampullary due to repeated episodes of cholangitis. Abdominal MRI showed adrenal masses of 4 and 5.7 cm. Six months after the diagnosis he was admitted to hospital due to acute adrenal insufficiency (Addison disease caused by neoplastic adrenal infiltration). Adrenal replacement therapy has clearly improved his quality of life but not his survival.
Conclusions
– The adrenal macrolesions in patients without known malignancy should be considered as metastases because of the rarity of endocrine tumors in this location.
– The metastatic adrenal involvement in patients with disseminated neoplasms may produce hypoadrenalism that must be treated in order to improve the quality of life of patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P113

**Usefulness of FDG–PET for detecting primary aldosteronism in patient who have bilateral adrenal incidentaloma**

Y. Kim, M. Ko, C. Park, I. Nam-Goong, Y. Na & E. Kim
University Hospital, College of Medicine, University of Ulsan, Ulsan, Republic of Korea.

Adrenal masses are common incidental radiological findings. It has been estimated that as many as 10–20% of patients with essential hypertension may suffer from undiagnosed primary aldosteronism (PA). In patients who have both adrenal incidentaloma, which the functioning one must be identified. We report a case where an unilateral PA was detected on $^{18}$F-fluorodexoyglucose (FDG)-positron emission tomography (PET), and comfirmed by adrenal venous sampling.
A 53-year-old man was referred to the clinic due to bilateral adrenal masses (right sized 1 cm, left 2.5 cm) on the abdominal computed tomography. The patient was receiving chemotherapy due to a colon cancer postoperatively. Subsequently, whole body FDG–PET was performed, and showed a focal increase of FDG uptake at the right adrenal adenoma. Serum aldosterone-renin ratio was 104, and not suppressed by captopril. As suspection of PA, adrenal venous sampling was performed. It revealed the aldosterone/cortisol ratio was 33 times higher on right adrenal side than left, which consistent with the result of FDG uptake. He was underwent laparascopic mass excision of right adrenal adenoma.
Therefore, we propose that FDG–PET can be useful diagnostic tool for identifying functional adrenal mass instead of adrenal venous sampling.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Next generation sequencing is a cost effective and time saving method in clinical genetic screening of patients with pheochromocytomas**

J. Crona, A. Delgado Verdugo, D. Granberg, S. Welin, P. Stålberg, P. Hellman & P. Björklund
Uppsala University, Uppsala, Sweden.

Background
Pheochromocytomas are rare tumours arising from adrenal medulla. Recent findings show that about 30–40% of pheochromocytomas are caused by germline mutations in one of the ten hereto known susceptibility genes: SDHA, SDHB, SDHC, SDHD, SDHAF2, RET, VHL, NF1, TMEM127 and MAX. This list of genes is constantly growing. These ten genes together consist of 128 exons and a genetic screening test is both extensive time-consuming and expensive. We introduce utilizing Next generation sequencing as a fast and cost effective method.
Methods
DNA was extracted from pheochromocytoma lesions and were subjected to whole genome sequencing utilizing Illumina Hi seq platform, performed at university core facility. Reads from pair-end fragments were mapped (GRCh37) and variation calling was performed using a commercially available software. Identified mutations were verified by automated Sanger sequencing.
Results
We have identified two point mutations, in RET and SDHC, in two different pheochromocytoma lesions, spending less than two hours hands on, in house,

time. Mutations were verified by traditional Sanger sequencing of a single fragment for each gene.
Conclusions
Utilizing next generation sequencing is a fast and cost effective method for clinical genetic screening in pheochromocytomas. Using this workflow, the analysis can be performed without expert skills in bioinformatics.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This work was supported, however funding details unavailable.

## P115

**Pheochromocytomas: a single centre experience**

S. Belo, A. Magalhães, C. Nogueira & D. Carvalho
Centro Hospitalar S. João, Porto, Portugal.

Introduction
Catecholamine-secreting tumors (pheochromocytomas and paragangliomas) are rare intra and extra-adrenal neoplasms, probably occurring in less than 0.2% of patients with hypertension. Serious morbidity and mortality rates are associated with these tumors which are related to the effects of catecholamines on various organs, especially those of the cardiovascular system.
Methods
We reviewed the cases of pheochromocytomas and paragangliomas that were diagnosed, treated and/or followed in our institution since 1983 till 2011. Statistical analyses was made using SPSS 17. Data is presented in frequencies and mean ± standard deviation.
RESULTS
In this review were included 88 patients (58% women; 42% men). The mean age of diagnosis was 49.2 ± 15.2 years and only 6.8% of the patients presented known familial history of the disease. The diagnosis of pheochromocytoma was made in 59% of the patients.
The most frequent form of presentation was as incidentaloma (36.4%) followed by persistent hypertension (27.3%) and other causes (ex: cervical mass: 26.1%). Urinary metanephrines were determined in 51% of the patients (normetanephrine 3042.7 ± 4702.0 μg/24 h; metanephrine 1991.8 ± 3741.0 μg/24 h). An imaging examination was done in 60% of the cases, being a MIBG scintigraphy in 68% of them.
Surgery preparation was made in 45.5% of the patients (34.1% only α blocking; 11.4% α and β blocking) for a mean time of 25.3 ± 44.9 days. Major surgery complications were observed in 8% of the patients, 43% of them didn't perform preoperative preparation according to clinical standards.
Patients were followed for a mean period of 48.5 ± 52.8 months, 10.5% were not cured after surgery, in 4.7% disease recurrence was observed and 29.1% were lost to following.
Discussion
Pheochromocytoma is a rare entity but with serious consequences if not diagnosed or properly managed. Judicious ad eternum follow up is necessary to ensure early detection of recurrences.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P116

**Removal of the dominantly secreting adrenal lateralized by bilateral adrenal venous sampling (BAVS) with glucagon stimulation significantly alleviated hypertension in patients with bilateral adrenal pheochromocytoma**

C. Malong[1], M. Ngo[1], P. Salvador[1], K. Pacak[2] & L. Mercado-Asis[1]
[1]University of Santo Tomas Hospital, Manila, Philippines; [2]National Institutes of Health, Bethesda, MD, USA.

Background
The current recommendation on the use of venous sampling is reserved for difficult cases of small pheochromocytoma. Bilateral adrenal venous sampling (BAVS) with glucagon stimulation has been reported to be safe and useful in the early diagnosis of the disease. For bilateral lesions, localization can be challenging but highly important since the removal of the dominant side can markedly improve fatal cardiovascular outcomes as a consequence of chronic hypertension.
Objective
To demonstrate the usefulness of glucagon-stimulated BAVS in determining the dominant adrenal to be removed.
Methodology
This is a cross-sectional study wherein records of patients who underwent BAVS with glucagon stimulation from 1997–2010 were reviewed.
Results
Of the 46 patients who underwent BAVS with glucagon stimulation, 19 were diagnosed with bilateral pheochromocytoma. The mean age at diagnosis was 33 ± 14 years. The mean duration of hypertension was 5 ± 6 years with an average highest systolic blood pressure (BP) of 186 ± 30 mmHg and diastolic BP of 113 ± 18 mmHg. Headache (68%) is the most common symptom followed by paroxysmal hypertension (58%), palpitation (42%), and flushing (37%).Majority were taking three or more anti-hypertensive drugs. On glucagon-stimulated BAVS, 63% had right adrenal dominance. The mean epinephrine and norepinephrine levels on the dominant side were 24,506 ± 30710 pg/ml and 8,642 ± 13,395 pg/ml, respectively. The mean ratio of the dominant versus nondominant adrenal for epinephrine and norepinephrine were 3.62 and 4.13, respectively. Three patients underwent unilateral adrenalectomy. On follow-up, there was marked improvement in BP and reduction of anti-hypertensive medications.
Conclusion
BAVS with glucagon stimulation is a valuable tool in the identification of the dominant adrenal to be removed in patients with bilateral pheochromocytoma to alleviate chronic hypertension.

Follow-up of patients who underwent adrenalectomy of the dominantly secreting adrenal gland

| Case | Duration of Hyperten-sion (years) | Follow-up Period (months) | Systolic BP (mm Hg) | | Diastolic BP (mm Hg) | | Anti-hypertensive Medications (N) | |

**Neuroendocrine markers in biochemical vs pathology diagnosis of pheochromocytoma**

C. Badiu[1,2], S. Muraru[1], S. Jercalau[2], R. Dobrescu[1] & A. Stefanescu[1]
[1]National Institute of Endocrinology, Bucharest, Romania; [2]'C. Davila' University of Medicine and Pharmacy, Bucharest, Romania.

Pheochromocytomas, tumors derived from adrenal medulla, are characterized by a polymorphic clinical picture dominated by paroxysmal hypertension. Between the clinical, laboratory and pathology data, discordances are frequently seen.
Patients and Methods
Thirty five cases of pheochromocytoma and paraganglioma (10 men) with adrenal tumors and hypertension were confirmed with pheochromocytoma. They were aged 53.68 ± 12.75 years (36–75), while the tumor diameter ranged from 1.5 to 13 cm. Five cases were oligosymptomatic, with only one or two crises in life suggesting catecholamine excess. The evaluation was done for plasma metanephrines and normetanephrines as well as chromogranin A (CGA) with Elisa commercial assays. Immunohistochemistry was performed on removed tumor tissue on paraffin sections by avidin biotin complex method using antibodies against CGA, neuron specific enolase (NSE), synapthophysin (SYN), protein S100, succinate dehydrogenase, as well as Ki67 index as marker of tumor proliferation. The staining intensity was marked from 0 to 3, considering the number of stained cells.
Results
The initial evaluation confirmed excess of plasma metanephrines (MN) (736.11 ± 886.51 pg/ml), normetanephrines (NMN) (2423.26 ± 1907.6 pg/ml) and CGA (790.44 ± 697.85 ng/ml). Immunostaining for CGA was moderate / intense positive in 30/35 cases, in 3 cases the plasma CGA values being in normal range.

Better pathology markers were NSE and SYN, while S100 protein was nonspecificaly high even in oligosymptomatic tumors. Olygosymptomatic patients were with similar plasma values as compared with pheochromocytoma with frequent crises, but SYN and NSE staining was weaker. Ki67 index, around 2–4%, was not related to plasma or pathology data.
Conclusions
From our data, there is no direct correlation between classical neuroendocrine plasma and pathology markers; still, low expression of NSE and SYN might reflect a lower metabolism rate in oligosymptomatic tumors.

**Geranylgeraniols are essential for adrenal catecholamine secretion**

E. Tachikawa[1], M. Kutsukake[1], K. Tamura[1], M. Yosie[1], M. Hossain[2] & H. Taira[3]
[1]Tokyo University of Pharmacy and Life Sciences, Hachioji, Japan; [2]Mississippi State University, Hachioji, MS; [3]Iwate University, Morioka, Japan.

Introduction
Dolichols are isoprenoids, which are synthesized from acetyl-CoA via mevalonic acid, and they are known to be abundant in endocrine system. Adrenal medulla, which is not only an endocrine organ but also an organ derived from neural crest, secrets catecholamines via sodium and subsequent calcium influxes into the cells through nicotinic ACh receptor-operated cation channels and voltage-sensitive calcium channels, respectively, when the medulla is stimulated by acetylcholine (ACh). In this study, therefore, we investigated the role of dolichols and other isoprenoids in ACh-evoked catecholamine secretion from bovine adrenal chromaffin cells.
Results and Discussion
The treatment of the adrenal chromaffin cells with dolichols did not affect the ACh-evoked secretion of catecholamines. However, fluvastatin, an inhibitor of 3-hydroxy-3-methylglutaryl CoA (HMG-CoA) reductase which is a key enzyme in the isoprenoids' synthesis, attenuated the ACh-evoked catecholamine secretion from the cells. The statin also reduced both thebACh-induced sodium and calcium influxes into the cells. Under the condition, the production of some isoprenoids in the cells is presumed to be very low. Mevalonate or geranylgeraniol, an alcohol type of geranylgeranyl pyrophosphate (GGPP), overcome the statin inhibition of catecholamine secretion, but not other isoprenoids, isopentenyl pyrophosphate, GGPP, geraniol, farnesol, farnesyl pyrophosphate, cholesterol and dolichols. Fluvastatin affected neither the expression of $\alpha$3 and $\beta$4 nicotinic ACh receptors mRNA nor of voltage-sensitive calcium channel mRNA in the chromaffin cells. Two-dimensional electrophoresis showed that there was no difference between the protein quantity in the control and the fluvastatin-treated cells. These results strongly suggest that geranylgeraniols and/or GGPP in the membranes are essential for calcium-dependent catecholamine secretion in adrenal chromaffin cells.

**Neither classical symptoms of phaeochromocytoma nor elevated urinary catecholamines are always seen in patients with histologically verified phaeochromocytoma**

S. Lumley, R. Reddy, N. Karavitaki & J. H Wass
University of Oxford, Oxford, UK.

Background
The symptom triad of 'headaches, palpitations and sweating' along with elevated urinary catecholamine levels are commonly used to diagnose phaeochromocytoma. We wanted to assess how often patients with histologically verified phaeochromocytoma did not have this triad or had normal urinary catecholamine excretion on one occasion or more.
Methods
Retrospective analysis of clinical presentation and urinary catecholamine levels in 75 patients with phaeochromocytoma in Oxford.
Results
Clinical features: Palpitations were the most commonly reported symptom (67%), followed by sweating (66%), hypertension (65%) and headache (63%). 12% did not have any of the classic triad of headache/palpitations/sweating, 8% did not have the classical triad or hypertension. Of these 8% (six patients), five patients were completely asymptomatic and one presented with isolated abdominal pain.
Urinary catecholamines: Pre-operative biochemical urine analysis was available for 51 patients; 44 had all three of normetadrenaline, metadrenaline and 3-methoxytyramine measured.
90% (4/44) had normal urinary catecholamine excretion on one occasion or more. Of these 4 patients, 1 (2% of the cohort) had multiple normal readings (on 6/7 measurements), 1 patient did not have levels repeated. The remaining 91% had at least one elevated urinary catecholamine on every measurement.
71% had one or more occasions where one of the catecholamines was normal, 3-methoxytyramine was most likely to be normal at some point during investigation (59%).
Conclusions
The triad of headaches, palpitation and sweating misses 12% of cases. The inclusion of hypertension to form a tetrad reduces this to 8%.
Normal urinary catecholamines on one occasion are not sufficient to exclude a phaeochromocytoma. If there is a strong clinical suspicion they should be repeated, only 2% had multiple normal readings.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**The unique case of adrenal malignant non-functioning oncocytic pheochromocytoma**

E. Przybylik-Mazurek, D. Pach, A. Hubalewska-Dydejczyk, S. Kuzniarz-Rymarz, M. Tracz-Bujnowicz, A. Urbanik & M. Bialas
Jagiellonian University Medical College, Krakow, Poland.

Introduction
Pheochromocytoma is a tumour of chromaffin cells of the sympathetic nervous system and its clinical symptoms are associated with excessive production and release of catecholamines.
Case report
We report a rare case of non-functioning malignant adrenal oncocytic pheochromocytoma incidentally found during yearly repeated ultrasound abdomen examination in a 78-year-old man with history of cardiovascular diseases: aortal abdominal aneurysm, ischemic heart disease and some years ago an episode of hypertension. The patient confirmed a polycyclic high density large left adrenal mass. The preoperative problem in the differential diagnosis of this case was to determine its origin (adrenal or renal). The lack of did not have clinical manifestations of pheochromocytoma. Computed tomography study typical symptoms and signs and the low level of catecholamine metabolites (Metanephrine 53.78 ug/24 h: No. 52-341, Normetanephrine 200.14 ug/24 h: No. 88–440, VMA 11.6 umol/24 h: No. 9–36) preoperatively further eliminated some clues for differential diagnosis. The tumor measured $80\times60\times60$ mm was subsequently excised. It was considered to be a malignant lesion because of the size, extracapsular extension and focal necrosis. Histological examination revealed an oncocytic pheochromocytoma. It consisted of large polygonal tumor cells containing eosinophilic granular cytoplasm. The latter were immunohistochemically positive for chromogranin, vimentin and s-100 protein. During three years follow up patient was in general good condition - free of disease. Three years after adreanlectomy he had a relapse and then died because of dissemination.
Conclusion
There are only few papers on cases of adrenal oncocytic pheochromocytoma.
Because of unusual histology and rarity of this type of tumor, we report a case of adrenal oncocytic pheochromocytoma including its' visual, histologic and immunohistochemical features.
The presented case appears to be the first adrenal oncocytic malignant and non-functioning pheochromocytoma. It confirms the complexity of biology and difficulties in diagnosing this type of neoplasm.

## P121

**A rare case of adrenocorticotropic hormone-producing Pheochromocytoma**

S. Galan & P. Kann
University Hospital Giessen and Marburg, Marburg, Germany.

Introduction
Cushing's syndrome caused by adrenocorticotropic hormone-producing pheochromocytoma has been rarely reported. In such cases, the high production of ectopic adrenocorticotropic hormone produced by pheochromocytoma results in bilateral adrenocortical hyperplasia and thus in consecutive Cushing's syndrome. We report a case of a 43-year-old patient with a 6 cm right-sided adrenal tumor producing both elevated levels of catecholamines and adrenocorticotropic hormone.
Case
The 43-year-old patient presented with a hypertensive crisis with blood pressure up to 230/160 mmHg, sinus tachycardia and pulmonary oedema. An arterial hypertension was 1 by the patient until the moment of admission. The abdominal ultrasonography and the later computerized tomography showed a 6 cm adrenal tumor with necrotic areas, typical for pheochromocytoma. Urinary catecholamines war extremely increased. The MIBG scan revealed a substantial uptake of the right adrenal tumor without any other pathological findings. The serum and urine cortisol concentrations were normal, but the cortisol was not at all suppressed on the overnight 2 mg and later 8 mg oral dexamethasone suppression test. After proper premedication the right adrenalectomy was performed. By means of histological examination the clinical, laboratory and imaging diagnosis of pheochromocytoma was confirmed. Furthermore, the cytoplasmatic staining revealed a positive reactivity for adrenocorticotropic hormone in about 5% of the cells. The laboratory test results concerning the preclinical Cushing's syndrome normalized after performing the right adrenalectomy. The genetic analysis showed no genetic mutations.
Discussion
Adrenocorticotropic hormone-producing pheochromocytomas are rare entities, which should not be overlooked. When investigating an adrenal adenoma, an overproduction of all specific hormones, including of adrenocorticotropic hormone, should therefore be excluded.

**A Novel SDHC mutation associated with Head-Neck Paraganglioma**

Rasmussen, L. Friis-Hansen, A. Gerdes, S. Langer & U. Feldt-Rasmussen
Copenhagen University Hospital, Copenhagen, Denmark.

Germline mutations in the succinate-dehydrogenase subunits A, B, C, and D (SDHA/B/C/D) predispose to development of the phaeochromocytoma-paraganglioma (FPGL) syndromes. SDHC and SDHD are anchoring proteins located in the inner mitochondrial membrane. The SDH complex has two major roles in energy production it is part of the tricarboxic acid cycle catalysing the oxidative dehydrogenation of succinate coupled to the reduction of ubiquinone. It is also the complex II component of the electron transport system. Mutations in SDHC are present in ~4% of Head-Neck paraganglioma (HNPGL) patients. In a paraganglioma cohort more than 80% of patients with SDHC mutations had HNPGL and two had a thoracic FPGL. We now report a 64 years old woman with a cerebral paraganglioma with metastases to the neck. Thirty years ago, the patient was diagnosed with a glomus tumor in the middle ear and received radiotherapy. In 2009, a MR scan revealed a large tumor in the posterior fossa. Histological examination showed an atypical neuroendocrine carcinoma, positive for chromogranin A and synaptophysin. The Ki67 index was 30%. Urine catecholamines, plasma metanephrines and plasma chromogranin A were 5 to 7 times upper normal limits. The patient was treated with neurosurgery and chemotherapy. Due to neck lymph node metastasis, radionuclide therapy is currently under consideration. Analysis of the SDHC gene revealed a 17 basepair germline deletion (c.191_207del17) in exon 4. The deletion causes a frameshift and has not been described before. The patient's son and two brothers were not interested in genetic testing.

**Features at presentation of adrenal pheochromocytomas in castilla la mancha (spain). Is the clinical spectrum changing ?**

E. Maqueda[5], A. Vicente[5], M. Aguirre[2], L. Louhibi[1], I. Gómez[3], M. Alramadán[4], C. Roa[7] & V. Alvarez de Frutos[6]
[1]General Universitario, Albacete, Spain; [2]Hospital General, Ciudad Real, Spain; [3]Hospital General La Mancha Centro, Alcázar de San Juan, Spain; [4]Hospital Virgen de la Luz, Cuenca, Spain; [5]Hospital Virgen de la Salud, Toledo, Spain; [6]Hospital Universitario, Guadalajara, Spain; [7]Hospital Santa Bárbara, Puertollano, Spain.

Background
Typical presentation of adrenal pheochromocytomas (PHEOs) is a combination of variable hypertension with paroxysmal symptoms. However, recent improvements in diagnostic imaging techniques and increasing availability of genetic testing have facilitated presymptomatic diagnosis of PHEOs.
Objetive
To analyse the clinical features at presentation of PHEOs in a multicentric study population.
Design and patients
Seven Spanish endocrine centres participated in this study. Medical records of 69 patients who were diagnosed of PHEO between 1991 and 2011 were reviewed.
Results
34 were male and 35 were female. Mean age at diagnosis was 52.11 years (17–78). Typical triad of symptoms was found only in 18.6% of cases. Nine patients (12.9%) were diagnosed during hypertension study. Hypertensive crises during diagnostic or surgical procedures occurred in 10.1% of cases. Thirty two patients (45.7%) were incidentally discovered. 5 cases were diagnosed before 2000, and 27 after this year. These patients were significantly older than patients in whom the diagnosis was suspected on clinical grounds. ($57.6 \pm 12.2$ vs $46.8 \pm 17.3$ years; $P < 0.01$) The mean size of incidental PHEOs were $4.79 \pm 2$ cm, smaller than the mean size of the whole study group PHEOs ($5.35 \pm 3.29$ cm). Seventeen genetic testing were done (seven negative and ten positive: nine MEN2 and one Von Hippel Lindau). Three patients (4,3%) was discovered by this way. Patients with positive genetic study were significantly younger ($32.1 \pm 11.4$ vs $52.1 \pm 16$ years; $P < 0.001$). Six patients (8.7%) had bilateral tumors; four of these were found to have MEN2. Only one patient had metastasic disease at the time of diagnosis.
Conclusions
In our study group, presymptomatic diagnosis were done in a half of the patients with PHEOs. Frecuency of incidentally discovered PHEOs seemed to be increasing over time and familial PHEO was found in a significant proportion of the patients. Every adrenal incidentaloma should be investigated for the presence of PHEO and genetic testing should be considered in patients with a family history, young age, or multifocal, bilateral, extra-adrenal, or malignant tumors.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P124

**Incidentally discovered pheochromocytoma (PH)**

N. Kesri[1], A. Boudiba[2] & F. Chentli[1]
[1]Chu Bab El Oued, Algiers, Algeria; [2]Chu Mustapha, Algiers, Algeria.

The main concern of endocrinologist exploring an adrenal incidentaloma (AI) is the identification of malignant and/or secretant AI leading to rapid cure by removal of the tumor. PH remains one of the most difficult lesions to diagnose. In this study we analyze PH clinic, morphologic and secretory profile. Among a series of 91 AI recruited between 1987 and 2007 having benefited from an adrenal exploration, 56 have been removed and 18/56 were diagnosed as tumors of medullar origin.

Results
This group is composed of 15 benign and 2 malignant PH and 1 neuroendocrine tumor. Benign PH are found in 7F/8H, 44.2+/−14y. Initial presentation includes HTA in 40%, paroxystic in 30%, adrenergic signs in 20%, DS in 20%, weight loss in 13.3%. Average axis PH=64.4+/−29.7 mm, heterogeneous spontaneous density in 84.6%. Rise of urinary metanephrines (uMN) is noted in 47.6% of PH, 23.8% of cortical AI and 28.6% of extra adrenal AI (sensitivity 52.9% specificity 61.7%) threshold 4times normal rates is more contributory to PH diagnosis. Within this group, PH are sécrétant in 60% with concentration of uMN =3.1+/−3.2 mg/24 h. Iodine 131 MIBG Adrenomedullary Scintigraphy showed a hormonal/isotopic match in 71% (sensitivity 62.5% specificity100%) Malignant PH have been diagnosed in one hypertensive male, AI 200 mm, uMN↑3,02 mg/24 h, no fixation and one female, AI 100 mm, ↑Dopamine.
Conclusion
In this study PH represented 32% of the operated AI and are in more than 80% benign, recruited among large AI with malignant radiological phenotype. 3/5 patients are normotensive. The current uMN assay is not very sensitive, secretory activity is noted in about half cases. Scintigraphy revealed excellent specificity and a hormone-isotopic match in about 3/4. The discordant aspects are related to the relative small size of AI, the significance of intratumoral metabolism or the scarcity of storage granules.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P125

**Pheochromocytoma incidentally discovered after thyroid surgery manifesting dramatic hypertensive crisis induced by metoclopramide**

S. Corsello, M. Ricciato, R. Paragliola, G. Bello, M. Bocci, C. De Crea, M. Raffaelli, C. Lombardi, M. Antonelli, A. Pontecorvi & R. Bellantone
Catholic University School of Medicine, Rome, Italy.

Introduction
Metoclopramide is known to exert stimulatory effects on catecholamine secretion, having been used in the past as provocative test in the diagnosis of pheochromocytoma. We describe a patient with an incidentally discovered pheochromocytoma after metoclopramide administration.
Case report
A 64 years-old woman underwent total thyroidectomy for multinodular goiter with 'follicular proliferation Thy 3' at FNAB of the target nodule. The patient was affected by mild not paroxysmal hypertension adequately treated with doxazosine 2 mg/day. About 12 h after surgery she has postoperative nausea treated with 10 mg i.v. metoclopramide. After few minutes she developed a severe hypertensive crisis non-responsive to i.v. furosemide and i.m. clonidine but responsive to 10 mg i.v. phentolamine. Blood samples showed a severe hyperglycemia (>700 mg/dl). The patient was transferred in intensive care unit for pulmonary edema and acute respiratory distress. Hypertensive crisis and hyperglycemia arisen after the administration of metoclopramide were strongly suggestive for pheochromocytoma. The diagnosis was confirmed by urinary catecholamines and metanephrines which resulted exceptionally high (epinephrines 95.8 mcg/day [n.v. 2–22]; norepinephrines 154.3 mcg/day [n.v. 12–86]; metanephrine 4424 mcg/day [n.v. 50–340]; normetanephrine 4288 mcg/day [n.v. 90–445]) while abdominal CT scan showed a 66 mm right adrenal mass. Therefore, patient underwent right adrenalectomy after one week treatment with doxazosine by nasogastric tube and i.v. phentolamine. Adrenal histology confirmed pheochromocytoma, while thyroid histology showed a papillary microcarcinoma. The patient was carefully followed after adrenal surgery by copious hydration: blood pressure normalized in absence of anti-hypertensive drugs. Urinary catecholamines and metanephrines normalized.
Conclusion
The incidentally diagnosis of pheochromocytoma after an hypertensive crisis induces by metoclopramide has been described in Literature. Thus, it is crucial to consider this possibility in presence of a severe hypertensive crisis after the administration of this drug particularly in the post-operative course.

**A case of adrenoleukodystrophy presenting as progressive cerebellar dysfunction**

F. Qari & T. Nasser
King Abdulaziz, Jeddah, Saudi Arabia.

Previously asymptomatic 29-year-old Saudi male patient, presented to with a history of dizziness, abdominal pain and diarrhea for three days.
His morning 800 h serum cortisol was 6.4 μg/dl (normal: 5–25 μg/dl); plasma ACTH was 7579 pg/ml (normal: <46.00). The diagnosis of acute adrenal crisis was made which confirmed later by a defective rise in the cortisol level with ACTH stimulation test.
The patient was admitted to ICU at Medical City in Jeddah, and made a full recovery within 24 h with fluids, hydrocortisone f. Six months post-treatment, the patient presented with complaints f calf muscle pain and weakness, exacerbated by exercise. These symptoms progressively worsened and neurological assessment a spastic diplegia associated with reduced sensation to vibration, light touch and pinprick. The neuropathic pain increased and the patient developed myoclonus. He became wheelchair-bound with an indwelling urinary catheter and subsequently developed features of a dementia. The diagnosis of AMN was confirmed by raised circulating concentrations of very-long-chain fatty acids (VLCFA). Molecular genetic analysis was performed and SSCP analysis of each of the exons of the adrenoleukodystrophy (ALD) gene suggested the presence of a gene mutation at Xq28 in our patient. The treatment of our patient included a comprehensive physiotherapy program for the neurological disturbances and hormone replacement therapy for the adrenal insufficiency. Dietary restriction of VLCFA o Lorenzo's oil were applied in our patient.
Adrenomyeloneuropathy is a rare X-linked inherited disorder of peroxisomes characterized by accumulation of very-long-chain fatty acids.
(VLCFA) in the central and peripheral nervous system, adrenal glands and testes, leading to dysfunction of these organs and systems.

**Clinical peculiarities of pheochromocytoma in a MEN2A family**

P. Sánchez Sobrino[1], C. Páramo Fernández[1], P. Gil Gil[1], J. De la Fuente Aguado[1], R. Palmeiro Carballeira[1] & R. García-Mayor[1]
[1]Complexo Hospitalario Universitario de Vigo, Vigo, Spain; [2]Complexo Hospitalario Universitario de Vigo, Vigo, Spain; [3]Hospital POVISA, Vigo, Spain.

Introduction
Pheochromocytoma occurs in 50% of patients with multiple endocrine neoplasia syndrome type 2A (MEN2A). It is characterized by bilateral location, production of large amounts of adrenalin and a benign course, extraadrenal location being rare. Diagnosis is achieved by measuring catecholamines and metanephrines in serum or urine and/or through imaging techniques, including CT, MRI and 123I-MIBG scintigraphy.
Objective
To describe clinical features of pheocromocytomas found in a MEN2A family.
Subjects and methods
Descriptive observational study. Eight MEN2A patients belonging to the same family who carry C634Y mutation at proto-oncogene RET.
Results
Three out of eight subjects developed pheochromocytomas. All of them of bilateral location. Case 1 (index) was diagnosed because of typical spells after the surgery of a thyroid nodule that proved to be a medullary thyroid cancer (MTC). CT evidenced bilateral adrenal masses. Case 2 (case 1's son) was diagnosed in a familial study through a MRI which showed an image suggestive of pheochromocytoma on the right adrenal gland, although metanephrines levels were normal. Five years later, another mass appeared at the left adrenal gland, suggestive of adenoma and with a non-conclusive 123-MIBG image. Epinephrine and metanephrine rose slightly although they did not reach a diagnostic value. Adrenalectomy was performed and anatomic pathology confirmed the diagnosis. Case 3 (case 1's daughter) was also diagnosed in a familial study. MRI evidenced a left adrenal nodule suggestive of adenoma but having a high uptake at 123I-MIBG. Adrenalectomy was executed and anatomic pathology confirmed diagnosis. Three years later MRI showed a right adrenal nodule suggestive of pheochromocytoma. Catecholamines and metanephrines were always moving among the normal limits.
Conclusion
In our family with MEN2A by C634Y mutation, pheochromocytoma showed peculiarities such as absence of catecholamines hyperproduction and bilateral but asynchronous presentation. It requires a continuous and combined follow-up with imaging and laboratory techniques.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P128

**Pheochromocytoma in neurofibromatosis type 1**

C. Moreno, M. Bastos, L. Ruas, A. Vieira, M. Alves, S. Gouveia, J. Saraiva & M. Carvalheiro
University Hospitals of Coimbra, Coimbra, Portugal.

Introduction
Neurofibromatosis type 1 (NF-1) is a relatively frequent syndrome, with an estimated incidence of 1/3000 per year. Patients with NF-1 are at an approximately fourfold higher risk of developing tumors than the general population, most frequently gastrointestinal stromal tumors, central nervous system tumors and endocrine tumors. Pheochromocytoma may occur in about 1% of these patients.
Case report
We report a 56-year-old male presenting with fatigue and chronic headaches, attended at an endocrinology consult for adrenal gland incidentaloma detected on a chest-CT. Previous diseases: hypertension and class I obesity. Family medical history: two sisters with NF-1.
Abdominal-CT showed a 6 cm nodule on the right adrenal gland, with 72 Hounsfield unit density pre-contrast and delayed contrast washout. Laboratory findings were consistent with pheocromocytoma: 24-h urinary fractionated metanephrines 1389 μg/24 h (25–312), 24-h urinary serotonin and 5-hydroxitriptophan 10.9 mg/24 h (0–5), 24-h urinary 5-hydroxyindoleacetic acid 9.74 mg/24 h (2–6). The other biochemical and hormonal tests as well as tumor markers were unremarkable. Several clinical diagnostic criteria of NF-1 were identified: $>6$ café-au-lait macules $>15$ mm in longest diameter, $>2$ neurofibromas, two first-degree relatives with NF-1; genetic testing was also preformed. The screening for additional endocrine and tumor disorders related with NF-1 was negative. The treatment with β-blockers (propranolol, 10 mg, b.i.d.) and alpha-blockers (phenoxybenzamine, 10 mg, b.i.d.) kept the patient asymptomatic. Right suprarenalectomy was successfully preformed and the anatomopathological examination of the surgical sample confirmed the diagnosis of pheochromocitoma.
Conclusion
Pheochromocytoma in genetic disorders is more commonly diagnosed at a younger age in asymptomatic patients, due to premature screening of related tumors. In this case, the lack of clinical follow-up allowed the development of a large tumor, however with benign characteristics and few symptoms, with successful medical and surgical treatment.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Unilateral and bilateral adrenal incidentaloma: comparing clinical and biochemical features**

C. Eller-Vainicher[1], V. Morelli[2], A. Salcuni[1], S. Palmieri[1], V. Zhukouskaya[2], A. Scillitani[1], P. Beck-Peccoz[1] & I. Chiodini[1]
[1]University of Milan, Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico, Milan, Italy; [2]'Casa Sollievo della Sofferenza', IRCCS, San Giovanni Rotondo, Foggia, Italy.

Introduction
Subclinical hypercortisolism (SH), affecting about 30% of patients with unilateral adrenal incidentaloma (UAI), has been associated to hypertension (HT), type 2 diabetes mellitus (T2DM), dyslipidemia (DL), osteoporosis and vertebral fractures (FX). The prevalence of SH in patients with bilateral adrenal incidentaloma (BAI) seems to be even higher. Data on metabolic and bone complications in these patients are lacking.
Methods/design
We enrolled 175 patients with UAI (116 F; 59 M) and 35 patients with BAI (24 F; 11 M). In all patients we evaluated: BMI, bone mineral density (BMD) by DEXA at spine, total and femoral neck (expressed as *Z*-values: Z-LS, Z-FT, Z-FN respectively), the presence of HT, T2DM, DL and FX (diagnosed using a

semi-quantitative visual assessment). We diagnosed SH in the presence of at least two out of: urinary free cortisol levels (UFC) >70 μg/24 h, serum cortisol levels after 1 mg-dexamethasone test (1 mg-DST) >3.0 μg/dl or ACTH levels <10 pg/ml.
Results
Age, BMI, diameter of adenoma, UFC, 1 mg-DST, ACTH e Z-LS were comparable between the two groups. Total and femoral BMD were significantly lower in patients with BAI when compared to those of UAI (−0.28±0.99 vs Z-FT: 0.25±1.1, $P=0.008$; Z-FN: −0.40±0.88 vs 0.09±1.1, $P=0.01$). The prevalence of SH, HT, T2DM, DL was comparable between groups, while the prevalence of FX was higher in BAI than in UAI (51% vs 28%, $P=0.007$). Logistic regression analysis showed that the presence of FX was independently associated to the presence of BAI (OR 2.7, 95% CI 1.2–6.0; $P=0.02$), age (OR1.07, 95% CI 1.0–1.1; $P=0.001$), and Z-LS (OR 0.7, 95% CI 0.6–0.9; $P=0.01$) regardless for the presence of SH (OR 2.0, 95% CI 0.9–4.1; $P=0.06$).
Conclusion
Patients with BAI show a lower BMD and a higher prevalence of FX than patients with UAI, independently of SH.

### Bone mineral density is associated with BsmI vitamin D receptor's polymorphism in adult patients with epilepsy

E. Armeni[1], N. Triantafyllou[2], G. Kaparos[1], A. Alexandrou[3], E. Logothetis[1], M. Creatsa[1], A. Antoniou[1], E. Kouskouni[1] & I. Lambrinoudaki[1]
[1]University of Athens, Aretaieio Hospital, Athens, Greece; [2]University of Athens, Aiginiteion Hospital, Athens, Greece; [3]University of Athens, Laiko Hospital, Athens, Greece.

Introduction
The BsmI restriction fragment polymorphism of the vitamin D receptor (VDR) has been related with the development of bone disease in postmenopause, homozygous β thalassemia and hyperthyroidism. The present study aimed to evaluate the association between bone metabolism in patients with epilepsy and the BsmI VDR's polymorphism.
Methods/design
This cross-sectional study evaluated 73 adult patients with epilepsy, under antiepileptic drug monotherapy for at least 1 year and with regular menses for women. Bone mineral density of the lumbar spine was measured by dual energy X-ray absorptiometry. Fasting blood samples were obtained for biochemical assessment and genotyping.
Results
Significant differences were observed in levels of BMD according to the VDR's genotype (BMD: Bb genotype 1.056±0.126 g/cm$^2$; BB genotype 1.059 ±0.113 g/cm$^2$; bb genotype 1.179±0.120 g/cm$^2$; $P$-value <0.05). Presence of at least one B allele associated with lower serum levels of 25 hydroxyvitamin D when compared with absence of the B allele (22.61 vs 33.27 ng/ml; $P$-value <0.05). Bone density below the expected range for age (4.1% of subjects) correlated with the presence of the BB genotype ($P$-value =0.031), even after adjusting for the daily drug dosage, duration of therapy, sex, age and BMI. Regression analysis revealed that the presence of at least one unfavorable B allele was a significant predictor of BMD, independently of age, sex, BMI, daily dosage and duration of therapy ($\beta=-0.149$; $P$-value=0.001)
Conclusion
BsmI VDR's polymorphism is significantly associated with BMD in patients with epilepsy. The potential role of this polymorphism in the development of bone disease in patients with epilepsy should be evaluated by larger studies, as it might be helpful to ordinate patients as high risk and low risk, regarding the development of osteoporosis.

### Vitamin D and estrogen receptors' polymorphisms in postmenopausal women

S. Oros[1], O. Ianas[1], S. Vladoiu[1], M. Giurcaneanu[1], E. Neacsu[1], G. Voicu[1], M. Stoiceanu[1], R. Rosca[1,2], C. Neamtu[1], C. Badiu[1,2] & C. Dumitrache[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Osteoporosis is a polygenic disease. The intensive search for genetic markers has led to the identification of several genetic polymorphisms, associated with the decrease of bone tissue and therefore a higher risk of osteoporosis.
The study aimed to evaluate estrogen receptor alpha (ESR1) and vitamin D receptor (VDR) polymorphisms in postmenopausal women with or without osteoporosis and their correlations with bone markers and adipocytokines.
Subjects and methods
We enrolled 56 postmenopausal women, aged over 60, without treated osteoporosis and no secondary osteoporosis. Subjects were divided into two groups: group 1 – postmenopausal women with osteoporosis (19 subjects), group 2 – postmenopausal women without osteoporosis (37 controls).
Hematological, biochemical profile, bone turnover markers and adipocytokines were assayed. DXA of the spine and the left hip was performed. ESR1 (XbaI and PvuII) and VDR (Bsm I, ApaI, TaqI and FokI) polymorphisms were determined by RFLP method on genomic DNA.
Results were statistically analyzed using SPSS program.
Results
Genotype distribution differed significantly in the osteoporosis group compared to controls for ESR1 PvuII ($P=0.03$) and XbaI ($P=0.04$) polymorphisms. VDR polymorphisms genotype distribution did not significantly differ between the two groups.
We found higher TNFα mean values in bb genotype (4.506±0.92) compared to Bb genotype (1.472±0.53, $P=0.036$) and TT with Tt genotype ($P=0.03$) in group 1.
Higher CRP mean values were present for PP genotype compared to Pp ($P=0.046$) in controls. In controls, VDR BsmI, Bb genotype associated lower $T$ hip scores ($P=0.035$) and lower BMD compared to BB genotype and lower $T$ hip scores ($P=0.035$) where present associated with VDR Taq1, Tt genotype compared to tt genotype.
Conclusion
XbaI and PvuII estrogen receptor α polymorphisms may be involved in the pathogenesis of osteoporosis, while Bsm I and TaqI VDR polymorphisms may influence BMD, bone turnover and the inflammatory state.

### Osteoporosis and vitamin D deficiency in patients with lipid storage disease

M. Del Prete, A. Negri, M. Sarnataro, C. Pivonello, V. Ramundo, V. Marotta, R. Russo, A. Carratù, B. Cianciaruso, A. Colao, A. Pisani & A. Faggiano
Federico II University, Naples, Italy.

Introduction
Bone metabolism is impaired in several lipid storage diseases. At now no data are available in Fabry disease (FD), a genetic lipid storage disease characterized by systemic accumulation of glicolipids. The aim of this study was to evaluate bone metabolism and calcium/vitamin-D pathway in patients with FD.
Methods/design
Study population included 15 FD patients (8 M and 7 F, age 28–59 years) and 15 sex-, age- and BMI-matched normal subjects. Measurements of serum concentrations of calcium, phosphorus, PTH, 25-hydroxy-vitamin-D and assessment of $T$-score by using MOC-DXA were obtained in all subjects. Vitamin D receptor (VDR) polymorphisms Fok1 and Taq1 were also investigated by using PCR.
Results
Osteopenia/osteoporosis was found in 80% patients and 33% controls ($P<0.05$). In FD patients, osteopenia/osteoporosis was found at lumbar spine in 10/15 and femur neck in 9/15 (5 M and 7 F, three of whom in premenopausal age). Serum concentrations of 25-hydroxy-vitamin-D were 11.2±1.40 ng/ml in patients and 30.7±2.55 ng/ml in controls ($P<0.01$). Vitamin-D deficiency was found in 60% and insufficiency in 40% of patients without significant difference between summer and autumn assessment. There was a significant correlation between 25-hydroxy-vitamin-D and $T$-score values ($P<0.05$). Fok1 FF and ff polymorphisms were found in 93 and 7% of patients and 15 and 25% of controls,

respectively, while Taq1 TT and tt polymorphisms were found in 13 and 67% of patients and 50% and 8% of controls, respectively ($P<0.05$).
Conclusion
Lumbar and femur osteoporosis is common in FD patients, regardless from age and gender and is associated with vitamin-D deficiency/insufficiency in all cases. There is also a different distribution of Fok1 and Taq1 polymorphisms between FD and controls which needs to be functionally characterized. To include bone evaluation in the work-up of patients with FD and to prevent bone damage by replacing vitamin-D deficiency in these subjects are suggested.

### *De novo* autoimmune hepatitis associated with PTH(1–34) and PTH(1–84) administration for severe osteoporosis in a liver transplant patient

P. Anagnostis[1], Z. Efstathiadou[1], E. Akriviadis[2], P. Hytiroglou[2] & M. Kita[1]
[1]Hippokration Hospital of Thessaloniki, Thessaloniki, Greece; [2]Aristotle University of Thessaloniki, Thessaloniki, Greece.

Introduction
Recombinant parathyroid hormone 1–34 (PTH(1–34)) and 1–84 (PTH(1–84)) stimulate new bone formation and are associated with significant decrease in the risk of vertebral and non-vertebral fractures. *De novo* autoimmune hepatitis (AIH) is a rare graft dysfunction occurring in patients having undergone liver transplantation (LT) for causes other than AIH.
Case report
A 61-year old woman was referred to our metabolic bone clinic due to severe osteoporosis (*T*-score of −2.7 in lumbar spine and −3.2 in femoral neck), 3 years after LT for primary biliary cirrhosis. The investigation for other conditions compromising her bone health revealed only vitamin D deficiency.
Taking into consideration the patient's severe osteoporosis in need of treatment, along with the impaired renal function that made the use of bisphosphonates rather problematic in addition to the prior use of glucocorticoids, the decision to proceed to teriparatide (PTH(1–34)) administration along with calcium carbonate 1000 mg and cholecalciferol 800 IU/day was made. At 3 month-assessment, asymptomatic hypertransaminasemia (two-fold the upper limit of normal) developed, which normalized after drug discontinuation.
A new flare of transaminases (three-fold the upper limit of normal), along with elevated alkaline phosphatase, was observed, after administration of PTH(1–84), which did not resolve after PTH(1-84) withdrawal. After exclusion of common causes of liver enzyme elevation, a liver biopsy was performed. Histological findings showed *de novo* AIH, which responded rapidly to treatment with methylprednisolone.
Conclusions
To our knowledge, this is the first case described in the literature involving development of post-LT *de novo* AIH, following PTH administration for severe osteoporosis. The exact mechanisms linking PTH with AIH are not clarified. However, it can be hypothesized that, since Kuppfer cells in the liver are implicated in PTH degradation, expressing the PTH/PTH-related protein type 1 receptor, they produce interleukin-6 which plays an important role in the pathogenesis of AIH.

## P134

### Osteogenesis imperfecta: phenotypic characteristics and response to treatment in an Irish cohort

E. O'Sullivan & M. McKenna
St Michaels Hospital, Dun Laoighaire, Ireland.

Background
Osteogenesis imperfecta is a group of heterogenous disorders affecting connective tissue. The disorders are inherited by autosomal dominant or recessive patterns. The phenotypes vary both between and within the subgroups of which there are eight described by the modified Sillence criteria. The common features are reduced bone mineralization, predisposition to fracture and resulting bony deformities. In addition blue sclerae and joint hyperlaxity can be present.
Methods
Charts of 17 patients with OI attending a metabolic bone disease clinic in Dublin were reviewed. The subtype of OI was determined by clinical characteristics in most cases. The treatment given in the form of calcium, vitamin D and bisphosphonates was identified. The response to treatment was assessed by DXA and bone turnover markers: osteocalcin, bone alkaline phosphatase, procollagen I amino propeptide, carboxy telopeptide, all in serum, and urine amino telopeptide.
Results
The response to treatment varied between patient and OI subtype. In general there was an increase in bone mineral density in response to bisphosphonates. The response in terms of frequency of fracture was not possible to determine from our data.
Conclusion
OI is debilitating but the course of the disease can be improved by treatment that increases bone mineral density. The response to treatment in our cohort is shown here. The optimum time course for bisphosphonate treatment is unclear and further study is needed to determine this and outcomes in terms of fracture incidence.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P135

### Bone mineral density in diabetic postmenopausal women with bone fracture

A. Gusova[1,2], M. Pavlova[2], G. Melnichenko[2] & G. Kavalersky[2]
[1]Scientific Research Institute of Neurosurgery named after N.N. Burdenko, Moscow, Russian Federation; [2]First Moscow State Medical University named after I.M. Sechenov, Moscow, Russian Federation.

Introduction
There are contradicting data about bone mineral density (BMD) in patients with type 2 diabetes mellitus (DM), although most studies describe increased BMD values in them. Due to this finding it is not clear how tightly bone fragility is bound with BMD in type 2 diabetic people.
Design
We provided dual-energy X-ray absorptiometry of lumbar spine and proximal femur to 46 postmenopausal women with type 2 diabetes mellitus (DM), 14 of them had bone fracture within last month. The control group included 40 non-diabetic women, 11 within a group were recently fractured. Groups were comparable in body mass index, age, duration of menopause and calcium intake. Diabetic subgroups were comparable in HbA1c level. We analysed lifestyle factors, calcium homeostasis indexes and bone turnover markers in all patients.
Results
There was a trend toward elevation of BMD in diabetic women (statistically significant for total hip). The frequency of osteoporosis and ostepenia in non-diabetic group was twice higher compared to diabetic group (correspondingly up to 45.2% vs up to 14.3% for osteoporosis and 24.1–81.8% vs 12.5–42.8% for osteopenia). In both groups with fracture (diabetic and non-diabetic) BMD was significantly lower than in groups without fracture ($P<0.01$ for most regions). Direct correlation with BMD were found for body mass index, lifetime weight gain and phosphorus excretion. There was inverse correlation BMD with C-terminal telopeptide of type I collagen ($r=-0.24$; $-0.55$). In diabetic group we found inverse relationships of BMD with target organs lesion (glomerular filtration rate decrease, presence of retinopathy and macroangiopathy).
Conclusion
Our data indicate that bone fragility in diabetic women is defined by BMD just the same as in non-diabetic ones despite elevation of BMD associated with type 2 DM.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Evidence for vitamin D deficiency and increased fractures' prevalence in autoimmune bullous skin diseases**

C. Eller-Vainicher, A. Marzano, V. Trevisan, E. Cairoli, V. Zhukouskaya, L. Marchese, V. Morelli, P. Beck-Peccoz, C. Crosti & I. Chiodini
Fondazione Ca'Granda Ospedale Maggiore Policlinico IRCCS, Milan, Italy.

Background
Vitamin D deficiency plays a role in autoimmune diseases and risk of fractures. No data are available on vitamin D levels and vertebral fractures in autoimmune bullous skin diseases.
Objectives
To assess vitamin D serum levels and vertebral fractures' prevalence in patients with pemphigus vulgaris (PV) and bullous pemphigoid (BP), potentially deadly autoimmune bullous disorders.
Methods
We studied 13 consecutive active untreated inpatients with PV (six males, seven females, age 53.5 ± 14.3 years), 15 with BP (seven males, eight females, age 76.9 ± 12.4 years) and 28 age- body mass index- and sex- matched controls. In all subjects, the 25(OH)Vitamin D (25OHD) levels and presence of vertebral fractures by spinal radiographs were assessed.
Results
In PV patients, 25OHD levels were lower (12 ± 4.4 ng/ml) and prevalence of severe hypovitaminosis D higher (61.5%) than in controls (22.2 ± 11.7 ng/ml, $P=0.012$; 23.1%, $P=0.0047$, respectively). The prevalences of fractures were 53.8 and 30.8% in PV patients and controls, respectively. Patients with BP showed lower 25OHD levels (9.6 ± 7.2 ng/ml) and higher prevalence of severe hypovitaminosis D (73.3%) than controls (22.6 ± 18.7 ng/ml, $P=0.022$; 26.7%, $P=0.01$, respectively). The prevalences of fractures tended to be higher in BP patients than in controls (66.7 vs 33.3%, respectively, $P=0.068$).
Conclusions
The low 25OHD levels found in PV and BP may suggest a role for this agent in their pathogenesis. The increased prevalence of fractures should be taken into consideration in patients who must be given corticosteroid.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P137

**A correlation between bone mass density and body mass index and the lipid profile?**

V. Radoi[1], M. Carsote[1], B. Virgolici[1] & C. Poiana[2]
[1]University of Medicine and Pharmacy 'Carol Davila', Bucharest, Romania; [2]C.I.Parhon' National Institute of Endocrinology, Bucharest, Romania.

Bone mass density and beta cross laps have been recognized as valid tests for the diagnostic and treatment control, as well as fracture prediction for osteoporotic patients. Statin treatment has been reported to be associated with a reduced risk fracture in these patients also. However, no studies, as of our knowledge, have tried to see if adding the lipid profile to the analysis of body mass density would improve the statistical power of prediction for any of the afore mentioned events. In our study 613 osteoporotic (*T*-score mean −3.16, S.D. 0.81) postmenopausal (mean 15.79 years, S.D. 8.88 years.) women were enrolled and they were grouped according to age (under 50 years, 51–60 years, 61–70 years, over 70 years) and the presence/absence of a history of bone fracture. Bone mass density was not correlated with body mass index ($P>0.05$, $r^2<0.02$). However, when bone mass density was correlated with both body mass index and the lipid profile (represented by triglycerides, cholesterol, LDLc, HDLc,) we obtained very good correlations in nine of the 12 groups, with five of them having a great statistical power: under 51 years ($n=72$, $r^2=0.27$, $P=0.11$) with fractures ($n=56$, $r^2=0.38$, $P=0.37$), 51–60 years with fractures ($n=61$, $r^2=0.14$, $P<0.01$), 61–70 years ($n=201$, $r^2=0.09$, $P<0.01$) with fractures ($n=88$, $r^2=0.14$, $P<0.01$) or without fractures ($n=113$, $r^2=0.24$, $P=0.02$) and over 70 years ($n=247$, $r^2=0.11$, $P<0.01$) with fractures ($n=67$, $r^2=0.35$, $P=0.11$) or without fractures ($n=51$, $r^2=0.35$, $P=0.08$). Similar results were obtained when bone mass density was correlated with alkaline phosphatase or 25OH Vitamin D or beta cross laps and the lipid profile.
Although we recognize the limitations of this study (the lack of complete data for some our patients and of statistical power in a part of the correlations), we consider that this pilot study opens a new perspective on the management of osteoporosis.

## P138

**Vertebral fracture risk and bone metabolism in patients with addison's disease**

V. Camozzi, C. Betterle, E. De Caneva, P. Lucato, M. Piccolo, M. Zaninotto, G. Silvia, S. Rizzati, F. Mantero & G. Luisetto
University of Padua, Padua, Italy.

Forty seven patients suffering from Addison's disease (AD: 12 males and 35 females, 44.5 ± 12.7 year old) were compared with 63 normal age-, sex- and BMI-matched subjects.
The duration of disease ranged from 0.6 to 44 years (10.23 ± 9.07 years). AD had received a cumulative dose of cortisone acetate of 290.5 ± 326.8 g, equivalent to a daily dose of 44.5 ± 15.5 mg, and to 26.34 ± 10.57 mg/m$^2$ of body surface. AD had average values of both daily urinary cortisol excretion and salivary cortisol higher than controls (583 ± 348 vs 374 ± 184 nmol/24 h, and 15.5 ± 11.2 vs 8.1 ± 4.2 ng/ml, respectively; $P<0.001$ in both cases), suggesting that cortisone replacement was higher than the physiological dose.
Vertebral fracture were assessed by DXA morphometric analysis in 25 AD patients and 43 controls. For this purpose a Hologic Discovery W device was used with a specific software for the vertebral height measurement. Eight patients showed at least one vertebral morphometric fracture, while only three subjects showed morphometric fractures in the control group (odds ratio = 6.27; 95% CI = 1.48–26.57; $P=0.013$).
Despite the higher number of vertebral fractures, AD showed densitometric variables similar to those of the control group in any evaluated area, including lumbar spine, femoral neck and whole body. Body composition (lean and fat body mass, expressed both in grams and in percent of total body mass) is similar in the two groups. Concerning laboratory parameters, daily calcium excretion is lower in AD patients than in controls (3.35 ± 2.32 vs 5.21 ± 2.38 mmol/24 h; $P=0.0001$). The other biochemical variables, including serum calcium and phosphate, bone alkaline phosphatase, serum CTx, 25OH vitamin D, 1,25(OH)2 vitamin D and PTH were similar in the two groups. No correlations were found between urinary cortisol excretion, salivary cortisol, duration of disease, cumulative and daily dose of replacement therapy and either laboratory or densitometric parameters in AD patients.
In conclusion, AD patients showed a risk of vertebral morphometric fractures higher than normals. Such risk does not seem to be related to a lower bone density or to common alterations of mineral metabolism, suggesting that fractures could be related to qualitative alterations of bone structure and the concomitant endocrine deficiency.

## P139

**Bone mineral density and muscle mass in women with multiple sclerosis**

V. Zikan[1], M. Tyblova[1], M. Luchavova[1], E. Havrdova[1], I. Raska[1], D. Michalska[1] & A. Kubena[2]
[1]First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Prague, Czech Republic; [2]Czech Academy of Sciences, Prague, Czech Republic.

Aim
The aim of this study was to compare the bone mineral density (BMD) and muscle mass between ambulatory women with multiple sclerosis (MS) and control subjects and to examine the influence of motor disability, muscle mass and/or glucocorticoids (GC) use on BMD.
Methods
Body composition and BMD were measured by dual-energy X-ray absorptiometry in 250 ambulatory MS women (153 premenopausal and 97 postmenopausal women) with Expanded Disability Status Scale (EDSS) $\leq$6.5 and in 193 controls.
Results
Compared to controls, patients had significantly lower values for total body bone mineral content and BMD at all measured sites except for the distal radius.

Patients with MS had significantly lower amount of total muscle mass as well as total leg muscle mass when compared to the control group. The EDSS score was negatively associated with BMD at the proximal femur in both premenopausal and postmenopausal women, while the deficit of total body muscle mass was significantly associated with a loss of BMD at the lumbar spine and whole body BMD only in premenopausal women. GC treatment was negatively associated with BMD at the lumbar spine in premenopausal women.
Conclusion
The total body muscle mass was an important predictive factor for the total body BMD and the lumbar spine BMD in premenopausal women with MS. Further prospective studies are required to verify the protective influence of muscle mass on BMD in patients with MS and to assess the role of systemic factors modulating the bone-muscle relationship (e.g. estrogen deficiency).
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P140

**Teriparatide: effects on cortical bone microstructure**

J. Stepan[1], H. Dobnig[2], A. Fahrleitner-Pammer[2], Y. Ma[3], Q. Zeng[3], X. Wan[3], F. Marin[4] & I. Pavo[4]
[1]Charles University Faculty of Medicine, Prague, Czech Republic; [2]Medical University of Graz, Graz, Austria; [3]Indianapolis, IN, USA; [4]Windlesham, UK.

Teriparatide (TPTD) reduces the vertebral and nonvertebral fracture risk. TPTD increases bone formation and improves the cancellous bone microstructure which is an important determinant of the mechanical integrity of vertebrae. The aim of our study was to evaluate first time the effect of TPTD on cortical microstructure and dynamic histomorphometric indices in patients with osteoporosis with or without prior therapy with ALN. Sixty-six postmenopausal women with osteoporosis, mean age (S.D.) of 68.0 (7.0) years and mean BMD *T*-score of $-1.7$ (0.9) at total hip and $-2.8$ (0.8) at lumbar spine; 62% with prevalent fractures, have been treated with 20 μg/day subcutaneous TPTD for 24 months; 28 were osteoporosis pretreatment naive (TN), 38 stopped previous ALN treatment (70 mg/week, mean duration of 63.6 months) and switched to TPTD. 45 paired iliac crest biopsies were collected and analyzed for three-dimensional structural changes by micro-computer tomography and for two dimensional structural and dynamic changes by histomorphometry at baseline and after 24-month. At baseline, mineralizing surface/bone surface (MS/BS, %) values were lower in the ALN pretreated group than in the TN, at both the periosteal ($0.61 \pm 1.29$ vs $1.39 \pm 0.96$; $P=0.04$) and endocortical surfaces (baseline: $3.16 \pm 5.05$ vs $6.19 \pm 5.07$; $P=0.06$). After 24 months TPTD treatment, the MS/BS (%) increased in the ALN and the TN patients at the periosteal surfaces ($1.34 \pm 1.05$ vs $3.94 \pm 2.7$; $P<0.0001$), and endocortical surfaces ($4.95 \pm 4.03$ vs $11 \pm 9.57$; $P=0.005$). The cortical porosity was not different between the two groups of patients indicating that alendronate treatment does not reduce cortical porosity. After 24 months TPTD treatment, a significant increase was observed in cortical area and thickness and in double tetracycline labeling of cortical osteons. In summary, TPTD therapy increased bone formation and improved the cancellous and cortical bone quality in postmenopausal women with osteoporosis irrespective of whether they had received prior ALN antiresorptive therapy.

## P141

**Serum soluble RANKL levels are related to breast arterial calcification and hypertension in Japanese osteoporotic postmenopausal women**

F. Hirano[1], H. Wada[2] & H. Nishimura[1]
[1]Asahikawa Medical Center, Asahikawa, Japan; [2]Wada Women's Clinic, Asahikawa, Japan.

It has been suggested that the association between osteoporosis and cardiovascular diseases is not just due to the aging process. The osteoprotegerin (OPG)/RANKL system has been identified as a possible mediator of arterial calcification suggesting common links between osteoporosis and vascular diseases. Moreover, breast arterial calcification (BAC) is reported to be associated with an increased prevalence of both cardiovascular risk factors and cardiovascular morbidity. In contrast, it has known that hypertension, diabetes or hyperlipidemia is one of risk factors for progressing arteriosclerosis and vascular calcification. The purpose of this study is to investigate the relationship between serum soluble RANKL (sRANKL) levels and breast arterial calcification in Japanese osteoporotic postmenopausal women. This study was carried out in 51 postmenopausal women aged 46–82 years who underwent screening mammography. Participants were divided into four groups of the number of calcified vessels including, 0BAC: no calcification, 1BAC: one calcified vessel, 2BAC: two calcified vessels and >3BAC: more than three calcified vessels. Serum sRANKL, OPG, alkaline phosphatase (Alp) and urinary type-I collagen cross-linked-N-telopeptide (uNTX) were measured. The mean age of these 51 women was $64.5+1.1$ years-old, 0BAC; $n=25$, 1BAC; $n=11$, 2BAC; $n=8$ and >3BAC; $n=7$. The prevalence of BAC was clearly increased in osteoporosis group as compared with normal BMD group. In the subgroups of BAC, BMD in >3BAC group was clearly decreased, and serum sRANKL levels were significantly increased in >3BAC group compared with those in 0BAC group. In addition, sRANKL/OPG ratio was pivotally higher in 2BAC and >3BAC groups compared with that in 0BAC group. Moreover, serum sRANKL levels are increased in postmenopausal women with hypertension, but not diabetes and hyperlipidemia. In contrast, serum Alp and uNTX were not significantly changed, increasing the number of BAC in postmenopausal women. In conclusion, the prevalence of BAC in Japanese postmenopausal women was remarkedly high in osteoporosis. Especially, that sRANKL and sRANKL/OPG ratio were increased in postmenopausal women with severe calcification of breast artery and hypertension, suggesting that serum sRANKL might play a role in common links between osteoporosis and cardio-vascular diseases.

**BMP-3b inhibits osteoblast differentiation via Smad2/3 pathway by counteracting Smad1/5/8 signaling**

F. Otsuka[1], J. Hino[2], Y. Matsumoto[1], T. Miyoshi[1], M. Takano[1], M. Miyazato[2], H. Makino[1] & K. Kangawa[2]
[1]Okayama University Graduate School, Okayama, Japan; [2]National Cerebral and Cardiovascular Center Research Institute, Osaka, Japan.

Involvement of BMP-3b (also called GDF-10) in osteogenesis, embryogenesis and adipogenesis has been reported to date. However, the functional receptors and intracellular signaling of BMP-3b have yet to be determined. In the present study, we studied the cellular mechanism of BMP-3b in osteoblast differentiation using mouse myoblastic C2C12 cells, which show osteoblasitc differentiation in response to osteogenetic BMP ligands. BMP-3b stimulated activin/TGF-β-responsive promoter activities. In contrast, the stimulatory actions of BMP-3b on activin/TGF-β-responsive activities were suppressed by co-treatment with BMP-2. BMP-responsive promoter activities stimulated by BMP-2 were significantly inhibited by treatment with BMP-3b. BMP-3b suppressed the expression of osteoblastic markers including Runx2, osteocalcin and type-1 collagen induced by BMP-2, -4, -6 and -7. BMP-2-induced Smad1/5/8 phosphorylation and mRNA levels of the BMP target gene Id-1 were also suppressed by co-treatment with BMP-3b, although BMP-3b failed to activate Smad1/5/8 signaling. Of interest, the BMP-3b suppression of BMP-2-induced Id-1 expression was not observed in cells overexpressing co-Smad4 molecules. On the other hand, BMP-3b directly activated Smad2/3 phosphorylation and activin/TGF-β target gene PAI-1 mRNA expression, while BMP-2 suppressed BMP-3b-induced Smad2/3 signal activation. BMP-2 inhibition of BMP-3b-induced PAI-1 expression was also reversed by overexpression of Smad4. Experiments using inhibitors (dorsomorphin and LDN-193189) for BMP-Smad1/5/8 pathways demonstrated that these BMP-3b effects were mediated via receptors other than ALK-2, -3 and -6. Furthermore, results of inhibitory studies using extracellular domains for BMP receptor constructs showed that the activity of BMP-3b was functionally facilitated by a combination of ALK-4 and ActRIIA. Collectively, BMP-3b plays an inhibitory role in the process of osteoblast differentiation, in which BMP-3b and BMP-2 are mutually antagonistic possibly by competing with the availability of Smad4.

**Glucocorticoid - treatment in the adrogenital syndrome due to deficit of 21-hydroxylase: long-term bone side effects**

V. Camozzi, C. Scaroni, P. De Toni, N. Albiger, M. Zaninotto, F. Mantero & G. Luisetto
University of Padua, Padua, Italy.

The purpose of this study was to compare bone mineral density (BMD) and bone metabolism in patients suffering from adrogenital syndrome due to deficit of 21-hydroxylase with those of a group of healthy subjects. A longitudinal follow-up was also carried out in a subgroup of patients.
Thirty-eight patients 19-47 years old were compared with a group of healthy, age- and sex-matched controls. Sodium, potassium, calcium, phosphorus, parathyroid hormone (PTH), bone alkaline phosphatase (bALP), serum CrossLaps (CTx), 25-hydroxy vitamin D, creatinine, daily urinary calcium excretion (uCa), 17-hydroxy progesterone, testosterone and androstenedione were dosed. Bone mineral density (BMD) was evaluated at lumbar spine L1-L4, femur (neck and total) and total body by a Dual X-Ray densitometry (Hologic-Discovery). A densitometric follow up was performed in 15 patients, 10 years after the first observation, with the same device.
A significant increase of CTx was observed only in female patients compared to normal women ($369 \pm 171$ vs $237.7 \pm 152$ pg/ml; $P = 0.04$); no difference was found in bALP serum levels. BMD was lower in patients at any site, however, adjusting BMD values for height, the difference remained significant only at the femoral neck ($0.422 \pm 0.16$ vs $0.498 \pm 0.05$ g/cm$^2$; $P = 0.0085$). In the 10-years follow-up lumbar spine BMD showed a slight increase, while the femoral parameters showed a slight decrease (L1L4 BMD basal $= 0.982 \pm 0.10$ vs 10-years BMD $= 1.007 \pm 0.10$ g/cm$^2$, $P = 0.04$; femoral neck BMD basal $= 0.813 \pm 0.12$ vs 10-years BMD $= 0.752 \pm 0.11$ g/cm$^2$, $P = 0.0004$; total femur BMD basal $= 0.911 \pm 0.11$ vs 10-years BMD $= 0.870 \pm 0.10$ g/cm$^2$, $P = 0.004$). The same trend is observed in the healthy population. No correlation was found between the densitometric and biochemical variables and the cumulative GCs dose assumed in the last 1-3 years or the time from diagnosis. The lower BMD in AS patients does not seem to be related to the GCs replacement therapy. It could be a consequence of the pathology itself, which causes a precocious bone development, thus leading to an earlier achievement of the peak of bone mass, that is consequently reduced.

**Polymorphism of the vitamin D3 receptor gene and bone mineral density in girls with functional hypothalamic amenorrhea subjected to estroprogestagen treatment**

E. Sowinska-Przepiera[1,2], J. Poblocki[1], Z. Friebe[2], G. Jarzabek-Bielecka[2], E. Andrysiak-Mamos[1] & A. Syrenicz[1]
[1]Pomeranian Medical University, Szczecin, Poland; [2]University of Medical Sciences, Poznan, Poland.

Background
We analyzed in the vitamin D3 receptor gene (VDR) polymorphism can modulate therapeutic response of functional hypothalamic amenorrhea (FHA) patients to the estroprogestagen (EP) treatment.
Material and methods
The study included 84 FHA girls and 50 controls. FHA patients underwent a 4-year sequential EP therapy with 17-β estradiol (2 mg from the 2nd to 25th day of the menstrual cycle) and didrogesterone (10 mg from the 16th to the 25th day). Their hormonal parameters were monitored along with bone turnover marker levels and bone mineral density (BMD). Additionally, the VDR gene BsmI polymorphism was determined.
Results
Hormonal therapy was reflected by a substantial improvement of BMD. However, the values of BMD observed after 4 years of treatment in FHA patients were still significantly lower than baseline bone mineral density determined in the control group ($1.007 \pm 0.100$ vs $1.141 \pm 0.093$ g/cm$^2$, respectively; $P < 0.001$). No significant effects of the VDR genotype were observed on the dynamics of BMD during consecutive years of hormonal treatment and mean bone mineral density determined after completing the therapy ($1.006 \pm 0.101$ vs $1.013 \pm 0.114$ vs $1.006 \pm 0.094$ g/cm$^2$ for BB, bb and Bb genotypes, respectively; $P = 0.973$).
Conclusions
This study did not confirm that VDR polymorphism can modulate therapeutic outcome of FHA girls subjected to the hormonal treatment. Nonetheless, this study confirmed the effectiveness of EP therapy in the simultaneous treatment of menstrual disorders and the normalization of bone mineral density in FHA patients.
Declaration of interest

## P145

**Altered bone mineral density in unilaterally orchiectomized subjects**

R. Selice, L. De Toni, G. Strapazzon, A. Di Mambro, A. Ferlin, A. Garolla & C. Foresta
University of Padova, Padova, Italy.

Introduction
Testicular cancer (TC) is the most common cancer in white males aged 20–40 years, with a worldwide incidence of 7.5/100.000. Recently, we demonstrated an association between testiculopathy and alteration of the bone status, despite conserved bone-sparing effects of androgens and estrogens. Furthermore, recent published data from our group documented a strong reduction in 25(OH)D plasma levels in bilaterally orchiectomized patients compensated by testosterone-replacement therapy. These data suggested a potential role of testis in vitamin D activation. In fact, we demonstrated that the Leydig cell represents a main actor in this process expressing a high amount of CYP2R1, a key enzyme involved in vitamin D 25-hydroxylation. Few reports have investigated the incidence and pathogenesis of altered bone status in subjects with TC and the available literature shows contrasting data.
Materials and methods
One hundred and twenty five patients orchiectomized for unilateral TC, followed up over a 2-year period, and 41 age-matched healthy male controls were enrolled. Serum levels of total testosterone, oestradiol, LH, FSH, PTH, 25(OH)D, 1,25-(OH)2D, bone-specific alkaline phosphatase (BAP), and carboxyl-terminal telopeptide of collagen type I (ICPT) were measured in all subjects. Eighty-four patients and 41 controls underwent bone densitometry analysis by DEXA.
Results
25-(OH)D levels were significantly lower and PTH, BAP and ICTP levels higher in TC patients compared to controls ($P < 0.05$). Femoral neck and/or lumbar spine $T$-score was $< -1$ S.D. (osteopenia) in 30/84 TC subjects (35.7%) and $< -2.5$ S.D. (osteoporosis) in 8/84 TC subjects (9.5%). None of 41 control subjects showed alterations of BMD.
Conclusions
Our data show an association in patients orchiectomized for unilateral TC and alteration of the bone status, despite unvaried androgen and oestrogen levels and no other evident cause of vitamin D reduction.

**Effects of aminobisphosphonates and thiazides in patients with osteopenia/osteoporosis, hypercalciuria and recurring renal calcium lithiasis**

Y. Sueliman-Martos[1], M. Arrabal-Polo[1], A. Jimenez-Pacheco[2], A. Zuluaga-Gomez[1], F. Escobar-Jimenez[1] & M. Arrbal-Martin[1]
[1]San Cecilio University Hospital, Granada, Spain; [2]Santa Ana Hospital, Granada, Spain.

Introduction
A relationship between osteopenia/osteoporosis and calcium nephrolithiasis has been recognized in several studies. An association has also been observed between bone mineral density loss, hypercalciuria, hypocitraturia and nephrolithiasis.

The aim of this study was to analyze the effects of aminobisphosphonates and thiazides on renal lithogenic activity and bone mineral density in patients with recurring renal calcium lithiasis.
Methods/design
A prospective cohort study with a 3-year clinical follow-up was performed in two groups of patients with recurring calcium lithiasis, hypercalciuria and bone mineral density loss. Group 1 included 35 patients undergoing treatment with 70 mg/week alendronate, and Group 2 included 35 patients undergoing treatment with 50 mg/day alendronate and 70 mg/week hydrochlorothiazide. Biochemical analysis was performed at baseline, 6 months and 2 years, bone densitometry at baseline and at 2 years and clinical follow-up during 3 years of treatment. Biochemical variables in blood and urine, recurrent lithiasis and bone mineral density were analyzed.
Results
Age, sex, baseline biochemical markers and bone density showed no differences between treatment groups at the onset of treatment. After 2 years of treatment, Group 1 showed a significant decrease in bone turnover markers and calciuria as well as a significant improvement in bone mineral density. After 2 years of treatment, Group 2 showed a decrease in calciuria and in bone markers. Bone densitometry improved significantly. At 2 years, the decrease in calciuria and the improvement in bone mineral density were greater in Group 2 in than Group 1, and the difference was statistically significant.
Conclusion
Aminobisphosphonates improve bone mineral density and slow lithogenic activity; however, administration of aminobisphosphonates in association with thiazides produces the same clinical effects and also reduces calciuria and improves bone mineral density. Bisphosphonate-thiazide coadministration is most appropriate in patients with bone mineral density loss, hypercalciuria and relapsing calcium lithiasis.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P147

**Bone mineral density in patients with thalassaemia major in the UK**

P. Tzoulis, A. Ang, F. Shah & M. Barnard
The Whittington Hospital NHS Trust, London, UK.

Introduction
Osteoporosis is a major cause of morbidity in β thalassaemia major patients. Our institution serves one of UK's largest populations of thalassaemia patients. This study aimed to examine the prevalence of osteopenia and osteoporosis in thalassaemia major patients and identify risk factors for low bone mineral density (BMD).
Methods
BMD of lumbar spine and neck of femur were measured using dual-emission X-ray absorptiometry (DEXA). Osteopenia was defined as $Z$ score between $-1.5$ and $-2.5$ and osteoporosis as $< -2.5$.
Age, gender, smoking, hepatitis C infection, compliance with chelation therapy, mean ferritin over 10 years, highest Ferriscan liver iron concentration from 2008 to 2010, highest liver iron concentration as estimated by T2* and lowest cardiac MR T2* value from 1999 to 2010, endocrinopathies, glycaemic status and vitamin D status were tested for associations with osteopenia and osteoporosis, using univariate analysis.
Results
Ninety-nine patients, 49 males and 50 females, with mean age $36 \pm 9$ years were included. 68.7% of patients had hypogonadism, 14.7% hypothyroidism and 13.7% hypoparathyroidism. 40.9% of patients had diabetes and 16.1% impaired glucose regulation. Lumbar spine BMD suggested that 22.4% had osteoporosis, 48.0% osteopenia and 29.6% normal BMD. Median $Z$ score was $-1.9$ (range 0.9 to $-5.0$). Neck of femur BMD demonstrated that 13.3% had osteoporosis, 40.8% osteopenia and 45.9% normal BMD. Median $Z$ score was $-1.5$ (range 0.8 to $-3.7$).
Parameters with $P$-values $<0.05$ on univariate analyses for associations with osteoporosis/osteopenia are presented in the table. On multivariate analysis, the only statistically significant association was between hypogonadism and spine low BMD ($P$ value $=0.048$).
Conclusions
Most β thalassaemia major patients have low BMD. Hypogonadism was an independent risk factor for reduced BMD in spine. Prevention of hypogonadism by effective iron chelation and hormone replacement therapy may help to prevent osteopenia/osteoporosis.

**Table 1**

| Type of abnormality in BMD | Parameter | *P*-value |
|---|---|---|
| Spine low BMD | Low cardiac T2* (1999–2010) | 0.038 |
| | Hypogonadism | 0.009 |
| | Diabetes mellitus/ impaired glucose regulation | 0.047 |
| Hip low BMD | Female gender | 0.005 |
| | Low Ferriscan® LIC (2008–2010) | 0.019 |
| | Hypothyroidism | 0.018 |
| | Diabetes mellitus/ impaired glucose regulation | 0.040 |

**Both high- and low levels of procollagen type 1 amino-terminal propeptide are associated with increased risk of hip fracture in elderly women. Norwegian Epidemiologic Osteoporosis Studies**

T. Finnes[1,2], C. Lofthus[2,3], H. Meyer[2,4], E. Eriksen[3], G. Tell[5] & K. Holvik[5,6]
[1]Innlandet Hospital, Trust, Hamar, Hamar, Norway; [2]University of Oslo, Oslo, Norway; [3]Oslo University Hospital, Oslo, Norway; [4]Institute of Public Health, Oslo, Norway; [5]University of Bergen, Bergen, Norway; [6]Diakonhjemmet Hospital, Oslo, Norway.

Aim
The study aimed to investigate the relation between the levels of the bone formation marker P1NP and the risk of subsequent hip fractures in elderly women.
Materials and methods
Women born 1924–27 who participated in two population-based health studies in Bergen (The Hordaland Health Study (HUSK) 1997–2000) and in Oslo (The Oslo Health Study (HUBRO) 2000–2001), were followed up regarding hip fractures from date of inclusion until end of 2007 in HUBRO and until end of 2008 in HUSK. Serum P1NP was determined by Multigamma RIA kit (Orion Diagnostica, Espoo, Finland) at the Hormone Laboratory at Oslo University Hospital, in serum samples collected at baseline and stored at $-80$ °C. The study was designed as a case-cohort study, including identified hip fracture patients ($n=306$) and a random sample of 9% of women in the same cohorts ($n=311$). Cox proportional hazards regression with inverse probability weighting and robust variance with serum P1NP as explanatory variable was performed.
Results
P1NP levels ranged from 7 to 127 ng/ml. A U-shaped relation between P1NP and hip fracture was suggested. Compared to the lowest quartile of P1NP, the hazard ratio (HR) in the 2nd quartile was: 0.68 (95% CI: 0.42–1.09), in the 3rd quartile:

0.77 (95% CI: 0.49–1.22), and in the 4th quartile: 1.04 (95% CI: 0.66–1.63). Adjusting for covariates or excluding participants using medication known to lower P1NP did not substantially alter the results. A confirmatory spline analysis showed a significant U-shaped relation.
Conclusion
A U-shaped relation between P1NP and hip fractures was found, suggesting both low and high levels of P1NP confer increased risk of osteoporotic fractures. Whether the fracture risk among those with the lowest P1NP levels is mediated through generally low bone turnover, or isolated impaired osteoblast collagen synthesis, remains to be elucidated.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Alendronate inhibits adipocyte differentiation in 3T3-L1 through a Vitamin D receptor mediated effect

M. Caprio[1], M. Calanchini[1,2], C. Mammi[1], A. Antelmi[1], F. Cinti[1] & A. Fabbri[2]
[1]IRCCS San Raffaele Pisana, Rome, Italy; [2]University 'Tor Vergata', Roma, Italy.

Background
Adipocyte and osteoblast derive from the same mesenchimal progenitor. Age-related decrease in bone mass is accompanied by an increase in marrow adipose tissue. Vitamin D3 (VD) inhibits adipogenesis in 3T3-L1 preadipocytes. Recently it has been demonstrated that alendronate (ALN) inhibits adipogenesis while promoting osteoblast differentiation of mesenchimal stem cells.
Aim of the study
To evaluate the *in vitro* role of ALN on 3T3-L1 adipose differentiation and the potential sinergic role of VD cotreatment.
Procedures
Murine 3T3-L1 and 3T3-F442A preadipocytes were routinely differentiated for 7 days adding ALN and VD 10-9-10-7M, then stained with Red Oil. We analyzed through RT-PCR the effect of such treatments upon mRNA expression of main molecular markers of differentiation, PPARγ and C/EBPα, and VD receptor (VDR).
Results
ALN displayed a marked anti-adipogenic effect on 3T3-L1 cells. VD showed a clear dose-dependent anti-adipogenic effect. Interestingly co-incubation of ALN 10-8M and VD 10-9M did not show synergic effect in inhibition of adipogenesis. PPARγ mRNA expression was significantly reduced by ALN and VD. mRNA expression of C/EBPα was reduced only by the highest doses of VD. Interestingly a concomitant increase in VDR mRNA expression was observed in the presence of ALN and VD, suggesting that VDR may represent the molecular target of the anti-adipogenic effect of ALN.
To confirm this hypothesis, we explored the effects of ALN and VD on 3T3-F44 cells that are in a more advanced differentiation stage in adipogenesis; the results were compared to those obtained in 3T3-L1 cells; we found that expression of VDR mRNA was much lower than in 3T3-L1 cells. Interestingly adipose differentiation in this cell model was not affected by ALN nor VD.
Conclusion
These data represent an indirect evidence of the role of VDR in mediating the anti-adipogenic effect of ALN. Further studies are required to clarify this mechanism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P151

### Genetic predispositions do not explain short- and long-term effects of hormonal therapy on bone mineral density in girls with functional hypothalamic amenorrhea

E. Sowinska-Przepiera[1,2], J. Poblocki[1], E. Andrysiak-Mamos[1], K. Chelstowski[1], Z. Friebe[2] & A. Syrenicz[1]
[1]Pomeranian Medical University, Szczecin, Poland; [2]University of Medical Sciences, Poznan, Poland.

The aim of this study was to verify if genetic factors influence the short- and long-term therapeutic response to estroprogestagen (EP) therapy implemented in girls with functional hypothalamic amenorrhea (FHA) in order to improve their bone mineral density (BMD). The study included 78 FHA girls who underwent a 4-year sequential EP therapy with 17β-estradiol and didrogesterone. Changes in the lumbar spine BMD were determined at the end of the therapy and 6 years after its discontinuation, and analyzed in regards to PvuII i XbaI polymorphisms of estrogen receptor-α gene, BsmI polymorphism of vitamin D3 receptor gene, and Sp1 polymorphism of the type-one collagen gene. After 4 years of EP therapy, significant increase of BMD was documented in the studied group. Follow-up densitometry performed 6 years after completing the therapy revealed significant decrease in BMD level; nonetheless, the values of this parameter were still significantly higher compared to pretreatment level. Neither single polymorphisms or their combinations did not influence the relative change in BMD at the end of the therapy and after 6-year follow-up.
Conclusion
Variability of genes involved in estrogen, vitamin D3 and collagen metabolism does not influence the short- and long-term results of EP therapy in girls with FHA.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P152

### Improved assessment of bone turnover by the PTH-(1–84)/ large C-PTH fragments ratio in dialysis patients

J. van Helden
MVZ Dr. Stein and Kollgen, Moenchengladbach, Germany.

Background
The 'intact' parathyroid hormone (PTH) assays recognizes PTH (1–84) as well as amino terminally truncated fragments (C-PTH fragments). The present study investigated whether the use of plasma PTH-(1–84)/C-PTH fragment ratio enhances the noninvasive assessment of bone metabolism in patients on dialysis.
Methods
Blood samples of 45 healthy subjects with normal 'intact'-PTH values and 135 samples of dialysis patients were collected from laboratory routine. The samples of the dialysis patients were classified in order of their 'intact'-PTH levels: 45 with a 'intact'-PTH value $<100$ pg/ ml, 45 with a 'intact'-PTH value between 100 and 500 pg/ ml, and a third group with 'intact'-PTH levels above 500 pg/ ml. The determination of the 'intact'-PTH was performed on a ROCHE E170 analyzer with the Elecsys PTH assay. The testing of PTH-(1–84) and of OSTASE (BAP) as a parameter of osteoblast activity was perfomed on a DiaSorin LIAISON analyzer with the LIAISON PTH3 assay and the LIAISON BAP Ostase assay respectively. Blood levels of large C-PTH fragments were calculated by subtracting PTH-(1–84) from 'intact'-PTH.
Results
Both plasma intact- and PTH-(1–84) were significantly higher in patients with high and normal Ostase levels as a parameter of bone turnover, whereas the calculated C-PTH fragments were similar. Patients with low Ostase levels had significantly more C-PTH fragments than PTH-(1–84) ($P<0.001$), whereas patients with high or normal bone turnover had significantly more PTH-(1–84) than C-PTH fragments ($P< 0.001$), and the PTH-(1–84)/C-PTH fragment ratio was significantly higher than in patients with high or normal (range of 0.66–12.2) than low bone turnover (range of 0.1–0.88).

Bone turnover is reflected by the balance between the relative amount of circulating PTH-(1–84) and the large C-PTH fragments. The data lend support to the notion of an antagonistic effect of the C-PTH fragments on the PTH-(1–84) action on bone. The wide range of the obtained resuts in the PTH-(1–84) / C-PTH fragments ratio demonstrates that a simple fixed percentage of intact PTH cannot be identified for prediction of the large C-PTH fragments.
Conclusions
The PTH-(1–84) / C-PTH fragment ratio predicts bone turnover with acceptable precision for biological measurements.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P153

**Comparaison of serum PTH concentrations obtained with a second and a third generation assay in a cohort of hemodialysis patients according to the KDIGO guidelines**

E. Laruelle & C. Massart
CHU Pontchaillou, Rennes, France.

Introduction
PTH concentrations obtained with the second generation (2G) assays may vary widely according cross-reactivities against 7–84 PTH fragments. 1–84 bio-intact PTH is only measured with a third generation (3G) assay.
Objective
To evaluate whether the results found with a 3G method improve the classification of dialysis patients according to the KDIGO recommendations.
Patients and methods
We studied the PTH values measured in 84 hemodialysis patients'sera with a 2G immunoradiometric assay (Total intact PTH IRMA, Scantibodies) and with an automated 3G PTH (Liaison, DiaSorin). The decrease of PTH 3G levels was calculated as ((PTH 2G–PTH 3G)/PTH 2G)×100. Bone alkaline phosphatase (bAP) levels were measured using an IRMA (Beckman-Coulter; reference values: 9–14 ng/ ml).
Results
PTH results obtained with both methods were significantly correlated ($r=0.97$ (IC95%=0.96–0.98); $P<0.000001$). Patients were classified according to the KDIGOs obtained with the PTH 2G: group one: <two×upper normal limit; group two: between two×and nine×upper normal limit; group three:> nine×upper normal limit) (Table 1).
A significant correlation was seen between bAP and PTH 2G ($r=0.49$ (0.31–0.64); $P<0.00001$ or PTH 3G ($r=0.46$ (0.27–0.61); $P<0.00001$). Among the patients, 93% were classified in the same group according to the PTH 2G or 3G values.
Conclusion
The new automated PTH 3G gives the same classification in 93% of patients. Further investigations including bone biopsy would be necessary in 7% of misclassified patients to evaluate the performance of PTH 2G or PTH 3G according to the KDIGO guidelines.

**Table 1**

| Group | BAP ( ng/ ml) | PTH 2G ( pg/ ml) | PTH 3G ( pg/ ml) | Decrease of PTH 3G (%) |
|---|---|---|---|---|
| Group 1 | 11.9±6.4 | 58.3±18 | 38±10 | <33±6 |
| Group 2 | 19.3±6.4 | 231±97 | 154±75 | <34±15 |

**Endoscopic comparison of esophageal and gastroduodenal mucosal effects of enterocoating alendronate with calcitriol combined drug and alendronate in Korean postmenopausal women**

J. Mok[1], C. Yu[1] & C. Lee[2]
[1]Soonchunhyang University Hospital, Bucheon, Republic of Korea; [2]Hanyang University Guri Hospital, Guri-si, Republic of Korea.

Introduction
The study was a single-center, open label, randomized, head-to-head clinical study to compare the mucosal findings after perform esophagogastroduodenoscopy between two groups before and after use of alendronate only and enterocoating alendronate (5 mg) with calcitriol (0.5 μg) combined drug (Maxmarvil).
Methods
The 33 postmenopausal healthy volunteers, aged 50–70 years (mean age: 58±5 years) without gastrointestinal symptoms and normal baseline endoscopic findings were participated. Esophagogastroduodenoscopy was taken at the time of the baseline and repeated at 2 weeks later after daily intake of Maxmarvil ($n=17$ subjects) or alendronate ($n=16$ subjects). Mucosal injury scores were reported by a endoscopist after 2 weeks of each medication.
Results
Esophageal mucosal injuries were developed in two out of 16 subjects with alendronate group only. Gastric mucosal injuries were developed in eight subjects in alendronate group and in four out of 17 subjects with Maxmarvil group, which showed statistically significant differences.
Conclusions
Our study showed that the mucosal damage scores for the alendronate group (total score; 24) are significantly higher than those of scores for the Maxmarvil group (total score; nine) in the esophagus and stomach. Therefore, this study suggests that enterocoating Maxmarvil is more safe on gastrointestinal mucosa than alendronate and may improve the tolerability of osteoporosis medication in clinical practice.

**Functional hypoparathyroidism is a risk factor for bone fragility of postmenopausal women with vitamin D insufficiency**

M. Yamauchi[1], K. Nawata[1,2], H. Kaji[3], S. Takaoka[1], T. Yamaguchi[1] & T. Sugimoto[1]
[1]Shimane University Faculty of Medicine, Izumo, Japan; [2]The University of Shimane, Matsue, Japan; [3]Kobe University Graduate School of Medicine, Kobe, Japan.

Aim
Vitamin D insufficiency is associated with an increase in PTH, which might be critical for an increase in bone fragility. However, the role of endogenous PTH in vitamin D insufficiency-induced increase in fracture risk still remains unclear. The present study was performed to examine the relationships among vitamin D insufficiency, bone fragility, PTH and sclerostin, which is produced by osteocytes and inhibits bone formation by inhibiting the Wnt pathway.
Methods
Subjects were 190 healthy postmenopausal women who had undergone osteoporosis screening. Bone mineral density (BMD) was measured using the DXA method at the lumbar vertebrae and femoral neck (FN). The presence of vertebral fractures was confirmed on X-ray and nonvertebral fractures were assessed by the clinical interview. Serum levels of Ca, P, Cr, C-terminal cross-linked telopeptide of type I collagen (CTX), intact PTH, 25-hydoroxyvitamin D (25(OH)D) and sclerostin were measured.
Results
Mean values of age and BMI were 63±8 years and 22.9±3.1 kg/ $m^2$, respectively. Levels of intact PTH, 25(OH)D, CTX and sclerostin were 46±15 pg/ ml, 16.3±4.4 ng/ ml, 0.4±0.2 ng/ ml and 1.3±0.4 ng/ ml,

respectively. The percentages of subjects with 25(OH)D levels below 20 ng/ ml were 80.7%. Serum 25(OH)D levels were negatively related to age, Cr, CTX and PTH, although it was positively related to BMD. Multiple logistic regression analysis showed that lower 25(OH)D levels were significantly related to prevalent fracture risk, when adjusted for age, BMI, Ca, P, Cr, CTX, PTH, FN BMD, and sclerostin. Logistic regression analysis revealed that the group with lower PTH and lower 25(OH)D was a significant risk factor for prevalent fracture (odds ratio, 2.33 (95% CI: 1.04–5.25), $P < 0.05$) even after adjustments for these indices.
Conclusions
Vitamin D insufficiency was related to prevalent fracture risk. In vitamin D insufficiency, functional hypoparathyroidism rather than functional hyperparathyroidism might be a risk factor for bone fragility.

**Platinum nanoparticle reduces ovariectomy-induced bone loss by decreasing osteoclastogenesis**

W. Kim, J. Kim, J. Kim & H. Choi
University of Ulsan, Ulsan, Republic of Korea.

Platinum nanoparticles have shown to have a remarkable antioxidant activity. Growing evidence between oxidative stress and bone loss suggests that platinum nanoparticle could protect bone loss via modulating oxidative stress. Intragastrical administration of platinum nanoparticle reduced ovariectomy (OVX)-induced bone loss with lowered level of *in vivo* bone resorption. Platinum nanoparticle inhibited osteoclast (OC) formation via an impaired receptor activator of nuclear factor-κB ligand (RANKL) signaling due to reduced reactive oxygen species. Our data clearly highlights the potential of platinum nanoparticle for amelioration of bone loss after estrogen deficiency via delayed OC formation.

**The level of Osterix expression in osteoblasts is important to prevent IL6-induced inflammatory-prone state**

W. Baek[1,2], Y. Kim[3], S. Park[4], T. Kwon[1,2], K. Park[1,2] & J. Kim[1,2]
[1]Cell and Matrix Research Institute, Daegu, Republic of Korea; [2]Kyungpook National University School of Medicine, Daegu, Republic of Korea; [3]Keimyung University School of Medicine, Daegu, Republic of Korea; [4]Dongguk University School of Medicine, Gyeongju, Republic of Korea.

Osterix (Osx) is an essential transcription factor for osteoblast differentiation and bone formation. Osx null mutants died perinatally with a complete absence of bone formation and Osx conditional knockouts in osteoblasts showed the osteopenic phenotype after birth. Even in Osx heterozygous mice with normal bone morphology, the reduced cortical thickness and osteoblast differentiation were observed by QCT and *in vitro* cell culture, respectively. This result exhibited that the level of Osx expression was still important for *in vivo* and *in vitro* bone formation. Here, we investigated a potential role of Osx to regulate physiological homeostasis in adult tissue. In Osx heterozygous mice with a low expression of Osx in bones, the expression levels of pro-inflammatory cytokines were significantly increased, indicating that their body due to the reduced Osx expression may remain an inflammatory-prone state. Especially, the expression of interleukin (IL)-6, a key mediator of chronic inflammation, was increased in Osx heterozygotes and decreased in Osx overexpressed osteoblastic cells. Kidney as well as bone is one of the most important organs in order to maintain a physiological balance for mineral ions controlled by numerous endocrine factors. The cross-talk between the bone and kidney for physiological homeostasis has been studied for a long time. In Osx heterozygous mice compared to wild-type, no significant difference was observed in renal morphology and urine calcium and phosphate levels. However, the recovery of kidney after ischemic damage was remarkably delayed in Osx heterozygous mice, as indicated by elevated blood urea nitrogen and creatinine levels, and morphological alterations consistent with acute tubular necrosis. Eventually, the low level of Osx expression caused an inflammatory-prone state in the body, resulting in the enhanced susceptibility to renal injury after ischemia/reperfusion. This study suggests that the maintenance of Osx expression in bone is important to prevent inflammatory-prone state.

**Osteopenia/osteoporosis in patients with calcium nephrolithiasis**

Y. Suleiman-Martos[1], M. Arrabal-Polo[1], A. Jimenez-Pacheco[2], A. Zuluaga-Gomez[1], F. Escobar-Jimenez[1] & M. Arrabal-Martin[1]
[1]San Cecilio University Hospital, Granada, Spain; [2]Santa Ana Hospital, Granada, Spain.

Introduction
Calcium nephrolithiasis is the most frequently diagnosed type of nephrolithiasis. It is related to metabolic alterations, inhibitor deficiencies, anatomical factors, alterations in urinary pH, and bone alterations.
The objective of this study is to analyze the alterations in bone mineral density and bone and calcium-phosphorus metabolism in patients with calcium nephrolithiasis.
Methods/design
We designed a study with 182 patients who were distributed among three groups: Group O included 56 patients without nephrolithiasis; group A included 67 patients with calcium nephrolithiasis and mild lithogenic activity; and group B included 59 patients with calcium nephrolithiasis and severe lithogenic activity. Metabolic parameters of blood and urine that were related to calcium-phosphorous and bone metabolism and bone densitometry were assessed in all patients. A comparative study was performed on the variables of bone and calcium-phosphorus metabolism and bone densitometry as well as the presence or absence of osteopenia/osteoporosis among the groups.
Results
The patients in group B had a greater loss of bone mineral density, measured by the *T*-score, than the patients in groups O and A. Moreover, the proportion of patients in group B with osteopenia/osteoporosis was statistically significantly higher than the proportion of patients in groups O and A. We observed higher values of calciuria, fasting calcium/creatinine ratio, and 24-h calcium/creatinine among the patients in group B compared to the other two groups. Calciuria, citraturia, and fasting calcium/creatinine were independent factors that showed a relationship with severe lithogenic activity compared to the control group, and -crosslaps is an independent factor that has a relationship with severe lithogenic activity as compared to mild lithogenic activity.
Conclusions
Patients with calcium lithiasis and severe lithogenic activity have a greater loss in bone mineral density and therefore a greater risk of osteopenia/osteoporosis compared to patients without lithiasis or with calcium lithiasis and mild lithogenic activity.

## P159

**No effect of long-term valproate monotherapy on bone mineral density in adults with epilepsy**

N. Triantafyllou[1], E. Armeni[2], F. Boufidou[1], A. Antoniou[3], G. Tsivgoulis[4] & I. Lambrinoudaki[2]
[1]University of Athens, Eginition Hospital, Athens, Greece; [2]University of Athens, Aretaieio Hospital, Athens, Greece; [3]University of Athens, Aretaieion Hospital, Athens, Greece; [4]Democritus University of Thrace, University Hospital of Alexandroupolis, Alexandroupolis, Greece.

Introduction
Anti-epileptic drugs, usually defined according to their effect on the cytochrome P450 system, might lead to bone mineral density (BMD) decrease and fractures. The anticonvulsant valproate is a hepatic enzyme inhibitor, effective in many types of epilepsy. The present study aimed to assess the impact of long-term valproate monotherapy on BMD in a sample of consecutive ambulatory adult patients with epilepsy.
Methods/design
This cross-sectional study recruited 41 consecutive adult epileptic patients receiving valproate monotherapy for at least two years. BMD at the level of the lumbar spine was assessed by dual energy X-ray absorptiometry (DXA). All subjects underwent an evaluation that included serum levels of total calcium, phosphorus, magnesium, 25-hydroxyvitamin D3 and parathormone.
Results
No case of osteoporosis was documented in the sample, while osteopenia was present in 24% of subjects. Duration and dosage of valproate monotherapy did not correlate with any of the *T*- and *Z*-scores at the lumbar spine. Dividing patients according to the duration of valproate monotherapy into long- and short-term group resulted in similar findings. In addition, no association was documented between duration or dosage of valproate monotherapy and biochemical parameters.
Conclusion
The present study could not identify any correlation between duration or dosage of valproate monotherapy with BMD measurements in adult patients with epilepsy. No case of osteoporosis was identified in patients treated with valproate for a mean period of more than ten years. These findings provide indirect evidence against a potential detrimental effect of long-term valproate monotherapy on bone metabolism.

**Bone cross-sectional geometry and strength parameters at the radius by pQCT in male obese adolescents**

S. Vandewalle[1], I. Roggen[2], M. Van Helvoirt[3], P. Debode[3], Y. Taes[1], J. Kaufman[1] & J. De Schepper[2,1]
[1]University Hospital Ghent, Ghent, Belgium; [2]University Hospital Brussels, Brussels, Belgium; [3]Zeepreventorium, De Haan, Belgium.

Introduction
Male gender, adolescence and obesity are known risk factors for upper limb fractures, although the mechanism by which obesity confers the increased fracture risk is unknown. In addition, most studies investigating the influence of body fat mass on bone in adolescents have been performed in school based populations using the DXA technique, which does not take into account the material and geometric bone properties.
Methods
We investigated volumetric bone density and cross-sectional bone geometry at the non-dominant forearm using peripheral quantitative computed tomography (pQCT) in 51 obese (BMI *z*-score $> +2$) male adolescents (aged 10–19 years) at entry of a residential weight loss program in comparison with 51 non-obese age, pubertal stage and height matched controls.
Results
Obese adolescents (OA) had a higher trabecular density ($215 \pm 33$ vs $197 \pm 32$ mg/cm$^3$; $P=0.007$) at the distal 4% end, but comparable cortical density ($996 \pm 60$ vs $992 \pm 54$ mg/cm$^3$; $P=0.720$) at the proximal 66% site. Trabecular area ($158 \pm 26$ vs $143 \pm 33$ mm$^2$; $P=0.02$) as well as cortical area ($72 \pm 21$ vs $65 \pm 17$ mm$^2$; $P=0.08$) and periosteal circumference ($46.8 \pm 4.7$ vs $44.8 \pm 4.8$ mm; $P=0.04$) were slightly larger in OA. While absolute bone strength index (BSI) assessed at the distal radius ($37.1 \pm 14.04$ vs $31.2 \pm 12.27$ mg/mm$^4$; $P=0.03$), was higher in OA, the ratio BSI/ forearm load was lower.
Conclusion
Male OA have greater periosteal circumference, trabecular bone area and density and absolute bone strength at the distal radius. Hence, the higher forearm fracture risk in obese adolescents is not due to a lower bone accumulation, but bone strength is probably not adapted to the excess body weight in case of unusual loading as a fall on outstretched hands.

## P161

**Osteonecrosis of the jaw (ONJ) with superimposed osteomyelitis related to actinomyces in a patient with multiple myeloma receiving thalidomide and intravenous zoledronic acid**

S. Chaudhari[1,2], K. Patibandla[1,2], M. Maritato[1,2], G. Bahtiyar[1,2,3] & A. Sacerdote[1,2,3]
[1]Woodhull Medical Center, Brooklyn, New York, USA; [2]NYU School Of Medicine, Brooklyn, New York, USA; [3]SUNY Downstate Medical Center, Brooklyn, New York, USA.

Patient, methods and case report
A 50-years-old AAF with a PMH of multiple myeloma (MM), hypertension, and schizophrenia presented with jaw pain for 2 months. The patient had been diagnosed with MM for 10 years and had been treated with thalidomide and IV zoledronic acid for 1 year. CT scan of facial bone was consistent with osteonecrosis of the jaw with possible, superimposed osteomyelitis. Jaw biopsy revealed necrosis with a fistulous tract and filamentous organism consistent with actinomycetes.
Discussion
Numerous reports and meta-analyses have linked bisphosphonate use with a rare, but significantly increased incidence of osteonecrosis of the jaw, especially in cancer patients treated with IV bisphosphonates. This is believed to be due to an anti-angiogenic effect resulting in inhibition and apoptosis of osteoclasts. Decrease in bone circulation and cellularity may impair bone remodeling in response to skeletal injury. Through inhibition of endothelial cell proliferation, bisphosphonates may compromise intraosseous blood flow, contributing to the development of bisphosphonate-related ONJ (BRONJ). Thalidomide also exerts an anti-angiogenic effect by inhibiting vascular endothelial growth factor (VEGF) and basic fibroblast growth factor. BRONJ was initially believed to be a direct, non-infectious complication of bisphosphonate therapy, however, recent histological/microbiological data strongly suggest that actinomyces play a pivotal role in the development of BRONJ.
Conclusions
Bisphosphonates and thalidomide have anti-angiogenic effects on bone predisposing to avascular necrosis and ONJ. Actinomyces are an underrecognized agent in the pathogenesis of ONJ, which can result in superimposed osteomyelitis. Timely actinomyces specific therapy in BRONJ may improve patients outcome.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P162

**Effect of alcohol consumption on bone mineral density in healthy elderly Spanish males**

J. Lavado-Garcia, J. Moran, L. Gonzalez Lopez-Arza, C. Costa-Fernandez, R. Guerrero-Bonmatty & M. Gonzalez Lopez-Arza
University of Extremadura, Caceres, Spain.

Background
There are no data concerning a relationship between alcohol and bone status of elderly Spanish men. Previous studies in other countries on the influence of alcohol intake on bone mineral density (BMD) in men are inconsistent and the effect of these variables on BMD is yet to be explored.
Objective
The aim of this study was to describe the associations between total and beverage-specific alcohol intake and both BMD and bone ultrasound in elderly Spanish men.
Research methods and procedures
A cross-sectional study of 250 healthy elderly men ($>65$ years) was undertaken. BMD was measured by DXA. Bone ultrasound was also performed and

amplitude-dependent speed of sound (Ad-SoS) in the phalanges and broadband ultrasound attenuation (BUA) in the calcaneus were also determined. Lifestyle variables were collected through a structured questionnaire.
Results
Participants with a moderate intake of alcohol (20 g/day) had both a significantly higher BMD at femur ($P=0.0098$) and Ad-SoS ($P=0.0016$) compared to non-alcohol consumers. The intake of alcohol (g/day) significantly and positively correlated with BMD ($r=0.199$; $P=0.0051$) and Ad-SoS ($r=0.193$; $P=0.0096$) but not with BUA ($P>0.05$). The intake of beer (g/day) also positively correlated with BMD ($r=0.148$; $P=0.0392$) and BUA ($r=0.153$; $P=0.0428$) but not with Ad-SoS parameter ($P>0.05$). Wine intake (g/day) significantly correlated with BMD ($r=0.164$; $P=0.0209$) and Ad-SoS ($r=0.176$; $P=0.0178$) but not with BUA ($P>0.05$).
Conclusions
In elderly healthy Spanish men with well-defined lifestyle conditions, alcohol consumption was associated with higher femoral BMD, and bone ultrasound. The effect of alcohol is complex and will need further studies to clarify its role in bone metabolism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P163

**Effect of alendronate on bone mineral density in primary hyperparathyroidism**

J. Szymczak, A. Bohdanowicz-Pawlak & J. Jakubowska
Wroclaw Medical University, Wroclaw, Poland.

Background
Bisphosphonates are capable of suppressing parathormone (PTH)-mediated bone resorption and can be used as an adjunct treatment in acute hypercalcemia. We investigated the effects of oral alendronate on bone mineral density (BMD) and biochemical markers of calcium and bone metabolism in patients with primary hyperparathyroidism (PHPT).
Methods
Twenty-six patients aged $58.5\pm13.9$ years with confirmed PHPT were treated with alendronate (70 mg once a week) for 1 year. The patients were low symptomatic or symptomatic and were unwilling to have parathyroid surgery. Five patients underwent previously unsuccessful parathyreoidectomy.
Results
After 1 year of treatment, mean BMD increased significantly at lumbar spine (2.5%), femoral neck (1.8%), ultradistal part of the forearm (3.2%) and total body (2.2%), but not at the distal part of the forearm. The highest increases in BMD were in the lumbar spine (13.4%) and ultradistal part of the forearm (17%). In some patients BMD decreased despite taking alendronate. Changes in BMD were not correlated with serum PTH, 25-OH vitamin D, baseline BMD values or age of the patients. PTH did not change with alendronate treatment (mean$\pm$S.E.M.: $164\pm13$ vs $144\pm10.5$ pg/ml of baseline value, reference range: 11–67 pg/ml). Serum calcium, and urinary calcium excretion did not change significantly from the baseline values. Mean alkaline phosphatase concentration decreased significantly.
Conclusions
Our results suggest that alendronate may be effective in decreasing bone resorption in some patients with PHPT and does not affect PTH or serum and urine calcium. The greatest increase in bone density occurs at ultradistal part of the forearm and lumbar spine: sites with a high content of trabecular bone which is more metabolically active than cortical bone.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P164

**Association of monocyte chemoatractant protein-1 and adiponectin with bone mineral density and osteocalcin in postmenopausal women**

V. Pandzic Jaksic, D. Grizelj, B. Gizdic & O. Jaksic
Dubrava University Hospital, Zagreb, Croatia.

Recent findings suggested two-way interaction between bone and adipose tissue. Osteocalcin, a hormone of osteoblasts, was shown to stimulate insulin sensitivity by direct interaction with insulin. Adipose tissue has an important effect on insulin sensitivity by secretion of anti-inflammatory and proinflammatory adipocytokines like adiponectin and monocyte chemoattractant protein-1 (MCP-1). It is unknown whether they are related to bone metabolism.
Aim of this study was to examine the association of MCP-1 and HMW-adiponectin with bone mineral density (BMD) and osteocalcin in postmenopausal women.
In 32 postmenopausal women we determined serum levels of HMW-adoponectin, MCP-1, osteocalcin, insulin, glucose, triglycerides, HDL-cholesterol and C-reactive protein. Anthropometric measurements, body composition analysis and bone densitometry were performed. Participants did not have any metabolic or inflammatory diseases.
Positive correlation was found between femoral BMD and measures of obesity ($P<0.05$). Negative correlation of HMW-adiponectin with femoral BMD was noted, but it didn't remain significant after adjusting for body weight. HMW-adiponectin was negatively associated with measures of obesity and insulin ($P<0.05$), but MCP-1 showed no relationship with these parameters. Osteocalcin was inversely correlated with weight circumference, insulin and MCP-1 ($P<0.05$). Association between MCP-1 and osteocalcin remained significant even after adjusting for insulin and body weight.
In our results adiponectin did not appear to be among adipocytokines related with bone metabolism but the close association between osteocalcin and insulin was confirmed. Serum levels of MCP-1 in our study did not reflect its presumed role of chemokine secreted in obesity by macrophages in adipose tissue. In fact, the link between MCP-1 and osteocalcin seems to result from a mechanism that is independent from obesity and insulin sensitivity, for instance the previously demonstrated MCP-1 secretion by osteoblasts during administration of parathyroid hormone. This suggests that close links of bone and adipose tissue involve additional mediators with probably simultaneous impact on bone remodeling and energy metabolism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This work was supported, however funding details unavailable.

## P165

**Age-dependent and sexual features of bone mineral density changes in rats with hyperthyroidism**

I. Gopkalova[2] & V. Povoroznyuk[1]
[1]Institute of Gerontology NAMS Ukraine, Kyiv, Ukraine; [2]SI "V. Danilevsky Institute of Endocrine Pathology Problems, AMS Ukraine, Kharkov, Ukraine.

The aim of the research was studying the influence of age and sex on the changes of bone mineral density detected on rats with experimental hyperthyroidism.
Research object
Research is conducted on 180 white females and males rats of 'Wistar' breed. Animals were arranged in the 12 groups: six controls groups (CG) of pre-pubertal, reproductive and old males and females; six age-dependent groups of males and females rats getting L-thyroxin injection in a dose of 25 μg/100 g of body weight/day i.m., during 30 days.
Research methods
Bone mineral density (BMD) was measured using dual energy X-ray densitometry (DXA). The index was calculated according to the formula: $\Delta$BMD (%)=($\Delta$BMD/BMD ref.)$\times$100, BMD ref.-initial indexes of bone mineral density of the entire body.
Research results
It was revealed that high doses of L-thyroxine injections in during 30 days caused the different changes of BMD of rats. Only of the pre-pubertal females increased the $\Delta$BMD30 index with $15.83\pm1.99\%$ in CG to $44.73\pm5.41\%$, Student's t-criterion=4.49, $P<0.0001$, and does not change of $\Delta$BMD30 index in the pre-pubertal male group. The maximum loss of $\Delta$BMD30 index occurred in reproductive age, as for females rats (with $15.16\pm3.43\%$ in CG to $-10.04\pm2.32\%$, Student's t-criterion$=-6.22$, $P<0.0001$), so for males (with $0.63\pm0.97\%$ in CG to $-4.31\pm2.63\%$, Student's t-criterion$=-4.17$, $P<0.0001$). Not much was detected $\Delta$BMD30 index at old males rats (with $1.43\pm1.20\%$ in CG to $6.91\pm1.49\%$, Student's t-criterion=2.73, $P=0.012$).
Conclusions
It is revealed that high doses of L-thyroxine injections during 30 days caused the different changes of BMD depending on sex and age rats.

**Sinomaxillary myopericytoma associated with oncogenic osteomalacia**

Z. Kender[1], G. Polony1[1], M. Gödény[2], G. Léránt[2], E. Székely[1], P. Igaz[1], K. Rácz[1] & M. Tóth[1]
[1]Semmelweis University, Budapest, Hungary; [2]National Institute of Oncology, Budapest, Hungary.

Oncogenic osteomalacia (tumor induced osteomalacia-TIO) is a rare disease that can lead to severe physical handicap and pains. Its pathogenesis involves the secretion of fibroblast growth factor-23 inducing urinary phosphate loss and consequent hypophosphataemia. We report a case of a TIO caused by a tumor in the nasal cavity. In 2010, a 61-years-old woman was examined because of muscle weakness and arthralgia in the extremities. Her symptomes started ~3 years before her presentation. He denied any family history of metabolic bone disease. At presentation, she was unable to walk without support. Upon physical examination diminished muscle strength of upper and lower limbs was found without any neurologic alteration. Radiological images, osteodensitometry and technetium-99 m bone scan were characteristic for osteomalacia. Initial laboratory testing revealed a normal serum calcium level, very low phosphate level of 0.46 mmol/l (normal range: 0.84–1.45 mmol/l), an elevated alkaline phosphatase, a normal parathyroid hormone level and slightly decreased 25-hydroxivitamin D. Based on the low serum phosphate levels and her symptoms, the possibility of oncogenic osteomalacia was raised. Chest and abdominal CT was negative. Since the patient reported some episodes of nasal bleeding, an otorhinolaryngological examination was performed. This was revealed a mass in the left nasal cavity. The cranial MRI showed a large soft tissue mass in the left nasal cavity, the sphenoethmoidal recess and the frontal sinus. Given the possibility that this tissue mass was associated with the osteomalacia, it was removed by endoscopic surgery. The histological examination revealed a mesenchymal tumor, myopericytoma. One week later, levels of serum phosphate returned to the normal range, confirming the diagnosis of TIO. At 6-month follow-up, she felt well, she can walk without support and her serum biochemistry is normal.

Conclusion

Tumor induced osteomalacia is mostly associated with mesenchymal tumors that are often occurred in nasal sinuses. Tumor removal - as in our case- may lead to complete recovery.

**Body composition in postmenopausal women with vertebral fractures**

V. Povoroznyuk & N. Dzerovych
Institute of Gerontology NAMS Ukraine, Kyiv, Ukraine.

The aim of this study is evaluating body composition in postmenopausal women depending on presence of vertebral fractures in their anamnesis.

Materials and methods

We've examined 144 postmenopausal women aged 50–83 years (mean age – 62.9 ± 0.7 years; mean height – 160.6 ± 0.5 cm; mean weight – 71.9 ± 1.2 kg). The patients were divided into two groups: group A – women without vertebral fractures ($n=82$), group B – women with vertebral fractures ($n=62$) in their anamnesis. We also divided the patients into the following age-dependent groups: 50–59 years, 60–69 years, 70 years and older. Total body, lumbar spine, femoral neck bone mineral density (BMD), lean and fat masses were measured by DXA using a densitometer Prodigy, GE.

Results

Fat mass significantly decreased with age (50–59 years – 31 906.9 ± 1508.0 g; 60–69 years – 30 876 ± 1186.5 g; 70 years and older – 25 257.4 ± 1398.6 g; $F=5.0$; $P=0.008$). Lean mass didn't show significant differences. Fat and lean masses in postmenopausal women with vertebral fractures were significantly lower compared with the data of women without vertebral fractures (fat mass: group A – 42 089 ± 583.4 g, group B – 38 421.4 ± 652.4 g, $F=17.4$, $P=0.00005$; lean mass: group A – 31 783.7 ± 1212.1 g, group B – 27 831.4 ± 1048.5 g, $F=5.6$, $P=0.02$). We have founded the positive significant correlation between fat mass and BMD of spine and femoral neck depending on the presence of vertebral fractures in patient's anamnesis:

- Group A: total fat (g) = 1.06 + 0.26 × BMD (L1–L4); $r=0.07$; $t=2.40$; $P=0.02$.
Total fat (g) = 0.87 + 0.34 × BMD (femoral neck); $r=0.12$; $t=3.23$; $P=0.002$.
Group B: total fat (g) = 0.84 + 0.45 × BMD (L1–L4); $r=0.20$; $t=3.91$; $P=0.0002$.
Total fat (g) = 0.70 + 0.32 × BMD (femoral neck); $r=0.10$; $t=2.54$; $P=0.01$.

Conclusion

Fat mass was significantly decreased with age. Fat and lean masses significantly differ in postmenopausal women depending on the presence of vertebral fractures in their anamnesis. The positive significant correlation was found between fat mass and BMD of spine and femoral neck.

**Bone mineral density in relation to metabolic syndrome in postmenopausal women with diabetes type 2**

S. Canecki-Varzic[1,2] & I. Bilic-Curcic[1,2]
[1]Clinical Hospital Center, Osijek, Croatia; [2]School of Medicine Osijek, J.J. Strossmayer University, Osijek, Croatia.

Diabetes type two is associated with greater bone mineral density (BMD) due to obesity although observed rapid bone loss over time could be explained with elevated chronic inflammation. The objective of this study was to investigate the relationship between central adiposity and hyperinsulinaemia as well as inflammation markers with vertebral and femoral BMD and bone turnover markers in postmenopausal women with type two diabetes. Femoral and vertebral BMD, osteocalcin, pyrilinks D, β-CrossLaps (B-CTx), insulin, CRP, fibrinogen and plasminogen activator inhibitor-1 (PAI-1) were measured in 114 female postmenopausal patients with diabetes type two. The patients similar in age, HbA1c levels and diabetes duration were divided in two groups based on their BMI values: lower or equal to 27 (31 patients) and higher than 27 kg/m$^2$ (83 patients). The sample means, S.D. and medians were calculated for all variables in each group, whereas *t*-test as parameter and Mann–Whitney as non-parameter test were used to calculate distribution differences for continuous variables. Spearman's correlation coefficients were computed to estimate the magnitude of the association between variables of interest. Lower levels of osteocalcin ($P=0.001$) and B-CTx ($P=0.000007$) compared to higher femoral BMD ($P=0.00006$) as well as insulin ($P=0.0002$), PAI-1 ($P=0.000000$) and CRP ($P=0.002$) were found in the overweight group. There were no significant differences in the vertebral BMD, pyrilinks D and fibrinogen. Osteocalcin and B-CTx were inversely correlated, while femoral BMD positively correlated with waist circumference, insulin levels and PAI-1 (Table 1). This suggests that components of the metabolic syndrome, abdominal obesity and hyperinsulinaemia could increase femoral BMD by lowering bone rate. In addition, the only inflammation marker linked with femoral BMD was PAI-1, which is associated with increased mineralization of cortical bone in mouse models.

Spearman's correlation coefficients for femoral BMD and bone turnover markers versus components of metabolic syndrome.

**Table 1**

| Femoral BMD<br>osteocalcin<br>B-CTx | Waist circumference | Insulin | PAI-1 |
|---|---|---|---|
| | $R=0.3616$<br>$P=0.001$ | $R=0.2981$<br>$P=0.005$ | $R=0.345$ $P=0.001$ |
| | $R=-0.2693$<br>$P=0.011$ | $R=-0.2439$<br>$P=0.021$ | $R=-0.2809$ $P=0.007$ |
| | $R=-0.3359$<br>$P=0.002$ | $R=-0.2239$<br>$P=0.037$ | $R=-0.2653$ $P=0.012$ |

**Assessment of bone turnover and vitamin D levels in women with postmenopausal osteoporosis and type 2 diabetes mellitus**

J. Novakovic-Paro, B. Vukovic, T. Icin, B. Kovacev-Zavisic, M. Medic-Stojanoska, M. Mitrovic, I. Bajkin & O. Rankov
Clinical Centre of Vojvodina, Novi Sad, Serbia.

Background
Past research suggests that diabetes mellitus, although with still insufficiently known mechanisms, has an effect on bone turnover.
Objective of this study was to determine the level of bone metabolism parameters and vitamin D in women with postmenopausal osteoporosis and type 2 diabetes mellitus.
Material and methods
The prospective study included 30 women with postmenopausal osteoporosis and type 2 diabetes mellitus and a controls – 30 women with postmenopausal osteoporosis. Osteoporosis is verified by lumbar spine and hip DXA. Levels of osteocalcin, β-crosslaps and 25(OH)D3 were measured.
Results
Diabetes mellitus duration was $15.37 \pm 11.08$ years. HbA1c was $7.52 \pm 1.62\%$. Women with diabetes mellitus was $61.6 \pm 8.07$years old and controls $61.9 \pm 7.23$ years. Women with diabetes mellitus BMI was $26.61 \pm 5.45$ kg/m$^2$ and $24.77 \pm 3.57$ kg/m$^2$ for controls. There was no statistically significant difference in age or BMI. Women with diabetes mellitus L1-L4BMD was $0.846 \pm 0.075$ g/cm$^2$, total hip $0.746 \pm 0.108$ g/cm$^2$ and femoral neck $0.704 \pm 0.078$ g/cm$^2$. Controls L1-L4BMD was $0.799 \pm 0.058$ g/cm$^2$, total hip $0.787 \pm 0.085$ g/cm$^2$ and femoral neck $0.749 \pm 0.084$ g/cm$^2$. BMD of the lumbar spine in women with diabetes mellitus were higher, without statistical significance, while the hip BMD was significantly lower on the femur neck ($P < 0.05$). Women with diabetes mellitus osteocalcin was $29.68 \pm 11.67$ ng/ml, crosslaps $530.73 \pm 239.96$ pg/ml and 25(OH)D3 $37.9 \pm 20.22$ nmol/l. Controls: osteocalcin $32.83 \pm 7.76$ ng/ml, crosslaps $525.03 \pm 167.94$ pg/ml, and 25(OH)D3 $40.85 \pm 17.79$ nmol/l. Among these parameters there was no statistically significant difference. All women with diabetes mellitus had a lack of vitamin D, and 14(46.7%) of them had vitamin D deficiency. Controls: sufficient levels of vitamin D had 2 (6.7%) women; vitamin D deficiency had 9(30%) women.
Conclusion
In women with type two diabetes mellitus bone density at the femur and the femoral neck is lower. There is no statistically significant difference in bone turnover in women with type two diabetes mellitus compared to healthy women with osteoporosis. Inadequacy of vitamin D is more often present in women with type two diabetes mellitus than in healthy women with osteoporosis.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Osteoblast and adipocyte differentiation from human adipose tissue-derived cells**

D. Manda[1], S. Oros[1], O. Popa[1], A. Baciu[3], S. Vladoiu[1], O. Ianas[1], I. Lascar[2] & C. Dumitrache[1]
[1]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Bucharest Emergency Hospital, Bucharest, Romania; [3]University of Bucharest, Faculty of Physics, Bucharest, Romania.

Human adipose tissue provides abundant source of mesenchymal stem cells, which can be easily and safely harvested as compared with human bone marrow. The aim of this study was to differentiate a viable osteoblast and adipocyte cell culture from mesenchymal stem cells, an experimental model to study the interrelation between adipocytes and bone forming cells, osteoblasts.
Materials and methods
Subcutaneous adipose tissue liposuction aspirate was obtained from a female subject, aged 27 years undergoing plastic surgical procedure in a specialized clinic, after she gave the informed consent.
The adipose tissue sample was extensively washed with sterile PBS containing antibiotic/antimycotic (AA) and let 30 min to decant. Blood fraction was collected into 50 ml conical tubes. Cells were cultured in DMEM, 10% FBS, AA. After 3 weeks, cells were splitted and seeded in osteogenic (DMEM, 10% FBS, 100 nm dexametasone, 10 mm beta glycerolphosphate, 0.05 mm ascorbic acid, 1% AA) and adipogenic medium (DMEM, 10% FBS, 1 μm dexametasone, 10 μm insulin, 200 μm indomethacin, 0.5 μm IBMX, 1% AA) respectively. Specific phenotype was assessed by von Kossa specific staining for osteoblasts and Oil red staining for adipocytes.
Results
The specific phenotype occurred in the second passage. Cell growth rate was higher in osteoblasts than adipocytes (4.5 vs 3.2 in passage 7). Osteoblasts were fully diferentiated (mineralized) in passage six. The log phase of the cellular growth curve was 10 passages long, that offers a reasonable period of time for experiments that require adipocyte-osteoblast co/culture.
Conclusion
Differentiation of osteoblasts and adipocytes starting from the same cellular sample from human adipose-tissue stromal derived cells confers a great advantage for co-culture studies because immunological rejection is overcome.

**Denosumab increases BMD in primary hyperparathyroidism**

W. Misiorowski & W. Zgliczynski
Medical Centre for Postgraduate Education, Warsaw, Poland.

Primary hyperparathyroidism (PHPT) is often associated with reduced bone mineral density (BMD). An open-labeled, prospective trial was conducted to determine whether denosumab 60 mg subcutaneously given every 6 months, maintains or improves BMD in patients with PHPT.
Six patients had symptomatic PHPT and met surgical guidelines however refused surgery, and twelve patients had mild PHPT, asymptomatic except low BMD. The primary outcome index, BMD, was measured at the lumbar spine (LS) and femoral neck (FN) after six and 12 months by dual-energy X-ray absorptiometry. Serum calcium, phosphorous and PTH, and urinary calcium excretion were monitored every 3 months.
Treatment with denosumab was associated with a significant ($5.8 \pm 0.4\%$; $P < 0.01$) increase in LS BMD after 12 months in comparison with baseline. FN BMD increased significantly at 12 months with denosumab by $2.3\% \pm 0.7$ ($P < 0.01$) from baseline. Serum calcium, phosphorus and PTH, and urine calcium excretion did not change significantly with denosumab therapy. In PHPT, denosumab given subcutaneously twice yearly, significantly increases BMD at the LS and FN at 12 months from baseline values with stable serum calcium and PTH levels. Denosumab may be a useful alternative to parathyroidectomy in PHPT among those with low BMD, who are candidates for surgery but either decline or for whom surgery is contraindicated.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P172

**Relationship between bone metabolism markers, bone mineral density and insulinresistance in healthy and diabetic postmenopausal women**

G. Perez Lopez[1], A. Becerra Fernandez[2] & M. Menacho Roman[2]
[1]Hospital Comarcal de Melilla, Melilla, Spain; [2]Hospital Universitario Ramon y Cajal, Madrid, Spain.

Introduction
Some metabolic diseases, including type 1 (T1DM) and type 2 (T2DM) diabetes mellitus have an influence on bone homeostasis. These facts are of great socio-medical impact, since currently the DM2 and osteoporosis are considered public health problems.
Objectives
(1) Determine the relationship between markers of bone metabolism and insulin resistance in postmenopausal women with and without T2DM.
(2) Compare the bone mineral density between the two groups.
Methodology
Prospective and case–control study. Postmenopausal women attending in outpatient Endocrinology from January to December 2010 were included consecutively. T2DM patients treated with oral hypoglycemic agents (except glitazones) and patients with other diseases that not interfere with bone

metabolism were included. The study included 18 women with diabetes and 58 without diabetes. The average age of the sample was 54.6±1.8 years. In the diabetic group the duration of diabetes was 4.6±2.4 years. Measurements included anthropometric (BMI), biochemical (insulin, C-peptide, HOMA-IR, P1NP, β-crosslap, osteocalcin, 25-OH-vitamin D, PTH, calcium, phosphorus, renal function) and radiographic (bone densitometry: *T*-score) variables.
Results
BMI was similar between groups. The HOMA-IR was 7.9±0.6 in the DM2 group and 3.0±0.7 in the control group ($P<0.05$). Osteocalcin was lower in diabetics (14.6±3.8 ng/ml, $P<0.01$) than in healthy patients. The same trend was observed at concentrations of P1NP. In densitometry, 20% of diabetics had osteoporosis and 40% osteopenia. In the healthy group, 35% had osteoporosis and 52% osteopenia. In the diabetic group HOMA-IR was associated directly with BMD ($r=0.568$, $P<0.05$) and HOMA-IR inversely with osteocalcin ($r=-0.624$, $P<0.05$). Also in the group of healthy patients with P1NP was related directly with BMD and HOMA-IR inversely with BMD.
Conclusions
Insulin resistance is a predictor of BMD. Osteocalcin is related to insulin resistance, as it is clearly diminished in diabetics. P1NP concentration is related directly with BMD in the healthy group. Osteoporosis and osteopenia were higher in the healthy patients than in diabetic patients. More studies are needed to explain the fact why despite having higher BMD, diabetics are more likely to fracture than healthy women.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P173

**The relation between quantitative characteristics of smoking and level of female skeleton damage**

M. Duskova, H. Pospisilova, H. Hruskovicova, K. Simunkova, I. Zofkova, M. Hill & L. Starka
Institute of Endocrinology, Prague, Czech Republic.

Objective
Skeletal disability pathogenesis is multifactorial. Many studies have proved a negative relation of smoking on calcium-phosphate metabolisms, bone density and quality; however in some other papers these results have not been confirmed. The aim of the study was to monitor the influence of the length of smoking, a number of cigarettes smoked and the age of the first use of cigarettes on the whole-body bone density.
Methods
Whole-body densitometry determining bone and soft tissues using dual-emission X-ray absorptiometry (DXA) was measured with 40 women, where 22 women were premenopausal (average age 35±8) and 18 women postmenopausal (average age 57±5). All probands had been smoking in the long term continuously until the day of examination. Partial correlations adjusted to constant age and physical activity were used to evaluate relations between the smoking intensity indicators on one side and anthropometric characteristics and bone quality indicators on the other side.
Results
Monitoring the effect of smoking upon whole-body bone density and the volume of muscle mass with women, we have not proved statistically significant relation of the whole-body mass to the number of cigarettes smoked, or to the length of smoking, or to the age of the first use of cigarettes.
Conclusions
Though the study is not fully comparable with those monitoring the relation of smoking to bone density of the selected high-risk skeleton localities, fundamentally it comes up with the identical results when compared with other studies.

## P174

**The assessment of the behavior of the interleukins IL1β and IL6 and bone mineral density (BMD) and bone metabolism (IBM) in women of postmenopausal age**

W. Tryniszewski, M. Gorska-Chrzastek, M. Kozlowska, M. Gadzicki, I. Raciborska, A. Zajac & Z. Maziarz
Medical University, Lodz, Poland.

Women's bone metabolism is regulated by estrogens and interleukins. During the menopausal period the estrogens' protective activity is decreased and the production of IL1β and IL6 is increased.
The aim of the study
The assessment of the dependency between IL1β i IL6 and estradiol values and BMD and IBM in postmenopausal women.
Material
Forty-eight women, age 49–61, without menstruation and not edocrinologically treated. Group I – 19 women with normal BMD, Group II – 29 women with osteoporosis.
Methods
Densitometric (BMD, *T*-score). Radioisotopic dynamic and static scintigraphy Tc 99 m MDP and IBM designation. Biochemical interleukins IL1β and IL6 and E2, P, ALP, Ca+i TSH.
Results
In Group I - IBM within the normal values range $86.2<IBM<98.9$, in Group II, the IBM within $75.1<IBM<90.3$ (in 40% of women the IBM was below the normal values).
Group I – a strong positive correlation between BMD and IBM
Group II – a medium positive correlation between BMD and IBM
Group I – normal biochemical and hormonal values
Group II – elevated concentrations of phosphatase and phosphates.
The estradiole value in Group I was higher than in Group II. The difference was statistically significant.
The interleukins concentrations in Group II were significantly higher than in Group I (statically significant $P=0.000$).
In Group I there was no correlation and in Group II a negative correlation between BMD and interleukins.
Conclusions
During the menopausal period the estradiol's decrease is accompanied by the increase of interleukins IL1β and IL6 which results with the loss of bone mass and slower bone metabolism and degradation of bone quality parameters.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P175

**Correction of bone mineral density losing in female rats with exogenous thyrotoxicosis with calcium and alendronate preparations**

V. Povoroznyuk[1], O. Oliynyk[2] & B. Oliynyk[2]
[1]Institute of Gerontology NAMS Ukraine, Kyiv, Ukraine; [2]Clinical Endocrinilogical Centre, Kyiv, Ukraine.

Numerous hormonal and metabolic disorders caused by thyrotoxicosis lead to serious complications, so early diagnosis and adequate treatment becomes very important in warning of functional and organic changes in several organ systems, particularly in the structure of bone tissue.
The aim was study of the effectiveness of calcium and alendronate for prevention and treatment of BMD losing in experimental models of thyreotoxicosis.
Material and methods
Used 47 female Wistar rats 8-10 month age with body mass 207.81±3.27 g. Depending on the medication, animals are divided into five groups: isotonic solution of sodium chloride (control), L-thyroxine, L-thyroxine and calcium, L-thyroxine, calcium and alendronate, L-thyroxine for two weeks before and during the experiment, calcium and alendronate. L-thyroxine (25 mcg/100 g) and solution of sodium chloride injected sucutaneously daily, calcium (2.1 mg/100 g) daily and alendronate (1.75 mg/100 g) once at week entered through the esophageal probe. BMD of whole skeleton, spine and hind limbs measured at

the beginning and after five weeks of experiment using a densitometer Prodigy (GE Medical systems). Data were analyzed using ANOVA and Student's *t*-test to examine differences among the groups.
Results
In the control group of animals BMD increases in all parts of the skeleton (1.25 ±3.2% to 15.76±1,05%). The greatest loss of BMD was observed in L-thyroxine medicated rats (−5.95±2.36 to −14.13±1.46%). In the group of animals with thyrotoxicosis that received medication calcium, observed retardation of sceleton growth and a moderate loss of BMD from (0.49±2.13% to −5,11±2.52%), that has significant differences with group with thyreotoxicosis at hind limbs and whole sceleton. In groups of animals with thyrotoxicosis and calcium and alendronate medication observed increasing BMD that has not significant differences with control group.
Conclusion
In the experiment, exogenous hyperthyroidism resulted in reliable loss of BMD, mainly peripheral skeleton (by 14.13% at the hind limbs and 5.95% at the spine). Use of calcium during exogenous hyperthyroidism in female rats significantly reduces bone loss. The combination of calcium and alendronate prevents losing BMD, regardless of the duration of hyperthyroidism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Reference intervals for serum N-MID osteocalcin concentration measured with the IDS-iSYS automated system**

A. Hannemann, N. Friedrich, C. Spielhagen, R. Rettig, M. Nauck & H. Wallaschofski
Ernst-Moritz-Arndt-University Greisfwald, Greifswald, Germany.

Background
Osteocalcin (OC) is a bone-specific protein produced primarily by osteoblasts during bone formation. The OC concentration is used to assess fracture risk and monitor treatment of osteoporosis and other disorders of bone metabolism. To adequately interpret the OC concentration, it is necessary to calculate reference ranges from a healthy reference population, adapted to a specific laboratory method.
Methods
We established a healthy reference population from the participants of the first follow-up of the Study of Health in Pomerania. Serum OC concentrations were measured from frozen aliquots with the IDS-iSYS N-Mid Osteocalcin assay on the IDS-iSYS Automated System (Immunodiagnostic Systems, Frankfurt am Main, Germany). The coefficients of variation were 6.98% at low, 6.44% at medium, and 5.44% at high levels of control material. The reference interval was defined as the central 95% range between the 2.5th and the 97.5th percentile. Age-specific reference intervals were calculated for men aged 25–80 years and for pre-menopausal women aged 25–54 years by means of quantile regression. As in post-menopausal women aged 50–80 years OC was not influenced by age, we calculated an age-independent reference interval.
Results
Median (1st–3rd quartile) OC concentrations were 15.4 ng/ml (12.0–19.5 ng/ml) in 1119 men, 14.4 ng/ml (11.3–18.5 ng/ml) in 545 pre-menopausal women, and 18.7 ng/ml (13.7–25.6 ng/ml) in 502 post-menopausal women. Median OC concentrations were highest in 25–29-year-old men and women, were stable during the middle ages, and rose again after 65 years of age in men, and at transition to post-menopause in women. We observed that subjects with type 2 diabetes, intake of oral contraceptives or hormone replacement therapy had lower OC concentrations than subjects without these conditions.
Conclusion
We present sex-specific reference intervals for the serum OC concentration over a broad range of age groups to assess bone metabolism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P177

**Prevalence of morphometric vertebral fractures and bone quality measured by spinal deformity index in type 1 diabetic patients**

V. Zhukouskaya[1], C. Eller-Vainicher[1], V. Vadzianava[3], I. Zhurava[4], G. Korolenko[5], E. Cairoli[1], P. Beck-Peccoz[1], A. Shepelkevich[2] & I. Chiodini[1]
[1]University of Milan, Endocrinology and Diabetology Unit, Fondazione IRRCS Cà Granda – Ospedale Maggiore Policlinico, Milan, Italy; [2]Belarusian State Medical University, Minsk, Belarus; [3]Republic Medical Rehabilitation and Balneotreatment Centre, Minsk, Belarus; [4]Out-patient clinic 18, Minsk, Belarus; [5]Hospital 10, Minsk, Belarus.

Background and objectives
There are a lot of studies demonstrating low bone mineral density (BMD) and elevated fracture risk in patients with type 1 diabetes. But there are scarce data about the prevalence of morphometric vertebral fractures (MorfoFx) and spinal deformity index (SDI) that is considered as a surrogate marker of bone quality. Therefore, the objective of this study was to evaluate BMD, the prevalence of MorfoFx and bone quality by SDI in type 1 diabetics.
Methods
There were evaluated 82 patients type 1 diabetes (26 males, 56 females, age 31.1±8.3 years, BMI 23.2±3.3 kg/m$^2$, disease duration 12.9±7.8 years) and age-, sex-, BMI-matched 48 controls (12 males, 36 females, age 33.8±7.3 years, BMI 23.0±4.7 kg/m$^2$). BMD and MorfoFx were measured with DXA. After then SDI was calculated in all patients.
Results
Type 1 diabetic patients, comparing with controls, had lower BMD either at spine (−0.5±1.2 vs 0.03±1.0, $P=0.012$ respectively) and at femoral neck (−0.7 ±1.1 vs 0.02±0.8, $P<0.001$ respectively), higher prevalence of MorfoFx (26.8%, $n=22$ vs 10.4%, $n=5$, $P=0.027$ respectively) and higher SDI (0.5±1.1 vs 0.15±0.5, $P=0.031$ respectively). Age, diabetes duration, age of diabetes manifestation, BMD and the prevalence of chronic complications were not different between type 1 diabetics with and without MorfoFx. In the multiply regression analysis MorfoFx/SDI were not associated with BMD, diabetes duration, age of diabetes manifestation, the presence of complications.
In conclusion, this study demonstrates that type 1 diabetic patients have low BMD, elevated prevalence of MorfoFx and poor bone quality evaluated by SDI.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Clinical evaluation of a new specific 1–84 PTH automated platform**

M. Manor & Y. Mayer
Clalit Health Care, Atidim Centarl Lab, Tel-Aviv, Israel.

Introduction
2nd generation 'Intact' PTH assays currently available, measure 1–84 PTH and additional fragments. Recently a third generation kit developed which detects only active.
1–84 PTH molecule, based on an immuno-radiometric sandwich assay.
Design
Evaluation took place in an HMO central lab. 240 plasma samples collected. One hundred and sixty-one randomly out patients and 78 hospitalized nephrologic patients. Patients samples, controls and NEQAS samples tested by CLIA.
Method
DiaSorin LIAISON 1–84 PTH assay, DiaSorin LIAISON N-TACT PTH II, SIEMENS Centaur iPTH and DiaSorin IRMA N-tact PTH SP ('Gold Standard'). Results were compared with laboratory parameters and patients clinical status.
Results
Correlation between LIAISON 1–84 PTH and LIAISON N-TACT PTH II showed $R=0.9164$, slope=0.9076. Correlation between LIAISON 1–84 PTH and Centaur iPTH showed $R=0.98$, slope=2.7622. Correlation between LIAISON 1–84 PTH and IRMA N-tact PTH SP showed $R=0.97$, slope=1.0893. The following LIAISON 1–84 PTH parameters obtained: samples and controls within run precision showed 2.58 and 5.34% CV. Samples and controls between run precision showed 4.03 and 4.65% CV. Functional sensitivity matched manufacturer claim at 4 pg/ml. Recovery between 77 and 101%. Clinical agreement between LIAISON 1–84 PTH and IRMA N-tact PTH SP on nephrologic patients was 97.5%. Three discrepant patients were clinical matched with LIAISON 1–84 PTH results. From the healthy out patients tested samples

54% were found high with SIEMENS Centaur iPTH and 16% were high with LIAISON 1–84 PTH. The same behavior observed with NEQAS data.
PTH levels were influenced similarly by low Ca levels.
Conclusions
High diagnostic correlation was observed between IRMA N-tact PTH SP and LIAISON 1–84 PTH together with high clinical correlation of patients status. It is concluded that the LIAISON 1–84 PTH can be used as a reliable and accurate kit for setting up a clinical and high throughput laboratory.

### Successful treatment of thyrotoxicosis is accompanied by a decrease in serum sclerostin levels

E. Skowronska-Jozwiak[1,2], K. Krawczyk-Rusiecka[1], K. Lewandowski[1,2], Z. Adamczewski[1,2], M. Bienkiewicz[2] & A. Lewinski[1,2]
[1]'Polish Mother' Memorial Hospital Research Institute, Lodz, Poland; [2]The Medical University of Lodz, Lodz, Poland.

Sclerostin, a product of a SOST gene, is a protein expressed by osteocytes that inhibits osteoblastic bone formation. Several hormones including PTH and glucocorticosteroids and have been suggested as possible regulators of sclerostin production. The influence of thyroid hormones on sclerostin synthesis has not been investigated so far. The aim of the study was to evaluate sclerostin concentrations in patients before and after treatment of thyrotoxicosis.
Patients and methods
The study involved 15 patients (four men), mean age 51.8 ± 15.3, mean BMI 24.7 ± 3.5, with thyrotoxicosis due to Graves' disease or toxic multinodular goitre. Serum sclerostin was measured by immunoassays at diagnosis of thyrotoxicosis and after 6–10 weeks of treatment with thiamazole. The data were analysed by means of simple descriptive statistics of location and dispersion and Mann–Whitney *U* test for pairs of results 'before' and 'after' therapy. Association between variables was evaluated with use of Spearman correlation coefficient.
Results
Here was a significant decrease in free $T_3$ and free $T_4$ concentrations (from 8.74 ± 4.79 to 3.54 ± 2.40 pg/ml, and from 4.48 ± 2.21 to 1.02 ± 1.07 ng/ml, $P < 0.001$), for free $T_3$ and free $T_4$ respectively. This was accompanied by a marked decrease of serum sclerostin levels from 55.46 ± 20.90 to 35.73 ± 15.70 pmol/l, $P < 0.0015$). Interestingly, however, sclerostin levels did not correlate with serum free $T_3$ or free $T_4$ concentrations.
Conclusions
Restoration of a euthyroid state in patients with thyrotoxicosis results in a significant decrease in serum sclerostin concentrations. The above mentioned phenomenon may reflect lowering of bone metabolism, but possible direct influence of thyroid hormones on SOST gene needs to be investigated.

### Investigating recurrent hypophostaemia

R. Agha-Jaffar[1], M. Reddy[1], D. Bassett[2] & J. Cox[1]
[1]St Mary's Hospital, Imperial College NHS Trust, London, UK; [2]Hammersmith Hospital, Imperial College NHS Trust, London, UK.

Oncogenic osteomalacia is a rare paraneoplastic phenomenon characterised by abnormal phosphate metabolism typically caused by discrete benign tumours. Due to the indolent presentation and slow progression, diagnosis is often delayed and localisation of the tumour can prove difficult. We present the case of a 64-years-old gentleman who was investigated by the endocrinology department for hypophosphataemia. Three years prior to this, he had started to experience exertional fatigue and myalgia. Within the same time frame, he sustained a minor injury to his ankle and later developed severe pain in the joint lasting several months. This was attributed to Looser zones on plain X-ray. He had no further significant medical history. Development and growth had been normal. Relevant results are tabulated. The low Tmp/GFR value confirmed renal phosphate wasting. In the context of a mildly elevated PTH level and inappropriately normal 1,25 (OH) Vitmain D/ FGF 23 levels, the hypophosphataemia was deemed consistent with oncogenic osteomalacia. Though CT images demonstrated low attenuation hepatic lesions, these were characterised as insignificant on MRI. No potential source was identified on functional imaging modalitites (octreotide scintigraphy, FDG-PET imaging or Ga68 DOTATATE PET). Symptomatic relief was gained with Sando Phosphate and alfcalcidol. Biochemical parameters normalised (fasting phosphate 0.77 mmol/l, ALP 117 μ/l) and a repeat bone scan showed full resolution in the areas of increased activity. Our case illustrates the difficulties in identifying tumours associated with this paraneoplastic phenomenon and how, despite unsuccessful localisation, medical therapy can be effective in the absence of definitive treatment.
Results

**Table 1**

| Variable | Values | Reference range |
|---|---|---|
| Fasting Phosphate Level | 0.53 mmol/l | 0.8–11.4 mmol/l |
| Corrected Calcium | 2.24 mmol/l | 2.15–2.60 mmol/l |
| Creatinine | 100 mmol/l | 75–114 mmol/l |
| Parathyroid Hormone Levels | 14.6 pmol/l | 1.1–6.8 pmol/l |
| Alkaline Phosphatase | 255 μ/l | 30–130 μ/l |
| 25-OH Vitamin D | 51.1 nmol/l | 25–100 nmol/l |
| 1–25(OH) Vit D | 73 pmol/l | 40–150 pmol/l |
| Fibroblast Growth Factor-23 | 63 RU/ml | < 100 RU/ml |
| 24 hour urinary phosphate excretion | 20.73 mmol | 16–48mmol |
| Fractional excretion of phosphate | 14% | |
| Tubular maximum for phosphate corrected for GFR (TmP/GFR) | 0.35 mmol/l | 0.89–1.34 mmol/l (corrected for age and gender) |
| Bone Scintigraphy | Multiple sites increased activity throughout skeleton with few small hot spots | |
| Bone Mineral Density (DEXA) Scan | T4-L2: (T score) −2.7: Femoral neck: (T score) −1.7 | |

### Ovariectomy modulates the effect of phytoestrogens on creatine kinase specific activity in skeletal organs in female rats

D. Somjen[1], B. Gayer[2], F. Kohen[2], G. Posner[3] & A. Kaye[2]
[1]Tel-Aviv Sourasky Medical Center and the Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv 64239, Israel; [2]The Weizmann Institute of Science, Rehovot 76100, Israel; [3]Johns Hopkins University, Baltimore, Maryland, USA.

Ovariectomy of immature female rats, results in significant decreased parameters in different organs. Previously we found that estradiol-17b ($E_2$) restored these parameters in the different organs of ovariectomized female rats (Ovx) to values obtained in intact immature female rats. $E_2$ also stimulated creatine kinase specific activity (CK) a hormonal-responsive marker in organs containing estrogen receptors. In the present study, we compared the effects of $E_2$ to those of the phytoestrogens: quercertin (Qu), daidzein (D), genistein (G), biochainin A (BA) and their carboxy-derivatives cD, cG and cBA in immature and Ovx female rats, on CK in diaphyseal bone (Di) and epiphyseal cartilage (Ep) as well as uterus (Ut) and pituitary (Pi), when injected for 24 h with and without the SERM raloxifene (Ral), or with and without pre-treatment for three days with the less-calcemic vitamin D analog JK 1624F2-2 (JKF). Ovariectomy resulted in significantly reduced CK levels in all organs tested. All estrogenic compounds tested in both age groups stimulated CK. Ral stimulated CK in all organs except Ut but inhibited enzymatic stimulation by $E_2$ and some of the estrogenic compounds in an age- and organ-specific patterns. Pre-treatment with JKF increased CK response to $E_2$ and some of the estrogenic compounds in age- and organ-specific patterns. In summary, estrogenic target organs of female rats are

modulated differently in an age- and organ-dependent manner in a yet unknown mechanism which might be connected to estrogen receptors in the organs.

**Bone turnover markers in medicamentous and physiological hyperprolactinemia in female rats**

D. Radojkovic[1], M. Pesic[1], S. Antic[1], V. Djordjevic[1], S. Radenkovic[1], S. Kostic[2], S. Curkovic[2], V. Ciric[2] & T. Ristic[2]
[1]Clinical Center Nis, Medical Faculty, University Nis, Nis, Serbia; [2]Clinical Center Nis, Nis, Serbia.

Background
The aim of this study was to compare the influence of medicamentous and physiological hyperprolactinemia on bone turnover in female rats.
Methods
Experimental animals (18 weeks old, Wistar female rats) were divided in the following groups: Group I: 9 rats, three week pregnant; Group II: ten female rats that were i.m. administrated Sulpirid (10 mg/kg) twice daily for three weeks; Group III: ten female rats that were i.m. administrated Sulpirid (10 mg/kg) twice daily for six weeks; Group IV: ten female rats, control group. Laboratory investigations included serum and urinary calcium, inorganic phosphorus, alkaline phosphatase and serum procollagen type 1 N-terminal propeptide (P1NP).
Results
Experimental animals in Group I (physiological hyperprolactinemia) compared to control group, displayed lower mean serum calcium ($0.5 \pm 0.2$ vs $1.12 \pm 0.04$ mmol/l; $P<0.001$); higher mean serum phosphorus ($2.42 \pm 0.46$ vs $2.05 \pm 0.2$ mmol/l; $P<0.05$); decreased urinary calcium ($0.13 \pm 0.06$ vs $0.39 \pm 0.18$ mmol/mmol creatinine;$P<0.001$) and significantly increased P1NP ($489.22 \pm 46.77$ vs $361.9 \pm 53.01$ pg/ml; $P<0.001$). Experimental animals in Group II (medicamentous hyperprolactinemia) had significantly decreased P1NP, compared to control group ($309.6 \pm 36.74$ vs $361.9 \pm 53.01$ pg/ml; $P<0.05$). Prolongated medicamentous hyperprolactinemia (Group III) induced increased serum calcium ($1.21 \pm 0.025$ vs $1.12 \pm 0.04$ mmol/l; $P<0.05$); decreased serum phosphorus ($1.69 \pm 0.13$ vs $2.05 \pm 0.2$ mmol/l; $P<0.001$); decreased alkaline phosphatase ($49.61 \pm 14.39$ vs $77.07 \pm 22.6$ U/l; $P<0.01$) and significantly decreased P1NP ($291.7 \pm 71.03$ vs $361.9 \pm 53.01$ pg/ml; $P<0.05$).
Conclusions
Physiological hyperprolactinemia does not determine such harmful effect on bone metabolism as medicamentous hyperprolactinemia. Chronic medicamentous hyperprolactinemia displayes lower serum levels of P1NP, which reflects poor bone formation. Assessment of bone turnover markers in prolongated medicamentous hyperprolactinemia, provides an opportunity for earlier diagnosis of bone metabolism disturbances and should be considered as mandatory.

## P183

**Adiponectin and bone mineral density in obese postmenopausal women**

J. Milin[2], D. Micic[1,2], D. Stamenkovic-Pejkovic[2], D. Jeremic[2], A. Kendereski[1,2], S. Zoric[2], G. Cvijovic[2] & M. Sumarac-Dumanovic[1,2]
[1]University of Belgrade, Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Belgrade, Serbia.

Introduction
Adiponectin and its receptors are expressed in human osteoblasts, suggesting that adiponectin may be a hormone linking bone and fat metabolism. In contrast to adiponectin anabolic effect on bone *in vitro* studies, clinical and animal studies suggest that adiponectin may have negative effects on bone by stimulating the receptor activator of nuclear factor-κB ligand (RANKL) pathway and inhibiting the production of the decoy receptor for RANKL and osteoprotegerin. Several clinical studies have shown a negative correlation between adiponectin and bone mineral density (BMD) in females independently of confounding factors.
Aim
The aim of this study was to investigate the relationship between adiponectin and bone mineral density in obese postmenopausal women.
Methods
Eleven obese postmenopausal women were recruited in our study (mean age $= 51.8 \pm 4.21$ years, mean BMI $= 30.5 \pm 2.29$ kg/m$^2$). Levels of adiponectin (ng/ml) were measured using ELISA test (Mercodia, Sweden). Bone mineral density (BMD) was assessed by dual energy X-ray absorptiometry (DXA) at the level of lumbar spine L2–L4 (BMD L2–L4) and left hip (Hologic). Statistical analysis was performed by SPSS 19. Pearson's correlation coefficients were calculated to evaluate the relationship between BMD and adiponectin.
Results
Adiponectin was inversely associated with BMD of left hip, ($r = -0.910$, $P<0.05$), *T*-score of left hip ($r = -0.992$, $P<0.01$). There was no statistically significant correlation between BMD of lumbar spine (L2–L4), *T*-score of lumbar spine and adiponectin.
Conclusion
Our result confirmed negative correlation between adiponectin and BMD of left hip but not with BMD of lumbar spine in obese women which suggest need for further investigation and elucidation of this interrelationship between adipokines and BMD.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P184

**The body mass index and heel quantitative ultrasound analyze in 300 women**

M. Carsote[1], G. Voicu[2], V. Radoi[1], C. Ene[2], C. Poiana[1,2] & M. Coculescu[1,1]
[1]UMPh Davila, Bucharest, Romania; [2]I. Parhon, Bucharest, Romania.

Introduction
The heel Quantitative Ultrasound (QUS) evaluates the bone health, with good results if the clinical risk factors are also evaluated for each patient. Among these, the body mass index (BMI) may be protective or risk factor for a fragility fracture, depending on the values.
Aim
We present a study in postmenpausal women evaluated by QUS and BMI.
Patients & method
This is a study in 330 patients (women in menopause who were drug free for osteoporosis). To all of them we evaluated the BMI and heel QUS (GE Lunar Achilles device). The QUS analyze was performed using the Stiffness Index (SI), in Units (U) a combined parameter, useful in evaluation of the fracture risk.
Results
Based on BMI, we formed three groups based on BMI: group 1 BMI $\leq 24.9$ kg/m$^2$, group 2 with BMI between 25 and 29.9 kg/m$^2$, and group 3 with BMI $\geq 30$ kg/m$^2$. The av. values for BMI in the three groups were: $22.45 \pm 1.99$, $27 \pm 1.64$, $34.5 \pm 4.09$ kg/m$^2$. The av. age for the three groups was: 56.3 +/7.99 years, $58.26 \pm 8.44$ years, $55.45 \pm 7.6$ years. The av. SI was for the three groups: $70.35 \pm 16.44$ U, $79.16 \pm 17.54$ U, $83.39 \pm 18.32$ U. The SI increases with BMI. The student *t*-test between the normal weight and overweight group was $P=0$, between obese and normal was $P=0$, and between overweighed and obese was $P=0.06$.
Conclusions
We found statistically significant results regarding the QUS-SI, between the BMI groups, meaning that a higher SI, so a lower fragility fracture risk associates a higher BMI.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P185

**Cimetidine (histamine H2-receptor antagonist and antiandrogenic drug) exerts a beneficial effect in the injured tissues by periodontal disease in male rat molars**

R. Longhini[2], P. de Oliveira[1], E. Sasso-Cerri[1] & P. Cerri[1]
[1]Dental School. UNESP - Univ. Estadual Paulista, Araraquara, Brazil; [2]Federal University of São Paulo (UNIFESP), São Paulo, Brazil.

Studies have demonstrated the presence of androgen receptors in osteoblasts and osteocytes, confirming that androgens are important for the maintenance of bone in men. Additionally to steroid hormones, histamine stimulates osteoclast differentiation and survival and plays a role in the inflammatory response via H2 receptors. We purposed to investigate whether cimetidine, an histamine H2 receptors antagonist and antiandrogenic drug, interferes in the periodontal tissue damages induced by periodontal disease (PD). PD was induced in the upper left first molars of male rats. Two PD groups ($n=8$ per group) were treated with 100 mg/kg bw of cimetidine (PD-Cim) or saline (PD-S), for 50 days. The right molars were used as controls: Cim and S groups, respectively. Blood samples were collected for detection of testosterone levels and the fragments of maxilla were removed and fixed in formaldehyde, decalcified in EDTA, and embedded in paraffin. Some fragments were processed for transmission electron microscopy (TEM). In HE-stained sections, the distances between cemento-enamel junction (CEJ) and the AB crest, as well as CEJ and junctional epithelium insertion level (JE) were measured; the number of inflammatory cells was also computed. TRAP method (osteoclast marker) was used for quantification of osteoclasts in the AB surface. Statistical analyses were performed ($P \leq 0{,}05$). Testosterone levels decreased significantly in cimetidine-treated rats. The significant increase in both CEJ-AB crest and CEJ-JE distances, observed in PD groups, were significantly softened in PD-Cim group. In Cim and PD-Cim groups, osteoclasts number decreased significantly in comparison to S and PD-S, respectively. Moreover, these cells exhibited apoptotic features under TEM. The inflammatory process reduced significantly in PD-Cim group. Although reduced testosterone levels promote osteoporosis, cimetidine treatment was able to reduce PD-induced periodontal tissue injuries. The possible histamine H2 receptors antagonist effect should be considered.

**Age-dependent and sexual features of bone mineral density changes in rats in remote terms after hyperthyroidism abolition**

V. Povoroznyuk[1] & I. Gopkalova[2]
[1]Institute of Gerontology NAMS Ukraine, Kyiv, Ukraine; [2]SI 'V. Danilevsky Institute of Endocrine Pathology Problems, AMS Ukraine, Kharkov, Ukraine.

The aim
To study age-dependent changes of bone mineral density of females and males rats in remote terms after hyperthyroidism abolition.
Research Object
Research is conducted on 180 white females and males rats of 'Wistar' breed. Animals were arranged in the 18 groups: six controls groups (CG) of pre-pubertal, reproductive and old males and females; six groups of rats with the experimental model hyperthyroidism (HTG); six groups of rats 30 days after stopping L-thyroxine injections (STI).
Research methods
Bone mineral density (BMD) was measured using dual energy X-ray densitometry (DEXA) and 'Experimental animals' software.
Research results
Through 30 days after STI, was revealed decline the Δ BMD of pubertal females rats at 4.3 time (with $44.73 \pm 5.41\%$ in HTG to $10.47 \pm 6.32\%$, Student's $t$-criterion $t = -4.03$, $P < 0.0001$) and of males at 5,7 time (with $22.83 \pm 2.84\%$ in HTG to $44.73 \pm 5.41\%$, Student's $t$-criterion $= 4.49$, $P < 0.0001$). Only reproductive females cans recover a total D BMD to the level of age control group (with $-10.04 \pm 2.32\%$ in HTG to $22.63 \pm 6.87\%$, Student's $t$-criterion $= 5.68$, $P < 0.0001$.). The reproductive males showed only 70 percent recover of DBMD (with $-4.31 \pm 2.63\%$ in HTG to $6.69 \pm 3.04\%$, Student's $t$-criterion $= -2.64$, $P < 0.015$). In old males rats D BMD was declined (with $6.91 \pm 1.49\%$ in HTG to $-3.75 \pm 1.93\%$, Student's $t$-criterion $= 4.30$, $P < 0.0001$). For females a decline of DBMD (%) was not statistically considerable.
Conclusions
The study age-dependent and gender characteristics of changes in bone mineral density of rats 30 days after hyperthyroidism abolition the exposed, that BMD is restored only at reproductive females of rats and a partial (70%) at reproductive males. The decline of BMD is exposed in other investigational groups.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P187

**Features of bone mineral density losing in ukranian woman of different ages with thyrotoxicosis**

O. Oliynyk[2] & V. Povoroznyuk[1]
[1]Clinical Endocrinilogical Centre, Kyiv, Ukraine; [2]Institute of Gerontology NAMS Ukraine, Kyiv, Ukraine.

Disorders of bone tissue as a complication of hyperthyroidism now become accepted fact. On other side decreasing of serum levels of estrogens in postmenopausal women potentially may increase effects of thyroid hormones on bone tissue.
The aim of our study was investigate with DXA the features of loss of bone mass in women suffering from thyrotoxicosis depending of age and thyrotoxicosis duration.
Material and methods
There were examined 192 Ukrainian women with age from 25 up to 72 years: 95 with thyrotoxicosis, which have a history of disease from 3 month to 20 years and 97 healthy women. Subjects were divided to five age groups (20–29, 30–39, 40–49, 50–59 and 60–72 years). BMD measurements of the lumbar spine (L1–L4), proximal femur, radial shaft (utradistal and 33% site) and total skeleton were determined by DXA using a densitometer Prodigy (GE Medical systems, Lunar). Data were analyzed using ANOVA and Student's $t$-test to examine differences among the groups.
Results
In womens with thyrotoxicosis BMD was significantly decreased in all age groups in whole skeleton and ultradistal radius level, except group 20–29 years at lumbar spine and radius 33% levels and 40–49 years at proximal femur level. Rate of osteoporosis in different age groups was 25, 28.6, 36.8, 62.5 and 89.5% in females with thyrotoxicosis against 15, 0, 0, 10 and 52.9% in control group. Deficiency of BMD rises with age since 50 years old up to 17.9% at lumbar spine, 12.2% at proximal femur and 23.4% at radial shaft levels. Most losing of bone tissue was observed in radial shaft in all age groups. Moreover patients with thyrotoxicosis duration over 5 years compare to rest patients has significant decreased BMD at site 33% radius level ($0.772 \pm 0.016$ g/m$^2$ against $0.681 \pm 0.035$ g/sm$^2$, $t = 2.69$, $F = 1.806$, $P = 0.009$).
Conclusion
Most deficiency of BMD in womens with thyrotoxicosis is observed in radial shaft especially. It increases with age and duration of thyrotoxicosis. Thus it is necessary to perform a measurement of BMD in radial shaft during DXA examination for thyrotoxic patients.

### Comparison of the effects of hormone replacement therapy on bone mineral density, lipid profiles, and biochemical markers of bone metabolism

J. Namkung, Y. Chung, S. Kwak, J. Kim & M. Kim
The Catholic University, Seoul, Republic of Korea.

Objective
To assess the effects of hormone replacement therapy on bone mineral density (BMD), biochemical markers of bone turnover, and lipid profiles in postmenopausal women.
Methods
We retrospectively reviewed the medical records of 199 postmenopausal women who had received care at the Department of Obstetrics and Gynecology of Catholic University Seoul St. Mary's Hospital between January 1994 and December 2008. The patients were divided into the following three groups: group 1 received combined estrogen and progesterone therapy ($n=91$); group 2 received estrogen only ($n=65$); and group 3 received tibolone ($n=43$). We compared the changes in biochemical markers of bone turnover, lipid profiles, and BMD during therapy.
Results
The BMD of the lumbar spine increased in groups 1 and 3 by 2.0 and 1.2%, respectively, and the BMD of the total femur increased in groups 1 and 2 by 2.3 and 0.5% from the initial values after 3 years, respectively. However, the BMD of the femoral neck and total femur decreased significantly in group 3 by 4.8 and 1.9%, respectively, 3 years after treatment initiation ($P<0.05$). Serum osteocalcin and urinary deoxypyridinoline decreased in all groups 1 year after treatment. In groups 1 and 3, the total cholesterol level decreased and the triglycerides level increased. However, there were no definite changes in the total cholesterol and triglycerides levels in group 2. The HDL-cholesterol level increased in groups 1 and 2, but decreased in group 3. As a result, the BMD of the lumbar spine increased and the total cholesterol level decreased in the combined therapy and tibolone groups. Tibolone had no beneficial effect on the BMD of the femoral neck.
Conclusions
Our results suggest that each therapy has different effects on BMD, biochemical markers of bone metabolism, and lipid profiles. A prospective study involving a larger group, and considering multiple factors, will be required to obtain more clinically meaningful conclusions.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Bone mass in diabetic patients measured by lumbar spine and hip densitometry

T. Icin, J. Novakovic-Paro, B. Vukovic, B. Kovacev-Zavisic, M. Medic-Stojanoska, D. Tomic-Naglic, D. Benc & D. Popovic
Clinical Centre of Vojvodina, Novi Sad, Serbia.

Introduction
It is known that diabetes mellitus and its complex yet insufficiently known mechanisms affect bone strength and increases the fracture risk.
Objective
The aim of this study was to assess bone mass measured by lumbar spine and hip DXA, in patients suffering from diabetes mellitus according to sex and type of diabetes.
Material and methods
It was a prospective study. Included 150 diabetic patients of both sexes.
Results
In type 1 diabetes mellitus were 11 men, age $40.82\pm8.99$ years, BMI $23.24\pm3.45$ kg/m$^2$ and duration of diabetes mellitus $12.67\pm9.30$ years. Also in type 1 diabetes mellitus were 20 women of age $42.81\pm11.77$ years, BMI $24.33\pm2.99$ kg/m$^2$ and duration of diabetes mellitus $23.65\pm11.57$ years. In type 2 diabetes mellitus were 21 male age $58.57\pm11.12$ years, BMI $29.51\pm7.67$ kg/m$^2$ and duration of diabetes $9.57\pm7.21$ years. Also in type 2 diabetes mellitus were 98 women, age $64.15\pm9.28$ years, BMI $29.99\pm5.57$ kg/m$^2$ and duration of diabetes mellitus $11.99\pm8.34$ years. In diabetes mellitus type 1 in four men has osteopenia (57%) and in seven (43%) normal results. The value of L1-L4 BMD was $1.233\pm0.147$ g/cm$^2$, total femur $0.998\pm0.149$ g/cm$^2$ and femoral neck $0.982\pm0.165$ g/cm$^2$. In women with type 1 diabetes mellitus was 6 (30%) with normal findings, 10 (50%) with osteopenia and 4 (20%) with osteoporosis. The value of L1–L4 BMD was $1.088\pm0.151$ g/cm$^2$, total femur $0.878\pm0.132$ g/cm$^2$ and femoral neck $0.864\pm0.138$ g/cm$^2$. In men with type 2 diabetes mellitus normal finding was identified in 12 (57.1%), osteopenia in 8 (38.1%) and in 1 (4.8%) osteoporosis. The value of L1–L4 BMD was $1.191\pm0.163$ g/cm$^2$, total hip $1.064\pm0.179$ g/cm$^2$ and femoral neck $0.895\pm0.457$ g/cm$^2$. In women with type 2 diabetes mellitus had normal findings 27 (27.6%), osteopenia 41 (41.8%) and osteoporosis 30 (30.6%). The value of L1–L4 BMD was $1.071\pm0.201$ g/cm$^2$, total femur $0.914\pm0.162$ g/cm$^2$ and femoral neck $0.858\pm0.153$ g/cm$^2$.
Conclusion
Osteopenia predominates in all patients with type 1 diabetes and in women with type 2 diabetes. It was determined a lower BMD at the femur, primarily in the neck of the femur, in all patients.

### Efficacy, safety and adherence to treatment of teriparatide: an observational study

P. Franceschetti, M. Ambrosio, M. Zatelli, T. Tommasin, S. Bianchi, S. Lupo, R La Corte & E degli Uberti
University of Ferrara, Ferrara, Italy.

Teriparatide is a skeletal anabolic drug that represents the first and new class of bone anabolic agents able to increase bone formation, bone mineral density and strength. Several studies demonstrated the efficacy of this drug in post-menopausal and glucocorticoid-induced osteoporosis, but few data are available on the effects of the drug in long-term therapy in humans, so far.
We analyzed a population of 135 women in post-menopausal age treated with teriparatide for 18 months between 2005 and 2011, with the aim to evaluate efficacy, safety and adherence to treatment. The efficacy of teriparatide was evaluated as the incidence of new fractures, which was low (0.74%). The overall tolerability of teriparatide was good. Treatment discontinuation because of adverse effects was 2.22% (1.48% for dispnoea, 0.74% for nausea and myalgia). Adherence and compliance to treatment were high (94.07%). Only eight women (5.93%) stopped treatment and only three of these (37.3%) due to an adverse reaction. In view of the most frequently occurring adverse effects, the levels of calcium, phosphorus, calciuria, uric acid, alkaline phosphatise and PTH were assessed at the beginning and at the end of treatment. The reduction of back pain was evaluated by using the visual analogic scale (VAS). We observed only a significant increase of phosphorus (10.9% $P<0.04$) and uric acid (57% $P<0.05$) levels; a significant reduction of back pain (VAS at the begin of treatment $9.0\pm2$; VAS at the end of treatment $4.2\pm1.8$; $P<0.0001$) was observed. None of the patients who completed 18 months therapy had significant side effects. These data show that teriparatide is a safe, well tolerated and effective therapy in post-menopausal osteoporosis.

### Thyroxin treatment of multinodular and normofunctional goiter and bone mass.

J. Suárez- Lledó
Hospital de León (Sacyl) Ambulatorio Condesa, León, Spain.

Objective
To research changes in bone mass during treatment on MNG with thyroxin.
Material and methods
For two years, patients and their clinical histories were examined when each ambulatory patient was personally visited by the author. MNG by Hashimoto's disease and classic MNG were included. The patients with MNG in treatment were placed in the problem group, while the patients who were visited for the first time, and the patients with other endocrine diseases, were placed in the control

group. The patients who presented high blood levels of parathyroid hormone (PTH) (above 64 pg/ml) and patients with less than one year evolution were excluded; also excluded were those with pathological causes or suspected of having lost bone mass for other causes, even local. 172 patients were in the treated group (9 males and 163 females) and 105 (8 males and 97 females) in the control group.
Thyroxin doses were adjusted in this way: TSH blood levels were around 1 μU/ml, and always below 3 μU/ml; the same dose was given each day to each patient, only excepting the adjustments.
Bone masses were compared by densitometry.
Results
There was no correlation between time of treatment and bone mass, neither for *Z*-score nor *T*-score ($P<0.01$). Bone mass was better in the treated group than in the control group ($P<0.01$), by both the mean and the frequency comparisons ($P<0.01$). This may be explained by the bone protection caused by calcium and cholecalciferol prescription or by the increase in bone matrix thyroxin mediate through protein synthesis.
Conclusion
Treatment of MNG by thyroid hormone in this dosage procedure does not cause osteoporosis, in accordance with the results above expounded. The prescription of calcium and cholecalciferol may be additional bone protection against matrix reabsorption.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Vitamin D status in patients treated with intravenous ibandronate: a cohort study**

L. Papierska, W. Misiorowski, M. Rabijewski & M. Gietka-Czernel
The Medical Centre for Postgraduate Education, Warsaw, Poland.

In 100 consecutive osteoporotic women referred to our clinic we assessed 25OHD3 and PTH levels. Patients suffered from postmenopausal osteoporosis and intolerance of oral bisphosphonates, were treated at least for 6 months with calcium and vitamin D. The reasons of intolerance of oral medication were gastritis (53), esophagitis (18) or peptic ulcer (29 cases). Patients were therefore chronically treated with proton pump inhibitors (PPI). They were referred to our Clinic in order to take intravenous ibandronate and were all assessed by referring physician as 'ready to medication' with it. We found, however, that only in eight of them the levels of 25OH D3 were proper (i.e. $>30$ ng/ml). Generally 25OH D3 levels were very low – on average 17.91 ng/ml ($\pm 4.04$), and in 69 patients were lower than 20 ng/ml. Ten patients had 25OHD concentrations even lower than 10 ng/ml with evident symptoms of muscle weakness. In all of them the levels of PTH were elevated (78.05 pg/ml $\pm 4.31$), however in all group we haven't found an evident correlation between PTH and 25OH D3 ($r=-0.48$; $P=0.11$).
The reason of these low vitamin D levels was using too low doses during supplementation. All, except 10 women were treated only with 400 – 800 j D3 daily. According to the data presented above, these doses are evidently too low to achieve recommended concentrations (i.e. $>30$ ng/ml), especially in subjects with gastritis or peptic ulcer and prolonged therapy with PPI.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P193

**Correlations between the bone matrix markers and bone mineral density in postmenopausal osteoporosis**

C. Gurban, M. Balas, I. Golu, D. Amzar & I. Zosin
University of Medicine and Pharmacy 'V. Babes', Timisoara, Romania.

Objectives
We assessed the implications of PINP (procollagen type I N-terminal propeptide), NTX (cross-linked N-telopeptides of type I collagen), $E_2$ (estradiol), calcium ($Ca^{2+}$), phosphorus (PHOS(2−)), and their correlation with bone mineral density (BMD) in the process of bone remodeling of postmenopausal osteoporosis.
Methods
The study was performed on two groups of women with postmenopausal osteoporosis (with different degrees of estrogenic deprivation): group I ($n=48$, with $<15$ years of estrogenic deprivation) and group II ($n=26$, over 15 years of estrogenic deprivation), compared with a control group ($n=20$, postmenopausal women without osteoporosis). Serum levels of the ions were measured by VitrosSlides quantitative technique. Bone levels of these ions were assessed by bone flame atomic absorption spectrometry (FAAS). BMD was measured by dual-energy X-ray absorptiometry (DXA) technique. Serum levels of the enunciated markers were measured by ELISA technique.
Results
Serum PINP levels were increased in group I ($+17.2\%$, $P<0.001$), and decreased in group II ($-66.2\%$, $P<0.001$), as compared to the controls. Serum levels of NTX were significantly higher (group I: $+33.5\%$, $P<0.001$ and group II: $+58.3\%$, $P<0.002$) vs control. Serum $Ca^{2+}$ and PHOS(2−) levels were increased in group I ($+12.06\%$, $P<0.005$ - calcium and $+36.78\%$, $P<0.004$ - phosphorus), and decreased in group II ($-85.65\%$, $P<0.006$-calcium and $-57.22\%$, $P<0.003$ - phosphorus). The bone levels of these ions were lower in both groups ($P<0.001$, respectively $P<0.002$, vs controls). Estradiol levels were significantly lower in both groups ($P<0.01$, respectively $P<0.02$), associated with low BMD.
Conclusions
The levels of these ions increase transitory in serum, as a result of bone demineralization through hidroxiapatite microcrystal solubilization and mobilization of these ions in the circulation. This imbalance produces a decrease in bone formation and an increase in bone resorption, leading to bone demineralization and increased risk for osteoporotic microfractures.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P194

**Zoledronic acid treatment improve bone strenght parameters assessed by BMD**

C. Galesanu, A. Loghin, A. Florescu, N. Lisnic, P. Aancute & V. Zaharia
University of Medicine and Pharmacy 'Gr.T.Popa', Iasi, Romania.

Introduction
Bisphosphonates therapy is the standard of care in postmenopausal osteoporosis. In the HORIZON-RFT, annual i.v. Zoledronic acid (ZOL) 5 mg infusion significantly reduced the rate of new fractures by increased bone mineral density (BMD). We proposed to evaluate the effect of ZOL treatment in BMD change in a group of postmenopausal osteoporotic women assessed by DXA–BMD. We have proposed also to assess the adverse events of this treatment.
Methods
Between 2008 and 2009 we have registered 520 postmenopausal osteoporotic women (PMOW). Among them, 22 were treated with ZOL i.v. 5 mg/yearly and 1000 mg calcium /day plus Alfacalcidol 1 μg/day for 24 months or more. DXA–BMD measurement for BMD change was used at baseline and after 12 and 24 months.
We analyzed also: changes in serum calcium, 25OHD, PTH and bone alkaline phosphatase (BAP) at baseline and one and two-years post ZOL. The mean age of the patients was $64.5\pm3.7$ years.
Results
No significant change in serum calcium, serum 25OHD, BAP. PTH level rested also normal. Clinical significantly reduced the hyperalgesia after a mean of 6.7 weeks (6–12 weeks). Adverse events after infusion were flu-like syndrome transient 18%, arthromyalgias 9%, arterial hypertension 4.5%. No cardiac

**Table 1**

| Time/ BMD ($g/cm^2$) | Baseline | 12 months | 24 months |
|---|---|---|---|
| Lumbar spine | 0.673 | 0.726 | 0.734 |
| Gain % | | +7.8 | +9.0 |
| Total hip | 0.773 | 0.809 | 0.818 |
| Gain % | | +4.6 | +5.8 |
| Femoral neck | 0.606 | 0.645 | 0.648 |
| Gain % | | +6.4 | +6.9 |

arrhytmias, no fractures. BMD changes at lombar, total hip and neck are presented in the Table 1.
Conclusions
In our experience, iv infusions of ZOL (5 mg) have shown to be effectively in increasing BMD. The other biologic parameters remained in normal level. The adverse effects only in the first administration without consequences.
Keywords: osteoporosis, Zoledronic acid, BMD.

**Therapeutical management in hypogonadal osteoporosis**
I. Bistriceanu[1], M. Bistriceanu[2], M. Popescu[2], S. Preda[2], S. Bondari[2], D. Bondari[2], A. Covei & M. Preda[1]
[1]Emergency Hospital, Craiova, Romania; [2]University of Medicine and Pharmacy, Craiova, Romania.

Hypogonadal osteoporosis may occur early, asymptomatic and diagnosis is long etiology is often laborious. Early diagnosis of gonadal failure prevention measures require changes already in the prepubertal bone, puberty or postpuberal to ensure adequate peak bone mass sex and age.
Casuistry is represented by 57 patients, of which the: late puberty (26 cases) and premature ovarian failure (31 cases). To elucidate the etiologic diagnosis was clinical and laboratory criteria used.
The paper suggests two major objectives in the strategic management of hypogonadal osteoporosis:
a) early diagnosis of gonadal failure in order to adopt preventive measures bone changes;
b) the estrogen-progestive substitution associated the antiresorbtion or proformation medication to prevent fragility fractures.

**PTH levels are associated with insulin resistance in PCOS women**
E. Lerchbaum, H. Gruber, V. Schwetz, A. Giuliani, T. Pieber & B. Obermayer-Pietsch
Medical University of Graz, Graz, Austria.

Introduction
Accumulating evidence suggests an association of vitamin D with insulin resistance (IR) in women with polycystic ovary syndrome (PCOS). The role of PTH in insulin metabolism is less clear. We aim to study the association of PTH and 25-hydroxyvitamin D (25(OH)D) levels with metabolic and endocrine parameters in a cohort of PCOS women.
Methods
We measured PTH and 25(OH)D levels in 544 PCOS and 139 healthy control women within the same age range. Metabolic, endocrine, and anthropometric measurements and oral glucose tolerance tests were performed.
Results
PCOS women had higher PTH levels than controls in age-adjusted analysis ($P=0.018$), but results were attenuated after adjustment for BMI ($P=0.073$). PCOS women with higher PTH levels were significantly older, had higher BMI, waist-to-hip ratio (WHR), systolic and diastolic blood pressure, fasting and stimulated insulin levels, homeostatic model assessment-IR (HOMA-IR), CRP levels, and Ferriman–Gallwey-scores and significantly lower 25(OH)D, SHBG, quantitative insulin sensitivity check index (QUICKI), serum calcium, and phosphorus ($P<0.05$ for all). In linear regression analysis, BMI ($P<0.001$), age ($P<0.001$), and PTH ($P=0.016$) were independent predictors of AUCinsulin, whereas 25(OH)D was not. In linear regression analysis using the same covariates, BMI ($P<0.001$) and PTH ($P=0.006$) independently predicted HOMA-IR, whereas age and 25(OH)D did not. Likewise, in linear regression analysis, BMI ($P<0.001$) and PTH ($P=0.037$) independently predicted insulin sensitivity assessed by QUICKI, whereas age and 25(OH)D were not related to insulin sensitivity.
Discussion
We present evidence that PTH levels are independently associated with IR and insulin sensitivity in a large cohort of PCOS women.

**Dietary effect of calcium and vitamin D on the gene expressions of tight junction in the duodenum and kidney of calbindin-D9k, -D28k and -D9k/D28k knockout mice**
I. Hwang, Y. Choi & E. Jeung
Chungbuk National University, Cheongju, Republic of Korea.

Introduction
Calcium transport is regulated by active transcellular and passive paracellular pathways which are responsible for calcium (re)absorption in the intestine and kidney. The activity of passive transport is determined by the permeability of tight junction. In general, the permeability of tight junction is inversely proportional with the expression of tight junction genes. Claudin and occludin among the tight junction genes are concerned directly with permeability of the tight junction. In this study, we examined the effect of reduced dietary supply of calcium and vitamin D on paracellular gene expression in the calbindin-D9k (CaBP-D9k), -D28k (CaBP-D28k), and -D9k/D28k knockout (KO) mice.
Methods
The tissue-specific mRNA and protein expressions of tight junction genes in the duodenum and kidney, the main organs for calcium (re)absorbtion, were examined using real-time PCR and western blot analysis. The localization of tight junction genes was also investigated by immunohistochemistry.
Results
The expression levels of tight junction genes showed similar patterns in CaBP-D9k and -D28k single KO mice. The most of tight junction genes in the intestine were less expressed in CaBP-D9k KO mice than wild-type (WT), while they were over expressed in the kidney. When the calcium or vitamin D deficient diet was given, this difference was accelerated. In addition, both calcium and vitamin D deficient diet in the KO mice showed additive effects on the tissue-specific regulation of tight junction gene expression. Immunohistochmical staining results indicated that the tight junction genes were mainly localized in apical site of paracellular region in both intestine and kidney.
Conclusions
The ablation of CaBPs and/or reduced dietary calcium resulted in the decreased expression of paracellular barrier genes, therefore, this may lead to acceleration of the paracellular transport of calcium.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P198

**Serum IGF1 concentration is positively associated with 25-hydroxy-vitamin D level and increases upon treatment with vitamin D**
P. Ameri, M. Bovio, G. Leoncini, M. Arvigo, F. Minuto, D. Ferone & G. Murialdo
University of Genova, Genova, Italy.

IGF1 concentrations have been reported to increase with 25-hydroxyvitamin D (25(OH)D) values in population studies, but it is unclear whether this association expresses a cause-effect relationship. Mice genetically deficient of steroid receptor coactivator 3, a transcriptional coactivator for the nuclear vitamin D receptor, have significantly lower circulating IGF1 levels than wild-types.
We measured serum fasting 25(OH)D and IGF1 by enzyme- and radioimmuno-assay, respectively, in 42 internal medicine outpatients, aged $61.7\pm8.9$ years, at follow-up visits for stable or recovering medical conditions. The study was performed in Genova, Italy, at latitude 44° North, over Spring and Summer.
Mean ($\pm$S.D.) 25(OH)D and IGF1 concentrations were 15.7 ($\pm$9.1) ng/ml and

182.6 (±77.8) ng/ml respectively. There was a positive correlation between 25(OH)D and IGF1 values ($r$ 0.33, $P<0.05$).
To understand in principle whether vitamin D status does affect GH/IGF1 axis, in 20 patients we measured 25(OH)D, IGF1, and GH (the latter by immunoradiometric assay) before and after 12 weeks of 5000 IU cholecalciferol/week (six subjects), 7000 IU cholecalciferol/week (seven subjects), or no treatment (controls, seven subjects). A significant increase in serum 25(OH)D was observed after supplementation with both cholecalciferol dosages (+16.2–17.7 ng/ml vs baseline, $P<0.01$). Nonsignificantly higher GH levels were also found after either cholecalciferol dose (+1.17–1.19 mIU/l). Seven thousands, but not 5000 IU/week significantly raised IGF1 concentration of 41.1 ng/ml ($P<0.05$ vs baseline).
A significant increase in 25(OH)D values of 7.8 ng/ml vs baseline ($P<0.05$) was also observed in controls after 12 weeks, likely because of sun exposure during normal outdoor life. GH and IGF1 levels did not change significantly.
These preliminary results suggest that treatment with at least 1000 IU/day vitamin D results in increased circulating IGF1, and that the relationship between 25(OH)D and IGF1 concentrations described in cross-sectional analyses may be causal.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P199

### Incidence of diabetes and vitamin D deficiency: a prospective cohort study

I. González-Molero, S. Morcillo, G. ROjo, C. Gutierrez Pepiso, E. Rubio-Matin & F. Soriguer
Carlos Haya Hospital, Málaga, Spain.

Background
Vitamin D deficiency is an important public health problem because of its great impact on bone metabolism and the possible implication in cardiovascular outcomes, diabetes, cancer and mortality. Cross-sectional studies have related vitamin D deficiency with the prevalence of diabetes but there are only a few prospective cohort studies on the incidence of type 2 diabetes.
Objective
To investigate the relationship between levels of 25-hydroxyvitamin D and the incidence of type 2 diabetes in a Spanish population.
Methods
We undertook a population-based prospective study in a population from southern Spain. The first phase of the study (1996–1998) included 1226 individuals. Of this original cohort, 988 persons were reassessed in 2002–2004 and 961 in 2005–2007. At the second evaluation, we measured 25-hydroxyvitamin D and intact parathyroid hormone (iPTH), glycosylated hemoglobin and did an oral glucose tolerance test (OGTT) to 855 subjects. For the incidence study we excluded 172 subjects with diagnosed diabetes. After 4 years of follow up, 412 subjects were re-evaluated in 2005–2007 with an OGTT and glycosylated hemoglobin. All the participants completed a clinical survey, underwent an anthropometric study and provided a venous blood.
Results
The incidence of diabetes in subjects with 25-hydroxyvitamin D levels $\leq$18.5 ng/ml (percentile 25) was 12.4 vs 4.7% in subjects with levels $>$18.5 ng/ml. The likelihood of having diabetes during the four years of follow-up was significantly lower in the subjects with higher levels of 25-hydroxyvitamin D (OR=0.17 (0.05–0.61)). None of the subjects with levels higher than 30 ng/ml developed diabetes.
Conclusion
In this prospective study, we found a significant inverse association between serum 25-hydroxyvitamin D levels and the risk for type 2 diabetes in a population from the south of Spain.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P200

### Tissue-specific expression of transcellular calcium transport and paracellular tight junction genes in the placentas of calbindin-D9k, -D28k, and -D9k/D28k knockout mice

I. Hwang, B. An & E. Jeung
Chungbuk National University, Cheongju, Republic of Korea.

Introduction
Placenta has many essential roles to maintain pregnancy and homeostasis. Calcium transport and its regulation are also important for vital roles of placenta. In general, calcium transport is regulated by active transcellular and passive paracellular pathways. Transient receptor potential cation channel subfamily V member 5/6 (TRPV5/6), calbindin-D9k (CaBP-9k), calbindin-D28k (CaBP-28k), and Na+/Ca2+ exchanger (NCX1) are involved in the transcellular pathway. Paracellular pathway is determined by expression of tight junction genes such as occludin, claudin, and ZO-1.
Methods
We examined whether the transcellular and paracellular calcium transport genes are differentially modulated in the placenta of CaBP-9k and/or CaBP-28k knockout (KO) mice on gestational day 19 (GD 19). The expressions of transcellular calcium transport and paracellular tight junction genes in the placenta were examined using real-time PCR and western blot analysis.
Results
The mRNA and protein expressions of calcium transport genes appeared to be increased in a compensatory manner. The expression levels of NCX1 and TPRV6 were increased at both mRNA and protein in KO compared to wild-type (WT) mice. CaBP-9k mRNA and protein were significantly induced in CaBP-28k KO mice, whereas these levels of CaBP-28k were reduced in the placenta of CaBP-9k mice compared to WT mice. Each tight junction gene was shown to be similarly expressed after ablation of CaBP-9k or CaBP-28k. Occludin and claudin levels were increased in single, CaBP-9k and CaBP-28k, KO mice, but not in double KO mice.
Conclusions
The disability of calcium buffering due to CaBP-9k and/or CaBP-28k KO, may lead to accelerate transcellular pathway of calcium, and also to decrease paracellular permeability through the tight junction to maintain calcium homeostasis in placenta of mice.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

### Gitelman's syndrome presenting with hypercalcaemia due to severe primary hyperparathyroidism

J. Bukowczan, A. Swiecicka, N. Siddaramaiah & V. Arutchelvam
James Cook University Hospital, Middlesbrough, UK.

Introduction
The combination of hypokalemia and hypercalcaemia is uncommon but potentially lethal. In primary hyperparthyroidism hypokalaemia most commonly occurs due to incomplete distal renal tubular acidosis. We present the first case of simultaneous primary hyperparathyroidism with Gitelman's syndrome resulting in profound electrolyte imbalance.
Case
A 48-year old man, referred with hypokalaemia (2.5 mmol/l) presented with a short history of extreme fatigue, myalgia, nausea and constipation. His adjusted serum calcium was raised (2.84 mmol/l). Patient was otherwise fit and well. He denied any regular medications or liquorice intake. He had no contributory medical family history and never smoked. There was nothing to suggest underlying tuberculosis, sarcoidosis or malignancy. He had normal stature and was normotensive. There was no stigmata of hypercortisolism or lymphadenopathy. Cardiovascular, respiratory and abdominal examinations were all normal. Subsequent bone profile check noted adjusted serum calcium rise to 4.01 mmol/l and prompted urgent administration of bisphosphonates.
Further investigations confirmed diagnosis of primary hyperparathyroidism secondary to large single parathyroid adenoma. Following parathyroidectomy patient's bone profile normalised, hypokalaemia however, persisted. It was accompanied by hypomagnesaemia and metabolic alkalosis. Battery of further endocrine investigations including random glucose (5.1 mmol/l), HbA1c (5.4%), thyroid, anterior pituitary, overnight dexamethasone suppression test, calcium/creatinine urine excretion ratio, fasting gut polypeptides and MEN genotyping all

proved normal. Chest and abdominal radiology were also normal. Notably, significant hyper-reninaemic hyperaldosteronism was discovered and confirmed twice on both supine and ambulatory sampling. Diagnosis of Gitelman's syndrome was made and patient was commenced on Amiloride with a desirable effect.

Conclusion

It is known that primary hyperparathyroidism can cause hypokalaemia, but we report this rare combination of Gitelman's syndrome in an otherwise healthy patient.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P202

### Vitamin D pathway in non-functioning pituitary adenomas

L. Vuolo, C. Di Somma, A. Negri, C. Pivonello, M. Savanelli, A. Faggiano, E. Guerra, R. Pivonello & A. Colao
University Federico II, Napoli, Italy.

Introduction

In addition to its well known effects on calcium homeostasis and bone metabolism, growing evidences shows that vitamin D plays an important role in regulation of cancer angiogenesis, cell apoptosis, differentiation, and proliferation. Vitamin D acts through vitamin D receptor (VDR), an intracellular nuclear receptor. It was found an association between different cancer histotypes and single nucleotide polymorphisms (SNPs) of VDR. Despite the close relationship between VDR and PIT-1 (pituitary trascription factor) suggests a potential role of vitamin D pathway in the onset of pituitary adenomas, however, to date no data are available on this issue.

Aim

This study evaluated 25OHvitD serum levels and VDR-SNPs expression in patients with non-functioning pituitary adenomas.

Patients and methods

We evaluated 14 patients with non-functioning pituitary adenomas and 14 healthy controls age and sex matched. Serum 25OHvitD levels were measured by solid-phase chemiluminescent enzyme immunoassays. The SNPs-VDR evaluated included Fok -1 and Taq-1, whose assessment was performed by PCR-restriction fragment length polymorphism (PCR-RFLP) analysis.

Results

Serum 25OHvitD levels were significantly lower in patients ($17.4 \pm 2.4$ ng/ml) than in controls ($31.3 \pm 1.7$ ng/ml) ($P < 0.01$). Allelic variants of Taq-1 VDR polymorphism had a different distribution in patients than in controls, with the variant TT and Tt present in 66 and 30% of patients and in 50 and 47% of controls ($P =$ NS), respectively. Allelic variants of Fok-1 VDR polymorphism were distributed similarly in patients and in controls.

Conclusions

Serum 25OHvitD levels are significantly lower in patients with non-functioning pituitary adenomas than in controls, suggesting a potential etiopathogenetic and therapeutic role of vitamin D pathway in these patients. The significance of different distribution of allelic variants of Taq-1 VDR polymorphism between patients and controls requires further investigation.

### A new cause of malignancy associated hypercalcemia (MAH): PTH releasing breast cancer

O. Helvaci, S. Akin, C. Aydin & M. Bayraktar
Faculty of Medicine, Hacettepe University, Ankara, Turkey.

Introduction

Here, we present a case of epithelial breast cancer releasing iPTH thereby causing MAH.

Case report

A 48-year-old woman with metastatic breast cancer was consulted for hypercalcemia. Previous medical record was insignificant except for nephrolitiasis. She had a left mastectomy + left axillary lymph node dissection in another hospital. Prior to surgery no calcium levels were obtained. Pathology revealed infiltrative ductal carcinoma. Postoperatively total calcium (tCa) was 12.04 mg/dl (8.4–10.2), albumin: 4.43 g/dl, inorganic phosphate (iP): 3.21 mg/dl. Simultaneous iPTH level was 94.3 pg/ml (0.5–75) and vitamin D was 20.8 μg/l (low). After forced diuresis, tCa was 11.01, albumin: 4.4. Bone scintigraphy was negative. Primary hyperparathyroidism was suspected. Parathyroidal pathology was not detected with MIBI scintigraphy and USG. Bone mineral dansity showed osteoporosis (lomber $T$ score: $-4.2$); pamidronate was begun. Prior to chemotherapy for remaining lymph nodes and liver metastasis her tCa: 9.87, albumin: 3.7. As to verify the source of iPTH, specimens were stained with PTH-antibodies. Focal positivity was observed (Figure 1). Plasma PTH-rp levels were non-detectable. Thus the diagnosis was iPTH releasing breast cancer. iPTH level was 254 on the tenth day of chemotherapy then declined to a level of 103 after 4th week.

Conclusion

In our knowledge this is the first case of iPTH releasing breast cancer. In patients without bone metastasis, release of iPTH as a reason for hypercalcemia should be kept in mind.

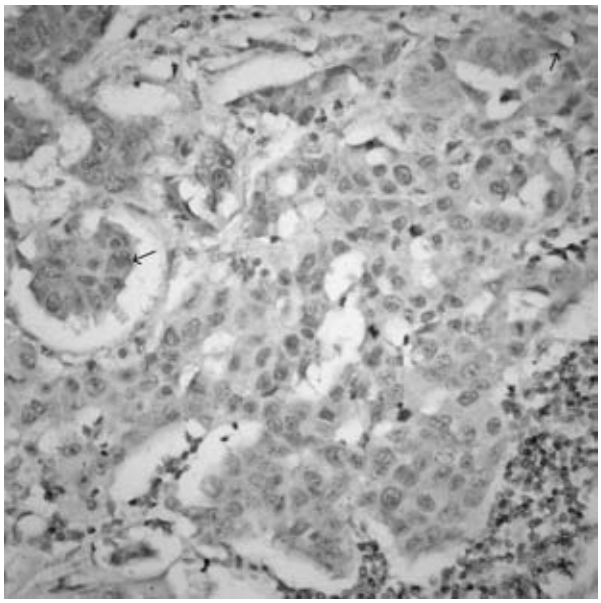

**Figure 1** Parathyroid hormone stain focal cytoplasmic positivity was observed in the neoplastic cells (arrows) (×40) (immunohistochemistry, Human Ab-1, Clone PTH01, Labvision).

### Two cases of alendronate induced atypical fracture of femur shaft

T. Varma, R. Panchani, A. Saini, S. Tripathi & N. Gupta
Sir Gangaram Hospital, New Delhi, India.

Studies show conflicting results regarding possible excess risk of atypical fractures associated with bisphosphonate (BSP) use. Since BSP reduces bone remodeling, they freeze the skeleton allowing accumulation of microcracks over time leading to atypical fractures. We present two cases of atypical fracture and discuss on monitoring therapy and drug holiday in chronic BSP users.

Methods

Over the period of last 8 months we diagnosed two cases of alendronate induced atypical fracture of femur shaft the details of which are given below. Case 1 A 48-year-old postmenopausal female presented with limp and right anterior thigh pain. X-ray revealed a focal beak of cortical thickening on lateral side of cortex which after 3 months resulted in to bicortical femoral shaft fracture. She was on BSP since last 10 years. Bone turnover markers were done. Stabilization of the fragile bone was done with intramedullary nailing. However, the femur cracked during surgery.

Case 2 A 52-year-old female patient presented with bilateral thigh pain and on evaluation showed cortical thickening and hairline fracture on both sides. She had a history of longterm use of alendronate since last 5 years. The fracture was stabilized on both the sides with intramedullary nailing. The right sided bone cracked during nailing. Urinary N telopeptide levels were done. And intraoperative bone biopsy was also taken.

Results

Both the patients had very low bone turnover markers and showed bone necrosis in bone biopsy. Tetracycline labeling was not done as was not available in our institute. Both the patients on follow up showed poor healing of fractures and were started on teripartide once daily.

Conclusion

Optimal protocols for dosage, duration of BSP therapy deserve consideration. Benefit of BSP use should be balanced against potential risk of atypical fractures. Painful pyramidal projection of cortical bone in subtrochanteric femoral shaft should be recognized as an impending fracture and treated expediously. Additional therapy after BSP discontinuation is needed to promote healing.

Declaration of interest

## P205

### Vitamin D levels and carbohydrate metabolism

F. Soriguer[1], I González Molero[1], S. Morcillo[1], S. Valdes[1], P. Botas[2], E. Delgado[2], G. ROjo[1] & E. Menendez[2]
[1]Carlos Haya Hospital, Málaga, Spain; [2]Hospital Central de Asturias, Oviedo, Spain.

Introduction and objective

The aim of this study has been to evaluate the relationship between vitamin D and iPTH levels and the status of carbohydrate metabolism in a representative sample of the Spanish population.

Material and methods

The study was conducted in two population of northern and southern Spain, evaluated in the same period of time and with a similar methodology: Pizarra Study (Málaga) and Asturias Study. Subjects in both groups underwent clinical and anthropometric assessment survey, a blood test (fasting glucose and insulin, creatinine, calcium, phosphorus, 25OH vitamin D, iPTH) homeostatic model assessment-insulin resistance (HOMA-IR) and an oral glucose tolerance test (OGTT). The number of subjects included was 1182. To calculate the statistical difference between the means of continuous variables we used the ANOVA test for quantitative and the $\chi^2$ test for qualitative variables. Strength of association between two variables was measured using odds ratio (OR).

Results

The mean age of participants was $50.3 \pm 14.4$ years (range: 20–83 years), with 57% female and 43% male. The mean of 25-hydroxyvitamin D and iPTH were: 22.46 ng/ml and 42.29 pg/ml, respectively. 65.6% had normal fasting glucose and OGTT, 6.45% impaired fasting glucose, 8.15% carbohydrate intolerance, 9.85% new diagnosed diabetes and 9.93% known diabetes.25-hydroxyvitaminD levels in these groups were, respectively: 23.43, 21.45, 22.97, 21.82 and 23.22 (*P* 0.034) and iPTH: 45.1, 48.26, 45.99, 49.31 and 41.08 (*P* 0.001) both adjusted for age, sex, BMI and season. The percentage of patients with 25-hydroxyvitaminD levels below 20 ng/ml was different in the five groups: 30.9, 35.5, 37.5, 49.1 and 36.8% (*P* 0.014).Vitamin D levels were significantly different for different values of HOMA-IR: quartile 1 (HOMA $<$ 1.07): 25.85; quartile 2 (HOMA 1.07–1.73): 22.94; quartile 3 (1.74–2.95): 22.54 and quartile 4 ($>$ 2.95): 22.05 (*P*0.041, all adjusted for age, sex, BMI and season).

Conclusions

1-One-third of the subjects studied have 25hydroxyvitaminD levels below 20 ng/ml,

2-The higher the insulin resistance (HOMA-IR) the lower the levels of vitamin D,

3-Patients with undiagnosed diabetes have 25hydroxyvitaminD levels significantly lower and iPTH significantly higher than normal population.

### A single metastatic lesion in the leg of a parathyroid carcinoma

A. Martins[1], J. Martins[1,2], S. Vale[1,2], L. Batista[1,2] & I. Carmo[1,2]
[1]Santa Maria Hospital, Lisbon, Portugal; [2]Lisbon Medical School, Lisbon, Portugal.

Introduction

We report a case of a parathyroid carcinoma with very unusual and revealing features.

Case report

DAB, male aged 66 was subjected to subtotal gastrectomy because of a localized gastric adenocarcinoma (intestinal type). A mild primary hyperparathyroidism (PTH $<$ 200 pg/ml) was simultaneously found. Calcium oxalate nephrolythiasis at 50 years was noted. Sonography revealed a nodular lesion in the right lower thyroid pole, while NMR showed a nodular lesion at the left lower thyroid pole and in the sestamibi scan late hyperfixation at the right lower pole. Bilateral inferior parathyroidectomy was performed and revealed on both sides adenoma with moderate nuclear polymorphism and no mitotic figures; on the left side a central cystic area was found. Clinical and biochemical cure apparently followed. Six months later a presumed unrelated nodular lesion in the right thigh muscular mass was removed and found to be a metastatic lesion of a carcinoma, with numerous mitotic figures and immunoreactivity for PTH. A sestamibi scan showed marked hyperfixation in the right leg and PET- FDG-F18 hyperfixation at the right quadricipital area.

Discussion

Some unusual features may shed light on the pathologic process. There is evidence for a long standing disease since nephrolytiasis was found 14 years before. Long standing hyperparathyroidism and increased gastric acid secretion can lead to chronic gastritis, intestinal metaplasia and gastric adenocarcinoma. There is evidence for evolution along bilateral hyperplasia, adenoma and carcinoma since bilateral disease was present and a left cystic nonfunctioning

lesion was found. Neither clinical nor pathological a priori suspicion of a carcinoma was present. Most surprisingly a single metastatic lesion was later found in a very unusual location and this lesion was highly undifferentiated in sharp contract with the primitive lesion.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

Funding

## P207

### Pseudohypoparathyroidism type Ia, hypothyroidism and insulin resistance

A. Gonçalves, J. Araguês, F. Baptita & I. Carmo
Santa Maria Hospital, Lisbon, Portugal.

Introduction

Pseudohypoparathyroidism type la (PHP-1a) is an uncommon disorder that results from an inactivating mutation in the GNAS gene. It can present with resistance to several hormones, in addition to parathyroid hormone (PTH). A characteristic skeletal phenotype also results, referred to as Albright's hereditary osteodystrophy, that occurs because of the crucial role of Gs-α signaling in the growth, differentiation, and structure of these tissues.

Objective

To report a rare case of pseudohypoparathyroidism type Ia, presenting with hypothyroidism and insulin resistance, and review the related literature.

Case report

A male patient with PHP type 1a caused by a heterozygous mutation of the GNAS gene (c.568_571del) is presented.

In addition to PHP, the patient presents hypothyroidism and insulin resistance. GH levels are within normal range. The phenotype includes obesity, mild mental retardation, psychosis, calcifications of basal ganglia and Albright's hereditary osteodystrophy.

The genetic study of the mather is still pending.

Discussion/conclusion

Patients diagnosed with PHP1a should be further evaluated for associated endocrinopathies. Hypothyroidism is the most common endocrinophathy in this context, that is frequently subclinical in infancy.

Severe obesity is characteristic of PHP1a. It has been postulated that paternal imprinting of Gsα occurs in the hypothalamus such that maternal Gsα mutations lead to loss of the melanocortin signaling cascade, which is important for energy balance.

Insulin resistance has not commonly been described. It most probably results from the combined effects of obesity, family history, and abnormal melanocortin signaling.

Soft-tissue calcification has been reported in various body parts, especially in the subcutaneous tissues, and rarely in the brain and cardiac septum.

### A diagnostic conundrum associated with hypercalcaemia

V. Kolovou & K. Steer
Northwick Park Hospital, NWLH NHS Trust, London, UK.

A 72-year-old woman was initially referred by her GP to the colorectal service of our Hospital. She had a 4-month history of weight loss, fatigue and appetite loss. The initial blood tests at the GP surgery revealed a normochromic normocytic anaemia.

She had a diagnosis of SVT and she was on sotalol. She had never smoked nor she had a history of excess alcohol.

In her initial blood tests: Hgb 9 g/dl, albumin 27 g/l, ALP: 187 IU/l (40–150), adjusted serum calcium 2.61 mmol/l (2.15–1.58), creatininine 51 μmol/l, normal serum electrophoresis.

She first saw a colorectal surgeon.

A gastroscopy showed gastritis and the colonoscopy was difficult therefore she had a CT virtual colonoscopy which did not show any tumour in the bowel. However it revealed a 15 mm lesion in the left kidney. She was then referred to the Urologists. A CT chest was organised and this was clear. She also had an isotope whole body scan and this did not show any evidence of bone matastases. Her case was discussed at the Urology MDT and it was deemed that the lesion is unlikely to be the cause of her systemic symptoms.

She was seen in the Endocrinology clinic for an opinion about her high calcium. Her repeat cCalcium was 2.59 mmol/l, PTH 3.7 pmol/l (1.2–6.2), 25(OH) Vitamin D low at 33 nmol/l, ACE 350 U/l (13–55), ESR: 115 mm in the first hour and a CRP 105 mg/l. Her autoantibody screen was negative.

Based on the results above we proceeded with a PET scan which identified a large vessel vasculitis.

The patient was started on high dose steroids at the Rheumatology clinic. She reported a great improvement in her symptoms and all the repeat laboratory values including cCalcium had normalised.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Expression of 25-hydroxyvitamin D3-1α-hydroxylase and 24-hydroxylase in human vascular smooth muscle cells

M. Lubczanska, D. Zehnder & R. Bland
The University of Warwick, Coventry, UK.

Medial calcification is a major cause of premature cardiovascular mortality in chronic kidney disease. Vascular smooth muscle cells (VSMC) play a key role in this process and studies have suggested a protective role for vitamin D. The exact mechanism for this is unclear but local synthesis of 1,25-dihydroxyvitamin D (1,25D) may be important. Production of 1,25D from 25-hydroxvitamin D (25D) is catalyzed by 25-hydroxyvitamin D-1α-hydroxylase (1α-OHase). 1,25D is metabolized by 24-hydroxylase (24-OHase). This study used normal arterial tissue (kidney donors; ethical approval obtained) and primary cultures of human aortic smooth muscle cells (HAoSMC) to examine the expression and regulation of 1α-OHase, 24-OHase and vitamin D receptor (VDR) mRNA (real-time PCR), protein (western blotting/immunohistochemistry) and synthesis of 1,25D. HAoSMC expressed 1α-OHase and 24-OHase mRNA. The PCR transcripts were similar to those in HKC-8 cells (a kidney cell line expressing both hydroxylases). Western blot analyses of 1α-OHase and 24-OHase identified single protein bands ($\sim$56 kDa) in HAoSMC and arteries, which were identical to those seen in HKC-8 cells and human kidney tissue. VDR mRNA and protein was detected in all samples. Immunohistochemistry of arteries indicated expression of 1α-OHase, 24-OHase and VDR in the medial layer. Incubation of HAoSMC with 1,25D (6 h) resulted in a dose dependent increase in VDR protein (1–100 nM). 1α-OHase mRNA and protein were significantly decreased (1 nM; $P<0.05$). Conversely, 24-OHase mRNA was significantly increased (10 nM; *P*lt;0.05). Importantly 24-OHase mRNA was also increased and 1α-OHase protein decreased by 25D3 (100 and 10 nM respectively; 6 h; *P*lt;0.05) indicating 1α-OHase activity in HAoSMC. These data demonstrate that arteries and VSMC cells express functional vitamin D signaling. We believe this is the first demonstration of 24-OHase in human arteries and VSMC. We have also shown that VSMC express 1α-OHase and are able to synthesize sufficient 1,25D to stimulate a local response.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Longitudinal changes in serum 25-hydroxyvitamin D levels of older persons during 6 and 13 years of follow-up**

N. van Schoor[1], D. Knol[1], D. Deeg[1], A. Heijboer[2] & P. Lips[1,2]
[1]EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, The Netherlands; [2]VU University Medical Center, Amsterdam, The Netherlands.

Background
Vitamin D deficiency is very common in older persons. It is not clear how serum 25-hydroxyvitamin D (25(OH)D) levels change during aging.
Objective
To examine longitudinal changes in serum 25(OH)D levels in two representative cohorts of Dutch older persons during 6 and 13 years of follow-up, respectively.
Methods
Data of the Longitudinal Aging Study Amsterdam (LASA) were used, an ongoing cohort study in older persons. Two different cohorts were included: i) younger cohort: aged 55–65 years at baseline, $n=738$, follow-up of 6 years; ii) older cohort: aged 65–88 years at baseline, $n=1320$, follow-up of 13 years. Linear mixed models were used to analyze the longitudinal change in serum 25(OH)D in both cohorts. Age and body mass index were added to the model. Seasonal variation was modeled by adding a cosine and sine function with a period of 1 year to the model.
Results
At baseline, average levels were 56.5 nmol/l in the younger cohort and 51.1 nmol/l in the older cohort. The seasonal variation was $\pm 11$ nmol/l in the younger cohort, and $\pm 7$ nmol/l in the older cohort. In the younger cohort, a longitudinal increase in mean serum 25(OH)D levels of 5 nmol/l in 6 years was observed after adjustment for age, sex, season and body mass index (BMI). In the older cohort, a longitudinal decrease in mean serum 25(OH)D levels of 5 nmol/l in 13 years was observed.
Conclusions
Serum 25-hydroxyvitamin D levels changed during follow-up with increasing levels in persons aged 55–65 years, and decreasing levels in persons aged 65–88 years. This implicates that vitamin D supplementation becomes more important in older age groups.
Declaration of interest

**Primary hyperparathyroidism, vitamin D deficiency and quality of life**

W. Åberg, S. Norenstedt, A. Eriksson, Y. Pernow, M. Sääf, J. Nordenström, J. Zedenius & I. Nilsson
Karolinska Institutet, Stockholm, Sweden.

Background
The study aimed to evaluate quality-of-life (QoL) aspects and impact of vitamin D deficiency in primary hyperparathyroidism (pHPT).
Method
One hundred and fifty consecutive patients (119 women) with pHPT (mean age $60\pm11$ years; BMI $27\pm5$ kg/m$^2$; ionized calcium $1.44\pm0.08$ mmol/l; PTH $130\pm69$ ng/l) were included. Six weeks postoperatively, the pHPT patients were reexamined and randomized (double-blind) to daily substitution with calcium carbonate (1 g), with or without cholecalciferol (1600 IE). Self-estimation questionnaires (SF-36) were completed at baseline and repeatedly during follow-up. A gender- and age-matched reference group ($n=459$) was randomly selected from the Swedish SF-36 norm database.
Results
Vitamin D deficiency, defined as 25-hydroxyvitamin D $<50$ nmol/l, was present preoperatively in 59% of the patients. The 25-hydroxyvitamin D level increased postoperatively (mean $49\pm18$ vs $52\pm17$ nmol/l, $P=0.019$). The calcium level normalized after parathyroidectomy in all patients, while the PTH level decreased but was not normalized in 45% of the cases. Compared to the reference population baseline, the patients scored significantly lower on all eight domains of the SF-36. Postoperatively, patients improved significantly but reached the level of the reference population in only two domains: GH (general health perceptions) and BP (bodily pain). No correlation was found between the SF-36 scores and the calcium, PTH or vitamin D levels at baseline. The baseline scores were inversely correlated to body mass index (BMI; $r=-0.226$–$r=-0.386$; $P<0.01$). The study will be deblinded on January 15 2012 and further follow-up data will be presented.
Conclusions
Patients with pHPT had worse QoL scores than the reference population on all eight domains of the SF-36. The outcome after parathyroid surgery was not predictable from preoperative calcium, PTH- or vitamin D status. The effects of vitamin D supplementation are yet to be evaluated.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P212

**Cinacalcet treatment in MEN1-associated hyperparathyroidism: a clinical trial**

M. Filopanti[1,2], U. Verga[1,2], F. Ermetici[3], C. Eller-Vainicher[1,2], S. Corbetta[1,3], P. Luca[1,4], P. Beck-Peccoz[1,2] & A. Spada[1,2]
[1]University of Milan, Milan, Italy; [2]Fondazione Istituto di Ricerca e Cura a Carattere Scientifico (IRCCS) Cà Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]IRCCS Policlinico San Donato, San Donato Milanese, Italy; [4]IRCCS Istituto Auxologico Italiano, Milan, Italy.

Introduction
In type 1 multiple endocrine neoplasia (MEN1), primary hyperparathyroidism (PHPT) is a challenging problem due to the high post-surgery recurrence rate. Cinacalcet is a calcimimetic agent which showed to be effective in patients in whom surgery is contraindicated or refused. In this study we assessed the efficacy and the safeness of cinacalcet in MEN1 patients, in comparison with patients with sporadic PHPT (sPHPT). Moreover, the influence of Arg990Gly CASR polymorphism was also evaluated.
Design and methods
A randomised, cross-over, double-blind study was set up in University Hospitals context. Fifteen patients with PHPT MEN1-associated were randomised in two groups, one treated with 30 mg daily cinacalcet, titrated until calcium normalization, and one with placebo. Patients were reassessed after 3 months and switched to the other treatment once washed out. Twenty patients with cinacalcet treated sPHPT, having similar calcium levels, were considered as comparison group. Calcium/phosphate metabolism, bone turnover markers, liver and kidney functions, and perceived quality of life were evaluated at each assessment step. Arg990Gly CASR polymorphism was genotyped on leukocyte DNA by direct sequencing.
Results
Cinacalcet was able to normalize calcium levels and to reduced PTH in all patients, without significant effects on bone metabolism markers and quality of life. Cinacalcet dosage in MEN1 was not significantly different to sPHPT patients ($45\pm21$ vs $54\pm25$ mg/day). Few mild adverse events were observed in both groups, not requiring drug withdrawal. No association between Arg990Gly CASR polymorphism and response to cinalcalcet was found.
Conclusions
Although this is a short-term prospective study, it demonstrated that efficacy and safety profile of cinacalcet was similar both in patients with MEN1-associated PHPT and in those with sporadic PHPT, with no 990Gly CASR variant influence. Thus, in MEN1 patients, cinacalcet treatment might be considered an effective and safe option.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This work was supported, however funding details unavailable.

## P213

**Serum levels of soluble secreted α-Klotho are decreased in the early stages of chronic kidney disease, making it a probable novel biomarker for early diagnosis**

Y. Terada[1], Y. Shimamura[1], K. Hamada[1], K. Inoue[1], K. Ogata[1], M. Ishihara[1], T. Kagawa[1], M. Inoue[1], S. Fujimoto[1], M. Ikebe[2], K. Yuasa[2], S. Yamanaka[1], T. Sugiura[1] & M. Nishiyama[1]
[1]Kochi Medical School, Nankoku, Japan; [2]Kochi-Takasu Hospital, Kochi, Japan.

Background
α-Klotho was first identified as an aging gene and was later shown to be a regulator of phosphate metabolism. Fibroblast growth factor 23 (FGF23) is the key regulator of phosphate metabolism. Serum levels of soluble α-Klotho in

chronic kidney disease (CKD) patients have not previously been determined, especially in relation with FGF23 and creatinine levels. This study was designed to investigate whether serum soluble α-Klotho levels are modulated by renal function, age, and FGF23 level in CKD patients. This study is the first report on the utility of measuring soluble α-Klotho levels in human CKD.
Methods
A total of 292 CKD patients were enrolled. Serum samples were collected, and FGF23 and soluble α-Klotho levels were measured using enzyme-linked immunosorbent assay kits. In addition, serum creatinine, hemoglobin, albumin, calcium, and phosphate levels were measured.
Results
Serum soluble α-Klotho levels were associated positively with estimated glomerular filtration rate (eGFR) ($P<0.0001$) and inversely with serum creatinine level ($P<0.01$). Interestingly, α-Klotho levels were significantly decreased in stage 2 CKD compared with stage 1 ($P=0.0001$). Serum FGF23 levels were associated positively with serum creatinine and negatively with eGFR. FGF23 levels were significantly increased in stage 5 compared with stage 1 CKD. Soluble α-Klotho was associated inversely with log-transformed FGF23 level ($P<0.01$).
Conclusion
Our data indicate that soluble α-Klotho levels are significantly decreased in stage 2 CKD compared to stage 1, and not only in the advanced stages of the disease. Soluble α-Klotho may thus represent a new biomarker for the diagnosis of CKD, especially in the early stage.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

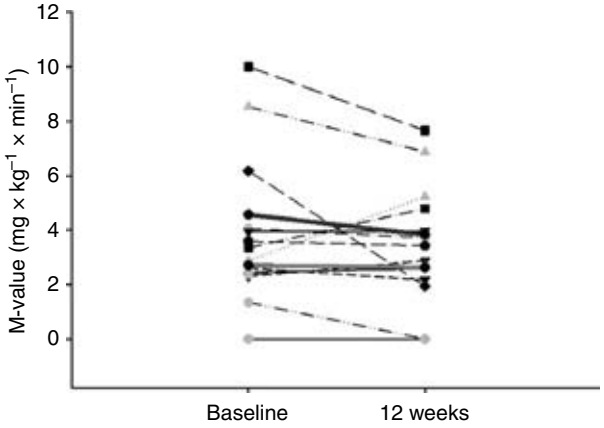
## P214

**Lack of effects of high dose colecalciferol (D3) on insulin sensitivity and metabolic markers in type 2 diabetic patients: a double-blind, randomised, placebo-controlled trial**

U. Kampmann[1], L. Mosekilde[2], O. Schmitz[1], N. Møller[1], B. Christensen[1], L. Wamberg[2] & L. Ørskov[3]
[1]Aarhus University Hospital, Nørrebrogade, Aarhus, Denmark; [2]Aarhus University Hospital, Tage Hansens Gade, Aarhus, Denmark; [3]Silkeborg Regional Hospital, Silkeborg, Denmark.

Introduction
Vitamin D insufficiency is common in subjects with type 2 diabetes. Observational studies suggest that vitamin D plays a role in the pathogenesis of type 2 diabetes. However, results of intervention studies have been inconsistent. We investigated the effects of improving vitamin D status on insulin sensitivity and inflammatory markers in type 2 diabetic patients with vitamin D insufficiency.
Methods
A double blind, randomized, placebo controlled, intervention study was conducted. Sixteen patients with type 2 diabetes and vitamin D insufficiency ($\leq$50 nmol/l) were recruited. Eight patients were randomized to supplementation with cholecalciferol for 12 weeks (11 200 IU (280 μg) daily for 2 weeks followed by 5600 IU (140 μg) daily for 10 weeks), and eight patients received identical placebo tablets for 12 weeks. To assess insulin sensitivity the hyperinsulinemic euglycemic clamp method was used. DEXA scan, 24-h-ambulatory blood pressure monitoring (ABPM) and fasting blood samples were performed at baseline and at the end of the 12 weeks intervention.
Results
Serum levels of 25(OH)vitamin D and 1,25$(OH)_2$vitamin D after 12 weeks increased significantly from baseline values in the intervention group ($P=0.01$ and $P=0.004$). Serum 25OHD concentrations increased from 31.0$\pm$4.9 nmol/l at baseline to 104.9$\pm$19.0 nmol/l in the intervention group, whereas a decrease from 34.8$\pm$3.8 to 32.1$\pm$3.4 nmol/l was observed in the placebo group. The change in serum 25OHD concentrations between the two groups differed significantly ($P=0.02$). However no significant changes in insulin sensitivity (*M*-value), inflammation, blood pressure, lipid profile, or HbA1c were found.
Conclusions
Significant improvement in vitamin D status after 12 weeks treatment with colecalciferol does not reduce insulin resistance, blood pressure, inflammation or glycosylated haemoglobin in patients with established type 2 diabetes.



Grey circles = Placebo, black = Vitamin D. Δ Vitamin D vs. Δ placebo: $P=0.431$ Blue line = Mean value Vitamin D, Red line = Mean value Placebo.

**Blood pressure after parathyroidectomy in patients with primary hyperparathyroidism and hypertension**

G Perez Lopez[1], M Menacho Roman[2], A Becerra Fernandez[2] & R. Villar[3]
[1]Hospital Comarcal de Melilla, Melilla, Spain; [2]Hospital Universitario Ramon y Cajal, Madrid, Spain; [3]Hospital Universitario de Fuenlabrada, Madrid, Spain.

Introduction
Primary hyperparathyroidism (PHPT) is emerging as a cause of secondary hypertension. Between 20 and 50% of patients with PHPT have hypertension, this being directly proportional to the calcemia. The elevation of blood pressure in PHPT is mediated by hypercalcemia that acts directly stimulating the contraction of muscle fibers of the arterial vessel wall, and increases plasma renin levels and the release of catecholamines.
Objectives
(1) Determine the rate of normalization of blood pressure (BP) in hypertensive patients with PHPT after parathyroidectomy.
(2) Showed a reduction in the number of drugs if hypertension persists after surgery.
Materials and methods
A retrospective study of hypertensive patients with PHPT operated between 2005 and 2010. We use the Excalibur database, and look for the following key words: PHPT, hypertension, and parathyroidectomy. The following data were collected: age, sex, BMI, time with hypertension, pre-surgical PTH, calcium, phosphorus, 25OHVitamin D, creatinine, GFR, mean pre-surgery BP, pre-surgery anti-hypertensive drugs, mean post-surgery BP and post-surgical anti-hypertensive drugs. All patients included had to have biochemical criteria of cure PHPT.
Results
There were 88 patients with the search criteria: 18 (20.4%) were male and 70 (79.6%) were women. There was no statistically significant gender differences when comparing the other variables. The average values of the sample were: BMI: 28.2 kg/m$^2$, duration of hypertension: 8.8 years, pre-operative PTH: 124.6 pg/ml, serum calcium: 11.1 mg/dl, phosphoremia: 2.2 mg/dl, 25OH Vitamin D: 18 ng/dl. Creatinine 1.2 mg/dl, GFR 58 ml/min, pre-surgical BP 136.2/88.6 mmHg vs postoperative BP 130.3/82.2 mmHg ($P<0.005$), pre-surgical anti-hypertensive drugs 2.7 vs 2.2 in the post-surgery ($P<0.005$). 26.4% normalized their BP after surgery and did not require antihypertensive therapy. 54.4% of patients reduced the number and doses of drugs.
Conclusions
Although most patients probably had essential hypertension, PHPT appears to increase BP probably by serum calcium-dependent mechanisms. This could explain normalization tension and decrease in the number and doses of antihypertensive drugs presented by patients after parathyroidectomy.

## P216

**Serum cystatin C is a reliable predictor of renal function and cardiometabolic risk in primary hyperparathyroidism**

F. Ermetici[1], M. Filopanti[2], U. Verga[2], E. Passeri[3], R. Zelaschi[1], M. Raggi[4], P. Beck-Peccoz[2], A. Spada[2] & S. Corbetta[3]
[1]IRCCS Policlinico San Donato, San Donato Milanese, Italy; [2]University of Milan, Fondazione IRCCS Ca' Granda - Ospedale Maggiore Policlinico, Milano, Italy; [3]University of Milan, IRCCS Policlinico San Donato, San Donato Milanese, Italy; [4]IRCCS E. Medea, Bosisio Parini, Italy.

Primary hyperparathyroidism (PHPT) negatively affects renal function. It is known that chronic kidney disease is a predictor of cardiometabolic diseases. Cystatin C (cystC), an alternative measure of renal function, has been associated with adverse cardiovascular events and cardiometabolic risk factors. This study was aimed to evaluate serum cystC, its relationships with PTH and cardiometabolic risk in patients with PHPT.
The following parameters were measured in 193 consecutive patients (46 males, 147 females, age 59.4±15 years, mean±S.D.) affected with PHPT: weight, height, arterial blood pressure, serum calcium, phosphate, PTH, 25-hydroxyvitamin $D_3$, glucose, insulin, triglycerides, HDL cholesterol, creatinine and cystC; BMI and the insulin-resistance index HOMA were calculated and the glomerular filtration rate was estimated with the Modification of Diet in Renal Disease Study formula (eGFR).
Mean eGFR was 88.7±26.6 ml/min×1.73 $m^2$ in PHPT patients, where only two patients showed an eGFR <30 ml/min×1.73 $m^2$. Median cystC value was 0.87 mg/l (range 0.45–3.13, 25th–75th percentile 0.73–1.04 mg/l) and it negatively correlated with eGFR ($r=-0.69$, $P<0.001$). Moreover, cystC showed a significant positive correlation with total and ionized calcium as well as PTH levels ($P<0.05$). In multiple regression analysis, cystC was a stronger determinant of PTH ($P<0.001$) than eGFR ($P=0.06$). Patients with cystC levels >75th percentile were older, they had higher BMI, insulin, HOMA, triglycerides, lower HDL and a greater prevalence of arterial blood hypertension, diabetes mellitus and dyslipidemia ($P<0.05$). After adjusting for age, cystC levels correlated with BMI, insulin, HOMA, triglycerides and HDL cholesterol levels ($P<0.05$).
In conclusion, in PHPT patients serum cystC demonstrated a good correlation with eGFR. Moreover, CystC seems a better predictor of PTH elevation than eGFR in PHPT patients. Elevated cystC levels identify a subgroup of PHPT patients with a cluster of cardiometabolic risk factors. CystC might be a reliable marker to evaluate renal function and cardiometabolic risk in PHPT patients.

**Usefulness of MS-MLPA for detection of genetic and epigenetic states of GNAS complex in Pseudohypoparathyroidism type1b**

A. Yuno[1], T. Usui[1], Y. Yambe[2], K. Higashi[3], I. Yokota[4], Y. Mashio[5], J. Shinoda[6] & A. Shimatsu[1]
[1]National Hospital Organization Kyoto Medical Center, Kyoto, Japan; [2]National Hospital Organaization Nagoya Medical Center, Nagoya, Japan; [3]National Hospital Organization Kumamoto Medical Center, Kumamoto, Japan; [4]National Hospital Organization Kagawa Children's Hospital, Zentsuji, Japan; [5]Hokkaido P.W.F.A.C Sapporo-Kosei Kyosai Clinic, Sapporo, Japan; [6]Toyota Memorial Hospital, Toyota, Japan.

Objective
Pseudohypoparathyroidism type 1b (PHP-1b) is rare disorders resulting from genetic and epigenetic aberrations in the GNAS locus. PHP-1b usually defined by isolated renal resistance to PTH, is due to a maternal loss of GNAS exonA/B methylation, leading to decreased Gs'$\alpha$ expression in specific tissues. To clarify the usefulness of methylation specific multiplex ligation-dependent probe amplification (MS-MLPA), we evaluate the genetic and epigenetic changes of GNAS comlex in PHP1b patients.
Patients and measurements
We studied a total of 13 subjects with PHP-1b (three families with nine affected members and four sporadic cases). The methylation status of GNAS DMRs was then evaluated using MS-MLPA. The presence of deletion mutation in GNAS complex and STX16 were assessed by using MLPA.
Results
In all the familial PHP1b cases, 3 kb deletion of STX16 and de-methylation of A/B domain were identified. In contrast, no deletion had been detected thoughout GNAS regions, however, methylation abnormalities were widely observed in the GNAS DMRs.
Conclusions
MS-MLPA facilitates precise and rapid analysis of methylation status in GNAS DMRs as well as detection of micro deletion mutation in PHP-Ib. MS-MLPA assays is useful molecular tools for understanding the molecular bases and confirming the diagnosis of PHP-1b.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Pathophysiological changes in extracellular pH regulate calcium-sensing receptor responsiveness in HEK-293 and isolated parathyroid cells but not as a result of altered histidine residue ionisation**

K. Campion, W. McCormick & D. Ward
The University of Manchester, Manchester, UK.

Parathyroid hormone (PTH) secretion maintains extracellular calcium ($Ca^{2+}_o$) homeostasis under the control of the calcium-sensing receptor (CaR). Supra-physiological $pH_o$ changes (±1 pH unit) significantly alter CaR activity in a heterologous expression system. Interestingly, metabolic acidosis and hyperparathyroidism are concomitant in both ageing and chronic kidney disease. Therefore, here we examined whether smaller, pathophysiological $pH_o$ changes modulate CaR activity and in isolated (bovine) parathyroid cells as well as in CaR stably-transfected HEK-293 (CaR-HEK) cells.
Fura2-loaded CaR-HEK cells were stimulated with 2.5 mM $Ca^{2+}_o$ (pH 7.4) to elicit CaR-induced $Ca^{2+}_i$ mobilisation and then switched to the same buffer at either pH 7.2 (acidosis) or 7.6 (alkalosis) resulting in rapidly attenuated (−59±7%; $P=0.012$) or elevated (+31±9%; $P=0.011$) responses respectively. Furthermore, in isolated parathyroid cells, acidosis (pH 7.2) elicited a similar inhibitory effect on CaR-induced $Ca^{2+}_i$ mobilisation (−42±9%; $P=0.017$) while, again, alkalosis (pH 7.6) increased it (+35±10%; $P=0.039$). All responses were rapidly reversible upon return to pH 7.4 and are unlikely to result from altered intracellular pH as 0.4 unit $pH_o$ changes (5 min) failed to alter $pH_i$ in BCECF-loaded cells. The abundance of serum albumin *in vivo* might be expected to attenuate this effect, however, the $pH_o$ effects on CaR activity were preserved in the presence of 5% albumin (equivalent to serum concentration). Furthermore, acidosis also attenuated the CaR-induced activation of extracellular signal-regulated kinase (3.5 mM $Ca^{2+}_o$) by 56±11% ($P<0.05$) while alkalosis potentiated the response (+125±52; $P<0.01$). Finally, the most likely explanation for CaR's $pH_o$-sensitivity is extracellular histidine residue ionisation. However, serial mutation of all 15 histidine residues (to valine) failed to significantly attenuate CaR $pH_o$ sensitivity.
Therefore, pathophysiological changes in $pH_o$ significantly modulate CaR sensitivity with extracellular alkalinisation potentiating and extracellular acidification inhibiting CaR activity. This could indicate a mechanistic link between metabolic acidosis and hyperparathyroidism in ageing and renal disease.

## P219

**Normocalcemic hyperparathyroidism: a personal experience**

R. Antonelli[1], S. Falcone[1], A. Scillitani[2], V. Carnevale[2], E. Romagnoli[3], S. Minisola[3], M. Passeri[1], M. Calanchini[1] & A. Fabbri[1]
[1]Università Tor Vergata, Rome, Italy; [2]Osp. Casa Sollievo della Sofferenza, S. Giovanni Rotondo, Italy; [3]Policlinico Umberto I, Rome, Italy.

There are limited data on the natural history of normocalcemic PHPT and it is unclear how the patients should be regarded vis a vis parathyroid surgery. Among the 1500 admissions/year for 10 years referred to our outpatient endocrine clinics for a variety of diseases, we collected 481 subjects with high serum levels of PTH.

In the presence of hypercalcemia, a diagnosis of primary hyperparathyroidism was performed in 127 (26%). Other 354 (74%) subjects were normocalcemic: 186 (51%) were vitamin D deficient, 94 (27%) had renal failure, 39 (11%) suffered from secondary hyperparathyroidism due to different causes (mainly use of lithium and thiazides); the remaining 37 subjects (11%) (33 females, 4 males, age range 71 ± 11 years) had serum calcium and creatinine in the normal range and had a high PTH level. Among them 10 dropped out and the other 27 were followed up for 1–10 years. Over time 10 out of the 25 hyperparathyroid subjects became hypercalcemic (group A, followed up for 4–10 years, mean 7 years) while the others(17 pt) continue to be normocalcemic (group B, followed up for 1–10 years). The two groups were not different at baseline for calcium, creatinine, BMD expressed as *T*-score at lumbar spine (LS) and femoral neck (FN) while subjects in group A were significantly older than in group B. In group A (normocalcemic hyperparathyroid group) followed over time, nine patients had a significant reduction of BMD, three had also a fracture (two vertebral and one Colles) and one a kidney stone, none deterioration of renal function. Eight patients were operated on and a parathyroid adenoma was removed. In group B, followed over time, five subjects had a significant reduction of BMD. In conclusion our retrospective longitudinal study suggest that patients with normocalcemic hyperparathyroidism have a more important involvement of bone than not in mild primary hyperparathyroid patients. More studies are needed to identify patients who may develop features of PHPT over time.

### Cardiac structure and functions in patients with asymptomatic primary hyperparathyroidism

B Aktas Yilmaz[1], A. Akyel[2], E. Kan[3], U. Ercin[4], Y. Tavil[1], A. Bilgihan[1], N. Cakir[1], M. Arslan[1] & F Balos Toruner[1]
[1]Gazi University School of Medicine, Ankara, Turkey; [2]Etlik Ihtisas Research and Education Hospital, Ankara, Turkey; [3]Afyonkarahisar City Hospital, Afyonkarahisar, Turkey; [4]Bilecik City Hospital, Bilecik, Turkey.

Introduction

Primary hyperparathyroidism is associated with cardiovascular disease. In addition, data about cardiovascular abnormalities in patients with asymptomatic primary hyperparathyroidsm (APHPT) is'nt clear. In this study, we aimed to examine the cardiac structure–functions and hs-CRP levels in patients with APHPT.

Materials and method

Thirty-one patients with APHPT and 32 sex- and age-matched control cases with similar cardiac risk factors were included.

Cardiac structure and functions were evaluated by two-dimensional Doppler echocardiography (PWD) and tissue Doppler echocardiography (TDI).

Results

Serum parathormone (PTH) and calcium (Ca) levels were higher in the APHPT group compared to the controls (181.38 (79–736) vs 58.36 (26.20–60.00) pg/ml $P<0.001$; 10.95 ± 0.62 vs 9.46 ± 0.30 mg/dl $P<0.001$). Left ventricular mass index (LVMI) was found to be significantly higher in APHPT group compared to the controls (112.09 ± 25.74 vs 93.42 ± 26.52 g/m$^2$, $P=0.006$). This statistical significance remained unchanged after the adjustment has been made according to the cardiovascular risk factors. LVMI was found to be correlated with the serum Ca level ($r=0.260$, $P=0.038$). Myocardial performance index (MPI) was significantly higher in the patient group compared to the controls (0.49 ± 0.64 vs 0.39 ± 0.48, $P<0.001$). MPI was found to be correlated to serum Ca ($r=0.493$, $P<0.001$), PTH ($r=0.494$, $P<0.001$), and LVMI ($r=0.334$, $P=0.007$). No difference was determined between two groups in terms of serum hs-CRP levels (2.38 (0.01–9.41) vs 3.07 (0.05–9.41) mg/l $P=0.063$). Also, no correlation was found between hs-CRP levels and LVMI and MPI ($P>0.005$).

Conclusion

Cardiac structure and functions are affected in patients with APHPT. These changes seem to occur independent of traditional cardiac risk factors, and correlated with serum PTH and Ca levels. Prognostic and clinical significance of these results should be investigated in larger and prospective studies.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P221

### Perioperative management difficulties in parathyroidectomy for primary vs secondary and tertiary hyperparathyroidism

C. Corneci[1], B. Stanescu[1,2], R. Trifanescu[1,2], E. Neacsu[1] & C. Poiana[1,2]
[1]'C.I. Parhon' Institute of Endocrinology, Bucharest, Romania; [2]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania.

Background

In patients with hyperparathyroidism, parathyroidectomy is the only curative therapy. Anesthetic management differs function of etiology (primary vs secondary or tertiary hyperparathyroidism) and surgical technique (minimally invasive or classic parathyroidectomy).

Aim

To evaluate peri-operative management in parathyroidectomy for hyperparathyroidism of various etiologies, in a tertiary center.

Patients and methods

Two hundred and ninety-two patients who underwent surgery for hyperparathyroidism between 2000 and 2010 were retrospectively reviewed; 96 patients (77F/19M) presented with primary hyperparathyroidism (group A) and 196 (116F/80M) with secondary and tertiary hyperparathyroidism due to renal failure (group B). Biochemical parameters (serum calcium, phosphate, creatinine) were determined by automated standard laboratory methods. Serum intact PTH was measured by ELISA (IPTH – normal range: 10–71 pg/ml).

Results

Median surgery duration was 30 minutes in group A (minimally invasive or classic parathyroidectomy) and 75 min in group B (total parathyroidectomy and re implantation of a small parathyroid fragment into the sternocleidomastoid muscle).

During anesthesia induction, arterial hypotension developed significantly more frequent in group B (57 out of 196 pts, 29.1%) than in group A (8 out of 96 pts, 8.34%), $P<0.0001$, especially in patients receiving Fentanyl -Propofol.

During surgery and anesthesia maintenance, bradycardia was significantly more frequent in group A (67 out of 96 pts, 69.8%) than in group B (26 out of 196 pts, 13.3%), $P<0.0001$, especially during searching of parathyroid glands. By contrary, ventricular premature beats were less frequent in group A (25 out of 96 pts, 25.25%) than in group B (84 out of 196 pts, 42.85%), $P=0.003$. There were no statistically significant differences between the studied group regarding frequency of arterial hypertension and hypotension, paroxysmal atrial fibrillation.

Conclusions

Anaesthetic management in parathyroid surgery may be difficult because of cardiac arrhythmias (bradycardia in primary hyperparathyroidism and ventricular premature beats in secondary and tertiary hyperparathyroidism, respectively) and arterial hypotension during anesthesia induction in patients with secondary and tertiary hyperparathyroidism.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

Funding

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P222

### Evaluation of glucose metabolism in primary hyperparathyroid patients

H. Baser[1], D. Tuzun[1], F. Saglam[1], A. Dirikoc[1], C. Aydin[1], R. Ersoy[2] & B. Cakir[2]
[1]Ankara Ataturk Training and Research Hospital, Ankara, Turkey; [2]Faculty of Medicine, Yildirim Beyazit University, Ankara, Turkey.

Aim

In this study, our aim was to investigate frequency of impaired glucose tolerance (IGT), undiagnosed diabetes mellitus (DM) and presence of insulin resistance by HOMA.

Material and method

Fifty-five primary hyperparathyroid patients without known glucose tolerance were included in this study. The control group was with similar BMI, normocalcemic, without known glucose tolerance. Seventy-five gram oral glucose tolerans test was performed to PHP patients and control group. Insulin resistance was calculated by HOMA-IR.

Results

Mean body mass index (BMI) was 29.16 ± 4.92 kg/m$^2$ in PHP group, 29.54 ± 4.38 kg/m$^2$ in control group ($P=0.676$). Serum Ca level was 10.46 ± 0.81 mg/dl

in patient group, 9.26±0.39 mg/dl in control group ($P=0.000$). While IGT was detected in 6 PHP patients (%11.3), there is no IGT in control group ($P=0.013$). Diabetes mellitus (DM) didn't detect in OGTT in PHP patients. HOMA-IR was 1.51±0.89 in PHP group, 1.36±0.92 in control group ($P=0.458$). Second hour glucose OGTT value was significantly higher than control group (respectively, 99.28±30.86 mg/dl, 81.05±24.89 mg/dl, $P=0.001$). Second hour insulin OGTT value was significantly higher than control group (respectively, 22.84 ±17.92 μIU/ml, 14.94±14.10 μIU/ml, $P=0.02$). In both groups there were positive correlation between Ca levels and fasting plasma glucose, OGTT second hour glucose, OGTT second hour insulin (respectively, $P=0.011$, $r=0.241$; $P=0.000$, $r=0.400$; $P=0.004$, $r=0.296$).

Conclusions

Frequency of IGT is increased in PHP patients. Increased levels of serum Ca affects the glucose metabolism and leads to glucose intolerance.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

Funding

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P223

### The prevalence of hypocalcaemia with low parathyroid hormone level in Polish elderly population

J. Chudek[1], M. Mossakowska[2], A. Szybalska[2], E. Franek[3] & A. Wiecek[1]
[1]Medical University of Silesia, Katowice, Poland; [2]International Institute of Molecular and Cell Biology, Warsaw, Poland; [3]Central Clinical Hospital MSWiA, Warsaw, Poland.

Introduction

The postoperative and idiopathic (autoimmune) hypoparathyroidism are the most frequent causes of hypocalcaemia with low parathyroid hormone level. Moderate chronic hypocalcaemia frequently is asymptomatic, thus the prevalence of hypocalcaemia with low parathyroid hormone level in the general population remains unknown. Therefore, the aim of this study is to assess the prevalence of hypocalcaemia with low parathyroid hormone level in a representative sample of Polish elderly population.

Description of methods/design

The study was carried out as a part of the nationwide PolSenior project (Medical, psychological and socioeconomic aspects of aging in Poland) in the population of randomly selected 5695 participants (2899 males and 2796 females) using the national PESEL database (the National Electronic System of Population Records). Serum calcium, phosphates, albumin, creatinine, 25-OH-D3 and serum intact PTH concentrations were assessed in 4270 participants accounting for 75.0% of the study group. Serum calcium corrected for albumins lower than 8.4 mg/dl was scored as hypocalcaemia. Hypoparathyroidism was diagnosed when hypocalcaemia was accompanied by low serum intact PTH (<15 pg/ml) concentration.

Results

Only in 10 participants hypocalcaemia with low PTH were identified including 6 of 2213 (0.27%) males and 4 of 2057 (0.19%) females. The prevalence of primary hypoparathyroidism in the Polish elderly population was estimated at 0.25%. The median levels of corrected calcium and phosphates in participants with hypocalcaemia and low parathyroid hormone level were 7.99 (7.02–8.25) mg/dl and 3.44 (2.98–5.68) mg/dl, respectively. Only in two subjects serum calcium level was below 7.0 mg/dl. Two out of 10 participants with hypoparathyroidism had serum vitamin D level lower than recommended (<30 ng/ml). None of the participants with hypoparathyroidism were receiving calcium or vitamin D supplementation.

Conclusions

The prevalence of such a rare disease as primary hypoparathyroidism is quite high in the polish elderly population. In most subjects hypocalcaemia was mild, asymptomatic and remained undiagnosed.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Obesity, carbohydrate, lipid metabolism and polymorphisms (Fok, Bsm) of vitamin D receptor gene in aging population: POLSENIOR study

A. Milewicz[1], L. Laczmanski[1], M. Puzianowska-Kuznicka[5,6], D. Jedrzejuk[1], M. Pawlak[1], K. Kolackov[1], J. Chudek[2], A. Arkowska[1], U. Mieszczanowicz[1], B. Krzyzanowska-Swiniarska[3] & E. Bar-Andziak[4]
[1]Wroclaw Medical University, Wroclaw, Poland; [2]Medical University of Silesia, Katowice, Poland; [3]Pomeranian Medical University, Szczecin, Poland; [4]Medical University of Warsaw, Warszawa, Poland; [5]Mossakowski Medical Research Centre Polish Academy of Sciences, Warszawa, Poland; [6]Medical Research Center, Warszawa, Poland.

Pleiotropic effects of vit. D in the etiology of obesity, metabolic syndrome and diabetes are still debated. So far published reports considered only changes in vit D plasma level in individuals with obesity and diabetes, and did not take into account the role of polymorphisms in the vit. D receptor gene.

The aim of the study was to evaluate obesity, carbohydrate and lipid metabolism and vitamin D level in two VDR polymorphisms (Fok and Bsm) in Polish aging population – POLSENIOR Study.

The study involved randomly selected out of 4737 individuals 982 subjects (456 women and 526 men) aged above 65, in whom the following measurements were performed: BMI, waist circumference, and blood serum HDL cholesterol, triglycerides, vitamin D, glucose and insulin (HOMA index) levels. In order to apply the genetic material, PCR was used. To identify polymorphisms, RFLP technique was used. The reaction products were analyzed by electrophoresis on 2% agarose gel. Statistical significance of the relationships between investigated metabolic parameters in relation to investigated polymorphisms was evaluated by means of the ANOVA test.

Results

Our findings revealed only statistically significant elevated levels of glucose for the polymorphic form digested with the Bsm enzyme of the VDR gene, both in homozygotes as well as heterozygotes, however when gender was taken into account, the statistical significance disappeared. The remaining metabolic parameters did not reveal and relationship to the investigated polymorphisms.

Conclusion

The polymorphisms VDR (Fok, Bsm) don't plays key role in metabolic disorders in aging polish population implemented under publicly-funded project no. PBZ-MEIN-9/2/2006.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P225

### Quality of life in premenopausal women with vitamin D deficiency and vitamin D insufficiency

G. Ecemis & A. Atmaca
Ondokuz Mayis University School of Medicine, Samsun, Turkey.

Introduction

The aim of this study was to compare quality of life among premenopausal women with vitamin D deficiency, vitamin D insufficiency and vitamin D sufficiency.

Methods

Premenopausal women with chronic fatigue, myalgia and nonspecific body pain were divided according to their vitamin D levels: ≤20 ng/ml (vitamin D deficient, $n=30$), 21–29 ng/ml (vitamin D insufficient, $n=30$) and ≥30 ng/ml (vitamin D sufficient, $n=20$). The groups were compared regarding the scales of short form-36 (SF-36). Higher scores in SF-36 were associated with better quality of life. Women with depression, thyroid disorders, diabetes mellitus, obesity, renal and hepatic disorders and other chronic diseases were exluded.

Results

Women with vitamin D deficiency had lower physical function scores than women with vitamin D insufficiency ($P=0.001$). Women with vitamin D insufficiency had lower physical component ($P=0.025$), mental component ($P=0.025$) and vitality ($P=0.02$) scores than women with vitamin D sufficiency. When women with vitamin D deficiency and insufficiency were combined ($n=60$) and compared with vitamin D sufficiency group, they had lower physical component ($P=0.002$), mental component ($P=0.01$), physical function ($P=0.0002$), social function ($P=0.04$) and vitality ($P=0.01$) scores. Vitamin D levels were positively correlated with physical component ($r=0.3$), physical function ($r=0.4$) and role physical ($r=0.3$) scores.

Conclusion
Vitamin D status affects quality of life in premenopausal women without other chronic disorders even in the insufficiency level. Impairment in quality of life is seen in both physical and mental components, but physical component seems to be more affected. This study is the first study evaluating quality of life in premenopausal women according to vitamin D status and the results may have an impact on daily clinical practice, espacially when evaluating women with nonspecific symptoms.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P226

**Intraoperative parathormone monitoring allows successful minimally invasive parathyroidectomy in patients with non concordant preoperative imaging**

P. Wignarajah, F. Paulo Prete, I. Philips, J. Smart & T. Kurzawinski
University College London Hospital, London, UK.

Introduction
Sestamibi (SM) and ultrasound (US) are routinely used for preoperative localisation of abnormal parathyroids in patients with hyperparathyroidism. Minimally invasive parathyroidectomy (MIP) is recommended if localisation is concordant, otherwise neck exploration is the method of choice.
Aim
To assess whether introduction of intraoperative parathormone (IOPTH) monitoring allows us to perform MIP successfully in patients with non concordant findings.
Method
Retrospective review of patients operated between 2006–2011.
Results
158 patients with hyperparathyroidism (120 female, 38 male) with median age 60 (13–85) had parathyroidectomies with IOPTH monitoring.
152 patients had US of which 118 identified an abnormal parathyroid and 153 patients had SM of which 106 identified an abnormal parathyroid. 73 (46.2%) patients had concordant imaging qualifying them for MIP but 85 patients (53.8%) with non-concordant findings were also scheduled for MIP.
114 patients (72.1%) had MIP of which 6 were converted to neck explorations (5%). 44 patients (27.8%) who had simultaneous thyroidectomies, sternotomies or mediastinoscopies for ectopic glands or all 4 glands removed had neck exploration.
Overall, 154 patients (97.4%) were cured. 107 (99%) of patients who underwent MIP and 41 (93%) patients who had neck explorations were cured.
Conclusions
Introduction of IOPTH monitoring allowed successful MIP not only in patients with concordant findings but also in patients with non concordant preoperative imaging. Use of IOPTH monitoring doubled the number of Minimally Invasive Parathyroidectomies in our series.

**Vitamin D status, chronic kidney disease and secondary hyperparathyroidism in Polish elderly population**

J. Chudek[1], M. Mossakowska[2], K. Broczek[3], E. Franek[4] & A. Wiecek[1]
[1]Medical University of Silesia, Katowice, Poland; [2]International Institute of Molecular and Cell Biology, Warsaw, Poland; [3]Medical University of Warsaw, Warsaw, Poland; [4]Central Clinical Hospital MSWiA, Warsaw, Poland.

Introduction
Secondary hyperparathyroidism (SHPT) develops more frequently in the elderly. The high prevalence of chronic kidney disease and inappropriate vitamin D status are among the predisposing factors. The aim of this study is to assess the prevalence of SHPT, chronic kidney disease (CKD) and vitamin D status in a representative group of Polish elderly population.
Objective
The study was carried out as a part of the nationwide PolSenior project (medical, psychological and socioeconomic aspects of aging in Poland) in the population of randomly selected 5695 participants (2899 males and 2796 females) using the national PESEL database (the National Electronic System of Population Records). Serum calcium, phosphates, creatinine, 25-OH-D3 and PTH concentrations, as well as albumin to creatinine ratio in urine were assessed in 4270 participants accounting for 75.0% of the study group. SHPT was diagnosed in participants with normal (8.4–10.0 mg/dl) or decreased ($<$8.4 mg/dl) corrected serum calcium concentration and increased ($>$65 pg/ml) intact PTH level. Estimated glomerular filtration rate (eGFR–CKD–EPI) below 60 ml/min per 1.73 $m^2$ or albuminuria $\geq$ 30 mg/g creatinine was interpreted as CKD. Low vitamin D status was ranked as hypovitaminosis (20–29.9 ng/dl), insufficiency (10–19.9 ng/dl) or deficiency ($<$10 ng/dl).
Results
Among the studied participants, 540 (12.6%) subjects were identified as having SHPT. The prevalence of SHPT in the Polish elderly population was estimated at 10.43%. It was increasing with age from 4.39% in the subjects aged 55–59, through 6.07% in those aged 65–69, 8.61% in those aged 70–74, 13.49% in those aged 75–79, 15.48% in those aged 80–84, 17.786% in those aged 85–89, to 25.97% in the group aged 90 years or more. Impaired eGFR was found in 267 (49.4%), albuminuria in 127 (23.5%) and CKD in 310 (57.4%) of participants with SHPT, while hypovitaminosis D was demonstrated in 150 (27.8%), vitamin D insufficiency in 147 (27.2%), and deficiency in 32 (5.9%). CKD or low vitamin D status was found in 82.6% of SHPT causes. Improper serum vitamin D concentration was found in 62,3% of participants with CKD.
Conclusions
Low serum vitamin D concentration is frequently observed in elderly patients with chronic kidney disease and secondary hyperparathyroidism.

## P228

**Vitamin D status in primary hyperparathyroidism: a 'Southern European' observational study**

F. Tassone, C. Baffoni, L. Gianotti, M. Pellegrino, S. Cassibba, G. Magro, F. Cesario & G. Borretta
S. Croce e Carle Hospital, Cuneo, Italy.

Introduction
It has been reported that vitamin D deficiency is common in patients with primary hyperparathyroidism (pHPT), and this could affect the clinical expression of the disease. However only few studies addressed this issue and refer to American or North European patients. In these studies, only about one third of the patients showed a vitamin D replete state.
Subjects and methods
In 207 consecutive pHPT patients (M/F=45/162, age (mean $\pm$S.D.): 60.1$\pm$13.6 years, PTH=216.1$\pm$202.8 pg/ml, calcium=11.1$\pm$1.2 mg/dl, asymptomatic/symptomatic=89/118)) we have assessed vitamin D status by measuring plasma 25-OH vitamin D (25-OHD) levels. Vitamin D deficiency was defined as 25-OHD $<$20 ng/ml, whereas vitamin D insufficiency was defined as 25-OHD $>$20 to $<$30 ng/ml.
Results
In our series 36.2% of the patients showed 25-OHD deficiency and 21.3% showed 25-OHD insufficiency. 37% of female patients resulted 25-OHD deficient and 19.8% insufficient. 33.3% of male patients resulted 25-OHD deficient and 26.7% insufficient. 38.1% of symptomatic patients resulted 25-OHD deficient and 22.1% insufficient. 33.7% of asymptomatic patients resulted 25-OHD deficient and 20.2% insufficient. 25-OHD levels were significantly related with BMD at forearm, at femur and at spine ($R=0.27$, $P<0.0003$ at forearm; $R=0.16$, $P<0.04$ at femur, $R=0.20$, $P<0.009$ at lumbar spine). Moreover 25OHD-levels were negatively related with PTH ($R=-0.38$, $P<0.000001$), calcium ($R=-0.27$, $P<0.00009$) and bone turnover markers levels ($R=-0.21$, $P<0.003$ for osteocalcin, $R=-0.38$, $P<0.0004$ for cross-links). No seasonal variability was observed in 25-OHD levels.

Conclusions
In this 'Southern European' pHPT case series the proportion of 25OHD deficiency is lower than that reported for North American and North European studies. These differences could be due to the different latitude/skin UV exposure. 25-OHD status is related to biochemical indexes of the disease but it does not seem to affect classical pHPT manifestations.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P229

**Vitamin D and rheumatoid arthritis**

I. Kostoglou-Athanassiou[1], A. Lyraki[2], P. Athanassiou[3], A. Gkountouvas[1], J. Myriokefalitakis[2], J. Raftakis[2], P. Kaldrymides[1] & C. Antoniades[2]
[1]Metaxa Hospital, Pireaus, Greece; [2]Asclepeion Hospital, Athens, Greece; [3]St. Paul's Hospital, Thessaloniki, Greece.

Vitamin D deficiency has been implicated in the pathogenesis of autoimmune diseases, such as diabetes mellitus type 1 and multiple sclerosis. Reduced vitamin D intake has been linked to increased susceptibility to the development of rheumatoid arthritis (RA) and vitamin D deficiency has been found to be associated with disease activity in RA patients. The aim was to evaluate vitamin D status in RA patients and to assess the relationship between vitamin D levels and disease activity.
In a cohort of 44 patients suffering from RA 25(OH)D3 levels, parathyroid hormone levels, C-reactive protein and ESR were measured. Disease activity was evaluated by calculating the DAS28 score. A control group ($n=44$), matched for age and sex, was evaluated as well. All patients fulfilled the American College of Rheumatology criteria for the classification of RA.
In the cohort of 44 RA patients 25(OH)D3 levels were found to be low as compared to the control group, 25(OH)D3 being $15.36\pm1.09$ and $24.9\pm1.2$ ng/ml, in the patient and control group respectively (Student's $t$-test, $P<0.05$). Parathyroid hormone levels were $70.82\pm7.22$ pg/ml (normal values 10.0–65.0 pg/ml), CRP $7.59\pm1.64$ mg/l (normal values $<3$ mg/l) and ESR was $36.7\pm4.5$ mm/h in the group of RA patients. Levels of 25(OH)D3 were found to be negatively correlated to the DAS28 score, correlation coefficient being $-0.065$. Levels of 25(OH)D3 were also found to be negatively correlated to CRP and ESR, correlation coefficient being $-0.11$ and $-0.16$ respectively.
It appears that vitamin D deficiency is highly prevalent in RA patients, and that vitamin D deficiency may be linked to disease severity in RA. As vitamin D deficiency has been linked to diffuse musculoskeletal pain, these results have therapeutic implications. Vitamin D supplementation may be needed both for the prevention of osteoporosis as well as for pain relief in rheumatoid arthritis patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P230

**The prevalence of primary hyperparathyroidism in Polish elderly population**

J. Chudek[1], M. Mossakowska[2], P. Slusarczyk[2], E. Franek[3] & A. Wiecek[1]
[1]Medical University of Silesia, Katowice, Poland; [2]International Institute of Molecular and Cell Biology, Warsaw, Poland; [3]Central Clinical Hospital MSWiA, Warsaw, Poland.

Introduction
Primary hyperparathyroidism (PHPT) develops more frequently in the elderly with marked predisposition for female gender. The prevalence of PHPT in Poland is unknown. Therefore, the aim of this study is to assess the prevalence of PHPT in a representative sample of Polish elderly population.
Description of methods/design
The study was carried out as a part of the nationwide PolSenior project (medical, psychological and socioeconomic aspects of aging in Poland) in the population of randomly selected 5695 participants (2899 males and 2796 females) using the national PESEL database (the National Electronic System of Population Records). Serum calcium, phosphates, 25-OH-vitamin D and PTH concentrations were assessed in 4588 out of 4737 obtained blood samples, constituting 80.6% of the study group. PHPT was diagnosed in participants with increased corrected serum calcium concentration ($>10.6$ mg/dl) and increased ($>65$ pg/ml) or normal (15–65 pg/ml) intact PTH level or corrected serum calcium $>10.0$ mg/dl and increased intact PTH concentration.
Results
Fifty-six participants including 18 out of 2358 (0.76%) males and 38 out of 2230 (1.70%) females with PHPT were identified. The prevalence of PHPT in the Polish elderly population was estimated at 0.99%. Female gender significantly increased the risk for PHPT (OR = 2.25(1.28–3.96); $P=0.005$). The higher prevalence of PTHP was found in the oldest subjects: aged 85–89 (1.31% of males and 3.01% of females) and 90 years. or above (1.83% of males and 3.93% of females). Thirty-six out of 56 participants with PHPT had vitamin D level lower than recommended ($<30$ ng/ml). None but one of the participants with PHPT had prior episode of stone expulsion or lithotripsy.
Conclusions
The prevalence of PHPT is increased in the very old. PHPT in the elderly does not seem to increase the risk of kidney stones.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Markers of bone turnover and polymorphism of vitamin D receptor gene in aging population: POLSENIOR study**

D. Jedrzejuk[1], A. Milewicz[1], L. Laczmanski[1], M. Puzianowska-Kuznicka[2,3], M. Pawlak[1], K. Kolackov[1], A. Arkowska[1], U. Mieszczanowicz[1], B. Krzyzanowska-Swiniarska[5] & E. Bar-Andziak[4]
[1]Wroclaw Medical University, Wroclaw, Poland; [2]Mossakowski Medical Research Centre, Warszawa, Poland; [3]Medical Research Center, Warszawa, Poland; [4]Medical University of Warsaw, Warszawa, Poland; [5]Pomeranian Medical University, Szczecin, Poland.

The levels of bone turnover markers are elevated e.g. in osteoporosis, neoplastic diseases with bone involvement (e.g. myeloma). Recently bone markers have been found to play an important role in other diseases, like cardiovascular diseases (CVD). Vitamin D, which plays a role in body metabolism, is also an important hormone maintaining bone homeostasis.
The aim of the study was to evaluate the levels of bone turnover markers (osteoprotegerin and ICTP) in vitamin D receptor gene polymorphisms in the population of responders of the POLSENIOR project.
Out of a group of 5695 randomly selected responders of the POLSENIOR study, blood was collected from 4737 individuals. Out of this group, 982 individuals (including 456 females and 526 males) aged above 65 had the levels of 25-OH-D3, ICTP and OPG (RIA method) measured. In order to amplify the genetic material, PCR was used. To identify polymorphisms of the VDR (Fok and Bsm) RFLP technique was used. The reaction products were analyzed by electrophoresis on 2% agarose gel.
No differences in the vitamin D level were found among the investigated polymorphisms in the whole investigated group. Among bone turnover markers, only in case of ICTP subjects with the bm polymorphic form (digested by BSM 1 enzyme) were characterized by lower ICTP level (on the borderline of significance = 0.08). When the group was divided into genders, it appeared that in males the bm polymorphic form revealed also lower level of OPG, which reached the level of statistical significance ($P=0.027$).
Conclusions
Our studies demonstrated that the bm polymorphic form of vitamin D receptor may play a protective role against bone resorption.
Implemented under publicly-funded project no. PBZ-MEIN-9/2/2006.

## P232

**Endothelial functions of the patients with hyperparathyroidism**

G. Yorulmaz[1], A. Akalin[2] & S. Atlanoglu[3]
[1]Batman State Hospital, Batman, Turkey; [2]Eskisehir Osmangazi University, Faculty of Medicine, Eskisehir, Turkey; [3]Sirnak State Hospital, Sirnak, Turkey.

Introduction
Primary hyperparathyroidism (PHPT) is associated with increased risk of mortality from cardiovascular disease and this appears to decrease with time after parathyroidectomy. However, data on hyperparathyroid patients are conflicting and there is no data regarding secondary hyperparathyroid patients. Our aim in this study was to determine the association between flow-mediated dilatation (endothelium dependent, FMD), nitroglycerine-induced dilatation (endothelium independent, NID) and carotid artery intima media thickness (IMT) in primary hyperparathyroidism (PHPT), secondary hyperparathyroidism (SHPT) and the control group.
Material and methods
Twenty patients with primary hyperparathyroidism, twenty with secondary hyperparathyroidism and 12 healthy subjects were included in the study. Both groups were matched with respect to age. Serum calcium level, parathormone(PTH) and daily urinary calcium excretion (UCE) were calculated and FMD, NID and IMT were also evaluated for all subjects.
Results
Serum Ca levels were significantly higher in patients with primary hyperparathyroid patients compared to both patients with secondary hyperparathyroidism and the control group ($P<0.001$ and $P<0.001$ respectively). As expected, urinary calcium excretion levels of the patients with primary hyperparathyroidism were higher than both the control group and the patients with secondary hyperparathyroidism ($P<0.001$, $P<0.001$ respectively). Serum PTH levels were also significantly higher in patients with primary and secondary hyperparathyroidism than the control group ($P<0.05$ and $P<0.05$ respectively). FMD, NID and IMT levels were not significantly different between the groups. But there was a negative correlation between serum calcium levels and FMD ($r:-0.41$ $P<0.01$).
Conclusion
This finding suggests that the cause of the cardiovascular diseases seen in hyperparathyroid patients is the increased calcium levels rather than the hyperparathyroidism itself.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P233

**The importance of citrate and the calcium/citrate ratio in patients with calcium renal lithiasis and severe lithogenesis**

Y. Suleiman-Martos[1], M. Arrabal-Polo[1], A. Jimenez-Pacheco[2], A. Zuluaga-Gomez[1], F. Escobar-Jimenez[1] & M. Arrabal-Martin[1]
[1]San Cecilio University Hospital, Granada, Spain; [2]Santa Ana Hospital, Granada, Spain.

Introduction
One of the factors influencing a predisposition to calcium renal lithiasis is a lack of crystallization inhibitors, the most important of which is citrate. The aim of our study was to analyze the importance of urinary citrate and the urinary calcium/citrate ratio in patients with calcium renal lithiasis and severe lithogenesis in comparison with control group patients without lithiasis.
Methods/Design
We conducted a cross-sectional study of 115 patients in eastern Andalusia (Spain). The patients were divided into two groups: groups A and B. Group A: 56 patients aged 25 to 60 years without calcium renal lithiasis. Group B: 59 patients aged 25 to 60 years presenting with calcium renal lithiasis and severe lithogenesis. We analyzed and compared the citrate levels and the calcium/citrate ratio in the patients' urine and the relationship of these two factors to lithiasic activity. In addition, we examined the bone mineral density across groups.
Results
In group B, 32.2% of the patients presented with hypocitraturia, compared with 14.3% of the patients in group A ($P=0.02$). The urinary citrate levels were lower in group B compared to group A ($P=0.001$), and the calcium/citrate ratio was higher in group B compared to group A ($P=0.005$). Our results suggest that a patient urine calcium/citrate ratio $\geq 0.25$ indicates serious lithogenesis (sensitivity of 89%, specificity of 57%). After a linear regression analysis, we found that the urinary citrate level is an independent factor associated with changes in bone densitometry *T*-score values of patients.
Conclusion
Compared to the control group, the patients with severe lithogenesis presented with hypocitraturia, which was associated with lower bone mineral density. The calcium/citrate ratio, which is linearly related to the bone resorption marker β-crossLaps, could be useful in evaluating the risk of serious lithogenesis when its value is exceeds 0.25.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P234

**The diagnostic values of serum intact parathyroid hormone, calcium and phosphorus for the prediction of vitamin D deficiency**

B. Oguz, S. Zuhur, S. Avci & Y. Altuntas
Sisli Etfal Training and Research Hospital, Istanbul, Turkey.

Background
The results of studies evaluating the relationship between serum 25-hydroxyvitamin D (25OHD) with intact PTH (iPTH), calcium (Ca) and phosphorus (P) levels are controversial.
Objective
To determine the diagnostic values of iPTH, Ca and P for the prediction of vitamin D deficiency.
Methods
We analysed iPTH, Ca and P levels in otherwise healthy 700 subjects (619 (88.4%) female, 81 (11.6%) male, mean age $47.44\pm16.58$ years). To define deficiency status, 25OHD were further classified into four groups, ($<25$ nmol/l as severely deficient, 25–49.9 nmol/l as deficient, 50–74.9 nmol/l as insufficient and $\geq 75$ nmol/l as sufficient, respectively).
Results
The mean 25OHD, iPTH, Ca and P levels were $39.42\pm29.43$ nmol/l, $66.16\pm34.57$ pg/ml, $9.63\pm0.46$ and $3.35\pm0.52$ mg/dl respectively. 271 (38.7%) of the subjects were classified as severely 25OHD deficient, 237 (33.9%) as deficient, 91 (13.0%) as insufficient and 101 (14.4%) as sufficient respectively. iPTH were inversely correlated with 25OHD ($r=-0.264$), while no correlation was found between Ca, P, age and gender with 25OHD ($r=0.099$; $r=0.065$; $r=0.003$ and $r=0.012$ respectively). Secondary hyperparathyroidism (sPTH) were present in 277 (46.24%) of the subjects with low 25OHD levels (in 167 (61.6%), 81 (34.2%) and 29 (31.9%) of the subjects with severely deficient, deficient and insufficient 25OHD levels respectively). In post-hoc analysis iPTH were significantly higher in subjects with severe 25OHD deficiency compared to those with deficient, insufficient and sufficient 25OHD levels ($P<0.0001$ for all). Nevertheless, iPTH were not significantly different when subjects with deficient 25OHD were compared with those who had insufficient and sufficient 25OHD levels ($P>0.05$ for all). In ROC analysis the overall sensitivity and specificity for the best iPTH cut-off value (62.5 pg/ml) in subjects with low 25OHD were 65.3 and 64.8% respectively.
Conclusions
Despite of a significantly higher iPTH levels in subjects with severe 25OHD deficiency, neither iPTH nor Ca and *P* have sufficient sensitivity and specificity to precisely predict vitamin D deficiency.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P235

**Vitamin D and gestational diabetes**

H. Parildar[1], A. Unal[1], G. Desteli[1], O. Cigerli[1], E. Caliskan[2], O. Tarcin[1] & N. Demirag[1]
[1]Baskent University Faculty of Medicine Istanbul Hospital, Istanbul, Turkey; [2]Kocaeli University Faculty of Medicine, Izmit, Turkey.

Background and aims
We aimed to establish the frequency of vitamin D deficiency and analyse its association with gestational diabetes (GDM).

Material and methods
In this descriptive, case control and cross sectional study, pregnant women were screened at 24–28 weeks of pregnancy using a 75 g, 2 h oral glucose tolerance test. Fourthy-six GDM diagnosed (case, group 1) and 43 healthy pregnants (control, group 2) were recruited. Plasma 25-hydroxyvitamin D levels of less than (20 ng/ml) were defined as deficiency. Groups were matched according to their serum magnesium levels, multivitamin use and hypertensive status. Mann–Whitney *U* test and Pearson correlation test were used for statistical comparisons.
Results
The mean ages were 33.3 ± 4.9 years (18–44 years) in group 1, and 29.9 ± 4.4 years (21–39 years) in group 2. Mean vitamin D levels were 20.5 ± 10.1 ng/ml (min. 4–max. 39.3) in group 1 and 23.1 ± 12.6 ng/ml (min. 6.6–max. 73) in group 2 ($P = 0.3$). Frequency of vitamin D deficiency status was not significantly difference between groups (51.4% ($n = 18$) in group 1 and 44.7% ($n = 17$) in group 2).
Plasma vitamin D levels were negatively correlated with OGTT (50 gr) and PTH levels (respectively $r = -0.7$, $P = 0.006$, $r = -0.8$, $P = 0.002$). There was no association between vitamin D levels and serum insulin, fasting glucose, HbA1c levels and BMI. Eleven of vitamin D-deficient pregnants (30.6%) were veiled and only seven pregnants (19.4%) were engaged in physical activity of at least 30 min/day duration.
Conclusion
Vitamin D deficiency is prevalant in our GDM patients as in our general population. This may be mostly attributable to lifestyle and genetic factors. As GDM and hypovitaminosis D continue to increase all in the world, we suggest that establishing potential factors that affect GDM and improving vitamin D status in pregnancy may prevent their possible adverse health outcomes.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P236

**Bone biomarkers, body composition and metabolic profile in patients with primary hyperparathyroidism**

G. Cvijovic[1,2], D. Micic[1,2], A. Kendereski[1,2], S. Zoric[1], M. Sumarac-Dumanovic[1,2], D. Stamenkovic-Pejkovic[1] & D. Jeremic[1]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Belgrade, Serbia; [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Objective
Primary hyperparathyroidism (PHPT) is systemic disease affecting bone metabolism and glucose homeostasis. Patients with PHPT are insulin resistant and have atherogenic dyslipidaemia. Osteocalcin (OC) is bone biomarker associated with increased insulin secretion and insulin sensitivity and decreased visceral fat The aim of our study was to evaluate the body composition and levels of bone biomarkers (osteocalcin and betaCTx), insulin sensitivity and lipids in patients with PHPT.
Material and methods
In 25 patients with PHPT (Group 1 – age: 55.08 ± 11.62 years, BMI 26.75 ± 4.44 kg/m$^2$, PTH 144.27 ± 138.17 ng/l, Calcium 2.94 ± 0.26 mmol/l) and 8 healthy controls (Group 2 – age: 55.00 ± 6.90 years, BMI 224.70 ± 3.94 kg/m$^2$, PTH 35.46 ± 10.82 ng/l, Calcium 2.52 ± 0.15 mmol/l) OC(ng/ml), betaCTx(ng/ml), glucose(mmol/l), insulin(IU/ml), phosphate (mmol/l), total cholesterol (TC, mmol/l), HDL-C, LDL-C, triglyceride (TG, mmol/l), ApoA1, ApoA2, ApoB, ApoE, Lp(a) and vitamin D levels were determinated. HOMA IR was calculated as a marker of insulin resistance, body composition was evaluated using DEXA.
Results
There was significant difference between Group 1 and Group 2 in total (35.00 ± 4.84 vs 29.90 ± 4.77%, $P < 0.05$) and truncal fat percent (33.59 ± 6.72 vs 24.60 ± 6.38%, $P < 0.05$), TC (6.47 ± 1.34 vs 5.32 ± 0.88, $P < 0.05$), LDL (4.27 ± 1.14 vs 3.26 ± 0.93, $P < 0.05$), TG (1.83 ± 0.82 vs 1.14 ± 0.61, $P < 0.05$) and Apo B (1.20 ± 0.0.29 vs 0.85 ± 0.23, $P < 0.05$). In Group 1 OC (67.93 ± 14.39 vs 30.08 ± 15.54, $P = 0.05$), betaCTx (1.11 ± 1.00 vs 0.61 ± 0.39, $P = 0.05$) and Apo E (50.17 ± 14.62 vs 40.37 ± 10.79, $P = 0.05$) were also higher than in Group 2. There was no difference in HOMA IR between groups (3.29 ± 1.24 vs 3.12 ± 1.38, $P > 0.05$). There was significant correlation between betaCTx and trunkal fat percent ($R = -0.44$, $P < 0.05$), insulin ($r = -0.42$, $P < 0.05$), OC ($r = 0.95$, $P < 0.01$) and PTH levels ($r = 0.62$, $P < 0.01$), as well between OC and phosphate ($r = -0.42$, $P < 0.05$) and PTH levels ($r = 0.68$, $P < 0.01$).
Conclusion
Patients with PHPT have atherogenic lipid profile, elevated bone biomarkers and more visceral fat in comparision to healthy controls. In our group of patients with PHPT betaCTx (but not the OC) levels suggest possible interrelation between bone, glucose and lipid metabolism.
Declaration of interest

**The daily calcium intake is associated with sarcopenia in older, non-obese koreans: the fourth korea national health an nutrition examination surveys (KNHANES IV) 2009**

C. Park, E. Rhee, K. Oh, S. Park, S. Park, S. Kim, W. Lee & M. Seo
Kangbuk Samsung Hospital, Seoul, Republic of Korea.

Backgroud
The association with daily calcium intake and sarcopenia has not been well established.
Objective
The objective was to assess the associate of daily calcium intake and sarcopenia.
Methods
We analysed the fourth Korea National Health and Nutrition Examination Survey (KNHANES) in old adult (over 50 years), conducted in 2009. A total of 1964 non-obese (body mass index (BMI) <25 kg/m$^2$) old adults (871 men and 1093 women) were enrolled. Dietary variables were assessed using a 24 h recall method in the nutrition survey. The intake of daily calcium from the consumption of each food item was calculated. Sarcopenia was defined as an appendicular skeletal muscle mass divided by body weight that was less than two S.D. below the sex-specific mean for young adults. Obesity was defined as a body mass index (BMI) of 25 kg/m$^2$ or higher.
Results
Daily calcium intake correlated negatively with appendicular fat mass, although not significant ($P = 0.201$). However, we found that Daily calcium intake correlated positively with appendicular skeletal mass ($P < 0.001$). Our study showed that participants with sarcopenia have significantly lower daily calcium intake compared to participants without sarcopenia ($P < 0.001$). The unadjusted prevalence of sarcopenia according to tertiles of daily calcium intake were 52.2, 31.9 and 15.9% in tertile1 – tertile 3. After adjustment for age, sex, BMI, total energy intake and lifestyle factors, compared with those in the lowest tertile of daily calcium intake, participants in the highest tertile had an odds ratio for sarcopenia of 0.311 (95% CI, 0.129–0.748).
Conclusion
Our study suggest that there is a strong inverse association between daily calcium intake and sarcopenia in non-obese old adult Korean.
Adjusted Odds ratiom and 95% CI of sarcopenia by tertiles of daily calcium intake.

| Tertile of daily calcium intake (mg/d) | T1(<274.8) *n*=654 | T2(274.6–488.7) *n*=656 | T3(>488.8) *n*=654 | P for trend |
|---|---|---|---|---|

### Role of chromogranin-A in the truncation of parathyroid hormone in cultured parathyroid cells from patients of the secondary hyperparathyroidism

G. Kanai & K. Sawada
Tokai University School of Medicine, Isehara-shi, Japan.

Introduction
Two major assay systems have been used for evaluation of parathyroid hormone (PTH) secretion. Whole PTH (wPTH) recognizes full-length 84 amino acid residues [PTH(1–84)], and Intact PTH (iPTH) recognizes NH2-truncated forms, such as PTH(7–84), in addition to PTH(1–84). Patients with chronic renal failure have increased amount of PTH(7–84) in circulations, so that the ratio of wPTH/iPTH indicates 0.7 or below usually. On the other hand, chromogranin-A (ChgA) is known to be a major protein costored and cosecreted with PTH in parathyroid glands. So, a role of ChgA in the process of biosynthesis of PTHs in cultured parathyroid cells was studied by using RNA interference (RNAi).
Method and result
RNAi was performed for 24 h to suppress the expression of ChgA in parathyroid cells. We observed that 50 nM of siRNA suppressed both values of wPTH and iPTH moderately, and importantly, they kept being almost equal for two weeks. Representatively, the mean values and S.D. of secreted wPTH and iPTH from cells transfected with siRNA for ChgA were $466.3 \pm 48.0$ ng and $477.0 \pm 18.4$ ng, respectively (wPTH/iPTH = 0.98), whereas those of cells transfected with a negative control siRNA were $602.0 \pm 168.9$ ng and $860.0 \pm 191.8$ ng, respectively (wPTH/iPTH = 0.70). The result indicates that almost no truncated PTH(7–84) was produced in cells of ChgA suppression.
Conclusion
It is suggested that ChgA plays a role in production of truncated forms of PTH. Parathyroid cell culture system with suppression of CgA is useful to examine processes of PTH biosynthesis.

### Correlations between vitamin D supply and PTH-intact and PTH-bio-intact levels in dialysis patients

G. Kovacs[1], L. Kovacs[2], D. Horvath[2], I. Kulcsar[2], Z. Locsei[2] & E. Toldy[1,2]
[1]University of Pecs, Pecs, Hungary; [2]Markusovszky Teaching Hospital, Szombathely, Hungary.

Parathormone (PTH) is the marker for bone remodelling in chronic renal failure. The biologically active PTH 1–84 intact molecule (PTHibio) is supposed to better correlate with the degree of remodelling than PTH-intact (PTHi) which also binds to the 1–34 fragment. Our aim was to examine the PTH levels in dialysed patients with these two methods, considering also the total 25-hydroxi-vitamin-D (t-25OHD) levels.
Methods
patients (age $63 \pm 15$ years) on hemo- (HD) and 37 on peritoneal dialysis (PD, age $62 \pm 20$ years) were enrolled. PTH was measured by an electro-chemiluminescent immuno-metric assay, while t-25OHD by a protein binding assay (Cobas e411, Roche). Total protein (TP), albumin (ALB), protein electrophoresis and ionized calcium were also determined. The time period spent in dialysis was significantly ($P < 0.001$) lower in PD than in HD ($2.1 \pm 1.7$ vs $4.7 \pm 3.8$ years).
Results
The t-25OHD level was significantly ($P < 0.001$) lower, while PTH levels (with either method) were significantly higher in PD (PTHi: $302 \pm 176$ pg/l, PTHibio: $186.3 \pm 82.2$ pg/ml) than in the HD patients (PTHi: $149.8 \pm 89.6$ pg/ml and PTHibio: $88.5 \pm 50.0$ pg/ml). We recorded significantly ($P < 0.001$) lower PTHibio levels compared to PTHi concentrations. Ionized calcium, as well as Alb, TP, and alfa-2-globulin levels were significantly ($P < 0.01$) lower in the PD group. In HD, a significant ($P < 0.01$) negative correlation ($-0.52$) was confirmed between PTHibio and t-25OHD levels, while no such correlation was present between PTHi and t-25OHD. Conclusions: PD patients suffer from severe vitamin D deficiency. PTHi and PTHibio levels in the PD patients are higher, which could be the consequence of lower ionized calcium and more frequent adynamia, common in PD, despite the relatively shorter time period spent in PD treatment. The lower serum protein levels in PD may explain the particularly low t-25OHD levels. In conclusion, PTHibio seems to be more suitable for monitoring bone metabolism, than any other parameter measured.

### Relationship among time outside, sun exposure, clothing worn, adiposity and serum 25(OH)D in overweight and obese adults

B. Piccolo[1], L. Hall[2], C. Stephensen[3], E. Gertz[3], L. Woodhouse[3], E. Souza[1], N. Keim[3], S. Adams[3] & M. Van Loan[3]
[1]University of California, Davis, Davis, California, USA; [2]California Polytechnic State University, San Luis Obispo, California, USA; [3]USDA/ARS, Davis, California, USA.

Introduction
Obese persons may have low vitamin D levels due to behaviors (clothing, time outdoors) that can reduce synthesis of vitamin D. In overweight and obese individuals there are limited quantitative data regarding relationships among serum 25(OH)D, time spent outdoors, sun exposure, and clothing worn.
Methods
We assessed environmental and behavioral factors that contribute to cutaneous synthesis of serum 25(OH)D in 63 overweight and obese individuals enrolled in a 12-week controlled feeding clinical trial. Vitamin D content in the food was known and varied based on treatment group. Sun exposure was recorded bi-weekly from sun exposure logs that included date, time of day, location, activity, minutes in direct sun, clothing worn, and sunscreen use. UV-B radiation measured by UV-B Broadband Pyranometer and converted to J/m$^2$. Total sun exposure (J) was measured as a product of UVB and total body surface area exposed from sun logs. Serum 25(OH)D was measured by RIA. Total body fat (TBF) and % body fat (%BF) was by DEXA. Intra-abdominal adipose tissue (IAAT) was by CT Scan.
Results
Sun exposure and % body surface area exposed (%BSAE) significantly correlated with serum 25(OH)D ($r = 0.2545$, $P = 0.0441$ and $r = 0.4614$, $P = 0.0001$, respectively). Time outside did not correlate with serum 25(OH)D ($r = 0.0387$, $P = 0.763$), but did relate to TBF ($r = -0.3935$, $P = 0.0014$), %BF ($r = -0.4132$, $P = 0.0008$), and BMI ($r = -0.3987$, $P = 0.0012$). Sun exposure significantly correlated with only BMI ($r = -0.2946$, $P = 0.0191$). %BSAE significantly correlated only with IAAT ($r = -0.3526$, $P = 0.0053$).
Conclusion
We found a significant association between serum 25(OH)D and indices of cutaneous sun exposure, indicating that these variables should be considered when addressing the etiology of often-reduce vitamin D status in obese individuals.

**Prospects of patients with oligosymptomatic primary hyperparathyroidism**

H. Siprova[1], Z. Frysak[2] & K. Sipr[2]
[1]St.Anne's University Hospital Brno, Brno, Czech Republic; [2]Palacky Univerzity Olomouc, Olomouc, Czech Republic.

The more sophisticated laboratory methods are used, the more likely a disease is found at its asymptomatic stage. In particular, diagnosis of primary hyperparathyroidism (PHPT) is currently based not only on the presence of clinical symptoms but on the typical upswing of the serum parathyroid hormone level. Outlooks of patients with PHPT and normal serum calcium level have not been quite clear so far. We tried to contribute to this question in a prospective study that has been in progress in the Czech Republic at a tertiary endocrinology center from January 1st, 2007, till December 31st, 2011. A total of 178 out-patients were diagnosed with PHPT, i.e. parathyroid hormone level was higher than 7.1 ng/l. Initially, the serum calcium level was not higher than 260 mmol/l in 154 cases (normocalcemic patients) and got over this limit in 24 cases (hypercalcemic patients). During a follow-up period, the serum calcium level exceeded 2.60 mmol/l in 22 originally normocalcemic patients. In 19 patients it raised to 2.85 mmol/l or less (moderate increase) and in 3 patients it transcended this value (high increase). In these patients, the increase followed after 1, 2 and 5 years of watching respectively. In a group of 24 patients in whom hypercalcemia was present from the very beginning, parathyroidectomy was performed in 16 cases (66.7%) during the study. In a group of 154 originally normocalcemic patients, parathyroidectomy was performed in 8 patients (5.2%). In normocalcemic patients, parathyreoidectomy was suggested mainly for parathyroid adenoma evidenced by MIBI scintigraphy, exceptionally by a surgeon recommendation finding parathyroid adenoma during thyreoidectomy.
Conclusion
Normocalcemic hyperparathyroidism is a strong reason for a 'watchful waiting' above all. Imaging methods, and rarely careful surgeon performing a thyroidectomy, may help to discover a parathyroid adenoma. One must be aware of risks and benefits of all attitudes.

## P242

**Cross-reactivity of 25-hydroxyvitamin D2 in ADVIA centaur vitamin D assay**

A. Fortunato[1] & E. Cavalier[2]
[1]ULSS 6, Vicenza, Italy; [2]University of Liège, CHU Sart-Tilman, Liège, Belgium.

Background
Vitamin D3 is the common supplemented form, vitamin D2 is often provided as prescribed supplement in many countries, such as the USA. In these countries, measuring 25(OH)D in patients treated with vitamin D2 using an assay that measures 25(OH)D2 poorly may confound clinical care. Recently, the ADVIA Centaur vitamin D assay has been commercialized for use in the clinical laboratory. We evaluated the assay's ability of measuring both 25(OH)D2 and 25(OH)D3 and compared the results to established automated and a LC-MS/MS method.
Methods
Adult volunteers, who gave informed consent, took orally 3000 IU vitamin D3 [D3], 3000 IU vitamin D2 [D2], or 1500 IU vitamin D2 plus 1500 IU vitamin D3 [D3+D2] daily for 3 months. Blood was obtained, processed, divided into aliquots, and stored at −20 °C until measurement. The Total 25(OH)D levels were measured with LC–MS/MS, DiaSorin Liaison, IDS-iSYS, and the Siemens ADVIA Centaur Total vitamin D immunoassays (Old and New calibration).
Results
In no supplementation subjects ($n=10$), the immunoassay values were similar to the LC/MS–MS. In D3 ($n=9$), the immunoassays were higher than LC/MS–MS. In D2 ($n=8$), Liaison (Mean + SD) (31.3+8.3) and IDS- iSYS (31.6+7.2) were similar to LC-MS/MS (35.3+8.8). The Centaur (Old and New) produced higher values: 52.7+21.1 ng/ml and 51.4+19.9 ng/ml. In D3+D2 group ($n=3$), we obtained 81.1+39.8 ng/ml (Centaur Old), 75.8+32.6 ng/ml (Centaur New). The LC–MS/MS, Liaison, and IDS-iSYS were: 52.1+13.0, 50.7+11.1, and 56.7+16.7, respectively.
Conclusions
The IDS-iSYS and Liaison 25-OH vitamin D results confirmed their D3 and D2 co-specificity. The elevated results in D2 and D3+D2 supplemented subjects suggested the Centaur method might significantly overestimated 25(OH)D level in patients treated with vitamin D2.

**Table 1** Total 25(OH) D Level (ng/ml)

| | Vitamin D supplementation type | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Vitamin D2 | | | Vitamin D3 | | | Vitamin D2 and Vitamin D3 | | | None | | |

## P243

**Primary hyperparathyroidism: association of imaging and pathology**

A. Abela[1,2], M. Gruppetta[1,2], M. Cachia[1,2], J. Vassallo[1,2] & S. Fava[1,2]
[1]University of Malta, Msida, Malta; [2]Mater Dei Hospital, Msida, Malta.

Background
We studied a cohort of hyperparathyroid patients in order to elucidate their clinical, laboratory, radiological and histological findings; the role of diagnostic imaging and concomitant thyroid pathologies.
Method
48 patients met our inclusion criteria for hypercalcaemic primary hyperparathyroidism (pHPT). We documented patients' demographic data, symptomatology, associated conditions and treatment and analysed the work-up, management and outcomes for each of these patients.
Results
pHPT patients had a median age of 62 years (range 20–79), median PTH of 145.5 pg/ml (range 27–4660) and mean serum calcium of 2.94 mmol/l (S.D. ± 0.33), while those operated (30/48, 62.5%) had a median age of 60 years (range 20–79), mean calcium of 3.02 mmol/l (S.D. ±0.39) and a median PTH of 176 pg/ml (range 37–4660). Histology showed parathyroid adenoma in 16/30 (53.3%), hyperplasia in 8/30 (26.7%), parathyroid carcinoma in 1/30 and normal tissue in 5/30. 19 of the 30 operated patients had a positive sestamibi scan of which 14/19 (73.7%) had an adenoma, 3/19 (15.8%) had hyperplasia, 1/19 had a carcinoma, and 1/19 had normal histology. Out of the 11 patients who had a negative sestamibi scan, 8/10 also had a negative ultrasound (US) and histologically 2/11 (18.2%) had an adenoma, 5/11(45.5%) had hyperplasia and 4/11 (36.4%) had normal histology.
Thyroid US showed a multinodular goitre in 12/41 (29.3%), solitary nodule in 5/41 (12.2%) thryoiditis in 4/41 (9.8%) and normal thyroid morphology in 20/41 (48.8%).
Conclusion
Parathyroid adenoma is the commonest pathology in patients with positive parathyroid imaging while hyperplasia is commoner in scan negative patients. This study highlights the need to proceed with surgery even when imaging is negative if clinically indicated. It is important to investigate associated thyroid

pathology prior to surgery though our data suggests similar incidence of thyroid pathology as documented in the general population.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Vitamin D modulates composition of extracellular matrix in cultured human vascular cells**

V. Ivanov, S. Ivanova, A. Niedzwiecki & M. Rath
Dr. Rath Research Institute, Santa Clara, California, USA.

Vitamin D (VitD) was shown to affect biology of vascular wall by regulating cell proliferation. However, its effects on vascular extracellular matrix (ECM) remain largely unaddressed. We investigated effects of VitD (calcitriol) on composition of ECM deposed by cultured endothelial cells (HAEC) and smooth muscle cells (HASMC) isolated from human aorta, and compared them to effects of ascorbate (VitC). Cellular monolayers were treated with or without vitamins for 72 h, then ECM were exposed by differential cell removal and ECM contents for collagen types I (CoI-I) and IV (Col-IV), elastin, heparan sulfate (HS), chondroitin sulfate (ChS) and hyaluronic acid (HA) were assessed immunoenzymatically. HASMC and HAEC demonstrated a significant difference in composition of ECM deposed under standard cultured conditions. HAEC deposed by one order more of Col-IV as compared to HASMC, whereas deposition of Col-I did not differ. HS deposition by HAEC was two-fold higher, whereas deposition of ChS was by two orders lower than by HASMC. Deposition of both elastin and HA were 30% higher in HAEC cultures. Treatment with 100 μM VitC increased Col-I, Col-IV, HS and HA content in HASMC-ECM by 8, 6, 2.3 and 1.5 folds, respectively. VitD had dose-dependent stimulatory effects on Col-I deposition by HASMC (increase by 42.5% at 1 μM), which were additive to the effects of VitC. In contrast, Col-IV and HS contents in HASMC-ECM were decreased by VitD by 25% each, counteracting stimulatory effects of VitC. HA content in HASMC-ECM was not affected by VitD. Neither vitamin had any effects on elastin nor ChS content in HASMC-ECM. Content of all tested compounds in ECM produced by HAEC was independent of either vitamin treatment. In conclusion, VitD was shown capable to affect composition of vascular ECM. Significance of these effects is a subject for discussion.

## P245

**Vitamin D level and ALT level in Chinese-American patients with chronic hepaitits B in the new york city downtown area**

M. Martell, P. Gao, L. Rincon-Bejarano, E. Chiu, R. Babbar & L. Mi
New York Downtown Hosptial, New York, New York, USA.

Background
Recent studies have suggested extensive associations between plasma levels of vitamin D and hepatobiliary diseases including viral hepatitis B or C. In hepatitis C, vitamin D deficiency may lead to a poor prognosis and a poor response to antiviral treatment. CHB has different pathophysiology. There has been no study on the association of vitamin D level and the ALT level in CHB patients, and it is not known whether vitamin D levels are associated with host response to hepatitis B infection.
Aims
To determine the association between serum 25-OH vitamin D3 levels and the severity of chronic hepatitis B based on HBV viral load and ALT levels in chronic HBV infected patients.
Method
One hundred seventy patients who visited the clinic at New York Downtown Hospital between November 4, 2010 and May 30, 2011 and due for other laboratory testing were screened for serum 25-OH vitamin D3. Thirty four Chinese-American patients were with non-cirrhotic CHB. Serum calcium, TSH, and phosphorus were also collected. Student t-test was used for the group comparison analysis. Correlation was analyzed using GraphPad Prism software.
Results
See Fig.1. More than 80% of our ethnic Chinese patient population had vitamin D levels lower than normal ($<30$ ng/ml). The mean vitamin D level (ng/ml) was $23.7 \pm 8.69$ in non-CHB patients and $22.9 \pm 8.6$ in CHB patients. The correlation between Vit D levels and ALT levels were, for all 170 patients: Pearson $r = 0.1664$ (95%CI $-0.0015$–0.00), $P > 0.05$ (not significant), and for 34 hepatitis B patients: Pearson $r = -0.027$ (95%CI $-$ 0.3668 – 0.30), $P > 0.05$ (not significant).
Discussion
The mean level of vitamin D in CHB patients was as low in non-CHB patients in this patient population. Apparently there is no correlation between vitamin D levels and CHB severity based on ALT levels in non-cirrhotic patients.

## P246

**High levels of parathormone after parathyroidectomy in primary hyperparathyroidism patients does not always mean disease recurrence**…

M. Ferreira, A. Silva, A. Caldas, J. Dores, C. Freitas, M. Costa, A. Canha, J. Polónia & J. Vilaverde
Centro Hospitalar do Porto, Porto, Portugal.

Introduction
Primary hyperparathyroidism (PHPT) patients who undergo parathyroidectomy can develop isolated intact parathormone (iPTH) elevation with normal calcemia. Common causes are: renal insufficiency (RI), vitamin D deficit and hypomagnesemia.
Aim
To identify clinical factors associated with iPTH elevation in patients submitted to surgery treatment.
Methods
The medical records of patients admitted into Santo António's Hospital between January/2000 and July/2011 with ICD-9 diagnosis of 'Hyperparathyroidism', 'Complete Hyperparathyroidectomy' and 'Other Hyperparathyroidectomy' were reviewed. Patients who underwent surgery and had post-operative iPTH elevation and eucalcemia were selected. Demographical and clinical data was collected.
Results
There were 82 patients who underwent surgery treatment, 31.7% ($n = 26$) of them had at least one elevated iPTH level throughout the fallow-up. This group consisted mainly of women (76.9%) with a mean age of $58.3 \pm 14$ years old at surgery. Eleven patients (42.3%) had high iPTH levels since the first measurement after surgery. In 18 patients (69.2%) there was at least one reason for iPTH elevation: 77.8% had low vitamin D levels; 23.5% had hypomagnesemia; 23.1% had RI (creatinine $= 2.5 \pm 1.4$ mg/dl). Three patients had MEN-1 mutation.
At last evaluation (mean follow-up of $4.1 \pm 3.4$ years) 13 patients maintained iPTH levels above normal range ($111.1 \pm 59.1$ pg/ml, 67–260). Four patients maintained RI, 6 low vitamin D levels and 1 hypomagnesemia. There was no analytical,

surgical or pathological differences between these patients and those with iPTH levels normalization.
Discussion and conclusions
Almost 1/3 of the PHPT patients submitted to parathyroidectomy had post-operative iPTH elevation mainly because of vitamin D deficit, hypomagnesemia or RI. The authors emphasize the need to identify those factors that may increase iPTH levels, and to monitor those who, despite supplementation, maintain iPTH elevation because of risk for persistent or recurrent PHPT.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Sporadic pseudohypoparathyroidism with osteitis fibrosa cystica**

L. Cianferotti[1], A. Biagini[1], E. Fernández-Rebollo[2], H. Jüppner[2] & C. Marcocci[1]
[1]University of Pisa, Pisa, Italy; [2]Massachusetts General Hospital and Harvard Medical School, Boston, Massachusetts, USA.

Pseudohypoparathyroidism (PHP) refers to a group of heterogeneous genetic diseases, characterized by resistance to PTH and frequently other hormones activating cAMP-dependent events down-stream of different G protein-coupled receptors. PHP-Ia and Ib, the most frequent forms, are caused by mutations within the GNAS locus that encodes Gαs and several splice variants thereof. We describe a 36-year-old man with sporadic PHP-Ib with renal PTH-resistance, yet severe hyperparathyroid bone disease. The patient presented at age 8 years with limping due to bone deformities, who was treated with multiple osteotomies. Biochemical evaluation showed hypocalcemia (7.5 mg/dl) with high PTH (504 pg/ml) and increased ALP (487 IU/l). After restoring serum calcium to the low-normal range by oral calcium (1 g/day) and calcitriol (0.5–1 μg/day), PTH and ALP progressively increased (2100 pg/ml and 980 IU/l, respectively). Cortical bone mineral density (BMD) was markedly reduced (distal radius T-score: −7.7). Subperiosteal bone resorption with acroosteolysis, salt-and-pepper appearance of the skull, bone cysts and long bone deformities were observed radiographically. Parathyroid ultrasound showed four-gland hyperplasia. Epigenetic analyses of GNAS locus documented loss of methylation at all four DMRs without evidence for patUPD20q; the 3-kb STX16 deletion was excluded. No features of PHP-Ib were present in first-degree relatives. After increasing calcitriol to 4 μg/day, a progressive fall of PTH and ALP occurred over the course of 8 months (130 pg/ml and 97 U/L, respectively), while serum calcium remained within normal limits without evidence for hypercalciuria. Cortical BMD markedly increased (+6.5%) and bone pain vanished. Nine months later hypercalcemia developed, likely because of completion of the remineralization process. Calcitriol was reduced to 1.5 μg/day and normocalcemia was restored. This is an unusual case of sporadic PHP-Ib with marked bone involvement, in whom the standard dose of calcitriol was insufficient. Despite long-standing disease, PTH levels declined dramatically and approached the normal range.

## P248

**Vitamin D supply in healthy blood donors: is there relationship with the use of oral contraceptives?**

E. Toldy[1,2], B. Varga[1], D. Horvath[1], E. Viragh[1], Z. Locsei[1], R. Jager[1] & G. Kovacs[2]
[1]Markusovszky Teaching Hospital of County Vas, Szombathely, Hungary; [2]University of Pecs, Pecs, Hungary.

Sufficient vitamin D supply is essential for general health. The total 25-hydoxy-vitamin-D (t-25OHD) level refers to the vitamin D supply and can be measured with various methods. Since these methods are not independent of the serum matrix, differences can be obtained among vitamin D levels measured with different methods. Our aim was to study the vitamin D in healthy blood donors, taking also into consideration the use of oral contraceptives (OC).
Methods
t-25OHD and intact parathormon (PTHi) (ECLIA, cobas e411, Roche) were measured in 131 healthy blood donors (mean age: 33.5±10.5 years; 50 men, 81 women: 41 of them taking OC). Calcium and albumin levels were measured with routine methods (Modular, Roche).
Results
The age of the patients correlated negatively with the t-25OHD ($r=-0.29$; $P<0.01$) and albumin ($P=-0.33$; $P<0.001$) levels. There was a negative correlation between t-25OHD and PTHi levels ($r=-0.26$; $P<0.01$), however, the PTHi was below the upper cut off level. Vitamin D supply was significantly more often insufficient in men (60%) than in women (24%). Only 12% of women taking OC had a poor (50–75 nmol/l) vitamin D supply and there was no lower D vitamin level than 50 nmol/l, while in women not taking OC, the suboptimal (<75 nmol/l) t-25OHD occured three times more often (14/40; 35%; $P<0.01$). The level of t-25OHD was significantly ($P<0.001$) higher in women taking OC (101.8±22.9 nmol/l) than in the other group of women (85.6±24.4 nmol/l) or in men (77.9±26.8 nmol/l).
Conclusions
Our results mostly correlate with the literature data; however, the surprisingly good vitamin D supply in women taking OC may suggest the increased production of vitamin D binding globulin in the liver, stimulated by ethynilestradiol.

## P249

**Chronic hypercalcemia, an unusual presentation in Q1011E heterozygous CaSR polymorphism**

S. Maqdasy[1,2], B. Roche[1], S. Roques[1], I. Tauveron[1,2] & M. Batisse-Lignier[1,2]
[1]CHU Clermont-Ferrand, Clermont Université, Clermont-Ferrand, France; [2]UMR GReD, CNRS 6247, Clermont Université, Clermont-Ferrand, France.

Introduction
The extracellular calcium-sensing receptor (CaSR) is a G-protein coupled receptor (GPCR) that is expressed in the parathyroids and kidneys, where it allows regulation of parathyroid hormone (PTH) secretion and extracellular calcium concentrations. Inactivating heterozyogous CaSR mutations result in familial benign hypocalciuric hypercalcaemia. However, the role of CaSR polymorphisms in controlling serum calcium, PTH and bone mineral density (BMD) remains controversial.
Case report
35 years old patient presented with abdominal pain and vomiting. Standard investigations showed a moderate chronic hypercalcemia (2.80 mmol/l). Further analysis showed a mild hypophosphatemia (0.58 mmol/l), mild hypocalciuria (2.4 mmol/24 h), normophosphaturia (15.8 mmol/l) and a normal parathyroid hormone (PTH) level (32 ng/ml). Imaging studies did not show any parathyroid nodule or radio isotope fixation. BMD was normal. Family history showed a sister with persistent hypercalcemia even after parathyroidectomy of 2 parathyroid glands, her grandmother underwent parathyroidectomy of the 4 glands. Genetic screening for CaSR mutations did not show any deleterious mutation, indeed, a heterozygous variation (c3031 C>G P.Gln1011Glu) on the exon 7 of CaSR gene was determined.
Discussion
The CaSR coding region polymorphisms involve evolutionary conserved residues with amino acid substitutions. In our patient, the polymorphysm involves non conservative changes at codon 1011. In the literature, polymorphisms of CaSR are known to be benign without an impact on serum calcium and PTH. We demonstrate an association between a polymorphism in the coding region of CaSR gene and serum calcium, PTH, 25-hydroxyvitamin D, urinary calcium excretion. Indeed, this polymorphism does not affect the BMD. This polymorphism associated with alterations in the dose-response functional modification of the receptor to Ca+2 concentrations explaining this moderate hypercalcemia.
Conclusion
Although studies showed that polymorphisms did not produce significant alterations in calcium homeostasis, it is clear that phenotypes of these polymorphisms could be variable and hypocalciuric hypercalcemia is not unexpected.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P250

**Quantification of serum 25-hydroxyvitamin D: a comparison among immunoassay, HPLC-UV, and HPLC-MS**

A. Saba[1], R. Bozic[2], G. Viccica[1], M. Maccheroni[3], L. Cianferotti[1], G. Chiellini[1], A. Raffaelli[4], R. Zucchi[1] & C. Marcocci[1]
[1]Università di Pisa, Pisa, Italy; [2]PerkinElmer Italia, Monza, Italy; [3]Azienda Ospedaliero Universitaria Pisana, Pisa, Italy; [4]Consiglio Nazionale delle Ricerche, Pisa, Italy.

Vitamin D deficiency is widespread among all age and ethnic groups. Serum 25-hydroxyvitamin D [25(OH)D] is the most reliable marker of vitamin D status. Adequate levels of serum 25(OH)D are necessary to sustain the pleiotropic effects of vitamin D, either skeletal (classical) or extra-skeletal (non-classical). Concentration levels $\geqq$50 nmol/L (20 ng/ml) are required for optimal musculoskeletal health. However, levels above 75 nmol/L (30 ng/ml) may be necessary to maximize musculoskeletal benefits and take advantage of the extra-skeletal effects of vitamin D. Traditional assays based on immunoassay display a substantial intra- and inter-assay variability (up to 30%) around the cut off limits, which may cause misclassification of individual vitamin D status. Conversely, Mass Spectrometry coupled to High Performances Liquid Chromatography (HPLC-MS) offers a high quantification accuracy. This is mainly due to its high selectivity, which reduces the contribution of interfering compounds to the final results.

Herein we report the results of measuring serum 25OHD using three different kits from DiaSorin (Liaison), Eureka (HPLC-UV), and PerkinElmer (HPLC-MS). Due to the features of MS, PerkinElmer method/kit was considered as the 'gold standard'. It involves a quick sample preparation, consisting just in the addition of stable-isotope-labeled internal standards (ISs) and protein precipitation. Quantification was performed by a tandem quadrupole mass spectrometer equipped with an atmospheric pressure chemical ionization (APCI) source, in positive ion mode and multiple reaction monitoring (MRM). Specific ISs allowed to quantify separately 25(OH)D2 and 25(OH)D3.

The analysis of about 200 blood samples, either from healthy volunteers (controls) or patients with endocrine pathologies, showed the real advantages of LC-MS/MS with respect to the other methods, consisting of a better accuracy due to the absence of cross-reactivity and the possibility of separately detect 25(OH)D3 and 25(OH)D2. The comparison results on real sample will be reported.

## P251

**Vitamin D deficiency and insufficiency and secondary hyperparathyroidism in Ukrainian population**

V. Povoroznyuk, N. Balatska, F. Klymovytsky, O. Synenky, V. Vayda, V. Muts & O. Vdovina
Institute of Gerontology NAMS Ukraine, Kyiv, Ukraine.

Introduction
Vitamin D is important for bone and muscle development, function, and preservation. The serum 25OHD concentration is the best available clinical indicator of vitamin D status. The optimal serum 25OHD concentration is considered to be that level associated with maximal parathyroid hormone (PTH) suppression.

The aim
To determine the frequency of vitamin D deficiency and insufficiency in patients of different region of Ukraine and to evaluate the influence of 25OHDto bone mineral density (BMD).

Methods
It was examined 1575 people aged 20–80 yrs. old who lived in different regions of Ukraine. 25OHD and PTH level were evaluated by electrochemiluminescence method (Elecsys 2010, Roche). Vitamin D deficiency was diagnosed in level of 25-OH vitamin D below 49.5 nmol/l, vitamin D insufficiency – between 74.5 and 50.0 nmol/l. BMD was determined by ultrasound densitometry Sahara (Hologic) and DXA (Lunar).

Results
Vitamin D deficiency was registered in 81.8% persons, 13.6% examined had vitamin D insufficiency. It was determined negative significant correlation between PTH and 25OHD ($r=-0.16$, $P<0.0000001$). Secondary hyperparathyroidism was diagnosed in 11.9% patients. The mean level of 25OHD was significantly higher in southern resident of the country ($P<0.001$) and during summer ($P<0.05$). No significant correlation between 25OHD and BMD was found. But, only patients with vitamin D deficiency had significant negative correlations between PTH level and BMD at the level of femur neck ($r=-0.12$, $P<0.004$), dual femur ($r=-0.09$, $P<0.004$), upper and lower extremities ($r=-0.11$, $P<0.01$ and $r=-0.10$, $P<0.01$ accordingly), forearm 33% ($r=-0.20$, $P<0.001$).

Summary
In Ukrainian population the frequency of vitamin D deficiency is 81.8%. Only patients with vitamin D deficiency have significant negative correlations between PTH level and BMD at the level of femur neck, dual femur, forearm 33%, upper and lower extremities.

## P252

**Prevalence of hypovitaminosis D in adult patients with hypopituitarism**

C. Di Somma, R. Esposito, M. Savanelli, E. Scarano, V. Brunelli, P.. Contaldi, M. Rubino, E. Guerra, L. Vuolo, S. Savastano & A. Colao
Federico II University, Naples, Italy.

Introduction
Italy is considered a country with high prevalence of 25 OH vitamin D deficiency. Changes in vitamin D serum levels were linked with the onset and progression of several diseases, including osteoporosis and cardiovascular diseases. The hypopituitary patients show several comorbidities like cardiovascular diseases and osteoporosis.

Purpose
To evaluate the prevalence of vitamin D deficiency in hypopituitary patients.

Patients and methods
57 patients were enrolled (27 M and 30 F), 24 with hypopituitarism and GH deficiency (GHD) and 33 non–GHD patients with hypopituitarism, aged between 30 and 80 years and 90 controls age, sex and BMI matched. In all subjects were evaluated serum levels of vitamin D, PTH, serum and urinary Ca and P. The 25 OH vitamin D levels were considered deficient when $<$20 ng/ml, insufficient when between 20–30 ng/ml and normal when $>$30 ng/ml.

Results
25 OH Vitamin D levels were lower in patients than in controls ($21.7\pm10$ ng/ml vs $31.4\pm12$, $P<0.01$). The levels of PTH, Ca, P did not differ between patients and controls. The 50% of patients vs 12% of controls had vitamin D deficiency ($P<0.01$); 28% vs 32% had vitamin D insufficiency ($P=$ns) and 21% vs 56% had normal levels of vitamin D ($P<0.01$), respectively in patiets and controls. There were no differences in both levels of vitamin D and in the prevalence of hypovitaminosis D between the 2 groups of patients ($P=$ns). In addition,Vitamin D levels were inversely related to age ($P<0.05$).

Conclusions
Hypopituitary patients show vitamin D levels lower than controls, so in these patients, vitamin D deficiency represents an additional risk factor for the hypopituitaric comorbidities such as cardiovascular disease and osteoporosis. It would therefore be advisable to ensure a vitamin D supplementation in all patients with inadequate levels.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P253

**Treatment of vitamin D insufficiency with oral loading doses of cholecalciferol**

R. Bo Jansen & O. Lander Svendsen
Bispebjerg Hospital, Copenhagen, Denmark.

Aim
To minimize the duration of vitamin-D insufficiency, current treatment regimes are initiated with an oral bolus dose of cholecalciferol. We have previously developed an algorithm (# Dekristol caps/Vigantol ml =(80 nmol/l – initial [s-25-OH-d-vit])/7 nmol/l) for determining the dosage of this bolus, aimed at reaching a serum 25-OH vitamin-D of 80 nmol/l. Our main aim was to investigate the accuracy of this algorithm.
Materials
A retrospective study of 88 patients attending the out-patient clinic with low vitamin-D status. 60 patients had been treated with a bolus dose of cholecalciferol, estimated by the algorithm, as either capsules (Dekristol, 20.000 IU/capsule) or drops (Vigantol, 20.000 IU/ml), along with supplementation treatment consisting of Unikalk Forte 2 to 4 tbl./day (1520–3040 IU). 28 patients received supplementation treatment alone (no-bolus group).
Results
The average baselines were <25–nmol/l (below the assay's detectable range) in the bolus group and 32,0 nmol/l in the no-bolus group. Follow-up samples were taken after 116 (±70) days. Both groups had received daily supplementation of cholecalciferol, averaging at 1787 IU and 1924 IU respectively. At the follow-up, the bolus group had an increase in s-25-OH-vitamin-D of 34.9 nmol/l – significantly higher ($P=0{,}005$) than in the other group (19.0 nmol/l). The bolus treated patients had a s-25-OH-vitamin-D of 55.9 nmol/l, 95% CI 46.3–58.9 – significantly lower than the desired value of 80 nmol/l ($P<0.001$).
Conclusion
Our findings suggest that our treatment regime wasn't sufficient to increase the serum 25-OH vitamin-D to 80 nmol/l. Based on present data we have developed a new algorithm incorporating patient BMI, which we plan to validate in a prospective study.

## P254

**A 10-year study of vitamin D in Moldova**

A. Voloc
State Medical and Pharmaceutical University 'Nicolae Testemitanu', Chisinau, Moldova.

For decades vitamin D by its complex action in the human organism is increasingly considered to be a hormone. Therefore, the author presents here the first complex study performed in Moldova for over 10 years examining the correlation between the vitamin D status in pregnant women, newborns, their physical development after birth, the incidence of hypocalcemic states postpartum, and the prevention of rickets within the first year of life by comparing the strategy of specific rickets prevention used in Moldova and the one recommended by the international group researching the phospho-calcic metabolism from Paris. Data on Moldovan neonates confirm the association between low 25(OH)D levels and low serum calcium and show a high frequency of vitamin D deficiency (27% with 25(OH)D levels below 25 nmol/l) in neonates born at the end of winter to mothers not supplemented with vitamin D. Our interventional study of maternal vitamin D prophylaxis shows beneficial impact on fetal growth, neonate vitamin D status and serum calcium, and on the risk to develop rickets, anemia or respiratory diseases during the first year of life of a 2.5 mg dose of vitamin D given orally to mothers on the 6th month of pregnancy. The study shows that the vitamin D status in Moldovan children is not different from that of other European children and that vitamin D prophylaxis of 'at-risk' children and adolescents should be discussed as in other European countries.
Genotypes of Moldovan children regarding variants of VDR gene's regulatory part and of the lactase gene were studied and compared with children of other European origin. Our study of VDR gene variants is the first to analyze a possible interrelation between genetic and environmental factors to achieve an optimal growth and calcium metabolism in children and adolescents.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P255

**25-Hydroxi-vitamin-D levels in clinical conditions with low plasma albumin**

E. Viragh[1], Z. Locsei[1], D. Horvath[1], T. Tornyos[1], B. Varga[1], L. Kovacs[1], G. Kovacs[2] & E. Toldy[1,2]
[1]Markusovszky Teaching Hospital of County Vas, Szombathely, Hungary; [2]University of Pecs, Pecs, Hungary.

The majority of circulating total 25-hydroxi-D-vitamin (t-25OHD) is bound to proteins – 90% to vitamin D binding protein (DBP) belonging to the alfa-2-globulin (a-2gl) fraction and 10% to albumin (ALB). Nowadays the t-25OHD level is the most accepted marker of vitamin D supply in physiological states. Our aim was to investigate the t-25OHD concentration in clinical conditions with low albumin levels.
Methods
Seventy-three patients (39 men, 34 women; mean age: 69.3±13.4 years) with low ALB or/and total protein (TP) were studied. 35 patients had chronic renal failure, 8 nephrosis, 19 cirrhosis and 11 malnutrition. The t-25OHD and intact parathormon (PTHi) were determined by ECLIA (Cobas e411, Roche), as well as calcium, TP, ALB were measured, proteinelectrophoresis was estimated (Gelelfo, INTERLAB).
Results
86% of the cases had vitamin D deficiency (<50 nmol/l), while an optimal vitamin D supply was measured in two cases only. In cases where low ALB (<34 g/l) and low TP (<64 g/l) were present simultaneously ($n=52$), significantly lower (20.8±17.3 nmol/l) t-25OHD levels were measured than in the patients with low ALB and normal TP levels ($n=21$; 36.0±26.7 nmol/l). There was a borderline positive correlation ($r=0.33$) between t-25OHD and TP and a significant ($P<0.05$) negative correlation between t-25OHD and a-2gl fraction% ($r=-0.35$). In the group of vitamin D deficient patients ($n=45$) a pathologically high a-2gl fraction was more frequently observed (71%) than in the group of patients with optimal vitamin D supply (30%).
Conclusions
Our results suggest that in clinical conditions with low ALB and TP levels – especially if hypoproteinemia is associated with an a-2gl excess – t-25OHD levels may not only depend on the vitamin D supply, but also on the presence of its binding proteins and binding capacity besides on increased t-25OHD uptake of cells.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P256

**The impact of different vitamin D preparations for the treatment of vitamin D deficiency in primary hyperparathyroidism (PTHP)**

Q. Altaf, S. Ludlam, T. Richardson, R. Kakad, A. Bates & A. Rahim
Birmingham Heartlands Hospital, Birmingham, UK.

We have previously demonstrated that 80% of patients with PTHP will have co-existing vitamin D deficiency suggesting an increased metabolism of vitamin D. There are few data assessing the impact and safety of different vitamin D preparations on calcium, parathyroid hormone (PTH) and vitamin D in this group. Here, we report the details of replacement therapy using different vitamin D preparations.
In a retrospective study of 22 (20 F:2 M and 8 Asian:14 Non-Asian) patients with confirmed PTHP and vitamin D deficiency, we assessed the impact and safety of treatment with osteo-D2 50 000 IU after four-eight weeks ($n=8$), calcium and vitamin D (e.g.Adcal-D3) twice daily for three months ($n=6$) and over the counter (OTC) vitamin D 1000 IU/day ($n=6$) or cod liver oil ($n=2$) for three months, on serum calcium, PTH and vitamin D levels.
Results
Mean (±SD) serum calcium was statistically significantly increased after treatment in the group as a whole (2.7(±0.23) vs 2.75 (±0.28) mmol/l; $P<0.05$)

and also in those treated with osteo-D2 50 000 IU (2.69($\pm$0.22) vs 2.76 ($\pm$0.25) mmol/l; *P*,0.05).
Patients with a pre-treatment calcium of $>3$ mmol/l ($n=3$), did not have a clinically significant increase in their mean serum calcium (3.18 vs 3.22 mmol/l). Eighteen of 22 patients were vitamin D replete in 2–3 months.
Conclusion
These data suggest that vitamin D repletion, regardless of the treatment regimen used, in patients with PTHP and co-existing vitamin D deficiency is safe. Moreover, treatment does not clinically significantly exacerbate hypercalcaemia for the majority of patients. We would still however, advocate close monitoring of calcium levels in these individuals. Finally, despite the increased metabolism of vitamin D in PHPT, most patients will be replete within 2–3 months regardless of vitamin D preparation.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P257

**Identification of a novel mutation in the calcium sensing receptor gene in FHH**

M. O'Cathail, D. Slattery, T. Hussain & D. O'Halloran
Cork University Hospital, Cork, Ireland.

Introduction
Familial hypocalciuric hypercalcemia (FHH) is an autosomal dominant trait comprising hypercalcemia, hypophosphatemia and an unusually low renal clearance of calcium. The vast majority of FHH is caused by loss-of-function mutations in the gene CASR, which codes for the calcium-sensing receptor (CASR). CASR is a G-protein coupled membrane receptor expressed in the parathyroid glands and the kidneys, among other tissues. It is generally asymptomatic and does not require treatment. Genetic testing for FHH-associated mutations in CASR can help to prevent unnecessary and inappropriate parathyroidectomy in patients with FHH.
Case
A 41-year-old male presented with an elevated serum calcium on routine testing. A non – tourniqued, corrected serum calcium taken showed a reading of 2.91 mmol/l, which remained elevated on repeated testing. He had no past medical history and did not take any regular medications. No symptoms of hypercalcaemia were present. There was no family history of note. Physical examination was unremarkable.
The remainder of his blood work showed a normal serum creatinine, ACE concentration, TFTs and serum protein electrophoresis. His parathyroid hormone was 58 pg/ml (reference range 10 – 65 pg/ml). A urinary calcium/creatinine ratio was abnormally low at 0.002.
Our patient subsequently underwent CASR gene testing. He was found to have a C to T nucleotide substitution in exon 7 of CASR gene (c.2254C$>$T), p.Arg752Cys (Arginine replaced with cysteine). This mutation has not been described previously.
Discussion
Given the biochemical findings it is likely this is an inactivating mutation causing FHH. The patient's mother and brother had normal serum calcium levels and were negative for CASR mutation. Unfortunately his father had died. We speculate that this is a de novo mutation causing FHH.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P258

**Vitamin D status in patients with musculoskeletal symptoms in Haryana, India**

S. Kalra & B. Kalra
BRIDE, Karnal, India.

This cross sectional single centre study was performed at an endocrine center in northern India (latitude 29°42′N and longitude 77°02′E) to assess the prevalence of vitamin D deficiency in 234 symptomatic women presenting with musculoskeletal symptoms. The study was conducted during winter (Nov 2010–Jan 2011).
Subjects were recruited from patients attending the OPD for various musculoskeletal symptoms. Inclusion criteria were symptomatic women, without known renal or hepatic disease or malignancy. Patients with history of surgery, hospitalization, or major medical illness within the past one year were excluded from the study. Patients on hormone replacement therapy, glucocorticoids, biophosphonates, teriparatide and other drugs affecting bone metabolism were excluded.
Intake of conventional calcium/vitamin D supplements was not considered an exclusion criterion. Only patients living at the same location, in Karnal district, for at least one year were included. All subjects enrolled after taking a written informed voluntary consent.
The cohort comprised of 165 urban dwellers (70.51%) and 69 (29.48%) rural dwellers. 171 (73.07%) were of Hindu religion, with the rest 63 being Sikh (26.92%). All women wore traditional Indian dress of sari or salwar-kameez. None of them observed purdah. All but 21 (8.97%) were vegetarian. The average age was 45.43$\pm$11.72 years (range 18.0 to 65.0 years).
Twenty-five (10.68%) had hemoglobin below 10 g%. Serum calcium levels were below 8.5 mg% in 24 subjects (10.25%), and were raised (above 10.5 mg%) in one (0.427%). Serum phosphorus was normal in all. Serum alkaline phosphatase was raised in 32 (13.67%) patients.
25-Hydroxy vitamin D levels measured $<10$ mg/ml in 130 subjects (55.55%) and between 10 and 30 mg/ml in 90 subjects (38.46%). Thus, the prevalence of vitamin D deficiency and insufficiency was 94.01% in this cohort of north Indian patients with musculoskeletal complaints. This was significantly higher than the 66.7% prevalence of Vitamin D deficiency/insufficiency reported in healthy asymptomatic postmenopausal women from the same centre.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P259

**Evaluation of the platelet functions in hyperparathyroid patients**

G. Yorulmaz[1], A. Akalin[2] & M. Akay[2]
[1]Batman State Hospital, Batman, Turkey; [2]Eskisehir Osmangazi University, Faculty of Medicine, Eskisehir, Turkey.

Introduction
Coagulation and fibrinolysis defects were reported in primary hyperparathyroid(PHPT) patients. However, there is not enough data regarding platelet functions in this group of patients. Platelet functions of hyperparathyroid patients were measured in very few studies and they have conflicting results. Our aim was to evaluate the platelet functions in primary and secondary hyperparathyroid(SHPT) patients and to compare it with the healthy subjects.
Material and methods
In our study 25 subjects with primary hyperparathyroidism and 25 subjects with secondary hyperparathyroidism and 25 healthy control subjects were included. Platelet functions of the subjects were evaluated by using platelet rich plasma and platelet aggregation tests with epinephrine, ADP, collagen and ristosetin. Also, serum P selectin levels that indicates platelet activation level were measured in all subjects.
Results
There was no significant difference between the groups with PHPT, SHPT and the control group regarding the platelet aggregation tests. Also,there was no significant correlation between parathormone levels and aggregation parameters and between P selectin levels. When we separated the group of subjects with high serum calcium levels, there was also no significant correlation between aggregation parameters and serum calcium levels. We could not find any significant correlation between p selectin levels and serum calcium levels in this group of patients.
Conclusion
There is no significant effect of primary and secondary hyperparathyroidism and serum calcium levels on platelet functions evaluated with aggregation tests.

**The relation between endocrine and radiological changes in adolescents with vitamin D deficiency**

A. Soliman & E. Bedair
Hamad Medical Center, Doha, Qatar.

Vitamin D deficiency causes rickets in children and osteomalacia in adolescents. Rickets cases are still being reported in the Arab gulf area and worldwide. The clinical spectrum ranges from subclinical (asymptomatic) form to severe symptoms and signs including progressive bone pains, myopathy, waddling gait and bone deformities.

We recorded the clinical, biochemical and radiological data 50 adolescents with severe vitamin D deficiency. Clinical symptoms included pain in weight bearing joints, back, thighs, knees, and calves (36/50) difficulty walking and/or climbing stairs and/or running (12/50), muscle cramps and/or facial twitches and/or carpopedal spasms (21/50). Significant inverse correlation was detected between serum 25OHD and PTH concentrations ($r=0.447$, $P<0.01$). Two radiological patterns have been identified. In pattern (I) ($n=8$),(Fig -right) the lesions appear as metaphyseal multilocular cystic lesion with sclerotic margins, located subcortically without significant cortical erosions, periosteal reaction, osteoporosis or other metaphyseal manifestations. Whereas pattern (II) ($n=18$)(fig -left) appears as generalized diminished bone density with prominent primary and secondary bone trabeculations, widening of the metaphyseal zone with relatively more lucency (loss of all bone trabeculations). Patients with pattern I had significantly higher body mass index and insulin- like growth factor-I (IGF-I) levels compared to those with pattern II (left). Complete healing of the radiological evidence of both patterns was achieved in all patients after one to 2 years of vitamin D therapy.

**Remember calcium! Fahr's syndrome diagnosed after repeated generalized seizures: a case report**

I. Ruza[1,2] & I. Leitane[1]
[1]Tornakalna Outpatient Clinic, Riga, Latvia; [2]Riga East Clinical University Hospital, Riga, Latvia.

Introduction
Idiopathic calcification of basal ganglia (Fahr's syndrome) is a rare pathology, mostly incidental finding or familial origin, characterized by cognitive, behavioural and motor impairment, as well as by metabolic changes, such as primary hypoparathyroidism.
Report
We report a case of a 59-years old white lady who was referred to our clinic for an evaluation due to suspected Fahr's syndrome. She had a 20 years long history of moderate radicular low back pain, progressive numbness in hands and feet during last 7 years. Two months before presentation the patient was hospitalized in emergency room (ER) due to a first-time generalized seizure followed by unconsciousness. Biochemical tests had shown normal serum glucose, creatinine, potassium, elevated liver enzymes and creatine kinase. Brain CT scan had demonstrated changes consistent with Fahr's syndrome – diffuse symmetrical parenchymal calcifications, including basal ganglia, subcortical regions of cerebral white matter and cerebellum. After discharge patient was seen by neurologist, but only treatment for vertigo has been prescribed. Multiple blood testing was repeated, but no calcium (Ca) or parathormone (PTH) was checked, fatigue progressed.
Two months after initial episode patient had a sudden fall with unconsciousness and was hospitalized, more detailed investigation was done, showing severe hypocalcaemia, hyperphosphataemia, undetectable PTH level and hypocalciuria. No cognitive or significant motor changes were observed. Chvostek's and Trousseau's signs were negative. In her past history bilateral cataract was diagnosed and operated 7 years ago. Secondary reasons of Fahr's syndrome were excluded. Family history showed no possible hereditary disease.
Based on these findings, diagnosis of Fahr's syndrome and primary hypoparathyroidism was done. Treatment was started with intravenous Ca and followed with oral calcitriol and Ca supplementation, showing gradual improvement in biochemical tests. In spite of a regular treatment, three years later the patient still has low serum Ca and PTH, high phosphates, but urinary electrolytes are normal, hand and feet numbness has disappeared and she has not experienced any seizures.
Conclusion
We would like to stress the importance of mandatory testing of Ca, phosphates and PTH in all patients with seizures or unexplained episodes of unconsciousness.
Declaration of interest

**Assessment of vitamin D 3 status in general population**

E. Puca[1], S. Bitri[1], A. Ylli[2] & E. Puca[2]
[1]American Hospital II, Tirana, Albania; [2]UHC 'Mother Teresa', Tirana, Albania.

Objective
The purpose of this study was to investigate the 25-hydroxyvitamin (25(OH)D3) levels in general population.
Introduction
Vitamin D is important for normal bone health. Vitamin D deficiency is a well-known cause of rickets in children and osteomalacia in adults, and it is also of importance for development of osteoporosis. Beyond this, vitamin D deficiency is suggested as a contributing factor in the development of several other diseases and conditions such as diabetes, some cancer types and immunologic diseases.
Materials and methods
We targeted 40 cases who participated in an annual health check-up from September 2011 until December 2011. In our evaluation we defined levels of 25-hydroxyvitamin D3 $<25$ ng/ml as vitamin D deficiency.
Results
The study consisted of 40 adults (35 women (83.4%)) and 5 men (16.6%)) with a mean age $49.66\pm18.22$DS, range from 16–76 years, and body mass index 28.5kg/m$^2$. Mean serum 25(OH)D3 concentration was 17.33 ng/ml. Using a cut-off point of 25 ng/ml, Seventy- two point five (72.5%) of this population had low vitamin D status. The highest 25(OH)D3 concentration was 47.24 ng/ml. We found vitamin (25(OH) D3 $<$ 10 ng/ml) in 40% of our cases. Mean serum level of calcium was normal 9.33 mg/dl (normal range 8.4–10.4). The level of calcium didn't correlated with low level of Vitamin D3.
Conclusion
Vitamin D deficiency was prevalent in our ambulatory patients. Based on our results, we feel that national recommendations for vitamin D intake should be increased in our country. During the study most of the days were sunny.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P263

**Unrecognized severe vitamin D deficiency**

Z. Visockiene[1], R. Juskiene[1] & L. Augutiene[2]
[1]Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania;
[2]Ukmerges Central Hospital, Ukmerge, Lithuania.

Introduction
Vitamin D deficiency is a common disorder and may manifest as a musculoskeletal, neurological, mental disorder or neoplastic disease.
Case report
A 47 year old woman of Caucasian origin suffered from back, muscle, bone pain and severe depression for 8 years. She was ineffectively treated at the departments of Neurology, Psychiatry, Pain Clinic several times a year. Brain, bone CT, internal ultrasound, routine biochemistry analyses were normal. X-Ray – lumbar spine osteochondrosis, spondylosis. Finally, she could hardly walk due to muscle weakness and cramps, when ionized calcium (Ca+2) was measured for the first time. With the severe hypocalcemia (Ca+2 0.62 mmol/l (*n* 1.05–1.3)) she was admitted to the Endocrinology Department. Further investigations confirmed secondary hyperparathyroidism with the 'empty bones' syndrome and osteoporosis due to severe longstanding vitamin D deficiency with the plasma alkaline phosphatase (ALP) of 425 U/l (*n* 40–150), phosphorus of 0,99 mmol/l (*n* 0.74–1.52), 24 hour urine Ca of 0.6 mmol/24 hours (*n* 2.5 – 7.5), parathyroid hormone (PTH) of 94.9 pmol/l (*n* 1.2–7.3), serum 25-hydroxyvitamin D of <4 ng/ml (local laboratory reference range 20–32). 99mTC-sestamibi parathyroid and whole body scintigraphy revealed no pathology, spinal Dual-emission X-ray absorptiometry showed T score of −5.3 at L2-L4. The patient was treated with intramuscular cholecalciferol 200 000 U followed by oral alfacalcidol 1 μg/day and oral calcium carbonate 3 g/day for six months. During the follow up period the analyses improved gradually resulting in Ca+2 of 1.09 mmol/l, ALP of 129 U/l, PTH of 10.6 pmol/l. The patient's overall condition improved significantly.
Conclusions
Severe vitamin D deficiency may remain unrecognised for many years, mimicking other disorders and leading to severe disability. Thus it has to be considered in all cases of unexplained, treatment resistant pain and weakness even the subject does not belong to the risk group.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P264

**Evaluation of clinical and laboratory findings of our primary hyperparathyroid patients**

H. Baser[1], D. Tuzun[1], A. Usluogullari[1], C. Aydin[1], R. Ersoy[2] & B. Cakir[2]
[1]Ankara Ataturk Training and Research Hospital, Ankara, Turkey;
[2]Yildirim Beyazit University, Faculty of Medicine, Ankara, Turkey.

Aim
In this study our aim was to evaluate clinical and laboratory findings of our primary hyperparathyroid patients and detect complications caused by hyperparathroidism.
Method
Eighty-three patients (73 women, 10 men) were included in this study. Serum calcium (Ca), phosphorus (P), parathormone (PTH), 25(OH) D, 24 hour urine Ca and P levels, bone mineral density (BMD) and renal ultrasonography were evaluated.
Results
The mean age at diagnosis was 52.4±9.6 years. The mean serum Ca level was 10.47±0.67 mg/dl, serum P level was 2.85±0.50 mg/dl, PTH level 254.12 ±140.72 pg/ml, 25-OH vitamin D3 level was 22.97±16.15 μg/l. Serum Ca was <11 mg/dl in 66 patients (%19.3), 11–12 mg/dl in 16 patients, >12 mg/dl in one patient. Mean 24 hour urine Ca was 354.52±177.23 mg/day, P was 868.42 ±385.86 mg/day. Hypercalciuria was detected in 27 patients (%32.5) while nephrolithiasis was determined in 17 patients (%20.5). In 16 patients (%19.3) BMD was normal. In 31 patients (%37.3) osteopenia, in 36 patients (%43.4) osteoporosis was determined. Vit D deficiency was found in 38 patients (%45.8). With these results operation was recommended to 44 patients (%47).
Conclusion
In recent years primary hyperparathyroidism is detected in asymptomatic phase and fewer complications are found. One of the factors that contribute to low bone density in patients with hyperparathyroidism may be lack of Vit D.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Experience in the treatment of primary hyperparathyroidism with cinacalcet: Preliminary data**

I. Luque-Fernández[1], A. García-Martín[2], A. Luque-Pazos[1], J. Sastre-Marcos[1], A. Marco-Martínez[1], A. Vicente-Delgado[1] & V. Peña-Cortés[1]
[1]Virgen de la Salud Hospital, Toledo, Spain; [2]Hospital Universitario San Cecilio, Granada, Spain.

Introduction
Cinacalcet is an oral calcimimetic indicated in treatment of primary hyperparathyroidism if patients do not accept surgery, do not carry out the surgical criteria, there is failure of previous surgery or serious comorbidity that makes surgery impossible.
Methods
Descriptive study that included 34 patients with primary hyperparathyroidism treated with cinacalcet. We recorded clinical and biochemical data before and after 6 months of treatement, dose and time of treatment, and adverse events.
Results
Median time of treatment was 10 months (2–42 months). 24 patients complete 6 months of treatment. Reasons for treatment with cinacalcet were 8 patients refusal to parathyroidectomy, 4 surgery not possible due to comorbidities and 21 progressive hypercalcemia prior to surgery. Cinacalcet initial dose was 30 mg/12 hours in 94% and 30 mg/24 h in 6%. Serum calcium level decreased significantly from 11.6±0.9 mg/dl at baseline to 10.1±0.9 mg/dl ($P<0.01$) at six months; also did serum phosphorus level (2.4±0.35 mg/dl to 2.75 ±0.35 mg/dl p <0.01) whereas serum PTHi level did not differ significantly before and after treatment (150±101.96 pg/ml vs 162,6±120.79 pg/ml $P=0.583$). Normocalcemia (S-Ca <10.1 mg/dl) was achieved in 44.1% of patients.
Most common adverse events were nausea and vomiting, especially at the beginning of therapy (8.8%). 4 required dose decrease and 3 withdrawal of treatment.
Conclusion
Cinacalcet is an effective alternative in non-surgical treatment of primary hyperparathyroidism in patients with recurrent disease or in case of surgical contraindications. Furthermore, cinacalcet may be useful in the preoperative hypercalcemia management.

**Primary hypoparathyroidism presenting as adult onset seizure: a report of two cases**

T. Varma, R. Panchani, A. Saini, S. Tripathi, N. Gupta & S.. Kumar
Sir Gangaram Hospital, New Delhi, India.

Introduction
Primary Hypoparathyroidism presents most commonly in childhood to early adolescence. Disease may be familial or sporadic.Most commonly hypoparathyroidism is secondary to neck operations especially Thyroid surgeries. Primary can be congenital eg- Digeorge syndrome or inherited by AD, AR or X linked mediated.We report 2 cases of late onset seizure due to Digeorge syndrome and Autosomal Dominant Hypoparathyroidism in a elderly lady.
Case Reports
Case 1
Twenty-seven year old female was brought with statue epilepticus and had hypocalcemia.CT Scan brain showed basal ganglia calcification.She also had mental retardation, cleft palate, posterior tongue tie and recurrent infections. Biochemical profile suggestive of severe hypocalcemia with bicytopenias. FISH for 22qdel11 was positive and diagnosis of Digeorge syndrome was made.

Case 2
Fifty-six year old lady presented with GTCS for first time. She was evaluated and found to have basal ganglia calcification and hypocalcemia.On evaluation her daughter and grand children also had asymptomatic hypocalcemia.
Conclusion
Chronic hypocalcemia may present with seizure, cognitive symptoms or psychiatry symptoms in most of the patients. All these symptoms show marked improvement with treatment. Prevalence of unrecognized Primary hypoparathyroidism in adults is very rare. It is important to evaluate serum calcium in all patients who present with new CNS symptoms.

## P267

**Vitamin D status in primary hyperparathyroidism**

M. Yazidi, I. Kammoun, R. Ben Said, G. Gharsallah, E. Haouet, Z. Turki & C. Ben Slama
Nutrition National Institute, Tunis, Tunisia.

Vitamin D deficiency seems to be more prevalent in patients with primary hyperparathyroidism (PHPT) than in general population. This association has many clinical and therapeutic implications.
The aim of this study was to assess the vitamin D status of patients with PHPT and to describe the clinical presentation of the disease when vitamin D deficiency is associated.
Methods
We studied in a retrospective manner, the case of seven patients (three men and four women) admitted to our department during the year 2011, for PHPT. During their hospitalization, serum calcium, parathyroid hormone (PTH) and 25-hydroxyvitamin D (25OHD) were measured concomitantly. A bone densitometry was performed for each patient.
Results
The mean age of our patients was $60.8 \pm 7.8$ years. Bone pain revealed the disease in three cases. The mean serum level of calcium was $2.9 \pm 0.4$ mmol/l. Mean PTH concentration was $384.2 \pm 378.7$ pg/ml. The mean serum level of 25OHD was $7.3 \pm 3.3$ µg/l. All the patients had vitamin D deficiency (25OHD $<$ 15µg/l). A single adenoma was localized in four patients with a mean size of $35 \pm 4.5$ mm. Bone densitometry revealed osteoporosis in one patient, osteopenia in 4 patients and was normal in two patients. Renal complications were present in three patients. Other complications (cardiovascular, neuropsychological and digestive complications) were found in three patients.
Conclusion
Our study suggests that vitamin D deficiency is very common in patients with PHPT. Thus, the assessment of vitamin D status should be done in all these patients because the disease seems to be more severe when vitamin D deficiency coexists and the risk of post operative hypocalcemia and hungry bone syndrome is higher.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P268

**Vitamin D deficiency repletion in patients with co-existing vitamin D deficiency and primary hyperparathyreoidism: pro for early postoperative or preoperative treatment: case reports**

D. Tesic, B. Kovacev-Zavisic, M. Mitrovic, N. Curic & R. Mijovic
Clinical Centre of Vojvodina, Novi Sad, Serbia.

The aim of this work is to present two patients with vitamin D deficiency and primary HPT.
A 51-year old woman (first refer, 2009-jul) was operated for pathohistologically confirmed parathyroid (PT) adenoma seen by ultrasound (US) and scintigraphy (Sc). Patient treated for previous years for hypertension and depression. Calcium (Ca; mmol/l): 3.1; Creatinine (Cre; µmol/l): 67. The results will be shown in following order: pre-/postoperatively, 3rd month, 27th m. (– / –, –, –). Symptoms of depression (yes/yes, yes, without). Ca (ionized; mmol/l): 1.53–1.81/1.0, 1.15, 1.11. Ca (Urine; mmol/d): 7.53/–, 0.81, –. Parathormone (PTH; pg/ml): 488/280, 372, 38.9. VitD3(25OH) (nmol/l): 24.5/–, 10, 51. US of the abdomen: bilateral nefrocalcinosis and nefrolithiasis, BMD (g/cm2) L1-4 T score: $-3.7$ / –, –, $-2.8$. Serum CrossLaps (CL; pg/ml): 2197/–, 521, –. Osteocalcin (OC; ng/ml): 171/–, 45.6, –. Therapy with 1α-OHvitD3 (µg/day): –/0.25, 1.0, 2.0. Second patient a 76-year old man (first presentation, 2011-may) with Sc accumulation in PT, US undetectable PT hipoehogenicity, aortocoronary bypass (2006), Cre 154 µmol/l (Adult Polycystic Kidney Disease), BMD (g/cm2) L1-4 T score: $-0.5$, CL(pg/ml): 243, OC(ng/ml): 22.6. The results: the first visit, after 4 m (–, –). Ca (ionized; mmol/l): 1.33, 0.94. PTH (pg/ml): 244.9, 74.4 (2009-Oct: 169.5). VitD3(25OH) (nmol/l): 13, 10 Therapy with 1α-OHvitD3 g/day: –, 2.0.
Discussion
The chronic vitD deficiency lead to adenoma growth or growth of preexisting adenoma. Adenoma size were not in relationship with 25(OH)D similar as we seen in Indian vs. American patients. Disease stability (Ca, Cre levels) will determine the length and dosage of conservative (nonsurgical) treatment in man with normocalcemic HPT and woman with 'hungry bones'. Losing symptoms of weakness and anxiety only three months after the booster dose of vitD could be the direct effect on the brain tissue.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Testosterone replacement therapy inhibits key enzymes of fatty acid synthesis in mouse liver**

J. Brooke[1,2], D. Kelly[1], S. Akhtar[1], V. Muraleedharan[1,2] & T. Jones[1,2]
[1]University of Sheffield, Sheffield, UK; [2]Barnsley Hospital, Barnsley, UK.

Fatty liver (Hepatic Steatosis) is common in men with type 2 diabetes mellitus (T2DM). Furthermore there is a high prevalence of testosterone deficiency (up to 40%) in this population. Testosterone replacement therapy (TRT) has been shown to reduce elevated serum liver transaminase levels in hypogonadal men. The testicular feminised (Tfm) mouse exhibits a non-functional androgen receptor (AR) and low circulating testosterone levels. We have previously shown that a high-fat diet promotes hepatic steatosis in the Tfm mouse and TRT attenuates

these changes. Our objectives were to determine the effect of testosterone on the key regulatory enzymes of fatty acid synthesis in mouse liver.
Tfm mice were fed a high-fat diet for 28 weeks and received either physiological testosterone replacement (Tfm + t, $n = 12$) or placebo (Tfm + p, $n = 12$) and were compared to wild-type (XY, $n = 12$) littermates. Relative concentrations of mRNA were analysed by qPCR for expression of Fatty Acid Synthase (FAS) and Acetyl-CoA Carboxylase (ACC). Protein expression was analysed by western blotting.
There was an increase in mRNA expression of FAS (Relative fold increase 11.4 $\pm$4.93, $P = 0.06$) and ACC (2.5 $\pm$ 0.64, $P = 0.05$) in the Tfm mice compared to wild-type littermates. In the Tfm + t group, mRNA expression was significantly reduced for FAS, but ACC showed a non-significant decrease relative to the Tfm + p group. Western blotting densitometry confirmed that the Tfm + p group had significantly increased levels of ACC (3.47 $\pm$ 0.27 vs 1.22 $\pm$ 0.22, $P < 0.001$) and FAS (2.43 $\pm$ 0.37 vs 0.88 $\pm$ 0.22, $P = 0.002$) protein expression compared to XY wild-type. In the Tfm + t group ACC protein decreased to a level comparable to the XY wild-type (1.53 $\pm$ 0.21 vs 1.22 $\pm$ 0.22, $P = 0.30$) as did FAS (0.88 $\pm$ 0.22 vs 0.89 $\pm$ 0.17, $P = 0.97$).
This is the first evidence to show that a testosterone deficient state is associated with increased FAS and ACC expression which promotes hepatic steatosis, and TRT suppresses both enzymes. This beneficial action of testosterone is independent of the androgen receptor.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P270

**Effect of testosterone on hepatic liver X receptor and ApoE expression as a potential mechanism of atheroprotection in the testicular feminised mouse**

D. Kelly[1], S. Akhtar[1], J. Brooke[1], K. Channer[2] & T. Jones[1,3]
[1]University of Sheffield, Sheffield, UK; [2]Sheffield Teaching Hospitals, NHS Foundation Trust, Sheffield, UK; [3]Barnsley Hospital NHS Foundation Trust, Sheffield, UK.

Testosterone deficiency is associated with several cardiovascular risk factors. Testosterone replacement therapy (TRT) improves insulin sensitivity, inflammation and cholesterol. Liver X receptor (LXR) is a nuclear receptor which regulates lipid and glucose metabolism, stimulates cholesterol efflux and ApoE, and suppresses inflammation. LXR agonists cause hepatic steatosis but protect against atherosclerosis. TRT attenuates high-cholesterol diet-induced hepatic steatosis in the testicular feminised mouse (Tfm), (which exhibit non-functional androgen receptors and low circulating testosterone) independent of androgen receptor (AR) function. This study investigates the effect of testosterone on LXR and ApoE expression in the Tfm mouse model.
Tfm mice were fed a high-cholesterol diet ad libitum for 28 weeks and received either physiological TRT (intramuscular mixed testosterone esters) or placebo (saline) and were compared to wild-type littermates. Liver tissue was collected and relative concentrations of mRNA and protein were analysed by qPCR and western blotting for expression of Liver X receptor (LXR), as well as Apolipoprotein E (ApoE).
The relative expression of LXR mRNA was significantly decreased in the Tfm mouse compared to wild type littermates (WT) (Relative fold change 0.7 $\pm$ 0.09 SEM, $P = 0.011$) and there was a non-significant decrease in ApoE (0.82 $\pm$ 0.1, $P = 0.07$). Following TRT, mRNA expression increased for LXR (1.3 $\pm$ 0.2 $P = 0.03$) and ApoE (1.2 $\pm$ 0.12, $P = 0.03$) in Tfm mice compared to placebo. Western blot analysis confirmed reduced LXR (0.16 $\pm$ 0.03 vs 0.07 $\pm$ 0.01, $P = 0.05$) and ApoE (3.07 $\pm$ 0.4 vs 2.45 $\pm$ 0.2, $P = 0.029$) protein expression in Tfm mice compared to WT. Following TRT ApoE protein expression increased to wild-type levels (2.92 $\pm$ 0.5 vs 3.07 $\pm$ 0.4, $P = 0.89$), however LXR protein expression was not significantly altered compared to Tfm placebo mice (0.05 $\pm$ 0.0 vs 0.07 $\pm$ 0.01, $P = 0.34$).
This is the first study to demonstrate that testosterone deficiency is associated with decreased expression of LXR and ApoE. TRT increased ApoE and LXR mRNA expression as well as ApoE protein expression, suggesting AR-independent actions. The atheroprotective action of testosterone may in part be mediated through activation of LXR and ApoE.

## P271

**The effect of potassium supplementation on the endothelium, the renin-angiotensin-aldosterone system (RAAS) and blood pressure in patients at moderate cardiovascular disease risk**

U. Graham[1], D. McCance[1], I. Young[2] & K. Mullan[2]
[1]Royal Victoria Hospital, Belfast, UK; [2]Queen's University, Belfast, UK.

There is limited evidence on the effect of potassium (K+) supplementation on endothelial function. Three studies suggest a beneficial effect in healthy volunteers and mild hypertensives. However potassium increases aldosterone due to a direct effect on the adrenal gland and there is evidence that aldosterone excess is detrimental to cardiovascular health. We therefore aimed to determine the effect of potassium supplementation on endothelial function in patients with >10% cardiovascular disease risk. We also aimed to determine the effect of potassium supplementation on brachial and central blood pressure, the RAAS and vascular inflammation.
Forty patients with >10% ten year cardiovascular disease risk were included in a randomised placebo controlled crossover study. Drugs which interfere with the RAAS were stopped and blood pressure controlled with doxazosin. Patients were assigned to either 64 mmol potassium chloride or placebo for 6 weeks with a 6 week washout period. Endothelial function was assessed using global pulse wave analysis (PWA) involving the detection of a change in augmentation index to salbutamol (endothelial dependent) and GTN (endothelial independent) induced vasodilation. Vascular inflammation was assessed using high sensitivity C-reactive protein (hsCRP).
K+ supplementation improved brachial and central systolic blood pressure ($P = 0.013$ and 0.011 respectively) but did not affect endothelial function or hsCRP. Plasma renin activity ($P = 0.048$) and serum aldosterone ($P = 0.001$) both increased significantly with K+ supplementation compared to placebo. Serum K+ increased with supplemental K+ vs placebo (4.1 vs 3.9 mmol/l; $P = 0.012$) but hyperkalaemia did not develop.
These data show that K+ supplementation lowered systolic blood pressure. Interestingly K+ supplementation was associated with an increase in both plasma renin activity and serum aldosterone suggesting that K+ may also stimulate the RAAS via the juxtaglomerular apparatus. Despite this rise in aldosterone K+ supplementation did not affect global PWA or hsCRP.

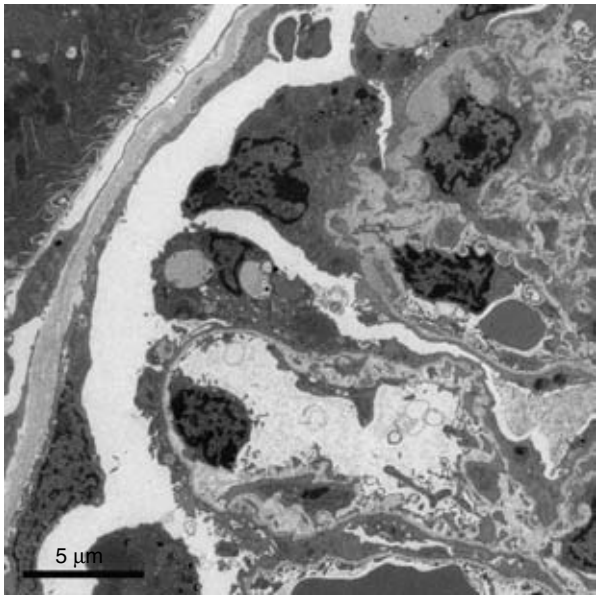
**(Pro)renin Receptor is essential for filtration barrier in glomerular podocyte**

K. Kinouchi[1], A. Ichihara[2], Y. Oshima[1], H. Kurosawa[1], G. Sun-Wada[3], Y. Wada[4], T. Yamada[5], M. Takemoto[6], M. Saleem[7], S. Quaggin[8] & H. Itoh[1]
[1]Keio University School of Medicine, Tokyo, Japan; [2]Tokyo Women's Medical University, Tokyo, Japan; [3]Doshisha Women's College, Kyoto, Japan; [4]Osaka University, Osaka, Japan; [5]Keio University School of Medicine, Tokyo, Japan; [6]Chiba University Graduate School of Medicine, Chiba, Japan; [7]University of Bristol, Bristol, UK; [8]University of Toronto, Toronto, Ontario, Canada.

Backgrounds
Podocytes are highly specialized postmitotic kidney cells that contribute to maintaining the filtration barrier and normal structure of glomerular capillaries. The (pro)renin receptor (PRR), as ATP6AP2, is an accessory subunit of the vacuolar H+-ATPase (V-ATPase), implying more fundamental, developmental functions for the PRR in addition to its role in activating the local renin-angiotensin system.
Results
Podocyte-specific conditional (P)RR knockout (CKO) in mice resulted in lethal kidney failure with severe proteinuria, with CKO mice dying within 4 weeks of birth. The histologic examination revealed that as early as on postnatal day 7, the podocytes of CKO mice exhibited foot process effacement and numerous

autophagic vacuoles, along with focal and segmental mesangium cell proliferation. This was confirmed by reduction and altered localization in nephrin and podocin expression, as well as increased expressions of RAB7, lysosomal-associated membrane protein 2 (LAMP2), and microtubule-associated protein 1 light chain 3 (LC3) in CKO podocytes. Notably, over the course of development in CKO mice, nephrin expression became discontinuous and was seen mainly in the cytosol of podocytes. The number of cells positive for WT1, a nuclear marker for podocytes, was significantly fewer in glomeruli from CKO mice on postnatal day 20, implying increased podocyte cell death or detachment from basement membrane. *In vitro* analysis revealed that the treatment with the siRNA knocking down of PRR/ATP6AP2 reduced the protein expression of nephrin in the human cultured podocytes despite the up-regulation of NPHS1 mRNA expression. Also, the inhibition of PRR expression selectively suppressed expression of VO subunit c of the V-ATPase in podocytes, resulting in deacidification of the intracellular vesicles and increased autophagic vacuoles.
Conclusions
A deficiency of the PRR in podocytes resulted in impaired expression of slit diaphragm proteins and increase in the late endosomes, lysosomes, and autophagosomes, due to V-ATPase dysfunction.



Electron microscopic examination of kidneys from conditional (pro)renin receptor-knockout (CKO) mice on postnatal day 14. Kidneys from CKO mice were found to contain prominently enlarged podocytes with extensive foot process effacement and actin filament aggregation. Numerous electron-dense autophagic vacuoles containing partially digested cellular components were observed in the cytoplasm of these podocytes. Mesangial matrix expansion was also noted in CKO glomeruli.

### Testosterone replacement therapy: a safety audit of clinical practice including men with Type 2 diabetes and cardiovascular disease

J. Brooke[1,2], D. Walter[1,2], V. Muraleedharan[1,2] & T. Jones[1,2]
[1]University of Sheffield, Sheffield, UK [2]Barnsley Hospital, Barnsley, UK.

Hypogonadism is highly prevalent in men with type 2 diabetes (T2D) and/or cardiovascular disease (CVD). Low testosterone levels are associated with CVD risk factors including obesity, insulin resistance, dyslipidaemia and hypertension. Testosterone replacement therapy (TRT) has been shown to have beneficial effects on these parameters; however, safety needs to be verified. An audit of 308 (50% with T2D, 32.1% CVD, 82.8% ED) hypogonadal men (age 59.02±13.23 years; mean baseline testosterone 7.33±2.85 nmol/l) receiving physiological TRT (86.3% testosterone gels) for up to 27 (mean 4.6±0.10) years in normal clinical practice. BMI, waist circumference, BP, Hb, haematocrit (Hct), lipid profile, liver function, testosterone, estradiol and PSA levels were monitored at 3, 6 and 12 months and yearly thereafter. Hospital admissions, major adverse cardiovascular events (MACEs) and mortalities were recorded.
TRT was associated with a reduction in total cholesterol (−0.26±0.11 mmol/l, $P=0.018$), non-fasting triglycerides (−0.30±0.14 mmol/l, $P=0.033$), liver transaminases (ALT and AST), HbA1c (−0.32% in whole cohort, $P=0.05$) at the primary endpoint. In diabetics with HbA1c >7.0% at baseline; HbA1c sharply fell: 8.65% vs 7.65%, $P<0.001$, $n=151$ after 3 months and 8.65% vs 6.74%, $P<0.001$ after five years with few changes in diabetic medications. HDL-cholesterol fell by 0.06 mmol/l ($P=0.04$). Hb increased by 0.63 g/dl ($P<0.001$), hematocrit by 0.02 ($P<0.001$) and PSA by 0.24 g/l ($P=0.038$). No significant changes in BMI, waist circumference or BP were observed. Adverse events: Hct exceeded 0.52 in eight cases, two new prostate carcinomas, two deaths, 13 MACEs (2 MIs, 2 angina, 5 TIAs, 2 CVAs, 1 CABG and 1 CCF) and 34 hospital admissions. This audit demonstrates that in over 1033 patient years, physiological TRT had beneficial effects on cardiovascular risk factors including glycaemic control, lipids and total cholesterol levels. Importantly, long-term TRT was not associated with any increase in prostate carcinoma, MACEs or mortality over that expected in this morbid population.

### Thyroid axis hormones and cortisol are associated with subjective fatigue in patients with coronary artery disease

A. Bunevicius[1,2], V. Gintauskiene[2], J. Brozaitiene[2], A. Prange[1] & R. Bunevicius[2]
[1]University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, USA; [2]Lithuanian University of Health Sciences, Palanga, Lithuania.

Introduction
Subjective fatigue is a common symptom in patients with coronary artery disease (CAD) and has a significant negative effect on quality of life of CAD patients. However, currently there are no studies evaluating possible association between endocrine measures and subjective fatigue in CAD patients. Therefore the aim of the current study was to evaluate possible associations of subjective fatigue with function of adrenal axis and thyroid axis in CAD patients.
Methods
Eighty-three CAD patients (65 men, 18 women; aged 55±9 years) attending a rehabilitation program within two weeks after inpatient treatment for acute coronary syndromes were evaluated for demographic and clinical characteristics, for subjective fatigue using the Multidimensional Fatigue Inventory and Dutch Exertion Fatigue Scale, for depressive and anxiety symptoms using the Hospital Anxiety and Depression Scale, and for serum concentrations of free tri-iodothyronine (T3), free thyroxine (T4), morning cortisol, afternoon cortisol and change in cortisol concentrations (delta-Cortisol).
Results
In univariate regression analysis lower free T4 concentrations were associated with greater general fatigue and exertion fatigue; lower free T3 concentrations were associated with greater general fatigue and physical fatigue; and lower delta-Cortisol was associated with greater mental fatigue.
After adjusting for age, gender, body mass index, hypertension, previous myocardial infarction, heart failure, New York Heart Association functional class, depressive and anxiety symptoms, lower free T3 concentrations remained associated with greater physical fatigue ($\beta=-0.224$, $P=0.03$); lower free T4 concentrations - with greater exertion fatigue ($\beta=-0.219$, $P=0.03$); and lower morning cortisol concentrations - with greater mental fatigue ($\beta=-0.193$, $P=0.03$).
Conclusions
In CAD patients function of adrenal axis and thyroid axis are associated with subjective fatigue independently from cardiac functional class or symptoms of depression and anxiety. Specifically, decreased thyroid hormone concentrations are associated with greater physical fatigue and greater exertion fatigue; and decreased cortisol concentrations are associated with greater mental fatigue.

## P275

**Familiar hypercholesterolemia: effects of treatment with rosuvastin**

I. González-Molero, M. Domínguez López, M. Gonzalo Marín & F. Soriguer
Carlos Haya Hospital, Málaga, Spain.

Introduction and objetives
There are few data in literature about the effects of rosuvastatin in patients with familial hypercholesterolemia in Spain. The objective of this study has been:
1-to evaluate the efficacy and security of rosuvastatin in patients with familiar hypercholesterolemia
2-to test the hypothesis that patients with diabetes have different response to treatment with rosuvastatin.
Material and methods
Descriptive study of patients followed in a Familial Dyslipidemia Unit, treated with rosuvastatin.
Results
Eighty-two patients with familial hipercholesterolemia. Mean age: 56.16±8.84 años.62,5% heterozygous familial hypercholesterolemia and 37.5% familial combined hyperlipidemia.Indication to initiate rosuvastatin: 68.8% non-achievement of objectives; 15.6% hepatic impairment with other statins, 12.5% patients polypharmacy(more risk of interaction) and 3.1% intolerance to other statins. Mean dose: 14.35±8.82 mg. 90.6% had previously statins, 59.4% ezetimibe and 31.3% fenofibrate.Average values of total cholesterol, LDL, HDL and TG before and after treatment were respectively (mg /dl): 245.75±67.44 vs 198.37 ±62.12(*P* 0, 000),decreased 19%, 159.62±62.36 vs 116.31±57.92 (*P* 0.000), decreased 27.5%, 41.8±10.29 vs 43.93±9.34 (*P* 0.36) and 309±475 vs 291 ±616 (*P* 0.76) Side effects were: 1 elevation of liver enzymes (less than twice normal values) and 3 patients had myalgia forcing to withdraw medication. *P*ercentage of patients achieving LDL target were: 9,4% before vs 62,5% after rosuvastatin. Diabetic patients had a minor decrease in CT and LDL levels than non-diabetics: CT decrease 20.78± 22.57 in diabetic vs 66.26±28.55 in non diabetic (*P* 0.000) and decrease of LDL 17.57±25.01 vs 62.2±30.99 (*P* 0.000) respectively.
Conclusions
Rosuvastatin produced significant decrease in CT and LDL cholesterol in patients with familial dyslipidemia, without significant changes in TG and HDL. Patients with familial hypercholesterolemia and type two diabetes, had a significantly lower decrease in CT and LDL than patients without diabetes despite similar doses of rosuvastatin.
Declaration of interest

**Metabolic and glycaemic profile in patients with acute coronary syndrome**

A. Maric, M. Gradiser, M. Igrec, I. Marodi & D. Katalinic
County Hospital Cakovec, Cakovec, Croatia.

Introduction
Components of metabolic syndrome, particularly overweight, dyslipidemia and diabetes mellitus (DM), are well known cardiovascular risk factors. The objective of this work was to evaluate the metabolic and glycaemic profile in patients (pts) with acute coronary syndrome (ACS), treated in our institution.
Methods
A total of 126 pts with ACS (unstable angina, acute myocardial infarction with /STEMI/or without ST-segment elevation/NSTEMI/) were admitted to the Coronary unit (CU) of a Department of Internal medicine, from January to December 2010.
We evaluated the following characteristics: sex, age, waist circumference, total cholesterol serum level, triglyceride level, HDL cholesterol level, LDL cholesterol level, plasma glucose concentration, uric acid, systolic (SBP) and diastolic blood pressure (DBP). All data were recorded at admission to CU. In patients with no previously known DM, and fasting plasma glucose concentration (FPG) $\geq$5.6 mmol/l measured the day after admission, the Oral glucose tolerance test (OGTT) was performed 1–3 days before hospital discharge.
Results
Of 126 patients studied, 73 pts (58%) were male. Five pts (4%) were hospitalized due to unstable angina, 56 pts (44.4%) had STEMI, and 65 pts (51.6%) had NSTEMI. Average age of pts was 64.9±13.65 years (min 33, max 89 years). Waist circumference was 101±3.2 cm in males, and 89.2±1.8 cm in females. Total cholesterol serum level was 4.93±1.28 mmol/l, triglyceride 1.95±0.89 mmol/l, HDL cholesterol 1.13±0.25 mmol/l, LDL cholesterol 2.90±1.08 mmol/l, plasma glucose concentration 7.65±3.78 mmol/l (min 4.4 mmol/l, max 26.9 mmol/l) and uric acid 350.9±114.2 mmol/l. Previously known DM was recorded in 40 pts (32%). According to OGTT test, 8 pts had impaired glucose tolerance (IGT), and 14 pts had newly diagnosed DM type 2.
Conclusion
High percentage of pts with occult or presenting DM, along with other metabolic abnormalities in ACS, suggest the need of early diagnosis and appropriate treatment of this conditions.

**Impact of 6-month course of 1 mg finasteride tablets on levels of lipid profile in men with androgenic alopecia**

S. Seiedmohammaddoulabi[1], H. Kavoussi[2], D. Isapour[1] & A. Hashemian[3]
[1]Kermanshah University of Medical Sciences, Kermanshah, Iran, Islamic Republic of Iran; [2]School of Medicine, Kermanshah University of Medical Sciences, Kermanshah, Islamic Republic of Iran; [3]School of Health, Kermanshah University of Medical Sciences, Kermanshah, Islamic Republic of Iran.

Background
Atherosclerosis constitutes one of the most frequent diseases and one of the important predisposing factor for atherosclerosis is lipid profile change. Androgen change lipid profile mainly high densitylipoprotein (HDL), and 1 mg finasteride tablets are used for treating androgenic hair loss through inhibition of 5-$\alpha$ reductase, and preventing convertion of testosterone to dihydrotestosterone (DHT) the most active derivative of testosterone in the other hands androgenic hair loss is considered a risk factor for atherosclerosis. this study was conducted in order to determine the impact of DHT suppression by 1mg finasteride tablets on lipid profile of patients with androgenic hair loss.
Method and materials
Twenty-five patients with androgenic hair loss were studied. The patients were prescribed one 1mg finasteride tablet daily. Fasting plasma levels of LDL, HDL, triglyceride, and total cholesterol of patients before therapy and after 3 and 6 months of therapy were measured. Nutritional status was evaluated. The study was conducted in the form of a before-after clinical trial. Data were analyzed using SPSS Software version 16.
Findings
A significant decreases in fasting plasma level of HDL was observed after 6 months of therapy ($P<0.001$). Moreover, a statistically significant rise in fasting plasma level of triglyceride was observed after 3 months of therapy ($P=0.014$). Plasma levels of LDL and total cholesterol were not altered significantly.
Conclusion
Our study demonstrated for the first time that using 1mg finasteride tablets to treat androgenic hair loss may lead to complications of the lipid profile through reducing HDL and increasing total cholesterol. Finasteride may decrease dihydrotestosterone and increased testosterone this change in lipid profile may be due to testosterone elevation by using finasteride.

**Transient glucocorticoid excess does not cause persisting metabolic changes in mice**

H. Auvinen, J. Romijn, N. Biermasz, M. Boon, L. Havekes, J. Smit, P. Rensen & A. Pereira
Leiden University Medical Center, Leiden, The Netherlands.

Introduction
In humans, Cushing's syndrome (CS) is associated with an increased incidence of the metabolic syndrome, increased cardiovascular morbidity and mortality, even after long-term correction of glucocorticoid (GC) excess.
Aim
To evaluate the effects of transient overexposure to GC on the metabolic changes in the long-term in mice.
Methods
Single housed male C57Bl/6J mice were given corticosterone (CORT; 50 μg/ml) or vehicle in the drinking water for 4 weeks, followed by a washout period for 4 or 8 weeks thereafter. Plasma circadian corticosterone levels were assessed at baseline, and at weeks 4, 8, and 12 after the start of exposure. Lipids, insulin, and glucose levels were measured after an overnight fast. Insulin sensitivity was assessed by hyperinsulenemic-euglycemic clamp at week 8 and 12, lean and body- and fat mass by DEXA analysis.
Results
CORT-treatment transiently increased plasma corticosterone by 37-, 13-, 3- and 13-fold at 0700, 1200, 1800 and 2200 h respectively. At week 8, evening peak CORT levels (1800 h) were suppressed, which returned to baseline levels at week 12. CORT-treatment increased food intake and plasma levels of insulin, trigycerides, free fatty acids and cholesterol. Abrogation of CORT normalized food intake, whereas body weight remained unchanged. At week 12, insulin was still significantly higher in CORT treated mice. There were no differences in the lean body or fat mass at week 8 and 12 weeks. Hyperinsulinemic–euglycemic clamp indicated no changes in CORT-treated mice at week 8 or 12.
Conclusion
In mice, transient glucocorticoid excess does not cause persisting metabolic changes. Recovery of these metabolic changes coincides with recovery of the HPA-axis.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P279

**Gastrectomy for early gastric cancer is associated with decreased cardiovascular mortality in accordance with amelioration of metabolic abnormalities, visceral adiposity and atherosclerosis**

Y. Lee[1], S. Han[2], H. Kim[1], W. Hyung[1], J. Lim[1], K. Lee[1], H. Lee[1], E. Lee[1], E. Kang[1], C. Ahn[1], B. Cha[1] & H. Lee[1]
[1]Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Ajou University School of Medicine, Suwon, Republic of Korea.

Objectives
We investigated cardiovascular and all-cause mortality in patients who underwent gastrectomies for early gastric cancer (EGC), and analyzed the changes in metabolic parameters in these patients after surgery.
Background
Bariatric surgery, including gastric banding and gastric bypass, effectively induces weight loss and resolves cardiovascular comorbidities in obese patients.
Methods
2477 patients who underwent gastrectomies for EGC between 1995 and 2004 were enrolled and followed for mortality through 2007. Standardized mortality ratios (SMRs) were calculated using sex- and age-matched mortality in the general Korean population in 2005. Effects of gastrectomy on changes in metabolic profiles including carotid intima-media thickness (CIMT) were investigated.
Results
During the 15 096.4 person-years of follow-up in 2477 patients, 244 deaths were recorded. The all-cause mortality was not significantly different from that of the general population (SMR (95% CI) = 1.01 (0.89–1.14)); however, cardiovascular mortality was significantly lower (SMR = 0.35 (0.22–0.53)). In the 51 patients included in the second part of the study, significant reductions in body weight and visceral fat areas occurred after surgery, regardless of whether the patients were previously obese. Triglycerides, LDL-cholesterol, and plasminogen activator inhibitor-1 levels were significantly decreased, whereas HDL-cholesterol and adiponectin levels were increased. CIMT was also significantly decreased in previously obese and non-obese patients.
Conclusions
Patients with EGC who undergo gastrectomy have a lower cardiovascular mortality but similar all-cause mortality as that of the general population. In these patients, a significant reduction in body weight and visceral fat after surgery may improve impaired fibrinolytic homeostasis and lipid metabolism and prevent atherosclerotic changes.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P280

**The role of testosterone activation of liver X receptor in a human macrophage cell line and its implications for the treatment of type 2 diabetes and atherosclerosis**

E. Kilby, S. Akhtar & T. Jones
University of Sheffield, Sheffield, UK.

Testosterone deficiency is common in men with type 2 diabetes (T2D) and cardiovascular diseases (CVD), such as atherosclerosis. Previous studies have shown that testosterone replacement improves several cardiovascular risk factors including insulin resistance, glycaemic control, cholesterol and inflammation. The mechanisms by which testosterone mediates these effects are unknown. LXR, a nuclear receptor also regulates these cardiovascular risk factors and the atheroprotective lipoprotein APOE. LXR agonists have been shown to reduce atherosclerosis but can cause hepatic stenosis. The objective of this study is to determine whether testosterone mediates its action via LXRα. Using the human monocyte cell line THP-1, differentiated into macrophages, which we have shown express the androgen receptor, the effect of $10^{-8}$ M testosterone on the expression of LXRα and LXR- targets including APOE, IL6 and TNFα, was investigated following RNA extraction and qPCR. Cells were exposed to testosterone for 24, 48 and 72 h. LXRα gene expression was increased in macrophages following exposure to $10^{-8}$ M testosterone for 72 h. Similarly the LXR-target gene APOE, which encodes the protein apolipoprotein E, involved in binding cholesterol following its removal from the cell, was also upregulated in these cells following testosterone exposure. Conversely, the expression of two pro-inflammatory genes IL6 and TNFα, were suppressed in macrophages following exposure to $10^{-8}$ M testosterone. This is the first study to show that testosterone induces expression of LXRα and APOE in human macrophages. The results suggest testosterone activates LXR and acts through this nuclear receptor to control the expression of LXR- target genes such as APOE, IL6 and TNFα to aid cholesterol efflux and suppress inflammation in human macrophages. We therefore hypothesize that testosterone exerts its anti-diabetic and anti-atherogenic effects in part through the activation of LXR and LXR-target genes.

## P281

**Chemerin/CMKLR1 and adiponectin/T-cadherin expression in human coronary arterial wall and pericoronary adipose tissue in correlation with atherosclerosis**

C. Kostopoulos[1], I. Karamouzis[2], S. Spiroglou[1,3] & H. Papadaki[1]
[1]University of Patras, Patras, Greece; [2]Ospedale S. Giovanni Battista-Molinette, University of Turin, Turin, Italy; [3]AHEPA University Hospital, Thessaloniki, Greece.

Introduction
Perivascular adipose tissue has been implicated in vascular physiology and pathology, including atherosclerosis. Local adipokine production is one of the

paracrine mechanisms involved in this adipose tissue fuction. We investigated the expression of adipokines chemerin and adiponectin and their receptors CMKLR1 and T-cadherin, respectively, in human coronary arterial wall and pericoronary fat as well as their correlation with coronary atherosclerosis.
Methods
Paraffin embedded samples of human left coronary arteries ($n=38$) including periadventitial fat were evaluated for chemerin, adiponectin, CMKLR1 and T-cadherin expression using immunohistochemistry. AHA classification was used for atherosclerosis assessment. PASW Statistics was used for statistical analysis.
Results
Atherosclerosis was detected in 35/38 coronary arteries. Chemerin was expressed in pericoronary fat (38/38 samples), coronary vascular smooth muscle cells (VSMCs; 38/38 samples) and foam cells in coronary atherosclerotic lesions (32/35 samples). Adiponectin was expressed by periadventitial fat in 37/38 samples. CMKLR1 was expressed in coronary VSMCs (15/38 samples) and foam cells (22/35 samples). T-cadherin was detected in VSMCs (38/38 samples) and endothelia (33/38 samples). Foam cell chemerin expression and CMKLR1 expression were positively interrelated in coronary atherosclerotic lesions ($r=0.406$, $P=0.016$). Periadventitial fat adiponectin expression was positively correlated with coronary VSMC ($r=0.427$, $P=0.007$) and endothelial ($r=0.432$, $P=0.007$) T-cadherin expression. Coronary atherosclerosis was positively correlated with coronary foam cell chemerin ($r=0.365$, $P=0.031$) and CMKLR1 expression ($r=0.349$, $P=0.04$), while negatively correlated with pericoronary fat adiponectin ($r=-0.531$, $P=0.001$) and marginally (not statistically significant) with coronary VSMC T-cadherin expression ($r=-0.307$, $P=0.06$).
Conclusions
Our data lend further support to a possible role for chemerin and its receptor in the atherosclerotic process, probably with pro-atherogenic effects. They also suggest that T-cadherin may serve as a receptor that mediates adiponectin's anti-atherogenic effects in human arterial wall.

## P282

**Six loci associated with high-density lipoprotein cholesterol or triglycerides in Chinese pregnant women**

M. Nie[1], Y. Wang[1,2], W. Li[1], F. Ping[1], J. Gao[1] & J. Liu[1]
[1]Key Laboratory of Endocrine, Ministry of Health, Peking Union Medical College, Chinese Academy of Medical Sciences, Peking Union Medical College Hospital, Beijing, China; [2]The Secondly Affiliated Hospital of ShanXi Medical College, Taiyuan, China.

Background
The serum concentrations of lipoproteins and lipids are heritable risk factors for cardiovascular disease. Pregnancy is associated with increases in plasma lipid profiles. Identifying the genetic determinants could provide novel insights into mechanisms of dyslipidemia and reveal avenues for developing new therapies. The objective of this study was to investigate the impact of six single nucleotide polymorphisms (SNPs) on serum lipid levels during pregnancy.
Method
In this study, 2085 unrelated pregnant women were recruited. Fasting serum lipids were measured in the third trimester of pregnancy. Six SNPs (rs1260326 in GCKR, rs1800775 in CETP, rs515135 in APOB, rs1800588 in LIPC, rs964184 in APOA1-C3-A4-A5 and rs4420638 in APOE-C1-C4-C2) were genotyped using TaqMan allelic discrimination assays. The individual and cumulative effects of the six loci on serum lipids were analyzed.
Results
We found that two variations, rs1260326 ($b=0.180$, 95% CI=0.184 to 0.300, $P=3.91\times10^{-16}$) and rs964184 ($b=0.114$, 95% CI 0.117 to 0.260, $P=2.69\times10^{-7}$) were significantly associated with triglycerides (TG) level. Another two variations rs1800775 ($b=-0.069$, 95% CI $-0.071$ to $-0.016$, $P=0.002$) and rs1800588 ($b=-0.129$, 95% CI $-0.112$ to $-0.055$, $P=8.14\times10^{-9}$) showed relation with high-density lipoprotein cholesterol (HDL-C). Besides, these loci exerted the combined effect on lipids. Subjects with increasing number of risk alleles showed higher TG concentration ($b=0.210$ mmol/l per allele, 95% CI 0.170 to 0.258, $P=2.51\times10^{-21}$) and lower value of HDL-C ($b=-0.140$ mmol/l per allele, 95% CI $-0.082$ to $-0.043$, $P=5.36\times10^{-10}$) in a dose-dependent manner. Other loci did not show the association with related serum lipid level in our population.
Conclusion
Previously identified lipid loci are associated with lipid levels in the Chinese pregnant population. An early lifestyle intervention incorporating exercise training and diet should be encouraged in the pregnant women who harboring risk alleles to keep their lipids in the normal range. Nevertheless more comprehensive investigation is still required to verify the significance of these loci in other population.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P283

**Development of primary hyperparathyroidism is closely associated with the onset of dyslipidemia and insulin resistance in a large family harboring a MEN1 gene mutation**

J. Anselmo, C. Moniz, I. Sousa & R. Cesar
Hospital Divino Espirito Santo, Ponta Delgada, Portugal.

Introduction
Dyslipidemia is a common finding in patients with primary hyperparathyroidism and together with hypertension and glucose intolerance seems to be responsible by the increased risk of cardiovascular disease in hyperparathyroid patients. In the present work we studied members of a family harboring a MEN1 gene mutation (type 1 multiple endocrine neoplasia syndrome). The penetrance of primary hyperparathyroidism in this condition is close to 100%, starting usually during the second decade of life.
Objective
To study the evolution of carbohydrate and lipid metabolism with the onset of primary hyperparathyroidism as well as with parathyroidectomy.
Patients and methods
All patients enrolled in the present study belong to the same family harboring a new MEN1 gene mutation located in the exon 2 (c124G>C), which leads to substitution of glycine by arginine (Gly42Arg). Three patients with symptomatic hyperparathyroidism exhibited severe combined dyslipidemia. Five young members without clinical and laboratorial evidence of the disease were followed at regular time intervals. Results are presented as the mean$\pm$S.D. of three consecutive determinations in each patient.
Results
Parathyroidectomy was followed by an immediate decline in total cholesterol (from 251$\pm$46 to 225$\pm$27 mg/dl) as well as in triglycerides (from 465$\pm$129 to 238$\pm$65 mg/dl). Fasting glycemia returned to values of $<100$ mg/dl. In young asymptomatic family members, the onset of hyperparathyroidism was closely followed by a twofold increase in insulinemia (from 9$\pm$6 to 21$\pm$7 mU/l) and in triglycerides (from 85$\pm$12 to 167$\pm$37 mg/dl), together with a decline of HDL cholesterol (from 67$\pm$9 to 52$\pm$5 mg/dl). None of these alterations was detected in non-affected family members.
Conclusion
In addition to normalization of serum calcium and PTH, parathyroidectomy corrected, at least partially, alterations in serum lipids as well as in the metabolism of carbohydrates. In previously asymptomatic patients, the onset of primary hyperparathyroidism was associated with an increase in insulin resistance and with the development of a more atherogenic lipid profile.

**Level of adiponectin and vaspin, and adiponectin/vaspin ratio is associated with insulin resistance and clinical expression of metabolic syndrome in type 2 diabetic patients**

S. Liu[1], J. Yang[1], T. Wang[2], X. Wang[3] & B. Niu[4]
[1]First Hospital of Shanxi Medical University, Taiyuan, China; [2]College of Public Health of Shanxi Medical University, Taiyuan, China; [3]Beijing Hospital of the Ministry of Health, Beijing, China; [4]Shanxi Medical University, Taiyuan, China.

Objective
The goal of this study is to evaluate the relationship between levels of adiponectin and vaspin, adiponectin/vaspin (A/V) ratio and metabolic syndrome, degree of adiposity, and insulin resistance (IR), as well as their correlation with metabolic variables.
Methods
Two hundred sixty patients with newly diagnosed type 2 diabetes (126 male, 134 female) were enrolled. Patients were grouped based on degree of adiposity, IR assessment (homeostasis model assessment of insulin resistance (HOMA-IR), and score of the International Diabetes Federation criteria for metabolic syndrome. Spearman's correlation coefficients and multiple regression analysis were used to determine the association between serum vaspin or adiponectin levels and other continuous variables of interest, and logistic regression analysis to ascertain the association between serum levels of vaspin and adiponectin, with metabolic syndrome as dependent variable.
Results
Metabolic syndrome positive patients had more atherogenic lipid profile, were more insulin resistant, and had higher vaspin compared to metabolic syndrome negative patients. Patient displayed stepwise decrease in adiponectin level and A/V ratio showed, with increasing scores of the criteria for diagnosis of the metabolic syndrome, while an opposite trend was observed for vaspin levels. Using multiple logistic regression, the odds ratio of the metabolic syndrome as protect factor by vaspin was calculated to be 0.469 (95% CI, 0.252–0.873; $P=0.017$). Overweight/obese patients had significantly lower adiponectin levels, lower A/V ratio, and higher vaspin level compared to patients with normal body weight. Insulin-sensitive patients had significantly higher adiponectin levels, higher A/V ratio, and lower vaspin levels than those with IR, after BMI, WC and other variable were adjusted. Receiver operating characteristic analysis demonstrated that vaspin and A/V ratio had significantly higher area under the curve (AUC) for the detection of the metabolic syndrome.
Conclusion
For type 2 diabetes patients, serum levels of adiponectin and vaspin, as well as A/V ratio were associated with obesity, IR, and the expression of the metabolic syndrome. Vaspin and A/V ratio may be a more useful and relevant biomarker for molecular diagnosis of metabolic syndrome.

**Insulin mediates the glucagon-induced decrease in atrial natriuretic peptide: a randomized controlled trial**

A. Arafat[1,2], N. Rudovich[1,2], M. Weickert[3,4], A. Adamidou[1], J. Spranger[1,5], A. Birkenfeld[1], M. Mohlig[1,2] & A. Pfeiffer[1,2]
[1]Charité-University Medicine Berlin, Berlin, Germany; [2]German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, Germany; [3]University Hospitals Coventry and Warwickshire NHS Trust, Coventry, UK; [4]Warwick Medical School, University of Warwick, Coventry, UK; [5]Charité-University Medicine Berlin and Max-Delbrück Centre Berlin-Buch, Berlin, Germany.

Objectives
Atrial natriuretic peptide (ANP) is a cardiac hormone that is known to play an essential role in regulation of blood pressure and vascular endothelial function. However, the metabolic regulation of ANP is not fully understood. In patients with the metabolic syndrome, hyperglucagonemia is a common feature, besides hypertension and hyperinsulinemia. Our aim was to evaluate the impact of glucagon on proANP and the possible mechanisms underlying this effect.
Methods
In this prospective, double-blind, placebo-controlled study, we studied hormonal and metabolic responses to intramuscular glucagon or placebo administration in 13 patients with type 1 diabetes mellitus (DM1; 6/7 males/females; BMI 24.8 $\pm$0.95 kg/m$^2$), in 12 obese healthy subjects (OS; 6/6; 33.9 $\pm$ 1.6 kg/m$^2$) and in 13 lean controls (LC; 6/7; 21.6 $\pm$ 0.5 kg/m$^2$). Furthermore, we studied the response of proANP to insulin (0.15 IU/kg BW) in OS and LC as a possible mediator for the glucagon-induced effects using insulin tolerance test. Finally, we further investigated the impact of hyperinsulinemia under euglycemic conditions on proANP in 32 healthy subjects.
Results
Gender, fasting glucose and glucagon levels were comparable between groups. Glucagon significantly decreased proANP in OS (proANP-AUC240: 203.4 $\pm$ 4.8 (glucagon) vs. 226.6 $\pm$ 6.9 (placebo), $P<0.01$) and LC (205.8 $\pm$ 2.6 vs 245.8 $\pm$ 9.2, $P<0.01$) but failed to affect proANP concentrations in DM1 ($P=0.737$) . Glucagon increased insulin in LS and OS ($P<0.01$) but did not affect it in DM1 ($P>0.05$).
Under hypoglycaemic hyperinsulinemic conditions, insulin markedly decreased proANP in OS and LC ($P<0.01$). Similarly, insulin significantly decreased proANP under euglycemic hyperinsulinemic conditions in healthy subjects ($P<0.01$).
Conclusions
We show that insulin mediates the glucagon-induced decrease in proANP, possibly providing a novel link between hyperinsulinemia and cardiovascular risk.

**The role of β-arrestin proteins in CB1 cannabinoid receptor endocytosis**

L. Hunyady, P. Gyombolai, E. Boros & G. Turu
Semmelweis University, Budapest, Hungary.

Introduction
β-Arrestins are cytosolic proteins, which play key roles in the desensitization, internalization and signaling of G protein-coupled receptors. Currently, little is known about the role of β-arrestins in the internalization of the CB1 cannabinoid receptor (CB1R). Therefore, the interaction between β-arrestins and CB1R, and its role in receptor internalization were studied.
Materials and methods
The β-arrestin binding of CB1R was studied by confocal microscopy and bioluminescence resonance energy transfer (BRET). To follow CB1R internalization, plasma membrane CB1 receptors were selectively stained using Halo-labeling technique. Internalization of the receptors was also monitored by a BRET assay through measuring non-specific BRET between CB1R and a plasma membrane marker protein (ICAM).
Results
We found that upon activation CB1R binds transiently to β-arrestin2 (β-arr2), but not β-arrestin1. Dominant negative β-arr2 (β-arr2-V54D) or knock-down of β-arr2 by siRNA inhibited the agonist-induced internalization of CB1Rs. Similar inhibitory effects on agonist-induced CB1R internalization were also demonstrated using BRET measurements. In contrast, neither β-arr2-V54D nor β-arr2-siRNA had a significant effect on the constitutive internalization of CB1R.
Conclusions
We conclude that upon activation, CB1R binds β-arr2 in a transient manner (class A GPCR), and this binding is required for the agonist-induced internalization of the receptor. In contrast, constitutive CB1R internalization is independent of the β-arr2 binding of the receptor, suggesting that the molecular mechanisms underlying these two processes are different.

**Plasma aldosterone to plasma renin ratio on an automated analyzer using two novel chemiluminescence immunoassays**

J. Manolopoulou[1], A. Bennett[1], P. Grimminger[2], E. Fischer[2], A. Pallauf[2], M. Reincke[2], S. Diederich[3] & M. Bidlingmaier[2]
[1]Immunodiagnostic Systems Ltd., Boldon, UK; [2]Medizinische Klinik Campus Innenstadt, Ludwig-Maximilians-University, Munich, Germany; [3]Zentrum für Hormon- und Stoffwechselerkrankungen, Berlin, Germany.

Background
Screening for primary aldosteronism (PA) using the aldosterone to renin ratio (ARR) is recommended by clinical practice guidelines in patient groups with a high prevalence as the disease is reported by several authors in more than 10% of essential hypertensives (EH).
Methods
Plasma aldosterone concentration (PAC) and direct renin (DR) were measured using two novel automated chemiluminescence assays (IDS-iSYS; Boldon, UK) and compared to the Siemens RIA and Diasorin Liaison (LSN) respectively. Plasma was taken from 20 controls, 26 EH and 36 PA patients. PA was defined by lack of aldosterone salt-load suppression to $<50$ pg/ml. Mineralocorticoid receptor antagonists and b-blockers were excluded, other medication was not restricted. Hypokalemia was controlled in all. Using Siemens PAC (pg/ml)/Liaison DR (mU/l), our laboratory cut-off for diagnosis of PA is 12.
Results
PACs in controls, EHs and PAs were (mean; 25–75%ile) RIA: 157 (84.2–196), 123 (73.3–137), and 274 (190–320) pg/ml and iSYS: 115 (50.5–182), 114 (68.7–131), and 279 (172–348) pg/ml. In the same groups DR using the LSN assay was at 33 (21.2–43.1), 62 (8.9–82.2), and 7.9 (2.0–9.5), and with the iSYS 40.1 (27.4–47.8), 77.9 (13.6–110), and 14.1(4.9–13.7). Using linear regression analysis aldosterone-iSYS $=1.073$RIA $\pm 0.082$, $r^2=0.69$ and renin-iSYS $=1.057$LSN $\pm 0.067$, $r^2=0.77$. Using a diagnostic cut-off of 12 with the RIA and LSN, ROC curve analysis of this cohort gives a sensitivity of 96.7% and specificity of 85.1%. As at this cut-off the iSYS assays provide 93.6% sensitivity, a lower cut-off at 6.3 would provide corresponding 96.7% sensitivity with 84.8% specificity.
Conclusions
The data presented here show good correlation between commonly used aldosterone and renin assays and the newly automated IDS-iSYS system. An overall trend for higher renin values using the iSYS, albeit with equivalent discrimination between the three cohort groups, would require a lower ARR cut-off to provide the same diagnostic power.

**Hypogonadism as a risk factor for cardiovascular mortality in men: a meta-analytic study**

G. Rastrelli[1], G. Corona[1,2], M. Monami[1], A. Guay[3], J. Buvat[4], A. Sforza[2], G. Forti[1], E. Mannucci[1] & M. Maggi[1]
[1]University of Florence, Florence, Italy; [2]Maggiore-Bellaria Hospital, Bologna, Italy; [3]Lahey Clinic, Peabody, Massachusetts, USA; [4]Centre d'Etude et de Traitement de la Pathologie de l'Appareil Reproducteur et de la Psychosomatique, Lille, France.

Objective
To verify whether hypogonadism represents a risk factor for cardiovascular (CV) morbidity and mortality and to verify whether testosterone replacement therapy (TRT) improves CV parameters in subjects with known CV diseases (CVDs).
Design
Meta-analysis.
Methods
An extensive Medline search was performed using the following words 'testosterone, CVD, and males'. The search was restricted to data from January 1, 1969, up to January 1, 2011.
Results
Of the 1178 retrieved articles, 70 were included in the study. Among cross-sectional studies, patients with CVD have significantly lower testosterone and higher 17-β estradiol ($E_2$) levels.
Conversely, no difference was observed for DHEAS. The association between low testosterone and high $E_2$ levels with CVD was confirmed in a logistic regression model, after adjusting for age and body mass index (hazard ratio (HR) $=0.763$ (0.744–0.783) and HR $=1.015$ (1.014–1.017), respectively, for each increment of total testosterone and $E_2$ levels; both $P$ 0.0001). Longitudinal studies showed that baseline testosterone level was significantly lower among patients with incident overall- and CV-related mortality, in comparison with controls. Conversely, we did not observe any difference in the baseline testosterone and $E_2$ levels between case and controls for incident CVD. Finally, TRT was positively associated with a significant increase in treadmill test duration and time to 1 mm ST segment depression.
Conclusions
Lower testosterone and higher $E_2$ levels correlate with increased risk of CVD and CV mortality. TRT in hypogonadism moderates metabolic components associated with CV risk. Whether low testosterone is just an association with CV risk, or an actual cause-effect relationship, awaits further studies.

**Testosterone and cardiovascular risk in patients with erectile dysfunction**

G. Corona[1,3], G. Rastrelli[1], G. Balercia[2], A. Sforza[3], G. Forti[1] & M. Maggi[1]
[1]University of Florence, Florence, Italy; [2]Polytechnic University of Marche, Ancona, Italy; [3]Medical Department, Azienda Usl, Maggiore-Bellaria Hospital, Bologna, Italy.

Background
The relationship between cardiovascular (CV) diseases (CVD) and testosterone levels in men has not been completely clarified.
Aim
To evaluate the association between testosterone levels and CV risk in subjects with erectile dysfunction (ED) and to verify whether their body mass index might (BMI) represents a possible confounder in testosterone-related CV stratification.
Material and methods
A consecutive series of 2269 male patients attending the outpatient clinic for ED was studied. The assessment of CV risk was evaluated using the engine derived from the Progetto Cuore study.
Results
After adjustment and for BMI and associated morbidities, sex hormone binding globulin bound (SHBG) and unbound testosterone levels decreased as a function of CV risk assessed thorough Progetto Cuore risk engine. In addition, a higher prevalence of hypogonadism related symptoms and signs was associated with a higher CV risk. Among factors included in the Progetto Cuore risk engine age, total and HDL cholesterol and diabetes were all significantly associated with CV risk-dependent modification of total and calculated free-testosterone levels. When the relationship between SHBG bound and unbound testosterone and CV risk was evaluated as a function of obesity (BMI $>30$ kg/m$^2$), all the aforementioned associations were confirmed only in non obese patients.
Conclusions
Hypogonadism could be associated either with an increased or reduced CV risk, depending on the characteristics of subjects. Low testosterone observed in obese patients might represent the result of higher CV risk rather than a direct pathogenetic mechanism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Oxytocin stimulates cardiomyogenesis and cardioprotection via stem cells activation**

M. Jankowski, N. Noiseux & J. Gutkowska
CR-CHUM, University of Montreal, Montreal, Quebec, Canada.

The functional oxytocin (OT) system is present in the heart and stimulate cardiomyocyte (CM) differentiation of embryonic stem cells. Presently, we are reporting that the OT stimulates CM differentiation of stem cells isolated from the rat heart and termed as side population cells (SP). Specifically, the phenotype of SP-CD31(−) cells, but not SP-CD31(+) cells, proliferate in the presence of OT; the OT treatment promote cell aggregation, and then stimulate differentiation into beating cell colonies. These colonies of contractile cells express the markers of a CMs phenotype such as troponin, MLC2V and actinin. Moreover, SP cells stimulated by OT produce endothelial phenotype in the Matrigel culture. Among adult stem cells, mesenchymal stem cells (MSCs) possess unique properties that make them eligible for convenient and highly effective cell therapy of the heart. The rat bone marrow MSCs preconditioned with the OT present a rapid increase and nuclear accumulation of phospho-Akt and of phospho-p44/42 (ERK1/2), indicating an activation of the protective way phosphatidylinositol-3-kinase (PI3K)/AKT and mitogen-activated protein kinases (MAPK) respectively. MSCs carrying OT gene stimulate angiogenesis *ex vivo* and *in vivo* in rat model of hind-limb ischemia. The preconditioning to the OT increases the metabolic activity of the MSCs cells in normoxia, stimulation of cellular trafficking of GLUT 4 transporter and seems to protect against the hypoxia and the serum deprivation as evaluated by the MTT test. As demonstrated by flow cytometry for annexin V and Tunel method, the OT preconditioning reduced apoptosis in rat MSCs exposed to hypoxia. This anti-apoptotic protection was transmitted from MSCs to CMs in co-culture. In conclusion, we propose that stem cells optimized by OT treatment may play the supportive role in injured heart via differentiation to cardiac cells and secretion of paracrine factors.

**Metabolism of angiotensin II and angiotensin III in HAC15 cells**

K. Oki[1], P. Kopf[3], W. Campbell[3], E. Gomez-Sanchez[1,2] & C. Gomez-Sanchez[1,2]
[1]University of Mississippi, Jackson, Mississippi, USA; [2]G.V. Montgomery VA Medical Center, Jackson, Mississippi, USA; [3]Medical College of Wisconsin, Milwaukee, Wisconsin, USA.

Angiotensin II (A-II) stimulates aldosterone (aldo) secretion through the zona glomerulosa AT1R. A-II can be metabolized to angiotensin III (A-III) which also stimulates aldo synthesis. In the rat A-III stimulates aldo secretion through the AT2R receptor.

The human adrenocortical HAC15 cells were incubated with A-II or A-III (10 nM) for 24 h and the concentration of aldo and cortisol (F) measured in the media. A-II produced a fourfold and A-III a twofold increase in aldo in the media. A-II produced a twofold increase in F concentration in the media, but A-III did not change F production. Losartan 10 μM inhibited the A-II and A-III stimulated production of aldo, but the AT2R antagonist PD123319 had no effect. Both A-II and A-III stimulated the expression of StAR, CYP11B1 and CYP11B2 mRNA. While A-II had no effect on CYP17A1 mRNA expression, A-III inhibited its expression.

HAC15 cells were incubated with 100 nM of A-II and A-III for 0.5, 1, 3 and 6 h, the media was extracted and angiotensin metabolites measured by HPLC–MS. Approximately 30% of A-II remained after 1 h incubation and was not detectable after 6 h. A-II was converted to angiotensin 1–7, angiotensin-IV and angiotensin 3–7, but not to A-III. A-III was decreased to ∼40% after 30 min and was undetectable after 1 h. A small amount of the A-III was converted to angiotensin 3–7 and angiotensin-IV.

Addition of more A-II (10 nM) at 1, 3, 6 or 12 h did not increase aldo production at 24 h further compared to cells stimulated only once with A-II (10 nM) at time 0.

In conclusion, A-II is not converted to A-III in HAC15 cells. A-III stimulates aldo, but not cortisol production: A-II stimulates both. The half-life of A-II and A-III in the media is short, but stimulation of steroidogenesis persists.

## P293

**Chemerin/CMKLR1 and adiponectin/T-cadherin expression in human aortic wall and periaortic adipose tissue in correlation with atherosclerosis**

C. Kostopoulos[1], I. Karamouzis[2], S. Spiroglou[1,3] & H. Papadaki[1]
[1]University of Patras, Patras, Greece; [2]Ospedale S. Giovanni Battista-Molinette, University of Turin, Turin, Italy; [3]AHEPA University Hospital, Thessaloniki, Greece.

Introduction

Periadventitial adipose tissue has been implicated in vascular physiology and pathology, including atherosclerosis, through paracrine and endocrine mechanisms, mainly adipokine production. We investigated the expression of adipokines chemerin and adiponectin and their receptors CMKLR1 and T-cadherin, respectively, in human aortic arterial wall and periaortic fat as well as their correlation with aortic atherosclerosis.

Methods

Paraffin embedded samples of human aortas ($n=37$) including periadventitial fat were evaluated for chemerin, adiponectin, CMKLR1 and T-cadherin expression using immunohistochemistry. AHA classification was used for atherosclerosis assessment. PASW Statistics was used for statistical analysis.

Results

Atherosclerosis was detected in 31/37 aortas. Chemerin was expressed in periaortic fat (34/37 samples), aortic vascular smooth muscle cells (VSMCs; 37/37 samples) and foam cells in aortic atherosclerotic lesions (25/31 samples). Adiponectin was expressed by periadventitial fat in 34/37 samples. CMKLR1 was expressed in aortic VSMCs (9/37 samples) and foam cells (28/31 samples). T-cadherin was detected in VSMCs (37/37 samples) and endothelia (32/37 samples). Periaortic fat chemerin expression was negatively correlated to adiponectin expression ($r=-0.620$, $P<0.001$). Foam cell chemerin expression and CMKLR1 expression were positively interrelated in aortic atherosclerotic lesions ($r=0.456$, $P=0.01$). Periadventitial fat adiponectin expression was positively correlated with endothelial T-cadherin expression ($r=0.326$, $P=0.049$). Aortic atherosclerosis was positively correlated with periaortic fat chemerin ($r=0.813$, $P<0.001$), aortic VSMC chemerin ($r=0.654$, $P<0.001$), aortic foam cell chemerin ($r=0.639$, $P<0.001$) and aortic foam cell CMKLR1 expression ($r=0.399$, $P=0.026$), while negatively correlated with periaortic fat adiponectin ($r=-0.690$, $P<0.001$), VSMC T-cadherin ($r=-0.413$, $P=0.011$) and endothelial T-cadherin ($r=-0.396$, $P=0.015$) expression.

Conclusions

Our data suggest a putative role for chemerin and its receptor in the atherosclerotic process, probably with opposite effects to adiponectin's. T-cadherin may also serve as a receptor that mediates adiponectin's actions regarding atherosclerosis deceleration.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**In primary aldosteronism, plasma aldosterone concentration is an independent risk factor for albuminuria, and the higher baseline urinary albumin excretion predicts the less glomerular filtration rate after treatment**

Y. Iwakura, R. Morimoto, M. Kudo, Y. Ono, S. Ito & F. Satoh
Tohoku University Hospital, Sendai, Japan.

Background
The higher prevalence of urinary albumin was reported in patients with primary aldosteronism (PA) than those with essential hypertension (EH). It remains to be unclear, although 'glomerular hyperfiltration (HF)' was hypothesized as one of the mechanisms of urinary albumin.
Objectives
To clarify the risk factor of urinary albumin and the relationship with HF in PA.
Methods
123 patients with PA were treated according to the result of adrenal vein sampling. Adrenalectomy was performed on patients diagnosed with unilateral disease (APA: $n=68$), while those who were diagnosed with bilateral disease were given medical treatment including with mineralcorticoid receptor antagonists (MRA; IHA: $n=55$).
Blood pressure, estimated glomerular filtration rate (eGFR:ml/min per 1.73 $m^2$) and urinary albumin excretion (UAE:mg/g Creatinine) were followed at baseline and during 24 months after treatment of PA in all patients. Multivariate regression analysis with stepwise procedure was performed to identify the potential risk factor of baseline UAE and the relation factor with the decline of GFR (ΔGFR) between at baseline and at 1 month after treatment. eGFR was estimated by the equation for Japanese established by Japan society of nephrology. UAE was adjusted by logarithm.
Results
Blood pressure, UAE, and GFR significantly decreased at 1 month after treatment and they remained a plateau during the follow-up. Positive relationship was observed between UAE and ΔGFR ($P=0.0003$, $R^2=0.165$). Baseline plasma aldosterone concentration and systolic blood pressure were the risk factors of UAE ($P=0.010$ and $P=0.013$, respectively, $R^2=0.164$). Baseline UAE and serum potassium were the predictors of ΔGFR ($P<0.01$, $R^2=0.275$).
Conclusion
In primary aldosteronism, plasma aldosterone concentration is an independent risk factor for albuminuria, and the higher baseline urinary albumin excretion predicts the less glomerular filtration rate after treatment.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P295

**Relationships between insulin resistance and cardiovascular risk factors in primary hyperparathyroidism**

F. Tassone, C. Baffoni, L. Gianotti, M. Pellegrino, S. Cassibba, G. Magro, F. Cesario & G. Borretta
S. Croce e Carle Hospital, Cuneo, Italy.

Introduction
Primary hyperparathyroidism (pHPT) is characterized by an increased frequency of glucose tolerance abnormalities associated with insulin-resistance. Few studies evaluated the relationship between insulin resistance and others cardiovascular risk factors in pHPT.
Subjects and methods
In 255 consecutive pHPT patients (M/F=66/189, age (mean±S.D.): 59.9±13.7 years, PTH: 215.6±219.4 pg/ml, calcium: 11.2±1.2 mg/dl, asymptomatic/symptomatic: 115/140) we assessed insulin resistance by means of homeostasis model assessment of insulin resistance (HOMA-IR). Then we evaluated biochemical and clinical features of pHPT subdividing our case series in two groups basing on median HOMA-IR (1.68).
Results
pHPT patients more insulin-resistant showed significantly higher systolic blood pressure values (142.5±20.6 vs 134.8±16.7 mmHg, $P<0.002$), BMI (27.3±4.7 vs 23.1±3.8 kg/$m^2$, $P<0.000001$), PTH (238.2±262.9 vs 193.0±162.9 pg/ml, $P<0.04$), calcium levels (11.35±1.27 vs 11.05±1.06 mg/dl, $P<0.04$) and triglycerides (142.8±63.8 vs 105.6±40.8 mg/dl, $P<0.00001$) than patients with lower HOMA-IR. HDL-cholesterol was lower in patients with higher HOMA-IR (51.6±16.2 vs 63.2±17.4, $P<0.00005$).
Conclusions
In PHPT increased insulin resistance is associated with a more severe alteration of biochemical indices of the disease and a worsening of overall cardiovascular risk profile.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P296

**Allosteric effects between the protomers of AT1 angiotensin receptor homodimer: role of the conserved DRY motif**

B. Szalai, P. Várnai & L. Hunyady
Semmelweis University, Budapest, Hungary.

Introduction
G protein coupled receptor dimerization is proposed to have great impact on receptor signaling. Allosteric communication between the protomers of a dimer can alter ligand binding, receptor conformation and the interactions with different effector proteins. Although the concept of intradimeric interactions is widely accepted, the molecular mechanism behind them is not clearly understood. In this study we investigated the allosteric interactions within the type I angiotensin receptor (AT1R) homodimer transiently expressed in CHO cells.
Methods
To detect the intradimeric interactions, one protomer of AT1R homodimer was selectively stimulated, while the activation process of the other protomer was followed by different bioluminescent resonance energy transfer (BRET) based assays. For the selective stimulation we used an antagonist resistant mutant AT1R. We monitored the activation of the non-stimulated protomer through its interaction with β-arrestin2 and followed the conformation alterations directly with an intramolecular receptor biosensor. Also cooperative ligand binding of the homodimer was examined by ligand dissociation experiments. To evaluate the molecular mechanism behind the allosteric interactions, different mutants of AT1R were investigated in our assays.
Results
We observed that agonist binding of one protomer is followed by the increased ligand dissociation, altered conformation and β-arrestin2 binding of the other protomer. The mutation of the conserved DRY sequence in the activated protomer abolished all the observed effects between the receptors.
Conclusion
The detected effects on the non-stimulated protomer are presumable the consequence of direct intradimeric allosteric interactions. Our results with AT1 receptor mutated in the DRY sequence suggest the crucial role of this motif in intradimeric interactions, and also highlight the molecular mechanisms behind them.

**Effect of triiodothyronine and angiotensin-II on expression of (pro)renin receptor in the human erythroid cell line, YN-1**

H. Nishiyama[1], K. Kaneko[1], K. Ohba[1], T. Yoshioka, T. Shimizu[1], T. Hirose[2], K. Totsune[3] & K. Takahashi[1]
[1]Tohoku University Graduate School of Medicine, Sendai, Japan; [2]Tohoku University Graduate School of Pharmaceutical Sciences and Medicine, Sendai, Japan; [3]Tohoku Fukushi University, Sendai, Japan.

The renin–angiotensin system is known to enhance erythropoiesis. (Pro)renin receptor ((P)RR), a specific receptor for renin and prorenin, has recently been identified. We have recently shown expression of (P)RR in a human erythroid cell line, YN-1. It is known that triiodothyronine ($T_3$) and angiotensin-II (A-II) stimulate proliferation of erythroid cells. The aim of the present study is to clarify effects of $T_3$ and A-II on expression of (P)RR in the human erythroid cell line, YN-1. YN-1 cells were maintained in Iscove's modified Dulbecco's medium containing 10% fetal bovine serum. To study effects of $T_3$ and A-II on (P)RR expression, the cells were cultured in the medium containing $T_3$ (10 and 100 nM) or A-II (10 and 100 nM) for 24 h. Expression of (P)RR mRNA and protein was examined by real time RT-PCR and western blot analysis respectively. The antiserum against (P)RR was raised in a rabbit by injecting the peptide fragment of human (P)RR corresponding to 224–237 a.a. (Hirose *et al*. 2009). Real time RT-PCR showed that $T_3$ increased expression levels of (P)RR mRNA significantly in a concentration dependent manner. $T_3$ caused a 1.6-fold increase at 100 nM compared with control. Western blot analysis showed increased expression of (P)RR protein by $T_3$ although this increase was not statistically significant. By contrast, A-II had no significant effects on (P)RR mRNA and protein levels in YN-1 cells. In this study, we have found that $T_3$ stimulates expression of (P)RR in YN-1 cells, suggesting a possibility that (P)RR is related to erythropoiesis induced by $T_3$.

**The combined use of serum interleukin 6 and C-reactive protein is better than either alone in predicting cardiovascular events in a Chinese population**

K. Lam[1], W. Chow[1], C. Yeung[1], A. Tso[1], M. Yuen[1], C. Fong[1], N. Wat[1], T. Lam[1], S. Lo[2], H. Tse[1] & B. Cheung[1]
[1]University of Hong Kong, Hong Kong, China; [2]Hong Kong Hospital Authority, Hong Kong, China.

Objectives

Obesity is associated with an increase in cardiovascular risk. We investigated whether the measurement of obesity-related biomarkers could enhance the prediction of cardiovascular (CVD) events when used in conjunction with traditional risk factors.

Methods

We studied subjects in the Hong Kong Cardiovascular Risk Factors Prevalence Study 2 (CRISPS 2) cohort without previous cardiovascular disease. Baseline serum levels of several biomarkers known to be increased in obesity, C-reactive protein (CRP), interleukin 6 (IL6), and soluble tumor necrosis factor-alpha receptor-2 (sTNFR2; a surrogate marker of TNFα), as well as those of adiponectin, an adipokine with reduced expression in obesity, were measured.

Results

Of the 1848 subjects with no known CVD at baseline, 104 (5.6%) developed CVD events during a median follow-up of 6 years. The CVD group had higher baseline levels of CRP, IL6, and sTNFR2 (all $P<0.001$), but similar adiponectin levels ($P=0.435$), compared to the non-CVD group. Likelihood ratio test showed that elevated levels of CRP and IL6 ($P<0.001$, adjusted for traditional CV risk factors) but not sTNFR2 (adjusted $P=0.05$) were independent predictors of incident CVD. IL6 remained a significant predictor after adjustment for CRP levels. These two biomarkers, alone or in combination, significantly improved the prediction by traditional risk factors, as estimated by c-statistics (Delong $P$ value being 0.0077, 0.035 and 0.0006 for CRP, IL6 and CRP + IL6 respectively). IL6 significantly increased the c-statistics when added to the model already including the traditional risk factors and CRP (Delong $P=0.0393$).

Conclusion

In this prospective study, CRP and IL6 were independent predictors of incident CVD in Hong Kong Chinese without prior CVD. The combined use of serum IL6 and CRP was superior to either alone in predicting CVD events in this community-based cohort.

## P299

**Short-term detraining cannot reverse insulin sensitivity improvement and serum retinol binding protein 4 in spontaneously hypertensive rats previously submitted to aerobic exercise**

A. Lehnen[1,2], G. Pinto[2], J. Borges[2], M. Markoski[2] & B. Schaan[1,2]
[1]Hospital de Clínicas de Porto Alegre, UFRGS, Porto Alegre, Brazil; [2]Instituto de Cardiologia do Rio Grande do Sul, Fundação Universitária de Cardiologia, Porto Alegre, Brazil.

Background

Elevated serum retinol binding protein 4 (RBP4) levels were previously described in insulin-resistance states. Recently it was shown that RBP4 contributes, at least partly, to the pathogenesis of insulin resistance in spontaneously hypertensive rats (SHR), but the effects of exercise training and time-course of changes after detraining on RBP4 levels have not yet been explored.

Aims

To examine the effects of exercise training and short-term detraining on serum RBP4 levels and insulin resistance in SHR.

Methods

Thirty-two male SHR, 4 months old, were submitted to 10-week treadmill training, 5 times/week (T) or kept sedentary for the same period (S). Two short periods of exercise detraining were also carried out (2 and 4 days: D2 and D4). Body weight, insulin sensitivity (insulin tolerance test, ITT), functional capacity (maximal exercise test) and serum RBP4 (ELISA) were measured. Repeated ANOVA and Pearson's correlation were used ($P<0.05$).

Results

Rats had the same characteristics at baseline. There was a ~43% gain in body weight over time ($P=0.004$) in all groups. However, in exercise-trained rats there was a ~40% ($P<0.001$) reduction of white fat tissue weight (epididymal) as compared to the S group. Exercise training determined an improvement of insulin sensitivity (S: 3.8±1.0, T: 4.4±1.0, D2: 5.9±1.2, D4: 4.1±1.7% per min, $P=0.001$) and increased function capacity (S: 1.4±0.3, T: 2.4±0.3, D2: 2.6±0.1, D4: 2.7±02 km/h, $P<0.001$), which was not lost after detraining. RBP4 levels were reduced in response to exercise training (~45%, $P=0.015$). There was a negative correlation between insulin resistance and serum RBP4 ($r=-0.690$, $P<0.001$). The short periods of detraining were not enough to change any 10-week training-induced benefits.

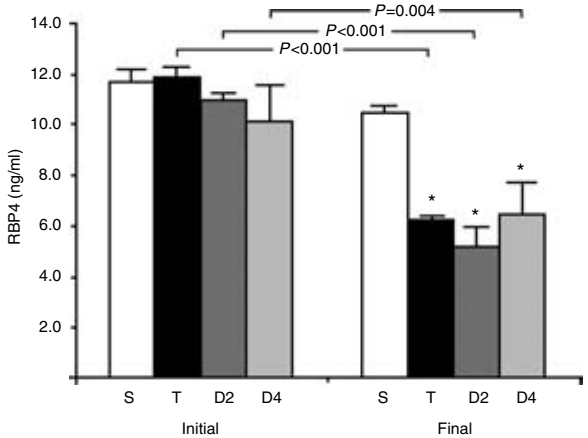

**Figure 1** Serum retinol binding protein 4 (RBP4) in response to exercise training and detraining. S, sedentary; T, 10-week trained; D2, 2 days detrained; D4, 4 days detrained. Initial: pre-training measures. Final: measures after exercise training period or after the respective periods of detraining. Repeated measures ANOVA: $P$ (group) $<0.001$, $P$ (time) $<0.001$ and $P$ (interaction) $=0.015$, followed by post hoc Bonferroni: $^*P<0.05$ vs S in the final period. Significances over time are also presented.

Conclusions
Exercise training determined a decrease in serum RBP4, accompanying the improvement in insulin sensitivity. These benefits were maintained for 4 days of exercise detraining. The inverse association between RBP4 levels and insulin resistance could represent a causal relationship between them.

### Multiple cardiovascular risk factors in patients with myotonic dystrophy type 1 and 2

E. Passeri[1], E. Bugiardini[1], V. Sansone[1], E. Costa[1], F. Bandera[1], A. Pizzocaro[2], G. Meola[1], B. Ambrosi[1] & S. Corbetta[1]
[1]IRCCS Policlinico San Donato, University of Milano, San Donato Milanese, Italy; [2]Istituto Clinico Humanitas, Rozzano, Italy.

Introduction
Myotonic dystrophy (DM) type 1 and 2 are multisystemic autosomal dominant disorders with visceral obesity, insulin resistance and hypogonadism. The prevalence of metabolic risk factors for coronary artery disease (CAD) in DM is not well defined, particularly in patients affected by DM2, a milder and clinical challenging condition.
Methods
We assessed the frequency of CAD risk factors in 31 male DM1 ($44 \pm 11$ years) and 13 male DM2 ($54 \pm 9$ years) patients.
Results
DM1 patients showed visceral fat distribution: waist was $>102$ cm in 32% of cases and epicardial fat thickness was increased in 52% of patients ($6.1 \pm 2.8$ mm). Hepatic steatosis with abnormal liver tests occurred in 54% of DM1 patients and dyslipidemia also was frequent (48%). Insulin-resistance was detected in 21% of cases, while diabetes in 3%. Overt and subclinical hypogonadism occurred in 26 and 68% of cases. Arterial blood hypertension was diagnosed in 9% and cardiac dysfunction, including arrhythmias, in 32% of DM1 patients, but CAD was never present. Though visceral body fat and lipid parameters in DM2 patients did not differ from those in DM1 patients, diabetes and insulin-resistance were more frequent in DM2 versus DM1 patients (38 and 61%, respectively, $P=0.006$) and hypogonadism was present in all DM2 (overt in 38%). Hypertension and CAD were also more frequent in DM2 patients (69 and 24%, respectively, $P<0.001$; $P=0.02$). Echocardiography showed higher left ventricular mass index (LVMI) in DM2 vs DM1 patients ($101.1 \pm 18$ vs $86.5 \pm 14$, $P=0.05$), suggesting that ventricular hypertrophy is more common in DM2.
Conclusion
Cardiovascular risk factors, namely diabetes mellitus, hypogonadism, hypertension and ventricular hypertrophy occurred more frequently in DM2 vs DM1 patients, though in DM2 the muscular phenotype is milder. DM2 represents a genetically determined model of metabolic syndrome.

### Role of peroxisome proliferator-activated receptor-γ (PPARγ) in regulation of glucocorticoid metabolism in vascular smooth muscle cells

J. Pacha, K. Vagnerova, P. Ergang & J. Loukotova
Czech Academy of Sciences, Prague, Czech Republic.

Glucocorticoids are known to have significant and diverse effects on the cardiovascular system. They have been shown to foster hypertension indirectly due to enhanced vascular tone by potentiation of the vasocontrictor hormones and directly by action on vascular smooth muscle cells (VSMC). The local concentration of glucocorticoids in various tissue including vessels is determined by the enzyme 11β-hydroxysteroid dehydrogenase type two (11HSD2) and 1 (11HSD1) that has been shown to be down-regulated by PPARγ agonists in hepatocytes and adipocytes. Thus it can be hypothesized that PPARγ activation is able to induce a vasodepressor effect. However, PPARγ knock-out mice and animals with VSMC-selective PPARγ deficiency have hypotension. Therefore, in the present study the effect of PPARγ agonist pioglitazone on 11HSDs expression was assessed in primary cultures of VSMC derived form rat aorta. Pioglitazone significantly increased 11HSD1 activity (11-reductase) and mRNA expression in a dose-dependent manner with EC50 243 nM and this effect was not blocked by RU 486, an antagonist of the glucocorticoid receptor. Corticosterone had no effect on 11HSD1 expression. Pioglitazone positively regulated transcription of two CCAAT/enhancer-binding proteins (C/EBPs), specifically C/EBPα a potent activator of 11HSD1 gene transcription in some cells types, and C/EBPζ, whereas C/EBPβ and C/EBPδ were not changed. In contrast, corticosterone stimulated the expression of C/EBPβ and C/EBPδ, but the levels of C/EBPα and C/EBPζ were not changed. 11β-oxidase activity was not detected in VSMC in either control or pioglitazone treated cells even if weak signal for 11HSD2 mRNA expression was found. In conclusion, activation of PPARγ in VSMC up-regulates vascular 11HSD1 and thus reactivates 11-oxo metabolites to biologically active glucocorticoids through a mechanism that seems to involve C/EBPα and C/EBPζ. Our data provide one of the possible explanations for PPARγ agonists' effects on the cardiovascular system.

### Recombinant erythropoietin treatment enhances mitochondrial function in human skeletal muscle

U. Plenge[1], A. Guadeloupe-Grau[2], P. Andersen[2], L. Carsten[3], F. Dela[2], F. Pott[1], H. Jørn[2], B. Belhage[1] & R. Boushel[1,2]
[1]Bispebjerg Hospital, University of Copenhagen, Copenhagen, Denmark; [2]University of Copenhagen, Copenhagen, Denmark; [3]University of Zurich Institute of Physiology, Zurich, Switzerland.

Erythropoietin (Epo) treatment has been shown to induce mitochondrial biogenesis in cardiac muscle along with enhanced mitochondrial capacity in mice. We hypothesized that recombinant human Epo (rhEpo) treatment enhances skeletal muscle mitochondrial oxidative phosphorylation (OXPHOS) capacity in humans. In six healthy volunteers rhEpo was administered by s.c. injection over eight weeks with oral iron (100 mg) supplementation taken daily. Mitochondrial OXPHOS was quantified by high-resolution respirometry in saponin-permeabilized muscle fibers obtained from biopsies of the vastus lateralis before and after rhEpo treatment. OXPHOS was determined with the mitochondrial complex I substrates malate, glutamate, pyruvate and complex II substrate succinate in the presence of saturating ADP concentrations, while maximal electron transport capacity (ETS) was assessed by addition of an uncoupler. rhEpo treatment increased OXPHOS (from $92 \pm 5$ to $113 \pm 7$ pmol/s per mg) and ETS ($107 \pm 4$ to $143 \pm 14$ pmol/s per mg, $P<0.05$), demonstrating that Epo treatment induces an upregulation of OXPHOS and ETS in human skeletal muscle.

### Association of IL4 receptor gene polymorphisms with high density lipoprotein cholesterol

M. Shiau[1], C. Huang[2] & Y. Chang[3]
[1]Hungkuang University, Taichung, Taiwan; [2]Chung Shan Medical University Hospital, Taichung, Taiwan; [3]National Yang-Ming University, Taipei, Taiwan.

Abundant evidence demonstrates that long-term cytokine-mediated inflammation is a risk factor for obesity and type 2 diabetes mellitus (T2DM). Our previous study shows a significant association between IL4 genotypes and T2DM, as well as between IL4 genotypes and the lower circulatory levels of high-density lipoprotein-cholesterol (HDL-C). In addition, IL4 has anti-hyperglycemic function by improving insulin sensitivity and glucose tolerance as well as being involved in lipid metabolism by regulating serum levels of adipokines and free fatty acids. Taking the above results together, it strongly suggests that IL4

involves in the regulation of lipid metabolism. Interleukin 4 receptor α chain (IL4Rα) is a crucial component for binding and signal transduction of IL4. Polymorphisms located in IL4Rα which alter the binding affinity to IL4 or downstream signaling pathways and thus contribute to the fine tune of IL4 responsive phenotypes, would also be linked to disease development. The aim of this study is to investigate the correlation between IL4Rα E400A polymorphisms and lipid metabolism. Genomic DNA from 121 type 2 diabetes mellitus patients and 113 non-diabetic non-obese control study subjects were extracted, and their IL4Rα E400A polymorphisms were analyzed by PCR–RFLP. The correlation between IL4Rα E400A genotypes and study subjects' lipid profile was then examined. Significant associations of the IL4Rα E400A genotypes and HDL-C levels among control individuals ($P=0.007$), as well as among the obese T2DM patients ($P=0.029$), were observed. Significant correlations between IL4Rα E400A genotypes with blood pressure, as well as with blood urea nitrogen, were also observed in lean control subjects. Our results reveal that IL4Rα may play certain roles in the lipid metabolism of Taiwanese population and suggest a novel link between lipid metabolism and the cytokine receptor.

### Cardiovascular risk factors in a large cohort of children with GH deficiency

L. De Martino, D. Capalbo, A. Esposito, M. Cerbone, N. Improda, M. Rezzuto & M. Salerno
University Federico II, Naples, Italy.

Background

Adults with GH deficiency (GHD) may have an increased risk of cardiovascular disease. Several studies showed that also GHD children may present cardiovascular risk factors. However results are controversial.

Objective

Aim of this prospective, case-control study on a large cohort of children with GHD was to evaluate the effects of GHD and GH therapy on cardiovascular risk factors, such as lipid profile, clinical measures of visceral adiposity and inflammatory markers in a large cohort of GHD children.

Subjects and methods

Total-, LDL- and HDL-cholesterol, triglycerides, fibrinogen, C reactive protein (CRP), waist circumference, waist-to-height (WHtR) and waist-to-hip ratio (WHR) were evaluated in 60 GHD children (40 males), aged $9.9\pm0.4$ years, before and after 2 years of GH therapy. 60 healthy, age-, sex- and BMI-matched healthy controls were enrolled.

Results

Compared with controls, GHD children at baseline had higher total-cholesterol ($163.8\pm3.0$ vs $150\pm2.8$ mg/dl, $P=0.001$), LDL-cholesterol ($96.7\pm2.7$ vs $83.3\pm3.7$ mg/dl, $P=0.003$), triglycerides ($73.2\pm5.4$ vs $59.5\pm3.6$ mg/dl, $P<0.04$), fibrinogen ($305\pm8.4$ vs $278\pm9$ mg/dl, $P=0.03$) and CRP ($0.4\pm0.03$ vs $0.31\pm0.006$, $P=0.001$).Waist circumference was slightly higher in GHD patients although this difference was not significant. However, GHD children had higher WHtR ($0.54\pm0.01$ vs $0.47\pm0.01$, $P<0.0001$) and WHR ($0.96\pm0.01$ vs $0.92\pm0.01$, $P=0.005$) than controls. Two years of GH therapy were associated with significantly reduced levels of total- ($149.4\pm3.27$, $P=0.001$) and LDL-cholesterol ($79.6\pm3.0$, $P<0.0001$), triglycerides ($60.9\pm3$, $P<0.04$), fibrinogen ($265\pm6.5$, $P=0.0003$), CRP ($0.32\pm0.01$, $P=0.002$), WHtR ($0.49\pm0.01$, $P=0.0006$) and WHR ($0.92\pm0.01$, $P+0.005$).

Conclusions

Our data suggest that in children GHD is associated with cardiovascular risk factors such as adverse lipid and inflammatory profile and increased visceral adiposity. GH replacement therapy improves body composition, lipid profile and it reduces inflammatory risk factors.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P305

### Lipid profile in children with persistent idiopathic subclinical hypothyroidism

L. De Martino, M. Cerbone, F. Barbieri, A. Esposito, I. Di Donato, R. Di Mase & M. Salerno
University Federico II, Naples Italy.

Background

There is a great controversy on whether subclinical hypothyroidism (SH) in children should be treated for TSH values between 4.5 and 10 mU/l. In adults SH has been associated with abnormalities in lipid profile and increased risk of atherosclerosis. Data in untreated SH children are scanty.

Objective

The aim of this cross-sectional controlled study was to evaluate in children the effects of long term untreated SH on lipid profile and endothelial function.

Patients and Methods

Twenty children aged $9.7\pm0.6$ years with long-term idiopathic SH (lasting $3.5\pm0.5$ years), and 20 age and sex matched healthy controls underwent clinical examination and lipid profile evaluation. Endothelial function with flow-mediated dilation (FMD), an early marker of atherosclerotic event, was assessed by brachial Doppler ultrasound.

Results

No significant differences were observed between SH children and controls in BMI ($0.2\pm0.2$ vs $-0.3\pm0.3$ SDS), total cholesterol (TC; $149.6\pm7.4$ vs $141.8\pm7.5$ mg/dl), LDL-cholesterol (LDL-C; $85.2\pm5.2$ vs $81.6\pm4.7$ mg/dl), triglycerides (TG; $72.0\pm8.3$ vs $66.0\pm5.1$ mg/dl), atherogenic index ($3.1\pm0.2$ vs $2.8\pm0.1$) and in mean FMD values ($12.3\pm1.2\%$ vs $12.9\pm1.1\%$). A significant difference was only observed in HDL-cholesterol (HDL-C) that was lower in SH children compared to controls ($50.3\pm3.2$ vs $58.0\pm6.8$ mg/dl, $P<0.0001$).

Conclusions

Untreated idiopathic SH in children is not associated with significant abnormalities of lipid profile and endothelial function. However, the mild decrease in HDL-C might represent a first unfavorable change in lipid profile. Further studies on a larger number of patients with long-term follow-up are needed to clarify whether children with SH are at risk of subclinical abnormalities that may require levothyroxine treatment.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P306

### Variants of endothelial nitric oxide synthase gene are associated with components of metabolic syndrome in an Arab population

K. Alkharfy[1], N. Al-Daghri[1], O. Al-Attas[1], M. Alokail[1], A. Mohammed[1], B. Vinodson[1], M. Clerici[2], U. Kazmi[1], T. Hussain[1] & H. Draz[1,3]
[1]King Saud University, Riyadh, Saudi Arabia; [2]University of Milano, Milano, Italy; [3]National Research Centre, Cairo, Egypt.

Genetics plays a crucial role in the development of metabolic syndrome (MetS). Here we examined the association between endothelial nitric oxide synthase (eNOS) gene polymorphisms and MetS in a Saudi Arabian cohort to extend the understanding of the genetic basis of MetS in diverse ethnic populations. Anthropometric, clinical and biochemical parameters as well as genotyping for 894G>T, −786T>C variants of eNOS gene by PCR–RFLP and 4a/b by direct PCR were performed in 886 Saudi Arabians (477 MetS and 409 Non-MetS). The genotype distribution (TT, $P=0.001$; TC, $P=0.001$; TC+CC, $P=0.001$) and allele (T, $P=0.007$; C, $P=0.007$) frequency of the −786T>C SNP were significantly different between Non-MetS and MetS subjects which remained significant after Bonferroni correction. Moreover: i) the GT and GT+TT genotypes of the 894G>T SNP were associated with elevated blood pressure ($P=0.017$, and $P=0.022$ respectively); ii) the ab variant of 4a/b polymorphism was associated with decreased HDL levels ($P=0.044$); and iii) the TC+CC genotype and C allele of the −786T>C SNP were associated with increased fasting glucose levels ($P=0.039$, and $P=0.028$ respectively). Also, G-a-C was identified as the risk haplotype for MetS susceptibility ($P=0.034$). The result suggest a significant association of 894G>T, 4a/b and −786T>C polymorphisms with MetS and its components is present in an Arab population. A genetic predisposition to develop abnormal metabolic phenotypes, consistent with an increased prevalence of metabolic phenotypes can be detected in this ethnic group.

**MRTF-A, a rho-dependent co-activator of SRF, regulates phenotypic modulation of vascular smooth muscle cells and plays an important role in vascular remodeling**

K. Kuwahara, T. Minami, J. Shibata, C. Yamada, Y. Kuwabara, K. Nakao, H. Kinoshita, S. Usami, Y. Nakagawa, T. Nishikimi & K. Nakao
Kyoto University Graduate School of Medicine, Kyoto, Japan.

Myocardin-related transcription factor (MRTF)-A is a Rho signaling-responsive co-activator of serum response factor (SRF). In this study we investigated roles of MRTF-A in the process underlying vascular diseases by using two different mouse models of vascular diseases. MRTF-A expression was significantly higher in the wire-injured femoral arteries of wild-type mice and in the atherosclerotic aortic tissues of ApoE$^{-/-}$ mice than in healthy control tissues, whereas myocardin expression was significantly lower. In MRTF-A$^{-/-}$ mice, neointimal formation induced by wire injury in femoral artery was significantly smaller than that in MRTF-A$^{+/+}$ mice (neointima to media ratio: 2.09$\pm$0.17 in MRTF-A$^{+/+}$ vs 0.96$\pm$0.10 in MRTF-A$^{-/-}$, $P<0.05$). Diet-induced atherosclerotic lesions in MRTF-A$^{-/-}$; ApoE$^{-/-}$ mice was also significantly smaller than those in MRTF-A$^{+/+}$; ApoE$^{-/-}$ mice (% area of atherosclerotic lesions: 11.8% in MRTF-A$^{+/+}$; ApoE$^{-/-}$ vs 2.5% in MRTF-A$^{-/-}$; ApoE$^{-/-}$, $P<0.05$). Expression of vinculin, MMP-9 and integrin beta1, three SRF targets and key regulators of cell migration, in injured arteries was significantly weaker in Mkl1$^{-/-}$ mice than in wild-type mice. Knocking down MRTF-A using siRNA in cultured rat aortic vascular smooth muscle cells reduced expression of these genes, resulting in a significant impairment in PDGF-BB-induced migration. Underlying the increased MRTF-A expression in dedifferentiated vascular smooth muscle cells was the down-regulation of microRNA-1 concomitant with a decrease in myocardin expression. Collectively, these results demonstrate that MRTF-A plays a critical role in vascular remodeling by regulating vascular smooth muscle cells migration.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P308

**Association of PON-1 activity and other anti-oxidative enzymes with long-chain fatty acids profile in T2DM**

Z. Rasic-Milutinovic[1], J. Tica[1], Z. Gluvic[1], V. Popovic-Radinovic[1], M. Vujovic[1], M. Lackovic[1], V. Samardzic[1], T. Popovic[2] & M. Glibetic[2]
[1]University Clinical Center Zemun/Belgrade, Belgrade, Serbia; [2]Institute for Medical Research,University Belgrade, Belgrade, Serbia.

Background
Serum paraoxonase-1 (PON-1) activity is decreased in clinical conditions associated with low high density-cholesterol (HDL-C), increased lipid peroxidation and low-grade chronic inflammation such as in type 2 diabetes mellitus (T2DM). Although many studies have shown that some poly unsaturated fatty acids (PUFA) modulate cardiovascular risk in T2DM, until now there is no data about the association of any fatty acid (FA) with PON-1 activity. This study aims to investigate this field.
Materials and methods
The 20 consenting adult T2DM patients, and 16 healthy controls were included in this cross-sectional study. Serum PON-1 activity, was measured together with other anti-oxidative enzymes activity, catalase (CAT), superoxide dismutase (SOD), glutathione peroxidase (GSH-Px), as well as plasma glucose level, HbA1c, lipids, high sensitive C-reactive protein (hs-CRP) and insulin resistance, homeostasis model assessment (HOMA-IR). The extraction and preparation of FA methyl esters and their GC analysis were performed too.
Results
HbA1c, plasma insulin, HOMA-IR and triglycerides were significantly higher in T2DM patients, whereas HDL-C was lower in those subjects. The levels of pro-oxidative enzyme malonildialdehyde (MDA), and the marker of chronic inflammation hs-CRP, were significantly higher in plasma of T2DM patients, and on contrary anti-oxidative enzymes SOD, and PON-1 activity were decreased in T2DM patients. Total PUFA and *n*-6 PUFA were significantly higher in T2DM patients, particularly linoleic acid (LA, 18:2 *n*-6) and arachidonic acid (AA, 20:4 *n*-6), whereas *n*-3 PUFA, particularly docosahexaenoic acid (DHA, 22:6 *n*-3) were significantly lower in T2DM patients. Stepwise multiple regression analysis have shown that only LA and DHA, independently predicted PON-1 activity of our subjects. LA, DHA and the presence of T2DM explained 70% of variance in PON-1 activity.
Conclusions
We have shown that decreased serum PON-1 activity may be in part influenced by higher level of LA and lower level of DHA in T2DM patients.

**Risk factors of metabolic syndrome in adolescent with classical congenital adrenal hyperplasia**

A. Esposito, L. De Martino, N. Improda, D. Capalbo, R. Di Mase, I. Di Donato & M. Salerno
University Federico II, Naples, Italy.

Background
Patients with classical congenital adrenal hyperplasia (CAH) require life-long therapy with glucocorticoids in order to suppress the androgen production through the inhibition of CRH and consequently ACTH. The therapy must be balanced to avoid either iatrogen hypercortisolism or hyperandrogenism both potentially associated with adverse cardiovascular risk profile.
Objective
Aim of this cross-sectional controlled study was to investigate the metabolic risk profile in children and adolescents with classical CAH.
Subjects and methods
Twenty CAH patients (ten males and ten females, age range 9–19 years) and 20 age- and sex-matched healthy controls underwent clinical examination and lipids, blood pressure, fasting glucose concentrations, serum insulin levels and HOMA evaluation. Adiposity was expressed as BMI SDS. Waist circumference (WC) and waist-to-hip ratio (WHR) were used to evaluate visceral adiposity.
Results
BMI (0.9$\pm$0.9 vs $-$0.13$\pm$1.53; $P=0.008$), WC (82.9$\pm$13.7 vs 72.77$\pm$13.6; $P=0.01$), fasting insulin levels (12.0$\pm$7.6 vs 5.1$\pm$5.08; $P=0.003$) and HOMA index (2$\pm$1.34 vs 0.98$\pm$1.03; $P=0.01$) were significantly higher in CAH patients compared to controls. A significant relationship was observed between WC and BMI SDS ($r=0.78$, $P<0.0001$), fasting insulin levels ($r=0.4525$, $P=0.04$) and HOMA ($r=0.45$, $P=0.04$). No differences between the two groups were observed for lipid profile and blood pressure.
Conclusions
Our data suggest that children and adolescents with classical CAH may have a cluster of metabolic abnormalities that may place them at an increased risk of metabolic syndrome and cardiovascular disease. WC seems to be a good predictor of these metabolic abnormalities and therefore it should be routinely measured in the follow-up of patients with classical CAH.

**Alterations of protein expression profiles in 3T3-L1 adipocytes by interleukin 4**

Y. Chang[1], S. Chen[2], Y. Chiu[3], C. Tsao[4] & M. Shiau[2]
[1]National Yang-Ming University, Taipei, Taiwan; [2]Hungkuang University, Taichung, Taiwan; [3]Chung Shan Medical University, Taichung, Taiwan; [4]National Defense Medical College, Taipei, Taiwan.

Obesity, characterized by excess intra-abdominal adipose tissue, is closely associated with a cluster of metabolic disorders such as type 2 diabetes mellitus (T2DM). Our previous study revealed significant associations between interleukin 4 (IL4) genotypes and T2DM, as well as IL4 genotypes and high density lipoprotein-cholesterol levels. Our most recent study results reveal that IL4 has anti-hyperglycemic function by improving insulin sensitivity and glucose tolerance. In addition, IL4 is also involved in lipid metabolism by regulating serum levels of adipokines and free fatty acids. Taking the above results together, it strongly suggests that IL4 involves in the regulation of lipid and glucose metabolism. The aim of the present study is to identify differentially expressed proteins in 3T3-L1 adipocytes under IL4 treatment for further elucidating roles of IL4 in adipocyte metabolism. Differentially expressed proteins in mature 3T3-L1 adipocytes under IL4 treatment were identified by proteomic strategy. Levels of ATP synthase δ chain, cytochrome c reductase, pyrophsphatase and vimentin are increased, whereas levels of alpha-enolase, gelsolin, vinculin and valosin are down-regulated in the presence of IL4 stimulus. IL4 tends to potentiate the elevation of intracellular ATP levels and promote metabolism in adipocytes by up-regulating expression levels of proteins accelerating ATP synthesis. Our results suggest that metabolism of adipocytes is deviated to catabolism with an unfavorable condition for lipid storage by IL4. The lipids in adipocytes might either be released into periphery or metabolized intracellularlly, which in turn influence the systemic energy metabolism of other insulin-targeted organs.

**Anti-Müllerian hormone may be a hormonal regulator of the cardiovascular system**

N. Dennis, G. Jones, A. van Rij & I. McLennan
University of Otago, Dunedin, New Zealand.

Anti-Müllerian hormone (AMH, Müllerian inhibiting substance) is a protein hormone expressed by the Sertoli cells of the testes and the granulosa cells of the ovaries. AMH is best known for its paracrine functions in reproductive organ development and function. The hormonal roles of AMH are largely unexplored, but functions are emerging in growth and brain development. To date, there is no putative function for AMH in the blood of adults. AMH belongs to the TGF-β superfamily, and shares signalling components with the BMP sub-family, which contributes to the regulation of blood pressure and cardiovascular morphology. We therefore postulated that AMH may be a hormonal regulator of the vasculature.

The potential function of AMH was examined in a cross-sectional study, which correlated the levels of AMH in 153 healthy mature men to their cardiovascular status. This included measurement of the exterior diameter of the abdominal aorta by ultrasound (4–7 MHz).

The men's level of serum AMH negatively correlated with the external diameter of their aortas at both the mid-infrarenal and distal-infrarenal sites. The suprarenal aorta, in contrast, has limited capacity for remodelling and its diameter did not associate with the men's level of serum AMH ($r=-0.10$). In regression models, the association of AMH to aortic diameter ($r=-0.37$, $P<0.001$) was equal but opposite to the men's body surface area (BSA), which is the strongest known determinant of aortic diameter. The association between AMH and aorta was independent of the men's lipid profile, history of smoking and intimal thickness of their carotid artery, indicating that AMH may affect aortic diameter independent of atherosclerosis.

In conclusion, the results are consistent with AMH being a hormone in adults, with one of its functions relating to an aspect(s) of cardiovascular physiology, which directly or indirectly regulates the remodeling of the aorta.

**Anti-oxidataive actions of urocortin on HL-1 cardiomyocytes**

K. Ikeda[1], K. Fujioka[1], W. Claycomb[2], Y. Manome[1] & K. Tojo[3]
[1]Institute of DNA Medicine, Research Center for Medical Sciences, Jikei University School of Medicine, Tokyo, Japan; [2]Louisiana State University Health Sciences Center, New Orleans, Louisiana, USA; [3]Jikei University School of Medicine, Tokyo, Japan.

Cardioprotective actions of urocortin (Ucn) I have been proposed by several studies and may play a critical role on stress adaptation. And one of the beneficial actions on cardiovascular cells may be anti-oxidative actions. In addition, Ucn I may be regulated by oxidative stress, therefore, the present study is designed to reveal anti-oxidative actions of Ucns on cardiomyocytes. Mouse atrial cell line, HL-1 cardiomyocytes, was cultured in standard Claycomb medium supplemented with 10% fetal bovine serum and norepinephrine. Thereafter, HL-1 cardiomyocytes were further incubated in serum- and norepinephrine-free Claycomb medium containing 0.1% BSA with or without Ucn I, Ucn II, and astressin 2B, an antagonist of corticotroipin-releasing factor type 2 receptors (CRFR2) and oxidative stress was evaluated by measurement of conversion of 2′,7′-dichlorodihydrofluorescin diacetate to 2′,7′-dichlorodihydrofluorescein. Interestingly, Ucn I, but not Ucn II, suppressed oxidative stress of HL-1 cardiomyocytes without other stimulatory agents of oxidative stress. In addition, astressin 2B (10–6 mol/l) did not abolish the anti-oxidative action of Ucn I. It have been already reported that Ucn I exert anti-oxidative actions against angiotensin II-induced oxidative stress in human umbilical vein endothelial cells. Taken together with the present results, Ucn I may also exert cardioprotective actions via the anti-oxidative stress in cardiomyocytes, not via the CRFR2 signaling pathway.

**Adipokine expression profile in pericoronary and periaortic adipose tissue in correlation with coronary and aortic atherosclerosis**

I. Karamouzis[1], S. Spiroglou[2,3], C. Kostopoulos[2], H. Papadaki[2] & J. Varakis[2]
[1]University of Turin, Ospedale S. Giovanni Battista-Molinette, Turin, Italy; [2]University of Patras, Patras, Greece; [3]AHEPA University Hospital, Thessaloniki, Greece.

Introduction
Adipose tissue is a source of peptides with paracrine and endocrine actions, called adipokines. Adipokines produced by periadventitial fat have been implicated in vascular pathology, including atherosclerosis. We investigated the expression of novel adipokines chemerin and vaspin, as well as visfatin, apelin and adiponectin in human pericoronary and periaortic fat in correlation with coronary and aortic atherosclerosis.
Methods
Paraffin embedded samples of human left coronary arteries ($n=40$) and abdominal aortas ($n=40$), including periadventitial fat, were evaluated for chemerin, vaspin, visfatin, apelin and adiponectin expression using immunohistochemistry. AHA classification was used for atherosclerosis assessment. PASW Statistics was used for statistical analysis.

Results
Chemerin, vaspin, visfatin, apelin and adiponectin expression of varied degree was detected in 40/40, 40/40, 40/40, 40/40 and 39/40 pericoronary fat samples and in 37/40, 40/40, 39/40, 40/40 and 37/40 periaortic fat samples respectively. Differences in expression of adipokines were observed between pericoronary and periaortic adipose tissue; visfatin showed higher expression in pericoronary fat ($P=0.001$), as did apelin ($P<0.001$). Atherosclerosis was detected in 37/40 coronary arteries and 34/40 aortas. Coronary atherosclerosis was negatively correlated with pericoronary fat adiponectin expression ($r=-0.496$, $P=0.001$) and positively correlated with pericoronary fat chemerin ($r=0.333$, $P=0.036$) expression. Aortic atherosclerosis was negatively correlated with periaortic adiponectin expression ($r=-0.701$, $P<0.001$) and positively correlated with periaortic chemerin ($r=0.824$, $P<0.001$), vaspin ($r=0.498$, $P=0.001$) and visfatin ($r=0.562$, $P<0.001$) expression. Pericoronary fat vaspin and visfatin expression was not associated with the severity of coronary atherosclerotic lesions. Finally, periadventitial apelin expression was not associated with atherosclerosis at any site.
Conclusions
Our results lend support to the concept of differential expression of adipokines at distinct sites of adipose tissue. Moreover, periadventitial fat may affect vascular function through local adipokine production and, more interestingly, might differently affect the atherosclerotic process in different locations.

## P314

**Fatty liver index and lipid accumulation product index as markers of liver steatosis in premenopausal women with nonalcoholic fatty liver disease**

E. Vassilatou, D. Vassiliadi, H. Lazaridou, G. Betsi, A. Pavlaki, N. Kelekis, D. Hadjidakis & G. Dimitriadis
Athens University Medical School 'Attikon' University Hospital, Athens, Greece.

Background
Nonalcoholic fatty liver disease (NAFLD) is an increasingly recognised disorder with an estimated prevalence of 20–30% in the general population and is considered as the hepatic manifestation of the metabolic syndrome. Fatty liver index (FLI) has been developed as an indicator of hepatic steatosis (HS). Another marker, the lipid accumulation product (LAP) index, initially developed to assess cardiovascular risk, has been recently shown to be a reliable marker of HS.
Objective
To evaluate the use of FLI and LAP markers for the identification of HS in premenopausal women with NAFLD.
Patients and methods
Forty apparently healthy overweight and obese (BMI: 26.0–46.9 kg/m$^2$) premenopausal women (age: 18–45 years) with a history of none or minimal alcohol consumption, were evaluated prospectively for the presence of NAFLD with abdominal ultrasonography and biochemical testing, after excluding causes of secondary liver disease. FLI was calculated using body mass index, waist circumference, serum triglycerides and gamma-glutamyl transferase levels and log-transformed LAP (lnLAP) was calculated using waist circumference and serum triglycerides levels. The diagnostic performance of FLI and lnLAP were assessed with receiver operating characteristic analysis.
Results
HS was detected in 22/40 women (55%) by ultrasonography. Metabolic syndrome was diagnosed in 9/22 HS(+) women (40.9%) and in 1/18 (5.6%) HS(−) women, $P=0.01$. FLI and lnLAP were higher in HS(+) compared to HS(−) women ($71.7\pm28.5$ vs $47.3\pm24.5$ ($P<0.01$) and $4.0\pm0.8$ vs $3.5\pm0.4$ ($P<0.01$) respectively). The best cut off for FLI to detect HS was $\geq$ 47 (sensitivity 77%, specificity 67%) and for lnLAP was $>3.5$ (sensitivity 82%, specificity 67%).
Conclusion
Calculation of FLI and lnLAP are useful for detecting patients at high risk for NAFLD. In our cohort of premenopausal women with NAFLD a cut-off level $\geq$ 47 for FLI and $\geq 3.5$ for lnLAP were more discriminative for HS.

**Effects of long-term treatment of hypogonadal men with testosterone undecanoate on blood pressure, fasting glucose, HbA1c and C-reactive protein**

F. Saad[1,2], A. Haider[3] & L. Gooren[4]
[1]Bayer Pharma AG, Berlin, Germany; [2]Gulf Medical University, Ajman, United Arab Emirates; [3]Private Practice, Bremerhaven, Germany; [4]VUMC Amsterdam, Amsterdam, The Netherlands.

Introduction
Hypogonadism is associated with metabolic syndrome and all its individual components. This study analysed effects of normalization of serum testosterone in mainly elderly, hypogonadal men.
Methods
Prospective registry study of 252 men (mean age $60.6\pm8.0$ years), with testosterone levels between $\leq 3.5$ ng/ml. They received parenteral testosterone undecanoate 1000 mg at day 1, week 6 and every 12 weeks thereafter for up to 66 months.
Results
After 60 months the following changes were observed: systolic blood pressure declined from $153.74\pm17.61$ to $137.74\pm10.92$ mm Hg, diastolic blood pressure from $93.67\pm11.26$ to $79.61\pm7.35$ mm Hg. The changes were statistically significant vs baseline ($P<0.0001$). Both systolic and diastolic blood pressure reached a plateau within the second year of treatment.
Fasting glucose declined from $103.46\pm14.51$ to $97.54\pm2.34$ mg/dl. This decline was statistically significant vs baseline ($P<0.0001$), and a plateau was reached after $\sim$2 years. HbA1c was only measured in a subset of 123 patients at baseline and declined from $6.97\pm1.55$ to $6.01\pm1.41\%$ after 60 months which was statistically significant vs baseline ($P<0.0001$).
C-reactive protein (CRP) decreased from $6.3\pm8.01$ to $1.03\pm1.87$ mg/dl ($P<0.0001$ vs baseline).
Conclusions
Raising serum testosterone to normal for up to 66 months resulted in improvements in blood pressure, glycemic control, and CRP.
Declaration of interest
I fully declare a conflict of interest. Details below:

**Dysregulation of tissue renin–angiotensin–aldosterone system in obese hypertensive rats**

Y. Takeda, Y. Cheng, M. Demura, T. Yoneda, M. Kometani, T. Sawamura & S. Karashima
Kanazawa University, Kanazawa, Japan.

The activation of local renin–angiotensin–aldosterone system (RAAS) plays a pivotal role in the overall pathophysiology of the cardiovascular and renal diseases. Aldosterone can activate local renin and angiotensin converting enzyme (ACE). However, the effects of blockade of aldosterone on tissue RAAS including (pro)renin receptor and ACE2 are unclear in obese hypertensive rats induced by high-salt diet. Obese Zucker rats (ZOR) were fed with normal or high-salt diet for 8 weeks, and treated with eplerenone (100 mg/kg per day). ZOR fed a high-salt diet increased blood pressure (BP), kidney weight, urinary albumin excretion and urinary angiotensinogen excretion. Under these conditions, the rats exhibited decreased PRA and plasma aldosterone concentration and concomitant with increased expression of renal (pro)renin receptor protein and mRNA levels of angiotensinogen and ACE in the kidney. Treatment with eplerenone in ZOR fed a high-salt diet was associated with significant improvements in BP, kidney weight, urinary albumin excretion, urinary angiotensinogen excretion and decreased renal (pro)renin receptor protein expression and angiotensinogen and ACE mRNA levels. These results suggest that a high-salt diet increased renal RAAS, while blockade of aldosterone attenuated renal injuries by decreasing the activity of tissue RAAS in obese hypertension.

### The relationship between 25(OH)D levels and markers of atherosclerosis and inflammation in type 2 diabetic patients

A. Akalin, A. Karakus & F. Urfali
Eskisehir Osmangazi University, Eskisehir, Turkey.

Vitamin D deficiency has a leading role in endothelial functions and pathogenesis of type two diabetes and is supposed to take part in atherosclerosis. In this study we aimed to investigate the correlation between markers of atherosclerosis and inflammation with 25(OH)D levels in patients with type two diabetes. Forty patients with type two diabetes and macrovascular complication and 40 patients without macrovascular complication were included in the study. Thirty healthy subjects served as the control group. As markers of inflammation hsCRP, homocysteine, erythrocyte sedimentation rate, fibrinogen and adiponectin levels were studied. Carotid artery intima-media thickness (IMT) that is supposed to be a marker of atherosclerotic process was measured and 25(OH)D levels were studied in all subjects.
Levels of hsCRP, parathormone and body mass indices(BMI) were significantly higher in patients with 25(OH)D levels below 30 nmol/l than patients with 25(OH)D levels above 30 nmol/l. HsCRP, fibrinogen, erythrocyte sedimentation rate and homocysteine levels showed a negative correlation with 25(OH)D levels in all cases. Also, there was a negative correlation between waist circumference, BMI and 25(OH)D levels among diabetics. No significant difference between patients with 25(OH)D levels above or below 30 nmol/l was found for IMT, however IMT was significantly higher in diabetic patients. No significant difference was observed between patients with 25(OH)D levels above or below 30 nmol/l for levels of adiponectin, but there was a positive correlation betweeen adiponectin and 25(OH)D levels. There was no significant difference between diabetics with and without macrovascular complications regarding 25(OH)D levels
Levels of 25(OH)D is closely associated with markers of inflammation. Vitamin D deficiency also correlates with a predisposition to obesity and inflammation.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Plasma total homocysteine levels in transsexuals after cross-sex hormonal treatment

A. Becerra[1,3], G. Perez-Lopez[1], M. Menacho[1], R. Villar[2], J. Del Rey[1], M. Lucio[1], N. Asenjo[1], J. Rodriguez-Molina[1,4], J. Llopis[5] & V. Aguilar[3]
[1]Hospital Universitario Ramon y Cajal, Madrid, Spain; [2]Hospital Universitario Fuenlabrada, Madrid, Spain; [3]University of Alcala, Alcalá de Henares, Spain; [4]University Autonoma, Madrid, Spain; [5]University Complutense, Madrid, Spain.

Introduction
The transsexuals are persons that having born with a biological sex feel to belong to the opposite sex. To obtain the sexual characters opposite to his (her) biological sex they need treatment with cross-sex hormones.
This treatment with sexual steroids can produce changes in cardiovascular risk factors (CRF). There has been described that hyperhomocysteinemia is an independent CRF that is modifiable by cross-sex hormonal treatment (CHT) in transsexuals but there is no agreement on the sense of these changes. We investigate the effects of CHT on plasma total homocysteine (Hcy) levels.
Material and methods
We measured at baseline and after 12 and 36 months of treatment with conjugated oral estrogens (2.4–3.6 mg/day), in combination with the antiandrogen, cyproterone acetate (100 mg/day), in 63 male-to-female transsexuals (MFT), aged 32.4 ± 8.5 years, and with testosterone gel (50 mg/day) in 79 female-to-male transsexuals (FMT), aged 29.0 ± 7.9 years. None had done gonadectomy.
Results
At baseline the levels of Hcy were significantly higher in the MFT group. In FMT, the plasma Hcy level increased from geometric mean 10.9 to 11.2 μmol/l ($P=0.032$) after 12 months, and to 11.8 μmol/l ($P=0.003$) after 36 months. In MFT, the plasma Hcy level decreased from geometric mean 11.7 to 10.6 μmol/l ($P=0.006$) after 12 months, on the contrary these levels increased to 12.5 μmol/l ($P=0.003$) after 36 months.
Conclusion
Hcy levels increase after androgen administration to female (transsexual) subjects, resulting in worsening of the cardiovascular risk in androgen-treated FMT. On the contrary after estrogens administration to male (transsexual) subjects, those decrease after 12 months but increase after 36 months. These changes may be due to the long-term different effects of testosterone and estrogens on metabolism of Hcy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

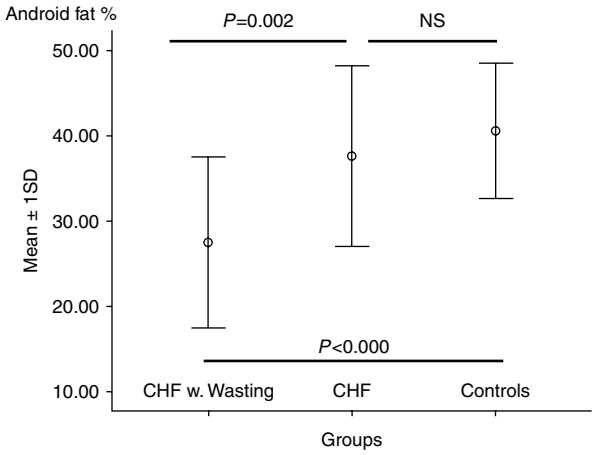
## P319

### Body composition and association to NT-proBNP and myostatin levels in heart failure patients

H. Christensen[1], C. Kistorp[1], M. Schou[2], B. Zerahn[1], N. Keller[1] & J. Faber[1]
[1]Herlev Hospital, Herlev, Denmark; [2]Rigshospitalet, Copenhagen, Denmark.

Objectivs
Plasma NT-proBNP is inversely associated with BMI in patients with heart failure (HF). A possible mechanism may be the lipolytic effect of natriuretic peptides on abdominal fat.
Myostatin is previously described as a negative regulator of skeletal muscle mass in cachexia.
We assessed the hypothesis that body composition is related to plasma NT-proBNP and that myostatin levels are associated with loss of fat free mass (FFM) in HF.
Methods
We included 57 patients (19 with systolic HF and cardiac cachexia, 19 HF patients without cachexia and 19 patients with prior MI). The groups were matched by age and gender, mean (S.E.M.) age 78.3 (1.0) years and 79% males. Body composition was assessed by DEXA, measuring FFM and fat mass as well as fat distribution.
Results
In univariate linear regression analyses abdominal fat % was inversely associated with NT-proBNP ($\beta=-0.30$; $P=0.025$) no association with gynoid fat % ($P=0.51$), FFM % ($P=0.20$) nor total body fat % ($P=0.12$) was observed. Multivariable linear regression analysis adjusted for well-established predictors of NT-proBNP (LVEF, kidney function, NYHA functional class and age) demonstrated no attenuation ($\beta=-0.28$; $P=0.018$) in this association.
No correlation between serum myostatin and fat free mass ($\beta=-0.058$; $P=0.67$) was observed. Mean (S.E.M.) myostatin was significant lower in the cachexia group (5.2 (0.3) ng/ml vs 6.2 (0.5) ng/ml and 6.7 (0.5) ng/ml, respectively; $P=0.036$).
Conclusions
Reduced abdominal fat mass was independently associated with high NT-proBNP, suggesting NT-proBNP could be related to the body composition alterations observed in HF patients with cachexia. The lack of association between myostatin and FFM was unexpected. However, the fact that myostatin was reduced among HF with cachexia raises the possibility that myostatin plays a secondary protective role in muscle loss in cachexia and has no primary involvement in pathogenesis.



Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P320

### Subclinical atherosclerosis and arterial stiffness are associated with levels of circulating androgens in healthy recently menopausal women

E. Armeni[1], K. Stamatelopoulos[2], M. Creatsa[1], D. Rizos[3], G. Georgiopoulos[2], M. Kazani[b], A. Alexandrou[1], S. Dendrinos[a], A. Augoulea[1], C. Papamichael[2] & I. Lambrinoudaki[1]
[1]2nd Department of Obstetrics and Gynecology, Athens, Greece; [2]Department of Therapeutics, Athens, Greece; [3]Hormonal Laboratory, Athens, Greece.

Introduction
Endogenous sex hormones may affect the cardiovascular risk profile in postmenopausal women indirectly by inducing metabolic, hemodynamic and immunological changes as well as directly through steroid receptors on the arterial wall. The results however, remain controversial.
Objectives
This cross-sectional study aims to examine associations between circulating sex hormone levels and indices of vascular function and structure.
Methods
One hundred and twenty healthy postmenopausal women, aged 41–60 years, were recruited. We performed biochemical and hormonal evaluation, including levels of FSH, LH, estradiol, testosterone, sex hormone-binding globulin, DHEAS, and Δ4-androstenedione. Indices of arterial structure and function included carotid and femoral intima-media thickness (IMT) and atheromatous plaques presence as well as flow-mediated dilation of brachial artery, carotid-femoral pulse wave velocity (PWV) and augmentation index (A.I.). Possible associations between circulating sex hormones and surrogate markers of vascular function and structure were investigated.
Results
Free androgen index predicted significantly mean levels of common carotid artery IMT ($\beta = 0.236$, $P$ value $= 0.014$) as well as levels of PWV ($\beta = 0.254$, $P$ value $= 0.027$) in multivariate models that included other confounders (e.g. age, smoking, BMI, HOMA-IR and blood lipids). Free estrogen index had a significant positive effect on PWV, but not independently of HOMA-IR and blood lipids. Age-adjusted levels of DHEAS exhibited a significant independent negative association with measures of A.I. ($\beta = -0.267$, $P$ value $= 0.029$). None of the remaining hormones associated with any of the vascular parameters independently of traditional cardiovascular risk factors.
Conclusion
Circulating testosterone is associated with both subclinical atherosclerosis and arterial stiffness in healthy recently menopausal women, independently of traditional cardiovascular risk factors or insulin resistance indicating a possible direct association. On the contrary, serum DHEAS exhibits a negative association with arterial stiffness. The documentation of elevated androgens as a risk factor for cardiovascular disease will have important implications with regard to primary prevention policies.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P321

### Metabolic syndrome, hormone levels and inflammation in patients with erectile dysfunction

Y. Suleiman-Martos[1], M. Arrabal-Polo[1], A. Jimenez-Pacheco[2], A. Zuluaga-Gomez[1], F. Escobar-Jimenez[1] & M. Arrabal-Martin[1]
[1]San Cecilio University Hospital, Granada, Spain; [2]Santa Ana Hospital, Granada, Spain.

Introduction
Chronic inflammation has been found to play an important role in the development of cardiovascular risk factors and erectile dysfunction (ED). Metabolic syndrome (MS) is associated with endothelial dysfunction and higher cardiovascular risk. The end point of this study was to investigate the prevalence of metabolic syndrome in patients with ED in comparison with control subjects and to analyse the association with acute phase reactants (CRP, ESR) and hormone levels.
Methods/Design
This case-control study included 65 patients, 37 with erectile dysfunction, according to the International Index of Erectile Function (IIEF) from the Urology Department of San Cecilio University Hospital, Granada (Spain), and 28 healthy controls. The prevalence of metabolic syndrome was calculated according to ATP-III criteria. Hormone levels and acute phase parameters were studied in samples drawn between 0800 and 0900 h after a rest period of $\geq 30$ min.
Results
The mean age of patients with ED was $55.8 \pm 7.7$ years vs. $52.5 \pm 4.8$ years in the control group ($P = 0.06$). The ATP-III criteria for MS were met by 64.9% of the patients with ED and only 9.5% of the controls ($P < 0.0001$, OR $= 17.53$, 95% CI: 3.52–87.37). Binary logistic regression analysis showed a strong association between patients with ED and MS, even after additional adjustment for confounding factors (OR $= 20.05$, 95% CI: 1.24–32.82, $P < 0.034$). Patients with hypogonadism presented a significantly higher prevalence of metabolic syndrome. Multiple linear regression analysis showed that systolic BP and CRP predicted 0.46 (model R2) of IIEF changes.
Conclusions
Chronic inflammation found in patients with ED might explain the association between ED and metabolic syndrome. Cardiovascular screening by MS criteria assessment in patients with ED may be useful to detect at-risk individuals and start preventive treatment against the development of cardiovascular disease.

### Duration effect of statin therapy on bone metabolism in dyslipidemic patients

O. Cvijanovic[1], Z. Crncevic-Orlic[2], N. Bicanic[2], T. Celic[1], D. Bobinac[1] & S. Klobucar[2]
[1]Medical Faculty University of Rijeka, Rijeka, Croatia; [2]Clinical Hospital Center Rijeka, Rijeka, Croatia.

Statins are cholesterol-lowering drugs decreasing bone resorption by inhibition of the farnesyl diphosphate synthase step in the mevalonic acid pathway and therefore are believed to have beneficial effects on bone status. Objective is to examine the relationship between lipid status and duration of statin therapy on the bone metabolism in dyslipidemic patients. A hundred and sixty subjects were divided into five groups depending on duration of statin therapy: (controls 0 years); (0.1–1.5 years); (2–5 years); (6–10 years); (11–30 years). ELISA method was performed on fasting serums using bone formation markers: osteoprotegerin (pmol/l) and osteocalcin (ng/ml) and bone resorption markers: s RANKL (pmol/l) and CrossLaps (ng/ml). For each bone marker and bone densitometry parametar, differences between statin groups were analyzed by repeated measures analysis of variance. Scheffe *post hoc* was used to identify specific differences between groups. Bone markers showed significant variation by duration of statin therapy ($F(16,268) = 2.49$; $P < 0.01$). The trend showed increase of bone formation markers and decrese of bone resorption markers with increasing duration of statin therapy. Bone mineral density (BMD g/cm$^2$) did not show significant changes due to statin therapy ($F(16,260) = 0.98$; $P = 0.47$). Clearly, statin therapy influences bone metabolism, which is observed by dynamics of bone markers changes.

## P323

### Coronary flow reserve is inversely related to urinary cortisol in Cushing's syndrome

F. Fallo[1], D. Capizzi[1], F. Dassie[1], N. Sonino[1], C. Martini[1], A. Paoletta[2], G. Famoso[1], S. Iliceto[1] & F. Tona[1]
[1]University of Padova, Padova, Italy; [2]City Hospital, Ciittadella Padova, Italy.

There is evidence for a strong association between Cushing's syndrome, characterized by a cluster of systemic complications, and increased

cardiovascular risk. To our knowledge, coronary circulatory function has not been explored in Cushing's syndrome. The aim of the study was to evaluate coronary flow reserve (CFR), an index of coronary microvascular function, in patients with Cushing's syndrome. Thirteen newly diagnosed patients with Cushing's syndrome (12 F/1M; mean age 42.3±9.9 years), were selected for having no clinical evidence of ischemic heart disease. There were 11 cases of pituitary-dependent Cushing's disease and two of cortisol-producing adrenal adenoma. Thirteen subjects matched for age, sex, and major cardiovascular risk factors were used as controls. Coronary flow velocity in the left anterior descending coronary artery was investigated by transthoracic Doppler echocardiography at rest and during adenosine infusion. CFR was obtained as the ratio hyperaemic/resting diastolic flow velocity. Mean CFR was similar in patients with Cushing's syndrome and controls (2.9±0.4 vs 3.1±1.4, *P* NS). A reduced coronary reserve (hyperaemic/resting ratio ≤2.5) was found in 4/12 (30.7%) Cushing patients and in 4/12 controls. In all patients with abnormal CFR epicardial coronary stenosis was excluded by multi-slice CT coronary angiography. CFR was inversely related to urinary cortisol levels in patients with endogenous hypercortisolism (Spearman's $\rho = -0.63$, $P = 0.02$) while no correlation was found in control subjects.
Conclusions
Coronary microvascular function, as assessed by CFR, is reduced in a considerable proportion of patients with Cushing's syndrome without clinical evidence of ischemic heart disease. The relationship between CFR and cortisol may contribute to explain the increased risk of cardiovascular mortality in Cushing's syndrome. Whether exposure to excess cortisol (possibly linked to duration of disease) may have per se a pathogenic role on coronary dysfunction, requires further studies.

## P324

**Myeloperoxidase is not associated with applications of coronary artery disease and type 2 diabetic patients**

T. Mokhort[1], N. Tsapaeva[2], I. Buko[2], E. Konstantinova[2] & O. Shyshko[1]
[1]Belorussian State Medical University, Minsk, Belarus; [2]Belorussian Republic Center of Cardiology, Minsk, Belarus.

Myeloperoxidase (MPO), an enzyme of the innate immune system, exhibits pro-atherogenic effects and includes influence on oxidative damage to LDL- and HDL-cholesterol, and promotion of endothelial dysfunction.
The aim
To investigate the disturbance of MPO in type 2 diabetic (T2D) patients depending on intensity of atherosclerosis
Material and methods
We investigated 244 patients aged from 45 to 60 years (M±SD 54.0±4.63) including 67 T2D patients treated with oral antidiabetic drugs with coronary artery disease; 88 patients with applications of coronary artery disease only and 89 healthy persons. The activity of MPO in plasma were estimated with special spectrophotometric method using *O*-dianisidine and MPO inhibitor hydraside 4-aminobenzoic acid. MPO concentration estimated with original IFA method with MPO antibodies from immunizated rats and rabbits.
Results
We revealed standart lipid abnormalities in examined patients. The MPO concentration in T2D were 46.9 (18.05–73.00) ng/ml to compare patients with control group 35.31 (19.30–84.40) ng/ml and patients without diabetes 40.20 (40.20–40.20) ng/ml. There were no difference of MPO activity: in T2D 0.0041 (0.008–0.010) EU; in healthy persons 0.0034 (0.001–0.007) EU and 0.0012 (0.001–0.001) EU in patients with applications of coronary artery disease.
Conclusions
T2D is not associated with higher concentration or activity of MPO.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P325

**Analysis of hyponatremia in a tertiary hospital during a 5 year period**

A. Duran, E. Gomez, A. Molino, C. Granda & J. Marco
Hospital Clinico San Carlos, Madrid, Spain.

Aims
Hiponatremia is the most frequent electrolyte disturbance. Our aim is to retrospectively analyze the diagnosis of hyponatremia in the discharge sheets of a tertiary hospital during 5 years
Method
Data from the MBDS (Minimum Basic Data Set) of the discharged patients from the Hospital Clínico San Carlos (Madrid) between the years 2005 and 2009 was analysed. The 5th Edition of the ICD-9-CM was used for the codification of the diagnoses and procedures. The system of patient classification of diagnosis related groups – AP-DRG (version 21.0) – was used for the grouping of discharge processes. The Charlson index was use as a measure of comorbidity. Patients with a main or secondary diagnosis of hyponatremia were analyzed. Age, sex, length of stay, comorbidity, procedures and mortality were taken into account.
Resultados
Concerning destiny after discharge, 81.6% go home, 1.4% to another hospital and 2.8% to a nursing home. Mortality was 13.1 vs 4.3% among the general population. We found a statistically significant difference between hyponatremic patients and the rest concerning destiny to nursing homes (0.8 vs 1.6%) and in the univariate analysis for the mortality rate between hyponatremic patients and the rest: 13.1 vs 4.3%.
Discusion
The first important observation of our study is the extremely low prevalence of hyponatremia in our series (1.5%). In some series, mild hyponatremia has been reported to be 30 and 2.5% of patients show sodium levels below 125 mmol/l. We have observe an increased in mortality for hyponatremic patients; alter correcting for other confusing variables, patients with hyponatremia have 23% more possibilities of dying than dose with normal sodium levels. Our observations showed the importance of treating this frequently underdiagnosed disturbance and its negative prognostic implications on hospital admittances.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P326

**Effect of melatonin supplementation on lipid peroxidation and on the enzymes of antioxidative system in patients with chronic coronary artery disease.**

Z. Podgajny[1], M. Kot[2], N. Szalus[1], P. Mitura[2] & G. Kaminski[1]
[1]Military Institute of Health Services, Warsaw, Poland; [2]Medical University, Lublin, Poland.

Background
Melatonin as strong antioxidant and free radical scavenger can play important, protective role in disease in which oxidative damage is a significant component e.g.: in coronary heart disease, neoplastic disease, neurodegenerative disease. The aim of our study was determination of the effect of melatonin supplementation on malonyldialdehyde (MDA) concentration and activity of: superoxide dismutase (SOD), glutathione peroxidase (GSH-Px) and catalase (CAT) in patients with chronic coronary artery disease.
Material and methods
The study included 20 patients with CAD at the mean age of 63.9±8.7 years. Patients were divided into subgroups (diabetics, nondiabetics, smokers, nonsmokers). Each patient received 5 mg melatonin for the mean of 96.3 ±14.2 days. The material of study was blood, taken at 08.00 am at the beginning of the study and after 3 months of the melatonin administration. MDA concentration was determined in plasma and SOD, CAT, GSH-Px activity were determined in hemolysate.
Results
There were found statistically significant differences in SOD activity in patients with diabetes mellitus comparison to non- diabetes mellitus patients (6.06±3.05 i 3.82±1.19 IU/mg protein; $P = 0.026$) and higher MDA concentration in smokers comparison to non-smokers (3.23±2.9 i 2.32±0.36 nmol/ml $P = 0.006$). After 3 months of melatonin treatment increase GSH-Px from 53.06±15.85 IU/mg protein to 92.06±78.55 IU/mg protein ($P = 0.036$), increase SOD activity in non-diabetes mellitus group from 3.82±1.19 to 5.28±1.31 IU/mg Protein ($P = 0.002$) and in non-smokers group from 3.99±1.18 to 5.06±1.20 IU/mg Protein

($P=0.014$) were found. In addition, decrease of MDA concentration were observed, from $2.85\pm0.98$ to $1.18\pm0.29$ nmol/ml ($P=0.017$), in Patients with diabetes mellitus.
Conclusions
The antioxidative Properties of melatonin were confirmed in the study. The supplementation of melatonin may be useful as a supportive therapy in Patients with chronic coronary artery disease.
Key words: melatonin, oxidative stress, coronary disease.

## P327

**N-terminal pro-brain natriuretic peptide (NT-proBNP) in patients with non-ST-elevation myocardial infarction (NSTEMI) compared to patients with unstable angina (UA) in a lot of patients admitted for non-ST-elevation acute coronary syndrome (NSTE-ACS)**

A. Pascu[1], M. Radoi[1], A. Bisoc[1], D. Barbu[1], I. Barbu[1], C. Ciurea[1], G. Totoianu[2] & M. Stanciu[2]
[1]Transilvania University, BRASOV, Romania; [2]Lucian Blaga University, SIBIU, Romania.

Introduction
The study aimed to evaluate the differences in secretion of NT-proBNP and cardiac troponin T (cTnT), in patients with NSTE-ACS for the early detection of myocardial ischemia in NSTE-ACS.
Methods
Hundred and sixteen patients admitted for non-ST-elevation ACS (NSTE-ACS), 71(61.2%) men, mean age $68.7\pm10.2$ were prospectively investigated. Plasma NT-proBNP and cTnT were measured by electrochemiluminescence (Elecsys/-Cobas e, Roche Diagnostics) on admission. Study population was divided into two groups, based on clinical findings, 12-lead electrocardiography (ECG), 2D echocardiograpy (ECHO) and the plasma cut-off level of cTnT $=0.1$ ng/ml, as follows: group 1, consisiting of $n=34$ (29.3)% patients with NSTEMI (cTnT $\geq$ 0.1 ng/ml) and group 2, including $n=82$ (70.7)% patients with UA (cTnT $<0.1$ ng/ml). Study protocol was approved by the local Ethics Committee and each patient enrolled signed an informed consent. Statistics: SPSS 16.0.; MedCalc 11.4.4.
Results
Plasma levels of NT-proBNP were significantly higher in patients with NSTEMI (group 1) compared to patients with UA (group 2): 1115 (235.7; 2289.5) vs 155.6 (60.4; 313.6) pg/ml, $P<0.0001$ values expressed as median (25th; 75th percentile). NT-proBNP did not significantly correlate to cTnT ($R=0.3$, $P=0.1$). The area under the receiver operating characteristic curve (AUC) for NT-proBNP in discriminating patients with NSTEMI from those with UA was 0.68 (95% Confidence Interval C.I. 0.55 - 0.81), $P < 0.001$.
Conclusion
Plasma levels of NT-proBNP was significantly higher in patients with non-ST-elevation acute myocardial infarction compared to patients with unstable angina, but did not significantly correlate with plasma levels of cTnT in our study group of patients with non-ST-elevation acute coronary syndrome.

## P328

**Effect of medical therapy on 24-h blood pressure profile in acromegaly**

C. Sardella, A. Nuzzo, C. Urbani, M. Lombardi, I. Scattina, L. Tomisti, E. Martino & F. Bogazzi
University of Pisa, Pisa, Italy.

To investigate the blood pressure profile (BP) in active acromegaly and the effect of medical treatment of acromegaly on BP circadian rhythm, we studied 21 acromegalics before and after 3–60 months of treatment with somatostatin analogs (15/21) or pegvisomant (5/21) or both (5/21). Ambulatory 24-h BP was recorded. The 24-h mean BP (MBP), the mean systolic BP (SBP) and diastolic BP (DBP), the day-time (day) and night-time (night) MBP, SBP and DBP and the 24-h mean heart rate (HR) were evaluated. At baseline, 11 patients were normotensive (NT) and ten were treated with antihypertensive drugs. In hypertensive (HT), mean night BP was higher than in NT ($P\leq0.01$). The BP circadian rhythm was abnormal in 62% of active acromegalics with no difference between the two groups. No correlation between BP and GH or IGF1 was found in HT acromegalics. After therapy, acromegaly was controlled (C) in 12 patients (6 NT and 6 HT) whereas in nine (5 NT and 4 HT) was not controlled (NC). After therapy, 24-h and night MBP and 24-h, day- and night DBP were lower ($P\leq0.05$, $P\leq0.01$) in HT and NC patients whereas SBP, MBP and DBP were increased ($P\leq0.05$, $P\leq0.01$) in NT and NC acromegalics. No difference before and after treatment was found in the C group although three patients reduced or discontinued the antihypertensive drugs after IGF1 normalization. After therapy, the BP circadian rhythm was disturbed in 47% of all patients and in 60% of NC. The 24-h mean HR was lower either in HT ($P=$NS) or NT ($P\leq0.05$) after treatment regardless of disease control. Active acromegaly is associated with alterations of 24-h BP profile; control of acromegaly may reduce the risk to develop hypertension and is associated with improvement of several BP parameters.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P329

**Polycystic ovary syndrome induces leukocyte/endothelial cell interactions**

V. Victor, C. Bañuls, L. Bellod, S. Rovira, M. Gomez, M. Rocha & AHernandez- Mijares
Hospital Dr. Peset, Valencia, Spain.

Insulin resistance is a feature of polycystic ovary syndrome (PCOS) and is related to mitochondrial and endothelial function.We tested whether hyperandrogenic insulin-resistant women with PCOS, who have an increased risk of vascular disease, display impaired leukocyte-endothelium interactions, and mitochondrial dysfunction. This was a prospective controlled study conducted in an academic medical center.
The study population consisted of 43 lean reproductive-age women with PCOS and 39 controls subjects.
We evaluated anthropometric and metabolic parameters, adhesion molecules, and interactions between leukocytes and human umbilical vein endothelial cells. Mitochondrial function was studied by assessing mitochondrial oxygen consumption, membrane potential, reactive oxygen species production, glutathione levels (GSH), and the oxidized glutathione (GSSG)/GSH ratio in polymorphonuclear cells.
Impairment of mitochondrial function was observed in the PCOS patients, evident in a decrease in oxygen consumption, an increase in reactive oxygen species production, a decrease in the GSH/GSSG ratio and GSH levels, and an undermining of the membrane potential. PCOS was related to a decrease in polymorphonuclear cell rolling velocity and an increase in rolling flux and adhesion. Increases in IL6 and TNF$\alpha$ and adhesion molecules (vascular cell adhesion molecule-1 and E-selectin) were also observed.
This study supports the hypothesis of an association between insulin resistance and an impaired endothelial and mitochondrial oxidative metabolism. The evidence obtained shows that the inflammatory state related to insulin resistance in PCOS induces a leukocyte-endothelium interaction. These findings may explain the increased risk of vascular disease in women with PCOS.

## P330

**Effect of weight loss on C3 and C4 components of complement in obesity**

V. Victor, C. Bañuls, L. Bellod, A. Jover, C. Morillas, R. Falcon, M. Rocha & AHernandez- Mijares
Hospital Dr Peset, Valencia, Spain.

Circulating C3 levels are elevated in obese patients, but how this factor is affected after weight loss through diet is a question that is yet unanswered. Therefore, the aim of this study was to evaluate the effects of weight loss on lipid and hydrocarbonated metabolism parameters and on the levels of C3 and C4 components of complement in obese patients. This is a longitudinal intervention study based on a 6 week very low calorie diet (VLCD), a liquid formula of 603 kcal/day. A total of 131 middle-aged patients were distributed among grades II, III and IV of obesity. Anthropometric parameters, total cholesterol, triglycerides, high-density lipoprotein cholesterol, LDLc, apolipoproteins A-I and B-100, glucose, insulin, HOMA-IR and C3 and C4 levels were evaluated at baseline and after 6 weeks of intervention. After VLCD, the moderate weight loss was accompanied by a significant reduction in C3 levels in grade III and grade IV patients (10.2 and 15.4%, respectively; $P<0.001$). C4 levels were not altered. Adherence to the diet improved anthropometric parameters and was accompanied by a significant decrease in all lipid profile parameters ($P<0.001$). In addition, weight loss was associated with an improvement in hydrocarbonated metabolism as shown by the decrease in glucose levels and HOMA-IR ($P<0.01$). Our findings show that in severely obese patients following a VLCD for 6 weeks produces reductions in factor C3, a biomarker of cardiovascular disease, and a significant improvement in some features of metabolic syndrome. In this way, the abovementioned diet may represent an effective strategy for treating obesity and related cardiovascular risk factors.

**Vitamin D serum levels and cardiovascular risk factors in postmenopausal women**

A. Bohdanowicz-Pawlak, A. Milewicz, D. Jedrzejuk, J. Szymczak & A. Arkowska
Wroclaw Medical University, Wroclaw, Poland.

Results of several clinical studies have suggested that there is an excess risk of cardiovascular disease in persons with vitamin D deficiency.

We examined association between serum levels of vitamin D - 25(OH)D and select cardiovascular risk factors in 254 postmenopausal women at a mean age of $55.38 \pm 205$ years.

Vitamin D levels, lipoproteins, TNF-$\alpha$, Interleukin 6, adiponectin, insulin (using RIA methods) and glucose were assessed in fasting blood samples of healthy postmenopausal women. Total body fat mass was measured by dual energy X-ray absorptiometry.

The mean vitamin D level was $24. \pm 11.5$ ng/ml. The group with vitamin D level $<15$ ng/ml vs group with vitamin D level $\geq 40$ ng/ml demonstrated significant elevated percent of total body fat ($P<0.033$), higher levels of Interleuki $n$ 6 ($16.12 \pm 5.3$ vs $14.03 \pm 3.16$ pg/ml, $P< 0.08$) and decrease level of adiponectin ($12.93 \pm 7.4$ vs $15.83 \pm 6.8$ µg/ml, $P<0.036$). An inverse correlations between vitamin D and % of total body fat ($P<0.0004$, $r=-0.198$, $n=254$) and interleukin 6 ($P<0.017$, $r=-0.147$, $n=254$) were observed in total group.

Vitamin D deficit is associated with cardiovascular risk factors in postmenopausal women.

## P332

**Sympathetic over-activity and low adrenocortical responses to hypoglycemia in patients in early stage of hypertension**

A. Penesova[1], Z. Radikova[1], E. Cizmarova[2], R. Kvetnansky[1], M. Vlcek[1] & R. Imrich[1]
[1]Institute of Experimental Endocrinology, Slovak Academy of Sciences, Bratislava, Slovakia; [2]Out -patient Clinic Karlova Ves, Bratislava, Slovakia.

Increased activity of sympathetic nervous system (SNS) was observed in early stage of hypertension onset. The aim of our present study was to estimate catecholamines response to stress stimulus (insulin induced hypoglycaemia) in young males with early diagnosed non-treated hypertension grade 1 (HT) and normotensive controls (NT).

Methods

Insulin tolerance test (ITT, 0.1 IU/kg body weight, Actrapid HM, i.v.) was performed in 21 HT male subjects aged $20.0 \pm 0.6$ (mean $\pm$ S.E.M.) years with BMI $22.0 \pm 0.5$ kg/m$^2$ and in 19 NT males aged $23.1 \pm 1.0$ years with BMI $22.8 \pm 0.4$ kg/m$^2$. Concentrations of glucose, epinephrine, norepinephrine, plasma renin activity (PRA), growth hormone (GH), prolactin (PRL), adrenocorticotropic hormone (ACTH) and cortisol were determined in venous plasma.

Results

Increased baseline levels of norepinephrine ($P<0.05$), increased response of norepinephrine ($P<0.001$) and decreased response of GH ($P<0.001$), PRL ($P<0.001$), ACTH ($P<0.05$) and cortisol ($P<0.001$) to hypoglycemia were found in hypertensive patients when compared to normotensive controls. We did not observe differences in PRA baseline concentration or response to insulin induced hypoglycemia.

Conclusions: The early stage of onset of hypertension (in normal weight and young patients) is associated with sympathetic overactivity and decreased pituitary response to metabolic stress stimulus. These changes may also contribute to metabolic cardiovascular risk factors.

## P333

**The effect of thyroxine replacement on reduction of small dense low-density lipoprotein (sdLDL) in patients with primary hypothyroidism.**

J. Saito, T. Watanabe, Y. Matsuzawa, M. Omura & T. Nishikawa
[1]Yokohama Rosai Hospital, Yokohama, Japan.

Background

Dyslipidemia is a well-known manifestation of thyroid dysfunction and there is evidence of an association between hypothyroidism and coronary heart disease. Recently, small dense low-density lipoprotein (sdLDL) has been linked with development of cardiovascular disease. But relations between thyroid function and sdLDL remain incompletely understood.

Objective

Our objective was to determine whether replacement therapy with thyroxine for patients with hypothyroidism is associated with improvement of lipid profiles including sdLDL.

Design

We conducted a prospective clinical study. Nine patients with primary hypothyroidism were enrolled in this study and treated by replacement with thyroxine. Lipid profiles, sdLDL, TSH, thyroid hormone were measured in pre- and post-treatment blood samples.

Results

Seven patients (3 males and 4 females with Hashimoto's disease) of the patients completed this study and mean duration of treatment that normalized TSH was 126 days (85–153 days). The pre-/post-treatment TSH, free T4 (fT4), LDL cholesterol (LDL), sdLDL and sdLDL/LDL ratio were $181.0 \pm 219.2/7.3 \pm 7.5$ µIU/ml, $0.4 \pm 0.2/1.3 \pm 0.3$ ng/dl, $160.7 \pm 61.1/121.8 \pm 25.6$ mg/dl, $26.1 \pm 16.8/14.7 \pm 4.7$ mg/dl, $0.157 \pm 0.047/0.138 \pm 0.043$, respectively. TSH and sdLDL were significantly decreased and fT4 was significantly increased after treatment.

Conclusion

The present study demonstrated a reduction of sdLDL levels of patients with hypothyroidism after treatment associated with an increase in thyroid hormone,

which may contribute to some cardiovascular alterations. Even though we found a reduction in sdLDL levels after treatment, the mechanism of this effect was still not well understood.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P334

**Metabolic consequences of obesity in children and adolescents**

I. Gherlan, M. Giurcaneanu, C. Perhaita, F. Alexiu, A. Caragheorgheopol, C. Dumitrescu & C. Procopiuc

'C.I.Parhon' National Institute of Endocrinology, Bucharest, Romania.

Introduction

The prevalence of obesity in children and adolescents has dramatically increased over the last 20–30 years.

Childhood overweight is associated with higher risk of obesity into adulthood and a higher incidence of metabolic consequences.

Objectives

To identify the prevalence of metabolic complications in obese children and adolescents.

Methods

One thirty-two obese children and adolescents (age over 10) admitted to our clinic over last two years were considered for participation in a transversal observational study.

There were performed auxological measurements (weight, height, abdominal circumference), clinical evaluations (blood pressure), bone age, blood samples for morning glucose, a 2 h glucose tolerance test, insulinemia, glicated haemoglobin, total cholesterol and its fractions, serum triglycerides.

Results

There were 65 girls and 67 boys, aged 10 to 18 years.

The metabolic syndrome (IDF consensus, Lancet 2007) was found in 31.8% of the obese children and adolescents.

Independent of their age, the independent risk factors for metabolic and cardiovascular disease had a high prevalence among the study' s subjects: impaired fasting glucose in three cases, an altered glucose tolerance in another four cases; 35.6% of the patients had biochemical criteria of insulinresistance (basal insulin levels $>24$ μUI/ml or HOMA-IR $>5.6$); 27% of patients had dyslipidemia; 8% of patients had serum levels of TGP slightly altered, suggesting steatosis; 30% of patients had high blood pressure.

The glycated haemoglobin values were not altered in any of our patients, suggesting a week correlation to the metabolic complications.

Conclusions

Metabolic consequences have a high rate of prevalence in obese children and adolescents (minimum 30% of cases).

Key words: obesity, children, metabolic syndrome

**Study on the DHEA-S secretion dynamics in elderly pacients with cardiovascular diseases**

D. Trasca, M. Popescu, E. Trasca, A. Popescu, M. Bistriceanu & S. Tudorica- Micu

University of Medicine and Pharmacy of Craiova, Craiova, Romania.

Background

The general population trend shows an increase in the elderly. The most affected systems in the aging process are the endocrine and cardiovascular systems. The cardiovascular conditions are very important among the diseases of the elderly, the mortality due to cardiovascular diseases holding the first place in geriatrics.

The aim of the study is to determine the peculiar aspect of dehydroepiandrosterone sulfate secretion dynamics in the elderly and correlate this hormonal parameter with the cardiovascular diseases, in order to realize ways to improve the early diagnosis of these patients.

Material and methods

The study group consists of 135 subjects aged over 65 years old divided in two subsets: the control subset comprising 66 healthy elderly and the subset of elderly diagnosed with various cardiovascular diseases (69 patients). The cases were investigated by clinical and paraclinic examination and the results were statistically processed.

Results

Serum dehydroepiandrosterone sulfate values in the subjects aged over 65 years old were normal, situated in the lower of the normal range. The patients with cardiovascular diseases showed a less DHEA-s average by about 50% compared to the one in the healthy subjects.

Conclusions

Healthy subjects have shown a decreasing trend in the DHEA-S levels with their aging. Diseases such as arterial hypertension, coronary ischemic heart disease, heart failure and atrial fibrillation might influence the DHEA-S secretion. The altered serum DHEA-S levels could become predictive factors for cardiovascular diseases.

Key words:DHEA-S, elderly, cardiovascular diseases.

Declaration of interest

## P336

**Testosterone and androstane-3α, 17β-diol glucuronide correlate with coronary disease**

O. Levalle[1], A. Hershson[2], P. Otero[1], E. Mormandi[1], N. Kogovsek[1] & S. Aszpis[1]

[1]Hospital Durand, Buenos Aires, Argentina; [2]Hospital Universitario Favaloro, Buenos Aires, Argentina.

The relationship between endogenous testosterone concentrations and coronary disease in men is controversial. Recently, it was demonstrated that the glucuronide metabolite of dihydrotestosterone (DHT), androstane-3α, 17β-diol (3-DIOL-G), but not testosterone (T), is strongly associated to several metabolic risk factors (fat mass, insulin, HOMA index, HDL, triglycerides, ApoA1, etc.) in young and elderly men. The object of the present trial was to evaluate the plasma levels of androgens and 3-DIOL-G in middle-aged men with coronary disease in comparison with a control group, independently of some risk factors.

Twenty-five patients (40–65 years old) with a history of cardiovascular disease (infarction, angina, etc.) were matched according to age, lipid status, diabetes and BMI with 33 men (42–63 years old) with no cardiovascular pathology.

Plasma levels of testosterone, 3-DIOL-G, estradiol, glucose and insulin, as well as the 3-DIOL-G/T ratio and HOMA index were determined.

The coronary group showed lower testosterone levels than the control group ($3.1\pm1.0$ vs $4.0\pm1.3$ ng/ml, $P<0.02$) but 3-DIOL-G level and 3-DIOL-G/T ratio were significantly higher ($6.7\pm3.1$ vs $4.8\pm2.8$ ng/ml, $P<0.02$ $\pm$and 2.5 $\pm1.4$ vs $1.3\pm0.8$, $P<0.001$, respectively). Besides, the insulin level and HOMA index were higher in the coronary group ($10.7\pm6.1$ vs $6.5\pm3.2$ mUI/ml, $P<0.002$ and $3.2\pm2.1$ vs $1.6\pm0.8$, $P<0.004$, respectively). Finally, there was an inverse correlation between insulin and testosterone ($r=-0.39$, $P<0.04$) while there was a direct correlation between insulin and the HOMA index with 3-DIOL-G/T ratio ($r=-0.43$, $P<0.01$, $r=0.39$, $P<0.04$, respectively).

The present results indicate that patients with history of coronary disease have higher plasma levels of 3-DIOL-G than controls, independently of their BMI. Unlike testosterone, the metabolite of the potent DHT androgen, is a steroid that correlates with parameters of insulin-resistance. Future studies are required to determine its participation on the development of coronary disease.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Cardiovascular function and IGF1 deficit (IGF1-D) in β-thalassemia major

V. Atzori[1], F. Pigliaru[1], S. Vacquer[2], M. Carta[2], A. Spiga[2], P. Bina[3], M. Pili[3], M. Manca[3], M. Lai[2] & S. Mariotti[1]
[1]University of Cagliari, Monserrato - Cagliari, Italy; [2]University of Cagliari, Cagliari, Italy; [3]Microcitemico Hospital, Cagliari, Italy.

Introduction
Both GH and IGF1 have important effects on the heart mass and contractility and deficiency of either hormone is associated with increased cardiovascular morbidity and mortality. GH/IGF1 axis abnormalities (mostly primary or secondary IGF1-D) are frequent in adult patients with β-thalassemia major (β-Thal). IGF1-D could therefore contribute with iron overload to the heart's damage of β-Thal patients, but this question has been little investigated so far.
Purpose
Retrospective evalutation of cardiovascular function by echocardiographic parameters in a cohort of 80 patients with β-Thal, 55 F and 25 M, aged 31–52 years, subdivided according to blood levels IGF1 using a cutoff of 70 ng/ml, indicative of marked IGF1-D for the entire age range.
Results
Patients with IGF1 $<70$ ng/ml showed significantly larger left atrium (LA), left ventricle (LV) and, to a lesser extent, right ventricle (RV) diameters (Table). No significant difference was found between the two groups in aorta diameter, ejection fraction (EF) and ferritin levels. The cumulative prevalence of several cardiac complications (atrial fibrillation, atrioventricular block, right or left bundle branch block, heart failure and cor pulmonale) was significantly ($P<0.01$) higher (25 in 53 patients) in patients with IGF1 $<70$ ng/ml, when compared to those with IGF1 $>$ 70 ng/ml (4 in 28 patients).
Conclusions
Our data provide evidence for a negative effect of IGF1-D on heart of β-Thal patients. These data provide the basis for further studies and suggest a potential indication for treatment with rhGH and/or IGF1 in β-Thal patients with low serum IGF1.

**Table 1**

| Patients ($n=80$) | Ferritin (ng/ml: m±s.d.) | EF (%: m±s.d.) | LA (mm: m±s.d.) | LV (mm: m±s.d.) | RV (mm: m±s.d.) | AORTA (mm: m±s.d.) |
|---|---|---|---|---|---|---|
| IGF1 $<70$ ng/ml ($n=53$) | 1004.1± 784.4 | 64.3±6.7 | 38.1±5.1 | 49.0±5.2 | 19.8±7.0 | 30.0±4.1 |
| IGF1 $>70$ ng/ml ($n=27$) | 769.7± 521.8 | 66.4±5.0 | 33.9±5.3 | 46.1±5.0 | 16.6±6.3 | 28.8±3.0 |
| $P$ | 0.15 | 0.15 | 0.0004 | 0.014 | 0.032 | 0.18 |

## P338

### Psoriasis is associated with decreased adiponectin levels beyond cardiovascular and metabolic risk factors

R. Li, P. Krishnamoorthy, Y. Yu, A. Raper, A. Baer, S. Derohannessian, M. Wilcox, A. Vorohees, M. Reilly, D. Rader, J. Gelfand & N. Mehta
University of Pennsylvania, Philadelphia, Pennsylvania, USA.

Introduction
Psoriasis is a systemic inflammatory skin disease, which is associated with increased cardiovascular disease (CVD) potentially through metabolic derangements due to chronic inflammation. Serum adiponectin appears to decrease the risk of CVD and has been shown to negatively associate with waist size and insulin resistance (IR), both of which are increased in psoriasis. It is unknown, however, if psoriasis is associated with decreased adiponectin levels beyond traditional CVD and metabolic risk factors.
Methods
We prospectively enrolled a consecutive sample of patients with psoriasis ($n=122$) and compared cardiometabolic risk factors with an asymptomatic sample without psoriasis from our practice ($n=129$). Fasting lipids, insulin, glucose, and total plasma adiponectin were measured by commercial assays. HOMA-IR was used to estimate IR. We performed stepwise multivariable linear regression adjusting for CVD (age, gender, smoking status, hypertension, lipids) and metabolic (HOMA-IR, waist size, triglycerides) risk factors using STATA12 software.
Results
Psoriasis patients were more insulin resistant (HOMA-IR: 3.5 (2.3–6.6) vs 1.4 (0.94–2.1), $P<0.001$) and had higher waist sizes (40 (35–44) vs 35.5 (33–39.5), $P<0.001$) than patients without psoriasis. Total serum adiponectin was lower in psoriasis than controls (7.1 (4.9–11.3) vs 14.5 (8.4–24.2), $\beta=-0.59$, $P<0.001$), even after adjustment for CVD ($\beta=-0.56$, $P<0.001$) and metabolic variables ($\beta=-0.49$, $P<0.001$).
Conclusion
Total serum adiponectin levels are lower in psoriasis patients compared to healthy controls, even after adjustment for CVD and metabolic risk factors. These results suggest that decreased adiponectin levels are a unique feature of psoriasis pathophysiology, which may play a role in the increased risk of CVD. Larger prospective studies looking at CVD outcomes and effects of psoriasis treatment on adiponectin are warranted.

## P339

### The importance of HDL cholesterol to predict adiponectin and retinol binding protein 4 concentration after one session resistance exercise

M. Mansouri, S. Hasani- Ranjbar, A. Keshtkar, R. Heshmat & B. Larijani
Endocrinology and Metabolism Research Center, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Introduction
The capability of exercise to induce useful effect on cardiovascular health could be partly attributed to its concomitant effect on adipokines and HDL cholesterol. Little information is available on whether post exercise concentration of these adipokines could be influenced by HDL cholesterol. Thus this study was designed to examine the possible independent effect of HDL cholesterol on serum level of adiponectin and retinol binding protein 4 following one session resistance exercise in healthy young men.
Method
Thirty-four healthy young BMI- matched male students (age, 20–26 years) were recruited. The study participants were allocated to experimental ($n=18$) and control ($n=16$) groups by using black balanced randomization method. The experimental group underwent a 120 minutes intensive resistance exercise session. Blood samples were taken at baseline and after 4 hours of training program to measure RBP4, adiponectin, HDL cholesterol and other cardio metabolic markers.
Results
The serum level of adiponectin, RBP4 and HDL cholesterol was not significantly different between two groups at baseline. We found that, after exercise concentration of adiponectin were negatively correlated with basal RBP4 and TG and positively correlated with basic level of adiponectin and HDL cholesterol.
Post exercise concentrations of RBP4 were negatively correlated with adiponectin and positively correlated with basal RBP4, age and BMI. Subsequent adjusted regression model showed HDL cholesterol ($\beta=0.28$, $P=0.03$) were the strong predictor of post exercise adiponectin concentration, explaining 28% of its variability. Whereas the basic level of RBP4 appeared to be the only predictor of after exercise RBP4 concentration ($\beta=0.46$, $P=0.02$) and HDL cholesterol has no role in this regard.
Conclusion
This study showed, HDL cholesterol, which was responsible for noticeable proportion of post exercise adiponectin variation, appeared to be a strong predictor of adiponectin but not for RBP4 following one session intensive resistance exercise in healthy young men.

## P340

### Intrinsic myocardial disease in adults with GH deficiency is characterised by subclinical left ventricular longitudinal dysfunction revealed by tissue Doppler

C. Badiu[1,3], S. Mihaila[2], R. Mincu[2], R. Dulgheru[2], S. Jercalau[3] & D. Vinereanu[2,3]
[1]National Institute of Endocrinology, Bucharest, Romania; [2]University Hospital, Bucharest, Romania; [3]'C. Davila' University of Medicine and Pharmacy, Bucharest, Romania.

Purpose
GH deficiency (GHD) is associated with increased cardiovascular events, however, the detailed mechanisms have not been assessed yet extensively. We set up this study in order to evaluate cardiac, arterial, and endothelial function, by conventional

echo, TDI, and biomarkers (proBNP and troponin I), in GHD patients by comparison with normal individuals with similar cardiovascular risk factors profile.
Methods
Thirty GHD patients (46±14 years, 18 males) with low cardiovascular risk factors were compared with 30 matched N. Global LV systolic and diastolic functions were assessed from ejection fraction (EF), indexed cardiac output (COi), E/Vp and E/Ea ratios; longitudinal function from global longitudinal strain (GLS), and the sum of all times from the AVC to peak strain (SumTAVC); radial function from global radial strain (GRS); circumferential function from global circumferential strain (GCS); and LV torsion from peak basal (RotB) and apical rotation (RotA), and derived times (time to RotB/RotA), LV torsion (LVtor), twist rate (TR), untwist rate (UTR), time-to-peak twist (TT), and time from the AVC to UTR (AVC-UTR). Arterial function was assessed from intima-media thickening (IMT) , local wave speed (LWS), and stiffness index (β); endothelial function from flow mediated dilation (FMD).
Results
GHD patients had all global, longitudinal, and circumferential systolic parameters significantly decreased, but with similar GRS (52±16 vs 52±15%) (Table). They had also higher dyssynchrony, end-diastolic LV pressure, and lower torsion with prolonged AVC-UTR. RotB correlated with GLS ($r=0.4$, $P<0.05$). Arterial and endothelial functions were similar to N.

**Table 1**

| | EF | COi | E/Vp | E/Ea | GLS | Sum-TAVC | GCS | RotB | LVtor | TR |
|---|---|---|---|---|---|---|---|---|---|---|
| GHD | 52±9 | 1.8±0.5 | 1.7±0.4 | 8±1 | −16.8±2.5 | 64±5.0 | −16.5±3.3 | −5.2±2.5 | 0.18±0.05 | 100±32 |
| N | 68±7 | 2.2±0.6 | 1.5±0.3 | 6±2 | −19.2±2.5 | 7±5 | −19.4±4.0 | −6.7±2.0 | 0.23±0.08 | 122±42 |
| *P* value | <0.001 | 0.03 | 0.033 | 0.002 | 0.001 | 0.003 | 0.004 | 0.02 | 0.03 | 0.027 |

Conclusions
GHD patients have subclinical longitudinal and circumferential LV dysfunction, with maintained radial function; these were correlated with impaired LV torsion. Since arterial and endothelial functions were not affected, our findings suggest that patients with GHD have intrinsic myocardial disease, due probably to insufficient development of the myocardial fibers.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Paraoxonase, malondialdehyde and lipids in subjects with asymptomatic gallstones

A. Atamer[1], A. Can[2], AKurdas Övünç[1], A. Yesil[1] & Y. Atamer[3]
[1]Republic of Turkey, Ministry of Health Haydarpasa Numune Training and Research Hospital, Istanbul, Turkey; [2]Gayrettepe Florence Nightingale Hospital, Istanbul, Turkey; [3]Dicle University, Medical Faculty, Diyarbakir, Turkey.

Aim
Gallstones are associated with excess body fat. Our aim was to evaluate lipid levels and markers of oxidative stress in subjects with asymptomatic gallstones.
Material and method
Eighty subjects (55 females, 25 males) with a mean age±S.D. of 51±14 years with asymptomatic gallstones were admitted to the study. Forty subjects (25 females, 15 males) with a mean age±S.D. of 57±12 years ($P<0.05$) without gallstones were enrolled as controls. Lipid levels were determined by routine methods. Serum paraoxonase (PON1) activity was measured spectrophotometrically. Malondialdehyde (MDA) level was determined by thiobarbituric acid method.
Results
Subjects with cholelithiasis was younger than control subjects, but there was no difference in body mass index (BMI) (27±2 kg/m$^2$ in both groups, $P=0.97$). Total cholesterol (TC) and MDA levels were significantly higher and HDL-C, PON1 ($P<0.01$) and LDL-C ($P<0.05$) levels were significantly lower in subjects with asymptomatic cholelithiasis than in subjects without cholelithiasis. Subjects with cholelithiasis who had impaired fasting glucose (glucose>100 mg/dl, $n=39$) had significantly higher serum triglyceride (TG), TC ($P<0.05$) and MDA levels ($P<0.01$) than subjects with cholelithiasis who had normal fasting glucose (glucose<100 mg/dl, $n=41$). PON1 activity was significantly lower in cholelithiasis patients with impaired fasting glucose ($P<0.01$). Subjects with cholelithiasis who had hypertriglyceridemia (TG>150 mg/dl, $n=32$) were older ($P<0.05$), had higher BMI, glucose, TC and MDA levels and lower HDL-C and PON1 activity ($P<0.01$) than subjects with cholelithiasis who had normal TG levels (TG< 150 mg/dl, $n=48$).
Conclusions
Patients with asymptomatic cholelithiasis have higher levels of total cholesterol and lower levels of HDL-C compared to subjects without cholelithiasis and have increased lipid peroxidation and decreased antioxidant capacity. Patients with asymptomatic cholelithiasis who have impaired fasting glucose or hypertriglyceridemia have more lipid peroxidation and less antioxidant capacity than subjects with asymptomatic cholelithiasis who do not have impaired fasting glucose or hypertriglyceridemia.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P341.1

### Cardiac hormones are dual inhibitors of vascular endothelial growth factor and the VEGFR2 receptor

J P Nguyen[1], C D Frost[2], M L Lane[2], W P Skelton[3], M Skelton[2] & D L Vesely[2]
[1]Department of Biology, Wichita State University, Wichita, Kansas , USA; [2]Departments of Medicine, Molecular Pharmacology and Physiology and University of South Florida, James A. Haley VA Medical Center, Tampa, Florida, USA; [3]Trinity College of Arts and Sciences, Duke University, Durham, North Carolina, USA.

Introduction
The growth of human tumors depends on the formation of new blood vessels and vascular endothelial growth factor (VEGF) helps control this process via inducing new capillaries to sprout from pre-existing blood vessels. Four cardiac hormones which eliminate up to 80% of human pancreatic cancers and up to 86% of human small-cell lung cancers growing in mice were investigated for their effects on VEGF and the VEGFR2/KDR/Flk-1 receptor. The VEGFR2 receptor is the main receptor mediating VEGF's cancer enhancing effects.
Methods
The cardiac hormones' effects on VEGF/VEGFR2 levels in three human cancer cell lines were measured by ELISAs.
Results
These four cardiac hormones, i.e. vessel dilator, long-acting natriuretic peptide (LANP), kaliuretic peptide, and atrial natriuretic peptide (ANP) over a concentration range of 100 pM to 10 μM maximally decreased the VEGFR2 receptor in human pancreatic adenocarcinoma cells by 48, 49, 74, and 83%. Vessel dilator, LANP, kaliuretic peptide, and ANP decreased the VEGFR2 receptor by 77, 89, 88, and 67%, respectively in human small-cell lung cancer cells. Maximal decrease of VEGFR2 receptor in human prostate cancer cells by vessel dilator, LANP, kaliuretic peptide, and ANP was 48, 92, 64, and 71%. VEGF itself in human pancreatic carcinoma cells was decreased by 42, 58, 36, and 40% respectively, by vessel dilator, LANP, kaliuretic peptide and ANP. In small-cell lung cancer cells, the maximal decrease in VEGF levels was 25, 23, 17 and 23% secondary to vessel dilator, LANP, kaliuretic peptide, and ANP. In human prostate cancer cells, VEGF was maximally decreased 24, 20, 23, and 24% secondary to vessel dilator, LANP, kaliuretic peptide, and ANP respectively.
Conclusion
Four cardiac hormones are the first dual inhibitors of VEGF and the VEGFR2/KDR/Flk-1 receptor.
COI Details
Dr Vesely has assigned the patent to treat cancer with these cardiac hormones to the University of South Florida, which has not licensed this patent to any commercial entity. There has been no pharmaceutical company funding or input into the studies described herein. The contents of this publication do not represent the views of the Department of Veterans Affairs or the United States Government. None of the other authors has any potential conflict of interest.
Funding Details

**Localization of occult adrenal tissue with cosyntropin-stimulated 18F-FDG-PET/CT in a patient with metachronous adrenocortical tumor who presented with persistently elevated SDHEA after bilateral adrenalectomy**

M. Franco[1], G. Alencar[1], A. Faria[1], J. Bezerra[2], C. Cruz[2], S. Domenice[1], L. Lima[1], A. Lerario[1], M. Almeida[1], A. Latronico[1], B. Mendonca[1] & M. Fragoso[1]
[1]Hospital das Clínicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Instituto do Cancer do estado de Sao Paulo, Sao Paulo, Brazil.

Introduction
Adrenocortical carcinoma (ACC) is a rare and potentially fatal disease in childhood. Complete resection of the tumor and metastasis can improve survival. Case: A 2.6 year-old boy presented isosexual pseudo-precocious puberty at 2.1 years. CT revealed a single nodule in the left adrenal (2 cm) which was resected by adrenalectomy. Histology revealed an adrenocortical tumor (2 cm, 3.0 g, Weiss score 4), ENSAT stage I. Partial regression of the puberty features and normalization of hormonal levels were observed. At 4.8 years, recurrence was observed, with high androgen levels and an 8 cm right adrenal mass on CT. Right adrenalectomy and nephrectomy was performed, which revealed an adrenocortical tumor (8 cm, 30 g, Weiss score 7) with no apparent metastasis at that time. At 6 years, DHEAS levels became increasingly high and CT showed a pulmonary nodule that was surgically removed. After 8 months of partial lung resection, abnormally high DHEAS was present with no obvious source on conventional imaging techniques. 18F-FDG-PET/CT showed a mediastinal lesion that was resected and histologically confirmed as metastatic ACC. DHEAS levels remained undetectable until he was 13 years-old, with a progressive increase not suppressible by high doses of dexamethasone (0.5 mg qid for 7 days). Conventional radiological techniques did not identify any metastatic lesions. At 18.5 years of age, the patient underwent 18F-FDG-PET/CT under stimulation with intravenous cosyntropin 250 mgc, which identified a 1.5 cm nodular lesion in left adrenal topography. FDG hypermetabolism was shown in that area pre-stimulus (SUV = 1.5), with an increase 60 min after stimulation to 3.6, suggesting remaining tumorous tissue.
Conclusions
We report a long-term evolution of a pediatric patient with an indolent ACC and suspected local recurrence identified by cosyntropin-stimulated $^{18}$F-FDG-PET/CT. This new diagnostic modality may be used in clinical practice to locate occult metastasis of ACC.

### P343

**A case of pheochromocytoma which represented multiple myeloma like change**

M. Sue[1], D. Nagase[1], F. Yamabe[1], D. Sasai[1], H. Willenberg[2], S. Kamimura[1], N. Hiroi[1], K. Shibuya[1] & G. Yoshino[1]
[1]Toho University School of Medicine, Tokyo, Japan; [2]University of Dusseldorf, Dusseldorf, Germany.

A 48-year-old female was admitted to our hospital because of prolonged fever of unknown origin for three months, anemia, renal dysfunction, and hypercalcemia. There were no abnormal parameters of physical examination except fever of 37.6 °C, BMI of 26 5 kg/m$^2$ after 11 kg of body weight loss in 2 months, and her blood pressure was 138/87 mmHg. C-reactive protein and WBC were 24.6 mg/dl and 10 900/μl, respectively. A/G ratio was elevated with total protein of 8.7 g/dl and albumin of 1.6 g/dl, platelet count was 858×104, serum creatinine was 0.89 mg/dl. Plasma glucose and HbA1C level were elevated to 150 mg/dl and 7.4% respectively. As her bone marrow biopsy revealed hyper cellular bone marrow with an increased number of plasma cells, we diagnosed her multiple myeloma with Durie-Salmon stage III.
At the same time, abdominal CT scan revealed left adrenal mass with a diameter of 35 mm, which was strongly enhanced in enhance CT, and hyper-intense and heterogeneous on T2-weighted images in MRI. Urine adrenalin, urine noradrenalin, and urine dopamine were 14.5, 1470, and 3100 μg/day respectively. Addition with that, as I-131 MIBG adrenal scintigraphy demonstrated high uptake of left adrenal area, we diagnosed her pheochromocytoma.
To avoid the risk of inducing adrenal crisis by administrating steroid, we gave priority to the treatment for left adrenal pheochromocytoma and performed adrenalectomy. Serum and urine catecholamine levels were normalized after surgery. Anemia and hypercalcemia is also normalized, and the hyperglycemia which required 68 units of insulin per day before surgery had stabilized only with dietary cure. As the multiple myeloma like changes disappeared in bone marrow biopsy, we are following her carefully only with the oral medication for hypertension.
Though there are several reports of the IL6 producing pheochromocytoma with systemic inflammatory responses, we could not find any case representing the multiple myeloma like changes as we experienced. On the other hand, IL6 is the cytokine reported to be an autocrine growth factor in myeloma and plasmacytoma. There are possibilities that cytokine secretion from pheochromocytoma itself or from the necrotic lesion of pheochromocytoma led the plasma cells over expression and represented multiple myeloma like changes, which are all normalized after adrenalectomy for pheochromocytoma.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### P344

**Reactivation of Takayasu arteritis in two patients with Cushing's disease after normalization of cortisol secretion.**

C. Simeoli, A. Cozzolino, MDe Leo, D. Iacuaniello, P. Vitale, L. Grasso, M. Triggiani, A. Colao & R. Pivonello
Federico II University, Naples, Italy.

Introduction
The reactivation of autoimmune disorders has been described in patients with hypercortisolism after normalization of cortisol secretion. This phenomenon is probably related to the loss of immunosuppressive effect of endogenous glucocorticoids. This is a report of two patients with Takayasu arteritis (TA) and Cushing's disease (CD), a novel association never described in literature, in whom TA was exacerbated after normalization of cortisol secretion.
Case report
Two women, 55 and 53 years old, presented with a clinical syndrome suggestive of hypercortisolism, in whom a diagnosis of CD was performed (urinary free cortisol: 188 and 264 mcg/day respectively), reported a history of TA, complicated by acute coronary syndrome, peripheral vascular disease and chronic renal failure. Not considered candidates for pituitary surgery, they were treated with inhibitors of adrenal steroidogenesis. Six months later, they had a normalization of daily cortisol excretion (urinary free cortisol: 98 and 118 mcg/day) but complained typical symptoms of a systemic vascular inflammatory process: fatigue, weight loss, fever and arthromyalgia; in one of the two patients, the strong inflammatory factor, inhibiting erythropoiesis, in association with iron and vitamin B12 deficiency, caused severe anemia (Hb 4 g/dl), requiring blood transfusions. The clinical picture, the strong increase of inflammatory markers such as VES, C-reactive protein and fibrinogen, and signs of vascular insufficiency such anisosphygmia in femoral and tibial pulses, in bilateral carotid axes and absence of right brachial and radial pulses, have suggested a process of reactivation of the TA. Treatment with corticosteroids was necessary to relieve the clinical symptoms of TA and to reduce the inflammatory markers.
Conclusions
These cases, particularly challenging because of the two concomitant disorders, CD and TA, confirm the crucial role of cortisol secretion reduction in the reactivation of the autoimmune process, supporting the hypothesis that TA activity was suppressed by endogenous glucocorticoids excess. This evidence suggests that it is mandatory to

investigate on the possible development or reactivation of autoimmune diseases after normalization of cortisol secretion in patients with a history of Cushing's syndrome.

**Delayed presentation of late onset CSF rhinorrhoea following dopamine agonist therapy for giant prolactinoma**

J. Prague[1], O. Mustafa[1], C. Ward[1], C. Manu[1], N. Thomas[1], T. Hampton[1], A. King[1], J. Kumar[2], J. Gilbert[1] & B. Whitelaw[1]
[1]King's College Hospital, London, UK; [2]Maidstone Hospital, Maidstone, UK.

Background
CSF rhinorrhoea is a rare but recognised complication of dopamine agonist therapy for macroprolactinoma. In the majority of cases, onset of CSF rhinorrhoea is within 4 months of commencing therapy.
Case report: A 23-year-old man presented to the Emergency Department in April 2010 with acute weakness in his left arm and leg associated with intermittent headaches. Examination revealed mild right-sided ptosis and inadequate androgenisation. Visual fields were full to confrontation.
MRI pituitary demonstrated a 5 cm lobular/cystic mass invading the right cavernous sinus, displacing and compressing the midbrain, with destruction of the bony sella. Serum prolactin was $>150\,000$ mIU/l.
Cabergoline was commenced (initially 250 μg twice/week). Neurological symptoms resolved with dramatic reduction in tumour size. Serum testosterone levels normalised. Prolactin level plateaued at 20 000 mIU/l despite repeated increments in the dose of cabergoline to 500 μg three times/week over the course of 12 months. There was still significant residual sellar and right parasellar tumour. Consequently, the cabergoline dose was increased to 500 μg/day following which he developed continuous daily rhinorrhoea (May 2011).
The patient presented to his general practitioner who referred him to an otolaryngology clinic. When next seen in the routine regional endocrine clinic (November 2011) he was admitted for urgent endoscopic transnasal transphenoidal repair of CSF leak. CT pituitary confirmed the likely site of the leak was in the left basisphenoid where there was marked thinning of the bone. Preoperative serum prolactin was 3240 mIU/l on cabergoline 500 μg/day. Histology confirmed a prolactinoma with proliferation index of 2%.
Discussion
In this case, CSF rhinorrhoea occurred 13 months after initiation of cabergoline suggesting a need for vigilance throughout therapy.
There was significant delay before this complication was brought to the attention of the regional pituitary team. There is a need for patients and healthcare professionals to be educated about early recognition and management of this complication.

**ACTH-dependent Cushing's syndrome secondary to an ectopic source of ACTH/CRH: three clinical cases with different prognosis and outcome**

B. Fibbi, C. Maggioli, L. Vannucci, E. Giurgola, M. De Feo, L. Petrone, G. Parenti, M. Mannelli, G. Forti & C. Pupilli
Careggi Hospital and University of Florence, Florence, Italy.

Introduction
Ectopic ACTH-dependent Cushing's syndrome (ACS) may present with different clinical pictures and it may represent a diagnostic challenge.
Methods
We describe the clinical presentation and the laboratory, imaging and pathologic findings of three patients with ectopic ACS.
Results
Case 1. A 31-year-old man with a 1-year history of spontaneous rib and vertebral fractures was admitted to our hospital for ACS evaluation. He displayed typical cushingoid features. Pituitary magnetic resonance imaging (MRI), chest/abdomen computed tomography (CT) and whole body Octreoscan (WBO) were unremarkable. Petrosal sinus sampling with corticotrophin-releasing hormone (CRH) stimulation was negative. A (68Ga)DOTATOC-PET/CT showed a 7 mm-pulmonary nodule that was excised and diagnosed as a typical carcinoid. Six months later, he showed nearly complete biochemical and clinical recovery.
Case 2. A 72-year-old man was referred to endocrinological evaluation for hyponatremia. Biochemical analysis revealed ACS, thrombocytopenia and monoclonal gammopathy. Chest CT showed a widespread mass in the left lung. Both the cytology on bronchoalveolar lavage and the osteomedullary biopsy revealed neuroendocrine-differentiated cells. He started chemotherapy, but died after few weeks.
Case 3. A 66-year-old man with a 2-year history of diabetes mellitus and hypogonadotropic hypogonadism and recent leg swelling was referred to our center for ACS. He didn't show cushingoid features except for muscle hypotrophy. Melanodermia, marked hypokalemia and psychosis were present. Chest/abdomen CT and WBO were negative. Pituitary MRI showed a microadenoma and petrosal sinus sampling with CRH stimulation was inconclusive. Despite ketokonazole and mifepristone treatment, he became hemodynamically unstable for a massive bilateral pleural effusion and sepsis, and rapidly died. The post-mortem result of cytologic analysis on pleural liquid was positive for adenocarcinoma.
Conclusions
Ectopic ACS can be caused by tumors with different degrees of malignancy, thus conditioning different prognosis. The disease course can also be complicated by the difficulty in tumor localization with conventional imaging techniques.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P347

**Hyponatraemia assessment and outcomes in acute medically ill patients**

A. Hughes, O. Taha, T. Tetlow & E. Jude
Tameside General Hospital, Ashton under Lyne, UK.

Hyponatraemia is the most common electrolyte abnormality, encountered in up to 30% of inpatients. Inappropriate management can have serious implications for patients; including demyelinating disease, coma, and death.
Methods
Patients ($n=100$) admitted to the medical admission unit of a district general hospital with a serum sodium (Na) $<130$ were selected for the study. All details including patient demographics, blood biochemistry, date of admission and date of death were taken from the case notes and hospital computerised system. Details on assessement of hyponatraemia including thyroid, adrenal and renal function were also recorded.
Results
Mean age was $69.7\pm18.1$ years; 41 males. Mean serum Na on admission was $125.8\pm4.1$ mmol/l. Of the 100 patients 32 died in hospital. Admission serum Na in survivors vs died was $126.5\pm3.8$ vs $124.3\pm4.5$ mmol/l ($P<0.01$). Patients investigated for hyponatraemia were as follows: serum cortisol ($n=6$), plasma osmolality ($n=9$), urine osmolality ($n=9$), short synacthen test ($n=0$), urine sodium ($n=3$), thyroid function tests ($n=19$).
Conclusions
Patients admitted with acute medical conditions with severe hyponatraemia have a high mortality and those with lower serum sodium have greater risk of death. Patients were also inadequately worked up for assessment of cause of the hyponatraemia and further education of medical specialists is urgently required to improve management and outcome.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P348

**A clinical case of a 21 years old man with inborn pituitary dystopia**

E. Sorkina, Y. Poteshkin, V. Pronin, G. Melnichenko, M. Pavlova & N. Likhodey
First MSMU I.M. Sechenov, Moscow, Russian Federation.

A 21 years old man had growth failure since 11 y.o., micropenis, high-pitched voice, the absence of secondary sex characteristics and male sexual behavior,

constant fatigue and weakness. The boy was born in time after 1st normal pregnancy, birth weight 3000 g, length 57 cm, had unilateral cryptorchidism (surgical treatment in 2002). At the age of 21 the height of the patient was 144 cm (SDS - 4.62), BMI 15 kg/m$^2$ (BMI SDS −3.89), Tanner G1P1, bone age 13 y.o. Inborn hypopituitarism as a result of inborn pituitary dystopia was diagnosed: GH deficiency (GH 0.38 ng/ml (0.5–5.0), IGF1 <25 ng/m (94–252)), ACTH deficiency (ACTH <1,1 pmol/l (0–10.2), cortisol (in blood) 55,5 nmol/l (119–618), daily urine free cortisol excretion - 10 nmol/day (20–200)), TSH deficiency (free T4 - 9,9 pmol/l (10–23.2), TSH - 0.63 μIU/l (0.4–4.0)), gonadotropin deficiency (LH - 2.3 IU/l (0.6–12), FSH - 2.3 IU/l (1.0 - 12.0), total testosterone 0.07 ng/ml (3–12)). MRI showed neurohypophysis dystopia in the floor of third ventricle, total absence of the infundibulum, small adenohypophysis (9x10x3 mm). Replacement therapy was started with recombinant GH 0.033 mg/kg per day s.c., hydrocortisone 7,5 mg/day. After establishing adequate adrenal function thyroid-replacement therapy was given: Levothyroxine 50 μg per day. Testosterone replacement therapy was started with Sustanon 0.2 ml by intramuscular injections every 4 weeks. Perspectives: The GH replacement therapy will be effective until the epiphyseal plates closure. Testosterone replacement therapy will help to maintain androgenic anabolic effects, although its efficacy in development of the external genitalia is questionable due to the age of the patient. Hypocorticism and hypothyrosis replacement therapy can show clinical efficacy and significantly improve the quality of life. Performing genetic test in patient and relatives is planned.

Conclusion

This case shows the importance of strict growth curves monitoring in children, highlights necessity of early diagnosing and treatment of hypopituitarism.

## P349

### A case of acromegaly without clear evidence of pituitary adenoma or ectopic GH/GHRH secreting tumors

B. Fibbi, C. Maggioli, L. Vannucci, M. De Feo, L. Petrone, A. Cilotti, G. Forti & C. Pupilli

Careggi Hospital and University of Florence, Florence, Italy.

Introduction

Acromegaly secondary to an extrapituitary source of GH or GHRH is rare, usually associated with bronchial/thymic carcinoids, neuroendocrine enteropancreatic tumors or extrasellar somatotropinomas. Few series of acromegalic patients with negative pituitary imaging and lack of an ectopic source are reported in the literature.

Methods

We report the clinical history and the laboratory and imaging results of an acromegalic woman with no clear evidence of pituitary somatotropinoma or ectopic GH/GHRH source.

Results

A 66-year-old woman was referred to our outpatient clinic for the follow-up of a multifocal differentiated thyroid carcinoma treated by total thyroidectomy 7 years before. The thyroid oncologic follow-up was negative but physical examination revealed acromegalic features. She also complained frontal headache, amaurosis, fatigue, paraesthesias, muscular pains and sleep apnea syndrome. Basal IGF1 levels resulted elevated for age (312 ng/ml; r.v. 78-212), and a nadir GH of 1.45 ng/ml during oral glucose tolerance test (OGTT) was diagnostic for acromegaly. Magnetic resonance imaging of the pituitary was unremarkable but an abnormal contrast-enhancement of the right cavernous sinus (CS) was present. Computed tomography of chest and abdomen and a whole body Octreoscan didn't show any evidence of ectopic GH/GHRH-releasing tumor. Short-acting octreotide formulation treatment was started as once-daily administration because of gastrointestinal intolerance, with a partial biochemical remission of acromegaly. Nine months later, octreotide was discontinued and OGTT and imaging scans were repeated, confirming previous observations.

Conclusions

The described patient did not show an obvious source of GH or GHRH secretion. So far, only one case of ectopic somatotropinoma has been described in the CS. A trans-sphenoidal exploration could be crucial in our patient in order to exclude a micro-adenoma of the pituitary and explore the possibility of an CS ectopic somatotropinoma, thus avoiding further invasive and expensive imaging tests.

## P350

### Evaluation on clinical application and long term outcomes of microwave endometrial ablation

L. Li & X. Luo

Guangzhou Medical University, Guangzhou, China.

Study objective

To evaluate the long term outcomes of menorrhagia treated by microwave endometrial ablation(MEA) as well as the factors which influence the outcomes.

Design

Prospective, single-arm study.

Setting

GuangDong Women's and Children's Hospital, GuangDong, China.

Patients

Three thirty four women with menorrhagia were selected for MEA, the age of these patients ranged from 29 to 59 years.

Interventions

Endometrial ablation using microwave endometial ablation.

Measurements and main results

All the patients were followed up, the change of menstrual cycle, the amount of flow, and complication of the procedure were recorded. 53 women underwent outpatient diagnostic hysteroscopy, the biopsy tissue was taken from the endometrium of these patients for histopathological examination. The mean duration of follow-up was 64.7 months (3–115 months). Overall effective rate was 91.3% (305/334), in which amenorrhea rate was 49.7% (166/334),menstruation reduction rate was 41.6% (139/334); 71.1% (140/197)of the cases who previously had dysmenorrheal had relieved their pain and the satisfaction rate was 91.9% (307/334); 42 cases required subsequent treatment as a result of recurrence, of which 9 cases were given repeat MEA and 33 cases underwent hysterectomy. A completely destroyed endometrium was seen after MEA by hysteroscopy, pathologic effects of MEA showed two zones of necrotic tissue.

Conclusions

MEA is characterized by simplicity of its performance, marked effectiveness and fewer complications, holding especially for patients complicated with severe diseases. Incomplete removal of endometrium was the important factor in reducing the effiency, young age and adenomyosis showed significant increased risk of treatment failure.

### Familial central diabetes insipidus due to a novel mutation in exon 3 of the arginine vasopressin gene

M. Ritter[1], U. Gross[2], J. Feldkamp[3], W. Höppner[4] & H. Schulte[2]

[1]Endokrinologikum, Osnabrück, Germany; [2]Endokrinologikum, Hamburg, Germany; [3]Klinikum Bielefeld, Bielefeld, Germany; [4]Bioglobe GmbH Hamburg, Hamburg, Germany.

Neurohypophyseal diabetes insipidus (DI) is said to be caused by familial forms in about 5% of cases[1]. Hereditary transmission is autosomal dominant in most families and is caused by a mutation in the arginine vasopressin (AVP) gene on chromosome 20p13, which encodes for a large precursor hormone.

A 19-years old otherwise healthy patient seeked endocrine care for an inadequately treated DI. He reported about an undoubtful disease history with about 10 l of diluted urine without therapy since his second year of life. His father and sister were affected as well. Adjustment of the patient's therapy resulted in a well-treated DI.

After informed consent, a genetic analysis was performed on the patient and his sister by sequence analysis of the AVP gene.

A hitherto undescribed heterozygous mutation p.Cys110 Arg in codon 110, exon 3 of the AVP gene was found, both in the patient and his sister. Since a stop mutation causing DI in the same codon has been described before[2] and since the mutation results in a non-conservative amino acid substitution, we conclude that this mutation is the cause for DI in this family.

Our findings add a new mutation to a list of 66 mutations so far described for the AVP gene (Biological Database HGMD Professional). Interestingly, the disease manifests not immediately after birth but later during the first and second year of life. This is in contrast to mutations in two other genes involved in familial DI (namely the arginine vasopressin receptor 2 gene and the vasopressin-sensitive water channel gene). Recent studies hypothesized that the disease is caused by formation of inclusion bodies hampering cell function[3] and that there is a

genotype–phenotype correlation[4]. Therefore, new mutations can add important information to the elucidation of the mechanisms that are involved in DI.

### Successful pregnancy during use of octreotide and pegvisomant in an acromegalic patient

M. van der Klauw[1], A. van der Horst-Schrivers[1], A. Hoek[1], M. Bidlingmaier[2] & B. Wolffenbuttel[1]
[1]University Medical Center Groningen, University of Groningen, Groningen, The Netherlands; [2]Ludwig-Maximilians Universität, Munich, Germany.

Introduction

Acromegaly is preferentially treated by surgery and/or radiotherapy before pregnancy, in order to avoid use of medication during pregnancy, and prevent GH excess related complications for mother and child. Only two cases of use of pegvisomant during pregnancy have been described; in one patient medication was discontinued after the first trimester, and in the other pegvisomant was used as monotherapy.

Case report

A 29-years old female had been treated for acromegaly with transsphenoidal surgery. Before surgery she started with octreotide. Surgery was incomplete, and pegvisomant was added because of insufficient control. Radiotherapy was proposed, but denied by the patient. We advised against pregnancy while using pegvisomant and octreotide, but she was adamant and became pregnant at the age of 32, and was under strict medical control during pregnancy. Pregnancy was uneventful. During pregnancy, her IGF1 levels declined from 39.8 to 19.4 nmol/l with unchanged doses of 30 mg octreotide LAR once every 3 weeks, and pegvisomant 40 mg twice weekly, as before pregnancy. A healthy child was born after a full term uneventful pregnancy. After pregnancy, IGF1 levels rose to values consistent with those before pregnancy. The levels of octreotide and pegvisomant were measured in peripheral blood samples from the mother and in umbilical cord blood samples taken immediately after birth. Octreotide levels in the mother's blood: 2142.790 and in umbilical cord blood: 807.106 pg/ml, pegvisomant levels in the mother's blood: 1543 ng/ml, and in umbilical cord blood: undetectable.

Conclusion

We report the first successful pregnancy in an acromegalic patient using the combination of pegvisomant and octreotide during complete pregnancy. There were no congenital malformations. Pegvisomant (80 mg weekly), was not detectable in umbilical cord blood, while detectable in the mother's blood. Octreotide was detectable, albeit in lower levels in umbilical cord blood than in the mother's blood.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P353

### Long-term efficacy and safety of pasireotide in Cushing's disease: a 36-month case report

G. Ning[1,2,3], W. Wang[1,2,3], M. Maldonado[4], A. Trovato[4] & W. Zhou[1,2,3]
[1]Institute of Endocrine and Metabolic Diseases, Shanghai, China; [2]Rui-jin Hospital, Shanghai Jiao-Tong University School of Medicine, Endocrine and Metabolic E-Institutes of Shanghai Universities, Shanghai, China; [3]Health Ministry, Shanghai, China; [4]Pharma AG, Basel, Switzerland.

Background

A recent, large phase III study ($n=162$) showed that treatment with pasireotide rapidly decreased urinary free cortisol (UFC) levels and improved signs and symptoms in patients with Cushing's disease. Here, we report the experience of a patient enrolled in this trial who received pasireotide for 36 months.

Results

A 31-year-old male presented in June 2008 with persistent Cushing's disease despite two previous pituitary surgical procedures. Examination revealed he was overweight (79 kg; BMI 28.3 kg/m$^2$), had mild hypertension (139/83 mmHg), and elevated UFC (112.5 μg/24 h; ULN, 52.6) and ACTH (55 ng/l; ULN, 46); his serum cortisol level was 10.5 μg/dl (ULN, 22.4). In July 2008, he began twice-daily injections of pasireotide 600 μg s.c. After 3 months, UFC had decreased to 72.0 μg/24 h. In January 2009 (UFC 73.8 μg/24 h), the pasireotide dose was increased to 900 μg s.c. bid. By July 2009 (end of 12-month core study), an improvement in all key biochemical parameters was observed: UFC (36.4 μg/24 h) and ACTH (31 ng/l) normalized, and serum cortisol decreased (7.8 μg/dl). Reductions in weight (69 kg), BMI (24.7 kg/m$^2$) and blood pressure (127/70 mmHg) were also reported. Pasireotide 900 μg bid was continued and at 18 months, although UFC was slightly elevated (58.0 μg/24 h), clinical improvements were maintained, including blood pressure (116/80 mmHg), weight (72 kg) and BMI (25.8 kg/m$^2$). After 36 months' treatment with pasireotide, UFC was normalized (33.7 μg/24 h), and improvements from baseline in weight (74 kg), BMI (26.2 kg/m$^2$) and blood pressure (125/82 mmHg) were sustained. The patient's health-related quality of life also improved, as evaluated by the CushingQoL questionnaire. Several adverse events occurred that were suspected to be related to the study drug: mild (grade 1) hyperglycemia was noted at 6 and 9 months, while at 18 months, moderate (grade 2) hyperglycemia occurred, necessitating initiation of metformin, then glimepiride due to gastrointestinal complaints. Mild hyperglycemia was reported again at 27 months. Grade 2 cholelithiasis was also reported at month 12.

Conclusions

This case report illustrates the long-term efficacy and safety of pasireotide in Cushing's disease, supporting its potential use as a targeted treatment for ACTH-secreting pituitary adenomas.

### Control of acromegaly in an era where it is technically feasible in almost every patient, is by no means invariable even in a specialist unit

S. Szamocki, N. Karavitaki & J. Wass
Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford, UK.

We have audited control of acromegaly in a specialist endocrine unit in Oxford now that this should usually obtainable. We have 240 patients under active surveillance, seen annually since diagnosis. Data from 115 of these seen in the last year have been used for this analysis.

Methods

We grouped patients according to whether they were controlled in either or both IGF1 and GH or uncontrolled. Controlled IGF1 was defined according to age and sex and GH was defined as basal $<5$ mU/l ($<2$ μg/l). We analysed the most recent IGF1 and GH values and compared these to initial GH levels, initial tumour size and the types of treatment given.

Results

Control of GH 72% ($n=83$), control of IGF1 62% ($n=71$), control of both 49% ($n=56$), uncontrolled of both 13% ($n=15$).

Control of IGF1- vs initial tumour size; extrasellar macro-, intrasellar macro- and microadenoma (71%, 58%, 56%) and for control of GH- (71%, 54%, 88%)

High GH ($>50$ mU/l) vs low ($<50$ mU/l) GH at presentation (74 vs 96% - controlled).

Analysis of the factors at presentation of uncontrolled patients were tumour size at diagnosis macroadenoma- 79% and initial GH 'high' at diagnosis 79%.

Conclusions

1. Even in a specialised unit, control of acromegaly is not invariable after treatment. This may relate in some patients to large tumour size and high initial GH levels at presentation but in some it relates to the inability to obtain funding for expensive drugs.
2. There is a considerable but previously described discordance between GH control (72%) and IGF1 control (62%).
3. Initial tumour size predicates GH control.
4. High levels of GH at commencement of treatment predicate a poorer outcome.
5. Uncontrolled patients almost invariably have a large tumour or initially high GH levels at diagnosis.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P355

### A case of adrenocortical carcinoma with fever of unknown origin and elevated serum IL6 level

N. Hiroi[1], M. Sue[1], A. Yoshihara[1], F. Yamabe[1], Y. Fukazawa[1], S. Kamimura[1], H. Willenberg[2], K. Shibuya[1] & G. Yoshino[1]
[1]Toho University School of Medicine, Ota-ku, Japan; [2]University of Dusseldorf, Dusseldorf, Germany.

A 31-years-old female was admitted to our hospital because of prolonged fever of unknown origin for 2 months. As she was originally diagnosed to have upper respiratory infection, antibiotics and antipyretic analgesics were prescribed. However, there is a recurrence of fever up to 39 °C without antipyretic analgesics. There were no changes in body weight or the size of clothes, and she did not notice any clinical features of Cushing's syndrome. Her height and weight was 152 cm and 58 kg, with BMI of 24.9 kg/m$^2$, and the blood pressure was 118/78 mmHg. Except light moon face like change and conjunctive anemia, she had no abnormal physical features including Cushing's syndrome such as buffalo hump, truncal obesity, or purple striae. C-reactive protein and WBC were 15.7 mg/dl and 8900 /μl, respectively. Hemoglobin level was decreased to 9.2 g/dl, and platelet count was 609×103. ACTH was 12.3 pg/ml while serum and urine cortisol levels were 26.3 μg/dl and 246 μg/day, respectively. A normal circadian rhythm was not present. Dexamethasone suppression testing (0.5, 1.0, and 8.0 mg) did not decrease serum cortisol levels to the reference levels. Abdominal CT scan revealed left adrenal mass with a diameter of 55 mm, which was weakly enhanced, and was also consisted of the poorly enhanced region, suggesting the necrosis inside the mass. While there were no high uptakes in I-131 MIBG, adosterol, or gallium scintigraphys, (18)-FDG–PET/ CT scan showed high uptake only in left adrenal mass. As we diagnosed her adrenocortical carcinoma (ACC) with stage 1 and Cushing's syndrome, adrenalectomy was performed. Histopathologic analysis revealed at least four parameters of the Weiss system, including atypical mitoses, high mitotic rate, or capsular invasion, and MIB-1 labeling index was over 10%. Adjuvant treatment with mitotane (o,p,-DDD) was initiated following surgery.

Not only the serum IL6 level, which showed elevated to 126 pg/ml before adrenalectomy, immediately decreased to 4.7 pg/ml, but also the fever and systemic inflammatory responses improved. IL6 is known to have various functions such as inducing B cell proliferation or systemic inflammatory responses, including elevations in ESR or CRP. We hypothesized the possibility of IL6 producing ACC or that IL6 elevation was part of the response for necrotic area of ACC, produced from endothelial.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

Funding

## P356

### Desmopressin and non steroidal anti-inflammatory drugs: a case report of severe water intoxication during replacement therapy and review of the literature

E. Verrua[1], G. Mantovani[1], A. Noto[2], E. Ferrante[1], E. Sala[1], E. Malchiodi[1], G. Iapichino[2,3], P. Beck-Peccoz[1] & A. Spada[1]
[1]University of Milan, Endocrinology and Diabetology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Ospedale San Paolo, Milan, Italy; [3]University of Milan, Milan, Italy.

Context

Most of the clinical data on safety profile of desmopressin (DDAVP), i.e. an effective treatment of both polyuric conditions and bleeding disorders, originates from studies on tailoring of drug treatment, whereas few reports describe severe side effects secondary to drug–drug interaction.

Objective

To describe a case of severe hyponatremia complicated with seizure and coma due to the intake of non steroidal anti-inflammatory drugs (NSAIDs) in a patient on DDAVP replacement therapy for central diabetes insipidus (DI).

Patient and methods

We report a 50-year-old Caucasian man, with congenital central DI, who developed an episode of generalized tonic-clonic seizure, resulting in coma immediately after being admitted to the Emergency Unit for weakness and emesis. Based on his medical history and clinical findings, water intoxication secondary to ketoprofen intake (200 mg/day for the last 3 days) concomitant with DDAVP replacement therapy (Minirin 60 μg four tablets a day) was hypothesized as cause of the severe euvolemic hypotonic hyponatremia (natremia 113 mEq/l, plasma osmolality 238 mOsm/kg). After emergency procedures, the aquaretic tolvaptan (Samsca 7.5 mg) was administered and hydratation was maintained according to water excretion. He completely recovered in 72 h. We discuss this case report in the context of the published literature.

Conclusions

Contrary to the several cases of hyponatremia reported in patients on DDAVP for different indications, no study has highlighted the potentially life-threatening side effects associated with over-the-counter NSAIDs during DDAVP replacement therapy for central diabetes insipidus so far. Risks and benefits of co-treatment should be carefully considered and therapeutic alternatives to NSAIDs should be recommended to patients with central DI, in order to improve DDAVP safety.

### Germ cell tumor of the pituitary–hypothalamic region: case series and clinical experience in the Hospital Universitario Virgen del Rocío

M. Tous Romero[1,2], E. Venegas[1,2], A. Soto Moreno[1,2], E. Dios Fuentes[1,2], E. García García[1], R. Oliva Rodriguez[1,2], N. García Hernandez[1,2] & A. Leal Cerro[1,2]
[1]Hospital Universitario Virgen del Rocío, Sevilla, Spain; [2]Instituto de Biomedicina de Sevilla, Sevilla, Spain.

Background

Germ cell tumors (germinoma, teratoma, embryonal carcinoma, yolk sac tumor and choriocarcinoma) constitute 0.3–3.4% of all primary intracraneal tumors. Germinoma is the most common and of better prognosis.

Aim

Describing the behaviour of germ cell tumors of the pituitary–hypothalamic region: location, clinical characteristics, diagnosis and follow-up.

Material and methods

Review of medical records of patients with germ cell tumors of the pituitary–hypothalamic region diagnosed between 1998 and 2011 attended at Hospital Universitario Virgen del Rocío in Seville. Were determined the clinical presentation, location, process followed to achieve diagnosis, treatment and evolution.

Results

Thirteen patients were diagnosed: four male (30.7%) and nine female (69.23%). Nine of the 13 patients (69.2%) had an age of 14 or younger.

Twelve patients (92.3%) displayed diabetes insipidus, being the first symptom in 11 of them (84.6%). All subjects displayed panhypopituitarism at the beginning of the treatment.

In four patients (30.7%) with diabetes insipidus, the initial MRI was normal or only displayed thickened pituitary stalk; these patients were finally diagnosed with a radiologic follow-up and/or biopsy.

Nine of the 13 patients (69%) were diagnosed after biopsy or surgery and in the four remainders (31%) by the elevation of the serum and/or cerebrospinal fluid (CSF) tumor markers.

In nine of which pathologic anatomy records were available, eight were germinomas and one was yolk sac tumor.

The average time of evolution since diagnostic is 4.67 years. Nowadays, 12 of the 13 patients are alive.

Conclusion

Diabetes insipidus is the most frequent symptom in the germinomas of the pituitary-hypothalamic region. When diabetes insipidus is diagnosed a close clinic and radiologic follow-up is compulsory as the patient might suffer a germinal tumor or develop other hormonal deficits.

**Adrenal venous sampling for two cases with primary pigmented nodular adrenocortical disease**

Y. Nishina[1], Y. Masuda[1,2], J. Kazaoka[1], I. Shirouzu[1], T. Machida[1], K. Ito[1], T. Konishi[1], H. Horiuchi[1] & M. Hayashi[1]
[1]NTT Medical Center Tokyo, Tokyo, Japan; [2]Faculty of Medicine, University of Tokyo, Tokyo, Japan.

Introduction
Primary pigmented nodular adrenocortical disease (PPNAD) is a rare cause of Cushing's syndrome. Total bilateral adrenalectomy is mostly chosen for treatment because pathological changes usually grow out in both adrenal glands among PPNAD cases. Meanwhile total adrenalectomy may result in life-threatening acute adrenal insufficiency. In this report, two PPNAD patients were examined to check the laterality of hormone secretion from both glands by adrenal venous sampling (AVS) ahead of surgical intervention, with a view to clarify the distribution of adrenal regions which could be spared during surgery.
Case report
Two females, aged 24 and 25 years, showed typical clinical features and laboratory findings of ACTH independent Cushing's syndrome. Imaging tests showed bilateral adrenal nodules and bilateral radioiodine uptake. Besides, other examinations revealed the history of atrial myxoma or the existence of breast tumor, which were characteristics of Carney complex. Although these findings validated the diagnosis of PPNAD, we investigated hormonal laterality to know whether there would be any way to avoid total adrenalectomy and symptoms due to cortisol deficiency. Cortisol, aldosterone, epinephrine, norepinephrine levels were measured by AVS including ACTH stimulation. The laterality of cortisol concentration varied from 1.3–1.5 times to 1.2–1.6 times, respectively before and after ACTH administration. The predominance of aldosterone and others were ipsilateral in the first case, but contralateral in the second case. The results seemed inadequate to prove the significant laterality of hormone secretion. Taking all these findings into consideration, both patients underwent laparoscopic bilateral complete adrenalectomy. Histopathological analyses diagnosed both as PPNAD and also revealed that some normal steroid synthetase expressions still remained in non-nodular area.
Conclusion
We have shown that AVS gave us meaningful information to elucidate the pathophysiologic mechanism of PPNAD. Further studies are waited to determine the optimum treatment for bilateral functional adrenal tumor.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P359

**Cyclic Cushing's syndrome due to occult ectopic ACTH secretion**

M. Alberiche Ruano, M. Boronat Cortés, C. Rodriguez Perez, R. Velasco Huici, R. Sanchez Hernandez & F. Novoa Mogollón
Complejo Hospitalario Universitari Insular-Materno Infantil de gran Canaria, Las Palmas de Gran Canaria, Spain.

Introduction
Cyclic Cushing's syndrome (CCS) is extremely rare. It's defined by periodic hypercortisolism with at least three proven peaks and two drops in cortisol secretion.
Case report
A 35-year-old woman was reffered for evaluation of endogenous hypercortisolism after a diagnosis of central serous coriorethinopathy. Initially she had mild symptoms. Urinary free cortisol (UFC) was 2.881 μg/24 h; ACTH 17.45 pg/ml and night salivary cortisol 7.08 mmol/l. Administration of 1 mg of dexametasone (DXM) failed to suppress cortisol secretion but adequate suppression was observed after 8 mg. Pituitary MRI was normal. Two hospital admissions over a period of 3 months showed normal UFC and night salivary cortisol and adequate suppression with 1 mg of DXM. Basal cortisol was about 7 μg/dl and response to i.v. ACTH (250 μg) was normal. During a third hospital admission due to clinical worsening UFC was >705 μg/24 h, night salivary cortisol 1.05 μg/dl, cortisol cyrcadian rhythm was absent and ACTH concentrations were 44 pg/ml. A desmopressin test showed an ACTH increase of 400%. Inferior petrosal sinus catheterization during hypercortisolism (UFC > 540 μg/dl) showed no gradient between petrosal sinuses and periphery. Diagnosis of CCS due to ectopic ACTH secretion was made. Cervical, chest and abdomen CT, PET and octreoscan were normal. Eighteen months later, the patient had gained 20 kg and had developed frontal alopecia, hirsutism, ankle edema and osteopenia. A laparoscopic bilateral adrenalectomy was performed. Annual imaging and ectopic co-secretion markers remain negative 3 years after surgery.

**Table 1** Inferior petrosal sinus catheterization during hypercortisolism (UFC > 540 μg/dl)

| | Cortisol (μg/dl) | ACTH Rps (pg/ml) | ACTH Lps (pg/ml) | ACTH p |
|---|---|---|---|---|
| −15′ | 24.5 | 84 | 80 | 83 |
| 0′ | 22.4 | 81 | 83 | 50 |
| 3′ | 21 | 81 | 81 | 85 |
| 5′ | 22.5 | 89 | 91 | 87 |
| 10′ | 22.2 | 44 | 99 | 96 |
| 30′ | 29.3 | | | 97 |
| 60′ | 29.4 | | | 51 |

Rps, right petrosal sinus; Lps, left petrosal sinus; p, periphery. Before and after surgery.

Discussion
Of the 66 cases of CCS described until now, only two are due to ectopic occult ACTH secretion. For a correct diagnosis, frequent determination of UFC and night salivary cortisol are necessary and diagnostic tests should be performed during hypercortisolism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Use of tolvaptan for delayed hyponatremia after transsphenoidal surgery for pituitary adenoma: a case report**

E. Ferrante[1], G. Mantovani[1], E. Verrua[1], E. Sala[1], E. Malchiodi[1], M. Locatelli[2], A. Spada[1] & P. Beck-Peccoz[1]
[1]Endocrinology and Diabetology Unit, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Neurosurgery Unit, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy.

Introduction
Disorder of water and electrolyte balance may develop after transsphenoidal (TNS) surgery for pituitary adenomas. In particular, delayed hyponatremia (Na < 135 mEq/l) due to SIADH is reported in 8–35% of patients and usually resolves with fluid-intake restriction within 6 days. The possible role of vasopressin-2 receptor antagonists in this clinical setting has not been elucidated.

Case report
We report a case of a 57-years-old Caucasian woman who underwent TNS surgery for nonfunctioning pituitary macroadenoma. Postoperative period was uncomplicated and serum sodium levels in the normal range were recorded. On postoperative day 5, sodium concentrations rapidly decreased to 127 mEq/l and symptoms related to hyponatremia (haedhache, weakness) occurred. Treatment by water restriction (<1000 ml/day) and salt rich diet was started. Thirty-six hours after the beginning of fluid restriction, the serum sodium concentration was 129 mEq/l and the patient remained symptomatic. Given the lack of efficacy, water restriction was stopped and tolvaptan (Samsca 15 mg) was administered. Four hours after vasopressin-2 receptor antagonist intake, sodium levels increased to 131 mEq/l and rose to 142 mEq/l in 24 h, with disappearance of symptoms. Tolvaptan was discontinued and clinical status and serum sodium concentration was monitored. The patient was discharged two days after with a sodium value of 140 mEq/l and in good clinical condition.
Conclusions
Although in many cases of delayed acute hyponatremia after transsphenoidal surgery fluid-intake restriction is effective, in our patient this treatment resulted insufficient to reverse hyponatremia and required a significant prolongation of hospitalization. Conversely, administration of a single dose of tolvaptan rapidly and safely resolved hyponatremia. In conclusion, treatment with tolvaptan may represent a useful alternative to fluid restriction in mild symptomatic delayed hyponatremia after TNS surgery and may possibly shorten hospitalization of these patients.

**Familial isolated pituitary adenoma cases in Hungary**

J. Dénes[1], G. Kovács[1], A. Patócs[2], E. Gláz[2], E. Mezõsi[3], E. Hubina[1], L. Kovács[1], Z. Görömbey[1], S. Czirják[4], M. Korbonits[5] & M. Góth[1]
[1]Military Hospital, Budapest, Hungary; [2]Semmelweis University, Budapest, Hungary; [3]University of Pécs, Pécs, Hungary; [4]National Institute of Neurosciences, Budapest, Hungary; [5]Barts and the London School of Medicine, Queen Mary University of London, London, UK.

Familial isolated pituitary adenoma (FIPA) occurs if two or more members of a family develop pituitary adenoma with no features of multiple endocrine neoplasia type 1 or Carney complex. FIPA is an autosomal dominant disease with incomplete penetrance. FIPA families can be divided into two distinct groups based on genetic and phenotypic features. In 20% of FIPA families mutations have been identified in the aryl hydrocarbon receptor interacting protein (AIP) gene. The AIP-positive families have a distinct phenotype with younger age at diagnosis and a predominance of somatotroph and lactotroph adenomas. In the AIP-negative group patients present with wider age-range at diagnosis and a more varied adenoma types. No causative gene has been identified.
We have identified four FIPA families in Hungary to date. Family 1 has two adult-onset (77 years and 54 years) acromegaly in the proband and her first cousin, twice removed. The proband responded well to primary medical treatment with somatostatin analogues. In Family 2 acromegaly was diagnosed in the proband at the age of 68 years and prolactinoma in his 34-years-old nephew. Families 3 and 4 have prolactinoma in two brothers and in a grandmother–mother–granddaughter triplet. None of these families harbour an AIP mutation. Harvey Cushing in 1910 has described a family with gigantism from Hungary, but their family members, if alive, have not been identified yet.
Current data suggest that familial pituitary adenomas are diagnosed at higher frequency than previously thought. Detailed family history helps to identify candidates for genetic and clinical screening in order to achieve early diagnosis and treatment at an earlier stage of the pituitary tumor.

**Hypopituitarism in an adult patient as the first sign of langerhans cell histiocytosis**

M. Passeri[1], R. Antonelli[1], S. Falcone[1], E. di Benedetto[1], G. Franconi[1], M. Calanchini[1], M. Caprio[2] & A. Fabbri[1]
[1]Università Tor Vergata, Rome, Italy; [2]IRCCS san raffaele pisana, Rome, Italy.

Langerhans cell histiocytosis (LCH) is a rare entity characterized by clonal proliferation and accumulation of cells resembling the epidermal dendritic cells called Langerhans cells (distinct margins, pink granular cytoplasm, Birbeck granules at electron microscopy and CD1 positivity by immunocytochemistry). These cells in combination with lymphocytes, eosinophils ad normal hystiocytes form the typical LCH lesions. About half of affected patients have extraskeletal manifestations, including involvement of the hypothalamus–pituitary axis, lung, heart, retroperitoneum, skin, liver, kidneys and spleen. There is an ongoing debate on the exact pathogenesis of this disorder and on its classification as reactive versus neoplastic.
This report describes the case of a 54-years-old man who presented with hypogonadism, central hypothyroidism, diabetes insipidus and GH deficiency ten years ago. At the time of diagnosis a thickening of the pituitary stalk, with a slight compression of the posterior region of the optic chiasma, was recorded at MRI images. A moderate hyperprolactinemia was also present. At that time a work-up for granulomatous or infectious diseases was negative. Nearly one year ago, the patient experienced skin involvement (skin biopsy of the perianal region positive for LCH) and massive bone involvement (sclerotic infiltration of vertebral bodies, femoral and tibial metaphysis and diaphysis). At the present time the patient is doing well after two cycles of chemotherapy. MRI imaging is still stable.
Hypopituitarism may be the first sign of a so far undiagnosed extracranial disease; mainly inflammatory or granulomatous disease should be carefully considered in differential diagnosis.

**A case of cyclic Cushing's syndrome which was induced remission dramatically by dopamine agonist**

S. Sakihara & T. Suda
Hirosaki University Graduate School of Medicine, Hirosaki, Japan.

Cyclic Cushing's syndrome (CysCS) is one of the peculiar types of Cushing's syndrome, characterized by the iteration between remission and recurrence. The precise mechanism in which the hormonal activity is changed suddenly has not been determined, while several hypotheses have been presented. Here, we report a case of CysCS which was induced remission dramatically by dopamine agonist. A 67-years-old woman was pointed out increasing ACTH and cortisol (F) levels during the examination for hyperglycemia and hypokalemia. Her ACTH and F were not decreased in midnight, and not suppressed by high dose dexamethasone. Then she was diagnosed as ACTH dependent Cushing's syndrome. Although cavernous sinus sampling suggested ectopic producing of ACTH, general whole-trunk CT, MRI, and FDG–PET could not detect any ACTH producing tumor. Interestingly excess ACTH and F were normalized dramatically and completely by the short-term treatment with cabergoline (Cab), potent dopamine receptor type 2 (D2R) agonist, where after they were kept in normal range for several months without any treatment. Similar episodes were recurred three times for recent 3 years, suggesting CycCS. Every active phase was terminated by D2R agonists, while abnormal secretion of ACTH was induced by domperidone (Dpm), D2R antagonist, even in the remission phase.
The clinical course of this case suggests D2R agonists are effective in the treatment of ACTH dependent Cushing's syndrome. In addition, this case suggests D2R might be involved in the conversion between remission and recurrence of CycCS, although the mechanism is unclear.

### Antinociceptive effect of pasireotide on octreotide-resistant acromegaly-related headache

D. Marina, M. Klose & U. Feldt-Rasmussen
Rigshospitalet, Copenhagen, Denmark.

Background
Headache often occurs as incapacitating symptom among the patients with acromegaly. GH involvement in the pathophysiologic mechanism and an analgesic effect of somatostatin analogues has been described, but the exact mechanism is not clear. Whether the pan somatostatine (sst)-receptor agonists are superior as concern the antinociceptive effect than the more selective ones is not evidenced.
Case report
A 21-year old woman, diagnosed with acromegaly, presented with visual disturbances and incapacitating headaches lasting for 8 months (MRI: pituitary macroadenoma with supra- and parasellar propagation). Several daily attacks of headache were resistant to high doses of pain-killers. Preoperative neuroendocrine values on oral contraceptives: elevated mean spontaneously GH and insulin-like growth factor (IGF1) (Table 1. apr-09); low-normal free $T_4$ (13.4 pmol/l (14–23 pmol/l)); low levels of FSH $<0.2$ IU/l and LH $<0.1$ IU/l; low-normal response to Synacthen test (peak cortisol: 904 nmol/l). After two surgeries in 2009, tumour size was significantly reduced. Different combinations and dose concepts of octreotide, sandostatin LAR and somavert were applied but IGF1 remained high and the headaches worsened. Pasireotide–pegvisomant combination was introduced with prompt marked headache-relief, persisting until few days before next injection. IGF1 normalized for the first time (Table 1. apr-11).
Conclusion
Pasireotide may have a superior antinociceptive effect, as compared to other somatostatin analogues. Very possibly pan-sst receptor agonists may be superior to selective sst2 ones regarding their antinociceptive effect, but further studies are needed to clarify this.

**Table 1** Overview of disease activity and medical therapy

### Giant cystic pheochromocytoma in an asymptomatic man

V. Dimarakis & C. Tsentidis
Nicaea Hospital 'Ag. Panteleimon', Piraeus, Greece.

Introduction
Cystic adrenal incidentalomas are relatively rare. Large cystic pheochromocytomas are extremely rare and there are few reports of them being clinically silent.
Case presentation
We report the case of a 57-years-old man, who was admitted to our clinic for evaluation of a large cystic lesion that was found ultrasonographicaly in a typical check-up. We ordered a CT that revealed a giant right adrenal cyst ($91.3\times96.8\times92.1$ mm) with thick wall (2–5.5 mm) and no enhancement after i.v. contrast agent infusion. Before admitting the patient for surgery he was evaluated for pheochromocytoma even if he was totally asymptomatic and his blood pressure was normal in multiple measurements. The results from two 24 h urine collection specimens were a surprise: metanephrine 1800–1132 μg/24 h (normal range 20–350), epinephrine 168–130 μg/24 h (<20), norepinephrine 163–239 μg/24 h (<110), normetanephrine 1697–2171 μg/24 h (30–600), dopamine 351 μg/24 h (<600). Evaluation for multiple endocrine neoplasia type 2 syndrome was negative. The patient was preoperatively prepared with very low dose of phenoxybenzamine and propranolol. Right adrenalectomy was performed and intra- and postoperative course was uncomplicated. The surgical specimen revealed pure cystic pheochromocytoma.
Conclusion
Large cystic pheochromocytomas are very rare and often asymptomatic. Pheochromocytoma should always be ruled out in patients presenting with cystic adrenal incidentalomas, even in the absence of hypertension or other symptoms.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P366

### Unusual presentation of hypopituitarism

C. Eboh, S. Baker & S. Ahmed
Great Western Hospital, Swindon, UK.

A 37-years-old man was referred to rheumatology with a 3 month history of widespread joint pains, worse on rising in the mornings with early morning stiffness lasting about 15 min. Hands were affected first followed by knees and hips. On further questioning, he also complained of generalised fatigue, loss of libido and thinning of the hair on his chest, as well as 15 kg weight loss over 6 months. He recalled a febrile illness with headache prior to the onset of his symptoms, but had no ongoing headache or visual symptoms.
On examination there was no evidence of joint synovitis. Blood testing done by his GP 2 months prior to referral showed: TSH 0.07 μU/ml (0.35–6.9), free $T_4$ 6.0 pmol/l (5.6–21) and free $T_3$ 5.1 pmol/l (3.7–7.0). ESR was mildly elevated at 12 mm/h and CRP was 8.0 mg/l. There was a mild normocytic anaemia (Hb 12.1 g/dl). On repeat testing 1 month later TSH was 0.1 μU/ml, free $T_4$ 3.0 pmol/l, free $T_3$ 3.0 pmol/l. 9 am blood tests were organised for the following day which showed the following: cortisol 16 nmol/l (138–690), free $T_4$ 3.0 pmol/l, testosterone <0.3 nmol/l (10–35), LH 0.4 IU/l (2–18), FSH 1.3 IU/l (1–16), prolactin 185 mIU/l (50–500), glucose 5.2 and IGF1 25 μg/l (75–344). X-ray of the joints were normal.
MRI pituitary confirmed a pituitary macroadenoma. Formal visual perimetry was normal. He was subsequently commenced on Hydrocortisone therapy and two weeks later on thyroxine replacement with resolution of joint symptoms. He is awaiting transphenoidal adenomectomy.
Discussion
There are reports of hypopituitarism presenting with musculoskeletal symptoms. These have been attributed mainly to hypothyroidism and hypoadrenalism. Hypothyroidism, as in this case, can present with polyarthralgia/polyarthritis or myalgia/myositis which may be associated with elevated muscle enzymes. Hypothyroidism is also associated with calcium pyrophosphate crystal deposition in joints (presenting as acute pseudogout or a chronic arthropathy) and carpal tunnel syndrome. Hypoadrenalism can produce various nonspecific symptoms including fatigue and myalgias which could lead to patients being referred for rheumatological assessment.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P367

### Rhabdomyolysis and myopathy in Addison's disease: is there a connection?

D. Katalinic[1], M. Solter[2], D. Planinc[2] & S. Plestina[1]
[1]University Hospital Centre (KBC Zagreb), University of Zagreb School of Medicine, Zagreb, Croatia; [2]University Hospital Centre 'Sisters of Charity', University of Zagreb School of Medicine, Zagreb, Croatia.

Introduction
Rhabdomyolysis coexisting with Addison's disease is a rare condition and the mechanism is not clearly defined. We report a patient presenting with sever rhabdomyolysis which resolved after steroid replacement therapy.

Case report
A 33-year-old man without accompanying comorbidity, presented with progressive myopathy and fatigue. He was hypotensive (RR 90/70), hypovolemic with hyponatremia (125 mmol/l, range 137–146), elevated serum CPK (12 560 U/l, range <177) and high serum (3003 μg/l, range 28–72) and urinary myoglobin (384 μg/l, range <30). The muscle biopsy and tests of humoral and cellular immunity were normal. The hormonal findings confirmed adrenal insufficiency: serum cortisol (33 nmol/l (0800 h) <20 nmol/l (0500 h), range 138–800), ACTH 415.7 pmol/l (range 2.0–13.3), serum aldosterone 28 pmol/l (range 105–868), urinary aldosterone <1.0 nmol/24 h (range 6.23–59.3), renin >300 pg/ml (range 3.5–65.5) (upright posture). The absence of neurological symptoms and a prompt remission following steroid administration were against adult-onset form of adrenoleukodystrophy. The PPD probe, chest X-ray and CT scan of adrenal glands were normal. The etiology of Addison's disease was problably autoimmune; this hypothesis is supported by a positive anti 21-OH autoantibody. Normal values of testosterone, gonadotropins and blood glucose suggested that no other glands were involved in the autoimmune disease. The patient was treated with a high (200 mg), gradually decreasing dose of hydrocortisone i.v., then with 20+10 mg p.o. Finally, two months later, all laboratory signs of rhabdomyolysis disappeared with complete clinical recovery.
Conclusion
The association between Addison's disease and rhabdomyolysis is not clearly understood. Hyponatremia has been blamed for myopathy due to maladaptive cellular mechanism in response to fluid hypoosmolality. Myopathy was described in hyponatremia resulting from water intoxication, but, in spite of hyponatremia we were unable to detect a syndrome of inappropriate ADH secretion. Possibly, a glucocorticoid deficiency per se, by a mechanism unknown, could be involved in rhabdomyolysis. This case suggests that, in patients with rhabdomyolysis, an adrenal failure should be considered. It also raises the question of potential benefit of a glucocorticoid administration in other forms of rhabdomyolysis.

**Efficacy of tolvaptan treatment in a patient with syndrome of inappropriate antidiuresis (SIAD) after severe traumatic brain injury**

M. Bondanelli[1], A. Malaspina[1], A. Montis[2], M. Ambrosio[1], S. Lavezzi[2], N. Basaglia[2], M. Zatelli[1] & E. degli Uberti[1]
[1]Section of Endocrinology, Ferrara, Italy; [2]Department of Rehabilitation Medicine, Ferrara, Italy.

Tolvaptan, an oral antagonist of the vasopressin V2 receptor, has been found to improve hyponatremia in patients with SIAD. We report the case of a 65-years-old male, who developed recurrent episodes of hyponatremia after severe traumatic brain injury, TBI, with polytrauma (CGS=8, decompressive craniectomy, spontaneous breathing by percutaneous tracheotomy). During hospitalization in intensive care unit he resumed alertness and received i.v. hypertonic saline infusion and oral fludrocortisone therapy for hyponatremia. At admission to the intensive rehabilitation unit (1 month after TBI) he was on fludrocortisone therapy and i.v. sodium supplementation, and presented an extremely severe disability (Functional Independence Measure, FIM=18/126; Disability Rating Scale, DRS=21/30; Levels of Cognitive Functioning, LCF=3/8), needing enteral nutrition. After discontinuing sodium supplementation, hyponatremia recurred (125 mEq/l); at the same time the patient underwent ventriculo-peritoneal shunt for hydrocephalus and presented seizures requiring antiepileptic drug (levetiracetam). Serum sodium continued to fluctuate for 2 months, despite fludrocortisone therapy, prolonged sodium supplementation (i.v. or enteral) and/or water restriction. Hypoadrenalism and hypothyroidism were excluded and SIAD was diagnosed, after endocrinologist consultation. Sodium returned to normal values and remained stable for 3 months. A sudden drop in sodium levels again required hypertonic saline infusion. Diagnosis of SIAD was confirmed and therapy with oral tolvaptan was started (SAMSCA 15 mg/die for one month, then 7.5 mg/die). Serum sodium rose to >135 mEq/l in three days and remained stable throughout treatment for five months until now. No side effects were observed, seizures disappeared, antihypertensive drugs were discontinued due to normal blood pressure levels. At discharge from inpatient rehabilitation, cognitive and motor functioning scales improved (FIM=35, DRS=16, LCF=4), but the patient still presented severe disability. This case demonstrates that tolvaptan is safe and effective in the treatment of hyponatremia due to SIAD after severe TBI.

**A rare case of primary tubercular pituitary abscess in a diabetic patient**

E. Madronio
Philippine General Hospital, Manila, Philippines.

Introduction
Primary tubercular pituitary abscess is an extremely rare disease. Only few cases had been reported and the diagnosis was reached only after surgery. There is a need to distinguish between a tuberculoma, pituitary abscess and other functioning and nonfunctioning pituitary adenoma to direct our management into either medical or surgical management, especially here in the Philippines where tuberculosis is an endemic disease.
Case
We present a case of a 50-years-old diabetic Filipina who came in for complains of gradual loss of vision, bitemporal, since four months prior to admission. This was associated with frequent headaches, polydipsia and polyuria. No previous history of pulmonary tuberculosis. Physical examination and vital signs were normal except for hemianopsia. Chest X-ray was normal. Perimetry exam revealed temporal hemianopsia on the right, and almost complete temporal anopsia, left. MRI showed a relatively large 2.8 cm cystic-appearing mass involving the sellar and suprasellar compartments compatible with a cystic adenoma or a craniopharyngioma. Serum $FT_4$ was 10.5 pmol/l (11–24), TSH 1.4 mIU/l, serum prolactin 2404.2 mIU/l (90–500) and serum cortisol at 409.8 nmol/l (154–638). The patient underwent transphenoidal pituitary surgery and intraoperatively the sellar floor was noted to be thinned out with noted egress of a purulent material during opening of the dura. Staining of the purulent material was positive for acid fast bacilli. Anti Kochs medication was started, together with vancomycin and cefepime. Postoperatively, patient developed diabetes insipidus, but there was significant improvement in vision.
Learning points
Always consider tubercular pituitary abscess in a diabetic patient living in a tuberculosis endemic area and presenting with a sellar suprasellar mass.
MRI of the brain showing a 2.8 cm cystic mass involving the sellar and suprasellar compartments causing severe compression of the overlying optic apparatus.

### Central diabetes insipidus as first sign of progression to accelerated phase in a chronic myeloid leukemia patient

A. Gedik, M. Yilmaz, D. Cimrin, S. Kahraman & A. Comlekci
Dokuz Eylul University Medical Faculty, Izmir, Turkey.

Introduction
Pituitary involvement has been rarely reported during the course of hematological diseases like thalessemia, Langerhans-cell histiocytosis and lymphoma. We here present a case of chronic myeloid leukemia (CML) with pituitary involvement, in which central diabetes insipidus (DI) was the first sign of progression to accelerated phase.
Case report
A 61-year-old man was consultated by our clinic due to polyuria with 6000 ml daily urine output. His past medical history revealed CML which was in complete remission for 2 years. He had signs of dehydration, orthostatic hypotension and splenomegaly. Laboratory tests demonstrated severe hypernatremia, decreased urinary and increased serum osmolarities (Table 1). Water deprivation test was not held due to severe signs of dehydration. Desmopressin was started with a presumptive diagnosis of DI after which urine output and biochemical tests returned to normal. Pituitary MRI revealed thickened enhancing pituitary stalk and loss of the bright spot of the neurohypophysis (Figure 1). Patient was referred for hematological reevaluation. Reappearance of the Philadelphia chromosome and increased blast ratio in bone marrow was documented which showed progression from chronic remission phase into accelerated phase.
Conclusion
Diabetes Insipidus has been reported in patients with acute leukemia or myelodysplastic syndrome and almost always been associated with gravid course. Monosomy 7 and/or inv(3) have been linked with DI in some cases. Direct infiltration by the leukemic cells, hemorrhage, thrombosis and infection have been suggested as the possible factors underlying the pituitary damage. Appearance of DI during the course of hematological malignancies should alert the physician for acceleration or blastic transformation of the disease.

**Table 1** Laboratory tests

| Test | Result | Reference range (unit) |
|---|---|---|
| Sodium | 167 | 136–145 (mEq/l) |
| Potassium | 3.8 | 3.5–5.1 (mEq/l) |
| BUN | 20.8 | 8.4–25.7 (mg/dl) |
| Creatinine | 1.03 | 0.1.3 (mg/dl) |
| Urine osmolarity | 146 | (mOsm/kg) |
| Serum osmolarity | 299 | (mOsm/kg) |
| WBC | 10.5 | 4–10.3 (μl) |

### Contrast-enhanced ultrasound supports diagnosis in a patient with paravesical paraganglioma

G. Meyer, M. Friedrich-Rust, A. Haferkamp, C. Bartsch, K. Badenhoop & J. Bojunga
J.W. Goethe-University Hospital, Frankfurt, Germany.

Introduction
We report the unusual case of a young patient with micturition induced headache, in which contrast-enhanced ultrasound helped to assure diagnosis of paravesical paraganglioma.
Case
An 18-year-old male presented with attacks of severe headache lasting several minutes and occurring strictly after micturition. Hypertensive values up to 200/105 mmHg were detected subsequent to nearly every micturition while values before and some minutes after it were normal.
A paravesical tumor with regressive changes, measuring 3.7×3 cm, was seen by B-mode ultrasound and confirmed by MRI. Contrast-enhanced ultrasound was performed. After i.v. injection of 2.4 ml SonoVue, the tumor showed an early arterial contrast enhancement with peripheral to central contrast filling and a distinct, irregular hypervascularisation – signs which have been described as typical for pheochromocytomas before.
Plasmametanephrines revealed a distinct elevation of normetanephrine (1934 pg/ml, norm $<180$), so we diagnosed a functional paravesical paraganglioma. The patient had no family history for phaeochromocytoma or other endocrine tumors. A Fluorodopamine (F-Dopa)-PET CT was performed with uptake of F-Dopa confined to the paravesical tumor but not in further locations. After adrenergic blockage with Urapidil the tumor was successfully removed. Mutational analysis of SDHB, VHL, SDHD and RET was performed without any pathologies.
Conclusions
There are only few reports of functional paravesical paragangliomas which are very rare tumors (less than 1% of all pheochromocytomas). However, to avoid serious complications including hypertensive crisis during operation, it is important to consider these tumors in the differential diagnosis of paravesical tumors. Contrast-enhanced ultrasound can be a cost-effective, less-invasive method to support diagnosis.

## P372

### Pituicytoma and meningeoma presenting as suprasellar tumor: case report

G. Pemovska, B. Krstevska & B. Jovanovska
University Clinical Center, Skopje, The Former Yugoslav Republic of Macedonia.

Pituicytoms is a very rare low-grade glioma of the neurohypophysis and can affect both the sellar and suprasellar regions. We describe a case of a suprasellar pituicytoma and mengioma of a patient admitted to our Clinic as a suprasellar tumor patient.
Clinical presentation
A 55-years-old man with a history of persistent headache in the right frontal area for a period of 10 years prior to the admission as well as visual disturbances and decreased libido for 1 year period prior to the admission. The hormonal profile revealed low FSH (0.368 mU/l), LH (0.1 mU/l), testosterone, cortisol (6.34 nmol/l) and PRL (19.39). Magnetic resonance imaging showed a solid homogeneously enhancing suprasellar mass 2.5 cm compressing the optic chiasm. A craniotomia pteryonal l. dex. was performed as well as a subtotal resection of the tumor. The hystopathological finding indicated meningeoma fibroblasticum. Due to the deterioration of the sight a new MRI was performed after 9 months that showed an identical finding of suprasellar macroadenoma. A recraniotomia reg, frontalis l. dex. and reextirpatio tumoris were performed and the hystopathological finding indicated pituicytoma (infundibuloma) Ki 67 $<3\%$.
After
The surgery was followed by a radiation therapy, after which the patient developed symptoms of frontal lobi, diabetes mellitus and diabetes insipidus. The patient died of a heavy adrenalin crisis.
Conclusion
Pituicytoma are rare tumors of the neurohypophysis. The clinical presentation is similar to other non-functional pituitary adenomas and imaging exams may suggest pituitary adenomas. The diagnostic is based on histopatological analysis.
Key words: Hypophysis, Pituicytoma, pituitary tumors, neurohypophyseal tumor.

### A clinical case report of an successful spontaneous pregnancy in acromegaly

F. Mohammadi, S. Sadri, M. Hedayati Omami & N. Amini
Guilan University of Medical Sciences, Rasht, Islamic Republic of Iran.

Introduction
Acromegaly is a clinical condition results from GH hypersecretion which is usually elaborated by a somatotroph adenoma. Mass effect of adenoma and resulting hormonal changes impair fertility during pregnancy, estrogen-mediated pituitary enlargement along with enhanced pituitary vascularity is a true risk for tumor hemorrhage.
Case presentation
The 28-years-old patient first visited by the endocrinologist in 2004 for secondary amenorrhea and increased GH level. She was married in 1999 and had a successful spontaneous pregnancy in 2000. She stayed amenorrheic for 5 years after delivery until she made an appointment with the gynecologist. The gynecologist noticed the early clinical and para-clinical features of acromegaly and referred her to the endocrinologist. Radiographic and lab results indicated an active pituitary adenoma. Prednisolone and levothyroxine started and 3 months later trans-sphenoidal surgery performed for tumor resection. Eight months later after surgery neither IGF1 nor GH decreased, so octreotide was prescribed and patient was sent for gamma knife therapy on November 2006. Four months after gamma therapy while she was still taking octreotide, she was became amenorrheic again. Work up started and revealed the pregnancy. Octerotide discontinued. Visual field assessments were normal and MRI did not show any changes in the tumor size. Treatment continued with bromocriptine and levothyroxine. Prednisolone replaced by hydrocortisone stayed under close observation till term. GH, IGF1, and prolactine levels were monitored every 3 months during pregnancy. Suppression test with 100 g glucose were performed. Results were in normal range. MRI in 6th month of pregnancy, revealed slight decrease in the size of tumor. Blood pressure was normal. At the end of 8th month of pregnancy, IGF1 returned to its normal level. Serial sonographies did not reveal any abnormalities. Lipid profile and BS were normal. In 39th week of pregnancy, C/S performed for delivery. The female newborn was healthy.
Discussion
Today with advent of advanced surgical and medical management of these patients, increasing numbers could have successful pregnancy and child bearing.

### Childhood onset hypopituitarism and central apnea: looking beyond hormonal replacement

A. Fernandez Martinez[1], J. Olivar Roldan[3], A. Campos[1], P. Lapunzina[1], A. Rodriguez Sanchez[2] & C. Alvarez Escola[1]
[1]Hospital La Paz, Madrid, Spain; [2]Hospital Gregorio Marañon, Madrid, Spain; [3]Hospital Infanta Sofia, San Sebastian de los Reyes, Spain.

Introduction
Childhood-onset hypopituitarism is an uncommon yet increasingly diagnosed disorder. As endocrinologists, we generally deal with the complexities of hormonal replacement and, when required, follow these patients to detect tumor recurrences. However, some causes of childhood- onset-hypopituitarism have comorbidities which can significantly increase morbi-mortality. We present the case of a 21-year-old girl who was diagnosed with ROHHAD syndrome.
Case report
A 3-year-old female child presented to a Pediatric Clinic in Madrid because of rapid-onset-hyperphagia and increased-body-weight. The patient did not receive hormonal assessment at that stage and was discharged with dietary advice. One year later the patient developed episodes of unprovoked respiratory arrest but could be resuscitated. Respiratory assessment revealed central apnea that required ongoing ventilatory support and nocturnal-oxygen airflow. The patient also showed impaired language skills and mild mental retardation, and continued surveillance detected a mediastinal neuroblastoma (successfully resected), and autonomic-dysfunction-related chronic diaphoresis and intermittent diarrhea.
The hyperphagic behaviour persisted and, on reporting growth arrest, the patient, aged 8, was finally referred to a Pediatric Endocrinology Department (PED). Hormonal profile confirmed GH deficiency, hypogonadotropic hypogonadism and secondary hypothyroidism, which were duly replaced. Genetic study did not find PHOX2B mutations, but the patient was nonetheless diagnosed with ROHHAD syndrome on clinical grounds.
The patient is now a 23-years-old adult female who follows daily outdoor activities at a specialised educational centre. She still receives estrogen–progestin replacement, levothyroxine, and she is about to restart GH after her transition from a PED to our Adult Endocrinology clinic was delayed for 2 years.
Conclusion
We present a case of ROHHAD syndrome, an uncommon cause of early-onset-hypopituitarism whose cardinal features include hyperphagia, neuroblastomas, autonomic dysfunction and life-threatening central apnea. Early recognition dramatically reduces morbimortality. These patients also need transition schedules to ensure that proper surveillance strategies continue through adult life.

## P375

### Cystic pituitary macroadenoma complicated by recurrent mucocoeles: a rare case report

R. Ahluwalia[1], J. Vora[1] & A. Sinha[2]
[1]The Royal Liverpool and Broadgreen University Hospitals NHS Trust, Liverpool, UK; [2]The Walton Centre NHS Foundation Trust, Liverpool, UK.

Introduction
Non-functioning pituitary adenomas, usually macroadenomas, represent around 30% of pituitary tumors. Patients often present with signs of mass effect and symptoms of pituitary insufficiency. We report a complicated case of a cystic pituitary 'macroadenoma' presenting with recurrent mucocoeles likely due to underlying sinusitis.
Case report
A 42-year-old Caucasian female presented with chronic headaches and unilateral temporal visual field defect. She also reported secondary amenorrhoea, intermittent galactorrhoea, polydipsia with polyuria. Investigations confirmed a cystic pituitary macroadenoma with chaismal compression associated with hyperprolactenaemia (adjusted PRL 1245, normal range $<400$). Rest of the baseline pituitary profile was normal. Histology following transsphenoidal surgery was suggestive of a necrotic tumour of unknown aetiology. Postoperative MRI scan showed a thickened stalk with crescentric residual tissue. She later developed sphenoid sinusitis requiring ENT intervention. Postoperatively, she presented with two further episodes of severe headaches with recurrent pituitary mucocoeles warranting further neurosurgery. On at least one occasion sterile purulent fluid was aspirated. Given the suspicion of sphenoid sinusitis causing recurrent mucocoeles, she received a prolonged course of intravenous antibiotics. She recently underwent radical excision of the inflamed sinusoidal mucosa with obliteration of the sinus with a fat graft. Since her last presentation with a pituitary mucocoele, she has had no further recurrence over past 22 months.
Conclusion
Recurrent pituitary cysts are usually craniopharyngiomas or remnants of Rathke's cleft. Infected pituitary cysts or abscesses are rare, characterized by systemic signs of toxaemia, mass effects due to enlarging pituitary and/or associated endocrine dysfunctions. Diabetes insipidus on presentation, has also been reported in the literature.The infection usually extends from paranasal sinuses, whereas involvement of the pituitary gland in systemic sepsis is quite rare because of effective blood brain barrier.
Hence we highlight the role of both medical and surgical intervention in the management of a rare and complicated case of a pituitary adenoma.
Declaration of interest

## P376

**A patient with TSH-secreting pituitary macroadenoma, after previous thyroid ablation, successfully treated with long-acting octreotide formulation (octreotide-LAR) and transsphenoidal surgery**

A. Gruszka & J. Kunert-Radek
[1]Medical University of Lodz, Lodz, Poland.

Introduction
Thyrotropin (TSH)-secreting pituitary adenomas are rare (<1% of all pituitary tumors) and cause secondary hyperthyroidism.
Case report
A 33-year old woman with type 1 diabetes mellitus presented in 2009 with palpitations. She had a past medical history of radioiodine therapy for thyrotoxicosis in 1998. After radioiodine treatment, she received an increasing daily dose of thyroxine (from 50 to 175 μg) because of her gradually rising serum TSH concentration.
Initial findings were: elevated serum TSH of 14.6 mIU/l (normal range: 0.27–4.2), elevated free-triiodothyronine ($fT_3$) concentration of 4.3 pg/ml (normal range: 1.64–3.45) and elevated free-thyroxine ($fT_4$) concentration of 1.87 ng/dl (normal range: 0.71–1.85). Thyroid antibodies were within normal ranges. After administration of 200 μg of thyrotropin-releasing hormone, TSH rose slightly from 24.9 to 31.26 mIU/l at 30 min. and to 29.14 mIU/l at 60 min. Alpha-subunit was 18 mIU/ml (normal range: 0.0–1.0). Other pituitary hormones and IGF1 were within normal ranges.
Magnetic resonance imaging (MRI) revealed a pituitary macroadenoma (13×12.5×10 mm) infiltrating the left cavernous sinus.
The patient was initially treated with octreotide-LAR (20 mg i.m. every 28 days) for ten months. During therapy serum TSH levels were reduced by more than 50%. No significant change in pituitary tumor volume was observed in MRI performed after octreotide-LAR treatment. In January 2011 the patient underwent uncomplicated transsphenoidal surgery, and immunohistochemical staining showed positive reactivity for TSH. Early postoperative TSH concentration was low (0.072 mIU/l) and became normal in 5 weeks. In subsequent months the patient remained euthyroid on 125 μg thyroxine daily. Pituitary MRI performed during one year follow-up did not reveal tumor recurrence.
Conclusions
We report for the first time the data on preoperative somatostatin analogue treatment of thyrotropinoma in a patient who previously underwent thyroid ablation by radioiodine. Since aggressive and invasive macroadenomas are more frequently observed in these patients, we suggest that preoperative treatment with somatostatin analogues should be mandatory in these patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P377

**Synchronous papillary and medullary thyroid carcinoma in an acromegaly patient**

M. Yilmaz, A. Gedik, O. Ozdogan, M. Durak, A. Sevinç & A. Cömlekçi
[1]Dokuz Eylul University Medical Faculty, Izmir, Turkey.

Introduction
The increased mortality in acromegaly is mainly related to cardiovascular, respiratory and neoplastic complications; neoplasms being responsible in 15%. Although most of the thyroid nodules in acromegaly are benign, there are studies revealing an increased ratio of differentiated thyroid cancer in this disease. Medullary thyroid carcinoma (MTC) has not been related with acromegaly so far. In this report, we aimed to present a patient with acromegaly whose thyroid pathology revealed coexisting medullary and papillary thyroid carcinoma (PTC).
Case report
Fourty nine year old woman had been operated for suspicios thyroid cytology after being evaluated for euthyroid multinodular goitre. Total thyroidectomy had been performed and her pathology revealed medullary carcinoma (2.3×2.3 cm) and multifocal papillary carcinoma. After ablative radioactive iodine therapy, she had been referred to our institution for thyroid hormone supression therapy. During the follow up, she complained of acral enlargement and weight gain. She had progressive coarsening of the facial features which reminded us acromegaly. Diagnostic tests consisting of basal and post-glucose load growth hormon, age adjusted insulin like growth factor 1 (IGF1) confirmed the diagnosis of acromegaly. Pituitary magnetic resonance imaging (MRG) showed a macro-adenoma (19×9×7 mm) in the right part of the pituitary. The patient has been referred to neurosurgery clinic for pituitary surgery.
Conclusion
MTC may be seen as a part of multiple endocrine neoplasia (MEN) type 2. Acromegaly may seldomly appear as a MEN1 component. Rarely, components of MEN1 and MEN2 coexist in a single patient simultaneously. Coexistance of acromegaly, MTC and PTC has not been reported in literature so far. Further analysis is needed to explain pathogenetic mechanism of this coexistence.

## P378

**Pregnancy in an acromegalic woman: a case report**

M. Ferreira, I. Palma, A. Caldas, J. Gonçalves, C. Pinto, J. Vilaverde & J. Dores
Centro Hospitalar do Porto, Porto, Portugal.

Introduction
Acromegaly is a rare disease caused by an increased secretion of GH, usually derived from a benign pituitary tumor. Women with acromegaly are usually infertile, because of tumoral hypersecretion, compression or surgical sequelae. We can prevent infertility with an adequate treatment. There are some reports describing pregnacies among acromegalic women. It is believed that there is an increased risk of devellopping diabetes mellitus and hypertension, especially when there is an active or uncontrolled acromegaly, and a symptomatic tumor size increase during pregnancy.
Case Report
Thirty five year-old woman, with acromegaly diagnosed when she was 24: IGF1 = 1305 ng/ml (*n*: 75–780); GH = 78 ng/ml (*n*: 0–18); prolactin = 38.8 ng/ml (*n*: 0–25). The sellar magnetic resonance imaging (MRI) showed an expansive rounded sellar lesion (20×20×20 mm), with supra-sellar expansion, optic chiasm stretch and left stalk deviation. She underwent transphenoidal adenomectomy on 20/09/2001 (9 months after diagnosis). The histology confirmed a GH producing adenoma. She wasn't cured by surgery (GH = 8.8 ng/ml (*n*: 0–8.6); IGF1 = 1355 ng/ml (*n*: 150–780)), so she started on medical treatment with octreotide-LAR (20 mg), once a month, on 25/01/2002, becoming assymptomatic. Seven and nine years after surgery, she had two term pregnancies, both delivered by elective caesarean, normossomic newborns, without malformations or neonatal complications. Octreotide was stopped once the pregnancy diagnosis was made. The patient had neither gestational diabetes nor hypertension. There was no sellar changes on MRI and no changes in visual fields. The levels of GH ranged between 1.47 and 8.68 ng/ml and the levels of IGF1 between 188 and 804 ng/ml throughout pregnancies.
Conclusion
As described in the literature, in this patient, acromegaly treatment kept the patient fertile, allowing two pregancies without complications, with normal neonates. Even with the use of octreotide-LAR until the knowledge of the pregnancy diagnosis, there weren't malformations in both neonates or other complications.
Declaration of interest

## P379

**Acromegaly, primary hyperparathyroidism and renal cell carcinoma**

C. Nogueira[1,2], E. Vinha[1], J. Mesquita[1,2], S. Belo[1,2], J. Capela[1,2], J. Pereira[1,2], H. Coutinho[1], L. Castro[1], C. Souto-Moura[1], A. Resende[1], I. Bernardes[1] & D. Carvalho[1,2]
[1]Centro Hospitalar São João, Porto, Portugal; [2]University of Porto, Porto, Portugal.

Introduction
Acromegaly is a rare disorder and sporadic cases are the most frequent. It can also occur in association with genetic syndromes, such as Carney complex, multiple endocrine neoplasia type 1 (MEN-1), MEN-1 like syndrome, isolated familial acromegaly and familial isolated pituitary adenomas.
Case report
Thirty five -year-old man was observed in 1994 for gynecomastia. Acromegaly was diagnosed based on clinical, biochemical (IGF1 1094.7 ng/ml, baseline GH 48.0 ng/ml) and imaging criteria. He was submitted to complete transsphenoidal resection of a macroadenoma in 7/6/1995 (staining for GH and prolactin) and reached surgical cure. In 2001 primary hyperparathyroidism was diagnosed and subtotal parathyroidectomy was performed. Biochemical and imaging screening of MEN-1 was negative, as well as the genetic test. Acromegaly biochemical recurrence was detected in 2003 but MRI showed no tumor mass. He was started on octreotide LAR (10 mg s.c. monthly) and IGF1 and GH levels normalized. Octreotide was stopped in 2008. In 2010 a kidney mass was detected and the cytology showed a papillary renal cell carcinoma. He underwent left nephrectomy in 8/9/2010. Currently, the patient maintains acromegaly cure criteria and no evidence of hyperparathyroidism or renal cell carcinoma recurrence.
Discussion
This is an unusual case of acromegaly associated with hyperparathyroidism and renal cell carcinoma. Although there is no family history of pituitary tumors and the search for MEN-1 mutation was negative we can't exclude a genetic syndrome. MEN-1 like syndrome remains a possibility but the search for the CDKN1B was not performed. Renal cell carcinoma was described in 0.5% of patients with acromegaly and its screening in these patients is not recommended. This case highlights the need for constant monitoring of acromegalic patients even when apparently cured. The search for GH and IGF1 receptor expression in neoplastic tissues of acromegalic patients could improve our understanding of cancer development mechanisms in these patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P380

**Late diagnosis of adrenal tuberculosis**

A. Bulgar, A. Brehar, D. Paun, D. Ioachim, L. Iconaru, I. Gherlan & C. Dumitrache
'C. I. Parhon' National Institute of Endocrinology, Bucharest, Romania.

Introduction
Tuberculosis is an insidious disease and may be diagnosed after it afected many organs.
Case presentation
We present the case of a 56 years old female, who followed antituberculosis treatment in 2003 for pulmonary tuberculosis and during the treatment developed acute renal failure and for this reason the treatment was stopped. During the evaluations a left kidney tumor was detected. Left nephrectomy was performed in 2003 (HP examination – angiomyolipoma), and left suprarenalectomy in 2003 for CSR non-secretive adenoma. In March 2007 she was diagnosed with a non-secretive adrenal tumor of 3/2/2.5 cm at the level of right adrenal gland. The patient was evaluated by PET with FDG imaging in August 2008, which raised suspicion of malignancy, and afterwards a transcutaneous biopsy was performed which showed areas of necrosis. In January 2010 the patient developed adrenal insufficiency. Because the adrenal tumor formation was in dimensional evolution, the PET examination and biopsy raised suspicion of malignancy and the patient developed adrenal insufficiency, surgery was decided. Intervention by laparoscopy was performed and an intensive process of left supra and inframezocolic perivisceritis was outlined. The adrenal gland with a volume enlarged to 10/8 cm presented an 8/2 cm tumor, hard, whitish, heterogeneous across the section, without invasion of adjacent structures. Histopatologic examination was suggestive for adrenal tuberculosis. Consequently, the previous histological pieces were reassessed and the conclusion was of tuberculosis with multiple determinations: adrenal (bilateral), peritoneal and retroperitoneal. Antituberculosis treatment was decided, the patient having a favorable evolution. Unfortunately, the diagnostis was performed after many years of tuberculosis evolution.
Conclusions
Tuberculosis remains a common cause of adrenal failure especially in patients who have not followed full treatment. Histopathological evaluation is very important for correct diagnosis in order to determine therapeutical aproach and the subsequent evolution and prognosis of these patients.

**Spontaneous remission of acromegaly due to pituitary apoplexy: case report**

A. Sucaliuc[1,2], D. Coles[1,3], L. Grigorascu[1,3], A. Caragheorgheopol[1], D. Hortopan[1] & D. Grigorie[1,2]
[1]National Institute of Endocrinology, Bucharest Romania, Bucharest, Romania; [2]University of Medicine and Pharmacy 'Carol Davila', Bucharest, Bucharest, Romania; [3]Medic Line Clinic, Bucharest, Romania.

Introduction
Pituitary apoplexy is a rare acute complication in patients with functioning pituitary adenomas (including acromegaly) often followed by hypopituitarism and occasionally may show remission of symptoms after an apoplectic episode. We report this in an acromegalic patient who developed remission following pituitary apoplexy.
Case report
A 24 years old woman is diagnosed with acromegaly after presenting for a period of 6 months moderate headache, subtle increase in her shoe size, mild soft tissue swelling, secondary amenorrhea, bilateral galactorrhea, no visual disturbances. Pituitary MRI revealed a macroadenoma with suprasellar extension. Laboratory tests sustain the diagnosis: nonsupressive GH level in glucose tolerance test (23.4 –19–18.1–15.7–13.9 ng/ml), high IGF1 929 ng/ml, hyperprolactinemia 126 ng/ml but no hypopituitarism. Within 2 weeks from the diagnosis, just before her schedule for surgery that was no longer performed, she presented an episode of severe headache not associated with other neurological signs, subsequently she noticed a reduction of swelling, with progressive remission of the headache and of galactorrhea, restoring of her menses and developed preprandial hypoglycemia (up to 33 mg/dl). Pituitary MRI 2 weeks after the acute episode, revealed reduction of the macroadenoma with peripheral hemorrhage areas. GH values in GTT were suppressed $<1$ ng/ml, IGF1 was low 87.11 ng/ml, normal prolactin, no gonadotrope, thyreotrope and corticotrope insufficiency; same results at 3 months reassessment.
Conclusion
We conclude the results as pituitary apoplexy in a patient with GH secreting pituitary macroadenoma subsequently only with somatotrope insufficiency (explaining the hypoglycemia too). Although apoplexy may occur with apparent precipitating factors, in our case, spontaneous apoplexy due to hemorrhage was diagnosed; no precipitating factors were determined.

**Oligosymptomatic paraganglioma in the setting of neurofibromatosis type 1**

R. Dobrescu, S. Jercalau & C. Badiu
National institute of Endocrinology, Bucharest, Romania.

Neurofibromatosis type 1 is an autosomal dominant genetic disorder that results from loss of function of the neurofibromin gene, leading to failure of a tumor suppressor mechanism. Usually characterized by 'café-au-lait' spots, cutaneous neurofibromas, and a predisposition for tumorigenesis occurring in childhood,

NF1 can have variable clinical expression, with 'mildly symptomatic' cases eluding diagnosis until adulthood.
A 53-year-old woman with mild clinical stigmata but no previous diagnosis of NF1, presented for endocrine assessment after the surgical excision of an oligosymptomatic pheochromocytoma. The voluminous (10.8 cm) cystic mass, located above the left kidney, was discovered incidentally on abdominal ultrasonography, confirmed by computed tomography and then surgically excised. The pathology report established pheochomocytoma, and serial imagining over the next year showed an expanding adrenal remnant (3.3–4.6 cm). At initial endocrine evaluation, the patient was hypertensive (150/90 mmHg) despite medication, but stable and without the 'adrenergic spells' of a pheochromocytoma. She presented with multiple 'café-au-lait' spots, freckling in the axillary and inframammary areas. Her daughter was diagnosed in childhood with NF type 1. Blood assays documented the normetanephrine hypersecretion (metanephrines = 14–44 pg/ml, normetanephrines = 436 pg/ml, chromogranin A = 40 ng/ml), which suggested a paraganglioma. Normal PTH and calcitonin levels excluded MEN type 2. After adequate alpha followed by beta blocade the patient undewent complete left adrenalectomy, with biochemical and morphological remission of the pheochromocytoma for 1.5 years post-operatively. She remained hypertensive but with more easily controlled BP levels (probably essential hypertension). As screening for the endocrine features of NF1, she was tested for carcinoid tumors and hypothalamic-pituitary dysfunction but had normal serotonin levels and pituitary function.
Atypical in the context of a disorder involving predominantly the skin, skeleton and nervous system, and unusual in an undiagnosed adult patient, our case illustrates the rare, clinically mild, but possibly severe endocrine complications of NF1.

**Histiocytosis X-manifested with insipid diabetes clinical case**

M. Petrova, K. Hristozov & P. Bochev
[1]Medical University, Varna, Bulgaria.

Histiocytosis is a group of syndromes /synonyms: eosinophilicgranulomatosis, pulmonary Langerhans cell histiocytosis, fibrous lung disease, disease of smokers, non-lipid reticuloendotheliosis; disease of Hand–Schuller–Christian; disease of Letterer–Siwe/. It is a rare disease and its real frequency is unknown. In a reference center in the U.S. the disease is found in 5% in patients with lung biopsy carried out in connection with the diagnosis of interstitial lung disease.
In adults inflammation leads to a loss of elasticity (fibrosis) and destruction of the walls of pulmonary alveoli. In some patients spontaneous improvement (remissions) can be observed, while others progress to an end-stage fibrotic lung disease.
A woman, 32, was born prematurely with a congenital atresia of the esophagus, with operational adjustment and plastic of the esophagus at an early age. Her development was according to the age. From the summer of 2009 complaints of polydipsia and polyuriaappeared – up to 7 l/day, headaches and dizziness, impaired memory, amenorrhea. MRI showed a tumor in chiasmaopticum and pressing on the third ventricle. Operation was madeon 05.02.2010 – right-sided craniotomy and partial extirpation of the tumor. Histological result-Langerhans histiocytic tumor cell / tests: plasma cortisol −54.6 in the morning at 0800 and 2200 h in the evening, 75.9 (normal 70–240 IU/l; prolactin −54 IU/l; LH −0.048 IU/l; FSH −0.06 IU/l). Concentration of sample Zimnitski-diuresis with relative weight -1000.
In the course of treatment there was a sequential adjustment of hipocorticismand hypothyroidism, electrolyte abnormalities. PET/CT did not reveal any dissemination process.
We present a clinical case of isolated hypothalamic–pituitary disease a form of insipid diabetes, panhypopituitarism, foudroyant stroke and death.

**A case history as example for diagnostics and treatment of acromegaly: started and ended with pregnancy**

S. Magony[1], Z. Valkusz[1], Csajbók[1], K. Sepp[1], J. Gardi[1], M. Szécsi[1], I. Kiss[2], T. Wittmann[1] & J. Julesz[1]
[1]Faculty of Medicine, Albert Szent-Györgyi Clinical Center, University of Szeged, Szeged, Hungary; [2]University of Szeged, Szeged, Hungary.

The history of a female patient is demonstrated as an example of diagnostic and therapeutical pitfalls in acromegaly. The patient was first operated on a pituitary macroadenoma at her age of 21. Prior to surgery, serum prolactin was found moderately elevated and the patient was raromenorrhoic, without galactorrhea. Soon recurrence of the tumour was trialed with bromocriptine medication, however, without any inhibitory effect on the process. The patient underwent a second neurosurgery at the age of 26. Serum prolactin was found normal without bromocriptine thereafter. Her primary sterility was treated with FSH and hCG injections resulting in a healthy trigeminal pregancy. After these preceding events, she first visited the present authors with amenorrhea and unequivocal signs of acromegaly. Diurnal variation of serum hGH and OGTT proved a GH-excess. Chronic administration of somatostatin octreotid LAR was ineffective. A third surgical intervention was performed on the re-recurred macroadenoma at the age of 30. Hormonal supression with lanreotide was not successful either. Further growing of the tumoral remnant was tried to be influenced by gamma knife at the age of 34 followed by pegvisomant administration in order to blunt the clinical effect of the still existing GH excess and in the hope of a GH-decrease as aimed consequence of the latter irradiation therapy. One year after irradiaton and pegvisomant administration, the IGF1 level was in the normal range, and the tumour remnant showed some regression. While continuing the pegvisomant treatment and after more then a decade amenorrhea, the patient conceived. Then, we stopped the pegvisomant administration; during pregnancy no tumour growing was detected with MRI, and the patient gave birth to a healthy boy. An update therapeutical regime may involve neurosurgery, dopamin agonists, somatostatin analogs, irradiation and GH-receptor antagonist alike; an individualized therapy may be sometimes be astonishingly complex.
Declaration of interest

**Adrenal neurilemoma**

M. Ivovic, V. Zivaljevic, L. Marina, M. Tancic Gajic, Z. Arizanovic, S. Vujovic & D. Micic
Clinic for Endocrinology, Clinical Center Serbia, Belgrade, Serbia.

Introduction
Adrenal neurilemoma (or schwannoma) are vary rare tumors. They usually present as incidental finding in asymptomatic patients, which makes them dificult to diagnose preoperatively.
Case report
We present a 60 year old woman with incidentally discovered adrenal mass of 5 cm on the right side. The tumor was detected by ultrasound and then it was confirmed by MSCT scan. We performed careful endocrine workup. Results showed normal levels of urinary catecholamines that excluded active pheochromocytoma. Midnight cortisol level was in the normal reference range with adequate suppression of cortisol in 1 mg overnight dexamethason suppression test and normal basal level of ACTH. Aldosteron was also in the normal reference range with normal aldosteron to PRA ratio. According to findings of MSCT scan, vena cava and diaphragm were infiltrated by tumor. Surgery was performed. Intraoperative findings showed adrenal tumor of about 6 cm in size. There was no evidence of the abdominal lymphadenopathy or vascular involvement. Tumor was completely and successfully removed with adrenalectomy. Pathohistology and immunohystochemistry of the tumor showed neurilemoma with perineural differentiation (diffusely positive on Vimentine, S100, Ki-67, and focally positive for EMA perineurium). Our patient is in good health recovering from surgery.
Conclusion
Although schwannomas are rare and usually benign, as it was in the case of our patient, malignant potency of these tumors raises complex questions regarding further follow up.

Declaration of interest

## P386

**A case of autoimmune polyglandular syndrome type II presenting with adrenal crisis**

N. Vallianou, P. Gounari, A. Skourtis, M. Kougias, T. Gounaris & E. Sioula
Evaggelismos General Hospital, Athens, Greece.

Introduction
Autoimmune polyglandular syndrome type II is defined by the occurrence of Addison's disease with thyroid autoimmune disease and/or type I diabetes mellitus.
Case presentation
A seventy-four-years old woman came to the hospital due to fatigue, nausea, vomiting and skin hyperpigmentation that had begun two months ago. On clinical examination, the patient had hyperpigmentation throughout the skin, large dark brown areas on the lips and the buccal mucosa and her blood pressure was 90/60 mm Hg. She had recently been diagnosed with hypothyroidism and had been receiving levothyroxine for two days before admission to the hospital. Her past medical history was otherwise unremarkable.
Laboratory tests revealed hyponatremia (serum sodium: 130 mEq/l), hyperkalemia (serum potassium: 5.56 mEq/l and anemia (hemoglobin: 11.8 g/dl).
Morning blood cortisol level was $<0.2$ μg/dl and ACTH levels were 1248.0 pg/ml. Addison's disease was confirmed and antibodies directed against 21-hydroxylase (OH) were positive, a finding suggestive of autoimmune adrenalitis. TSH levels were 6.62 μU/l, $T_3$: 204.5 ng/dl, $FT_4$: 1.02 ng/dl, anti-TPO: 314.6 IU/ml, anti-Tg: 613.6 IU/ml.
Autoimmune adrenalitis together with autoimmune thyroid disease was diagnosed, a combination known as autoimmune polyglandular syndrome type II or Schmidt's syndrome. It seems likely that the prescription of levothyroxine prior to adrenal steroid hormone replacement in this patient with concurrent Addison's disease precipitated an adrenal crisis.
Conclusions
In hypothyroid patients, careful history taking, thorough clinical examination and laboratory tests should be performed to exclude concurrent Addison's disease before the initiation of levothyroxine replacement as prescription of levothyroxine prior to adrenal steroid hormone replacement may be hazardous.

## P387

**Elephantiasis nostras verrucosa as a presenting cause of Cushings' disease**

S. Zuhur, N. Demir, S. Velet, I. Kuzu, F Yener Öztürk & Y. Altuntas
Sisli Etfal Training and Research Hospital, Istanbul, Turkey.

Introduction
Elephantiasis nostras verrucosa (ENV) is a rare, chronic, deforming disorder characterized by hyperkeratosis and papillomatosis of the epidermis with underlying woody fibrosis of the dermis and subcutaneous tissue resulting from chronic nonfilarial lymphoedema. Lymphatic obstruction can be primary or due to various causes such as surgery, tumour, radiation, congestive heart failure or obesity. However, to the best of our knowledge, it has not been reported as a presenting sign of Cushing's disease.
Case
A 28 years old male patient presented with obesity and left lower extremity enlargement and deformity which was present since 6 years. Physical findings revealed central obesity, purple stria on abdomen, buffalo hump and moon face. Non-pitting edema with lichenification, hyperkeratotic papules, nodules, and verrucous cobblestone-like plaques was found on left lower extremity. Histopathological examination of the tissue obtained by biopsy revealed dense dermal fibrosis, edema of the papillary dermis and extensive pseudo-epitheliomatous changes consistent with ENV. His laboratory findings demonstrated ACTH: 60 pg/ml (0–46 pg/ml), baseline cortisol level 26.8 μg/dl (6.2–19 μg/dl), midnight cortisol level: 17.17 μg/dl, urine cortisol level: 530 μg/24 h. Serum cortisol levels failed to supress after low dose dexamethasone supression test (DST) and supressed after high dose DST (1 mg: 9 μg/dl, 8 mg: 4.2 μg/dl respectively). A combined CRH-DST was consistent with Cushing's disease (3.6 μg/dl). His pituitary MRI was normal. Inferior Petrosal sinus sampling was consistent with Cushing's disease resulting from the left side of the pituitary gland. The patient refused trans-sphenoidal surgery.
Conclusion
ENV is a very rare disease. This case demonstrates that ENV may also developes secondary to Cushing's disease. Therefore, patients with ENV should also be searched for Cushing's disease.

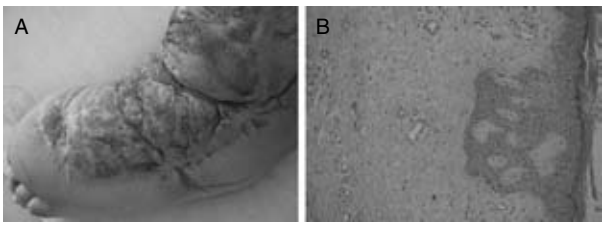

**Figure 1** (A) ENV on the left lower extremity of the patient. (B) H&E stained tissue section demonstrates dense dermal fibrosis, edema of the papillary dermis and extensive pseudo-epitheliomatous changes consistent with ENV.

## P388

**Syndrome of inappropriate secretion of antidiuretic hormone in a elderly women affected with herpes zoster infection: a case report**

M. Filippella[1], C. Musso[1], D. Verani[1], L. Pecorelli[1,2] & A. Faggiano[1,3]
[1]Clinical Institute, Aosta, Italy; [2]Hospital, Aosta, Italy; [3]University, Naples, Italy.

Introduction
SIADH is a disorder of sodium and water balance characterized by hypotonic hyponatremia and impaired urinary dilution in the absence of renal disease or any identifiable non-osmotic stimulus known to relase ADH. SIADH is usually observed in hospitalized patients and its prevalence may be as high as 35%.
Case Report
A 70 year old women was admitted to the Medicine and Rehabilitation Clinical Institute of Aosta on October 2011. She had a change of mental status. Physical examination was normal. There was a vesicular erythematous rash at the chest level, which was consistent with a diagnosis of HZI. The patient was disoriented and confused. Laboratory results showed blood count in the normal range, serum concentration of sodium was 119 mEq/l, potassium 4 mEq/l, creatinine 0.8 mg/ml. Urine sodium was 45 mEq/l and potassium 50 mEq/l. Urine was highly concentrated with an osmolality of 620 mOsm/kg $H_2O$, while plasma osmolality was 243 mOsm/kg $H_2O$. Thyroid and adrenal function was normal. Plasma antidiuretic hormone (ADH) was 3.8 pg/ml (normal range 0.3–3.5 pg/ml). Given these results, a diagnosis of SIADH was made. Under water restriction, infusion of 3% saline, treatment with loop diuretics and with complete acyclovir therapy, mental function returned to normal within 2 day. Seven day later, serum sodium concentration was increased to 136 mEq/l with plasma osmolality of 275 mOsm/kg.
Conclusion
We postulate that although the association between HZI and SIADH has been rarely reported in the literature, this is likely to be an under representation of its true incidence.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P389

**Hyponatremia and cytolysis as first signs of decompensated pituitary insufficiency: case report**

I. Potorac, C. Preda, D. Cimpoesu, R. Stanciu, J. Idriceanu, I. Vasiliu, L. Leustean, M. Ungureanu, V. Mogos & C. Vulpoi
University of Medicine and Pharmacy 'Gr. T. Popa', Iasi, Romania.

Introduction
Pituitary insufficiency of the adult is a rare pathology (~30–40/1 000 000 per year). Among the acquired causes, Sheehan syndrome (SS) is often characterized by an insidious evolution, which allows it to pass unnoticed for a long time.
Case report
R Maria, 58 years-old, known with SS for 10 years, was hospitalized in the ER with severe asthenia, obnubilation, symptomatic arterial hypotension. Laboratory studies revealed severe hyponatremia (115 mmol/l) and important cytolysis (CK = 21 520 U/l, CKMB = 326 U/l, LDH = 731 U/l) with normal ECG. A myocardial or skeletal muscle etiology was excluded. After successful intensive care she was transferred to Endocrinology. Anamnesis revealed cessation of corticotherapy and intermittent thyroid substitution. Physical examination showed bradylalia, generalized myalgia, pale, infiltrated, depigmented, depilated skin. Biology confirmed pituitary insufficiency: low $FT_4$ = 3.72 pmol/l, paradoxically normal TSH = 2.15 mUI/ml, low ACTH = 15.5 pg/ml, low LH = 0.4 mUI/ml despite the menopausal status. Under substitution therapy (glucocorticoides and L-thyroxin) and hydroelectrolytic equilibration, patient's general status improved progressively, as well as the biological parameters (Na = 137 mmol/l, $FT_4$ = 8.17 pmol/l, CK = 129 U/l, CKMB = 10 U/l, LDH = 370 U/l).
Conclusions
Due to the rarity of both the SS and its therapeutic non-compliance, few studies have evaluated its evolution. High enzymes are found in 1/3 of the cases of hypothyroidism, but the values are rarely significant. Due to normal TSH (as in our case), secondary hypothyroidism can be ignored in the differential diagnosis. Our case is particular because of the severe hypothyroidism manifestations, despite the coexistence of the pituitary corticotrope insufficiency.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Acromegaly and pregnancy: two acromegalic patients treated with somatostatin analogues**

T. Sabino, F. Fonseca & A. Agapito
Curry Cabral Hospital, Lisbon, Portugal.

Pregnancy in acromegalic patients is an infrequent event, but with earlier diagnosis and advanced surgical/medical management, more affected women get pregnant.
The use of Somatostatin analogues (SSA) during pregnancy seems safe, but there are few reported pregnancies under this treatment.
We report two acromegalic patients treated with SSA that became pregnant.
Case 1
Thirty-three year old woman diagnosed with acromegaly at the age of 31 (March 2008: IGF1: 901 ng/ml; Pituitary MR: intrasellar macroadenoma). She underwent two selective adenomectomies by transphenoidal route (April 2008; March 2009), without cure. Lanreotide, 120 mg – 6/6 weeks was prescribed since June 2008. At appointment (7/10/09) she referred a 12 weeks pregnancy and last Lanreotide injection at 19/8/09. SSA was discontinued. Pregnancy was uneventful and a full-term boy was born, with a normal postnatal development.
Case 2
The patient developed secondary amenorrhea and progressive enlargement of her hands/feet since age 24, 2 years after a normal pregnancy. In 2007, (33-year-old), acromegaly was diagnosed (invasive macroadenoma) that persisted after transphenoidal and transfrontal adenomectomy, (IGF1:912 ng/ml). In June 2008 after stereotaxic radiotherapy she began octreotide 30 mg 4/4 weeks. After 14 months (IGF1: 512 ng/ml) on evaluation for leucorrhea, a pelvic ultrasound revealed a 6 weeks pregnancy. She chooses to abort.
Conclusions
Case 1: although the embryo had been exposed to Lanreotide during the first trimester, pregnancy, fetal and postnatal development were uneventful. Despite reassuring reports in literature, it seems safest to discontinue SSA before or as soon as pregnancy is detected.
Case 2: pregnancy occurred despite prolonged amenorrhea. Women in fertile age should receive adequate contraception if treated with SSA, as it may improve fertility.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P391

**Particular course of a case of acromegaly associated with Waldenström's macroglobulinaemia**

Z. Szanto, I. Kun & E. Benedek
University of Medicine and Pharmacy, Targu Mures, Romania.

Introduction
Acromegaly and Waldenstrom's macroglobulinaemia are two rare diseases (about 3–4 and 10 cases/million per year respectively), the association between them is even more infrequent, one case being reported in the available literature.
Case report
We present the case of a 74-years-old female (I.I.) suffering with both diseases. In 1997 acromegaly diagnosed by dysmorphic syndrome, than in 2004 hormonal/imagistical investigations (GH at baseline: 2.5 ng/ml, suppressed GH with OGTT: 2.3–2.9–11.6–7.5 ng/ml; 12/15 mm pituitary adenoma on MRI) confirmed the diagnosis. She refused any therapeutical approaches. Cardiovascular diseases (hypertension, left ventricular hypertrophy, major left bundle branch block, left ventricle failure NYHA III) and osteoarticular involvement (osteoporosis with right hip fracture and multiple vertebral fractures) have slowly progressed in time. In 2008 Waldenström's disease was diagnosed and chemotherapy was administered (cyclophosphamide, vincristine, corticosteroids), the outcome being favourable. Affirmatively the dysmorphic syndrome has not aggravated during the last 7 years, but in May 2011 a sudden severe aggravation of the general status, weight loss, tongue-mandibular hypertrophy, malocclusion, swallowing and respiratory disturbances developed within 6 weeks. Surprisingly, hormonal results (GH at baseline: 3.3 ng/ml, GH after OGTT: 1.58–1.58–1.76–1.24 ng/ml; PRL: 72.3 ng/ml), IGF1: 114 ng/ml (101–267) and pituitary CT (11 mm adenoma) did not showed the reactivation of acromegaly. In August–September 2011 a severe gastroparesis, malabsorption syndrome and cachexia developed.
Conclusion
We present a particular course of acromegaly: a very slow progression without any specific treatment, than a rapid aggravation of facial dysmorphic signs. The favourable laboratory/imagistic evolution of acromegaly, confirmed by the involution of adenoma on CT, the slightly elevated GH and normal IGF1, may be attributed to a partial apoplexy in the adenoma or eventually to the medications used for the haematological disease. The discordance between evolutive clinical signs and non-evolutive laboratory/imagistic results needs supplementary investigations (directed towards a local viscerocranial/buccal process).
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P392

**A case of acromegaly with nephrogenic adenoma of the bladder: a rare association?**

G. Kocabas, IYildirim Simsir, M. Erdogan, S. Cetinkalp, A. Ozgen, C. Yilmaz & F. Saygili
Ege University School of Medicine, Izmir, Turkey.

A 60-year-old woman with a previous history of twice transsphenoidal pituitary surgery due to acromegaly,had a surgery with a presumed diagnosis of bladder stone. She was reevaluated after the surgery when her hematuria persisted. Percutaneous nephrolitotomy was planned. when multiple stones were identified in the left ureter, but the operation had to be postponed till the achievement of glycemic control. At the meantime endocrinological evaluation revealed a 30×15 mm macroadenoma in the pituitary invading both cavernose sinuses.

Her random GH level was >40 ng/ml and IGF1:1225 ng/ml (age and sex adjusted reference range 71–263 ng/ml).
Octreotid LAR 30 mg/4 weeks was started and conventional radiotherapy was performed. When glycemic contol was maintained she underwent cystoscopy. A mass lesion was identified and resected. The pathology of the specimen revealed nephrogenic adenoma of the urinary bladder. Immunohistochemically lesion was cytoceratin 7 positive, CD 10, *P*63 and TTF-1 negative.
Nephrogenic adenoma, also referred to as nephrogenic metaplasia, is an uncommon benign lesion of the urothelial tract.It is a benign metaplastic response of the urothelium to injury or insult. It is most commonly seen in bladder (80%) however urethra (12%) or ureter (8%) can be involved. Nephrogenic adenoma can be a significant diagnostic pitfall as certain histologic features, such as the presence of enlarged nuclei with prominent nucleoli, degenerative nuclear atypia, tiny tubules with blue mucin simulating signet ring cells, and focal invasion into superficial muscle, when taken out of context, can mimic malignancy.
Up to date there is no reported case of acromegaly with nephrogenic adenoma of the bladder. Considering the increased neoplasia risk in acromegaly, more data are needed to explain if there is a causal relationship between acromegaly and nephrogenic adenoma, or if this is a coincidental finding.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P393

**Recovery of prolactin function following spontaneous pregnancy in a patient with Sheehan's syndrome**

B. Laway & S. Mir
Sher-I-Kashmir Institute of Medical Sciences, Srinagar, India.

Introduction
Sheehan's syndrome presents with hypopituitarism of variable severity after parturition usually preceded by *post partum* hemorrhage. Recovery of lactotroph function after initial insult has not been reported in the literature.
Case report
A 41-year woman delivered her 1st child in 1994 at the age of 25 years, complicated by profuse vaginal bleeding and received two blood transfusions at a city hospital. She had lactation failure and did not resume menstrual cycles after. She was investigated in 1996, revealing central hypothyroidism, GH, prolactin and cortisol deficiency on insulin tolerance test. She was put on prednisolone 7.5 mg/day, thyroxine 0.75 mg/day and cyclic estrogen/progesterone. She came to the hospital with pregnancy of 12 weeks duration and delivered in Dec 2003. After the present delivery, she lactated normally. She resumed infrequent cycles after the lactation amenorrhea. In 2007 incidentally she was again found to have pregnancy of 20 weeks on a routine ultrasound, she delivered after a cesarean section and again lactated normally. Metochlopramide test revealed normal stimulable prolactin. MRI pituitary revealed empty sella.
Conclusion
Recovery of lactotroph function after initial failure has not been reported in patients with Sheehan's syndrome. We presume that recovery of lactotroph function after the second pregnancy in this patient is possibly because of stimulatory effect of estrogen and progesterone on residual lactotroph cells.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Table 1** Hormonal parameters before and after lactotroph recovery

| Before 2nd pregnancy | | | After 2nd pregnancy | | |
|---|---|---|---|---|---|
| Hormone | Basal | Peak | Basal | Peak | Normal value |
| $T_4$ (μg/dl) | 3.43 | – | 6.5[a] | – | 5.5–13.5 |
| TSH (U/l) | 0.83 | | 0.85 | – | 0.5–6.5 |

**Giant macroprolactinoma: recidive after 12 years (case report)**

A. Loghin, A. Florescu, I. Grozavu, D. Haba, L. Apostu & C. Galesanu
University of Medicine and Pharmacy 'Gr.T.Popa', Iasi, Romania.

Introduction
Prolactinomas are rare in childhood and adolescence, representing a half of pituitary adenomas (1% of intracranial tumors); macroadenomas are more frequent than microadenomas. The signs and symptoms depend on age, sex, tumor size and prolactin level. Due to a higher frequency of macroadenomas in boys, they present more often neuro-ophthalmologic findings (impaired vision, headache)
Case report
We present a case of 25-year-old pacient diagnosed at age 13 with giant prolactinoma. He came to our observation after neurosurgery was performed for symptoms of tumor expansion. No pituitary insufficiency was observed after surgery. Dopamine-agonist therapy was required postoperatively due to persistent hyperprolactinemia (PRL>250 ng/ml *n* 0.7–17 ng/ml). The pacient developed normal puberty, reaching a final high=172 cm. After 7 years of prolactin level control and no IRM signs of recidive under medical therapy, we lost follow-up. At current evaluation (nov. 2011) PRL level was very high=3575 μIU/ml (*n*86–324 μIU/ml); clinical and biological signs of pituitary insufficiency were absent. Visual field was normal. Pituitary X-ray revealed a raised intrasellar volume, undefined sellar walls and a deeply declined sellar floor in the sphenoidal sinus. IRM described a 2/1.3/2.5 cm tumor residue with extension in the right cavernous sinus. Cabergoline therapy was reinitiated.
Discussions
Surgery is reserved for pacients resistant to medical therapy and those with severe neurological symptoms at diagnosis. First-line treatment is represented by dopamine-agonists.
Conclusions
The pacient had severe symptoms at diagnosis. Neurosurgery was performed before endocrinological evaluation and was not curative. Dopamine-agonists were needed postoperatively. After 7 years of good evolution we lost follow-up. The absence of symptoms at current evaluation raised the suspicion of macroprolactinemia. Dopamine-agonist therapy was reinitiated and might be necessary life-long.

**An uncommon cause of hypoglycaemia: a case report**
H. Tan[1], M. Butt[2] & N. Waheed[1]
[1]Hereford County Hospital, Hereford, UK; [2]Royal Infirmary, Huddersfield, UK.

Introduction
Hypoglycaemia in a non-diabetic patient is not a common condition and is often a diagnostic challenge.
Case report
A 78-year-old gentleman was admitted to hospital by paramedics when his neighbours found him unresponsive. He had a background history of primary hypothyroidism. Capillary blood glucose reading done on site was 1.0 mmol/l. He received intravenous glucose which resulted in prompt recovery. All other vital signs were normal.
Clinical examination was unremarkable. He had normal blood count, inflammatory markers, renal and liver function tests. He had an inadequate response to synacthen with basal serum cortisol of 137 nmol/l and peak serum cortisol of 381 nmol/l at 60 min. Serum ACTH level is still pending but we expect it to be suppressed, consistent with secondary hypocortisolism. There was evidence of secondary hypogonadism with low testosterone level at 3.2 nmol/l (NR 7–26 nmol/l) and inappropriately normal gonadotrophins (FSH 9.3 U/l (NR 2–17 U/l), LH 9.2 U/l (NR 1–7)). Rest of the basal anterior pituitary profile included a low IGF1 of $<$3.3 nmol/l (NR 7.7 to 24.6 nmol/l), TSH 0.33mu/l (NR 0.25–5mu/l), free $T_4$ 19.1 pmol/l (NR 12–25 pmol/l) and prolactin 144 mu/l. An MRI scan of the pituitary gland was consistent with an empty sella. Patient was treated with intravenous hydrocortisone and is now maintained on oral hydrocortisone. We shall review him in the clinic to discuss testosterone supplementation and assess his GH axis given his low IGF1 levels.
Conclusion
Empty sella is usually an incidental finding on an MRI scan. Approximately one third of these patients present with endocrinopathies and neurological symptoms. Our patient presented with a significant hypoglycaemic episode which is a recognized though a rare presentation of empty sella syndrome and this case serves as a reminder of this rare cause of hypoglycaemia in a non-diabetic patient.

## P396

**Central diabetes insipidus: about two clinical cases**
C. Nogueira[1,3], M. Matos[1,3], C. Esteves[1,3], G. Jorge[1], J. Couto[2], C. Neves[1,3], J. Queirós[1], E. Vinha[1], I. Bernardes[1] & D. Carvalho[1,3]
[1]Centro Hospitalar São João, Porto, Portugal; [2]Instituto Português de Oncologia, Porto, Portugal; [3]University of Porto, Porto, Portugal.

Introduction
Central diabetes insipidus (CDI) is produced by the destruction of the magnocellular neurons of the hypothalamic supraoptic and paraventricular nuclei which results in decreased arginine vasopressin (AVP) synthesis and secretion.
Case report 1
Forty-five year old female, previously healthy, was observed in April 2011 complaining of polydipsia, polyuria, nocturia and weight loss since January. Diabetes mellitus (DM) was excluded and she was admitted for study of possible diabetes insipidus. Water deprivation test was suggestive of CDI. Magnetic resonance imaging (MRI) showed infundibular hypophysitis and no hyperintense signal in the neurohypophysis. Autoimmune diseases, infections and infiltrative diseases were excluded. Imaging (chest x-ray, abdominal ultrasound, mammography, breast ultrasound and thoracoabdominal CT) was normal. No other pituitary deficits were shown. She started therapy with oral desmopressin with clinical improvement.
Case report 2
Fourty-three year old man, previously healthy, was seen in August 2011 complaining of polydipsia, polyuria and nocturia during the previous 3 months. DM was excluded. Water deprivation test was positive for CDI. Pituitary MRI was normal, with normal signal of high intensity in the neutohypophysis. He had no other hormonal deficits. Autoimmune and infectous diseases were excluded. After initiation of oral desmopressin the symptoms disappeared.
Discussion
In both cases it was not determined the etiology of CDI, as it may occur in 20–50% of CDI cases. In our institution is not possible to determine antibodies towards vasopressin secretory cells, which does not allow the diagnosis of this autoimmune form of CDI. The infundibular hypophysitis, observed in the first case, can occur in about 50% of idiopathic cases and more frequently in women. The lymphocytic hypophysitis can be diagnosed by pituitary biopsy, but it's a very aggressive procedure and almost never performed. These cases highlight the difficulty of the etiologic diagnosis of CDI. However, proper treatment allows the symptoms control.

## P397

**Macroprolactinomas: therapy compliance (case report)**
A. Florescu, A. Loghin, I. Grozavu, D. Haba, L. Apostu & C. Galesanu
Universitty of Medicine and Pharmacy Gr T Popa, Iasi, Romania.

Prolactinomas represent 60% of primary pituitary tumors, galactorrrhoea and menstrual disturbances beeing the most frequent clinical features in women. The mass effect of macroadenomas is expressed by headache, visual field defects and hypopituitarism. The aims of therapy are reduction of tumour size, prevention of tumour expansion and restoration of gonadal function. Dopamine agonists normalize prolactin secretion and reduce tumour size in 40% of patients with macroadenoma.
We are presenting a case of an 49 year old female, who came to us first in 1995, presenting headache, galactorrrhoea and secondary amenorrhea. Her prolactine level was very high with the rest of the pituitary hormones in normal range. We performed an MRI, which showed the presence of a macroadenoma. After the patient refuses surgery, we started dopamine agonists therapy, with reevaluation every 6 months, until 2004, when the patient discontinues therapy (at that moment the prolactin levels were still high, and the adenoma offered signs of protrusion in the sphenoidal sinus). The patient came to us in november 2011 with a prolactine level of 7742 μUI/ml (102–496) and a MRI image of empty sella and a tumoral mass which evolves in the sphenoidal sinus. Again, the patient refuses surgery, so we started once more dopamine agonists therapy.
Discussions
In routine practice, hyperprolactinaemia recurs early in most macroprolactinomas (93%) and microprolactinomas (64%) following dopamine agonists discontinuation. For most macroprolactinomas, cesssation of dopamine agonists cannot be recommended even after 7 years of therapy.
Conclusions
The patient refused surgery, although it was an early diagnosis and all the treatment options were discussed. Dopamine agonists therapy was initiated and after 9 years of intermitent therapy she stopped the treatment and we had no contact afterwards. For this type of patients in particulary, the 1 year followup is very important.

## P398

**Endocrine hypertension due to primary aldosteronism**

P. Rodrigues[1,2], J. Mesquita[1,2], S. Souto[1,2], S. Belo[1,2], P. Morgado[1], A. Varela[1,2], J. Castedo[1], Magalhães[1,2] & D. Carvalho[1,2]
[1]Centro Hospitalar de São João EPE, Porto, Portugal; [2]University of Porto, Porto, Portugal.

Introduction
Primary aldosteronism (PA) is currently believed to be the most frequent form of secondary endocrine hypertension, accounting for 5–10% of all hypertensive patients. After confirming the diagnosis, adrenal venous sampling (AVS) is considered the most accurate means of distinguishing between unilateral and bilateral adrenal disease.
Case report
Female patient, 36 years-old, referred to an Endocrinology appointment in May 2009 due to left adrenal nodule and hypertension refractory to treatment. Hypertension diagnosed at age 24 with progressive drug resistance since February 2009. Left adrenal nodule known since 2004 showing an increase from 15 to 20 mm in 5 years. Family history of hypertension. On physical examination was noteworthy a blood pressure value of 210/110 mmHg. Laboratory assays showed hypokalemia (2.3 mEq/l; *n*: 3.5–5.1), increased aldosterone (ng/dl)/direct renin (μU/ml) ratio (12.6; *n*: 2.4–4.9) and negative screening for other secondary causes of hypertension. Oral potassium supplements were prescribed although with potassium levels difficult to control. Diagnosis of PA was confirmed by saline infusion test (post-infusion plasma aldosterone 62.9 ng/dl) and captopril challenge test (plasma aldosterone remained elevated and direct renin suppressed). AVS was performed but results were inconclusive. Abdominal MRI performed in July 2010 showed a 31 mm nodule in the left adrenal. Spironolactone 100 mg/day was initiated in July 2011 due to symptomatic hypokalemia. A left adrenalectomy was performed in September 2011 and spironolactone and potassium supplements were suspended in the postoperative period. Histological examination showed an adrenal adenoma. In October 2011 she presented blood pressure values of 136/83 mmHg (only medicated with verapamil) and normokalemia (4.3 mEq/l).
Conclusions
Early recognition and treatment of PA is important to overcome the high cardiovascular morbidity and mortality rates associated with this condition. PA case detection is recommended in patient groups with relatively high prevalence of the disease, such as in the clinical case described.

**Unusual association between pheochromocytoma, adrenocortical nodular hyperplasia and empty sella: case report**

C. Preda, A. Grigorovici, D. Ciobanu, L. Moisii, C. Vulpoi, M. Ungureanu, L. Leustean & V. Mogos
University of Medecine and Pharmacy 'Gr. T. Popa', iasi, Romania.

Introduction
Pheochromocytoma occasionally associates with pathological lesions of the adrenal cortex. We report a case of non-functional adrenocortical nodular hyperplasia with a concomitant pheochromocytoma in the controlateral adrenal and empty sella.
Case report
We describe the case of a 52 year old women with a history of essential hypertension and type 2 diabetes mellitus. She complained of: nausea, abdominal pain, vomiting and constipation. The computed tomography revealed a 5.3 cm left adrenal highly vascular tumor with multiple necrosis areas and a 3.5 cm well-encapsulated right adrenal mass. ACTH and plasma cortisol (after 1 mg dexametasone overnight test) levels were normal but the levels of urinary metanefrines were high. The patient was put on preoperative α-adrenoreceptor blockade and after 4 days due to important abdominal pain and lack of transit the surgery was performed and both adrenal glands were removed. Histopathological examination disclosed typical pheochromocytoma on the left side and nodular hyperplasia of the fasciculata on the right side. One month after surgery a full evaluation was made in order to exclude a multiple endocrine neoplasia: PTH and calcitonine levels were normal and the pituitary MRI revealed empty sella.
Conclusions
The present report is a rare case of pheochromocytoma with nodular hyperplasia of the fasciculata in the controlateral adrenal and empty sella. Also the diagnosis circumstances were unusual due to the clinical picture of acute abdomen and lack of endocrine manifestation of both adrenal masses.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

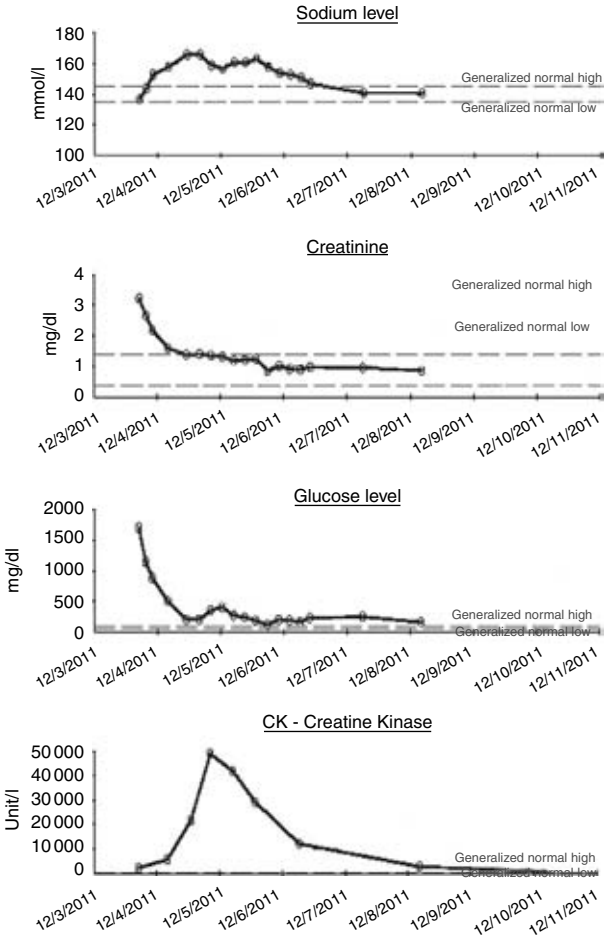
**New diabetic emergency; acute rhabdomyolysis complicating hyperglycemic hyperosmolar coma successful management and insight into pathogenesis**

C. Vaz & A. Chaudhuri
[1]State University of New York, Buffalo, New York, USA.

We describe a case of severe rhabdomyolysis(peak CK 48897 μ/ml and massive myoglobinuria) complicating hyperglycemic hyperosmolar coma. A 57y/o M with DM2 on metformin presented with polyuria, polydipsia, weakness and confusion. On admission he had GCS E2M3V1 no signs of trauma or infection. Na 137 mEq/l K 4.8 mEq/l $HCO_3$ 22 mEq/l Cl 93 mEq/l BUN 116 mg/dl Cr 3.2 mg/dl glucose 1710 mg/dl pH 7.22 ketones +small, Mg 5.2 mg/dl P 3.3 mg/dl Ca 9.6 mg/dl TSH 1.47 μU/ml Ethanol <5 mg/dl, toxicology screen negative, osmolality 364 mOsm/kg. Initial Troponin 0.03 ng/ml, peak 0.12 ng/ml 28 h later. Initial CK 2379 μ/l, 21767 μ/l at 24 h, peak 48 897 μ/l 28 h later. CK isoenzyme 100%MM. Urine myoglobin >10 000 ng/ml (nl<1). As he was



on flexeril, serum and urine cyclobenzaprine level were checked and were negative. He received aggressive i.v. hydration with NS and Bicarb drip along with insulin drip. Blood glucose control was achieved over 48 h. Cr normalized in 28 h. Na peaked to 166 mg/dl and corrected over 3 days. P and K levels remained nl. CK trended down to 881 μ/l on day 7. Mental status was at baseline by day 3. Hyperglycemic hyperosmolar state precipitates rhabdomyolysis which aggravates acute renal failure. Pathogenesis of this nontraumatic rhabdomyolysis is multifactorial including, inhibition of the Na pump by hyperosmolar state, acidosis, hypernatremia, K deficiency, decrease in intramuscular energy supply from insulin deficiency[1]. Resultant fall in transmembrane potential and elevated intracellular Ca, activates proteases with leakage of muscle enzymes resulting in rhabdomyolysis[2]. We also hypothesize that the prothrombotic state induced by severe hyperglycemia causes muscle tissue infarction and elevated CK, confirmed in our case as 100% MM. Prompt recognition and treatment with bicarb drip as in our case can avert acute renal failure precipitated by this unusual cause of rhabdomyolysis. CK is not routinely measured in hyperosmolar hyperglycemic states. We recommend routine monitoring of CK in these cases with particular attention to cases with very high Na as without early recognition and treatment of rhabdomyolysis, patients could have potentially fatal outcomes. We suggest CK be remeasured a day after peak glucose and serum osmolality given the temporal association demonstrated by our case.

**Laminopathy and auto-immune sclerodermia: chance or necessity?**

E. Parent[1], A. Balavoine[1], B. Lamblin[1], H. Ytier[2], C. Vigouroux[3] & M. Vantyghem[1]
[1]Lille University Hospital, Lille, France; [2]Roubaix General Hospital, Roubaix, France; [3]Faculté de médecine Pierre et Marie Curie Site Saint-Antoine, Paris, France.

Some laminopathies associate both progeria and sclerodermic components (*Am J Med Genet A* 2006 Hennekam, *J Cell Sci* 2008 Sagelius), but most sclerodermic syndromes are not associated to LMNA mutations despite the presence of nuclear envelope antibodies, mainly directed to lamin (*PNAS* 1983 McKeon, *Eur Respir J* 2011 Dib).

A 15-th year old girl was referred for severely imbalanced diabetes and a voracious appetite interpreted as binge eating disorders. This girl had been diagnosed at 8 years old with auto-immune sclerodermic and insulin resistance syndromes. Hypertension, polycystic ovaries and insulin requiring hypertriglyceridemic diabetes occurred at 13 years old. Clinical features associated: weight 43 kg, height 160 cm, normal blood pressure with treatment, mandibular hypoplasia, face-sparing generalized lipoatrophy, muscular–skeleton disorders, distal sclerodermia with tendinous retractions and telangiectasies confirmed by capillaroscopy. Fasting blood glucose and C-peptide levels were respectively 2.5 g/l ($n<1$) and 13 ng/ml ($n<2$). HbA1c was 9.2% ($n<6$), ALAT 126, ASAT 307 ($n<40$ UI/l), leptin 2 ng/ml ($n$ 3.5–11), total fat mass 11% ($n$:30–40 DEXA), intra/ total abdominal fat mass 52/84cc with severe liver steatosis 26% (MRI) and fibrosis F2 (biopsy). Cardiac investigations showed mild anomalies. Anti-nuclear autoantibodies have been found constantly positive since the age of 8 (1/640ème)), without other auto-antibodies. A *de novo* D47Y LMNA mutation was found.

This sclerodermic syndrome associated to this laminopathy could be linked i) to the severity of the glucose imbalance, generating a disorder of glycosylation ii) to the N-terminal type of LMNA mutation, rather encountered in progeria with sclerodermic disorders iii) to the cell or nucleus stress induced by the laminopathy leading to a release of nuclear envelope antigens, generating a non-specific occurrence of anti-nuclear auto-antibodies. Altogether, this case report offers new insights on the mechanisms linking inherited and auto-immune forms of lipodystrophies and sclerodermia, in line with those reported in PSMB8 mutations.

Sclerodermia with telangiectasies.

## P402

**Pendred's syndrome: genetics and phenotypic variability**

M. Alves, M. Bastos, A. Vieira, S. Gouveia, J. Saraiva, C. Moreno & M. Carvalheiro
Hospitais da Universidade de Coimbra, EPE, Coimbra, Coimbra, Portugal.

Background

Pendred syndrome (PS) is an autosomal recessive disorder characterized by defective organification of iodine, goiter and deafness. It is caused by mutations in pendrin gene (SLC26A4), a transporter of chloride/iodide that mediates the efflux of iodine from thyroid follicular cells to the follicular lumen.

Clinical case

Case-index: MJFS, female, refered to consultation at 35 years for enlarged neck. Personal history: congenital deafness, thyroidectomy at age 19, under levothyroxine therapy. Family history: deafness and goiter in several family members. Physical examination: goiter. Evaluation: normal thyroid function; thyroid hypertrophy with bilateral homogeneous hyperfixation in cintigraphy. Clinical evolution: at 55 years presented a nodule in the right lobe with cytology suspicion of papillary carcinoma; underwent right lobectomy with isthmectomy. The histology revealed a microfolicular adenoma, nodular hyperplasia and papillary hyperplasia. At 63 years presented left lobe enlargement, with suspicious nodule. The cytology was benign (colloid). The molecular study of SLC26A4 gene was performed and revealed mutations c.367C>T (p.Pro123Ser) and c.412G>T (p.Val138Phe), in heterozygosity in exon 4, confirming the diagnosis of PS.

The daughter of case-index: MSF, female, consultation at 3 years for enlarged neck. Personal history: congenital deafness. Evaluation: diffuse goiter without thyroid dysfunction, autoimmunity negative. Evolution: at 11 old years presented thyroid enlargement; levothyroxine therapy was initiated. At 18 years had a multinodular goiter. At 22 years had complains of pain and cervical compression; the cytology was colloid. A total thyroidectomy was performed. Histology: diffuse hyperplasia without malignancy. The molecular study of SLC26A4 gene revealed mutation c.367C> T (p.Pro123Ser), in homozygosity in exon 4, confirming the diagnosis of PS.

The husband of index case, without genetic relashionship, but also with goiter and neurosensorial deafness, as well as other family members, waits for genetic study.
Conclusions
The association of familial goiter and congenital deafness should cause suspicion of this entity. Although thyroid function isn't usually affected, the structural change is often significant, putting difficulties in differential diagnosis. The diagnosis is confirmed by molecular studies, which must be performed in all family members.

## P403

**A rare case of vanishing fetal goiter and role of colour doppler ultrasound in the diagnosis**

R. Panchani, A. Saini, T. Varma & S. Tripathi
Sir Ganga Ram Hospital, Delhi, India.

Introduction
Fetal goiter is a rare condition. The incidence of goitrous hypothyroidism is 1/30 000–50 000 live births. We describe a case of antenatal fetal goiter that vanished upon delivery and was not detected in the newborn. The case report is followed by a discussion wherein we review the literature on thyroid problems in pregnancy and management of fetal goiter.
Case report
A 27-year-old known hypothyroid woman with bichorial biamniotic pregnancy had antenatal ultrasound (USG) at 24 weeks of gestation and found to have a butterfly shaped, uniformly echogenic and highly vascular solid mass on the anterior aspect of fetal neck of one twin. Polyhydramnios and other complications were absent. Thyroid swelling was confirmed on fetal MRI. The other twin was normal. Color Doppler indicated hypofunction of thyroid which was confirmed with cordocentesis. Mother was hypothyroid with very high anti TPO antibody titre. The case was managed by titrating maternal thyroxin and serial monitoring of fetal thyroid size and function. Patient delivered preterm at 30 weeks of gestation. There was no thyroid swelling in any of the twins which was confirmed on USG. Both babies were euthyroid at birth had normal development on follow up so far.
Conclusion
Fetal goiter results in compression of the esophagus and the trachea and leading to polyhydramnios, hyperextension of the neck and dystocia during labor and mental and motor retardation later in life. Therefore, diagnosis of fetal hypothyroidism should be established at an early stage and appropriate hormone replacement treatment should be started. Fetal thyroid color Doppler is a new modality that helps in determining fetal thyroid function and can help to avoid invasive procedures like cordocentesis in appropriate cases. We emphasize on importance of noninvasive USG and maternal biochemical monitoring and correction as required. Hence, a strategic approach to fetal goiter is required to achieve optimal benefits at minimal fetal and maternal risk.

## P404

**Gastrostomy solves severe hypoglycemias after bariatric surgery**

M. Gonzalo Marín, I. González-Molero, M. Domínguez-López & J. García Arnés
Carlos Haya Hospital, Málaga, Spain.

Introduction
Patients with bariatric surgery require close monitoring because of possible metabolic complications. It has been published some cases of severe and persistent hypoglycemias resistant to diet and pharmacologic treatment being necessary a pancreatectomy. We present a case report of nesidioblastosis after gastric bypass that required subtotal pancreatectomy but despite this, hypoglycemias persisted. Before performing total pancreatectomy we placed a tube feeding in remnant stomach and hypoglycemias disappeared.
Case report
45 years woman with morbid obesity (BMI $=48$) underwent gastrojejunal bypass. One year later (BMI$=25.9$) she began with postprandial hypoglycemia that did not improve after diet and acarbose. Basal analysis and fasting test were normal. OGGT revealed hyperinsulinism and hypoglycemia. Imaging test were normal. After oral load of three enteral nutrition products (1, rich in fast absortion carbohidrates; 2, slow absorption carbohydrate with insoluble fiber and 3, monounsaturated fatty acids rich) were observed descending degrees, respectively, of hyperinsulinism and hypoglycemia. Mesenteric arteriography with intra-arterial calcium stimulation and measurement of insulin and C peptide in hepatic vein revealed a right hypersecretion in splenic and superior mesenteric area (pancreatic body and tail) Given the persistence of hypog. partial pancreatic resection was decided. Pathologic examination revealed diffuse hyperplasia of islets supporting diagnosis of nesidioblastosis. Despite initial improvement, hypoglycemias returned so it was decided to perform a gastrostomy for enteral nutrition, while orally she only ate proteins and fats. After this, hypoglycemias disappeared.
Conclusion
The clinical significance of this case resides in the few cases reported to date with this evolution to our knowledge (only one previously published case) and the possible therapeutic implications:published literature advises complete pancreatectomy if hypoglycemia persists after partial pancreatectomy, however the performance of gastrostomy may be a much less aggressive therapeutic approach. Likewise, the persistence of hypoglycemia after subtotal pancreatectomy with subsequent resolution after gastrostomy in remnant stomach supports a major role of rapid release of food to the ileum and production of gastrointestinal peptides more than the cell hyperplasia of islets in itself as main cause of hypoglycemia.

## P405

**Pubertal induction with testosterone of a boy with bilateral anorchia guided by the development of his monozygotic twin brother**

E. Van Caenegem, S. Vandewalle, K. Wierckx, Y. Taes, J. Kaufman, M. Craen & G. T'Sjoen
Ghent University Hospital, Ghent, Belgium.

Introduction
We describe a monozygotic twin pair, of which one boy was diagnosed with anorchia. Both were followed-up till age 17.
Case report
At birth, in one twin 46 XY boy (A), testes were not palpable while his brother (B) was unaffected. Stimulation with human chorionic gonadotrophin (hCG) and orchidopexia were unsuccessful at age 3. A second hCG-stimulation test was performed at age 8, where serum testosterone response failed to increase. No testicular tissue was detected by abdominal laparoscopy. At the age of 10.5, when the bone age was 11.6 years both in A and B, low dose testosterone substitution therapy (25 mg/2 weeks) was started. Before puberty induction, A and B had similar weight and height. During puberty, a slightly faster increase in weight (A–B 11–19%) and height (A–B 3–7%) was observed in A. A and B ended up with a similar and normal final height, weight, arm span and sitting height. Secondary sexual characteristics developed normally in both brothers. At the age of 17, bone mineral density, body composition (dual X-ray absorptiometry, DXA-scan), volumetric bone parameters at forearm and calf (peripheral quantitative CT-scan) were evaluated. We observed similar bone mineral density at the lumbar spine, total hip, distal radius and whole body (DXA, A–B $<5\%$). Fat percentage was 14% in A vs 11% in B. Trabecular (distal radius) and cortical volumetric bone parameters (mid and proximal tibia) were comparable (A–B $<5\%$). However, at one cortical site (proximal radius), A had a smaller cortical bone size with a thicker cortex (all A–B 10–20%).
Conclusion
Low dose testosterone substitution in bilateral anorchia, guided by the pubertal evolution in the healthy twin, led to a comparable pubertal development, final height and bone mineral density. Moreover, testosterone did not seem to be necessary for normal increase in length before puberty.

**Pseudohypoparathyroidism type Ib: a case of occult familial disease**

F. Adamidou, P. Anagnostis & M. Kita
Hippokrationn Hospital of Thessaloniki, Thessaloniki, Greece.

Introduction
Pseudohypoparathyroidism (PHP) constitutes a heterogenous group of disorders characterized by end-organ resistance to parathyroid hormone (PTH), due to a defect in the stimulatory G protein-activated cAMP formation. PHP type Ib is characterized by renal resistance to PTH, without the phenotypic features of Albright hereditary osteodystrophy (AHO).
Case report
A 31-year old woman was referred to our clinic for investigation of severe hypocalcemia, detected on routine laboratory examination. Apart from mild hand numbness, no further symptoms of hypocalcemia or signs of AHO were evident. There was no relevant family history and both proband's parents were normocalcemic and unrelated. Her serum calcium levels were 6.6 mg/dl (normal range 8.8–10.6), serum phosphate: 4.9 mg/dl (normal range: 2.5–4.5), PTH: 1629 pg/ml (normal range: 10–52), 25-hydroxyvitamin-D: 15.7 ng/ml (normal $>30$ ng/ml), 1,25-dihydrohyvitamin-D3: 31 ng/ml (normal range: 19.6–54.3), 24 h-urinary calcium: 45 mg (normal range 0–250) and 24 h-urinary phosphate: 681 mg (normal range: 400–1300). Thyrotropin levels were 5.67 mIU/ml (normal range 0.4–4), and anti-thyroid autoantibodies were negative.
GNAS methylation analysis showed a methylation defect in the maternally derived exon A/B, with a normal methylation pattern of the paternal NESP55-DM allele, presumably caused by microdeletions disrupting the upstream *STX16* gene. Treatment with alfacalcidol and calcium was initiated, which restored calcium and PTH levels.
One year after diagnosis, the patient successfully carried a twin pregnancy to term, following *in vitro* fertilization for idiopathic infertility. During pregnancy, she remained metabolically stable. GNAS methylation analysis in the offspring, revealed the same methylation defect in the male infant, establishing an autosomal dominant mode of inheritance pattern.
Conclusions
PHP Ib is a rare disease that can remain undetected to mid life. Establishing the diagnosis is important not only for appropriate case management but also for genetic counseling.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P407

**Considering familial benign hypocalciuric hypercalcemia on differential diagnosis of primary hyperparathyroidism**

S. Gouveia, S. Paiva, L. Gomes, C. Ribeiro, A. Vieira, M. Alves, J. Saraiva, C. Moreno & M. Carvalheiro
Coimbra's University Hospital, Coimbra, Portugal.

Introduction
Primary hyperparathyroidism is the most common cause for hypercalcemia. Familial benign hypocalciuric hypercalcemia (FBHH) is an unusual autosomal dominant disease. The mutation in the calcium sensing receptor (CaSR) determines a shift to the right in the calcemia set-point that inhibits PTH secretion. Generally asymptomatic, these patients present with mild hypercalcemia and hypophosphatemia, normal or slightly increased PTH levels and hypocalciuria. Daily calciuria lower than 50 mg and calcium to creatinine clearance ratio below 0.01 favour FBHH hypothesis instead of typical primary hyperparathyroidism.
Family case report
We describe a family whose propositus was a 37-years-old male, referred to our Department due to diabetes secondary to alcoholic pancreatitis. His routine analysis revealed hypercalcemia (11.2 mg/dl; RR: 8.4–10.4). He didn't exhibit any cardiac, gastrointestinal or psychiatric symptom that could support a primary hyperparathyroidism hypothesis. Absence of ancestor family history suggesting hypercalcemia. The following investigation confirmed hypercalcemia (10.9 mg/dl), hypophosphatemia (1.7 mg/dl; RR: 2.7–4.5), high PTH (75 pg/ml; RR: 9–72) and regular magnesium, albumin and creatinine levels. He showed hypocalciuria (85.6 mg/24 h; RR: 100–300) and a calcium to creatinine clearance ratio of 0.004. Cervical ultrasonography and 99 mTc-sestamibi scintigraphy did not display any abnormality. Bone mineral density was preserved at dual energy X-ray absorptiometry. The propositus has three children, two of them presenting hypocalciuric hypercalcemia. Genetic study has identified R648X mutation in the CASR gene (heterozigoty).
Conclusion
Family history and analytical abnormalities led to FBHH diagnosis, which was genetically confirmed.
We emphasize the need of ruling out FBHH through an investigation triggered by hypercalcemia. Propositus and affected relatives should be warned against undergoing parathyroidectomy, as long as it would be unnecessary (considerable renal reabsorption of calcium and subsequent hypocalciuria still remain after total parathyroidectomy) and hazardous.
Due to neonatal severe hypercalcemia risk, consanguineous relationships are strongly discouraged.

## P408

**The diagnostic challenge of a parathyroid adenoma undetectable by Tc-99m Sestamibi scintigraphy or computed tomography in a patient with newly diagnosed sarcoidosis and hypercalcaemia**

J. El-Sheikha[1,2], I. Hutchinson[2] & A. Pettit[2]
[1]NHS, Hull, UK; [2]Airedale General Hospital, Steeton, UK.

Hypercalcaemia is a common finding in numerous diseases processes but is non-specific to its cause. We report a case of a 55-year-old lady with known sarcoidosis who developed hypercalcaemia and elevated parathyroid hormone due to a parathyroid adenoma. Both these disease processes are independently associated with hypercalcamia, but it is unusual to have both in combination and difficult to establish which is the primary cause. In our case the diagnosis was complicated by a negative Technetium Sestamibi and computed tomography (CT) scan specifically looking for a parathyroid adenoma. This led to an incorrect diagnosis of sarcoid hypercalcaemia with tertiary hyperparathyroidism secondary to osteomalaciea. This diagnosis was reconsidered when a trial of steroids showed an unexpectedly poor response. A lesion noted in the patients CT scan behind the patients left clavicle was investigated further by surgical exploration. Although this lesion was identified as a sarcoid granuloma, the opportunity was taken to explore the patients thyroid. A solitary parathyroid adenoma was detected and following parathyroidectomy her hypercalcaemia resolved. This rare combination highlights the importance good clinical judgment and a healthy scepticism of advanced investigations.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P409

**Severe gestational hypothyroidism due to anti-TSH receptor blocking antibodies**

B. Di Bella[1], M. Moleti[1], S. Presti[1], F. Di Mauro[1], G. Sturniolo[1], P. Agretti[2], G. De Marco[2], M. Tonacchera[2], F. Trimarchi[1] & F. Vermiglio[1]
[1]University of Messina, Messina, Italy; [2]University of Pisa, Pisa, Italy.

Autoimmune hypothyroidism due to thyroid stimulation blocking antibodies (TSB-Ab) is uncommon. When occurring in pregnancy, this condition may be responsible for feto-neonatal complications as a result of both maternal hypothyroidism and trans-placental TSB-Ab transfer to the fetus.
Clinical case
September 2010: a 27 year-old woman was diagnosed with autoimmune severe hypothyroidism (TSH 325 mIU/l (n.v 0.4–4.0), $FT_4$ 1.54 pmol/l (n.v. 11.5–22.6), $FT_3$ 0.67 pmol/l (n.v. 3.7–8.3); TPOAb and TgAb positive). Levo-thyroxine (L-$T_4$) treatment was started (100 μg/day) and euthyroidism achieved in November 2010 (TSH 0.34 mIU/l, $FT_4$ 18.6 pmol/l, $FT_3$ 7.0 pmol/l). In December 2010 pregnancy was ascertained (5 weeks) and thyroid function tests revealed

l–$T_4$ dose inadequacy (TSH 13.9 mIU/l (trimester-specific n.v.: 0.03–2.3); $FT_4$ 10.3 pmol/l (trimester-specific n.v.: 11.9-21)). L-$T_4$ dose was therefore increased (1300 μg/week) with prompt restoration of euthyroidism (January 2011, 8 weeks: TSH 0.16 mIU/l). Thyroid receptor antibodies (TRAb) at 10 weeks of gestation were found to be positive with high titer (>40 UI/l). TSH receptor bioassay revealed these antibodies to be only partially active (30%) in blocking TSH receptors. In the further follow-up L-$T_4$ dose was progressively adjusted to maintain TSH and $FT_4$ within the normal range for pregnancy. Both TRAb titer and Ig-activity proved consistently unchanged (at 20 and 30 weeks).
Fetal/neonatal data. Morphological US, umbilical flowmetry and fetal echo-cardiography were normal for gestational age at 20 and 30 weeks. Fetal thyroid volume and vascularization, bone maturation, and fetal mobility were normal as well, at 32 weeks of gestation. August 2011 (38 weeks): cesarean section delivery. Neonatal data: TSH 29.4, 25.9 e 4.4 μU/ml and $FT_4$ 22.0, 31.4 e 16.0 pm/l, at 12 and 36 h and at 3 weeks of post-natal life, respectively. TRAb >40 UI/l at 36 h. Thyroid US was normal.
Severe hypothyroidism in child-bearing age women should advice routinely TRAb bioassay.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P410

**A case of refractory hypoglycemia**

J. Wang, D. Singh, A. Jayashekara, S. Ellis & F. Kaplan
Lister Hospital, Stevenage, UK.

A 74-year-old diabetic lady presented to emergency-department following a collapse due to hypoglycaemia (blood glucose 1.7 mmol/l) and responded dramatically to intravenous–glucose. She had recurrent hypoglycaemic episodes in the last-fortnight, despite discontinuation of her oral hypoglycaemics and no other obvious precipitating factors/toxins like alcohol. She was on prednisolone, 10 mg along with azathioprine, 150 mg, atenolol, 25 mg, and candesartan, 8 mg. She has rheumatoid-arthritis, skin-psoriasis and essential-hypertension. She was diagnosed with a large right sided intra-thoracic fibrosarcoma (Fig. 1) for which she underwent surgery in 1995 and was confirmed histologically. Subsequently, she had further recurrence which deemed inoperable. These hypoglycaemic-episodes were investigated by ruling-out any obvious cardiac, renal, hepatic, or adrenal-dysfunction or sepsis. Perhaps coexistent fibrosarcoma and recurrent hypoglycaemia pointed towards possibility of non-islet cell tumour-hypoglycaemia. She was managed initially with i.v./oral-glucose and high-dose prednisolone along with carbohydrate rich diet; without controlling her hypoglycaemic attacks. Diazoxide, which inhibits pancreatic insulin-release, was introduced at a low-dose and up titrated to 150 mg TDS. Hypoglycaemia are usually fully-reversible after surgical removal of tumours; however, in our case with an inoperable-tumour, alleviating hypoglycaemia was becoming a therapeutic challenge. With limited options available, the role of GH was considered; as it is well established that GH stimulates hepatic gluconeogenesis and glycogenolysis, probably suggesting a role in managing non-islet cell tumour hypoglycaemia. She was thereby treated with GH which reduced frequency of her hypoglycaemic episodes and rendered her near-euglycemic.
Conclusion
Hypoglycaemia being a common reversible medical-emergency is frequently associated with oral hypoglycaemic-agents/insulin-therapy; however, it can rarely be a paraneoplastic manifestation of underlying tumour. Our case report illustrates therapeutic challenges encountered in a patient with inoperable fibrosarcoma, presenting with resistant hypoglycaemia and perhaps suggesting role of GH in similar cases.

**Double jeopardy in pregnancy: a case of autoimmune polyglandular syndrome type 2 in a pregnant patient**

R. Li, A. Mejia, M. Manalo, F. Lantion-Ang & C. Tamban
University of the Philippines - Philippine General Hospital, Manila, Philippines.

This is a case of an adult female who presented with 1 year history of palpitations, heat intolerance, easy fatigability, hyperdefecation and proptosis. She was admitted to this institution due to 3 month history of nausea, vomiting, abdominal pain, flank pain and generalized weakness. During admission, she was diagnosed with hyperthyroidism supported by laboratory findings of suppressed thyroid stimulating hormone and elevated free thyroxine levels and was then treated with methimazole. However, patient's condition did not improve. She remained hypotensive and tachycardic for 3 days which was initially attributed to septic shock secondary to urinary tract infection. Further work-up which includes serum cortisol level determination and co-syntropin test revealed adrenal insufficiency. She was given glucocorticoids, and eventually she became hemodynamically stable. Unfortunately, patient had abortion necessitating dilatation and curettage. With the presence of hyperthyroidism and adrenal insufficiency, she was then diagnosed with autoimmune polyglandular syndrome (APS) in Pregnancy. At present, there are very few published case reports of APS in pregnancy.

## P412

**Pseudo malabsorption of levothyroxine**

M. Alves, D. Rodrigues, C. Baptista, C. Ribeiro, P. Oliveira, A. Vieira, S. Gouveia, J. Saraiva, C. Moreno, M. Bastos & M. Carvalheiro
Hospitais da Universidade de Coimbra, EPE, Coimbra, Coimbra, Portugal.

Background
Therapy with levothyroxine (L-$T_4$) is essential in hypothyroidism treatment. The marked elevation of thyrotropin (TSH) in patients treated with appropriate doses of L-$T_4$ is rare and can result from malabsorption, drug interaction or poor adherence. The non-adherence, omitted by the patient, is called pseudo malabsorption.
Clinical report
ACCS, female, 30 years old, hospitalized for persistent hypothyroidism despite L-$T_4$ therapy. Personal history: submitted to total thyroidectomy in March 2010 because cytological suspicion of follicular tumor in a simple multinodular goiter. The histology revealed a papillary microcarcinoma (T1N0M0), without other changes. Started replacement therapy with L-$T_4$. After increasing doses of L-$T_4$ (125 to 400 μg/day) there was no normalization of TSH or thyroid hormones

(TSH 74.3→93→50 μUI/ml (RR: 0.4–4.0), $FT_4$ 0.2→0.4→0.5 ng/dl (RR: 0.8–1.9)), with reappearance of thyroid tissue in surgical loca. Admitted to hospital for surveillance of taking L-$T_4$ and study of possible L-$T_4$ malabsorption.No drug habits. Physical examination: BMI 29 kg/$m^2$, without major clinical signs of thyroid dysfunction. Laboratory: TSH 74 μUI/ml, $FT_4$ 0.4 ng/dl. Blood count, biochemistry, folic acid, vitamin B12, iron metabolism, stool examination, research and degree of fat digestion of feces, autoimmunity for celiac disease or pernicious anemia: all normal. Esophagus and gastric endoscopy was macroscopically normal; a gastric biopsy was performed and showed chronic antral gastritis, non-atrophic, with mild activity and colonization by *H. pylori*. The test of oral overload with 1 mg of L-$T_4$ revealed: TSH 60 μUI/ml at baseline→33 μUI/ml after 4 h, $FT_4$ 0.7 ng/dl at baseline → 1.0 ng/dl after 4 h. This result confirmed the diagnosis of pseudo malabsorption of L-$T_4$. The therapeutic regimens included confronting the patient with the results and the eradication of H. pylori.

Conclusions

The poor adherence to therapy is the most common cause of persistent hypothyroidism in patients receiving adequate doses of levothyroxine. Clinical suspicion should be investigated excluding malabsorption syndromes or drug interaction. In this patient, the high dose overload of levothyroxine allowed the confirmation of the diagnosis. Psychological counseling may be necessary.

## P413

### Vitamin D deficiency and elevation of para-thyroid in Thalassemia minor: a case study

S. Debnath

Women's Polytechnic, Hapania, Govt. of Tripura, Agartala, India.

βThalassemia Minor cases unlike Thal-Major don't require immediate medical attention, due to effective compensatory haematopoiesis and remain transfusion independent and patients may remain metabolically deficient lowering quality of life. To impose an artificial genetic bottleneck and suppress the dispersion of Thal-minor and Thal-major mutationsas in a population early detection is the only way out. Hypocholestreloemia, Vitamin D deficiency and marginally elevated Parathyroid hormone may be found in Thal-minors as reported in the case study. Absence of significant anaemia may make the condition cryptic or latent, delaying diagnosis of the condition and the situation may be complicate in longterm. Parathyroid level may be evaluated for secondary hyperparathyroidism due to deficiency of vitamin D. If several findings of Ca crystals (++/+) are present in urine RE, Bisphosphonate therapy may provide relief. This case study reports occurrence of pancreatic insufficiency, resultant steatorrhoea, Vitamin D (25-OH) deficiency (13.86 ng/ml) with Hypocholesterolemia (85 mg/dl). Para thyroid hormone was in upper limit (62 pg/ml) and Ca+2 was 9.5 mg/ml in a 30 years old male Thal-minor patient (fetal hemoglobin 2.10%, HbA2 4.60% and Hb Adult 84.80%).

**Table 1** Some diagnostic parameters of the patient case

| Hemato-logical profile | Endocrineand related par-ameters profile | Serum enzymes | Serum anti bodies | Metabolic par-ameters and vitamin pro-file | Minerals and electrolytes |
|---|---|---|---|---|---|
| Hemoglobin 13.8 mg/dl | Para thyroid hor-mone 62 pg/ml | SGPT 333 IU/ml | Anti CCP antibody negative | F sugar 85 mg/dl | Serum calcium was moderately low at 8.6 mg/dl |
| Reticulocyte count 1.08% | Serum aldoster-one 304.99 pg/ml | Alk phos 400 IU/ml | ANA negative | PP sugar 100 mg/dl | Serum bi-carbon-ate mod-eraly elevated at 63 mmol |
| Fetal hemo-globin 2.10% | Erythropoietin 22.80 mIU/ml | | CRP negative | Total choles-terol 80 mg/dl | Serum chloride WNR |
| HbA2 4.60% | Homocysteine 11.97 μmol/l | | | HbA1c was 5.60% | Serum sodium WNR |
| Hb adult 84.80% | TSH WNR | | | Total bilirubin 3 mg/dl | Serum pot-assium was 5 mg/dl |
| TIBC was normal | $FT_3$ WNR | | | Total protein 6 mg/dl | |

### Study of hormone and thyroid antibodies of auto-immune thyroid disorders

G. Buukuu

Shastin Central Hospital, Ulaanbaatar, Mongolia.

Auto-immune thyroid diseases (AITD) such as Graves' disease (GD) and Hashimoto's thyroiditis (HT) which are archetypical organ specific auto-immune diseases are increasing in recent years and about 2–4% of women and up to 1% of men are affected worldwide, and the prevalence rate increases with advancing age. The AITD are characterized by the presence of raised serum antibodies directed against thyroid antigens. The development of antibodies to antithyroid microsomal antibody, antithyroglobulin antibody and antithyrotropin receptor antibody (TR-Ab) is the main hallmark of AITD. HT is diagnosed by TPO-Ab, and/or Tg-Ab positively, a negative TR-Ab level and, the presence of diffuse goiter. Thyroid antibody testing is not routinely available in developing countries, and few studies have measured thyroid antibodies in Mongolia.

Thyroid hormones in serum, Tg-Ab, TPO-Ab using an ELISA technique in 209 patients with various thyroid pathologies attending an endocrine department in Shastin Central Hospital. Patients were clinically grouped into Graves' disease ($n=160$) and Hashimoto's thyroiditis ($n=39$). Blood donors without thyroid disease ($n=30$) acted as controls. During the study we performed blood test for thyroid hormones in nine patients with enlarged thyroid gland in euthyroidism, 30-hypothyroidism with unknown etiology.

The levels of thyroid hormones were analyzed in patients with Graves' disease. To determine thyroid hormones in patients with GD, thyroid hormones were $3.97\pm0.3$ nm/l, determine thyroid hormones in the euthyroidism were $1.72\pm0.13$ nm/l, in patients with hypothyroidism $0.29\pm0.03$ ng/ml. Thyroid TPO–Ab was 100% positive in all euthyroidism and hypothyroidism. In subjects with euthyroidism TG–Ab was $189.27\pm94$ IU/ml, and during hypothyroidism TG–Ab was $888.8\pm216.7$ IU/ml.

Study results showed the increase in $T_3$ and $T_4$ levels decreased TSH with Graves' disease. In the euthyroidism of thyroid hormones were revealed normal, in patients with hypothyroidism $T_3$, $T_4$ were low, TSH was high with Hashimoto's thyroiditis.Thyroid autoimmunity appears more common in patients with GD and HT, and Tg-Ab, TPO-Ab were significantly associated with auto-immune thyroid disease.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**New insulin receptor mutation in a patient with primary amenorrhea**

L. Proietti Pannunzi[1], S. Morgante[1], M. Deiana[1], A. Chiefari[1], S. Caprioli[1], S. Vottari[1], S. Monti[1], F. Barbetti[2] & V. Toscano[1]
[1]Azienda Ospedaliera S. Andrea-University of Rome Sapienza, Rome, Italy; [2]University of Rome Tor Vergata, Rome, Italy.

Primary amenorrhea is a rare disease that affects <1% of adolescent girls. The most common causes of primary amenorrhea include chromosomal abnormalities, hypothalamic and pituitary disorders, lack or structural abnormality of reproductive organs.
18 years old woman was referred to us by her pediatric physician for evaluation of primary amenorrhea and hirsutism. She had low birth weight, 1.9 kg, and hypostaturism. At the age of 6 years underwent to clonidine provocation test that showed normal values of growth hormone secretion. At the age of 17 the patient noticed some signs of masculinization (fine hairs on her cheeks) in the absence of menarche or evidence of sex development.
She is currently eighteen years old, her height is 132 cm (20 cm <3rd percentile), her weight 33 kg (BMI=18.9). Clinical evaluation of hirsutism according to Ferriman and Gallway has given a score of 23 (severe), no signs of acanthosis nigricans on the neck.
Endocrinological evaluation showed high levels of testosterone (3.4 ng/ml), with normal gonadotropins, estradiol, TSH and thyroid hormones, PRL, GH, IGF1, PTH, ACTH, 17-OH-P, DHEA-S. Pelvis ultrasonography showed microplolycystic ovaries and a small uterus. Metabolic assessment revealed fasting hyperinsulinemia (88 μU/ml) with normal fasting plasma glucose (89 mg/dl), but diabetes at 2 h of oral glucose tolerance test (289 mg/dl) with very high insulin levels (2123 μU/ml). Given the basal and glucose tolerance test insulin levels, considering the possibility of insulin receptor gene alterations, DNA direct sequencing of the exons 17–21 of the insulin receptor gene, encoding the tyrosine kinase domain, was maden.
An heterozygous mutation in exon 19 with arginine substituting glycine in position 1146 was found. The rest of the family is currently under investigation. Patient started therapy with flutamide 125 mg once a day *per os*, and metformin 850 mg three time/daily. After 6 month from the beginning of therapy menarche occurs.
Conclusions
To the best of our knowledge, this is the third Italian patient with severe insulin resistance due to a mutation of IR gene and the first patient presenting with primary amenorrhea.

**Plasmapheresis therapy in a case with recurrent pancraetitis attacks as a consequence of hypertryglyceridemia**

B. Polat[1], E. Onal[1], G. Kaya[1], I. Dilek[1], R. Ersoy[2] & B. Cakir[2]
[1]Ankara Ataturk Training and Research Hospital, Ankara, Turkey; [2]Yildirim Beyazit University, Faculty of Medicine, Ankara, Turkey.

Hypertygiceridemia is responsible from the 1–4% of acute pancreatitis cases. When serum triglyceride level rises above 1000–2000 mg/dl, risk of having acute pancreatitis also increases. Medical therapy is usually inadequate for treatment of hypertryglyceridemia cases which cause severe and recurrent pancreatitis attacks. In our case we have reported a patient having recurrent attacks under medical therapy and underwent plasmapheresis.
Case
45 years old female patient has admitted to the hospital with epigastric pain and had the diagnosis of billiary pancreatitis and underwent cholecystectomy. After that operation she was hospitalized in every 2 or 3 months with severe abdominal pain, detected to have pancreatitis and further investigation was made to explain the reason of recurrent attacks. Severe hypertyglyceridemia was detected in laboratory tests. Although she was receiving fibrate therapy with the maximum tolerable and allowed dosage, her triglyceride levels did not fall below 2000 mg/dl. She was referred to our department in 2011. At the time of hospitalization her TG level was 9000 mg/dl.She underwent plasmapheresis with albumin for once. Her TG level was 600 mg/dl on the first day and 400 mg/dl at the third day after plasmapheresis. It has been 4 months from the plasmapheresis and she did not have any pancreatitis attack. Her triglyceride levels are below 400 mg/dl under fibrate therapy.
Result
Acute pancreatitis occurring secondary to hyperlipidemia is principally treated with hydration and pain palliation. Severe and recurrent attacks can be counted as plasmapheresis indication.Plasmapheresis reduces tryglyceride levels, removes active enzymes and preinflammatory molecules from the circulation. Although there is information about benefits of plasmapheresis for prevention of recurrent pancreatitis in hypertrygiceridemic patients there is no consensus about the ideal frequency and duration of therapy. As we see from our case sometimes only one plasmapheresis might be cost-effective and adequate for secondary prevention.

**Association of thyroid hormone resistance and hypogonadotropic hypogonadism**

J. Perez-Luis, E. Jerez-Arzola & J. Lopez-Fernandez
Hospital Universitario de Canarias, La Laguna, Spain.

Introduction
Patients with resistance to thyroid hormone (RTH) have variable tissue hyporesponsiveness to thyroid hormone (TH) due to a defect in the TH receptor (TR) β gene. So far, 124 different mutations have been identified among 343 unrelated families. Despite the TH resistance, some patients have symptoms and signs of hyperthyroidism and may have goiter. RTH is characterised by high TH and normal or high TSH concentrations. Differential diagnosis includes a TSH-producing pituitary adenoma, TH cell membrane transport and metabolism defects and euthyroid hyperthyroxinemia. RTH is associated with autoimmune thyroid disease but not with other endocrinopathies.
Case report
A 47-year-old male with antecedents of atrial flutter, ischemic ictus and hypercholesterolemia was sent to rule out hyperthyroidism. He complains of flushing, sexual dysfunction and infertility. On examination there was no goiter, heart rate: 72 beats/min, weight: 78 kg, height: 173 cm, BMI: 29 kg/m$^2$, normal genitalia and secondary sexual characters. His IQ was slightly low. He had high $T_4$ and $RT_3$, normal $T_3$ and high-normal TSH levels: $TT_4$:17.5 ng/ml (5.0–12.0), $FT_4$: 2.96–4.32 ng/ml (0.70–1.85), $FT_3$: 2.8–5.1 pg/ml (2.0–6.8), RT3: 0.38 ng/ml (0.10–0.35) and TSH: 2.11– 4.03 μU/l (0.40–4.00). A TSH producing pituitary adenoma was excluded (normal pituitary MRI, SHBG: 22.6 nmol/l (10–50), α-subunit, TSH and α-subunit responses to IV TRH (0, 15, 30, 60 min: TSH: 1.70, 11.10, 14.80, 8.33 μU/l;α-subunit (0.02–0.8): 0.23, 0.49;0.42, 0.29 UI/l). Ultrasound scan showed mixed nodules with citology of nodular hyperplasia. Antithyroid antibodies were negative. Thyroglobulin: 48 ng/ml (1.5–56) and binding proteins were normal: TBG 18 mcg/ml (10–40), albumin 4.6 g/dl (3.7–5.4), prealbumin 30 mg/dl (10–40). Gonadal function tests showed total testosterone 2.41–2.60 ng/ml (2.70–10.69), FSH 7.09–11.10 mUl/ml (1.5–15), LH 0, 89–1.68 mUl/ml (1.4–7.7), PRL basal 4.79–6.56 ng/ml (2.50–17.00) and ferritin 316 ng/ml (20–300). The other pituitary hormones were normal as well as TH in his relatives (parents and a daughter). A TR β gene mutation was detected: switch G>T in heterozygosis in the c.959 position that produces a switch of the aminoacids p.Arg320Leu (R320L). This mutation have been described before.
Conclusions
We present a case of RTH clinically euthyroid due to a de novo mutation in the TR combined with idiopathic hypogonadotropic hypogonadism. This association have not been reported previously.

**5-Alpha reductase type 2 deficiency: a case report**

Z. Hekimsoy, O. Hatipoglu, D. Öz, P. Alarslan & B. Özmen
Medical Faculty, Celal Bayar University, Manisa, Turkey.

5-Alpha reductase deficiency is a rare 46, XY disorder of sex differentation caused by mutations in the 5-alpha reductase type 2 gene (SRD5A2) located on chromosome 2p23. Affected patients have a deficiency of the 5-alpha reductase type 2 enzyme, which becomes partially or totally unable to convert testosterone into dihydrotestosterone, the latter being responsible for the development of the external genitalia, prostate, and urethra in the male fetus. Most affected individuals are characterized at birth by predominantly female external genitalia and are often raised as girls. Patients raised as girls exhibit spontaneous virilization at puberty. Some patients are sufficiently masculinized at birth and are raised as boys.

In this article we describe a 22-year-old patient who had female external genitalia at birth and was raised as a girl. When puberty was reached, she had amenorrhea, virilization and lack of secondary sex characteristics. For these reasons, she was brought to our clinic and 5-alpha reductase deficiency was diagnosed. The woman exhibited a masculine build and muscle development, male hair characteristics, micropenis, and perineoscrotal hypospadias. Testes were palpable in the right and left inguinal canals. Chromosome analysis revealed a 46,XY karyotype. On pelvic MRI, ovaries and uterus were absent. A 41×11 mm vagina-like structure was seen, as were testes within labia-like scrota bilaterally, and seminal vesicles with corpus cavernosa. Hormonal studies included serum total testosterone level 1.54–2.67 ng/mL (normal: 0.1–0.75), free testosterone level 13.79 pg/ml (normal: 0.29–3.18), free androgen index 40%, 17-OHP level 2.34 ng/ml (normal: 0.5–2.4), FSH 28.23 IU/ml (normal: 1.7–19.26), and LH 7.93 mIU/ml (normal: 1.24–8.22). While the serum testosterone was 9.80 nmol/l, serum DHT was 0.52 nmol/l and T/DHT ratio was calculated to be 18.8 (normal is $<12$). Upon further analysis of the 5-alpha reductase type 2 gene, a previously unreported heterozygous R178S mutation was found.

**Subacute or hashimoto thyroiditis? a diagnostic dilemma: case report**

R. Popovici, D. Ciobanu, L. Ionescu, J. Idriceanu, I. Vasiliu, I. Potorac, E. Bivoleanu, C. Cristea, V. Mogos & C. Vulpoi
University of Medicine and Pharmacy 'Gr.T.Popa', Iasi, Romania.

Introduction

Subacute thyroiditis (SAT) is characterized by cervical pain. Rarely, other thyroid diseases, like Hashimoto's thyroiditis (HT), may be associated with cervical pain, leading to confusions with SAT. We report a particular case of painful goitre.

Case report

D Maria, 50 years old, presented with cervical pain, low grade fever, inflammatory syndrome (ESR = 132 mm/1 h), and was diagnosed with SAT. Thyroid function was normal. Ultrasound (US) aspect of goiter (30 ml) was in homogeneous, hypoechoic, pseudo-nodule in the left lobe. Treatment with prednisone (30 mg/day) induced a rapid improvement of pain and inflammatory syndrome (6 weeks after ESR = 26 mm/1 h). After 3 months, with 10 mg Prednisone/day, she had a relapse (thyroid pain, ESR = 95 mm/1 h) with new remission after increasing dose followed, 2 months later, by a new episode of severe cervical pain and high ESR = 87 mm/1 h. Euthyroidism, positive antiTPO antibodies. Thyroid US revealed a hypoechoic irregular left nodule, with suspect cytology. This aspect and the intolerance to anti-inflammatory drugs have led to surgery – quasitotale thyroidectomy. Histology described an association of lymphocytic thyroiditis with giant cells. Postoperative hypothyroidism is compensated until present with 100 mg $LT_4$/day.

Discussion

The overlap of symptoms may determine the confusion between SAT and HT. Painful HT is rare; in most literature cases the response to anti-inflammatory treatment was transitory and surgery was imposed by the evolution of the disease. The histological exam of our case suggests a rare association between the two forms of thyroiditis. We may speculate that inflammation of SAT has determined an immune response inducing the appearance of TH.

**True hermaphroditism with a rare 46,XX/47,XXY Klinefelter's mosaicism: a new unique case and review of previous reports**

N. Akulevich[1,2], J. Boiko[1,2], Y. Makarava[1] & I. Khmara[1]
[1]State Center of Medical Rehabilitation, Minsk, Belarus; [2]Belarusian Medical Academy for Postgraduate Education, Minsk, Belarus.

Introduction

Only few cases of true hermaphroditism with male phenotype and 46,XX/47,XXY Klinefelter's mosaic karyotype with clinical features different among cases have been previously described.

Case report

A 12-year-old patient was referred to our clinic for mixed gonadal dysgenesis. Since birth he has ambigous genitalia: unilateral criptorchidism on the right and perineal hypospadia; left gonad was palpable in the scrotum since birth. At the age of 1.5 months the child underwent surgery for the strangulated right inguinal hernia: fallopian tube and a necroticised right gonad were removed. Histopathological examination revealed ovarian tissue. Cytogenetic analysis of peripheric blood at the age of 1.5 years detected 46,XX (80%)/47,XXY (20%) karyotype. He had hypospadia repairing in several steps. Further, the Mullerian remnants were removed laparoscopically also on the left. At presentation, his stature was 145.5 cm (−0.2 SDS), weight: 34 kg (−1 SDS), bone age: 13 years, pubertal stage: Px3Ax1; left testis 1 ml, penis 4.5×2.5 cm; bilateral ginecomastia. Both serum LH and FSH levels were evevated, basal testosterone and estradiol were low. At ultrasound, a structure typical for testicular tissue with the epididimal cyst on the left and the rudimentary uterus were present. As the patient is raised as a male, testosterone replacement therapy for primary hypogonadism has been prescribed; surgical removal of any Mullerian structures left was recommended. The left gonade, presumably testis, requires biopsy and further monitoring for malignancy.

Conclusion

This case of disorder of sexual differentiation with male phenotype and 46,XX/47,XXY Klinefelter syndrome's mosaic karyotype is intriguing for finding of Mullerian remnants on both sites. A comparative review of previoulsy reported ten cases will be done to empaphazyse doctors's awareness and the necessity of multidisciplinary approach to cover differnt aspects of follow-up for every such a patient.

**Genetics of HLA-identical monozygous twins with different manifestations of polyglandular autoimmune syndrome**

Csajbók[1], S. Magony[1], Z. Valkusz[1], L. Puskás[2] & Zvara[2]
[1]University of Szeged, Szeged, Hungary; [2]Biological Research Center, Szeged, Hungary.

Summary

The autoimmune polyglandular syndromes (APS) comprise a wide spectrum of autoimmune disorders and are divided into a very rare juvenile (APS 1) and a

relatively common adult type with (APS 2) or without adrenal failure (APS 3). APS 1 is caused by mutations in the autoimmune regulatory (AIRE) gene on chromosome 21 and is inherited in an autosomal recessive manner. Mutations of the AIRE gene result in defective proteins which cause autoimmune destruction of target organs by disturbing the immunological tolerance of the patients. Genetic testing may identify patients with APS 1, but not those with APS 2 and 3. For APS 2/3, susceptibility genes are known which increase the risk for developing autoimmune disorders, but without being causative. These are certain HLA genes, the cytotoxic T lymphocyte antigen (CTLA-4)gene, and the protein tyrosine phosphatase nonreceptor type 22 (PTPN22) gene on chromosomes 6, 2, and 1, respectively. Actual diagnosis of APS involves serological measurement of organ-specific autoantibodies and subsequent functional testing.

Our patients

We present the history of a 30-year-old monozygotic female twin pair. One of them (KDN) had Hashimoto's thyroiditis as first manifestation of APS and, 4 years later, Addison's disease occured and gestational diabetes was found during her first pregnancy. The first clinical sign of the second patient (NDN) was type 1 diabetes with severe hyperglycemia and, at the same time, hypothyroidism was also found due to Hashimoto's thyroiditis, which was followed with Addison's disease 5 years later. These monozygotic twins presenting polyglandular autoimmunity had different manifestations of diabetes mellitus although they were HLA-identical. Genetic testing was performed for trying to find the difference in their genome and subseptibility genes.

Results

The DNA chip data showed in both patients insertion in the 12. chromosome (q21.1) and gain of ANTXRL gene the GDM (KDN) positive patient (pseudogene) and different LCHSs (loss of heterozygosity) in both patients. The RNA chip and real time PCR data revealed in the patient with T1DM (NDN) overexpression of the IFNinduced transmembrane protein, IFN$\gamma$R 2, HLA DOB, PTPN2

### Papillary thyroid-type carcinoma arising from struma ovarii: a case report

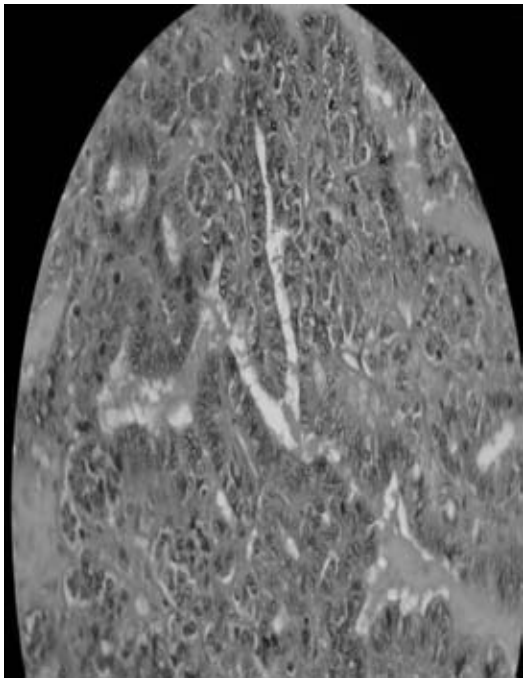
J. Barrera & F. Ang

University of the Philippines-Philippine General Hospital, Manila, Philippines.

Struma Ovarii and its malignant transformation to thyroid-type carcinoma are rare conditions. In recent reviews of reported literatures, only 53 cases of papillary thyroid-type carcinoma arising from struma ovarii were documented from 1924 to 2008. Due to the rarity of the disease, lack of uniform histological criteria for malignancy and protracted clinical course, its management is not also universally accepted by physicians. The aim of this paper is to present a very rare case of papillary thyroid-type carcinoma arising from struma ovarii, and review literatures on the suggested consensus for diagnosis and management of case.

A 41-year-old Filipino woman presented to our section after she underwent total abdominal hysterectomy with bilateral salphingectomy for suspected primary ovarian carcinoma. She has been complaining of vague abdominal pain and distention for almost a year. Her pre-operative CT scan of the abdomen revealed large cystic mass with calcification suggestive of ovarian teratoma. Intra-operatively, the left ovary was converted to an $11\times8\times3.5$ cm multiloculated, multiseptated mass densely adherent to the bowels and uterus. On pathologic examination, the large ovarian mass proved to be a papillary thyroid-type carcinoma arising from a struma ovarii. She underwent platinum-based chemotherapy used for ovarian teratoma.

On review of available case reports and case series done on papillary thyroid-type carcinoma, surgical resection of the tumor has been shown as effective treatment modality. Total thyroidectomy to facilitate whole body scan, radioactive iodine ablation, and thyroxine suppression therapy have shown to significantly decrease tumor recurrence and mortality. Chemotherapy and radiotherapy did not show any benefits on clinical outcomes.



Our patient underwent total thyroidectomy, radioactive ablation therapy and levothyroxine suppression therapy after tumor resection.

Papillary thyroid-type carcinoma arising from stuma ovarii as presented in our case should, therefore, be diagnosed and managed as primary papillary carcinoma of thyroid gland.

### Hypothyroidism with extensive pericardial effusion: different therapeutical approaches

H. Kvasnickova[1], J. Svejda[2], J. Kvasnicka[3], J. Sochman[4], J. Veselka[5] & K. Vondra[1]

[1]Institute of Endocrinology, Prague, Czech Republic; [2]Nemocnice Milosrdnych Sester sv. Karla Boromejskeho, Prague, Czech Republic; [3]Centre for Cardiovascular Diseases, Prague, Czech Republic; [4]Institute for Clinical and Experimental Medicine, Prague, Czech Republic; [5]University Hospital Motol, Prague, Czech Republic.

Introduction

Disturbances of the thyroid gland are the most common diseases of the endocrine system. Their prevalence is increasing with age and can be easily under diagnosed. Advanced forms of thyroid disease can mimic cardiovascular, psychiatric disorders, malignancy or other disorders and can result in life threatening conditions.

Case reports

In the current study we present two case reports concerning patients with cardiovascular symptoms. In both patients an extensive pericardial effusion was found as the first sign of undiagnosed hypothyroidism. The first patient (50-year-old woman), a pericardiocentesis was performed because of clinical and

echocardiographic signs of cardiac tamponade. The pericardiocentesis resulted in a removal of effusion of 2560 ml. The second patient (34-year-old woman), the pericardial effusion was concentrated predominantly in a hardly accessible place. Therefore a conservative approach was decided also because of absence of clinical symptoms of tamponade and despite of a presence of a right atrial collapse. Both patients received levothyroxine replacement therapy in order to treat the hypothyroidism. No refill of pericardial effusion has occurred in the patient treated by pericardiocentesis. The volume of the pericardial effusion was reduced substantially in the patient treated conservatively.

Conclusions

In both patients insidious non-treated hypothyroidism can result in major cardiologic impairment. Correct diagnosis of hypothyroidism was of essential importance concerning successful treatment of pericardial effusion. A matter concerns the rate of replacement therapy: long lasting hypothyroidism could induce a recurrence of a pericardial effusion after pericardiocentesis or its progression in patient treated conservatively. In the contrary a rapid increasing of replacement dose could induce a heart failure or acute forms of coronary heart disease in patient with underlying coronary artery disease.

**A case of persistent hypoglycemia in the setting of connective tissue disease**

K. Choong, Y. Venugopal, S. Vethakkan & R. Pendek
Universiti Malaya, Kuala Lumpur, Malaysia.

Introduction

Autoimmune forms of hypoglycemia are uncommon. However, they should be considered in any patient with hyperinsulinemic hypoglycemia. Here we present a case of persistent hyperinsulinemic hypoglycemia caused by insulin receptor antibodies.

Case report

A 65-year-old chinese woman with mixed connective tissue disease (MCTD) and hypothyroidism presents with a 2-week history of persistent hypoglycemia since discontinuation of her immunosuppresants. A 72 h fast was consistent with hyperinsulinism; serum glucose was 1.1 mmol/l, insulin was 823 pmol/l (normal fasting: $<$118 pmol/l), c-peptide was 615 pmol/l (normal fastng: 264–1026 pmol/l). Adiponectin was 56 μg/ml (normal: 8.3–13.9 μg/ml). There was no history of insulin use. Screening for plasma sulfonylureas, biguanides, insulin analogs and insulin antibodies were negative. Imaging of the abdomen and pancreas was normal. Given the hyperinsulinism, screening for insulin receptor antibody was performed which confirmed the presence of anti-insulin receptor antibodies. She was diagnosed with Type B insulin resistance and started on immunosuppressants resulting in improvement of her hypoglycemia.

Conclusion

In patients with hyperinsulinemic hypoglycemia, especially in the setting of connective tissue disease, the diagnosis of Type B insulin resistance needs to be considered. In this syndrome, insulin receptor antibodies are present and are either antagonistic or agonistic to the insulin receptor. Typically, patients present with severe hyperglycemia. Initial presentation of persistent hypoglycemia, as in our patient, is rare. The insulin:c-peptide ratio is usually 0.2–0.5. In our case, the insulin:c-peptide ratio was 1.3. Possible explanation includes altered metabolism and degradation of insulin. A paradoxical elevation of adiponectin is seen and may be caused by altered insulin action on adipocytes. The presence of elevated adiponectin can aid in the diagnosis of this rare syndrome. Despite the rarity of this condition, awareness of type B insulin resistance is essential to allow for proper management since treatment usually includes multi- modal immunosuppresion to target pathogenic antibodies, and to prevent unnecessary pancreatic surgery.

**Successful pregnancy in a patient with biologically inactive LH or partial LHCGR resistance**

P. Rao[1], A. Straffen[1], J. Skull[2] & H. Jones[1]
[1]Barnsley Hospital NHS foundation trust, Barnsley, UK; [2]Sheffield Teaching Hospitals, Sheffield, UK.

Introduction

LH resistance is very rare and there are only a few case reports in the literature. We describe a patient who presented to us with secondary amenorrhea and very high isolated LH levels who subsequently had a successful pregnancy with IVF.

Case report

A 16 year old girl was referred to us to investigate the cause of her oligomenhorrea. She had attained menarche at the age of 13 and had only 5 periods in 3 years. She had no symptoms/signs of any endocrine abnormality.

Her blood results showed elevated LH levels more than 250 U/l. Her FSH, prolactin and the rest were normal. There was no evidence of interference from heterophile antibodies. MRI scan of her pituitary was normal. We suspected she had LHCGR mutation causing LH resistance, however genetic analysis did not identify any such mutation in exon 11.

She was started on the OCP. There was some suppression of LH from the baseline although incomplete. She was having regular bleeding on the OCP. In 2008 she wanted to start a family. Since she did not have LHCGR gene mutation, we wondered if the receptor function was normal and hence decided to give a trial of IVF cycle. She received Zoladex to induce pituitary down regulation followed by recombinant FSH to induce follicular growth and hCG. She had a successful pregnancy. Currently her LH is not fully suppressed in spite of being on the OCP confirming that the hypothalamic pituitary dysfunction persists.

Conclusion

LH resistance in women is a very rare phenomenon. Our patient is likely to have either partial LHCGR resistance or biologically inactive LH. Our patient had a positive pregnancy with IVF making it a success story however the molecular diagnosis for her LH resistance is still unclear.

**Quadruple metachronous malignancy in a single patient with multiple sclerosis: case report**

M. Buta[1], Z. Milovanovic[1], D. Lavrnic[2,3], I. Djurisic[1], M. Oruci[1], G. Pupic[1] & R. Dzodic[1,3]
[1]Institute of Oncology and Radiology of Serbia, Belgrade, Serbia; [2]Institute of Neurology of the Clinical Center of Serbia, Belgrade, Serbia; [3]University of Belgrade School of Medicine, Belgrade, Serbia.

Introduction

Quadruple primary malignancies occur with an incidence of $<$0.1% and $<$100 cases have been published to our best knowledge. We are presenting a patient with multiple sclerosis and triple thyroid carcinoma, double melanoma and a breast cancer.

Case report
Over the course of 4 years we treated a single patient due to stage III (T3, N1a, M0) medullary thyroid carcinoma size 45 mm in the right lobe and two micropapillary carcinomas in the left lobe, 1.24 mm thick scapular melanoma (Clark II, Breslow II) and 0.85 mm thick lumbar melanoma (Clark II, Breslow II) with negative sentinel node, lobular invasive 4 mm breast carcinoma with clear resectional margins and negative nodes followed by 20 mg tamoxifen daily. FDG–PET scan peformed 1 month ago was negative, CA 15–3 level was within normal values and calcitonin level was 83 ng/l. There are no signs of disease reccurence. From 1980 to 2011 only 89 cases of primary quadruple malignancy have been reported. The number of multiple malignancies report is slowly but gradually increasing.
Conclusion
Quadruple malignancy is a rare phenomenon in medicine and most cases of multiple malignancies affect one organ in a female patient. Our patient had family history of malignancy on mother's and father's side (father, grandmother and uncle) . She has not received chemotherapy with alkylating agents which are well known cause of secondary cancers. The patient received mitoxanthrone, drug extensively used as a disease-modifying therapy for multiple sclerosis. However, this treatment could be linked to non-malanocytic skin tumors and increased susceptibility to develop acute promyelocytic leukemia.
Further studies and closer clinical attention is needed to clarify the relation between secondary malignancies, applied treatment and endogenous and exogenous carcinogens.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P428

**Hungry bone syndrome in a patient with McCune–Albright syndrome after total thyroidectomy: case report**

J. Kollerova, T. Koller, L. Kostalova & J. Payer
University Hospital Bratislava, Bratislava, Slovakia.

McCune–Albright syndrome (MAS) is a rare disease. It is characterized by a combination of polyostotic fibrous dysplasia, autonomous overproduction of hormones and skin hyperpigmentation.
Thirty-year-old patient with significant bone deformities and the history of multiple fractures of long bones despite treatment presented with multinodular goiter with long standing hyperthyroidism. During thyroidectomy in 2009 two enlarged nodules suspected for being inferior parathyroid adenomas were removed. In the postoperative period the patient developed severe symptoms of hypoparathyroidism: overt hypocalcaemia with tetany and the need for parenteral and then oral substitution of calcium and vitamin D. The doses required to achieve normal calcaemia are shown in Fig. 1. High bone turnover in fibrous bone dysplasia and removal of the functioning parathyroid glands were probably the causes of hungry bone syndrome described. We also assume hyperthyroidism as the aggravating factor. Primary hyperparathyroidism could also be one of the manifestations of autonomous endocrine overproduction in MAS but it was not confirmed in our case (biochemical parameters prior to operation, no parathyroid hyperplasia on histology). Two years postoperatively parathyroid hormone levels are within the normal range, but the doses of vitamin D and calcium supplementation remain unusually high, Fig. 1. Currently the patient has no symptoms and is surprisingly free of fractures since the operation with marked improvement in *T*-score.
In our report we describe a case of hungry bone syndrome with severe hypocalcaemia after accidental removal of two parathyroid glands during total thyroidectomy and subsequent need of unusually high doses of calcium and vitamin D substitution in a patient with McCune–Albright syndrome.

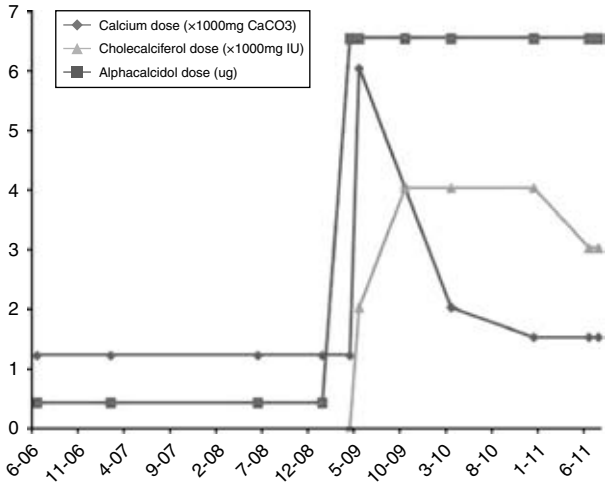

**Figure 1** Doses of vitamin D and calcium.

**A case with thyroid metastasis from small cell lung carcinoma**

A. Can[1], G. Köksal[1] & M. Sarman[2]
[1]Gayrettepe Florence Nightingale Hospital, Istanbul, Turkey; [2]Istanbul Pathology Group, Istanbul, Turkey.

Background
Among the lung carcinomas metastasizing to the thyroid, adenocarcinomas are the commonest followed by squamous, small cell, large cell and bronchioloalveolar carcinomas.
Case presentation
A 55-year-old man who presented with superior vena cava syndrome was found to have an 11 cm mediastinal mass encasing superior vena cava and compressing trachea and esophagus. The mass reached right pulmonary hilus. A bronchoscopic biopsy showed small cell carcinoma of the lung. The thyroid appeared normal on computed tomography (CT) of the chest. The patient was given chemotherapy with cisplatin and etoposide and external radiotherapy. Six months after the presentation, multiple brain metastases were detected on magnetic resonance imaging. Chemotherapy was changed to topotecan and cranial irradiation was performed. Ten months after the presentation a right thyroid nodule was detected on CT scan of the chest. On physical exam, a right thyroid nodule was palpable. $FT_4$, $FT_3$, TSH levels were within normal limits at that point, as well as antithyroglobulin and antithyroid peroxidase antibodies which were performed at a later date. Thyroid ultrasonography (USG) showed a $26.2 \times 16.8 \times 15.7$ mm hypoechoic solid nodule with irregular borders in the right thyroid lobe. USG-guided fine needle aspiration showed metastasis from small cell lung carcinoma. His cranial metastases worsened. He developed right cervical lymph node, pancreatic and meningeal metastases and passed away 15 months after the initial presentation.
Discussion
We report a rare case of thyroid metastasis from small cell lung carcinoma. After reviewing the literature and this case, we conclude the following:
1) Metastasis to the thyroid gland indicate poor prognosis, especially metastasis to the thyroid from lung carcinomas represent preterminal events.
2) In any patient with a known history of malignant disease, the appearance of a new thyroid mass should trigger a thyroid fine needle aspiration biopsy to search for metastatic disease.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P430

**Central hypothyroidism following peripheral hyperthyroidism: a brief case report**

T. Crea, E. Frehling, S. Malvaux, N. Laguerre & P. Cuny
Chr Metz Thionville, Thionville, France.

Objective
Measuring thyroid stimulating hormone levels alone may be insufficient to appropriately evaluate thyroid function. Reduced thyroid stimulating hormone

levels associated to normal/reduced $FT_4$ levels should prompt investigation of pituitary function.
Case
A 31-year-old man underwent biochemistry and thyroid function assessment for asthenia. He developed thyrotoxicosis due to painless thyroiditis with. positive.antithyroid antibodies. He had TSH level $<0.010$ mU/l (*n*: 0.35 to 4.9 mU/l), $FT_4$ level was 2.5 ng/dl (*n*: 0.7 to 1.5 ng/dl) and $FT_3$ level increased to 4.5 pg/ml (*n*: 1.7 to 3.7 pg/ml).
Subsequently 5 months later, we showed without any treatment reduced thyroid stimulating hormone levels associated to slightly decreased $FT_4$ levels and low-normal $FT_3$ levels. Endocrine assessment revealed deficiency in ACTH-cortisol, GH and IGF1 with hyperprolactinemia. Dynamic endocrine tests confirmed panhypopituitarism.
In fact, central hypothyroidism followed peripheral hyperthyroidism.
Magnetic resonance imaging showed a large pituitary tumor with cystic component with extension intra-and suprasellar suggestive of a craniopharyngioma.
The patient has a neurosurgical endoscopic transphenoidal allowing removal of the tumor and the histological analysis confirmed the diagnosis.
Conclusion
This association of peripheral hyperthyroidism with central hypothyroidism must be a rare occurrence, as a literature search has found only one case almost similar. Especially as the craniopharyngioma is a rare brain tumor and accounts for ~1.2–4.6% of all intracranial tumors. Our case illustrates coexistence of craniopharyngioma with hypopituitarism and clinically significant autoimmune thyroid disease. The presence of hypopituitarism does not preclude the development of autoimmune thyrotoxicosis.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

[2]Hospital Maria Pia, Centro Hospitalar do Porto, Oporto, Portugal.

Introduction
Neonatal diabetes is a rare condition diagnosed within the first months of life. Activating mutation of KCNJ11, the gene encoding the Ki6.2 subunit of the ATP-sensitive potassium channel, is the most common cause of permanent neonatal diabetes, and ~20% of patients have neurological features.
Patients with the severe neurological phenotype exhibit developmental delay, motor weakness, and epilepsy in addition to diabetes (DEND syndrome). Intermediate DEND syndrome is a less severe clinical picture.
Sulfonylurea therapy is associated with metabolic and neurologic improvement in these patients.
Case report
We report the case of a boy diagnosed diabetes at the age of 6 weeks, which proved to be permanent, and who was treated with insulin from diagnosis. He immigrated and was lost in follow-up since the age of 18 months until he was 19 years. When we reviewed him, there was a past of behavioural and psychomotor disabilities since the age of 4, so DEND syndrome was suspected, and he was tested for K ATP channel defects. A heterozygous mutation *p*.VAL59Met (c.175G>A) was found in exon 1 of the KCNJ11gene, confirming the diagnosis of intermediate DEND syndrome.
Glibenclamide treatment was started at age 19 and increased up the dosage of 0.6 mg/kg per day, and insulin doses were gradually reduced, leading not only to improved glycaemic control (HbA(1c) fell from 11.6 to 8.9%), but also an impressive improvement in several aspects of cognitive function.
Conclusion
Although neonatal diabetes is a rare form of diabetes mellitus, genetic studies are critical in the diagnosis and treatment of these patients.
In this case neurological and glycaemic control improvement was seen after starting glibenclamide, but did not result in freedom from exogenous insulin.

**Parkinson-like syndrom as a unusual manifestation of primary hypoparathyroidism: case report**

M. Krcma
University Hospital Plzen, Plzen, Czech Republic.

We describe case of 50-year patient with poliomyelitis in childhood, no other concomitant ilnesses, admitted in 2010 to neurologic departement of our hospital for grave parkinson-like syndrom with loss of motor function, symetric quadruparesis with spasticity, epileptic seizures and mental deterioration. These problems started about 12 months before and progressively worsened, patient was treated by levodopa and primidone. Patient was after bilateral intraocular lens implantation for cataracta of unknown origin in 40 years.
Brain CT scan reveals basal ganglia and cerebellum calcifications, blood calcium level was extremely low (1.04 mmol/l) as well as parathormone level (<5 pg/ml). Neck sonography, renal sonography, electroencephalography was without pathologic changes.
After intensive calcium i.v. supplementation (at beginning 20 mmol/day) and calcitriol supplementation patient status rapidly ameliorated. Symetric quadruparesis almost disappeared after 14-days treatment and patient was dismissed to out-patient care on peroral calcium and calcitriol medication. Next was antiparkinsonic and antiepileptic therapy diminished and 6 months after event was discontinued with no side effect.
Now, 1 year after diagnosis, patient is completely asymptomatic, with normal EEG findings, with no motor problems, fully self-sufficient, with normal ionisated and total calcium level with only substitution of calcitriol (1.5 µg daily). Screening for concomitant autoimmunities (thyroid, adrenal, pancreatic antibodies) was performed with no abnormality.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Van Wyk e Grumbach syndrome: case report**

B. Francisco[1], J. Haber[2] & R. Santos[1]
[1]Irmandade Santa Casa de Misericordia de Sao Paulo, Sao Paulo, Brazil;
[2]Universidade de Marilia - UNIMAR, Marilia, Brazil.

Introduction
In 1960, Van Wyk and Grumbach described the association of hypothyroidism and precocious puberty. Hypothyroidism leads to delayed bone age and a reduction in growth rate by reducing the amplitude of GH pulses. When precocious puberty is associated with thyroid hypofunction, estrogen action on the epiphyseal plates reduce this delay. We report the case of a child who developed incomplete puberty and reduced growth rate, caused by primary hypothyroidism.
Case report
G. 7th, female, complaining to grow 1 cm in 1 year and weight gain. Father 172 cm tall and the mother 168 cm. Child with 115 cm, 29 kg, BMI: 22 and short stature. FC: 52, TSH> 100, IO 4–5 years. Treatment with levothyroxine, TSH normalize and child thinned, antibodies. After 6 months of starting treatment developed central precocious puberty: 0.66 LH, FSH 2 TO 9.4 and Prolactin 6:36 ng/ml - normal skull CT. M2 P1, TSH 0.09, T4 1.33, IO 5 years.
Discussion
Hypothyroidism is a rare cause of precocious puberty. Van Wyk and Grumbach proposed that chronic hypothyroidism cause a negative feedback to the absence of TSH, gonadotropins and prolactin and their removal would be responsible for increased levels of TRH. The high HRT cause the increase of FSH which in turn would trigger puberty. In this case the patient did not have hyperprolactinemia.
Conclusion
This syndrome, when untreated and recently diagnosed as well as physical damage loss in stature, can provide psychosocial impairment. Therefore, immediate action is necessary to lessen or prevent the damage height and provide psychological support to children and parents in order to avoid major behavioral disorders.
Declaration of interest

## P434

**Primary hyperparathyroidism associated with autoimmune polyglandular syndrome type III and isolated IgA deficiency**

S. Savic, M. Zarkovic, J. Ciric, B. Beleslin, M. Stojkovic, T. Nisic, M. Stojanovic & B. Trbojevic
Clinical Centre of Serbia, Belgrade, Serbia.

Introduction
Isolated IgA deficiency (SIgAD) is the most common form of primary immunodeficiency. Patients with SIgAD have an increased risk of both systemic and organ-specific autoimmune diseases. Autoimmune thyroid diseases (AITD) and type 1 diabetes mellitus (T1DM) are the most common autoimmune endocrine disorders. They occur frequently together, and this combination is nominated as autoimmune polyglandular syndrome type 3 (APS 3). Primary hyperparathyroidism (PHPT) is the most common cause of hypercalcemia, most cases occur in women, mainly as a sporadic disease, most often caused by a single adenoma.
Case report
A 55-year-old woman with a past history of diabetes mellitus was admitted to the hospital for hypercalcemia found on routine laboratory testing. Her family history is negative for hypercalcemia or endocrine tumors. In addition to the presence of vitiligo, the patient was found to have AITD (anti-thyroid peroxidase antibody-positive subclinical hypothyroidism) and anti-glutamic acid decarboxylase antibody-positive diabetes mellitus (T1DM). Subsequent workup confirmed the presence of PHPT (elevated total 3.21 mmol/l and ionized serum calcium 1.70 mmol/l; serum creatinine level was normal; urinary calcium excretion was 7.7 mmol/24 h; serum intact PTH 393 pg/ml inappropriately elevated; bone densitometry showed *T* scores at the lumbar spine of $-2.5$, at the total hip of $-1.7$, and at the distal radius of $-3.0$; (99 m)Tc-sestamibi scintigraphy localized abnormal lower right parathyroid gland). Immunological investigation revealed SIgAD with serum IgA $<$ 0.24 g/l in the presence of normal levels of other immunoglobulin isotypes and no history of recurrent infections. The patient was cured after parathyroidectomy, histopathological diagnosis was parathyroid adenoma.
Conclusion
There are only rare cases of immune-mediated hyperparathyroidism, associated with anti-calcium- sensing receptor autoantibodies, frequently in context with other immune diseases. The case presented here describes association of PHPT caused by adenoma with APS 3 and SIgAD. Genetic basis for this antibody deficiency and associated autoimmunity remains to be defined.

## P435

**Reversible Hashimoto's thyroiditis: clinical, hormonal, autoimmune and ultrasonographic evidence**

M. Niedziela
Poznan University of Medical Sciences, Poznan, Poland.

Introduction
Hashimoto's thyroiditis (HT) and Graves' disease (GD) constitute a spectrum of autoimmune thyroid diseases (AITD). An abnormal thyroid echographic pattern characterized by a diffuse low echogenicity has been described in both AITD. This hypoechogenicity is due to three components: increase of intrathyroidal flow, functional changes in thyroid follicles with increased cellularity and decrease of the colloid content, resulting in the reduction of the cell/colloid interface, variable degree of lymphocytic infiltration. The first two components may be reversible during medical treatment and seem to be characteristic for GD, whereas lymphocytic infiltration may rather represent mostly HT.
Case report
A 19-year-old boy manifested initially, at the age of 15 years, the typical clinical signs of hyperthyroidism (excessive sweating, heat intolerance, sleep disturbances firm goiter (II degree), tachycardia, palpitations, nervousness, excessive sweating and tremor). Laboratory tests evidenced mild T3-dependent hyperthyroidism with decreased TSH and a positive titer of anti-TPO and anti-TG antibodies whereas TRAb were negative. Thyroid ultrasound (TUS) was heterogenous, predominantly hypoechogenic. Hashitoxicosis was diagnosed. 2.5 years later, after more than 1.5 years of no control, he was readmitted to the ward with clinical an hormonal features of hypothyroidism of autoimmune origin. Ultrasound examination showed hypoechogenicity of the gland and enhanced vascular flow based on Power Doppler analysis. L-thyroxine (L-T4) was added. 6 months later, the primary care physician withdraw L-T4 since TSH was normal as well as 3 months later. 6 months after L-T4 withdrawal the patient was still euthyroid with no goiter and full recovery of normal blood flow and normal echogenicity of the thyroid was documented (Fig. 1) thus confirming the ultrasonographic remission and reversibility of the disease however anti-TPO were still mildly elevated. Conclusion: This is the first evidence that HT, with its classic manifestation, might be reversible on clinical, hormonal and ultrasonographic grounds.

**Hypoparathyroidism - a rare cause of heart failure**

S. Zoric[1], D. Micic[1,2], A. Kendereski[1,2], G. Cvijovic[1,2], M. Sumarac-Dumanovic[1,2], D. Stamenkovic-Pejkovic[1,2] & D. Jeremic[1]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Belgrade, Serbia; [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction
Calcium plays a key role in myocardial contractions and relaxation. Heart failure induced by hypocalcemia is rare but potentially reversible case.
Case report
We present the case of 50 years old woman with muscle cramps, cataract, chest pain and dyspnea that lasts 2 years. In regional health center she was treated as psychiatric patient and COPD. Last few months she became extremely malaise with crural edemas and walking distance of 100 m. She was referred to Clinic for Cardiology and rtg of chest show cardiomegaly and bilateral pleural effusion. ECG report show negative T waves between V1-6. CK levels were extremely high, while CKMB and troponin levels were normal. Echocardiography suggested systolic and diastolic dysfunction of both left and right ventricules with mitral and tricuspid regurgitation, while EF was 37%. Standardized therapy for heart failure was started but there was no clinical effect. Coronarography was normal. Endocrinologist was consulted due to high CK levels, clinical signs of hypocalcemia were observed and calcium (1.3 mmol/l) and PTH (6 ng/ml) levels suggested hypoparathyroidism. Substitution therapy with calcium and vitamin D was started. After 1 year of therapy patient was asymptomatic. Control echocardiography was performed and both systolic and diastolic function of ventricules were normal, EF was 51%.

Conclusion
In patients with heart failure calcium levels should be tested, especially if heart failure is refractory to therapy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Hypogonadism with subsequent multi-organ involvement: a mystery solved**

C. Mohandas[1], D. Barnes[1], D. Harrington[2] & M. Haq[1]
[1]King's College Hospital, London, UK; [2]Tunbridge Wells Hospital, Pembury, UK.

A 53-year-old gentleman was seen following a recent diagnosis of type 2 diabetes in May 2009. He had suffered a subarachnoid haemorrhage in 1993 and remained under the local tertiary centre after developing secondary hypogonadism treated with testosterone replacement. The cause had never been established.
The patient had previously been diagnosed with seronegative HLA B27 arthropathy and in December 2008 was admitted with acute cardiac failure and atrial fibrillation. An echocardiogram demonstrated a moderately dilated right and left heart, global left ventricular hypokinesia, an ejection fraction of 20% consistent with dilated cardiomyopathy. He responded well to medical therapy.
He had mildly abnormal liver function tests in the past but his AST level was twice the upper limit of normal in May 2009. Subsequent iron studies revealed a transferrin saturation of 90% and ferritin of 8989 μ/l. Testosterone replacement was therefore discontinued.
Hepatitis screen and liver autoantibodies proved negative. AFP level was $< 2$. Abdominal ultrasound confirmed 23 cm hepatomegaly but no splenomegaly. The patient was confirmed to have primary haemochromatosis (codon 63-HH, codon 282-YY).
Baseline tests revealed: $FT_4$ 12.5 pmol/l, TSH of 0.6 mU/l; 0900 h cortisol 454 nmol/l; prolactin 101 mIU/l; testosterone 0.2 nmol/l, LH $<0.1$ IU/l, FSH $<$ 0.2 IU/l; IGF-1 7.1 nmol/l and GH 1.26 μ/l. A TRH test was normal but a glucagon test confirmed GH deficiency with normal cortisol response.
An MRI did not demonstrate pituitary enhancement but cardiac MRI has shown a grossly dilated LV with globally impaired function and severe myocardial iron loading. The latest ferritin is now back to normal with regular venesection and IGF1 is also normal. A recent ECHO has demonstrated return of good systolic function.
Primary haemochromatosis is an autosomal recessive disorder characterised by excess iron deposition especially in the liver, heart, pancreas, and pituitary. This case is an excellent example of why this diagnosis should be excluded in patients with unexplained cardiac failure or hypogonadism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Thyrotoxicosis-associated acute myocardial infarction and ventricular fibrillation in a patient with normal epicardial coronary arteries**

R. Trifanescu[1,2], G. Bicescu[3], L. Radulescu[2] & C. Poiana[1,2]
[1]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania; [2]'C.I. Parhon' Institute of Endocrinology, Bucharest, Romania; [3]Emergency University Hospital, Bucharest, Romania.

Introduction
Hyperthyroidism-associated myocardial infarction with normal epicardial coronary arteries on angiogram is seldom reported.
Case report
A 61-year-old Caucasian man, resident in an iodine sufficient area, presented with chest pain in the emergency unit. ECG revealed inferolateral myocardial infarction with ST-segment elevation. Soon after admission, the patients developed collapse due to primary ventricular fibrillation, requiring defibrillation. Coronary angiogram revealed normal epicardial vessels. These findings suggest that the acute myocardial ischemia was secondary to coronary vasospasm. Biochemical data showed hypokalemia ($K+=3$ mmol/l) and elevated $TT_4$ (18.26 μg/dl). After cardiac stabilization and kallium repletion, the patient was referred for endocrine assessment. Severe hyperthyroidism was confirmed (TSH $<0.03$ mUI/l, $FT_4=47.5$ pmol/l, TT3$=352$ ng/dl). TPO antibodies were slightly increased (48 IU/ml). Thyroid ultrasound revealed small diffuse goiter. Antithyroid therapy was started (Methimazole $45\rightarrow30\rightarrow20\rightarrow15$ mg/day). Despite iodine overload via coronary angiography, normalization of $FT_4$ levels (11.2 pmol/l) was noticed seven weeks later. The patient did not repeat angina, arrhythmic events or hypokalemia after normalization of thyroid function.
Conclusion
This case highlights the importance of considering hyperthyroidism in cases of myocardial infarction with normal epicardial coronary arteries. We suggest thyroid function screening in patients with coronary spasm.

## P439

**A case of papillary thyroid carcinoma with esophageal invasion treated by targeting PEI and transesophageal argon plasma coagulation**

M. Nakano & N. Fukunari
Showa University School of Medicine Northern Yokohama Hospital, Yokohama, Japan.

There are several choices for treating esophageal cancer. But only operation is the standard therapy of papillary thyroid carcinoma with esophageal invasion. Esophageal stent and gastric fistula are chose when the patient can't swallow because of esophageal stenosis by tumor invasion. But those put a lot of strain on the patient, and lower their quality of life. To reduce the burden on patient, it is useful to adopt targeting percutaneous ethanol injection (targeting PEI) and transesophageal argon plasma coagulation (APC). Targeting PEI can reduce the volume of main tumor with cutting off feeding artery. APC is used treating benign esophageal disease like a varix generally. Recently, it began to be used for treating early esophageal cancer, and some reports say it is effective treatment for tracheal invasion of head and neck tumor. We present a patient of Papillary Thyroid Carcinoma (PTC) with esophageal invasion who kept prognosis well with treatment of targeting PEI and transesophageal APC. The patient was 83 years old woman who complained dysphagia. There was a tumor at right lobe of the thyroid gland, its size was $30\times29\times24$ mm. Lung metastasis and invasion to esophagus and trachea were found by CT. Endoscopic examination detected globular tumor 20 cm away from front tooth, and it occupied 80% of esophageal lumen. We treated main tumor with Targeting PEI twice. After treatment, the size was reduced about $22\times17\times16$ mm. Next, we treated esophageal invasion with APC and PEI. After first time treatment, its size reduced to 50% of lumen. Total 5 times we did, and its size reduced to 20% finally. It has been about 40 months from last treatment, no any problems appeared.

## P440

**Association between diabetes mellitus and sarcoidosis: a case report**

A. Bulgar[1], A. Brehar[1], D. Paun[1], A. Cojocaru[2] & C. Dumitrache[1]
[1]'C. I. Parhon' National Institute of Endocrinology, Bucharest, Romania; [2]"Nova Medical Center", Bucharest, Romania.

Introduction
Sarcoidosis is a multisystemic inflammatory disease of unknown etiology, characterized by noncaseating granulomas, predominantly in the lymph nodes, lungs, eyes and skin, although any organ may be involved.
Sarcoidosis may also be associated with endocrine autoimmune diseases such as type 1 diabetes, autoimmune thyroiditis.
Case report
We present a case of a 24-year-old young man who was diagnosed in August 2010 with type 1 diabetes mellitus with a fasting plasma glucose value over 300 mg/dl. We initiated insulinotherapy with biphasic insulin aspart 30/70 22 units per day for 6 month and then insuline Glargine 26 units per day because the patient refused intensive insulin treatement. After 2 month the patient complained of chest pain and dispnoea. The chest radiography showed bilateral hilar limphadenopathy and the chest computed tomography (CT) revealed many mediastinal adenopathy (1.7–2.5 cm) and some hilar adenopathy (3 cm). A tuberculin skin test was nonreactive. Serum ACE level measured at 36.7 μ/ml (normal: 15–28 μ/ml). The performed tests infirmed tuberculosis diagnosis. Bronchoscopy: bilateral diffuse bronchitis aspect without active lesions or mucosal proliferative elements.
Bronchial aspirate revealed isolated and grouped cylindrical epithelium, squamous epithelium, posters of squamous metaplastic epithelium, relatively frequent macrophages and lymphocytes, rare neutrophils. After the diagnosis of sarcoidosis grade I–II the patient was treated with NSAIDs because corticotherapy would be negatively affected glycemic status.
Conclusion
The association between type 1 diabetes and sarcoidosis is rare and the question is if sarcoidosis was caused by the therapy with insuline Glargine. Patient should be followed up for other autoimmune diseases as sarcoidosis may be associated with autoimmune hemolytic anemia, autoimmune idiopathic thrombocythaemia, Sjogren's syndrome, autoimmune thyroid disease.

## P441

**Noninsulinoma pancreatogenous hypoglycemia syndrome as a rare cause of hyperinsulinemic hypoglycemia: case report**

B. Vukovic, T. Icin, J. Novakovic-Paro, M. Mitrovic, B. Kovacev-Zavisic, L. Todorovic-Djilas & M. Medic-Stojanoska
University of Novi Sad Medical Faculty, Clinical Center of Vojvodina, Novi Sad, Serbia.

Introduction
Adult-onset noninsulinoma pancreatogenous hypoglycemia syndrome (NIPHS) associated with hyperinsulinemic hypoglycemia is a very rare entity. Clinical features of NIPHS are similar to those of insulinoma. Hypoglycemia with neuroglycopenic symptoms presents the main diagnostic condition. NIPHS is often poorly responsive or unresponsive to medical management necessitating surgical intervention with resection of pancreatic tissue.
Case report
We report case of a 50 years old man that was addmited to our hospital 6 years ago with symptoms of postprandial hypoglycemia with low level of glucose and high level of insulin. Fasting 72 h test was performed and it was positive. CT scan showed small pancreatic lesion and patient underwent surgical resection of pancreas in pursuit of insulinoma. Microscopically and immunohistochemicaly, the pancreas exhibited nodular islet cell hyperplasia and high positivity to chromogranin A and synaptophysin. Six months after surgery patient had symptomatic hypoglycemia again, and fasting 72 h test was positive. Abdominal CT and MRI showed small multifocal pancreatic lesions and suspected hepatic metastasis, whole body scintigraphy with Tc99 m-Tektroyd and CT confirmed pancreatic lesions without hepatic metastasis. Medical management with lanreotide (120 mg subcutaneous injections once monthly) was introduced. For 2 years during treatment with lanreotide patient was euglycemic. Because we excluded metastatic disease we changed medical management from lanreotide to diazoxide. Introduction of diazoxide was associated with improvement. Unfortunately patient stopped treatment with diazoxide and after 2 years he came back with hypoglycemic symptoms and extreme obesity. We again confirmed hyperinsulinemic hypoglycemia with unchanged radiological finding on pancreas and without metastasis. Diazoxide therapy was introduced again.
Conclusion
A rare cause of hyperinsulinemic hypoglycemia in adults can be diffuse pancreatic islet cell hyperplasia. Differentiating between NIPHS and insulinoma is tricky and can present difficulty for treatment.
Declaration of interest

## P442

**A case of pneumomediastinum and tracheomalasia in thyroid storm with longstanding goiter**

K. Lee[1] & C. Park[2]
[1]Gachon university, Incheon, Republic of Korea; [2]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

Tracheomalasia is extremely rare condition in Graves' disease and may result in pneumomediastium with fistular formation from longstanding compression by a large goiter. There is no report that Graves' disease combined with tracheomalasia and pneumomediastinum. A 24-year-old woman presented with abdominal pain, diarrhea and fever. On physical examination, a large goiter was detected on her anterior neck. Computed tomography of chest showed large amount of air in anterior mediastinum. Twelve years ago, she was diagnosed Graves' disease and had not taken antithyroid drug regularly. The laboratory findings were markedly decreased TSH compared to increased thyroid hormone level and positive auto-antibody for thyroid (TBII, TSH binding inhibitory immunoglobulin). Thyroid storm was diagnosed and appropriate management was performed by using antithyroid drug, lugol solution, dexamethasone and propranolol. Dyspnea was developed because of aspiration pneumonia, mechanical ventilation was needed. After being normal range of free $T_4$, total thyroidectomy was performed. four soft and floppy tracheal rings with fistular formation were found on operation field. Extubation of endotracheal tube was difficult due to tracheomalasia, so tracheostomy was done. Weight of thyroid gland was 119.5 g. Airway obstruction is also possible due to flaccid tracheal ring after removing hard goiter encasing trachea.Therefore, in cases of total thyroidectomy with large longstanding goiter, extreme caution should be used.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P443

**A case of pancytopenia with hyperthyroidism**

K. Won, S. Park, J. Moon, J. Yoon & H. Lee
College of Medicine, Yeungnam University, Taegu, Republic of Korea.

Atypical manifestations of hyperthyroidism include hematological, cardiovascular, dermatological manifestation. Especially single lineage abnormalities such as anemia (34%), leukopenia (5.8%), thrombocytopenia (3.3%) are reported, but pancytopenia is a rare presentation of hyperthyroidism. The suspected etiologic mechanisms include ineffective hematopoiesis, reduction in blood cell life span, autoimmune process, toxicity of thyroid hormone.
We report a case of pancytopenia that was precipitated by hyperthyroidism. A 69-year-old woman presented to emergency department with more than 2 months history of general weakness, easy fatigability, weight loss of 12 kg. She took no regular medications and had no significant past medical history or family history. Laboratory data on admission were as follows: WBC 3.12 K/ul, Hb 8.4 g/dl, PLT 17 K/ul, thyroid function tests showed abnormally high concentrations of free $T_4$ ($FT_4$) and total $T_3$ ($TT_3$)($FT_4$: 51.64 pmol/l, $TT_3$: 4.58 nmol/l) with a TSH concentration below the detection limit. TRAb 264.2 U/l, anti-Tgn 773.1 u/ml, anti-TPO 3000 u/ml. Thyroid ultrasound and thyroid scan (Tc-99 m) suggested diffuse thyroiditis. Abdominal ultrasonogram showed no abnormal findings

including hepatosplenomegaly. Normocellular marrow was noted in Bone marrow aspiration and biopsy. From these results, the patient was diagnosed with pancytopenia with primary hyperthyroidism. She was started on propylthiouracil 100 mg qd, propanolol 40 mg bid and parenteral dexamethasone 1 mg bid. $FT_4$ and $TT_3$ levels decreased gradually and pancytopenia improved after 2 weeks (TSH $<0.16$ mu/l, $FT_4$ 24.42 pmol/l, $TT_3$ 2.34 nmol/l).
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P444

**Struma ovarii and the thyroid surgeon**

R. Srivastava, S. Gunasekaran, E. Kopecka, K. Maung & J. England
Castle Hill Hospital, Cottingham, UK.

Introduction
Struma ovarii is a rare ovarian monodermal teratoma. The most common presentation is an abdominal pelvic mass with pain, traditionally managed by gynaecologists. The malignant form is extremely rare and consists of differentiated thyroid cancer. It is rare for a struma ovarii to present with features of hyperthyroidism. We present a case series of struma ovarii and discuss the role of the thyroid surgeon in their management.
Methods/Results
Case 1: A 40 year old lady presented with a 2 month history of swelling in the lower abdomen. Investigations revealed a mass arising from the left ovary. Surgical histology revealed a follicular carcinoma arising in struma ovarii. She needed a total thyroidectomy prior to radio iodine therapy.
Case 2: A 60 year old lady underwent thyroidectomy for thyrotoxicosis.Three months post operatively she remained thyrotoxic despite stopping thyroxine. A whole body radio iodine scan revealed a high uptake in the left ovary. Surgical histology of the ovary showed a benign struma ovarii.
