There were significant differences between diabetic patient with coronary heart disease and control groups in MCP-1 A-2518G genotype (P: 0.01%2 χ^2: 9.11) and allele distribution (P: 0.01%2 χ^2: 6.53). MCP-1 AA genotype was significantly increased in coronary artery patients compared with controls but MCP-1 G allele frequency was increased in controls.

Conclusion
We found that MCP-1 2518 AA genotype may associate with diabetic coronary artery disease susceptibility while G allele seems to be have protective effect against diabetic coronary disease.

Phenotype-directed personalisation of therapy in type 2 diabetes mellitus patients and criteria of prescription

Tatjana Mikijanska, Viktors Snigirovs & Valdis Pirags
University of Latvia, Riga, Latvia.

Methods
We studied 228 patients with T2DM treated in Pauls Stradins Clinical University Hospital in Endocrinology Department from Jan 2013 to Sep 2014. The greatest attention was paid to the patients' biochemical analyses, such as triglycerides (TG), c-peptide, HbA1c and prescribed treatment, as well as BMI and the doctor who treated each patient. Phenotypically patients were divided into four major groups. The first group included 73 patients with chronic kidney disease (GFR <60 ml/min per 1.73 m^2), the second – 31 patient with obesity (BMI >30 kg/m^2), 66 persons represented older patients group (>65 years old) and 58 – with early diabetes (<10 years).

Results
For patients with obesity, treatment was started with insulin and metformin combination; chronic kidney disease group – with insulin monotherapy; in groups of old patients (>65 years) and early diabetes patients – with insulin monotherapy. Insulin monotherapy was used for patients with c-peptide 0.1–0.9 ng/l; for patients with c-peptide 1–2 ng/ml was used metformin combination with insulin, but patients with c-peptide more than 2 ng/ml were treated more often with DPP-4/metformin combination with insulin. There was no correlation between HbA1c level and prescribed therapy. For patients with TG level from 1.7 to 5.6 mmol/l was used metformin together with insulin, with TG <1.7 mmol/l – only insulin, but with TG over 5.7 mmol/l DPP-4/metformin combination with insulin. We found some correlation between prescribed therapy and treating physicians: three of five physicians treated their patients more often with insulin. One treated patients mostly with combination of insulin and metformin, while last – with combination of DPP-4/metformin and insulin.

Conclusion
As T2DM is a special medical condition that requires an individualised approach to each patient to achieve adequate glycaemia and HbA1c levels.

Glucogenic hepatopathy: a rare and underdiagnosed condition in type 1 diabetes

Demet Ozgil Yetkin
Kolan International Hospital, Istanbul, Turkey.

Introduction
Glycogenic hepatopathy (GH) has been reported as a very rare and under recognized complication in longstanding poorly controlled type 1 diabetes patients. GH is characterised by transient elevation of liver transaminase and hepatomegaly caused by reversible and excessive glycogen accumulation in hepatocytes. Here we report a 20 years old type 1 poorly controlled diabetic female patient with elevated transaminases.

Clinical presentation
A 20-year-old type 1 diabetic female with poor glycaemic control, complicated by recurrent diabetic ketoacidosis (DKA) was admitted, with symptoms of fatigue, nausea, abdominal pain, and vomiting. Her glycaemia had been poorly controlled with several episodes of DKA for several years. Her physical examination revealed hepatomegaly. Abdominal US showed mild fatty change of liver and mild hepatomegaly. Her HbA1c, 14.2%, SGOT: 79 (0–35) U/l, SGPT: 97 (0–35) U/l, ALP: 125 (47–119) U/l, and GGT: 247 (4–24) U/l. Auto-antibody including anti-nuclear antibody (ANA), smooth muscle antibodies (ASMA), and mitochondrial antibodies (AMA) were all negative. Thyroid function test, serum cupper, alfa1 antitripsin, and serum ceruloplasmin were also normal. The serologic findings for viral infection such as IgM anti-HAV, HBsAg, anti-HCV, HCV-RNA, cytomegalovirus, and Epstein–Barr virus were also all negative. Serum albumin and coagulation tests remained normal. She was not an alcohol or drug consumer and was not taking any medication except insulin. In addition, she did not show any symptom and sign compatible with acute hepatitis. So, we recommend her for a liver biopsy to elucidate the cause of acute elevation of liver enzyme. In hematoxylin and eosin stain, liver biopsy showed normal liver architecture, however, the hepatocytes were diffusely swollen with pale cytoplasm. The periodic acid-Schiff (PAS) staining showed abundant glycogen accumulation within hepatocytes. So, histologically, it was diagnosed as a glycogenic hepatopathy. Six weeks later, her transaminases were drooped to high normal levels via glycaemic control.

Conclusion
GH is a rare cause of increased transaminases in diabetic patients. Clinician awareness of GH should prevent diagnostic delay and will provide better insight into the prevalence of GH.

Assessment of dependence of the hypoglycaemic episodes frequency on gender factor

Elena Mahlina[1], Yana Navmenova[2] & Tatiana Mokhort[3]
[1]Republican Research Centre for Radiation Medicine and Human Ecology, Gomel, Belarus; [2]Gomel State Medical University, Gomel, Belarus; [3]Belarusian State Medical University, Minsk, Belarus.

Objective
Assessment of the frequency of hypoglycaemic episodes during daily monitoring of glucose in the subcutaneous water of women and men with type 1 diabetes mellitus.

Methods
The study of daily dynamics of glucose has been performed with continuous glucose monitoring system (CGMS) Medtronik MINIMED company (USA). The study involved 162 patients with type 1 diabetes mellitus. The patients were divided into two groups: group 1 – women with regular menstrual cycle ($n=117$) and group 2 – men ($n=45$). The groups were compared in mean age (29.14 ± 7.56 years) and duration of type 1 diabetes mellitus (10.74 ± 7.67 years).

Results
In the first group of women 53%, registered hidden hypoglycaemic episodes, and 47% were not observed ($P<0.05$). In the second group of men 69% has been registered hidden hypoglycaemic episodes, and 31% were not observed ($P<0.01$). As for the incidence of hidden hypoglycaemic episodes between the groups, the significant differences were not observed (in the first group – 53% and in the second group – 69%), $P>0.05$. Depending on the time of day, the incidence of hidden hypoglycaemic episodes (in the first group – 83% and in the second group – 75%) prevailed in comparison with explicit (in the first group – 17% and in the second group – 25%), $P<0.001$. The daytime incidence of hypoglycaemic episodes in the first group was 72%, in the second group was 85% in comparison with the incidence of night hypoglycaemic episodes (in the first group – 28% and in the second group – 15%), $P<0.05$.

Conclusions
i) Regardless of gender, the bulk of the cases occurred in hidden hypoglycaemic episodes compared with explicit ones. ii) The incidence of hidden day-time hypoglycaemic episodes was prevailed over the night incidence of hypoglycaemic episodes, regardless of gender. iii) The incidence of hidden hypoglycaemic episodes does not depend on gender.

Comparison of umbilical cord ghrelin concentrations in full-term pregnant women with or without gestational diabetes

Murat Karakulak[1], Ugur Saygili[2], Muzaffer Temur[3], Özgür Yilmaz[3], Elif Pelin Özün Özbay[4], Mehmet Calan[5] & Hese Cosar[6]
[1]Department of Obstetrics and Gynecology, Silivri State Hospital, Istanbul, Turkey; [2]Department of Obstetrics and Gynecology, Dokuzeylul University Medical School, Izmir, Turkey; [3]Department of Obstetrics and Gynecology, Manisa Merkezefendi Hospital, Manisa, Turkey; [4]Department of Obstetrics and Gynecology, Aydin Obstetrics and Pediatrics Hospital, Aydin, Turkey; [5]Department of Endocrinology, Izmir Bozyaka Research Hospital, Izmir, Turkey; [6]Division of Neonatology, Department of Pediatrics, Manisa Merkezefendi Hospital, Manisa, Turkey.

Purpose
The purpose of this study was to analyse ghrelin concentrations in the umbilical cord of pregnant women with a diagnosis of gestational diabetes mellitus. The relationship between ghrelin concentrations and birth weights was investigated.
Materials and methods
Sixty pregnant women with gestational diabetes mellitus and 64 healthy pregnant women with three oral glucose tolerance test results within normal limits were included in the study. Following birth but before extraction of the placenta, 10-ml blood samples were drawn from the umbilical vein in both groups. Ghrelin concentrations were measured.
Results
The mean birth weights of the babies born to mothers with GDM were higher than those in the control group ($P=0.04$). The cord blood ghrelin levels in pregnant women with GDM were significantly lower than those of the healthy women in the control group (879.6 pg/ml vs 972.2 pg/ml; $P=0.03$). The umbilical cord blood ghrelin concentrations in pregnant women with GDM undergoing insulin therapy were significantly lower than those of the control group (792.61 pg/dl vs 972.2 pg/dl; $P=0.01$). Inverse correlations were detected between umbilical cord blood ghrelin levels and birth weights of the babies both in the group with GDM patients ($r: -0.785$; $P=0.001$) and in the control group ($r: -0.749$; $P=0.001$).
Conclusions
In pregnant women with GDM, umbilical cord ghrelin concentrations are closely related to the birth weights of the babies. Ghrelin presumably may be among the factors influencing foetal development potentially with its GH stimulating effects or by means of other mechanisms.

The relationship between metabolic syndrome and albuminuria in patients with type 2 diabetes mellitus

Osman Sahin, Serap Baydur Sahin, Teslime Ayaz & Ekrem Algun
Recep Tayyip Erdogan University Medical School, Rize, Turkey.

Background and aims
Obesity, as a central piece inside metabolic syndrome, is as an independent risk factor for the onset, aggravated course, and poor outcomes of chronic kidney disease (CKD) including diabetic nephropathy (DN). Our aim was to investigate the relationship between metabolic syndrome (MS), diabetic nephropathy and renal function in patients with type 2 diabetes mellitus (T2DM).
Materials and Methods
197 patients with T2DM (mean age; 56.1 ± 10.2 years, female/male; 127/70) were enrolled. NCEP ATP III criteria was used for the diagnosis of MetS. Albuminuria and estimated glomerular filtration rate (eGFR) were measured.
Results
79.3% of the patients had MS. HbA1c levels were similar in patients with (8.5 ± 2.2 vs 8.5 ± 2.1) and without MS ($P=0.888$). The frequencies of diabetic retinopathy and neuropathy were not different in patients according to the presence of MS ($P>0.05$). Prevalence of microalbuminuria (32.2% vs 46%) and macroalbuminuria (12.3% vs 7.7%) was similar in subjects with and without MS ($P=0.248$). We did not find a decrease in eGFR in patients with MS compared to the patients without MS. While uric acid levels were higher in patients with MS (5.5 ± 1.5 mg/dl vs 4.7 ± 1.5 mg/dl, $P=0.006$), hsCRP values did not differ ($P=0.689$). 72.4% of the subjects were obese and the prevalence of albuminuria was not different in obese and nonobese patients ($P=0.596$).
Conclusion
In this study we did not find an association between obesity, MS, and DN.

EP418

Achievement of recommended glucose, lipid, and blood pressure targets in patients with type 2 diabetes mellitus

Ines Barka, Ines Slim, Senda Ouerdeni, Koussay Ach, Amel Maaroufi, Yosra Hasni, Maha Kacem, Molka Chaieb & Larbi Chaieb
Department of Endocrinology, Farhat Hached University Hospital, Sousse, Tunisia.

Background
Patients with type 2 diabetes mellitus (T2DM) have a greater risk for cardiovascular morbidity and mortality than those without T2DM. This risk is even further aggravated if they also suffer from hypertension and/or dyslipidaemia. However, better cardiovascular outcome can be reached by tight control of blood glucose, serum lipids, and blood pressure (BP).
Patients and methods
One hundred and nineteen patients were consecutively enrolled. Well-controlled metabolic parameters are defined as follows: HbA1c $<7.0\%$, BP $<140/90$, and LDL cholesterol (LDL-c) <2.6 mmol/l. For all patients, anthropometric measurements and metabolic risk factors were carried.
Results
A total of 119 subjects (61 men and 58 women) were included. The mean age was 58.0 ± 10.6 years old. Of these patients, 60% had hypertension. The mean value of HbA1c was $8.8\pm2.3\%$ and glycaemic control was optimal (HBA1c $<7\%$) in $20.0\pm4.1\%$. Mean values of systolic BP and diastolic BP were 135 ± 16 and 76 ± 12 mmHg respectively. BP therapeutic goal was achieved in $50\pm5\%$ of patients. The mean value of LDL-c was 2.7 ± 1 mmol/l. We noticed that 48.3% of patients had LDL-c <2.6 mmo/l. All three targets were achieved only by 5% of patients ($n=6$).
Conclusion
Even if targets of assessed metabolic parameters are known to be important to achieve in diabetic patients in order to reduce cardiovascular risk, our results shows that few individuals had achieved goals; especially oh HbA1c compared to lipids and BP goals. An urgent action is needed to increase the proportion of these individuals achieving recommended glycaemic goals by adapting lifestyle measures and medications and also by using motivational interviewing to insure therapeutic adherence.

***Staphylococcus aureus* nasal carriage and related risk factors in diabetic foot patients**

İlhan Kurultak[1], Mustafa Altay[2], Salih Cesur[3], Eda Yıldız[4] & Murat Duranay[5]
[1]Department of Nephrology, Medical Faculty, Trakya University, Edirne, Turkey; [2]Department of Endocrinology and Metabolism, Keçiören Education and Research Hospital, Ankara, Turkey; [3]Department of Infectious Disease and Clinical Microbiology, Ankara Education and Research Hospital, Ankara, Turkey; [4]Department of Microbiology, Ankara Education and Research Hospital, Ankara, Turkey; [5]Department of Nephrology, Ankara Education and Research Hospital, Ankara, Turkey.

Introduction
Infections are the major cause of increased mortality and morbidity rate in diabetic foot patients. There are little data in literature about the effects of *Staphylococcus aureus* nasal carriage on DF infection, the risk factors that

influence nasal carriage and its incidence in diabetics. We aimed to detect of the incidence, risk factors and relationship between wound culture and *S. aureus* nasal carriage in diabetic patients who have DF with this study.
Material and methods
The study was designed as a prospective, cross-sectional, controlled study. Group 1 ($n=40$): nondiabetic patients, group 2 ($n=40$): diabetics patients without DF, and group 3 ($n=40$): diabetics patients with DF. The incidence of *S. aureus* nasal carriage and effects of determined factors to nasal carriage were investigated in these three groups. The relationship between nasal carriage and wound culture was analysed in the last group.
Results
We found the incidence of *S. aureus* nasal carriage 17.5, 20, and 10% in the groups 1–3 respectively ($P=0.47$). Determined parameters (age, sex, usage of insulin/oral anti-diabetic drugs, time of diabetes, level of HbA1c, and levels of fasting and after meal glucose) did not affect the *S. aureus* nasal carriage. We did not detect the relationship between wound cultures and nasal swap cultures in group 3. We observed no effect of the history of antibiotic usage in the last 6 months and existence of hospitalization or operation on *S. aureus* nasal carriage.
Conclusion
We detected that having diabetes and/or DF did not alter the risk of *S. aureus* nasal carriage and also carriage did not affect the results of wound culture. Better designed studies are needed for the detection of possible relationship between the factors belongs to the patients who have higher risk for *S. aureus* infections and nasal carriage.

The role of fetuin A as a biomarker of atherosclerosis and its relation to type 2 diabetes

Nermeen Sheriba, Rania Sayed, Merhan Nasr, Sara Shelbaya & Magdy Abbas
Ain Shams University, Cairo, Egypt.

Background
Hyperglycaemia produces various changes in the vascular tissue at the cellular level that accelerates the atherosclerosis. There is a direct correlation among carotid arterial stiffness and serum fetuin-A level. Fetuin-A is a marker of the inflammatory nutritional state and acts as a protective agent because it solubilises the calcium phosphate salt.
Aim of this work
To study the role of fetuin A in atherosclerosis and its association with type 2 diabetes.
Subjects and methods
This cross sectional study was conducted on 50 subjects aged from 40 to 60 years old divided into group I: 20 T2DM patients having atherosclerosis. Group II: 20 non diabetic patients having atherosclerosis. Group III: ten healthy subjects as control group. They were subjected to full clinical history, thorough clinical examination, laboratory investigations including fasting and 2-h postprandial blood glucose level, HbA1c, lipid profile, measurement of plasma fetuin-A level using ELISA, and measurement of carotid intimal thickness using duplex ultrasound.
Results
There was a highly significant difference between the three groups as regard SBP, DBP, FBG, PBG, HbA1c, TG, HDL-c, LDL-c, carotid intimal thickness, and fetuin-A level ($P<0.001$) and on comparing the diabetics with atherosclerosis (group I) with non diabetics with atherosclerosis (group II) we found a highly statistical significant decrease in plasma fetuin-A level ($P<0.001$) being lower in group (I) and a highly significant increase in carotid intimal thickness, SBP, and LDL-c ($P<0.001$) in group I. We also found a highly significant negative correlation between fetuin-A and SBP, LDL-c, and carotid intimal thickness ($P<0.001$). A significant positive correlation was also found between carotid intimal thickness and SBP, HbA1c, and LDL-c ($P<0.05$). We found that the cutoff point of fetuin-A level using the ROC curve is 125 µg/ml with 100% sensitivity, 90% specificity, 97.1% accuracy, and a positive predictive value of 97.6%.
Conclusion
Our results postulate that there is an association between lower plasma fetuin-A level and the development of atherosclerosis especially in those having type 2 diabetes.

DOI: 10.1530/endoabs.37.EP420

EP421

Association of plasma fetuin-A levels and peripheral vascular disease in type 2 diabetic patients

Salah Shelbaya, Rania Sayed, Merhan Nasr & Ahmed Abd El Aziz
Ain Shams University, Cairo, Egypt.

Background
Diabetes is a risk factor for both PAD and PAD-associated mortality. Diabetic patients have worse arterial disease and a poorer outcome than nondiabetic patients. Fetuins are blood proteins made in the liver more abundant in fetal blood. Fetuin-A is regarded as an inhibitor of systemic calcification.
Aim of this work
To assess the relationship between plasma fetuin-A levels and peripheral vascular disease in type 2 diabetes mellitus.
Subjects and methods
This cross sectional study was conducted on 50 subjects aged from 50 to 65 years old divided into group 1: 20 T2DM patients with PVD. Group 2: 20 T2DM patients without PVD. Group 3: ten healthy subjects as control group. They were subjected to full clinical history, thorough clinical examination, laboratory investigations including fasting and 2-h postprandial blood glucose level, HbA1c, measurement of plasma fetuin-A level using ELISA and arterial Doppler ultrasound on peripheral vasculature for assessment of ankle peak systolic velocity (APSV).
Results
There was a highly significant increase in weight and BMI, FBG, and PBG in group 1 (diabetics with PVD) and group 2 (diabetics without PVD) than group 3 (control) ($P<0.001$). While there was a highly significant decrease in plasma fetuin-A level and APSV in diabetics with PVD when compared with diabetics without PVD and also when compared with control ($P<0.001$) While there was no statistical significant difference between group 2 (diabetics without PVD) and group 3 (control) as regard fetuin-A level ($P=0.065$). There was a highly statistical significant decrease in plasma fetuin-A level and APSV ($P<0.001$) being lower in group 1 than group 2 but there was no statistical significant difference as regard weight, height, BMI, FBG, PBG, and HbA1c. There was a highly significant positive correlation between fetuin-A and APSV ($r=0.737$, $P<0.001$) but a negative non-significant correlation between fetuin-A and the other parameters.
Conclusion
These results postulate an association between lower plasma fetuin-A level and peripheral vascular disease in type 2 diabetic patients.

DOI: 10.1530/endoabs.37.EP421

Glycaemic variability in pregnant women with gestational diabetes

Nida Oztop, Selda Celik, Yildiz Tutuncu, Elif Bagdemir, Cemile Idiz, Ayse Kubat Uzum, Ilhan Satman & Nevin Dinccag
Endocrinology and Metabolism Division, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey.

Introduction
The accurate and comprehensive assessment of glycaemic control in pregnant with gestational diabetes (GDM) is important for preventing foetal complications. We aimed to determine glycaemic variation on women with GDM with using a continuous glucose monitoring system (CGMS) and to investigate the relationship between reflecting glucose markers such as HbA1c, fructosamine (FRM), and 1,5-anhydroglucitol (1,5-AG).
Materials and methods
31 women with GDM on diet therapy only (mean age 31.9 ± 6.9 years, gestational week ≥35) were recruited from outpatient clinic. Those patients were screened by self-monitoring blood glucose (SMBG) and monitored for three consecutive days to obtain mean daily glucose data; glycaemic fluctuations were evaluated using postprandial incremental area under curve (AUC) and percent of mean absolute difference (MAD%). Venous blood samples were collected to measure HbA1c, FRM, and 1,5-AG.
Results
Prepregnancy BMI of participants was 26.2 ± 5.9 kg/m^2, weight gain during pregnancy was obtained as 12.2 ± 3.5 kg; levels of reflecting glucose markers were measured as following: HbA1c 5.0 ± 0.3 %, FRM 2.1 ± 0.2 µmol/l, and 1,5-AG 17.0 ± 4.9 ng/ml; according the results of CGM, MAD % was found as 6.7 ± 3.1%, the total number of fluctuations in glucose levels were counted as 5.8 ± 3.6. Glucose figures, measured by SMBG or CGMS were found similar (82.9 ± 10.2 and 86.1 ± 10.3 mg/dl); I statistically, there wasn't any correlation between

determinants of CGM and other glucose reflection parameters. It was realised that birth of weight and size of head circumference of babies were affected by maternal glucose levels.
Conclusion
Although, it seems that normoglycaemia is sustained, there should be glucose variability in diabetic patients especially during pregnancy and all known glucose reflecting parameters do not show fluctuations. CGMS is an alternative method for detecting glucose variations in spite of having difficulties to afford and apply the tool. We concluded that higher glucose fluctuations were observed on pregnants with GDM who have high triglyceride at fasting and high glucose levels at third hour of OGTT at the beginning.

Sexual function in women with diabetes at a Diabetes Care Unit

Eva-Karin Brannestam
Höglandssjukhuset, Eksjö, Sweden.

The true prevalence of sexual dysfunction in women with diabetes is difficult to estimate. Studies of the area have shown varying and conflicting results. There is also disagreement about the conditions that influence this relationship and the risk factors that can be linked to the phenomenon. The purpose of this study was to investigate sexual function in women with diabetes at a Diabetes Care Unit. The study was conducted using a quantitative approach. Fifty women aged 18–65 years with type 1 or type 2 diabetes were enrolled in the study in which respondents were asked to complete a questionnaire containing background questions and the questionnaire, Female Sexual Function Index (FSFI). Twenty-nine women with diabetes (60%) showed a total score below 30, which can be classified as sexual dysfunction. Those domains that showed the lowest scores of these 29 women were the domains desire, orgasm and satisfaction. Sixty-four percent of the 50 women had not received any information about sexuality linked to diabetes, but 82% thought that it was quite important or very important to discuss any changes in sexuality. The prevalence of sexual dysfunction in women with diabetes is a phenomenon that one cannot disregard. A deeper knowledge in this area would be desirable. This study demonstrated that there might be women with diabetes who experience sexual dysfunction. The majority of the women felt that it was important to discuss changes in sexuality linked to diabetes. In addition, the majority stated that it was not informed about the area through their clinic.

Particular characteristics of breath during night sleep in type 1 diabetes patients

Ina Darashkevich[1], Tatsiana Mokhort[2], Lola Nikonova[1], Serhej Tishkovsky[1] & Elina Davydchik[1]
[1]Grodno State Medical University, Grodno, Belarus; [2]Belorussian State Medical University, Minsk, Belarus.

Objective
Assessing the impact of glycaemic control on indicators of breathing during night sleep in type 1 diabetes patients.
Methods
Continuous blood glucose monitoring by 'SGMSGold' (Medtronik MINIMED) with estimation of average glycaemic value (AG) and other parameters; polysomnographic monitoring by 'SOMNOlab 2 (PSG) Polysomnography (R&K)'. Group 1 included patients with AG levels <8.0. Group 2: AG $>$ 8.0 mmol/l regardless of HbA1c (7.50 (5.00–9.40) and 8.01 (5.60–12.00)% respectively).
Results of the study
The differences in the characteristics of sleep and periods of hyperglycaemia, normoglycaemia, AG, MGL in the comparison groups were detected. There was an inverse relationship between AG <8.0 mmol/l and the mean respiratory rate TST, deep sleep S4 stage ($r=-0.64$), sleep latency ($r=-0.58$); direct correlation between amount of apnoea ($r=0.74$ and $r=0.90$); MGL with the duration of slow wave sleep ($r=-0.61$) and reverse with RE NREM ($r=0.57$).

Indicator	Group 1, mean (min–max)	Group 2, mean (min–max)
Amount (*n*)	13	20
Age	34.5 (25.0–54.0)	35.9 (20.0–56.0)
The average value of blood glucose (AG) (mmol/l)	6.6 (3.2–8.0)*	10.0 (8.1–16.6)
Hyperglycaemia (%)	11.5 (0.0–22.0)*	43.5 (10.0–86.0)
Hypoglycaemia (%)	14.4 (0.0–80.0)*	3.75 (0.0–25.0)
Normoglycaemia (%)	74.1 (20.0–92.0)*	52.7 (0.0–77.0)
The minimum glucose level during sleep (MGL) (mmol/l)	3.7 (2.0–6.1)*	5.8 (2.5–11.5)
The index of apnoea/ hypopnea (AI)	0.4 (0.3–14.8)*	2.1 (0.0–16.4)
The average duration of all respiratory events (RE) during total sleep time (TST)	25.0 (0.0–41.0)*	15.8 (0.00–40.0)

*$P<0.05$.

Conclusions
AG <8 mmol/l is associated with violations of the respiratory rate and sleep latency. It is noted that the MGL correlated with the duration of SWS, indicating that the effect of hypoglycaemia on sleep quality, the average length of all RE during TST.

DOI: 10.1530/endoabs.37.EP424

EP425

Obstructive sleep apnoea, incident type 2 diabetes mellitus, and cardiovascular risk

N Muñoz-Rivas, M Mendez-Bailon, M J Buendia, F J del Cañizo-Gomez, A Partido, A Alcorta, J de Miguel-Llanes & F J Solis-Villa
Hospital Universitario Infanta Leonor, Madrid, Spain.

Obstructive sleep apnoea (OSA) is a condition strongly associated with cardiovascular disease. Obesity is often related to both clinical problems and it is also a risk factor for incident type 2 diabetes mellitus (T2DM).
Aim
To assess cardiovascular risk among a cohort of patients with OSA in order to identify and optimise treatment of high risk patients.
Methods
Prospective study that included 72 patients with OSA under continuous positive airway pressure treatment. In all patients hypertension, T2DM, dyslipidaemia, smoking status, and history of cardiovascular disease were assessed; blood pressure (BP), body weight and height, waist circumference and neck size were measured; and BMI was calculated. Blood and urine samples were taken to evaluate fasting plasma glucose, cholesterol levels, glomerular filtration rate, microalbuminuria and HbA1c. T2DM was diagnosed with ADA criteria, and score was used to evaluate global cardiovascular risk and stratify high risk patients (score ≥ 5) in non diabetics.
Results
Of the 72 patients, 73% were male. Mean age was 52 years, and mean BMI 34.4 kg/m^2. At baseline, 52% had hypertension, 40% uncontrolled systolic BP, 50.8% dyslipidemia, 15% T2DM, 39% impaired fasting glucose (IFG), 7.6% previously unknown DM, 8.9% microalbuminuria, 44% a score >5%, and 38% were current smokers. There was a significant relationship between neck size (43.50 cm vs 40.52 cm, $P<0.05$) and BMI (35.7 kg/m^2 vs 33.4 kg/m^2, $P<0.05$) with IFG, and a significant association between apnoea–hypopnoea index (48.8 vs 37.3 apnoea/h, $P<0.05$) with high cardiovascular risk.
Conclusions
Compared with the general population, patients with OSA studied had a high cardiovascular risk and a high frequency of IFG and T2DM, especially in those with grade 2 obesity and a bigger neck size. Screening for diabetes and other cardiovascular risk factors in this population may be of particular interest.

Simultaneous pancreas–kidney transplantation effect on stabilisation/progression of diabetic complications in patients with type 1 diabetes

Alexandra Glazunova[1], Margarita Arutyunova[1], Gulia Musaeva[5], Minara Shamkhalova[1], Marina Shestakova[1,5], Yan Moysyuk[2], Alexey Pinchuk[3], Ilya Dmitriev[3] & Sergey Arzumanov[4]
[1]Research Centre of Endocrinology, Moscow, Russia; [2]Academician V.I. Shumakov Federal Research Centre of Transplantology and Artificial organs, Moscow, Russia; [3]N.V. Sklifosofskiy Moscow Health Department, Research Institute of Emergency Care, Moscow, Russia; [4]Federal Research Centre of Urology, Moscow, Russia; [5]I.M. Sechenov First Moscow State Medical University, Moscow, Russia.

Objective
To evaluate the simultaneous pancreas–kidney transplantation (SPK) effect on stabilisation/progression of complications in patients with T1DM.
Materials and methods
The study included 16 patients after SPK. Eleven peoples received standard triple immunosuppressive therapy during the study period, five patients canceled steroid therapy after 6 months. The average age was 34 years old (31; 40), duration of T1DM 22 years (20.5; 28), the duration of diabetic nephropathy10 years (8; 14.5). The duration of dialysis therapy was 2 years (0.9; 2.5). All patients remained in the study for at least months 21 (10; 36) after the transplantation. Pancreas transplant chronic rejection with normal kidney transplant function was observed in one patient in 1 year after the operation.
Results
The mean level of HbA1c before the study was 8.65% (8.4; 9.1), then decreased to 5.6% (5.5; 5.8) after SPK. According to a continuous glucose monitoring system using «iPRO2» euglycaemia (glycaemia (mmol/l) 3.9–8.9–89%, lower than 3.9–11%, and higher than 8.9–0%) was marked during the day. The level of C-peptide was 2.02 ng/ml (1.07; 2.77), of insulin 12.5 mkE/ml (11.4; 15.3), and GFR 76 ml/min per 1.73 m^2 (68; 90). All patients had normoalbuminuria, normal levels of hemoglobin 120 g/l (112; 130), parathormone 77.3 pg/ml (60.4; 92.5), phosphorus 1.2 mmol/l (1.05; 1.4), and blood pressure 110 mmHg (100.0; 120). The proliferative diabetic retinopathy progression which required vitrectomy and additional laser panretinal photocoagulation sessions was observed in 18.75% of patients. Nonstenotic atherosclerosis of the lower extremities was detected in 13 peoples, ulcerative defects in the lower limbs in five patients and chronic osteoarthropathy progression in four cases.
Conclusions
Despite the euglycaemia and renal function normalisation after SPK the progression of diabetic complications was observed. This fact indicates the need of further monitoring and treatment in this category of patients.

Influence of diabetic polyneuropathy on the severity of pain in patients with osteoarthritis of the knee joints and type 2 diabetes mellitus

Leonid Strongin, Ksenia Korneva & Elena Trifonova
Nizhny Novgorod State Medical Academy, Nizhny Novgorod, Russia.

Introduction
Osteoarthritis (OA) and type 2 diabetes mellitus (T2DM) are common diseases among middle-aged and elderly persons. Aim of our study was to assess the influence of diabetic polyneuropathy (DPN) on the severity of pain in OA in patients with concomitant T2DM.
Methods
80 female patients with OA of the knee joints in combination with T2DM were examined. The severity of gonarthrosis were assessed by Lequesne index (IL) (version 1997) using a valid questionnaire. Neurological examination included the use of the electroneuromyography (EMG).
Results
The patients were divided into two groups depending on the results of motor conduction velocity (MCV) of n. peroneus and sensory conduction velocity (SCV) of nervus suralis. Group 1 consisted of patients with normal MCV/SCV and group 2 – reduced. In group 1 with normal MCV values on n.peroneus more prominent pain associated with inflammatory changes in the knee joints by IL were noted: nocturnal pain in the knee joints was 1.32 ± 0.78 vs 0.81 ± 0.66 points in group 2 ($P = 0.04$), the ability to kneel 1.73 ± 0.46 vs 1.26 ± 0.45 points ($P = 0.01$). In contrast functional disorders (the intensity of pain during the descent one flight of stairs) were more pronounced in group 2 – 1.26 ± 0.45 vs 0.8 ± 0.68 points in group 1 ($P = 0.02$). Reduction of SCV on sensory fibres of n.suralis intensified pain when walking: in group 1 – 0.95 ± 0.40 vs 1.32 ± 0.58 points in group 2 ($P = 0.03$).
Conclusions
DPN was associated with changes in OA pain perception dependent on involvement of motor and sensory fibres. Decreased MCV masked pain associated with inflammatory changes in the knee joints. On the other hand, functional disorders associated with degenerative-dystrophic changes in OA were more marked by damage of both sensitive and motor fibres.

Lixisenatide clinical experience on patients with type 2 diabetes and obesity in Endocrinology Offices

M Mar Roca-Rodríguez[1], María Teresa Muros de Fuentes[2], Gonzalo Piédrola-Maroto[2], Miguel Quesada-Charneco[3], Silvia Maraver-Selfa[1], M José Tapia-Guerrero[1], Daniel Cepero-García[4], Rosa Orduña-Espinosa[3], Joaquín Pechuán-Asensio[5], Elena Ferrándiz-Millón[4], Purificación Galera-Martínez[2], Mercedes Vázquez-Gutiérrez[4] & Isabel Mancha-Doblas[1]
[1]Department of Endocrinology, Virgen de la Victoria and Regional Hospitals, Malaga, Spain; [2]Department of Endocrinology, Virgen de las Nieves Hospital, Granada, Spain; [3]Department of Endocrinology, San Cecilio Hospital, Granada, Spain; [4]Department of Endocrinology, Torrecardenas Hospital, Almeria, Spain; [5]Endocrinology Private Office, Granada, Spain.

Introduction
Some treatments of diabetes, such as lixisenatide, improve global metabolic status beyond glycaemic control.
Aim
To evaluate tolerance to lixisenatide and its effects on weight and metabolic control in type 2 diabetes and obese patients attended in Endocrinology Offices.
Material and method
A prospective study of patients with type 2 diabetes and obesity. In an intra-subject analysis, clinical and analytical data were evaluated at baseline and after lixisenatide treatment.
Results
We studied 104 patients (51% women) with type 2 diabetes and obesity. Average age was 58.4 ± 10.5 years, average duration of diabetes was 11.2 ± 6.7 years, and 35.6 and 69.6% had family history of cardiovascular disease and diabetes respectively. At baseline, 92.2% of the patients had oral hypoglycaemic agents, 13.5% GLP1 agonists and 67.3% insulin (44.2% basal insulin, 12.5% premixed insulin, and 10.6% basal-bolus insulin). We re-evaluated the patients 3.8 ± 1.6 months after treatment with lixisenatide. We found significant improvements in weight ($P < 0.001$), BMI ($P < 0.001$), WC ($P = 0.002$), SBP ($P < 0.001$), DBP ($P = 0.001$), fasting glucose ($P \leq 0.001$), HbA1c ($P = 0.022$), total-chol ($P < 0.001$), LDL-chol ($P = 0.046$), TG ($P = 0.020$), hypertension drugs ($P < 0.001$), and lipids drugs ($P < 0.001$). We checked that blood pressure and lipid improvement were not due to hypertension and lipid treatment intensification. No changes in levels of amylase related to lixisenatide treatment were observed. Regarding digestive tolerance to lixisenatide, 7.9% of patients did not tolerate, 5% tolerated 10 μg/day, and 85.1% tolerated 20 μg/day.
Conclusions
Significant improvement of anthropometric parameters and glycaemic control in terms of fasting glucose and HbA1c, and significant decrease of blood pressure and lipid profile were observed. Lixisenatide was safety and well tolerated in most patients. In addition, we found a significant intensification of antihypertensive and lipid-lowering therapy, not only hypoglycaemic, in our clinical practice with an overall metabolic approach of patients.

Nonglycemic effects of incretins in patients with long history diabetes type 1 and chronic kidney disease

Margarita Arutyunova, Alexandra Glazunova, Inna Klephortova, Sergey Martynov, Oxana Manchenko, Irina Ulianova, Alexandr Ilin, Minara Shamkhalova & Marina Shestakova
Endocrinology Research Centre, Moscow, Russia.

Aims
To estimate the nonglycaemic effects of incretins in patients with long history of type 1 diabetes (T1D) and chronic kidney disease (CKD).

Materials and methods
We examined 75 patients with a long history T1D (more than 20 years) and CKD on the different stages: 32 patients with CKD at the stages 1–4, 17 patients on haemodialysis, 11 with kidney transplantation, and 15 patients without CKD. In addition to routine methods of investigation we have estimated mineral and bone disorders (MBD) factors (phosphorus (P), phosphorus and calcium product (PxCa) parathormone (PTH), 25(OH)vitamin D (vitamin D), and fibroblast growth factor 23 (FGF 23)), made a multispiral computed tomography of heart with Agatston index definition. Markers of proinflammatory (monocyte chemoattractant protein-1 (MCP-1) and C-reactive protein (CRP)), fibrosis (transforming growth factor-beta (TGFβ)), and cardiovascular collapse (atrial natriuretic peptide (NTpro-BNP)) were defined. Determining the level of glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP).
Results
The study showed no difference on the level of GLP-1 and GIP in patients with a long history of T1D, regardless of the presence and stage of CKD and the degree of compensation of diabetes. Received confirmation inverse relationship between GLP-1 and the level of total cholesterol ($r=-0.320$; $P<0.05$), Agatston index ($r=-0.317$; $P<0.05$), as well as the GYP and fibrinogen level ($r=-0.285$; $P<0.05$), CRP ($r=-0.626$; $P<0.05$), FGF-23 ($r=-0.341$; $P<0.05$), and MCP-1 ($r=0.277$; $P<0.05$).
Conclusions
In patients with T1D is defined inhibitory role of incretins in the progression of atherosclerosis and MBD, actively involved in the development of cardiovascular disease, irrespective of the stage of CKD. The obtained data require further study from the standpoint of application nonglycaemic effects of drugs of incretins in the treatment of patients with T1D.

COMMODITY12 telemedicine system is effective in primary care setting in patients with type 2 diabetes

Krzysztof Lewandowski[1], Maciej Mazurkiewicz[2] & Przemyslaw Kardas[2]
[1]Department of Endocrinology and Metabolic Diseases, The Medical University of Lodz, Lodz, Poland; [2]The First Department of Family Medicine, The Medical University of Lodz, Lodz, Poland.

Background
The COMMODITY12 is a telemedicine system designed for continuous monitoring of diabetes type 1 (DM1) and DM2, as well as the cardiovascular comorbidities. The system has been created in collaboration of nine European academic and industrial partners under FP7 (www.commodity12.eu).
Aim
The aim of this study was to assess clinical utility of the COMMODITY12 system in DM2 patients, under a design of a mini feasibility trial.
Methods
Sixty outpatients from Lodz region (central Poland) with DM2 were randomly ascribed to either control arm ($n=30$), in which they received standard care, or intervention arm ($n=30$), in which they used COMMODITY12 system for daily monitoring of their diabetes-related parameters (glucose level, blood pressure, weight, ECG, heart rate, mobility, a range of lab tests, and adherence to medication). All patients were monitored for a period of 6 weeks. Primary outcome measures was system operability and whole trial feasibility, defined as harmonic technical functioning of all layers of the system, and appropriateness of the personal health system (PHS) for patient use, respectively.
Results
In general, the COMMODITY12 system functioned well, with only some problems with transmission of the data from ECG sensor to the hub. Patients accepted telemedicine system well, and found it to be helpful in self-management of diabetes. System was effective in collecting and analysing data related to both diabetes, and comorbidities (such as hypertension, arrhythmias, or sleep apnoea). In some patients using COMMODITY12 system, trend toward better metabolic control was also observed, as compared to their previous results, as well as to the control group.
Conclusion
These results point at the usefulness of COMMODITY12 system in diabetes care. Further studies on larger groups are warranted to determine the effect of the system on clinical outcomes, as well as its cost-effectiveness.
Disclosure
This Study was a part of the Commodity12 Project (COntinuous Multi-parametric and Multi-layered analysis Of DIabetes TYpe 1 and 2, www.commodity12.eu). EU 7th framework programme.

Microangiopathic complications in latent autoimmune diabetes in adults: relationship with thyroid autoimmunity

Aura Reghina[1,2], Elisabeta Sava[1], Suzana Florea[1] & Simona Fica[1]
[1]Elias University Hospital, University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; [2]National Institute of Development and Research in Pathology and Biomedical Sciences 'Victor Babes', Bucharest, Romania.

Background
Patients with latent autoimmune diabetes in adults (LADA) are a clinically, immunologically, genetically heterogeneous group and the presence of thyroid autoimmunity (TA) appears to contribute to his heterogeneity.
The aim was to evaluate the impact of TA on microangiopathic complications in LADA patients.
Materials and method
LADA has been defined by the onset of diabetes at ages above 30 years, the lack of need for insulin therapy for at least 6 months after its first appearance, the presence of anti-GAD antibodies (GADA). Positive titers of anti-thyroid peroxidase antibodies (TPOAbs) were observed in 30 (28.8%) out of 104 LADA patients. Prevalence of retinopathy (DR), peripheral neuropathy (PN), autonomic neuropathy (AN), and diabetic nephropathy (DN) were also evaluated.
Results
Patients with TA had twice the risk of RD compared to patients without TA, odds ratios 2.27 (95% CI 0.8–5.7, $P=0.004$). The risk of NP was 1.8 times higher in patients with TA compared with patients without TA (95% CI 0.7–4.4, $P=0.04$). Patients with TA are three times more likely to develop AN than patients without TA, odds ratio 3.4 (95% CI 1–11, $P=0.014$). From ten patients with DN, four of them (40%) had TA compared to 26 patients (27.7%) of 94 without DN. Patients with TA had the probability to develop this complication 1.7 times higher than those without TA, odds ratio 1.74 (95% CI 0.4–6.6, $P=0.46$).
Conclusions
Except diabetic nephropathy, the presence of TA in patients with LADA has determined a significantly higher prevalence of microangiopathic complications.

Evaluation series on safety and efficacy of nutritional supplements (ESSENS) in newly diagnosed hyperglycaemia

Sanjay Kalra
Bharthi Hospital and Research Institute, Karnal, Harayana, India.

Diabetes is endemic in society. Beyond lifestyle modification (often short lived) and metformin, which while effective has gastrointestinal side effects, other available pharmacological options are challenging to implement across populations of newly diagnosed patients. The recent position statement by ADA/EASD calls for patient-centred individualised therapies to suit patients' need. Glucose-lowering nutritional supplements may be an effective and safe option for newly diagnosed hyperglycaemia. But, their safety and efficacy have not been systematically evaluated in randomized clinical trials. In this 12-week, investigator-initiated, six-centre, randomized, double-blind, placebo-controlled, phase 3 trial, newly diagnosed subjects ($n=232$) with FPG >100 mg/dl received PreCrea (a proprietary nutritional supplement containing standardized plant extracts and dietary elements) or placebo one capsule twice daily along with lifestyle modification. Primary endpoint was the change from baseline HbA1c at week 12. Secondary endpoint was change from baseline in FPG. At week 12, HbA1c was significantly reduced from baseline with PreCrea compared to placebo (-0.91 vs $+0.08\%$); $P<0.001$). Reductions in FPG in the PreCrea group compared to placebo (P 0.0428) (-23.1 mg/dl vs -7.2 mg/dl at week 12), with no hypoglycaemia, no weight gain and no adverse effects and no difference in safety parameters. PreCrea provided clinically important and statistically significant improvements in glycaemic control compared to placebo. The efficacy (nearly 1% reduction in HbA1c), safety and tolerability profile of PreCrea

highlights its potential as an initial therapy choice in newly diagnosed hyperglycaemia and in patients intolerant or reluctant to take metformin. Longer head-to-head comparative studies would be required to evaluate efficacy with PreCrea over other oral hypoglycaemia agents in such patients. (ClinicalTrials.gov: NCT02189005; www.essens-study.com).

Association between cardiovascular disease and microvascular complications in diabetic patients

Gonzalo Allo Miguel, Elena García Fernández, Juan Carlos Romero Rodríguez, Guillermo Martínez Díaz-Guerra & Federico Hawkins Carranza
Endocrinology Service, 12 de Octubre University Hospital, Madrid, Spain.

Introduction
Diabetes mellitus is a condition on the increase, carrying a high risk of cardiovascular complications. It is, also, well known that diabetes confers a substantial burden of microvascular disease. Previous studies suggest a link between microvascular and macrovascular events in diabetes. However, just a few studies have investigated whether the presence of previous cardiovascular events is associated with microvascular disease in diabetes patients. So, this is the aim of our study.
Patients and methods
98 diabetic (48 males/50 females) patients were included. Adverse cardiovascular events were collected, including: myocardial infarction, angina, revascularization, etc. Microvascular complications include: retinopathy, nephropathy and peripheral neuropathy.
Statistical analysis
χ^2 test was used to compare the existence of microvascular complications between the groups with and without cardiovascular events.
Results
68 patients with type 2 and 20 with type 1 diabetes with mean age (52.58 ± 20.70) and mean HbA1c ($11.21 \pm 2.33\%$) were included. 14 patients (15.56%) had previous cardiovascular events. The existence of cardiovascular events was significantly correlated with the existence of, al least, one microvascular complication ($P<0.02$). Also, significant differences between the groups of patients with o without cardiovascular disease were found in the rate of neuropathy (71.43 and 24.66%, respectively, $P<0.001$) and in the rate of nephropathy (57.14 and 23.61%, respectively, $P<0.001$). These differences remained significant after adjusting for age, sex, and hypertension. There were no significant differences in the rate of retinopathy between both groups.
Conclusions
Our results show significant correlation between the existence of previous cardiovascular events and the existence of one or more microvascular complications. Moreover, we have found that diabetic patients with cardiovascular disease present significant higher rates of nephropathy and neuropathy than diabetic patients without cardiovascular events. Despite the limitations of the study, our results suggest that proper microvascular complications screening seems mandatory in diabetic patients with past cardiovascular events.

Intima–media thickness of internal carotid arteries in the diagnosis of coronary atherosclerosis in patients with type 2 diabetes and silent ischaemia

Larysa Zhuravlyova & Natalia Lopina
Kharkiv National Medical University, Kharkiv, Ukraine.

Aims
To determine the role of intima–media thickness (IMT) of internal carotid artery (ICA) in the diagnosis of coronary atherosclerosis in patients with type 2 diabetes (T2D) and silent ischaemia (SI).
Methods
We provide a retrospective analysis of 60 cases of patients with T2D (24 men, age 60.5 ± 4.7 years), history of diabetes – 4.7 ± 0.5 years. SI was diagnosed by comparing complaints, anamnesis, ECG data and daily ECG monitoring. All patients underwent carotid ultrasound in B-mode to determine the degree of ICA IMT stenosis. The degree of coronary atherosclerosis was evaluated by coronary angiography (CAG).
Results
In 55% of patients with T2D and SI the presence of atherosclerotic lesions of two or three coronary arteries (CA) localised in the middle and distal segments was identified. In 13% of patients with T2D critical subocclusion of CA was found. ICA IMT values were significantly higher in patients with SI and coronary atherosclerosis compared to patients with T2D without atherosclerotic CA lesions (1.41 ± 0.12 vs 1.21 ± 0.11, $P<0.05$), in 20% of patients with T2D and SI the presence of atherosclerotic plaques of ICA was revealed. When conducting multiple logistic regressions in patients with T2D and SI the following predictors of atherosclerotic CA lesions were identified: duration of T2D (OR 4.07, 95% CI 2.56–4.32; $P<0.05$), dyslipidaemia (OR 2.17 95% CI 1.47–3.12; $P<0.05$), gender (OR 1.52, 95% CI 1.14–2.31; $P<0.05$), and ICA IMT (OR 2.81, 95% CI 1.76–3.21; $P<0.05$). AUC value in the analysis of ROC-curve for ICA IMT was 0.75 (95% CI 0.61–0.79; $P<0.05$).
Conclusion
Increased thickness of ICA intima–media and CA atherosclerotic plaques combined with coronary atherosclerosis in patients with T2D and SI should be considered during the screening of this group of patients to identify those to perform CAG and early revascularisation for the prevention of cardiovascular events.

The relationship between adipokines and diastolic dysfunction in patients with type 2 diabetes mellitus with overweight

Larysa Zhuravlyova & Nelya Sokolnikova
Kharkiv National Medical University, Kharkiv, Ukraine.

The mechanisms of myocardial damage are complex and studied insufficiently in patients with diabetes mellitus type 2 (DM2) with overweight. The contribution of adipokines leptin and resistin into the formation of diastolic dysfunction (DD) in patients with DM2 remains understudied. The purpose of the study was to evaluate the relationship between the state of leptin and resistin activity and DD in patients with DM2 with normal and overweight.
Methods
94 patients with DM2 without systolic dysfunction were randomized into two groups: group 1 ($n=34$) patients with DM2 with a BMI <25 kg/m^2 and group 2 ($n=60$) patients with a BMI >25 kg/m^2. The levels of leptin and resistin were determined by ELISA. Echocardiographic method was performed to measure peak velocity of early diastolic filling flow (peak E), peak velocity of late diastolic filling flow (peak A), the peak E/peak A ratio (E/A), and deceleration time of early diastolic filling (DT).
Results
In group 1 the level of BMI was 24.47 ± 0.52 kg/m^2, leptin 11.76 ± 0.68 ng/ml, resistin 10.17 ± 0.35 ng/ml, the value of the E/A 0.94 ± 0.04, and DT 230.47 ± 3.51 ms. In group 2 the level of BMI was 34.49 ± 0.68 kg/m^2, leptin 22.75 ± 0.49 ng/ml, resistin 14.19 ± 0.18 ng/ml; the value of the E/A 0.81 ± 0.03, and DT 241.72 ± 2.18 ms. In the group 1 a reliable correlation wasn't revealed. In the group 2 a significant correlation was revealed between E/A and leptin ($R=-0.27$ ($P<0.05$)); between DT and leptin ($R=0.35$ ($P<0.05$)); between E/A and resistin ($R=-0.26$ ($P<0.05$)); and between DT and resistin ($R=0.28$ ($P<0.05$)).
Conclusion
Hyperleptinaemia and hyperresistinaemia make a significant contribution to the DD in patients with DM2 with overweight and increase the risk of cardiovascular complications.

Stroke in prediabetic patients

Julia Silva-Fernández[1], Rafael García-Ruiz[2], Paloma Moreno-Moreno[3], Rosa María García-Ruiz[4] & Carolina González-Pereira[5]
[1]Endocrinology Unit, Mancha Centro General Hospital, Alcázar de San Juan (Ciudad Real), Spain; [2]Neurology Unit, Mancha Centro General Hospital, Alcázar de San Juan (Ciudad Real), Spain; [3]Endocrinology Unit, Reina Sofía University Hospital, Córdoba, Spain; [4]Pedreguer Primary Care Center, Pedreguer (Alicante), Spain; [5]Intensive Care Unit, Central de Asturias University Hospital, Obiedo (Asturias), Spain.

Objective
To describe the clinical characteristics of stroke in patients with prediabetes mellitus (pre-DM) and to compare them with DM and non-DM patient characteristics.
Methods
Retrospective analysis of a prospective series of acute stroke patients. Demographic and clinical characteristics were compared among the three groups, along with outcome data. Stroke severity was evaluated by modified Rankin scale (mRS) and NIHSS (NIH stroke scale).
Results
138 patients (50 non-DM, 32 pre-DM (23%), and 56 DM). Median age was 74.5±15.35, 73.38±13.20, and 73.84±11.44 years respectively. 44% of non-DM, 53.1% of pre-DM and 58.9% of DM patients were men. The prevalence of other vascular risk factors in non-DM, pre-DM, and DM patients was: hypertension (46, 71, and 89%, $^{**}P<0.05$), hypercholesterolemia (42, 65, and 69%, $^{*}P<0.05$), peripheral artery disease (4, 6.2, and 7.1%), and atrial fibrillation (6, 15.6, and 16%). Smoking habit was more common in pre-DM patients (15.6% vs 14% in non-DM patients and 7.5% in DM patients). Stroke characteristics: prevalence of ischemic stroke (IS) was 88% in non-DM patients, 84.3% in pre-DM and 94.6% in DM patients (P 0.24). Transient ischemic attack was more common in non-DM patients (36.3% of IS vs 33.3% in pre-DM and 20.7% in DM patients) (P 0.28). There were no differences in stroke severity between non-DM, pre-DM, and DM patients (4.9±6.2; 4.5±6; and 4.9±5.4 NIHSS median points each group), neither in 3-month mortality (12, 12.5, and 7.1%) and in 3-month mRS (2.18±2.21; 1.81±2.2; and 1.96±1.92). rtPA success rate was 80, 66, and 33% respectively (P 0.91). P (all groups), $^{*}P$ (non-DM/pre-DM patients), and $^{**}P$ (pre-DM/DM patients).
Conclusion
Frequency of pre-DM in higher than observed in general population (10%). Pre-DM patients occupy an intermediate situation regarding vascular risk factors but has no impact on stroke outcomes.

Introduction
Type 2 diabetes mellitus is a conformational disease (CD), characterised by deposition (fibrils and cytotoxic oligomers) of the human islet amyloid peptide (hIAPP). CDs have devastating effects on the sufferers and their caregivers, as well as a tremendous economic impact on families and the health system. Novel molecule candidates targeting self-assembled amyloidogenic proteins represent a potential therapeutic approach for CDs.
Methods/design
In this work we carried out a systematic study in order to determine the interrelation between the IAPP and IAPP 20–29 fragments in aggregation kinetic with a novel family of naphthalene compounds, used as chemical chaperones. *N*-(2-aminoethyl)-*N′*-1-naphthylsuccinamide A; methyl (2-((4-(1-naphthylamino)-4-oxobutanoyl)amino)ethyl) dithiocarbamate B; (2R)-2-(6-methoxy-2-naphthyl) propanoic acid (Naproxen) C; *N*-(4-(1-naphthylamino)-4-oxobutanoyl)-β-alanine D; 6-((4-(1-naphthylamino)-4-oxobutanoyl)amino) hexanoic acid E; *N*3,*N*3′-ethane-1,2-dyilbis(*N*1-1-naphthylsuccinamide) F; *N*-(4-aminobutyl)-*N′*-1-naphthyl-succinamide G; and (1E,6E)-1,8-*bis*(4-hydroxy-3-methoxyphenyl)octa-1,6-diene-3,5-dione (Curcumine). We describe the structural features, aggregation kinetics, and toxic properties of the, in presence or absence of a novel naphthalene of the chemical chaperones family.
Results
We found a stronger inhibitory effect in the fibril formation of the chaperones B, C, D, E, and G. Transmission electron microscopy showed the presence of long and curly fibers in the sample control, while the samples treated with chaperones A, B. C, D, and E, generated several amorphous and disaggregated structures. A cytoprotective effect of the chaperones family on cerebellar granule cells was found in the MTT assays. Furthermore, the binding sites of the chemical chaperones to hIAPP were located by means of docking on the IAPP 3D model.
Conclusion
In this study we managed to obtain chaperones that bind to the native state, to the cytotoxic oligomers and the amyloid fibrils. Chaperones derived from naphthalene can regulate fibre formation processes by binding to the native state, minimising the formation of amorphous aggregates, as well as cytotoxic oligomers.

Continuous glucose monitoring systems and the improvement in hypoglycaemic awareness post-islet transplantation: a single-centre cohort study

Clare Flood & Shareen Forbes
University of Edinburgh, Edinburgh, UK.

Background
Islet transplantation is an NHS-funded procedure introduced to the UK in 2011 for patients with the most severe type 1 diabetes mellitus (T1DM). These particular patients have unstable blood glucose, frequently occurring episodes of severe hypoglycaemia and impaired awareness of hypoglycaemia (IAH).
Objectives
To evaluate the effectiveness of islet transplantation in improving glycaemic control, reducing the burden of hypoglycaemia and improving awareness of hypoglycaemia through a single-centre cohort study at the Royal Infirmary of Edinburgh.
Methods
A retrospective analysis of data collected over 3 years from the 16 patients who have undergone islet transplantation in Scotland. HbA1c was measured and continuous glucose monitoring systems (CGMS) were utilised to assess glycaemic control, while Gold and Clarke score questionnaires tested IAH.
Results
Glycaemic control significantly improved, as illustrated by percentage time in hypoglycaemia in the months following transplant ($P=0.0211$) and HbA1c ($P=0.0426$). Improved Clarke ($P=0.0034$) and Gold ($P=0.0001$) scores indicate improved glycaemic awareness following transplant.
Conclusion
Our observations in 16 patients suggest that in selected patients, islet transplantation can be a life-changing procedure capable of improving glycaemic control and IAH in select patients with a history of frequent and severe hypoglycaemia. Data can be collated with that from other UK centres to increase statistical power and establish statistical significance for correlation statistics.

EP439

HDL levels is associated with left ventricular ejection fraction in type 2 diabetic patients

Eui-Hyun Kim & Hyun-Ae Seo
Daegu Fatima Hospital, Daegu, Republic of Korea.

Introduction
Considering the high prevalence and significant morbidity and mortality of heart failure in type 2 diabetic patients, identification of risk factors for cardiac

dysfunction is important. The ejection fraction represents how well the heart is pumping out blood and is used to diagnose heart failure. In this study, we investigated the factors associated with left ventricular ejection fraction (LVEF) in type 2 diabetic patients.
Methods
A total of 369 type 2 diabetes patients were included in the present study. We conducted trans-thoracic Doppler echocardiography for evaluating cardiac function. Height, body weight, blood pressure, and biochemical markers were measured for each patient.
Result
The mean age of total patients was 61.24 ± 12.27. The mean LVEF was $58.63 \pm 9.15\%$. In total patients, HDL was significantly positively correlated with LVEF ($r=0.163$, $P=0.002$). This significant association was retained in multivariate analysis adjusted for age, BMI, creatinine, haemoglobin, and presence of hypertension ($r=0.164$, $P=0.003$). In order to rule out the possibility of increasing LVEF due to diastolic heart failure, we performed subgroup analysis. In patients with type 2 diabetes who have normal diastolic function, LVEF and HDL was significantly positively correlated ($r=0.246$, $P=0.013$). Triglyceride (TG) was significantly negatively associated ($r=-0.217$, $P=0.029$). After adjusted by age, BMI, creatinine, haemoglobin, and presence of hypertension, the positive correlation between LVEF and HDL was retained ($r=0.206$, $P=0.045$). TG was not associated with LVEF after adjustment ($r=-0.089$, $P=0.393$).
Conclusion
In the present study, we found that HDL level is significantly associated with LVEF in type 2 diabetic patients with or without diastolic heart failure. This suggests that the treatment for raising HDL might have a role in the improvement of heart function in type 2 diabetic patients.

Low testosterone and erectile function in male patients with type 2 diabetes

Vitaliy Luchytskiy & Eugen Luchytskiy
SE 'Institute of Endocrinology and Metabolism named after V.P. Komissarenko National Academy of Medical Science of Ukraine', Kyiv, Ukraine.

Erectile dysfunction (ED) – frequent disease that accompanies diabetes or is its complication. According to various reports the prevalence of ED in males with type 2 diabetes (T2DM) varies from 25 to 90%. In recent years, the ED is considered as predict factor in the development of T2DM in men and as a marker of vascular complications progression.
Aim
To examine the state of androgens in men suffering from T2DM and erectile dysfunction.
Material and methods
We observed 205 male patients (48 ± 4.6 years) with T2DM (HbA1c did not exceed 6.5%) with complaints on ED. Erectile function was determined with international index of erectile function scale. Levels of total testosterone (tT), estradiol (E_2), and LH in blood serum were measured with immunoferment method. The controls – 24 healthy men without diabetes and ED (25–58 years).
Results
The average index of erectile function scored 17.23 ± 2.08 points and was lower than in the controls – 26.75 ± 0.79 ($P<0.01$). Satisfaction with sexual intercourse was reduced compared with the controls (9.34 ± 0.93 vs 16.18 ± 0.68 points ($P<0.01$). Orgasmic feelings and sexual desire were lower in T2DM patients than is controls (6.48 ± 0.72 vs 9.23 ± 0.26 points ($P<0.05$) and 9.44 ± 0.95 vs 13.93 ± 0.56 points ($P<0.01$) respectively). The index of erectile function in T2DM patients studied showed moderate ED in 62.4% cases (15.1 ± 0.68) and severe ED in 22.4% of patients (12.2 ± 0.44). Levels of tT in group 41–50 years was 3.1 ± 0.47 ng/ml, 51–60 years was 2.7 ± 0.71 ng/ml, and >60 years was 2.9 ± 0.55 ng/ml vs 5.63 ± 0.9 ng/ml and were lover than in control (5.63 ± 0.9 ng/ml). Serum levels of E_2 in patients did not differ from the controls (0.17 ± 0.04 pmol/l vs 0.14 ± 0.02 pmol/l), as well as LH concentrations (4.28 ± 0.36 IU/l vs 4.2 ± 0.5 IU/l).
Conclusions
Low testosterone is an important pathogenic factor in the development of ED in men with T2DM.

Glargine insulin treatment during pregnancy in type 1 diabetes mellitus

Paloma Moreno-Moreno, Rafael Palomares-Ortega, Concepción Muñoz-Jiménez & María Ángeles Gálvez-Moreno
Management Unit of Clinical Endocrinology and Nutrition, University Hospital Reina Sofía, Córdoba, Spain.

Objective
The aim of this study was to evaluate maternal and neonatal outcomes in women with type 1 diabetes mellitus (DM1), and analysing differences associated to insulin glargine exposure during pregnancy.
Patients and methods
Retrospective descriptive study of pregnancies in women with DM1 (2004–2012). Variables analysed: baseline characteristics (age, time of diabetes evolution, microvascular complications, and weight), maternal outcomes (weight gain, HbA1c, hypoglycaemia, preeclampsia, abortions, and vaginal delivery and caesarean section) and neonatal outcomes (gestational age at delivery, birth weight, and congenital malformations). The pregnancies were divided in groups attending to their exposition to glargine insulin and were analysed to evaluate possible differences between them (group 1: exposed and group 2: unexposed).
Statistical analysis
Comparing proportions with the χ^2 and comparing means with Student's *t*-test.
Results
132 pregnancies in women with DM1. Group 1: 57 (43.2%) and group 2: 75 (56.8%). Baseline characteristics were similar in both groups. HbA1c was different before pregnancy (group 1 vs group 2: 7.95% vs 7.02%; $P=0.001$), but similar during pregnancy (group 1 vs group 2: first trimester 6.83% vs 6.47%; second trimester 6.45% vs 6.33%; and third trimester 6.67% vs 6.42%; $P>0.05$). Maternal weight gain was similar in both groups (group 1 vs group 2: 10.28 kg vs 11.02 kg, $P=0.4$). Maternal and neonatal outcomes (group 1 vs group 2): abortions 1 (2%) vs 9 (12%), $P=0.05$; caesarean section 18 (31.5%) vs 39 (52%), $P=0.005$; gestational age at delivery 38.02 weeks vs 38.12 weeks, $P=0.93$; macrosomia 13 (23%) vs 21 (28%), $P=0.29$; congenital malformations 3 (23%) vs 6 (28%), $P=0.49$; and neonatal hypoglyceamia 1 (2%) vs 5 (7%), $P=0.13$.
Conclusions
The number of caesarean sections was higher in women not exposed to insulin glargine. Insulin glargine use before and during pregnancy is not associated with worse maternal and neonatal outcome, or congenital malformation.

Hemorheological alterations in type 2 diabetes patients with nephropathy

Min Young Lee, Sehee Jo, Min Jin Kim, Ji Sun Nam, Shinae Kang, Jong Suk Park, Chul Woo Ahn & Kyung Rae Kim
YUMC, Seoul, Republic of Korea.

Background
Hemorheologic alterations or changes in blood viscosity have been suggested to play a role in the pathogenesis of diabetic microvascular complications. We measured various hemorheologic parameters in type 2 diabetes patients at different stages of chronic kidney disease (CKD) and assessed their possible role as early markers of diabetic nephropathy and renal insufficiency.
Methods
One hundred and five patients with type 2 diabetes were divided into four groups according to glomerular filtration rate (GFR). Hemorheologic parameters, including erythrocyte deformability, fibrinogen/elongation index (EI), and aggregation index (AI) were measured using microfluidic hemorheometer. Various metabolic parameters were assessed from fasting blood samples and urine albumin/creatinine ratio (ACR) was calculated from first morning voided urine.
Results
There were significant differences in RBC deformability, AI, critical stress, fibrinogen/EI, and albumin/creatinine ratio among patients in different stages of CKD (all $P<0.05$), RBC deformability and fibrinogen/EI significantly differed between normal and CKD 2 patients while there was no such difference in ACR. In multiple regression analysis, fibrinogen/EI at 3Pa was an independent predictor of GFR ($\beta=-0.328$, $P<0.05$). Also, AI, critical stress, and fibrinogen/EI were significantly different among patients at different stages of diabetic nephropathy, with a significant difference in fibrinogen/EI between normal and microalbuminuric patients (all $P<0.05$).
Conclusions
RBC deformability and fibrinogen/EI are sensitive parameters measured via point-of-care testing for detecting erythrocyte alterations in early CKD and

nephropathy in patients with type 2 diabetes. Further studies are warranted to verify their use as screening tools for diabetic nephropathy and renal impairment.

Impact on quality of life in peoples with painful diabetic peripheral neuropathy

Chong Hwa Kim[1], Su Jin Jeong[1], Ji Oh Mok[2], Ki Young Lee[3] & Sung Rae Kim[4]
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Sejong General Hospital, Bucheon, Republic of Korea; [2]Division of Endocrinology and Metabolism, Department of Internal Medicine, Soon Chun Hyang University Bucheon Hospital, Bucheon, Republic of Korea; [3]Division of Endocrinology and Metabolism, Department of Internal Medicine, Gacheon University Gil Hospital, Incheon, Republic of Korea; [4]Division of Endocrinology and Metabolism, Department of Internal Medicine, Bucheon St. Mary's Hospital, The Catholic University of Korea, Bucheon, Republic of Korea.

Objective
This study was performed to determine the impact on quality of life and sleep impairment of painful diabetic peripheral neuropathy (PDPN).
Research design and method
The study pool consisted of 200 randomly selected peoples with type 2 diabetic peripheral neuropathy. PDPN was diagnosed using visual analogue scales (VAS) and medical history. The patients were asked to answer the Brief Pain Inventory-Short Form (BPI-SF), Medical Outcomes Study Sleep (MOS-Sleep) Scale, EuroQol (EQ-5D), and VAS and estimate the quality of life in people with diabetic peripheral neuropathy.
Results
Among the patients with diabetic peripheral neuropathy ($n=200$), 82 (41%) were diagnosed with PDPN. PDPN was independently associated with age, fasting plasma glucose, hypertension, dyslipidaemia, and previous cerebrovascular events. All pain severity and interference measures were higher in patients with PDPN than those in patients with painless DPN and patients with PDPN reported more impaired sleep and lower EQ-5D and VAS scores. 200 patients had DPN and Pain Severity Index and pain interference items such as general activity, mood, walking, normal work, relationship, sleep, and enjoyment of life in BPI–DPN were higher in patients with painful DPN compared to those in patients with painless DPN. MOS 6 items-sleep adequacy, respiratory problem during sleep, sleep initiation problem, sleep maintenance problem, and somnolence-sleep scale were lower in patient with painful DPN than painless DPN. EQ-5D index were lower in patients with painful DPN compared to those in patients with painless DPN.
Conclusions
Patients with painful DPN have greater discomfort during daily activities and sleep, and reduced QoL compared to patients with painless DPN. This study provides on the extent of the impact of pain on QoL in patients with painful DPN and physicians should carefully consider pain symptoms in patients with diabetic peripheral neuropathy.

Prevalence and management of peripheral diabetic neuropathic pain in a hospital diabetes clinic: how are we doing?

Anna Haley & Parijat De
Department of Diabetes and Endocrinology, City Hospital, Birmingham, UK.

Introduction
Peripheral diabetic neuropathic pain (PDNP) as a significant complication of diabetes mellitus (DM), which is present in 16–26% of patients. NICE UK guidelines recommend that physicians should make an formal enquiry about distressing neuropathic symptoms annually and that either duloxetine, amitriptyline, gabapentin, or pregabalin should be used as first-line treatment for neuropathic pain.
Aims
To assess the prevalence PDNP in a diabetic cohort and whether management was according to NICE guidelines. Patients attending an outpatient clinic in SWBH, Birmingham were prospectively consented to answer questions regarding sensations in their feet and lower legs using an adapted and validated questionnaire from the 'Lily Toolkit' and validated 'S-LANSS score' for identifying pain of neuropathic origin.
Results
A total of 100 patients (July–Oct 2014) agreed to answer questions, of which 65% were males (average age 62 years). 98% of patients had an annual foot check: via GP (88), podiatrist (6), or hospital specialist (4), with formal assessment of their ulcer risk but did not include questions about painful neuropathy. 27% ($n=27$) patients admitted getting pain in their feet or lower legs, which was consistent with PDNP. The average pain score in this group was seven out of ten and two-thirds had spoken to a healthcare professional about their symptoms in the past. Of these, 5/27 (19%) were on one of the recommended medications for PDNP; amitriptyline ($n=1$), gabapentin ($n=2$), and combined amitriptyline and gabapentin ($n=2$).
Discussion
In this diabetic cohort, foot checks with respect to ulcer risk were reliably undertaken by the GP. However, 27% of patients had symptoms consistent with PDNP but nearly 79% weren't on any of the first line treatments recommended by NICE. Would incorporation of questions about symptoms of PDNP into the annual primary care foot checks improve the detection rates and subsequently the management of these patients?

EP445

The effect of metformin on spontaneous apoptosis in patients with type 2 diabetes

Aleksandra Panchenko, Kondratska Iryna & Mankovsky Boris
P.L. Shupyk National Medical Academy of Post-graduate Education, Kiev, Ukraine.

Today, there are 382 million people living with diabetes. The overwhelming majority have a type 2 diabetes. Metformin is first-line drug is for many of them.
Materials and methods
The study involved 26 patients in mean age 54.46 ± 1.2 years (from 41 to 65), among them, 14 women and 12 men. 21 patients with newly diagnosed diabetes and five patients receiving treatment with sulfonylureas. All patients were prescribed metformin in mean dose 2000 mg. During the study were determined the levels of HbA1c and spontaneous apoptosis before and after treatment. Measurement of apoptosis were performed by flow cytometry.
Results

Showing	Before treatment ($n=26$)	After treatment ($n=26$)
HbA1c (%)	8.34 ± 0.24	7.57 ± 0.22*
Spontaneous apoptosis (%)	15.9 ± 1.7	11.8 ± 1.2*

Significant difference between the indices before and after treatment (*$P<0.05$). Analysing the results obtained in the groups of patients a significant decrease in HbA1c and a significant decrease in spontaneous apoptosis.

Conclusions
Metformin in the treatment of diabetes mellitus leads to a decrease in blood glucose and compensation of diabetes. And also metformin reduces the level of spontaneous apoptosis. However, studies of mitochondrial changes membrane potential revealed statistically ($P<0.05$) significant reduction cells with signs of apoptosis $15.9 \pm 1.7\%$–$11.8 \pm 1.2\%$ after 90 days of therapy. It the increase in mitochondrial activity and resistance MNCs that turn points to restore energy components of blood cells. And no changes on indicators of surface markers indicating exactly on stimulatory effect of therapy.

Microalbuminuria by concentration serum and urine levels of adropin in patients with type 2 diabetes mellitus

Kader Ugur[1], Burak Oz[3], Yusuf Ozkan[1], Selcuk Yusuf Sener[1], Bedrettin Orhan[3] & Suleyman Aydin[2]
[1]Department of Endocrinology, Faculty of Medicine, First University, Elazig, Turkey; [2]Department of Biochemistry, Faculty of Medicine, First University, Elazig, Turkey; [3]Department of Internal Medicine, Faculty of Medicine, First University, Elazig, Turkey.

Introduction
Diabetes mellitus is an important public health problem due to defects of the effect of the insulin or insulin deficiency, accompanied by chronic microvascular complications with diabetic nephropathy is characterised by proteinuria that the increasing number of patients progress to end stage renal disease. Many peptide hormone made in etiopathogenesis is situated, although adropin which discovered in recent years involves in glucose homeostasis, its relation to diabetes and nephropathy has still not been investigated. Thus, in this research, the determining of serum and urine levels of adropin in diabetic patients, the relationship between adropin and diabetes mellitus with diabetic nephropathy were aimed to investigate.
Methods
The serum and urine levels of adropin in 20 healthy individuals to form a control group with total of 60 diabetic patients including normoalbuminuric 20, microalbuminuric 20, and overt albuminuric 20 ones were measured.
Results
Serum adropin levels compared with the overt albuminuric group were significantly as lower in healthy control, normoalbuminuric, and microalbuminüric groups (respectively; $P=0.007$, $P<0.001$, and $P=0.008$). Adropin were found to be positively correlated with serum creatinine and microalbuminuria levels (respectively; $P=0.031$, $r=0.242$ vs $P=0.001$, $r=0.379$). Adropin urine levels were significantly as higher in diabetic patients than in healthy controls ($P=0.001$). Compared with the normo and overt albuminuric groups, adropin urine levels were lower in microalbuminuric group ($P=0.026$ for both).
Discussion
As a result, the serum adropin levels appear to be increased in overt albuminuric group. The cause of increased activity of these peptides associated with endothelial function and energy homeostasis can be considered for renal hemostasis. Urinary adropin levels to be lower only in the diabetic microalbuminuric group, can be identified triggering factor clinically at the initial phase of diabetic nephropathy due to the fact that a peptide hormone.

Remitting seronegative symmetrical synovitis with pitting oedema syndrome in association with saxagliptine: case report

Muge Bilge[1], Mine Adas[1,2], Aysen Helvaci[1] & Recep Yilmaz Bayraktarli[1,3]
[1]Internal Medicine, Okmeydani Education and Research Hospital, Istanbul, Turkey; [2]Endocrinology, Okmeydani Education and Research Hospital, Istanbul, Turkey; [3]Radiology, Okmeydani Education and Research Hospital, Istanbul, Turkey.

Background
Remitting seronegative symmetrical synovitis with pitting oedema (RS3PE syndrome) is a very rare clinical entity including a tenosynovitis of the hands and wrists, and marked pitting oedema on upper and lower extremities. RS3PE has been suggested to be associated with many disease conditions and drugs. Saxagliptine is DPP4 inhibitor that relatively new oral hypoglycaemic agent. This case is the second report of the occurrence of RS3PE in patients receiving a DPP4 inhibitor.
Case
A 51-year-old man presented with bilateral hand oedema. The symptoms onset within after initiating saxagliptine of the treatment. He had type 2 diabetes mellitus (HbA1c = 6.6%), and hyperlipidaemia. At the time of presentation, his other medications were metformin, premixed insülin (aspart and protamine), and rosuvastatine. He did not have any history of drug allergy or systemic rheumatic illness. Physical examination revealed tenosynovitis characterized by swelling and moderate tenderness of the metacarpophalangeal and proximal interphalangeal joints bilaterally. There was marked non-tender pitting edema on the dorsum of both hands and wrist joints. Physical exam results were otherwise normal. Laboratory evaluation revealed normal ESR, and negative ANA, ANCA, RF, and ACPA. X-rays and MRI revealed only soft-tissue swelling without evidence of joint destruction. Owing to the absence of complete remission with removal of saxagliptine during the 4 weeks, saxagliptine was tought to be responsible for the aetiology of RS3PE syndrome. Than patient was treated with prednisone 20 mg daily. Clinical findings were dramatic response to prednisone.
Conclusions
This case demonstrates a possible direct aetiological link between saxagliptine and RS3PE.

Effects of dietary nitrate on metabolic status and myocardial ischaemia–reperfusion injury in type 2 diabetic rats

Asghar Ghasemi[1], Sajad Jeddi[1], Saeedeh Khalifi[2], Mahboubeh Ghanbari[2], Ali Rahimipour[2] & Faranak Kazerouni[2]
[1]Research Institute for Endocrine Sciences, Endocrine Physiology Research Center and Endocrine Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Department of Medical Laboratory Sciences, Faculty of Paramedical Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran.

Introduction
Considering the protective effects nitrate has against diabetes and cardiovascular diseases, we aimed to determine effects of dietary nitrate on metabolic status and myocardial ischemia–reperfusion (IR) injury in type 2 diabetic rats.
Methods
Rats were divided into four groups ($n=7$): control, control + nitrate, diabetes, and diabetes + nitrate. Diabetes was induced by nicotinamide + streptozotocin, and nitrate added to drinking water (100 mg/l) of animals for 2 months. Serum nitrate + nitrite (NOx), glucose, lipid profile, total antioxidant capacity (TAC), catalase (CAT) activity, and systolic blood pressure (SBP) were measured before and after the study. After 2 months, i.v. glucose tolerance test was performed and hearts were perfused by Langendorff apparatus; before and after IR, LVDP, and $\pm$dp/dt, and heart levels of malondialdehyde (MDA) and NOx were measured.
Results
Diabetic rats had lower serum NOx values compared to baseline (29.2 ± 5.6 µmol/l vs 39.0 ± 3.2 µmol/l, $P<0.05$), which normalized after nitrate therapy. Serum glucose in the diabetes + nitrate group was less increased, than the diabetes one (24.1% vs 90.2%; $P<0.05$). Nitrate therapy in diabetic rats significantly improved glucose tolerance and decreased serum cholesterol, LDL-C, and triglycerides by 22.9, 54.2, and 47.6% respectively and increased serum HDL-C by 42.4% compared to baseline. Diabetic rats had lower TAC and CAT activity, which normalized after dietary nitrate therapy. Recovery of LVDP and + dp/dt were 15 and 17% lower in diabetic rats vs controls respectively, but almost normalized after dietary nitrate, which also restored elevated SBP to near normal status (131.2 ± 4.4 vs 120.6 ± 2.2). Compared to controls, heart NOx level was lower in diabetic rats before IR, but was higher after. Diabetic rats had higher MDA levels both before and after IR, which along with heart NOx levels stabilized following dietary nitrate.
Conclusions
Nitrate therapy improved glucose tolerance, restored dyslipidaemia, prevented increase in SBP, and provided cardioprotection against IR injury in diabetic rats.

The influence of erythropoietin therapy on serum level of tumour necrosis factor alpha in anaemic patients with early stages of diabetic nephropathy

Ivan Pchelin & Alexander Shishkin
St. Petersburg State University, St. Petersburg, Russia.

Aims
Anaemia occurs early and predicts high risk of cardiovascular events and death in patients with diabetic nephropathy. In our previous studies we have shown that haemoglobin level has a negative correlation with serum levels of proinflammatory cytokines in this clinical group. It could be hypothesised that treatment of anaemia has anti-inflammatory effects. The aim of this study was to assess the influence of treatment with erythropoietin alpha on serum level of tumour necrosis factor alpha (TNFα) in patients with early diabetic nephropathy.
Methods
We included 36 patients with type 2 diabetes mellitus and early diabetic nephropathy (CKD stages 1–3) complicated with anaemia. Patients with non-renal causes of anaemia and/or iron overload were not included. The main group (17 patients) received erythropoietin alpha subcutaneously (starting from 30 IU/kg with further correction of dose according to NKF-K/DOQI Guidelines, 2006) and iron medication orally (ferrous sulphate, 200 mg/day) for 16 weeks. The control group (19 patients) received only oral iron medication (ferrous sulphate, 200 mg/day) for the same period of time. Besides performing routine clinical tests we measured serum concentrations of TNFα using EIA before and after 16 weeks of treatment. Mann–Whitney *U* test was used to compare mean levels of TNFα in study groups. Wilcoxon's test was used to assess dynamics of this parameter during treatment in each group.
Results
Before treatment we found no difference in mean serum levels of TNFα in clinical groups: main group – 30.8 ± 4.5 pg/ml, control group – 27.5 ± 3.9 pg/ml (reference value <50 pg/ml). After 16 weeks of treatment both groups had no significant changes in concentrations of TNFα as compared to initial values. Mean serum levels of TNFα were as follows: main group – 25.0 ± 3.6 pg/ml, control group – 31.1 ± 4.2 pg/ml ($P>0.05$ for the difference between studied groups).
Conclusion
The results of the study suggest that neither treatment with iron sulphate nor comprehensive antianaemic therapy with erythropoietin alpha and iron medication don't lead to a reduction in serum concentration of TNFα in anaemic patients with early stages of diabetic nephropathy.

Metabolic status in patients with type 1 diabetes mellitus

Elena Vashchenko
The Republican Research Centre for Radiation Medicine and Human Ecology, Gomel, Belarus.

Objective of the study was to analyse the relationship of compensation, lipid profile parameters and androgenic status in patients with type 1 (DM1) depending on the duration of diabetes. There were examined 76 men with DM1 aged 20–49 years (mean age 35.8 ± 8.2) and duration of diabetes more than a year. The control group consisted of 25 healthy men aged 21–41 years (mean age 34.6 ± 7.8). Compensation of diabetes was assessed by the level of HbA1c. Also there were assessed the lipid profile parameters (total amount of cholesterol and triglycerides), total testosterone, FSH, LH, prolactin hormone, sex hormone binding globulin, and homocysteine. Statistical analysis of the data was performed using the software package Microsoft Exel 2003 (SPSS 17.0).

It has been determined that at the absence of compensation in patients with DM1 (HbA1c $8.3 \pm 1.4\%$), with the increasing duration of diabetes there was noticed the increasing of BMI: a group with DM <10 years, 24.6 ± 3.9 kg/m^2, the group with DM >10 years, 27.6 ± 4.4 kg/m^2 ($P=0.01$), progression of lipid storage disease (increased level of triglycerides: 1.4 ± 1.1 mmol/l vs 3.7 ± 1.3 mmol/l in the group with DM >10 years ($P=0.01$)). We were not found the difference in levels of total cholesterol, LH, FSH, prolactin hormone, sex hormone binding globulin, and homocysteine. The absence of androgenic status disorders and changes of homocysteine level are probably associated with the young age of patients, a slight excess of weight and a lack of decrease in GFR. The detected changes are important risk factors of development and progression, and require appropriate arrangements, including the correction of body weight and secondary dyslipidaemia.

The effect of exenatide treatment on serum ghrelin levels in patients with type 2 diabetes

Figen Topyildiz[1], Sinem Kiyici[1], Zulfiye Gul[2], Deniz Sigirli[3], Metin Guclu[1], Gurcan Kisakol[1] & Sinan Cavun[2]
[1]Department of Internal Medicine, Sevket Yilmaz Education and Research Hospital, Bursa, Turkey; [2]Department of Pharmacology, Medical Faculty, Uludag University, Bursa, Turkey; [3]Department of Bio-Statistics, Medical Faculty, Uludag Univesity, Bursa, Turkey.

Aim
Ghrelin plays an important role in stimulation of food intake and long-term regulation of body weight. In present study we aimed to investigate the effect of exenatide treatment on serum ghrelin levels in patients with type 2 diabetes.
Methods
Fourteen women patients with type 2 diabetes treated with metformin and exenatide were enrolled in the study. A mixed meal test was applied to the patients while they were using their daily medications. Serum total ghrelin, glucose and insulin levels were investigated at baseline (0th min) and at the 60th, 120th, and 180th min after a mixed meal test. On the following week exenatide treatment of the patients was paused for 24 h and the same experimental procedures were repeated.
Results
Serum ghrelin levels were found suppressed significantly at the 60th and 180th min compared with baseline values after mixed meal test with exenatide treatment ($P=0.042$ and $P=0.000$ respectively). While percentage change in serum ghrelin levels after mix meal tests with and without exenatide usage were compared, no significant difference was found at the 60th and 120th min. But percent changes in serum ghrelin levels at the 180th min was statistically significant ($P=0.001$).
Conclusions
In present study we found that exenatide treatment suppresses serum ghrelin levels for longer time compared with the results of skipped exenatide treatment. These results suggest that the effect of exenatide on weight loss may be related with prolonged suppression of serum ghrelin levels, which is an orexigenic peptide.

EP453

The effect of compensation of diabetes on ulcer healing in patients with diabetic foot syndrome

Maksym Prystupiuk
Bogomolets National Medical University, Kyiv, Ukraine.

Introduction
Diabetic foot syndrome is a common surgical pathology. It is the main cause of lower limb amputations, which can be avoided in 85% of cases by active detection and long-term compensation of T2DM, timely diagnostics of peripheral neuropathy.
Purpose
To study relation between compensation of diabetes (by HbA1c) and time needed for healing of ulcers and purulent processes in patients with neuroischaemic forms of diabetic foot.
Results
The results of treatment of 363 patients were worked out: 164 males (45%) and 199 females (55%), the average age of men 65 ± 0.20 years, women 70 ± 0.22 years ($P<0.001$). By admission, patients had been treated by oral hypoglycaemic medicines in combinations of up to three drugs at the time with maximum permissible doses. In hospital all subjects were treated with insulin. The most common surgery was opening of abscesses and phlegmons in 40% of males and 60% of females. Amputations of lower limbs and phalanges were performed in 40% of men (over 66 years) and 20% of women (over 70 years). In terms of post-prandial glycaemia, compensation of diabetes was achieved in 22% of males and 32% of females, stay period in hospital of whom was the lowest.
Conclusions
i) With HbA1c $15.5 \pm 1.0\%$, duration of treatment of neuroischaemic forms of diabetic foot lasted 34.66 ± 0.40 days for males and 31.42 ± 1.18 days for females, while with HbA1c $12.6 \pm 1.2\%$ it lasted 16.60 ± 0.26 and 18.95 ± 0.51 days respectively. ii) Fasting glycaemia up to 6 mmol/l and post-prandial glycaemia up to 10 mmol/l are the best values for enhancing reparative processes in patients and shortening their hospital stay. iii) Among patients with uncompensated diabetes, number of limb amputations is so high that this should motivate patients for conducting adequate treatment and self-control of diabetes.

Lixisenatide improves glycaemic control and body composition in uncontrolled type 2 diabetic patients treated with insulin

Florentino Carral, Carmen Ayala, Antonia Piñero, Ana Isabel Jiménez, Coral Exposito & Concepción García
Endocrinology Department, Puerto Real University Hospital, Puerto Real, Cádiz, Spain.

Objective
Evaluate the efficacy and safety of adding lixisenatide to uncontrolled type 2 diabetic (T2DM) patients treated with insulin.
Methods
A prospective uncontrolled study was designed. Primary endpoints (measured at 3 and 6 months) were change in HbA1c, weight, and insulin doses. Variables analysed were: HbA1c level, insulin and other hypoglycaemic agents doses, capillary glucose tests, number and type of hypoglycaemias, side effects and body composition analysis (Tanita SC-330).
Results
Data from 42 T2DM patients (55% women; mean age: 57.7 ± 7.4 years; and T2DM duration: 13.5 ± 8.7 years) treated with insulin were analysed. A significant decrease in HbA1c levels (7.6 ± 0.8% vs 7.8 ± 1.1% vs 9.1 ± 1.6%; $P < 0.001$) and weight (95.2 ± 14.8 kg vs 95.8 ± 14.4 kg vs 98.5 ± 13.9 kg) was observed at 3 and 6 months compared to baseline and % of fat mass had also reduced at 6 months (33.9 ± 7.6% vs 38.8 ± 8.1%; *P*: 0.01). Total insulin doses decreased from baseline (61.2 ± 37.3 UI/day) to 3 (52.5 ± 34.8 UI/day; *P*: 0.02) and 6 months (49.4 ± 30.5 UI/day; *P*: 0.021). Low incidence of no serious hypoglycaemias (1.0 ± 1.7 mean episodes/month) was referred. Six patients (14.2%) discontinued lixisenatide treatment due to side effects (four patients for nausea or vomiting, one patients for hypertransaminasemia, and one patient for uncontrolled hyperglycaemia). Three patients (7.1%) were lost to follow-up for unknown reasons.
Conclusions
In our clinical experience, lixisenatide contributes to improving glycaemic control as facilitates weight loss and insulin doses reduction in T2DM patients uncontrolled with insulin.

EP455

Liraglutide improves β-cell function, measured by the C-peptide/glucose ratio, in obese patients with type 2 diabetes

Ana M Ramos-Leví[1] & Miguel A Rubio[2]
[1]Department of Endocrinology and Nutrition, Instituto de Investigación Princesa, Hospital Universitario Princesa, Universidad Autónoma, Madrid, Spain; [2]Department of Endocrinology and Nutrition, Instituto de Investigación San Carlos, Hospital Clínico San Carlos, Universidad Complutense, Madrid, Spain.

Introduction
β-cell function declines progressively in patients with type 2 diabetes (T2D). the fasting C-peptide/glucose ratio (Cp/G) is used for its evaluation. The GLP1 receptor agonist liraglutide improves glucose and weight control, presumably due to improvement of β-cell function and/or mass. This study evaluates the effect of a 6-months' treatment with liraglutide in β-cell function, measured by Cp/G, in patients with obesity and T2D.
Materials and methods
We analysed 43 patients (24 women) with orally treated T2D and obesity, to whom liraglutide 1.2 mg/day was added. At 3 months, liraglutide was increased to 1.8 mg/day if HbA1c or weight goals were not fully achieved. We evaluated clinical and analytical data before and after a 6-months' treatment. Cp/G was used to assess β-cell function.
Results
Basal characteristics before liraglutide (mean ± S.D.): BMI 39.3 ± 4.9 kg/m^2, T2D duration 6.7 ± 3.8 years, fasting glucose (FG) 149.8 ± 36.9 mg/dl, HbA1c 7.6 ± 0.8%, HOMA 6.1 ± 3.3, and Cp/G 0.0261 ± 0.0103. 26 (60.5%) patients previously received one oral-hypoglycemic-agent (OHA), and the rest, two. At 3 months, dosage was increased to 1.8 mg/day in 24 (55.8%) cases; these patients had higher pre-treatment HbA1c (7.8 ± 0.9% vs 7.3 ± 0.7%, $P = 0.025$) and lower Cp/G (0.0235 ± 0.0099 vs 0.0295 ± 0.0101, $P = 0.057$), compared to those who remained on 1.2 mg/day. After 6 months of liraglutide, BMI 37.3 ± 5.2 kg/m^2, percentage weight loss (%WL) 5.2 ± 4.8 kg, FG 132.5 ± 47.3 mg/dl, HbA1c 6.8 ± 1.2%, and HOMA 4.8 ± 3.2 ($P < 0.05$ in all cases). Cp/G at 6 months increased 15.4 ± 36.6%, reaching 0.0296 ± 0.0148 ($P = 0.047$), regardless of pre-treatment HbA1c or final dosage of liraglutide. Pre-treatment Cp/G correlated with %WL ($r = 0.310$, $P = 0.043$) and HbA1c at 6 months ($r = -0.482$, $P = 0.001$) . Decrease of HbA1c and %WL were similar regardless of pre-treatment HbA1c, BMI, or Cp/G. Individuals with pre-treatment Cp/G within the lower quartile achieved 6-month HbA1c levels <7% less frequently.
Conclusions
Liraglutide seems to improve β-cell function, measured by Cp/G, after 6 months, regardless of basal BMI, HbA1c, or Cp/G. A lower basal Cp/G is associated to lower rates of optimal glucose control after 6 months of treatment with GLP1 agonists.

Study of irisin hormone level in type 2 diabetic patients with and without diabetic neuropathy

Mohammad Halawa[1], Manal Abushady[1], Mohammed Abd El Fattah[2] & Mohammed Hassan[2]
[1]Ain Shams University, Cairo, Egypt; [2]Military Medical Academy, Cairo, Egypt.

Background and aims
Irisin is a novel myokine that promote energy expenditure. It could act on adipocyte metabolism through a novel neural pathway and on the other hand irisin induces neural proliferation and adequate neural differentiation. We aimed to assess serum irisin level in type 2 diabetics (T2DM) and correlate it with metabolic parameters. Also, we assessed the relation between irisin level and diabetic peripheral neuropathy (DPN).
Methods
We recruited 60 T2DM subjects and 30 healthy controls. Diabetics will be divided into 30 patients without complications and 30 with DPN. DN4 questionnaire was used to screen for diabetic neuropathy. Serum irisin, FPG, 2 h PG, HbA1c, TG, fasting insulin, and HOMA-IR were measured.
Results
Irisin level was significantly lower in diabetics than control (40.92 ± 17.99 ng/ml vs 160.14 ± 58.67 ng/ml, $P < 0.01$). Diabetics with PN had lower irisin than diabetics without complications (27.57 ± 7.61 ng/ml vs 54.27 ± 15.24 ng/ml, $P < 0.01$). Irisin levels were negatively correlated with FBS ($r = -0.487$), 2 h PG ($r = -0.570$), HbA1c ($r = -0.596$), fasting insulin ($r = -0.368$), HOMA-IR ($r = -0.441$), and TGs ($r = -0.327$) in all studied groups ($P < 0.01$). Also, it was negatively correlated with the duration of diabetes in all diabetics (-0.764, $P < 0.01$). We found a negative correlation between irisin and age only in healthy subjects (-0.480, $P < 0.01$). Multiple regression analysis revealed that HbA1c, age, F. Insulin, BMI, and HOMA-IR respectively were independent determinants for irisin level.
Conclusion
We found that serum irisin levels were decreased in T2DM. Lower irisin level may be associated with peripheral neuropathy. Irisin levels associated inversely with insulin resistance.

Clinical experience with lixisenatide in patients with obesity and type 2 diabetes

Cristina Tejera[1], Esther Delgado[2], Cristina Porca[1], Francisco Morales[2], Diego Bellido[1] & José Díaz[2]
[1]Endocrinology and Nutrition Unit, University Hospital of Ferrol, Ferrol (Galicia), Spain; [2]Endocrinology and Nutrition, University Hospital of Badajoz, Badajoz (Extremadura), Spain.

Introduction
Agonist receptor-GLP1 (AR-GLP1) had demonstrated its utility in obese patients with diabetes type 2. Since August 2013 we have available in Spain a new AR-GLP1 with prandial action in a single daily dose, lixisenatide. There are different clinical trials that support its efficacy and security but the dates from real clinical practice are scarce.
Aim
To analyse the efficacy and security in real clinical practice for the treatment of diabetic type 2 patients with BMI ≥ 30 kg/m^2 in a 12 months period.
Materials and methods
Data from patients attending in an Endocrinology Unit from two Spanish centres were collected in a retrospective way ($n = 77$). Initially, during 7 days patients received lixisenatide 10 μg in single dose and later, they received the maintenance dose of lixisenatide 20 μg. Primary endpoint was change in HbA1c from baseline.

Body weight, adverse effects and others treatment for diabetes were collected. Available data were analysed with SPSS 20.
Results
77 obese (32 males, age 58.02 ± 12.5 years old) and type 2 diabetic patients (mean weight 94.53 kg, mean duration of diabetes 7.1 years, and mean HbA1c 9.01%). Data at 12 months of treatment were analysed. In this period, the HbA1c decreased −1.04 ± 0.29% ($P<0.001$) and the body weight decreased 6.26 ± 2.56 kg ($P=0.01$). Insulin was discontinued in 12.5% of the patients, mean initial dose 44 UI, mean final dose 29 UI, $P=0.01$. Mild transient gastrointestinal side effects were experimented by 8%. Three patients discontinued treatment (vomiting and refusing s.c. injection).
Conclusions
In our study, the efficacy of lixisenatide had been superior that reported in clinical trials in both aspects, HbA1c control and weight lost. In addition, this treatment had reduced the insulin requirements. Side effects are infrequent and mostly mild. More studies are necessary to support our results.

Controlled attenuation parameter have close relationship with the prevalence and the severity of non-alcoholic fatty liver disease in a type 2 diabetes mellitus population

Jaehyuk Lee[1], Kwang Joon Kim[2], Bong Soo Cha[2] & Eun Seok Kang[2]
[1]Division of Endocrinology, Department of Internal Medicine, Myongji Hospital, Goyang-si, Republic of Korea; [2]Division of Endocrinology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.

Background
The severity of non-alcoholic fatty liver disease (NAFLD) in type 2 diabetes mellitus (T2DM) population compared with that in normal glucose tolerance (NGT) individuals has not yet been assessed by a quantitative method. We investigated the prevalence and the severity of NAFLD in a T2DM population using controlled attenuation parameter (CAP).
Methods
Subjects who underwent testing for biomarkers related to T2DMand CAP using Fibroscan during a regular health check-up were enrolled. CAP values of 250 and 300 dB/m were selected as the cutoffs for the presence of NAFLD and for moderate to severe NAFLD respectively. Biomarkers related to T2DM included fasting glucose/insulin, C-peptide, HbA1c, glycoalbumin, and HOMA-IR.
Results
Among 340 study participants (T2DM, $n=66$; pre-diabetes, $n=202$; and NGT, $n=72$), the proportion of subjects with NAFLD increased according to the glucose tolerance status (31.9% in NGT; 47.0% in pre-diabetes; and 57.6% in T2DM). The median CAP value was significantly higher in subjects with T2DM (265 dB/m) than in those with pre-diabetes (245 dB/m) or NGT (231 dB/m) (all $P<0.05$). Logistic regression analysis showed that subjects with moderate to severe NAFLD had a 2.4-fold (odds ratio) higher risk of having T2DM than those without NAFLD ($P=0.02$; 95% CI 1.13–4.86), and positive correlations between the CAP value and HOMA-IR ($\rho=0.407$) or C-peptide ($\rho=0.402$) were demonstrated.
Conclusion
Subjects with T2DM had a higher prevalence of severe NAFLD than those with NGT. Increased hepatic steatosis was independently associated with the presence of T2DM, and insulin resistance induced by hepatic fat may be an important mechanistic connection.

Risk factors, aetiology, and prognosis in patients with ischaemic stroke and diabetes mellitus

Julia Silva-Fernández[1], Rafael García-Ruiz[2], Paloma Moreno-Moreno[3], Rosa M García-Ruiz[4] & Carolina González-Pereira[5]
[1]Endocrinolgy Unit, Mancha Centro General Hospital, Alcázar de San Juan, Ciudad Real, Spain; [2]Neurology Unit, Mancha Centro General Hospital, Alcázar de San Juan, Ciudad Real, Spain; [3]Endocrinology Unit, Reina Sofia University Hospital, Córdoba, Spain; [4]Pedreguer Primary Care Center, Pedreguer, Alicante, Spain; [5]Intensive Care Unit, University Central Hospital of Asturias, Oviedo, Asturias, Spain.

Objective
To describe the clinical, aetiological and prognostic differences in diabetic and non-diabetic ischaemic stroke (IS) patients.
Materials and methods
Retrospective analysis of prospective series of IS patients. Patients were classified as non-DM and DM patients. Demographic and clinical characteristics were compared between two groups. IS prognosis was evaluated by modified Rankin scale (mRS) and NIHSS (NIH stroke scale).
Results
138 were included (53 diabetic and 71 non-diabetic). Mean age was 73.95 (± 14.43) years in DM patients and 74 (±11.51) in non-DM. The prevalence of hypertension (88.6% vs 66.9%, $P<0.05$), hypercholesterolemia (56.6% vs 33.8%, $P<0.05$), coronary artery disease (15% vs 8.4%, P 0.18), peripheral artery disease (3.7% vs 2.8%, P 0.76), previous stroke (33.9% vs 15.4%, $P<0.05$), and atrial fibrillation (16.9% vs 9.8%, P 0.24) was higher in DM patients compared to non-DM patients. Smoking habit was more common among non-DM patients (15.4% vs 7.5%, P 0.13). Stroke subtype distribution didn't differ between two groups: Atherothrombotic etiology (18.8% in DM patients vs 14% in non-DM patients), cardioembolic (24.5% vs 28.1%), lacunar (20.7% vs 18.3%), and undetermined (35% vs 39.4%). The prevalence of transient ischaemic attack was higher among non-DM patients (33.8% vs 22.6%, P 0.19). There were no differences in stroke severity between DM patients and non-DM patients. mRS 0–2 at discharge prevalence was 74.5% vs 76%, P 0.94. NIHSS ≥8 was 25% vs 21.1%, P 0.49 respectively.
Conclusions
Our study reveals a higher prevalence of other vascular risk factors in diabetes patients. We have found no differences in relation to IS subtype and IS prognosis.

Establishing the relationship between third-trimester foetal abdominal circumference, birthweight, and neonatal morbidity in gestational diabetes

Maria Teresa Pereira[1], Susana Garrido[1], Raquel Almeida[1], Joana Vilaverde[1], Fernando Pichel[2], Clara Pinto[3], Joaquim Gonçalves[3] & Jorge Dores[1]
[1]Division of Endocrinology, Diabetes and Metabolism, Centro Hospitalar do Porto, Porto, Portugal; [2]Division of Nutrition, Centro Hospitalar do Porto, Porto, Portugal; [3]Division of Obstetrics, Centro Hospitalar do Porto, Porto, Portugal.

Introduction
Gestational diabetes (GD) is associated with a significantly higher risk of perinatal complications. It has been suggested that third-trimester (3thT) foetal abdominal circumference ($_f$AC) determination is an important predictor of macrossomia and large for gestational age (LGA).
Aims
The purpose of this study was to evaluate the association between the 3thT $_f$AC percentile with birthweight (BW) and adverse neonatal outcomes in a cohort of women with GD.
Methods
We retrospectively analysed the $_f$AC percentile of the 3thT ultrasound screening in pregnant women with GD within a 2 years period in a Central University Hospital. We enrolled 268 pregnant women with singleton pregnancy undergoing routine fetal biometry after 28 weeks. The relationship between $_f$AC and BW was explored using the Spearman's correlation and among $_f$AC percentile groups (<50; ≥50) and adverse neonatal outcomes using the Fisher's exact test.
Results
The study included 268 singleton pregnancies; the median maternal age was 33 years old (range, 17–52) with a median delivery week of 39 weeks (range, 29–41). The median BW was 3165 g (range, 1370–4450), 3thT ultrasound gestational age measurement 36 weeks (range, 29–40) and $_f$AC percentile 50 (range, 1–100). Neonatal outcomes prevalences: neonatal morbidity compositum ($n=67$; 25%), small for gestational age ($n=25$; 9.3%), LGA ($n=24$; 9.0%), macrossomia ($n=12$; 4.5%), and neonatal hypoglycaemia ($n=5$; 1.9%). The macrossomia and LGA rates were greater in the $_f$AC percentile group ≥50 compared to <50 (91.7% vs 8.3% and 95.8 vs 4.2% respectively) ($P<0.05$). There was no significant difference in neonatal hypoglycaemia rate between groups (80% vs 20%, $P=0.384$). We documented a strong positive correlation between $_f$AC and BW: $R=+0.626$, $P<0.001$ ($R^2=0.392$).
Conclusions
The intrapartum $_f$AC measurement was useful in screening fetal macrossomia and LGA. These results suggest that $_f$AC measured by ultrasound can help to predict the BW and seems to be a valuable parameter to be included when we evaluate a gestational diabetic pregnant woman.

Usefulness of carotid ultrasonography as a screening test for coronary artery disease in Korean diabetic patients

In-Jin Cho[1], Sei Hyun Baik[2], Yoo-Chul Hwang[1], Kyu Jeung Ahn[1], Ho-Yeon Chung[1] & In-Kyung Jeong[1]
[1]Department of Endocrinology and Metabolism, Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; [2]Department of Endocrinology and Metabolism, Korea University Guro Hospital, Seoul, Republic of Korea.

Carotid intima–media thickness (IMT) has been shown an independent predictive marker of coronary artery disease (CAD) and cardiovascular disease in many studies. We investigated the usefulness of carotid IMT as a screening test for CAD in Korean diabetic patients. We conducted retrospective study and found the type 2 diabetic patients without cardiovascular disease history who underwent carotid ultrasonography (US) and stress echocardiography (SE) from June 2006 to December 2012 at Kyung Hee University Hospital at Gangdong. Total 218 patients were reviewed by medical record, laboratory data, carotid US, SE, and coronary angiography results. Carotid US abnormalities were defined as $\geq$1 mm IMT or detection of plaque. Significant CAD was defined as $\geq$50% luminal narrowing in $\geq$1 epicardial arteries or their major branches. We assessed predictive value for CAD according to results of carotid US or SE.
116 patients (53.2% of 218 patients) had carotid US abnormalities and 34 patients (15.6% of 218 patients) shown positive SE. Patients with carotid plaque were old age (65.4$\pm$9.5 years vs 56.7$\pm$9.3 years, $P<0.001$), had long duration of diabetes (11.8 years vs 7.8 years, $P<0.001$), and low BMI (25.1$\pm$3.4 kg/m^2 vs 26.4$\pm$3.6 kg/m^2, $P<0.001$) compared to patients with normal carotid US. However, there was no difference in prevalence of positive SE between patients with carotid plaque and patients with normal carotid US (15.5% vs 15.7%, $P=0.968$). In patients with positive SE, there was no difference in prevalence of significant CAD whether they had carotid plaque or not.
52 of 218 patients underwent coronary angiography. 32 of 52 patients had positive SE and positive predictive value of SE in significant CAD was 84.4% (27 of 32 patients). Of 32 patients with positive SE, 16 patients had carotid plaque and all of them had significant CAD. In conclusion, carotid US abnormalities alone had limitation to correlated SE results and predict significant CAD. However, when taking into carotid US results with SE results, they improved positive predictive value in significant CAD.

Beneficial effects of antioxidant property of *Aegle marmelos* leaves serum antioxidant status on blood glucose levels in diabetes type 2 subjects

Vinita Nigam & Vanisha Nambiar
MS University, Vadodara, Gujarat, India.

Background
Diabetes mellitus is one of the most recognized and clinically significant disorders of the endocrine system, Based on recent advances and involvement of oxidative stress in complicating diabetes mellitus, efforts are on to find suitable antidiabetic and antioxidant therapy. *Aegle marmelos* (L.) Corr. is one of the most important Indian medicinal plants which has enormous traditional values against various diseases and many bioactive compounds have been isolated from this plant.
Methods
In the present study 60 NIDDM patients on oral hypoglycaemic drugs were randomly divided into two groups; 30 subjects (11 males and 19 females) were supplemented with the juice of *A. marmelos* fresh leaves (20 g/100 ml) every morning empty stomach for 60 days against 30 (14 males and 16 females) subjects as controls. The 'antioxidant power' of the serum (ferric reducing ability of plasma), was taken as the indicator of total antioxidant potential.
Results
Supplementation of the juice significantly ($P<0.0001$) decreased fasting blood glucose and HbA1c levels and significant ($P<0.0001$) increase in serum antioxidant activity (serum FRAP). Whereas significant ($P=0.008$) increase in fasting blood glucose levels and significant decrease in serum antioxidant activity ($P<0.0001$) was observed for control.
Conclusion
The present study proves the antidiabetic activity of the *A. marmelos* leaves. We believe antioxidant therapy along with monitoring of host antioxidant defence would definitely help in blocking the effects of oxidative stress. We propose that *A. marmelos* leaf juice as an antioxidant therapy monitored with the help of FRAP assay along with oral hypoglycaemic drugs can control blood glucose to normal levels in patients whose diabetes is not controlled with these agents or produce adverse effects on dose increments.

Male patients benefit from initial exenatide treatment: a real-world experience

Liang Chen, Jian Kuang, Jianhao Pei, Hongmei Chen, Zhong Chen, Zhongwen Li, Huazhang Yang, Xiaoyin Fu, Long Wang & Zhijiang Chen
The First Division of Endocrinology, Guangdong Academy of Medical Sciences, Guangdong General Hospital, Guangzhou City, China.

Objective
The purpose of this study was to describe the outcome after initiation of exenatide therapy and to determine whether the impact of adverse drug reactions on compliance was affected by gender.
Methods
A retrospective study was performed of 18 diabetic patients (eight males) that were prescribed exenatide between June 2013 and September 2014. Each included patient received exenatide for $\geq$1 month. Age, disease course, race, BMI, medical history, chronic complications associated with diabetes, and the state of pretreatment glycaemic control were analyzed. Both 1 and 4 weeks after treatment, data such as blood glucose, blood lipids, and body weight were collected to determine any adverse drug reactions and the impact of gender on exenatide withdrawal.
Results
The incidence of adverse drug reaction was significantly higher in female than male patients following exenatide treatment ($P<0.05$). Although there was no significant difference between the male and female group 1 week, adverse drug reactions continued longer in females and the incidence of adverse drug reaction was significantly higher in female patients 4 weeks after initiating treatment ($P<0.01$). As a result, four female patients stopped taking the medication, whereas only one male patient stopped taking the medication because the patient was unaccustomed to the drug injection process. The efficacy of exenatide was similar between the two groups at both 1 and 4 weeks.
Conclusion
Exenatide, a glucagon-like peptide 1 agonist often causes relatively significant gastrointestinal reactions during its initial application. Gender difference in adverse drug reactions may be due to the impact of this drug on the feeding centre in the CNS.

Occurrence frequency of diabetic foot syndrome in three pilot regions of Uzbekistan

Nilufar Ibragimova[2], Telman Kamalov[1], Khamidulla Shokirov[1], Lyudmila Kokareva[1] & Oxana Platonova[2]
[1]Republican Research and Practical Medical Centre of Endocrinology, Tashkent, Uzbekistan; [2]Public Association of the Disabled and People with Diabetes Mellitus 'UMID', Tashkent, Uzbekistan.

Goal
To study occurrence frequency of diabetic foot syndrome (DFS) in three pilot regions of Uzbekistan.
Material and methods
Upon WDF project, 'UMID' Association of Tashkent and RRPMCE have screened T1DM and T2DM patients for DFS in three pilot regions (Andizhan, Tashkent, and Kashkadarya areas). 663 patients examined; of them 581 T2DM patients and 82 T1DM peoples in the 25–65 age groups with duration of the disease 5–15 years. Results of USI Doppler velocimetry, levels of glycaemia, HbA1c, cholesterol, HDL, LDL, and triglycerides were studied.
Results
83.2% of T2DM and 67.4% of T1DM had diabetic polyneuropathy. Frequency of DFS occurrence was 55.3% (T2DM) and 31.7% (T1DM) accordingly. The greatest number of lower limb amputations (3.8%) and re-amputations (2.0%) was found in T2DM patients with disease of 7–10 years. Results of interviews

pertaining to rules of foot care showed a poor knowledge on DFS prevention which explains a rise in a number of amputations in PDM in rural regions. 94.2% of PDM were in a decompensation stage (HbA1c $>9.5\%$) irrespective of history of the disease. 68% of PDM were hypertensive. 36% of PDM (mostly T2DM patients with obesity grades 1 and 2) had high levels of cholesterol and LDL (5.6 ± 0.7 and 4.01 ± 0.12 mmol/l respectively) with low level of HDL (0.53 ± 0.05 mmol/l) and level of triglycerides of 2.8 ± 0.3 mmol/l.

Conclusions

i) Frequency of DFS occurrence in three pilot regions of Uzbekistan made 55.3% in T2DM patients and 31.7% in those of T1DM; ii) the greatest number of lower limb amputations (3.8%) and re-amputations (2.0%) was found in T2DM patients with duration of the disease 7–10 years; and iii) decompensation stage (HbA1c $>$ 9.5%) in 94.2% of PDM is one of principal causes of high frequency of DFS occurrence and a considerable number of amputations in PDM.

Nocturnal blood pressure is related to the progression of retinopathy in type 1 diabetic patients

Francisco Javier Vílchez-López[1], Isabel Mateo-Gavira[1], Laura Larrán-Escandón[1], Ana Montero-Galván[1], José Ortego-Rojo[1], María Victoria García-Palacios[2] & Manuel Aguilar-Diosdado[1]

[1]Endocrinology, Puerta del Mar Hospital, Cádiz, Spain; [2]Preventive Medicine and Public Health, Cádiz, Spain.

Introduction

The objective is to evaluate the relationship between early blood pressure alterations (detected by ambulatory blood pressure monitoring (abpm)) and the development/progression of retinopathy in patients with type 1 diabetes clinically normotensive.

Methods

We designed a prospective observational study of 85 patients, clinically normotensive and without microalbuminuria, monitored over 7 years. Abpm was performed over 24 h and subclinical hypertension was considered if: i) mean systolic pressure (sbp) was >130 mmHg in the 24 h and daytime periods and >120 mmHg in the nighttime period and/or mean diastolic pressure (dbp) >80 or 70 mmHg in the same periods respectively and/or ii) more than 50% of the readings were higher than the defined previous criteria. Non dipper pattern was defined as nocturnal sbp or dbp $<10\%$ relative to the diurnal mean value. We evaluated the development or progression of retinopathy during the following period.

Results

Of the 85 patients included in the analysis, 55.3% (*n*: 47) were women with an average age of 27.9 ± 6.1 years and a length of disease of 12.3 ± 6.5 years. 23.5% were diagnosed with subclinical hypertension and 36% with non-dipper pattern as the only pathological finding. 69 patients completed the seven-year follow-up. During this period, 31.8% presented development or progression of retinopathy. Initial mean nocturnal dbp (OR: 1.122, *P*: 0.034), waist perimeter (OR: 1.075, *P*: 0.028), and final non-dipper pattern (OR: 5.857, *P*: 0.005) showed as independent risk factors of progression/development of retinopathy.

Conclusions

In type 1 diabetic patients clinically normotensive there is a high prevalence of blood pressure alterations detected by abpm. Nocturnal blood pressure parameters predisposes the development or progression of retinopathy.

Introduction

The objective is to evaluate the relationship between early blood pressure alterations (detected by ambulatory blood pressure monitoring (abpm)) and the development of microalbuminuria and arterial hypertension in patients with type 1 diabetes clinically normotensive.

Methods

We designed a prospective observational study of 85 patients, clinically normotensive and without microalbuminuria, monitored over 7 years. Abpm was performed over 24 h and subclinical hypertension was considered if: i) mean systolic pressure (sbp) was >130 mmHg in the 24 h and daytime periods and >120 mmHg in the nighttime period and/or mean diastolic pressure (dbp) >80 or 70 mmHg in the same periods respectively and/or ii) more than 50% of the readings were higher than the defined previous criteria. Non-dipper pattern was defined as nocturnal sbp or dbp $<10\%$ relative to the diurnal mean value. We evaluated the development of microalbuminuria and established hypertension during the following period.

Results

Of the 85 patients included in the analysis, 55.3% (*n*: 47) were women with an average age of 27.9 ± 6.1 years and a length of disease of 12.3 ± 6.5 years. 23.5% were diagnosed with subclinical hypertension and 36% with non-dipper pattern as the only pathological finding. 69 patients completed the 7-year study. During this period: i) 10.14% developed microalbuminuria, showing the mean nocturnal sbp as a risk factor (OR: 1.129, *P*: 0.007) and ii) 7.24% of the normotensive patients progressed to established hypertension, showing historical HbA1c (OR: 2.767, *P*: 0.046) and mean nocturnal dbp (OR: 1.243, *P*: 0.046) as related factors.

Conclusions

In type 1 diabetic patients clinically normotensive with normoalbuminuria, nocturnal blood pressure parameters predisposes the development of micro-albuminuria and established hypertension.

Subclinical blood pressure alterations are related to proinflammatory markers in type 1 diabetes mellitus

Francisco Javier Vílchez-López[1], Isabel Mateo-Gavira[1], Ana Montero-Galván[1], Francisco Visiedo-García[2], María Victoria García-Palacios[3], Laura Larrán-Escandón[1] & Manuel Aguilar-Diosdado[1]

[1]Endocrinology, Puerta del Mar Hospital, Cádiz, Spain; [2]Investigation Unit, Hospital Puerta del Mar, Cádiz, Spain; [3]Preventive Medicine and Public Health, Puerta del Mar Hospital, Cádiz, Spain.

Introduction

The objective is to evaluate the relationship between precocious subclinical hypertension and inflammatory and endothelial dysfunction markers in normotensive and normoalbuminuric patients with type 1 diabetes.

Methods

We designed an observational transversal study of 85 patients, clinically normotensive and without microalbuminuria. Ambulatory blood pressure monitoring (abpm) was performed over 24 h and subclinical hypertension was considered if: i) mean systolic pressure (sbp) was >130 mmHg in the 24 h and daytime periods and >120 mmHg in the nighttime period and/or mean diastolic pressure (dbp) >80 or 70 mmHg in the same periods respectively and/or ii) more than 50% of the readings were higher than the defined previous criteria. Non dipper pattern was defined as nocturnal sbp or dbp $<10\%$ relative to the diurnal mean value. We analyzed the relationship between the blood pressure alterations detected by abpm and inflammatory cytokines (IL6, TNFα, and VEGF) and markers of endothelial damage (VCAM, ICAM, and PAI).

Results

Of the 85 patients included in the analysis, 55.3% (*n*: 47) were women with an average age of 27.9 ± 6.1 years and a length of disease of 12.3 ± 6.5 years. 31.8% presented pathological mean blood pressure parameters in some of the periods. VEGF levels were significantly higher in patients with diurnal blood pressure alterations relative to normotensive patients (112.33 (72.87–213.53) pg/ml vs 71.03 (37.71–107.92) pg/ml; $P=0.007$). In addition, VEGF levels showed a significant correlation with mean daytime and 24 h blood pressure parameters. IL6 levels showed as a risk factor in patients diagnosed with subclinical hypertension (OR: 1.406, *P*: 0.027). There were no modifications in the level of markers of endothelial damage.

Conclusions

An increase in proinflammatory cytokines, although not markers of endothelial damage, exists in precocious stages of hypertension in type 1 diabetic patients.

Different stress hormone response in insulin pump treatment compared with multiple daily injection: preliminary data

Antonio Mancini, Jacopo Pareo, Chantal Di Segni, Sebastiano Raimondo, Alessandro Rizzi & Dario Pitocco
Department of Medical Sciences, Catholic University of Sacred Heart, Rome, Italy.

It is known that in type 1 diabetes mellitus (T1DM) continuous subcutaneous insulin infusion (CSII) therapy improves metabolic control and reduces risk of hypoglycaemia in comparison with multiple daily injection (MDI). Metabolic outcomes usually considered are HbA1c, BMI, and inflammatory parameters. However few data are available on pituitary and gonadal hormone responses, which are involved in metabolic processes. In order to study the response of anabolic hormones in patients treated with CSII or MDI, we have evaluated IGF1, DHEAS, and testosterone levels in a cohort of T1DM patients, comparing these two different ways of intensive insulin administration. We enrolled 41 patients, aged 19–55 years, 25 males and 16 females; 23 were treated by MDI (group 1) and 18 by CSII (group 2). The groups were similar for age, BMI, and duration of DM. IGF1 was assayed using the electro-chemiluminescent immunoassay (ECLIA) method instead testosterone and DHEAS using the chemiluminescent microparticle immunoassay (CMIA) method. Despite similar glycaemic control (mean ± s.d., HbA1c: 8 ± 0.01 in males and 7 ± 0.01 in females of group 1; 7 ± 0.01 both in males and females of group 2), we found in males a significant difference in IGF1 levels (138.8 ± 9.4 in group 1 and 96.2 ± 11.2 ng/ml in group 2, $P<0.05$) and a not significant trend toward higher DHEAS levels (2912 ± 432.9 and 1909.6 ± 216.9 ng/ml); T levels were higher in females of group 1 than group 2 (1.2 ± 0.8 and 0.5 ± 0.1 ng/ml).
These preliminary data seem to indicate a different hormone response in patients treated by CSII or MDI, with lower stress hormone pattern response for patients on CSII, despite similar glycaemic control. Better ovarian response was observed in women on CSII, with lower androgen production. Further studies are needed to better understand these complex relationships and their prognostic implications.

Evaluating analogue vs human insulin efficacy in real life: observational study in type 2 Albanian diabetic patients, previously insulin treated

Florian Toti[1,2], Gjinal Gjonçaj[1], Blerina Resulaj[2], Luftime Bruka[1], Adriana Lapardhaja[1], Manjola Carçani[1], Rajmonda Tare[1] & Varvara Lile[1]
[1]University Hospital Center 'Mother Theresa', Tirana, Albania; [2]Faculty of Medicine, Tirana, Albania.

Background and aims
Insulin therapy is an important part of diabetes treatment. A lot of studies have compared the efficacy of new insulin therapies, but in our country, specialists still have to demonstrate at the institutions the treatment's efficacy and cost-effectiveness for new insulin analogues. The aims of our study is to evaluate the efficacy of analogues vs human insulins and differences between various analogue insulin, in type 2 diabetes patients, previously treated with human insulin.
Methods
This study is realised in real life patients. We retrospectively included 384 patients, previously treated ≥24 months with human insulins, switched to an analogue insulin for ≥12 months. Treatment efficacy was evaluated by HbA1c levels, weight difference and changes in total daily dose (TDD) analogue vs human.
Results
384 patients, 185 (48.17%) males. Glargine 194 (50.5%), detemir 110 (28.65%), and all other analogs (AOA) 80 (20.85%). Mean age 62.19 (s.d. 10.12) years, mean diabetes duration 10.8 (s.d. 5.35) years. Mean duration on analogue insulin therapy was 19.1 months. Overall mean HbA1c was 8.86 (s.d. 1.06) vs 7.51 (s.d. 1.51) on analogues $P<0.01$. TDD was 54.9 UI (s.d. 20.1) vs 62.56 UI (s.d. 27.95) on analogues $P<0.05$, but smaller basal doses 29.28 UI vs 28.1 UI. 21% of the patients on human insulin had an HbA1c <7% vs 63.1% on analogues. Patients on analogues had a slight weight increase +3.18 kg during the study period (P 0.55), but DE/GL 1.48 kg vs 4.14 kg ($P<0.01$).
Conclusions
A better metabolic control was noted with analogue vs human insulins, with smaller daily doses of basal insulin and minimal weight increase. Even in our study detemir group had a smaller weight gain, making it preferable for obese type 2 diabetics.

Telemedicine as a motivational tool to optimise metabolic control in patients with diabetes in Turkey: results from a randomised controlled trial

Ilhan Satman[1], Elif Bagdemir[1], Fulya Turker[1], Selda Celik[1], Cemile Idiz[1] & Haluk Ozsari[2]
[1]Division of Endocrinology and Metabolism, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey; [2]Faculty of Health Science, Istanbul University, Istanbul, Turkey.

Objective
Our purpose was to evaluate the impact of a transmission system on metabolic control of patients with diabetes.
Research design and methods
This ongoing-prospective, randomized, comparative study included adult patients with type 1 ($n=71$) and type 2 diabetes ($n=139$). Consecutive patients were equally allocated into two groups. Both groups received routine care by the same health care professionals (HCPs) 3-monthly. TeleDiab group additionally transmissed SMBG data and received feedbacks and SMSs regularly.
Results
We reviewed metabolic parameters based on mean difference from baseline to 9 months. In TeleDiab group, fasting blood glucose (FBG: −19 mg/dl, $P=0.089$), HbA1c (0.6%, $P<0.001$), HDL-cholesterol (−3.6 mg/dl, $P=0.006$), systolic (SBP: −5.3 mmHg, $P=0.001$), and diastolic blood pressures (DBP: −2.7 mmHg, $P=0.055$) remarkably reduced from baseline. While in control group HbA1c (−0.4%, $P=0.004$) only reduced but BMI (0.6 kg/m^2, $P=0.014$) increased significantly; additionally, SBP (−2.8 mmHg, $P=0.099$) and DBP (−2.4 mmHg, $P=0.079$) tended to decrease tended to increase from baseline.
In TeleDiab group, we observed positive correlations between average number of SMBG and change from baseline to 9 months FBG (monthly post-prandial: $r=0.256$, $P=0.029$) and weight (daily post-prandial: $r=0.229$, $P=0.049$); and negative correlations between average number of SMBG and change from baseline to 9 months HDL-cholesterol (daily postprandial: $r=-0.261$, $P=0.026$), SBP (weekly total: $r=-0.276$, $P=0.017$; weekly pre-prandial: $r=-0.233$, $P=0.046$; monthly total: $r=-0.272$, $P=0.019$; monthly pre-prandial: $r=-0.247$, $P=0.034$; and monthly post-prandial: $r=-0.247$, $P=0.035$), and DBP (weekly post-prandial: $r=-0.284$, $P=0.044$; monthly total: $r=-0.234$, $P=0.044$; and monthly post-prandial: $r=-0.316$, $P=0.006$).
At 9-month, more patients with type 2 diabetes in TeleDiab group achieved optimal HbA1c as compared with control group (52.1% vs 38.3%, $P=0.061$).
Conclusion
Regular follow-up visits by the same HCPs resulted with improved glycaemic, lipid and BP control in subjects with diabetes. However, further improvement was achieved with the use of electronic transmission system.

Long-term tele-monitoring of patients with type 2 diabetes mellitus: ancillary analysis of the results of the Greek pilot of the renewing health multicentre randomised control trial

George E Dafoulas[1,2], Afentoula Mavrodi[3], Charalampos Giannakakos[4], Paraskevi Gkiata[5], Kyriaki Theodorou[1], Vasilios Aletras[3], Panagiotis Stafylas[6], Georgios Koukoulis[1,7] & Alexandra Bargiota[1,7]
[1]Faculty of Medicine, University of Thessaly, Larisa, Greece; [2]E-Trikala Telehealth Center, Municipality of Trikala, Trikala, Greece; [3]Department of Business Administration, University of Macedonia, Thessaloniki, Greece; [4]5th Regional Health Authority of Thessaly and Sterea, Larisa, Greece; [5]Telehealth Center, Intermunicipal Digital Community of Central Greece, Trikala, Greece; [6]Health Information Management, Brussels, Belgium; [7]Department of Endocrinology and Metabolic Diseases, Regional University Hospital, Larisa, Greece.

Introduction
To evaluate the impact of a long-term telemonitoring programme for patients with type 2 diabetes mellitus (DMT2) on glycaemic control and lipid disorders.
Methods/design
In the Greek pilot of a prospective, randomised, single-blinded, multicentre study 154 patients with DMT2, HbA1c >53 mmol/mol (7.0% according to NGSP) and capable of using the telemonitoring device, were studied after randomly assigned in the telemonitoring (IG) ($n=74$) and the control group (CG) ($n=80$) and after having signed the informed consent form. In the IG group patients' blood glucose

profiles were collected weekly using a mobile phone health platform, for a period of 1 year. Allocated health professionals provided via phone the appropriate counselling on lifestyle and medication changes whenever required. Patients in (CG) group received usual care with face-to-face consultations. Levels of HbA1c (primary outcome), total cholesterol (TChol), LDL, and triglycerides (Tg) were measured at the beginning and the end of the study.

Results

The table shows the outcome of the variables studied in both groups. A greater reduction in HbA1c was observed in the IG compared to the CG. Linear regression analysis performed proved that no significant contribution to the reduction of HbA1c level could be attributed to patients' demographics, age ($R^2=0.099$, $P=0.103$), gender ($R^2=0.061$, $P=0.316$), level of education ($R^2=0.034$, $P=0.572$), prior use of computer ($R^2=0.062$, $P=0.309$), and prior use of mobile phone ($R^2=0.005$, $P=0.406$).

Outcome	Mean difference between groups (95% CI)	*P* value
HbA1c (mmol/mol)	−6.13 (−10.45 to −1.81)	0.001
TChol (mg/dl)	−2.41 (−18.48 to 13.65)	0.765
LDL (mg/dl)	−6.72 (−16.02 to 2.57)	0.155
Tg (mg/dl)	−12.90 (−49.97 to 24.17)	0.490

Conclusion

In the present study home telemonitoring was proven to be more effective than usual care in improving glycaemic control.

Is diabetes an independent risk factor of perioperative complications after abdominal gynecologic interventions?

Joanna Swirska[1,2], Beata Matyjaszek-Matuszek[1], Piotr Czuczwar[3] & Agnieszka Zwolak[1,2]

[1]Department of Endocrinology, Medical University of Lublin, Lublin, Poland; [2]Chair of Internal Medicine, Department of Internal Medicine in Nursing, Medical University in Lublin, Lublin, Poland; [3]3rd Chair and Department of Gynecology, Medical University of Lublin, Lublin, Poland.

Purpose

We sought to determine if in the group of patients who underwent gynecologic abdominal interventions diabetes was an independent risk factor of perioperative complications.

Material and methods

The study group included 62 women from both the diabetic and the control group who underwent elective gynecologic laparotomies such as hysterectomy or adnexectomy. The patients from diabetic group were pair-matched with patients without diabetes based on the following criteria: similar age and BMI, the same gynecologic diagnosis, undergoing the same type of gynecologic surgery, operation being performed on in the same operating room and hospitalization within the same time interval. In every matched couple of patients (diabetic vs non-diabetic patient) we compared: number and characteristics of intra- and postoperative complications, postoperative length of stay in hospital, decrease in hemoglobin level, increase in body temperature and postoperative use of antibiotics.

Results

The study did not show any statistically significant differences between the diabetic patients and corresponding patients from the control group in terms of the examined parameters.

Conclusion

Diabetes was not an independent risk factor of early postoperative complications after abdominal adnexectomies and hysterectomies in the examined group of patients. Good pre-operative glycemic control and keeping blood glucose in intra and postoperative time within normal ranges results in the reduction of complications in diabetic patients to the level typical of non-diabetics.

Education for diabetes self-management improves quality of life and reduces HbA1c levels in people with diabetes

Florian Toti[1], Elvisa Sokoli[2], Eliora Kulluri[2], Adriana Lapardhaja[1] & Manjola Carçani[1]

[1]University Hospital Center 'Mother Theresa', Tirana, Albania; [2]Faculty of Psychology and Social Work, Tirana, Albania.

Backgrounds and aims

Knowing about patient's quality of life (QoL) is becoming increasingly important in delivering diabetes care and education. The purpose of our study was to estimate if the diabetes education improves patient QoL and reduces HbA1c levels.

Material and methods

The study sample included diabetic patients who attended a 5-day educational sessions at the Service of Endocrinology in Tirana/Albania. Patients were evaluated regarding their QoL at baseline and 6 or 12 months after their hospitalization. The HbA1c was measured at baseline, 6 and 12 months later. The diabetes QoL (DQoL) measure was used to assess the subjective QoL. DQoL is a validated 46 items survey covering four areas of interest: satisfaction and impact of treatment, worry about the future effects of diabetes and worry about social issues, as well a single question about the general health. A satisfactory level is accepted as a transformed score >60.

Results

The group consisted of 395 patients, 139 males (35%) and 256 females, 97 (24.5%) type 1 diabetes, mean age 44.2 ± 4.7 years, diabetes duration 11.4 ± 5.4 years, treated with insulin in 45% of cases, with baseline HbA1c $9.1\pm1.67\%$, having decreased respectively $8.5\pm1.1\%$ at 6 months ($P<0.05$) and $8.02\pm1.23\%$ at 12 months after hospitalization ($P<0.001$). DQoL at baseline was 56 ± 4.5, 68.2 ± 5.7 at 6 months later and 75.1 ± 3.5 at 12 months interval ($P<0.05$). The satisfaction with treatment and worry about the future were the most improved scores at 6 and 12 months after.

Conclusions

The education for self-management of the disease improves patients' QoL as well their metabolic control.

Prevalence of microalbuminuria and predictive factors in a group of Albanian diabetic adults

Eduard Spahiu[1], Mimoza Ismaili[1], Aldi Shehu[2], Erion Thengjilli[1], Albana Doko[1] & Florian Toti[1]

[1]University Hospital Center 'Mother Theresa', Tirana, Albania; [2]Laboratory 'Intermedica', Tirana, Albania.

Background and aims

Diabetic nephropathy is one of the most prevalent and dangerous chronic complication of diabetes mellitus. Its end-stage, renal chronic failure is the most important cause of premature death in diabetic patients. Microalbuminuria (MA), one of the first signs of diabetic nephropathy, may be present from the moment of diagnosis in type 2 diabetes. The aim of our study was to determine the prevalence of microalbuminuria and to identify predictor factors in a group of Albanian diabetic adult patients.

Material and methods

Diabetic patients selected randomly, assigned by hospital admissions in Tirana University Hospital Center, Shkodra and Pogradec regional hospitals. Biochemical examinations, anthropometric measurements, and measurement of microalbuminuria by DCA 2000 in a urine spot, was performed. Microalbuminuria was considered positive if ≥20 mg or albumine/creatinine report ≥25.

Results

321 patients participated in the study. 163 women (50.78%). The mean age 58.21 ± 11.87 years, type 1 diabetes 19 patients (8.6%), mean diabetes duration 8.19 ± 6.96, and mean HbA1c $8.2\pm2.1\%$. Prevalence of MA 40.81%, while the

overt diabetic nephropathy was present in 2.8% of cases. 9/27 patients (33.3%) with newly diagnosed diabetes presented already MA. Central obesity, presence of hypertension >140/90 mmHg, HbA1c >8%, and diabetes duration >15 years were risk factors for microalbuminuria.
Conclusions
Diabetic nephropathy is a common chronic complication of diabetes mellitus. Its early detection, and an aggressive treatment of its risk factors may prevent its progression. The search for the presence of MA might be part of the initial assessment for each person with type 2 diabetes.

Glycaemic control and weight evolution in type 2 diabetic patients with dapagliflozina in addition to their previous treatment

Lidia Urbón López de Linares, Maria Cristina Crespo Soto, Marta Ventosa Viña, Concepción Terroba Larumbre, Claudia Martín Monclús, Tomás Martín Martín & Luis Cuellar Olmedo
Hospital Universitario Rio Hortega, Valladolid, Spain.

Introduction
From November 2013 it is available in Spain a new drug to treat type 2 diabetes (DM2): dapagliflozina. The new mechanism of action consists in the inhibition of the sodium–glucose co transporters (SLGT2) inhibiting glucose reabsorption in the proximale tubule and increasing glucose excreted in the urine. Therefore hyperglycaemia decreases and so does weight as a consequence of glycosuria. This is a very convenient side effect since DM2 is highly associated with overweight/obesity.
Methodology
This is an observational retrospective study where the results of ten patients (eight females and two males) after 3 months of treatment are shown.
Results
The average age was 58.2 (±10.5) years, nine patients had been diagnosed of obesity, average BMI was 37.1 (±8.6). The initial average HbA1c was 8.43% (±1.62) and the average weight was 94.5 (±20.9) kg, after 3 months of treatment, The average HbA1c was 7.45 (±0.86) and average weight 90.4 (±19.2) kg with a medium loss of 4.26 (0.2–14.5) kg. The uric acid levels were evaluated in eight patients. The initial average level was 5.63 (±1.46) mg/dl, and after 3 months of treatment it was 4.68 (±1.15) mg/dl. In the follow-up visit 90% of the patients were still on dapagliflozine. Three of them had a case of urinary infection, one decided to stop using the drug by herself, the other two patients were given antibiotic therapy and there was no need to stop using the drug. No other side effects were described.
Conclusions
Dapagliflozina improved the glycaemic control; all the patients experienced a loss of weight; a decrease of the uric acid serum levels was seen; the most common side effect was non-complicated urinary infection that was solved with antibiotic therapy.

Pregnancy planning in type 1 diabetes mellitus

Paloma Moreno-Moreno, Rafael Palomares-Ortega, Ana Barrera-Martin & María Ángeles Gálvez-Moreno
Management Unit of Clinical Endocrinology and Nutrition, University Hospital Reina Sofía, Córdoba, Spain.

Objective
The aim of this study was to determine the prevalence of pregnancy planning in women with type 1 diabetes mellitus (DM1) and analysing differences associated with unplanned pregnancy.
Patients and methods
Retrospective descriptive study of pregnancies in women with DM1 (2004–2012). Variables analysed: age, time of diabetes evolution, microvascular complications, and maternal outcomes (HbA1c, preeclampsia, abortions, and Caesarean section) and neonatal outcomes (perinatal death, gestational age at delivery, birth weight, and congenital malformations). The pregnancies were divided in groups attending to pregnancy planning and were analysed to evaluate possible differences between them (group 1: planned and group 2: unplanned).
Statistical analysis
Comparing proportions with the χ^2 and comparing means with Student's *t*-test.
Results
132 pregnancies. Caucasian 99.2%. Unplanned pregnancy: 67.4%. Group 1 vs group 2: 31.84±4 years old vs 29±4.5 years old, $P=0.34$; time of diabetes evolution: 13.5±8.1 years vs 13.1±7.7 years, $P=0.56$; nonproliferative diabetic retinopathy: 4.6% vs 5.6%, $P=0.5$; proliferative diabetic retinopathy 9.3% vs 8.9%, $P=0.9$; microalbuminuria 0% vs 3.3%, $P=0.22$; nephropathy 0% vs 2.24%, $P=0.32$; hypertension 0% vs 2.24%, $P=0.32$; undertreated hypothyroidism: 23% vs 18.2%, $P=0.45$; smoking 7% vs 12.5%, $P=0.33$; HbA1c (%): before pregnancy 6.4±0.4 vs 8.04±1.3, $P=0.00$; first trimester 6.36±0.5 vs 7.6±1, $P=0.004$; second trimester 6.01±0.5 vs 6.63±1, $P=0.01$; and third trimester 6.14±6.77 vs 6.77±0.7, $P=0.21$. Maternal and neonatal outcomes (group 1 vs group 2): preeclampsia 0% vs 3.5%, $P=0.21$; abortions 6.9% vs 8.04%, $P=0.7$; Caesarean section 55% vs 44.8%, $P=0.3$; perinatal death 0% vs 1.1%, $P=0.9$; gestational age at delivery 38.5±1.8 weeks vs 37.8±2.4 weeks, $P=0.1$; macrosomia 25.6% vs 35%, $P=0.28$; neonatal hypoglycaemia 5% vs 5.3%, $P=0.9$; and congenital malformations 7.2% vs 7.3%, $P=0.9$.
Conclusions
Gestation planning is deficient and is associated with glycaemic control deficit at the beginning of gestation. Glycaemic control is similar in third trimester of pregnancy, and maternal and neonatal outcomes were similar in both groups.

Web-based telemedicine system is useful for monitoring glucose control in pregnant women with diabetes

María del Carmen Ayala Ortega[1], Florentino Carral San Laureano[1], Carmen González Macías[2], Ana Isabel Jiménez Millán[1], Juan Jesus Fernandez Alba[2], Antonia Piñero Zaldivar[1] & Concepción García Calzado[1]
[1]Endocrinology Department, Puerto Real University Hospital, Puerto Real, Cádiz, Spain; [2]Obstetric and Gynecology Department, Puerto Real University Hospital, Puerto Real, Cádiz, Spain.

Objective
The aim of this study was to examine the impact of a web-based telemedicine system for monitoring glucose control in pregnant women with diabetes on health care visits, metabolic control and pregnancy outcomes.
Subjects and methods
A prospective, single-centre, and interventional study with two parallel groups was performed in Puerto Real University Hospital (Spain). Women were assigned to two different glucose monitoring groups: control group (CG) that was managed only by follow-up with the Gestational Diabetes Unit (GDU) and telemedicine group (TMG) that was monitored both by more spaced GDU visits and a web-based telemedicine system. The number of health care visits, degree of metabolic control and maternal and neonatal outcomes were evaluated.
Results
104 pregnant women with diabetes (77 with gestational diabetes, 16 with type 1 diabetes, and 11 with type 2 diabetes) were included in the TMG ($n=40$) or in the CG ($n=64$). There were no significant differences in mean HbA1c level during pregnancy or after delivery, despite significantly lower number of visits to the GDU (3.2±2.3 vs 5.9±2.3 visits, $P<0.001$), nurse educator (1.7±1.3 vs 3.0±1.7 visits, $P<0.001$), and general practitioner (3.7±2.0 vs 4.9±2.8 visits, $P<0.034$) in the TMG. There were no significant differences between groups in maternal or neonatal outcomes.
Conclusions
Web-based telemedicine system can be a useful tool facilitating the management of pregnant diabetic patients, as a complement to conventional follow up and could contribute to reduce the outpatient clinic visits.

DOI: 10.1530/endoabs.37.EP477

EP478

Changes in diabetes related quality of life and clinical outcomes in patients with type 2 diabetes, after initiation of injectable treatment

Georgios Georgas
Endocrine Private Clinic, Rhodes, Greece.

In this study, we enrolled 123 patients with DM2 that accordingly to the based on evidence clinical judgment, needed injectable treatment for the achievement of good glycaemic control. There was not significant changes at the whole sample in anthropometrics, but there was increase in insulin treated subgroup and decrease in GLP1 treated subgroup. Glycaemic control was improved ($P<0.001$), without differences between detemir vs glargine subgroups, but with more improvement of HbA1c in insulin treated vs GLP1 treated subgroup ($P<0.05$). Lipid parameters (TC, TG, LDL, and HDL) were improved ($P<0.001$), without changes between the subgroups, except the more significant reduction at TC in insulin treated vs GLP1 treated. No changes were detected at kidney function, neither at the SPP, but there was a reduction at the DPP ($P<0.05$). Hypoglycaemic episodes were increased after injectable treatment at the whole sample, and in the different subgroups, but GLP1 treated patients had less serious hypoglycaemic crisis. There was an improvement at the present quality of life (overview item I), no changes at the quality of live without diabetes (overview item II) and deterioration at the average weighed impact score of the 19 diabetes specific items of ADDQoL19, after commencement of injectable treatment.

DOI: 10.1530/endoabs.37.EP478

EP479

Does a nurse-led Diabetic Renal Clinic improve outcomes?

Susan Irwin, Alvin Shrestha & Parijat De
Department of Diabetes and Endocrinology, City Hospital, Birmingham, UK.

Aim
To audit outcomes and adherence to prescription recommendations in a nurse-led Diabetic Renal Clinic.
Method
Baseline data at time of referral to the clinic was compared to the final clinic visit within a 12-month period (T1) of the first visit (T0), using information from clinic letters and electronic records of patients attending the clinic in our hospital between 2010 and 2014. Patients without at least one follow-up data within a 12-month period were excluded.
Results
We had complete data in 91/208 patients seen. Average age was 63 years and 54 were males. A mean reduction of HbA1c from 74 to 69 mmol/mol ($P=0.01$) was achieved. Systolic blood pressure reduced from 152 to 142 mmHg ($P<0.01$), although no significant change in diastolic blood pressure was seen (75–73, $P=0.113$). Significant urinary albumin:creatinine ratio (ACR) improvement was observed – 53 down to 31 mg/mmol ($P<0.01$). Renal function declined from eGFR 54 to 51 ml/min per 1.73 m^2 ($P=0.001$). There was no significant difference in total cholesterol (4.4–4.3, $P=0.371$). 50 patients (54%) were not on an antiplatelet agent at T1. All of these patients had at least one risk factor (age 50 years or above, systolic BP above 145 or microalbuminuria) and thus aspirin would have been indicated. Six of 17 (35%) patients not on a statin were prescribed one by T1. 79 (86%) were on a lipid-lowering agent at T1. 85% received an ACE inhibitor, ARB, or both.
Conclusion
These results from 1 year follow-up suggests that the nurse-led clinic is effective in reducing HbA1c, systolic blood pressure, and urine ACR levels in this high CV risk patients. This should hopefully result in improved cardiovascular and renal outcomes and appropriate referrals to renal specialist clinic. Most patients received lipid-lowering agents and ACE inhibitors/ARBs, whilst aspirin prescription remained low.

EP480

Effect of liraglutide 1.8 mg in patients with non-controlled type 2 diabetes mellitus at an Endocrinology Clinic: LIED-2 study

Alvaro J Muriel[1], Alvaro A Herrera[2] & Alin Abreu Lomba[2]
[1]Universidad Libre, Cali, Colombia; [2]Centro Médico Imbanaco, Cali, Colombia.

Background and aims
To describe the characteristics of patients with non-controlled type 2 diabetes mellitus with liraglutide treatment.
Materials and methods
Retrospective descriptive study. 85 outpatients (women 49, ages 18–86 years old with non-controlled type 2 diabetes mellitus) were evaluated between July 2013 and March 2014 and received treatment with liraglutide 1.8 mg SQ/day (0.6 mg SQ during the first week, 1.2 mg SQ during the second week, and 1.8 mg during the third week and the rest of the treatment). Age, sex, diagnosis time, weight, HbA1c, fasting glucose, systolic and diastolic blood pressure, pharmacological treatment during 6 months were extracted for analysis.
Results
Patients treated with liraglutide 1.8 mg as monotherapy or in conjunction with a therapeutic scheme decreased HbA1c values at 3 and 6 months (1.02%, 95% CI $\pm$0.93, $P<0.0001$ and 2.08%, 95% CI $\pm$0.8, $P<0.0001$); fasting glucose at 3 and 6 months (37 mg/dl, 95% CI $\pm$33, $P<0.0001$ and 68 mg/dl, 95% CI $\pm$26, $P<0.0001$); weight at 3 and 6 months (3 kg, 95% CI $\pm$10, $P<0.0001$ and 5 kg, 95% CI $\pm$10, $P<0.0001$); SBP at 3 and 6 months (9 mmHg, 95% CI $\pm$15, $P<0.0001$ and 16 mmHg, 95% CI $\pm$16, $P<0.0001$); and DBP at 3 and 6 months (3 mmHg, 95% CI $\pm$6, $P<0.0001$ and 6 mmHg, 95% CI $\pm$6, $P<0.002$). 40% of patients reached HbA1c $<$7.0; 20% reduction of HbA1c, 39% reduction in fasting blood glucose, 6% reduction in mean weight (1–18%, 1–12 kg), 95% reached SBP $<$140 mmHg; 100% reached DBP $<$90 mmHg. Reported adverse events during treatment were nausea (27%), abdominal pain (18%), hypoglycaemia (14%), diarrhoea (9%), and respiratory symptoms (7%). Metformin was present in 65% cases of nausea, 55% cases of diarrhoea, and 43% of cases of abdominal pain. No fatal adverse events occurred.
Conclusion
Patients treated with liraglutide 1.8 mg SQ per day in monotherapy or in conjunction with a therapeutical scheme showed a decrease in HbA1c, fasting glucose, weight, SBP, and DBP during a 6-month treatment.

Initial experience of SGLT2 inhibitor use in type 2 diabetes

Barbara Cooke, Kathryn Ryan, Mark Gormley & John Lindsay
Mater Infirmorum Hospital, Belfast, UK.

Introduction
SGLT2 inhibitors offer a novel approach to improve glycaemic control in patients with type 2 diabetes through inhibition of renal glucose reabsorption. Phase 3 clinical trials demonstrated consistent glucose lowering effects and weight loss. The objective of our audit was to assess the early effects of treatment with dapagliflozin 10 mg in our clinic population.
Methods
We performed a retrospective audit of clinical parameters in patients ($n=36$, mean age 55.2 years and diabetes mean duration 9.6 years) who attended our hospital in the previous year over a mean follow-up interval of 144 days (25–359 days). 13 patients were previously treated with dual oral agents and 15 with insulin (16–540 units).
Results
We observed a significant improvement in glycaemic control with an HbA1c fall from 85.6 to 72.9 mmol/mol ($P<0.01$). This was accompanied by a mean weight loss of 2.7 kg ($P<0.01$). There was a trend for BP reduction but this was non-significant. No significant correlations were observed between weight loss and other clinical variables. Non-responders were comparable to responders in terms of weight, age, and duration of diabetes. One patient discontinued therapy due to side effects (vulval candidiasis). Improvements in glycaemic control allowed for withdrawal of other agents in three patients including withdrawal of prandial insulin in one individual.
Conclusion
In conclusion, this audit of our early experience with the SGLT2 inhibitor dapagliflozin highlighted clinically meaningful improvements in parameters of glycaemic control, weight, and BMI. Long-term follow up for evidence of sustained drug efficacy in clinical practice is awaited.

Fungal sinusitis caused by *Aspergillus* in a patient with type 1 diabetes

Goknur Yorulmaz[1], Nurettin Erben[2], Mustafa Acikalin[3], Ercan Kaya[4], Esra Akcan[5] & Nilay Unal Carmik[6]
[1]Department of Endocrinology, Eskisehir State Hospital, Eskisehir, Turkey; [2]Department of Infectious Diseases and Clinical Microbiology, Eskisehir Osmangazi University, Eskisehir, Turkey; [3]Department of Pathology, Eskisehir Osmangazi University, Eskisehir, Turkey; [4]Department of Otorhinolaryngology, Eskisehir Osmangazi University, Eskisehir, Turkey; [5]Department of Radiology, Eskisehir State Hospital, Eskisehir, Turkey; [6]Department of Otorhinolaryngology, Eskisehir State Hospital, Eskisehir, Turkey.

Objective
Aspergillosis is defined as the infection of the *Aspergillus* type mold and is commonly seen in hematologic malignancies, hematopoietic stem cell transplantation, aplastic anemia, primary immunodeficiency, and immunocompromised patients. Fungal sinusitis in diabetes mellitus is generally presented as rhinoorbitocerebral involvement of mucormycosis. Herein, a fungal sinusitis caused by *Aspergillus* case presented with headache is reported.
Case
Twenty-three-year-old male with a history of 9-year diabetes was admitted to our clinic because of high blood glucose level (with a HbA1c level of 14%) and headache which was lasting for 1 month without any pain relief. Cerebral computerized tomography was performed and hyper dens foci fulfilling left maxillary sinus was found. Fungal sinusitis was firstly thought. Tissue sampling from the foci was performed by Ear–Nose–Throat specialist by using endoscopic method. There was no reproduction of any organism in culture but *Aspergillus* hif structure was seen in biopsy sample. Bone destruction or orbital involvement wasn't seen according to radiological findings. Patient was diagnosed as fungal sinusitis. He was empirically treated with itraconazole. His tomography 3 months after the initiation of therapy and there was no sinusitis finding.
Discussion
Rhinocerebral aspergillosis is commonly seen in neutropenic patients whereas mucormycosis is more frequent in diabetic patients. Aspergillosis is detected in a diabetic patient who did not have an additional risk factor. Fungus can colonize in upper and lower airways without causing infection. Only culture positivity is not enough for diagnosis. Invasive fungal sinusitis is diagnosed with the histopathologic evaluation of the biopsy material. Invasive fungal sinusitis is commonly seen in immunosuppressive patients and can cause life threatening conditions. In patients with uncontrolled diabetes and ketoacidosis, invasive fungal sinusitis can be seen.
Conclusion
Although, the most common cause of fungal sinusitis in diabetic patients is mucormycos, *Aspergillus* must be kept in mind.

Once-weekly exenatide in a real-world clinical setting: clinical outcomes and analysis of potential predictors of response

María del Mar Roca-Rodriguez[1], Jose Carlos Fernandez-Garcia[1], Carmen Maria Cortes-Salazar[2], Isabel Moya-Carmona[3], Ana María Gomez-Perez[1], Isabel Cornejo-Pareja[1], Araceli Muñoz-Garach[1], Maria Molina-Vega[1], Isabel Mancha Doblas[1] & Francisco Tinahones[1]
[1]Endocrinology Department, Virgen de la Victoria University Hospital, Malaga, Spain; [2]Badolatosa Primary Care Centre, Seville, Spain; [3]Pharmacy Department, Virgen de la Victoria University Hospital, Malaga, Spain.

Objective
The aim of this study is to evaluate the effectiveness of once-weekly exenatide on metabolic control, weight, blood pressure, and lipid profile in obese patients with type 2 diabetes (T2DM), and to assess possible predictive factors of response.
Material and methods
Retrospective observational study, conducted with adult obese (BMI ≥ 30 kg/m^2) T2DM subjects that had been initiated once-weekly exenatide following routine clinical practice. Anthropometric measures, blood analysis, and blood pressure measures were collected at the initiation of once-weekly exenatide (V0) and after 16 ± 4 weeks of treatment (V1). Predictors of target metabolic response (HbA1c $<7\%$), were evaluated by using a multiple logistic model.
Results
31 patients were included (mean age 54.4 ± 10.7 years; female 54.8%; and mean duration of T2DM 7.9 ± 5.4 years). Significant changes from V0 to V1 were observed in weight-related parameters (body weight 108.1 ± 28.8 kg vs 101.3 ± 22.3 kg and BMI 41.2 ± 8 kg/m^2 vs 39.3 ± 7.3 kg/m^2, $P<0.001$ for both); HbA1c ($8.6 \pm 1.6\%$ vs $7.3 \pm 1.3\%$, $P<0.001$), lipid profile (total cholesterol 206.4 ± 37 mg/dl vs 181 ± 41.5 mg/dl, $P=0.002$; LDL-cholesterol 124.3 ± 35.8 mg/dl vs 101.6 ± 39.2 mg/dl, $P=0.003$; HDL-cholesterol 39.4 ± 10.7 vs 40.7 ± 10.3, $P=0.331$; and triglycerides 288.1 ± 125.7 mg/dl vs 195.1 ± 80 mg/dl, $P=0.001$). No differences in blood pressure (systolic or diastolic) or number of antihypertensive drugs were found. 45.2% of patients achieved HbA1c $<7\%$, 64.5% lost weight, and 41.9% simultaneously achieved HbA1c $<7\%$ and lost weight. None of the studied variables (age, sex, duration of diabetes, baseline HbA1c, and BMI) were confirmed as predictors of response.
Conclusions
In obese patients with T2DM, once-weekly exenatide increases metabolic control, decreases body weight, and improves lipid profile. However, once-weekly exenatide does not exert beneficial effects on blood pressure. Age, sex, duration of diabetes, baseline HbA1c, and BMI were not predictors of efficacy of once-weekly exenatide.

Association between peripheral vascular disease and other macrovascular and microvascular complications in diabetic patients

Gonzalo Allo Miguel, Elena García Fernández, Milagros Sierra Bracamonte, Guillermo Martínez Díaz-Guerra & Federico Hawkins Carranza
Endocrinology Service, 12 de Octubre University Hospital, Madrid, Spain.

Introduction
Diabetes mellitus is a condition on the increase, carrying a high risk of macro and microvascular disease. Previous studies suggest a link between microvascular and macrovascular complications in diabetes. However, just a few studies have investigated whether the presence of peripheral vascular disease (PVD) is associated with other macrovascular and microvascular complications in diabetes patients. So, this was the aim of our study.
Patients and methods
98 diabetic patients (68 with type 2 and 20 with type 1 diabetes) were included. PVD was confirmed by arteriography. Other macrovascular complications were collected, including: adverse cardiovascular events (myocardial infarction, angina, etc.) and stroke. Microvascular complications were, also, collected: retinopathy, nephropathy, and peripheral neuropathy.
Statistical analysis
χ^2 test was used to compare the existence of macro and microvascular complications between the groups with and without PVD.
Results
48 males and 50 females with mean age (52.58 ± 20.70) and mean HbA1c ($11.21 \pm 2.33\%$) were included. 14 patients (15.73%) were diagnosed of PVD. The existence of PVD was significantly correlated with the existence of more macrovascular complications ($P<0.001$) and, at least, one microvascular complication ($P<0.005$). Also, significant differences between the groups of patients with or without PVD were found in the rate of neuropathy (78.57 and 23.61%, respectively, $P<0.001$); cardiovascular events (50.00 and 9.59%, respectively, $P=0.002$) and in the rate of strokes (28.57 and 6.67%, respectively; $P=0.01$). There were no significant differences in the rate of retinopathy and nephropathy between both groups.
Conclusions
Our results show significant correlation between the existence of PVD and the existence of more macrovascular complications and one or more microvascular complications. We have found that diabetic patients with PVD present significant higher rates of neuropathy, cardiovascular events and strokes. Despite the limitations of the study, our results suggest that diabetic patients with PVD require proper micro and macrovascular complications screening.

EP485

Diabetic kidney disease and its association with macrovascular disease in diabetic patients

Elena García Fernández, Gonzalo Allo Miguel, Lucas Arroyave Villa, Guillermo Martínez Díaz-Guerra & Federico Hawkins Carranza
Endocrinology Service, 12 de Octubre University Hospital, Madrid, Spain.

Introduction
It is well known that diabetes confers a substantial burden of macrovascular disease. However, just a few studies have investigated the association between

diabetic kidney disease (DKD) and cardiovascular disease. The purpose of this study is to investigate whether the presence of DKD is associated with macrovascular disease in diabetic patients.
Patients and methods
98 diabetic patients (48 males/50 females) were included in the study. DKD was confirmed by the presence of moderately or severely increased albuminuria. Adverse cardiovascular events were collected, including: cardiac events, left ventricular hypertrophy (LVH), peripheral vascular disease (PVD), and stroke.
Statistical analysis
χ^2 test was used to compare the existence of macrovascular complications between groups with and without DKD.
Results
68 patients with type 2 diabetes and 20 with type 1, with mean age (52.58 ± 20.70) and mean HbA1c ($11.21 \pm 2.33\%$), were included in the study. DKD was diagnosed in 24 patients: 16 with moderately increased albuminuria and eight with severely increased. DKD was significantly correlated with the existence of, at least, one macrovascular complication ($P<0.02$). Significant differences between the groups with or without DKD were found in the rate of: cardiac events (32.00 and 9.84%, respectively; $P=0.01$); LVH (36.00 and 1.59%, respectively; $P<0.001$), and PVD (20.00 and 13.33%, respectively; $P=0.04$). These differences remained significant after adjusting for age, sex, hypertension, smoking habit, HbA1c, duration of diabetes, and BMI. No significant differences in the rate of strokes.
Conclusions
Our results show significant correlation between DKD and the existence of one or more macrovascular complications. Moreover, we have found that diabetic patients with DKD present significant higher rates of cardiac events, LVH and PVD than diabetic patients without DKD. Despite the limitations of the study, our results suggest that early detection of DKD might be a valuable component of macrovascular risk assessment in diabetic patients.

Intensive glycemic control fails to improve indices of vascular dysfunction in patients with type 2 diabetes; results at 6–12 months follow-up

Sofia Antoniou[1], Katerina Naka[2], Aris Bechlioulis[2], Lampros Michalis[2], Agathocles Tsatsoulis[1] & Stelios Tigas[1]
[1]Department of Endocrinology, University of Ioannina, Ioannina, Greece; [2]Department of Cardiology, University of Ioannina, Ioannina, Greece.

Background
In subjects with long duration of type 2 diabetes (T2DM), strict glycaemic control fails to decrease the incidence of cardiovascular disease (CVD). Impaired vascular indices have been associated with adverse cardiovascular prognosis in T2DM. We examined whether intensive glycaemic control in T2DM patients improves vascular indices.
Methods
We studied 68 T2DM patients (64 ± 9 years, 52% males, and T2DM duration 14 ± 10 years) with poor glycaemic control (HbA1c $\geq 7.5\%$), at baseline and 6–12 months after intensive treatment to achieve optimal glycaemic control. Brachial artery flow-mediated dilation (FMD), carotid–femoral pulse wave velocity (PWV), central augmentation index (AIx), large and small artery elasticity indices, common carotid intima–media thickness (cIMT), and ankle–brachial index were measured.
Results
Improvement of HbA1c $>0.5\%$ was achieved in 55 (81%) patients (HbA1c decrease from 9.6 ± 1.8 to $7.3 \pm 1.0\%$, $P<0.001$). In this group of patients, triglycerides decreased (177 ± 140–137 ± 73 mg/dl, $P=0.008$), cIMT increased (0.70 ± 0.20–0.74 ± 0.22 mm, $P=0.038$), and large artery distensibility decreased (14.2 ± 5.2–12.4 ± 4.1 AU, $P=0.045$) at follow-up, while no other changes in vascular indices, blood pressure, lipids, or other laboratory values were found. No difference in vascular indices' changes at follow-up was observed between patients with or without improved glycaemic control (repeated measures (RM)-ANOVA, $P=$NS for all). When patients with improved glycaemic control were compared based on T2DM duration, AIx was decreased in those with short disease duration (<5 years), while it remained unchanged in those with >5 years duration (RM-ANOVA, $P=0.013$).
Conclusions
In T2DM patients, agressive glycaemic control without concomitant improvement in other cardiovascular risk factors was not associated with an improvement in vascular function indices at 6–12 months. However, in patients of <5 years duration, intensive glycaemic control improved only augmentation index, a combined index of aortic stiffness and peripheral vascular function. Multifactorial interventions of longer duration are needed to improve cardiovascular risk in T2DM.

Intraocular pressure change during oral glucose tolerance test in non-diabetic individuals

Pinar Yildiz[1], Medine Nur Kebapci[2], Fezan Mutlu[3], Harun Servet Yasar[4] & Nilgun Yildirim[4]
[1]Department of Internal Medicine, Eskisehir Osmangazi Medical Faculty, Eskisehir, Turkey; [2]Department of Endocrinology, Eskisehir Osmangazi Medical Faculty, Eskisehir, Turkey; [3]Department of Biostatistics, Eskisehir Osmangazi Medical Faculty, Eskisehir, Turkey; [4]Department of Ophtalmology, Eskisehir Osmangazi Medical Faculty, Eskisehir, Turkey.

Introduction
A significance of chronic hyperglycaemia related to the rising intraocular pressure are discussed in the previous studies. The purpose of the present study was to investigate changes of intraocular pressure induced by acute changes of glucose levels during oral glucose tolerance test in non-diabetic subjects.
Methods
Fifty-one individuals who were needed to be screened for diabetes, were scheduled for oral glucose tolerance test according to the World Health Organization criteria. Biochemical parameters associated with metabolic syndrome, insulin resistance (HOMA-IR) and systolic and diastolic pressure were also measured. Complete ophthalmologic examination was performed before the test. The inclusion criteria were having a normal intraocular pressure (<21 mmHg), and having no eye disease, no ophthalmic surgery or no glaucomatous optic nerve appearance. During the test, intraocular pressure was measured by using rebound tonometry (ICARE) two times at the fasting state and at first and second hours after oral glucose administration.
Results
The mean age of the patients was 46.24 ± 11.31 years. The mean BMI was 29.63 ± 5.25 kg/m^2. The median fasting glucose and intraocular pressure for right was 100 mg/dl (91.250–105.750) and 17 mmHg. The median glucose and intraocular pressure level for right eye in the first hour and in the second hour in OGTT were 153 mg/dl (123.5–190.5), 18 mmHg (14–22) and 117 mg/dl (92.25–140) and 18 mmHg (14–20.75) respectively. The intraocular pressure right eye were significantly higher in the first hour compared to the fasting values ($P<0.05$).
Conclusion
The relation between diabetes mellitus and glaucoma has been addressed in many studies with no clear underlying mechanisms. In our study on healthy non-diabetic individuals, acute hyperglycaemia has found to have a positive relationship with intraocular pressure, suggesting that acute hyperglycaemia may represent a possible mechanism.

EP488

Hypoglycaemia due to drug interaction with clarithromycin

João Silva, Catarina Ivo, Mafalda Marcelino, Luís Lopes, Dolores Passos, Hélder Simões & João Jácome de Castro
Armed Forces University Hospital, Lisbon, Portugal.

Introduction
Interaction between diabetes mellitus (DM) and an infection usually results in hyperglycaemia. However, there is data describing hypoglycaemia events related with the association between certain antibiotics and oral anti-diabetic drugs or insulin.
Case report
Male, 73 years old, with history of hypertension, obesity and dyslipidaemia. DM type 2 was diagnosed 13 years ago with any macro or microvascular complications so far. Currently he's treated with insulin detemir ($40+28$U) and vildagliptin + metformin 50/1000 2id, maintaining good metabolic control (HbA1c 6.9%) with rare episodes of hypoglycaemia. Owing to dental abscess he started a treatment with clarithromycin 500 mg bid. After 36 h of taking the drug, referred two episodes of night symptomatic hypoglycaemia, on consecutive days (42 and 37 mg/dl respectively), which reversed after sugar intake. In this context, he went to our clinic, and the antibiotic was changed to amoxicillin + clavulanic $850+125$ mg, keeping the usual therapy for DM. There weren't any more episodes of hypoglycaemia.

Conclusions
In the literature there are few reports of hypoglycaemia induced by clarithromycin in combination with insulin detemir. 40–70% of clarithromycin circulates bound to proteins, which can dissociate insulin detemir of protein binding sites (98% binds to albumin), increasing the free concentration and its pharmacological effects. This phenomenon can cause a faster beginning of action, simulating an insulin with intermediate or short-action, leading to hypoglycaemia. Clarithromycin is a potent inhibitor of CYP3A4. Vildagliptin isn't a substract of this cytochrome. Metformin is a substract of this cytochrome's family, but there isn't any report of hypoglycaemia with this association.
Clinicians should be aware of this drug interaction, regarding the need of adjustments of insulin doses to avoid possible adverse effects and hospitalizations. Patients who start clarithromycin should be advised to have more frequent monitoring capillary blood glucose and re-educated about the signs, symptoms, and treatment of hypoglycaemia.

Insulin oedema in newly diagnosed type 1 diabetes patient: a case report

Ayten Oguz[1], Dilek Tuzun[1], Murat Sahin[1], Didem Atay[2], Berivan Ganidagli[2], Safa Ersen Ganidagli[2] & Kamile Gul[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [2]Department of Internal Medicine, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey.

Aim
In this case report we present a newly diagnosed, underweight type 1 diabetes mellitus (DM) patient developed insulin oedema following high dose insulin therapy.
Case
A 18-year-old male patient was admitted to the hospital with a 1-month history of excessive water consumption, pollakiuria, polyuria, and weight loss 6 kg. In laboratory examination, hyperglycaemia and ketonuria were detected; arterial blood pH was 7.38. Patient was hospitalised to the Endocrinology Clinic with a diagnosis of type 1 DM with ketosis. The patient was initially treated with an i.v. infusion of insulin and isotonic saline for hyperglisaemia and ketonuria. After clinical improvement basal-bolus therapy was started. At the follow-up visits, insulin requirement increased to $\sim$2 U/kg per day. 15 days after discharge, the patient was again admitted to the clinic with a swelling in both legs. The patient had pitting pretibial and ankle oedema in both extremities. In laboratory examination, hyperglycaemia (fasting blood glucose 211 mg/dl), mild hypoalbuminaemia (3.5 g/dl) were detected. Other biochemical blood test results were normal. Patient was hospitalized again. No proteinuria was detected in his urine. Chest X-ray, echocardiography, abdominal and lower extremity Doppler ultrasonography results were also within normal limits. So as a result of these examinations, other factors that could cause oedema have been ruled out. Basal-bolus therapy was continued. At the follow-up visits, his insulin need was observed to decline (1.5 U/kg per day). With reduced insulin doses, oedema regressed spontaneously.
Conclusion
Oedema formation is one of the rare complications of insulin therapy. The cause and incidence rate of insulin oedema are not clearly defined. The cause of this condition is not exactly known. In case of a catabolic state due to lack of insulin, intensive fluid therapy may lead to liquid extravasation in subcutaneous tissue and this may result in peripheral oedema. This condition can also worsen due to increased capillary permeability caused by chronic hyperglycaemia. In this case report we present a newly diagnosed, underweight type 1 DM patient developed insulin oedema following high dose insulin therapy.

Associations of serum magnesium levels with diabetes and diabetic complications

Dilek Arpaci[1], Aysel Gurkan Tocoglu[1], Hasan Ergenc[1], Sumeyye Korkmaz[1], Aysenur Ucar[1], Atilla Onmez[1], Mehmet Yildirim[1], Ozlem Hurmeydan[2] & Ali Tamer[1]
[1]Department of Internal Medicine, Sakarya Education and Research Hospital, Sakarya University, Sakarya, Turkey; [2]Department of Biochemistry, Sakarya Education and Research Hospital, Sakarya, Turkey.

Background
Magnesium (Mg) deficiency is a common problem in diabetic patients. Deficiency of Mg may increase the incidence of diabetes. Development of hypomagnesemia may affect glycaemic regulation and trigger complications of diabetes. The aim of our present study was to explore relationships between the serum Mg level and diabetes complications.
Materials and methods
In this retrospective study, we evaluated 673 diabetic patients, of whom 57.8% were males and 42.2% females. Mean patient age was 55.6 years and the mean duration of diabetes 81 ± 86.9 months.
Results
The mean level of HbA1c was $9.0 \pm 2.4\%$ (4.5–18); the mean serum creatinine level 0.83 ± 0.22 mg/dl (0.3–1.5); and the mean Mg level 1.97 ± 0.25 (1.13–3.0) mg/dl. Total of 55 (8.2%) patients had diabetic retinopathy and 95 (14.1%) diabetic neuropathy. Of all patients, Five hundred patients 74.3% of patients had normoalbuminuria, 133 19.8% of microalbuminuria, and 40 5.9% of overt proteinuria. 171 patients (25.4%) had HbA1c levels equal or below 7%; and 502 patients (74.6%) had HbA1c levels above 7%. The patients were divided into two groups in terms of their serum Mg levels; low-level ($\leq$1.8 μg/dl) and normal (1.9–2.6 μg/dl). No between-group difference in any of BMI, fat mass, total body water (TBW), fasting glucose (FG) level, lipid parameters, sodium or potassium levels, or glomerular filtration rate (GFR), was apparent. Although, the groups did not differ in terms of retinopathy or neuropathy levels, microalbuminuria was more common in hypomagnesemic patients ($P=0.004$). HbA1c levels did not differ between the groups ($P=0.243$). However, a weak negative correlation was apparent between serum Mg and HbA1c levels ($r=-0.110$, $P=0.004$) and also between serum Mg level and overt proteinuria ($r=-0.127$, $P=0.018$).
Conclusion
Mg depletion is a common problem in patients with diabetes mellitus. It affects both glycaemic regulation and emergency of complications. Serum Mg level affected both glycaemic regulation and the extent of emergency diabetic complications. Also, poor glycaemic regulation affected serum Mg levels.

Scleredema in a patient with long-standing type 2 diabetes mellitus

Isilay Kalan Sari[1,2], Senay Arikan Durmaz[2], Önder Bozdogan[3], Mukadder Kocak[4] & Ramazan Cosar[5]
[1]Department of Endocrinology and Metabolic Diseases, Burdur State Hospital, Burdur, Turkey; [2]Department of Endocrinology and Metabolic Diseases, Faculty of Medicine, Kirikkale University, Kirikkale, Turkey; [3]Department of Pathology, Faculty of Medicine, Kirikkale University, Kirikkale, Turkey; [4]Department of Dermatology, Faculty of Medicine, Kirikkale University, Kirikkale, Turkey; [5]Department of Internal Medicine, Faculty of Medicine, Kirikkale University, Kirikkale, Turkey.

Introduction
Scleredema is a rare skin disease, clinically presents as diffuse, painless induration, and thickening of skin. It primarily affects the upper part of body and usually occurs in association with diabetes mellitus, infections or monoclonal gammopathy. We discussed a case of scleredema in patient with history of diabetes mellitus.
Case report
A 54-year-old woman with history of long-standing, poorly-controlled diabetes mellitus, hypertension, and coronary artery disease was referred to our department. She complained to gradually-developing several months, and hardening erythematous plaques on the neck and upper back. Her medication included metformin (2000 mg/day) and premixed insulin (50 U/day). Physical examination revealed edematous, erythematous plaques on posterior neck and upper back. Other systemic evaluations were normal. Complete blood count and comprehensive biochemical panel were normal, exception of fasting blood glucose of 277 mg/dl. HbA1c was 11.8%. The patient was examined by dermatologist and skin biopsy was performed. On histopathological examination; epidermis was normal but there is prominent separation of collagen fibres throughout the dermis, thickening of the dermis and coarsening of collagen. Focal alcian blue positive mucine was also detected. Histopathological findings were consistent with scleredema. She had shown no infection signs. Scleredema was thought to be secondary to diabetes. She was started on intensive insulin regimen and glucose levels decreased within normal range. She was started on local PUVA therapy. After 2 months; redness and oedema of skin has partially disappeared, mobility of the back improved and skin of upper back was softer.
Conclusion
Scleredema diabeticorum is a rare complication of diabetes and reveals in obese subjects with long standing and poorly controlled diabetes mellitus. It can be clinically and histopathologically differentiated by other fibrosing disorders.

Tight glycaemic control is recommended but efficiency has not been proven. Ultraviolet A-1 phototherapy and PUVA seem to be most effective treatments for this disease.

Coated pellets with controlled glucose release for interdiction of hypoglycaemia in children with diabetes

David Neumann[1], Aleš Franc[2], Jan Muselík[2] & Dana Sabadková[2]
[1]University Hospital Hradec Kralove, Hradec Kralove, Czech Republic; [2]University of Veterinary and Pharmaceutical Sciences, Brno, Czech Republic.

Introduction
A diet plan, meals with suitable glycaemic index and sophisticated insulin delivery are used for balanced sacharides–insulin intake. In specific real day-to-day life situations patients must break their activities. Urgency to east in socially inappropriate time harm their lives, especially in young children with diabetes. Night hypoglycaemia, a parental fear of insufficient snack in nursery, sports with prolonged race periods, etc. are among these situations. Controlled glucose release formulation with 2, 4, and 6 h lag time offers chance to substitute snacks or other meals in advance, allowing to decrease life inconvenience and improve therapy adherence of children with diabetes and their parents.
Design
A dosage form with controlled glucose release was prepared, a release period of 2–4 h was achieved. Optimal diameter, resistance of the coat, volume, taste, and acceptable form to swallow were refined in pharmaceutical treat.
Results
An amount of two exchange units is easy to add to standard meals, e.g. yoghurt. Pellets (clinically powder) do not cause abdominal discomfort. In CGM studies, formulation prevent night hypoglycaemia.
Conclusions
The formulation with controlled glucose release with specific easy-to-explain lag time offers additional means for diabetes treatment.

Different glycaemic patterns in patients with steroid diabetes and type 2 diabetes

Andreja Maric & Bozidar Poljak
County Hospital Cakovec, Cakovec, Croatia.

Introduction
Long-term use of glucocorticoids has impact on reduction of β-cell function and peripheral insulin sensitivity, leading to a steroid diabetes.
Aim
To assess patterns of change of glycaemia and need for insulin at admission to hospital, during days 1–5 and at discharge in patients with newly diagnosed type 2 diabetes (NST) compared with patients with a history of taking corticosteroids and newly diagnosed diabetes mellitus (ST).
Material and methods
Twenty patients with newly diagnosed diabetes were included; ten without, and ten with a history of taking corticosteroids. The day after admission (day 1) basal-bolus insulin scheme was introduced. Bolus insulin was used in the initial dose of 0.05 U/kg per meal, and a basal insulin (NPH) 0.2 IU/kg BW at bedtime. The changes of glycaemia during 1–5 days were observed by measurement of plasma glucose profile before meals and 2 h after/before bedtime, and the need for insulin during the investigated time was recorded. A statistical analysis of data was performed.
Results
12 women (six NST and six ST) and eight men (four NST and four ST) were included in the study. The longest period of taking corticosteroids was 150 days, with a cumulative dose of 9600 mg of methylprednisolone. Statistically significant differences ($P<0.05$) were obtained: in total dose bolus insulin and the number of units per kilogram BW before dinner between NST and ST groups, and in the ST group in the first 5 days of treatment vs. at discharge; changes in plasma glucose in the period after lunch to dinner in ST group. There was a positive correlation between the cumulative dose of corticosteroids and the plasma glucose at admission at women in ST group.
Conclusion
Corticosteroids primarily cause hyperglycaemia in the afternoon and evening, and the targeted treatment and monitoring of glycaemic control should be directed to the above hours.

Angiopoietin 1 in patients with type 2 diabetes mellitus and diabetic retinopathy

Abd El Sattar El-Deeb[1], Mohamed Halawa[1], Ahmed Saad[2], Inas Sabry[1], Maram Mahdy[1], Mohamed Abd El Aziz[3] & Nagwa Roshdy[1]
[1]Internal Medicine Department, Faculty of Medicine, Ain Shams University, Cairo, Egypt; [2]Ophthamology Department, Faculty of Medicine, Ain Shams University, Cairo, Egypt; [3]Biochemistry Department, Faculty of Medicine, Ain Shams University, Cairo, Egypt.

Background
Diabetic retinopathy (DR) is a clinically well-defined sight-threatening complication in type 2 diabetes. Angiopoietin 1 (Ang1) has been shown to promote endothelial cell survival without causing proliferation, stabilise endothelial interactions with surrounding support cells and can block the vascular permeability effects of vascular endothelial growth factor (VEGF). More recent data suggest that balance between these growth factors may affect vascular endothelial integrity and may be involved in the pathogenesis of diabetic retinopathy.
Aim of the study
To evaluate serum level of Ang1 in patients with DR and its relation to the severity of DR.
Methods
This is a cross sectional study comprised 75 patients with type 2 diabetes mellitus. They were divided into four groups, group A: 25 diabetic patients with proliferative DR (PDR), group B: 25 diabetic patients with non-proliferative DR (NPDR), group C: 25 diabetic patients with normal fundus, and group D: 50 healthy volunteers of matched age and sex.
Results
There was a high statistically significant reduction in serum level of Ang1 in diabetic patients ($622.53+394.94$) than the healthy control group ($1637.00+253.50$), $P<0.001$. Ang1 was significantly lower among group A (PDR) ($330.80+145.19$) than group B (NPDR) ($489.60+226.89$), and group C ($1047.20+336.83$). Correlation between Ang1 vs the other variables showed a highly significant negative correlation between Ang1 and HbA1c ($P<0.001$) and a significant negative correlation with albumin/creatinine ratio (ACR), $P<0.02$.
Conclusion
There is a significant reduction in serum Ang1 in patients with DR and correlated with the severity of DR. This reduction of Ang1 may reflect a role in the pathogenesis and progression of DR.

Eighteen grams of glucose are necessary to treat severe hypoglycaemia: experience from the Emergency Medical Services Department

Charlotte Cohen[1,3], Marinos Fysekidis[3], Célia Etiennar[1], Lucie Ginaux[1], Jean-Luc Sebbah[1], Régis Cohen[2] & Philippe Lakhnati[1]
[1]SMUR Centre Hospitalier de Gonesse, Gonesse, France; [2]Hopital Delafontaine, Saint Denis, France; [3]Hôpital Avicenne, Bobigny, France.

We know that non-severe hypoglycaemia (SH) should be treated with the immediate intake of 15–20 g of oral glucose, there are no data according to our knowledge in the current literature for the dose of glucose that is necessary to inject in SH. We have analysed retrospectively the treatment of pre hospital SHs as reported after an emergency call for intervention. Our primary objective was to know the dose of the given glucose and our secondary objective was to know the factors involved in determining these doses. Between April 2012 and December 2013 148 cases with SH were analysed retrospectively. A total of 104 cases (77 patients) were included in the final analysis, there were 29 women, patients had a mean age of 62 ± 19 years and 62/77 were on insulin therapy. The kidney function, the insulin dose and the duration of symptoms on arrival was unknown in most cases. Almost half of the patients (49.53%) were admitted in the nearby hospital. after the intervention Patients that were not admitted had a pasta meal. Average blood glucose on arrival was 29 and 121 mg/dl at the departure of the emergency team. The average dose of injected glucose was 18 g (range 6–69 g)

according to the following procedure (first injection, 7 g glucose; second, 6 g; third, 5 g; mean glucose levels were 83 ± 33 for second and 108 ± 57 mg/dl for the third injection). The administered dose was inversely correlated with the duration of the intervention ($\beta = -0.267$, $P = 0.007$) and the Glasgow index ($\beta = -0.357$, $P = 0.001$) even after adjustment for patient's age. It seems that treatment is guided from the clinical severity of consciousness and can be treated injecting 60 ml glucose 30% (18 g of glucose), for most patients.

SUMO4 163G > A variation is associated with kidney disease in type 2 diabetes in Indian population

Vinod Kumar[1], Nisha Sinha[1], Ashok K Yadav[1], Anil Bhansali[2], Pinaki Dutta[2] & Vivekanand Jha[1]
[1]Department of Nephrology, Postgraduate Institute of Medical Education and Research, Chandigarh, India; [2]Department of Endocrinology, Postgraduate Institute of Medical Education and Research, Chandigarh, India.

Background
Various genetic and environmental factors are appear to contribute to the development of kidney disease in type 2 diabetes. Small ubiquitin-related modifier 4 (SUMO4) appear to play a role in development and/or progression of diabetic nephropathy. Substitution of methionine with valine at codon 55 (M55V) of SUMO4 enhances activity of nuclear factor-kB, a central mediator of inflammation proapoptotic events.
Aims
To investigate the association between the SUMO4 M55V (rs237025, 163G > A) variant and kidney disease in north Indian individuals with type 2 diabetes.
Materials and methods
A case–control analysis was performed using genomic DNA samples from 201 subjects with diabetic nephropathy (DN) and 216 patients with diabetes but no kidney disease (DM). The SUMO4 163G > A polymorphic region was amplified using PCR and genotyping was done by digestion of amplified PCR product with restriction enzyme MseI.
Results
The duration of diabetes was higher in DN compared to DM ($P = 0.001$). Clinical characteristics like blood pressure, cholesterol, triglycerides, HbA1c, and serum creatinine were significantly different between the two groups ($P < 0.001$). The frequency of other diabetic complication like neuropathy and retinopathy was also significantly greater in DN ($P < 0.001$). The genotypic and allelic frequencies of the studies variant were significantly different in DM and DN groups. GG genotype and G allele were significantly more frequent in DN as compared to DM ((GG: $P = 0.018$, OR = 1.72, 95% CI 1.1–2.7) (G: $P = 0.017$, OR = 1.4, 95% CI 1.1–1.8)).
Conclusions
This study shows that SUMO4 163G > A polymorphism might be associated with susceptibility to diabetic nephropathy.

Feasibility, acceptability, and uptake rates of gestational diabetes mellitus screening in primary care vs secondary care: findings from a randomised controlled mixed methods trial

Marie Tierney, Angela O'Dea, Andriy Danyliv, Liam Glynn, Brian McGuire, Louise Carmody, John Newell & Fidelma Dunne
National University of Ireland, Galway, Ireland.

Introduction
It is postulated that uptake rates for gestational diabetes mellitus (GDM) screening would be improved if offered in a setting more accessible to the patient. However, this has not been previously investigated, nor has the feasibility or the acceptability of such an alternative. The aim of this study is to evaluate the rate of uptake of GDM screening in the primary vs secondary care setting, and to qualitatively explore the providers' experience of primary care screening provision.
Methods
This mixed methods study was composed of a quantitative unblinded parallel group randomised controlled trial and qualitative interview trial. 781 pregnant women were randomised to receive a 2-h, 75 g oral glucose tolerance test in either the primary ($n = 391$) or secondary care ($n = 390$) setting. Semi-structured interviews with 13 primary care providers were conducted.
Results
Statistically significant differences were noted between the two quantitative study arms for uptake rates (52.7% in primary care compared to 89.2% in secondary care; $P < 0.001$), crossover rates (32.5% in primary care compared to 2.3% in secondary care; $P < 0.001$), and non-uptake rates (14.8% in primary care compared to 8.5% in secondary care; $P = 0.005$). Of the total potential participants, 37.2% ($n = 1206$) could not be involved as their primary care provider did not engage with the trial. Primary care providers reported difficulties with the conductance of GDM screening citing workload, logistical challenges and lack of remuneration as problematic, while recognising primary care as the most appropriate and preferable location for screening.
Conclusions
Currently, provision of GDM screening in primary care in Ireland, despite its acknowledged benefits, is unfeasible due to poor uptake rates, poor rates of primary care provider engagement and primary care provider concerns, particularly with regard to resourcing limitations.

Real-time sonoelastography and ultrasound evaluation of Achilles tendon of diabetic patients

Berna Evranos[1], Ilkay Idilman[2], Ali Ipek[2], Sefika Burcak Polat[1], Bekir Cakir[1] & Reyhan Ersoy[1]
[1]Endocrinology and Metabolism Department, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey; [2]Radiology Department, Ataturk Education and Research Hospital, Ankara, Turkey.

Introduction
Diabetes mellitus (DM) is an endocrine disease characterised by metabolic abnormalities and long-term complications. Achilles tendon (AT) play an important role in foot biomechanics. We aimed to investigate the effect of DM on the AT, which may contribute to the long-term complications in the foot–ankle complex.
Materials and methods
78 diabetic patients with (35 cases) or without (43 cases) diabetic foot ulcers were recruited from Endocrinology Clinic. Thirty-three age, gender, and BMI matched non-diabetic healthy individuals with no history of Achilles tendinopathy were selected among hospital staff as controls. All participants underwent ultrasonography and sonoelastography of their ATs for evaluating AT thickness (ATT) and stiffness (ATS). Each patient was also tested for fasting plasma glucose (FPG) and HbA1c as a measure of diabetes control. Other chronic complications were also evaluated in all diabetic patients.
Results
The AT was significantly thicker in the diabetic patients with diabetic foot ulcers compared to diabetics without any ulcer and the controls ($P < 0.001$). The ATT correlated with the BMI ($r = 0.224$, $P = 0.04$) and age ($r = 0.419$, $P = 0.001$). HbA1c, FPG, and duration of diabetes were higher for diabetic patients with foot ulcers. We observed that the ATT values were positively correlated with neuropathy ($P = 0.001$), retinopathy ($P = 0.001$), nephropathy ($P = 0.006$), peripheral arterial disease ($P = 0.001$), and coronary arterial disease ($P = 0.005$) in diabetic patients without foot ulcers. But this correlation wasn't detected for diabetic patients with foot ulcers. ATS decreased in the diabetic patients with diabetic foot ulcers.
Conclusion
Diabetic patients with diabetic foot ulcers have softer and thicker AT then the other diabetics and healthy controls. This is the first study reported that research sonoelastosonography of AT of diabetic patients.

Effect of gemigliptin switching from pioglitazone with metformin in type 2 diabetes

Yonghyun Kim & Donghyun Shin
Bundang Jesaeng Hospital, Seongnam, Kyeonggido, Republic of Korea.

The DPP4 inhibitors that increase insulin secretion by glucose dependently can also relieve insulin resistance because they improve early phage insulin secretion and prevent late hyperinsulinaemia. It also can be more effective in controlling the blood glucose because it acts synergistically with metformin by improving insulin secretory dysfunction compared TZD with metformin that has similar action mechanism. One of those is gemigliptin that was developed in this country recently and there are not many clinical studies. So, we observed the effect of gemigliptin with metformin compared to pioglitazone with metformin. We recruited 81 type 2 DM who failed in glucose control target below 7% of HbA1c or have side effect such as weight gain with metformin plus pioglitazone. The 15 mg of pioglitazone was used when it was switched because the usual dose permitted by national insurance was 15 mg at that time. Pioglitazone was switched to gemigliptin without changing the dose of metformin. The mean HbA1c level of 3 months and just before switching was compared to the mean of 3 and 6 months after switching. The difference of weight and HOMA-IR just before and 6 months after switching was also compared. The age was 56.4 ± 10.0 and mean BMI was 26.3 ± 5.4. The mean HbA1c level before switching was 7.1 ± 4.46. The HbA1c level was decreased in 72 patients (89%). The mean decrement of HbA1c was 0.58 ± 0.39 in above group. The body weight was increased (1.2 ± 0.39 kg) in 27 (33%) and decreased (2.9 ± 2.58 kg) in 48 (59%). The mean BMI was lower in weight gain group (24.1 ± 9.7) than in weight loss group (29.0 ± 5.5). The mean HOMA-IR before switching was 2.54 ± 2.55. HOMA-IR was increased in 67% and mean was 1.51 ± 1.47. It was decreased in 33% and mean was 0.43 ± 0.16. The gemigliptin can be a good substitute to improve glucose control when failed with 15 mg of pioglitazone with metformin. It is more effective in weight control especially in high BMI group.

Cytokine status and subpopulations of peripheral blood lymphocytes in patients with type 2 diabetes mellitus and non-alcoholic fatty liver disease

Kateryna Kondratiuk[1], Petro Bodnar[1], Mykola Lysianyj[2], Liudmyla Belska[2] & Antonina Potapova[2]
[1]Bogomolets National Medical University, Kyiv, Ukraine; [2]Romodanov Institute of Neurosurgery, Kyiv, Ukraine.

One of the leading roles in the mechanisms of type 2 diabetes mellitus (T2DM) belongs to immunopathological link of pathogenesis, which determines the development rate and severity of its specific complications, in particular, non-alcoholic fatty liver disease (NAFLD).

The purpose

To examine the contents of cytokines and major lymphocyte subsets in patients with T2DM and NAFLD.

Description of methods

We observed 118 patients, including 64 patients with T2DM and NAFLD, 26 patients with T2DM and 28 patients with NAFLD. The control group consisted of 25 apparently healthy individuals.

Results

Identified changes in the level of cytokines and lymphocyte subpopulation composition in combination of T2DM with NAFLD can be used both for diagnosis and for predicting adverse development of this disease, in particular the development of the inflammatory response in the liver (increased level of IL1β), intensity and orientation of immunopathological reactions (increased IFNγ level, decreased IL4 level, and changed NK cells level), the intensity of proliferation of connective tissue and fibrosis formation (increased IL10 level).

Conclusions

In patients with T2DM, NAFLD or a combination of these abnormalities are observed changes in cytokine status, reflecting the intensity of the inflammatory immune responses, their direction and possible forecast of liver fibrosis. Increased blood levels of IL1β, IL17, and IFNγ indicate the presence of high inflammatory and immunopathological reactions in patients with T2DM and NAFLD. Imbalance is observed in the composition of lymphocyte subpopulations, manifested by decries of CD8+ and CD16+ lymphocytes at a relatively stable level of T helper (CD4+) lymphocytes and increased content of CD20+ lymphocytes which develops against the background of increased level of circulating immune complexes. In patients with NAFLD and T2DM increased apoptotic preparedness of lymphocytes were revealed, which manifests as increased content of CD95+ cells in the blood.

Evaluation of violation vibration sensitivity for early diagnosis of diabetic distal polyneuropathy in patients with type 1 diabetes in the Republic of Belarus

Shepelkevich Alla[1], Bilodid Irina[1], Sosedkova Alexandra[1], Salko Olga[2], Malkevich Alexandra[1], Volkov Nikita[1] & Yurkovec Vladislav[1]
[1]Belarusian State Medical University, Minsk, Belarus; [2]Republic Medical Rehabilitation and Balneo Treatment Cente, Minsk, Belarus.

Screening for diabetic polyneuropathy (DP) is advisable for all patients with type 1 diabetes mellitus (T1DM) after 5 years the detection of the disease. The aim of the study was to evaluate the vibration sensitivity disorders in T1DM patients using Vibratip device for early diagnosis of DP.

Materials and methods

509 patients with T1DM (224 women and 285 men) (mean age: 28.5 ± 8.5 years, mean BMI −24.2 ± 4.1 kg/m^2) were examined. The research was conducted within the framework of the republic action 'optimization of approaches to improve the early diagnosis and prevention of diabetic polyneuropathy'. According to the criteria for inclusion in the research were examined patients with T1DM duration of disease is not more than 5 years (duration of DM: 3.3 ± 1.6 years). During the campaign was carried out a survey in individuals who seek health care institutions of the Republic of Belarus, the analysis of the medical documentation and examination of patients with an estimate of the sensitivity stop using the device Vibratip.

Results

The most common clinical symptoms of DP were: pain – 69 (13.6%) patients, burning – 83 (16.3%), numbness – 134 (26.3%), feeling of pins and needles – 132 (25.9%), and feeling of electric shock – 25 (4.9%) in patients with T1DM. Sensory disturbances feet were found in 23.6% (120) of diabetic patients: 12.6% (64) women and 11% (56) males using Vibratip device.

Conclusions

The data confirmed the high incidence of violation of vibration sensitivity in patients with T1DM with disease duration of <5 years.

Disabilities of the arm, shoulder, and hand (DASH) questionnaire and diabetic complications: preliminary results

Dilek Tuzun[1], Emine Duygu Ersozlu Bozkirli[2], Ayten Oguz[1], Murat Sahin[1], Hanife Bolat[3], Mustafa Saygin Deniz[3], Omer Faruk Akgul[3] & Kamile Gul[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [2]Division of Rheumatology, Adana Numune Training and Research Hospital, Adana, Turkey; [3]Department of Internal Medicine, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey.

Aim

Disabilities of the arm, shoulder, and hand (DASH) questionnaire is a self-administered region-specific outcome instrument developed as a measure of self-rated upper-extremity disability and symptoms. The DASH consists mainly of a 30-item disability/symptom scale. In this study, we aimed to evaluate DASH questionnaire in 1000 type 2 diabetes mellitus (T2DM) patients.

Material and methods

297 patients (mean age 52.13 ± 9.37 years, 190 women and 107 men) who had T2DM were included as a preliminary in this study. The presence of cheiroarthropathy, Dupuytren's contracture, tinnel sign, and tendinitis was assessed. Diabetic retinopathy was assessed by direct ophthalmoscopy. Urinary albumin excretion was determined in at least two 24 h urine samples. DASH questionnaire was administered to the diabetic patients. Direct measurements of parameters were performed with a Tanita body composition analyser. The bioimpedance parameters we measured were body fat percentage (%BF), total body fat (TBF, kg), and BMI.

Results

The mean diabetic duration was 7.71 ± 6.28 years. Dupuytren's contracture was present in 7.7%, cheiroarthropathy in 11.1%, tinnel sign in 19.5%, and tendinitis in 4.4%. Retinopathy was present in 15.5%, nephropathy in 18.2%. DASH score was 68.00 ± 31.70. Mean BMI was 32.28 ± 5.80. Mean TBF was 29.222 ± 11.77 kg. Mean %BF was 34.00 ± 10.19. There was positive correlation between DASH score and cheiroarthropathy, tinnel sign, and tendinitis ($P = 0.006$, $r = 159$; $P = 0.000$, $r = 214$; and $P = 0.004$, $r = 168$ respectively). There was positive correlation between DASH score and BMI and TBF and %BF ($P = 0.000$, $r = 288$;

$P=0.000$, $r=284$; and $P=0.000$, $r=319$ respectively). No correlation was found between DASH score and diabetic nephropathy and retinopathy.
Conclusions
DASH questionnaire is useful instrument for measuring functional disability in upper extremity complaints of diabetes mellitus patients. It should also be taken into consideration in order to increase the quality of life in DM patients.

Can the onset of type 2 diabetes be delayed by a group-based lifestyle intervention in women with prediabetes following gestational diabetes mellitus? Findings from a randomised control mixed methods trial

Angela O'Dea[1], Marie Tierney[1], Brian McGuire[1], John Newell[1], Irene Gibson[2], Liam Glynn[1], Eoin Noctor[1], Susan Connolly[3] & Fidelma Dunne[1]
[1]National University of Ireland, Galway, Ireland; [2]Croí West of Ireland Cardiac Foundation, Galway, Ireland; [3]Imperial College London, International Centre for Circulatory Health, London, UK.

Aim
The aim of this paper is to report on the outcomes of a randomized controlled trial designed to evaluate the effectiveness of a group-based lifestyle intervention programme for reducing the risk factors associated with diabetes in women with pre diabetes following gestational diabetes. We expected that the group based intervention through its educational and supportive approach would enable improvements in psychosocial health, health behaviours, anthropometry, and glucose function.
Design and methods
A two groups, mixed methods randomized controlled trial in which 50 women with a history of gestational diabetes mellitus (GDM) and abnormal glucose tolerance *postpartum* were randomly assigned to MyAction ($n=24$) or wait control ($n=26$). The primary outcome variable was the change in fasting plasma glucose (FPG) from study entry to 1-year follow-up. Secondary outcomes were: glucose tolerance (2 h), insulin resistance, lipid profile, weight, shape, diet, and exercise levels. The role of mood, cognition and wellbeing were also explored. Post intervention qualitative interviews with participants are also reported.
Results
At 1-year follow-up, the intervention group showed significant improvements over the wait control group on stress, diet self-efficacy, and quality of life. There was no evidence of an effect of the intervention on measures of biochemistry or anthropometry the effect on one health behaviour – diet adherence, was close to significance. For many participants improvements made during the intervention were not sustained in the post intervention period.
Conclusions
Optimal approaches for preventative measures must tackle the barriers to participation faced by this population, home-based interventions should be investigated. Strategies for promoting long-term health self-management need to be developed and tested. The role of psychosocial factors in facilitating health related behaviour change should be explored further.

Topical wound pressurised oxygen therapy: new approach in treatment of diabetic foot ulcers?

Maja Čavlović Naglić, Maja Bakula & Lea Smirčić Duvnjak
Merkur University Clinic, Zagreb, Croatia.

Introduction
Topical wound oxygen therapy (TWO_2) is therapeutic modality that delivers humidified pressurised O_2 directly to the specific body part to achieve tissue penetration and increased O_2 levels to the open ischaemia wound. O_2 is vital in the synthesis of collagen, enhancement of fibroblasts, angiogenesis, leukocyte function, energy metabolism, and the inhibition of mycrobial growth. TWO_2 therapy has showed effectiveness as an adjunctive therapy for the management of acute and chronic diabetic foot ulcers, venous stasis ulcers, pressure ulcers, and mixed ulcers.
Materials and methods
Five male patients aged 50–77 years with chronic diabetic foot ulcers grade 2A or worse according to the University of Texas wound Classification system (UTI) and ankle–brachial index (ABI) at least 0.5 in the affected limb were treated with TWO_2 60 min daily, Monday through Friday for 6 weeks. Wound size measuring, microbiological samples, and digital photography of the wound were done once weekly. Wounds were debrided prior to therapy by the vascular surgeon, who assessed the wound every 7–10 days and debrided it if necessary. If infection was present antibiotics were given according to the antibiogram.
Results
Wound area reduced from average 8.86–2.54 cm^2. Ulcer classification changed from UTI 2-B, 2-C and 2-D to 1-A and 0-A. Infection was absent in all wounds comparing to four infected wounds at the beginning.
Conclusion
Although current studies have shown effectiveness of TWO_2 in treatment of diabetic foot ulcers, there are no specific cost effectiveness studies completed and there have been no studies found that show improved quality of life for patients receiving TWO_2. The most important thing is that there are no standardised protocols for TWO_2. So, randomised control studies are needed to increase the evidence around the use and effectiveness of TWO_2 therapy and to establish optimal parameters for use.

The use of insulin pump therapy in the paediatric age group

Hanna Mikhno[1], Angelica Solntsava[2] & Natalia Volkova[2]
[1]2nd City Children's Hospital, Minsk, Belarus; [2]Belarusian State Medical University, Minsk, Belarus.

The use insulin pump therapy (IPT) (continuous subcutaneous insulin infusion (CSII)) has increased dramatically in youth with type 1 diabetes (T1D) in the past decade.
Objective
Rate metabolic compensation of diabetes mellitus in children on IPT on the level HbA1c and self-control of glycaemia.
Methods
The examination of 19 children aged 12.55 ± 3.75 years (boys/girls = 13/6), with T1D, observed in '2nd City Children's Hospital' in Minsk. Up to IPT patients were on basal-bolus insulin therapy. Patients transferred to the IPT because of frequent uncontrolled hypoglycaemia. Evaluated the dose of insulin per kilogram body weight, blood glucose self-monitoring during the day, the presence of ketoacidosis, hypoglycaemic and hyperglycaemic conditions, the level of HbA1c.
Results
100% of the patients complained of unstable blood glucose levels throughout the day. Clinical manifestation of diabetes observed in age 6.83 ± 3.72 years. Longevity of diabetes this patients was from 0.5 to 16 years (4.91 ± 4.10 years). Insulin dose per kilogram body weight on a basis of bolus insulin was 0.88 ± 0.40 U/kg. HbA1c was 7.30 ± 0.86%. Hypoglycaemic coma was in two children (10.53%). Self-monitoring of blood glucose was performed 8.9 ± 3.6 times a day. Term of use pump 1.31 ± 1.15 years. Five patients were in the ICU for more than 1 year (2.49 ± 1.02 years). The IPT insulin dose per kilogram of body weight was 0.90 ± 0.29 U/kg ($P=0.005$), HbA1c was 6.49 ± 0.74% ($P=0.002$). Self-monitoring of blood glucose for IPT 7.15 ± 2.89 times a day. IPT is not mentioned on the hypoglycaemic, severe hypoglycaemia, ketoacidosis, and hyperglycaemic conditions. The frequency change modes basal insulin dose during the day 4.8 ± 1.5 times.
Conclusions
Children who are on insulin pump therapy during the year was a significant reduction in HbA1c at 11.10% ($P=0.002$), indicating that the long-term metabolic compensation in all age groups.

Relation between psychiatric symptoms and diabetic complications: preliminary results

Dilek Tuzun[1], Emine Duygu Ersozlu Bozkirli[2], Ayten Oguz[1], Murat Sahin[1], Tugba Yilmaz[3], Berivan Ganidagli[3], Omer Faruk Akgul[3] & Kamile Gul[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [2]Division of Rheumatology, Adana Numune Training and Research Hospital, Adana, Turkey; [3]Department of Internal Medicine, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey.

Aim
In this study, we aimed to assess psychiatric symptoms in 1000 type 2 diabetes mellitus (T2DM) patients.
Material and methods
297 patients (mean age 52.13±9.37 years, 190 women and 107 men) who had T2DM were included as a preliminary in this study. The presence of cheiroarthropathy, Dupuytren's contracture, tinnel sign, and tendinitis was assessed. Diabetic retinopathy was assessed by direct ophthalmoscopy. Urinary albumin excretion was determined in at least two 24 h urine samples. Beck's Depression Inventory (BDI) and Beck's Anxiety Inventory (BAI) were administered.
Results
The mean diabetic duration was 7.71±6.28 years. Dupuytren's contracture was present in 7.7%, cheiroarthropathy in 11.1%, tinnel sign in 19.5%, and tendinitis in 4.4%. Retinopathy was present in 15.5%, nephropathy in 18.2%. BDI score was 13.92±9.93 and BAI score was 16.89±13.63. There was positive correlation between BDI score and diabetic nephropathy ($P=0.001$, $r=197$). Also, there was positive correlation between BDI score and tinnel sign ($P=0.000$, $r=241$). Positive correlation between BAI score and diabetic nephropathy was detected ($P=0.019$, $r=136$). There was positive correlation between BAI score and tinnel sign ($P=0.00$, $r=232$). The suggested BDI cutoff of ≥ 17 had 81% sensitivity and 79% specificity and classified as clinically depressed. In our study BDI score ≥ 17 was 33.3%. BAI score ≥ 17 was classified as moderate and serious anxious. In our study BAI score ≥ 17 was 40.4%.
Conclusions
Psychiatric symptoms, especially depression and anxiety, are widely seen in patients with diabetes mellitus. Quality of life and disability are correlated with depression and anxiety levels. Therefore, in addition to the recent management of DM, psychiatric symptoms such as depressed mood and anxiety should also be taken into consideration in order to increase the quality of life in DM patients.

The diabetic hand: a forgotten complication?

Dilek Tuzun[1], Emine Duygu Ersozlu Bozkirli[2], Ayten Oguz[1], Murat Sahin[1], Irem Sahin[3], Hakan Demir[3], Elif Inanc[3], Berivan Ganidagli[3] & Kamile Gul[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [2]Division of Rheumatology, Adana Numune Training and Research Hospital, Adana, Turkey; [3]Department of Internal Medicine, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey.

Aim
Diabetes mellitus is a chronic metabolic condition characterised by persistent hyperglycaemia with resultant morbidity and mortality related primarily to its associated microvascular and macrovascular complications In this study our aim was to investigate the prevalence of the most frequently occurring hand complications in 1000 type 2 diabetes mellitus (T2DM) patients.
Material and methods
297 patients (mean age 52.13±9.37 years, 190 women and 107 men) who had T2DM were included as a preliminary in this study. The presence of cheiroarthropathy, Dupuytren's contracture, tinnel sign, and tendinitis was assessed. All patients were evaluated also by the Rheumatology Division. Diabetic retinopathy was assessed by direct ophthalmoscopy. Urinary albumin excretion was determined in at least two 24 h urine samples.
Results
The mean diabetic duration was 7.71±6.28 years. Dupuytren's contracture was present in 7.7%, cheiroarthropathy in 11.1%, tinnel sign in 19.5%, and tendinitis in 4.4%. Retinopathy was present in 15.5% and nephropathy in 18.2%. Mean HbA1c was 8.58±2.03. Mean fasting glucose was 174.6±69.22 mg/dl. The relationship between these complications and patients' age, sex, duration of diabetes, and glycaemic control was also analysed. There was positive correlation between age and cheiroarthropathy and dupuytren's contracture ($P=0.01$, $r=193$ and $P=0.000$, $r=248$ respectively). There was positive correlation between diabetic duration and diabetic retinopathy ($P=0.000$, $r=216$). There was positive correlation between diabetic duration and cheiroarthropathy ($P=0.044$, $r=117$). There was positive correlation between diabetic nephropathy and tinnel sign ($P=0.005$, $r=164$).
Conclusions
Some musculoskeletal disorders are more prevalent in T2DM patients and this may be associated with duration of diabetes. Also the hand abnormalities were associated with the diabetic complications. Long-term prospective randomised controlled trials on preventing musculoskeletal complications and disability in diabetics are needed.

Moderate and severe hypoglycaemia associated metabolic changes in cortex and hippocampus of mice

Vigneshwaran Pitchaimani
Niigata University of Pharmacy and Applied Life Sciences, Niigata, Japan.

Objective
It is common in the clinical setting that the reperfusion of glucose after severe hypoglycaemia. Starvation leads to decrease in blood glucose level (BGL) and this shifts the brain to utilize less glucose and utilize other alternative fuels. This led us investigate how the brain decreases the glucose uptake during starvation and how it utilizes the glucose under severe hypoglycaemia.
Results
To understand the mechanism we checked the neuronal glut3, glut1 in expression by western blot analysis in the cortex and hippocampus in 24 h fasted and 2 IU/kg insulin induced hypoglycaemia mice at different intervals (10, 30, and 90 min). Our results suggesting that 24 h fasting significantly decreases the BGL (58± 2 mg/dl) from fed mice BGL (120.3±6) and it slightly decreases the glut3 in cortex and hippocampus. In the insulin induced hypoglycaemia group, the BGL of 10 min after was (67.8 mg/dl), 30 min after was (54.80 mg/dl) and 90 min after was below (20 mg/dl). The glut3 expression in the 10 min was not altered but the 30 min after insulin administration decreases the glut3 more but not significant, whereas the glut3 in the 90 min after was restored to normal level. No change in the expression glut1 was observed.
Conclusion
The decreased BGL at the range nearly of 60 mg/dl during fasting or insulin induced hypoglycaemia, the neuron may utilize less glucose (decreased glut3) and may prefer astrocyte lactate (no change in glut1) and other fuel for metabolism. The decreased BGL below 20 mg/dl, the neuron may try to utilize the glucose directly (restored glut3) and from astrocytes (no change in glut1) and also from other fuels to restore the normal metabolism.

Diabetes mellitus and chronic kidney disease: two decades of consultation of diabetes and kidney transplant, a retrospective study

Ana Margarida Balsa[1], Margarida Bastos[2], Rosa Dantas[1], Carla Batista[2], Rui Alves[3], António Roseiro[3], Carolina Moreno[2], Daniela Guelho[2], Luís Cardoso[2], Nuno Vicente[2], Diana Martins[2], Diana Oliveira[2], Márcia Alves[1], Joana Guimarães[1], Alfredo Mota[4] & Francisco Carrilho[2]
[1]Serviço de Endocrinologia, Diabetes e Nutrição do Centro Hospitalar do Baixo Vouga, Aveiro, Portugal; [2]Serviço de Endocrinologia, Diabetes e Metabolismo do Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [3]Serviço de Nefrologia do Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [4]Serviço de Urologia e Transplantação Renal do Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal.

Introduction
Diabetic nephropathy is the main global cause of end stage renal disease. According to the annual report from the Portuguese National Diabetes Observatory, in 2013, the prevalence of diabetes mellitus (DM) in new cases of chronic kidney disease was 31.2 and 11.1% in kidney transplant patients.
Aim
To characterise the population of type 2 diabetic patients admitted in diabetes and kidney transplant consult (DKTC), comparing those admitted between the decades of Jan 1992–Dec 2001 (D1) and Jan 2002–Dec 2011 (D2).
Methods
Retrospective analysis of 238 out of 332 patients admitted in DKTC (D1, $n=66$ and D2, $n=172$); the registered data included age, sex, weight, BMI, age of diagnosis, duration of DM and therapeutic, metabolic control, macro and microvascular complications at first admission. Statistical analysis was performed with SPSS.
Results
D1 patients had an average age at of 56.91 ± 7.75 and 15.36 ± 8.29 years of DM and a HbA1c of $7.56\pm1.83\%$. 68.2% of patients D1 had retinopathy (51.5% proliferative); 31.8% had neuropathy; 7.6% had been submitted to amputation (6.1% minor and 1.5% major); 36.4% presented macrovascular complications. 33.8% completed the selection process and were transplanted. D2 patients had an average age of 59.46 ± 7.08 and 15.76 ± 8.61 years of DM and a HbA1c of $7.13\pm1.47\%$. Retinopathy was present in 65.1% of D2 patients (43.1% proliferative); neuropathy in 33.1%; 8.8% had been submitted to amputation (5.9% minor and 2.9% major); 27.2% had macrovascular complications. 32.1% D2 patients were transplanted. D2 patients were older than D1 ($P=0.016$) but had a lower prevalence of cardiac ischemic disease ($P=0.007$). No other statistical significant differences were found between the two decades.
Conclusion
Diabetic patients admitted in DKTC generally have a long evolution of DM, with several co-morbidities and complications. Even though in the last decade more and older DM2 patients were referred to kidney transplantation, we did not find an increase in those patient's complications.

Study of irisin hormone level in type 2 diabetic patients and patients with diabetic nephropathy

Salah Shelbaya, Manal Abushady, Merhan Samy, Yasmin Abd El Mageed & Magdy Abbas
Ain Shams University, Cairo, Egypt.

Background
Chronic kidney disease secondary to type 2 diabetes is associated with multifactorial energy dysmetabolism. Irisin has been identified recently as an exercise induced hormone secreted by skeletal muscles. It is hypothesised that patients with CKD may have altered irisin levels.
Aim of the work
We aimed to study irisin hormone in type 2 diabetic patient and to assess its relation with diabetic nephropathy (DN).
Subjects and methods
We recruited 60 type 2 diabetic subjects and 30 healthy controls. Diabetics will be divided into 30 patients without complications and 30 with DN. Serum irisin, fasting blood glucose (FBG), 2 h plasma glucose (2 h PG), HbA1c, serum creatinine, and albumin/creatinine ratio were measured.
Results
Irisin was significantly decreased in type 2 diabetic patients compared to control (34.46 ± 15.28 ng/ml vs 152.600 ± 39.581 ng/ml, $P<0.001$). Patients with DN had lower irisin than diabetics without complications (20.967 ± 4.476 ng/ml vs 47.967 ± 8.853 ng/ml, $P<0.01$). There was a significant negative correlation between irisin and systolic blood pressure ($r=-0.493$), diastolic blood pressure ($r=-0.625$), serum creatinine ($r=-0.729$), duration of diabetes ($r=-0.942$), albumin/creatinine ratio ($r=-0.696$), BMI ($r=-0.396$), and HbA1c ($r=-0.305$) in all diabetic patients.($P<0.05$). Multivariant regression analysis showed that duration of diabetes is the only independent determinant for irisin level.
Conclusion
There is a decrease in serum irisin level in patients with type 2 diabetes and a further significant decrease in patients with DN.

A puzzling bilateral diabetic foot problem

Nathalie Denecker, Dimitri Aerden & Michel De Maeseneer
UZ Brussel, Brussels, Belgium.

Introduction
Charcot neuroartropathy (CN) is a devastating complication of diabetes rapidly leading to irreversible foot deformity when misdiagnosed. Differential diagnosis with foot infections and other foot-related diseases remains challenging.
Case
A 58-year-old woman with type 2 diabetes was hospitalised with a red, swollen left leg and high fever. The diagnosis of erysipelas with a neuropathic wound of the first digit as the entry wound was established. After antibiotic treatment, the infection abated and the patient was discharged. Twelve days later she visited the Emergency Department with increased swelling and pain of the left leg, residual redness and a new skin defect on the left second toe. Ten days later, she was seen at the diabetic foot clinic. The patient reported a recent trauma, which had resulted in pain and a swollen, red right foot. X-rays and a bone scintigraphy with SPECT–CT were performed and surprisingly suggested CN of both feet, a finding that was later confirmed by MRI. A clinically suspected osteomyelitis of the left second digit was ruled out with a leucocyte scan and SPECT–CT. Immobilisation for 3 months with bilateral total contact casts (TCC) was deemed impracticable, so the left foot was treated with an aircast walker instead. Clinically the inflammatory signs subsided but bilateral talar oedema remained noticeable on MRI. Bilateral aircast walkers were advised for another 2 months until custom-made shoes became available.
Conclusion
The diagnosis of an active Charcot foot remains challenging, especially after previous infection or trauma which both may trigger CN. Bilateral CN, although extremely rare, further complicates early diagnosis and efficient bilateral offloading.

Continuous subcutaneous insulin infusion decreases hypoglycaemia during nighttime

Nuno Vicente, Luís Cardoso, Carla Baptista, Luísa Barros, Daniela Guelho, Diana Oliveira, Diana Martins & Francisco Carrilho
Serviço de Endocrinologia, Diabetes e Metabolismo, Centro Hospitalar Universitário de Coimbra, EPE, Coimbra, Portugal.

Introduction
Continuous subcutaneous insulin infusion (CSII) and multiple daily injections (MDI) are forms of intensified insulin therapy and the most used regimens for type 1 diabetes (T1D). Owing to its continuous basal output, hypoglycaemic events tend to be rarer with CSII. Our goal was to evaluate the differences in nocturnal hypoglycemia between these two treatment strategies.
Methods
Retrospective analysis of 61 patients who had performed continuous glucose monitoring (Ipro2, Medtronic, Northridge, CA, USA). All patients had T1D and were either on CSII or MDI. Hypoglycaemia was defined as glucose level <70 mg/dl. Daytime (DT) was defined as the period from 0700 to 2300 h and nighttime (NT) was from 2300 to 0700 h.
Results
We obtained 112 714 glucose measurements (42 132 on CSII and 70 582 on MDI). Our sample had mean age of 31.7 ± 8.8 years, BMI of 22.7 ± 7.5 kg/m^2 and a mean glucose of 156 ± 73 mg/dl. Those on CSII were older (33.0 years vs 31.2 years, $P<0.05$), heavier (25.7 kg/m^2 vs 20.8 kg/m^2, $P<0.05$), had a more prolonged duration of T1D (19.4 years vs 16.4 years, $P<0.05$) and a higher mean glucose measurement (162 mg/dl vs 154 mg/dl, $P<0.05$) than those on MDI. Hypoglycaemia was more frequent in the MDI group (7410 vs 2608 measurements, $P<0.05$) and mean HbA1c was similar (7.9 vs 8.0, $P>0.05$). Hypoglycaemia was more frequent in the MDI group, especially during NT ($P<0.05$ for both).
Conclusion
Despite similar HbA1c in the two groups, hypoglycaemia is more frequent in the MDI group, particularly at NT period.

Insulin prescription audit

Nabeel Saeed[1,2] & Mary Jane Brassill[1]
[1]South Tipperary General Hospital, Clonmel, Ireland; [2]Queen Elizabeth Hospital, Kingslynn, UK.

Insulin is a life-saving drug but can be life threatening if not prescribed properly. A prospective, consecutive audit of insulin prescription was carried out on all medical and surgical patients admitted to South Tipperary General Hospital with types 1 and 2 diabetes mellitus in November 2013. The practice was compared with hospital guidelines which are consistent with other hospitals nationally. Three prescribing practices were audited: i) the prescription of insulin on insulin prescription sheets (as per hospital policy) or drug kardex; ii) the adjustment of insulin doses on insulin prescription sheets as per blood sugar levels; and iii) the prescription of insulin on discharge prescription. Twenty consecutive patients were audited. 65% had insulin charted on insulin prescription sheet, 15% on drug kardex alone and 20% on both. 80% of patients had their insulin dosage corrected as per blood glucose readings on insulin prescription sheet, 10% on both and 10% did not need insulin dose correction. 60% of patients had insulin prescribed on discharge prescription whereas 40% did not and the reasons for this were analysed. As a result of these findings a new insulin prescription sheet was recommended and introduced with regular and supplementary insulin sections. Educational sessions on insulin prescription were also organised. A re-audit of a further twenty patients was performed in June 2014 to look at the above three prescribing practices. It showed 100% compliance in terms of insulin prescription. 90% compliance was observed in terms of insulin dose adjustment as per blood glucose readings. The remaining 10% did not require correction of insulin dose. 65% of patients had insulin prescribed on discharge, 10% did not require insulin on discharge, 10% died and 15% were still inpatients at time of re-audit. The re-audit showed an improvement in the practice of insulin prescribing and therefore improved patient safety.

Distribution of fat mass in young type 1 diabetic patients

Yulia Dydyshko & Alla Shepelkevich
Belarusian State Medical University, Minsk, Belarus.

Background
There is convincing evidence that the increasing of visceral fat is a risk factor for vascular disease. Type 1 diabetes mellitus (T1DM) is characterized by the development of micro-, and later, and macrovascular complications. The aim of the study was to examine features of body composition fat distribution parameters in T1DM patients.
Materials and methods
96 patients with T1DM (59 women and 37 men) (mean age: 32.52±10.71 years, duration of DM: 12 (7.5–20) years, age of manifestation: 18 (13–23.5) years), BMI: 23.47±3.16, HbA1c: 8.45±1.2% and 54 (30 women and 24 men) controls matched for age, sex, and BMI were examined. Body composition was determined by dual energy X-ray absorptiometry.
Results
Fat mass parameters in T1DM males and controls males were: android fat: 27.41±11.43% vs 28.8±9.67% ($P=0.627$); gynoid fat: 28.06±7.15% vs 26.74±7.74% ($P=0.506$); A/G ratio: 0.95±0.24 vs 1.06±0.15 ($P=0.048$); total body: 23.02±7.9% vs 22.55±7.5% ($P=0.819$); trunk/total: 0.516±0.07 vs 0.54±0.034 ($P=0.094$); legs/total: 0.35±0.06 vs 0.32±0.032 ($P=0.093$); and (arms+legs)/trunk: 0.9±0.28 vs 0.77±0.105 ($P=0.034$). Similar features in T1DM women and controls women were: android fat: 32.29±8.44% vs 32.37±10.81% ($P=0.97$); gynoid fat: 41.72±6.63% vs 41.36±7.16% ($P=0.81$); A/G ratio: 0.76±0.14 vs 0.45±0.05 ($P=0.97$); total body: 33.25±6.7% vs 32.3±7.59 g ($P=0.551$); trunk/total: 0.44±0.048 vs 0.45±0.056 ($P=0.611$); legs/total: 0.412±0.05 vs 0.415±0.054 ($P=0.812$); and (arms±legs)/trunk: 1.18±0.25 vs 1.17±0.3 ($P=0.837$). Gynoid (peripheric) fat distribution was positively correlated with the age of T1DM males ($r=0.19$; $P=0.018$), however no correlation was found with the duration of the disease, level HbA1c, the total daily insulin dose.
Conclusions
The peripheral type of fat mass distribution is dominated at T1DM males compared with control, while there were no differences in the distribution of adipose tissue among the investigated women. The obtained data indicate gender differences in the distribution of fat mass in T1DM patients.

Roux-en-Y gastric bypass reduces proteinuria in diabetic kidney disease to a greater extent than weight loss alone in the Zucker diabetic fatty rat without a greater improvement in renal inflammation

Karl Neff[1], Jessie Elliott[1], Sabrina Jackson[1], Kathrin Abegg[2,3], Caroline Corteville[2,3], Rodrigo Munoz[4], Neil Docherty[1], Thomas Lutz[2,3] & Carel le Roux[1]
[1]School of Medicine and Medical Sciences, Conway Institute, Diabetes Complications Research Centre, University College Dublin, Dublin, Ireland; [2]Vetsuisse Faculty, Institute of Veterinary Physiology, University of Zurich, Zurich, Switzerland; [3]Institute of Laboratory Animal Sciences, University of Zurich, Zurich, Switzerland; [4]Department of Digestive Surgery, School of Medicine Santiago, Pontificia Universidad Católica, Santiago, Chile.

Background
The effect of Roux-en-Y gastric bypass (RYGB) on diabetic kidney disease (DKD) is unclear. We used a Zucker diabetic fatty rat (ZDF) model of DKD to determine the effect of RYGB on histopathological markers of DKD, proteinuria, and MCP1 excretion.
Methods
ZDF rats underwent RYGB ($n=15$) or sham surgery ($n=14$) at 18 weeks of age. Eight sham operated animals were food restricted to match the weight loss of the RYGB group (body-weight matched (BWM) group). Animals were sacrificed at age 31 weeks.
Results
Macrophage infiltration (ED1 staining), urinary MCP1:creatinine ratio and MCP1 expression was reduced by in both RYGB and BWM groups ($P<0.05$). Despite similar effects on inflammation, RYGB had a greater effect on reducing proteinuria ($P=0.01$).
Conclusions
Weight loss alone can remediate renal inflammation, but RYGB has a greater effect on proteinuria. This may be due to other mechanisms such as incretin effects.

Assessment of the myelin damage degree in patients with and without diabetic neuropathy

Iryna Kostitska
Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine.

Background and aims
Diabetic neuropathy is associated with impaired neuron myelination, nerve conduction, and muscle function. The pathogenic mechanisms of reduced myelination in diabetes mellitus are poorly understood. Peripheral myelin protein 22 (PMP22) is glycoprotein with proposed roles in peripheral nerve myelin formation. This study allows us to consider the changes in the plasma levels of PMP22 in patients with and without diabetic neuropathy.
Materials and methods
We studied 34 subjects with DM duration of 15.2±2.1 years, mean value of HbA1c was 8.4±1.2% divided into two groups: diabetic patients without symptoms of peripheral somatic neuropathy (PSN) (consisted of 12 participants (five males/seven females), mean age was 42.7±10.1 years) and patients with diabetes and confirmed diagnosis of diabetic PSN (22 patients (eight males/14 females), mean age was 42.8±10.1 years) and 20 healthy volunteers (nine males/11 females, mean age was 48.3±9.5 years) as the control group. The plasma concentrations of PMP22 were measured by immunoassay. No subjects studied had signs of other disorders of peripheral nervous system.
Results
We found that plasma levels of PMP22 were significantly higher in the patients with PSN (9.1±1.32 ng/ml) compared to diabetic subjects without PSN (3.8±0.15 ng/ml) and control group (1.53±0.31 ng/ml), $P<0.05$.
Conclusion
These findings could suggest the occurrence of the neuron demyelination reflected by the elevated PMP22 in patients with diabetic neuropathy.

Tear function tests in pregnant women with gestational diabetes mellitus

Seyfullah Kan[1], Ugur Acar[2,5], Muhammed Kizilgul[3], Emrullah Beyazyildiz[4], Ali Bulent Cankaya[2], Mahmut Apaydin[3], Selvihan Beysel[3], Mustafa Ozbek[3] & Tuncay Delibasi[3]
[1]Department of Endocrinology and Metabolism, Ankara Teaching and Research Hospital, Ankara, Turkey; [2]Department of Ophthalmology, Faculty of Medicine, Hacettepe University, Ankara, Turkey; [3]Department of Endocrinology and Metabolism, Diskapi Teaching and Research Hospital, Ankara, Turkey; [4]Department of Ophthalmology, Samsun Teaching and Research Hospital, Samsun, Turkey; [5]Department of Internal Medicine, School of Medicine (Kastamonu), Hacettepe University, Kastamonu, Turkey.

Aim
Gestational diabetes mellitus (GDM) is a disorder which is described as impaired glucose tolerance which firstly occurs first time during pregnancy. We aimed to evaluate the tear function tests such as Schirmer, tear break-up time (TBUT), tear film osmolarity (TFO), and ocular surface disease index (OSDI) score in pregnant with GDM.
Methods
Pregnant women with GDM and healthy pregnant who were matched in both age and gestational age were enrolled into the study. The women with ocular or systemic disorders that may affect the tear function tests, and who use topical medications were excluded from the study. All of the pregnant answered the OSDI questionnaire, afterwards they underwent a detailed ophthalmic examination including Schirmer, TBUT, and TFO by the same ophthalmologist.
Results
Forty-six pregnant with GDM whose mean age of 30.43 ± 4.75 years and 36 healthy pregnant whose mean age of 28.83 ± 4.42 years were enrolled into the study. The mean gestational ages were 25.80 ± 1.61 and 26.19 ± 1.43 weeks respectively. There were not statistically significant differences between two groups in terms of age and gestational age. The mean fast blood glucose and the mean HbA1c levels were statistically significantly higher ($P < 0.001$, for each) in GDM group (105.17 ± 7.28 mg/ml and $5.57 \pm 0.50\%$) compared to healthy group (70.17 ± 6.54 mg/ml and $4.93 \pm 0.29\%$). The levels of Schirmer test, TBUT test, TFO, and OSDI score were 11.20 ± 4.93 mm, 5.59 ± 2.16 s, 309.65 ± 14.80 mOsm/l and 9.59 ± 9.69 points in GDM group, and 12.33 ± 5.33 mm, 5.67 ± 2.68 s, 308.36 ± 16.00 mOsm/l and 10.62 ± 8.66 points in healthy group. There were not statistically significant difference in any of the tear function tests between two groups.
Conclusions
To the best of our knowledge, there is no study in the literature about the effects of GDM on dry eye parameters. Although, GDM cause many negative consequences on pregnant women, it seems to be no negative effects on tear function tests.

The impact of non-alcoholic fatty liver disease on carotid artery intima–media thickness as a risk factor for atherosclerosis

Cristina Alina Silaghi[1,2], Anca Elena Craciun[2], Daniel Tudor Cosma[2], Horatiu Silaghi[2], Romina Negru[2], Cristina Feurdean[2], Andrada Oltean[2], Nicolae Hancu[2] & Carmen Georgescu[2]
[1]County Clinic Emergency Hospital Cluj, Cluj, Romania; [2]'Iuliu Hatieganu' University of Medicine and Pharmacy Cluj-Napoca, Cluj, Romania.

Introduction
Non-alcoholic fatty liver disease (NAFLD) is considered a hepatic manifestation of metabolic syndrome and is closely associated with abdominal obesity, atherogenic dyslipidaemia, and diabetes exposing subjects with NAFLD to an increased risk of developing cardiovascular disease. The aim of this study is to determine the prevalence of NAFLD in diabetes mellitus (DM) patients, to correlate it to the subclinical atherosclerosis in these patients.
Description of method
One hundred and twenty-four consecutive patients with type 2 DM were enrolled. NAFLD was diagnosed using fatty liver index (FLI), an algorithm based on BMI, waist circumference, triglycerides, and gamma glutamyl-transferase (GGT). Carotid atherosclerosis (intima–media thickness (IMT)) was evaluated by high-resolution carotid B-mode ultrasonography. Plasma liver function tests and other biochemical blood measurements were determined.
Results
Patients were divided into three groups: G1: FLI < 30 ($n = 56$); G3: FLI > 60 ($n = 40$); and G2: intermediate group ($n = 28$). The prevalence of NAFLD using FLI ≥ 60 in DM patients was 40 patients (32%). CIMT increased with FLI (G3 = 0.54 ± 0.08 mm vs G1 = 0.40 ± 0.08 mm, $P < 0.0001$). FLI was associated with increased LDL cholesterol ($r = 0.38$), alanine aminotransferase ($r = 0.55$), BMI ($r = 0.34$), diastolic blood pressure ($r = 0.41$) and triglycerides ($r = 0.49$), and reduced HDL cholesterol ($r = -0.52$) and insulinaemia ($r = -0.30$, all $P < 0.0001$). The correlations hold also in multivariate analysis after adjusting for age and gender. Behavioural variables (smoking and diet) and fasting plasma glucose, did not significantly differ between subjects with and without FLI.
Conclusion
NAFLD increases the risk of subclinical atherosclerosis in DZ patients. DM patients with NAFLD in our study showed significant correlation with cardiovascular risk factors.

Self-monitoring of blood glucose patterns among Turkish diabetic patients

Kevser Onbasi, Turkan Pasali Kilit & Orcun Kuet
Dumlupinar University, Kutahya, Turkey.

Self-monitoring of blood glucose (SMBG) increases life expectancy and improves diabetic patients' quality of life. 17 type 1 diabetic patients and 159 type 2 diabetic patients' files were randomly evaluated to evaluate SMBG practice patterns in our hospital. All type 1 patients used insulin, while 38 type 2 diabetic patients used drug only, 35 type 2 diabetic patients used drugs in combination with insulin and 86 type 2 diabetic patients used insulin only. 90.3% of our patients owned a glucometer. Although, this high percentage one of the type 1 and nine of the type 2 diabetic patients did not practice SMBG despite owning a glucometer. 23.5% of type 1 diabetic patients and 47.2% of type 2 diabetic patients only measured their fasting glucose levels. 11.8% of type 1 diabetic patients and 4.4% of type 2 diabetic patients only measured their postprandial glucose levels. 58.8% of type 1 diabetic patients and 40.9% of type 2 diabetic patients measured fasting and postprandial glucose levels. Only a minority (33.3%) of those using insulin practiced daily SMBG. Seven patients of those using insulin did not practice SMBG. 31 patients reported to examine their blood glucose levels if they were symptomatic. 20 patients monitored their blood glucose weekly, three patients once monthly and 15 every second day. Seven patients checked their blood glucose level twice daily, three patients three times, five patients four times, and one patient checked their blood glucose levels six times daily. Adjusting the insulin dose according to SMBG levels is performed only in 39.1% of patients. 84 patients do not make an adjustment of the insulin dose despite performing SMBG. 56 patients did never check postprandial glucose levels. In summary the majority of our patients does not perform SMBG levels adequately and do not adjust their medicament doses or insulin doses.

New-onset diabetes after renal transplantation (NODAT) and nodular glomerulosclerosis of the renal allograft

Diana Martins[1], Carla Baptista[1], Margarida Bastos[1], Jorge Pratas[2], Rui Alves[2], Catarina Romãozinho[2], Carol Marinho[3], Joana Saraiva[1], Carolina Moreno[1], Daniela Guelho[1], Nuno Vicente[1], Luís Cardoso[1], Margarida Balsa[4], Diana Oliveira[1], Alfredo Mota[5] & Francisco Carrilho[1]
[1]Endocrinology, Diabetes and Metabolism Department, Coimbra Hospital and University Centre, Coimbra, Portugal; [2]Nephrology Department, Coimbra Hospital and University Centre, Coimbra, Portugal; [3]Pathological Anatomy Department, Coimbra Hospital and University Centre, Coimbra, Portugal; [4]Endocrinology, Diabetes and Nutrition Department, Baixo Vouga Hospital Centre, Aveiro, Portugal; [5]Urology and Renal Transplantation Department, Coimbra Hospital and University Centre, Coimbra, Portugal.

Introduction
Diabetes mellitus is a common metabolic complication after kidney transplantation, occurring with a frequency of 15–30% in the first year. However, despite the high incidence, there are described few cases of diabetic nephropathy with nodular glomerulosclerosis of the allograft.
Case
Female patient, 49, with autosomal dominant familial renal poliquistose diagnosed at 17 and progression for chronic end-stage renal disease, underwent renal transplantation of cadaver in June 2004. Five months after transplant and having started immunosuppressive therapy with tacrolimus, sirolimus, and prednisone, was diagnosed with diabetes mellitus. Initiated conventional intensive insulin therapy, with gradual decrease of the total daily dose after suspension of prednisone and reduction of the remaining immunosuppressants.
Instead of maintaining an optimized glycaemic control (HbA1c $<7\%$), it was found chronic renal allograft dysfunction, 9 years and 5 months after transplantation, the patient had marked reduction of glomerular filtration rate (<20 ml/min) with proteinuria in nephrotic range. Graft biopsy was performed and histopathological and immunohistochemical evaluation demonstrated 'nodular glomerulosclerosis in diabetes mellitus context, without acute rejection, with observed mild chronic rejection phenomena with mild tubular atrophy and fibrosis'. In April 2014, the patient kept worsening glomerular filtration rate of $\sim$15 ml/min per 1.73 m^2 and an HbA1c of 6.6%, under exclusive immunosuppression with tacrolimus.
Conclusions
In the case described, there was progressive graft dysfunction despite good glycemic control, with confirmed nodular glomerulosclerosis typical lesions. Thus, in the NODAT with renal allograft dysfunction, it is not excluded the possibility of association with diabetic nephropathy. This case also shows that in NODAT there are the same risk factors for the occurrence of late diabetic complications.

Sexual functioning and distress in types 1 and 2 diabetic women: a two-centres experience

Konstantinos Dimitropoulos[1], Vassilios Tzortzis[1], Agathi Vassiliou[2], Eleftheria Mparmpa[2], Magdalini Mpristianou[3] & Alexandra Bargiota[2]
[1]Department of Urology, Faculty of Medicine, University of Thessaly, Larissa, Thessaly, Greece; [2]Department of Endocrinology and Metabolic Diseases, Faculty of Medicine, University of Thessaly, Larissa, Thessaly, Greece; [3]Department of Internal Medicine, General Hospital of Lamia, Lamia, Greece.

Introduction
A high prevalence of sexual disorders has been observed in women with types 1 and 2 diabetes mellitus (DM). Here we present 4 years, two-center results of the study of disorders of female sexual functioning in female patients with diabetes.
Materials and methods
During the time period 2011–2014, female DM patients and healthy controls were enrolled according to the protocol inclusion criteria. The FSFI, FSDS, and GHQ-28 questionnaires were used to evaluate sexual functioning, sexual distress, and general health respectively. Comparative and regression tests were used to analyse data.
Results
In total, 221 patients and 218 healthy controls were enrolled. Of the 221 patients, 107 (48.4%) had a diagnosis of T1DM and the remaining 114 (51.6%) had T2DM. Control group was divided to CG-1 and CG-2 (104 and 114 women respectively) subgroups, each one age matched for T1DM and T2DM subgroups.
Diabetic patients in general, had significantly lower FSFI and higher FSDS scores compared to the healthy controls ($P<0.05$). T1DM and T2DM women also had significantly lower FSFI and higher FSDS scores compared to CG-1 and CG-2 controls ($P<0.05$).
Diagnosis of 'any' diabetes, was found to be a significant predictor of FSD (OR 2.746, $P<0.05$). T1DM and T2DM women were 2.698 and 2.887 times more likely to have FSD compared to CG-1 and CG-2 non patients respectively ($P<0.05$). Psychosocial factors, mainly depression, were found to be significant determinants for FSD in diabetic and non diabetic women ($P<0.05$).
Conclusion
The current study findings confirm that FSD is more prevalent in women with diabetes. Both types of diabetes were found to be significant determinants for FSD in the patients of our study. Moreover, the role of psychosocial factors, such as depression, in the pathogenesis of sexual disorders and distress in both diabetic and non-diabetic women is highlighted.

Association of SNPs in the intergenic region of OCT2 and OCT3 with short-term efficiency of metformin monotherapy in the type 2 diabetes patients

Janis Klovins[1], Linda Zaharenko[1], Kristine Geldnere[2], Ilze Konrade[5], Solveiga Grinberga[4], Osvalds Pugovics[4], Ineta Kalnina[1] & Valdis Pirags[2,3]
[1]Latvian Biomedical Research and Study Centre, Ratsupites 1, LV1067 Riga, Latvia; [2]Department of Endocrinology, Pauls Stradins Clinical University Hospital, Pilsonu Str. 13, LV1002 Riga, Latvia; [3]Faculty of Medicine, University of Latvia, Sarlotes Str. 1a, LV1001 Riga, Latvia; [4]Latvian Institute of Organic Synthesis, Riga, Latvia; [5]Department of Medicine, Riga East Clinical University Hospital, Riga Stradins University, Riga, Latvia.

Clinical response to metformin is highly variable in type 2 diabetes (T2D) patients highlighting the need for identification of genetic components affecting the efficiency of metformin therapy. Aim of this study was to evaluate the role of systematically selected tagSNPs from genomic regions coding for six organic cation transporters implicated in transport of metformin with respect to the short-term efficiency. The study involved 102 drug naïve newly diagnosed T2D patients who were treated with metformin monotherapy for 3 months. We genotyped 104 tagSNPs from six metformin transporter genes coding for OCT1, OCT2, OCT3, MATE1, MATE2, and PMAT. Minor alleles of rs3119309, rs7757336l, and rs2481030 located in the intergenic region between *SLC22A2* (OCT1) and *SLC22A3* (OCT3) were significantly associated ($P=1.849\times10^{-6}$ to 2.663×10^{-5}) with metformin inefficiency defined as no decrease of HbA1c blood level after 3 months of treatment. Carriers of risk alleles were 8.4 times more likely to exhibit non-responder phenotype than participants with wild type alleles. Pharmacokinetic study in 15 healthy participants was conducted to investigate the effects of identified polymorphisms on kinetics of plasma and erythrocytes metformin after acute administration in healthy subjects. Subjects with combined risk alleles of polymorphisms rs3119309, rs7757336, and rs2481030 showed strongly reduced AUC_∞ of metformin exposure. In conclusion we have identified for the first time strong association between metformin non-response and three SNPs located in the $5'$ flanking regions of the *SLC22A2* (OCT2) and *SLC22A3* (OCT3). These results indicate the importance of metformin transporters in the short- term efficiency of metformin.

Hyperosmolar hyperglycaemic state and diabetic ketoacidosis: a 5-year retrospective study in a university hospital

Claudia Coelho, Catarina Nunes, Vera Fernandes, Maria Luísa Pinto, Selma B Souto & Olinda Marques
Hospital de Braga, Braga, Portugal.

Introduction
Hyperosmolar hyperglycaemic state (HHS) and diabetic ketoacidosis (DKA) are the two most serious acute metabolic complication of diabetes mellitus (DM). The authors propose to characterise the admissions for HHS and DKA at a univeristy hospital.
Methods
An observational, descriptive, and retrospective study in adults admitted to the hospital between January 2009 and October 2013 due to HHS and DKA. The information was accessed via the patients' electronic records. Statistical analysis was carried out using SPSS.
Results
71 patients were admitted with HHS, with a dominance of female patients (62%). The median age was 79 years and 38% were considered to have economic difficulties. A quarter of the patients was unaware they were diabetic. The most common clinical manifestation on admission was prostration (65%) and the precipitating factor infections (47%). On admission, 25% were treated with insulin but when they became orientated this percentage went up to 62%. During their admission, 41% of the patients were referred to endocrinology. The median time of stay was 9 days. One year after discharge, 11% of patients had been readmitted for the same reason and 23% had passed away.
In the case of DKA, 44 patients were admitted, 63% being female patients. The median age was 57 years and 51% were considered to have economic difficulties. Half the patients presented with prostration and in 35% of the cases the precipitating factor was lack of compliance with therapy. The median time of stay was 8 days. A quarter of the patients had already had a previous admission and a year after discharge, 30% had been readmitted for the same reason whilst 22% had passed away.
Conclusion
In 5 years, 115 patients were admitted com acute complications of DM. The high incidence of readmissions and mortality in the year following discharge as well as the lack of the compliance with therapy in those admitted with DKA are noteworthy. This shows a need for improved assisted care post-discharge in these patients.

The value of ankle–brachial index in patients above 40 years old with type 2 diabetes mellitus on the diagnosis of peripheral artery disease and the association between peripheral artery disease and chronic diabetes complications

Nur Kebapci & Tugce Nur Turkozu
Eskisehir Osmangazi University, Eskisehir, Turkey.

Peripheral artery disease (PAD); is a chronic occlusive disease in lower extremities. PAD is an important sign of atherosclerosis, and an important predictor of mortality and morbidity during the cerebrovascular and cardiovascular diseases. Since the cardiovascular diseases are the most important cause of death in type 2 DM patients, diagnosing the mortality and morbidity predictor PAD in the early period is very important. The ankle–brachial index is an easy and cheap method to diagnose PAD. In this study, we aim to identify PAD prevalence by measuring ankle–arm index in type 2 DM patients, by compare with arterial Doppler ultrasonography findings of lower extremity and to identify the association between chronic complications of type 2 DM and PAD. 111 type 2 DM patients above 40 years old were included in our study. The PAD prevalence was found to be 19.8%. Dorsalis pedis artery palpation was found to be an important physical exam finding to diagnose PAD. Instead of ABI calculation in the AHA and TASC2 guidelines, there was a stronger correlation between PAD prevalence and the method of dividing the lower systolic blood pressure of dorsalis pedis or tibialis posterior artery by the higher systolic blood pressure of brachial artery. A significant association was found between PAD diagnosed with lower extremity arterial Doppler and age, DM duration, BMI, coronary artery disease, cerebrovascular disease, GFR, albuminuria, uric acid and homocystein levels, insulin resistance, diabetic rethinopaty and vibration test. The ankle–brachial index was found to be a reliable method to diagnose PAD.

Bone mineral density in patients with type 1 diabetes mellitus by DEXA and QCT

Eleftheria Mparmpa[1], Spyros Karamagiolis[2], Stelios Tigas[3], Parthena Navrozidou[4], Marianna Vlychou[4], Ioannis Fezoulidis[4], Georgios N Koukoulis[1] & Alexandra Bargiota[1]
[1]Department of Endocrinology and Metabolic Diseases, University of Thessaly, Larissa, Greece; [2]General Hospital of Larissa, Larissa, Greece; [3]Department of Endocrinology, University of Ioannina, Ioannina, Greece; [4]Department of Radiology, University of Thessaly, Larissa, Greece.

Introduction
Type 1 DM (T1DM) has been associated with low bone mineral density (BMD) measured by dual energy X-ray absorptiometry (DEXA) but not with quantitative computed tomography (QCT). QCT provides a three-dimensional image and measures bone's volume directly as density, independent of the surrounding tissues. The purpose of this study was to evaluate BMD in patients with T1DM using DEXA and QCT.
Methods/design
We studied 81 patients with T1DM (group D) (age: 36+9.7 years, M/F: 32/49) and 70 healthy controls (group C) matched for age, sex, and BMI. In both groups, we measured HbA1c, lumbar spine (LS), and femoral neck (FN) BMD by DEXA and LS BMD by QCT.
Results
Mean BMI (kg/m^2) was similar in both groups (D: 23.3+8.1 vs C: 23.7+8.3, $P=0.39$). In group D, mean duration of diabetes was 16.1+9.9 years and mean HbA1c was 8.1+1.3%. BMD (g/cm^2) and z-score measured by DEXA were lower in group D compared to group C at LS (1.02±0.20 vs 1.05±0.14, $P=0.03$) (−0.31±1.61 vs 0.78±1.76, $P=0.01$) and at FN (0.69±0.12 vs 0.89±0.11, $P=0.043$) (−0.1+1.47 vs 1.35±1.04, $P=0.037$). Also, LS z-scores measured by QCT were lower compared to DEXA (D: −0.16+1.08 vs −0.31±1.61, $P=0.022$). The lower DEXA z-scores were negative correlated with young onset age ($r=-0.74$, $P=0.021$) and longer duration of T1DM ($r=-0.78$, $P=0.032$) but not with glycaemic control ($r=0.36$, $P=0.18$). In group D, DEXA detected 9/81 patients (11.1%) with osteopenia and 1/81 with osteoporosis (1.2%) at LS and 5/81 (6.2%) with osteopenia and 1/81 with osteoporosis (1.2%) at FN. In contrast, QCT has detected 14/81 patients (17.3%) with osteopenia and 2/81 patients (2.5%) with osteoporosis at LS.
Conclusion
T1DM is associated with lower BMD compared to controls with both methods used. The choice of measuring method may define a different degree of bone loss.

EP527

Is early measurement of HbA1c useful for the prediction of treatment response in type 2 diabetes?

Michaela Luconi[1], Besmir Nreu[2], Jinous Samavat[1], Agostino Ognibene[2], Matteo Monami[2] & Edoardo Mannucci[2]
[1]University of Florence, Florence, Italy; [2]Careggi University Hospital, Florence, Italy.

HbA1c, which is correlated with 3-month mean glycaemia, is usually measured every 3–6 months. Effects of variations of treatment are routinely assessed through HbA1c not earlier than 3 months. Glycated albumin (GA) has been proposed as an indicator of shorter-term (2-week) glucose control Aim of the present pilot study was to explore the possibility of predicting 3-month HbA1c by measuring HbA1c or GA at 15–30 days. Twenty-seven metformin-treated patients with type 2 diabetes initiating a pharmacological treatment other than insulin were enrolled after written informed consent. The patients (16M:11F, aged 64.7±10.1 years) had a duration of diabetes of 8.6±8.5 years, baseline HbA1c 59.0±12.0 mmol/mol. The prescribed treatment was maintained throughout the 3-month follow-up. HbA1c and GA were measured at baseline, 15, and 30 days, and HbA1c only at 90 (±3) days. HbA1c at 90 days (50.0±7.2 mmol/mol) was significantly ($P<0.001$) reduced from baseline (59.0±12.0 mmol/mol). A significant reduction was already present at 15 days (56±7.8 mmol/mol, $P<0.01$) and confirmed at 30 days (53.0±7.0 mmol/mol, $P<0.001$). A similar pattern was found for GA, which was significantly lower at 15 (28.8±10.8%, $P=0.03$) and 30 (27.0±9.8%, $P<0.001$) days than at baseline (31.9±11.3%). Variations of both HbA1c and GA at 15 days showed a significant correlation with 90-day variation of HbA1c: $R=0.895$, $P=0.001$ and $R=0.418$, $P=0.030$, respectively, confirmed at 30 days. The early identification of patients

not adequately responding to the prescription of a new drug could be very useful for clinicians, allowing a greater timeliness in further modifications of therapy. This pilot study suggests that a measurement of HbA1c as early as 15 days from the start of treatment can accurately predict 3-month results being of help for the assessment of treatment response. This result deserves to be further verified in larger samples.

Sex steroids levels and body composition in male patients with type 1 diabetes mellitus

Eleftheria Mparmpa[1], Spyros Karamagiolis[2], Stelios Tigas[3], Parthena Navrozidou[4], Marianna Vlychou[4], Ioannis Fezoulidis[4], Georgios N Koukoulis[1] & Alexandra Bargiota[1]
[1]Department of Endocrinology and Metabolic Diseases, University of Thessaly, Larissa, Greece; [2]General Hospital of Larissa, Larissa, Greece; [3]Department of Endocrinology, University of Ioannina, Ioannina, Greece; [4]Department of Radiology, University of Thessaly, Larissa, Greece.

Introduction
Limited data exists regarding testosterone levels in type 1 diabetes mellitus (T1DM). The objective of this study was to evaluate serum sex steroids levels and body composition using dual energy X-ray absorptiometry method (DEXA) in male patients with T1DM.
Methods/design
We studied 36 male patients with T1DM (group D) (age: 35.3 + 11.66, years) and 35 healthy control (group C) matched for age, sex, and BMI. In both groups waist circumference (WC), HbA1c, total testosterone (TT), sex hormone-binding globulin (SHBG), LH, FSH, and IGF1 were measured. Calculated free (cFT) and bioavailable testosterone were estimated by standard formulas. Moreover, body composition was determined by DEXA and was calculated central abdominal fat (CAF).
Results
Mean BMI (kg/m^2) and mean WC (cm) were similar in both groups (D: 25.8 + 3.44 vs C: 25.2 + 3.2, $P = 0.37$) and (D: 94.5 + 9.6 vs C: 92.9 + 8.7, $P = 0.24$). In group D, mean duration of DM was 16.8 + 10.5 years and mean HbA1c was 8.2 + 1.1%. We did not observe significant difference in TT, LH, and FSH levels between two groups. Group D had significantly lower SHBG (nmol/l) and IGF1 (ng/ml) levels than group C (39.57 + 7.5 vs 37.32 + 6.9, $P = 0.043$ and 144.7 + 30.1 vs 180.2 + 27.1, $P = 0.031$). Lower cFT (nmol/l) and bioT (nmol/l) levels were observed in group D compared to C but but did not reach clinical significance (0.608 + 0.136 vs 0.812 + 0.119, $P = 0.052$ and 14.7 + 2.3 vs 15.2 + 2.5, $P = 0.057$). Total fat and CAF were similar in both groups. CAF was negative correlated to TT and FT levels ($r = -0.73$, $P = 0.029$ and $r = -0.79$, $P = 0.034$). In group D, 2/36 (5.6%) had TT levels below the normal range after adjustment for age and BMI but none of group C.
Conclusion
Patients with T1DM seem to have a tendency to hypogonadism and its existence mainly occurred in association to obesity.

Diabetic 'holiday' foot: cautionary tales of sun, sandals, and risk

James O'Hare[1], Fiona Nolan[1], Eamon Kavanagh[2], Paul Burke[2] & Elizebeth Carraig[2]
[1]Department of Endocrinology, Univesity Hospital Limerick, Limerick, Ireland; [2]Department of Vascular Surgery, Univesity Hospital Limerick, Limerick, Ireland.

Diabetic polyneuropathy is the most prevalent complication of diabetes. Diabetic foot lesions become limb threatening from a combination of injury, infection and impaired micro and macrocirculation. When diabetic patients go on holiday they usually change their routine and may become careless in routine care of their feet. We report a case series of seven middle aged Irish born diabetic male patients who developed serious foot lesion on holiday. They were identified from the podiatry services of a regional centre over 3 years. The median age was 59, range 57–68 years. Six of seven had type 2 diabetes duration 1–30 years. HbA1c ranged from 7 to 10.6%, median: 9.6%. One smoked. All had signs of peripheral polyneuropathy. Two had Charcot joint. Six of seven had a holiday in a warmer climate. The median delay to seeking care was 2 weeks, range 1 day–12 weeks. Lesions had a variety of sites, they were bilateral in 5/7. Lesions included: massive blister, ulceration, pressure necrosis, and maceration. Infection was present in six of seven. Two of seven required partial foot amputation. Two had a hospital stay over 60 days. Healing took 4–20 weeks. All walked more than was their customary habit and often on uneven surfaces. One walked barefoot for a week incurring deep planter ulceration. Another wore tight golf shoes incurring pressure necrosis. One walked extensively in an orthopaedic boots. The majority wore sandals resulting in tissue maceration and infection. All reported heat as an aggravating factor. Middle-aged diabetic males with polyneuropathy seem particularly vulnerable on holiday. The common factors were: i) a change in or inappropriate footware, ii) unaccustomed walking and surfaces, and iii) heat causing tissue maceration. Patient education should emphasis the hazards of holidays in high-risk patients.

Macrovascular complications in type 1 diabetes mellitus

Ennaifer Houda, Chaker Fatma, Ben Salah Dhouha, Hamdi Med Salah, Yazidi Mariem, Chihaoui Malika & Slimane Hedia
Department of Endocrinology and Diabetes, Rabta University Hospital, Tunis, Tunisia.

Introduction
Cardiovascular complications are well known in type 2 diabetes with other factors of cardiovascular disease. Recently, with the intensive treatment of type 1 diabetes, many studies have focused on macrovascular complications in type 1 diabetes. The aim of our study was to determine the long-term cardiovascular risk factors and macrovascular complications in type 1 diabetic patients.
Patients and methods
A retrospective study involving 45 patients hospitalised in Rabta Endocrinology Department between 1997 and 2005 for type 1 diabetes. We noted after a minimum follow-up of 10 years the appearance of cardiovascular events. We also reported cardiovascular risk factors such as family history of cardiovascular events, smoking, obesity, dyslipidaemia, and hypertension, insulin dose, and glycaemic control.
Results
Our patients were 21 men and 24 women. The average age of our patients at diagnosis was 25.3 years (10–50), their mean BMI was 22 (15.8–26.95). The average waist circumference was 75.88 cm. Ten patients were smokers, four patients had a family history of cardiovascular events. The lipid profile was normal in all patients. The mean insulin dose was 1 UI/kg per day (0.16–1.54). The mean duration of diabetes in our patients was 14 years (range 10–30). Six patients developed hypertension. After a follow-up of 10 years, the mean BMI was 20 (18.19–38) and the mean insulin dose was 1 UI/kg per day. The mean of HbA1c was 10%. We didn't report any macrovascular events in our patients.
Conclusion
Type 2 diabetes is usually associated with other cardiovascular risk factors related to the metabolic syndrome. Poor glycaemic control is a common factor to both types 1 and 2 diabetes. Intensive treatment of type 1 diabetes with a strict glycaemic control result often in a long-term overweight. Comprehensive prevention beyond glycaemic control is necessary to prevent the occurrence of cardiovascular events in type 1 diabetes.

EP531

Is dyslipidaemia adequately controlled in type 2 diabetics in primary care? Analysis of 183 patients

Carmen Maria Cortes-Salazar[1] & Jose Carlos Fernandez-Garcia[2]
[1]Badolatosa Primary Care Centre, Seville, Spain; [2]Endocrinology Department, Virgen de la Victoria University Hospital, Malaga, Spain.

Objectives
To evaluate the degree of control of atherogenic dyslipidaemia in patients with type 2 diabetes mellitus (T2DM).
Methods
Retrospective cohort study which included patients with T2DM followed in a primary care setting. Patients were classified according to the following criteria: strict control of dyslipidaemia (LDL <100 mg/dl and triglycerides <150 mg/dl), partial control of dyslipidaemia (LDL ≥ 100 mg/dl or triglycerides ≥ 150 mg/dl), or absence of control of dyslipidaemia (LDL ≥ 100 mg/dl and triglycerides ≥ 150 mg/dl). Treatment with lipid-lowering drugs (statins, fibrates, nicotinic acid, and ezetimibe) was also collected.
Results
183 patients were included, with a mean age of 62.1 ± 8.3 years (58.4% women). After stratification of patients according to previous criteria, only 32% of patients had strict control of dyslipidaemia, 43% had partial control of dyslipidaemia, and 25% had absence of control of dyslipidaemia. Associated lipid-lowering treatment was present in 72% of patients with strict control, in 81% of patients with partial control and in 90% of patients with absence of control.
Conclusions
Despite the high rate of lipid-lowering therapy in patients with T2DM, a significant percentage of patients do not achieve recommended lipid goals.

Evaluation of plantar pressure and force in diabetes using Tekscan F-Scan in-shoe foot force and gait analysis system

Ie Byung Park, Soojung Lee, Suneung Kim & Gyucheol Han
Gachon University Gil Medical Center, Incheon, Republic of Korea.

Background
Evaluation of plantar pressure is useful for detecting functional abnormality of foot, especially in diabetic patients. The aim of this study was to evaluate plantar pressure and force in diabetic patients using Tekscan F-Scan in-shoe foot force and gait analysis system.
Methods
Plantar pressure and force were measured by selecting an area of interest under the six areas of the foot: hallux, first metatarsal, second metatarsal, 3–5 metatarsal, midfoot and heel based on previous reports. 65 diabetic patients and age-matched 25 controls were enrolled. Mean age of diabetic patients was 58.4 ± 8.2 years, diabetic duration 8.39 ± 5.26 years, and mean HbA1c 7.7 ± 1.3%, and female 43.1% (28/65). Of the included 65 patients, 16 had diabetic polyneuropathy (DPN), 12 had cardiac autonomic neuropathy (CAN), 31 were without CAN, and 18 had inconclusive tests.
Results
Contact area distribution in diabetics were higher tendency than those in controls. Maximum force distribution was different between two group nearly all areas of foot, especially second metatarsal (109.4 N in DM vs 72.2 N in control, $P<0.001$) and condyle (307.4 N in DM vs 236.9 N in control, $P<0.001$). Pressure average distribution were similar differences between two groups. Right-to-left foot unbalancing of force and pressure in diabetics were showed compared with controls.
Conclusion
Evaluation of plantar pressure is useful for diabetic foot abnormalities. Plantar force and pressure distributions in diabetics are higher than those in controls, especially, in second metatarsal and condyle area. This method may be useful to detect diabetic foot and ulcerative disease early.

Knowledge assessment of diabetic patients about their disease: a prospective study

Senda Ouerdani, Ines Slim, Amel Maaroufi, Yosra Hasni, Maha Kacem, Koussay Ach, Molka Chaieb & Larbi Chaieb
Department of Endocrinology, Sousse, Tunisia.

Introduction
Therapeutic education of diabetic patients is an integral part of management care of the disease and a permanent way to empower patients and to promote their self-care. The purpose of this study is to evaluate the knowledge of diabetic patients about their disease.
Patients and methods
This prospective study has been conducted during 9 months and included 312 patients with type 2 diabetes mellitus (T2DM) diagnosed at least 3 months ago. All patients were followed in third care consultation without history of structured education program. Clinical and biological data in addition to an Individual Knowledge Scale (SKILLD). A value above 50% reflects a good level of knowledge.
Results
The mean age was 54-year-old and 61% of patients were females. The average of T2DM history was of 11 years with a mean HbA1c of 9.35 ± 1.85%. Symptoms of hypoglycaemia were known by 58% of patients, but its immediate management was only known by 41% of patients. Education on lifestyle rules revealed poor knowledge in 67% of our patients. HbA1c target was unkown in 82% of patients. The average score on SKILLD was at 37 ± 26%. A score >50% was observed in 32.4% of patients. SKILLD value was positively correlated with education level ($r=0.661$; $P<0.001$), and negatively correlated with duration of diabetes and HbA1c ($r=-0.384$; $P<0.001$ and $r=-0.497$; $P<0.001$ respectively). Patients with low SKILLD scores had significantly higher HbA1c (9.78% vs 8.45%, $P<0.001$) and higher age (54.07-year-old vs 40.55-year-old, $P<0.001$) compared to patients with high SKILLD score.
Conclusion
Our study shows knowledge lack about diabetes. This may reflects the difficulty of education during consultation probably because time limitation. We insist through these results on the need of a complementary structured and multidisciplinary therapeutic education.

Diabetic foot infection: study of 109 patients

Faten Hadj Kacem, Mouna Ammar, Nadia Charfi, Nesrine Cheikrouhou, Fatma Mnif, Mouna Mnif, Nabila Rekik & Mohamed Abid
Department of Endocrinology, Sfax, Tunisia.

Introduction
Diabetic foot infection (DFI) is a major public health problem, both for its morbid clinical consequences mainly ulcers and the economic social cost due to repeated hospitalisations and the high rate of amputation.
Objectives
Analyse the clinical presentation of DFI, study risk factors of developing this infection and describe the therapeutic management.
Materials and methods
Retrospective study spread over 8 years old, of 109 patients hospitalised in the University Hospital of Endocrinology of Sfax and who had a DFI.
Results
The average age of patients was 57.5 years (25–82). Sex ratio was 2.02. Most patients were type 2 diabetics (87.2%) with diabetic history of more than 15 years in 34% of cases. A history of hospitalisation for diabetic feet before the study period was found in 39.4%. On admission diabetes were poorly controlled in the majority of our patients. Among the chronic microangiopathic complications, we found neuropathy (64.2%), nephropathy (20.2%), and retinopathy 37.6%. Macroangiopathic complications were dominated by arteriopathy of the lower limbs in 20.2%. The DFI were unique or multiple. It was 'non-threatening member' infection in 64.2%, dominated by infected wounds in 57.1%. The infection was severe, dominated by infected gangrene in 33%, followed by infected plantar ulcer in 22%. Samples for bacteriological test were performed in 29 patients. The bacteria involved were dominated by *Staphylococcus* 20.7% and gram-negative bacteria in 17.2%. 105 of our patients received an antibiotherapy. The association amoxicillin–clavulanic acid +/− ciprofloxacin were prescribed in first intention in 47%. The average duration of antibiotherapy was 9.7 days in case of infection 'non-threatening member' and 17.3 days for severe infection. Surgical treatment was performed in 45%. Conservative treatment or amputations were done in 15 and 30% cases respectively.
Conclusion
Prevention is the only way to reduce morbidity caused by lesions of the diabetic foot.

Diabetes and ischaemic stroke: prospective study in hospitalised patients

Ana Margarida Monteiro[1], Cátia Cabral[2], Vera Fernandes[1], Marta Alves[1] & Olinda Marques[1]
[1]Department of Endocrinology, Hospital de Braga, Braga, Portugal; [2]Department of Internal Medicine, Hospital de Braga, Braga, Portugal.

Introduction
Diabetes mellitus (DM) is a major risk factor for stroke and has been shown that diabetic patients who suffer stroke have a worse prognosis, with greater morbidity and mortality.
Objectives
Determination of the prevalence of DM in hospitalised patients for ischaemic stroke. Comparison of demographic variables, complications prevalence, length of hospital stay and in-hospital mortality among diabetic and non-diabetic patients. Assessment of glycaemic control and therapy used in the treatment of DM.
Methods
Observational, analytical, and prospective study of hospitalised patients for ischaemic stroke in Hospital de Braga between August and November 2013. Statistical analysis: SPSS v.20.
Results
Of the 134 patients, 30.6% had a previous diagnosis of DM, 79.9% were over 65 years, and 53.7% were women. The median age was 79 years with no statistical significance between groups ($P=0.624$). The median blood glucose at admission was 115 mg/dl, with statistical significance between groups (156 mg/dl vs 108 mg/dl; $P<0.05$). The median hospital stay was 10 days for both groups. Although, not statistically significant, the prevalence of neurological and infectious complications was lower in diabetic patients (24.4% vs 36.6%; $P=0.167$) as well as in-hospital mortality (2.4% vs 10.8%; $P=0.106$). There was no statistical significance between blood glucose on admission, prevalence of complications and in-hospital mortality. In the group of diabetic patients, the median HbA1c was 7.2%. There was no statistical significance between glycaemic control (HbA1c) and prevalence of complications or in-hospital mortality. About DM treatment at admission vs discharge: 61.0% vs 56.1% were treated with oral antidiabetics (OA), 17.1% vs 17.1% with insulin and OA, 9.8% vs 24.4% only with insulin, and 12.2% vs 2.4% without drug therapy.
Conclusion
Glycaemic control in the diabetic group is reasonable, in most patients, assuming the age, pre-existing comorbidities and chronic complications. We admit that the absence of a higher prevalence of complications and mortality in diabetic vs non-diabetic group, may be related to the small sample size.

DOI: 10.1530/endoabs.37.EP535

EP536

Renal disease risk in type 2 diabetic patients with metabolic syndrome

Yllka Themeli[1,2], Myftar Barbullushi[2,3] & Aqif Gjokutaj[2,3]
[1]'IKEDA' Hospital, Tirana, Albania; [2]DC 'Med.al', Tirana, Albania; [3]UHC 'Mother Teresa', Tirana, Albania.

Background
Patients with diabetes mellitus (DM), diabetic nephropathy (DN), and metabolic syndrome (MS) have a high risk of cardiac morbidity and mortality. Thus, identifying and treating risk factors associated with cardiovascular disease in DM may offer the best approach for preventing and delaying adverse renal and cardiovascular outcomes.
Aim
To determine the relationships between MS, DN, and renal function in type 2 DM.
Methods
In our clinic-based kohort study were enrolled 216 type 2 diabetic patients, from which 59% males and 41% females, with a mean age 54 ± 10 years. We analysed MS, detected DN, and estimated glomerular filtration rate (eGFR) during a 4 years period.
Results
Prevalence of both microalbuminuria and macroalbuminuria were higher in subjects with MS, increasing proportionally with the number of MS components. EGFR was lower in subjects with MS than in those without it (84 ± 12 ml/min per 1.73 m^2 vs 90 ± 21 ml/min per 1.73 m^2; $P<0.001$). The lowest eGFR values were found in those with four or more components of MS. Prevalence of low eGFR increased with the stage of DN and was affected by MS only in normoalbuminuric patients. The most important result was that MS was independently associated with DN, but not with low eGFR, after adjustment for all of the individual components of the MS.
Conclusions
In this study we have noted an independent association between MS and DN. This is a strong argument for treating the MS by an intensive therapy, in order to prevent the progression of DN to the renal failure.

EP537

Optimal regimens of the basal-bolus insulin therapy in adolescents with diabetes mellitus of type 1

Galina Galkina, Angelina Voropay, Marina Levkovich, Alexey Afonin, Marina Komkova & Natalia Morozova
Rostov Scientific Research Institute of Obstetrics and Pediatrics, Rostov-on-Don, Russia.

To achieve the optimal glycaemic control in adolescents with type 1 diabetes mellitus (DM1) is a difficult task. The reason is a low compliance of teenagers caused by psychoemotional peculiarities as well as decreased insulin sensitivity due to a physiologically high concentration of contrainsular hormones (androgens, GH, etc.). This study was aimed to determine peculiarities in regimens of the pump insulin therapy that are necessary for achieving treatment goals in adolescents with DM1. 68 adolescents at the age of 14–18 with DM1, who received continuous subcutaneous infusion of insulin (CSII) from 6 months to 6 years, were examined. The patients were subdivided into two groups: i) adolescents with the optimal and suboptimal metabolic control ($n=46$) and ii) adolescents with long-standing poorly controlled DM1 ($n=22$). Compared with patients in group 2, adolescents in group 1 had significantly higher average total daily dose of insulin (group 1 – 70.0 (53.2; 83.8) U and group 2 – 54.0 (46.3; 68.4) U, $P=0.038$), average daily dose of basal insulin (group 1 – 35.2 (24.7; 40.8) U and group 2 – 25.2 (22.7; 32.7) U, $P=0.019$). The average basal-to-bolus ratio from group 1 patients was 51/49%, compared with group 2 patients – 45/55%. Prevalence of bolus insulin in adolescents with poorly controlled DM1 was caused by frequent use of correction boluses in order to lower postprandial hyperglycemia resulting from the excessive intake of carbohydrates. Group 2 patients had a low level of skills which did not allow them to use additional functions of the pump. A large part of group 1 patients adapted pump settings on their own according to their individual peculiarities, physical activity, etc. Thus, well-balanced basal-to-bolus ratio in adolescents on CSII, which can provide improvements in blood glucose management is 51/49%. An important condition is also a high level of compliance and skills of patients, intention to control actively the disease.

Prof. Egas Moniz, 1649-028 Lisboa, Portugal; [4]Instituto de Investigação Científica Bento da Rocha Cabral, Calçada Bento da Rocha Cabral, 14, 1250-047 Lisboa, Portugal; [5]Associação Protectora dos Diabéticos de Portugal, Rua do Salitre 118-120, 1250-203 Lisboa, Portugal; [6]REQUIMTE/Faculdade de Farmácia da Universidade do Porto, Porto, Portugal.

Introduction
There is a lack of epidemiological data on the distribution of haptoglobin and C677T of MTHFR polymorphisms in Caucasians type 2 diabetic patients. The contribution of these two genetic factors to hyperhomocysteinemia and hypercysteinemia can be useful to prevent cardiovascular events and to reduce public health costs. The aim of this study is to evaluate the contribution of haptoglobin and C677T polymorphisms for hyperhomocysteinemia and hypercysteinemia in Portuguese type 2 diabetic patients with and without angiopathy.
Methods
A population-based case–control study in 150 Portuguese type 2 diabetic patients was performed. The study population: group I – 75 patients with angiopathy and

group II – 75 patients without angiopathy. Homocysteine and cysteine plasma levels were obtained by validated HPLC methods. The haptoglobin polymorphism was identified by PAGE and peroxidase staining and C677T MTHFR polymorphism by PCR and RFLP. Statistical analysis was performed by odd ratio calculation and linear regression model.
Results
The Hp 2-1 was the most prevalent. The CT and TT genotypes were more frequent in group I (46.4%; 7.2%) than in group II (41.5%; 6.2%). The diabetic patients of group I with the genotypes Hp 2-1 or Hp 2-2 had a higher probability to have hyperhomocysteinemia (OR: 4.19; $P=0.021$) and hypercysteinemia (OR: 4.55; $P=0.028$) than diabetic patients from group II. The presence of 677TT and C677T genotypes in group I increased in five times (OR: 5.37; $P=0.040$) the probability to have hyperhomocysteinemia compared to group II. The association between haptoglobin and C677T polymorphisms increased the probability (OR: 4.14; $P=0.004$) of having hypercysteinemia in group I.
Conclusion
The haptoglobin and C677T of MTHFR polymorphisms are associated with a predisposition to hyperhomocysteinemia and can be considered genetic risk factors in angiopathy development of Caucasians type 2 diabetic patients.

EP539

Type IV renal tubular acidosis in type 2 diabetes: case report of 4 patients

Carlos Tavares Bello, Ricardo Castro Fonseca, João Sequeira Duarte & Carlos Vasconcelos
Hospital de Egas Moniz, Lisboa, Portugal.

Introduction
Type IV Renal Tubular Acidosis (Type 4 RTA) is an underdiagnosed condition known to be more frequent in Diabetes Mellitus patients with moderate renal impairment. It is thought to be very common, with an incidence of 3.8% of hospital admissions in some series, being an increasing problem among the elderly and aggravated by polypharmacy.
Methods/design
The authors describe 4 cases of Type 4 RTA associated with type 2 Diabetes diagnosed and followed in the Endocrinology department of Hospital de Egas Moniz.
Results
The population studied had an average age of 67 years, mean Diabetes duration of 8 years and all had arterial hypertension and hypercholesterolemia. All patients were on insulin therapy and had some degree of chronic renal disease. None suffered from coronary artery disease and only one had cerebrovascular disease. 75% had the full microvascular burden (nephropathy, retinopathy and neuropathy). Mean time from hyperkalemia onset and type 4 RTA diagnosis was 17.2 months. Mean glycated hemoglobin during follow up was 8.7%. Mean glomerular filtration (CKD-EPI) rate at type 4 RTA diagnosis was 40.3 ml/min/1.73m^2. The average number of hospital admissions was 5. Only one patient required therapy with fludrocortisone.
Conclusion
Type 4 RTA is often a late diagnosis in type 2 Diabetes. In our small series we documented a high microvascular complication burden. The associated hyperkalemia poses a significant threat to the affected patients, which often have a limited cardiovascular reserve. Timely diagnosis and adequate treatment are essential for optimizing patient care.

Glycaemic variability and subclinical inflammation in type 2 diabetes: experience of a Portuguese centre in the last decade

Carlos Tavares Bello, Ricardo Castro Fonseca, Ricardo Capitão, Francisco Sousa Santos, João Sequeira Duarte, Manuela Oliveira, Catarina Saraiva, Clotilde Limbert, Carlos Vasconcelos & Jorge Azinheira
Hospital de Egas Moniz, Hospital de Egas Moniz, Portugal.

Introduction
Adequate glycaemic, along with other cardiovascular risk factor control in type 2 Diabetes (T2D), and its beneficial impact on subclinical inflammation is associated with better microvascular outcomes.
Objectives
To analyse the correlation between glycaemic control adequacy and systemic inflammatory markers, renal disease progression and cardiovascular risk factors.
Material and methods
Retrospective cohort observational study of T2D patients ($n=1900$) with a minimum of 2 year follow up in the Endocrinology Department of Hospital de Egas Moniz from the year 2005 until 2014. Patients younger than 18 years of age and/or suffering from secondary diabetes were excluded. Fasting blood glucose and glycated hemoglobin variation were analysed and correlated with blood pressure control and renal function, systemic inflammatory and blood lipid profile markers. Descriptive statistical methods were employed: t-test student, ANOVA for continuous and chi-square for categorical variables.
Results
The patient sample had an average age of 61.2 years, being 59.7% female. A statistical significant relationship was documented between the glycaemic variation and renal disease progression (CKD-EPI P 0.045; spot urinary albumin $P<0.001$), lipid profile (non-HDL Cholesterol $P<0.001$) and inflammatory markers (CPR P 0.028; ESR P 0.01; Leucocyte count P 0.004).
Conclusions
Despite having the known limitations of a retrospective study, the sample size allowed the authors to document a possible association between glycaemic variation, renal disease progression, subclinical inflammation and blood lipid profile.

Weight and weight variability correlates with subclinical inflammation and comorbidities in diabetes type 2: a retrospective study over the last decade

Catarina Roque, Sequeira Duarte, Rute Ferreira, Filipa Serra, Catarina Moniz, Jorge Azinheira & Carlos Vasconcelos
CHLO, Lisboa, Portugal.

Background
Management of obesity and overweight greatly improves glycemic control in type 2 diabetic (T2DM) patients and also provides positive impact in other cardiovascular risk factors in this population.
Objectives
Evaluate the impact of weight and weight variability in subclinical inflammation and comorbidities of T2DM patients, over the last decade.
Methods
Retrospective study of 1900 patients with T2DM, with a minimum of 2 years of follow-up and five evaluations at our Endocrinology outpatient clinic between 2005 and 2014. Patients under 18 years old, with secondary diabetes and BMI >40 kg/m^2 were excluded. The weight variation was calculated using the S.D. of BMI for each patient with 11.0 ± 0.2 determinations per patient over a mean follow-up of 7.25 ± 1.1 years. The main outcomes of management selected included: BMI, blood pressure, lipid profile, renal function and systemic inflammatory markers. Descriptive statistical methods were applied, *t*-test and Pearson's correlations where used to continuous variables and the χ^2 in categorical ones.
Results
The 1900 patients were aged 61.2 ± 0.3 years at the first observation and 769 were men. There was a statistically significant relationship between BMI and BMI variability for systolic blood pressure ($P<0.001$ and $P=0.036$), BMI for diastolic blood pressure ($P<0.001$), creatinine ($P=0.049$), uric acid ($P<0.001$); albuminuria ($P<0.01$), triglycerides $P<0.001$, HDL ($P<0.001$), and non HDH cholesterol ($P<0.015$); monocytes ($P=0.008$).
Conclusions
This retrospective study has the inherent limitations. Allows an insight to the problem by the data volume. The BMI and its variability in this population was associated with elevation of chronic inflammatory markers (monocytes), creatinine and lipid panel. These data reinforce the importance of weight control in T2DM patients.

Subclinical hypothyroidism and features of metabolic syndrome in Saudi elderly women

Eman Alissa[1] & Gordon Ferns[2]
[1]Faculty of Medicine, Kingabdulaziz University, Jeddah, Saudi Arabia; [2]Medical Education and Metabolic Medicine, Brighton and Sussex Medical School, University of Brighton, Brighton, UK.

To investigate the frequency of subclinical hypothyroidism (SCH) in adults with metabolic syndrome (MetS). To assess whether MetS features were associated with SCH. Study subjects were recruited from consecutive patients attending outpatient clinics within the department of internal medicine at KAUH, Jeddah city, KSA. A case–control study was conducted among 122 elderly women. Each patient was matched with a control whose age did not differ by more than 2 years. Demographic and medical data were obtained. MetS was defined according to the American Heart Association. Continuous data are presented as means ± S.E.M. Differences between subjects with and without MetS were determined by Mann–Whitney's U test and χ^2 tests where appropriate. Univariate relationships were estimates by Spearman's correlation analysis. The level of significance was set at two-sided P values <0.05. The data were analysed using SPSS version 20. The prevalence of SCH was 26% in the MetS group and 15% in the control group ($P>0.05$). The prevalence of SCH increased with age ($r=0.241$, $P<0.01$). All obesity measures were consistently inversely associated with serum TSH level. Subjects with MetS had significantly higher levels of blood pressure, fasting blood glucose, fasting blood profile (except for HDL-C which was significantly lower), and serum insulin than their control counterparts ($P<0.01$). All anthropometric measurements and insulin resistance measures were lower in the control group than in MetS patients ($P<0.01$). C-reactive protein was higher in the MetS patients than their matching controls ($P<0.01$). SCH is increased in patients with MetS, therefore hypothyroidism should be considered in newly diagnosed MetS patients. Of all MetS components, waist circumference was the only component negatively associated with serum TSH levels. Low-grade inflammation was more prevalent among the National Cholesterol Education Program-defined MetS patients than their age-matched controls.

Controlling the obesity epidemic: where does the pharmacist weigh in?

Edmond Pistja & Alba Themeli
Medical Health Training Center Santa Maria, Lezhe, Albania.

Background
Obesity is a growing health concern in Albania. Obesity has been identified as a key risk factor for many chronic diseases including hypertension, dyslipidaemia and type 2 diabetes mellitus. This study was conducted to investigate the role of community pharmacists in obesity counselling, and to identify the barriers to counselling in Albania.
Methods
It was used a descriptive cross-sectional study involved ten community pharmacies that were selected via stratified and systematic random sampling. A pretested self-administered questionnaire collected information on frequency and comfort level with obesity counselling, and the perceived effectiveness of four aspects of obesity management (diet and exercise, prescribed antiobesity medications, diet foods, and nonprescription products and dietary supplements). Information on perceived confidence in achieving positive outcomes as a result of counselling and barriers to counselling was also collected. Descriptive and Spearman' r analysis were conducted using SPSS version 17. Responses with Likert scale rating 1(low score) to 5 (high score) and binary choices (yes/no) were presented as mean (S.D.) and (95% CI), respectively.
Results
The response rate was 83.6%. The overall mean (S.D.) responses indicated that pharmacists counselled obese patients sometimes to most of the time, 3.67 (1.19) and were neutral to comfortable with counselling about aspects of obesity management, 3.77 (1.19). Respondents perceived obesity management aspects to be somewhat effective, 3.80 (1.05). Of the four aspects of obesity management, diet and exercise, and diet foods were the highest ranked in terms of frequency of counselling, comfort level and perceived effectiveness. Pharmacists were neutral to confident in achieving positive outcomes as a result of obesity counselling, 3.44 (1.09). Overall mean responses of counselling obese patients by pharmacists were positively correlated with their perceived comfort with counseling and perceived effectiveness of obesity management aspects. The most anticipated barriers to obesity counselling were lack of patient awareness about pharmacists' expertise in counselling and pharmacists' opinions that obese patients lack willpower and are non-adherent to weight reduction interventions.
Conclusions
Strengths, weaknesses and barriers related to obesity counselling by pharmacists in Albania were identified, and suggestions were provided to strengthen that role.

EP544

Effect of site of waist measurement on the prevalence of metabolic syndrome

Syed Mohd Razi[1], Manish Gutch[1], Sukriti Kumar[2], Abhinav Gupta[1] & Keshav Kumar Gupta[1]
[1]Llrm Medical College, Meerut, Uttar Pradesh, India; [2]Sgpgi, Lucknow, Uttar Pradesh, India.

Background
The metabolic syndrome is one of the fastest growing epidemics of the modern era in both the industrialised as well as developing world. Waist circumference (WC) is an important component to diagnose metabolic syndrome. Cut off point of WC to diagnose metabolic syndrome is different in.different ethnic groups.
Objective
To study and correlate the variation in prevalence of metabolic syndrome depending on the site of waist measurement and to study the effect of gender on the prevalence of metabolic syndrome with variation of site of waist measurement.
Methods
In a prospective, observational and non interventional study, 1000 patients (550 males and 450 females) were screened, out of which 151 patients found to have metabolic syndrome based on Asian Indian guidelines. Patients with gross ascites, pregnancy, substance abuse and age <20 and >70 years were excluded from study. Waist circumference (WC) of each study subject was taken at four different sites.
Results
The prevalence of metabolic syndrome in study population found to be 15.1%. There is no statistically significant difference between male and female in the age, TG level, systolic and diastolic blood pressure while the difference in HDL levels, and fasting blood sugar levels found to be statistic significance ($P<0.001$).The mean WC was maximum when measured at WC4 in both male and female groups. In males, the sensitivity of detection of metabolic syndrome and PPV were maximum at WC4 and minimum at WC2 while specificity and NPV were same at all four sites.
Conclusion
The females in study population have higher HDL than males while males have higher fasting blood sugar than females. WC4 is statistically the best site for detection of metabolic syndrome in whole population sample and in females but in males the sensitivity is maximally at WC4 but it is not statistically significant.

Calculating serum LDL cholesterol (LDL-C): comparison of LDL-C measured by direct assay with various formulae by combination of ages, genders, and triglycerides

Joana Menezes Nunes[1,2], Elisabete Rodrigues[1,2], Davide Carvalho[1,2] & João Tiago Guimarães[2,3]
[1]Endocrinology, Diabetes and Metabolism Department, Centro Hospitalar São João, Porto, Portugal; [2]Faculty of Medicine, Porto University, Porto, Portugal; [3]Pathology Department, Centro Hospitalar São João, Porto, Portugal.

Introduction
LDL cholesterol (LDL-C) is a major risk factor for atherosclerosis. The Friedewald formula (FF) is limited by hypertriglyceridaemia. We aimed to correlate serum LDL-C measured by direct assay with serum LDL-C estimated by several formulas: Friedewald (FF): LDL-C = CT-HDL − TG/5; Tsai (TsaiF): LDL-C = TC-HDL − TG/8 (TG/8 represents very-LDL-C); DeLong (DeLongF):

LDL-C = TC-HDL − TG × 0.16 and Chen (ChenF): LDL-C = non-HDL-cholesterol × 0.9 − TG × 0.1; and analyse LDL-C estimated values by combination of age, gender and triglycerides (TG).
Methods
Statistical analysis of 52 925 lipid profiles performed in our laboratory (SPSS.v21; Mac). Data are expressed in means ± s.d.s. Student's *t*-test, Pearson's correlation and linear regression were used for a statistical significance <0.01.
Results
For TG $\leq$4.5 mmol/l ($n=51\,975$), LDL-C measured by direct assay was 3.12 ± 0.96 mmol/l (120.8 ± 37.0 mg/dl), by FF 3.07 ± 1.11 mmol/l (118.6 ± 42.8 mg/dl), ChenF 3.26 ± 1.14 mmol/l (126.2 ± 44.2 mg/dl), TsaiF 3.32 ± 1.13 mmol/l (128.3 ± 43.6 mg/dl) and DeLongF 3.20 ± 1.11 mmol/l (123.8 ± 43.1 mg/dl). Linear regression showed a significant ($P<0.001$) better correlation ($\rho=0.947$, $r^2=0.897$) between the measured and calculated LDL-C by the ChenF. Regarding age, ChenF revealed more accurate results. For TG >4.5 mmol/l ($n=950$), LDL-C measured by direct assay was 3.88 ± 1.32 mmol/l (150.1 ± 51.1 mg/dl), by FF 2.39 ± 2.50 mmol/l (92.4 ± 96.8 mg/dl), ChenF 4.13 ± 1.93 mmol/l (159.8 ± 74.8 mg/dl), TsaiF 3.62 ± 2.01 mmol/l (140.2 ± 77.8 mg/dl) and DeLongF 3.05 ± 2.20 mmol/l (117.9 ± 85.1 mg/dl). TsaiF showed the best significant correlation ($\rho=0.849$, $r^2=0.720$). ChenF revealed significant better correlations for children and elderly and TsaiF for adults from 18 to 64 years. Regarding gender, linear regression showed a significant better correlation for ChenF for both TG categories.
Conclusions
FF underestimates LDL-C and the other formulas overestimate it. For patients with TG $\leq$4.5 mmol/l, ChenF provided more accurate for all studied groups. For TG > 4.5 mmol/l, TsaiF showed better correlation but regarding age ChenF revealed to be better for children and elderly and TsaiF for middle age patients. Our results suggest that TsaiF and ChenF may be more suitable for LDL-C estimation, even in the presence of moderate to severe hypertriglyceridaemia.

Glucose metabolism regulation in morbidly obese patients and in patients after biliopancreatic diversion

Natalya Mazurina[1], Ekaterina Troshina[1], Natalya Ogneva[1] & Yuri Yashkov[2]
[1]Endocrinology Research Center, Moscow, Russia; [2]Endosurgery and Lithotripsy Center, Moscow, Russia.

Introduction
Morbid obesity (MO) is associated with high frequency of type 2 diabetes mellitus (T2DM). Biliopancreatic diversion (BPD) is bariatric operation that results in rapid T2DM remission and increased GLP-1 levels. The aim of the study was to compare non-diabetic MO patients with normal weight controls and with patients who underwent BPD more than 2 years ago.
Methods
Blood glucose levels, IRI, GLP-1, GIP and glucagon were measured during the oral glucose tolerance test (OGTT) in three groups of patients. Patients of the 1st group (MO) had BMI >40 ($n=22$) and no history of diabetes mellitus. Patients after BPD were included in the 2nd group ($n=23$), post-operative period median was 4.7 years (2.3–7.2). The 3rd group were normal weight controls ($n=22$).
Results
Impaired glucose metabolism was revealed in 68.2% of MO patients ($n=10$). In MO group fasting glucose, IRI and HOMA-IR were maximal ($P<0.001$). MO patients had higher fasting and stimulated GIP and glucagons levels. In the BPD patients postprandial glucose (120 min) was lower, in 17.4% we found postprandial hypoglycemia (<2.8 mmol/l). Stimulated IRI concentration was significantly higher in the BPD group ($P=0.026$). Fasting and stimulated GLP-1 were significantly higher in BPD ($P=0.037$ and $P=0.022$, respectively).
Conclusion
Hyperglucagonaemia, increased GIP levels and decreased GLP-1 levels are observed in MO. Glucose intolerance and insulin resistance incidence is higher in MO patients. Stimulated plasma IRI and GLP concentrations are significantly increased in BPD patients.

The relationship between the subclinical target organ damage and the levels of ischemia-modified albumin in hypertensive patients

Nihal Ozkayar[1], İhsan Ates[1], Fatma Akyel[1], Cüneyt Tayman[2], Mehmet Namuslu[3], A Nurdan Barça[4], Serdar Akyel[5] & Fatih Dede[1]
[1]Ankara Numune Education and Research Hospital, Ankara, Turkey; [2]Department of Neonatology, Denizli Denizli Goverment Hospital, Denizli, Turkey; [3]Department of Medical Biochemistry, Turgut Ozal University Medical School, Ankara, Turkey; [4]Department of Radiology, Ankara Numune Education and Research Hospital, Ankara, Turkey; [5]Department of Cardiology, Ankara Numune Education and Research Hospital, Ankara, Turkey.

Aim
To investigate the relationship between the presence of subclinical target organ damage (STOD) and the levels of ischemia-modified albumin (IMA) in hypertensive patients.
Methods
The study included a total of 106 patients, 53 with STOD and 53 without STOD. STOD was deemed present if fundus examination revealed a grade 3–4 retinopathy; the left ventricular mass index (LVMI) was >95 g/m^2 in females and >115 g/m^2 in males at echocardiography; carotid intimal media thickness (CIMT) was $\geq$0.9 mm; and 24-h urine had 30–300 mg albumin. IMA levels were assessed by spectrophotometric method using albumin cobalt binding test. All patients underwent ambulatory blood pressure monitoring (ABPM) for 24-h.
Results
The mean whole-day systolic blood pressure was higher in patients with STOD (128.19 ± 15.9 vs 118.55 ± 10.5, respectively $P=0.001$). The mean diastolic blood pressure was similar in both of the groups ($P>0.05$). The mean IMA level was higher in patients with STOD (0.63 ± 0.09 vs 0.53 ± 0.1 respectively $P=0.013$).
Conclusion
Elevated IMA in patients with STOD is consistent with the role of ischemia and oxidative stress in development of target organ damage in hypertensive patients, and suggests that IMA can be used as an indicator to predict the presence of STOD.

The relationship between socioeconomic level, and the prevalence of masked hypertension and asymptomatic organ damage

İhsan Ates[1], Mustafa Altay[1], Mustafa Kaplan[1], Nihal Ozkayar[2], Güvenç Toprak[1], M Erdem Alagüney[1] & Adem Ozkara[3,4]
[1]Internal Medicine Department, Ankara Numune Education and Research Hospital, Ankara, Turkey; [2]Nephrology Department, Ankara Numune Education and Research Hospital, Ankara, Turkey; [3]Family Medicine Department, Hitit University Medical Faculty, Çorum, Turkey; [4]Family Medicine Department, Ankara Numune Education and Research Hospital, Ankara, Turkey.

Background
This study aimed to determine the prevalence of masked hypertension (MHT) and its association with asymptomatic organ damage (AOD) in a low socioeconomic district of Ankara, Turkey.
Material and methods
Data obtained from the medical records of 712 patients with no known diagnosis of hypertension that presented to a polyclinic due to symptoms related to elevated blood pressure (BP) and were screened for MHT were retrospectively reviewed. The essential hypertension (EHT) included 86 patients screened for AOD. The presence of AOD in patients diagnosed with MHT and the EHT group was recorded.
Results
Among the 712 patients, 206 were diagnosed with EHT and among the remaining 506 patients, 73 were diagnosed with MHT. The patients with MHT had a significantly higher left ventricular mass index, carotid intima media thickness, and 24-h urinary microalbuminuria level (all indicators of AOD) than those with EHT.
Conclusion
A significantly higher percentage of patients with MHT had AOD, as compared with those with EHT, in a low socioeconomic district of Ankara. Based on this

finding, we think patients that present with hypertensive symptoms but have a normal BP should be advised to measure their BP at home.

Management of hypoglycaemia after gastric bypass: a difficult challenge

Julia Silva-Fernández[1], Álvaro García-Manzanares Vázquez de Agredos[1], Francisco Javier Gómez-Alfonso[1], María López-Iglesias[1], Inés Gómez-García[1] & Carolina González-Pereira[2]
[1]Endocrinology Unit, Mancha Centro General Hospital, Alcázar de San Juan, Ciudad Real, Spain; [2]Intensive Unit Care, Central Asturias University Hospital, Oviedo, Asturias, Spain.

Introduction
Postprandial hypoglucaemia with hyperinsulinism after laparoscopic gastric bypass is an uncommon complication with an estimated prevalence of 0.2%. Its treatment includes acarbose, diazoxide, somatostatin and GLP-1 analogues or calcium channel blockers in case a strict diet does not work.
Case report
A 42-year-old woman with history of gastric bypass in 2005 due to severe obesity (preoperative weight 150 kg) attended our clinic 3 years after surgery reporting hypoglycaemic episodes occasionally accompanied by unconsciousness, occurring 3 h after food intake. The episodes resolved after sugar intake. ACTH stimulation test ruled out adrenal insufficiency. A 72-h fasting test was done with no pathological findings. A glucose tolerance test was also performed showing hypoglycaemia and hyperinsulinism. A CT scan of the abdomen did not find pancreatic nodules. Fractionated diet was started, followed by treatment with acarbose. Both measures were ineffective. Lanreotide treatment was subsequently administered with intolerance and no improvement. Diazoxide was titrated achieving only a partial response and the patient was referred to surgery for corporocaudal pancreatectomy in 2013. Pathological examination found diffuse nesidioblastosis. After the surgery, no hypoglycaemic episodes were observed. Moreover, the patient developed diabetes requiring treatment with insulin. One year after pancreatectomy the patient had a relapse of hypoglycaemia episodes even after insulin withdrawal. An overload test with mixed meal showed hyperinsulinaemic hypoglycaemia. Liraglutide 0.6 mg/24 h was prescribed but we had to stop it because of side effects. The patient was referred to a second surgery for total pancreatectomy.
Conclusions
There is no treatment of choice for patients with nesidioblastosis. Medical treatment, including somatostatin and GLP-1 analogues, should be tried before surgery. When medical treatment fails, subtotal pancreatectomy is a good option to control hypoglucaemia and preserve pancreatic function. When hypoglycaemia persists, total pancreatectomy should be considered.

The impact of the socio-demographic and lifestyle factors on central obesity and overweight status using structural equation modelling: Tehran Lipid and Glucose Study

Sara Jalali-Farahani[1,2], Parisa Amiri[1,2], Mehrdad Karimi[1,3], Safoora Gharibzadeh[3,4], Parvin Mirmiran[5] & Fereidoun Azizi[4]
[1]Research Institute for Endocrine Sciences, Research Center for Social Determinants of Endocrine Health, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Research Institute for Endocrine Sciences, Obesity Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [3]Department of Epidemiology and Biostatistics, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran; [4]Research Institute for Endocrine Sciences, Endocrine Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [5]Department of Clinical Nutrition and Dietetics, Faculty of Nutrition Sciences and Food Technology, National Nutrition and Food Technology Research Institute, Shahid Beheshti University of Medical Sciences, Tehran, Iran.

Introduction
This study aimed to investigate possible direct and indirect association of socio-demographic and lifestyle factors with central obesity and overweight status in the Tehran Lipid and Glucose Study (TLGS) population.
Methods
After excluding under- and over-reporters, a sample of 2747 TLGS participants (58.3% female) aged $\geq$20 years were recruited in the study. Overweight and central obesity were defined as having BMI $\geq$25 kg/m^2 and waist circumference $\geq$91 cm (Iranian cut-off point) respectively. Socio-demographic factors, lifestyle factors including leisure time physical activity, dietary patterns and daily energy intake were included in the hypothesised model for the testing direct and indirect effects on overweight and central obesity, using structural equation modelling (SEM), conducted by AMOS V20.
Results
Overweight and central obesity were present in 61.6 and 48.1% of respondents, respectively. Fit indices had acceptable fit for the hypothesized model (χ^2/df = 3.13, GFI = 0.98, CFI = 0.97, RMSEA = 0.028). Among lifestyle factors, daily energy intake had a direct effect on overweight and central obesity in both men (β = 0.44 and 0.47 respectively; $P<0.01$) and women (β = 0.33 and 0.33 respectively; $P<0.01$); while, poor dietary pattern had a direct effect on overweight and central obesity, only in men (β = 0.10 and 0.13; $P<0.01$). Of socio-demographic factors, in women, higher age, being married and lower educational level had direct effects on overweight (β = 0.28, 0.15 and $-$0.09 respectively) and central obesity (β = 0.30, 0.05 and $-$0.12 respectively, $P<0.05$); in men however, only higher age and being married had direct effects on overweight (β = 0.14 and 0.18 respectively) and central obesity (β = 0.23 and 0.14 respectively, $P<$ 0.01). Furthermore, lower age and marital status in both sexes and lower education in women had indirect effects on overweight and abdominal obesity via lifestyle factors.
Conclusion
Interventions aiming at some socio-demographic and lifestyle factors may help health policy makers to reduce the burden of obesity among this adult population.

EP551

The influence of metabolic syndrome to cardiovascular events in a 10-year prospective study

Laura Kazlauskiene, Jurate Butnoriene & Antanas Norkus
Lithuanian University of Health Sciences, Kaunas, Lithuania.

The aim of the study was to evaluate frequency of cardiovascular events (myocardial infarction, stroke) among the individuals with metabolic syndrome (MS).
Materials and methods
The study design was prospective. It was started in 2003 to assess the risk factors, clinical components, diagnostic criteria of MS and to determine correlation between MS and neuropsychiatric disorders. At the second stage in 2013 the individuals were repeatedly invited to evaluate cardiovascular pathology that was confirmed by cardiologist and neurologist. The 45 years old and older citizens of Lithuanian district participated in the study. 1115 individuals (562 men and 553 women) were randomly selected in 2003. 538 respondents: 278 (51.70%) men and 260 (48.30%) women participated in the repeated study in 2013. The age of the individuals was 55 to 92 years.
Results
During the study myocardial infarction (MI) was confirmed to 40 (7.43%) individuals taken part in the study, stroke – to 23 (4.28%) individuals. The odds ratio of MI between individuals with MS and without MS was 1.80 (95% CI 1.67–1.97), $P<0.05$. The odds ratio of stroke for individuals with MS and without MS was 2.05 (95% CI 1.21–2.54), $P<0.05$. According to data of the study, occurrence of MI was higher in the group of individuals with MS than to individuals without MS, respectively 23; 9.75% vs 17; 5.63%, $P>$ 0.05. Occurrence of stroke was higher in the group of individuals with MS, accordingly 14; 5.93% vs 9; 2.98%, $P>0.05$. Comparing the frequency of MI between genders, the pathology was found more frequently in women's group: 14; 10.30% vs 9; 9.00%, $P>0.05$. The frequency of stroke was equal in both groups, accordingly 7; 5.15% vs 7; 7.00%, $P>$ 0.05.
Conclusion
Individuals with identified MS have 1.80 and 2.05 times higher statistically significant probability, respectively, for MI and stroke events, than individuals without MS.

EP552

Influence of normal food intake on the lipid profile of diabetic patients

Susana Garrido[1], Raquel Almeida[1], Teresa Pereira[1], Lia Ferreira[1], Helena Neto[1], Joana Vilaverde[1], Fernando Pichel[1], José Carlos Oliveira[2] & Isabel Palma[1]
[1]S. de Endocrinologia, Diabetes e Metabolismo, Centro Hospitalar do Porto, Porto, Portugal; [2]S. de Química Clínica, Centro Hospitalar do Porto, Porto, Portugal.

Introduction
The need to fast for the determination of lipid profile has been discussed in the past years, for several reasons – i) most of the day time is spent in a postprandial state; ii) the lipid concentrations seem to be only slightly affected by a normal meal; both fasting and postprandial can predict cardiovascular risk.
Aim
Determine the influence of normal food intake on the lipid profile of diabetic patients.
Methods
A total of 248 diabetic patients were included (49.6% male; median age 57 years, range 40–79 years), recruited between April/2013 and August/2014 from the Outpatient Diabetes Education Program of Hospital de Santo António, Centro Hospitalar do Porto. Clinical and analytical evaluation took place in two moments (fasting $=t_0$; 2 h after a standard breakfast $=t_1$), with measurements of total cholesterol (TC), LDL cholesterol (LDL-C), HDL-cholesterol (HDL-C) and triglycerides (TG). Paired LDL-C samples of patients with TG >400 mg/dl and outliers (≥ 3 S.D. from the mean) were excluded from the analysis.
Results
TG concentration increased between the two moments (median difference $t_1-t_0=6$ mg/dl, $P=0.002$) but the TC, HDL-C, LDL-C and non-HDL-C did not change significantly (P: 0.69; 0.75; 0.06 e 0,60 respectively). Performing an analysis according to the two therapeutic goals for LDL-C proposed by the ATP III, we found that the proportion of patients with LDL-C $t_0 \geq 100$ mg/dl and LDL-C $t_1 < 100$ mg/dl was 9.3% (5/54); and LDL-C $t_0 \geq 70$ mg/dl and LDL-C $t_1 < 70$ mg/dl of 3.3% (3/91). Similarly, also a small percentage of patients with LDL-C t_0 <100 mg/dl had values of LDL-C $t_1 \geq 100$ mg/dl (8.6%, 5/58). Considering the objective of 70 mg/dl, this percentage reached 14.3% (3/21).
Conclusion
The data presented question the need to fast for the determination of lipid profile. Further studies are needed to confirm these results and to demonstrate an association of postprandial lipid profile and cardiovascular risk in diabetic population.

DOI: 10.1530/endoabs.37.EP552

The functional parameters of renin-angiotensin-aldosterone system in obese patients

Nadezhda Platonova, Natalya Mazurina, Teona Shvangiradze, Ekaterina Troshina & Gulnara Katzia
Endocrinology Research Center, Moscow, Russia.

Introduction
Renin-angiotensin-aldosterone system (RAAS) plays a significant role in the development of arterial hypertension (AH) in obese patient. Angiotensinogen expression in adipose tissue decreases during fasting and increases in case of overeating, that leads to changes in blood pressure (BP). The aim of the study was to assess the impact of obesity on the activity of RAAS and its role in the development of hypertension.
Methods
60 women, mean age 28.0 ± 2.1 years, BMI 37.7 ± 1.2 kg/m^2 participated in the study. Subjects were divided into groups depending of the AH presence: the 1st group consisted of 28 women with normal BP (systolic BP 115.6 ± 1.28 mm Hg; diastolic 81.0 ± 3.0 mm Hg). 32 women with AH (systolic BP 166.6 ± 5.4 mm Hg; diastolic BP 96.0 ± 3.2 mm Hg) were included in the 2nd group. 15 healthy normal weight women (19–25 years old, BMI 10.4 ± 2.3 kg/m^2) were included in the control group. NaCl consumption not <5 g/day was recommended to all patients. Plasma aldosterone concentration and renin activity were measured by radioimmunoassay with an automatic analyser («Immunotech», France). Blood samples were taken every 4 h during the day (8, 12, 16, 20, 24, 4 h) to evaluate the circadian rhythm of aldosterone secretion.
Results
In all obese patients plasma Na^+ and K^+ concentrations were normal. Urinary potassium excretion did not differ significantly from the control group ($P>0.05$), sodium excretion was significantly decreased ($P<0.05$). Both groups of obese patients have demonstrated low basal plasma renin activity compared with the control group ($P<0.001$). Plasma renin activity values were not significantly different in the 1st and the 2nd groups (1st – 1.4 ± 0.06, 2nd – 1.15 ± 0.004 ng/ml per h, control group 2.18 ± 0.2 ng/ml per h). Morning aldosterone level was increased in the 1st group. At the same time, morning aldosterone level in the 2nd group was higher in comparison with the 1st group and with the control group (1st – 413.8 ± 20.6 pmol/l; 2nd – 664.1 ± 26.6 pmol/l; control group – 290.0 ± 19.6 pmol/l). Circadian rhythm of aldosterone in the control group was characterized by a maximum concentration in the morning hours (4–8 h) and lower concentration during the day, evening and night hours. A circadian rhythm of aldosterone in patients of the 1st group did not differ from the control group, while the 2nd group demonstrated an inversion of the circadian rhythm of aldosterone with maximum at midnight (24.00 h – 960.4 ± 140.7 pmol/l; 8.00 h – 597.6 ± 96.1 pmol/l, $P<0.05$).
Conclusions
1. Plasma aldosterone concentration in the morning hours was elevated in the obese patients without hypertension.
2. Obese hypertensive patients had inverse aldosterone biorhythm with maximum at midnight.

Enzymes of the vitamin K cycle and progression of calcification in the vessel wall

Natascha Schweighofer[1], Ariane Aigelsreiter[2], Olivia Trummer[1], Martina Graf-Rechberger[2], Nicole Hacker[1], Florian Iberer[3], Doris Wagner[3], Daniela Kniepeiss[3], Philipp Stiegler[3], Thomas Pieber[1], Helmut Müller[3] & Barbara Obermayer-Pietsch[1]
[1]Department of Internal Medicine, Divison of Endocrinology and Metabolism, Medical University of Graz, Graz, Austria; [2]Institute of Pathology, Medical University of Graz, Graz, Austria; [3]Department of Surgery, Division of Transplantation Surgery, Medical University of Graz, Graz, Austria.

Calcification is a physiological process in bone but occurs also pathologically in the vasculature, favouring cardio- and cerebrovascular diseases (CVD). Vitamin K metabolites, particularly K1 and MK-4, are associated with decreased vascular calcification especially in patients with chronic kidney disease. We investigated the expression of components of the vitamin K cycle (VKC) and the MK-4 synthesis (MKS) in aorta and bone of 26 brain dead organ donors in order to identify differences in the expression pattern during atherosclerosis (AS) stages in aortic vascular tissue and to compare these profiles in both tissue types. Gene expression was performed using TaqMan gene expression assays with a LC480 system. Determination of calcification stage was done histologically: (0 (unaffected vessels), 1 (intima thickening), 2 (intima calcification)). VKC enzymes VKOR, VKORL1, GGCX and the chaperone calu and the enzymes NQO1 and UBIAD1, necessary for MKS are both expressed in aortic and bone tissue. In the aorta, gene expression of VKOR, VKORL1, and calu differed significantly between the three atherosclerotic stages ($P=0.040$; $P=0.023$ and $P=0.038$, respectively), whereas the expression of GGCX showed borderline significance ($P=0.060$). In bone, gene expression of VKC and the MKS proteins did not differ in respective AS stages. Comparison of bone and aorta showed only significant differences in gene expression of calu, GGCX and NQO1 in the last stage of intima calcification. We are able to demonstrate that bone and aorta express the components of vitamin K cycle and of MK-4 synthesis. We also show the existence of a different gene expression pattern in AS progression in bone and aorta. These data might lead to a more comprehensive insight into the role of vitamin K metabolising enzymes in vascular calcification.

Weight loss with bariatric surgery improves ischaemia modified albumin levels and oxidative status in morbidly obese patients

Adnan Yay[1], Muzaffer Ilhan[1], Saime Turan[2], Ümit Zeybek[2], Ozcan Karaman[1], Ilhan Yaylim[2] & Ertugrul Tasan[1]
[1]Bezmialem University, Istanbul, Turkey; [2]Istanbul University, Istanbul, Turkey.

Introduction
Oxidative stress is one of the possible mechanisms involved in the pathogenesis of the obesity-related metabolic complication. In this study, we aimed to investigate effect of weight loss with bariatric surgery on IMA, high sensitive C-reactive protein (hs-CRP), serum total antioxidant status (TAS), total oxidant status (TOS) levels.
Materials and methods
In this prospective study, plasma IMA, hs-CRP, TAS and TOS levels were measured before and 6 months after laparoscopic sleeve gastrectomy in 60 morbidly obese patients with a BMI of 46.6 ± 6.7 kg/m^2. 43 age-matched healthy subjects with a BMI of 24.6 ± 3 recruited as controls. Metabolic parameters including serum levels of fasting glucose, HbA1c, homeostatic model assessment of insulin resistance (HOMA-IR), C-peptide, LDL, HDL, triglyceride were also measured before and after surgery.
Results
Excess weight loss (EWL) and percentage of EWL were 34.9 ± 10.5 kg and 27.8% in obese patients. Plasma IMA levels before surgery was significantly increased in patients compared to controls ($P<0.05$). We found significantly increased hs-CRP levels in patients compared to controls ($P<0.001$). Plasma IMA and hs-CRP levels were significantly decreased in patients after 6 month of bariatric surgery ($P<0.05$ and $P<0.001$, respectively). At 6th month of surgery, BMI of patients was still significantly higher than controls ($P<0.01$), hs-CRP levels were significantly increased in patients ($P<0.001$) but there was no significant difference in IMA levels. A statistically significant reduction was found in the TOS values after the surgery ($P<0.001$), but there were no significant changes in the TAS levels. Significantly decreased levels of fasting glucose ($P<0.01$), HbA1c ($P<0.001$), HOMA-IR ($P<0.01$), C-peptide ($P<0.001$), LDL-C ($P<0.001$) and triglyceride ($P<0.001$) and increased levels of HDL-C ($P<0.001$) were observed after bariatric surgery.
Conclusion
Our findings supported that weight loss with bariatric surgery improves IMA, hs-CRP, TOS levels and metabolic profile in patients. Along with still higher BMI in patients after surgery, no significant difference in IMA levels between obese and healthy group suggested that bariatric surgery could have beneficial effects on oxidative stress beyond weight loss.

Metformin treatment of hypothalamic obesity: the lesson of two cases

Codruta Nemes[1], Sabina Secara[1], Ioan Stefan Florian[2,3] & Cristina Ghervan[1,3]
[1]Department of Endocrinology, Cluj Napoca, Romania; [2]Department of Neurosurgery, Cluj Napoca, Romania; [3]University of Medicine and Pharmacy, Iuliu Hatieganu, Cluj Napoca, Romania.

Introduction
Hypothalamic obesity is defined as a syndrome of intractable weight gain as a result of hypothalamic lesions. Craniopharyngioma is responsible for more than half of the cases of hypothalamic obesity, but other pathologies can be implied. The syndrome can occur due to the tumour itself or its treatment (surgery or radiotherapy). Metformin is an antidiabetic drug that has also been used to treat nondiabetic obese patients, as it has been demonstrated to promote weight loss. Metformin alone has not been previously tested in patients with hypothalamic obesity.
Case presentation
We present the case of two patients with hypothalamic obesity, which were efficiently treated with metformin. The first case is a 44-year-old woman who has gained 45 kg following surgery for cranyopharyngioma, despite caloric restriction and treatment with sibutramine and then orlistat. When she reached 150 kg, treatment with Metformin was initiated. During treatment she lost 34 kg in 30 months and her insulin resistance decreased significantly. The second case is a patient who was diagnosed at 6.4 years with a suprasellar mixed germ cell tumour (immature teratoma and germinoma). She underwent surgery, radiotherapy and chemotherapy. Following surgery, she developed severe hypothalamic obesity with insatiable bulimia, gaining dramatically 32 kg in 2.5 years. As complication of this major weight gain she had severe insulin resistance, dyslipidaemia, and steatohepatitis. As nutritional intervention and treatment with sibutramine and orlistat failed, treatment with metformin was initiated. After 1 year she lost 21 kg, her lipid profile and insulinaemia improved considerably and her liver enzymes normalised.
Conclusion
Metformin proved to be an efficient and well tolerated treatment in these two patients with hypothalamic obesity, showing that it can be an option in these dramatic cases.

Glycolysis in septic patients during early ICU hospitalisation shows differences vis-à-vis shock resolution

Ioannis Ilias[1], Sofia Apolonatou[2], Nikitas Nikitas[2], Maria Theodorakopoulou[2], Frantzeska Frantzeskaki[2], Dimitra Vasiliadi[3] & Ioanna Dimopoulou[2]
[1]Department of Endocrinology, E Venizelou Hospital, Athens, Greece; [2]Second Department of Critical Care Medicine, University of Athens Medical School, Attikon University Hospital, Athens, Greece; [3]Second Department of Internal Medicine, University of Athens Medical School, Attikon University Hospital, Athens, Greece.

Introduction
In glycolysis, glucose is converted into pyruvate. Patients with sepsis are prone to numerous metabolic alterations, including changes in carbohydrate metabolism.
Aim
To assess glucose metabolism in septic patients during the first day of ICU hospitalisation and evaluate this vis-à-vis shock resolution.
Subjects and methods
Ten patients with septic shock during the first day of ICU hospitalization were studied; measurements were done every 2 h in blood for glucose and in tissue (with microdialysis (MD)) for pyruvate. Patients with diabetes were excluded. Six patients recovered from shock within 1–9 days. We analyzed the data on a cross-correlation matrix of 2-h' increments of blood glucose and MD pyruvate for patients with shock resolution and no shock resolution separately.
Results
In patients with shock resolution significant correlations were noted for blood glucose vs MD pyruvate (maximum r: $+0.96$, P: 0.004; with pyruvate lagging by 12 h); no significant correlations between blood glucose and MD pyruvate were measured in the patients with no shock resolution.
Discussion
During the first day of ICU hospitalisation septic shock patients who eventually resolved their shock status showed active glycolysis, whereas patients who remained in shock had early on no appreciable glycolysis.

EP558

Renal hemodynamic status in patients with different classes of obesity

Lyndina Maria & Shishkin Alex
Medical Faculty, Saint-Petersburg State University, Saint-Petersburg, Russia.

Introduction and aims
Obesity is associated with increased single-nephron glomerular filtration rate, which may increase the risk of chronic kidney disease (CKD). Several biopsy studies showed the association between obesity and higher prevalence of CKD features, including segmental glomerulosclerosis, tubular atrophy, interstitial fibrosis, and arterial sclerosis. Another approach is to study intra-renal

hemodynamics by ultrasound, where renal parenchymal damage in obesity may be reflected by intra-renal resistive indices.
Methods
We examined 108 patients with different classes of obesity (90 women and 18 men, mean age: 54.62 ± 0.4 years). All patients were divided into three groups (III classes of obesity, divided by BMI). They underwent clinical and laboratory examination, which included lipidogram, insulin, plasma homocysteine levels, microalbuminuria (MAU) in the morning urine. The result was determined directly, without any recalculation. UIA identified in excess of index higher than 20 mg/l. Study of intrarenal blood flow was performed by color Doppler with pulsed doplerometry on the device Aloka SSD-5500. We studied the main and intrarenal renal artery (segmental and interlobar) in the projection of the three segments of both kidneys. We determined the resistive characteristics of the arterial blood flow (RI and PI), calculated automatically by the standard formulas.
Results
The average level of insulin plasma and homocystein exceeded the normal laboratory data in the III class – 31.57 ± 0.41 mE/l ($P < 0.001$) and 18.43 ± 0.57 mol/l ($P < 0.001$). The level of MAU exceeded in the II class – 20.44 ± 0.46 mg/l ($P < 0.05$) and III class – 53.09 ± 7.87 mg/l ($P < 0.001$). In the study of intrarenal blood flow RI and PI in the segmental and interlobar level of the arteries in this groups of patients were above normal values. In the segmental level: I class – RI = 0.64 ± 0.01 ($P < 0.05$) and PI = 0.99 ± 0.2 ($P < 0.001$); II class – RI = 0.71 ± 0.01 ($P < 0.05$) and PI = 1.24 ± 0.03 ($P < 0.001$); III class – RI = 0.70 ± 0.01 ($P < 0.05$) and PI = 1.33 ± 0.04 ($P < 0.001$). In the interlobar level: I class – RI = 0.63 ± 0.01 ($P < 0.05$) and PI = 0.99 ± 0.2 ($P < 0.001$); II class – RI = 0.70 ± 0.01 ($P < 0.05$) and PI = 1.24 ± 0.03 ($P < 0.001$); III class – RI = 0.68 ± 0.01 ($P < 0.05$) and PI = 1.31 ± 0.04 ($P < 0.001$).
Conclusions
These results suggest that obese patients have a sign of intravascular renal resistance and an increased risk for CKD.

Influence of anthropometric parameters, leptin, adiponectin, and insulin resistance on blood pressure in obese women

Milena Velojic Golubovic, Dragan Dimic, Milica Pesic, Sasa Radenkovic & Danijela Stojic
Clinic of Endocrinology, Clinical Center Nis, Nis, Serbia.

Relationship of body weight and blood pressure is very complex and still incompletely explained. Obesity, especially visceral, is one of the strongest predictors of arterial hypertension. Hypertension is six times higher in obese than in lean people, with its prevalence increases with an increase in BMI progressively. The mechanisms underlying hypertension in obese are not fully defined. The aim of this research was to determine the influence of various parameters on blood pressure and assume the possible pathogenetic mechanisms.
Materials and methods
The study included 90 obese women who were determined of average values of blood pressure, anthropometric parameters, levels of leptin, adiponectin, insulin levels, and HOMA-R index and established their mutual correlation.
Results
The mean values of blood pressure of patients was 146 ± 15.68 mmHg for systolic and 92 ± 10.83 mmHg for diastolic blood pressure. 33% of the subjects were normotensive. Correlation of anthropometric parameters and blood pressure values established their positive correlation, with a statistically significant impact of a waist circumference ($P < 0.001$) and waist/hip ratio ($P < 0.01$). Insulinaemia and HOMA-R index correlated positively and significantly with the values of systolic and diastolic blood pressure ($P < 0.05$). Leptin levels correlated positively and statistically significant with the systolic ($P < 0.001$) and diastolic blood pressure ($P < 0.05$). Correlations between adiponectin levels with the systolic and diastolic pressure are negative and not statistically significant. There is statistical significance of the negative correlation of adiponectin with fasting insulin levels and HOMA-R index.
Conclusion
Waist circumference, waist/hip ratio, insulin resistance, and leptin levels have statistically significant effect on blood pressure, and thus the occurrence of hypertension in obese women. Adiponectin through impact on insulin sensitivity probably contributes to the development of arterial hypertension.

Galectin-3 and fibulin-1 in systolic heart failure patients with and without diabetes: relation to glucose metabolism and left ventricular contractile reserve

Pernille Holmager[1], Michael Egstrup[2], Ida Gustafsson[3], Morten Schou[4], Jordi Dahl[5], Lars Melholt Ramussen[6], Jacob Møller[5], Christian Tuxen[7], Jens Faber[1,8] & Caroline Kistorp[1,8]
[1]Department of Medicine, Herlev University Hospital, Herlev, Denmark; [2]Department of Cardiology, Rigshospitalet, Copenhagen, Denmark; [3]Department of Cardiology, Hvidovre University Hospital, Hvidovre, Denmark; [4]Department of Cardiology, Herlev Universty Hospital, Herlev, Denmark; [5]Department of Cardiology, Odense Univeristy Hospital, Odense, Denmark; [6]Department of Clinical Biochemistry and Pharmacology, Odense University Hospital, Odense, Denmark; [7]Department of Cardiology, Bispebjerg Hospital, Copenhagen, Denmark; [8]Faculty of Health and Science, Copenhagen University, Copenhagen, Denmark.

Aims
Diabetic patients with heart failure (HF) have an adverse prognosis, which could be linked with reduced left ventricular (LV) contractile reserve. Galectin-3 (Gal-3) and fibulin-1 are potential biomarkers of fibrosis. The aims were to evaluate the impact of DM on Gal-3 and fibulin-1 levels and the association to LV contractile reserve in HF patients with and without diabetes (DM).
Methods and results
From an out-patient HF clinic 155 patients with systolic HF were included and underwent a low-dose dobutamine echocardiography and blood sampling for analyses of plasma Gal-3 and fibulin levels. Oral glucose tolerance test (OGTT) was performed in non-diabetic HF patients. Based on history of DM and OGTT patients were divided into normal glucose tolerance (NGT) ($n = 95$), impaired glucose tolerance (IGT) ($n = 25$), and DM ($n = 60$).
Results
Galectin-3 levels were 17.9 ng/ml in diabetics ($P = 0.02$) while fibulin-1 levels were not influenced by DM status. Gal-3 was associated with LV contractile reserve in a univariable regression model; standardized β (S.E.M.) ($\beta = -0.19$, $P = 0.03$), but not in a multivariable model including eGFR, ($\beta = -0.04$, $P = 0.66$). Fibulin-1 was not associated with LV contractile reserve in a univariable model ($\beta = -0.06$, $P = 0.51$). HbA1c was independently associated with Gal-3 ($\beta = 0.16$, $P = 0.02$) and fibulin-1 ($\beta = 0.16$, $P = 0.04$) in a multivariable regression model including eGFR.
Conclusion
Gal-3 and fibulin-1 levels were elevated in diabetic HF patients, associated with HbA1c, but not with LV contractile reserve.

The effect of the type of the bariatric surgery in the lipid profile: an age, sex, BMI, and excess weight loss matched study

Filipe Cunha[1,2], Joana Oliveira[1,2], John Preto[3], Ana Saavedra[1,2], Maria Costa[1,2], Daniela Magalhães[1], Rita Bettencourt-Silva[1], Paula Freitas[1,2], Ana Varela[1,2] & Davide Carvalho[1,2]
[1]Serviço Endocrinologia, Diabetes e Metabolismo do Centro Hospitalar São João, Porto, Portugal; [2]Faculdade de Medicina da Universidade do Porto, Porto, Portugal; [3]Serviço de Cirurgia Geral do Centro Hospitalar São João, Porto, Portugal.

Introduction
Bariatric surgery improves lipid profile. A still unanswered question is whether this improvement is merely weight dependent or also results from factors inherent to specificities of the bariatric procedure itself. We aimed to study lipid profile 1 year after bariatric surgery and compare its changes between the different procedures in patients matched for initial weight and for weight loss.
Methods
We retrospectively analysed patients submitted Roux-en-Y gastric bypass (RYGB), adjustable gastric banding (AGB), or sleeve gastrectomy (SG) between 2010 and 2013. Patients were matched for age (±5years), sex, pre-surgery BMI (±2 kg/m^2), and EWL (±5%). Baseline and 1-year lipid profile, its variation and percentage of variation was compared between surgeries.
Results
We analysed 229 patients: 72 pairs RYGB-AGB; 47 pairs RYGB-SG; and 33 pairs AGB-SG. The median age was 41 (35–52) years and 11.8% were males. BMI at the time of surgery was 44.0 ± 4.6 and 32.1 ± 4.4 kg/m^2 at 1 year. EWL at 1 year was 64.2 ± 18.9%. There were no differences in baseline lipid profile between patients submitted to different types of bariatric surgery. At 1 year, HDL

and TG improved similarly with all surgeries. TC and LDL at 1 year decreased significantly more in patients submitted to RYGB than in weight-matched patients undergoing AGB or SG.
Conclusions
RYGB is the only bariatric surgery that reduces TC and LDL in age-, sex-, BMI-, and EWL-matched patients. All three procedures improved TG and HDL similarly when the confounding effect of weight loss is eliminated.

Comparison of demographic and biochemical characteristics among younger and older patients with metabolic syndrome

Pelin Tutuncuoglu[1], Fulden Sarac[2], Sumru Savas[2] & Sefa Sarac[3]
[1]Department of Endocrinology and Metabolism, Atatürk Training and Research Hospital, Izmir, Turkey; [2]Department of Geriatrics Medicine, Ege University Medical Faculty, Izmir, Turkey; [3]Department of Cardiology, Atatürk Training and Research Hospital, Izmir, Turkey.

Aims
The metabolic syndrome (MetS) is a summary measure of important CVD risk factors that frequently coexist. The syndrome is evident in 20–30% of middle-aged women and has been linked to the development of CVD and diabetes. The aim of the study was to examine the differences in demographic and clinical profiles among older ($\geq$60 years) and younger ($<$60 years) patients with MetS.
Methods
The study was included 45 older (mean age 63.1$\pm$12.1 years, 25 females and 20 males) and 40 younger (mean age 42.3$\pm$9.9 years, 30 females and ten males) patients wih MetS. MetS was defined as in ATP III. Demographic and biochemical parameters were compared between groups. Insulin resistance (IR) was estimated using the homeostasis model assessment (HOMA).
Results
Among older patients, 11.9% were smokers and 9.1% informed alcohol consumption. However, 29.5% of younger patients were smokers and only 12.1% of them consumed alcohol ($P=0.05$ and $P=0.30$). Mean levels of waist circumference, systolic, diastolic blood pressures, triglyceride, and LDL-cholesterol were statistically significantly higher than those of younger patients with MetS ($P=0.001$, $P=0.01$, $P=0.001$, $P=0.02$, and $P=0.002$ respectively). Mean levels of HOMA-IR were found to be 2.3$\pm$0.9 in young and 2.7$\pm$0.02 in elderly group.
Conclusions
There are differences between older and young patients with metabolic syndrome for waist circumference, smoking, blood pressures, and lipid levels.

DOI: 10.1530/endoabs.37.EP562

The risk of future IRS among women with history of gestational diabetes

Nevin Dinccag[1], Sevda Ozel Yıldız[2], Selda Gedik[1], Cemile Idız[1], Yıldız Tütüncü[1] & Bülent Canbaz[1]
[1]Endocrinology and Metabolism Division, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey; [2]Biostatistics Department, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey.

Background and aims
The history of GDM predisposes to cardiovascular disease (CVD) in the future. The aim of this study was to evaluate risk factors predicting the development of glucose intolerance and insulin resistance syndrome (IRS) in women with history of GDM in the future.
Materials and methods
55 women who had GDM 11$\pm$2 years before were enrolled into the study. After clinical examination 75 g OGTT and inflammatory markers(hsCRP, uric acid, interleukin 6 (IL6), tumor necrosis factor alpha (TNFα), visfatin, plasminogen activated inhibitor 1 (PAI1), asymmetric dimetilarginine (ADMA), and adiponectin) was performed to evaluate of current metabolic status after a decade of delivery. Based on IDF criteria participants were classified into two groups as normal (group 1) and IRS (group 2). We evaluated the relationship between metabolic status and possible risk factors such as; age, BMI, family history of DM, poor obstetric history, HbA1c and OGTT glucose levels at diagnosis of GDM; weight gain and insulin requirement during index pregnancy. SPSS 21 was used to analyse data.
Results
51% of participants developed IRS after 10th year of delivery. No predictive factor was found except screening time, first hour glucose level at the diagnosis of GDM and insulin requirement during index pregnancy Although difference was not significantly, patients in group 2 were found to have higher BMI, much more family history of DM before pregnancy and also they put less excess weight during pregnancy. As compared inflammatory parameters between two groups; HOMA-IR, hsCRP, visfatin, IL6, and PAI1 levels were detected istatistically higher; on contrary adiponectin level was less in group 2 than group 1. And currently, 43% of all participants were found that they had at any level glucose intolerance and higher insulin levels at basal and first hour of OGTT.
Conclusion
Early screening of GDM and following the patient during gestational period is important but it's much more important to follow those individuals who had high BMI, family history of DM and high glucose at first hour of OGTT at the beginning; they should be monitored closely postpartum and at least yearly follow-up should be done based on increased risk for developing IRS and therefore CVD.

Haematopoietic system 3 years after gastric bypass

Snezana Polovina[1], Jelena Gligorijevic[2], Mirjana Sumarac/Dumanovic[1], Pavle Gregoric[3], Aleksandra Kendereski[1], Goran Cvijovic[1], Svetlana Zoric[1], Danica Stamenkovic/Pejkovic[1], Dusan Micic[3], Danka Jeremic[1], Ana Gligic[1], Aleksandra Divnic[1] & Dragan Micic[1]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Clinical Center of Serbia, Belgrade, Serbia; [2]Dietary Unit, Clinical Center of Serbia, Belgrade, Serbia; [3]Emergency Center, Clinical Center of Serbia, Belgrade, Serbia.

Bariatric surgery, especially malapsorptive procedures like gastric bypass, can lead to anaemia due to lack of iron absorption as well as vitamins essential for the normal functioning of the hematopoietic system.
Methods
We have analysed changes in red blood cells (RBC), haemoglobin (Hb), white blood cells (WBC), serum iron (Fe), and vitamin B12 3 years after gastric bypass in 142 morbidly obese patients (female, $n=108$ and male, $n=34$). All patients were on oral supplementation with 100 mg of iron and 200–400 mg of folic acid after surgery as well as 2500 µg of OHB12, i.m. injections every 3 months.
Results
Before surgery average BMI was 43.9 kg/m^2 and 3 years after BMI was 30.5 kg/m^2 ($P<0.001$). Change in number of RBC was nonsignificant (4.65.9$\pm$1.31$\times10^{12}$/l vs 4.42$\pm$1.12$\times10^{12}$/l; $P>0.05$) before and after surgery. There was no difference in Hb concentration between two measurements (137.9$\pm$15.5 g/l vs 128.9$\pm$16.3 g/l; $P>0.05$). Number of WBC was lower after surgery (10.7$\pm$3.2$\times10^9$/l vs 5.7$\pm$1.3$\times10^9$/l) with significance: $P>0.001$, but among reference range. Serum iron level increased after surgery but that was not significant (11.4$\pm$1.3 µmol/l vs 13.03$\pm$1.8 µmol/l; $P>0.05$). Vitamin B12 level remained within normal range 3 years after gastric bypass (922.5$\pm$212.2 pmol/l vs 866.7$\pm$201.1 pmol/l; $P>0.05$) without difference.
Conclusion
Even gastric bypass as malapsorptive bariatric procedure, can lead to anaemia, adequate supplementation of iron, folic acid and vitamin B12, after surgery, may prevent anaemia and vitamins essential for haematopoietic system deficiency during 3 years follow-up period.

Patients with acute coronary syndrome have lower testosterone then healthy controls

Adriana Bednárová, Martin Kužma & Juraj Payer
5th Department of Internal Medicine, Faculty of Medicine, Comenius Univeristy and University Hospital, Bratislava, Slovakia.

Objective
Several studies report the association of low testosterone with ischaemic heart disease although the results are inconsistent. In our study we tried to evaluate the relationship between sex hormones and incidence of acute coronary syndrome (ACS).

Methods
This was a cross-sectional study. In 111 subjects (69 patients with ACS and 42 age-matched controls) we measured total testosterone, estradiol, SHBG, FSH, and LH by electrochemiluminiscence and calculate free androgen index (FAI). Patients with cancer, antiandrogen or testosterone treatment were excluded. In all patients we examined risk factors of myocardial infarction (hypertension, diabetes mellitus, dyslipidaemia, smoking, waist circumference, and BMI). Results were correlated by unpaired *T*-test and linear regression in SPCC system. In all subjects quartile analysis according to testosterone levels was performed.
Results
Patients with ACS have lower total testosterone levels comparing with controls (12.37 nmol/l vs 15.66 nmol/l, $P=0.009$). Patients had also lower levels of FAI and higher levels of FSH and LH but these were not significant. There was no difference in estradiol levels between the groups. In linear regression model testosterone correlated with waist circumference ($R^2=0.082$, $P=0.002$) and weight ($R^2=0.076$, $P=0.002$). In quartile testosterone analysis patients with testosterone levels in the lowest quartile had significantly higher incidence of ACS comparing with patients in the highest quartile (RR 1.72, CI 1.1; 2.6). Patients in the lowest testosterone quartile had also higher incidence of diabetes mellitus, dyslipidaemia, hypertension, and smoking.
Conclusions
Patients with ACS have significantly lower total testosterone levels and inversely, patients in the lowest testosterone quartile have higher incidence of ACS. Testosterone level correlates significantly with weight and waist circumference. Low testosterone is strongly associated with adiposity in patients with ACS and probably plays a role in metabolic syndrome.

HLA and metabolic parameters that define obesity in Amerindians for the first time

Antonio Arnaiz-Villena, Cristina Areces, Mercedes Enríquez-de-Salamanca, Ester Muñiz, Narcisa Martínez-Quiles, José Manuel Martín-Villa, Pablo Vargas & Diego Rey
University Complutense, Madrid, Spain.

Metabolic syndrome and obesity are principal causes of morbidity all over the world, particularly for their association to cardiovascular risk. There is now an obesity worldwide epidemic (Globesity). Amerindians are often living in countries and remote areas with unavailable sophisticated diagnoses methodologies. However, waist circumference is a reliable and easy to record parameter of visceral obesity and MS. Waist circumference normal values are not yet established in Amerindians: South Asian and Japanese values have been recommended for Amerindian use. The purpose of this study is to objectively determine for the first time the waist circumference measure cut-off points for Amerindians, by using i) HLA phenotype to ensure that population tested is Amerindian and ii) measurement of biochemical markers which were diet independent. A total of 303 unrelated Amerindian adults recently immigrated to Madrid were studied; they were healthy, since they were questioned and tested as appropriate for blood donation and recent weight increase. Waist circumference was measured in these voluntary blood donors after written consent. Chosen subjects for study had HLA quasi-specific Amerindian genes. Amerindians with type 1 or 2 diabetes or family antecedents were removed from the study. A receiver operating characteristic analysis was used to compare the predictive validity and to find out the optimal cut-off points of waist circumference normal values. Cut-off points were $\leq$88.5 cm in males and $\leq$82.5 cm in females. Obtained waist circumference values recorded here in normal Amerindians are different to the previously recommended ones: those of South Asians. In addition, PPARγ and adiponectin gene linkage to obese Amerindians was not observed. These parameters may be of great value for Spain and American countries for establishing preventive programs in order to predict and control metabolic syndrome.

Does the presence of obesity and/or metabolic syndrome affect the course of acute pancreatitis?

Samer Al-Sawalhi & Hamdi Al-Maramhy
Taibah University, Al-Madina, Saudi Arabia.

Objective
The incidence of acute pancreatitis (AP) is rising with increased prevalence of obesity, which exacerbates pancreatic injury. Metabolic syndrome (MS) is defined as a cluster condition of cardiovascular risk factors, including hyperglycaemia, dyslipidaemia, hypertension, and central obesity. We analysed if the presence of obesity and/or MS affects the course of pancreatitis.
Methods
Data were collected from 140 patients with AP between January 2010 and February 2013. Anthropometric data, including BMI and waist circumference, were measured. Biochemical tests were used including fasting glucose, triglyceride, LDL and HDL cholesterol levels, and total cholesterol level. Atlanta criteria, Acute Physiology and Chronic Health Evaluation II, and Ranson scoring system were used to define severe AP. Patients were classified as having MS based on the International Diabetic Federation criteria.
Results
The mean BMI was 30.15 kg/m^2. Sixteen (11.4%) patients had severe AP, whereas 124 (88.6%) patients had mild AP. We found that 62.8% of patients with AP fulfilled the criteria of MS ($P=0.000$). Body weight can be used to predict clinical severity of AP with significant P value $=0.009$.
Conclusions
The presence of MS in patients with pancreatitis is noticeable, but it does not affect the course of disease severity, whereas obesity correlates with pancreatitis severity.

EP568

Gender-related risk of cardiovascular diseases in patients with type 2 diabetes mellitus

Lev Prystupiuk, Oleksandr Prystupiuk & Marianna Naumova
Bogomolets National Medical University, Kyiv, Ukraine.

Introduction
The main causes of death in the world today is non-communicable diseases (NCDs). A research of the World Bank found out that 82% of deaths in Ukraine are caused by chronic NCDs, 3.6% of which compose diabetes mellitus. And since the course of type 2 diabetes mellitus (T2DM) is usually long, it requires special, costly medical care for significant period of patient's lifetime.
Materials and results
Our research involved 592 males and 1170 females with T2DM. We determined BMI, glycaemia, total cholesterol, HDL-C, and non-HDL-C. Dyslipidaemia is established with cholesterolaemia over 5.20 mmol/l and with HDL-C under 1.02 mmol/l in males and under 1.29 mmol/l in females. In our study group, cholesterol level in men was 6.41 ± 0.03 mmol/l in women – 6.23 ± 0.01 mmol/l ($P<0.05$), while HDL-C was respectively 1.89 ± 0.88 and 1.88 ± 0.07 mmol/l ($P<0.05$), and non-HDL-C – 4.60 ± 0.02 and 3.38 ± 0.05 mmol/l ($P<0.05$). Patients were divided, according to cholesterolaemia, into the following groups: under 5.3, 5.3–6.5, and over 6.5 mmol/l. In relation to this, males were the following percentages: 38, 57, and 5%; females: 28, 64, and 8%. Regarding fasting glycaemia, patients' groups were: under 6.2, 6.2–7.8, and over 7.8 mmol/l. Accordingly, cholesterol level related to glycaemic groups in men was 5.70 ± 0.01, 5.90 ± 0.05, and 5.99 ± 0.04 mmol/l ($P<0.001$) and in women: 4.86 ± 0.03, 6.50 ± 0.03, and 7.50 ± 0.03 mmol/l ($P<0.001$) respectively. In accordance with BMI we had the following classification: normal weight, overweight, obesity. And male patients' cholesterol was respectively as follows: 5.81 ± 0.06, 6.12 ± 0.04, and 6.10 ± 0.05 mmol/l, while female cholesterol: 5.48 ± 0.04, 5.56 ± 0.02, and 5.77 ± 0.01 mmol/l.
Conclusions
i) Atherogenic dyslipidemia in 70% of patients with T2DM of both sexes is caused by an increase in blood non-HDL-C. ii) Atherogenic dyslipidaemia correlated with the state of compensation of diabetes and body weight. iii) Therapeutic correction of dyslipidaemia in patients with T2DM should be normalization of blood glucose and body weight.

DOI: 10.1530/endoabs.37.EP568

EP569

Effect of obesity and diabetes mellitus type 2 on vascular stiffness

Olga Bourko[1], Tatiana Netchessova[1], Irina Bourko[2], Larisa Danilova[2], Elena Dashkevich[2] & Galina Korolenko[2]
[1]Republican Scientific and Practical Center Cardiology, Minsk, Belarus; [2]Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus.

Aim
To investigate the impact of overall obesity (Ob) and diabetes mellitus type 2 (DM2) on arterial stiffness and degree of insulin resistance in patients with arterial hypertension (AH) and abdominal Ob (AOb).
Design and method
74 subjects were divided according to presence of AH, AOb, Ob, and DM2 without insulin therapy. Control group 1 consisted of 26 subjects without AH, AOb, Ob, and DM2. All patients with AH were also diagnosed with AOb and amounted to 48 subjects. Then patients with AH and AOb were divided into two groups (groups 2 and 3 respectively) according to presence of Ob, defined by BMI and furthermore, DM2. Carotid-femoral pulse wave velocity (PWVc-f) measurements were performed using SphygmoCor. Homeostasis model assessment-insulin resistance (HOMA-IR) was calculated by the following formula: fasting plasma insulin (mU/ml) × fasting plasma glucose (mmol/l)/22.5.
Results
In the group comparison by BMI: PWVc-f and HOMA-IR increased consistently from groups 1 to 3. PWVc-f was significantly higher in hypertensive patients with AOb and Ob than in hypertensive patients with AOb and without Ob (PWVc-f = 8.69 ± 1.8 and PWVc-f = 7.43 ± 1.3; $P < 0.05$). HOMA-IR did not show significance. In the group comparison by presence of DM2: PWVc-f and HOMA-IR increased consistently from groups 1 to 3. PWVc-f and HOMA-IR were significantly higher in hypertensive patients with AOb and DM2 than in hypertensive patients with Aob and without DM2 (PWVc-f = 9.5 ± 1.8 and PWVc-f = 7.71 ± 1.5, $P < 0.001$; and HOMA-IR = 7.09 ± 3.54 and HOMA-IR = 2.83 ± 1.2; $P < 0.001$). Significant differences between groups persisted after adjustment for age, sex, and BMI.
Conclusions
Presence of overall Ob together with AOb had a significant adverse effect on arterial stiffness in patients with AH both men and women. This adverse effect is similar with impact of DM2 on arterial stiffness in patients with AH together with AOb. Measurement of PWVc-f showed higher significance vs HOMA-IR measurements in the study groups.

Metabolism of sphingolipids in experimental obesity and insulin resistance

Talat Saatov[1], Bakhodyr Zainutdinov[1], Elvira Ibragimova[1], Sanobar Irgasheva[1], Akmaral Tashmanova[2] & Mukhamadjon Mustafakulov[1]
[1]Institute of Bioorganic Chemistry, Uzbekistan Academy of Sciences, Tashkent, Uzbekistan; [2]Uzbekistan Ministry of Education, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan.

Sphingolipids constitute the structural base for all types of biological membranes, and are numerous in human and animal tissues. Metabolites of sphingolipids act as biological effectors, modulators and mediators in a number of biochemical processes; they are known to be pathogens in various human pathologies.
We aimed at studying activity of sphingomyelinase, concentrations of sphingomyelin and its metabolites, such as ceramide and sphingosine, in organs of rats with experimental diabetes.
Experimental model of obesity and insulin resistance was used to study activity of sphingomyelinase, and concentrations of sphingosine and ceramide. As compared with the controls, in the liver of experimental animals activity of neutral and acid sphingomyelinase was found to increase by 25 and 21% respectively. In skeletal muscles of obese animals, activity of neutral and acid sphingomyelinase increased by 45 and 70% respectively. The findings can be the evidence for stimulation of sphingomyelinase activity in the liver and skeletal muscles in rats with experimental obesity. Significant alterations in the content of sphingomyelin and its metabolites were observed in obese rats; these alterations were found to be oppositely directed. In the liver of obese rats, sphingomyelin was found to decrease by 25%; while in skeletal muscles its concentration decreased more than by 31%. Concentrations of ceramide and sphingosine in the liver of obese rats were found to increase by 15 and 23%, respectively, as compared with the controls. In skeletal muscle of obese rats, concentrations of ceramide and sphingosine increased by 19 and 68% respectively.
We have established increase in the activity of sphingomyelinase and accumulation of ceramide and sphingosine, metabolites of sphingomyelin, in the liver and skeletal muscles of rats with experimental obesity and insulin resistance. Ceramide overproduction plays a key role in the onset and development of insulin resistance.

Adiponectin response to vegetarian diet is gender-dependent and inversely related to uric acid

Marijana Vučić Lovrenčić[1], Iva Košuta[1], Marko Gerić[2], Goran Gajski[2] & Verica Garaj Vrhovac[2]
[1]Merkur University Hospital, Zagreb, Croatia; [2]Medical Research and Occupational Health, Zagreb, Croatia.

Introduction
Beneficial influence of vegetarian dietary habits in reducing common risk factors of metabolic syndrome has been recently evidenced. However, adiponectin production and secretion has been scarcely studied in vegetarians, despite its important potential in recovering metabolic homeostasis by reducing inflammation and insulin resistance.
The aim of this study was to evaluate the influence of vegetarian diet on serum adiponectin levels and it's association to the established inflammatory and metabolic biomarkers.
Methods/design
Total serum adiponectin (ADN), leukocytes (L), CRP, plasma glucose (PG), insulin (INS), and uric acid (UA) were measured in healthy, non-obese, age-matched vegetarian ($n = 40$; M/F = 16/24) and omnivore subjects ($n = 39$; M/F = 15/24). HOMA-2 model was used for the assessment of β-cell function (BS), insulin sensitivity (IS), and insulin resistance index (IRI).
Results
Serum ADN levels were significantly higher in female vegetarians than the respective omnivore controls (14.2 ± 5.82 mg/l vs 10.82 ± 3.29 mg/l; $P = 0.017$), whereas no dietary-associated difference was observed in male vegetarian and omnivore subjects respectively (6.87 ± 2.57 mg/l vs 6.74 ± 3.07 mg/l; $P = 0.898$). Stepwise multiple regression analysis identified uric acid as the significant negative determinant of ADN in vegetarians ($r_{partial} = -0.4585$, $P = 0.002$), while in omnivore subjects only BMI was found to be significantly associated to ADN levels ($r_{partial} = -0.4439$, $P = 0.016$). In comparison to controls, significantly lower INS (47.6 ± 19.2 pmol/l vs 57.7 ± 23.7 pmol/l; $P = 0.042$) and IRI (1.01 ± 0.42 vs 1.22 ± 0.49; $P = 0.041$), as well as higher BS ($115.5 \pm 42.9\%$ vs $94.2 \pm 35.3\%$; $P = 0.019$) were found in vegetarians.
Conclusion
Vegetarian dietary habits result into improved insulin sensitivity and β-cell function. Gender diversity in adiponectin response and inverse association to uric acid indicate distinct effects of vegetarian diet to adipose tissue metabolism.

Fibrate therapy predispose to influenza vaccine-induced rabdomyolysis

Goknur Yorulmaz[1], Hatice Hamarat[2], Emel Gonullu[3] & Ayse Ekim[4]
[1]Endocrinology Department, Eskisehir State Hospital, Eskisehir, Turkey; [2]Internal Medicine Department, Eskisehir State Hospital, Eskisehir, Turkey; [3]Rheumatology Department, Eskisehir State Hospital, Eskisehir, Turkey; [4]Department of Physical Medicine Rehabilitation, Eskisehir State Hospital, Eskisehir, Turkey.

Introduction
Fibrates are widely used to manage dyslipidemia but these drugs can induce rhabdomyolysis with acute renal failure. Rhabdomyolysis is a skeletal muscle cell damage condition associated with the release of toxic components of the cells and to the end;renal failure. The onset of rhabdomyolisis can extend to 6 months with fibrate therapy. Some researchers purpose that the influenza vaccıne can induce the rhabdomyolisis in patients who receive myotoxic drugs.Here we present a case who develops rhabdomyolisis and acute renal failure after influenza vaccine during fibrate therapy.
Case
A 65-year-old male patient admitted to the hospital with weakness and pain of the extremity muscles. He had tenderness widespread of the body and feel difficulty to move. He had coronary heart disease and hyperlipidemia. He was taking 267 mg of fenofibrate daily for 5 months and had influenza vaccine administration a week before admission to the hospital. Laboratory examination showed markedly elevated serum creatine kinase levels (27 730 U/l) and creatinine was

2.16 mg/dl (creatinine level was normal range before the vaccine administration). After discontinuing the fibrate therapy and adequate fluid resuscitation renal function recovered and the symptoms of myopathy resolved.
Conclusion
The risk of rhabdomyolysis increases with polypharmacy with myotoxic agents like lipid lowering medications. Also influenza vaccination administration must keep in mind an another myotoxic situation especially during lipid lowering drugs like fenofibrate.

Outcomes of gastric bypass for morbid obesity after 5-year follow-up

María Belén Ojeda-Schuldt[1], Isabel Mateo-Gavira[1], Francisco Javier Vilchez-López[1], María Ángeles Mayo-Osorio[2], José Manuel Pacheco-García[2], Luis Escobar-Jiménez[1] & Manuel Aguilar-Diosdado[1]
[1]Department of Endocrinology, University Hospital Puerta del Mar, Cádiz, Spain; [2]Department of Surgery, University Hospital Puerta del Mar, Cádiz, Spain.

Introduction
Currently, there are few data on long-term effects of bariatric surgery. We present the results of 5-year follow-up of a cohort of patients with gastric bypass surgery (GBP).
Objectives
i) To determine the prevalence of major comorbidities of morbid obese; ii) to evaluate the gastric bypass effect on this comorbidities, and 10-year estimated cardiovascular risk after 5-year follow-up; and iii) to assess the impact of bariatric surgery on the quality of life in these patients.
Methods
Prospective analysis in a cohort of 124 patients with morbid obesity who underwent bypass surgery. Demographic and anthropometric parameters, 10-year risk for coronary heart disease (estimated by Framingham risk score), complications from surgery and quality of life through Bariatric Analysis and Reporting Outcome System (BAROS) test were analysed before surgery and during follow-up.
Results
A total of 124 patients, who underwent surgery between 2005 and 2009, where included. The mean age was 37.88 ± 10.29 years, 76.6% were women and the mean preoperative BMI was 51.71 ± 7.35 kg/m^2. At 2 and 5 years of follow-up, remains a BMI of 30.48 ± 4.7 and 31.27 ± 7.08 kg/m^2 respectively. After 5 years of follow up, the percentage of weight lost was 68.31%. Remission of hypertension, dyslipidemia, and diabetes mellitus type 2 had occurred in 89.5, 95.8, and 95.7% respectively ($P<0.001$). The Framingham risk score was reduced from 7.7 ± 9.5 to 2.8 ± 3.5% ($P<0.005$). Regarding surgical complications, 14.7% showed early complications and 29% late complications. BAROS test was successful in 95% of cases.
Conclusions
In our area, outcomes from gastric bypass in obtaining weight lost and resolution of comorbidities after 2 years of surgery also remains at 5-year follow up with a minimum rate of surgical complications.

DOI: 10.1530/endoabs.37.EP573

The prevalence of obesity and metabolic syndrome among inpatients at a Forensic Psychiatric Hospital in the Republic of Ireland

Arimin Mat[1], Tomas Ahern[2], Tracey Hoare[3], Paul McCarran[3], Harry G Kennedy[3,4] & Donal O'Shea[1,2]
[1]Weight Management Service, St Columcilles Hospital, Loughlinstown, Ireland; [2]Department of Endocrinology, St Vincent's University Hospital, Dublin 4, Ireland; [3]National Forensic Mental Health Service, Central Mental Hospital, Dublin 14, Ireland; [4]Department of Psychiatry, Trinity College, Dublin 8, Ireland.

Introduction
Patients in secure forensic psychiatric units are at high risk of developing obesity due to complex interplay of factors including antipsychotic medications, restrictions on freedom and poor motivation to healthy lifestyle and physical activities.
Aim
To establish the prevalence of obesity and metabolic syndrome (MetS) in a secure forensic psychiatric hospital in the Republic of Ireland (ROI).
Methods
We carried out a longitudinal study in the National Forensic Mental Health Service in the (institution name, four words), Dublin. National Cholesterol Educational Program, Adult Treatment Panel III (NCEP/ATP III) definition was used to diagnose MetS.
Results
Number of patients was 76 (males = 68 (89.5%)). Mean age was 44.7 years (s.d. = 13.4). All patients were on long-term antipsychotics. Duration of admission was longer in males (9.6 years (s.d. = 10.5) vs 3.8 (s.d. = 2.9) in females, $P=0.1232$), mean was 9.2 (s.d. = 10.2). Mean weight at admission was 90.2 kg (s.d. = 17.7), BMI = 30.0 kg/m^2 (s.d. = 5.9); this increased at time of study (TOS) to 98.3 kg (s.d. = 17.9, $P=0.006$), BMI = 32.8 (s.d. = 6.1, $P<0.001$). Average weight gain was 8.1 kg. At admission, 24 (31.6%) patients were overweight and 35 (46.0%) were obese; at TOS, 9 (11.8%) were overweight and 57 (75%) were obese ($P<0.001$). Twenty-nine (37.2%) patients met the criteria for MetS at admission, 44 (56.6%) at TOS (the additional 15 met the criteria solely due to weight gain). Three had diabetes at admission, 12 (15.8%) at TOS ($P=0.012$).
Conclusion
We conclude that obesity and MetS are highly prevalent in our centre. Given that obesity is a significant contributor to MetS and its complications, patients in forensic institutions such as this should receive appropriate weight management programme from time of admission. Urgent investment in dietetic and physiotherapy service is needed.

EP575

Can obese patients on antipsychotic medications achieve weight loss in an unmodified general population lifestyle-intervention weight management programme?

Arimin Mat[1], Tomas Ahern[2], Cathy Breen[1], Colin Dunlevy[1] & Donal O'Shea[2]
[1]Weight Management Service, St Columcille's Hospital, Loughlinstown, Ireland; [2]Department of Endocrinology, St Vincent's University Hospital, Dublin 4, Ireland.

Background
Many antipsychotics are obesogenic and contribute to significant weight gain with serious implications on patients' physical and mental well-being. However, patients on antipsychotics are often excluded from unmodified lifestyle-intervention weight management programmes and trials.
Objectives
To determine if weight loss is possible for antipsychotic-medicated obese patients when enrolled in an unmodified lifestyle-intervention weight management programme.
Methods
Data from 44 antipsychotic-medicated participants (AP) and 88 matched control participants (CP) were analysed to determine weight outcomes. Dietary and activity behaviours at baseline for an AP sub-cohort were also reported. Results were expressed as mean (95% CI); Mann–Whitney U test was used to assess differences between cohorts.
Results
Enrolment mean weight of AP was 139.8 kg (130.5–149.0 kg) compared with CP of 140.5 kg (134.4–146.6 kg; $P=0.478$). Enrolment BMI was 49.1 kg/m^2 (46.0–52.3) compared with 48.9 kg/m^2 (46.8–51.1; $P=0.515$). Twenty-five AP participants lost weight (mean weight loss: -9.1 kg). There was no difference in weight outcomes in AP compared to CP groups (-2.0 vs -2.4 kg; $P=0.824$). Also 9 (20.5%) AP participants lost 5% baseline weight compared with 18 (20.5%) in CP ($P>0.99$) while 5 (11.4%) in AP lost 10% weight compared with 6 (6.8%) in CP ($P=0.373$). At baseline, the AP group ate fast food 1.7 ± 1.2 times/week, fresh fruit 1.0 ± 1.4 times/day and reported 2.5 ± 3.0 missed breakfasts/week. Baseline gait speed was lower in AP group (0.99 ± 0.2 m/s vs 1.09 ± 0.34 m/s in CP cohort) and improved slightly to 1.01 ± 0.3 m/s.
Conclusion
Modest weight loss can be achieved in patients on long-term antipsychotics enrolled into an unmodified weight management programme designed for the general population. Typical dietary strategies such as encouraging breakfast

consumption and reducing fast food and increased physical activities are relevant to this cohort of patients.

Factors affecting gender differences in the association between health-related quality of life and metabolic syndrome components: Tehran Lipid and Glucose Study (TLGS)

Parisa Amiri[1], Tina Deihim[1], Reza Taherian[1], Mehrdad Karimi[1,2], Safoora Gharibzadeh[2,3], Mohammad Asghari-Jafarabadi[4] & Fereidoun Azizi[3]

[1]Research Institute for Endocrine Sciences, Research Center for Social Determinants of Health and Obesity Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Department of Epidemiology and Biostatistics, School of Public Health, Tehran University of Medical Sciences, Tehran, Iran; [3]Research Institute for Endocrine Sciences, Endocrine Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [4]Faculty of Health and Nutrition, Tabriz University of Medical Sciences, Tabriz, Iran.

Introduction

Gender differences in the association between health-related quality of life (HRQoL) and metabolic syndrome (MetS) have been studied by previous researches. This study aimed to assess influential factors causing gender differences between HRQoL and MetS components using structural equation modelling.

Methods

A sample of 950 adults from TLGS were recruited in this study between 2005 and 2007. Health-related quality of life was assessed using the Iranian version of SF-36. Structural equation modelling was applied to determine the relationships between the constructs of MetS components (MetSCs) and HRQoL within the gender groups.

Results

Based on the primary hypothesis, MetSCs, physical and mental HRQoL were fitted in a model (χ^2/df = 1.52, RMSEA = 0.023, CFI = 0.98, and GFI = 0.97). The adjusted negative effect of MetSCs on physical HRQoL was significant only in women. The proportion of all the cardio-metabolic risk factors as well as physical domain subscales were higher in women ($P<0.05$). Among socio-behavioural factors, physical activity in both men ($\beta=3.19$, $P<0.05$) and women ($\beta=3.94$, $P<0.05$), age ($\beta=-3.28$, $P<0.05$) and education ($\beta=2.68$, $P<0.05$) just in women and smoking ($\beta=2.28$, $P<0.05$) just in men directly affected physical HRQoL. Regarding the mental domain, physical activity ($\beta=3.37$, $P<0.05$) and marital status ($\beta=3.44$, $P<0.05$) in women and age ($\beta=2.01$, $P<0.05$) in men were direct effective factors. While age and smoking had a sex-specific indirect effect on the association between physical HRQoL and MetSCs, none of the socio-behavioural factors was found to have a direct effect on this association between men and women significantly.

Conclusion

Structural differences of physical HRQoL and MetSCs as well as different influential patterns of socio-behavioural factors specifically age and smoking seems to have a pivotal role to create this gender differences. Although, the proportion of SBP, WC and bodily pain were the highest in both genders, except for DBP, all the cardio-metabolic risk factors and physical subscales had significant higher proportion in women.

Secondary prevention after acute coronary syndrome in patients with type 2 diabetes: results from a routine clinical practice

Manuel Cayón Blanco, Ana Del Río Lechuga, Carolina García-Figueras Mateos & Patricia Rubio Marín

Hospital SAS Jerez de la Frontera, Andalusia, Spain.

Rationale

Secondary prevention of coronary artery disease (CAD) in patients with type 2 diabetes mellitus (T2DM) has shown benefit but the level of control is still disappointing. Most of the results are documented within clinical trials. There isn't enough information in routine clinical practice at short-term tracing. The main aim of this study is to collect information about the level of control of major risk factors in non-selected patients.

Methods

Observational and retrospective study. Patients with T2D who had suffered myocardial infarction between January and December 2012 were included. Data provided by clinical history, with special regard to major cardiovascular risk factors were recorded. Optimal control of risk factors was defined by current clinical guidelines. Clinical events and achievement of targets at baseline, 6 months and 1 year after coronary event were recorded.

Results

Data from 48 T2DM patients (47.9% females, mean age: 70.6 ± 8.7 years, and mean diabetes duration: 10.9 ± 9 years) were collected. 79.2% had hypertension and 66.7% had hyperlipidaemia. At baseline, proportion of patients who met target for non-smoking, SBP, LDL-C, and HbA1c was 89.6, 62.2, 40, and 22.2% respectively. The rates of patients with adequate control at 6 and 12 months after discharge were as follows: non-smokers: 93.9 and 97.1% ($P=0.01$); SBP: 74.4 and 71.4% ($P=0.004$); LDL-C: 70 and 83.3% ($P<0.001$), and HbA1c: 41.4 and 35.5% ($P=$not significant). Although, follow-up HbA1c level was lower than at baseline, no significantly difference was observed (7.9 ± 1.3% vs 7.3 ± 1.2% vs 7.3 ± 2.1%; $P=0.06$).

Conclusions

Our outcomes from a routine clinical practice are relatively poor and don't differ much from the trials results. The rate of adequate control for each risk factor was similar at 6 months and at 1-year after coronary event. It reflects that there is an early improvement that is maintained after optimising treatment.

A 5-year review of the metabolic changes after laparoscopic sleeve gastrectomy among obese Hong Kong Chinese in a regional hospital

Cheuk Wah Ho, Grace Kam & Man Wo Tsang

United Christian Hospital, Hong Kong, China.

Background and aims

Obesity is a global problem. Laparoscopic sleeve gastrectomy (LSG) was introduced in our hospital since 2008. This study aimed at reviewing the metabolic changes after LSG among Hong Kong Chinese in a regional hospital.

Materials and methods

47 patients who received LSG in our hospital from June 2008 to October 2012 were retrospectively reviewed. Change in body weight (BW) and glycaemic control up to 5 years were evaluated. Rate of remission of diabetes at 1 year after operation was also reviewed. Statistical method used include Wilcoxon's signed rank test for paired-related groups and Mann–Whitney *U* test for paired non-related groups.

Results

The mean age was 43.7 (19–63) years. The mean baseline BW and BMI were 105.7 ± 3.5 and 39.7 ± 4.6 kg/m^2 respectively. The maximum weight loss was achieved at post-operative 1 year, i.e. 25.1 ± 1.7 kg (23.7 ± 1.49%) ($P=0.00$). Significant % weight loss was still maintained at post-operative 5 years i.e. 21.9 ± 1.39% ($P=0.011$, $n=9$). For diabetic patients, the improvement in diabetic control was already shown before maximum weight loss. The greatest improvement in fasting blood glucose (FBG) was seen at 1 month dropping from 7.8 ± 0.6 to 6.2 ± 0.5 mmol/l ($P=0.00$). The HbA1c reduced from baseline of 7.9 ± 0.4 to 6.7 ± 0.3% at 3 months ($P<0.05$). At 1 year after operation, patients achieving remission of diabetes showed statistically significant greater % weight loss (24.9 ± 1.3% vs 17.6 ± 3.6%), lower baseline FBG (6.1 ± 0.2 mmol/l vs 10.2 ± 1.0 mmol/l) and shorter duration of diabetes (2.7 years vs 9.6 years) All diabetic patients who were on diet control before operation achieved remission while the rate for those on oral anti-diabetic drugs and insulin were 58.3 and 27.2% respectively. Remission of diabetes was defined as FBG <7 mmol/l and HbA1c <6.5% without medication.

Conclusion

LSG showed sustainable weight loss 5 years after operation. Characteristics of patients achieving remission of diabetes were evaluated which helped to predict outcome.

Malignant tumours in patients with type 2 diabetes mellitus and obesity

Siarhei Shymanets[1,2], Larisa Danilova[2], Maxim Lushchik[2], Vyacheslav Dudarev[1,2], Andrey Karman[1], Siarhei Kharuzhyk[1] & Veronika Dovgalo[1]
[1]N.N. Alexandrov National Cancer Centre of Belarus, Minsk District, Belarus; [2]Belarusian Medical Academy of Post-Graduate Education, Minsk, Belarus.

Backgrounds and aim
Epidemiologic evidence suggests that people with diabetes are at significantly higher risk for many forms of cancer. The aim of the research was to identify cancer incidence distribution in Belarusian patients with type 2 diabetes mellitus.
Methods
The study group included 73 patients: 46 (63%) women (mean age 65 ± 8 years) and 27 (37%) men (70 ± 7 years) with concurrent diabetes and cancer treated at Alexandrov National Cancer Centre of Belarus in 2013. The mean time of type 2 diabetes mellitus course before cancer diagnosis was 7.8 ± 5.8 years. A meaningful associations between diabetes and cancer incidence in men and women subgroups were analysed.
Results
Among women breast cancer was the leading malignancy, accounting for 59% (27 patients), corpus uteri cancer mentioned in 15% (seven patients), cervix in 7% (three patients), lung in 4% (two patients), and other localizations occurred in 15% (seven patients). In men subgroup the higher incidence were registered for lung and prostate cancers, accounting 22% (six cases) and 19% (five cases) accordantly, stomach cancer revealed in 15% (four persons), bladder 11% (three persons), kidneys 7% (two persons), and other localisations 26% (seven persons). Multiple primary malignancies were diagnosed in 18% (ten women and three men). The most frequent initial cancer types were women breast (five patients), lung (two patients), and corpus uteri (two patients), the other types made stomach, colon, cervix uteri cancer, and myeloleucosis.
Conclusion
Breast cancer was the predominated neoplasm (59%) in women with diabetes mellitus. The most common cancer in males was lung cancer (22%) and prostate cancer (19%). 18% of the patients with type 2 diabetes mellitus had multiple primary malignancies. Future researches are needed for better understanding of possible biologic links between diabetes and cancer risk.

EP580

Preoperative endocrinological evaluation of patients apply for bariatric surgery

Ilkay Cakir[1], Yasin Simsek[2], Riza Kutanis[3], Serkan Menekse[4], Emine Isil Ustun[5] & Dede Sit[6]
[1]Department of Endocrinology, Bagcilar Research and Education Hospital, Istanbul, Turkey; [2]Department of Endocrinology, Hitit University Hospital, Çorum, Turkey; [3]Department of General Surgery, Bagcilar Research and Education Hospital, Istanbul, Turkey; [4]Department of Oncology, Bagcilar Research and Education Hospital, Istanbul, Turkey; [5]Department of Physical Therapy, Bagcilar Research and Education Hospital, Istanbul, Turkey; [6]Department of Internal Medicine, Bagcilar Research and Education Hospital, Istanbul, Turkey.

Introduction
Since bariatric surgery is considered to be a more effective treatment modality for morbid obesity, a growing number of patients have been referred to endocrinology clinics in order to exclude an underlying cause. Routine preoperative testing to screen Cushing's syndrome (CS) or hypothyroidism is still debatable. The aim of this study is to evaluate the accuracy of routine testing in preoperative endocrinological evaluation.
Methods/design
Clinical files of 164 patients who applied for bariatric surgery to our outpatient clinic between January 2014 and January 2015 were reviewed. Cortisol levels following low-dose dexamethasone administration, and free thyroxine, TSH were measured to exclude CS and hypothyroidism respectively. Serum cortisol <1.8 μg/dl was the cut-off point for normal suppression. We also have measured HbA1c, insülin, and fasting glucose as a part of our pre-surgical protocol. HOMA-IR was used to determine insulin resistance.
Results
One hundred and sixty-four patients (43 men and 121 women) with a mean age of 39.96 ± 10.95 years and a mean BMI of 49.50 ± 34.36 kg/m^2 were reviewed. Only in one patient pseudo CS was considered. Primary subclinical hypothyroidism was 12% and primary subclinical hyperthyroidism was 1%, while 151 patients were euthyroidic (92%). The prevalence of known diabetes mellitus was 26%. No new patient of diabetes mellitus was diagnosed, while the prevalence of impaired fasting glucose was 38%. Mean HOMA-IR levels were 5.94 ± 3.5 and mean HbA1c levels were 5.6 ± 0.4% when previously known diabetics were excluded.
Conclusion
Routine screening for CS, hypothyroidism seems to be not required and may cause needless expenditures for national health systems in patients who apply for preoperative evaluation for bariatric surgery. For the time being, diagnostic tests for CS and hypothyroidism in morbidly obese patients should be limited to patients who have accompanying more clinical signs and symptoms.

DOI: 10.1530/endoabs.37.EP580

EP581

Liver enzymes and triglycerides predict biomarkers of insulin sensitivity in obese, non-diabetic adult patients

Ana Gligic[1], Mirjana Sumarac-Dumanovic[1,2], Snezana Polovina[1], Aleksandra Kendereski[1,2], Danica Stamenkovic-Pejkovic[1], Goran Cvijovic[1,2], Svetlana Zoric[1], Danka Jeremic[1], Jelena Milin-Lazovic[1] & Dragan Micic[1,2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia; [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction
Obesity is a risk factor for the development of insulin resistance, type 2 diabetes, cardiovascular diseases and non-alcoholic fatty liver disease. The aim of our study was to examine predictive value of liver enzymes in assessing biomarkers of insulin sensitivity in obese, non-diabetic adults.
Methods
1104 obese, non-diabetic adults were included in the study. Patients were divided into two groups: Group A (BMI 30.0–39.9 kg/m^2, $n=499$) and Group B (BMI ≥ 40 kg/m^2, $n=605$). After 12 h of fasting, anthropometric evaluation (BMI, waist-to-hip ratio and percentage body fat) was performed and blood levels of glucose, insulin, HbA1c, total cholesterol, HDL, LDL, triglycerides, AST, ALT, γ-GT and CRP were obtained. HOMA-IR was calculated. Multiple linear regression was used for statistical analysis.
Results
We found that ALT, γ-GT and triglycerides are predictors of HOMA-IR score in Group A ($R^2=0.02$, $P=0.007$; $R^2=0.04$, $P<0.001$; $R^2=0.06$, $P<0.001$, respectively), as well as in Group B ($R^2=0.03$, $P=0.002$; $R^2=0.07$, $P<0.001$, $R^2=0.04$, $P<0.001$, respectively). Percentage of body fat predicts HOMA-IR score in Group A ($R^2=0.02$, $P=0.021$), whereas waist-to-hip ratio predicts HOMA-IR score in Group B ($R^2=0.05$, $P<0.001$). Moreover, ALT and γ-GT predict HbA1c in Group B ($R^2=0.03$, $P<0.001$; $R^2=0.06$, $P<0.001$, respectively).
Conclusion
These results have verified that parameters of insulin sensitivity in obese, non-diabetic patients could be presumed mainly by levels of liver enzymes and triglycerides. Therefore, these data contribute to the essential role of liver function tests in the detection of metabolically abnormal obesity.

Neutrophil to lymphocyte ratio as an inflammatory marker in obesity

Neslihan Soysal-Atile[1], Betül Ekiz-Bilir[1], Bülent Bilir[2], Derya Baykiz[3], Birol Topçu[4] & Murat Aydin[5]
[1]Endocrinology Department, Tekirdag State Hospital, Tekirdag, Turkey; [2]Internal Medicine Department, Namik Kemal University Faculty of Medicine, Tekirdag, Turkey; [3]Cardiology Department, Tekirdag State Hospital, Tekirdag, Turkey; [4]Biostatistics Department, Namik Kemal University Faculty of Medicine, Tekirdag, Turkey; [5]Biochemistry Department, Namik Kemal University Faculty of Medicine, Tekirdag, Turkey.

Aim
Cardiovascular morbidity and mortality of obesity is associated with classic risk factors, namely dyslipidaemia, hypertension and impaired glucose metabolism.

Aim of this study is to evaluate inflammation as an independent risk factor by using neutrophil to lymphocyte ratio (NLR).
Materials and methods
Patients who admitted to our outpatient clinic between January and December 2014 were assessed retrospectively. Patients diagnosed as diabetes, prediabetes, hypertension, thyroid dysfunction and any acute or chronic inflammatory disorder were excluded. A total of 437 female cases were included in the study. Cases were grouped according to BMI.
Results
Groups were age-matched ($P=0.513$). HOMA-IR and trigliseride values were positively, HDL levels were negatively correlated with BMI ($P<0.05$). There was no association between LDL values and BMI. There was no statistically significant difference between NLR values of groups 0, 1, 2 and 3. A trend toward higher NLR in group 4 was observed but the difference did not reach statistical significance ($P=0.117$). Group 5 however had significantly higher NLR values ($P=0.000$).

Group (BMI kg/m^2)	*n*	HOMA-IR	Trigliseride	HDL	LDL	NLR
0 (18.0–24.9)	45	1.33±0.63	90.67±47.71	58.79±15.43	123.48±50.51	1.85±0.68
1 (25.0–29.9)	86	1.93±0.89	106.42±62.13	53.30±14.85	133.31±39.83	1.86±0.53
2 (30.0–34.9)	98	2.43±1.29	126.00±59.38	46.93±11.89	135.40±33.55	1.75±0.63
3 (35.0–39.9)	76	2.80±1.50	147.10±75.07	48.48±15.20	131.03±36.28	1.79±0.56
4 (40.0–44.9)	67	3.87±2.26	152.17±70.21	46.64±21.46	130.19±32.46	2.28±0.53
5 (>45)	65	3.98±1.45	144.85±82.09	44.98±11.12	126.94±34.59	3.07±2.23

Conclusion
Increased NLR value is considered as an inflammatory marker and an indicator of cardiovascular risk. Our results established higher NLR values in morbid obesity patients and emphasised the increased cardiovascular risk in morbid obesity.

A prospective prevalence study of functional adrenal insufficiency and its outcome in acute myocardial infarction in UKMMC

Norasyikin A Wahab, Shazatul Reza Mohd Redzuan, Norlela Sukor, Norlaila Mustafa, Oteh Maskom, Shamsul Azhar Shah & Nor Azmi Kamaruddin
Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia.

Introduction
Acute myocardial infarction (AMI) is a stressful condition in which it stimulates the hypothalamus-pituitary-adrenal axis leading to mark increase in the production of cortisol. Adrenal insufficiency (AI) has been shown to be associated with morbidity and mortality in acute coronary syndrome patients. To date, none study has been performed to determine prevalence of AI among patient with AMI.
Objectives
The aim of this study is to determine the prevalence of AI in AMI by using the low dose (LD) and standard dose (SD) synacthen tests and to correlate with morbidity and mortality.
Method
Fifty-six patients who fulfilled the diagnosis of AMI within 48 h of onset were subjected to LD (1 μg) synacthen test (LDST) followed by a SD (250 μg) synacthen test (SDST) 2-h later. Those who had AI, repeat synacthen test had to perform at day 30 of AMI.
Result
Thirty-five (62.5%) patients had ST elevation AMI and 21 (35.5%) non-ST elevation AMI. Using an increment of <250 nmol/l following LDST and SDST, 39 (69.6%) and 2 (3.6%) patients had adrenal insufficiency respectively. Based on LDST, the diagnosis of AI was associated with significant morbidity and mortality. One patient died during the study period and he had very high cortisol levels. Out of 15 patients who underwent repeat synacthen, only two of them had responded to the synacthen test.
Conclusion
Utilising the LDST, adrenal insufficiency was found in 69.6% of AMI patients. Mortality of AMI showed less cortisol increment to LDST but able to reach the peak cortisol level for both tests. Functional AI in AMI takes longer than 30 days to recover.
Disclosure
This study was approved by Research and Ethics committee of the Faculty of Medicine, UKM and the project code was FF-2014-214. Funding for this study was provided by the research Grant of Faculty Of Medicine UKM.

Adipocytokine responses to acute exercise in athletes with different body fat content and sedentary controls

Marina Djelic[1], Sanja Mazic[1], Mirjana Sumarac Dumanovic[2], Tijana Durmic[1], Snezana Cvetkovic[3], Biljana Lazovic[4], Jelena Suzic Lazic[5] & Dragan Micic[2]
[1]Faculty of Medicine, Institute of Physiology, Belgrade, Serbia; [2]Faculty of Medicine, Institute of Endocrinology, Diabetes and Diseases of Metabolism, Belgrade, Serbia; [3]Faculty of Medicine, Clinical Centre Serbia, Belgrade, Serbia; [4]Faculty of Medicine, University Clinical Centre Zemun, Belgrade, Serbia; [5]Faculty of Medicine, University Clinical Centre Dragisa Misovic, Belgrade, Serbia.

The aim of this study was to investigate adipocytokine responses to an single bout acute exercise in elite athletes with a low percentage of body fat, elite athletes with a high percentage of body fat and sedentary controls. Sixteen athletes with low percentage of body fat (volleyball players, low fat athletes group, LFAG), 15 athletes with high percentage of body fat (the elite water polo players, high fat athletes group, HFAG) and 15 sedentary subjects participated in this study (age (years) 20±2; 20±2; 20±1, respectively). All subjects were exposed to anthropometric measurements and one bout exercise test on treadmill in order to examine acute changes of adipocytokines. Blood samples were obtained at baseline levels, immediately after the exercise test and 30 min after recovery. Separated serum or plasma were used for hormone (leptin, adiponectin and visfatin) ELISA analysis. In athletes in LFAG, baseline leptin concentration was significantly lower, but adiponectin and visfatin concentrations were significantly higher, compared to sedentary controls and athletes in HFAG ($P<0.05$, all). There were no significant post exercise or recovery changes in adiponectin concentration ($P>0.05$). No differences in leptin concentration over time were observed in athletes groups ($P>0.05$). In contrast, leptin concentration in sedentary controls was significantly reduced after exercise and decreased even more during the recovery period ($P<0.05$). Only in athletes in HFAG, visfatin concentration increased significantly after exercise, but reduces in recovery period ($P<0.05$). In controls, visfatin concentration was significantly reduced and stayed lower throughout the recovery period ($P<0.05$). In conclusion, our findings show leptin and visfatin levels, but not adiponectin respond to acute exercise. Acute exercise elicited an inverse visfatin response in athletes in HFAG and controls. Also, these results suggest that leptin is altered after acute exercise only in sedentary individuals.

Anti-obesity effect of Aster spathulifolius Maxim extract

In-Jin Cho[1], Se Young Choung[2], Do Un Kim[3], You-Cheol Hwang[1], Kyu Jeung Ahn[1], Ho Yeon Chung[1] & In-Kyung Jeong[1]
[1]Department of Endocrinology and Metabolism, Kyung Hee University Hospital at Gangdong, Kyung Hee University School of Medicine, Seoul, Republic of Korea; [2]College of Pharmacy, Kyung Hee University, Seoul, Republic of Korea; [3]Newtree. Co., Ltd, Seoul, Republic of Korea.

Purpose
Aster spathulifolius Maxim is one of plants of chrysanthemum, which has shown an anti-obesity activity in diet induced mice model. We performed clinical trial for evaluating the anti-obesity efficacy and safety of Aster spathulifolius Maxim extract on obese human.
Methods
This study was randomised, double-blind, placebo-controlled clinical trial in Korea. A total of 41 obese subjects (BMI 25–30 kg/m^2) aged ≥20 years were randomized to one of two groups: i) placebo group ($n=20$), ii) Aster spathulifolius extract (AE) 700 mg/day ($n=21$). All subjects were instructed to take a pill of once-daily regimen for 12 weeks. Weight, BMI, waist circumference, fat mass (measured by bioimpedance method, DEXA, and abdominal computed tomography (CT)), and laboratory test were assessed at baseline and 12 weeks.
Results
Body weight was significantly decreased in AE group after 12-week treatment (placebo vs. AE: −0.08±2.11 kg vs −3.30±3.15 kg, $n<0.05$). Body fat mass reduction was significantly shown in AE group after 12-week treatment (placebo vs AE; bioimpedance method: −0.51±1.89 kg vs −2.38±2.30 kg, $P<0.05$; DEXA: 0.38±1.59 kg vs −2.26±2.37 kg, $P<0.05$; visceral fat area in CT: 8.11±18.13 vs −24.9±37.0 cm.sp, $P<0.05$; subcutaneous fat area in CT: 5.51±34.58 vs −24.4±31.8 cm.sp, $P<0.05$). Reduction of apo-B was significantly observed in AE group compared with placebo group (placebo vs

AE: 7.42±20.65 vs −2.76±15.86 mg/dl, $P<0.05$). The changes of fasting plasma glucose and HbA1c did not differ between two groups. In safety, there were no drug-related adverse events during the study.
Conclusion
In conclusion, Aster spathulifolius Maxim extract significantly decreases body weight, body fat, and apo-B level in obese human.

The assessment of environmental and hereditary factors in obesity patients
Veranika Labashova, Alla Shepelkevich, Julia Dydyshko & Veranika Dovgalo
Belarusian State Medical University, Minsk, Belarus.

The aim of the research was to reveal and assess the interaction between environmental and hereditary factors in obese patients seeking for weight loss.
Materials and methods
We analysed the anamnesis of 134 overweight and obese patients, having asked to endocrinologist for losing weight (20 men and 112 women). The mean age of the respondents was 45.78+8, 76 years. 15.7% of patients were overweight, and 84.3% were obese. Heritability of obesity was determined according to family history of obesity, anamnesis of diabetes in relatives, childhood appearance of excess body weight. The environmental changes included eating habits, level of physical activity and water regime of participants.
Results
The assessment of the hereditary factors of obesity revealed that 76.5% (101 person) had a family history of obesity: 59.7% (80 patients) mentioned excess body weight on the maternal line and 40.3% (54 patients) described obesity for father's relatives. Diabetes was diagnosed in 14.9% (20 persons) – on the maternal line and in 9.7% (13 persons) on the fatherly line. 41% of respondents (55 patients) remarked childhood obesity in themselves. The analysis of environmental factors showed that 71, 7% of respondents skipping meals during the day, 13.4% (18 persons) had only one meal, 55.2% (74 persons) had 2–3 meals/day. Everyday moderate activity 30 min or more described only 11% of respondents, physical activity 30 min or less 3 days a week described 46% of patients, 30 min of activity 5–6 times a week 43% patients. The vast majority of patients 97.7% drank <2 l of water per day.
Conclusions
The occurrences of obesity relatives was 59.7% on the maternal line, 40.3% on the paternal line. Interaction with environment factors related to low physical activity and inadequate water consumption.

EP587

Significance of cognitive-behavioural therapy in the treatment of obesity
Snjezana Popovic-Pejicic[1] & Zelija Velija-Asimi[2]
[1]University Hospitail, Clinical Center Banja Luka, Medical Faculty University of Banja Luka, Banja Luka, Republic of Srpska, Bosnia and Herzegovina; [2]Clinic for Endocrinology, Diabetes and Metbolic Disease, Sarajevo, Bosnia and Herzegovina.

Introduction
Dietary therapy (DT), programmed physical activity (PPA) and cognitive-behavioural therapy (CBT) are basic measures in the treatment of obesity. CBT applies methods which change eating habits of obese persons, aiming to remove barriers relating DT and PPA. The goal of this study is to try efficiency of applying CBT in the programme for the reduction of body mass of obese persons, vs the application of DT and PPA alone.
Design
The study included 60 obese persons, who were divided into two groups (1 and 2), with 30 patients in each group, 20–58 years of age, with the BMI ≥30 kg/m^2 and hyperlipidaemia (LDL-cholesterol ≥4.2 mmol/l serum). Patients have not been previously treated for obesity and were unhappy with their weight. Patients from both groups were on hypocaloric diet, individually designed and had programmed physical activity every day. Patient in group 2 underwent group CBT, under the supervision of psychiatrist once a week with duration of 120 min, but in group 1 no. Both groups also went to see an endocrinologist six times, on which occasions their body weight, parameters of lipid status serum and level of glucose in serum were measured. Results showed that in group 2, the medium value of BM reduction after 12 weeks of treatment was 9.5 kg (8.9%), LDL-cholesterol decreased for 34.5%, HDL-cholesterol increased for 2.7%, triglycerides decreased for 15.3%, glycaemia decreased for 14.8%, which is the significantly better metabolic profile, then in group 1.
Conclusion
CBT affected the improvement of motivation and readiness of patients to stick to the dietary regimen and physical activity. In designing the program for the reduction of obesity it is necessary to include CBT, which brings significantly better therapy outcomes, then the application of DT and PPA alone.

Fine motor skill proficiency in obese children
David Gaul & Johann Issartel
Multisensory Motor Learning Lab, Dublin City University, Dublin, Ireland.

Introduction
Motor skill proficiency has shown to be a key predictor of children's engagement and enjoyment of regular physical activity. Recent evidence suggests that obese children have increased difficulties in the planning, initiation and control of motor skills compared to their normal weighted peers (D'Hondt *et al*. 2009, Gentier *et al*. 2013). These difficulties often manifest themselves as slower or less efficient performance of motor skills. This could impede the performance of everyday activities as well as affect their willingness to engage in physical activity. However the majority of research focuses on gross motor skill performance despite fine motor skills being prerequisites to many activities of daily living.
Methods
A sample of a 46 children were equally divided into two groups (obese (OB) vs normal weight (NW)) based on their BMI calculated using the IOTF cut points for children (Cole *et al*. 2000). Each group were equally matched for gender (11 male and 12 Female) and age ($M=9.101$ s.d. $=1.832$ and $M=9.103$ s.d. $=1.746$). The children were tested using the Fine Motor Skills Composite of the Bruininks Oseretsky Test of Motor Proficiency (BOT-2). The children's raw scores were converted according to the manual into standardised scores based on normative data.
Results
The OB group ($M=46.13$, s.d. $=9.16$) was found to score significantly lower ($P<0.05$) than their NW ($M=52.04$, s.d. $=5.36$) peers using the standard scores of the Fine Motor Skill Composite. This score represents whether a child possesses the expected level of fine motor skill for their age/gender.
Conclusion
The assumption that mass alone is responsible for these differences between BMI groups is not sufficient as additional body mass would only have a limited effect on fine motor skill. The above findings suggest the existence of a deficit in how OB children integrate and process sensory information compared to their normal weighted peers.

High mean platelet volume in morbid obesity
Senay Arikan Durmaz[1], Zehra Bacanli[3], Ayse Carlioglu[2], Aydin Cifci[3] & Abdulmuttalip Arslan[2]
[1]Department of Endocrinology and Metabolism, Kirikkale University, Kirikkale, Turkey; [2]Department of Endocrinology and Metabolism, Erzurum Region Education and Research Hospital, Erzurum, Turkey; [3]Department of Internal Medicine, Kirikkale University, Kirikkale, Turkey.

Introduction and aim
The incidence of atherosclerotic vascular disease is high in obesity. Our aim is to determine the mean platelet volume (MPV) as a new indicator of atherosclerosis in morbid obesity.
Materials and methods
Thirty-three patients with morbid obesity who applied to endocrinology department (mean age 41.5±11.3 years, body weight 118.2±16.9 kg and BMI: 45.9±7.2 kg/m^2) and 39 age-matched (mean age 35.3±13.1 years; body weight 60.4±11.3 kg; BMI: 21.6±2.6 kg/m^2) healthy individuals were included in the study. Patients have haematological and other endocrinological diseases

were excluded from the study. All complete blood count analysis was performed by automatic analyser.
Results
We found that mean MPV values and platelet counts in morbid obesity group were higher than control subjects (8.7 ± 1.1 and 6.9 ± 0.5 fl, $P=0.0001$; 267 921.2 ± 81 475/mm^3 0.3; 163 710.8 ± 13 993.3 × 103/μl, $P=0.0001$, respectively). In addition, neutrophil lymphocyte ratio in morbid obesity group was not significantly different than those in control subjects (1.9 ± 0.7 and 1.7 ± 1.0, $P=0.225$, respectively). In addition, platelet to lymphocyte ratio was not statistically different between groups (102.9 ± 32.1 in morbid obesity and 104.8 ± 38.3 in control group). No statistically significant differences were found for the other parameters such as lymphocyte, WBC count and PCT. There were positive correlations both between MPV and BMI ($r=0.649$, $P=0.0001$) and between MPV and body weight ($r=0.599$, $P=0.0001$).
Conclusions
High MPV was associated with the presence of more metabolically active platelets. Therefore, increases of MPV in morbid obesity may lead to high risk for atherosclerosis.

Genetic variation in GLP1 receptor is associated with interindividual differences in weight lowering potential of liraglutide in obese women with PCOS

Mojca Jensterle[1], Boštjan Pirš[2], Katja Goričar[2], Vita Dolžan[2] & Andrej Janež[1]
[1]Department of Endocrinology, Diabetes and Metabolic Diseases, University Medical Centre Ljubljana, Ljubljana, Slovenia; [2]Faculty of Medicine, Institute of Biochemistry, University of Ljubljana, Ljubljana, Slovenia.

Objective
The weight lowering potential of glucagon-like peptide (GLP) 1 receptor agonists (RAs) is interindividually different and clinically unpredictable. The potential role of genetic variability of GLP1R on body weight response to GLP1 RA has not yet been evaluated. The aim of the study was to assess the effect of common non-synonymous *GLP1R* single nucleotide polymorphisms (SNPs) rs6923761 and rs10305420 on weight loss in response to long acting GLP1 RA liraglutide in obese women with PCOS.
Methods
59 obese women with PCOS (aged 30.7 ± 6.9, BMI 38.4 ± 5.3 kg/m^2) were assigned to liraglutide 1.2 mg QD sc. for 12 weeks. They were genotyped for *GLP1R* rs6923761 and rs10305420. Changes of body mass, BMI, waist circumference and visceral adipose tissue (VAT) area were measured before and at the end of the study.
Results
After treatment intervention women lost on average 3.96 ± 3.24 kg ($P<0.001$), BMI was reduced for 1.44 ± 1.22 kg/m^2 ($P<0.001$), waist circumference for 3.31 ± 4.13 cm ($P<0.001$) and VAT for 7.05 ± 18.55 cm^2 ($P=0.002$). Twenty (34%) out of 59 subjects were good responders and lost 5% or more of their initial body weight. Carriers of at least one polymorphic rs10305420 allele had worse treatment response compared to carriers of two WT alleles (OR = 0.27, 95% CI = 0.09–0.85, $P=0.025$). Carriers of at least one polymorphic rs6923761 allele tended to have better treatment response compared to carriers of two WT alleles, but the difference was not statistically significant (OR = 3.06, 95% CI = 0.96–9.74, $P=0.058$).
Conclusion
Polymorphism of *GLP1R* rs10305420 accounts for interindividual differences in response to liraglutide regarding weight loss in obese women with PCOS. Future studies will determine whether such genetic variation may be clinically useful in prediction of the weight lowering potential of GLP1 RAs in obese individuals.

The efficacy of lifestyle modification in preventing type 2 diabetes mellitus in subjects with impaired glucose homeostasis

Elena Shishko & Tatyana Mokhort
Medical, Minsk, Belarus.

Aims
The aim of our study is to assess the efficacy of lifestyle modification in preventing diabetes mellitus type 2 (DM 2)
Materials and methods
The study included 100 patients (69 m 258 f) 25–65 years with impaired glucose tolerance/impaired fasting glucose (IGT/IFG) and newly diagnosed DM 2. Patients were divided into two groups matched by sex, age, weight, BMI, waist-to-hip ratio (WHR). Research group included 54 patients who received and carried out recommendations of a balanced diet and physical activity. Control group included 46 patients who did not lifestyle modification. The study was 48 weeks. We measured fasting plasma glucose (FPG), 2-h plasma glucose concentrations (2-h PG) following a 75-g oral glucose tolerance test and related to fasting leptin (FL).
Results
Patients of the research group demonstrated reduction of BMI (-2.3 ± 3.1 kg/m^2) and WHR (-0.02 ± 0.025) ($P<0.01$ for all). They had positive dynamics of FPG and 2-h PG concentrations ($P<0.001$). Persons of the control group had increase BMI and WHR as also FPG and 2-h PG concentrations elevation ($P<0.05$). The main novel finding was that median serum leptin in research group decreased on −23.9% ($P<0.01$) and increased in control group on +27.6% ($P<0.01$). Among subjects with IGT from the research group, glucose levels normalised in 49.3% ($P<0.001$) and serum leptin levels decreased on 26.9% ($P<0.01$). In control group glucose levels normalized in 4.5% ($P<0.01$) persons with IGT. By the end of the study 12% of non-diabetic subjects with obese have developed DM 2 and 48% IGT. Among patients of the research group was a reduction of DM 2 by 11.9% and an increase in the control group by 35.1%.
Conclusion
Thereby, lifestyle modifications lead to reduction not only fasting plasma glucose, 2-h plasma glucose concentrations but and fasting leptin concentrations in individuals with impaired glucose tolerance.

Relationship between thyroid hormone status and concomitant medication in hyperlipidaemic patients with statin induced adverse effects

Eszter Berta[1,2], Noémi Zsíros[3], Endre Nagy[1], György Paragh[3] & Miklós Bodor[1,2]
[1]Division of Endocrinology, Department of Medicine, University of Debrecen, Debrecen, Hungary; [2]Department of Clinical Pharmacology, University of Debrecen, Debrecen, Hungary; [3]Division of Metabolism, Department of Medicine, University of Debrecen, Debrecen, Hungary.

Statins are effective treatment for the prevention of cardiovascular diseases and used extensively worldwide. However, adverse effects induced by statins are the major barrier of maximalising cardiovascular risk reduction. Hypothyroidism and administration of drugs metabolised on the same cytochrome P450 (CYPP450) pathways where statin biotransformation occurs represent a significant risk factor for statin induced adverse effects including myopathy. Simvastatin, atorvastatin and lovastatin are metabolized by CYP3A4, fluvastatin by CYP2C9, while rosuvastatin by CYP2C9 and 2C19.
We investigated the levels of the free thyroid hormones and CYP metabolism of concomitant medication in 101 hyperlipidaemic patients (age 61.3 ± 9.9 years) with statin induced adverse effects including myopathy (56 cases; 55.4%), hepatopathy (39 cases; 38.6%) and gastrointestinal adverse effects (24 cases; 23.8%). Abnormal thyroid hormone levels were found in five patients (4.95%); clinical hypothyroidism in two and hyperthyroidism in three cases. 11patients had a positive history for hypothyroidism (10.9%). There were no significant differences in the TSH, fT_4 and fT_3 levels between patients with myopathy and patients with other adverse effects. 78 patients (77.2%) were administered drugs metabolized by CYP isoforms used by statins (3A4: 66 cases (65.3%); 2C9: 67 cases (66.3%); 2C19: 54 cases (53.5%)). Patients with myopathy took significantly more drugs metabolized by CYP3A4 compared to patients with other adverse effects ($P<0.05$). More myopathy cases were found in patients on simvastatin treatment (52% vs 38%, NS), while significantly less patients with myopathy were on fluvastatin treatment (13% vs 33%, $P<0.05$) compared to patients with other types of statin induced adverse effects. Both abnormal thyroid hormone status and administration of drugs metabolized by CYP3A4, 2C9 and 2C19 are common in our patients with statin induced adverse effects. Normalising the thyroid hormone status and optimising of the concomitant medication may reduce the risk of statin induced adverse effects.

Is there a relationship between parathyroid hormone and obesity-linked disorders

Sule Temizkan, Sevin Demir, Kadriye Aydin, Hilal Toplu Ozturk, Aysenur Ozderya & Mehmet Sargin
Kartal Dr Lutfi Kirdar Training and Research Hospital, Istanbul, Turkey.

Introduction
Accumulating evidence indicate that high PTH resulting from primary or secondary hyperparathyroidism, is associated with hypertension, insulin resistance, dyslipidaemia, obesity, and cardiovascular mortality. Here, we aimed to show whether high PTH levels in obese population contribute the metabolic complications of obesity.
Methods/design
The medical records of all subjects attending the obesity outpatient clinic of Kartal Dr Lutfi Kirdar Training and Research Hospital in Istanbul between April 2014 and January 2015 were retrospectively evaluated. Subjects who had chronic illness, endocrine disease (diabetes mellitus, thyroid dysfunction, Cushing disease) and subjects with any medication were excluded. A total of 400 obese patients included in the study. Anthropometric, bioelectrical bioimpedence measures, blood examinations and 75-g glucose tolerance tests results were evaluated. Data are presented as means $\pm$ S.D.S for continuous or median (25 and 75% interquartiles) for non-normally distributed variables.
Results
Of the 400 obese subjects 335 were female. Mean age was 39 ± 10. Median BMI was 36 (34–41). Subjects were divided to quartiles according to blood PTH levels. Groups included Quartile 1 ($n=100$, median PTH; 42 (36–45)), Quartile 2 ($n=100$, median PTH; 55 (51–59)), Quartile 3 ($n=100$, median PTH; 73 (68–78)), Quartile 4 ($n=100$, median PTH; 99 (89–125)). Quartiles were evaluated with generalized linear model adjusted for age, sex and season of recruitment. Log was performed for non-normally distributed variables. Systolic and dystolic blood pressure, HOMA-IR, insulin sensitivity index (ISI), triglyceride (TG), HDL-cholesterol were not different among quartiles. Although, BMI was not different ($P=0.05$), trunk mean body fat (MBF) and percent trunk fat (PTF) were statistically different among quartiles ($P=0.03$, $P=0.01$, respectively).
Conclusion
Serum PTH adjusted for age, sex and season of recruitment, is positively associated with trunk MBF and PTF, but was not associated with obesity linked metabolic parameters.

Cardiovascular disease in patients with primary hyperparathyroidism

Elena Brutskaya-Stempkovskaya[1], Alla Shepelkevich[1], Natalya Rekechinskaya[2], Tatyana Leonova[2] & Tatyana Churay[3]
[1]Belarusian State Medical University, Minsk, Belarus; [2]Minsk Cancer Center, Minsk, Belarus; [3]Minsk Endocrinology Center, Minsk, Belarus.

Introduction
Patients with primary hyperparathyroidism (PHPT) have an increased cardiovascular risk. However, the data on the relationship severity of PHPT clinical forms and prevalence of cardiovascular disorders are controversial.
Objective
Studying cardiovascular disease in patients with manifested forms of PHPT compared with mild forms.
Materials and methods
We studied 136 patients with PHPT (assesses arrhythmias, hypertension, coronary disease), a general medical examination were made. The indicators calcium and phosphorus metabolism (PTH, vitamin D, Ca general, Ca++, phosphates) were investigated.
Results
The mild PHPT were diagnosed in 54 patients with a mean age of patients was 51.5 ± 11.6 years, manifested forms PHPT were diagnosed in 82 patients, the average age of the patients was 52 ± 10.4 years. Cardiovascular disease were found in 19 (35.1%) patients with mild forms of PHPT and 38 (45.2%) with the manifested PHPT. A strong statistically significant correlation between the severity of clinical manifestations PHPT and incidence of cardiovascular disease in patients with PHPT ($R=0.81$, $P<0.05$).
Conclusion
These results suggest the high incidence of cardiovascular disease in patients with manifested PHPT and the low diagnostic rate of mild forms of PHPT.

N-terminal pro-brain natriuretic peptide – an early independent predictor of anthracycline-induced cardiomyopathy

Alina Mihaela Pascu, Alina Bisoc & Mariana Radoi
Faculty of Medicine, Transilvania University of Brasov, Romania, Brasov, Romania.

Introduction
Early prediction of anticancer therapy cardiotoxicity is essential for applying proper preventive and supporting therapeutic strategies.
Objective
To evaluate plasma N-terminal fragment of pro-brain natriuretic peptide (NT-proBNP) related to cardiac dysfunction assessed by transthoracic 2D echocardiography (2D-TTE) in patients with cancer and early onset asymptomatic anthracycline-induced cardiomyopathy (AIC).
Methods
Prospective study of 68 patients with cancer treated with anthracyclines, followed up for 6 months. Diagnosis of AIC was set at 6 months by decreasing of left ventricular ejection fraction (LVEF) below 50% or with more than ten units or 20% from baseline. NT-proBNP and 2D-TTE were assessed at enrolment, and thereafter at 3 and 6 months.
Results
Fifteen (22.1%) patients developed AIC at 6 months of anthracycline treatment (group 1), and 53 (77.95%) patients did not evolve with AIC (group 2). At 3 months, in patients from group 1 NT pro-BNP was significantly higher compared to group 2 (121.0 (119.8; 140.8) pg/ml vs 97.7 (75.5; 111.7) pg/ml, $P=0.0001$, values expressed as median (25th; 75th percentiles)). Left ventricular (LV) diastolic dysfunction was significantly more frequent in group 1 (93.3%) vs group 2 (37.7%), $P=0.0002$. NT-proBNP at 3 months proved accurate in predicting asymptomatic AIC at 6 months (area under the receiver operating characteristic curve (AUC)$=0.845$, 95% CI: 0.735–0.954, $P=0.0001$). New-installed diastolic dysfunction at 3 months had a sensitivity of 60%, a specificity of 77% in predicting AIC at 6 months. NT-proBNP assessed at 3 months above a cut-off $=118.5$ pg/ml was an independent predictor of AIC at 6 months.
Conclusions
Plasma NT-proBNP at 3 months of anthracycline therapy proved to be an early independent predictor of asymptomatic anthracycline-induced cardiomyopathy.

Increased expression of ATP-binding cassette transporter A1 by cilostazol may be a possible mechanism for its protective effect against hepatic steatosis

Bong-Soo Cha[1], Tae Sun Park[2], Byung Hun Jeon[1], Yong-Ho Lee[1], Mi Ra Yun[1], Byung Wan Lee[1], Eun Seok Kang[1] & Hyun Chul Lee[1]
[1]Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Chonbuk National University Medical School, Jeonju, Republic of Korea.

Objective
Cilostazol, a selective inhibitor of phosphodiesterase 3, which has been widely used in patients with atherosclerotic diseases, is known to have additional beneficial effects on dyslipidemia. ATP-binding cassette transporter A1 (ABCA1) plays a critical role in the regulation of intracellular cholesterol levels in hepatocytes. We aimed to investigate the effect of Cilostazol on hepatic steatosis and its underlying mechanism related to ABCA1.
Methods
Male C57BL/6 mice were randomly divided into three groups: i) fed normal chow diet with vehicle. ii) fed high-fat diet (HFD) with vehicle. iii) fed HFD with

Cilostazol. Cilostazol (30 mg/kg) was orally administered once daily for 9 weeks. Oral glucose tolerance test was done and liver tissues were examined. HepG2 cells were also used as an *in vitro* model by incubating with saturated fatty acid (palmitate) in the presence or absence of Cilostazol.
Results
In HFD-fed mice, Cilostazol treatment significantly decreased hepatic fat and liver weight. Cilostazol-treated mice also showed improved glucose tolerance and decreased levels of serum LDL, VLDL and total cholesterol. The expression of ABCA1 was significantly increased in the liver of cilostazol-treated mice by 2.4-folds ($P<0.05$) compared to HFD-fed control mice. In palmitate-treated HepG2 cells, lipid accumulation was significantly decreased after treatment with Cilostazol. Palmitate reduced the expression of ABCA1, which was restored with Cilostazol treatment by 1.3-folds ($P<0.05$). The HDL-cholesterol levels in the cell cultured media were also increased, while intracellular LDL and VLDL-cholesterol levels were decreased in HepG2 cells treated with palmitate and cilostazol compared to those with palmitate only.
Conclusion
Our results showed that cilostazol ameliorated hepatic steatosis by increasing ABCA1 expression in the hepatocytes. This implicates that cilostazol may have a beneficial role in the treatment of non-alcoholic fatty liver disease.

Exploratory study a Brazilian population with multiple chronic conditions from the perspective of smoking

Arise Galil[1], Kimber Richter[2], Eliane Banhato[1], Tatiane Campos[1], Rafael Henrique Santos[1], Marilaine Souza[1], Mariane Almeida[1], Sonielle Oliveira[1], Fernando Colugnati[1], Ana Paula Cupertino[2] & Marcus Bastos[1]
[1]Federal University of Juiz de Fora, Juiz de Fora, Minas Gerais, Brazil; [2]Kansas University, Kansas City, Missouri, USA.

Recent evidence shows that are modifiable risk factors and preventable, the most responsible for the high morbidity and mortality secondary to multiple chronic conditions (MCC), and smoking is one of the most important representatives. However, we still lack studies of populations with MCC and its association with smoking status.
Objectives
To identify clinical and psychosocial characteristics according to the status of smoking among users with MCC, at high cardiovascular risk.
Methods
Cross-sectional study with evaluation of socio-demographic, clinical and laboratory data, in HIPERDIA Center Juiz de Fora, Minas Gerais (CHM-JF), Brazil, assisting users with MCC (hypertension, diabetes mellitus and chronic kidney disease). To check the status of smoking was considered smokers (S), former smokers (FS) and nonsmokers (NS). Control blood pressure (systolic blood pressure <130 mmHg); metabolic (normal fasting blood glucose <100 mg/dl and/ or regular glycated hemoglobin $<7\%$, for users <60 and $<8\%$ for those with ≥ 60 years); Normal LDL-cholesterol (<100 mg/dl); chronic kidney disease absent, the glomerular filtration rate (GFR) >60 ml/min per SC. Depression (PHQ-2 ≥ 3 points) and alcohol abuse (AUDIT-C >5 points). Declared atherosclerotic disease, DAD (vascular damage documented, regardless of the affected territory).
Results
1558 users reviews, of which 12% were S; 41% and 47%, FS and NS. Compared to FS and NS, S were younger, less obese and more often female, higher prevalence of low education, physical inactivity, depression, alcohol abuse and lack lipid. Additionally, FS had better lipid control in relation to S and NS. Chronic obstructive pulmonary disease (COPD) and DAD were more prevalent among S and FS, even after adjusting for confounding variables.
Conclusion
The current smoking was more common in the younger population, sedentary, alcohol abuse, depressive symptoms, users declared atherosclerotic disease, COPD and a history of cancer. These data gave to S, a worse clinical profile compared to the NS. For despite the termination, the FS remained with similar comorbidities that active smokers.

TNFα induces lipolysis by downregulating CIDEC via MEK/ERK-dependent PPARγ phosphorylation and nuclear exportation

Xinrui Tan, Meizhen zhang & Yanfeng Xiao
The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China.

CIDEC is a lipid droplet-targeting protein that promotes triglyceride accumulation and inhibits lipolysis. CIDEC is regulated by peroxisome proliferator-activated receptor γ (PPARγ). Previous studies demonstrate that CIDEC down-regulation is involved in TNFα-induced lipolysis. Here, we focus on the signalling pathway to clarify the mechanism of TNFα-mediated CIDEC down-regulation. CIDEC is significantly decreased in subcutaneous adipose tissue in obese subjects. Also, CIDEC mRNA expression inversely correlates with serum TNFα levels in our cohort of 68 patients. Using SW872 human adipocyte-differentiation model, we verify that TNFα causes lipolysis and CIDEC down-regulation in a dose and time-dependent manner.10 ng/ml TNFα almost abolishes CIDEC protein expression at 12-h exposure, while the MEK/ERK inhibitor U0126, but not the JNK inhibitor SP600125 or the P38 inhibitor SB203580, blocks this response. In addition, RNAi Knockdown of ERK1/2 inhibits TNFα-induced CIDEC down-regulation and phosphorylation of PPARγ. Furthermore, depletion of MEK1/2 which are the upstream activators of ERK1/2 reverse CIDEC down-regulation to a larger extent. Immunostaining of PPARγ and subcellular fractionation confirm that MEK1/2 rather than ERK1/2 mediate PPARγ nuclear exportation. Taken together, TNFα down-regulates CIDEC protein levels due to phosphorylation and nuclear export of PPARγ by MEK/ERK cascade and this adds new aspects of TNFα-induced lipolysis.

Magnitude of overweight and obesity amongst school children in Delhi, India

Umesh Kapil
All India Institute Of Medical Sciences, New Delhi, India.

Obesity has emerged as an epidemic in India. The present study was conducted to assess the magnitude of overweight and obesity amongst children in the age group of 5–18 years belonging to low, middle and high income group in National Capital Territory NCT of Delhi. A total of 16 595 children (LIG 5087, MIG 5134 and HIG 6368) were covered in the present study. Overweight and obesity were assessed using BMI and triceps skin fold thickness (TSFT) utilizing age and sex specific cut off points. Considering the BMI cut off points, the prevalence of obesity and overweight in Low Income Group (LIG) school children was 0.1 and 2.7% respectively, amongst Middle Income Group (MIG) school children it was 0.6 and 6.5% and in High Income Group (HIG) school children was 6.8 and 15.3% respectively ($P<0001$). With regard to the TSFT criteria, the prevalence of obesity and overweight in LIG school children was 1.2 and 2.4%, amongst MIG school children it was 2.5 and 4.9% and in children belonging to HIG schools was 9.3 and 13.1% respectively ($P<0.001$). The present study documented that the prevalence of overweight and obesity was higher in the HIG children as compared to the MIG and the LIG for all age groups, highlighting the possible role of change in the dietary pattern and physical activities with increase in income levels.

Altered sensory motor integration of obese adults

Johann Issartel[1], David Gaul[1], Arimin Mat[2] & Donal O'Shea[2]
[1]Multisensory Motor Learning Lab., Dublin City University, Dublin, Ireland; [2]Department of Endocrinology, St Vincent's University Hospital, Dublin, Ireland.

Introduction
It appears recently that the lack of physical activity might not be a factor for obesity but rather a consequence of perceptual-motor difficulties (D'Hondt *et al*. 2011). Perception and action are two intertwined processes: perception is a means to action and action is a means to perception. Not being able to perceive correctly visual or auditory information would alter someone's movement kinematics of any given task. The key question is how do these different senses interact in situations that rely on the tight coupling between perception and action? To which extend obesity modifies the sensory motor integration and the movement output?
Methods
88 participants (44 Obese and 44 matched-control) sat on a chair equipped with a wrist pendulum that moves in the sagittal plane. The pendulum had a potentiometer built-in that records the angular wrist movement. For one of the experimental conditions, an oscillating visual stimulus was displayed on the screen. Another experimental condition consisted of an auditory signal oscillating between the right and left ears of the participants. The task was to synchronise the pendulum with either or both sensory modalities.
Results
The key findings from the repeated-measures ANOVAs revealed a strong reduction of the movement accuracy of the obese participants. For all sensory modalities, patients struggled to synchronise their action with the stimuli ($P<0.05$). To make an analogy with a dance performance, one can imagine someone dancing off the beat of the music. The movement variability of the obese patients was also higher than the control group ($P<0.05$).
Conclusion
This perceptual problem reduces the motor control of obese patients revealing even more encompassed difficulties. The identification of the origin of the perceptual problem will allow us to address the problem to its source and eventually to break the vicious circle of a deficient perception and action coupling.

The effectiveness of an integrated approach in the treatment of obesity

Irina Bourko[1], Maksim Lushchyk[1], Aleksey Romanousky[1], Olga Isachkina[2], Galina Korolenko[2], Elena Kholodova[1] & Larisa Danilova[1]
[1]BelMAPE, Minsk, Belarus; [2]10 City Hospital, Minsk, Belarus.

Introduction
To assess the effectiveness of treatment of obesity using complex integrated approach. In the treatment of obesity were used: instructions of patient in healthy eating habits, diet, taking medication that reduces fat absorption – lipid-adsorbent tablets, polyglucosamine (L112). Survey of patients was conducted. The received data were analysed.
Description of methods
61 obese patients (18 males and 43 females) were followed up for 12 weeks. Mean age 48.2 ± 9.2 years; BMI 34.9 ± 5.21 kg/m^2. BMI, waist circumference (WC) measurements, visceral fat content (%) before and after treatment were measured. Levels of total cholesterol (TC), triglycerides (TG), LDL cholesterol (LDLC), and HDL cholesterol (HDLC) were also measured.
Results
Followed up patients reached weight loss by 3.7%, in BMI of 1.31 kg/m^2, WC decreased by 4.15 cm, visceral fat by 0.68%. Metabolic parameters improved. The maximum effect was achieved among the patients with university education, stable job, motivation to lose weight and among those that were keeping a food diary.
Conclusion
An integrated approach in treatment of obesity is effective and consists of education of patients, presence of motivational reasons to lose weight, level of education, adherence to the principles of healthy eating and receiving supplementary medication to reduce fat absorption.

SHBG-C57BL/ksJ-*db/db*: a new mouse model to study the link between SHBG regulation and obesity development

Cristina Sáez López, Cristina Hernández, Rafael Simó & David Martínez Selva
Vall d'Hebron Research Institute, Barcelona, Spain.

Low plasma SHBG levels in overweight individuals are a biomarker for the metabolic syndrome and are predictive of type 2 diabetes and risk of cardiovascular disease. There are no *in vivo* models to study SHBG expression and regulation during obesity development. The main reason for this is that the obesity-prone rodent models cannot be used to study this issue since rodents unlike humans do not express the *SHBG* gene in their livers. We have developed by crossing the human *SHBG* transgenic mice with the C57BL/ksJ-*db/db* mice, a unique mouse model that expresses the human SHBG and it develops obesity. We have also used a set of human liver biopsies. The results obtained with the SHBG-C57BL/ksJ-*db/db* mouse model have allowed us to determine that the SHBG overexpression in the C57BL/ksJ-*db/db* reduced the body weight gain but did not change the metabolic profile of these mice. Moreover, we elucidated the molecular mechanisms and transcription factors causing the SHBG down-regulation during obesity development, which involved changes in liver hepatocyte nuclear factor 4 alpha (HNF4α) and peroxisome proliferator-activated receptor gamma (PPARγ) mRNA and protein levels. Furthermore, these results were confirmed using human liver biopsies. Finally, obese mice had reduced plasma SHBG and total and free testosterone levels when compared to lean mice. We have created the first mouse model that resembles what occurs in human obese subjects in terms of SHBG expression and regulation as well as the reduction of total and free testosterone levels. Future research using this unique mouse model will determine the role of SHBG in the development and progression of obesity, type 2 diabetes or fatty liver disease.

Adiponectin deletion impairs insulin signalling in insulin-sensitive but not insulin-resistant 3T3-L1 adipocytes

Cheol-Young Park[1], Eugene Chang[2] & Sungrae Kim[3]
[1]Kangbuk Samsung Hospital, Sungkyunkwan University, Seoul, Republic of Korea; [2]Ewha Womans University, Seoul, Republic of Korea; [3]Bucheon St. Mary's Hospital, Bucheon, Republic of Korea.

Aims
Previous reports have demonstrated that the adipocyte-derived peptide adiponectin is closely associated with insulin resistance due to its insulin-sensitizing and anti-inflammatory properties in peripheral tissues; however the autocrine effects of adiponectin remain elusive. This study investigated regulatory effects of adiponectin on glucose transport and insulin signalling in insulin-sensitive or insulin-resistant 3T3-L1 adipocytes.
Methods
3T3-L1 fibroblasts were transfected with non-target or adiponectin (ADN) siRNA and differentiated. Chronic treatment with insulin (24 h, 100 nM) was employed to induce insulin resistance in differentiated adipocytes. Insulin-stimulated glucose transport was measured and protein and mRNA levels were assessed by western blot and RT-PCR.
Results
Prolonged incubation with insulin significantly reduced insulin-stimulated glucose uptake, suggesting the development of insulin resistance and adiponectin mRNA expression. In this insulin-resistant condition, adiponectin deletion did not alter insulin-stimulated glucose uptake. In insulin-sensitive adipocytes, adiponectin ablation reduced insulin-stimulated glucose uptake, expression of IRS-1 and GLUT4, and GLUT4 translocation to the membrane. Adiponectin knockdown did not affect the activation of AKT and p38MAPK (phosphorylation form/total form), but significantly decreased the activation of AMPK in insulin-responsive adipocytes.
Conclusion
Adiponectin deficiency suppresses insulin-induced glucose uptake, insulin signalling, and the AMPK pathway only in insulin-responsive 3T3-L1 adipocytes.

Who is the Belarusian citizen seeking for losing weight?!

Veranika Labashova, Alla Shepelkevich, Julia Dydyshko & Veranika Dovgalo
Belarusian State Medical University, Minsk, Belarus.

Backgrounds and aim
Millions of people all over the world are in a search for the perfect weight loss plan. The aim of our research was to make a typical portrait of a Belarusian citizen who is trying to lose weight.
Methods
Participants were individuals ($n=70$) who were screened for a behavioral weight-loss treatment program. The majority of patients were women (88.4%). The mean age was 46.56+9.43 years. Among the participants three of 70 persons had normal BMI but felt themselves fat, 13 patients were overweight and 53 were obese (23 persons had BMI 30–34.9 kg/m^2; 14 persons – BMI 35.0–39.9 kg/m^2; and 17 persons BMI >40 kg/m^2). We analyzed the anamnesis of obesity, eating habits, physical activity, and comorbidity of the participants.
Results
We revealed that 18 of 67 participants (26.8%) had the excess weight from childhood, 17% of women become overweight after delivery. 41 of 67 persons (61.2%) had obese relatives on the maternal line, 28 of 67 persons (41.8%) on the paternal line. Among the participants 17 of 67 participants (25.3%) had hypertension and cardiovascular diseases, four of 67 (6%) registered hyperglycemia, 22.3% osteoarthritis. The majority of patients 52.2% made attempts to lose weight earlier; 47.7% of the participants follow unproven dieting advices; 19.4% used supplements and diet pills. The analyses of the eating habits revealed that 37.3% follow the starvation diet, 31.3% of participants were breakfast skippers. Physical activity <30 min five times per week was registered in 65.6% cases. The episodes of night eating described 8.9% participants. 13.4% of respondents felt teasing and social rejection.
Conclusion
Thus the typical obese Belarusian patient looking for losing weight is a women of 46.5 years old, who often had a severe anamnesis of obesity, series of comorbities, and disordered eating patterns.

Long-term glucocorticoid concentrations as a risk factor for childhood obesity and adverse body fat distribution

Gerard Noppe[1,2], Erica L T van den Akker[2], Yolanda B de Rijke[3], Jan W Koper[1], Vincent W Jaddoe[4] & Elisabeth F C van Rossum[1]
[1]Department of Endocrinology, Erasmus MC, University Medical Center Rotterdam, Rotterdam, The Netherlands; [2]Department of Pediatrics, Sophia Erasmus MC, Children's Hospital, University Medical Center Rotterdam, Rotterdam, The Netherlands; [3]Department of Clinical Chemistry, Erasmus MC, University Medical Center Rotterdam, Rotterdam, The Netherlands; [4]Department of Epidemiology, Erasmus MC, University Medical Center Rotterdam, Rotterdam, The Netherlands.

Background
Childhood obesity is an increasing health problem, affecting over 40 million children aged 0–5 years worldwide. It is associated with premature onset of diabetes and cardiovascular disease in adulthood. Pathologically elevated cortisol is known to induce obesity and cardio-metabolic complications, suggesting cortisol is implicated in the onset of obesity. Indeed, recent pilot-studies showed an increase in hair cortisol concentrations in obese adults and adolescents. Additionally, polymorphisms in the glucocorticoid receptor (GR) gene increasing glucocorticoid (GC) sensitivity have been associated with metabolically adverse body composition.
Aim
To explore the role of GCs in the onset of obesity, we studied the associations of long-term GC exposure and genetically determined GC sensitivity with obesity and body fat distribution in children.
Methods
Average cortisol and cortisone concentrations over a 3-month period were measured by LC–MS/MS in scalp hair of 3019 6-year-old children participating in the Generation R study, a population-based cohort-study. Four polymorphisms (GR-9Beta, ER22-23EK, N363S, Bcl1) in the *GR* gene affecting GC sensitivity were genotyped. Anthropometrics were measured and DEXA scans were performed. World Obesity Federation criteria for weight-cutoffs were used.
Results
A total of 4.3% of the children were obese and 13.4% overweight. Long-term cortisol concentrations were associated with obesity (OR 10.3, $P<0.001$) and overweight (OR 1.5, $P<0.05$). Cortisone showed the same trend for obesity (OR 2.1, $P<0.05$), and overweight (OR 1.4, $P=0.08$). Cortisol and cortisone showed a positive linear association with BMI ($P<0.001$ and $P<0.01$), fat mass index (kg/height^2) ($P<0.01$ and $P<0.001$) and android/gynecoid fat mass ratio ($P=0.04$ and $P<0.001$). Fat mass index was increased in homozygous Bcl1− carriers ($P=0.03$). We found no effects of other polymorphisms.
Conclusion
Long-term GC levels are strongly associated with an increased risk of childhood obesity, and show linear associations with adverse fat distribution. The contribution of GR gene polymorphisms to body composition at the age of 6 years seems limited.

From genome to gene: genes and genetic variations to be associated with metabolic syndrome

Maryam Daneshpour[1], Bahareh Sedaghati Khayat[1], Mehdi Hedayati[1] & Fereidoun Azizi[2]
[1]Research Institute for Endocrine Sciences, Cellular and Molecular Endocrine Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Research Institute for Endocrine Sciences, Endocrine Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran.

Introduction
The prevalence of non-communicable disorders such as metabolic syndrome (MetS) is high in developing countries. MetS is a disorder of energy utilisation and storage, diagnosed by a co-occurrence of three out of five of the following medical conditions: abdominal (central) obesity, elevated blood pressure, elevated fasting plasma glucose, high serum triglycerides, and low HDL cholesterol levels. The present review aims to discover the genetic variant reported in association with MetS.
Method and materials
The database for genotypes and phenotypes (dbGaP) and the database for genetic associations and human genome (HuGE navigator) were utilised in order to search for genes and their corresponding polymorphisms related to MetS. Additionally, an electronic literature search for other Iranian studies and the genetic aspect of TLGS was completed using PubMed.
Results
For phenotype selection in PheGenI, 30 traits were chosen and after the analysis, 21 of them were in common results with MetS. After finding the common variation between traits and MetS, omitting the repeated SNPs, 173 variations were remained. Finally, results distinguished six of the most important genetic regions found to have strong association with MetS.
Conclusion
Identifying major genes that are responsible for the MetS may improve the medical care for treating individuals with MetS, and eventually may lead to personalised medicine in which treatment is tailored genetically to the patient's needs. The present candidate regions is a respectable start to replicate genetic studies in large affected Iranian individual which we hope leads us to improve our medical care in this field.

Audit of metabolic profiles in women with Turner syndrome

Ma Pyeh Kyithar & Siobhán McQuaid
Endocrinology Department, Mater Misericordiae University Hospital, Dublin, Ireland.

Introduction
Adults with Turner syndrome (TS) are at increased risk of cardiovascular morbidity and mortality. The aim of this study was to evaluate the compliance

with clinical guidelines (Bondy 2007) in measuring metabolic profiles in adults with TS.
Methods
Case notes of patients attending a dedicated TS clinic were studied. Variables assessed included anthropometric measurements, blood pressure (BP), fasting plasma glucose (FPG), HbA1c, fasting lipid profile, and thyroid function.
Results
Of 40 women with TS (mean age 35.9 years (18–56 years)), karyotyping was available on 70%: 17.5% had monosomy (45,X); 52.5% had other X chromosome abnormalities (mosaic 45,X/46,XX, ring X chromosome, isochromosome Xq, deletions Xp, and other structural abnormality of Y chromosome). Anthropometric and BP measurements were performed in all patients. FPG, HbA1c, fasting lipid profile, and thyroid function were measured in 90, 82, 92.5, and 100% of women respectively. 27.5% were overweight and 35% were obese. 10% had impaired glucose tolerance and 7.5% had type 2 diabetes mellitus. 67.5% had LDL-cholesterol between 2.5 and 4 mmol/l and 7.5% had LDL-cholesterol more than 4 mmol/l. 15% had triglycerides level between 1.7 and 2.3 mmol/l and 5% had triglycerides more than 2.3 mmol/l. 27.5% were on antihypertensive medications.17.5% were on cholesterol-lowering medications. 40% had primary hypothyroidism on L-thyroxine replacement. Systolic BP was significantly higher in monosomy group than those with other X chromosome abnormalities (128 ± 7 mmHg vs 117 ± 12 mmHg, $P = 0.034$). There were no significant differences in age, BMI, diastolic BP, HbA1c, lipid profiles, use of cholesterol-lowering medications or HRT between women with monosomy and those with other X chromosome abnormalities.
Conclusion
Service evaluation reveals good performance in measuring metabolic parameters in women with TS. Overweight/obesity, hypertension, and dyslipidaemia are common in our group of patients. Ongoing efforts are aimed at improving these cardiovascular risk factors.

Metabolic syndrome and cardiovascular risk in frail elderly people

Olga Vasovic[1], Katarina Lalic[2,4], Danijela Trifunovic[3,4], Zvezdana Jemuovic[2] & Marina Nikolic Djurovic[2,4]
[1]Institute for Gerontology and Palliative Care, Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes and Metabolism, Clinical Center of Serbia, Belgrade, Serbia; [3]Clinic for Cardiology, Clinical Center of Serbia, Belgrade, Serbia; [4]Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction
Objective of this study was to examine the importance of metabolic syndrome (MetS) as a predictor of cardiovascular mortality in frail elderly people.
Methods
Participants of the study were 253 community dwelling elderly aged 65–99 years. It was a prospective study with 32 months follow-up period. Patients were divided into four main groups according to the presence of MetS and prior major cardiovascular event (MACE): group A – patients without MetS and without MACE – the control group; group B – patients with MetS, without MACE; group C – patients without MetS, with MACE; and group D – patients with MetS and with MACE. We used Cox proportional hazards regression model for survival analysis. The results are presented as relative risk (RR) and 95% CI. Statistically significant differences were $P < 0.05$.
Results
The baseline mean age of participants was 82 years (78.3% women) (53.8% had prior MACE. During the study 109 patients (43.1%) died from cardiovascular cause of death. In our patients there was no statistically significant difference between four groups in functional ability, smoking habits and presence of hypertension. Women were more represented in groups with MetS compared with groups without MetS. Control group was statistically older than group D only. The best survival was in group B (75.9%), and the worst in group C (43.8%). Comparing to group B, participants in group C have almost three times higher risk for cardiovascular mortality (RR 2.978; 95% CI: 1.605–5.523; $P = 0.001$), whereas participants in group D have 2.5 times higher cardiovascular mortality risk (RR 2.457; 95% CI: 1.273–4.744; $P = 0.01$). Comparing to group A (the control group), only group C have statistically higher mortality rate (RR 1.894; 95% CI: 1.145–3.131; $P = 0.01$).
Conclusion
In our study, presence of prior MACE, but not the presence of MetS raises risk for cardiovascular mortality in frail elderly people.

Investigation of the transient receptor potential channel gene expressions in metabolic syndrome

Suzan Tabur[1], Serdar Oztuzcu[1], Irfan Veysel Duzen[2], Ayten Eraydin[1], Mesut Ozkaya[1] & Abdullah Tuncay Demiryurek[1]
[1]Gaziantep University, Gaziantep, Sahinbey, Turkey; [2]25 Aralik State Hospital, Gaziantep, Sehitkamil, Turkey.

Introduction
Metabolic syndrome (MetS) is correlated with increased cardiovascular risk and characterized by several factors, including visceral obesity, hypertension, dyslipidemia, and insulin resistance. Several members of a large family of nonselective cation channels, e.g., transient receptor potential (TRP) channels, have been associated with the development of cardiovascular diseases. Thus, changes of TRP channel expression may account for the observed increased cardiovascular risk in MetS patients. The aim of this study was to investigate the possible contribution of TRP channel gene expressions in MetS.
Methods
A total of 54 patients with obesity-related MetS, and 41 healthy control subjects with similar age and sex were included to this study. mRNA from blood samples was extracted, and real-time PCR on the BioMark HD dynamic array system (Fluidigm, South San Francisco, CA, USA) was performed for the TRP channel gene expressions. For calculation of the significance of differences in gene expressions, the Mann–Whitney *U* test was used.
Results
We observed marked decreases in *TRPC1, TRPC3, TRPM2, TRPM5, TRPV4, TRPV5, TRPV6, MCOLN2* (*TRPML2*), and *MCOLN3* (*TRPML3*) gene expressions in MetS ($P < 0.05$). However, there was an augmentation in *TRPC6* gene expression ($P < 0.05$). No significant changes in expressions were found with *TRPA1, TRPC4, TRPC5, TRPC7, TRPM1, TRPM3, TRPM4, TRPM6, TRPM7, TRPM8, TRPV1, TRPV2, TRPV3, MCOLN1* (*TRPML1*), and *PKD2* (*TRPP2*) genes in MetS patients ($P > 0.05$).
Conclusion
This study revealed that there is a statistically significant relationship between TRP channels gene expressions and MetS. Our data showed that TRP channel gene expressions may contribute to the pathology of MetS.

Linking temperature to metabolism: the role of brown adipose tissue in humans

Jenny Backhaus, Leonie Rademacher, Alexander Iwen, Maren Waltl, Melanie Noll, Hendrik Lehnert & Sebastian M Schmid
Department of Internal Medicine 1, Lübeck, Schleswig-Holstein, Germany.

The increasing prevalence of obesity is paralleled by related metabolic disorders such as insulin resistance and type 2 diabetes mellitus (T2DM). Extensive efforts across disciplines are made to reveal underlying mechanisms and develop effective therapies against obesity and its comorbidities. Since PET–CT studies provided evidence for functional brown adipose tissue (BAT) in adult humans, this specialized thermogenic compartment of adipocytes is in the focus of current research. Activated by moderate cold BAT utilises significant amounts of carbohydrates and fatty acids as substrates for heat production, thereby contributing to whole-body energy homeostasis. Beneficial metabolic effects of BAT activation lipid metabolism have been shown in mice and men. Here we assessed glucose homeostasis by Botnia clamping during cold-induced BAT activation in 15 healthy normal-weight men. Botnia clamp experiments combine an intravenous glucose tolerance test with a subsequent hyperinsulinaemic–euglycaemic clamp thereby allowing measurement of pancreatic β-cell capacity and peripheral insulin sensitivity within one session. BAT activation induced a highly significant 20% increase in glucose uptake due to improved insulin sensitivity while β-cell capacity remained unchanged as compared to thermoneutral conditions. Interestingly, resting energy expenditure and pituitary–thyroid axis activity as possible pathways linking BAT activation and glucose homeostasis were not affected during BAT activation. Although, underlying molecular mechanisms remain to be established in follow-up studies, these findings clearly highlight the metabolic significance of BAT activation in men and therefore might be a promising target for novel treatment approaches in obesity and T2DM.

C-reactive protein assay in obese paediatric patients: comparison of two laboratory methods

José Alves, Marta Manaças, Carolina Faria, Lia Filipe, Susana Silva & Helena Proença
Centro Hospitalar Lisboa Norte, Hospital de Santa Maria, Lisbon, Portugal.

Introduction
Obesity as a pro-inflammatory state is associated to increased levels of C-reactive protein (CRP). CPR is considered as a cardiovascular (CV) risk independent marker and is being researched as a predictive atherosclerosis biomarker in obese children. The American Heart Association (AHA) recommends a three classes approach when aiming at CV risk stratification (low <1.0 mg/l; moderate 1.0–3.0 mg/l; and high >3.0 mg/l). These classes were extrapolated to the paediatric aged patients.
Objective
Compare the performance of two different CPR assays, using blood samples from an obese paediatric population.
Methods
79 patients were enrolled (convenience sample) (ages 12–17). Serum CPR levels were simultaneously assayed using two distinct analytical methods: Classic wide rage CPR assay (wrCPR Siemens Latex enhanced immunoturbidimetry; ADVIA 2400; CMD = 0.03 mg/l normalization: CRM 470 IFCC), and high sensitivity PCR (CardioPhase hsCRP Siemens BNproSpec Siemens CMD = 0.175 mg/l). SPSS 20V Software was used for statistical analysis.
Results
The correlation coefficient ($R=0.9971$) ($P<0.001$) (Pearson's test) showed a very strong positive correlation between the two assays ($y=1.26x-0.34$). The Bland–Altman dispersion plot, pointed that the inter assay (absolute (AD) and percentual (PD)) differences were in 95% CI (except one outlier (>10 mg/l) (AD) and the six lowest pairs (PD)). PCR values of both assays were stratified according to AHA CV risk classes (72 pairs (91.14%) were grouped in the same class, including the aforementioned six lowest pairs). The Fleiss' test ($\kappa=0.858$) ($P<0.001$) showed a very strong AHA class agreement of both assays.
Conclusion
A strong correlation and agreement has been shown between the two assays.

Does IGF influence the prognosis 10 months after myocardial infarction?

Yücel Yılmaz[1], Fatih Tanrıverdi[2] & Mustafa Altay[3]
[1]Department of Cardiology, Kayseri Education and Research Hospital, Kayseri, Turkey; [2]Faculty of Medicine, Erciyes University, Kayseri, Turkey; [3]Department of Endocrinology and Metabolism, Keçiören Education and Research Hospital, Ankara, Turkey.

Introduction
We investigated the levels of IGF1 in acute myocardial infarction (AMI) and sought to determine whether a decrease might influence the long-term prognosis.
Material and methods
Sixty-five patients who were admitted to our hospital with AMI were included in the study along with 26 other patients without coronary artery disease (CAD) who served as the control group. Fasting blood samples of all of the patients with AMI were obtained at the hospital and ~10 months later in order to evaluate their IGF1 and IGF-binding protein 3 (IGFBP3) levels.
Results
In the patients with AMI, the IGF1 levels were higher than in the control group ($P=0.002$). At the 10th month, the levels of IGFBP3 were significantly higher, and the IGF1 levels were higher but were not more significant than those in the control group ($P=0.006$ and $P=0.05$ respectively). When we compared the 10-month and baseline values, the levels of IGFBP3 were significantly higher at 10 months. In addition, the IGF1 levels were lower but did not achieve significance at 10 months ($P=0.04$) or at the time baseline measurements were taken ($P=0.06$). Furthermore, no significant differences were found between the patients with low or high IGF1 and IGFBP3 levels at the two different time periods when they were compared in terms of cardiac events.
Conclusion
At the 10-month follow-up after AMI, the serum total IGF1 and IGFBP3 levels were still high, and no correlations existed between the IGF1 and IGFBP3 levels and cardiac events.

EP613

Association between the transient receptor potential channel gene polymorphisms and metabolic syndrome

Suzan Tabur[1], Serdar Oztuzcu[1], Irfan Veysel Duzen[2], Sercan Ergun[1] & Mesut Ozkaya[1]
[1]Gaziantep University, Gaziantep, Sahinbey, Turkey; [2]25 Aralik State Hospital, Gaziantep, Sehitkamil, Turkey.

Introduction
Metabolic syndrome (MetS) is characterised by a combination of visceral obesity, hypertension, insulin resistance, dyslipidemia, and impaired glucose tolerance. It is a prominent risk factor for cardiovascular morbidity and mortality. The etiology of MetS is complex. The progression of MetS is influenced by genetic susceptibility and environmental factors. The aim of this study was to investigate a possible association between transient receptor potential (TRP) channels gene polymorphisms and MetS in a Turkish population.
Methods
A total of 142 patients with obesity-related MetS and 166 healthy controls with similar age and sex were enrolled to this study. Genomic DNA from the participants was analyzed by a BioMark 96.96 dynamic array system (Fluidigm, South San Francisco, CA, USA). For calculation of the significance of differences in genotype and allele frequencies, the χ^2 test or Fisher's exact test was used. A P value of <0.002 (0.05/25) was considered statistically significant after Bonferroni's correction for multiple testing.
Results
There was an increase in A allele (64.6% in patients vs 49.5% in controls) and decrease in G allele frequencies (35.4% in patients vs 50.5% in control, $P=0.0019$) of the *TRPM5* gene rs4929982 (Arg578Gln) polymorphism. We also observed that the distribution of genotype and allele frequencies of the *TRPM8* gene rs12472151 in MetS patients were significantly different from controls ($P<0.0001$). However, no associations were found with the other 23 polymorphisms studied.
Conclusion
In conclusion, to the best of our knowledge, the present case–control study is the first to examine the potential involvement of TRP channel gene variations in the risk of incident MetS. Our data showed that genetic polymorphisms in *TRPM5* and *TRPM8* genes may modify individual susceptibility to MetS in the Turkish population.

Effects of omega-3 fatty acid on pre- and post-prandial triglyceride and metabolic parameters with standard meals in patients with hypertriglyceridemia: open, multicentre study

Won Jun Kim[1], Sangmo Hong[2], Jun Goo Kang[3] & Chang Beom Lee[2]
[1]Department of Endocrinology and Metabolism, Gangneung Asan Hospital, University of Ulsan College of Medicine, Gangneung, Republic of Korea; [2]Department of Endocrinology and Metabolism, Hanyang Guri Hospital, University of Hanyang College of Medicine, Guri, Republic of Korea; [3]Department of Endocrinology and Metabolism, Hallym University Sacred Heart Hospital, Hallym University School of Medicine, Pyungchon, Republic of Korea.

Introduction
Nonfasting duration is much longer than fasting time in a day. Although there is a few reports on the importance of postprandial triacylglycerol (TG) on cardiovascular outcome, TG variation after meal is one of main obstacle of clinical trial. The purpose of this study is to determine effects of a 6-week period of omega-3 fatty acid supplementation on fasting and postprandial TG and metabolic parameters in response to standard test meals.
Methods
The study population included 26 patients with hypertriglyceridaemia ($\geq$200 mg/dl). They were educated and randomly allocated to treatment group by omega-3 fatty acid supplementation (Omacor, 2 g/day) or control group, and followed-up for 6 weeks in three hospitals. At days 1 and 42 visit, fasting and postprandial-3 h data were obtained respectively, before and after standard meals with 710 kcal.
Results
In intragroup analysis, treatment group with omega-3 fatty acids showed significant decrease on fasting TG (258.2 mg/dl vs 254.2 mg/dl, $P=0.046$) and especially post-prandial TG (357.3 mg/dl vs 277.2 mg/dl, $P=0.033$), while control group showed no significant difference during follow-up (271.2 mg/dl vs 255.1 mg/dl, $P=0.790$ for fasting TG and 343.7 mg/dl vs 324.7 mg/dl for post-prandial TG). However, in intergroup analysis, there was no significant difference between two groups in fasting and post-prandial TG (% change: $P=0.287$ and 0.303 respectively). There was no significant improvement in other lipid profiles. No significant adverse events were registered during this study.
Conclusion
The omega-3 fatty acids achieved a significant reduction of fasting and post-prandial triglycerides without adverse reactions. Because the trend of improvement in post-prandial TG appeared in the treatment group than control group, further study including more subjects will be needed.

Neutrophil to lymphocyte ratio: relationship with anthropometric and metabolic parameters in morbidly obese patients

Cristina Serbanescu[1], Liliana Topor[1], Ivona Gheorghe-Fronea[1], Alexandra Nila[1], Anca Sirbu[1,2] & Simona Fica[1,2]
[1]Elias Emergency University Hospital, Bucharest, Romania; [2]University of Medicine and Pharmacy 'Carol Davila', Bucharest, Romania.

Introduction
Obesity is generally associated with a chronic state of subclinical inflammation. The assessment of the inflammatory status is routinely made by measuring circulating levels of nonspecific proinflammatory markers. Neutrophil to lymphocyte ratio (NRL) is a new simple inflammatory marker which can be reliable in evaluating the inflammatory status occurring in morbidly obese patients. The aim of this study was to investigate the relationship between NLR as an index of chronic inflammation and anthropometric and metabolic parameters in a group of morbidly obese patients.
Patients and methods
Our study included 415 patients (130 men) with severe obesity (mean BMI$=45.46\pm8.68$ kg/m^2, mean age$=41.31\pm11.33$ years), who were evaluated clinically (medical history, anthropometrics, and blood pressure measurements) and biologically (blood count, complete metabolic tests, and leptin level) in a research program for bariatric surgery.
Results
NLR was significantly higher in women (2.33 ± 0.95 vs 2.09 ± 0.87, $P<0.05$) and in non-smokers (2.35 ± 1.01 vs 2.14 ± 0.81, $P<0.05$). After adjusting for gender and smoking status, NLR positively correlated with BMI ($r=0.132$, $P<0.01$) waist circumference ($r=0.225$, $P<0.001$), and waist/height ratio ($r=0.203$, $P<0.001$), as well as with systolic blood pressure ($r=0.136$, $P<0.05$), serum C-reactive protein ($r=0.170$, $P<0.001$), HOMA-IR ($r=0.121$, $P<0.05$), and serum leptin level ($r=0.172$, $P<0.01$). In a linear regression analysis, with NLR as dependent variable and factors previously shown to significantly correlate to its level as independent variables, gender, BMI, and systolic blood pressure remained independently associated with NLR.
Conclusions
Gender, systolic blood pressure, and adiposity level are independent determinants of NLR in severely obese patients. Further studies are needed to elucidate the association of this parameter with obesity complications and prognosis.

A low glycaemic index, low glycaemic load snack based on stevia and fortified with vitamin D, improves metabolic/hormonal profile, and compliance in normal subjects and prediabetics; results from a 4 months, controlled trial

Sarantis Livadas, Antonia Dastamani, Charikleia Stefanaki, Emily Mantzou, Areti Painesi, Eleni Papanikolaou & George Chrousos
Endocrine Unit, Evgenidion Hospital, University of Athens Medical School, Athens, Greece.

Introduction
Half of subjects following a low-calorie dietary program cannot tolerate its nutritional restrictions and abandon it. A realistic approach to overcome this obstacle is the addition of low glycaemic index (GI), low glycaemic load (GL) snacks in their nutrition. Stevia, a potent, low calorie natural sweetener exerts anti-hyperglycaemic and insulinotropic activities. Furthermore, Vitamin D deficiency may affect diabetes development in the long run.
Aim
To assess a new bioactive, low GI/ low GL product, based on stevia glycosides and fortified with vitamins A and D, regarding metabolic/hormonal profile and the compliance of subjects undergoing a hypocaloric nutritional approach.
Methods
A 4-month controlled, prospective trial in healthy subjects ($n=80$) and prediabetics ($n=39$). 119 overweight/obese subjects were enrolled and given the same hypocaloric nutritional approach and the choice of either a stevia snack consumption (4/week, $n=60$) or the consumption of a personal choice dessert (1/week, $n=59$).
Results
In all groups, a significant weight loss was observed ($P<0.05$). In healthy subjects waist circumference, insulin, and HOMA index were significantly improved, irrespectively of the method of intervention ($P<0.05$). In prediabetics, insulin, HbA1c, HOMA index, CRP, and vitamin D levels were ameliorated only in the stevia group. The attrition rate was similar between groups ($\sim$8%), but the majority of the stevia group suggested that they preferred this approach.
Conclusions
The consumption of low GI, low GL snacks based on stevia and fortified with vitamin D, increases compliance in subjects following a nutritional programme and exerts a beneficial role on the metabolic/hormonal profile of people with prediabetes.

Intima–media thickness measurement of the carotid artery in patients with primary hyperparathyroidism

Dilek Tuzun, Ayten Oguz[1], Murat Sahin[1], Safa Ersen Ganidagli[2], Didem Atay[2], Hanife Bolat[2], Cansu Yilmaz Cabioglu[2], Ahmet Celik[3] & Kamile Gul[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [2]Department of Internal Medicine, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [3]Department of Biochemistry, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey.

Aim
The intima–media thickness (IMT) measurement of the common carotid artery is recognised as an important marker of systemic atherosclerosis. It may be useful in

predicting the cardiovascular events, since it is related to the severity of coronary artery disease. The aims of this study were to analyse whether correlations exist between the IMT of the common carotid artery and the main clinical and biochemical parameters in patients with primary hyperparathyroidism (PHPT).
Patients and methods
Thirty patients with biochemically confirmed PHPT (group A, cases), 26 patients (group B, control group who have DM and/or HT), and 24 healthy volunteers (group C, healthy controls) were prospectively enrolled in the study. All patients underwent ultrasound examination and the IMT of each carotid artery were recorded.
Results
The final pathology showed a solitary parathyroid adenoma in all cases. Age, sex, mean IMT, and biochemical parameters, except serum calcium and PTH, did not differ significantly between groups (Table 1). But IMT is higher than case group compared to the other groups. But it was not statistically significant ($P=0.05$). In group A, DM and/or HT rate was 37.5% while 32.5% in group B and 0% in group C. There was positive significant correlation between serum calcium and IMT ($r=324$, $P=0.003$). But there was no correlation between IMT and serum parathyroid hormone and or serum phosphate.

Table 1 Main clinical and biochemical parameters of groups.

	Group A	Group B	Group C	*P*
Age (years)	49.07±12.95	53.85±5.98	47.75±6.08	0.05
Sex (female/male) (*n*)	24/6	24/2	20/4	0.421
Ca (mg/dl)	11.45±1.04	8.88±0.44	9.02±0.43	<0.001
P (mg/dl)	2.76±0.48	2.96±0.16	2.94±0.13	0.05
PTH (pg/ml)	229.98±182.84	41.38±3.62	42.87±2.67	<0.001
IMT (mm)	0.83±0.14	0.76±0.19	0.72±0.51	0.05

Group A, cases; group B, controls with DM and/or HT; group C, healthy controls; PTH, parathyroid hormone; IMT, intima–media thickness of the common carotid artery.

Conclusion
Several cardiovascular risk factors have been reported in patients with PHPT since both calcium and PTH are related to heart function. Our results suggest that hypercalcaemia may represent a risk of carotid atherosclerosis in patients with PHPT.

Impact of laparoscopic gastric bypass and sleeve gastrectomy on anti-hyperglycaemic medication use in pre-existing type 2 diabetes mellitus

Seamus O'Boyle, Hayder Shabana, Colm O'Boyle & Eoin O'Sullivan
Bon Secours Hospital, Cork, Ireland.

The beneficial effects of metabolic surgery on clinical and biochemical parameters in patients with type 2 diabetes are well-described. Laparoscopic sleeve gastrectomy has more recently gained recognition as an effective form of surgery along with laparoscopic gastric bypass. We wished to evaluate the impact on anti-hyperglycaemic medication use and glycaemic control in patients with pre-existing diabetes undergoing surgery by a single surgeon in the country's highest volume metabolic surgery unit. Between 2008 and 2013, 74 (28%) of 264 (176 gastric bypass and 88 sleeve gastrectomy) patients who underwent surgery had pre-existing diabetes. Mean duration of diabetes was 36 (1–240) months. Forty-six (62%) were female with median age 51 (33–75) years. Pre-operatively, 14 were diet controlled, 50 were on oral hypoglycaemic agents and a further ten were treated with insulin. Mean BMI and HbA1c pre-operatively were 48.6 (±7.0) kg/m^2 and 62.9 (±18.2) mmol/mol respectively. At a 12-month minimum post-operative follow-up, BMI had fallen to 34.0±6.3 kg/m^2 ($P<0.001$) and HbA1c to 45.3±11.7 mmol/mol ($P<0.001$). Of the 50 patients taking oral medications pre-operatively, 40 were able to discontinue all medications, and of the ten on insulin pre-operatively, seven no longer needed insulin therapy.
Our findings from the largest surgical Irish centre are in keeping with similar published international data and again demonstrate the positive benefit which may be seen in patients with diabetes undergoing metabolic surgery.

Steroid hormones related to 11β-hydroxysteroid dehydrogenase in obese adolescents and non-obese controls

Ludmila Macova, Hana Zamrazilova, Barbora Sedlackova & Martin Hill
Institute of Endocrinology, Prague, Czech Republic.

Introduction
Elevated activity and expression of 11beta-hydroxysteroid dehydrogenase type 1 (11β-HSD1) are associated with the development of obesity and metabolic syndrome. This enzyme is responsible for majority of the extra-adrenal production of glucocorticoids. It regenerates active cortisol from biologically inactive cortisone. Human 11β-HSD1 also reversibly catalyzes the interconversion of 7α-hydroxy- and 7β-hydroxy-DHEA into 7-oxo-DHEA. In order to examine the role of 11β-HSD1 in human obesity, we followed the circulating levels of steroids related to 11β-HSD1 in obese patients and non-obese controls.
Methods/design
The cohort of 282 obese adolescents, 154 girls (median age 15.31, range 14.17–16.68 years) and 128 boys (median age 14.95, range 13.87–16.16 years), BMI >90th percentile and the cohort of 100 normostenic controls including 50 girls (median age 15.29, range 14.32–16.79 years) and 50 boys (median age 15.29, range 14.47–16.77 years), BMI 25th–75th percentiles were examined. Circulating levels of cortisol, cortisone, DHEA, 7-oxo-, 7α-hydroxy-, 7β-hydroxy-, and 16α-hydroxy-DHEA were analysed by liquid chromatography-tandem mass spectrometry method.
Results
We found significantly increased levels of cortisone in obese subjects, while cortisol levels did not differ between obese and normostenic adolescents. Higher circulating levels of DHEA in obese girls, higher 7β-hydroxy-DHEA in both sexes, higher 7-oxo-DHEA in obese boys and reduced levels of 16α-hydroxy-DHEA in obese girls were observed. While the absolute levels of circulating 7α-hydroxy-DHEA did not differ between examined groups, the 7α-hydroxy-DHEA/DHEA ratio was significantly lower in obese subjects suggesting reduced 7α-hydroxylation in obesity.
Conclusion
Our findings support a role of 11β-HSD1 as well as derivatives of DHEA in the control of human metabolism.

Liraglutide improves surfactant protein-B production and reduces right ventricular hypertrophy in a rat model of intersitial pulmonary fibrosis

Juan Fandiño Gómez[1,2], Marina Romaní Pérez[3], Verónica Outeiriño Iglesias[1,2], Yolanda Diz Chaves[1,2], María González Núñez[1,2], Houcine Dab[4], Eva MaríaVigo Gago[1,2], Lucas González Matías[1,2] & Federico Mallo Ferrer[1,2]
[1]Faculty of Biology, University of Vigo, Vigo, Pontevedra, Spain; [2]Group of Endocrinology and Neurophysiology, Biomedical Research Center (CINBIO), University of Vigo, Vigo, Pontevedra, Spain; [3]Nutrineuro, University of Bordeaux, INRA, Bordeaux, Aquitaine, France; [4]Higher Institute of Applied Biology Medenine (ISBAM), University of Gabes, Medenine, Tunisia.

Idiopathic pulmonary fibrosis (IPF) is a chronic, progressive and fatal lung disease characterized by excessive matrix deposition that disrupts the normal alveolar architecture and lung physiology. Glucagon-like peptide 1 (GLP1) is a gut-produced hormone with insulinotropic effects. GLP1 receptor is expressed in the lung where it is implicated in the synthesis of the protein (SPs) and lipid fractions of the surfactant. We have previously shown that the GLP1 receptor agonist, liraglutide (LIR), is able to restore surfactant protein-B (SP-B, a limiting factor for survival) production and right ventricular hypertrophy in streptozotocin-diabetic rats. The aim of this work was to study the effects of the GLP-1 receptor agonist liraglutide in the production of SPs, fibrosis indicators and right ventricle mass in a rat model of IPF. IPF was induced in rats by the single intratracheal instillation of bleomycin (BLM, 2.5 mg/kg). From day 10 rats were treated with liraglutide (100 μg/kg per 12 h s.c.), once overwhelmed the acute inflammatory phase, and then they were sacrificed in day 21. Heart ventricles and lungs were isolated, weighted, and frozen. The expression levels of SP-B, thyroid

transcription factor 1 (TTF1, a transcription factor for SP-B) and receptors for GLP1 and leptin were lower in lungs of BLM-treated rats; but their levels were restored by liraglutide treatment. The right ventricle weight was also augmented in BLM-treated rats and liraglutide administration partially restored right ventricle masses. We have also measured the expression levels of lung fibrosis indicators as collagen type-IαI and connective tissue growth factor (CTGF), which yielded higher levels in BLM-treated animals, but liraglutide did not modified those. In conclusion, we found that liraglutide was able to increasing pulmonary SP-B and partially reverse right ventricular hypertrophy associated to the lung fibrosis induced by BLM, however, it can't improve the interstitial fibrosis once consolidated.

Metabolic syndrome and muscle mass

Nilay Ergen, Aslı Dogruk Unal, Ozlem Cigerli, Hulya Parildar, Ozlem Tarcin, Betul Ugur Altun & Nilgun Guvener Demirag
Baskent University Istanbul Hospital, Istanbul, Turkey.

Objective
Low skeletal muscle mass is an emerging risk factor for metabolic disorders. In this study, we aimed to evaluate the relationships between fat mass, muscle mass, muscle fat mass ratio, total fat mass, and abdominal fat mass ratio by comparing the body compositions in obese women with and without metabolic syndrome.
Methods
Totally 89 obese women (mean ± S.D., age 42.1 ± 12 years, BMI 36.5 ± 4.2%) with newly diagnosed metabolic syndrome (MS, $n=64$, case group) and without metabolic syndrome (NMS, $n=25$, control group) were included into study. Body composition was measured by bioelectrical impedance analysis (BIA). Metabolic syndrome was defined using the International Diabetes Federation 2005 diagnostic criteria.
Results
It was found that subjects with MS had 57.2 ± 13.2 kg muscle mass, 41.2 ± 8.9 kg of fat mass. Their muscle/fat ratio was 1.46 ± 0.49 and total fat/abdominal fat ratio was 1.99 ± 0.25. Subjects without MS had 53.5 ± 8.4 kg of muscle mass 39.2 ± 9.3 kg of fat mass. Their muscle/fat ratio was 1.44 ± 0.42 and total fat/abdominal fat ratio was 1.96 ± 0.37 and there was no statistical significant difference ($P>0.05$). On the other hand subjects who had MS and non-MS, fasting serum insulin and HOMA-IR values were 21.1 ± 11.8 and 11.3 ± 5.5 μU/ml; 5.5 ± 3.5 and 2.7 ± 1.5 μU/ml respectively ($P<0.01$).
Conclusion
There is evidence that reduction in muscle mass and muscle/fat ratio is a risk factor for metabolic syndrome, but we did not find any significant reduction of muscle mass in subjects with MS in this study. This study should be redesigned in larger population to evaluate the meaning of these results. This may be explained by the anabolic effect of increased serum insulin levels in metabolic syndrome patients.

Increased FNDC5 (irisin) expression in subcutaneous adipose tissue in obese patients with type 2 diabetes 1 year after bariatric surgery

Julia Muenzker[1], Alexandra Harger[1], Alexandru Tuca[1], Lisa Lindheim[1], Verena Zachhuber[1], Eva Svehlikova[1], Oana Freisinger[2], Johanna Fruhmann[2], Friedrich Tadler[3], Thomas R Pieber[1] & Barbara Obermayer-Pietsch[1]
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Medical University of Graz, Graz, Austria; [2]Department of Surgery, Medical University of Graz, Graz, Austria; [3]Department of Surgery, Krankenhaus der Elisabethinen, Graz, Austria.

Aim
Gastric bypass surgery improves glycaemic control, but the underlying mechanisms including potential changes in adipoinsular axis are incompletely understood. The aim of this study was to investigate potentially causal or associated alterations in gene expression of adipokines, myokines, and hormones in the subcutaneous and visceral adipose tissue of diabetic and non-diabetic obese subjects before and after gastric bypass.
Material and methods
Biopsy specimens from the subcutaneous adipose tissue of 12 diabetic and 12 non-diabetic patients at and 1 year after gastric bypass were analysed with quantitative real-time PCR for the expression levels of various adipokines, myokines, and hormones such as adiponectin, leptin, irisin (FNDC5), osteocalcin, and osteopontin.
Results
Non-diabetic subjects were found to express significantly higher levels of FNDC5 in the subcutaneous adipose tissue than diabetic subjects before gastric bypass ($P=0.0167$). FNDC5 expression in the subcutaneous adipose tissue of diabetic patients was significantly increased one year after surgery ($P<0.001$). In non-diabetic subjects, there was no significant increase observable ($P=0.158$). The increase in FNDC5 in diabetic subjects correlated with reduction in BMI (Pearson's $r=0.718$, $P=0.009$). No correlation was observed between FNDC5 expression and early insulin response or insulin sensitivity index.
Conclusion
To our knowledge, this is the first study to investigate the role of the novel myokine irisin in bariatric surgery mediated weight loss. The results of this study demonstrate that exercise-independent weight loss increases irisin expression levels in subcutaneous adipose tissue of diabetic subjects.

Relationship between TSH and cortisol levels in euthyroid obese subjects

Neslihan Soysal-Atile[1], Betül Ekiz-Bilir[1], Bülent Bilir[2] & Sonat Dilek Kara[2]
[1]Endocrinology Department, Tekirdag State Hospital, Tekirdag, Turkey; [2]Internal Medicine Department, Namik Kemal University Faculty of Medicine, Tekirdag, Turkey.

Several studies have reported that TSH is positively correlated with obesity, dyslipidaemia, and impaired glucose metabolism even in normal range limits. We aimed to evaluate the TSH levels in a cohort of otherwise healthy obese women without clinical evidence of thyroid dysfunction.
Materials and methods
127 female patients were enrolled in this study. Anthropometric and laboratory measurements were retrospectively analysed. Patients were divided into subgroups according to BMIs.
Results
Groups were age-matched. No statistically significant correlation was found between TSH and BMI, HOMA-IR, triglyseride, HDL, or LDL values. But a significant positive correlation between TSH and cortisol levels was revealed ($P=0.000$). As expected, HOMA-IR and triglyseride values were positively, HDL levels were negatively correlated with BMI ($P<0.05$).
Conclusion
In our euthyroid cohort, we did not found any significant association between plasma TSH levels and obesity. However, the positive relationship between TSH and cortisol is a compelling finding. It's known that overt hypothyroidism is associated with frankly elevated cortisol levels. But our study finding suggested a correlation within normal range limits and requires further investigations in order to better understand the mechanisms involved in the TSH–cortisol relationship.

Levels of advanced glycation end products (AGEs), AGE's receptor (sRAGE) and their relationship with cardiovascular risk factors in newly diagnosed type 2 diabetic patients

Etzabel Villegas-Rodriguez[1], Sergio Solorio-Meza[2], Martha Eugenia Fajardo-Araujo[1], Jaime Uribarri[3], Juan Manuel Malacara[1], Sofia Torres-Graciano[1] & Ma Eugenia Garay-Sevilla[1]
[1]Department of Medical Science, University of Guanajuato, Leon, Gto., Mexico; [2]Instituto Mexicano del Seguro Social, Leon, Gto., Mexico; [3]Department of Medicine, The Mount Sinai Health System, Incahn School of Medicine, Mount Sinai, New York, USA.

Diabetes is associated with a greatly increased risk of cardiovascular disease and the advanced glycation end products (AGEs) and their receptors play an important role in these complications.
Objective
To study the association between AGEs and sRAGE levels with cardiovascular risk factors in obese and non-obese newly diagnosed type 2 diabetic patients.
Material and methods
We conducted a cross-sectional study in subjects with type 2 diabetes mellitus of recent diagnosis, by means of a glucose tolerance test according to the ADA criteria (age 35–65). We studied two groups, one with obesity ($n=40$) and other with normal weight ($n=40$). We measured somatometric variables, SBP, DBP, glucose, HbA1c, lipid profile, insulin, HOMA-IR, serum AGEs, ICAM-1, VCAM-1, 8-oxo-DG, MDA, and sRAGE. We also measured carotid intima–media thickness (cIMT) and flow-mediated dilation (FMD) by ultrasound.
Results
We studied 80 patients with average age: 48 ± 7.3 years old and HbA1c: 6.53 ± 1.08. Serum AGEs ($P<0.0001$), sRAGE ($P<0.0001$), ICAM-1 ($P<0.0001$), VCAM-1 ($P<0.0001$), 8-oxo-dG ($P<0.0001$), MDA ($P<0.00$), HOMA-IR ($P<0.001$), and cIMT ($P<0.001$), were lower in the non-obese than in obese patients, while FMD ($P<0.02$) was higher in the obesity group. In the total group serum AGEs was associated with age ($P<0.02$), ICAM-1 ($P<0.0001$), and HOMA-IR ($P<0.01$); in the obesity group, sAGEs were associated with age ($P<0.01$), HbA1c ($P<0.01$), HOMA-IR ($P<0.0001$), and in the normal weight subjects with FMD ($P<0.001$). In the total group sRAGE were associated with VCAM-1 ($P<0.0001$), ICAM-1 ($P<0.001$), MDA ($P<0.001$), and cIMT ($P<0.001$); in the obesity group with HbA1c ($P<0.02$), VCAM-1 ($P<0.02$), MDA ($P<0.0001$), and 8-oxo-DG ($P<0.00001$).
Conclusion
The results show association of serum AGEs with ICAM-1 and HOMA-IR and strong association of sRAGE with VCAM-1, ICAM-1, MDA, and cIMT.

EP625

The body distribution of iodine-125 labeled irisin in 10-week-old rats: preliminary data

Ariadna Zybek[1], Marcin Trejter[2], Maciej Zabel[2] & Marek Ruchała[1]
[1]Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; [2]Department of Histology and Embryology, Poznan University of Medical Sciences, Poznan, Poland.

Introduction
Irisin is a newly discovered adipo-myokine, that has a significant influence on body metabolism. Available data about this peptide is still insufficient. The aim of the study is to provide some initial information about body distribution of irisin in rats.
Methods
The studied group consisted of 27 10-week-old female Wistar rats, which received intraperitoneally ~0.7 mcCi of iodine-125 labeled irisin. The studied rats were divided on five subgroups: six were decapitated after 15 min, five after 30 min, 1 h and 2.5 h and last six after 5 h. The samples from blood, kidneys, liver, subcutaneous and visceral fat, heart, skeletal muscles, diaphragm, adrenals, brain and cerebellum were taken, scaled and the radiation was measured (counts per minute (CPM)). The same procedure was applied for five rats which received only saline intraperitoneally – control group.
Results
The maximum radiation (CPM/1 g) in the blood was registered 1 h after the injection. At that moment the highest radiation was detected in kidneys. After 1 h the maximum radiation was registered also in liver, heart, and skeletal muscles. In case of brain and cerebellum the maximum point was depicted after 2.5 h. The diaphragm, subcutenaus fat, visceral fat, and adrenals presented very high radiation just after the injection, which decreased rapidly with time. At every point of the study the studied group tissue radiation was significantly higher than in the control group ($P<0.05$).
Conclusions
It may be assumed that intraperitoneally injected irisin has a standard distribution associated with blood perfusion and crosses the blood–brain barrier. There is no specific accumulation in described organs. The initial high radiation of diaphragm, subcutaneous fat, visceral fat and adrenals may be associated with the place of injection, thus is not reliable.

Obesity and breast cancer – does size matter?

Ioana Armasu[1], Iulia Crumpei[1], Constantin Volovat[2], Alina Daniela Belceanu[1], Georgiana Andreea Constantinescu[1], Mariana Tofan[2], Maria Christina Ungureanu[1], Letitia Leustean[1] & Carmen Vulpoi[1]
[1]Department of Endocrinology, University of Medicine and Pharmacy 'Gr.T. Popa', Iasi, Romania; [2]Victoria Hospital, Iasi, Romania.

Introduction
The epidemic of obesity has risen many health concerns, beneath the metabolic syndrome. One of these problems is the effect of obesity on cancer evolution. Populational studies have shown a direct correlation of BMI with worse prognostic, life quality and occurrence of comorbidities in neoplastic diseases, one of the most studied being breast cancer.
Patients and methods
We retrospectively analysed the evolution of postmenopausal obese and overweight women with non-metastatic breast cancer with antioestrogen treatment (selective oestrogen receptor modulators and/or aromatase inhibitors). From the 235 patients who received this treatment we selected) 62 with regular records of BMI. Excluding criteria were previous hormonal treatment of menopause, diabetes mellitus at the diagnostic, and smoking. Mean age at the diagnostic was 57.5 ± 12 years, mean BMI 28.5 ± 4.6 kg/m^2. Survival was between 3 months and 20 years.
Results
Pearson correlation showed a negative correlation between BMI and survival time ($r=-0.357$, $P=0.04$), however, there were no statistical differences between normal (N), overweight (OW), and obese (O) women respectively (*t*-test N vs OW $P=0.33$. N vs O $P=0.41$, OW vs O $P=0.46$). No modifications of life style could be noticed, at least in the OW and O women, since their weight remained practically unchanged. Women with longer survival were included in a quality of life study and, also all had a slight deterioration of role functions, emotional and cognitive functions, no differences associated with higher BMI could be observed.
Conclusions
Breast cancer is a multifactorial disease. Obesity is considered a predisposing factor, especially in postmenopausal women. However, many studies showed that not the obesity *per se* but that associated with sarcopenia has a most deleterious effect. Our study is limited by its retrospective design and the absence of body composition evaluation but had demonstrated direct association between obesity and a poor survival rate.

Irisin/leptin ratio, a biological marker of lean/fat mass, may help to identify LMNA-mutated familial partial lipodystrophies

Faiza Bensmaine[1], Kristell Le Mapihan[1], Samuel Bourry[2], Georges Lion[3], Corinne Vigouroux[4], Pascal Pigny[5] & Marie Christine Vantyghem[1,6]
[1]Department of Endocrinology and Metabolism, Lille University Hospital, Lille, France; [2]Department of Radiology, Lille University Hospital, Lille, France; [3]Department of Nuclear Medicine, Lille University Hospital, Lille, France; [4]Saint-Antoine University Hospital, Pierre and Marie-Curie University Paris, Paris, France; [5]Department of Biology, Lille University Hospital, Lille, France; [6]INSERM, U859 Biotherapies for Diabetes, European Genomic Institute for Diabetes, Lille, France.

Irisin is a myokine correlated with lean body mass, despite its association with cardiovascular events (Mantzoros 2014). Increased muscle volume and

lipoatrophy have been reported in female FPLD (Ji JCEM 214). Our aim was to determine whether irisin could help to distinguish certain lipodystrophic obesities from FPLD.
Methods and patients
Circulating irisin levels (EIA Phoenix) were measured in 20 LMNA-related FPLD, 19 normal-weighed controls (H) and 13 obese non-diabetic (OND) patients, and correlated with body composition (DEXA/MRI), and metabolic and inflammatory (CRP, leukocytes CD4) parameters (Clin.gov2009-AO-1169-48).
Results
Irisin medians differed between the three groups (P: 0.0076) and were higher in OND (P: 0.0099) and FPLD (P: 0.047) than in H groups, without difference between FPLD and OND. Irisinaemia, similar between male and female, was positively correlated to lean mass (g)/height^2 ($r=0.51$; $P<0.0001$), BMI, triglycerides ($r=0.45$–0.49; $P<0.001$) and to a lesser extent to insulin, body weight, MRI-intra-abdominal fat mass, MRI-intra-abdominal/MRI-total fat mass, FBG, A1c, cholesterol, and ASAT ($r=0.42$–0.33; $P<0.01$). The ratio 'lean mass/height^2' differed significantly between the three groups ($P<0.0001$) with higher values in OND ($P<0.0001$) and FPLD ($P=0.03$) compared to H groups, without difference between FPLD and OND. Leptinaemia was higher in OND compared to H and FPLD ($P<0.0001$), without difference between these two groups. The ratio «irisin/leptin» differed between the three groups ($P<0.0001$) with higher values in FPLD and H (both $P<0.0001$) compared to OND, without difference between FPLD and H. Irisin was not correlated with leptin and inflammatory parameters.
Conclusion
FPLD is characterized by high irisinemia and low leptinemia, OND by both high leptinaemia and irisinaemia. Irisin is increased in diseases characterised by higher lean mass whatever the amount of fat mass. Irisin/leptin ratio, a biological marker of lean/fat mass, may help to identify FPLD.

The relation between metabolic syndrome and cognitive decline in type 2 diabetes elderly Tunisian people

Hela Marmouch[1,2], Tasnim Slim[1], Fadia Boubaker[1], Sondes Arfa[1], Manel Jmal[1,2], Hanene Sayadi[1,2] & Ines Khochtali[1,2]
[1]Department of Internal Medecine-Endocrinology, Monastir, Tunisia; [2]Faculty of Medecine, Monastir, Tunisia.

Objective
To determine the relationship between metabolic syndrome (MS) and cognitive decline in type 2 diabetes patients over 65 years age.
Methods
The age of the participants were between 60 and 87 years old. According to NCEP ATP III criteria 30 had MS and 28 had not. Cognitive performance was determined with the use of standardised mini mental test and the mini mental scores (MMS) of the two groups were compared. Apart from the MS we investigated the relationship between MMS and age, gender, educational status, tobacco and alcohol use, the history of acute myocardial infarction (AMI) and stroke, medication use (antihypertensive, insulin, oral antidiabetic, statin) and BMI. Depression, which is a cause of pseudodementia, was also assessed with the use of geriatric depression scale (GDS).
Results
The MMS was low in ten patients (33.3%) in the MS group, and in ten subjects (25%) in the control group. We could not find difference between MMS's of two groups statistically. In this study the MMS was low in subjects with high fasting plasma glucose level, tobacco use, insulin use, advanced age and depression. The GDS's of two groups were similar. There was not difference in the MMS's between patients with high blood pressure, high triglyceride level, low HDL cholesterol level, history of AMI and stroke, low educational status, high BMI and in whom without them. We also could not find difference between MMS's of the patients who use antihypertensives, oral antidiabetics and statins and in whom not using these medications.
Conclusion
The number of elderly people increases in Tunisian, however, cognitive decline related to diseases also increases. The establishment of the risk factors, which affect the cognitive functions and prevention of them in elderly, would prevent the cognitive decline, one of the important causes of mortality and morbidity in today's world.

IGF-1 levels correlate with T_3 status in chronic heart failure outpatients: preliminary data

Vincenzo Triggiani[1], Massimo Iacoviello[2], Marta Leone[2], Vito Angelo Giagulli[1], Edoardo Guastamacchia[1], Andrea Salzano[3], Emanuele Bobbio[3], Michele Arcopinto[4] & Antonio Cittadini[3]
[1]Unit of Endocrinology, Interdisciplinary Department of Medicine, University of Bari, Bari, Italy; [2]Unit of Cardiology, Department of Emergency and Organs Transplantation, University of Bari, Bari, Italy; [3]Department of Translational Medical Science, Federico II University, Naples, Italy; [4]Department of Cardiac Surgery, IRCCS, Policlinico S. Donato, Milan, Italy.

Background
A variety of hormones may be down-regulated in CHF patients. Impaired activity of the GH/IGF-1 axis has been described and is associated with poor clinical status and outcome. Moreover, a decrease in serum T_3 is correlated to the severity of the heart disease as assessed by the NYHA classification. Aim of this study was to evaluate a possible correlation between IGF-1 levels and T_3 status in a cohort of CHF outpatients.
Materials and methods
Forty-eight consecutive CHF outpatients (79% males; age 61 ± 13 years; BMI 29 ± 5 kg/m^2; NYHA class 2.3 ± 0.6; 47% with ischemic disease), in stable clinical conditions from at least 30 days, in conventional electrical and medical therapy (87% taking ACE-inhibitors or angiotensin receptor blockers, 96% β blockers, 96% diuretics, 72% anti-aldosterone drugs, 13% digitalis, 14% nitrates), were enrolled in the study. They were submitted to physical examination, electrocardiography and echocardiography. Blood samples were drawn to assess renal function, Na^+, haemoglobin, NT-proBNPs, fT_3, fT_4, TSH, IGF-1, testosterone, DHEA and insulin levels.
Results
At univariate analysis, IGF-1 showed a direct correlation with fT_3 and the same was found between IGF-1 levels and fT_3/fT_4 ratio, whereas no correlation was found between IGF-1 and the other measures. Furthermore, at multivariate analysis, including also NHYA class, fT_3 was the only independent predictor of IGF-1 levels. The figure below shows a direct correlation between IGF-1 levels and both fT3 levels and fT_3/fT_4 ratio.
Conclusions
Impaired IGF-1 and fT_3 status may both represent a derangement strictly correlated to the severity of the clinical condition in CHF.

Diet relationship with the metabolic syndrome's elements

Raluca-Monica Pop, Ionela Pascanu, Grigore Dogaru & Marian Pop
University of Medicine and Pharmacy Tg Mures, Tirgu-Mures, Romania.

Background
Diet modification is an important part of the metabolic syndrome's management but there is limited data regarding a direct relationship between food groups and the metabolic profile.
Aim
Evaluation of the influence of food groups on the elements of metabolic syndrome in a group of subjects with abdominal obesity.

Material and methods
A cross sectional study was conducted in the Endocrinology Outpatient Clinic between February 2013 and April 2014. A sample of 290 subjects was analysed. Inclusion criteria: abdominal obesity defined according to IDF definition. Exclusion criteria: treatment for the metabolic syndrome's elements. Variables: age, sex, environment, waist, BMI, blood pressure, blood glucose, triglycerides, HDL cholesterol, food pyramid.
Method
Anthropometric evaluation, fasting blood sample, blood pressure measurement, food pyramid constructed based on an adapted food frequency questionnaire with 126 items analyzed with a web-based application especially developed. Statistical analysis used GraphPad Prism v. 5 and SPSS v17 with a level of significance $\alpha = 0.05$.
Results
Mean age was 50.6 ± 13.1 years with a sex distribution F:M 6.8:1 with the majority of subjects coming from urban areas (68.27%). In multiple regression analysis, the food pyramid elements explain 6.26% of the triglycerides variation ($P = 0.02$), 3.14% of the HDL cholesterol ($P = 0.31$), 4.55% of the blood glucose ($P = 0.09$), 7.25% of the blood pressure value ($P = 0.08$) and 5.75% of the waist circumference ($P = 0.01$). All of the metabolic syndrome elements are correlated with waist circumference and significantly influence each other's variability.
Conclusion
The main food groups explain a small percentage of the metabolic syndrome's elements underlying the need for a more detailed dietary evaluation to define specific patterns associated with increase cardio-vascular risk.

A common variant (rs9939609) in the fat mass and obesity associated gene is not associated with obesity, but associated with metabolic syndrome in girls among adolescents

Nilgun Col Araz[1], Mustafa Araz[2] & Muradiye Nacak[3]
[1]Department of Pediatrics, Gaziantep University Hospital, Gaziantep, Turkey; [2]Department of Endocrinology, Gaziantep University Hospital, Gaziantep, Turkey; [3]Department of Pharmacology, Gaziantep University Hospital, Gaziantep, Turkey.

Introduction
Fat mass and obesity associated (FTO) gene was the first susceptibility locus for obesity identified by genome wide association studies. The association of the FTO gene with obesity and metabolic syndrome is conflicting in both adults and adolescents. The aim of this study was to examine the role of the FTO gene variant rs9939609 as a candidate gene for obesity and metabolic syndrome, among Caucasian adolescents in South-eastern Turkey.
Methods
One hundred obese adolescents and 100 healthy controls were included. Obesity and metabolic syndrome were defined according to the international obesity task force's international standards and to the NCEP criteria, respectively. Rs9939609 polymorphism in FTO gene was genotyped by PCR–SNaPshot.
Results
The prevalence of metabolic syndrome was 60%. For *FTO* T/A polymorphism, the distribution of T/T, T/A, and A/A genotypes was 32.0, 48.0 and 20.0% in obese children compared with 41.0, 36.0 and 23.0% in controls ($P > 0.05$). The allele frequency of T and A was 56.0, 44.0% in patients compared with 59.0, 41.0% in controls ($P = 0.306$). There was no significant difference in genotype and allele frequencies between obese patients and controls. Also, the distribution of genotypes and alleles was not different in patients with and without MetS. However, the prevalence of metabolic syndrome in female patients with A allele carriers was more frequent than with non-carriers (carriers: 23/36, 63.9%; non-carriers: 4/14, 28.6%; $\chi^2 = 5.062$; $P = 0.024$).
Conclusion
We could not confirm the FTO rs9939609 variant as an obesity and metabolic syndrome susceptibility gene in adolescents, but we observe an association with metabolic syndrome in girls. There is a need to explain the possible gender effect of FTO gene polymorphism.

The relationship between haemoglobin and BMI in overweight and obese patients

Ayse Gozkaman[1], Yildiz Okuturlar[2], Meral Mert[3], Ozlem Harmankaya[1] & Abdulbaki Kumbasar[1]
[1]Department of Internal Medicine, Uludag University School of Medicine, Bursa, Turkey; [2]Department of Internal Medicine, Bakirkoy Dr Sadi Konuk Education and Research Hospital, Istanbul, Turkey; [3]Department of Endocrinology and Metabolism, Bakirkoy Dr Sadi Konuk Education and Research Hospital, Istanbul, Turkey.

Introduction
Both overweight/obesity and central obesity were inversely associated with anemia in the studies. In our study, we aimed to determine the relationship between different haemoglobin (Hb) levels and BMI.
Materials and methods
A total of 146 patients (131 (89.1%) female and 15 (10.2%) male) were enrolled in the study. Patients were divided into five groups namely group-1 (Hb $\leq$7 g/dl), group-2 (7 g/dl $<$ Hb $\leq$10 g/dl), group-3 (10 g/dl $<$ Hb $\leq$12 g/dl), group-4 (12 g/dl $<$ Hb $\leq$14 g/dl) and group-5 (14 g/dl $<$ Hb). Complete blood count, BMI, biochemical parameters, iron and iron binding capacity (IBC), ferritin, vitamin B12 and folic acid levels of all patients were measured.
Results
BMI levels were found to be significantly different in each five groups. These differences were found between group-1 and 3 ($P = 0.0001$), group-2 and 3 ($P = 0.0001$), group-3 and 4 ($P = 0.011$) and group-3 and 5 ($P = 0.032$). A positive correlation was found between BMI and Hb ($r = 0.199$, $P = 0.017$). There was a positive correlation between BMI and mean corpuscular volume (MCV) ($r = 0.298$, $P = 0.001$), negative correlation between BMI and IBC ($r = -0.223$, $P = 0.011$).
Conclusion
In obese patients, adverse effects on quality of life, exercise capacity and cardiovascular diseases of the anemia should be considered while planning lifestyle changes in obesity.

Advanced glycation end products, their receptors RAGE and AGER-1 and their association with insulin resistance and inflammation in obese and non-obese young subjects

Sofia Torres-Graciano[1], Etzabel Villegas-Rodriguez[1], Martha E Fajardo-Araujo[1], Juan Manuel Malacara[1], Antonio E Rivera-Cisneros[2] & Ma Eugenia Garay-Sevilla[1]
[1]Departmen of Medical Science, University of Guanajuato, Leon, Gto., Mexico; [2]Decanato de Salud, Universidad Autónoma de Guadalajara, Guadalajara, Jal., Mexico.

In obesity the combined effects of enhanced food consumption, enhanced oxidative stress and inflammation could increase levels of advanced glycation end products (AGEs) and the action of their receptors.
Objective
To study circulating levels of AGEs, soluble RAGE and AGER-1 and their association with insulin resistance and inflammation in young subjects with obesity and normal weight.
Material and methods
We conducted a cross-sectional study in obese Young ($n = 80$) and normal weight ($n = 80$). We calculated the BMI according to Cole *et al*., and the consumption of AGEs in the diet (dAGEs) with the tables of Uribarri *et al*. We measured glucose, lipid profile, insulin, HOMA-IR, TNF-α, serum AGEs (CML) and sRAGE. In a subsample of 27 subjects with normal weight and 21 subject with obesity we also measured the expression of RAGE and AGER1 by qPCR.
Results
We studied a total of 160 subjects (16 ± 1 years old) and 55% females. The group with obesity show higher levels of triglycerides ($P < 0.003$), insulin ($P < 0.001$), HOMA-IR ($P < 0.001$) and TNF-α ($P < 0.04$). In the groups with obesity and consumption of AGEs $>$9000 KU/day we found higher levels of insulin ($P < 0.0001$), HOMA-IR ($P < 0.01$) and sRAGE ($P < 0.04$). CML was associated with HOMA-IR ($P < 0.02$) and TNF-α ($P < 0.03$). In the sample were we studied the expression of cellular receptors we found higher expression of AGER-1 in the obesity group ($P < 0.02$) and association of AGER-1 with weight ($P < 0.02$) and dAGE ($P < 0.02$) and RAGE with physical activity (t-2.14; $P < 0.03$).

Conclusion
The results show higher insulin resistance and inflammation in the subjects with obesity, also association of CML with insulin resistance and TNF-α; and higher expression of AGER1 in the obesity group.

EP634

Bone and calcium markers in relation to cardiovascular risk in patients with osteoporosis

Carmen Gabriela Barbu[1,2], Suzana Florea[3], Anca Sirbu[1,2], Alice Albu[1,2], Sorina Martin[1,2] & Simona Fica[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]Elias Hospital Endocrinology Department, Bucharest, Romania; [3]Elias Hospital Core Laboratory, Bucharest, Romania.

Aim of the study was to evaluate the relationship between biochemical bone turnover markers, calcium homeostasis parameters and the cardiovascular risk in patients with osteoporosis.
Materials and methods
Subjects were 246 patients (mean age of 56.64) diagnosed with osteoporosis referred to the endocrine department of Elias Hospital, between 2009 and 2013, and who agreed with the terms of the study. Data collection consisted of clinical evaluation, physical exam and biochemical routine blood tests and hormones and the parameters of calcium homeostasis needed for differential diagnosis of osteoporosis. Osteoporosis was diagnosed based on the WHO criteria and metabolic syndrome based on the IDF 2007 guidelines. In order to evaluate the relationship between calcium and bone parameters and cardiovascular risk, we used metabolic syndrome as the criteria to segregate the subjects in control group (without Mets) and study subjects (with Mets).
Results
Serum intact PTH levels were significantly higher in Mets group: 76.2 (40.8) pg/ml, comparing to 65.6 (42.8) pg/ml in control group ($P<0.01$). No other calcium or bone biochemical marker (serum calcium, 24 h calciuria, serum osteocalcin, 25HO vitamin D, serum betacrosslaps) was significantly different across the study groups.
Conclusion
Hyperparathyroidism, either secondary or primary is frequent among patients with osteoporosis. Increased level of parathyroid hormone was found to be associated with increased risk in cardiovascular disease in our patients with osteoporosis suggesting that, beside the bone aspects, there may be also some other metabolic effects of the excess of the parathyroid hormone.

Therapeutic education contributes to minimise excess weight in Prader-Willi syndrome

Roxana Stefan[1], Cristina Rusu[2], Ioana Armasu[3], Alina Belceanu[3], Elena Braha[2], Carmen Gorduza[3], Bogdan Mihai[4], Cristina Lacatusu[4], Mihaela Negru[3] & Carmen Vulpoi[3]
[1]Clinic Center Providenta, Iasi, Romania; [2]Department of Genetics, Iasi, Romania; [3]Department of Endocrinology, Iasi, Romania; [4]Department of Diabetes, Nutrition and Metabolic Disease, Iasi, Romania.

Introduction
Prader-Willi syndrome (PWS) is a complex genetic disorder characterised by hyperphagia with progressive obesity, dysmorphic features, hypotonia, mental retardation, behavioural abnormalities and endocrine dysfunctions as hypogonadism and growth hormone (GH) deficiency. PWS is the most commonly identified genetic cause of obesity.
Methods
We reviewed five cases of confirmed PWS (three female and two male patients, aged between 8 and 32 years old) evaluated at the Endocrinology Department of Iaşi between January 2008 and July 2013. Clinical and hormonal data were documented.
Results
All patients had specific clinical features of PWS and genetic confirmation. They were all born in non-sanguine couples, four of them with low birth weight. After the first year of life they presented hyperfagia with rapid and important weight gain, except for one case where hyperphagia began in adolescence (at 13 years of age). The major weight gain was until late adolescence ($>+6$ S.D.). Nutritional counselling, with detailed information about diet, exercise, and subsequent adverse consequences of obesity, was offered to patients and family in order to ameliorate their eating behaviour. After that, the three patients that reached adulthood achieved a mean weight at $+1.5$ S.D. (under rigorous alimentation). Paradoxally, all patients had a higher height than expected (mean $+1.5$ S.D.) in childhood and adolescence, even though three of them had low IGF1. Two patients had their first endocrinological examination in adulthood and presented a satisfactory final height (>155 cm).
Conclusions
Therapeutical education of the family, performed as early as possible, is an important determinant of the disease evolution and diminishes the potential weight gain. Although most patients with PWS have morbid obesity it seems that caregivers involvement in weight management may lead to favorable results.

The use of intermittent 7.5 mg tolvaptan on an out-patient basis for SIADH: a retrospective audit from a tertiary cancer hospital

Mohit Kumar, Lakshminarayanan Pichaipillai, Peter Trainer & Claire Higham
Department of Endocrinology, Christie Hospital, Manchester, UK.

Tolvaptan (a V2 receptor antagonist) is licensed for correction of hyponatraemia in patients with SIADH at an initial dose of 15 mg od. Data in oncology patients with SIADH suggest 7.5 mg can safely and effectively increase sodium levels where 15 mg can on occasion lead to too rapid a correction. Recommendations suggest a repeat sodium taken at 4–6 h. We retrospectively assessed the safety and efficacy of intermittent out-patient dosing with 7.5 mg tolvaptan. Pharmacy records and casenotes were interrogated to find all patients given out-patient prescriptions for tolvaptan between April 12 and January 15. 15 doses were administered in a total of four patients (three men, one female; mean age 63 years). All had biochemically confirmed SIADH secondary to small cell lung cancer, had received fluid restriction and demeclocycline prior to tolvaptan as inpatients and were euvolaemic. All patients were also receiving therapy for the primary malignancy concurrently. Indications for treatment were symptomatic hyponatraemia or downward trending sodium. Mean pre-out-patient tolvaptan sodium was 126 mmol/l (range 122–128). Mean first sodium post-tolvaptan was 133.6 mmol/l (range 128–139), with mean increase 7.6 mmol/l. Timing of repeat sodium ranged from 6 h to 6 days. On eight occasions a repeat sodium was done at 6 h – mean sodium rose from 125.75 (122–128) to 132 mmol/l (128–137). The largest rise was 10 mmol/l at 6 h. No adverse events were encountered. One patient died due to progressive malignancy.
Conclusion
Outpatient use of single 7.5 mg doses of tolvaptan is effective at raising serum sodium in oncology patients with SIADH, thus potentially reducing admissions with economic (dose and bed-stay) and patient benefits. There were no adverse effects encountered in the small patient cohort analysed, but robust protocols need to be in place to prevent complications. Improvements need to be made in checking a 6-h sodium.

EP637

Type 2 diabetes mellitus and obesity: the possibilities of antihypertensive therapy

Tatiana Shebuniaeva & Marina Sergeeva-Kondrachenko
SEI APE 'Penza Postgraduate Medical Institute' of Ministry of Health of Russia, Penza, Russia.

Purpose
To evaluate the effectiveness of a combined antihypertensive therapy in treating arterial hypertension (AH) in patients suffering from diabetes mellitus (Type 2 DM) on different stages of obesity.
Materials and methods
80 patients suffering from Type 2 DM and AH on different stages of obesity underwent a monitoring. Depending on the stage of obesity, the patients were divided into three groups. The groups were comparable by age, sex, AH stage. The patients received comparable oral hypoglycemic agents. On voluntary basis the patients did not receive antihypertensive agents 5–7 days before being included into the research. Aiming at correcting AH, the patients received PRESTANCE (the combination of perindopril and amlodipine) in the doses of: 5/5, 5/10,10/5,10/10 during 12 months. Daily monitoring of AP (ABPM) was conducted with the help of a non-invasive portable system, HbA1c was determined. The blood glucose was determined on an empty stomach and 2 h after meals. The treatment of results was carried out with the use of STATISTICA pack.
Results
The average age of the patients was 57.5 ± 3.4 years, women prevailed – 75%. The average ABP value was: 168 ± 11 and 105 ± 7 mmHg – for systolic and diastolic blood pressure respectively. By week 12 observations of 85% patients from group 1 reached the target ABP and was retained until week 48, 78% patients from group 2 reached the target values of ABP and 72% patients from group 3 retaining it until observation week 48. By week 12 of observation in each group was significantly ($P < 0.01$) decreased the level of total cholesterol plasma, LDL cholesterol, triglycerides, fasting and postprandial blood glucose, HbA1c and BMI showed a decrease. All the patients participating in the research, showed good tolerance of PRESTANCE.
Conclusions
The combination of perindopril and amlodipine provides sustainable management of ABP in patients with Type 2 DM and different obesity stages, is well tolerated, has a beneficial effect on carbohydrate and lipid metabolism, leads to weight decrease.

Serum adipokine profile and adiponectin gene expression in neck adipose tissue in premenopausal and postmenopausal women

Vlatka Pandzic Jaksic[1], Danijela Grizelj[1], Drago Boscic[1], Marko Ajduk[1], Tomislav Kelava[2], Danka Grcevic[2], Maruska Marusic[1], Rajko Kusec[1,2] & Ozren Jaksic[1,2]
[1]Dubrava University Hospital, Zagreb, Croatia; [2]School of Medicine, Zagreb, Croatia.

Adipokines are an important contributor to the circulatory milieu of the body. The spectrum of adipokines changes as dysfunctional features of adipose tissue develop and the menopause is a time when an impairment of metabolic balance appears. The aim of this study was to examine several serum adipokines and adiponectin gene expression in subcutaneous and deep neck adipose tissue in women. Samples of serum, subcutaneous and deep neck adipose tissue were taken in 41 (12 premenopausal and 29 postmenopausal) women undergoing routine thyroid or vascular surgery. Serum adiponectin, leptin, omentin-1, monocyte chemoattractant protein-1 (MCP-1), fibroblast growth factor 21 (FGF21), retinol binding protein 4 (RBP4), insulin, glucose, triglycerides, HDL-cholesterol and C-reactive protein were determined. HOMA-IR was calculated and anthropometric measurements were performed. Adiponectin gene expression in adipose tissue samples was analysed by RQ–PCR method. Serum adiponectin and omentin-1 were negatively and leptin was positively associated with body weight, BMI and waist and neck circumference. RBP4 correlated with waist circumference and triglycerides. Leptin also was associated positively and omentin-1 negatively with triglycerides. FGF21 correlated with glucose and HDL-cholesterol. Omentin-1 negatively correlated with RBP4 and positively with serum adiponectin. Both serum adiponectin and omentin-1 were negatively associated with leptin. MCP-1 correlated only with RBP4. FGF21 didn't correlate with other adipokines. Subcutaneous and deep adiponectin gene expressions were negatively associated with insulin, HOMA-IR and RBP4 but positively with omentin-1. Comparisons between premenopausal and postmenopausal group yielded significant differences in insulin, HOMA-IR, MCP-1 and RBP4. These results confirm multiple associations of various adipokines with metabolic parameters and secretory features of the neck adipose tissue depot. However, they also suggest that some adipokines cluster in specific profiles with potential particular biologic functions that should be further elucidated.

Impact of visceral adiposity on blood pressure in normotensive people: a study among health staff

Nayananjani Karunasena[1,2] & Uditha Bulugahapitiya[1]
[1]Diabetes and Endocrine Unit, Colombo South Teaching Hospital, Colombo, Sri Lanka; [2]Academic Unit of Diabetes, Endocrinology and Metabolism, Department of Human Metabolism, University of Sheffield, Sheffield, UK.

Background
Obesity is often complicated by cardiovascular and atherosclerotic disease. Central or visceral obesity is known to be associated with hypertension and cardiovascular disease. Even though BMI is a good indicator of obesity in epidemiological studies, it does not differentiate between lean and fat mass. Furthermore waist circumference (WC) and visceral fat percentages are better indicators of visceral obesity. Aim of this study was to investigate the correlation of blood pressure with different measures of obesity in normotensive people.
Method
A cross sectional study carried out among the health staff in a tertiary care setting. 452 were screened among all categories of health staff and 410 were enrolled for the study excluding the known hypertensive people. Body fat and visceral fat percentages were estimated using bioelectrical impedance analysis (BIA) method.
Results
Out of the 410 subjects 63% ($n = 258$) were females and 37%($n = 152$) were males. Mean age of the study population was 41.7 ± 9.4 years. Mean systolic blood pressure (SBP) was 121 ± 13 mmHg among males and 118 ± 12.5 mmHg among females. Mean diastolic blood pressure (DBP) was 77.82 ± 8.9 and 75.3 ± 9.0 mmHg among males and females respectively. In females both SBP ($r = 0.268$, $P < 0.001$) and DBP ($r = 0.209$, $P = 0.001$) showed strongest correlation with WC compared to visceral fat percentage, total fat percentage and BMI. In females there was a good but less strong correlation with visceral fat percentage as well (SBP $P = 0.001$, DBP $P = 0.017$). In males both SBP ($r = 0.225$, $P = 0.006$) and DBP ($r = 0.180$, $P = 0.029$) showed strongest correlation with total body fat percentage compared to the other measures of obesity.
Conclusions
Among females both systolic and diastolic blood pressures are significantly affected by increased visceral adiposity as reflected by correlation with waist circumference and visceral fat percentage. However, among males blood pressure is not significantly affected by the visceral adiposity.

Metabolic consequences of abdominal obesity: about 105 Algerian obese patients

Aziza Smili[1], Remini Djida[1], Djamila Meskine[2], Eh Ahmed Koceir[3] & Yacine Soltani[1]
[1]Endocrinology Laboratory, Organisms Biology and Physiology Department, FSB, USTHB, Algies, Algeria; [2]Departement of Endocrinology, EPH Bologine Ibn Ziri, Algies, Algeria; [3]Bioenergitic and Intermediate Metabolism Laboratory, FSB USTHB, Algies, Algeria.

Introduction
The frequency of obesity is increasing in Algeria, insulin resistance is one of the consequences pathological of the abdominal obesity. The purpose of this work is to study the implication of the abdominal obesity in the insulinorésistance and the complications which arise by the latter.
Materials and methods
The study is realised on 105 obese (85 women and 20 men) (BMI > 30) and 55 thin (40 women and 15 men) with mean age 37.60 ± 1.18 and 31.03 ± 1.73 years respectively. Glycaemia, lipidaemia, cortisol, insulin and the leptin are analysed. The resistance and the sensibility in the insulin are estimated by the index HOMA-R and QUIKI. The obesity android was held in the criteria of the US NCEP ATP III Defines by a WHR ≥ 0.85 for women and WHR ≥ 1.00 for men.

Results
92% sick suffer from an obesity android associated with critical insulin resistance (HOMA-IR: HOMAR-R: 12.88 ± 1.03 vs 5.17 ± 0.86 $P < 0.001$.QUIKI: 0.29 ± 0.002 vs 0.31 ± 0.002; $P < 0.001$). Plasma cortisol and leptin were higher in obese group by 16% ($P < 0.05$) and 75% ($P < 0.001$) respectively, compared to control group. According to US NCEP ATP III 52 obese (50%) show lipid disturbances associated to dyslipidaemia and metabolic syndrome. Our results show a negative correlation between QUIKI and TT ($r = -0.29$ $P = 0.02$).
Conclusion
Abdominal obesity associated with metabolic disorders have led to a metabolic syndrome according to US NCEP-ATP III and a physiological stress which stimulated the secretion of cortisol. Despite the significant increase of leptin, known to inhibit adrenal axis. These data suggest that leptin resistance is developed in obese subjects.

Body composition in HIV-infected patients under combined antiretroviral therapy over 5 years

Inês Grenha[1,4], Joana Oliveira[1,4], Eva Lau[1,4], Romana Vieira[2,4], Rosário Serrão[3,4], António Sarmento[3,4], Davide Carvalho[1,4] & Paula Freitas[1,4]
[1]Endocrinology, Diabetes and Metabolism Department, Centro Hospitalar São João, Porto, Portugal; [2]Reumathology Department, Centro Hospitalar São João, Porto, Portugal; [3]nfectious Diseases Department, Centro Hospitar São João, Porto, Portugal; [4]Faculty of Medicine of University of Porto, Porto, Portugal

Introduction
HIV infection and combined antiretroviral therapy (cART) have been associated with lipodistrophy and changes in body composition. However, there are few studies on body composition evolution of HIV-infected patients, under cART.
Aims
To evaluate the evolution of body composition in HIV-1 infected patients under cART over 5 years.
Methods
Retrospective, observational study in a cohort of HIV-infected patients on cART. Evaluation of clinical data and body composition (total fat mass, upper-limbs fat mass, lower-limbs fat mass, trunk fat mass and fat-free mass) by DXA (whole-body dual-energy X-ray absorptiometry).
Results
A total of 257 patients were evaluated, with a mean age of 45.98 (11.51) years. 63% were males. The median duration of HIV infection was 7.92 (IQR: 3.90) years and the median duration of cART was 6.61 (IQR: 3.9) years. Males had a baseline mean BMI of 24.37 (22.17–26.91) Kg/m^2. Over the five years, there was a significant increase in their % of upper limbs, lower limbs, trunk and total fat mass. At baseline, women had a mean BMI of 25.33 (21.92–29.18) Kg/m^2. Women showed significant decrease in their % of lower limbs fat mass and an increase in % of trunk fat mass; % of total fat mass increased during the first two years and decreased since then. No differences were found regarding fat mass ratio, in both genders. During the five years of follow-up period, man showed a decrease of total fat-free mass and increase of upper-limbs fat-free mass; significant changes were also observed in lower-limbs and trunk fat-free mass distribution. Women also showed significant changes in total, lower-limbs, upper-limbs and trunk fat-free mass during follow-up.
Conclusion
Over the 5 years, there were significant changes in body composition, in HIV-infected patients on cART. Different from women, men showed a sustained increase in % of fat mass of all segments evaluated.

Patients' expectations and post-bariatric surgery satisfaction

Susana Garrido, Isabel Silva, Luísa Gonçalves, Ana Rita Caldas & M Helena Cardoso
Serviço de Endocrinologia, Diabetes e Metabolismo, Hospital de Santo António, Centro Hospitalar do Porto, Porto, Portugal.

Introduction
Treatment satisfaction is simultaneously a cause and consequence of the success of bariatric surgery – not only it is a reflection of the efficacy of treatment, it also enhances weight loss. A questionnaire that evaluates this variable has recently been created and validated by the authors (Post-Bariatric Surgery Satisfaction Questionnaire).
Objectives
To identify patients' expectations regarding bariatric surgery; to identify the domains that contribute to the degree of satisfaction after bariatric surgery.
Methods
Patients submitted to bariatric surgery who presented to our Obesity Outpatient Clinic between June and December/2013 were asked to complete two questionnaires – Patients' Expectations Questionnaire and Post-Bariatric Surgery Satisfaction Questionnaire (22 items, five-point scale – 1 – very dissatisfied, 5 – very satisfied). Demographic and clinical data were also collected.
Results
A total of 86 patients were included (67% submitted to laparoscopic gastric bypass and 33% to adjustable gastric banding): 86% female, median age 50 years (min–max = 23–73), median follow-up time since surgery 37 months (min–max = 1–220). Actual and idealized BMI of patients was 31.7 kg/m^2 and 27.7 kg/m^2, respectively. Actual and idealized percentage of excess BMI lost was 68.8 and 85.1%, respectively. The majority of the patients selected the items 'reduce weight' (98.8%), 'improve health' (98.8%), 'be able to choose clothing I like' (91.9%) and 'improve self-esteem' (91.9%). Patients were satisfied to very satisfied in all analyzed items (median score between 1.0 and 2.0). However, 34.9% of patients feel dissatisfied to very dissatisfied with their 'naked physical appearance', and 12.8% with 'the need of chronic medication'. 91.9% of the patients would recommend surgery to others and 90.1% of patients would undergo surgery again.
Conclusion
Patients were satisfied to very satisfied in all items tested, despite having unrealistic expectations. It is essential to assess what affects patients' satisfaction in order to understand their behavior and optimize our intervention.

Insulin resistance does not play a major role in lipid and apolipoprotein profile in obese women

José Silva-Nunes[1,2], Miguel Brito[2] & Luísa Veiga[2]
[1]Endocrinology Department, Curry Cabral Hospital – Lisbon's Central Hospital Group, Lisbon, Portugal; [2]Escola Superior de Tecnologia da Saude de Lisboa, Lisbon, Portugal.

Background
Obesity is associated with increased atherogenesis through alterations in lipids, among other potential factors. Some of those abnormalities might be mediated by insulin resistance (IR).
Aims
To compare lipid and apolipoprotein profile between lean and obese women; to evaluate the influence of IR on lipid and apolipoprotein profile, in obese women.
Methods
We studied 112 obese and 100 normal-weight premenopausal women without known cardiovascular disease. Both groups were characterized for anthropometrics and a fasting blood sample was collected for assessment of glucose, insulin, triglycerides, cholesterol (total, LDL and HDL), and apolipoproteins A-I, A-II, B, C-II, C-III, and E; IR was assessed by the homeostatic model assessment (HOMA-IR). We compared lipids between obese and lean women; we looked for correlation of those levels with anthropometrics and IR (independently from anthropometrics) in obese women.
Results
Obese women were characterized by mean age = 34.6 ± 8.3 years, BMI = 43.6 ± 7.9 kg/m^2, waist circumference (Wc) = 117.5 ± 15.1 cm, and HOMA-IR = 4.28 ± 3.5. Lean women (age = 34.2 ± 8.3 years, BMI = 21.4 ± 1.7 kg/m^2, Wc = 71.7 ± 5.8 cm, and HOMA-IR = 1.21 ± 0.76) presented with significantly lower levels of total cholesterol ($P = 0.001$), LDL-cholesterol ($P < 0.001$), and triglycerides ($P < 0.001$); they presented higher levels of HDL-cholesterol ($P < 0.001$), Apo A-I ($P < 0.001$) and Apo A-II ($P = 0.037$). HOMA-IR showed no significant association with apolipoproteins. HOMA-IR was inversely associated with HDL-cholesterol ($P = 0.048$; $r = -0.187$) but that association disappeared when we adjusted for waist circumference. Only triglycerides were directly associated with HOMA-IR ($P < 0.001$; $r = 0.343$) independently from anthropometrics.

Conclusion
We confirm that obese women present worst lipid and apolipoprotein profile. However, with the exception for triglycerides, insulin resistance *per se* does not play a major role in lipid and apolipoprotein abnormalities observed in obese women.

VEGFA expression is regulated by 17β-oestradiol and its receptors (ESR1 and ESR2) on 3T3-L1 adipocytes

Luciana Fatima, Raquel Campello & Ubiratan Machado
Department of Physiology and Biophysics, Institute of Biomedical Sciences, University of São Paulo, Sao Paulo, Brazil.

Introduction
VEGFA is considered the main angiogenic factor in adipose tissue. It is believed that a low angiogenic capacity may decrease the adipogenic potential and consequently promotes adipocyte hypertrophy, which in turn, is closely related to insulin resistance (IR). Oestradiol (E_2) is a regulator of the VEGFA gene and a protector against obesity. However nothing is known about the E_2 effects on VEGF adipocyte production, and its consequence for cellular sensitivity and much less about the adjacent molecular mechanisms. Thus, the aim of the present work was to investigate the role of E_2 on the VEGFA expression determining the participation of the estrogen receptors ESR1 and ESR2 in this process.
Methods
Differentiated 3T3-L1 adipocytes were treated (24 h) with 10 e 100 nmol/l of 17β-E_2 and/or selective ESR1-agonist PPT, ESR1-antagonist MPP, ESR2-agonist DPN and ESR2-antagonist PHTPP. We analyzed VEGFA mRNA and protein expression by real time PCR and Western blotting, respectively.
Results
E_2 enhanced VEGFA mRNA and protein (20–30%) expression at 10 and 100 nmol/l. Treatment with PPT enhanced VEGFA expression ($\sim$30%) in the absence or presence of E_2. However treatment with ESR2 agonist DPN didn't change VEGFA expression. In addition, the ESR1-antagonist MPP or the ESR2-antagonist PHTPP alone were not able to change the VEGFA expression, but in the presence of E_2 the VEGFA expression was increased (20–30%) in both treatments as compared to control.
Conclusion
The present results reveal that E_2 induced VEGFA production in adipocytes, in part, via activation of ESR1 receptor. However, there is evidence of co-regulation of both receptors, since in the absence of ESR1, high dose of E_2 was able to induce VEGFA expression. Taken together, the increased VEGFA production induced by E_2 in adipocytes can improve the local angiogenesis, protecting the adipose tissue from obesity-induced hypoxia, and consequently, from insulin resistance.

Time-of-day-dependent rhythms in the transcriptional responsiveness of the rat heart to triiodothyronine

Rodrigo Peliciari-Garcia[1], Rafael Prévide[1], Martin Young[2] & Maria Tereza Nunes[1]
[1]Department of Physiology and Biophysics, Institute of Biomedical Sciences-I, University of Sao Paulo, Sao Paulo, SP., Brazil; [2]Division of Cardiovascular Diseases, Department of Medicine, University of Alabama at Birmingham, Birmingham, Alabama, USA.

Myocardial gene expression and metabolism fluctuate over the course of the day, in association with changes in energy supply and demand. Recently, time-of-day-dependent oscillations in myocardial processes have been linked to the intrinsic cardiomyocyte circadian clock. Triiodothyronine (T_3) is an important modulator of cardiac form and function. The genomic actions of T_3 are triggered after its interaction with thyroid hormone nuclear receptors that often dimerized with RXR or RORA. Some target proteins, such as PDK4, are regulated not only by the cardiomyocyte circadian clock, but also by T_3, suggesting a potential interrelationship between the two mechanisms. Circulating levels of T_3 and its intermediates exhibit a time-of-day-dependent oscillation. However, whether the sensitivity of T_3 responsive tissues oscillate in a time-of-day-dependent manner is unknown. Thus, the purpose of the present study was to investigate whether the heart exhibits a diurnal variation in T_3 responsiveness, at a transcriptional level, and/or whether T_3 impacts the circadian clock in the heart. For this, euthyroid (C) male Wistar rats were divided in two groups: vehicle or T_3 (supraphysiological dose), administered 4 h prior each ZT. The animals were euthanized at the respective Zeitgeber Times, during 24 h. The hearts were excised and the mRNA expression was evaluated by RT-qPCR using Taqman probe specific for each target gene; cyclophilin was used as a housekeeping gene. One and two-way ANOVA analysis were used to evaluate the time-of-day-dependent differential expression for each gene/group and their interactions. In general, the administration of T_3 promoted a marked alteration in the expression of Bmal1, Pdk4 and Ucp3, revealing a time-of-day-dependent responsiveness specially at the end of the dark period for Bmal1 and throughout the whole investigated period for Pdk4 and Ucp3. Our study shows that T_3 might acts as a Zeitgeber, and alters the cardiac functions, which may help to explain some metabolic and functional disorders observed in thyroid diseases.

Influences on post-bariatric surgery satisfaction

Susana Garrido, Isabel Silva, Luisa Gonçalves, Ana Rita Caldas & M Helena Cardoso
S. de Endocrinologia, Diabetes e Metabolismo, Centro Hospitalar do Porto, Porto, Portugal.

Introduction
Post-bariatric surgery satisfaction relies on psychosocial and clinical factors. A questionnaire that evaluates this variable has recently been created and validated by the authors (Post-Bariatric Surgery Satisfaction Questionnaire).
Objective
To assess the relationship between treatment satisfaction and several demographic and clinical variables.
Methods
Patients submitted to bariatric surgery who presented to our Obesity Outpatient Clinic between June 2013 and December 2013 were asked to complete the Post-Bariatric Surgery Satisfaction Questionnaire (22 items, five-point scale – 1, very dissatisfied and 5, very satisfied). Demographic and clinical data were also collected.
Results
A total of 86 patients were included (67% submitted to laparoscopic gastric bypass and 33% to adjustable gastric banding): 86% females, median age 50 years (min–max = 23–73), median follow-up time since surgery 37 months (min–max = 1–220). Age, adjusted to percentage of excess BMI lost, was negatively correlated with 'physical well-being' ($r = -0.27$; $P = 0.012$) and with 'enhancement of movement capabilities' ($r = -0.25$; $P = 0.019$), but not with global satisfaction. There was no correlation between the degree of satisfaction and the follow-up time since surgery, nor differences between genders. There was a positive correlation between percentage of excess BMI lost and 15 of the items ($r = 0.21$–0.54; $P < 0.001$–0.047) and with global satisfaction ($r = 0.45$, $P < 0.001$). Patients submitted to adjustable gastric banding were less satisfied globally ($P = 0.007$) and in seven of the items. Results from the linear regression analysis indicate that the percentage of excess BMI lost and the type of surgery explain 29% of the variance in patients' global satisfaction. Both variables were statistically significant, with percentage of excess BMI lost recording a higher β value (0.45 and 0.20 respectively).
Conclusion
The percentage of excess BMI lost, the type of surgery, and patient's age influenced post-bariatric surgery satisfaction. However, these only partially explain treatment satisfaction. Other factors, namely psychosocial, are probably also involved.

Effects of an 8-week supervised, structured lifestyle modification programme on anthropometric, metabolic, and cardiovascular risk factors in severely obese adults

Catherine Crowe[1], Irene Gibson[2], Katie Cunningham[1,2], Claire Kerins[2], Caroline Costello[2], Jane Windle[2], Paula O'Shea[3], Mary Hynes[1,4], Brian McGuire[1,4], Katriona Kilkelly[1], Helena Griffin[1], Timothy O'Brien[1], Jenni Jones[2,5] & Francis Finucane[1,5]
[1]Bariatric Medicine Service, Galway Diabetes Research Centre, HRB Clinical Research Facility, Galway, Ireland; [2]Croi, The West of Ireland Cardiac Foundation, Heart and Stroke Centre, Moyola Lane, Newcastle, Galway, Ireland; [3]Department of Clinical Biochemistry, Galway University Hospitals, Galway, Ireland; [4]School of Psychology, National University of Ireland, Galway, Ireland; [5]Discipline of Health Promotion, National Institute of Preventive Cardiology, National University of Ireland, Galway, Ireland.

Background
Lifestyle modification is fundamental to obesity treatment, but few studies have described the effects of structured lifestyle programmes specifically in bariatric patients. We sought to describe changes in anthropometric and metabolic characteristics in a cohort of bariatric patients after participation in a nurse-led, structured lifestyle programme.
Methods
We conducted a retrospective, observational cohort study of adults with a BMI $\geqq$40 kg/m^2 (or $\geqq$35 kg/m^2 with significant co-morbidity) who were attending a regional bariatric service and who completed a single centre, 8-week, nurse-led multidisciplinary lifestyle modification programme. Weight, height, waist circumference, blood pressure, HbA1c, fasting glucose and lipid profiles, functional capacity (Incremental Shuttle Walk Test) and anxiety, and depression scores before and after the programme were compared in per-protocol analyses.
Results
Of 183 bariatric patients enrolled, 150 (81.9%) completed the programme. Mean age of completers was 47.9$\pm$11.2 years. 34.7% were males. There were statistically significant reductions in weight (129.6$\pm$25.9 kg vs 126.9$\pm$26.1 kg, $P<0.001$), BMI (46.3$\pm$8.3 kg/m^2 vs 44.9$\pm$9.0 kg/m^2, $P<0.001$), waist circumference (133.0$\pm$17.1 cm vs 129.3$\pm$17.5 cm in women and 143.8$\pm$19.0 cm vs 135.1$\pm$17.9 cm in men, both $P<0.001$) as well as anxiety and depression scores, total- and LDL-cholesterol and triglyceride levels, with an increase in functional capacity (5.9$\pm$1.7 vs 6.8$\pm$2.1 METS, $P<0.001$) in completers at the end of the programme compared to the start. Blood pressure improved, with reductions in systolic and diastolic blood pressure from 135$\pm$16.2 to 131.6$\pm$17.1 ($P=0.009$) and 84.7$\pm$10.2 to 81.4$\pm$10.9 mmHg ($P<0.001$) respectively. The proportion of patients achieving target blood pressure increased from 50.3 to 59.3% ($P=0.04$). The proportion of patients with diabetes achieving HbA1c $<$53 mmol/mol increased from 28.6 to 42.9%, $P=0.02$.
Conclusions
Bariatric patients completing an eight week, nurse-led structured lifestyle programme had improved adiposity, fitness, lipid profiles, psychosocial health, blood pressure, and glycaemia. Further assessment of this programme in a pragmatic randomised controlled trial seems warranted.

Skin tags and metabolic phenotype in severely obese adults: the STAMP cohort study

Catherine Crowe[1], Irene Gibson[2], Helena Griffin[1], Anette Murphy[3] & Francis Finucane[1]
[1]Bariatric Medicine Service, Galway Diabetes Research Centre, HRB Clinical Research Facility, Galway, Ireland; [2]Croí, The West of Ireland Cardiac Foundation, Galway, Ireland; [3]Department of Dermatology, Galway University Hospitals, Galway, Ireland.

Introduction
Skin tags (acrochordons) are a recognised feature of insulin resistance, but the extent to which they predict an adverse metabolic profile or the response to lifestyle modification in severely obese adults is not known.
Aims
We sought to quantify prospectively differences in anthropometric and metabolic characteristics in severely obese adults with acrochordons vs those without acrochordons, and to determine whether the presence of acrochordons predicted how well bariatric patients respond to an 8-week structured lifestyle programme.
Methods
Weight, height, blood pressure, fasting glucose, and lipid profiles and a detailed dermatological assessment were conducted in a cohort of bariatric patients undergoing a structured lifestyle modification programme. Baseline differences between those with and without acrochordons were measured using a two-sample *t*-test, while differences in the response to the lifestyle intervention were quantified using linear regression.
Results
100 bariatric patients (mean age 50$\pm$11.4 years, 31% males) were enrolled. There was a non-significant trend to those with acrochordons being heavier (weight 131.2$\pm$26.6 kg vs 121.8$\pm$15.3 kg, $P=0.06$) but also taller, with lower BMI (46.1$\pm$7.8 kg/m^2 vs 47.3$\pm$6.4 kg/m^2, $P=0.53$). They had higher HbA1c and systolic blood pressure (137.6$\pm$15.5 mmHg vs 124.4$\pm$9.1 mmHg, $P<0.001$), as expected. The intervention led to improvements in fitness and adiposity overall, but these improvements were no different in those with compared to those without acrochordons.
Discussion
In severely obese adults, acrochordons are an important marker of metabolic adversity but do not seem to predict the response to a lifestyle modification-programme.

Prevalence of metabolic syndrome among human immunodeficiency virus and hepatitis C subjects in Southern Brazil

Maristela Beck, Helen Cezimbra Cezimbra, Fábio Pedro Pedro, Francisco Galarreta & Luiz Felipe Barin
Federal University of Santa Maria, Santa Maria, Brazil.

Objective
To investigate the metabolic syndrome and dyslipidemia prevalence among human immunodeficiency virus (HIV) and hepatitis C (HCV) subjects in Southern Brazil.
Methods
Cross-sectional study, including 127 subjects ($n=59$ HIV positive only, $n=36$ HIV/HCV positive, and $n=32$ HCV positive only) were accessed for HOMA index, metabolic syndrome, and dyslipidaemias.
Results
In HIV group there were 27% metabolic syndrome by IDF criteria and 26% by HOMA2-IR index (1.4 cut-off), 63% larger waist by IDF criteria and 26% abdominal obesity. To HIV/HCV coinfection group there were 30% metabolic syndrome by IDF, but 54% by HOMA2-IR index, 42% larger waist, but 52% abdominal obesity. To HCV group there were 25% metabolic syndrome by IDF and 38% by HOMA2-IR index, 67% larger waist, and 47% abdominal obesity.
Conclusions
The presence of HCV coinfection is responsible for alarming levels of insulin resistance, associated with a more favorable lipid profile that could act as a confounder in the clinical diagnosis of metabolic syndrome.

Introduction
Ectopic ACTH syndrome (EAS) is a rare cause of ACTH-dependent endogenous hypercortisolism.
Objective
The objective of this study was to analyse the clinical, biochemical, and radiological features, management, and treatment outcome of patients with EAS.

Design
It was a retrospective case-record study of 52 patients with EAS.
Materials and methods
Clinical, biochemical, and radiological features and response to therapy and survival were measured.
Results
The median follow-up was 7 years (range, 1–13 years). None of the dynamic tests achieved 100% accuracy. Imaging correctly identified the lesion at first investigation in 83% of cases. Bronchial carcinoid tumors were the most common cause of EAS ($n=34$; 65.4%), followed by other neuroendocrine tumors ($n=13$, 25%). In 9.6% (5) of patients, the source of EAS was never found. Octreotide scintigraphy and whole-body venous sampling were of limited value. Surgical attempt at curative resection was successful in 83% (43 of 52) of all patients; 9 (19.1%) responded generally well to bilateral adrenalectomy by vital necessity. Tumour histology and the presence of distant metastases were the main predictors of overall survival ($P<0.05$).
Conclusions
No single test provides to find the source of EAS correctly. Despite a variety of tests and imaging studies for the correct diagnosis of the EAS, up to 10% of cases present an occult EAS. These cases require a prolonged follow-up, review, and repetition of diagnostic tests and scans, but, if it is necessary, do bilateral adrenalectomy.

EP651

Assessment of GH–IGF1 axis in adults with beta-thalassemia major: when to do a GH stimulation test?

Vincenzo De Sanctis[1], Ashraf Soliman[2], Giancarlo Candini[3] & Heba Elsedfy[4]
[1]Quisisana Hospital, Ferrara, Italy; [2]Hamad Medical Center, Doha, Qatar; [3]St. Anna Hospital, Ferrara, Italy; [4]Ain Shams University, Cairo, Egypt.

GHD in adults (AGHD) is a clinical syndrome associated with lack of positive well-being, depressed mood, feelings of social isolation, decreased energy, alterations in body composition with reduced bone and muscle mass, diminished exercise performance, and cardiac capacity. These manifestations are also common in adults with beta-thalassemia major (BTM). Performing provocative testing in all patients is cumbersome and expensive. Many studies suggested that IGF1 may be used for primary screening, to avoid performing GH stimulation tests in the majority of healthy or diseased subjects, when appropriate normative sex and age-correlated ranges are available.
Objectives
The International Network of Clinicians for Endocrinopathies in Thalassemia and Adolescence Medicine (ICET-A) promoted a study to collect more information on IGF1 values in young adult Italian BTM patients.
Methods
Plasma total IGF1 was measured by CLIA method for 120 patients with BTM (58M, 62F) with an age range of 26.0–53.2 years for females and 20.8–51.2 years for males. 64.4% of the patients were above 35 years of age. The mean BMI was 22.48 ± 3.34 kg/m^2.
Results
IGF1 data, expressed in percentiles. No significant differences were observed between IGF1 values in men and women with TM.
Analysis and discussion
On the basis of the present results and data from the literature, ICET-A concluded their survey with the following recommendations: a GH stimulation test should be indicated in presence of the following clinical and laboratory parameters: short stature (HtSDS < -2.5), severe and/or prolonged iron overload, presence of severe osteoporosis and/or serum IGF1 level < -2 SDS. In adult TM patients, with normal liver function, an IGF1 level $<$50th percentile should be taken in consideration as a cut-off level for the GH assessment.

IGF1 deficiency in newly diagnosed Graves' disease patients

Sorina Martin[1,2], Minodora Betivoiu[1], Suzana Florea[3] & Simona Fica[1,2]
[1]Endocrinology Department, Elias Hospital, Bucharest, Romania; [2]Endocrinology Department, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Laboratory Department, Elias Hospital, Bucharest, Romania.

Introduction
Thyroid hormones influence GH/IGF1 axis, but previous studies reported discrepant results regarding serum IGF1 levels in hyperthyroidism. We have therefore investigated, at diagnosis, the relationship between serum IGF1 levels/IGF1 z scores and clinical and biological characteristics of Graves' disease (GD) patients. We also compared IGF1 levels/IGF1 z scores, at diagnosis, between GD and autonomous hyperthyroidism patients.
Methods
This cross-sectional study included 119 newly diagnosed hyperthyroid patients (98 with GD and 21 with toxic multinodular goitre) that presented consecutively to our clinic. The main measured parameters: TSH, FT_4, FT_3, TT_3, thyroglobulin, TPOAb, ATA, TRAb, and IGF1. Patients were considered IGF-deficient if IGF1 z score was ≤ -2 S.D. from mean for age.
Results
In GD patients men had higher IGF1 levels ($P=0.023$) and IGF1 z scores ($P=0.013$) than women. 18.4% of GD patients were, at diagnosis, IGF1 deficient. Compared with patients without IGF1 deficiency, these patients presented, at diagnosis, higher thyroglobulin (median = 72.55, IQR = 116.02 vs median = 11.40, IQR = 80.74 ng/ml, $P=0.002$), FT_3 (median = 11.30, IQR = 7.64 vs median = 7.33, IQR = 5.72 pg/ml, $P=0.027$), and lower ATA (median = 20, IQR = 0 vs median = 34.05, IQR = 161 UI/ml, $P=0.001$) levels. Thyroglobulin was identified as strong predictor for IGF1 deficiency (AUROC = 0.732, 95% CI: 0.620–0.844, $P=0.002$; cut-off for thyroglobulin = 50.40 ng/ml, Se = 77.8%, Sp = 70%). IGF1 status was not influenced by gender ($P=0.08$), current smoking ($P=0.55$), goitre size ($P=0.53$), opthalmopathy ($P=0.33$), TRAb ($P=0.23$), and TPOAb status ($P=0.36$). The prevalence of IGF1 deficiency was higher in GD patients compared to patients with toxic goitre (18% vs 0%, $\chi^2=4.54$, $P=0.033$).
Conclusions
Our study shows, for the first time, the presence of IGF1 deficiency in nearly one-fifth of newly diagnosed GD patients. IGF1 deficiency was associated with lower ATA titres, higher thyroglobulin levels and more severe FT_3 hyperthyroidism. The presence of active GO did not influence IGF1 status. GD patients had higher prevalence of IGF1 deficiency than patients with toxic multinodular goitre.

DOI: 10.1530/endoabs.37.EP652

EP653

The NAD- and NADP-dependent blood lymphocytes dehydrogenases level and their interaction with GH/IGF1 in active acromegaly

Margarita A Dudina[1,3], Sergey A Dogadin[1,3] & Andrey A Sacvhenko[2]
[1]Krasnoyarsk State Medical University named after Prof. V. F. Voino-Yasenetsky, Krasnoyarsk, Russia; [2]Siberian Division, Institute for Medical Problems of the North, Russian Academy of Medical Sciences, Krasnoyarsk, Russia; [3]Krasnoyarsk Regional Clinical Hospital, Krasnoyarsk, Russia.

Somatotropin (GH) and IGF1 realise their influence on the system of intracellular metabolism and a number of important biochemical lymphocytes reactions through the receptor apparatus. It is allows to use the peripheral blood lymphocytes as the investigations object of intracellular metabolism disorders in acromegaly.
Aim
To study the NAD- and NADP-dependent dehydrogenases activity in blood lymphocytes in active acromegaly patients.
Methods
The activity of NAD(P)-dependent dehydrogenases in blood lymphocytes was studied in a group of 88 patients (35 men and 53 women) with active acromegaly, mean age 51.0 ± 12.5 years. The NAD(P)-dependent dehydrogenases activity was determined by biochemiluminescence method. The concentrations of GH and IGF1 were measured by ELISA.
Results
Studying the activity of mitochondrial NAD(P)-dependent dehydrogenases found a decrease in all NAD-dependent oxidoreductase: NADIDH, NADGDH, and MDH ($P<0.01$), which allows to state the low level flow in the tricarboxylic acid cycle. In active acromegaly were revealed the decreasing activity of all studied oxidoreductases: glucose-6-phosphate dehydrogenase ($P<0.01$), NAD–lactate dehydrogenase (LDH) ($P<0.001$), NADH–LDH ($P<0.001$), NAD–malate dehydrogenase (MDH) ($P<0.001$), NADH–MDH ($P<0.001$), NADP–MDH ($P<0.001$), NAD–glutamate dehydrogenases (GDH) and NADH–GDH ($P<0.001$), NADP–GDH and NADPH–GDH ($P<0.001$), NAD–isocitrate dehydrogenases (IDH) and NADP–IDH ($P<0.01$ and $P<0.001$ respectively), and glutathione reductase ($P<0.001$). Our data observed that decreasing activity of NADP–GDH positively correlated with the basal GH level ($r=+0.23$,

$P=0.04$) and NADP–MDH activity with IGF1 level ($r=+0.30$, $P=0.008$). The low NADH–MDH activity negatively correlated to the basal GH concentration ($P=-0.23$, $P=0.04$).
Conclusion
The chronic excess of GH and IGF1 in acromegaly causes a significant depletion of metabolic lymphocytes reserves. The main indicators of functional lymphocytes impairment in acromegaly are: the reduction of intermediates formation for the reactions of macromolecular synthesis and aerobic processes, the low intensity of glycolysis, nitrogen metabolism and inhibition of glutathione complex activity.

Symptoms and complaints of patients with Cushing's disease (CD) according to Moscow region database of patients with CD

Irina Komerdus[1], Alexander Dreval[1], Anastasia Murzina[1], Timur Britvin[1], Larisa Akulkina[2] & Olga Nechaeva[1]
[1]Moscow Regional Research Clinical Institute N.A. M.F. Vladimirsky, Moscow, Russia; [2]Moscow State University, Moscow, Russia.

Objective
To evaluate the frequency of symptoms of Cushing's disease (CD) at baseline and it dependence on different quantities.
Material and methods
Clinical and laboratory data of 44 patients with CD (40 females and four males, 37.9 ± 10.5 years old), duration of the disease 35.5 (22; 75) months.
Results
Complaints: i) >80% – fatigability, weight gain, apathy, and headache, ii) 40–50% – loss of libido, bruisability, muscle weakness, insomnia, and hair loss, iii) <40% – irritability, striae, back pain, memory loss, impaired wound healing, increased appetite, and acne. 6/15 (34.1%) patients with back pain had spinal fracture. One patient with spinal fracture had no back pain. Regular menstruation – in 5/40 (12.5%) women, 12 (30%) – menstrual irregularities, and 23 (57.5%) – amenorrhea. Clinical examination: arterial hypertension – in 100% (by BPM). More than 70% had facial plethora, overweight/obesity, dorsocervical fat pad, hirsutism (females), and leg edema. BMI at baseline – 33.7 (30.4; 38.4). Normal weight 7%, 16.3% – overweight, 76.7% – obese (34.9% – I grade). Median weight gain 13.0 (10.0; 26.2) kg, correlated with duration of the disease ($r^2=0.2$; $P=0.007$). Positive correlations were found between: i) midnight serum cortisol level and apathy, muscle weakness, hair loss, and waist to hip ratio ($r^2=0.35$, $P=0.005$; $r^2=0.3$, $P=0.009$; $r^2=0.2$, $P=0.04$; and $r^2=0.2$, $P=0.049$ respectively), ii) morning serum cortisol level with apathy and impaired wound healing ($r^2=0.1$, $P=0.04$ and $r^2=0.2$, $P=0.006$), iii) morning and midnight serum ACTH levels with increased appetite ($r^2=0.2$, $P=0.01$ and $r^2=0.3$, $P=0.01$ respectively), iv) midnight serum ACTH with fatigability ($r^2=0.2$, $P=0.03$), and v) UFC with supraclavicular fat pads ($r^2=0.15$, $P=0.04$) . Back pain and striae correlated with BMI ($r^2=0.1$, $P=0.04$ and $r^2=0.17$, $P=0.006$ respectively). Weight gain and acne had a positive correlation with duration of the disease ($r^2=0.2$, $P=0.007$ and $r^2=0.14$, $P=0.001$ respectively).
Conclusions
The most frequent symptoms of CD are nonspecific. The strongest correlation observed between symptoms and midnight serum cortisol and ACTH levels.

Transgenic human gene reporter cell line for evaluating interactions between androgen receptor and xenobiotics

Iveta Bartonkova, Aneta Novotna & Zdenek Dvorak
Department of Cell Biology and Genetics, Faculty of Science, Palacky University Olomouc, Olomouc, Czech Republic.

Androgen receptor (AR, NR3C4) is a 110-kDa ligand-activated transcriptional factor that belongs to the steroid hormone receptor superfamily. It has broad developmental effects and its mutations may have a great impact on pubertal development, genesis of prostatic hyperplasia, and even prostate cancer. Commonly known endogenous ligands of AR are testosterone and 5α-dihydrotestosterone (DHT). In the last years, several drugs and environmental pollutants were identified to alter AR activity leading to drug interactions or to endocrine disruption. Therefore, development of *in-vitro* experimental tools for analysing androgenic or antiandrogenic effects of various compounds is of great importance. In our work, we describe construction and characterisation of a novel stably transfected human reporter cell line AIZ-AR for assessment of transcriptional activity of human androgen receptor. Cell line AIZ-AR is derived from human prostate carcinoma epithelial cell line 22Rv1 that was stably transfected with a reporter plasmid containing three copies of androgen response regions (ARRs) followed by a single copy of androgen response element (ARE) from the promoter region of human prostate specific antigen (PSA) gene. Presented AIZ-AR cell line remained fully functional for over 60 days and more than 25 passages in the culture as well as after cryopreservation. Time-course analyses revealed that AIZ-AR cells allow detection of AR ligands as soon as after 8 h of the treatment. Upon dose–response analyses with 23 steroids in 96-well plate format, we observed induction of luciferase activity by androgens, but not by mineralocorticoids and oestrogens. Some glucocorticoids and progesterone also activated AR, but with potencies two to three orders of magnitude lower as compared with androgens. Taken together, we have developed a rapid, sensitive, selective, high-throughput and reproducible tool for detection of human AR ligands, with potential use in pharmacological and environmental applications.

Diabetes insipidus as a rare neuroendocrine complication associated with Behcet's syndrome

Pooja Rao[1,2] & Maya Petlsverger[1,2]
[1]New Hanover Regional Medical Center, Wilmington, North Carolina, USA; [2]University of North Carolina, Chapel Hill, North Carolina, USA.

Behcet's disease (BD) is a chronic disease characterised by systemic involvement of blood vessels of all sizes on both arterial and venous circulation resulting in recurrent ulcers. The posterior infundibulo-hypophysitis, causing DI, has been commonly reported in association with systemic inflammatory/autoimmune disorders, however there are a handful of cases presenting with DI and Behcet's disease.
A 26-year-old African-American woman diagnosed with BD in 2006 after receiving a flu vaccine resulting in oral and genital ulcerations. She presented to ED with malaise, dizziness, severe polyuria, polydipsia with requests for iced water. On physical examination there was evidence of multiple oral apthous ulcers and genital ulcers. The serum level of sodium was 150 mEq/l, urine specific gravity was 1.003, and urine osmolality was 126 mOsm/kg. Estimated urine output volume was 5600 ml collected over 12 h. Complete evaluation of anterior pituitary hormone function tests including serum TSH, FT_4, FSH, LH, oestradiol, prolactin, IGF1, and ACTH stimulation test were unremarkable. MRI of the brain was suggestive of possible thickening of the pituitary stalk, but otherwise normal. Patient was started on oral DDAVP 0.1 mg twice daily with complete resolution of symptoms associated with DI. Formal water deprivation test was scheduled but not done due to a sudden resolution of DI over the course of 6 weeks.
Involvement of the CNS in Bechet's can be severe, leading to a devastating neurological deficit. Central DI in patients with BD has been rarely reported with possible correlation to autoimmune mediated vasculitis involving the blood vessels supplying the hypothalamus. In contrast with all prior cases reported, our patient's central DI had self-limiting course with complete resolution of symptoms (Molloy). Lymphocytic or autoimmune hypophysitis is commonly described as a transient but possibly relapsing condition.

Effect of phenols and phthalates on rat and human pituitary cell proliferation

Laura Tapella[1], Antonella Sesta[2], Marco Losa[3], Francesco Cavagnini[2] & Francesca Pecori Giraldi[1,2]
[1]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [2]Neuroendocrinology Research Laboratory, Istituto Auxologico Italiano, Milan, Italy; [3]Department of Neurosurgery, Ospedale San Raffaele, Milan, Italy.

An increased prevalence of acromegaly and pituitary tumors has recently been observed in high industrial density areas (Cannavò *et al*. *J Endocrinol* 2010) or after dioxin exposure (Pesatori *et al*. *Eur J Endocrinol* 2008). These data as well as *vitro* studies on endocrine disruptors (EDs) suggest that environmental pollutants may affect hormonal secretion and pituitary cell proliferation (Blake *et al*. *Proc Soc Exp Biol Med* 1997, Wilson *et al*. *Endocrinology* 1998, Maruyama *et al*. *Endocr J* 1999, Elango *et al*. *Gen Comp Endocrinol* 2006, Dang *et al*. *Toxicol Sci* 2007, Dang *et al*. *J Reprod Dev* 2009, Dang *et al*. *Steroids* 2009). The aim of our study was to verify the effect of endocrine disruptors on rat pituitary and human pituitary adenoma proliferative activity.

Methods

Pituitary primary cultures were incubated with 250 pM–1.25 nM phenol or *bis*-(2-ethylhexyl)-phthalate for 24 and 96 h. Cell viability, apoptosis and proliferation were assessed by ATP lite (Perkin Elmer, USA), MTT assay (Sigma), Caspases 3–7 (Promega), and 5-bromo-2′-deoxyuridine labeling (BrdU-labeling; Roche).

Results

In rat pituitary primary cultures, ATP cell content was reduced by phenol ($100 \pm 2\%$ vs $75.3 \pm 3.4\%$, $P < 0.0001$ control vs treatment) and *bis*-(2-ethylhexyl)-phthalate ($100 \pm 2\%$ vs $83.2 \pm 3.1\%$, $P < 0.0001$) at 24 h. After 96 h, ATP was clearly increased by phenol ($100 \pm 2\%$ vs $123.9 \pm 7\%$, $P < 0.05$, control vs treatment), less by *bis*-(2-ethylhexyl)-phthalate ($100 \pm 2\%$ vs $111.4 \pm 13\%$, NS). BrdU-labeling and MTT were also increased at the latter timepoint (BrdU-labeling: $100 \pm 12\%$ vs $136 \pm 12\%$, $P < 0.05$ and $100 \pm 12\%$ vs $137 \pm 8\%$, $P < 0.05$, for phenol and *bis*-(2-ethylhexyl)-phthalate respectively; MTT: $100 \pm 4\%$ vs $118 \pm 5\%$, $P < 0.05$ and $100 \pm 4\%$ vs $123 \pm 10\%$, $P < 0.05$, for phenol and *bis*-(2-ethylhexyl)-phthalate respectively). No changes in caspase activation were observed at 24 or 96 h. In two human GH-secreting primary adenomas, ATP content was increased by 40 and 100%, respectively, after 24 h incubation with 650 pM phenol.

Conclusions

Our findings show than phenol and *bis*-(2-ethylhexyl)-phthalate initially reduce then increase pituitary cell energy content; further, long-term incubation with EDs is associated with increased cell proliferation. This study indicates that both normal and adenomatous pituitary cell proliferation is modulated by endocrine disruptors, thus supporting the role of pollutants in pituitary adenoma aetiology.

Neuronal and synaptic ultra-structural organization in layer 5 of the human Gyrus temporalis

Rachida Yakoubi[1], Rachid Mosbah[1,2], Astrid Rollenhagen[3] & Joachim Lübke[3]

[1]Department of Biology, Faculty of sciences, University of Boumerdes, Boumerdes, Algeria; [2]Laboratory of Animal Eco-Biology, ENS, Kouba, Algeria; [3]Institute of Neuroscience and Medicine (INM-2), Jülich GmbH, Jülich, Germany.

Synapses are the key elements for signal transduction and plasticity in the brain. Despite a relatively large number of assumptions that have been made on the structure of mature cortical synapses in many other animal species, little is known about these structures in human. Hence, synapses in cortical layer 5 (L5), the main recipient layer of thalamocortical efferents, which representing the first station of cortical information processing were investigated structurally and quantitatively using serial ultrathin sections and digital electron microscopic images (DEMI) followed by three dimensional (3D) reconstruction and immunohistochemistry against glutamine synthetase. The quantitative 3D-reconstructions of cortical synapses will allow to directly comparing structural and functional aspects of synaptic transmission and plasticity thus leading to a better understanding of the function of cortical networks in the human neocortex.

The structural parameters such as the size, number, and distribution of active zones as well as the size and organisation of the pools of synaptic vesicles were the most critical factors investigated not only for the induction but also for the maintenance of synaptic transmission and plasticity in the neocortex. The DEMI examination followed by 3D-reconstruction of cortical L5 showed clearly a large pyramidal neurons (85%); GABAergic interneurons and astrocytes, multiple innervations on either the same or different dendrites, multivesicular bodies (MVBs) and mitochondria (two to eight) in the pre-synaptic element and perforations exist in the pre and post-synaptic densities. Besides, in 85% of the spines have a spine apparatus and a specialized form of endoplasmic reticulum. For the quantitative geometry study, the results showed a total pool of synaptic vesicles of 1671.57 ± 391.55 (ranging from 88 to 5841) with a mean diameter of 31.99 ± 0.87 nm, and a dense-core vesicles of 66.2 ± 11.27 nm, while, the volume of mitochondria and synaptic boutons and their surface were 0.05 ± 0.01 μm^3, 0.63 ± 0.09 μm^3, and 8.05 ± 0.27 μm^2 respectively. We can conclude that the morphological parameters observed in this study will help to better understand the mechanisms underlying synaptic transmission and plasticity in the adult cortical synapses.

Influence of neurotransmitters on GnRH release in letrozole induced PCOS rat model

Nirja Chaudhari & Laxmipriya Nampoothiri

Department of Biochemistry, The Maharaja Sayajirao University of Baroda, Vadodara, Gujarat, India.

Background

Polycystic ovarian syndrome (PCOS) is a common reproductive-endocrine disorder seen in women; characterized by increased GnRH pulsatility, hyperandrogenism, and cyst formation in ovary. GnRH release is controlled by higher centres of brain namely, hypothalamus and pituitary through various feedback mechanisms, one of them being neurotransmitters. However, no clear data is available with respect to GnRH regulation by neurotransmitters in PCOS. The aim of the present study was to evaluate status of neurotransmitters and their receptors in PCOS and to correlate this with GnRH pulsatility.

Materials and methods

PCOS was induced in rats using letrozole – an aromatase inhibitor – and validated for structural and metabolic characteristics of PCOS. Neurotransmitters were estimated from different regions of rat brain by HPLC and detected electrochemically. RNA was isolated from hypothalamus and pituitary using TRIzol reagent and cDNA was synthesized by first strand cDNA synthesis kit. This cDNA was further used for real-time expression studies of gonadotropins and neurotransmitter receptors.

Results

PCOS rats demonstrated increased hypothalamic GnRH1; pituitary GnRHR and LHβ mRNA levels as compared to control rats. Reduced levels of norepinephrine, dopamine, serotonin, γ-amino butyric acid, and epinephrine with increased glutamate levels were observed in pituitary and hypothalamus of PCOS rats as compared to control rats. Expression of neurotransmitter receptors – 5HT1A, GABAB1, D2R, and α1A receptor decreased while that of NMDA receptor increased in hypothalamus and pituitary of PCOS rats.

Conclusion

Letrozole treated rat demonstrated hormonal and metabolic characteristics of PCOS with peripheral cysts in the ovary. Present study confirms that modulation in GnRH stimulatory as well as inhibitory neurotransmitters could have contributed to increased GnRH pulsatility, further resulting into increased LH to FSH ratio in PCOS.

High metabolic risk is associated with small hypothalamic volume in acute lymphoblastic leukemia survivors 34 years after cranial radiotherapy

Cecilia Follin[1], Sanaz Gabery[2], Åsa Petrsen[2], Pia Maly Sundgren[1], Isabella Björkman-Burtcher[1], Peter Mannfolk[1], Jimmy Lätt[1] & Eva Marie Erfurth[1]

[1]Institution of Clinical Sciences, Lund University, Lund, Sweden; [2]Institution of Translational Neuroendocrinology, Lund, Sweden.

Background

Metabolic complications (obesity, lipid abnormalities, and insulin resistance) are prevalent in acute lymphoblastic leukemia (ALL) survivors treated with cranial radiotherapy (CRT). The hypothalamus (HT) is a complex area involved in endocrine function and metabolic control. In ALL survivors, assessment of the volume of the HT in relation to metabolic parameters including ghrelin, a peptide stimulating food intake, has not been performed previously.

Method
Thirty-four (21 women) ALL survivors, on complete hormone supplementation, were investigated 34 years after ALL diagnosis. Their median age was 38 (27–46) years and they had been treated with a CRT dose of 24 Gy. Comparison was made with 31 matched controls. Assessments of BMI (kg/m^2), waist (cm), fat mass (DEXA/kg), fat free mass (kg), plasma (p)-glucose (mmol/l), p-insulin (mIE/l), HOMA-index, s-leptin (μg/l), and s-ghrelin (ng/l) was performed. Magnetic resonance imaging (MRI) was performed to conduct volumetric analysis of the HT.
Results
S-leptin levels ($r=-0.4$, $P=0.04$) and fat mass ($r=-0.4$, $P=0.01$) were negatively correlated with the HT volume among the 34 ALL survivors, but not among the matched controls ($P>0.3$). There was a trend of a smaller HT volume among the ALL women compared to gender matched controls (846 mm^3 vs 869 mm^3, $P=0.06$). Significantly higher BMI (27.9 kg/m^2 vs 22.6 kg/m^2), waist (89 cm vs 79 cm), fat mass (29.9 kg vs 22.4 kg), p-insulin (10 mIE/l vs 6 mIE/l), HOMA-index (0.15 vs 0.07), leptin/kg fat mass (1.09 vs 0.6), and s-ghrelin (1560 ng/l vs 993 ng/l) and significantly lower fat free mass (35.4 kg vs 41.6 kg) were recorded among the female ALL survivors compared to matched controls (all $P<0.01$).
Conclusion
ALL women treated with CRT are at high risk of metabolic abnormalities in association with a smaller HT volume 34 years after ALL diagnosis. These findings suggest a hypothalamic effect of the metabolic complications.

Long-term follow-up of cranially irradiated childhood leukaemia survivors show cognitive impairment and progressive decline in sustained attention, in spite of on complete hormone replacement

Cecilia Follin[1], Aki Johansson[2], Kai Österberg[2], Andrea Rovira[2], Magdalena Jansson[2], Thomas Wiebe[1] & Eva Marie Erfurth[1]
[1]Institution of Clinical Sciences, Lund University, Lund, Sweden; [2]Institution of Psychology, Lund University, Lund, Sweden.

Background
Survivors of childhood leukaemia (ALL) treated with cranial radiotherapy (CRT) are at risk for cognitive impairment. Whether the impairment progresses with follow-up time and if survivors with cognitive impairment have an increased risk for overweight, is unknown. We aimed to investigate the long-term cognitive functioning in ALL survivors treated with CRT in comparison to matched controls.
Method
Cognitive functioning was investigated in 38 ALL survivors, treated with CRT (24 Gy), at a median age of 5 years (1–17). The survivors were on complete hormone substitution. Median age at follow-up was 38 years (33–46) and the survivors were investigated 34 years (26–40) after diagnosis. Comparisons were made with 28 controls, matched for gender and age.
Results
After 34 years of treatment survivors demonstrated a lower performance in vocabulary, memory, learning capacity, spatial ability, executive functions, and attention (all, $P<0.001$), compared to controls. 58t % of the survivors had moderate/severe impairment in visuo-spatial function and episodic memory, and had significantly higher BMI (28.4 vs 25.9) ($P=0.01$), compared to survivors with normal cognitive function. Furthermore, this group was treated at younger age (3; 1–9) compared to the survivors with normal cognition (6; 3–17). From the age of 26 years to the age of 38 years, and in comparison to the same matched controls 69%, of the survivors, demonstrated a decline in psychomotor speed tests of reaction time (RT) (sustained attention) ($P=0.02$ and $P<0.001$). A significantly higher BMI was recorded among the survivors with an increased RT of >15%, compared to survivors with <15% increased RT.
Conclusion
34 years after ALL diagnosis, we report persistent cognitive impairment and a progressive decline in sustained attention in survivors. The survivors with overweight had the most attenuated impairment in cognitive function. Intervention strategies should be multidimensional and include tailored psychosocial and healthy life-style support.

Neuroendocrine complications of radiation therapy for pituitary somatotropinomas

Zamira Khalimova[1] & Saodat Issaeva[1,2]
[1]Republican Specialized Scientific-Practical Medical Center of Endocrinology, Tashkent, Uzbekistan; [2]Tashkent Pediatric Medical Center, Tashkent, Uzbekistan.

The purpose of the study
To examine the incidence of neuroendocrine complications after radiation therapy (RT) of pituitary somatotropinomas.
Materials and methods
30 patients surveyed after receiving RT at a dose of 45 g in 25 fractions a day. Of these, 21 (70%) females, 9 (30%) men. The age of patients ranged from 36 to 71 years. 37% of them had pituitary macroadenoma with para-, supra-, and infrasellar growth. Duration of illness was 15 years on average. Period of observation after RT averaged to 10 years. The levels of GH, IGF1, PRL, TSH, LH, FSH, fT_4, cortisol, oestradiol, testosterone, CT/MRI of the brain covering pituitary, visual field and acuity tests, and fundoscopy were assessed. All patients received RT in combination with drug therapy. 6 (20%) received RT with drug therapy, 11 (37%) after TAG and 13 (43%) were primary. All parameters were checked before (I group) and a year or more after RT (II group).
Results
The following impairments took place in I group: increased GH ($M=107$), IGF1 ($M=1138$) in 75%, and PRL in 33%; decreased gonadotropins in 80%, TSH and fT_4 in 17%, cortisol in 10%, decreased visual acuity in 30%, menstrual disorder in 62%, and impaired potency in 11% of patients. Group II showed following results: GH ($M=33$) and IGF1 ($M=434$) in 38%, PRL in 9%; decreased gonadotropins in 80%, TSH and fT_4 in 30%, cortisol in 50%, menstrual disorder in 67%, impaired potency in 33%, and decreased visual acuity in 57% of patients. Moreover, 20% developed ESS and 3% necrosis of brain tissue.
Conclusions
RT in pituitary somatotropinomas leads to the stabilization of the pathological process.

Social stress promotes changes in local metabolism of glucocorticoids

Jiri Pacha[1], Petra Klusonova[1], Peter Ergang[1], Martin Vodicka[1], Anna Mikulecka[1] & Petr Zach[2]
[1]Institute of Physiology, Czech Academy of Sciences, Prague, Czech Republic; [2]3rd Faculty of Medicine, Institute of Anatomy, Charles University, Prague, Czech Republic.

Stressful experiences produce profound physiological and behavioural disturbances that may contribute to many psychiatric disorders. Stress activates HPA axis whose end products glucocorticoids modulate immune cells and cytokine activity. Local effect of glucocorticoids depends not only on its concentration but also on the enzyme 11β-hydroxysteroid dehydrogenase type 1 (11HSD1), which amplifies intracellular glucocorticoid concentration by the conversion of inactive 11-dehydrocorticosterone to active corticosterone. As cytokines are potent modulators of 11HSD1, it was interested to establish whether cytokines could modulate metabolism of glucocorticoids in response to various stressors. Fisher 344 rats were exposed to chronic emotional homotypic stress (resident-intruder paradigm) or short-term variable stress combining emotional and physical stressors. Plasma level of corticosterone, TNFα and IL1β were measured by commercial kits, expression of 11HSD1, TNFα, and IL1β mRNAs by RT-PCR and 11-reductase activity by radiometric assay. We found that long-term homotypic stress increased corticosterone and decreased TNFα and IL1β in plasma. Expression of 11HSD1 mRNA was increased in thymus and spleen but not in mesenteric lymph nodes and liver. Similar pattern was found in expression of TNFα and IL1β – both cytokines were upregulated in thymus and spleen but not in liver and lymph nodes. Stimulatory effect of stress on 11-redutase activity was observed in both mobile cells and stroma of all three lymphoid organs. Vagotomy did not affect the stress-dependent upregulation of 11HSD1 in spleen and mesenteric lymph nodes. In contrast to chronic stress, the short-term variable stress up-regulated 11HSD1 only in thymus but not in spleen and lymph nodes. The findings demonstrate that a powerful stressor may have strong effect on glucocorticoid signaling in some peripheral organs, in particular lymphoid, but the nature of the effect varies with the specificity of stress and tissue. In lymphoid organs, the stressful episodes increase 11HSD1 in parallel with upregulation of TNFα and IL1β, which have been shown previously to stimulate 11HSD1 in vitro.

The status of blood antioxidant system in patients with active acromegaly

Maria Faassen[1], Maria Pankratova[1], Natalia Molitvoslovova[1], Valentina Peterkova[1], Adil Baizhumanov[2], Alexander Yusipovich[2], Svetlana Kovalenko[2] & Georgy Maksimov[2]
[1]Endocrinology Research Centre, Moscow, Russia; [2]Biophysics Department, Lomonosov Moscow State University, Moscow, Russia.

Introduction
The oxidative stress is supposed to be key factor in multiple diseases.
The aim of the study was to examine the effects of excessive GH secretion on the blood antioxidant system: total antioxidant capacity (TAC) of plasma; superoxide dismutase (SOD) and catalase activities (CAT); ceruloplasmin (CP); non-protein thiol (NT), and level of thiobarbituric acid reactive substances (TBARS).
Materials
Eleven patients with active acromegaly were included in the study. The state of the antioxidant system was examined and compared with these of a control group (nine persons).
Results
In patients with acromegaly the TAC levels and SOD activity were significantly lower (for 20 and 30%), than corresponding control data, whilst TBARS and CP levels were significantly higher (for 50 and 40% respectively).
Conclusions
The present work has demonstrated that parameters of the blood antioxidant system are impaired in patients with active acromegaly, what indicates the development of oxidative stress.
Disclosure
Authors have nothing to disclose.

The PATRO adult study of Omnitrope® for the treatment of adult patients with GH deficiency: latest results

Paolo Beck-Peccoz[1], Charlotte Höybye[2], Robert D Murray[3], Suat Simsek[4], Alfonso Leal-Cerro[5], Markus Zabransky[6] & Gunter Stalla[7]
[1]Fondazione Istituto di Ricovero e Cura a Carattere Scientifico Cà Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Department of Endocrinology, Metabolism and Diabetology, Karolinska University Hospital, Stockholm, Sweden; [3]Department of Endocrinology, Leeds Centre for Diabetes and Endocrinology, St James's University Hospital, Leeds, UK; [4]Medisch Centrum Alkmaar, Alkmaar, The Netherlands; [5]Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocío, Seville, Spain; [6]Sandoz International GmbH, Holzkirchen, Germany; [7]Department of Internal Medicine, Endocrinology and Clinical Chemistry, Max Planck Institute of Psychiatry, Munich, Germany.

Introduction
PATRO adults is an ongoing, international, open, longitudinal, non-interventional study of the long-term safety and efficacy of recombinant human GH (rhGH; Omnitrope, Sandoz). The study will provide further data on the long-term safety of rhGH in adult patients with severe GH deficiency (GHD). Here, we present safety data from an interim analysis.
Methods
Adults who are receiving treatment with Omnitrope and who have provided informed consent are eligible for inclusion. Patients treated with another rhGH before starting Omnitrope therapy can also be included. The primary objective of the study is to assess the safety and efficacy of Omnitrope in adults treated in routine clinical practice. Particular emphasis is placed on the risk of glucose intolerance or diabetes and normalisation of IGF1 levels.
Results
As of November 2014, 800 patients have been enrolled in the study; 414 (52%) have received previous GH treatment. Mean (S.D.) age of enrolled patients is 50.4 (15.5) years, and mean (S.D.) BMI is 29.7 (6.5) kg/m^2. So far, 1033 adverse events (AEs) have been reported in 321 (40%) patients, with 92 (8.9%, in 59 (7.4%) patients) regarded as serious. Eighty-nine AEs (8.6%) in 58 (7.3%) patients were suspected as drug-related. These included 17 nervous system disorders, 17 general disorders/administration site conditions, 11 musculoskeletal/connective tissue disorders, and 11 investigations (increased IGF levels). One serious AE (dyspnoea) in 1 (0.2%) patient was suspected as drug-related. Seventy-six patients have discontinued treatment; 17 of these did so due to an AE.
Conclusions
Based on this interim analysis, Omnitrope treatment in adults with GHD is well tolerated in real-life clinical practice, both in rhGH-naïve and previously treated patients. The PATRO adults study will continue to provide important data on the diabetogenic potential and overall safety of long-term GH treatment in this population.
Disclosure
The PATRO adults study is funded by Sandoz.

EP666

Dose interval injection extension and costs of lanreotide Autogel 120 mg used in routine acromegaly care in Poland: 2 years data from Lanro study

Ewa Orlewska[1], Beata Kos-Kudla[2], Jerzy Sowinski[3], Krzysztof Sworczak[4] & Wojciech Zgliczynski[5]
[1]Faculty of Health Sciences, The Jan Kochanowski University, Kielce, Poland; [2]Division of Endocrinology, Department of Pathophysiology and Endocrinology, Silesian Medical University, Katowice, Poland; [3]Chair and Department of Endocrinology, Metabolism and Internal Diseases, Poznan University of Medical Sciences, Poznan, Poland; [4]Endocrinology and Internal Diseases Department, Medical University, Gdansk, Poland; [5]Centre of Postgraduate Medical Education, Warsaw, Poland.

Objective
To determine the percentage of patients with acromegaly who received lanreotide Autogel 120 mg (ATG120) in extended duration interval and to evaluate the mean costs of ATG120 administered as part of routine care in Poland.
Methods
National, multicentre, non-interventional, observational prospective study with 2-years' time horizon. The study population consisted of adult acromegaly patients who received at least three injections of ATG120 before inclusion. The endpoints were: percentage of patients treated with ATG120 at an extended duration interval (>4 weeks) and mean cost of ATG120. Costs were calculated in PLN from the public health-care payer and patient perspective for the year 2014 (one PLN$=0.25$ EURO).
Results
151 patients suffering from acromegaly for at least 1 year were screened and 143 enrolled in 35 centres. Of those, 11 patients were excluded from the analysis because of missing of follow-up visits or because they did not complete the treatment period. 70% of them were women, 81% had macroadenoma, and 75% underwent surgical treatment in the past. During 2 years, changes in the treatment pattern – decrease or increase of injection interval or change of treatment, were reported in 41 (31%) patients. In other patients treatment has not been changed. 63 patients (48%) received ATG120 at an extended duration interval. The mean number of days between injections was 35.1 (S.D. 8.2). ATG120 was predominantly administered in out-patient setting (84%) and by health-care professional (97%). The mean cost of ATG120 per patient per month was 4062.5 PLN and 3.6 PLN from the public payer and patient perspective respectively. Meanwhile the retail price of ATG120 per pack is 4770.5 PLN.
Conclusion
The results demonstrated that extended duration interval of ATG120 is used in almost half of acromegaly patients, indicating the reduction of financial burden for the health care system.

GH therapy has a beneficial effect on HbA1c levels in adult patients with GH deficiency: a report from the NordiNet® International Outcome Study

Matthias Weber[1], Birgitte Tønnes Pedersen[2], Effie Pournara[3], Jens Sandahl Christiansen[4] & Charlotte Höybye[5]
[1]I. Medical Clinic, University of Mainz, Mainz, Germany; [2]Novo Nordisk A/S, Søborg, Denmark; [3]Novo Nordisk Health Care AG, Zurich, Switzerland; [4]Aarhus University Hospital, Aarhus C, Denmark; [5]Karolinska University Hospital, Stockholm, Sweden.

Introduction
The clinical significance of the impact of GH on glucose homeostasis in adults with GH deficiency (GHD) remains unclear. We report the impact of 4 years of continuous GH therapy on HbA1c and progression to diabetes.
Methods
Data were analysed from patients with adult-onset GHD (>20 years old) enrolled in NordiNet® International Outcome Study (IOS) (NCT00960128), an observational study, and treated with GH (Norditropin®, Novo Nordisk A/S, Denmark) for 4 years. Change in HbA1c (ΔHbA1c) from baseline was calculated for all patients, by GH dose group (≤0.2 and >0.2 mg/day), for patients with clinically relevant decrease in HbA1c (≥0.3% decrease), unchanged, or clinically relevant increase in HbA1c (≥0.3% increase), and by baseline health status (% patients) (low–normal, HbA1c <5.8% (75.2%); pre-diabetes/high–normal, HbA1c 5.8–<6.5% (17.3%); diabetes, HbA1c ≥6.5% (7.5%)).
Results
Among the 278 patients (48% females) mean±S.D. age was 49.4±14.5 years, BMI, 29.0±6.1 kg/m^2 and HbA1c 5.29±0.85%. Patients receiving ≤0.2 mg/day GH (n=120) were older than those receiving >0.2 mg/day GH (53.9 years vs 46.0 years). At 4 years, 54.32% of patients had no change, 20.14% a decrease and 25.54% an increase in HbA1c. ΔHbA1c at 4 years was greater for patients receiving ≤0.2 than >0.2 mg/day GH (0.10±0.61% vs −0.20±0.56%). A significant association (P=0.045) between GH dose >0.2 mg/day and the proportion of patients with clinically significant decrease in HbA1c (≥0.3% vs baseline) was observed. After 4 years, among patients with pre-diabetes/high–normal HbA1c at baseline (n=48), 48% had low–normal HbA1c, 10% developed diabetes, and 42% were unchanged. No overall association between change in health status (baseline to 4 years) and GH dose was found.
Conclusions
Four years of GH therapy was not associated with deterioration in HbA1c or progression to diabetes. Indeed, almost half of patients with pre-diabetes/high–normal HbA1c showed a clinically relevant improvement in health status after 4 years of GH therapy.

Radio-induced meningioma: a long-term consequence of pituitary radiotherapy

Concepción Páramo-Fernández, Yolanda López-Vázquez, Gloria Barragáns, Angel Martínez, Javier Lago & Susana Gomara
Complejo Hospitalario Universitario de Vigo, Vigo, Spain.

Long-term sequels of pituitary radiotherapy include hypopituitarism, optic nerve atrophy, sensorineural hearing loss, neurocognitive impairment and second intracranial neoplasms, the meningioma being the most frequent. The cumulative incidence of second cerebral tumours within 20 years of the radiation is 2% and, unlike its primary forms, they show a more aggressive atypical histology, and the age of appearance varies depending on the latency time, which in its turn is proportional to the dose of received radiation.
Material and methods
We present three patients with meningiomas secondary to pituitary adenoma radiation, all of them of somatomammotroph lineage. All these meningiomas were developed on the area of pituitary irradiation, over 20 years after it, and they were neither present on the diagnose nor was there an environmental or genetic proneoplastic condition.
Results
Case 1: A 65-year-old man, diagnosed with macroprolactinoma on 1977. He received cobalt therapy after a subtotal resection of the tumour. He debuted 29 years later with fronto-orbital cephalea in relation with a prebulbar meningioma with extension to the foramen magnum.
Case 2: A 72-year-old male diagnosed with GH releasing macroadenoma in 1968. He was treated with cobalt-therapy and 44 years later presented with apathy and bradypsychia. Neuroimaging revealed the presence of a right frontal convexity meningioma.
Case 3: A 50-year-old man, diagnosed with a macroprolactinoma on 1973 and treated with radiotherapy. After 40 years of treatment, a 1′1 cm meningioma is discovered on the right sylvian fissure following a study of dementia due to memory loss, mental dispersion, and depressed mood. The total dose of radiation received was 40–50 Gy on each patient.
Conclusions
Second cerebral neoplasms may appear more than 30 years after the pituitary radiotherapy and its detection advices permanent monitoring in neuroendocrinology consultations by means of periodic neuroimaging studies.

MiR-7 has a role in behaviour of somatotroph adenomas

Ruth Sanchez-Ortiga[1], Laura Sanchez-Tejada[5], Cristina Lamas[2], Rosa Cámara[4], Javier Abarca[6], Irene Monjas[7], Pedro Riesgo[8], Carmen Fajardo[3] & Antonio Picó[1]
[1]Endocrinology Department, Hospital General Universitario Alicante, Alicante, Spain; [2]Endocrinology Department, Hospital General Universitario Albacete, Albacete, Spain; [3]Endocrinology Department, Hospital La Ribera, Alzira, Spain; [4]Endocrinology Department, Hospital Universitario La Fe, Valencia, Spain; [5]Research Unit, Hospital General Universitario Alicante, Alicante, Spain; [6]Neurosurgery Department, Hospital General Universitario Alicante, Alicante, Spain; [7]Otorhinolaryngology Department, Hospital General Universitario Alicante, Alicante, Spain; [8]Neurosurgery Department, Hospital La Ribera, Alzira, Spain.

Purpose
IGF receptor 1 (IGF1R) and epidermal growth factor receptor (EGFR) are receptors tyrosine-kinase (RTK) whose altered signaling are critical factors in development of many types of tumours. These RTK are some of the main targets of the microRNA miR-7. This important tumor supressor miRNA has the ability to inhibit the motility, invasiveness and anchorage-independent growth, suggesting a strong therapeutic potential in many types of cancer. Pituitary adenomas (PA) are a heterogeneous group of tumors with diverse clinical behaviour. The aim of this study is to investigate the role of this miRNA in the behaviour of different PA subtypes.
Methods
In this cross-sectional descriptive study, we evaluated miR-7 by qRT-PCR on 60 human PA: 29 gonadotrophs (GT), 15 somatotrophs (ST), eight functioning corticotroph (CT), and eight silent corticotroph adenomas (SCA). Nine healthy pituitary from autopsies were used as calibrator reference. Aggressiveness was graded according to invasiveness (Hardy's grade IV) and Ki-67 gene expression (>2.59-fold change (FC)).
Results
MiR-7 showed different expression depending on PA subtype (P=0.005). Its highest expression was found in ST (5.21 (2.06–5.80) FC), in which miR-7 was mainly overexpressed and only repressed in 33% of ST with high grade of aggressiveness. Thus, miR-7 repression entailed a risk of 7 (2–25) times higher to ST tumours reached high grade of aggressiveness (P=0.038). In addition, miR-7 was negatively correlated with age (r=−0.583, P=0.022). In GT and SCA, expression was similar (0.91 (0.46–4.70) and 0.80 (0.26–3.18) FC respectively) and in CT, miR-7 showed its lower expression (0.69 (0.31–1.32) FC). However, we did not find associations with their behaviours.
Conclusion
According with our results, miR-7 plays an important role in the behaviour on ST, acting as tumor supressor miRNA and participating against its aggressiveness. Further studies are needed to clarify its potential therapeutic utility.

The dynamics of anthropometric and hormonal parameters in adolescents (boys) with physical and sexual development during therapy with thyroid medications

Utkir Mavlonov[1,2], Yulduz Urmanova[1,2], Shakhlo Babakhodgaeva[1,2], Feruza Khodgaeva[1,2] & Nazira Rikhsieva[1,2]
[1]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan; [2]Bukhara Endocrine Regional Clinic, Bukhara, Uzbekistan.

The purpose of research
To study the dynamics of anthropometric and hormonal indicators of adolescent boys with physical and sexual development (ZFPR) and iodine deficiency disorders (IDD), received treatment for 12 months replacement therapy of thyroid (jodomarin, L-thyroxine, Berlin-Chemie).
Material and methods
We have inspected and examined the whole for the period from 30th May 2012 to 15th October 2013 1066 adolescent boys in different regions of Uzbekistan. In the city of Bukhara and four districts of Bukhara region were examined 523 adolescents (boys) in Namangan region – 200, in Tashkent – 343, aged 11–17 years. The main contingent made up of college students and schools.
In the future, selected 163 patients with various disorders of growth and sexual development was carried spectrum of research includes the study of endocrine status, clinical, biochemical, and hormonal.
Among these patients, we have selected a further 60 adolescents with ZFPR (delayed puberty and growth) + IDD from the city of Bukhara and Bukhara region, which were carried out additional studies (TSH, T_4, X-ray hand, skull, EEG, Echo-EG, etc.) and anthropometric estimates the dynamics before and 12 months after replacement therapy with thyroid (jodomarin 100 and 150 mg/day, L-thyroxine 25 and 50 μg/day).
The results of the study
At 3, 6, and 12 months after treatment with thyroid dynamics in patients with mental retardation + IDD there was a significant improvement in hormonal parameters, namely, the mean values of TSH and free T_4 ($P<0.05$). If the growth rate in patients with CP + IDD before treatment was 5.3 ± 0.2 cm/year, after 12 months of treatment with thyroid averaged 6.3 ± 0.3 cm/year (6.6–9.6 cm/year), and absolute increase growth in 12 months in average: 8.1 ± 0.4 cm.
Conclusions
Thus, on the basis of completed research can be concluded that therapy with thyroid cancer in patients with mental retardation + IDD significantly improves both hormonal and anthropometric indicators, which confirms the need for primary prevention of IDD among children and adolescents.

G protein signalling of native somatostatin receptors 2 and 5 in pituitary cells using a fluorescence-based membrane potential assay

Thomas Günther & Stefan Schulz
Institute of Pharmacology and Toxikology, Jena, Thuringia, Germany.

Somatostatin and dopamine receptors are the major G_i-coupled receptors in somatotrope cells that inhibit hormone secretion from the anterior pituitary. Here, we adapted a novel fluorescence-based screening assay to characterize somatostatin and dopamine receptor signaling in a time-resolved manner. This minimal-invasive technique provides a robust and reliable read out for ligand-induced receptor activation in permanent cell lines and primary pituitary culture. The pituitary cell line AtT-20 expresses both sst2 and sst5 endogenously. Exposure of WT AtT-20 cells to the sst2- and sst5-selective agonists BIM23120 and BIM23268, respectively, promoted a PTX- and tertiapin-Q-sensitive reduction in fluorescent signal intensity, which is indicative of activation of G protein-coupled inwardly rectifying potassium (GIRK) channels. In contrast, exposure to BIM23926 (sst1-selective), L-796/778 (sst3-selective), or L-803/067 (sst4-selective) did not produce any change in fluorescent signal intensity. However, after heterologous expression of sst1, sst3, or sst4 receptors BIM23926 and L-796/778 but not L-803/087 promoted a reduction in fluorescent signal indicating that sst1 and sst3 receptors can also couple to GIRK channels. Similar activation of GIRK channels by dopamine in AtT-20 required overexpression of D2 dopamine receptors.

The use of an oral salt load followed by furosemide in the treatment of euvolemic SIADH-induced hyponatremia

Ana Ortolá[1], Irene Crespo[1], Teresa Ruiz-Gracia[1], Emilia Gomez-Hoyos[2], Martin Cuesta[3], Rona Penso[1], Angela Amengual[1], Paz de Miguel[1], Alfonso Calle-Pascual[1] & Isabelle Runkle[1]
[1]Hospital Clinico San Carlos, Madrid, Spain; [2]Hospital Clinico de Valladoilid, Valladolid, Spain; [3]Beaumont Hospital, Dublin, Ireland.

Introduction
Furosemide can be used in the treatment of SIADH. However, to be effective, renal medulla osmolality (Osm_{RM}) as reflected in urinary osmolality (U_{OSM}) must be high. Sodium is the most important contributor to Osm_{RM}, which increases following the administration of oral salt. We analyze the use of an oral salt load followed by furosemide for the acute/short-term treatment of euvolemic SIADH hyponatremia.
Methods
Retrospective analysis of nine patients with SIADH-induced hyponatremia and moderate hyponatremic encephalopathy receiving 4–5 g of oral salt, followed 3 h later by 20 mg furosemide i.v. or 40 mg furosemide po (salt-plus-furosemide). Serum sodium levels (SNa), serum potassium (SK), and urinary sodium (UNa) were measured at baseline, and 12–16 h following salt administration. In six out of nine patients, a SNa level was available from 24 h or less previously (PSNa). Electrolytes in mmol/l. Plasma (P_{OSM}) and U_{OSM} in mOsm/kg. Wilcoxon and Mann–Whitney *U* tests. SPSS15.
Results
Baseline: 4/9 (44.4%) were women. Median age: 69.3 (S.D.: 20.7). Prior to salt-plus-furosemide, SNa levels were descending in five out of six patients with a median change of −1.5 (IQR −2.3 to −0.25). PSNa: 121 (S.D.: 4.5). Initial SNa: 119 (S.D.: 4.8), SK: 4.4 (S.D.: 0.6), UNa 54 (IQR: 42.5–86), P_{OSM} 249 (S.D.: 7.9), and U_{OSM} 449 (S.D.: 251.2). Following salt-plus-furosemide, SNa rose from 3 to 7 mmol/l, with a median increment of 5 (IQR: 4–7), reaching a SNa of 124 (IQR: 121–127), SK: 4.1 (S.D.: 0.4), UNa 66.4 (S.D.: 24.6), P_{OSM}: 259 (S.D.: 7.4), and U_{OSM}: 370 (S.D.: 151.4). The SNa change post salt-plus-furosemide vs the change prior to salt-plus-furosemide was statistically significant ($P=0.027$). SK descent was also significant ($P=0.017$). All blood pressure levels were below 130/85 mmHg before and after salt administration.
Conclusions
The oral administration of 4–5 g of salt followed by furosemide was useful for the acute/short-term treatment of euvolemic SIADH-hyponatremia in our patients. However, this therapy should not be attempted in severe hyponatremia, since a minimum 4 mmol/l SNa rise was not assured.

DOI: 10.1530/endoabs.37.EP672

EP673

Progressive reduction of tolvaptan doses in the treatment of chronic SIADH

Teresa Ruiz-Gracia[1], Ana Ortolá[1], Irene Crespo[1], Alejando Santiago[1], Emilia Gomez-Hoyos[2], Lourdes Recio[1], Martin Cuesta[3], Maria Paz Pacheco[1], Alfonso Calle-Pascual[1] & Isabelle Runkle[1]
[1]Hospital Clínico San Carlos, Madrid, Spain; [2]Hospital Clinico de Valladolid, Valladolid, Spain; [3]Beaumont Hospital, Dublin, Ireland.

Introduction
Chronic tolvaptan (TV) therapy has been found to be safe and effective in the treatment of chronic SIADH. However, experience with modification of doses over time is limited.
Methods
We conducted a retrospective analysis of weekly TV doses (mg) in 41 patients with chronic SIADH treated for a minimum of 3 months, seen a week following discharge and monthly thereafter. Serum sodium (SNa) goal was 137–140 mmol/l, with 50% TV dose reduction when SNa ≥ 141 and increase when SNa <137. SNa (mmol/l) corrected for glycemia/total proteins. Kruskal–Wallis, Mann–Whitney *U*, SPSS15.
Results
25/41(61%) women, median age of 76 (67–85). Median Nadir SNa: 119 (S.D.: 6.2). Etiology of SIADH: idiopathic 12/41 (29.3%), oncological 10/41 (24.4)%, pulmonary 7/41 (17.1%), pharmacological 5/41 (12.2%), neurological 5/41 (12.2%), and others 2/41 (4.9%). Average duration of therapy was 18.4 (S.D.: 12.0) months. Median weekly hospital discharge dose: 105 (105–105) with SNa 137 (S.D.: 3.0); at 1 month: 105 (78.7–105), SNa 139 (S.D.: 3.3); at 3 months: 52.5

(26.3–135), SNa 138 (s.d.: 3.7); at 6 months: 52.5 (25.3–88.1), SNa 139 (s.d.: 3.3); and at 1 year: 37.5 (22.5–105), SNa 138 (s.d.: 2.7). Oncological patients needed higher doses when compared to the rest at discharge: 157.5 (105–210) vs 105 (105–105), $P=0.049$; at 3 months: 210 (52.5–236.2) vs 52.5 (26.3–105), $P=0.021$; and at 6 months 105 (52.5–420) vs 52.5 (22.5–75), $P=0.022$. Pharmacological patients needed lower doses when compared to the rest at 3 months: 26.25 (18.8–65.6) vs 52.5 (52.5–198.8), $P=0.042$, at 6 months 22.5 (7.5–37.5) vs 52.5 (28.1–105), $P=0.010$, and at 1 year 22.5 (11.3–28.1) vs 52.5 (30–105), $P=0.024$. Side effects: 1/41 patients presented persistent thirst. None presented elevation of liver enzymes.

Conclusions

Chronic tolvaptan therapy is safe and can maintain strict eunatremia in patients with chronic SIADH. Progressively lower doses are needed, thus contributing to economic sustainability of therapy. The minimum dose is usually attained after 6 months of therapy. Oncological patients require higher doses, and pharmacological patients lower ones.

Results of molecular genetic studies for determination of latent mosaicism and parental origin of X chromosome in girls with Turner syndrome in Uzbek population

Ravshan Mukhamedov, Nilufar Ibragimova & Malika Mirkhaidarova
Laboratory of Genomics under the Institute of Bioorganic Chemistry, Republic of Uzbekistan Academy of Sciences, Tashkent, Uzbekistan.

Goal

Identification of latent mosaicism and determination of a parental origin of an X chromosome in TS patients in Uzbek population.

Methods

Molecular genetic studies are carried out in 35 patients with TS (26 with monosomy and nine with mosaicism) at the age of 7–16 and their parents with a set of DIATOMTMDNA prep 200 reagents. DNA amplification was performed in Applied Biosystems thermocyclers. PCR products were subjected to electrophoresis on 12% acrylamide *bis*-acrylamide gel (29:1) with subsequent DNA staining with ethidium bromide and visualization by a BioDocAnalyze (Biometra) system.

Results

Three X-linked markers (DMD 49, AR and DX1283E) were studied on the basis of their high level of heterozygosis (varying from 88.6 to 93.3%), a number of alleles (11–19) and localisation both on a short and long X chromosome arm. The results obtained confirm that the use of a set of these primers (DMD 49, AR and DX1283E) will allow enhancing a probability of obtaining an informative marker and detection of latent X-mosaicism. Monozygosity on all three markers indicates the presence of only one X chromosome that in female patients will correspond to true monosomy (X0). Heterozygosis of one marker suggests on the presence of an additional second X chromosome or a part of an X chromosome which is observed both in 46XX karyotype (healthy) and in mosaic variants of chromosomal anomalies (45X0–46XX and 45X0–46XY).

Conclusions

A comparative analysis of polymorphic markers in TS patients and their parents enable us to establish the origin of an X chromosome and determine in gametogenesis of which parents meiotic impairment occurred. Identification of mosaicism in Turner syndrome is very important from the viewpoint of setting correlations between a phenotype and karyotype.

Inferior petrosal sinus sampling in ACTH-dependent Cushing's syndrome: experience of a Tertiary Portuguese Hospital

Ana Coelho Gomes[1], Lia Lucas Neto[2], Maria Raquel Carvalho[1], Eduardo Barreiros[1], José Maria Aragüés[1], Luís Barreiros[1], Jorge Campos[2] & Mário Rui Mascarenhas[1]
[1]Endocrinology, Diabetes and Metabolism Department, Santa Maria Hospital, Lisbon, Portugal; [2]Neuroradiology Department, Santa Maria Hospital, Lisbon, Portugal.

Introduction

Cushing's disease (CD) is responsible for 80% of endogenous Cushing's syndrome (CS). However, distinguishing the cause of ACTH-dependent CS – CD vs ectopic CS – can be extremely difficult. Bilateral inferior petrosal sinus sampling (IPSS) has the highest diagnostic accuracy in this evaluation.

Objectives

The aims of this study were to determine the accuracy of bilateral IPSS in the differential diagnosis of ACTH-dependent CS and in predicting adenoma lateralisation in CD.

Design

We retrospectively analysed the ACTH levels in inferior petrosal sinus and peripheral blood samples of eleven consecutive patients with ACTH-dependent CS that performed bilateral IPSS between 2005 and 2014 in Santa Maria Hospital in Lisbon. ACTH levels from both inferior petrosal sinus and peripheral blood were measured before and after corticotropin-releasing hormone (CRH) administration – $0'$, $5'$, $10'$, and $15'$. Ratios of central-to-peripheral and interpetrosal ACTH levels were calculated.

Results

IPSS was uneventfully performed in the eleven patients and it was suggestive of CD in nine patients, ectopic CS in one patient and inconclusive in another one. Concerning the nine patients with CD, the basal IPSS central-to-peripheral ACTH ratios were diagnostic for CD (>2) in eight patients (88.9%) and the post-CRH IPSS central-to-peripheral ACTH ratios were diagnostic for CD (>3) in nine patients (100%). ACTH lateralization was found (interpetrosal ratios ≥ 1.4) in eight patients (88.9%). In the patient with ectopic ACTH CS, the IPSS pre- and post-CRH ACTH ratios were negative, as expected. Transsphenoidal surgery was performed in seven of the nine patients with CD and the histologic examination confirmed the diagnosis of ACTH-secreting pituitary adenoma in all of them. Two patients are waiting for surgery.

Conclusion

IPSS was a safe and well-tolerated procedure in our study group. It was effective in the differential diagnosis of ACTH-dependent CS and useful in planning CD surgical therapy.

Placental IGF1R–PI3K/Akt pathway and its relationship to idiopathic birth weight alterations

Maria-Luisa Lazo-de-la-Vega-Monroy[1], Martha I González-Domínguez[1], Leonel Daza-Benítez[2] & Gloria Barbosa-Sabanero[1]
[1]Health Sciences Division, Medical Sciences Department, University of Guanajuato, Leon Campus, León, Guanajuato, Mexico; [2]UMAE, No. 48 IMSS, León, Guanajuato, Mexico.

Introduction

Alterations in foetal growth lead to neonatal health risks and favour metabolic diseases during adult life. Therefore, the study of birth weight determination and its modifications is crucial for metabolic diseases prevention. Placental growth is a key factor in foetal growth. It has been suggested that insulin and the IGF system play an important role in foetal growth and placental development and function. Although, insulin and IGFs in the umbilical cord blood have been associated to birth weight, the roles of placental IGF1 and insulin receptors (IGF1R and IR), and the PI3K/Akt signalling pathway, shared by both receptors, are not fully elucidated. We aimed to analyse protein expression of insulin/IGF receptors and activation of the PI3K/Akt pathway in relation to placental weight and birth weight.

Methods

Transversal comparative study in placentas from healthy mothers of term newborns small gestational age (SGA), adequate gestational age (AGA), and large for gestational age (LGA) ($n=20$/group). Protein expression of IR, IGF1R, and phosphorylation of signalling molecules were analysed by western blot.

Results

IGF1R expression decreased 20% significantly in SGA compared to control AGA, and positively correlated with placental weight ($r=0.34$, $P=0.007$) and birth weight ($r=0.285$, $P=0.027$). IR protein expression was not modified between groups. Phosphorylation of PDK1, main kinase for Akt activation, decreased 40% in both SGA and LGA compared to control. In line with this, we observed a nearly 30% decrease in total Akt in SGA and LGA compared to AGA. PDK1-dependent phosphorylation pAkt–Thr308 showed a tendency, albeit not significant, to decrease in SGA and LGA, while pAkt–Ser273 did not differ between groups.

Conclusion

These results suggest PI3K/Akt pathway may be differentially regulated in SGA and LGA placentas, possibly related to decreased IGF1R expression in SGA, and

perhaps other signalling pathways in LGA, consequently leading to alterations in birth weight.

The impact of correcting the serum sodium level for total proteins in patients receiving parenteral nutrition

Emilia Gomez Hoyos[3], Pilar Matia Martin[2], Martin Cuesta Hernandez[1], Teresa Ruiz Gracia[2], Natalia Perez Ferre[2], Lucio Cabrerizo Garcia[2], Miguel Angel Rubio Herrera[2], Daniel De Luis Roman[3], Alfonso Calle Pascual[2] & Isabelle Runkle de la Vega[2]
[1]Beaumont Hospital, Dublin, Ireland; [2]Clinico San Carlos Hospital, Madrid, Spain; [3]Clinico Universitario de Valladolid, Valladolid, Spain.

Introduction
In a majority of Spanish hospitals, serum sodium levels (SNa) are determined by indirect electrode methodology (sodium in the liquid fraction of serum) divided by the total serum volume (mmol/l). To avoid over/underestimating SNa, a formula can be applied: SNa corrected for total proteins (TP) = SNa × 93 divided by (99.1 − (0.7 × TP)). Hypoproteinaemia is frequent in patients receiving parenteral nutrition (PN), and is probably related to surgery, acute disease, and malnutrition. We have evaluated the impact of hypoproteinaemia on the frequency and degree of hyponatremia in PN patients.
Methods
A retrospective study of patients prescribed PN from 01/11/11 to 01/06/12. SNa was determined at baseline and during PN, and corrected for TP. All sodium levels were corrected for glycemia and presented in mmol/l. Patients with triglycerides >400 mg/dl were excluded. Indirect SNa (SNa) was compared to SNa as corrected for TP (TP-SNa). χ^2, Student's, and Mann–Whitney *U* test.
Results
222 patients were prescribed PN, 57.2% of whom were men. The median age was 75 (61–82). 47.3% were on the general surgery ward, 12% internal medicine, 12.1% oncology, and 8.6% hematology. 14.5% presented malnutrition (by BMI). Median duration of PN was 8 (5–14) days. Average baseline TP was 5.25 (S.D.: 0.76), with 93% presenting hypoproteinaemia (TP <6.5 g/dl). Baseline SNa: 138.1 (S.D.: 4.5) ($P<0.001$), TP-SNa: 134.6 (S.D.: 4.5) with a difference of 3.5 mmol/l (95% CI: 3.4–3.6) ($P<0.001$). 20% presented initial hyponatremia (SNa <135 mmol/) vs 52% (TP-SNa <135) ($P<0.001$). 28.7% developed SNa hyponatremia during PN, vs 64.2% with TP-SNa ($P<0.001$), within 4 (2–7) and 3 (1–14) days respectively ($P=0.05$).
Conclusions
Patients receiving parenteral nutrition often present hypoproteinaemia. Therefore, correction of indirect SNa for total proteins becomes essential, both to avoid underestimation of the number of patients with hyponatremia, as well as to correctly take into account its degree.

Long-term safety, tolerability, and efficacy of extended release somatostatin analogues

Javier González, Rogelio García-Centeno, María Arnoriaga, María Picallo, María Laura Ramírez, Victor Manuel Andía, Yoko Lucía Olmedilla, Aurelio López & Susana Monereo
General University Hospital Gregorio Marañón, Madrid, Spain.

Introduction
The main indications for the somatostatin analogues (SST-A) are acromegalies and/or neuroendocrine tumors. They can increase fecal fats, which could lead to the loss of fat soluble vitamins. There are few published studies showing the effects of the long-term use.
Methods
Retrospective study of patients with SST-A indicated from our endocrinology department in the last 10 years. We analysed indications and different epidemiological, clinical, and laboratory data, at baseline and after treatment with SST-A. Results expressed as: percentages (qualitative variables), average and S.D. (quantitative variables), with a significance level of $P<0.05$.
Results
39 patients (66.6% women and 33.3% men) of 57.5 (13.68) years. Indications: acromegaly 71.8%, gastroenteropancreatic NETs 15.4% (four MEN1, one VHL, and one sporadic), gigantism 5.1%, advanced medullary thyroid cancer 2.6%, Graves' ophthalmopathy 2.5% and thoracic neurofibroma in NFI 2.6%. 69.2% was treated with octreotide LAR average dose of 44.73 (32.27) mg/28 days and 25.6%, with lanreotide Autogel 46.5 (35.88) mg/28 days or both 5.1%. Durability of 57.12 (13.68) months. 7.6% were cured, 79′58% controlled the disease, 12.82% had persistent disease (two acromegalies and three NETs progressed). Side effects: gastrointestinal 17.9%, biliary 20.5% (7.69% asymptomatic cholelithiasis, 2.6% symptomatic cholelithiasis, and 10.3% cholecystectomy), and 2.6% post-injection reactions. Analytical changes after treatment: HbA1c 6.3% (3.20) vs 6.5% (3.02), *P* 0.008; AST 18.02 (6.97) vs 24.87 (25.78), *P* 0.008; GGT 31.89 (44.09) vs 76.52 (160.75), *P* 0.075, and FA 98 (68.92) vs 149.34 (202.74), *P* 0.06. There were no significant differences in other analytical or vitamin parameters. 12.6% of patients discontinued treatment for: healing 7.6%, intolerance 2.5%, and ineffectiveness 2.5%.
Conclusions
SST-A are effective and well tolerated drugs. We found no evidence of malabsorption due to its use. Most frequent adverse effects were digestive, hepatobiliary and glycemic alterations, as described in the literature.

EP679

Hyponatremia and mortality in patients hospitalised for heart failure (2005–2011)

Javier Marco[1], Irene Crespo[1], Ana Ortolá[1], Teresa Ruiz Gracia[1], Paz De Miguel[1], Manuel Mendez[1], Karla Nuñez[1], Judith Lopez[2] & Alejandra Duran[1]
[1]Hospital Clinico San Carlos, Madrid, Spain; [2]Hospital Universitario de Canarias, San Cristobal de la Laguna, Spain.

Introduction
Hyponatremia is the most frequent electrolyte disorder in hospitalised patients. Our aim was to determine the incidence, mean hospital stay, readmission rate and mortality rate among patients with acute heart failure (HF) and hyponatremia.
Methods
Retrospective analysis of data collected from the minimum data set (MDS) of Spanish National health System during 2005–2012 from discharged patients of Internal Medicine with HF and hyponatremia. A bivariate analysis was conducted in order to detect differences in the mortality rate, mean hospital stay and readmission. A logistic regression analysis was performed using as dependent variable in hospital mortality, adjusted for age and Charlson's index. χ^2 and Student's *t*-tests were performed.
Results
A total of 11 095 (2.2%) out of 504.860 cases with HF presented hyponatremia and 64.6% were women. Mean age was 81.9 (S.D.: 9.27) years in hyponatremia groups vs 79.7 (S.D.: 9.76) in normonatremic patients. In our study we found an increased prevalence of encoded hyponatremia as the mean diagnosis, from 7.7% in 2005 to 24.4% in 2011. The overall mortality in hyponatremic patients was 17.5% vs 10.9% ($P<0.001$) in non hyponatremic. Readmission rate was 22.2% vs 16.8% ($P<0.001$). Hyponatremia was associated with an increased risk of mortality, with an OR 1.58 (95% CI 1.50–1.66); $P<0.05$. The same results were found in the logistc regression analyses adjusted for age (OR 1.061 (95% CI 1.060–1.062); $P<0.05$) and for Charlson's index (OR 1.388 (95% CI 1.361–1.461); $P<0.05$).
Conclusions
Hyponatremia was associated with an increased mortality risk in hospitalised patients with HF, as described in previous studies. Thus, its accurate diagnosis and treatment is crucial. Nowadays, hyponatremia is considered to be a mayor diagnosis as reflected in the increased prevalence of its coding in discharged sheets. Nonetheless, further prospective studies regarding hyponatremia and mortality are needed.

Giant prolactinoma: a current challenge

Ana Pires Gonçalves[1], Ana Rita Clara[2], Artur Lourenço[3], Miguel Cordeiro[4], Rui Almeida[2] & Mário Lazaro[2]
[1]Internal Medicine Service, Endocrinology's Division, CHAlgarve, Faro, Portugal; [2]Internal Medicine Service, CHAlgarve, Faro, Portugal; [3]Neurosurgery Service, CHAlgarve, Faro, Portugal; [4]Neuroradiology Service, CHAlgarve, Faro, Portugal.

Introduction
Giant prolactinomas are rare tumours, representing 2–3% of all prolactin (PRL)-secreting tumours. Their definition is restricted to pituitary adenomas with a diameter $\geq$4 or $\geq$2 cm of suprasellar extension, very high PRL concentrations ($\geq$1000 ng/ml) and no concomitant GH or ACTH secretion. They are more common in young to middle-aged men. Endocrine symptoms are often present for a long period of time, but most times the diagnosis is made when neurologic complications occur.
Purpose
We present a rare case of giant prolactinoma and review related literature.
Clinical case
The patient is a 40 years old male, with no personal or family history of endocrinopathy. On July 2014 he rushed to the Emergency Department at CHAlgarve due to a change in behaviour, confusion and loss of sphincter control occurring over the previous 2 days. The sellar-MR showed a mass with 68×46×50 mm, intense contrast enhancement, involving intra and left parasellar with hydrocephalus and erosion of bone pavement. The patient underwent ventriculoperitoneal drainage and was admitted in the neurosurgery department. The laboratory study showed PRL >2000 ng/ml (3.46–19.40 ng/ml) and free testosterone 3.1 pg/ml (7.20–23 pg/ml). He started cabergoline 0.5 mg/day, two pills per week. While recovering in the ward it was possible to establish a 2 years of progressive worsening headache, left lateralized, about 1-month, diplopia, right hemianopsia and symptoms of hypogonadism. One month after starting therapy he presented with rinorraquia, needing an endoscopic intervention to repair the sellar pavement. Patient re-evaluation after 6 weeks therapy revealed a 29.4% tumour diameter reduction and after 5 months a significant symptomatic improvement occurred, with normalisation of PRL and testosterone.
Conclusion
In patients with giant invasive pituitary adenoma it is important to evaluate pituitary function. Clinicians should be aware of hook effect. Although naïve or acquire resistance to dopaminergic agonists are most frequently in these tumours, medical therapy should be considered as first-line treatment in most patients.

EP681

Clinical case of TSH-secreting pituitary adenoma

Anna Lipatenkova[1], Larisa Dzeranova[1], Ekaterina Pigarova[1] & Liudmila Astafieva[2]
[1]Endocrinology Research Centre, Moscow, Russia; [2]Burdenko Neurosurgery Institute, Moscow, Russia.

TSH-secreting pituitary adenoma (thyrotropinoma) is a rare (0.5% of all pituitary adenomas) and usually benign pituitary lesion, arising from the monoclonal expansion of neoplastic thyrotrophes. Thyrotropinoma usually presents with symptoms thyrotoxicosis (milder compared to those originating from the primary thyroid disorders) and mass effects of the pituitary tumour.
Aim
To describe the clinical course of thyrotropinoma presented with paroxysmal atrial fibrillation with high sensitivity to somatostatin analogues.
Case presentation
In a 53 years old man the disease manifested in 2001 at the age of 41 years with paroxysmal atrial fibrillation and hypertension effectively medically treated with β-blockers. The paroxysms were well controlled but became a lot frequent since December 2013. The hormonal profile showed elevated levels of TSH – 4.3 μU/ml (0.25–3.5), FT_4 – 23.56 pmol/l (9.0–20.0), FT_3 – 7.63 pg/ml (2.5–5.5), and normal levels of IGF1, ACTH, cortisol, LH, and FSH. Thyroid autoantibodies were negative. Ultrasound revealed diffuse changes without increasing the thyroid gland size, MRI demonstrated a pituitary macroadenoma 18×12×11 mm with para(D)-sellar extension. Test with short acting octreotide showed normalization of TSH, FT_4, and FT_3 levels during the first week of treatment. Subsequent therapy with octreotide LAR was started with dose 10 mg once in 28 days with further induction of euthyroidism, decrease of vertical size of pituitary adenoma on MRI at 5 months of medical treatment. Subjectively, the patient noted an improved health with disappearance of atrial fibrillation paroxysms. In 2014 the patient underwent a transnasal adenomectomy. The immunohistochemical analysis of the removed tumor showed positive staining for TSH, GH, SSTR2, and SSTR5. One week after surgery, TSH was suppressed. Postoperative laboratory tests 1 month after surgery confirmed euthyroidism: TSH – 2.21 μU/ml (0.4–4.0), FT_4 – 11.1 pmol/l (9.0–20.0), and FT_3 – 5.3 pg/ml (2.3–6.3).
Conclusion
The TSH-secreting adenoma is a rare cause of hyperthyroidism. Diagnosis is usually delayed due to milder and nonspecific clinical picture, because of that patients can be managed by cardiologists for long periods of time. Surgery is still the mainstay of treatment, although somatostatin analogues may be effectively used as medical therapy which is reflected by expression somatostatin receptors in the adenoma.

Granins (chromogranin A, secretogranin II, and secretoneurin) as biochemical and immunohistochemical markers of non-functioning pituitary adenomas

Anna Lipatenkova[1], Larisa Dzeranova[1], Ekaterina Pigarova[1], Liudmila Astafieva[2], Liudmila Shishkina[2] & Anastasia Ektova[3]
[1]Endocrinology Research Centre, Moscow, Russia; [2]Burdenko Neurosurgery Institute, Moscow, Russia; [3]Russian Pediatric Clinical Hospital, Moscow, Russia.

Objective
To assess the sensitivity of granins – chromogranin A (CgA), secretogranin II (SgII), and secretoneurin (Sn) as biochemical and immunohistochemical markers of non-functioning pituitary adenomas (NFPAs):
Methods
50 patients with NFPAs were included in the study. Tissue samples were immunostained for pituitary hormones, Ki-67, αSU, CgA, SgII, and Sn. Furthermore, we have determined the levels of CgA, SgII in the serum and Sn in the plasma samples by ELISA method in patients before and after surgical treatment.
Results
Of the 50 NFPA 27 (54%) were gonadotropic tumours, 12 (24%) were null cell adenomas, immunopositivity for ACTH was determined in six cases (12%), for GH in four cases (8%), and for PRL in one case (2%). The median level of Ki-67 was 2.8% (min. 0.2% and max. 7%). We divided all patients in four groups by the degree of granin immunopositivity. High immunopositivity for CgA was found in ten cases (21%), for SgII in 17 (34%), for Sn in 24 (52%) compared to negative staining in 8 (17%), 10 (20%), and 2 (4%) respectively. High immunopositivity for all granin types was more frequent in gonadotropinomas, negative or slow staining for CgA and medium to high staining for SgII and Sn was more typical for ACTH and GH silent adenomas. The average serum CgA concentration before operation was 60.3 nmol/l (±5.2), after surgical treatment 67.84 (±9.8), SgII serum 24.9 (±8.9) and 27.6 (±8.9), plasma Sn 3.2 (±0.2) and 3.4 (±0.3) serum respectively. In healthy subjects the average levels of CgA and Sn were comparable with NFPAs patients 60.2 (±10.5) and 4.1 (±0.7), respectively, but healthy subjects had lower levels of SgII 14.8 (±7.30). We did not found any correlation between granin levels and their tissue expression.
Conclusions
Our work shows that a majority of NFPAs are truly secreting adenomas with significant numbers comprising potentially hazardous cortico- and somatotropinomas. CgA, SgII, and Sn have a high expression in most of the NFPAs, but their serum/plasma levels before and after surgical treatment were not much different from the controls and did not correlate with immunohistochemical results. So serum CgA and plasma SN measurement do not represent a helpful biochemical marker of NFPAs potential hypersecretion, except of SgII, but this requires further study on a large sample of patients.

The role of tolvaptan in syndrome of inappropriate antidiuretic hormone secretion: clinical outcomes and effect on length of stay

Yolanda López Vázquez, María Barragans Pérez, Cristina Trigo Barros, Ángel Martínez González, Javier Lago Garma & Concepción Páramo Fernández
Complexo Hospitalario Universitario de Vigo (EOXI), Vigo (Pontevedra), Spain.

Introduction
Hyponatremia is the most common electrolyte imbalance among hospitalised patients. Syndrome of inappropriate antidiuretic hormone secretion (SIADH) is considered the most frequent etiology on patients with euvolemic hiponatremia. Conventional treatment includes water restriction and salt tablets with limited efficacy and very slow onset of action in certain patients.
Material and methods
Systematic sampling of all SIADH patients treated with tolvaptan (group A, $n=12$) in our service over the last 2 years was compared to 12 within the conservative treatment group (group B). The average age was similar in both groups (A: 71.8 years vs B: 71.6 years) with a clear male predominance in the whole sample. The average plasma sodium was also similar (A: 123.4 mmol/l vs B: 123.8 mmol/l). SIADH etiology was mainly neurosurgical (A: nine patients and B: seven patients).
The length of hospital stays was compared with the time span until natremia normalization in both groups. The variables are expressed as mean $\pm$ S.D. The statistical analysis used was Student's *t*-test. P value <0.05 was considered significant.
Results
The length of hospital stay from the beginning of the treatment was 11.1 ± 8.1 days in the tolvaptan-treated group and 16.7 ± 11.5 days in the conservative-treatment group ($P=0.18$). The mean hospital stay was higher for those treated with conservative therapy. Normalisation of natremia took 2.7 ± 2.7 days in the tolvaptan-treated group and 11.3 ± 9.4 days in the conservative-treatment group. The speed of correction of the hyponatremia was statistically significant for those in the tolvaptan-treated group ($P=0.04$).
Conclusion
Tolvaptan treatment in SIADH patients shows a rapid normalisation of natremia, effectively reducing inpatient length of stay.

Opposite effects of dexamethasone and retinoic acid on neuronal actin cytoskeleton

Hélène Roumes[1], Julie Brossaud[1,2], Marie-Pierre Moisan[1], Véronique Pallet[1], Anabelle Redonnet[1] & Jean-Benoît Corcuff[1,2]
[1]UMR 1286 INRA Univ. Bordeaux, Bordeaux, France; [2]University Hospital, Bordeaux, France.

Brain ageing associates decreased neuronal plasticity, increased glucocorticoid and decreased retinoic acid (RA) signalling. We previously showed an interaction of these pathways on the regulation of a synaptic plasticity gene, BDNF. We thus investigated the effects of GC and RA on two BDNF-dependent genes: activity-regulated cytoskeleton protein (Arc) and Ca^{2+}/calmodulin-dependent protein kinase II (CaMK). Dexamethasone (Dex, 10^{-6} M) and/or RA (10^{-6} M) were applied on HT22 hippocampal cells during 4 days. Dex significantly decreased (55%) whereas RA increased cellular (145%) CaMKII mRNA compared to control. When combined RA reduced Dex effect. Dex alone did not affect (95%) whereas RA increased (195%) Arc mRNA levels. When combined to Dex RA had the same effect on Arc mRNA as when used alone. As plasticity is closely related to the formation of cell processes, we investigated cell morphology and F-actin cytoskeleton organisation. Dex affected cell morphology: Dex-treated cells areas were significantly larger and rounder than controls and these increases were suppressed when RA was added. Actin expression (mRNA) and abundance (protein) were unchanged by Dex or RA.
Conversely, phalloidin-stained polymerised actin was doubled by Dex. RA suppressed this effect. Both cortical actin and stress fibres were significantly increased by Dex (276% of control). RA suppressed this effect down to the level attained with RA alone: either moderately increased (190%) for cortical actin or decreased under control level for stress fibres (79%). Both glucocorticoids and RA target cell actin cytoskeleton and subsequently cell remodelling. The positive effects of RA on memory processes may then be due to counteracting some of the deleterious effects of glucocorticoids observed in brain ageing.

The relationship of genetic factors to the development of nephrolithiasis in primary hyperparathyroidism

Elena Peretokina[1], Natalia Mokrysheva[1], Lyudmila Rozhinskaya[1] & Ekaterina Zakharova[2]
[1]Endocrinology Research Center, Moscow, Russia; [2]Medical Genetics Research Center, Moscow, Russia.

Factors affecting the development of nephrolithiasis (NL) in primary hyperparathyroidism (PHPT) actively studied. CASR polymorphisms may be linked with the development of NL in PHPT. Supposed to the role of VDR in the development of nephrolithiasis in patients without PHPT.
Objective
To assess the relationship of polymorphisms CASR and VDR with the development of the NL at PGPT.
Methods
The study included 187 patients with PTPT (54 (49; 64) years), 110 with NL and 77 without NL. The study of polymorphisms CASR (R990G, A986S, and Q1011E). In 166 patients (110 with NL and 56 without NL) were analyzed polymorphisms VDR – ApaI, BsmI, FokI, Cdx2, and TaqI. The distribution of genotypes consistent with the condition of Hardy–Weinberg.
Results
The most common in both groups were polymorphisms R990G (23.6% vs 21.8%) and A986S (29.1% vs 37.9%), and Q1011E (16.4% vs 9.2%) met the most rare, the differences are not reliable ($P>0.05$). The genotype distribution was as follows CASR, with NL: AA-70.9%, AS-23.6%, SS-5.5%; RR-76.4%, RG-20.9%, GG-2.7%; QQ-83.6%, QE-14.5%, and GG-1.8%; without NL: AA-62.1%, AS-32.2%, SS-5.7%; QQ-90.8%, QE-8.0%, EE-1.1%, RR-78.2%, RG-19.5%, and GG-2.3%; not obtained differences in the frequency of genotypes and alleles CASR between the groups ($P>0.05$). VDR polymorphisms frequency did not differ between the groups ($P>0.05$). with NL: allele A-54.9%, a-45.1%; allele B-65.5%, b-34.5%; allele F-61.2%, f-38.8%; allele G 84.5%, A-15.5%; allele T-61.2%, and allele t-38.8%. In the group without NL: allele A-55.4%, a-45.5%; allele B-65.5%, b-59.6%; allele F-55.7%, f-44.3%; allele G-86.6%, A-13.4%; allele T-55.7%, and t-44.3%. The distribution of genotypes and alleles of VDR polymorphisms in the presence and absence of NL was not significantly different ($P>0.05$).
Conclusion
According to the results revealed a high prevalence of polymorphisms of VDR and CASR patients with PHPT. Development of NL is not associated with the presence of VDR polymorphisms and CASR.

Pineal gland and thymus: structural and functional unity

Michael Paltsev[1], Igor Kvetnoy[2], Victoria Polyakova[2], Natalia Linkova[2] & Tatiana Zubareva[2]
[1]Russian Academy of Science, Moscow, Russia; [2]Ott Institute of Obstetrics and Gynecology, Saint-Petersburg, Russia.

Neuroimmunoendocrine changes of the pineal and thymic function, are now believed to pay an important role in the mechanisms of age-associated diseases development. Here we studied the morphofunctional and signal molecules unity of pineal gland and thymus during ageing. Autopsic pineal gland and thymus

material sampled from people was divided into groups 1 – middle-aged people (60–74 years) and 2 – old people (75–89 years). Ultra-thin slices were used for electron microscopy. The study was carried out on the electron microscope JEM-100S. The identification of markers of signal molecules serotonin, melatonin, CD8, CD20 was carried out with immunohistochemical method using primary mouse MABs, and secondary antibodies, biotinylated anti-mouse immunoglobulins. The data of electronic microscopy had shown the ultrastructure similarity of pinealocytes and thymic epithelial cells (TEC) in autopsy samples of pineal gland and thymus. Pinealocytes and TEC have the high number of round vesicules with, as we suppose, can consist biological activity signal molecules, in pinealocytes and TEC cytoplasm. These data can show that the both types of cells can belong to neuroimmunoendocrine system. By immunohistochemical method it was verified the expression of common signal molecules – endocrine cells markers (melatonin, serotonin) and lymphocytes (CD8, CD20) in the human pineal gland and thymus. The expression of melatonin, serotonin, CD8, CD20 in the pineal gland and thymus decreased during aging.
Thus, the melatonin, serotonin CD8, CD20 expression in the pinealocytes and thymic cells confirms the unity of pineal gland and thymus as an neuroimmunoendocrine organs.

Serum melatonin levels in pharyngo-laryngeal carcinomas

Adina Zamfir Chiru Anton[1], Dana Manda[2], Radu Cristian Popescu[3] & Dan Cristian Gheorghe[4]
[1]Childrens' Hospital Grigore Alexandrescu, Bucharest, Romania; [2]C.I.Parhon National Institute of Endocrinology, Bucharest, Romania; [3]Coltea Clinical Hospital, Bucharest, Romania; [4]Childrens' Hospital M.S. Curie, Bucharest, Romania.

Background
Melatonin is mostly known as a circadian hormone, but it also has effects in a large number of cellular processes (cell differentiation, proliferation, apoptosis, redox balance). Although it was studied in many tumours, very little is known about his role in pharyngo-laryngeal carcinomas.
Aim
To evaluate serum melatonin levels in patients with pharyngo-laryngeal malignant tumours preoperatively and after surgical excision of the malignancy.
Materials and methods
45 patients (41 men and four women, 59 ± 7.42 years) and 35 age-matched healthy subjects have been tested for melatonin levels using ELISA method after serum extraction by reverse phase chromatography. Each patient had two blood samples, one in the morning and one at midnight in order to record the day and night melatonin levels. 19 patients (42.2%) presented a laryngeal squamous cell carcinoma, 22 patients (48.8%) pharyngeal, base of tongue or tonsil squamous cell carcinoma, and four patients (9%) had other malignant tumours in the head and neck region. Patients with β-adrenergic blockers medication have been excluded.
Results
43.7% of the patients had a T1 stage tumour, while T2, T3 and T4 stages were recorded in 18.75, 25.05 and 12.5% respectively. Biopsy revealed a squamous cell carcinoma in 82.9% of the patients. Tumour patients have been monitored postoperatively and their melatonin secretion tested after surgery as well (2 days after the surgery). Before surgery, cancer patients had significant lower levels of melatonin compared to healthy subjects. There were no significant changes immediately after surgical removal of the tumours.
Conclusion
Serum melatonin levels are lower in patients harbouring a pharyngeal or laryngeal tumour compared to healthy subjects. The idea of long-term recording of melatonin levels in head and neck cancer patients treated by different therapeutical approaches and future possibilities of using melatonin substitution in therapy is discussed.

Plasma β-endorphins level is higher in lean patients with polycystic ovary syndrome than in lean women without this disorder

Marta Kialka[1], Magdalena Spalkowska[2], Tomasz Milewicz[1], Anna Pelka[3], Barbara Wasyl[4], Iwona Rogatko[5] & Rita Tomczyk[1]
[1]Department of Gynecological Endocrinology, Collegium Medicum, Jagiellonian University, Cracow, Poland, [2]Department of Dermatology, Collegium Medicum, Jagielonian University, Cracow, Poland, [3]Internal Disease Department, Dietl Specialist Hospital, Cracow, Poland, [4]Department of Pediatrics, L. Rydygiera Hospital, Cracow, Poland, [5]Department of Clinical Biochemistry, Polish-American Institute of Pediatrics, Cracow, Poland.

Introduction
Polycystic ovary syndrome (PCOS) is one of the most common causes of anovulatory and infertility. According to the widespread data it affects 3–10% of women in the procreative age. Although many research have been done, it is still unclear which of mechanisms are responsible for the development of PCOS. The most up-to-date scientific trial indicates that the evolution of PCOS is related to the activity of the endogenous opioid system but precise mechanism is not completely understood.
Description of methods/design
26 lean women (BMI $= 21.34 \pm 1.83$) were enrolled to the study and divided into two groups: group A consisted of 12 PCOS patients with FAI > 5 and group B consisted of 14 women without features of PCOS and with FAI < 5. Standard diagnostic hormone profile was made in all the patients and the level of β-endorphins was measured. The following hormones were measured: FT_3, TSH, FT_4, aTPO, aTG, LH, estradiol, testosterone, cortisol, DHEAS, prolactin in metoclopramide test, insulin in OGGT test, vitamin D3, C-peptide, CA125. BMI was assessed.
Results
Mean β-endorphin levels was significantly higher in group with FAI > 5 (14.73 pg/ml ± 4.97 vs 7.26 pg/ml ± 2.62; Mann–Whitney test; $P = 0.000018$). Spearman test indicated also a positive correlation between β-endorphin level and weight ($r = 0.682$; $P < 0.05$) and β-endorphin level and C-peptide level ($r = 0.778$; $P = 0.05$) in FAI < 5 group. Absence of the significant correlation was observed in FAI > 5 group. It might be a consequence of limited number of this group.
Conclusion
Our study showed that the level of β-endorphins was statistically significant higher in patients with PCOS. Further experimental research is required to evaluate the correlation between β-endorphins and PCOS evolution.

Endocrinology Research Centre, Moscow, Russia.

Introduction
Several genetic syndromes are associated with familial pituitary adenomas. The penetrance of clinical manifestations of these syndromes is not ubiquitous and this might be the reason for the lack of detection of genetic mutations when only one or few genes are studied.
Aim
Clinical characterisation and molecular genetic study of a panel with ten genes involved in formation of pituitary adenomas in familial setting.
Materials and methods
Study included six families (13 patients) with familial pituitary adenomas with no other features of known genetic syndromes. Three families were with the homogeneous type of secretion (acromegaly) and three families with the heterogeneous type (acromegaly/nonactive pituitary adenoma). The study involved five men (38%) and eightt women (62%).
Results
Median age was 55.6 years (40–69 years), the average height for females was 160 cm, for males 170 cm. Most adenomas were GH-producing and non-secreting. The diagnosis of acromegaly was confirmed by hormone testing (GH $>$ 2.5 ng/ml $<$ no suppression on OGTT and high IGF1). Maximum GH was 23.9 ng/ml, medium -13.9 (0.42–23.9), IGF1: maximum – 1817, medium – 1517 (439–1817). Minimum size of adenomas was 7 mm, maximum – 17 mm.

Tumour extensions were: supra – (three cases, 23%), latero – (two cases, 15%). In most patients, adenomas were extended in more than 2 directions. Genomic DNA from a blood samples of patients (probands) underwent high-throughput sequencing on the Ion Torrent Personal Genome Machine (Life Technologies) using a custom-designed AmpliSeq panel for the sequencing of a panel of genes (MEN1, CDKN1B, PRKAR1A, GNAS, AIP, SDHA, SDHB, SDHC, SDHD, PRKCA, CDKN2C, CDKN2A, POU1F1, PTTG2) but no pathological mutations were detected.
Conclusions
Families with hereditary pituitary adenomas can have tumours with homogenous and heterogeneous types of secretion. We were not able to show any genetic alteration in the group of patients studied.

Quality of life in patients with acromegaly vs non-functioning pituitary adenomas and healthy control group

Aleksandra Jawiarczyk-Przybylowska[1], Dorota Szczesniak[2], Joanna Rymaszewska[2] & Marek Bolanowski[1]
[1]Department of Endocrinology, Diabetes and Isotope Therapy, Medical University, Wroclaw, Poland; [2]Department of Psychiatry, Division of Consulting Psychiatry and Neurobiological Research, Medical University, Wroclaw, Poland.

Objective
Acromegaly has an important impact on health-related quality of life. The aim of study was to ascertain the quality of life of patients with uncontrolled vs controlled acromegaly and compared to those with non-functioning adenomas and healthy control group.
Methods
124 participants underwent a cross-sectional assessment including the quality of life (AcroQoL, WHOQoL BREF), psychiatric morbidity (GHQ-28) and acceptance of illness (AIS). The sample consists of patients with acromegaly divided into two subgroups accordingly to minimal GH concentration during the OGTT or profile of GH and level of IGF1: controlled and cured acromegaly group (CAG $n=19$) and active acromegaly group (AAG $n=31$); patients with non-functioning adenomas group (NAG $n=37$) and healthy control group (CG $n=37$) matched according to age.
Results
No significant differences were identified between CAG, AAG and NAG groups referring to quality of life, psychiatric morbidity and acceptance of illness. Compared with healthy controls, AAG group suffered more from anxiety and insomnia ($P=0.031$) and had significantly poorer quality of life in psychological domain measured with WHOQoL BREF ($P=0.004$). In acromegaly group we observed statistically significant positive correlation between the level of IGF1 and prevalence of psychopathological symptoms measured by the GHO-28. We also observed negative correlation with the level of GH and AcroQoL in total score as well as in psychological dimension, including subscale '*appearance*'. The illness duration since diagnosis was identified as a negative predictor of physical dimension of AcroQoL ($r=-0.35$, $P=0.035$), social domain of WHOQoL ($r=-0.43$, $P=0.009$) and acceptance of the illness ($r=-0.42$, $P=0.011$).
Conclusion
Concerning the diagnosis, not only biochemical and radiological parameters, but also psychological aspect should be evaluated in acromegaly. IGF1 and GH could be an independent negative predictors of quality of life among those patients.

Acute octreotide suppression test in acromegaly: predictive value in long-term response to long-acting somatostatin analogues

Ana Palha, Luisa Cortez, António Afonso, Fernando Fonseca & Ana Agapito
Centro Hospitalar Lisboa Central – Hospital Curry Cabral, Lisbon, Portugal.

Introduction
The usefulness of acute octreotide suppression test (OST) in the selection of patients with acromegaly for chronic somatostatin analogues (SA) treatment is still controversial.
Aim
To investigate the predictive value of OST for long-term responsiveness to long-acting SA.
Materials and methods
Retrospective study of 25 drug-naive patients (13 males) with active acromegaly, subjected to an OST (hourly serum GH concentrations for 8 h were measured before and after last administration of s.c. octreotide 100 μg q8 h for 48 h). The mean achieved GH was used for analysis. GH nadir response during OST was also evaluated. GH < 1 ng/ml and normal IGF1 (both evaluated as mean of three values) were used as parameters for biochemical control during SA therapy.
Results
On average, during OST a GH decline of $70.15 \pm 23.4\%$ was observed in this cohort. Most patients (72%; $n=18$) showed a decrease > 50% of GH during OST (group A), while 28% had ≤50% GH reduction (group B). During SA treatment, 61.1% of group A achieved IFG1 and/or GH normalization, with a mean reduction of 54.6 and 68.2% respectively. In Group B, 28.5% reached IFG1 and/or GH normalization, with a mean reduction of 42 and 52.7%, respectively. Biochemical control was observed in 11.1% of patients on group A and 14.3% on group B. In total, 36% of patients achieved a GH value < 1 ng/ml during the OST. In this group 77.8% ($n=7$) had mean reduction >50% during OST. This test showed positive (PPV) and negative predictive (PNV) values of 64.71 and 71.43% for 50% GH reduction and PPV (66.67%) and PNV (56.25%) for minimal GH level < 1 ng/ml during OST. A 50% reduction and a nadir GH < 1 ng/ml during OST didn't show correlation with the long-term normalisation of serum IGF1 and/or GH ($P=0.106$ and $P=0.271$ respectively).
Conclusion
In this cohort, a reduction of 50% and nadir GH < 1 ng/ml following an OST weren't predictive of remission on long-term SA as defined by updated criteria.

Clinical experience in the treatment of acromegaly: 5 years follow-up results

Zelija Velija-Asimi[1] & Snjezana Pejicic[2]
[1]University Clinical Centre of Sarajevo, Sarajevo, Bosnia and Herzegovina; [2]Clinical Centre of Banja Luka, Banja Luka, Bosnia and Herzegovina.

The aim of this study was to evaluate our clinical experience in the treatment of acromegaly during 5-year follow-up period.
Methods
Seventeen acromegaly patients (11 women and six men) monitored during 5-year follow-up period. A level of GH of <2.5 ng/ml and the normal IGF range were considered as the criterion for remission. The GH level and IGF1 level were evaluated every 6 months, while magnetic resonance imaging was taken every year during follow-up period.
Results
All patients had growth in hands and feet and typical facial asymmetry in the beginning of the study. Six patients had diabetes mellitus (35%), four patients had hyperprolactinaemia (24%), two patients had hypothyroidism (12%) and five of patients had hypertension (29%). Visual field defect was in five patients (29%). Microadenomas founded in six patients and macroadenomas in 11 patients. Nine patients were treated by trans-sphenoidal surgery. One of them was cured, three patients developed postoperative pituitary deficiency. Two patients were treated by transcranial surgery, but not cured. One of them was treated by Gamma Knife radiosurgery and after that developed pituitary deficiency. Sixteen out of 17 acromegaly patients were treated by octreotide (six of patients as primary therapy and ten patients as secondary therapy after surgery). Biochemical remission was achieved in 12 of 16 patients (75%) who received octreotide treatment. Tumour size decrease was achieved in 54% of patients. The treatment was successful withdrawn at five patient (29%) without recurrence for 2–3 years follow-up. One patient passed away due to co-morbidities and at one patient treatment was cancelled due to kidney cancer. Only one patient (6.25%) who regularly used high dosage of octreotide has uncontrolled acromegaly.
Conclusion
Our findings demonstrated that octreotide LAR treatment successfully controlls clinical, biochemical and neuroradiological parameters.

Fenofibrate has differential effects on cell proliferation and GH secretion in GH_3 cells

Sandra Rotondi[1], Alessio Modarelli[1], Patrizia Sanità[1], Adriano Angelucci[1] & Marie-Lise Jaffrain-Rea[1,2]
[1]Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, L'Aquila, Italy; [2]Neuroendocrinology, Neuromed, IRCCS, Pozzilli, Italy.

We have recently observed that the peroxisome proliferator receptor α was expressed by normal and tumoural pituitary tissues, in particular by somatotrophs. To elucidate its function, we have studied the effects of fenofibrate on cell proliferation and GH secretion in GH_3 cells.
Material and methods
GH_3 cells were grown in Ham's F10 and treated for 24, 48 and 72 h by different concentrations of fenofibrate (12.5–50 μM). Cells were counted and GH concentration was measured in the medium by ELISA. GH concentration was then corrected by cell number. Real time RT-PCR and western blotting were performed on RNA and protein extracts to further analyse GH transcription and intracellular content. Cyclophilin B, which expression was not influenced by fenofibrate, was used as a housekeeping gene and a protein load control. Data were analysed by ANOVA with *post-hoc* Tukey analysis. $P<0.05$ was considered significant.
Results
A significant time- and dose-dependent decrease in cell proliferation was observed in treated cells, with a simultaneous increase in GH concentration. GH increase was maximal at 48 h and reached about three-folds at 25 μM and four-folds at 50 μM ($P=0.004$ and $P=0.0004$ vs controls, respectively). Analysis of *GH* mRNA at 48 h showed a bimodal response, with a significant increase in gene transcription at 25 μM ($P=0.0094$) and levels similar to control cells at 50 μM ($P=0.002$ vs 25 μM). Compared to control cells, a modest increase in intracellular GH content was also observed at 25 μM, with a modest decrease at 50 μM, respectively.
Conclusion
Fenofibrate in its therapeutic concentration range is able to reduce cell proliferation in GH_3 cells, with a dose-dependent increase in GH secretion which may reflect either an increased in GH synthesis (at low dose) or an increase in GH release (especially at high dose). It may be of interest to evaluate the clinical implications of these findings, especially in acromegalics.

Single dose irradiation of GH3 cells increase GH and PRL secretion in vitro

Amato Fratticci[1,2], Sandra Rotondi[1], Alessio Modarelli[1], Pierluigi Bonfili[2], Ernesto Di Cesare[1,2], Edoardo Alesse[1] & Marie-Lise Jaffrain-Rea[1,3]
[1]Department of Biotechnological and Applied Clinical Sciences; University of L'Aquila, L'Aquila, Italy; [2]Radiotherapy, S.Salvatore Hospital, L'Aquila, Italy; [3]Neuroendocrinology, Neuromed, IRCCS, Pozzilli, Italy.

Radiotherapy (RT) may represent a useful tool in the treatment of GH-secreting tumours in the presence of a post-operative active disease and single dose stereotactic RT/gamma knife is the preferred option in most cases. The effects of RT on the control of hormone secretion are very slow and pharmacological treatment remains necessary for years. Some authors advocate withdrawal of somatostatin analogues (SSA) during RT, although the short-term effects of RT on hormone secretion have been poorly studied. To address this issue, we used GH_3 cells as a model of GH-secreting tumours to evaluate the acute endocrine effects of a single irradiation dose.
Methods
GH_3 cells were treated with a LINAC and single 5 and 10 Gy irradiation were evaluated after 6, 24, 72 and 144 h in terms of cell proliferation and GH/PRL secretion/gene transcription by ELISA/Real Time RT-PCR assays.
Results
A significant time- and dose- dependent reduction of cell proliferation was observed in irradiated cells vs controls. In contrast, a significant time- and dose-dependent increase of GH and PRL release (ng/10^6 cells) was observed after 72 and 144 h in irradiated cells (up to five- and 11-fold at 10 Gy, respectively, $P<0.0001$ vs controls). A progressive time-dependent increase in PRL gene transcripts was observed in both irradiated and control cells, with a modest increase in irradiated vs control cells at 6 and 24 h. GH transcription also tended to increase immediately after irradiation, but was markedly reduced in irradiated cells at 72 and 144 h ($P<0.0001$ vs controls), suggesting a predominant effect of RT on GH release.
Conclusion
Transient increases in hormone secretion may occur after irradiation of GH/PRL-secreting cells, with potential differential effects in hormone synthesis and release. Such data should be evaluated in clinical practice in order to reconsider the indications for SSA withdrawal before irradiation in acromegalic patients.

Associations between radiological parameters and molecular phenotype in human GH-secreting pituitary tumours: could they help in predicting the appropriate medical therapy?

Maria Rosa Alhambra-Expósito[1], María Sagrario Lombardo-Galera[3], Alejandro Ibañez-Costa[2], Esther Rivero-Cortés[2], Manuel Gahete[2], Raúl Luque-Huertas[2], María Ángeles Galvez-Moreno[1] & Justo Castaño-Pastor[2]
[1]Endocrinology and Nutrition Unit, Reina Sofia University Hospital, Córdoba, Andalucía, Spain; [2]Department of Cell Biology, Physiology and Immunology University of Córdoba, Córdoba, Andalucía, Spain; [3]Radiology Unit, Reina Sofia University Hospital, Córdoba, Andalucía, Spain.

Acromegaly is caused by excessive GH secretion from pituitary adenomas. Transphenoidal surgery is the first-choice treatment, but new drug therapies (e.g. somatostatin analogues, SSA) offer promising avenues for medical treatment. Complementary diagnostic tools may assist this strategy, helping to refine drug choice. Here, we investigate the associations between radiological features and molecular phenotype of pituitary tumours from acromegalic patients. This observational study included 17 acromegaly patients (38.4 ± 15.6 years; 64.7% women), diagnosed from 2007 to 2012 at the Endocrinology and Nutrition Unit of the Reina Sofia Hospital, in whom surgery, radiology and molecular phenotyping of the adenoma was carried out. Magnetic resonance was performed to localise the tumours, which were all macroadenomas (94.6%) at diagnosis except for one microadenoma. Anterior–posterior mean diameter (APD) was 18.3 ± 6.6 mm, inferior–posterior diameter (IPD) 18.8 ± 6.7, and left-right diameter (LRD) 17.9 ± 6.4 mm. Average volume was 33.36 mm^3. Extrasellar growth was observed in 73.3%, suprasellar growth in 60%, right sphenoid sinus invasion in 26.7%, left sinus invasion in 20%, and 20% in both sinus. Compared to isointense adenomas, T2 hyperintense tumours showed greater IPD (23.4 ± 5.3 vs 14.3 ± 5.4 $P=0.009$), LRD (21.2 ± 4.5 vs 14.6 ± 7.2 $P=0.035$), total volume (4.5 ± 2.6 vs 2.2 ± 3.1 $P=0.025$), and Knosp index (2.9 ± 1.2 vs 1.1 ± 1.5 $P=0.036$). T2 hyperintense adenomas had higher dopamine receptor subtype-5 (DR5) expression ($P=0.038$)) and Ki67 ($P=0.044$). Adenoma IPD directly correlated with expression of DR5 (Rho+0.770 ($P=0.006$)) and somatostatin receptor subtype-3 (sst3) (Rho+0.549 ($P=0.034$)); and DR5 expression correlated with APD (Rho+0.735 ($P=0.010$)). Adenoma volume was directly associated with sst3 (Rho+0.535 ($P=0.038$)) and DR5 (Rho+0.736 ($P=0.010$)) expression. Knosp index directly correlated with all diameters: APD ($P<0.001$), IPD ($P<0.001$), LRD ($P=0.002$); tumour volume ($P<0.001$); sst3 ($P=0.015$); and Ki67 ($P=0.044$). Our results reveal significant correlations among key pre-surgical radiological parameters and specific molecular phenotypic features of pharmacological relevance in GH-producing adenomas. Future studies should explore the molecular basis of these findings and their potential value in helping to select the appropriate medical therapy for these patients.

Unravelling the role of stress regulators on GnRH release in Letrozole induced PCOS rat model

Nirja Chaudhari & Laxmipriya Nampoothiri
Department of Biochemistry, The Maharaja Sayajirao University of Baroda, Vadodara, Gujarat, India

Background and aim
polycystic ovarian syndrome is a multi aetiological female endocrinopathy wherein one of the major target organs affected is adrenal. It is important to note that adrenal plays key role in evoking stress mediated responses in brain; which can in turn affect GnRH, the main regulator of HPG axis. Along with corticotrophin releasing factor (CRF), newly discovered neuropeptides-urocortin2 and RF-amide related peptide-3 (RFRP-3) (mammalian GnIH analogue) are also known to modulate stress. However, complex regulation of GnRH axis via stress regulatory molecules and gonadal function adaptations is not clear. Thereby, current study was undertaken to elucidate the interaction of stress regulators with GnRH in PCOS pathology.
Material and methods
PCOS was induced in rat using letrozole-an aromatase inhibitor and confirmed for pathology. Hormones-gonadotropins, androgen, oestradiol, progesterone levels were measured by ELISA. Regulatory neurotransmitter-GABA was estimated by HPLC. Expression studies of GnRH regulatory neuropetides and their receptors-CRF1, CRFR1, Ucn2, CRFR2, GnRH, GnRHR, RFRP-3, GPR-147 were carried out using real-time PCR.
Results
Hypothalamus and pituitary of PCOS rats demonstrated an increase in corticosterone ($P<0.01$) and androgen levels ($P<0.01$) whereas progesterone ($P<0.05$) and estradiol ($P<0.01$) levels were decreased. These altered levels of steroids were parallel to changes obtained in their receptors (GR, AR, ER-α, ER-β, PR). GABA levels were significantly decreased in hypothalamus ($P<0.01$) and pituitary ($P<0.05$) with reduced GABAB1 receptor expression in PCOS rats. PCOS rats also showed significant alterations in mRNA expressions of Ucn2, RFRP-3 and GnRH1 with their receptors CRF2, GPR-147 and GnRHR, respectively.
Conclusion
This study elucidates the complex regulation of GnRH in the hypothalamus and pituitary by stress elements- Ucn2, RFRP-3 and their involvement in altered GnRH release in PCOS pathology.

Patients with neuroendocrine neoplasms: the experience of a referral centre in Greece

Krystallenia Alexandraki, Georgios Boutzios, Eleftherios Chatzellis, Dimitrios Thomas, Maria Chrysochoou, Marina Tsoli, Maria Kaltsatou, Georgios Nikolopoulos, Panagiotis Moschouris & Gregory Kaltsas
Endocrine Unit, Department of Pathophysiology, Medical School, Laiko Hospital, University of Athens, Athens, Greece.

Introduction
Neuroendocrine neoplasms (NENs) are rare and heterogeneous neoplasms with variable biological behaviour but generally slow progression.
Methods/design
355 patients with NENs registered in our data-base have been studied (166 females, mean age: 52 years; range: 11–88), during the period 2004–2014. TNM system has been used for staging and proliferation index Ki-67 for grading.
Results
Out of 355 patients, 35 (10%) had neoplasms in the context of familiar disorders: MEN-1($n=32$) and Von Hippel Lindau ($n=2$). The following primary sites were registered: stomach: 56 (15.8%); duodenum: 13 (3.7%); pancreas: 131 (36.9%); small intestine: 40 (11.3%); appendix: 31(8.8%); colon: 14 (4%); lung: 27 (7.6%); thymus: 1 (0.3%), other sites: 22 (6.2%), unknown origin: 15 (4.2%); 4 (1.2%) had two concomitant neoplasms. 54 (15.3%) had functional syndrome. Metastatic deposits were found in 103 (29%) patients: bones: 16 (4.5%), lung: 5 (1.4%), liver: 94 (22.5%), peritoneum: 7 (2%), pancreatic: 2 (0.6%), brain: 2 (0.6%), omentum: 2 (0.6%), ovaries/kidneys/spleen: 1 (0.28%). 139 (47.8%) patients had Ki-67 $\leq$2% (grade 1), 111 (31.3%) 3–20% (grade 2), 24 (8.2%) $>$20% (grade 3) for gastro-intestinal NENs and for lung 4 (1.4%) atypical, 10 (3.4%) atypical, 1 (0.3%) large and 1 (0.3%) small cell lung carcinomas and 1 (0.3%) atypical thymic NEN. Stage1 were found in 135 (38.8%), stage2: 63 (18.1%), stage3: 48 (13.8%), stage4: 102 (29.3%). 197 patients had surgical removal of the neoplasms, 46 had an endoscopic resection. The other systemic or local therapies that the patients received as monotherapy or in combination as first line treatment are as following: somatostatin analogs ($n=100$), chemotherapy ($n=45$), neoplasm-targeted molecular therapy ($n=22$), radionucleotides ($n=9$), conventional radiotherapy ($n=6$), cauterisation with radiofrequencies/RFA ($n=8$), chemoembolisation ($n=6$), interferon ($n=2$). 99 patients received second, 44 third, 23 forth, 12 fifth, 5 sixth line treatment. In the last follow-up of the present analysis 21 patients died from their disease: five had grade1 neoplasm, ten grade 2, two grade 3, one atypical thymic and another atypical lung NEN but two patients did not have an available Ki-67.
Conclusion
The present registry imply that the majority of the patients with NENs have slow progression and long survival despite the presence of disseminated disease, confirming the necessity of the recent introduced therapeutic and diagnostic options following the guidelines as well as their management from referral centres under multidisciplinary teams.

Review of assessment (diagnosis) of hyponatraemia

Penny Dhanjal[1] & Jayadave Shakher[2]
[1]Birmingham Heartlands Hospitals, Birmingham, UK; [2]Otsuka Pharmaceuticals UK Ltd., Wexham, UK.

Introduction
Hyponatraemia is the commonest electrolyte disorders encountered in hospitals. The aetiology of hyponatraemia is based on clinic assessment and biochemical investigations. However, studies have shown that recommended guidelines are usually not implemented.
Aim
Review of assessment (diagnosis) of Hyponatraemia and outcome based on length of stay (LOS) in hospitals.
Methods
A systematic search using PUB Med and Med Line, including an Internet search of published abstracts from British Endocrine Society, European Endocrine Society and Lung Oncology was conducted between 2002 and 2014 in UK hospital settings.
Results
18 publications were identified using search criteria using key word hyponatraemia combined with investigations, management and outcomes. Two were journal publications and the rest were abstract submissions which were of retrospective audit analysis of patients admitted with hyponatraemia in hospitals. Total of 2052 patients and the duration of the studies vary from 2 weeks to 52 weeks. There was wide variability with definition of hyponatraemia and S Na <130 and <125 mmol/l were commonly used. The aetiology diagnosis of SIADH was mentioned in all studies but only average score of 25% was recorded in all domains with regards to serum and urine osmolality and urine sodium. The average score improved to over 50% when cut off S Na was $<$ 125 mmol/l. The LOS was reported in nine studies and overall mean was 16 days.
Conclusion
Though the definition of hyponatraemia is <135 mmol/l, the audit findings seem to indicate there is higher threshold for detailed biochemical investigations when S Na is <125 mmol/l and to some extent when S Na falls to $<$ 130 mmol/l. This probably reflects under investigations with accurate diagnosis of hyponatraemia which would have an impact on management as shown in recent published study (Tzoulis *et al.*, *PGMJ* 2014;0:1–5).

Addisonian crisis as a manifestation of a partially empty sella in a 68-year-old woman

Zadalla Mouslech[1], Maria Somali[1], Anastasia-Konstantina Sakali[2], Pavlina Koulara[1], Alexandros Mourouglakis[1], Georgios Tsoutsas[1], Christos Savopoulos[1], George Mastorakos[2] & Apostolos Ioannis Hatzitolios[1]
[1]1st Medical Propedeutic Department of Internal Medicine, AHEPA University Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Department of Endocrinoloy, Metabolism and Diabetes, Aretaeio Hospital, School of Medicine, University of Athens, Athens, Greece

Introduction
Empty sella syndrome (EES) is a condition often discovered incidentally, where the sella turcica, the structure containing the pituitary gland, appears to be empty.

Patients either remain asymptomatic or, rarely, manifest signs of declined pituitary function. Patients experiencing hypopituitarism are offered hormonal replacement. Autopsy studies estimated a 5% EES prevalence among healthy individuals.
Case report
A 68-year-old post-menopausal woman, overweight (BMI = 29), mother of three children, presented with a 3-day history of fever (T = 38, 5 °C), excessive vomiting and nausea and a history of 15 days of anorexia, weakness and fatigue. Five years ago, during the course of a hospitalization for the investigation of leukopenia, she was diagnosed with myelodysplastic syndrome. Physical examination yielded no pathological findings, whereas laboratory results revealed leukopenia (WBC = 2.900), hypokalaemia (K + 3.2 mmol/l), low TSH levels = 0.18 μIU/ml (n.v. 0.27–4.2), low FT_4 = 6.01 pmol/l, (n.v. 12–22), decreased gonadotropin levels (FSH = 1.3 mIU/ml, n.v. in menopause > 30 and LH = 0.2 mIU/ml, n.v. in menopause > 10), hypocortisolaemia (cortisol = 51 nmol/l,n.v. 171–536 nmol/l) and normal ACTH = 17.3 pg/ml (n.v. 10–60). Adrenal function investigation with the short Synacthen test was positive (cortisol 0 min = 110 nmol/l.30 min = 283 nmol/l, 60 min = 410 nmol/l) and MRI of the pituitary gland demonstrated a partially empty sella turcica, with herniation of the suprasellar cistern. The patient was diagnosed with panhypopituitarism and was initially treated with i.v. administration of methylprednisolone. After discharge, outpatient treatment included levothyroxine and prednisone.
Conclusions
Empty sella may be primary or secondary to surgery, irradiation or infarction of the pituitary gland. Idiopathic ESS usually generates from congenital defects of the sellar diaphragm where arachnoid membrane herniates through the deficient diaphragm, compressing the pituitary gland. In up to 50% of the cases, primary ESS is associated with benign intracranial hypertension. MRI usually demonstrates the compression of the pituitary tissue against the floor of the sella and the subsequent deviation of the pituitary stalk. Hypopituitarism is a rare complication of EES as it manifests when > 90% of the pituitary tissue is compressed or atrophied.

Fracture of the left wrist as a possible indication of Cushing's disease

Zadalla Mouslech[1], Maria Somali[1], Anastasia-Konstantina Sakali[2], Nikolaos Kakaletsis[1], Georgios Tsoutsas[1], Christos Savopoulos[1], George Mastorakos[2] & Apostolos Ioannis Hatzitolios[1]
[1]1st Medical Propedeutic Department of Internal Medicine, AHEPA University Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Department of Endocrinoloy, Metabolism and Diabetes, Aretaeio Hospital, School of Medicine, University of Athens, Athens, Greece.

Introduction
Cushing's syndrome is a rare (0.004%) hormonal disorder, which develops due to hypercortisolaemia. Cushing's disease refers to a corticothroph cell pituitary tumour overproducing ACTH, which induces abnormally increased cortisol production from the adrenal glands. Cushing's disease is a causative factor of osteoporosis, hypertension, glucose intolerance and dyslipidaemia.
Case report
A 50-year old woman was referred to our department for the investigation of osteoporosis. She reported a 2-year history of weight gain, hypertension and hair loss and currently a fracture of her left wrist. Reported age of menopause, 49 years. On physical examination her blood pressure was 140/90, she was overweight (BMI = 25) and had bilateral supraclavicular fullness, buffalo hump, calf bruises and white striae on the abdomen. Laboratory examination revealed shortened APTT, eosinopenia, increased fasting glucose, dyslipidemia, high-normal sodium levels (Na + = 145 mmol/l), mild hypokalemia (K + = 3.4), hypercortisolaemia (cortisol = 754 nmol/l, n.v. 171–536), FSH = 132 mIU/ml, LH = 36.9 mIU/ml, ACTH = 136 pg/ml (n.v. 0–60), PTH = 10.8 (n.v. 1.58–6.03) and 24-h urinary free cortisol = 436.4 μg/dl (n.v.10–110). Estimation of lumbar spine bone mineral density by dual-energy X-ray absorptiometry was diagnostic of osteoporosis (T score −3.3). The patient underwent dynamic investigation with dexamethasone-suppressed CRH stimulation (Dex-CRH) test, which indicated ACTH-dependent Cushing's disease. 3 Tesla MRI of the pituitary gland suggested the presence of a microadenoma. Bilateral inferior petrosal sinus sampling (IPSS) established the diagnosis of a microadenoma on the right anterior part of the pituitary gland. Treatment was started with pasireotide 2 × 900 μg daily.
Conclusion
Mortality in Cushing's disease is by eight-times higher than in the general population, especially when the disease is not fully controlled. Unfortunately, many disease-related complications such as hypertension, dyslipidemia and osteoporosis are not completely reversible when diagnosis is delayed. We suggest the diagnosis of Cushing's disease to be considered in the differential diagnosis of osteoporotic fractures or osteoporosis.

Clinical and molecular differences between invasive and non-invasive pituitary adenomas

David Cano[1], Mariola Mendez-Muros[1], Eva Maria Venegas-Moreno[1], Noelia Gros[1], Elena Dios[1], Natividad Garcia-Hernandez[1], Ainara Madrazo-Atutxa[1], Ignacio Martin[2], Eugenio Cardenas[2], Ariel Kaen[2], Florinda Roldan[3] & Alfonso Soto-Moreno[1]
[1]Endocrinology and Nutrition Unit, Institute of Biomedicine of Sevilla (IBiS), Hospital Universitario Virgen del Rocío/CSIC/Universidad de Sevilla, Sevilla, Spain; [2]Neurosurgery Unit, Hospital Universitario Virgen del Rocío, Sevilla, Spain; [3]Radiology Unit, Hospital Universitario Virgen del Rocío, Sevilla, Spain.

Pituitary adenomas are usually benign. However, a significant number of pituitary adenomas show an aggressive behaviour, with local invasion, increased risk of recurrence after surgery and lack of therapeutic response. In this study, we aimed to determine whether invasive and non-invasive pituitary adenomas display differences in clinical features and molecular parameters. In this retrospective descriptive study, 46 pituitary adenomas were analysed. Invasiveness was defined as invasion of surrounding structures like cavernous or sphenoidal sinus on the basis of magnetic resonance imaging and surgical findings. Clinical variables, histological subtype and need for radiotherapy were collected. Quantitative PCR was used to measure the expression of several membrane receptors important for pituitary function: somatostatin receptors (SSTR1–SSTR5), dopamine receptors (DR1-DR5) including the long isoform of dopamine D2 receptor 2, GHRHR, GHSRS1, GHSRS1b, proliferation genes (ki67 and PTTG1) and housekeeping genes (HPRT, GAPDH and β-actin). 30 invasive pituitary adenomas (63.3% non-functioning; 23.3% GH-producing; 13.3% ACTH-producing) and 16 non-invasive adenomas (37.5% non-functioning; 43.8% GH-producing; 18.75% ACTH-producing) were analysed. No significant differences were observed in age and sex between invasive and non-invasive adenomas. Growth of tumour remnants (P < 0,0001) and need for radiotherapy (P = 0.016) was higher in invasive adenomas. Only SSTR3 (P = 0.043), the long isoform of dopamine D2 receptor 2 (P = 0.048) and PTTG1 (P = 0.029) display significant differences between invasive and non-invasive adenomas. SSTR1 (P = 0.007), dopamine D2 receptor (P = 0.019) and PTTG1 (P = 0.039) expression was higher in histological subtypes of aggressive pituitary adenomas. Our preliminary results indicate that invasive pituitary adenomas display differences in clinical features and gene expression. It remains to be determined whether these differences in gene expression might represent a mechanistic link to the invasion process.

Molecular analysis of miRNA expression profiles in AIP mutation positive somatotropinomas

Nikolai Falk[1], Adrian Daly[2], Albert Beckers[1] & Natalia Pellegata[2]
[1]Institute of Pathology, Helmholtz Zentrum München, Munich, Germany, [2]Department of Endocrinology, CHU de Liège, University of Liège, Liège, Belgium.

Germline mutations in the aryl hydrocarbon receptor interacting protein gene (AIP) predispose to pituitary adenomas in young patients, often presenting as familial isolated pituitary adenoma (FIPA) kindreds. Pituitary adenomas in patients with AIP mutations (AIPmut) are usually somatotropinomas, which are more aggressive and have poorer responses to somatostatin analogues than their non-mutated counterparts. Given the rarity of this condition, the molecular pathogenesis of the AIP mutated tumors is still incomplete.
The aim of this study was to determine the microRNA (miRNA) expression profile of AIP mutation-positive somatotropinomas. Tumours from patients carrying AIP mutations (AIPmut; seven tumors from six patients) were compared with somatotropinomas from mutation-negative individuals (AIPwt). RNA was extracted from formalin-fixed, paraffin-embedded tissues. For miRNA profiling, the GeneChip miRNA 1.0 arrays from Affymetrix were used. After filtering for

detection and applying the Benjamini-Hochberg correction of data, a cut-off *P*-value of <0.05 was chosen. This resulted in a total of nine non-coding RNAs significantly differentially expressed between AIPmut and AIPwt adenomas by a fold change $>$ 1.5. Six were up-regulated and three down-regulated in AIPmut *versus* AIPwt tumors. Based on Ingenuity Pathway Analysis, these miRNAs are involved in cell proliferation and motility, cell death and cell cycle. We validated the expression of 5 differentially regulated miRNAs using individual Taqman RT-PCR assays, which allowed us to discount one miRNA. The functions of the differentially regulated miRNAs were assessed in *in vitro* studies, in addition to the role of mutant AIP proteins in regulating miRNAs expression. The identification of biologically relevant miRNAs regulated by AIPmut may give insights into the molecular pathogenesis of AIP-associated somatotropinomas.

Mortality in SIADH is similar to that in non-SIADH hyponatraemia; preliminary data

Christopher J Thompson[1], David Slattery[1], Saket Gupta[1], William Tormey[2] & Martin Cuesta Hernandez[1]
[1]Academic Department of Endocrinology, RCSI Medical School, Beaumont Hospital, Dublin, Ireland; [2]Department of Chemical Pathology, RCSI Medical School, Beaumont Hospital, Dublin, Ireland.

Introduction
Excess mortality due to hyponatraemia is well documented but it is not clear whether the mortality associated with SIADH is different to that associated with non-SIADH hyponatraemia (NSH).
Methods/design
Prospective evaluation of all patients admitted with or developing hyponatraemia in a tertiary hospital (pNa $<$130 mmol/l) in January 2015. Diagnosis of SIADH was based on standard clinical and biochemical criteria (pNa, spot urine sodium, urine osmolarity, 0900 h cortisol and TFTs). Statistics were by Mann–Whitney *U*, Student's *t*, or χ^2 tests, as appropriate.
Results (SIADH VS NSH)
180 patients were included. 89 (45 females) were classified as SIADH vs 91 (45 females) as NSH. Clinical data: mean age was similar; SIADH 68 years (S.D.: 15) vs NSH 72 years (S.D.: 15), $P=0.09$. Premorbid history of hypertension, diabetes, COPD, liver disease, and cognitive impairment were similar ($P>0.05$) but CCF (6.7% vs 30.7%, $P<0.0001$) and ischemic heart disease (17.9% vs 31.8%, $P=0.02$) were commoner in NSH. Laboratory data: admission pNa was similar; SIADH 126 mmol/l (S.D.: 5) vs NSH 126 mmol/l (S.D.: 3), $P=0.68$. Other laboratory results (median (IQR), SIADH first): pK: 4 mmol/l (3.6, 4.3) vs 4.1 mmol/l (3.7, 4.9), $P=0.003$. pUrea: 5.3 mmol/l (4, 6.9) vs 11.6 mmol/l (7.4, 18.8), $P<0.0001$, pCreatinine 64 μmol/l (53.5, 74) vs 128 μmol/l (85, 213), $P<0.0001$, and spot uNa: 53.5 mmol/l (32, 89) vs 30 mmol/l (18, 59), $P=0.005$. In SIADH, 0900-h cortisol: 482 nmol/l (IQR: 412, 578), 21% were receiving therapeutic glucocorticoids. One patient with COPD had a subnormal post Synacthen peak cortisol of 363 mmol/l due to recent oral prednisolone course. No patient had hypothyroidism. Duration of hospital admission was similar: SIADH 13 days (11) vs 11 days (10), $P=0.55$ and mortality was similar in SIADH, 5.6% compared to NSH 9.8% ($P=0.34$).
Conclusion
Preliminary results show similar mortality rate in patients with SIADH compared to non-SIADH, although larger number of patients will confirm these observations.

The higher gastrin levels were associated with better glycaemic control

Georgios Boutzios[1], Krystallenia Alexandraki[1], Panagiotis Moschouris[1], Eleni Lampropoulou[1], Anastasia Evaggelatou[2], Antigoni Velidaki[2], Eufrosyni Kitsou[2] & Gregory Kaltsas[1]
[1]Endocrine Unit, Department of Pathophysiology, Medical School, Laiko Hospital, University of Athens, Athens, Greece; [2]Department of Nuclear Medicine, Laiko University Hospital, Athens, Greece.

Background
Gastrin is an early incretin candidate, since it is released by oral glucose and potentiates the glucose-induced insulin secretion. It has been shown that only in hypoglycaemic or hyperglycaemic conditions gastrin release is influenced by changes in blood glucose and insulin concentrations.
Aim
To evaluate whether there is a relation between fasting serum glucose and serum gastrin concentrations.
Methods
Gastrin and glucose levels and HbA1c were measured in 202 blood samples. We studied gastrin serum concentrations dividing the samples in three subgroups with glucose concentrations $<$100, 101–126, $>$126 mg/dl, and in three subgroups with HbA1c $<$5.7, 5.7–6.4, $>$6.5%, and glucose levels in three subgroups with different gastrin levels 100–200, 200–500, and $>$500 ng/ml.
Results
Gastrin and HbA1c were negatively correlated ($r=-0.27$, $P=0.04$) in the total population of samples studied. No difference was found in gastric concentration in the subgroups of normal, moderately increased, increased glucose concentrations (462.2 ± 311.9, 568.1 ± 164.9, and 387.8 ± 46.2 respectively), or in the subgroups of normal, prediabetic, diabetic range of HbA1c (520.8 ± 285.3, 428.7 ± 327.1, and 297.9 ± 236.5 respectively) but a trend value between normal and diabetic values ($P=0.08$). In low, mid-high, high gastrin levels HbA1c (6.3 ± 9.7, 6.14 ± 0.7, and 5.8 ± 0.6) values but not glucose (109.2 ± 35.9, 111.6 ± 30.6, and 106.2 ± 25.4 respectively) levels different only between low and high gastrin levels ($P<0.001$).
Conclusion
A negative correlation between glucose and gastrin levels has been shown in the present study. In patients with higher gastrin levels, HbA1c was statistically significant lower compared to patients with lower gastrin levels, indicating a better glycaemic control. Nevertheless further studies are needed to confirm these findings.

Association of polymorphisms of VDR and CASR with clinical and laboratory manifestations of primary hyperparathyroidism

Elena Peretokina[1], Natalia Mokrysheva[1], Lyudmila Rozhinskaya[1] & Ekaterina Zakharova[2]
[1]Endocrinology Research Center, Moscow, Russia; [2]Medical Genetics Research Center, Moscow, Russia.

Clinical manifestations and severity vary considerably primary hyperparathyroidism (PHPT) patients. Several studies indicate that the variation of clinical manifestations PHPT may be associated with genetic factors, in particular the VDR gene polymorphisms and CASR. The purpose of this study was to evaluate the effect of VDR gene polymorphisms and CASR on indicators calcium and phosphorus metabolism, levels of 25(OH)D, PTH, and condition of bone density in patients with PHPT.
Methods
The study involved 187 patients with PGPT (median age 54 (49; 64) years, 160W/27M). The study of polymorphisms CASR (R990G, A986S, and Q1011E). In 166 (139W/27M) patients analyzed polymorphisms VDR – ApaI, Bstm, FokI, Cdx2, and Taq. The distribution of genotypes consistent with the condition of Hardy–Weinberg. All patients were investigated levels of total calcium, ionized calcium, phosphorus in the blood, alkaline phosphatase, calcium in daily urine, PTH, 25(OH)D, and densitometry three parts of the skeleton. 25(OH)D was investigated during the period from November to May.
Result
The analysis of polymorphisms of VDR revealed that polymorphisms FokI and BsmI influence the clinical manifestations PHPT. Carriers of FF genotype polymorphisms FokI level of 25(OH)D was significantly higher than that of genotype ff and Ff ($P=0.014$). In carriers bb genotype polymorphism Bsml level of β-cross laps and osteocalcin was lower than the combined genotype Bb+bb ($P=0.036$ and $P=0.041$) and higher mean values of BMD in the spine ($P=0.038$). Relationship with the calcium levels in the blood, urinary calcium or PTH has been received. There were no associations with different polymorphisms CASR indicators calcium and phosphorus metabolism, PTH, bone turnover markers, BMD in patients with PGPT.
Conclusion
The polymorphisms FokI and BsmI VDR may affect the clinic PGPT that is of interest, given the large variability manifestations PHPT. This result requires further study.

Physiological area of normality of copeptin in normal-to-hyperosmolar states

Ingeborg Schnyder[1], Konrad Strauß[2], Gilbert Koch[3], Carla Walti[4], Marc Pfister[3], Bruno Allolio[2], Wiebke Kristin Fenske[5] & Mirjam Christ-Crain[1]
[1]Universitätsspital Basel, Basel, Switzerland; [2]Universitätsklinikum Würzburg, Würzburg, Germany; [3]Universitäts-Kinderspital beider Basel, Basel, Switzerland; [4]Spital Uster, Uster, Switzerland; [5]Universität Leipzig, Leipzig, Germany.

Background
Copeptin is the C-terminal portion of the precursor of vasopressin. In contrast to vasopressin copeptin is stable *in vitro* and easy to measure. Similar kinetics of both peptides have been described in different trials. However, the physiological area of normality of copeptin has never been evaluated.
Methods
We measured plasma copeptin, sodium, and osmolality levels in 93 healthy volunteers at baseline, during/after i.v. infusion of 3% saline until a sodium level of at least 150 mmol/l was reached, and during/after an oral waterload/i.v. infusion of glucose 5%. In total, 4–19 (median 12) measurements per patient were performed.
Results
Median age of the study participants was 28 years (range 20–54 years) with a balanced gender distribution male/female (46/47). Upon hypertonic saline infusion plasma sodium levels increased from a median of 140 mmol/l (S.D. 2.21) to 152 mmol/l (S.D. 2.44), plasma osmolality from 293 mOsmol/kg (S.D. 6.62.) to 317 mOsmol/kg (S.D. 6.4) and plasma copeptin from 4.1 pmol (S.D. 4.56) to 34.2 pmol/l (S.D. 31.9). The maximal value of copeptin was reached after 150 min (S.D. 28.1), without a time lag to the maximum of plasma sodium or osmolality (reached after 145 (33.9) and 150 (27.4) min respectively). There was a moderate to strong positive correlation between plasma copeptin and plasma sodium ($r=0.58$, $P<0.05$) and plasma copeptin and plasma osmolality ($r=0.48$, $P<0.05$).
Conclusion
There is a correlation between plasma copeptin, plasma sodium, and plasma osmolality levels from normo-to-hyperosmolar states.

Pancreatic neuroendocrine tumour presenting with malignant hypercalcaemia

Rosa Quilez Toboso, Silvia Aznar Rodriguez & Antonio Hernandez Lopez
Hospital General Albacete, Albacete, Spain.

Introduction
The aim of this report is to present the uncommon clinical presentation of a patient with a pancreatic NET.
Case report
A 55-year-old man with personal history of hypertension, dyslipidaemia, and depression. He was referred to the outpatient for high levels of calcium in repeated assessments during the last year. He referred polyuria and polydipsia. Not clinical history of bone fractures, abdominal pain, or another digestive symptoms. Initial biochemical assessment demonstrated: calcium 11.8 mg/dl (8.5–10.5), phosphate 2.4 mg/dl (2.5–4.5), creatinine 0.68 mg/dl, GGT 121 U/l, FA 182 U/l, PTHi 7 pg/ml (10–65), 25-OH-vit D 8.78 ng/ml (>20), 1,25-OH-vit D 98.8 pg/ml (16–56), ECA 26 U/l (8–52), calciuria 545 mg/day (<400), chromogranin A 152 ng/ml (<100), and rPTH 1.5 pmol/l (<1). Proteinogram and bone scintigraphy negative. Abdominal CT, revealed a 6.6-cm lobular mass at the tail of the pancreas with collateral circulation and multiple focal liver lesions, which occupied 70% of the hepatic parenchyma. Somatostatin receptor scintigraphy exhibited multiple lesions that overexpress somatostatin receptors suggestive of multiple hepatic metastases from neuroendocrine tumor, without pancreatic uptake. Percutaneous FNA (guided by endoscopy) of the pancreatic lesion revealed a well-differentiated NET. Initially, octreotide long-acting release (LAR) 20 mg every 28 days was administrated and calcium levels decreased from 13.7 to 9.4 mg/dl in 3 months. After that, calcium levels increased again so we increased octreotide LAR 30 mg every 28 days, and then every 15 days, but due to biochemical progression everolimus treatment was initiated. After 2 years treatment with SA and 1 year with everolimus there has not been radiological progression. The patient is clinically asymptomatic.
Conclusion
The manifestation of paraneoplastic syndrome due to PTHrP hypersecretion, despite its rareness in NET, should be considered in the differential diagnosis of hypercalcaemia in such tumours.

The role of adipocytokinic markers in the prognosis of survival and sepsis at critical postsurgical patients

Alexandru Florescu[1,3], Irina Ristescu[2,3], Ioana Grigoras[2,3], Voichita Mogos[1,3] & Dumitru Branisteanu[1,3]
[1]Spitalul Sfantul Spiridon, Iasi, Romania; [2]Institutul Regional de Oncologie, Iasi, Romania; [3]Universitatea de Medicina si Farmacie Gr. T. Popa, Iasi, Romania.

The secretion of adipocytokines is influenced by fat mass, but also by various situations related to acute stress (food deprivation, or critical state related to inflamatory or infectious syndromes). Adipocytokinic secretory profile could be therefore used for the diagnosis of the type of critical state, as well for the evolution and survival prognosis of patients. The modifications of adipocytokinic markers during the first hours after surgical intervention are insufficiently described. We characterised for the first time the precocious dynamics of leptin comparated to classical inflammation markers (C-reactive protein and interleukin 6 (IL6)) during the systemic inflammatory response syndrome (SIRS) or sepsis at patients submitted to surgical intervention. Our prospective study included three groups of 20 patients – the SIRS group (SI) with major elective abdominal surgery, the sepsis group (SE) witn communitary intraabdominal infections and the control group (C). Leptin, C-reactive protein, an IL6 were measured at 0 point in all three groups and then serially for 5 days after surgery. We observed that leptin values increase precociously at 12–24 h in group SI ($P<0.05$), but remain within the normal range in the SE group. The patients from the SE group had a higher survival rate when they had higher leptin (>6 ng/ml) and lower IL6 levels (<150 pg/ml) within the first 24 h. The prognosis was worsened at patients having low leptin and increased IL6 at this time. Leptin has, therefore, a different precocious dynamics in SIRS than in sepsis patients.Early measurement of leptin levels, together with other inflammatory markers, may be useful for the differential diagnosis and prognosis of surgical critical patients.

Triiodothyronine inhibits TSH secretion through a non-genomic mechanism

Paula Bargi-Souza[1], Francemilson Goulart-Silva[1], Luis M Rendon[2], Tatiana Fioderlisio[2] & Maria Tereza Nunes[1]
[1]Institute of Biomedical Science, University of São Paulo, São Paulo, São Paulo, Brazil; [2]College of Science, Autonomous University of Mexico, City of Mexico, Mexico.

TSH is the main regulator of the thyroid hormones (THs) synthesis/secretion, which in turn exert a negative feedback mechanism on the *Tshb* mRNA expression in the pituitary gland by reducing their transcription rate. Some of triiodothyronine (T_3) effects are also shown in short period of time, characterizing the non genomic actions of THs. It has been shown previously that T_3 acts on posttranscriptional steps of TSH synthesis and reduces its secretion when acutely administered to hypothyroid rats. The present study aimed to: i) characterize the pathways involved in the rapid inhibition of the TSH secretion induced by T_3 in primary cultures of anterior pituitary cells and ii) evaluate the participation of T_3 on calcium and magnesium intracellular mobilization in slices of pituitary of hypothyroid rats. The cultured plates were treated with three different stimuli, RGD (100 μg/ml – 50 min), Wortmannin (1 μM – 30 min), and EGTA (1 mM). Lately, T_3 was added (10^{-8} M) for 30 min. Slices of pituitary were incubated with Fluo-4AM and Magnesium Green AM probes to address the mobilization of calcium and magnesium after T_3 treatment. The results showed a rapid increase of TSHB content in intracellular extracts while the amount of TSH in extracellular media was reduced after T_3 challenge. The treatment with RGD and Wortmannin abolished T_3 effects. No alteration on TSH secretion induced by T_3 was observed in the presence of EGTA in the culture media neither in calcium intracellular

mobilisation, while intracellular concentration of magnesium was altered under the same condition T_3 treatment (16% of pituitary cells). The Therefore, we propose the existence of an additional mechanism that decreases the TSH synthesis/secretion, triggered in few minutes by T_3, through its interaction with αVβ3 integrin at the plasma membrane, featuring a non genomic action of this thyroid hormone on its own synthesis/secretion.

Patient reported outcomes comparing octreotide capsules to somatostatin analogues injections: results from a multicentre, baseline controlled, phase 3 study in acromegaly

Asi Haviv[1], Gary Patou[1] & Susan Mathias[2]
[1]Chiasma Pharmaceuticals, Newton, Massachusetts, USA; [2]Health Outcomes Solutions, Winter Park, Florida, USA.

Background
Somatostatin analogues are the most widely used medical treatment in acromegaly. The available long-acting formulations are administered parenterally (i.m. or deep s.c. injections). Results of a multicentre, baseline controlled, phase 3 study have recently showed that octreotide capsules are an effective and safe treatment in acromegaly. The Treatment Satisfaction Questionnaire for Medication (TQ15M), assessed in the phase 3 study, as exploratory endpoint, compared patient reported outcomes (PRO) in responders to injections vs. responders to oral treatment.
Methods
TQ15M, a validated PRO, consists of 14 multiple choice items encompassing four domains: effectiveness, side effects, convenience, and overall satisfaction. Additional supplemental items were developed specifically for this study and relate to wear-off effects/breakthrough symptoms and direct comparison of the overall satisfaction on octreotide capsules to injections. The results herein include a cohort of 88 patients (of 151 enrolled), who were controlled on oral and continued treatment with octreotide capsules up to 13 months.
Results
More patients reported improvement than deterioration in all domain scores for effectiveness, side effects, convenience, and overall satisfaction (improvement 41, 38, 48, and 39% respectively vs deterioration 28, 13, 39, and 29%, while others maintained their scores). The improved effectiveness score supported the improvement in acromegaly symptoms (AIS score), reported in the phase 3. Mean satisfaction with oral therapy compared to injections based on the direct comparative supplemental question – was 5.2 (scores 0–7), reflecting the answer 'I am satisfied with this medication compared to others' and aligned with 86% of core study completers electing voluntarily to continue into the extension phase.
Conclusions
Patients' satisfaction with octreotide capsules was high. Improvements were noted compared to injections in all TQ15M domain scores, and specifically for effectiveness and side effects. these results correlates with patients electing to continue oral treatment and the improvements noted for acromegaly symptoms.

Parenteral somatostatin analogues: a focus on injection site adverse reactions

Asi Haviv[1], Susan Kramer[1], Gary Patou[1] & Gary Tillotson[2]
[1]Chiasma Pharmaceuticals, Newton, Massachusetts, USA; [2]Transcrip Partners, Downingtown, Pennsylvania, USA.

Introduction
Injectable somatostatin analogues (SRLs) are the standard medical management of acromegaly. Injection site adverse reactions reported for parenteral SRLs were examined in the literature and in the FDA Adverse Events Reporting System (AERS), and compared to the respective drug labels.
Methods
PubMed was searched using criteria: period 1995–2013, drugs – octreotide (Sandostatin®), lanreotide (Somatuline®), or somatostatin analogues and adverse reactions of interest – e.g. injection site reactions, in treatment of acromegaly and/or carcinoid tumours. FDA AERS files were reviewed for period Q1/2004 to Q1/2014. Adverse events reported in patients treated with somatostatin analogs were extracted as follows: i) drugs – octreotide (Sandostatin®) and lanreotide (Somatuline®), ii) adverse events on which somatostatin analogs were the primary or secondary suspected drug, and iii) preferred terms (MedDRA) containing the keywords: Injection site, Application site and Administration site.
Results
Literature data showed injection site pain in up to 76%, with severe pain in 11%. Other adverse reactions included injection site erythema, hematoma, bruising, edema, induration, nodule formation, pruritus, and lipohypertrophy. In AERS the most frequent injection site adverse reactions reported were injection site mass (85 cases), haemorrhage (74), swelling (41), induration (29), discomfort, erythema, nodule (28 each), and haematoma (26). AERS cases increased annually from ten in 2004 to 434 in 2012 with a total of 858 AEs by case and 2389 AEs by individual report by Q1/2014.
Conclusion
The incidence of injection site adverse reactions in both the literature and the FDA AERS database is higher than that reported in respective somatostatin analog labels and includes AEs of significant concern. Because of the nature of reported injection site AEs and their potential physical burden to patients, an oral alternative to chronic parenteral injections would mitigate these parenteral adverse events and significantly benefit patient care.

Sheehan's syndrome: a clinical, biochemical, hormonal, radiological, bone mineral density, and quality of life assessment

Syed Mohd Razi[1], Manish Gutch[1], Sukriti Kumar[2], Abhinav Gupta[1] & Keshav Kumar Gupta[1]
[1]LLRM Medical College, Meerut, Uttar Pradesh, India; [2]SGPGI, Lucknow, Uttar Pradesh, India.

Background
Sheehan's syndrome or *postpartum* pituitary necrosis though rare, is still remains one of the commonest causes of hypopituitarism in the developing parts of world like Indian subcontinent. The clinical presentation is often variable and frequently accompanied by hypogonadism which leads to low bone density due to loss of bone protective effect of oestrogen.
Aims
To find out the bone mineral density and the quality of life (QoL) in patients of Sheehan's syndrome, and to find out the effect of hormonal replacement therapy on outcome.
Material and methods
All patients previously diagnosed as Sheehan's syndrome or newly admitted during the study period of 3 years were enrolled in the study after obtaining an informed consent. Their clinical, biochemical, hormonal, radiological, and bone mineral density (BMD) data were collected. QoL was assessed using the disease-specific QoL both before and after hormone replacement therapy.
Results
Twenty-three patients were enrolled in the study, the mean age of diagnosis was 43.4 ± 14.2 years; mean diagnostic delay was 13.2 ± 7.4 years. Secondary amenorrhoea and lactation failure were the most common clinical presentations. The bone mineral characteristic of patients with Sheehan's syndrome, revels *T*-score, were found to be significantly reduced in lumbar spine (-2.8 ± 0.6) and femoral neck (-2.9 ± 0.8) as also *Z*-score; these are -1.6 ± 0.6 and -1.4 ± 0.6 respectively. Severe osteoporosis (osteoporosis with fracture) was found in three patients (13%), osteoporosis in four patients (17.3%), osteopenia in six patients (26%), and rest ten patients had normal BMD. The QoL of patients with Sheehan's syndrome before and after hormonal replacement therapy for 1 year, before start of therapy the score was 25 ± 8 and it increased to 59.4 ± 8.6 after 1 year of hormonal replacement therapy.
Conclusion
Sheehan's syndrome resulted in multiple pituitary hormone deficiencies in all the patients. Low bone mass and low QoL were frequently seen in patients with Sheehan's syndrome. Both low mineral density ($P < 0.05$) and QoL improved significantly ($P < 0.05$) after hormonal replacement therapy.

Coexistence of pituitary cyst, ovary dermoid cyst, and mammary fibroadenomas

Evrim Cakir[1] & Aysel Atak[2]
[1]Endocrinology and Metabolism Department, Haseki Training and Research Hospital, Istanbul, Turkey; [2]Family Physician, Haseki Training and Research Hospital, Istanbul, Turkey.

A 17-year-old girl was referred to Endocrinology Unit by her neurosurgeon. She had complained of severe headache, palpation induced galactorrhoea on left mammary and visual abnormalities for 1–2 months. Her menstrual period was regular. On physical examination a pale face and fatigued appearance was noticed. Biochemical and hormonal analyses are as follows: fasting glucose level was 84 mg/dl, serum sodium level was 140 mmol/l (136–145), serum potassium level was 3.9 mmol/l, FSH level was 9.24 mIU/ml, LH level was 13.26 mIU/ml, oestradiol level was 70 pg/ml, prolactin level was 22.14 ng/dl, cortisol level was 16.13 μg/dl, free T_4 level was 0.9 ng/dl, and TSH level was 2.01 mIU/l. Her urine analysis showed a normal density. The laboratory analyses did not reveal any anterior or posterior pituitary deficiencies or excess. She underwent a pelvic and breast evaluation for palpation induced galactorrhoea which has existed the last 6 months. Her pelvic ultrasonography revealed a 2.5 cm hyperechoic mass on her right paraoverian area. Magnetic resonance (MR) evaluation showed a 3.5×4 cm right adnexial mass. Signal characteristic of mass was suggestive of dermoid cyst. Breast ultrasound revealed a 18×11 mm hypoechoic heterogeneous solid lesion. Histopathologic examination of the breast mass was consistent with fibroadenoma. Pituitary MR revealed a $10.8 \times 6.5 \times 7$ mm sellar mass with homogeneous hyperintensity on T1 weight imaging. The mass was localised posteroinferiorly on left pituitary gland. The features of mass was considered to intense cystic adenom or rathke cleft cyst. The coexistence of pituitary cyst, dermoid ovary cyst, and fibrocystic mammary adenoma was seen in the presented case. Patients with cystic lesion in any tissue should be screened for cystic lesions in other compartments of the body and those cystic lesions including solid components should be followed for the functional activation or loss and malign transformation.

A case of lung cancer with pituitary metastases presented by diabetes insipidus

H Sebila Dokmetas, Hande Ogul Hincal & Ahmet Bilici
Departments of Endocrinology and Oncology, Medical School, Istanbul Medipol University, Istanbul, Turkey.

Cancer metastases on pituitary gland are seen rarely. A 71-year-old male was admitted to Endocrinology Department with polydipsia, polyuria, and diplopia. Urine volume was ~5 l/day. In medical history; he had been diagnosed as having non-small cell lung carcinoma with multiple liver and bone metastases 1 year ago. He took chemotherapies with four cycles of paclitaxel, carboplatin, and zoledronic acid for bone metastases and radiation therapy (RT) was given to L4-S1 vertebras. The size of the lung mass was reduced on the follow-up computed tomography scan; thus, the patient exhibited a partial response. Owing to his complaints like as diabetes insipidus (DI), pituitary MRI was done that showed a sellar and suprasellar mass which occupied infundibulum and the pituitary gland. Older MRI was explored again by us and seen an undiagnosed smaller sellar mass. Also on T1-weighted MRI, the signal intensity was decreased, suggesting the pituitary and infundibulum metastases of current lung cancer. On physical examination; blood pressure was 100/60 mmHg and there was any abnormality. The serum osmolality was 310 mOsm/kg, whereas the urine density was 1005. Laboratory results were GH: 0.098 ng/ml, IGF1: 51.4 μg/l (64–188), TSH: 0.249 IU/ml (0.27–4.2), free T_4: 0.452 ng/dl (0.93–1.7), FSH: 0.492 IU/ml (1.5–12.4), LH: 0.1 IU/ml (1.7–8.6), total testosterone: 0.025 ng/ml (1.93–7.4), ACTH: <1 pg/ml (7.2–63.3), cortisol: 0.755 μg/dl (6.2–19.4), prolactin: 2.71 ng/ml (4.04–15.2), and Na: 143 mEq/l (135–145). Patient started to use desmopressin nasal spray 0.1 mg/ml two puffs per day, prednisolone 5 mg, levothyroxine 25 μg/day for panhypopituitarism and DI. His urine volume was normalized; the polydipsia ceased and his condition becomes clinically better. Also radiation oncology department planned RT for pituitary metastases. When symptoms of DI appear in a patient with lung cancer, pituitary metastases should be considered and evaluated properly, thus, panhypopituitarism is not skipped.

Evaluation of thyroid nodules in acromegaly

G Gonca Oruk[1], Melike Bedel Koruyucu[2], Husnu Yilmaz[1] & Baris Pamuk[1]
[1]Katip Celebi University Ataturk Training and Research Hospital, Izmir, Turkey; [2]Yildirim Beyazit University Ataturk Training and Research Hospital, Ankara, Turkey.

Nodular thyroid disease is frequently observed in patients with acromegaly. The aim of this study is to evaluate thyroid nodules and thyroid cancer frequency in acromegalic patients. The data of 125 acromegalic (55 males and 70 females) patients followed over 10 years were evaluated retrospectively from the recorded files. Data for gender, age, duration of acromegaly, thyroid function tests, thyroid ultrasonography (US), and thyroid fine needle aspiration biopsy (FNAB) and thyroidectomy pathological specimen results were analysed. The mean age of the patients was 46.9 ± 10.4 years and the mean disease duration was 10 ± 4.8 years. Multinodular goitre was discovered in 66 patients (42.5%), solitary nodule in 11 patients (8.8%), diffuse goitre in three patients (2.4%), and nodule was not detected in 45 patients (36.0%). Nodule size was smaller than 10 mm in 31 patients (40.2%) and larger than 10 mm in 46 patients (59.7%). FNAB was recommended to all of the patients who had nodules larger than 10 mm and whose nodules were smaller than 10 mm and looked suspicious at imaging. FNAB was performed in 35 patients who accepted the procedure and the results were benign in 30 patients, malignant in three patients, atypia of undetermined significance in one patient and suspicious for follicular neoplasm in one patient. Total thyroidectomy was administered to 14 patients and subtotal thyroidectomy to two patients. One thyroid follicular carcinoma and four thyroid papillary carcinomas (4%) were diagnosed and all of the patients received radioactive iodine treatment for ablation of the residual tissue. Thus acromegalic patients should be routinely submitted to thyroid ultrasound evaluation, followed by FNAB of nodules when indicated. Acromegalic patients must be considered as a high-risk group for the development of thyroid cancer and must be closely followed for thyroid nodules and tumours.

Escape from response to long-term pasireotide treatment in recurrent Cushing's disease

Filip Gabalec[1,3], Petr Husek[2,3], Jaroslav Pacovsky[2,3] & Jan Cap[1,3]
[1]4th Department of Internal Medicine, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic; [2]Department of Urology, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic; [3]Faculty of Medicine in Hradec Kralove, Charles University in Prague, Hradec Kralove, Czech Republic.

Introduction
A transsphenoidal adenectomy (TSFE) is primary treatment of Cushing's disease. Pharmacological management when the disease persists after surgery is a challenge.
Case report
A 47-year-old man was initially diagnosed with CD (petrosal sinus sampling with CRH testing included) after suffering from multiple organ failure in sepsis. Microadenoma 2×4 mm was suspected on the pituitary MRI. Clinical symptoms were markedly improved after first TSFE, but normalisation was not achieved, so he underwent reoperation. No adenoma was present on control MRI, but CD remained active – altered diurnal rhythm, morning cortisol 574 nmol/l, midnight cortisol 555 nmol/l, urinary free cortisol (UFC) 1008 nmol/24 h, altered suppression in suppression tests (111 nmol/l), and ACTH 115 pg/ml. Ketoconazole was no longer available so treatment with cabergoline according to national guidelines was started. Because no effect was observed we started treatment with pasireotide 0.6 mg b.i.d. In 2 months this treatment led to normalization of UFC (208 nmol/24 h), plasma cortisol in normal range, ACTH 49 pg/ml. Mild elevation of HbA1c was observed (from 5.6 to 8.0…6.6…6.3), but diabetes was under control with oral antihyperglycaemic agents. Patient was doing well, reporting better quality of life and physical condition. Unfortunately 16 months after pasireotide introduction he was admitted for diabetes decompensation (glycaemia 37 mmol/l) and bad condition for symptomatic CD (plasma cortisol >2000 mmol/l, ACTH 321 pg/ml, and UFC 12240 nmol/24 h). Pasireotide was discontinued, treatment with insulin was started. For fast deteriorating of his clinical status due to active CD he was indicated to laparoscopic bilateral adrenalectomy as 'ultimum refugium'. The patient is now dispensarised for eventual Nelson's syndrome.

Conclusion
Mild hyperglycaemia at the start of pasireotide is not the reason for discontinuation. According to our best knowledge this is the first case reported of sudden lack of efficacy of pasireotide after long-term effective treatment.

Isolated pituitary sarcoidosis stained with a specific MAB against *Propionibacterium acnes*: a case report

Kaoru Yamashita[1], Michita Niiyama[1], Yasufumi Seki[1], Daisuke Watanabe[1], Osamu Isozaki[1], Kosaku Amano[2], Takashi Komori[3], Yoshikazu Okada[2], Yoshinobu Eishi[3] & Atsuhiro Ichihara[1]
[1]Department of Endocrinology and Hypertension, Tokyo Women's Medical University, Tokyo, Japan; [2]Department of Neurosurgery, Tokyo Women's Medical University, Tokyo, Japan; [3]Department of Human Pathology, Tokyo Medical and Dental University Graduate School, Tokyo, Japan.

Introduction
Sarcoidosis is a systemic granulomatous disorder usually affects multiple organs. Approximately 10% of sarcoidosis occurs as isolated neurosarcoidosis in CNS and <10% of neurosarcoidosis develops in a restricted hypothalamic–pituitary area. Recent study has identified *Propionibacterium acnes* in lungs and lymph nodes of many patients with sarcoidosis using a MAB specific for this bacterium (PAB), providing strong evidence for *P. acne* as a pathogen of sarcoidosis (*Modern Pathology*, 2012). We report a case of isolated pituitary sarcoidosis, manifested as an acute onset of secondary adrenocortical insufficiency.
Case
A 29-year-old man suddenly developed severe headache, malaise, and appetite loss 1 year after an extensive skin peeling therapy for pimples. MRI revealed a diffusely and symmetrically enlarged pituitary, protruded upward with a thickened stalk and inhomogeneously enhanced with gadolinium, suggesting anterior hypophysitis. Endocrinologically, baseline ACTH and cortisol was 4.8 pg/ml and 0.4 μg/dl respectively. FT_4 was 0.72 ng/dl, testosterone was 10.3 ng/dl, PRL was 36.1 μg/l, and peak GH response to GHRP2 was 2.3 μg/l. Administration of hydrocortisone improved clinical symptoms and recovered hypogonadism and hypothyroidism by 2 weeks. Blood levels of ACE, lysozyme, and IgG4 were normal. Whole body gallium scanning did not detect any organ involvement other than the pituitary. Pituitary biopsy revealed many non-caseous granulomas accompanied with calcification. Immunostaining with PAB was positive for giant cells and infiltrated mononuclear cells. This patient fulfilled a diagnostic criterion of neurosarcoidosis by clinical manifestation of hypopituitarism, exclusion of other systemic inflammatory disorders, and histological identification of typical sarcoid granulomas.
Conclusion
Isolated pituitary sarcoidosis is an extremely rare inflammatory disorder. Currently six cases were reported and only three of them were biopsy-proven. This is the seventh case of isolated pituitary sarcoidosis and the first case in which *P. acnes* were identified definitely in sarcoid granulomas of the pituitary.

Pituitary adenoma of aggressive behaviour

Silvia Maraver Selfa, Ana Gómez Pérez, Isabel Mancha Doblas, Isabel María Cornejo Pareja, Maria Molina Vega, Cristina Díaz Perdigones & Francisco Tinahones Madueño
Endocrinology and Nutrition Unity, Virgen de la Victoria Hospital, Malaga, Spain.

Pituitary ACTH-secreting tumour presents with variety of clinical features: normal cortisol secretion and ACTH-immunopositive staining and mild hypercortisolism without typical features of Cushing's disease. We present a 53-year-old male with history of hypertension. First visit (2005): visual loss, bitemporal hemianopsia in campimetry and in MRI pituitary adenoma (2.5 cm) invading cavernous sinus and suprasellar cister. Hormonal study supported panhypopituitarism. After transsphenoidal surgery, there was a tumour rest (9 mm) with left cavernous sinus invasion. Pathology: atypical pituitary adenoma and ACTH-immunopositive staining. There were normal campimetry and persistence of hormonal deficit. In 2006, he received photon radiotherapy (50 Gy) with radiologic stability. After 6 years, left eyelid ptosis (cranial nerves III–VI palsy) appeared. In replacement therapy with hydrocortisone, levothyroxine, and testosterone, presented TSH <0.05 μgUI/ml, FT_4 1.1 ng/dl, prolactin 3.2 ng/ml, testosterone 3.7 ng/ml, cortisol 10 μg/dl, ACTH 53 pg/ml, and IGF1 24 ng/ml. MRI: pituitary solid lesion (1.7 cm) with left cavernous sinus. Transsphenoidal surgery was performed. Ophthalmoplegia persisted. Pathology: pituitary adenoma ACTH-producer, Ki <1%, P53 75%. After surgery: TSH <0.005 μgUI/ml, FT_4 1.2 ng/dl, cortisol 10 μg/dl, and ACTH 64 pg/ml. Hydrocortisone was suspended and an ACTH-test was performed: peak cortisol 14.4 μg/dl. Corticosteroid therapy was maintained. 6 months after surgery: MRI with tumour rest (11 mm) in the left cavernous sinus and right cavernous sinus (16 mm). PET–TC–FDG–metionine: metabolically active injury in both cavernous sinuses. Hormone study: cortisol 17 μg/dl and ACTH 97 pg/ml, so we suspended hydrocortisone. Without treatment cortisol was 16 μg/dl. Nugent test: cortisol 18 μg/dl. FSR (50 Gy) was administered. After 2 months: cortisol 16 μg/dl, ACTH 127 pg/ml, and UFC 320 μg/24 h. We began cabergoline 1 mg/week. The development of Cushing's syndrome in patients with silent corticotropinomas determines a factor of aggressiveness in these tumours. Intensification with cabergoline was performed, and temozolomide was planned in case of progression.

Somatostatin analogues effectiveness in non-functioning pituitary adenomas in comparison with acromegaly

Jolanta Kunert-Radek[1], Natalia Bozena Zawada[1], Marek Pawlikowski[2], Hanna Pisarek[3] & Maciej Radek[4]
[1]Department of Clinical Endocrinology, Medical University of Lodz, Lodz, Poland; [2]Department of Immunoendocrinology, Medical University of Lodz, Lodz, Poland; [3]Department of Neuroendocrinology, Medical University of Lodz, Lodz, Poland; [4]Department of Neurosurgery and Surgery of Peripheral Nerves, Medical University of Lodz, Lodz, Poland.

Introduction
Somatostatin analogues (SSAs) are used in the treatment of somatotropinomas. Actually, the use of these drugs in clinically non-functioning pituitary adenomas (NFPA) is raised. The aim of the study is to assess the effectiveness of SSA therapy in both groups.
Materials and methods
40 acromegalic patients and 22 patients with NFPA were treated with SSA for the total therapy duration up to 10 years. Hormonal profile, dynamics of tumour size changes, ophthalmic exam with assessement of visual field, somatostatin receptor scintigraphy, immunohistochemistry of somatostatin receptor subtypes of operated tumours as well as patients' quality of life and undesirable effects were analysed.
Results
The significant decrease of GH and IGF1 concentrations was noticed in 95% of acromegalic patients (16 recurrent tumours and 24 primary tumours). The complete normalisation of hormone levels was observed in 57.5% of patients. The evaluation of the tumours' size in MRI revealed their significant decrease in 40% of acromegalic patients including 81% of primary adenomas. The quality of life was improved in almost all patients. Two patients developed cholelithiasis with indication to cholecystectomy. Considering the patients with NFPA the stabilisation of tumour size and visual field was observed in 68% while the reduction of tumour size was noticed in 9% of cases. 23% of patients revealed an increase of adenoma size regarding the reoperation.
Conclusions
SSAs are effective in the treatment of acromegaly. In patients with NFPA the effectiveness of SSA is much lower. However, pharmacotherapy with SSA in the cases of NFPA allows the stabilisation of the disease and can be considered as an alternative for the next neurosurgeries.

No evidence of impaired oral hormone substitution after gastric bypass surgery in patients with morbid hypothalamic obesity and hypopituitarism secondary to craniopharyngioma

Peter Wolf[1], Yvonne Winhofer[1], Sabina Smajis[1], Renate Kruschitz[1], Karin Schindler[1], Alois Gessl[1], Greisa Vila[1], Wolfgang Raber[1], Felix Langer[2], Gerhard Prager[2], Bernhard Ludvik[3], Anton Luger[1] & Michael Krebs[1]
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Department of Surgery, Medical University of Vienna, Vienna, Austria; [3]Division of Endocrinology, Diabetology and Nephrology, Department of Internal Medicine I, Rudolfstiftung, Vienna, Austria.

Background
Craniopharyngiomas (CP) are benign brain tumours presenting in childhood treated by tumour resection together with radiotherapy. In about half of the cured patients hypothalamic damage leading to eating disorders and obesity as well as to hypopituitarism, necessitating consequent hormone substitution therapy, is observed. Bariatric surgery is an efficient treatment strategy for morbid obesity. However, so far it is unknown, whether oral hormone substitution is hampered by impaired intestinal absorption, leading to severe hypopituitarism or adrenal insufficiency.
Methods
Four CP patients with hypopituitarism and morbid obesity treated by gastric bypass surgery were included in this retrospective analysis. Dosage of hormone substitution, hormonal blood concentrations, adverse effects of impaired drug absorption, and anthropometric characteristics were investigated pre and 3–12 months post operatively.
Results
In all CP patients (3W/1M; BMI_{basal} 49 ± 7 kg/m^2) gastric bypass resulted in distinct weight loss (-35 ± 27 kg). In follow-up examinations mean concentration of fT_4 increased ($fT_{4\ basal}$ 0.9 ± 0.31 ng/dl vs $fT_{4\ follow\ up}$ 1.28 ± 0.29 ng/dl). No patient developed any signs of adrenal insufficiency postoperatively. Mean daily dosage of oral thyroid hormone substitution ($levothyroxine_{basal}$ 156 ± 44 µg/day vs $levothyroxine_{follow\ up}$ 150 ± 30 µg/day) and hydrocortisone ($hydrocortisone_{basal}$ 29 ± 12 mg/day vs $hydrocortisone_{follow\ up}$ 26 ± 2 mg/day) was unchanged. Mean IGF1 concentration decreased after weight loss ($IGF1_{basal}$ 217 ± 93 ng/ml vs $IGF1_{follow\ up}$ 111 ± 36 ng/ml), whereas daily growth-hormone substitution was slightly increased ($somatotropin_{basal}$ 0.9 ± 0.5 mg/day vs $somatotropin_{follow\ up}$ 1.0 ± 0.4 mg/day). Minirin dosage and daily fluid intake remained unchanged.
Discussion
Our results in $n=4$ CP patients suffering from hypopituitarism indicate that oral hormone substitution therapy is not impaired following gastric bypass operation, probably making it a safe and considerable treatment strategy in patients suffering from hypothalamic obesity.

Cabergoline is an effective treatment for clinically non-functioning pituitary adenomas

Yona Greenman[1,2], Odelia Cooper[6], Iris Yaish[1], Eyal Robenshtok[2,5], Nadav Sagiv[1], Tali Jonash-Kimchi[2,4], Jayati Mallick[7], Arkadiusz Gertych[7], Ilan Shimon[2,5], Ram Zvi[2,3], Shlomo Melmed[6] & Naftali Stern[1,2]
[1]Institute of Endocrinology, Metabolism and Hypertension, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [3]Department of Neurosurgery, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; [4]Neuroradiology Unit, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; [5]Institute of Endocrinology and Metabolism, Rabin Medical Center, Petach Tikva, Israel; [6]Pituitary Center, Cedars Sinai Medical Center, Los Angeles, California, USA; [7]Pathology Department, Cedars Sinai Medical Center, Los Angeles, California, USA.

As optimal postoperative management of patients with clinically nonfunctioning pituitary adenomas (NFPA) is a matter of debate, the role of dopamine agonist (DA) therapy in this clinical setting was evaluated.
Methods
Retrospective analysis of prospectively collected data was conducted at two pituitary referral centrer with different standard practices for post-operative management of NFPA: DA therapy or conservative follow up. Dopamine receptor 2 (D2R) expression was examined by immunohistochemistry, D2R long and short isoform mRNA expression was measured by quantitative RT-PCR.
Results
Seventy-nine patients (mean follow-up, 8.8 ± 6.5 years) were treated with DA, either initiated upon detection of residual tumour on postoperative MRI (preventive treatment (PT) group, $n=55$), or when tumour growth was detected during follow-up (remedial treatment (RT) group, $n=24$). The control group received no medication and comprised 60 patients (mean follow-up 6.3 ± 5 years). Tumour mass decreased, remained stable or enlarged respectively in 38.2, 49.1, and 12.7% of patients in the PT group. Shrinkage or stabilization was achieved in 58.4% of the enlarging tumours in the RT group, whereas tumour growth persisted in only 41.6% of them. In contrast, tumour size enlarged in 53.3% and remained stable in 46.7% of subjects in the control group ($P<0.0001$ for all comparisons). 15 years progression-free survival rate was 0.805 for the PT group, 0.48 for the RT group and 0.12 for controls; $P<0.0001$(PT vs control), $P=0.04$ (RT vs control), and $P=0.0053$ (PT vs RT). 41.7% of patients in the control group required additional surgery or radiotherapy as compared to 20.2% of the combined treatment groups ($P=0.0084$). There was no correlation between D2R expression and tumour response to DA treatment.
Conclusions
Dopamine agonist therapy is associated with decreased prevalence of residual tumour enlargement in patients with non-functioning pituitary adenomas, particularly when treatment is instituted prophylactically after surgical resection.

A rare adventure of a lymphocytic hypophysitis

Zeynep Canturk[1], Alev Selek[1], Berrin Cetinarslan[1], Ilhan Tarkun[1], Zeynep Akyay[1], Burak Cabuk[2] & Savas Ceylan[2]
[1]Department of Endocrinology and Metabolism, Kocaeli University Faculty of Medicine, Kocaeli, Turkey; [2]Department of Neurosurgery, Kocaeli University Faculty of Medicine, Kocaeli, Turkey.

Introduction
Lymphocytic hypophysitis is a rare endocrine disease involving lymphocytic infiltration and chronic pituitary inflammation. It may result in significant morbidity by loss of pituitary functions and neurological deficits. Pituitary abscess is another rare disease which may be associated with underlying parasellar pathology. Here, we report a case of lymphocytic hypophysitis diagnosed with a pituitary abscess and recurrent suprasellar involvement after surgery.
Case
A 58-year-old female presented with headache, panhypopituitarism and a pituitary lesion with thickening of pituitary stalk. A pituitary surgery was done for definitive diagnosis and it revealed pituitary abscess associated with lymphocytic hypophysitis. Four months after antibiotherapy, the lesion recurred with extension to hypothalamus and compressive symptoms. High dose glucocorticoid treatment was initiated after exclusion of recurrent pituitary abscess with second surgery. The pituitary lesion reduced significantly in 3 months. However, the glucocorticoid treatment had to be stopped earlier due to toxic hepatitis and replaced to azathioprine.
Discussion
Lymphocytic hypophysitis may cause complete loss of vital pituitary functions and neurological deficits. The disease may rarely be complicated with abscess, therefore careful evaluation and surgical treatment should be performed in these cases. Most symptomatic LH require pulse doses of methyl-prednisolone or prednisone followed by a slow taper over a period of weeks to months. Despite good response to these first-line therapies in the majority of patients, relapses are common. In recurrent and symptomatic lymphocytic hypophysitis, high-dose glucocorticoids combined with azathioprine may be a successful choice of treatment.

Determinants of neutrophil/lymphocyte ratio in acromegaly patients

Merve Yilmaz[1], Arzu Gedik[2], Tevfik Demir[3], Dilek Cimrin[4] & Abdurrahman Comlekci[3]
[1]Endocrinology Department, Samsun Gazi State Hospital, Samsun, Turkey; [2]Endocrinology Department, Agri State Hospital, Agri, Turkey; [3]Endocrinology Department, Dokuz Eylül University Medical Faculty, Izmir, Turkey; [4]Biochemistry Department, Dokuz Eylül University Medical Faculty, Izmir, Turkey.

Introduction
Neutrophil/lymphocyte ratio (NLR) is an indicative of the acute phase response. It is a significant indicator of the systemic inflammation, and considered as a poor prognosis indicator in various disease. We aimed to evaluate NLR and its determinants in acromegaly patients.
Patients and methods
A retrospective chart review of 40 patients with acromegaly and 45 age and sex matched healthy individuals was performed. Patients with active infection, malignancy, chronic inflammatory or autoimmune disease, history of drug use or disease which may affect the hemogram values were excluded from the study. GH, IGF-I and hemogram values of patients were recorded and NLR was calculated. Correlation analysis was performed between GH, IGF-I levels and NLR.
Results
Mean age of the acromegalic patients was 47.68 ± 12.33 and the control group was 45.16 ± 6.83. NLR in acromegalics was 2.04 ± 0.63 and in the control group 1.88 ± 0.70. In terms of NLR, the difference between the two groups was not statistically significant ($P=0.075$). When acromegalics were divided into active ($n=27$) and controlled group ($n=13$) no statistically significant difference was observed between all three groups ($P=0.204$). NLR was 2.08 ± 0.70 in active group and 1.95 ± 0.45 in controlled acromegalics and the difference between the two groups was not statistically significant ($P=0.556$). There wasn't significant correlation between GH, IGF-I levels and NLR. Negative correlation was observed between age and NLR in acromegalics, especially the active acromegalics.
Conclusion
Cardiovascular disease is a major cause of morbidity and mortality in acromegaly patients. Studies reported an association between elevated NLR and increased risk of cardiovascular disease. We didn't found an increase in NLR in acromegalic patients. Also in these patients, there wasn't significant association between GH, IGF-I levels and NLR. However, in the literature we couldn't find any study on this issue. Further studies are required in order to make adequate comment on this topic.

Serum cortisol in the early postoperative period as predictor of remission in Cushing's disease

Joana Oliveira[1,4], Eva Lau[1,4], Sandra Belo[1,4], Paula Freitas[1,4], Eduardo Vinha[1], Josué Pereira[2], Lígia Castro[3] & Davide Carvalho[1,4]
[1]Endocrinology, Diabetes and Metabolism Department, Centro Hospitalar São João, Porto, Portugal; [2]Neurosurgery Department, Centro Hospitalar São João, Porto, Portugal; [3]Pathological Anatomy Department, Centro Hospitalar São João, Porto, Portugal; [4]Faculty of Medicine of University of Porto, Porto, Portugal.

Introduction
Pituitary surgery is currently considered the preferred treatment for Cushing's disease (CD) and achieves remission in 55–85% of patients. Cortisol falls quickly after surgery, so that early post-operative cortisol level has been used as predictor of remission. There's no agreement about optimal timing for cortisol measurement, with wide variability between centres.
Objective
To assess the value of early post-operative serum cortisol as predictor of remission after pituitary surgery in CD.
Methods
Cross-sectional, retrospective study of patients who underwent pituitary surgery for CD between January/1998 and October/2013. No glucocorticoid replacement therapy was initiated until blood samples were drawn (0800 h the day after surgery).
Results
We evaluated 45 patients, 86.7% (39) female, with a mean age of 38.2 ± 12.9 years at diagnosis. Mean follow-up was 90.4 ± 56.7 months. After surgery, 33 patients (73.3%) achieved cure, 12 patients (26.7%) presented persistent disease. Ten patients relapsed (30.3%), with mean follow-up time until relapse of 64.4 ± 36 months. There were no significant differences in urinary free cortisol, ACTH, serum cortisol and cortisol in the overnight dexamethasone suppression test at diagnosis between patients with and without disease remission after surgery, or between patients with and without disease recurrence. Morning serum cortisol (obtained from 36 patients) the day after surgery was 16.5 ± 18.3 µg/dl, with higher values in patients without cure in comparison with those in remission (27.6 ± 19.3 vs 12.2 ± 16.3; $P=0.043$). Despite this difference, the postoperative serum cortisol was not a good predictor of remission of CD. The value of ACTH 3 months after surgery was not predictive of disease recurrence.
Conclusion
Serum cortisol measured at 24 h after pituitary surgery was not predictive of remission of CD. A longer interval between surgery and hormonal evaluation may allow a more accurate classification of these patients, including those with later remission.

Predictive factors for remission and recurrence in Cushing's disease: a single-centre study

Joana Oliveira[1,4], Eva Lau[1,4], Sandra Belo[1,4], Paula Freitas[1,4], Eduardo Vinha[1], Josué Pereira[2], Lígia Castro[3] & Davide Carvalho[1,4]
[1]Endocrinology, Diabetes and Metabolism Department, Centro Hospitalar São João, Porto, Portugal; [2]Neurosurgery Department, Centro Hospitalar São João, Porto, Portugal; [3]Pathological Anatomy Department, Centro Hospitalar São João, Porto, Portugal; [4]Faculty of Medicine of University of Porto, Porto, Portugal.

Introduction
Cushing's disease (CD) is characterised by pathologic hypercortisolism caused by an ACTH-secreting pituitary adenoma. The primary modality for definitive treatment is pituitary surgery. The rarity of CD has made it difficult to establish reliable predictive factors of outcomes.
Aim
Assessment of clinical, hormonal, radiological, surgical and histological findings as predictors of remission and relapse of CD.
Methods
Cross-sectional, retrospective study of patients with CD who underwent pituitary surgery between January/1998 and October/2013.
Results
45 patients were evaluated, 39 women (86.7%), with a mean age at diagnosis of 38.2 ± 12.9 years, and a mean follow-up of 90.4 ± 56.7 months. After surgery (1st or 2nd intervention), remission of CD was achieved in 26 patients (57.8%) without recurrence until the last evaluation, and it persisted in nine patients (20%). Ten patients (22.2%) relapsed during follow-up. There were no differences between groups (cured, not cured, with disease recurrence) relating age, gender, presence of preoperative comorbidities (hypertension, diabetes, dyslipidemia and psychiatric disorders), hormonal study at diagnosis, magnetic resonance imaging findings or surgical technique. In eight of 45 patients (17.8%) the histological study did not identify the adenoma. Cured patients presented a higher percentage of positive histology for adenoma, followed by patients with disease relapse and uncured patients (92.3% vs 80% vs 55.6%; $P=0.045$).
Conclusion
The absence of adenoma identification in pituitary histology after surgery was associated with higher risk of persistence or recurrence of CD. Those patients would benefit from a closer follow-up and early evaluation. No other predictive factors were found.

Effectiveness of somatostatin analogs as first-line or second-line treatment of acromegaly: single centre experience

Agne Abraitiene[1,2] & Vaidotas Urbanavicius[1,2]
[1]Vilnius University Faculty of Medicine, Vilnius, Lithuania; [2]Vinius University Hospital Santariskiu klinikos, Vilnius, Lithuania.

Introduction
The purpose of this study was to evaluate and compare disease outcomes in patients with acromegaly receiving first-line and second-line (after transphenoidal surgery) somatostatin analogs (SSA) treatment.
Methods
The study involved retrospective data collection from charts of 49 patients with acromegaly who were consulted by an endocrinologist in Vilnius University Hospital Santariskiu klinikos between 2007 and 2013.
Results
Patient population consisted of 16 males (32.7%) and 33 (67.3%) females (mean age at diagnosis 54 ± 13 years). Primary SSA therapy was administered in 14 (28.6%) patients who refused or had contraindications to surgical treatment. Transsphenoidal operation was applied as the first-line therapy in 31 (63.3%) patients and led to disease remission in 16 (51.6%) of them. Of surgically treated patients, 15 (48.4%) were diagnosed with desease recurrence and received second-line SSA therapy. Based on the latest GH and IGF-1 results, control and partial control were achieved in 4 (28.6%) and 5 (35.7%) patients in first-line SSA therapy group, and in 7 (46.7%) and 4 (26.7%) patients in second-line SSA therapy group. 5 (35.7%) and 4 (26.7%) of patients in first-line and second-line SSA treatment groups remained uncontrolled. Although we observed higher mean observational period IGF-1 in the first-line SSA treatment group (511.0 (230.9; 791.1) μg/l) as compared to second-line SSA therapy group (403.3 (280.3; 526.2) μg/l), the difference was not statistically significant ($P = 0.384$).
Conclusions
SSAs are more effective in the treatment of acromegaly when applied after transphenoidal surgery, as they help to achieve control of the disease in a greater percentage of patients. Control of the disease remains a challenge despite availability of high-dose SSA treatment as 27–36% of patients receiving primary or second-line SSA treatment remain uncontrolled.

The impact of diabetes mellitus on the survival of patients with acromegaly

Wen-Ko Chiou[1], Szu-Tah Chen[2], Feng-Hsuan Liu[2], Chen-Nen Chang[2], Ming-Hsu Wang[1] & Jen-Der Lin[2]
[1]Chang Gung University, Taoyuan Hsien, Taiwan; [2]Chang Gung Memorial Hospital, Taoyuan Hsien, Taiwan.

Aims
An increased risk of mortality in patients with uncontrolled acromegaly has been reported in several studies. We aimed to assess the impact of co-morbidities on the survival of patients with acromegaly after long-term treatment and follow-up.
Methods
A retrospective analysis was performed for 285 patients with active acromegaly who were admitted to the Chang Gung Memorial Hospital, Taiwan between 1978 and 2012.
Results
Of these patients, 106 (37.2%) were diagnosed with diabetes mellitus (DM). During the follow-up period, 21 cases of histological proved malignant in acromegalic patients, and DM with acromegaly had a higher incidence of malignancy (13.2% vs 3.8%; $P < 0.01$). The 5-, 10-, and 20-year survival rates were 93.1, 86.9, and 84.7% for the DM group, respectively, and 96.7, 96.7, and 96.7% for the non-DM group, respectively. After a mean follow-up of 15.1 ± 0.6 years, age, DM, coronary heart disease, and malignancy were found to be significant factors of mortality. Control of growth hormone and IGF-1 levels also conferred a marginal survival benefit.
Conclusions
DM and malignancy significantly influence the survival of patients with acromegaly; thus, these patients need close follow-up and appropriate therapy.

Gennimatas', Athens, Greece; [6]Department of Internal Medicine, Division of Endocrinology, University Hospital of Patras, Rio, Greece; [7]Department of Endocrinology, University of Ioannina, Ioannina, Greece; [8]Endocrine Unit, Second Department of Internal Medicine, University of Athens, Medical School, 'Attikon' Hospital, Athens, Greece; [9]Endocrine Unit, Department of Medical Therapeutics, Athens University School of Medicine, Athens, Greece; [10]Department of Endocrinology, Evangelismos Hospital, Athens, Greece.

Objective
Somatic mutations in the GNAS1 gene, which encodes the alpha-subunit of G stimulatory proteins (gsp), are frequently detected in somatotroph pituitary tumors and have been associated to specific clinical-smaller and less invasive tumors occurring in older patients- and histopathological-densely granulated adenomas- characteristics. However, the question whether the presence of a somatic gsp mutation affects the response to somatostatin analogue treatment remains unresolved.
Design
Following a literature search, we performed a meta-analysis, including eight eligible studies, in order to estimate the effect of gsp mutation on the percent reduction of growth hormone (GH) levels during an acute octreotide suppression test (OST). A total of 310 patients with acromegaly (126 gsp (+) and 184 gsp (−)) were included in the analysis.
Results
The presence of the gsp mutation was related with a greater reduction in GH levels on OST (weighted mean difference (WMD): 9.08% (95% CI, 2.73, 15.42; $P = 0.005$; random effects model). There was significant heterogeneity for this effect estimate ($I^2 = 58\%$, P value for heterogeneity = 0.02). A sensitivity analysis after exclusion of a study with different methodology of OST provided similar estimates (WMD: 6.93% (95% CI, 1.40, 12.46); $P = 0.01$) albeit with no significant heterogeneity ($I^2 = 35\%$, P value for heterogeneity = 0.16).
Conclusions
The present meta-analysis suggests a role for gsp mutation as a predictive factor of which patients with acromegaly are best candidates for treatment with somatostatin analogs. In order to further clarify this position, studies evaluating the long term effect of treatment, using the combination of GH and IGF-1 measurements are needed.

Does cigarette smoking affect serum total cortisol and salivary cortisol levels?

Gulsah Elbuken, Zuleyha Karaca, Fatih Tanriverdi, Kursad Unluhizarci, Yasin Simsek & Fahrettin Kelestimur
Department of Endocrinology and Metabolism, Erciyes University, Medical School, Kayseri, Turkey.

Aim
Although there are some studies regarding the effects of cigarette smoking on serum total cortisol (STC) and salivary cortisol (SaC) levels, the results are still challenging. For this purpose, we aimed to determine the effects of cigarette smoking on STC and/ or SaC levels in a small group of healthy volunteers.
Study design
15 (five female and ten male) cigarette smoker with the mean age of 39.47 ± 14.27, and 15 age and gender matched non-smoker (mean age: 42.47 ± 13.46)

healthy people recruited to the study. Hypothalamo-pituitary-adrenal (HPA) axis was evaluated by basal STC and SaC levels, and STC and SaC responses to standard dose (250 μg) ACTH stimulation test. STC and SaC levels were obtained basal and stimulated conditions.
Results
Basal STC levels were statistically lower in smokers than non-smokers (8.41 ± 4.52 and 13.36 ± 6.68 μg/dl, respectively). Although peak STC were lower in smoker male group than non-smoker male group (30.41 ± 5.79 and 41.10 ± 12.87 μg/dl, respectively), SaC levels were not different (2.41 ± 0.31 and 2.16 ± 1.00 μg/dl, respectively). SaC levels were not affected by cigarette smoking in overall group or in the sub-groups of gender, either.
Conclusion
In our study, SaC levels were not found to be different in smoker group than non-smokers. Further studies including more subjects are needed.

Evaluation of long term soccer playing caused growth hormone deficiency: a pilot study

Gábor László Kovács[1], Piroska Turbucz[1], Éva Rimanóczy[2], Gergely Pánics[3], Katalin Bánáti[1] & Miklós Góth[4]
[1]1st Department Internal Medicine Flor Ferenc Hospital, Kistarcsa, Hungary; [2]Department of Laboratory Heim Pal Pediatric Hospital, Budapest, Hungary; [3]Department of Orthopedics and Traumatology Uzsoki Hospital, Budapest, Hungary; [4]2nd Department of Internal Medicine, Medical Centre, Hungarian Defence Forces, Budapest, Hungary.

Objective
Our aim was to evaluate whether multiple mild head trauma or repetitive heading of long term soccer playing causes growth hormone deficiency.
Patients and methods
28 retired previously professional male soccer players were investigated. Nine of them had sport related head injuries. Mean age: 48.7 years (range 36–70; S.D. ± 7.4); mean sport duration (professional and senior activity): 27.4 years (S.D. ± 8.17). IGF-I, luteinizing hormone (LH), total testosterone (TT) and quality of life with the QoL-Assessment of Growth Hormone Deficiency in Adults (AGHDA) questionnaire were investigated.
Results
The mean IGF-I was 376.87 ng/ml (range 214.30–503.26 ng/ml S.D. ± 81.42), the mean IGF-I-S.D. score (SDS) value was 2.19 (range 0.74–3.02). The mean LH was 4.12 IU/l (S.D. ± 1.25; normal range: 0.57–12.07), mean TT was 17.44 nmol/l (S.D. ± 7.03; normal range 5.76–30,4). The mean QoL – AGHDA score showed normal value 2.4 points (range 0–12 S.D. ± 3.4), but only four of the subjects had more, than five scores (normal <6). No significant differences ($P>0.05$ in all cases) were found between players with or without head injuries in IGF-1 (385.99 ng/ml ± 85.9 vs 368.41 ng/ml ± 81.21), in IGF-I-SDS (2.23 vs 2.13), in LH (3.36 ± 1.08 vs 4.42 ± 1.19), in TT (16.64 nmol/l ± 7.94 vs 17.92 nmol/l ± 6.59) and in QoL-AGHDA scores (3.22 ± 3.76 vs 2.05 ± 3.23).
Conclusions
There was no difference between normal populations and retired soccer players in IGF-I SDS values, LH, TT levels and QoL-AGHDA scores. The results suggest that long term soccer playing does not damage the most vulnerable pituitary hormone secretion. Although the dynamic tests (e.g. insulin tolerance test) in a larger population would result more reliable data, but according to our pilot study the consequence of these dynamic investigations are ambiguous.

Carney complex – a case report

Helena Urbánková, Michal Kulich, Elena Vetešková & Peter Vanuga
National Institute of Endocrinology and Diabetology, Lubochna, Slovakia.

Carney complex (CNC) is rare autosomal dominant disorder, which was firstly described as a combination of manifestation of myxomas, spotty skin pigmentation and endocrine overactivity in 1985. This condition affects many organs and varies in clinical manifestation. The presence of at least two clinical signs is considered as pathognomonic with regard to a sporadic form of CNC, and an evidence of at least one sign with simultaneous manifestation of CNC in any of first degree relatives is considered as pathognomonic with regard to a familiar form. Intracardiac and extracardiac myxomas are the most common diagnostic signs. In our report, we present a case of 36-year male patient with history of surgery for testicular Sertoli – cell tumour and surgery of thyroid nodule, with diagnosis of acromegaly. The patient was examined for persistence of hypersomatotropism after partial resection of growth hormone secreting pituitary adenoma, followed by radiation treatment with Leksell γ knife and treated by somatostatin analogues. Recently, as a part of differential diagnosis procedure aiming to discover other increased endocrine activity, we consider potential occurrence of intermittent hypercortisolism based on primary pigmented nodular adrenocortical disease. As a part of comprehensive examination of associated complications of acromegaly we added echocardiography with findings of intracardiac tumours. Drifting thrombus, or bacterial flora, or myxomas were considered as options in differential diagnosis. Patient underwent urgent surgical excision of myxomas in left and right atrium at Cardiac Surgery Clinic. The diagnosis of Carney complex was confirmed by genetic testing.

Efficacy and safety of tolvaptan in treatment of SIADH; case-series from 2 UK hospitals

Ploutarchos Tzoulis[1], Julian Waung[2], Bernard Khoo[1], Mark Cohen[2] & Pierre-Marc Bouloux[1]
[1]Royal Free Hospital/UCL Medical School, Centre for Neuroendocrinology, London, UK; [2]Barnet Hospital, London, UK.

Introduction
Contrary to US guidelines, recent European guidelines do not recommend tolvaptan for the treatment of SIADH.
Methods
Retrospective data collection of all inpatients treated with tolvaptan for SIADH in two UK hospitals between November 2010 and February 2014. All values were calculated as mean ± S.D.
Results
This case series included 61 patients (33 females, 28 males) aged 74.4 ± 15.3 years with serum sodium (sNa) 119.9 ± 5.5 mmol/l. The aetiology of SIADH was malignancy (24.6%), unknown (24.6%), pulmonary (14.7%), neurosurgical (11.5%), drug-induced (9.8%), post-operative (9.8%) and various (5%). Initiation tolvaptan dose was 15 mg in 55/61 and 7.5 mg in 6/61 cases. 24 h after administration of tolvaptan, sNa increased by 9 ± 3.9 mmol/l; specifically, 2–8 mmol/l in 45.9%, 9–10 mmol/l in 16.4%, 11–12 mmol/l in 19.7% and >12 mmol/l in 18% of patients. Overcorrection, defined as sNa increase of >12 mmol/l in 24 h or >18 mmol/l in 48 h, was observed in 22.3%, while increase of >10 mmol/l in 24 h occurred in 39.3% of patients. No patients developed osmotic demyelination syndrome. None of 12 patients with baseline sNa $\geqq 125$ mmol/l exhibited increase >10 mmol/l in 24 h. The duration of tolvaptan use was 4.2 ± 4 days. At the end of tolvaptan therapy, sNa increased by 13.5 ± 5.9 mmol/l with only 2/61 (3.3%) 'non-responders', having sNa increase ≤ 5 mmol/l or sNa ≤ 130 mmol/l.
Five days after withdrawal of tolvaptan, mean change of sNa was −3.8 ± 6.6 mmol/l with sNa reduction by $\geqq 5$ mmol/l in 21/50 (42%) patients.
Conclusions
Tolvaptan is effective, but can often lead to overcorrection of hyponatraemia. Physicians should monitor closely sodium levels and take appropriate measures to prevent or reverse overcorrection, especially in patients with baseline sNa ≤ 125 mmol/l.

Evaluation of GH secretion after stroke

Orsolya Nemes[1], Zita Tarjanyi[1], Laszlo Szapary[2], Beata Ruzsa[1], Beata Bodis[1], Laszlo Bajnok[1] & Emese Mezosi[1]
[1]1st Department of Internal Medicine, University of Pecs, Pecs, Hungary; [2]Department of Neurology, University of Pecs, Pecs, Hungary.

Objective
According to recent studies, impaired secretion of GH is a frequent finding after ischaemic stroke. The aim of our study was to compare various available GH stimulation tests in post-stroke patients.
Design
Seventeen patients were included in the study (12 males; mean age: 60.5 years; mean BMI, 27.7 kg/m^2) with a mean 19.6 ($\pm$7.3) months after stroke. For screening, glucagon and small dose (0.15 μg/kg) GHRH-arginine (sdGHRH-A) stimulation tests were carried out in consecutive days. If either or both of them were abnormal, a large dose (1 μg/kg) GHRH-arginine (ldGHRH-A) stimulation, as a standard confirmatory test was carried out, as well.
Results
Maximum GH values reached in sdGHRH-A and glucagon stimulation tests were strongly correlated to each other ($r=0.943$; $P<0.001$), but neither showed association with ldGHRH-A results. Furthermore, IGF-I levels did not correlate with stimulated peak GH values received in any of the three tests. Comparing diagnostic interpretations of stimulation tests to each other, considerable discrepancies were detected in all directions, partly due to various cut-off values of the applicable criteria.
Conclusions
Abnormal GH secretion is common after stroke. If this indication were being included in the screening for GH insufficiency, a larger trial is warranted to evaluate which tests are appropriate because a single GH stimulation test may not necessarily be enough in this population.

Association of serum IGF1 concentration with efficacy and safety measures in adults with GH deficiency with different GH treatment regimes: a randomised clinical trial

Christa C. van Bunderen[1], Paul Lips[1], Mark H. Kramer[2] & Madeleine L. Drent[1]
[1]Department of Internal Medicine, Section Endocrinology, VU University Medical Center, Amsterdam, The Netherlands; [2]Department of Internal Medicine, VU University Medical Center, Amsterdam, The Netherlands.

Introduction
The current guidelines state that the goals of growth hormone (GH) therapy should be an appropriate clinical response and avoidance of side effects. The target level for IGF1 is commonly the upper half of the reference range, although no published studies offer specific guidance in this regard. Therefore, the aim of the present study is to investigate associations between IGF1 levels within the reference range and several efficacy and safety measures of GH treatment in substituted GH deficient adults.
Methods
32 subjects receiving GH therapy for at least a year with a stable IGF1 concentration of -1 to 1 S.D. score (SDS) were included and randomized to receive either a decrease of their regular dose (IGF1 target level of -2 to -1 SDS) or an increase of their dose (IGF1 target level of 1–2 SDS) for a period of 6 months. Measurements of body composition, lipid profile, glucose metabolism, physical performance and quality of life, next to information on tolerability were collected.
Results
Thirty subjects (65.6% male, mean age 46.6 (9.9 S.D.) years) could be analysed. Decreasing the GH dose lead to more experienced fatigue. Increasing the GH dose lead to an improvement of the walking distance (6-min walking test: change 25.5 (29.7 S.D.) meters, $P=0.01$), and to an overall better feeling ($P=0.04$). There was a trend of a difference in change between de- and increasing GH dose in waist circumference ($P=0.07$) in favour of increasing dose. However, increasing GH dose resulted in a higher fasting glucose (0.4 (0.7 S.D.) mmol/l, $P=0.05$) and subjects experienced more myalgia.
Conclusion
Although increasing GH dose to IGF1 levels of 1 to 2 SDS improved physical performance and subjects reported an overall better feeling, safety is not guaranteed with the demonstrated effect on glucose metabolism and reported adverse events.

Aetiology of hypopituitarism in adult life: last 10 years' experience in single centre database in Serbian population

Mirjana Doknic[1,2], Sandra Pekic[1,2], Dragana Miljic[1,2], Marko Stojanovic[1], Vera Popovic[1,2] & Milan Petakov[1,2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Belgrade, Serbia; [2]School of Medicine, University of Belgrade, Belgrade, Serbia.

Hypopituitarism as deficiency of one or more anterior pituitary hormones, in adults can be consequence of acquired or genetic causes. Only few published studies investigated population-based aetiology of hypopituitarism. In the last 10 years new risks for hypopituitarism have been recognised (traumatic brain injury-TBI, subarachnoid haemorrhage, cranial irradiation).
Aim
To present our experiences in the aetiology of hypopituitarism based on data collected during last 10 years in Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia. This is a single centre cross-sectional database study.
Patients
A total of 426 patients with hypopituitarism were included, mean age 44.6$\pm$0.8 years (range 16–82), male 60.3%.The mean age at diagnosis of hypopituitarism was 37.7$\pm$1.2 years. Inclusion criteria were: patients older than 16 years, hypopititarism confirmed by endocrine assessment of pituitary function and MRI of the sellar region. Results are expressed as mean$\pm$SE and percentages (%). Adult onset of hypopituitarism (AOGHD) is reported in 73% pts, while childhood onset of hypopituitarism (COGHD) in 27% pts.
Results
The most common causes of hypopituitarism are: nonfunctional pituitary adenoma (160 pts, 37.6%), followed by congenital causes (66 pts, 15.5%). Acromegaly and prolactinomas are present in 30 pts (7.0%) each, followed by craniopharyngiomas (28 pts, 6.6%). TBI was the cause of hypopituitarism in 19 pts, (4.5%). Other aetiologies are reported in less than 4% in each category. Gonadotroph (FSH/LH) and growth hormone (GH) deficiency are the most common pituitary hormone deficiencies (71% and 70.3% respectively) followed by TSH (69%) and ACTH (69%) deficiency.
Conclusion
Our results show that aetiology of hypopituitarism may depend on the period of time study. Our transition clinic with paediatric endocrinologists in the last years influenced high prevalence of congenital hypopituitarism. Similarly our database confirms that patients with brain damage either by traumatic brain injury or cranial irradiation are at high risk for hypopituitarism.

Persistent hyponatremia in patient with acromegaly, congestive heart failure and diabetes insipidus

Maria Kurowska, Joanna Malicka, Agnieszka Zwolak & Jerzy S Tarach
Department of Endocrinology, Medical University, Lublin, Poland.

Introduction
Increased production of vasopressin plays a key role in the development of fluid retention and hyponatremia in patients with decompensated heart failure. Antidiuretic hormone deficiency in the course of diabetes insipidus leads to the loss of water, dehydration and hypernatremia. The aim of the study was to present difficulties in successful treatment of hyponatremia in a patient with cardiomyopathy and heart failure, receiving desmopressin because of post-operative diabetes insipidus.
Case report
70-year-old man with somatic features of acromegaly, after transsphenoidal surgery propter pituitary microadenoma (7.2 mm). Postoperative histopathological examination showed pituitary adenoma, ACTH ($-$); TSH ($-$); FSH ($+$); PRL ($+$), HGH ($+$). He developed postsurgical pituitary insufficiency requiring long-term substitution of hydrocortisone, thyroxin, testosterone and desmopressin. Before the diagnosis of acromegaly, the clinical picture was dominated by symptoms of cardiomyopathy. After surgery there was an improvement of heart failure, lasting for about 8 years. 4 years ago the worsening of heart failure

appeared with an increased atrial natriuretic peptide ranging from 701–2358 pg/ml. Between 2010–2011 the patient was hospitalised eight times in cardiological and endocrinological departments because of circulatory decompensation and severe hyponatremia (118–120 mmol/l). Dilated cardiomyopathy was diagnosed with insufficiency of mitral valve III°, tricuspid valve III°, aortic valve II° and congestive heart failure NYHA II/III. Substitution of adrenal and thyroid insufficiency was correct. In October 2011, after a withdrawal of desmopressin, normalisation of sodium levels and improvement of heart function persisting up to now were achieved.
Conclusion
An improvement of heart failure and normalization of blood natremia after the desmopressin withdrawal may suggest the regression of diabetes insipidus in our patient (9 years after an operation?), or, what is more likely, the beneficial influence of partial deficiency of antidiuretic hormone on reduction of the retention of body fluids and cardiovascular efficiency.

Background
Pituitary adenomas (PAs) in the elderly, defined as people older than 65 years, represent less than 10% of all PAs. Because of increasing life expectancy and improving health care, diagnosis PAs in this age group is increasing with time. Age-related changes and associated diseases may significantly modify the clinical presentation in these patients, delaying the diagnosis of PAs.
Objective
To analyse the clinical features of PAs in elderly patients in a study population from Castilla – La Mancha (Spain).
Design
Retrospective observational study.
Methods
The study included 346 patients with a presumptive diagnosis of pituitary adenoma between 2000 and 2012. Review of medical records of elderly patients with PAs was carried out.
Results
67 patients, 19.4% of whole PAs, were studied (62.7% women). Mean age was 73 years (range 65–87). At presentation, visual impairment, headache and deficiency of $\geqq 1$ pituitary axes were detected respectively in 43.3, 47.6 and 50.8% of the patients with available data. There were statisti-cally significant differences in visual impairment (43.3% vs 16.3%, $P<0.001$), deficiency of $\geqq 1$ pituitary axes (50.8% vs 30.5%, $P<0.001$), incidental diagnosis (47.8% vs 14.9%, $P<0.001$) or pituitary apoplexy (10,4% vs 1%, $P<0.001$) between elderly and younger patients at presentation. 59 (88,1%) out of 67 patients had macroadenomas whereas 8 (11.9%) had microadenomas. Mean size of PAs in elderly patients was significantly greater than non elderly patients ($23.9 \pm 12 \pm 0$ mm vs 15.2 ± 12.4 mm, $P<0.001$). 58 (86.8%) were non-functioning pituitary adenomas, 3 (4.5%) prolactinomas, and 6 (8.9%) GH-secreting adenoma. There was none ACTH – secreting adenoma.
Conclusions
The proportion of elderly patients in our study is higher than in other studies. Our data show that there are age-related differences in PAs clinical features at diagnosis. Visual impairment, hypopituitarism, incidental diagnosis, pituitary apoplexy and larger size are more frecuent features in elderly patients than in their younger counterparts. Most of PAs in elderly patients are macroadenomas and clinically non-functioning.

Obstructive sleep apnoea is common in patients who have had surgery for non-functioning pituitary adenomas; preliminary data

Martin Cuesta Hernandez[1], Rachel Crowley[1], Richard Costello[2] & Christopher Thompson[1]
[1]Academic Department of Endocrinology, Beaumont Hospital, Dublin, Ireland; [2]Academic Department of Pulmonology, Dublin, Ireland.

Introduction
Some patients complain of excessive daytime somnolence following pituitary surgery.
Aim
To investigate the presence of obstructive sleep apnoea (OSA) following surgery for non functioning pituitary adenomas (NFPA).
Design and methods
We assessed the prevalence of OSA in 16 routinely selected patients following surgery for NFPA and 13 obese controls attending a tertiary referral centre, by means of the Epworth Sleepiness Score (ESS) and polysomnography. All subjects with sleep apnoea were offered continuous positive airway pressure therapy (CPAP).
Results
The median age in NFPA group was 60 years (IQR: 51, 67) vs 49 years (IQR: 43, 56), $p=0.023$. Gender: Male: 9/16 (56%) in NFPA vs 7/13(53%) in control group, $P=0.89$. 15/16 (93%) patients had postoperative hypopituitarism and were on appropriate hormone replacement at the time of evaluation Median ESS was 13 (IQR: 5.25, 36) in NFPA patients and 5.7 (1.75, 18.55) in controls, $P=0.04$. 14 (87%) NFPA patients had apnoea hypopnoea index (AHI)>5, compared to seven patients (53%) in the obese control group, $P=0.043$, with 10/15 (66%) with complete anterior pituitary failure. 9/10 (90%) patients with complete anterior pituitary failure were diagnosed from OSA (AHI>5) and were started on CPAP. There were no statistically significant differences in the prevalence of OSA in patients with complete anterior pituitary failure after surgery (90%) compared to those with partial anterior hypopituitarism 4/6 (66%), $P=0.24$. BMI did not correlate with apnoea hypopnoea index (apnoea – hypopnoea index (AHI), $r=-0.17$, $P=0.54$), which suggests that factors other than obesity might explain the prevalence of sleep apnoea after surgery in patients with NFPA.
Conclusions
OSA is common following surgery for NFPA, and is not explainable solely by associated obesity. Polysomnography should be offered to NFPA patients with somnolence or symptoms of OSA.

Mean platelet volume in patients with prolactinoma

Abbas Ali Tam[1], Cafer Kaya[1], Reyhan Ersoy[2] & Bekir Çakır[1]
[1]Department of Endocrinology and Metabolism, Ataturk Training and Research Hospital, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Yıldırım Beyazıt University, Ankara, Turkey.

Introduction
Prolactin is a multifunctional pituitary hormone. The effect of prolactin on platelet activation is not well understood. Prolactinomas are the most common type of pituitary adenomas, and they are medically responsive to dopamine agonists. Mean platelet volume (MPV) is a marker of platelet function and activation. The aim of this study was to evaluate MPV values before and 6 months of cabergoline treatment when normoprolactinemia was achieved.
Methods
A total of 101 newly diagnosed prolactinoma patients and 102 healthy control subjects were included in the study. Patients with haematological disorders that affect MPV and those on medications were excluded. Prolactin, platelet count and MPV levels were recorded before and 6 months after the initiation of cabergoline treatment (0.5–1 mg, two times a week).
Results
There was no significant difference in platelet count and MPV before and after 6 months of treatment with cabergoline in patients with prolactinoma compared with the control group ($P>0.05$).
Conclusion
Our results showed that MPV, a marker of platelet function, was unchanged in patients with prolactinoma.

Differentiated thyroid cancer in patients with prolactinoma

Abbas Ali Tam[1], Cafer Kaya[1], Cevdet Aydın[1], Reyhan Ersoy[2] & Bekir Çakır[2]
[1]Department of Endocrinology and Metabolism, Ataturk Training and Research Hospital, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Yıldırım Beyazıt University, Ankara, Turkey.

Introduction
Increasing evidence is available for the role of prolactin in the development of various cancers. The purpose of this study is to evaluate the frequency of thyroid cancer in patients with prolactinoma followed up at a single site.
Materials and methods
Medical records of 182 patients, diagnosed with prolactinoma, were reviewed retrospectively. Out of these patients, 114 patients (103 female patients, 11 male patients, mean age 35 ± 10.4), who had undergone thyroid ultrasonography (US), were included in the study. Serum prolactin, anti-thyroglobulin (antiTg), anti-thyroid peroxidase antibody (anti TPO), thyroid stimulating hormone (TSH), free T_4 (fT_4), free T_3 (fT_3) values, and pituitary gland magnetic resonance imaging (MRI) and US reports were evaluated.
Results
It was found that 45(39.5%) patients had thyroid nodule (13 solitary, 32 multiple). ten patients were administered thyroidectomy, and differentiated thyroid cancer (DTC) was detected in six of these patients (5.3%). One patient had lung metastasis. Control group consisted of 113 individuals (101 females, 12 males, mean age 32.1 ± 9.1). In US, 28 of these individuals (24.8%) had thyroid nodule (five solitary, 23 multiple). One individual (0.8%) had DTC.
Conclusion
When compared to control group, thyroid volume and thyroid nodularity were significantly higher in patients with prolactinoma (respectively, $P < 0.001$, $P = 0.018$), however, no statistically significant difference was available for the incidence of thyroid cancer ($P = 0.196$).

Squamous cell carcinoma of the sphenoid sinus presenting as a sellar mass

Chin Ee Ong, Timothy Peng Lim Quek, Melvin Khee Shing Leow & Daniel Ek Kwang Chew
Tan Tock Seng Hospital, Singapore, Singapore.

Introduction
We present a rare case of squamous cell carcinoma of the sphenoid sinus presenting as a sellar mass and panhypopituitarism.
Case presentation
A 60-year-old Chinese male with schizophrenia and a 20 pack year smoking history, was admitted to our hospital with headache and diplopia without visual field loss. Brain imaging with computed tomography (CT) and magnetic resonance imaging (MRI) revealed a 2.9 cm sellar mass based in the sphenoid sinus, bulging into the suprasellar cistern with post contrast enhancement and pituitary stalk thickening. The optic chiasm was indented, with involvement of the cavernous sinuses and superior portion of the clivus. Subsequent hormonal investigations revealed panhypopituitarism (central hypocortisolism, hypothyroidism and hypogonadism) with hyperprolactinaemia likely from pituitary stalk compression and anti-psychotic medication. There were however no symptoms of central diabetes insipidus (DI). Hormonal replacement with oral hydrocortisone and thyroxine was commenced. An initial biopsy showed focal moderate to severe keratinising dysplasia but no definite invasive malignancy, and a repeat biopsy was planned. Repeat imaging done for worsening symptoms 2 weeks later showed an increase in the size of the sellar mass to 4 cm. Trans-sphenoidal debulking surgery was carried out, and intra-operative biopsy and frozen section revealed the diagnosis of squamous cell carcinoma. Staging CT scans did not reveal any lymph node or distant metastases. Post operatively, patient developed central DI with a biphasic pattern. In view of the advanced intracranial involvement of the tumour, palliative chemotherapy and radiotherapy was planned but patient unfortunately developed progressive worsening neurological deficits likely from tumour progression and passed away.
Conclusion
Squamous cell carcinoma of the sphenoid sinus can rarely present as a sellar mass. Although pituitary adenomas are the most common cause of sellar masses, atypical features such as pituitary stalk thickening or central DI necessitate a high index of suspicion to look for other causes.

Tumour regrowth in growth hormone deficient adults with non-functioning pituitary adenomas using growth hormone replacement therapy – a sub-analysis from the Dutch National Registry of growth hormone treatment in Adults

Nadège van Varsseveld[1], Christa van Bunderen, Anton Franken[2], Hans Koppeschaar[3], Aart Jan van der Lely[4] & Madeleine Drent[1]
[1]VU University Medical Center, Amsterdam, The Netherlands; [2]Isala Clinics, Zwolle, The Netherlands; [3]Emotional Brain and Alan Turing Institute for multidisciplinary health research, Almere, The Netherlands; [4]Erasmus Medical Center, Rotterdam, The Netherlands.

Objective
Growth hormone treatment (GHT) is a widely accepted treatment in growth hormone deficient (GHD) adults with nonfunctioning pituitary adenoma (NFPAs). However, concerns remain about the safety of GHT, because of its potentially stimulating effect on tumour (re)growth. The aim of this study was to evaluate tumour progression in NFPA patients using GHT.
Patients and methods
From the Dutch National Registry of growth hormone treatment in adults, a nationwide surveillance study in severe GHD adults (1998–2009), all NFPA patients with >30 days of GHT were selected ($n = 783$). Anonymized data of all patients were thoroughly and retrospectively collected from the start of GHT in adulthood (baseline). Recurrent tumour after apparent complete remission at baseline and regrowth of residual tumour were both defined as tumour progression.
Results
Tumour progression developed in 12.5% of the patients after a median time of 2.2 (0.14–14.9) years. Median follow-up time for patients with and without tumour progression was 5.1 (0.2–20.2) and 6.0 (0.71–5.2) years respectively ($P = 0.10$). After adjustment for age and gender, initial radiotherapy decreased the risk of developing tumour progression compared to no initial radiotherapy (Hazard ratio (HR) = 0.16, 95% confidence interval (CI) = 0.09–0.26). Analysis in 577 patients with available baseline imaging data showed that, after adjustment for age and gender, residual tumour at baseline increased the risk of tumour progression compared to no residual tumour (HR = 3.7, 95% CI 2.0–6.8).
Conclusions
In this large cohort of adult NFPA patients using GHT tumour progression was observed in 12.5% of the patients. Pituitary radiotherapy decreased the risk of developing tumour progression, while the presence of residual tumour at baseline increased this risk. More large studies, ideally long-term randomized studies, are needed to provide conclusive evidence with regard to the safety of GHT in GHD patients with a (treated) NFPA.

Symptoms and comorbidities at diagnosis of 472 acromegalic patients diagnosed between 2009 and 2014

Philippe Caron[1], Thierry Brue[2], Philippe Chanson[3], Gérald Raverot[4], Antoine Tabarin[5], Anne Cailleux[6], Brigitte Delemer[7], Peggy Pierre Renoult[8], Aude Houchard[9] & Frédérique Dupuis-Siméon[9]
[1]Larrey University Hospital, Toulouse, France; [2]La Timone University Hospital, Marseille, France; [3]Bicêtre University Hospital, Kremlin Bicêtre, France; [4]Neuro-Cardiologic Hospital, Bron, France; [5]Haut-Levêque Hospital, Pessac, France; [6]Charles Nicolle University Hospital, Rouen, France; [7]Robert Debré University Hospital, Reims, France; [8]Bretonneau University Hospital, Tours, France; [9]Ipsen Pharma SAS, Boulogne Billancourt, France.

Introduction
Acromegaly is characterised by chronic, excessive secretion of GH and increased IGF1 levels caused by benign pituitary adenoma. This study aimed at describing the symptoms and comorbidities of acromegaly at diagnosis, in a large cohort of patients diagnosed between 2009 and 2014.
Methods
Observational, cross-sectional, multicentre study conducted in France between September 2013 and June 2014. Adult patients with acromegaly diagnosed for <5 years were included. Data were collected retrospectively from patient medical files and confirmed by patients' questionnaires.
Results
472 patients were analysed. Age (mean $\pm$ S.D.) was 51.9 (± 14.3) years and 57.2% were female. BMI was 27.7 (± 5.3) kg/m^2. Time since diagnosis was 30.6 (± 17.8) months. Acromegaly was most frequently diagnosed by endocrinologists

(29.5%) and general practitioners (16.1%). GH- and GH/PRL-secreting pituitary adenomas were reported in 78.8% and 18.2% of patients, respectively. Most patients had a macroadenoma (80.3%). At diagnosis, GH level was 18.7 (±30.1) µg/l and IGF1 level was 295 (±160) %ULN. Among patients with GH/PRL adenoma, serum prolactin level was 183 (±650) µg/l.
At diagnosis, patients presented morphological signs (coarse facial feature, enlargement of hands and feet) (96.2%), skin manifestations (85.8%), respiratory problems (83.5%), asthenia (79.2%), osteoarthropathies (76.1%), endocrine complications (73.3%), tumour mass effects (69.1%), weight gain (64.6%), cardiovascular diseases (62.9%), ear-nose-throat disorders (62.1%), carpal/cubital tunnel syndromes (58.1%), gastrointestinal symptoms (57.8%), sexual dysfunctions (47.7%), metabolic abnormalities (42.8%) ((diabetes mellitus (27.5%), impaired glucose tolerance (9.5%)), psychologic changes (28.8%), and malignant diseases (11.9%). Overall, mean time between symptom or comorbidity onset and diagnosis of acromegaly was 5.1 (±4.3) years.
Conclusion
This study provides insights on symptoms and comorbidities of acromegalic patients recently diagnosed. Results confirm the broad range of comorbidities at diagnosis and the delay for the diagnosis of acromegaly, and therefore emphasise the efforts needed in improving the early recognition of the disease.

EP744

Symptoms of gonadal dysfunction are more predictive of hypopituitarism than non-specific symptoms in screening for pituitary dysfunction following moderate or severe traumatic brain injury

Martin Cuesta Hernandez[1], Mark J Hannon[1], Rachel K Crowley[1], Lucy Ann Behan[1], William Tormey[2], Daniel Rawluk[3], Mark Delargy[4], Amar Agha[1] & Christopher J Thompson[1]
[1]Academic Department of Endocrinology. Beaumont Hospital/RCSI Medical School, Dublin, Ireland; [2]Department of Chemical Pathology, Beaumont Hospital/RCSI Medical School, Dublin, Ireland; [3]National Neurosurgery Unit, Beaumont Hospital/RCSI Medical School, Dublin, Ireland; [4]National Rehabilitation Unit, Beaumont Hospital/RCSI Medical School, Dublin, Ireland.

Context
The economic and logistic burden of screening for hypopituitarism following moderate/severe traumatic brain injury (TBI) is considerable. Published guidelines suggest prioritisation for screening of patients with symptoms of pituitary dysfunction.
Objective
To evaluate the implementation of targeted symptom-based screening for hypopituitarism after moderate/severe TBI, compared with routine consecutive screening.
Design
Group 1 (G1); consecutive patients were screened. Group 2 (G2); screening targeted based on symptoms of pituitary dysfunction. Setting: G1 patients were recruited from the Irish National Neurosurgery Centre and in G2 on symptom based referral from external caregivers. Patients: G1, 137 patients (113 male) and G2 111 patients (77 male) referred for pituitary evaluation (G2).
Main outcome measures
The rate of pituitary hormone deficiency between groups.
Results
Patients with menstrual dysfunction ($n=10$) had more GH (50% vs 11%, $P=0.001$), ACTH (60% vs 14%, $P<0.0001$) or gonadotrophin (90% vs 16%, $P<0.0001$) deficiency and any pituitary hormone deficit (100% vs 33%, $P<0.0001$) than G1. Men with symptomatic hypogonadism ($n=12$) had more GH (33% vs 11%, $P=0.03$), gonadotrophin (58% vs 16%, $P<0.0001$) and TSH (16% vs 1%, $P=0.03$) deficiency than G1. Patients with non-specific symptoms ($n=89$) were no more likely to have hypopituitarism than those consecutively screened. The rates of GH (19% vs 11%, $P=0.12$), ACTH (14% vs 14%, $P=0.99$), TSH (3% vs 1%, $P=0.34$), ADH (7% vs 2%, $P=0.44$) or any pituitary hormone deficit (25% vs 33%, $P=0.21$) were not different between those referred with non-specific symptoms in G2 and G1.
Conclusions
Symptoms of hypogonadism are sufficiently predictive of hypopituitarism to justify inclusion in protocols for screening for hypopituitarism after moderate/severe TBI. Non-specific symptoms of hypopituitarism are no more predictive than systematic screening in identifying pituitary hormone deficits: their place as indicators for screening is therefore questionable.
Disclosure
The work in this study was supported by unrestricted grants from Pfizer Pharmaceuticals and Novo Nordisk Pharmaceuticals.

A 5 years retrospective studies looking at trends in water deprivation tests and roles for endocrine specialist nurses

Phillip Yeoh[1], Pierre Bouloux[1,2], Shern Chew[1], Bernard Khoo[1,2], Paul Carroll[1,3] & Ashley Grossman[1,4]
[1]Endocrinology & Diabetes Department, The London Clinic, London, UK; [2]Department of Endocrinology, Royal Free Hospital, London, UK; [3]Department of Endocrinology & Diabetes, St Thomas NHS Trust, London, UK; [4]Department of Endocrinology, University of Oxford, Churchill Hospital, Oxford, UK.

Performing water deprivation test (WDT) and prolonged water deprivation test (PWDT) is some of the roles undertaken by endocrine nurse in specialist endocrine units. These tests need to be done in a safe and control environment.
Objectives
To provide safe information to patients to avoid fluids overload when they arrive for the tests. Can the specialist endocrine nurse make clinical decision to terminate the test base on clinical evidence and at what point the communication with consultant is crucial in order to collect results of clinical relevance?
Methodology
35 patients who completed WDT and PWDT over the last 5 years were studied.
Results
Three with overt normal (ON), five with normal (N), three with nephrogenic diabetes insipidus (NDI), 14 with cranial diabetes insipidus (CDI), two with primary polydipsia (PP), eight were excluded due to inability to complete their tests or lack of diagnosis and medical information. ON has the highest mean urine/serum osmolarity ratio at begin and termination of tests. Delay DDAVP during WDT is useful in some cases.
ADH measurement at Peak urine osmolarity can be used to distinguish NDI from CDI. Primary Polydipsia urine/serum osmolarity Ratio increase according to the length of fluid fasting.
Conclusions/recommendations
Address fluids overloading with patients who are coming for these tests. The length of fluids fasting before these tests will be based on patient's symptoms. Endocrine specialist nurse can make clinical decisions if the tests are overtly normal or serum osmolarity goes above 305 mOsm/kg. Additional markers such as ADH and serum sodium can be useful if needed at certain point during the tests.

EP746

The effect of intra-articular glucocorticoid injections on hypothalamic-pituitary-adrenal-axis function: a review

Philip C Johnston[1], M Cecilia Lansang[1], Soumya Chatterjee[2] & Laurence Kennedy[1]
[1]Department of Endocrinology, Diabetes and Metabolism, Cleveland Clinic, Cleveland, OH, USA; [2]Department of Rheumatic and Immunologic Diseases, Cleveland Clinic, Cleveland, OH, USA.

Background
The use of intra-articular (IA) glucocorticoids for reducing pain and inflammation in patients with osteoarthritis, rheumatoid arthritis, and other inflammatory arthropathies is widespread among primary care physicians, specialists and non-specialists in the United States. Injectable glucocorticoids have anti-inflammatory and analgesic properties which can be effective in improving clinical parameters such as pain, range of motion, and quality of life. After injection into the IA space, glucocorticoids may be systemically absorbed; the degree of absorption can depend on the size of joint injection, the preparation used, the dosage and frequency of injection. The adverse effects of IAGC can often be overlooked by both the patient and physician who administer them, in particular the potential deleterious effect on the hypothalamic-pituitary-adrenal (HPA)-axis which can result in adrenal suppression and/or iatrogenic Cushing syndrome.
Aim
We provide an overview on the often under-recognised effects of IAGC on HPA-axis function.

Results and conclusions
IAGC can result in a sharp decline in cortisol to low or undetectable levels within the first days after administration. HPA-axis suppression can typically last for up to 4 weeks after a single injection, although recovery of HPA-axis to baseline can take longer depending on the dose and frequency of injections. Considering the widespread use of IA steroid injections and their clinical effectiveness, physicians who administer them need to be aware of the potential risks of HPA-axis suppression and/or iatrogenic Cushing syndrome. Guidelines for the frequency of dosing in addition to defined time intervals between each injection should be clear. High risk populations have the potential to be screened for adrenal suppression and could include those who receive high doses and multiple injections particularly within the previous 6 months. The potential use of the measurement of salivary cortisol in identifying patients who have subtle changes in HPA-axis function remains to be seen.

Prolactinomas: do age and gender affect clinic?

Farida Nasybullina[1], Gulnar Vagapova[1] & Bakhtiyar Pashaev[2]
[1]Kazan State Medical Academy, Kazan, Russia; [2]Kazan State Medical University, Kazan, Russia.

Objective
To study the effect of age and gender on manifestation of hyperprolactinaemia.
Methods
Patients were examined using generally accepted methods of diagnosis. 207 patients with prolactinomas were divided into two groups: before and after 50 years. It was a retrospective study with no interventions to generally accepted methods of diagnosis and treatment. The outcomes were measured by frequency of hyperprolactinaemia symptoms according to age and gender.
Results
In patients who are <50 years prolactinomas were observed in 91% of women and 9% of men. The main clinical symptoms in women and men were presented by hyperprolactinaemic hypogonadism. Menstrual irregularities were observed in 70% of women, galactorrhoea – in 54%, infertility – in 53%. Macroadenomas were detected in 13% of women. Clinical signs of hypogonadism in men were presented by decreased libido (100%), erectile dysfunction (80%), infertility (6%) and depression (98%). Macroadenomas were diagnosed in 58% of men. In group over the age of 50 years prolactinomas were diagnosed in 61% of women and 39% of men. Clinical manifestation of the disease, both in women and men, was presented by neurological symptoms: headaches – in 86% of women and in 79% of men; visual disturbances – in 56% of women and 78% of men. Macroadenomas were detected in 68% of women and 89% of men.
Conclusion
People of reproductive age developed typical clinical picture of hyperprolactinaemic hypogonadism, which is well recognised in women, while often ignored in men. The frequency of macroprolactinomas with chiasmatic syndrome increases in both sexes over the age of 50 years, that is partly due to the lack of vivid clinical signs of hyperprolactinaemia in the period of menopause.

EP748

Body weight changes in patients with active Cushing disease after transsphenoidal surgery

Philip C Johnston[1], Amir H Hamrahian[1], Robert J Weil[2] & Laurence Kennedy[1]
[1]Department of Endocrinology and Diabetes, Cleveland Clinic, Cleveland, OH, USA; [2]Department of Neurosurgery, Cleveland Clinic, Cleveland, OH, USA.

Background
Successful pituitary surgery in patients with Cushing disease (CD) can result in long term remission and sustained weight loss. We examined rates of body weight changes in the post-operative period (within 6 months) in patients with active CD who underwent transsphenoidal surgery (TSS) and the relationship of weight loss to remission status.
Methods
Clinical data was obtained from a CD database in addition to an online patient medical record (EPIC). All patients with biochemically confirmed active CD underwent their first TSS by a single neurosurgeon at the Cleveland Clinic (October 2004–August 2013). No patients received glucocorticoids during surgery. Initial remission was defined by nadir cortisol <3 ng/dl, ACTH <5 pg/ml within the immediate post-operative period (72 h). Long term remission was defined as 24 h UFC $<$ULN (upper limit of normal), and/or sequential midnight salivary cortisols $<$ULN, and 1mg DST cortisol <1.8 μg/dl.
Results
88 patients (female: 63, male: 25), with a mean age at presentation of 47 years (range 24–87 years), median follow up 52 months (12–118 months) underwent TSS. No significant differences in baseline demographics including pituitary adenoma size ($P=0.25$) and BMI ($P=0.21$) were observed between the two groups. 64: pituitary microadenoma, 24: macroadenoma, 74 (84%) patients had initial remission after surgery, during follow up six of those with initial remission had recurrence. Those with initial remission had greater mean $\pm$S.D. weight loss at 3 months (kg: -8.1 ± 11.3 (initial remission, $n=59$) v 0.8 ± 8.8 (non-remission, $n=12$), $P=0.007$) and at 6 months (kg: -14.5 ± 12.1 (initial remission, $n=46$) v -6.1 ± 12.1 (non-remission, $n=12$), $P=0.045$). Less weight loss or weight gain at three ($P=0.002$) and six ($P=0.014$) months was associated with increased relapse risk.
Conclusions
After TSS for CD, weight loss within the first 6 months is an additional early clinical indicator associated with initial biochemical remission.

The development and validation of a new burden and needs assessment questionnaire for patients with pituitary diseases: the BNQ-pituitary

Cornelie Andela[1], Margreet Scharloo[1], Steven Ramondt[2], Jitske Tiemensma[1,2], Ad Kaptein[1], Alberto Pereira[1], Noëlle Kamminga[1] & Nienke Biermasz[1]
[1]Leiden University Medical Center, Leiden, The Netherlands; [2]University of California, Merced, CA, USA.

Background
An increasing number of studies assess quality of life (QoL) in patients with pituitary diseases. At present, available disease-specific QoL questionnaires do not completely cover the patient perspective of QoL. Furthermore, there are no disease-specific questionnaires available which inventories patient's needs for help for impairments in QoL.
Objective
To develop and validate a disease-specific QoL questionnaire for patients with pituitary diseases based on the patient perspective on QoL, which also incorporates the needs for help: the burden and needs assessment questionnaire for patients with pituitary diseases (BNQ-Pituitary).
Methods
337 patients with pituitary diseases fill-out the BNQ-Pituitary and eight other psychosocial questionnaires (i.e. EuroQoL-5D, SF-36, MFI-20, HADS, UCL, GSE, IPQ-brief, IPA). Items were formulated based on results of a recent focus group study of our department. Construct validity was examined by using an exploratory factor analysis with oblique rotation on principal components. Reliabilities were calculated with Cronbach's α, and concurrent validity was measured by calculating Spearman correlations between BNQ-Pituitary reported burden and subscales of the other questionnaires.
Results
The exploratory factor analysis revealed seven subscales (i.e. Mood, Cognitive functioning, Illness perceptions, sexual functioning, social functioning, anxiety, physical complaints) containing a total of 33 items. Subscales reliabilities were all >0.736 and strong and consistent correlations were observed between BNQ-Pituitary scores and scores on the other psychosocial questionnaires. A significant effect of type of pituitary disease was observed, with patients with Cushing's disease reporting the highest burden compared to patients with prolactinoma or non-functioning pituitary adenoma.
Conclusion
The BNQ-Pituitary is a valid and reliable instrument to measure not only the burden of pituitary disease, but also the need for help considering the consequences of the disease. Furthermore, the BNQ-Pituitary can facilitate the efficient assessment of patients' unmet needs. We postulate that paying attention to potential unmet needs may positively affect QoL.

Rate of Prolactin suppression can predict future prolactin normalisation, tumour shrinkage and time to remission in male macroprolactinomas

Amit Tirosh[1,2], Carlos Benbassat[1,2] & Ilan Shimon[1,2]
[1]Endocrine Institute, Rabin Medical Center, Petah Tiqva, Israel; [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.

Introduction
Dopamine agonists are the mainstay treatment for prolactinomas, but clinical characteristics that predict their effects on prolactin (PRL) suppression and tumour shrinkage are missing. Our study aimed to find measures in early follow-up of men harbouring macroprolactinomas, that will predict dynamics of PRL decrease and adenoma shrinkage.
Methods
A single centre historical prospective study, including a consecutive group of 71 men with pituitary macroadenomas ($\geq$10 mm) and hyperporlactinaemia (>7xULN), treated medically with cabergoline. Comparisons of PRL normalisation rates were performed according to PRL levels achieved at 6 months, maximal adenoma shrinkage during follow-up, and other patient characteristics. Correlations were performed to identify characteristics of PRL suppression dynamics.
Results
Five patients had nadir PRL levels $\geq$x 3 ULN (51 ng/ml), and showed slower response to treatment with cabergoline with consistently higher PRL levels compared to other patients throughout follow-up (6 months mean PRL levels, 519$\pm$403 vs. 59$\pm$118 ng/ml, $P<0.001$). PRL levels after 6 months of treatment correlated positively with current PRL levels ($r=0.74$, $P<0.001$), with adenoma diameter following treatment ($r=0.38$, $P=0.01$), and with time to PRL normalisation ($r=0.75$, $P<0.001$). Shrinkage of adenoma size depicted by first MRI on treatment correlated with maximal adenoma shrinkage during follow-up ($r=0.56$, $P=0.006$).
Conclusions
Six months PRL level might serve as a surrogate marker for PRL normalization and adenoma shrinkage dynamics among men harbouring macroprolactinomas. Among these patients with persistent hyperprolactinaemia at 6 months, higher PRL levels are associated with resistance to cabergoline.

Endonasal endoscopic pituitary adenoma resection

Václav Masopust[1], David Netuka[1], Vladimír Beneš[1], Ondrej Bradáč[1], Josef Marek[2], Václav Hána[2] & Michal Kršek[2]
[1]Department of Neurosurgery, Central Military Hospital, 1st. Medical Faculty of Charles University, Prague, Czech Republic; [2]Department of Internal Medicine, General Teaching Hospital, 1st Medical Faculty of Charles University, Prague, Czech Republic.

Introduction
In the past 10 years, endoscopic resection of pituitary adenomas has become an alternative to microsurgical resection with the additional advantage of increasing the patient's postoperative comfort. This analysis explored whether endoscopic resection can reduce the risk of postoperative neurohypophyseal dysfunction.
Material and methods
We rated and compared the need to administer desmopressin during the first four postoperative days and with the need after a follow-up of at least 3 months (chronic administration). Two groups of patients were compare: Patients in group 1 were operated on microscopically. Patients in group 2 were operated on endoscopically. Group 1 was made up of 50 patients treated in 1999, group 2 comprised 50 patients operated on from 2006 to 2007.
Results
In group 1 the need to use desmopressin postoperatively occurred in eight patients: three needed chronic treatment. In group 2 the need for postoperative application of desmopressin occurred in four patients, none required chronic treatment.
Conclusions
Endoscopic surgery is a safe and effective method for the resection of pituitary adenomas. The rate of chronic desmopressin application was reduce.

The comparison of echocardiographic parameters, carotid intima thickness, arterial stiffness and plasma soluble CD40 ligand levels in active and inactive acromegalic patients

Guven Baris Cansu[1], Nusret Yilmaz[1], Atakan Yanikoglu[2], Sebahat Ozdem[3], Aytul Yildirim[2], Gultekin Suleymanlar[4] & Hasan Altunbas[1]
[1]Akdeniz Universty Faculty of Medicine, Endocrinology and Metabolism, Antalya, Turkey; [2]Akdeniz Universty Faculty of Medicine, Cardiology, Antalya, Turkey; [3]Akdeniz Universty Faculty of Medicine, Biochemistry, Antalya, Turkey; [4]Akdeniz Universty Faculty of Medicine, Nephrology, Antalya, Turkey.

Introduction
In acromegalic patients, the increased mortality and morbidity are generally due to cardiovascular, metabolic, respiratory and cerebrovascular diseases, so early diagnosis and treatment of cardiovascular lesions may save lives. The aim of this study is to find out the any possible difference in terms of carotid intima media thickness (CIMT), indices of arterial stiffness, soluble CD40 ligand (sCD40L) and some echocardiographic parameters between active and inactive acromegalic patients.
Methods
The study involved 26 active, 24 inactive acromegalic patients and 20 healthy subjects. 47 of 50 acromegalic patients had underwent transsphenoidal surgery and 41 of 50 patients were using somatostatin analogues at least 6 months and nine patients have no treatment after transsphenoidal surgery. CIMT, arterial stiffness, sCD40L and some echocardiographic parameters were compared.
Results
The study showed that CIMT and indices of arterial stiffness were higher in acromegalic group ($P=0.003$ and $P=0.008$ respectively). Left ventricular diastolic dysfunctions were comparable between groups, whereas the left ventricle mass index, DOPPTEI and left atrial diameter were higher, and ejection fraction was lower in acromegalic patients. CIMT, arterial stiffness, sCD40L and parameters of echocardiography were comparable in patients with active and inactive patients.
Discussion
Getting the disease under control hormonally didn't cause a reduction in the subclinical cardiovascular risk. This can point out that in acromegalic patients the structural and functional damage may be due to long-term exposure to excess growth hormone/IGF1.

An audit of transsphenoidal surgery on nonfunctioning pituitary adenomas

Dolores Moure, Javier Santamaría, Ihintza Larrañaga, Pedro González, Sara Valle & Sonia Gaztambide
Endocrinology and Nutrition, Cruces University Hospital, Barakaldo, Spain.

Introduction and objective
Clinically nonfunctional pituitary adenomas are relatively an uncommon disease. The aim of this work is to describe the clinical characteristics and to review the results of transsphenoidal surgery (TS) of pituitary adenomas in a reference centre.
Methods
A retrospective study (1995–2014) of 66 patients (50% men) diagnosed with pituitary adenomas by a magnetic resonance imaging (MRI) was conducted. demographic, clinical, biochemical data and the results of TS were collected. For statistical processing program SPSS version 22.0 was used.
Results
The mean age of the patients was 57$\pm$16'8 years. The most frequent clinical presentations were as an incidental pituitary mass (34.8%) and visual symptoms (36.4%). The mean size of the sellar tumour was 26.6$\pm$8.8 mm. A 59% of them had pathological visual field testing (34.8% bitemporal hemianopsia). Some hormone deficiency was found in 66.7% of patients before surgery (16.7% of them presented panhypopituitarism). 52 out of 66 were referred for surgery, 49 because of the optic chiasm compression and three due to pituitary apoplexy. The mean size of the tumour was 28.55 mm in those who underwent surgery Vs 20.1 mm in nonsurgical patients ($P<0.001$). Transsphenoidal approach was used in all patients (endoscope visualisation in 13/52). 12 months after the surgery, 50% had no tumour image on MRI. Some hormone deficiency was detected in 90.4% (38.5% of whom had panhypopituitarism) and the visual field deficits improved in 30%. Nine out of 52 patients required a second surgery and 11/52 received radiotherapy due to residual mass.

Conclusion
Considering tumour size results they are similar to those reported in the literature but with a higher risk of hypopituitarism.

Optic neuropathy following radiotherapy for Cushing's disease followed by the diagnosis of pituitary carcinoma

Krystallenia Alexandraki, Georgios Boutzios, Georgios Nikolopoulos, Panagoula Roussaki, Maria Chrysochoou, Eleftherios Chatzellis, Marina Tsoli, Maria Kaltsatou, Panagiotis Moschouris & Gregory Kaltsas
Endocrine Unit, Department of Pathophysiology, Laiko Hospital, University of Athens Medical School, Athens, Greece.

Introduction
ACTH-secreting pituitary carcinomas are rare neoplasms but there are not factors till now to predict their aggressive evolution nor a standard practice to their management.
Case report
We report a 43-year-old female patient presented in 1990 with Cushing's syndrome due to ACTH-secreting pituitary microadenoma who had been submitted on trans-sphenoidal surgery with cure as defined by post-operative cortisol serum levels <50 nmol/l. In 2000 she represented with clinical, biochemical and imaging recurrence, hence, 10 years after her first remission. She had repeat surgery similarly with cure as defined by post-operative cortisol serum levels <50 nmol/l but again a recurrence within 2 years. Since, no tumour was documented in imaging studies, she received external beam irradiation (in total a dose as high as 54 Gy) in 2005. However, her hypercortisolaemia was still uncontrolled and she was submitted in bilateral adrenalectomy. Ten months after radiotherapy, the patient was presented with declining visual acuity, and radiation-induced optic neuropathy (RON) was diagnosed. Despite treatment with glucocorticoids and hyperbaric oxygen, her vision did not improve. Two years later she was hyperpigmented with increased ACTH plasma levels. The ACTH plasma levels continued to increase reaching very high levels and in 2010 FDG–PET and conventional imaging confirmed the diagnosis of pituitary carcinoma with multiple liver metastasis and local disease. Since today we are trying to control, her disease with several recent chemotherapeutic and biological agents (cisplatin + etoposide and temozolamide + bevacizumab).
Conclusions
This case implies that the appearance of pituitary carcinoma cannot be excluded by the cure post trans-sphenoidal surgery nor can be prevented by a high dose of irradiation even this is so high to cause RON.

Mortality of patients with non-functioning pituitary macroadenoma is significantly elevated: systematic analysis of 546 cases in a tertiary referral centre in the UK

Georgia Ntali[1], Cristina Capatina[1], Violet Fazal-Sanderson[1], James V Byrne[2], Simon Cudlip[3], John Ah Wass[1], Ashley B Grossman[1] & Niki Karavitaki[1]
[1]Department of Endocrinology, Oxford Centre for Diabetes, Endocrinology and Metabolism, Churchill Hospital, Oxford, UK; [2]Department of Neuroradiology, John Radcliffe Hospital, Oxford, UK; [3]Department of Neurosurgery, John Radcliffe Hospital, Oxford, UK.

Introduction
Data on the mortality of patients with non-functioning pituitary macroadenoma (NFA) are very limited.
Aim
To assess the mortality of patients with NFA and factors predicting it.
Patients and methods
All patients presenting to our department with NFA between 1963 and 2011 were studied. Status was recorded as either dead or alive, as of 31st December 2011.
Results
546 patients (333 males) were identified (median age at surgery 58.7 years; range 16.1–94.2). Data on mortality were available for all patients covering a median period of 8 years (range 1 month–48.5 years); 83 patients died (median age 77.8 years; range 36.4–98.3) (causes: cardio/cerebrovascular 32.5%, infections 30.1%, malignancies 28.9%, peri-operatively 1.2%, gastrointestinal hemorrhage 1.2%, suicide 1.2%, unknown 3.6%, and old age 1.2%). The SMR for the total group was 3.62 (95% CI: 2.90–4.47; $P<0.001$), for those diagnosed before 1990 4.66 (95% CI: 2.65–7.63; $P<0.001$) and for those after 1990 3.53 (95% CI: 2.77–4.44; $P<0.001$). Clinical follow-up data (until date of death or date the database was frozen) were available for 436 patients (269 males, median age at surgery 58.5 years (range 16.11–94.19), 203/431 with no or intrasellar remnant – 228/431 with extrasellar remnant after surgery, median follow-up 6.9 years (range 1 month–48.5 years), 111/436 with regrowth of NFA, 188/436 received radiotherapy after primary surgery or for regrowth). Cox regression analysis (univariate approach) demonstrated that amongst age at surgery, NFA regrowth, radiotherapy, sex and extent of removal, the first three were significant predictors of mortality; after multivariate analysis using these three parameters, only age remained an independent significant factor (HR 1.099, 95% CI: 1.073–1.126; $P<0.001$).
Conclusions
Despite the improvement in the last three decades, mortality of patients with NFA remains high. Apart from age, factors related with the management/outcome of the tumour including radiotherapy and recurrence are not independent predictors of mortality in this group of patients.

Sheehan's syndrome: a rare disease with typical symptoms

Anna Dabrowska[1], Jerzy Tarach[1], Agnieszka Zwolak[1,2] & Anna Oszywa-Chabros[1]
[1]Chair and Department of Endocrinology, Medical University of Lublin, Lublin, Poland; [2]Chair of Internal Medicine, Department of Internal Medicine in Nursing, Medical University of Lublin, Lublin, Poland.

Introduction
The enlarged pituitary gland of pregnancy is susceptible to any compromise to its blood supply. Sheehan's syndrome (SS) occurs as a result of *post-partum* pituitary infarction or haemorrhage and usually leads to hypopituitarism. It can be fatal but clinical manifestations may change from one patient to another and symptoms may not occur for many years.
Methods
We analysed retrospectively five cases of women with SS aged 26–56 years, treated at Endocrinology Department between 2003 and 2014, to describe clinical manifestations. In the studied subjects the diagnosis of SS was made based on medical history, clinical symptoms, hormonal tests, and MRI scans.
Results
Mean age of the patients was 41.00 ± 12.33 years (range 26–56 years). All subjects had typical physical signs of SS. The duration between date of the last delivery and time of diagnosis was 9.82 ± 8.85 years (ranged from 1 month to 19 years). The number of pregnancies was from 1 to 4. We observed typical obstetric history of massive hemorrhage at delivery in three women, two of them received a blood transfusion. In two cases there was no overt obstetric complications. All patients lacked *post-partum* milk production and did not menstruate following delivery. According to the hormonal values, five analyzed women had total or partial secondary hypothyroidism, adrenal cortex failure and hypogonadotropic hypogonadism, prolactin, and GH deficiency. They used therapy such as: hydrocortisone (mean 25.00 ± 7.07 mg/day), levothyroxine (mean 75.00 ± 43.30 μg/day), and sex hormone replacement. Diabetes insipidus was found in one patient but it was transient. She was treated with desmopressin (120 μg/day) for 17 months. MRI scans revealed total or partially empty sella in three women and small (beyond the normal range) pituitary gland in two cases.
Conclusion
Although, SS is not a common disease, it should be remembered about concerning women with pituitary insufficiency developing at different times after delivery.

Cure rates and survival in patients with acromegaly

Simona Galoiu[1,2], Andreea Suvoiala[2], Mariana Purice[2], Andra Caragheorgheopol[2], Raluca Trifanescu[1,2], Mihail Coculescu[1,2] & Catalina Poiana[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania.

Introduction
An improvement of survival in patients with acromegaly was claimed in the last years, with multimodal new therapies.

Aims
To assess cure rates of different therapeutic protocols and the impact of these therapies on survival.
Methods
334 patients (224 F/110 M, mean age 48.1 ± 0.7 years) with acromegaly admitted in a single Neuroendocrinology Department between Jan 2001 and Dec 2013 were retrospectively studied by GH, IGF1 levels at baseline and at final visit, therapy, pituitary failure, and date of the death. PAMCOMP computation program calculated standardized mortality ratio (SMR). Kaplan–Meier curve was used to compare the impact of different therapies on survival. Serum GH levels were measured by IRMA (sensitivity 0.1 ng/ml).
Results
35.02% patients obtained control of acromegaly: 17.3% were cured after neurosurgery and/or radiotherapy and additionally 17.6% were controlled by medication. Cure rate for surgery was 17.7% (35/197) and 15.03% (23/153) for radiotherapy. 49/128 (33.5%) patients treated by somatostatin receptor analogues (SSA), 8.3% (4/48) treated with dopamine agonist and 6/16 patients (37.5%) treated by GH receptor agonist were adequately controlled. All causes mortality ratio was similar with general population: SMR = 1.07 (95% CI 0.70–1.52), average follow-up of 2252.11 person-years (median 6.9 years). Females with last GH above 2 ng/ml had a high SMR = 2.51 (95% CI 1.37–4.22).
Operated patients with/without medication and/or radiotherapy had a better survival than untreated patients (rank log Mantel-Cox: $P = 0.04$ operated vs untreated patients, 0.05 operated + SSA patients vs untreated and 0.02 operated + irradiated vs untreated).
Conclusions
Patients with acromegaly and posttreatment GH level ≥ 2 ng/ml had a high mortality, especially women. Surgery treated patients, with additionally treatment for postoperatory remnants, had a better survival, similar with general population.

Implementation of clinical guidelines on the cancellation of dopamine agonists in the event of pregnancy in patients with hyperprolactinaemia tumour origin

Julia Gallinger[2], Ekaterina Pigarova[1] & Larisa Dzeranova[1]
[1]Endocrinology Research Centre, Moscow, Russia; [2]Lomonosov Moscow State University, Moscow, Russia.

Aim
Clinical guidelines recommend the cancellation of dopamine agonists after confirmation of pregnancy as because further their use is unnecessary. However, an implementation of these recommendations in real clinical practice is unknown which became the aim of our present research.
Materials and methods
The study included 21 patients with prolactinomas who had 26 pregnancies ended in childbirth. These patients were found archived medical records of Endocrinology Research Centre (Moscow, Russia) and consent to personal/telephone interview to complete specialized survey questionnaire.
Results
In the period up to 6 weeks dopamine agonists have been cancelled in 46% of patients (12/26) of those 42% (5/12) were taking bromocriptine and 58% (7/12) cabergoline. Toxicosis was observed in 8.3% (1/12), intrauterine growth retardation (IUGR) in 16.7% (2/12), and threatened miscarriage in 16.7% (2/12). For more than 6 weeks dopamine agonists took 54% (14/26) of patients, with 29% (4/14) taking bromocriptine, 64% (9/14) – cabergoline and in one patient took quinagolide (7%). In this group toxicosis was observed in 21% (3/14) of cases, IUGR in 7% (1/14), and threatened miscarriage in 21% (3/14). The patient on quinagolide was not aware of the need to discontinue the drug at pregnancy. At 8th week of gestation she had a threatened miscarriage, which doctors regarded as quinagolide-mediated and the drug was canceled; this pregnancy proceeded uncomplicated, ended in term delivery of a healthy child. Another patient with microadenoma as advised by a doctor took cabergoline during whole pregnancy, despite the absence of symptoms of tumor growth and normal otherwise state of health; she had a term delivery, the child had patent foramen ovale. In one case, the dose of cabergoline was gradually decreased till 20 weeks of gestation; first trimester of this pregnancy was complicated by toxicosis; the child was born at term and later was found to have adrenal incidentalomas.
Conclusions
Our study show not ubiquitous implementation of clinical guidelines in the issue of cancellation of dopamine agonists at pregnancy confirmation with 54% patients continuing medications for more than 6 weeks of gestation.

Alterations in thyroid hormone levels following GH replacement exert complex biological effects

Nigel Glynn[1], Helena Kenny[2], Tarik Salim[1], David J Halsall[3], Gerard Boran[4], Paul Cook[5], Diarmuid Smith[1], Tommy Tun[6], John H McDermott[6], William Tormey[1], Chris J Thompson[1], Brendan McAdam[1], Donal O'Gorman[2] & Amar Agha[1]
[1]Beaumont Hospital and RCSI Medical School, Dublin, Ireland; [2]Dublin City University, Dublin, Ireland; [3]Addenbrooke's Hospital, Cambridge, UK; [4]Adelaide and Meath Hospital, Dublin, Ireland; [5]University Hospital Southampton, Southampton, UK; [6]Connolly Memorial Hospital, Dublin, Ireland.

Introduction
Alterations in the hypothalamic–pituitary–thyroid axis have been reported following GH replacement, with a decline in circulating T_4 concentration the most consistent finding. However, the clinical significance of GH-induced alterations in circulating levels of thyroid hormone is unclear.
Aim
To examine the relationship between changes in serum concentration of thyroid hormones and known biological markers of thyroid hormone action.
Methods
We performed a prospective study of 20 hypopituitary adult men before and after routine GH replacement. Serum TSH and thyroid hormone (free T_4, total T_4, free T_3, total T_3, and reverse T_3) were measured before and after GH substitution. Changes in thyroid hormone concentrations were compared to alterations in serum biomarkers of thyroid hormone action. Resting energy expenditure (REE) and cardiac systolic time intervals were also evaluated as sensitive markers of thyroid hormone exposure.
Results
The mean daily dose of GH was 0.34 ± 0.11 mg. Following GH replacement, free T_4 levels declined as expected (−1.28 ± 0.44 pmol/l, $P = 0.02$). Reverse T_3 levels also fell (−3.44 ± 1.42; $P = 0.03$) and free T_3 levels increased significantly (+0.34 ± 0.15; $P = 0.03$). REE did not rise as expected with GH substitution. SHBG and CK levels were unchanged. However, ferritin, copper, and caeruloplasmin declined suggesting reduced hepatic exposure to thyroid hormone (−26.8 ± 8.5; $P = 0.005$); (−1.7 ± 0.63; $P = 0.02$); and (−0.02 ± 0.01; $P = 0.04$). Complex alterations in lipid profile, including a rise in large HDL particles (+1.75 ± 0.69; $P = 0.02$) and Lp (a) (+12.5 ± 4.7; $P = 0.002$) as well as a fall in intermediate density lipoprotein concentration were variably associated with changes in thyroid hormone and GH. Cardiac systolic time intervals were unchanged. Observed changes in thyroid hormone biomarkers were more pronounced in subjects with multiple pituitary hormone deficiencies.
Conclusion
Our study demonstrates that GH replacement does not improve the biological actions of thyroid hormone in adults.

Assessment of mean platelet volume in acromegaly and its relation with disease outcome

Berrin Cetinarslan, Ozlem Zeynep Akyay, Alev Selek, Adnan Batman, Zeynep Canturk & İlhan Tarkun
Endocrinology and Metabolism, Kocaeli University, Kocaeli, Turkey.

Background
Acromegaly is associated with increased risk of coronary atherosclerosis and cardiovascular mortality. Changes in coagulation and fibrinolysis markers in acromegalic patients have been shown to indicate increase in the risk of developing cardiovascular disease. Mean platelet volume (MPV) is a marker of platelet functions and activity, and increased MPV is an independent risk factor of myocardial infarction and thrombotic events. In this study, we examined the levels of MPV in acromegalic patients before and after treatment compared to a control group.

Methods
A total of 80 patients (24 were diabetic) treated in our clinic with the diagnosis of acromegaly between 2009 and 2014 and 65 (23 were diabetic) age- and gender-matched healthy controls were reviewed retrospectively. Demographic data of all subjects and postoperative cure and remission with medical management among acromegalic patients were recorded. Preoperative and postoperative MPV values as well as MPV values observed in patients with controlled disease on medical treatment were compared. In both groups HbA1c levels and their relationship with MPV were also evaluated.
Findings
In this study, 47% of the acromegaly patients and 48% of the control subjects were females. The mean age both groups and the mean HbA1c among diabetics in both groups were similar. MPV values were significantly higher in both the diabetic and non-diabetic acromegaly patients compared with the control subjects. Postoperative MPV values were significantly reduced compared to preoperative values in patients cured with surgery. Patients who achieved control with medical therapy after the failure of surgical intervention demonstrated MPV values similar to those reported in patients cured with surgery. When MPV values at presentation were evaluated in the acromegaly and control groups, it was shown that presence of diabetes mellitus, age and gender had no effect on MPV.
Conclusion
MPV can be considered as a marker for atherothrombotic process and prognosis of acromegalic patients.

A rare case of papillary thyroid cancer: pituitary metastasis

Ozlem Zeynep Akyay, Berrin Cetinarslan, Ilhan Tarkun, Zeynep Canturk, Alev Selek & Adnan Batman
Endocrinology and Metabolism, Kocaeli University, Kocaeli, Turkey.

Introduction
Differentiated thyroid carcinoma (DTC) rarely represents with distant organ metastasis. Cerebral metastasis is seen in 0.4–1.2% of patients with distant organ metastasis. There are only 14 patients of DTC with pituitary metastasis reported in the literature. Here, we report a papillary thyroid carcinoma (PTC) patient represented with pituitary metastasis.
Case
A 68-year-old male patient has admitted to our hospital with a growing tumour on his anterior chest wall. On imaging there was a 5 cm mass on the manubrium sterni. The patient was referred to our clinic as the biopsy of the mass revealed PTC metastasis. During clinical evaluation there was 5 cm hypoecoic, hypervascular nodule on left thyroid lobe. Also, there were high fluorodeoxyglucose (FDG) affinity on pituitary region, thyroid left lobe, sternum, first lumber vertebrae and left humerus on positron emission tomography–computerized tomography (PET–CT) consistent with metastasis. Total thyroidectomy with lymph node dissection was performed and pathology revealed poorly differentiated insular type PTC. The pituitary lesion was also operated but could only be partially resected. The pituitary pathology showed PTC metastasis. The sternal mass could not be operated due to high morbidity and invasiveness. Radiofrequency ablation was performed but the mass was continued grow. After 3 months arterial embolisation was performed to the lesion. As the pituitary lesion was very close to the brain stem structures, radio-iodine treatment was decided to be contraindicated. 36 Gy conventional radiation therapy was given to the pituitary region. During all these treatment procedures sorafenib 2×400 mg/day medical treatment was also initiated. He is still as follow up with stable disease.
Result
The pituitary metastasis of PTC is a rare entity. The management strategy of distant organ metastasis of PTC should include multidisciplinary approach.

Adult inpatients on desmopressin: a patient safety initiative using e-prescribing

Adam Bonfield[1], Winston Crasto[2], Elizabeth Hackett[3] & Helena Gleeson[4]
[1]Department of Emergency Medicine, University Hospitals Leicester, Leicester, Leicestershire, UK; [2]Department of Diabetes and Endocrinology, University Hospitals of Leicester, Leicester, Leicestershire, UK; [3]Pharmacy Department, University Hospitals of Leicester, Leicester, Leicestershire, UK; [4]Department of Endocrinology, University Hospitals Birmingham NHS Foundation Trust, Birmingham, West Midlands, UK.

Background
Errors made with critical medicines such as desmopressin and hydrocortisone used in the treatment of endocrine conditions in hospitalised patients can undermine patient safety but are largely preventable.
Methods
Retrospective audit of adult patients admitted at the University Hospitals of Leicester NHS Trust between January 2013 and June 2014, prescribed desmopressin for cranial diabetes insipidus (CDI) or other medical conditions using electronic prescribing (ePMA). Safety concerns were recorded on a scoring system according to pre-defined parameters including patient confusion, abnormalities of serum sodium levels, evidence of missed or delayed administration of desmopressin and hydrocortisone.
Results
15 patients (seven males) with a median (IQR) age of 56 (17–85) years were identified. 31 hospital admissions were recorded with a median length of stay of 5 days (range 1–30). Among eight patients (17 hospital admissions) with CDI, history of confusion was observed in 12 admissions (70%), six admissions (35%) had abnormal admitting serum sodium levels, and 14 admissions (88%) had 39 missed/delayed doses of desmopressin. Common reasons included, medications unavailable (64.9%), no reason mentioned (15.8%), patient declined (7.0%) and nil orally or wrong timing of medication (12.3%). At least one dose of hydrocortisone was missed in 35.7% admissions. In the non-CDI cohort, seven patients had 14 admissions and in 64% admissions there were 18 missed/delayed doses of desmopressin. At least one safety concern was seen at every hospital admission in the CDI patient group.
Conclusion
Errors in critical medications such as desmopressin in prescribing and administration can affect patient safety and cause clinical harm. Increased pharmacovigilance and robust policies supporting medicines management of desmopressin in clinical areas are of paramount importance and will continue to be needed.

When the improbable happens: a case of acromegaly diagnosed during pregnancy

Carolina Faria, Sílvia Guerra & Mário Mascarenhas
CHLN–Hospital de Santa Maria, Lisboa, Portugal.

Introduction
Pregnancy in a patient with acromegaly is uncommon, as the enlarging pituitary adenoma suppresses gonadotropin secretion rendering the patient amenorrhoeic and infertile. About 40% of the women with pituitary adenomas also have hyperprolactinaemia, which further decreases the likelihood of pregnancy.
Case report
A 32-year-old woman was sent to our centre in the first trimester of pregnancy with the diagnostic of gestational diabetes. Clinical examination revealed acromegalic features. Her blood pressure was normal. A few weeks before getting pregnant, because of a history of headaches and amenorrhoea, she underwent a brain magnetic resonance imaging (MRI) that showed a pituitary macroadenoma, with left cavernous sinus invasion but without compression of the optic chiasma. However, this result became available when she was already pregnant. Hormonal profile revealed elevated GH (80 ng/ml) and IGF1 (1442 ng/ml). Prolactin was also mildly elevated (38 ng/ml). She had no changes in visual acuity, visual fields, or fundus. She was medicated only with insulin for her diabetes, with excellent control. Serial visual field monitoring was performed, which remained normal, and signs and symptoms of acromegaly were stable. She delivered a full-term baby girl by caesarean section, healthy and without any malformations. Three months later, octreotide 20 mg once a month was started, with progressive decrease in GH and IGF1. After 6 months of treatment, a new MRI was performed showing a significant reduction of the tumour. She is now under octreotide 30 mg once a month and about 1 year after the beginning of somastostatin analogue the IGF1 level is 578 ng/ml, GH 3 ng/ml, and prolactin 19.7 ng/ml. Her acromegalic features had regressed.
Conclusion
Pregnancy in women with acromegaly can have a normal course, without obstetrical or foetal complications, and treatment can be postponed to the *postpartum* period.

Pituitary adenoma in the elderly: a 10 years experience

Sandra Pekic Djurdjevic[1,2], Mirjana Doknic[1,2], Dragana Miljic[1,2], Marko Stojanovic[1], Milan Petakov[1,2] & Vera Popovic[1,2]
[1]Neuroendocrine Unit, Clinic for Endocrinology, Diabetes and Diseases of Metabolism, University Clinical Center, Belgrade, Serbia; [2]Medical Faculty, University of Belgrade, Belgrade, Serbia.

Background
Pituitary adenoma (PA) is an under-investigated pathology in the elderly.
Objective
To review our case records of patients >70 years with PA, in order to evaluate presentation symptoms, hormonal results, and pituitary morphology.
Patients
48 patients aged 70 years or older (21 females/27 males) were identified from the group of 610 patients with PA (7.9%) diagnosed at Neuroendocrine Unit, Clinic for Endocrinology, Belgrade, between 2005 and 2014. Median age in our group of elderly was 73 years (range 70–83).
Results
Thirty-six patients had nonfunctioning pituitary adenoma (NFPA), seven patients had acromegaly (ACRO), four patients had prolactinoma (PRL), and one patient had ACTH secreting PA. In majority of patients ($n=44$; 92%) macroadenoma was diagnosed (20–46 mm in diameter). Pituitary microadenoma was diagnosed in four patients (three ACRO and one NFPA). The commonest presenting symptoms were visual deterioration ($n=23$; 48%) and headache ($n=22$). Hyponatremia (due to secondary hypocorticism) was diagnosed in eight patients (17%). In five patients (all with hyponatremia and hypocorticism) loss of consciousness was the leading symptom. Other patients (20%) reported dizziness ($n=5$), loss of memory, confusion, and depression ($n=5$). In four patients (8%), the disease was incidentally discovered during CT or MRI for cerebral ischemic attacks. Endocrinological evaluation showed global anterior hypopituitarism in 18 patients (38%) and partial hypopituitarism in seven patients (15%; four patients had GH and gonadotropin deficiency and three patients had GH, gonadotropin, and TSH deficiency). Twenty-eight patients (58%; 24 NFPA, three ACRO, and one silent PRL) underwent transsphenoidal surgery, with no severe perioperative complications. Immunohistochemistry was performed in 12 patients (seven NFPA were positive for gonadotropins, one NFPA was GH sparsely granulated, and four NFPA patients were null cell PA). Ki-67 antigen expression was indicative of low proliferative activity.
Conclusion
In the last 10 years pituitary adenomas have been recognised more frequently in the elderly. Most were non-functioning pituitary macroadenomas which presented with visual deterioration and hypopituitarism. If hyponatremia is diagnosed in the elderly with PA, then it can be a life-threatening condition.

Effectiveness and tolerability of lanreotide in acromegaly: a German database analysis

Christina Dimopoulou[1], Sylvere Störmann[2], Jochen Schopohl[2], Johanna Faust[1] & Günter Karl Stalla[1]
[1]Department of Endocrinology, Max Planck Institute of Psychiatry, Munich, Germany; [2]Medizinische Klinik und Poliklinik IV, Ludwig-Maximilians University, Munich, Germany.

Introduction
Somatostatin analogues (SSA) present the treatment of choice in patients with previously poorly controlled acromegaly.
Methods
We conducted a retrospective analysis of acromegalic patients enrolled in the Network of Excellence for Neuroendocrine Tumors Munich and treated with the SSA lanreotide.
Results
Fifty-six acromegalic patients (25 females; mean age 59 years; 33 with macroadenoma) switched to lanreotide from previous medical therapies for acromegaly ($n=33$; 19 due to insufficient biochemical control, 14 due to poor treatment tolerability) ($n=11$ switch from dopamine agonists, $n=15$ switch from octreotide, $n=3$ switch from pegvisomant, and $n=4$ switch from combination therapy) or were medically treatment-naïve ($n=23$). Of the 56 patients, 29 patients started on 60 mg, four patients started on 90 mg, and 20 patients started on 120 mg lanreotide; three patients started on combination therapy with dopamine agonists or pegvisomant. Mean follow-up time on lanreotide were 4.6 ± 4.6 years. Lanreotide led to clinical improvement of acromegalic signs and symptoms in 96%. Mean GH concentration decreased from 10.5 ± 25.9 to 3.2 ± 4.9 ng/ml after 3–6 months ($P=0.017$) and to 2.6 ± 3.2 ng/ml ($P<0.001$) at the last evaluation on lanreotide (GH ≤2.5 ng/ml in 44 and GH ≤1.0 ng/ml in 37 patients). Mean IGF1 concentration decreased from 1.6 ± 1.0 to 1.1 ± 0.5 xULN after 3–6 months ($P<0.001$) and to 0.8 ± 0.3 xULN ($P<0.001$) at the last evaluation on lanreotide. Acromegaly was biochemically controlled in 20 and 73% of patients at baseline and at the last evaluation on lanreotide respectively. Additionally, lanreotide had significant favorable impact on patients' glycemic status, leading to significant decrease of fasting plasma glucose after 3-6 months of treatment (157.4 ± 141 mg/dl vs 106.9 ± 20.9 mg/dl; $P<0.001$). Lanreotide was well tolerated with the exception of transient mild gastrointestinal discomfort in 21%.
Conclusion
The SSA lanreotide alone or in combination is safe, effective and well-tolerable in the treatment of previously poorly controlled acromegaly.

The metabolic relevance of angiopoietin-like protein 4 in different states of GH/IGF1 excess or deficiency

Nicoleta Cristina Olarescu[1,2], Anders P Jørgensen[1], Ansgar Heck[1], Kjersti R Normann[1,2], Kristin Godang[1] & Jens Bollerslev[1,2]
[1]Section of Specialized Endocrinology, Department of Endocrinology, Oslo University Hospital, Rikshospitalet, Oslo, Norway; [2]Faculty of Medicine, University of Oslo, Oslo, Norway.

Context
Angiopoietin-like protein 4 (Angptl4) is a protein involved in lipolysis, that is regulated by non-esterified free fatty acids (FFA). GH promotes lipolysis and increases circulating FFA. Hypothesis: GH increases circulating Angptl4 levels by modulating its expression and secretion from fat and muscle. Angptl4 might be of metabolic relevance for the insulin resistance associated with GH/IGF1 excess or deficiency.
Objective
To evaluate Angptl4 in acromegaly (ACRO) and adult onset GHD (aoGHD) before and after treatment. Furthermore, to assess the *in vitro* effects of GH/IGF1 on Angptl4 gene expression and protein secretion in human visceral (VA) and subcutaneous (SC) adipocytes, hepatocytes, endothelial cells (HUVEC), and rat H9C2 muscle cells.
Design and patients
Body composition (DXA), glucose metabolism parameters, FFA and Angptl4 were measured in two study populations: a cohort of patients with ACRO at baseline ($n=94$) and after treatment ($n=58$), and a cohort of patients with aoGHD ($n=39$) before, and after receiving GH substitution (9 months, placebo/controlled).
Results
At baseline Angptl4 was positively associated with serum FFA (ACRO, $r=0.48$, $P<0.001$ and aoGHD, $r=0.47$, $P=0.003$). Angptl4 was correlated with body fat ($r=0.46$, $P=0.027$) in aoGHD, whereas no correlation with body fat or glucose metabolism parameters was found in ACRO. In ACRO Angptl4 decreased (62 (40) ng/ml vs 54 (30) ng/ml, $P<0.001$) and FFA did not change (0.509 ± 0.22 mEq/l vs 0.516 ± 0.23 mEq/l, $P=0.633$) with treatment. The decrease of Angptl4 was associated with the decrease of GH ($r=0.55$, $P=0.005$). In aoGHD Angptl4 (54 (28) ng/ml vs 74 (37) ng/ml, $P<0.001$) and FFA (0.471 ± 0.19 mEq/l vs 0.557 ± 0.22 mEq/l, $P=0.009$) increased significantly during active treatment. The increase of Angptl4 was strongly associated with the increase of FFA ($r=0.70$, $P<0.001$). *In vitro* GH, but not IGF1, increased *Angptl4* gene expression and protein secretion from mature SC and VA adipocytes, effect blocked after the addition of GH receptor antibody. No effect was recorded in human hepatocytes, HUVEC and rat muscle cells.
Conclusion
i) GH increases Angptl4 in patients, an effect most probably mediated by the circulating FFA. ii) Angptl4 does not directly regulate glucose homeostasis associated with GH/IGF1 excess or deficiency. iii) Adipocytes, respond to GH stimulation, and should be considered a source of Angptl4.

Response to pasireotide in an acromegalic patient with resistance to conventional medical treatment

María Sonia Gaztambide Saenz, Pedro González Fernández, Ihintza Larrañaga Unanue & María Dolores Moure Rodríguez
Hospital Universitario Cruces, Bizkaia, Spain.

Introduction
Surgery is the primary therapy in most acromelagic patients. When persistent disease is observed, adjuvant medical therapy is used. Pasireotide is a somatostatin analogue (SSA) not approved for acromegaly therapy yet, but with a potentially better response, given that it binds to four out of five somatostatin receptors.
Materials and methods
We present the case of an acromegalic patient with resistance to many therapies and response to treatment with pasireotide.
Clinical case
A woman diagnosed in 1993, at the age of 24 years, of GH-producing pituitary macroadenoma (3×2×2.5 cm). She underwent surgery twice, with only partial resection, followed by radiotherapy and medical treatment. She was on s.c. octreotide, with partial response. Later on, bromocriptine was added with no improvement in GH/IGF1 levels. MRI showed empty sella at 1996. In 2001 medical therapy was switched to a dose of 30 mg of octreotide LAR/4 weeks plus a maximum tolerated dose of cabergoline (2 mg/week), without normalisation of IGF1 levels. In 2008 pegvisomant (15 mg s.c. daily) was used, achieving normal levels of IGF1, but causing headache and lipohypertrophy. On 3 days/week administration (120 mg/week), elevation in IGF1 level and persisting lipohypertrophy were observed. We requested compassionate-use treatment with pasireotide 40 mg/4 weeks. First dose on June 6th 2012 and increased to 60 on 2013.

	01/06/2012	01/09/2012	29/08/2014
GH (ng/ml)	33.9	8.0	2.3
IGF1 (101–267 ng/ml)	661	709	261

In November 2013 a basal glucose value of 145 mg/dl and HbA1c 6.7% were observed. Metformin and later on vildagliptin were indicated and glucose control was achieved.
Conclusion
Pasireotide has got a clinical improvement and IGF1 control in this patient. Diabetes is under control on dual therapy.

Exogenous administration of GH increases linear growth velocity at higher doses during pre- and early puberty in GH deficient short stature children

Urooj Anwar[1], Amjad Rashid Kiani[1], Sadia Saqib[1], Maleeha Akram[1], Gulbin Shahid[2], Osama Ishtiaq[3], Afzaal Ahmad[1], Mazhar Qayyum[1] & Shakeel Raza Rizvi[1]
[1]Department of Zoology, Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Rawalpindi, Pakistan; [2]The Children's Hospital Pakistan Institute of Medical Sciences (PIMS), Islamabad, Pakistan; [3]Shifa International Hospital, Islamabad, Pakistan.

In GH deficiency (GHD), which is a medical condition caused by problems in the pituitary gland, the body does not produce sufficient amount of GH, resulting in short stature in children. The treatment of GHD short children with exogenous GH increases linear growth velocity (LGV). The present study determined the effect of exogenous GH treatment on LGV, the dose(s) of exogenous GH that effectively impacts LGV and the stage(s) of puberty at which the effect of exogenous GH treatment on LGV is more pronounced. Blood samples, height, weight, and LGV of forty (20 boys and 20 girls) GHD short children were obtained, plasma was separated and plasma concentrations of GH and IGF1 were determined using specific assay systems. Data were analysed using Student's *t*-test and ANOVA. The GHD short children, diagnosed on the basis of low plasma GH, IGF1 and lower responses to stimulation tests, were given varying doses of GH (0.02–1.7 mg/day for 12–42 months) administered intramuscularly at different ages (5–18 years) and stages (pre-, early, mid, and late) of pubertal development. GH replacement therapy caused greater increases in LGV at higher doses at pre- and early puberty in both female and male patients as compared to GH treatment at mid and late puberty. The plasma concentrations of GH and IGF1 increased significantly in all patients as compared to those found prior to GH treatment, which indicates that increases in LGV is secondary to augmentation in IGF1 secretion. In conclusion, the present study demonstrates that patients of GHD grow at a greater rate at higher doses of GH. The current investigation also shows that GH therapy caused higher increases in LGV at pre- and early puberty in both girls and boys through its effects on IGF1.

Evolution of metabolic and psychiatric disorders after remission of Cushing's disease

Eva Lau[1,4], Joana Oliveira[1,4], Sandra Belo[1,4], Paula Freitas[1,4], AnaIsabel Oliveira[1,4], Eduardo Vinha[1], Lígia Castro[3], Josué Pereira[2] & Davide Carvaho[1,4]
[1]Endocrinology, Diabetes and Metabolism Department, Centro Hospitalar São João, EPE, Porto, Portugal; [2]Neurosurgery Department, Centro Hospitalar São João, EPE, Porto, Portugal; [3]Pathological Anatomy Department, Centro Hospitalar São João, EPE, Porto, Portugal; [4]Faculty of Medicine of University of Porto, Porto, Portugal.

Introduction
Cushing's disease (CD) is a rare endocrine disorder characterized by endogenous hypercortisolism, which is associated with metabolic and psychiatric disorders. It is essential to understand the impact of normalization of serum cortisol in the evolution of these comorbidities.
Aims
To evaluate the evolution of metabolic and psychiatric disorders after biochemical control of hypercortisolism in patients with CD.
Methods
Retrospective observational study of patients with CD who underwent pituitary surgery between January 1998 and October 2013. Clinical data were evaluated at diagnosis and at the last evaluation of hospital consultation. Remission was defined as normal urinary free cortisol and normal plasma cortisol after overnight or low-dose dexamethasone suppression test.
Results
Forty-five patients were included: 87% ($n=39$) females, mean age 38.2 (12.9) years and mean follow-up period 90.4 (56.7) months. After pituitary surgery, remission of CD was observed in 73.3% ($n=33$). Recurrence of CD was detected in 30.3% ($n=10$) of those patients after a mean of 64.4 (36.0) months after the first intervention. At diagnosis, 65.8% were hypertensive, 31.7% diabetic, 41.5% had dyslipidemia, and 46.3% psychiatric disorders. Of the 41 patients in remission at the last evaluation: 29.1% were under the same number of antihypertensive drugs, 20.8% discontinued them, 20.8% reduced their number, 16.7% remained without medication, and 12.5% increased; remission of diabetes occurred in 15.3% of patients and 80% of those who initially were on insulin suspended it; the anti-dyslipidaemic therapy was discontinued in 11.8% and psychotropic drugs were suspended in 55.5%. The mean initial BMI was 32 kg/m^2 and no significant differences regarding BMI were found after biochemical control of hypercortisolism. However, 46% of patients had a reduction in BMI class.
Conclusion
Biochemical control of hypercortisolism seems to improve the associated metabolic and psychiatric disorders in CD. However, as it is not possible to predict the evolution of these comorbidities it is mandatory an appropriate follow-up, evaluation and treatment of these patients.

Sex-related differences in clinical presentation and outcomes of Cushing's disease: a study from a referral centre

Eva Lau[1,4], Joana Oliveira[1,4], Sandra Belo[1,4], Paula Freitas[1,4], Ana Isabel Oliveira[1,4], Eduardo Vinha[1], Lígia Castro[2], Josué Pereira[3] & Davide Carvalho[1,4]
[1]Endocrinology, Diabetes and Metabolism Department, Centro Hospitalar São João, EPE, Porto, Portugal; [2]Pathological Anatomy Department, Centro Hospitalar São João, EPE, Porto, Portugal; [3]Neurosurgery Department, Centro Hospitalar São João, EPE, Porto, Portugal; [4]Faculty of Medicine, University of Porto, Porto, Portugal.

Introduction
Cushing's disease (CD) presents a marked female preponderance, with a female-to-male ratio of 3–8:1, but whether this skewed gender distribution has any relevance to the presentation and outcomes of CD is not well understood.
Aim
To evaluate sex-related differences in the presentation of CD, as regards: biochemical indices of hypercortisolism; complications of disease and outcomes.
Methods
Observational, retrospective study of patients with CD confirmed on pituitary surgery between January 1998 and October 2013.
Results
We included 45 patients, of whom 39 (87%) were women. The mean age at diagnosis was 38.2 (12.9) years and the mean follow-up period was 90.4 (56.7) months. Diabetes was more prevalent in males (50% vs 26.3%), as well as hypertension (83% vs 61%) and dyslipidaemia (66.7% vs 40.5%). The psychiatric disorders were more frequent in females (56.8% vs 16.7%). Most women (56.8%) presented a microadenoma on MRI; 33% of men had a microadenoma and 50% a macroadenoma. CD remission was found in 74.4% of women who underwent pituitary surgery; in men remission occurred in 66.7%. At diagnosis, there were no significant differences in serum cortisol levels, urinary free cortisol, midnight cortisol or cortisol levels after overnight dexamethasone suppression test. Male patients had higher basal levels of ACTH (106.5 (46.0) pg/ml vs 70.5 (38.7) pg/ml, $P=0.048$) and serum cortisol after 2-day dexamethasone suppression test (40.5 (51.7) μg/dl vs 13.3 (11.0) μg/dl, $P=0.015$). No differences were found in serum cortisol or urinary free cortisol suppression after high-dose suppression test, by sex.
Conclusion
Biochemical indices of hypercortisolism, metabolic and psychiatric disorders, as long as outcomes of CD differed by sex. Understanding this dimorphic pattern may be relevant in order to define the adequate diagnostic work-up and follow-up of these patients.

Association of hormonal changes with disease severity and mortality rate in critically ill patients

Neslihan Cuhaci[1], Berna Ogmen[2], Cihan Doger[3], Burcak Polat[2], Seval Izdes[4], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Ataturk Education and Research Hospital, Ankara, Turkey; [3]Department of Intensive Care Unit, Ataturk Education and Research Hospital, Ankara, Turkey; [4]Department of Intensive Care Unit, Faculty of Medicine, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey.

Introduction
Endocrinological and metabolic changes can occur in critically ill patients, which may affect the prognosis and outcome. The hypothalamic–anterior–pituitary axis (HPA) plays a crucial role in the endocrine regulation of metabolic and immunological homeostasis. In this prospective study, we evaluated the pituitary–adrenal–gonadal–thyroid axis in the adult Intensive Care Unit (ICU) patients,their outcome, the association between these hormonal changes and 'The Acute Physiology and Chronic Health Evaluation II score (APACHE II)', Sequential Organ Failure Assessment (SOFA), length of hospitalisation and mortality.
Methods
Patients hospitalised in adult ICU (not for trauma or operation) between January 2014 and January 2015 were enrolled in this study. Severity of illness was assessed by APACHE II and SOFA on admission to the ICU and 15 days later. Blood samples were collected within the first 4 h of ICU admission and 15 days later for measurement of anterior pituitary and end organ hormones.
Results
Total patient number was 157. Eighty-five patients were in survival (S), 72 patients were in the non-survival (NS) group. In the NS group, patients' mean age, APACHE II and SOFA scores at the admission were significantly higher. In the NS group median GH, E_2, and cortisol levels were significantly higher whereas median FSH, LH, fT_3, and fT_4 were lower. Fifteen days after admission, there was significant increase in median IGF1 and ACTH levels and decrease in median cortisol and SOFA scores compared to baseline values. Strongest predictors for mortality were found to be hospitalization length, SOFA score, deltaTSH, and age. None of the other endocrine parameters had an effect on mortality.
Conclusion
In critical illness, activation of the HPA and the cortisol response are essential for survival. Combinations of endocrine parameters may provide better indices than measurement of a single hormone or an APACHE II-based score.

Indirect immunofluorescence for detection of pituitary antibodies

Nuno Vicente[1], Monica Taylor[2], Luísa Barros[1], Leonor Gomes[1], Dírcea Rodrigues[1], Sandra Paiva[1], Isabel Paiva[1], Daniela Guelho[1], Luís Cardoso[1], Diana Martins[1], Diana Oliveira[1], Patrizio Caturegli[2] & Francisco Carrilho[1]
[1]Serviço de Endocrinologia, Diabetes e Metabolismo, Centro Hospitalar Universitário Coimbra, EPE, Coimbra, Portugal; [2]Department of Pathology, School of Medicine, The John Hopkins University, Baltimore, Maryland, USA.

Introduction
Definitive diagnosis of lymphocytic hypophisitis (LH) lacks a pathological analysis. The detection of pituitary antibodies (PAB) with the current methods presents variable results and its clinical utility is therefore limited. Recently, new methods were released for the interpretation of indirect immunofluorescence (IIF), which can increase the specificity for detection of PAB.
Methods
We evaluated four patients followed in endocrinology consultation with clinical suspicion of LH (patient 1: 49 years old female with pan-hypopituitarism beginning 40 days after delivery and an empty sella on MRI; patient 2: 20 years old male with isolated ACTH deficiency and gynecomastia; patient 3: 59 years old female with previous complaints of severe headache and dyplopia starting at 42 years, MRI showing pituitary enlargement with diffuse enhancement after contrast and pan-hypopituitarism ever since; patient 4: 39 years old male with hypogonadotrophic hypogonadism and autoimmune thyroiditis) and one patient with definitive diagnosis of LH; and patient 5: 27 years old female, with severe headaches beginning 1 week before delivery, MRI compatible with a pituitary macroadenoma with diffuse enhancement after contrast. Detection of PAB by IIF was carried out in a specialised centre. The presence of PAB was considered positive whenever a granular of diffuse cytosolic pattern were present, after using purified IgG and Fc blockade, if necessary.
Results
We obtained positive results in 40% of samples (two out of five). Patient 1: negative; patient 2: mild perinuclear positivity (1+); patient 3: negative; patient 4: cytosolic positivity, granular pattern; and patient 5: cytosolic positivity, diffuse pattern.
Discussion and conclusions
The patient with histological diagnosis of LH exhibits a diffuse cytosolic pattern, as usually happens in pituitary disease of autoimmune etiology. The granular cytosolic pattern of patient 4, which is strongly suggestive of autoimmunity, might establish diagnosis of LH. Detection of PAB by IFI, according to the immunostaining patterns, can help in the classification and management of these patients.

Clinical characterisation of acromegaloidism in a controlled prospective study

Pablo F Catalina[1,3], Wilfredo Guanipa[1,3], Concepción Páramo[2], Enrique Suárez González[3], Lucas González Matías[3], Elías Álvarez[2] & Federico Mallo[3]
[1]Department of Endocrinology, Pontevedra University Hospital, Pontevedra, Spain; [2]Department of Endocrinology, Vigo University Hospital, Vigo, Spain; [3]Centre for Biomedical Research (CINBIO), University of Vigo, Vigo, Spain.

Acromegaloidisms are usually reported as isolated cases that are not well characterised clinically. Indeed, most such cases were reported several decades ago, part of the reason why our knowledge about this entity is scarce. By contrast, clinical situations suggestive of acromegaly are not so infrequent, in which basal GH and IGF1 levels lie within a normal range, the GH responses to OGTT

challenge are conserved and there is no radiological (MRI) evidence of hypothalamic-pituitary masses. These unclassified patients are considered as individuals with acromegaloidism. We made a systematic study of a cohort of 15 such individuals, comparing them to cases of acromegaly and to healthy controls in a prospective follow-up protocol. The subjects in each group were matched by gender, age and BMI, and they were all submitted to current diagnostic tests for acromegaly, including conventional blood and biochemical tests, oral glucose overload and MRI exploration. In addition, the subjects were evaluated using a previously validated clinical activity scale (ACA index), and they were submitted to ultrasonography (USG) exploration of the carpal tunnel, non-dominant knee cartilage and the thyroid gland. The subjects with acromegaloidism obtained similar ACA scores to acromegaly patients and USG explorations revealed similar alterations to those in acromegaly subjects. Although spontaneously remitting acromegaly is thought to be an unlikely cause of acromegaloidism, periodic follow-up of these subjects is recommended and we provide here a systematic protocol to characterise such acromegaloidism.

Can use of the European diagnostic pathway improve diagnosis and management of hyponatraemia in a District General Hospital? An audit cycle

Alex Asher, Mazin Sirelkhatim, Stephen Wong & Aye Nyunt
Glan Clwyd Hospital, Rhyl, UK.

Introduction
Despite the commonality of hyponatraemia in everyday clinical medicine it is often a poorly management condition in acute medical patients. A European guideline for diagnosis and management was published in 2014 to address such problems.
Aims
To assess the standard of management of patients with hyponatraemia admitted to the medical departments in a rural District General Hospital. To improve investigation, diagnosis, and management of these patients where necessary.
Methods
A review of medical notes and biochemical tests was carried out for 69 patients admitted to the medical assessment unit with serum sodium below 130 mmol/l over a 3-month period. Adoption of the European guideline diagnostic pathway, creation of an investigation set' and educating junior doctors and nurses were used as tools to improve management. Emphasis was placed on use of urine osmolality and sodium as a first line investigation in the diagnostic process. Subsequent re-review of management after change was carried out for 79 patients over a similar timeframe.
Results
Before change: only 13% of euvolaemic patients had a urine osmolality and sodium performed, only 25% of patients had causative medications stopped and only 45% of all patients had a cause established. After change: 51% of euvolaemic patients had a urine osmolality and sodium performed, 66% of causative medications stopped, and 73% of all patients had a cause established. In patients who had a urine osmolality and sodium performed a 90% diagnostic pick-up rate was found, compared to just 63% in those who didn't.
Conclusions
Investigation and management is often neglected in acute medical patients. Using guidelines, education and support tools for doctors and nurses improvements can be made in both investigation and management of these patients. Our findings support European guidance on use of urine osmolality and sodium early in the diagnostic process.

Congenital pituitary stalk interruption syndrome with isolated GH and TSH deficiency and Rathke's cleft cyst: an incidental association

Ana Wessling, Raquel Paixão, José Maria Aragüés & Mário Mascarenhas
Endocrinology Department, Santa Maria University Hospital, Lisbon, Portugal.

Introduction
Congenital pituitary stalk interruption syndrome (PSIS) is a rare condition, characterized by the triad (not always complete): absence/hypoplasia of the pituitary stalk, hypoplasia/aplasia of the anterior pituitary and absence or ectopy of the posterior pituitary high signal intensity, on magnetic resonance imaging (MRI). PSIS implies a permanent GH deficiency, in 77% associated with other pituitary hormones deficiencies. The aetiology remains uncertain, but some genes have been implied. Rathke's cleft cysts (RCC) present typically as intrasellar and/or suprasellar benign lesions, the most common incidentally discovered sellar lesions (few mm to 2 cm diameter), with a female:male ratio of 1:3.
Clinical case
A 18-year-old boy was referred from the Pediatric Endocrinology Department, with GH deficiency and central hypothyroidism (CH) diagnosed at the age of 9. Recombinant GH therapy had already been suspended (after 9 years; target height 170 cm achieved) and he was only on levothyroxine. MRI at 8 years of age had revealed a small pituitary gland, absence of the high signal intensity in the posterior pituitary, pituitary stalk atrophy, and a small pineal cyst. Reevaluation showed no other pituitary hormone deficiencies. There were no symptoms of diabetes insipidus. Follow up MRI (23 years old) showed a 7 mm sellar and suprasellar cystic lesion, suggestive of RCC, causing pituitary compression, pituitary stalk hypoplasia, and absence of posterior pituitary bright spot in T1. Until now, 1 year later, his clinical condition remains stable.
Conclusions
In this clinical case, a patient with PSIS had a RCC incidentally diagnosed in a follow up MRI. Paediatric cases have been reported but rarely, as RCCs grow slowly, becoming clinically evident later in life. Symptoms are uncommon and associated with mass effects. As there is compression of the pituitary gland, closed follow-up must be kept. Genetic tests results are pending.

High diversity of Cushing's disease in patients with corticotrophic macroadenoma

Maria Kurowska, Joanna Malicka & Jerzy S Tarach
Department of Endocrinology, Medical University, Lublin, Poland.

Introduction
In 7–20% of cases, Cushing's disease is due to ACTH-producing macroadenoma. Aim of the study was to present our observations concerning etiologic, clinical, and therapeutic diversity of Cushing's disease in patients with macrocortico-tropinomas.
Material and methods
Retrospective analysis of medical records of nine patients (5F; 4M) hospitalized in 2002–2015.
Results
Four of the patients (2F; 2M) were diagnosed before they were 40 years old (mean age 28.5) and five (3F; 2M), >40 (mean age 50). In 3F tumour was initially discovered as microadenoma. A woman (23) first underwent bilateral adrenalectomy because of inability to neurosurgery and 5 years later Nelson's syndrome developed. In two consecutive females (49 and 52) at the moment of diagnosis MRI revealed microadenomas 9×7 and 5×4 mm respectively. In the first female 2 years after initial neurosurgery consecutive four transsphenoidal reoperations, stereotactic radiotherapy, and bilateral adrenalectomy were conducted. Then she developed Nelson's syndrome. Propter a consecutive rapid tumour's invasion, themozolomide and bevacuzimab were introduced. She died 7 years after the diagnosis. In the second patient tumour regrowth was observed 6 years after the first neurosurgery and because of failure of second adrenalectomy and mild hypercortisolism she was qualified to pasireotyd therapy. In six patients (2F; 4M) the pituitary tumours were initially diagnosed as macroadenomas. One patient with 5 cm tumour and overt hypercortisolism died after craniotomy. Another patient presented cyclic Cushing's syndrome with pituitary macroadenoma discovered after 7 years' observation. In the next patient unique cause of Cushing's disease was Crooke's macroadenoma, refractory to two neurosurgeries with good response to themozolomide. In two cases (1F; 1M) macrocorticotropinomas were discovered as incidentalomas and operated as clinically inactive (silent) tumours. In these patients the tumour recurred 5 years after the first neurosurgery and visible hypercortisolism developed.
Conclusion
Macrocorticotropinomas are very heterogenic group of pituitary tumours with high aetiologic, clinical and therapeutic diversity.

Changes of prolactinomas during pregnancy and lactation

Larisa Dzeranova[1], Julia Gallinger[2], Ekaterina Pigarova[1], Svetlana Vorotnikova[1], Natalia Bykanova[1], Liudmila Rozhinskaya[1] & OGGO Consortium[3]
[1]Endocrinology Research Centre, Moscow, Russia; [2]Lomonosov Moscow State University, Moscow, Russia; [3]Head Endocrinologists, Federal Districts, Russia.

Aim
To assess the size changers of prolactinomas after pregnancy and lactation.
Material and methods
We have analyzed the Russian register of tumors of the hypothalamic–pituitary region and conducted additional surveys of patients with prolactinomas who had pregnancy. We obtained data from 33 patients with prolactinomas who had 45 pregnancies and MRI studies prior and during/after pregnancy and lactation. Five patients had macroadenomas and 40 microadenomas.
Results
In 55.6% (25/45) of prolactinomas did not change after the pregnancy (including in three patients with macroadenomas). In 20% (9/45) they increased in size, including two macroadenomas. Growth of pituitary adenomas in two cases was accompanied by clinical symptomatology (visual field loss and complete loss of vision in one eye). 22.2% (10/45) of patients experience the decreased in size of prolactinomas, which was observed only with microadenomas, and in three cases complete involution was noted. Information on lactation period and MRI evaluation was available for 34 pregnancies in patients with prolactinomas. According to the recommendations of doctors lactation was stopped immediately after birth with the help of dopamine agonists in 23.5% (8/34) of cases. In 87.5% (7/8) of these patients MRI did not show any changes from baseline and in one patient (12.5%) microadenoma had increased in size to macroadenoma without clinical significance. 26/34 patients nursed their children on average of 12 ($\pm$8) months and often stopped lactation due to doctor's recommendations with the help of dopamine agonists. In these patients according to MRI no changes were found in the pituitary adenoma size in 50.0% (13/26) cases, adenoma decreased in 26.9% (7/26), and increased in 23.1% (6/26). The patients with the increased size of prolactinoma during lactation had the shortest duration of lactation – 5 ($\pm$2) months.
Conclusion
While the majority of pregnancies and lactation in patients with prolactinomas is not associated with adverse complications from the adenoma site, there is still a substantial risk in one in five women to experience tumor growth, though mostly subclinical, which raises the need of better prediction of such unfavorable outcomes.

Pituicytoma: a rare tumour

Diana Oliveira[1], Leonor Gomes[1], Dírcea Rodrigues[1], Francisco Belo[2], Olinda Rebelo[3], Sandra Paiva[1], Carolina Moreno[1], Daniela Guelho[1], Ana Margarida Balsa[4], Nuno Vicente[1], Luís Cardoso[1], Diana Martins[1] & Francisco Carrilho[1]
[1]Endocrinology, Diabetes and Metabolism Department, Coimbra Hospital and University Centre, Coimbra, Portugal; [2]Neurosurgery Department, Coimbra Hospital and University Centre, Coimbra, Portugal; [3]Neuropathology Laboratory, Neurology Department, Coimbra Hospital and University Centre, Coimbra, Portugal; [4]Endocrinology, Diabetes and Nutrition Department, Baixo Vouga Hospital Centre, Aveiro, Portugal.

Introduction
Pituicytoma is a low-grade glioma of the suprasellar and sellar regions that is rarely described (about 60 cases in the literature). The clinical, laboratory, and neuroradiological findings are not pathognomonic, and therefore definitive diagnosis is only possible after surgery and histopathological study. Total resection is the treatment of choice, since subtotal removal can often lead to recurrence or progression.
Case report
We report the case of a Caucasian male with no significant medical history who develops isolated frontal headache at the age of 48. Magnetic resonance imaging (MRI) revealed an expansive sellar and suprasellar lesion, with 14 mm, well-defined limits, bright homogeneous enhancement with gadolinium, associated with a slight deviation of the optic chiasm. Hormonal study was normal. The patient continued to be followed in Neurosurgery consultation and after 4 years presented complaints of gradually worsening visual disturbances, progressively decreased libido and erectile dysfunction. On visual field testing, a bitemporal hemianopia was noted. MRI revealed millimetrical increase of the tumour. He underwent transnasal/transsphenoidal surgery, which resulted in a partial removal due to difficulty in controlling bleeding. The histopathological examination showed a tumor composed of bipolar cells, with immunohistochemical positivity for vimentin and S100 protein, Ki-67 $<2\%$ – pituicytoma. The postoperative hormone study revealed panhypopituitarism. The control MRI detected significant residual tumour, so it was decided to propose the patient for radiosurgery treatment.
Conclusions
This pituicytoma case illustrates a diagnosis that, although rare, should not be excluded from the possibilities available before a suprasellar or sellar lesion that presents with certain cardinal radiological features. The persistence of significant residual tumour was due to the bleeding tendency of the lesion during surgery. Awareness of the possibitlity of pituicytoma before surgery would be ideal for appropriate treatment planning, with possible preoperative embolisation of the tumour.

The impact of surgical management of Cushing's disease in pregnancy on foetal outcomes

Philip C Johnston[1], Mahmoud Abbassy[2], Amir Hamrahian[1], Laurence Kennedy[1] & Pablo Recinos[2]
[1]Department of Endocrinology, Diabetes, and Metabolism, Cleveland Clinic, Cleveland Ohio, USA; [2]Neurological Institute, Rose Ella Burkhardt Brain Tumor and Neuro-Oncology Center, Cleveland Clinic, Cleveland, Ohio, USA.

Background
Cushing's disease is a condition rarely encountered during pregnancy. It is known that hypercortisolism is associated with increased maternal and foetal morbidity and mortality.
Aims and methods
A comprehensive search of the literature was performed for cases of Cushing's disease in pregnancy including our own case. Analysis was performed of all pregnant patients with Cushing's disease who were treated with surgery compared to a surrogate control group of pregnant patients with untreated Cushing's syndrome. Foetal outcomes were compared including preterm labour, intrauterine growth retardation, intrauterine foetal death, and neonatal death. Cases of Cushing's disease who were not in remission or with missing post-operative data were mentioned but excluded from our statistical analysis.
Results
There were 11 previously reported cases of Cushing's disease surgically managed between the 10th and 23rd weeks of pregnancy. Of those, three cases were excluded due to lack of post-operative biochemical results or follow-up information and one case was excluded due to lack of biochemical remission. Foetal complications occurred as follows: preterm labour 29% (2/7), intrauterine growth retardation 29% (2/7), neonatal death 14% (1/7), and intrauterine foetal death 0% (0/7). Of these, there was a significant reduction ($P=0.04$) in preterm labour when compared to the preterm labour rates occurring in untreated Cushing's syndrome. Other foetal complications were not statistically different. Out of the 11 case reports, maternal and surgical complications included pre-eclampsia ($n=4$), syndrome of inappropriate antidiuretic hormone ($n=2$), diabetes insipidus ($n=1$), cerebrospinal fluid leak ($n=1$). Three patients did not have any maternal or surgical complications.
Conclusions
Transsphenoidal surgery for Cushing's disease can be performed safely during the second trimester of pregnancy. The rate of preterm labour is significantly lowered when Cushing's disease is surgically treated and biochemical remission is achieved during pregnancy.

Neutrophil/lymphocytes ratio in patients who have hypogonadotropic hypogodanism

Havva Keskin[1], Yasemin Kaya[4], Kenan Cadirci[2], Hakan Gozcu[2], Elif Ziypak[2], Senay Arikan[3] & Ayse Carlioglu[2]
[1]Medeniyet University, Istanbul, Turkey; [2]Erzurum Training and Research Hospital, Erzurum, Turkey; [3]Kirikkale University, Kirikkale, Turkey; [4]Ordu University, Ordu, Turkey.

Introduction
The effects of sex steroids on lymphocytes count and functions are well known and it is propounded that autoimmune diseases more common in women. NLO index is an indicator of inflammative situation. In this study, it has been aimed that neutrophil/lymphocytes ratio (NLO) calculation by determining neutrophil/lymphocytes values in patients who diagnosed as hypogonadotropic hypogodanism and searching that whether there is significant difference between healthy group or not.
Method
33 patients who have been diagnosed as hypogonadotropic hypogodanism, 56 people who have no statistically significant difference in point of age, BMI among them and they are completely healthy people as a control group, totally 89 people have been incorporated to the study. It has been calculated that patient group's age average is 22.4 ± 7.4 and control group's age average is 23.1 ± 6.4. Statistically significant difference couldn't be determined among them ($P=0.6$). Patients' neutrophile and lymphocytes values have been evaluated by studying. Patients' C-reactive protein(CRP) and testosterone levels have been registered again by studying.
Results
In the study results; patient group NLO has been founded as 1.8 ± 1.3 and healthy group NLO has been founded as 1.4 ± 0.3 and statistically significant difference has been determined among them ($P=0.03$). Statistically significant difference has been respectively determined between patient group and healthy group in point of white blood cell count (7.9 ± 3.1 and 6.7 ± 1.1, *P*.0.04), neutrophil (4.6 ± 2.7 ve 3.7 ± 0.7, $P=0.03$), lymphocytes (2.4 ± 0.6 and 2.7 ± 0.7, $P=0.04$) and CRP(2.0 ± 1.3 and 0.9 ± 1.0, $P=0.01$).In the group which has hypogonadotropic hypogodanism; while positive correlation is being determined between NLO ($r=0.228$, $P=0.03$), white blood cell ($r=0.564$, $P<0.001$) and neutrophil ($r=0.847$, $P<0.0001$), negative correlation has been determined between testosterone and lymphocytes count ($r=-0395$, $P=0.001$).
Discussion
We can say that sex steroids can be effective on lymphocytes and neutrophil count depending on the results from this study. Whether to return to normal of sex steroids replacement with these functions must be demonstrated by more detailed studies.

Childhood onset GH deficiency: re-evaluation at the point of transition to adult care

Mariana Grace[1], Stephen O'Riordan[2], Rose Morissey[2], Mary Stapeton[3] & Susan O'Connell[2]
[1]Department of Paediatric and Child Health, University College Cork, Cork, Ireland; [2]Paediartric Endocrinology Unit, Cork University Hospital, Cork, Ireland; [3]Department of Biochemistry, Cork University Hospital, Cork, Ireland.

Childhood onset GH deficiency (CO-GHD) usually presents with aberrant growth. Treatment is recombinant GH (r-GH) to attain target height. The 2005 European Consensus statement on management of CO-CHD at transition indicates that most adolescents will require repeat GH testing at completion of linear growth. Patients with persistent GHD will require continuation of r-GH for wellbeing, optimal body composition and metabolism. However, there is little data supporting predictors of persistent GHD, which include underlying diagnosis (structural pituitary defects or idiopathic, multiple or isolated pituitary hormonal deficiencies) and serum IGFPB3, IGF1 levels on completion of linear growth.
Objectives
To (1.) classify patients according to European Society of Paediatric Endocrinology Classification of Paediatric Endocrine Diagnoses (Cohort 1) (2.) evaluate patients aged >14 years in this cohort (Cohort 2).
Methodology
A retrospective review of all patients receiving GH treatment ($n=65$) attending a regional tertiary Paediatric Endocrinology centre over an 18 month period, and prospective re-testing of those fulfilling the criteria.
Results
Cohort 1: 47% had primary and 52% secondary growth failure. Cohort 2: 24 patients aged >14 years (75% males), 29% with primary growth failure. 71%had secondary growth failure, of whom 35% had idiopathic GHD (iGHD) (normal pituitary structure), 64% had structural pituitary abnormalities (congenital/acquired). Four patients fulfilled criteria for retesting, all with normal IGF-1 after one month off GH; two had normal GH levels (iGHD) and two had persistent GHD (1 craniopharyngioma and one suspected genetic aetiology due to family history of CO-GHD).
Conclusion
This is the first study of CO-GHD in an Irish cohort. The results are consistent with international literature. In addition, family history of CO-GHD may be a predictor for persistent GHD. We anticipate that >60% of our cohort will have persistent GHD at the time of transition warranting continuation of GH.

Some clinical characteristics and cardiovascular risk of our patients with hypopituitarism during long-time follow-up

Milica Medic-Stojanoska[1,3], Andrijana Milankov[1,3], Bojan Vukovic[2,3], Tijana Icin[1,3], Ivana Bajkin[1,3], Jovanka Novakovic-Paro[1,3], Ivanka Percic[2,3] & Branka Kovacev-Zavisic[1,3]
[1]Clinical Center of Vojvodina, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Novi Sad, Serbia; [2]Clinical Center of Vojvodina, Emergency Center, Novi Sad, Serbia; [3]Medical Faculty of Novi Sad, University of Novi Sad, Novi Sad, Serbia.

Several studies have pointed to increased morbidity and mortality in patients with hypopituitarism, particularly from cardiovascular diseases, regardless of the application of the substitution therapy. The aim of this study was to present clinical characteristics and cardiovascular risk of our patients with hypopituitarism during 20 years of follow-up.
Methods
Sixty patients with hypopituitarism without patients with acromegaly and Cushing disease were analysed retrospectively/prospectively. The investigated group consisted of 32 men and 28 women, of the average age of 52.18 ± 17.51.
Results
Mean BMI values were 27.78 ± 6.53 kg/m^2. The average age of the examinees at the time of diagnosis was 40.20 ± 18.69. The most common causes of hypopituitarism were pituitary macroadenomas (53.33%) and craniopharyngeoma (21.66%). Partial hypopituitarism with lesion of two and more functions was present in 64.41%, panhypopituitarism in 28.81%, and 6.78% had an isolated deficiency of one adenopituitary hormone. Patients were treated with substitution therapy L-thyroxine, hydrocortisone, growth hormone, sexual steroids, while diabetes insipidus was treated with desmopressin. 6.66% of subjects treated with dietary nutrition regime had diabetes mellitus type 2. The therapy of hypopituitarism was followed by insignificant reduction in systolic and diastolic blood pressure. Elevated values of total cholesterol over the course of therapy significantly decreased ($P\leq0.009$) as well as values of LDL cholesterol ($P\leq0.005$). The values of HDL cholesterol and triglycerides were not significantly changed during treatment. Cardiovascular incidents were recorded in only 11.66% of the subjects, and a lethal outcome in one patient due to sepsis.
Conclusion
The results indicate that the middle aged people are most prone to the risk developing hypopituitarism, mostly due to a tumor in the sellar region and its treatment. Cardiovascular risk factors are present in untreated hypopituitarism. Despite substitution therapy, the ofteness of cardiovascular incidents is present.

Long-term recurrence in nonfunctional pituitary adenomas after surgery

Maria Galiana Rodriguez Caballero, Nuria Valdés Gallego, Jessica Ares Blanco, Cecilia Sánchez Ragnarsson, Laura Cacho, Joaquín Pertierra de la Uz, Antonio Rabal Artal, Lorena Suárez Gutierrez, Elias Delgado, Pablo Martinez Camblor, Ceferino Faedo & Edelmiro Menéndez Torre
Hospital Universitario Central de Asturias, Oviedo, Spain.

Object
Nonfunctioning pituitary adenomas can experiment recurrence and/or progression (R/P) several years after surgery in about 15–50% of patients. There is few evidence about risk factors that could predict R/P. The aim of this study is to identify them and describe our experience through a long term of follow-up in pituitary macroadenomas.
Methods
Retrospective cohort analysis of 64 patients who underwent surgery between 1990 and 2013. The main outcome was to evaluate prevalence of R/P during the follow-up, based on imaging criteria and identify some risk factors for R/P.

Results
Over a median follow-up of 10.12 years, there was 46% of R/P after surgery at a median time of 4.6 years, the cumulative risk of being free of R/P was 62% by 5 years and decrease to 45% by 15 years after surgery. Multivariate cox proportional hazard regression analysis identified the following risk factors as associated with increased risk of recurrence: radiotherapy after surgery (hazard ratio 2.90, 95% CI 1.15–7.46, $P=0.023$) and the tumour size at diagnosis (hazard ratio 1.05 CI 1.009–1.10, $P=0.019$).
Conclusions
Patients with NFPA need long-term follow-up because they have a high risk of R/P over time. Radiotherapy after surgery decreases the risk of recurrence or progression specially after five years. The tumour size at diagnosis is an independently risk of R/P.

DOI: 10.1530/endoabs.37.EP783

Recurrence of GH-secreting pituitary adenomas during puberty in children with germline AIP mutations: a clinical challenge

Silvia Filipponi[1], Vincenzo Esposito[1], Adrian F Daly[2], Albert Beckers[2] & Marie-Lise Jaffrain-Rea[1,3]
[1]Neuromed, IRCCS, Pozzilli, Italy; [2]Endocrinology, CHU of Liège, University of Liège, Liège, Belgium; [3]Dept of Biotechnological and Applied Clinical Sciences, University of L'Aquila, L'Aquila, Italy.

Germline AIP mutations (AIP^{mut}) predispose to young onset somatotroph pituitary adenomas (GHPA) and gigantism. AIP^{mut} GHPA are often aggressive and resistant to pharmacological treatment, which may be especially challenging in the paediatric setting. We report our experience with two young Italian AIP^{mut} male patients with incipient gigantism due to childhood pituitary macroadenomas, who both experienced recurrent GH/IGF1 hypersecretion followed by tumour regrowth during puberty.
Case 1
Patient A developed incipient gigantism due to a familial R304X AIP^{mut}. He was successfully operated on at the age of 9 years. for an intrasellar macroadenoma (12 mm). Two years later, spontaneous puberty occurred and IGF1 increased progressively. Final diagnosis of disease recurrence was made at the age of 14.5 years and pharmacological treatment with cabergoline (CAB) and somatostatin analogues (SSA) was started with a partial response.
Case 2
Patient B complained of visual defects at the age of 11.5 years. in a sporadic setting of accelerated growth. MRI showed a pituitary macroadenoma with suprasellar extension (27 mm), which was successfully operated on. Plasma GH/IGF1/PRL and growth velocity normalized. A germline A277P AIP^{mut} was found. Soon afterwards spontaneous puberty occurred and IGF1 increased progressively. Two years later he was started on CAB due to modest biochemical/clinical worsening and initial tumour regrowth. Thereafter, an increasingly aggressive tumour recurrence developed, requiring multiple treatment modalities with SSA, CAB and/or pegvisomant. He was re-operated at the ages of 14 and 18 years. and then underwent radiotherapy. Medical therapy was progressively withdrawn, with no need for hormone replacement therapy currently.
Comments
Both patients completed puberty, with heights stabilising at 191 and 190 cm, respectively. Early diagnosis of disease recurrence is of special importance in patients with incipient gigantism, but this may be very challenging during puberty in the absence of radiological evidence of tumour regrowth.

Interpretation of dynamic test results in secondary hypocortisolism post pituitary surgery and hydrocortisone replacement doses

Aikaterini Theodoraki[1], Christopher McAlpine[1], Anne Dawnay[1], Neil Dorward[2], Michael Powell[2], Joan Grieve[2] & Stephanie Baldeweg[1]
[1]University London College Hospital, London, UK; [2]National Hospital for Neurology and Neurosurgery, London, UK.

Background
Following pituitary surgery, dynamic testing with insulin tolerance (ITT) or glucagon stimulation testing (GST) is used to identify patients with secondary hypocortisolism who require glucocorticoids. High glucocorticoid replacement doses are associated with adverse effects, and the optimal replacement dose is unknown.
Aim
We aimed to assess the interpretation of dynamic testing post pituitary surgery in clinical practice and its relation with the hydrocortisone replacement doses used.
Methods
Retrospective review of all dynamic testing results post pituitary surgery between 2004 and 2014 in a tertiary centre, and of the medical notes.
Results
101 patients fulfilled the inclusion criteria, out of which 61 (60.4%) were tested with an ITT and 40 (39.6%) with a GST. 27 patients were prescribed glucocorticoids following ITT testing, and 26 following GST. The decision regarding the hydrocortisone dose was made by the trainee or Consultant who had requested the test from clinic. Patients that were prescribed hydrocortisone 20 mg/day had significantly lower peak cortisol levels on dynamic testing compared to patients prescribed 10 mg/day (252 ± 142 nmol/l vs 356 ± 95 nmol/l, $P<0.05$) or emergency steroids only (484 ± 45 nmol/l, $P<0.005$), but no different peak cortisol levels compared to patients prescribed 15 mg/day (313 ± 149 nmol/l). Similarly, patients prescribed 10 mg/day or 15 mg/day had significantly lower dynamic testing peak cortisol compared to patients prescribed emergency hydrocortisone only ($P<0.005$ and <0.05 respectively). There was a trend to treat patients who had with radiotherapy with higher doses of hydrocortisone. Most patients continued the steroid dose recommended post dynamic testing and did not require dose changes in stable conditions with a follow-up of 4.4 ± 3 years. On the day of dynamic testing, patients that failed an ITT or a GST had baseline cortisol of 205 ± 112 nmol/l.
Conclusion
Patients diagnosed with hypocortisolism on dynamic testing post-pituitary surgery require variable dose or emergency only glucocorticoid replacement. The peak cortisol level on dynamic testing is useful when deciding the glucocorticoid replacement scheme.

Cushing's Syndrome: An ominous and commonly forgotten cause of hypokalaemia

Cherng Jye Seow[1], Zhiguang Ng[1], Claire Min-Li Teo[1], Grace Lum[1], Minyang Chow[1], Chin Ee Ong[1], Tian Ray Lai[1] & Davin Ryanputra[2]
[1]Tan Tock Seng Hospital, Singapore, Singapore; [2]Yong Loo Lin School of Medicine, Singapore, Singapore.

Introduction
We report a patient with hypokalaemia secondary to Cushing's syndrome (CS) to reinforce this commonly forgotten association.
Case report
A 57 years old lady with newly diagnosed hypertension, hyperlipidaemia and diabetes mellitus presented with persistent hypokalaemia for evaluation. She had tinea corporis but otherwise did not look Cushingoid. Investigations: K 2.6 (RI: 3.50–5 mmol/l), HCO_3 35 (RI: 19–31 mmol/l), Urine K/Cr 8.1. Both renin and aldosterone were suppressed. 24 h urinary free cortisol (UFC) was elevated at 1811 (RI: 59–413 nmol/day); 0800 h cortisol after 1 mg overnight dexamethasone suppression test (DST) was elevated at 1156 nmol/l. The patient denied taking any liquorice or corticosteroids. ACTH dependent CS was made with ACTH level of 12.1 pmol/l. Overnight 8 mg DST suppressed the cortisol to more than 50% (1223 nmol/l→ 351 nmol/l). Brain imaging revealed a lytic lesion epicentered in the body of the sphenoid bone, involving the sella and clivus, suspicious for a chordoma. BIPSS was not performed as interpretation may be difficult given the proximity of the lesion to the pituitary. Spironolactone was started to block the mineralocorticoid (MC) effect of cortisol and she was promptly referred to neurosurgery.
Discussion
Activation of MC receptors by cortisol is normally limited due to its conversion to inactive cortisone at the sites of aldosterone action by the enzyme 11-β-hydroxysteroid dehydrogenase type 2 (11-β-HSD2). In ACTH-dependent CS, cortisol secretion exceeds the metabolic capacity of 11-β-HSD2. ACTH inhibits 11-β-HSD2 and there may also be hypersecretion of nonaldosterone mineralocorticoids such as deoxycorticosterone (DOC) and corticosterone. Excess MC activity leads to sodium retention, hypertension, hypokalaemia, metabolic alkalosis, low plasma aldosterone and renin activity. Besides CS, other differentials to consider include 11-β-HSD2 deficiency, liquorice ingestion, Liddle's syndrome, DOC-secreting tumour and certain forms of congenital adrenal hyperplasia.

Conclusion
CS presents with hypokalaemia. Earlier diagnosis and management may improve outcome.

The effect of pregnancy and lactation on prolactinoma

Wonjin Kim[1], Cheol Ryong Ku[2], Jae Won Hong[3] & Eun Jig Lee[2]
[1]Department of Internal Medicine, Gangnam CHA Hospital, CHA University, Seoul, Republic of Korea; [2]Department of internal medicine, Yonsei University College of Medicine, Seoul, Republic of Korea; [3]Department of internal medicine, Ilsan-Paik Hospital, College of Medicine, Inje University, Koyang, Gyeonggi-do, Republic of Korea.

Prolactinoma predominantly occurred in young women of reproductive age. But there are limited data about the effect of pregnancy and lactation on prolactinoma progression. We evaluated the safety of dopamine agonists including bromocriptine and cabergoline and pregnancy outcome in prolactinoma patients. Patients diagnosed with prolactinoma who experienced pregnancies were included. Sellar MRI and serum prolactin levels were performed before and after pregnancy and lactation. Total 46 patients with 62 pregnancies were included. Among 62 pregnancies, spontaneous pregnancies analysed 61 (98.3%) and only one pregnancy was made by IVF. Live births were in 51 (82.3%), while spontaneous abortions occurred in 11 (17.7%). Twenty-one were treated with cabergoline at the time of conception, whereas 28 with bromocriptine. We divided patients into two groups by their changes of adenoma size after delivery; increased ($n=22$) or decreased ($n=15$). Patients with bigger adenoma size before pregnancy showed significantly increased after childbirth. However, the enlarged adenoma did not cause any clinical problems. Of all, breast-feeding was performed in 38 pregnancies. Mean duration of lactation was 4.9 ± 4.4 months. Among those 38, 16 patients had done MRI follow-up after the lactation. There were decreased adenoma sizes in nine patients, no changes in five patients, while increased only in two patients. In conclusion, breast-feeding is not contra-indicated in patients with prolactinoma, especially those who had smaller adenoma.

Prevalence of the sleep breathing disorders in untreated and treated patients with acromegaly

Yulia Kovaleva, Alexander Dreval, Irena Ilovayskaya, Margarita Krukovskaya, Nikolay Kulakov & Svetlana Fedorova
Moscow Regional Research and Clinical Institute n.a. M.F.Vladimirskiy, Moscow, Russia.

For the purpose to compare sleep breathing disorders (SBD) in untreated and treated patients with acromegaly, we examined 55 patients with acromegaly (18 men and 37 women): 27 patients with newly diagnosed acromegaly, age 56.0 (47.0; 64.0) y.o., BMI 30.2 (27.8; 34.4) kg/m2, GH levels 12.8 (4.6; 23.0) ng/ml, IGF-1 245 (106; 331) % of upper normal limit (UNL), hypertension duration 6.5 (1.0; 14.8) years; 28 patients with treated acromegaly, age 57.0 (47.3; 64.8) y.o., BMI 30.7 (27.9; 35.0) kg/m2, GH levels 2.1 (1.2; 3.4) ng/ml, IGF-1 14 (7; 21) % UNL, hypertension duration 9.0 (3.0; 10.0) years. Data are expressed in Median (25%;75%). Respiratory monitoring was conducted using device ApneaLink, ResMedInc, Australia. Statistical analysis: SPSSv.22. High index of apnoe-hypopnoe (IAH) was found in 91.9% untreated and in 78.6% treated patients: severe SBD in 51.9% and 46.5% patients (IAH 46.6 (40.8; 57.8) and 47.0 (43.9; 59.0), respectively); moderate SBD – in 25.9% and 21.4% (IAH 21.3 (20.0; 23.0) and 23.2 (18.0; 26.3)), mild – in 14.8% and 10.7% (IAH 10.5 (8.3; 12.1) and 5.0 (5.0; 11.0)). The saturation level (normally 94-98%) was decreased in 54.2% untreated and 42.3% treated patients; the average saturation level was 93.0 (90.0; 94.0)% and 94.0 (91.8; 95.3)%, correspondingly. Desaturation level (normally 90-98%) was below normal in 91.7% untreated and 83.3% treated patients; the average desaturation was 79.5 (70.3; 86.8) % and 84 (72.3; 88.8) %, respectively. Severity of SBD did not correlated with GH/IGF-1 levels. Moderate correlations were found between IAH and age, IAH and duration of hypertension. Thus, sleep breathing disorders (with high prevalence of severe IAH and significant desaturation) could be found in most of the patients with untreated and treated acromegaly, and regression of SBD after acromegaly treatment is not so significant. Specific methods of apnoe treatment should be considered for patients with acromegaly and SBD.

Introduction
This study aimed to determine the timeframe to achieve hormonal normalization considering dosing patterns of Somatuline Autogel (SOM, lanreotide) used in clinical practice.
Methods
From March 2013 to October 2013 clinical data from 62 patients with active acromegaly treated with SOM for ≧4 months who achieved hormonal control (GH levels <2.5 ng/ml and/or normalised IGF1 on ≧two evaluations) at 17 Spanish hospitals were collected into a database. Primary objective was to determine the timeframe from initiating SOM treatment to hormonal normalisation. Secondary objectives included use of health resources, tumour size control, patient satisfaction and adherence.
Results
Non-compliance excluded five patients. Median age of 57 patients was 64 years (23–90), 21 (36.8%) were male, 35 (61.4%) had macroadenoma, 39 (68.4%) had undergone surgery, 14 (24.6%) had received radiotherapy. Median hormonal values at start of SOM treatment were GH: 2.6 ng/ml (95%CI 2.6–7.4), IGF1: 1.6xULN (95% CI 1.6–2.1). SOM 120 mg was the most frequent initial dose (51% patients), with prolonged interval use (≧6 weeks) in 44% patients. Main starting regimens were 60 mg per 4 weeks ($n=13$), 90 mg per 4 weeks ($n=6$), 120 mg per 4 weeks ($n=13$), 120 mg per 6 weeks ($n=6$), 120 mg per 8 weeks ($n=9$). Median length of SOM treatment was 68 months (7–205). Hormonal control was achieved in 4.9 months (95%CI 7.9–20.1). 13 (22.8%) patients managed injections without assistance of health care nurses: 8 (14.0%) were able to self-inject and 5 (8.8%) had injections administered by close relatives. Median number of specialist physician visits until hormonal control was 3 (95%CI 4–10). During SOM treatment tumour shrinkage up to 46.7% was reported in ten patients with available information. 51 (89.5%) patients were 'satisfied'/'very satisfied' with SOM treatment and 49 (86.0%) patients did not miss any doses.
Conclusion
Real-life treatment with SOM led to a fast hormonal control in acromegaly responder patients, with a high treatment adherence and treatment satisfaction, despite disparity of SOM starting doses and interval dosing.

Prevalence of the sleep breathing disorders in untreated and treated patients with acromegaly

Irena Ilovayskaya, Alexander Dreval, Yulia Krivosheeva, Alexander Abramenko & Galina Stashuk
Moscow Regional Research & Clinical Institute n.a. M.F.Vladimirskiy, Moscow, Russia.

There are some data concerning high prevalence of infrasellar extension of somatotropinomas. To reveal any differences expansion of pitutary macroadenomas with various hormonal secretion, we have analyzed MRI data of 175 pituitary macroadenomas: 87 non-functioning adenomas (NFAs), 48 prolactinomas, 43 somatotropinomas. The sizes of pituitary tumour (vertical, sagittal, frontal): NFAs 24 (17.5; 34.5)mm, 23 (17.4; 28) mm, 23 (18; 30) mm; prolactinomas 21 (15; 31) mm, 20 (16; 30) mm, 20 (14; 30) mm; somatotropinomas – 18 (14; 25) mm, 18.2 (14; 24) mm, ? 17 (14.5; 23) mm. The tumour volume varied: in NFAs from 618 to 68753 mm^3 (median 6620 (2638; 14492) mm^3), in prolactinomas 565–86871 mm3 (median 5365 (1495; 10316) mm^3), in somatotropinomas 352–124501 mm^3 (median 3052 (1696; 5727) mm^3) ($P<0.001$). Prevalence of suprasellar, infrasellar and laterosellar extensions were: NFAs–94, 62, and 39%; prolactinomas – 75, 64 and 62%; somatotropinomas – 61, 75, and 44%, respectively. Suprasellar tumour growth was predominant in NFAs and prolactinomas but not in somatotropinomas ($P<0.001$). Higher frequency of infrasellar growth of somatotropinomas was noted but the difference was not significant in comparison with other tumours ($P>0.05$). Obvious prevalent incidence of laterosellar growth of prolactinomas was observed compared with both NFAs ($P=0.002$) and somatotropinomas ($P<0.016$). Optic chiasm compression according to MRI data was found in 55% of NFAs, 35% of prolactinomas and 19% of somatotropinomas ($P<0.001$) and it was correlated with suprasellar growth and vertical size >18 mm. Thus, in our cohort of patients non-functioning pituitary adenomas have markedly larger volume with predominant suprasellar growth and high frequency of chiasm compression compared with hormonally active pituitary tumours. Prolactinomas and somatotropinomas did not differ in volume, however, had some differences in growth directions: this is the first data concerning high prevalence of laterosellar extension of prolactinomas, predominant infrasellar growth of somatotropinomas was also observed without significant difference in comparison with other pituitary tumours.

Lung function tests in 109 acromegalic patients

Sylvère Störmann[1], Bodo Gutt[2], Josefine Roemmler-Zehrer[1], Martin Bidlingmaier[1], Jochen Schopohl[1] & Matthias Angstwurm[1]
[1]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, Munich, Germany; [2]Asklepios Klinik Birkenwerder, Abteilung für Diabetologie, Asklepios Klinik Birkenwerder, Abteilung für Diabetologie, Germany.

Introduction
Acromegaly is a chronic disease that affects morphology and organ functions. These changes lead to clinically relevant comorbidities. Untreated acromegaly reduces life expectancy by 10 years, mostly due to cardiovascular events, malignancies and respiratory disorders. We present the results of a series of 109 acromegalic patients at a single institution.
Methods
Lung function tests were performed under standardized conditions in patients with acromegaly treated in our outpatient clinic. Normative data was used to compare our patients (measured value) with healthy controls (predicted value); percentage of predicted value was used to perform subgroup analysis. Criteria of cure were IGF1 in the age- and sex-adjusted normal range and random GH <1.0 µg/dl.
Results
We investigated 109 acromegalic patients without history of pulmonary disease (53 male, 49%) with a mean age of 54.6 ($\pm$13.5) and mean duration of acromegaly of 12.6 years ($\pm$11.6). 20 patients had active, untreated acromegaly at time of assessment. 29 patients were biochemically normalized. Lung function significantly differed from healthy controls in terms of higher volume regarding intrathoracal gas volume, maximal vital capacity, residual volume, total lung capacity, and forced expiratory volume in 1 second. Patients showed signs of obstruction with significantly lower peak expiratory flow and maximum expiratory flow when 75% of the FVC has been exhaled (FEF75/MEF25). 56.5% of patients had a reduced FEF75/MEF25 and 40.4% increased residual volume. There was no significant difference between active and inactive acromegaly. Female patients had significantly smaller flow rates of peak expiratory flow, FEF25/MEF75 and FEF50/MEF50.
Conclusions
In our cross-sectional analysis of lung function in 109 patients with acromegaly lung function volumes were increased compared to healthy controls. Patients showed signs of small airway obstruction at time of diagnosis, unchanged in remission. Subclinical airway obstruction was significantly more pronounced in female patients.

Thyroid lesions in patients with acromegaly–case-control study

Kosma Wolinski, Adam Stangierski, Edyta Gurgul, Barbara Brominska & Marek Ruchala
Department of Endocrinology, Metaboilsm and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland.

Introduction
Acromegaly is a disease caused by excessive secretion of growth hormone and subsequently insulin growth factor 1. It is believed that this oversecretion can cause increased prevalence of nodular goiter and thyroid cancer. However, the amount of studies comparing acromegalic patients with control groups is low. The aim of the study was to assess the prevalence of thyroid lesions in patients with acromegaly in comparison with age and sex-matched control group.
Materials and methods
We have searched the medical documentation of patients with acromegaly treated in single endocrine department in the years 2003–2013. The prevalence of thyroid lesions was compared with the group of patients with hormonally inactive adrenal incidentalomas. Thyroid ultrasonography is routine procedure performing in every patient hospitalised in our department.
Results
patients with acromegaly and 184 patients with incidentalomas were included. mean age was 52.6 and 53.9 years respectively (P=0.44), percent of women – 60.5 vs 65.2% respectively (P=0.35). Any thyroid lesions were present in 77.6% of patients with acromegaly and 63.0% with incidentalomas (P=0.002), multinodular goiter in 66.8% vs 47.8% (P=0.0002), thyroid cancer in 5.4% vs 2.7% (P=0.21) respectively. RRs were 1.2 with 95% confidence interval (CI) 1.1–1.4, 1.3 (1.1–1.6) and 2.0 (95% CI 0.7–5.6) respectively. In case of subjects with at least one thyroid lesion, maximal diameter of the biggest thyroid lesion was significantly higher in patients with acromegaly than in control group – median 13.0 vs 9.0 mm (P=0.0008). Also the mean thyroid volume was significantly higher in acromegalic patients (35.5 vs 17.7 cm^3, P<0.0001).
Conclusions
Structural thyroid abnormalities are significantly more common in patients with acromegaly. Our study, performed on one of the largest described groups of acromegalic patients, confirms that systematic thyroid examination should be important part of follow-up in case of patients with acromegaly.

Anterior pituitary hormone deficiencies in primary and surgery related empty sella cases and its effect on quality of life

Hafize Titiz, Yusuf Aydin, Elif Onder, Alper Koc & Tuba Soysal
Department of Internal Medicine and Endocrinology and Metabolism, Medical Faculty, Duzce University, Duzce, Turkey.

Introduction
Primary empty sella (PES) is often found incidentally during neuroradiological studies. Although pituitary function is usually normal in patients with PES, it could be associated with serious clinical conditions including different degrees of hypopituitarism. Post-operative empty sella (POES), the most common group, results from pituitary adenoma and their treatments. Our aim is to compare anterior pituitary functions and quality of life (QoL) with Short Form-36 (SF-36) between patients with PES (total and partial) and POES.

Material and methods
Totally 75 patients (34 partial, 20 total PES and 21 SES) were evaluated. Basal anterior pituitary and its target hormones were measured. When we determined low basal cortisol levels and/or low insulin like growth factor-1 levels, underwent insulin tolerance test (ITT) or synacten test. After the patient gave informed consent to participate in the study, we performed SF-36 to evaluate the QoL.
Results
We classified the patients according to the radiological findings as partial empty sella (group 1), total empty sella (group 2) and POES (group 3). 9 (26.5%) patients in group 1 didn't have any hormone deficiency however 15 (75%) patients from group 2 and 10 (47.6%) patients from group 3 and 7 (20.6%) patients from group 1 had panhypopituitarism. The ratio of panhypopituitarism was significantly higher in group 2. According to SF-36 scales, Mean score of physical role functioning was significantly higher in group 3. Score of general health perceptions was significantly lower in group 1.
Conclusion
Endocrinological evaluation should be performed during each visit of patients with PES (partial and total) and POES. All hormonal deficiencies should be treated with appropriate medical substitution to maintain the quality of life. QoL in pituitary deficiency were affected in adults, the results showed to physical role functioning and general health perceptions significant difference between groups.

Multimodal management of GH-secreting pituitary adenomas – the experience of the endocrinology department Tirgu-Mures, Romania, in the last decade

Imre Zoltan Kun[1], Zsuzsa Tanko[2], Anisie Nasalean[2], Jozsef Balazs[2], Camelia Gliga[2,3], Ionela Pascanu[2,4] & Zsuzsanna Szanto[2,4]
[1]Doctoral School, University of Medicine and Pharmacy, Tirgu-Mures, Romania; [2]Clinical Department of Endocrinology, Clinical Hospital Mures County, Tirgu-Mures, Romania; [3]Department of Histology, University of Medicine and Pharmacy, Tirgu-Mures, Romania; [4]Department of Endocrinology, University of Medicine and Pharmacy, Tirgu-Mures, Romania.

Introduction
The diagnostical and therapeutical management of GH-secreting pituitary adenomas has been modified in many aspects in the last decade, and the guidelines also have been considerably changed.
Objective
To evaluate the management of acromegaly applied in an endocrinological clinical unit from Romania, and the efficiency of different therapeutical schemes.
Materials and methods
23 patients with acromegaly, treated and followed-up were included in this study. The positive diagnosis of GH-secreting pituitary adenoma was based on the elevated age-related IGF-1-level, suppressed GH-value >1 ng/ml during oral glucose tolerance test and conclusive hypothalamo-pituitary MRI. The applied different therapeutical schemes (surgery, drugs, radiotherapy and combination), and the efficacy of these – assessed by periodic control of IGF-1-level, suppressed GH-value and MRI – were evaluated.
Results
78.3% of the patients had GH-secreting adenoma, the other 21.7% mixed, GH/PRL-secreting form. At diagnosis the mean suppressed GH-level was 23.2+/−6.8 ng/ml, mean IGF-1-value 784.5+/−139.4 ng/ml, mean adenoma size 17.7+/−2.8 mm. First line therapy was neurosurgery in 14 cases, medical treatment (somatostatine-analogue+/−dopamine-agonist) in six and conventional radiotherapy in three patients, out of which in five cases (21.7%, four after surgery, one after radiotherapy) a good control was achieved. The uncontrolled cases received a second therapeutical procedure, and from them other four cases (17.4%, two reinterventions, one after drug administration and one after radiotherapy) reached a good control. Finally, at eight patients combined multiple therapeutical management (surgery+drug+/−radiotherapy) was applied, and other three cases (13%) been brought under control. During long-term follow-up six patients become non-compliant, and they did not return to reevaluations.
Conclusion
From all the 23 subjects in 52.1% an optimal therapeutic control was achieved with all the applied treatment schemes. Acromegaly could be controlled by monotherapy, mainly neurosurgery in 21.7%, by double treatment scheme in an other 17.4% and by multiple therapeutical combinations in 13% of the cases.

Early diagnosis and treatment of pituitary apoplexy in a diabetic pregnant woman

Elif Onder[1], Yusuf Aydın[1], Hafize Titiz[1], Tuba Soysal[1], Esra Ozen[1] & Ramazan Buyukkaya[2]
[1]Duzce University Medical Faculty Department of Internal Medicine and Endocrinology and Metabolism, Duzce, Turkey; [2]Duzce University Medical Faculty Department of Radiology, Duzce, Turkey.

Introduction
Pituitary apoplexy results from haemorrhagic infarction of a pre-existing pituitary adenoma or within physiologically enlarged gland. Pituitary apoplexy during pregnancy is rare but serious event with significant morbidity and mortality if not recognised in time. Pituitary apoplexy is characterised by sudden onset of headache, nausea, vomiting, visual disturbances, eye movements restricted and varying degrees of pituitary insufficiency and accompanied by change of consciousness may be clinically overt or as subclinical. Our case report describes a woman who presented with pituitary apoplexy in the 27 weeks of pregnancy.
Case report
A 30-year-old female patient receiving intensive insulin therapy with diagnosis of gestational Diabetes Mellitus. Patient was presented with severe headache, nausea, and vomiting complaints in the 27 weeks of pregnancy. Patient was hospitalised in with urinary tract infection and hyperglycaemia. Early morning serum cortisol was 3.02 μg/dl (6.2–19.4), fT_4:0.57 (*n*: 0.93–1.70) ng/dl and TSH: 0.84 μIU/ml (*n*: 0.34–4.3), other metabolic parameters were within normal limits. Magnetic resonance imaging (MRI) of the pituitary showed pituitary apoplexy. Patient was started with IV 80 mg twice daily and desmopressin nasal spray twice daily. Patient's electrolytes was monitored twice daily. The second day was added to patients levothyroxine 50 μg. Surgery was not planned due to risk of loss of baby. Clinical improvement continued in the following days and after supplementation of methylprednisolone, levothyroxine and desmopressin. Reduction in bleeding site was detected in the control of pituitary MRI. Delivery after 36 weeks of pregnancy was uneventful and a healthy girl was born.
Conclusion
Pituitary apoplexy is a very rare but serious complication that can likely be precipitated by the physiologic changes associated with pregnancy in patients. Because early diagnosis and treatment can and often does result in complete recovery, it is important to recognise and effectively manage this event when it occurs immediately.

Background
The water deprivation test as the accepted gold standard in the differential diagnosis of polyuria polydipsia syndrome can be associated with a decrease in extracellular fluid volume in patients with diabetes insipidus (DI). We herein evaluated mid-regional pro-atrial natriuretic peptide (MR-proANP) as marker of extracellular body volume in patients with diabetes insipidus compared to primary polydipsia (PP), at baseline and after water deprivation.

Methods
Patients >18 years old with a history of polyuria and polydipsia were prospectively included. Participants underwent a standardized combined water deprivation and 3% saline infusion test that was terminated when serum sodium levels exceeded 147 mmol/l. MR-proANP levels were determined at baseline and when serum sodium exceeded 147 mmol/l.
Results
55 patients with polyuria polydipsia syndrome were enrolled: 37 had complete or partial DI and 18 had PP. At baseline median MR-proANP levels in patients with DI were similar as compared to patients with PP (median (IQR) 51.2 pmol/l (31.9; 74.4) vs 42.6 pmol/l (28.4; 63.6); $P=0.23$). Upon the water deprivation test, in patients with DI MR-proANP levels decreased to 46.9 pmol/l (29; 64.1) ($P=0.004$), whereas there was no change in patients with PP (45.8 pmol/l (26.1; 61.3), $P=0.28$). The change of MR-proANP was significantly more pronounced in patients with DI compared to patients with PP ($P=0.009$). A delta-ANP of >0.9 had an AUC of 0.77 (95% CI, 0.63–0.90) with a sensitivity of 75.7% and a specificity of 72.2% to differentiate patients with DI from patients with PP.
Conclusion
MR-proANP levels decrease upon a water deprivation test in patients with DI, without a change in PP. Changes in MR-proANP during thirsting may separate patients with diabetes insipidus from those with PP.
Disclosure
This work was supported by the Swiss National Foundation (grant number PP00P3-123346) and Thermo Scientific Biomarkers, Henningsdorf, Germany, the developer and manufacturer of the MR-proANP-Assay, who provided all the kits for measurement of MR-proANP levels.

Cardiovascular risk factors and metabolic parameters in GH deficient patients

Zoe A Efstathiadou[1], Sideris P Delaroudis[2], George N Koukoulis[3] & Marina D Kita[1]
[1]Department of Endocrinology, 'Hippokration' General Hospital of Thessaloniki, Thessaloniki, Greece; [2]Department of Endocrinology, 424 General Military Hospital, Thessaloniki, Greece; [3]Endocrine Unit, Department of Internal Medicine, University of Thessaly School of Medicine, Larissa, Greece.

Introduction
GH deficiency in adulthood is associated with increased cardiovascular risk, which is attributed to unfavorable changes in body composition and in metabolic parameters.
Aim
We evaluated haemodynamic, metabolic, inflammatory and coagulation indices that may contribute to the increased cardiovascular risk in GH deficient subjects.
Methods
Twenty-four patients diagnosed with GH deficiency (13 male), with a mean (S.D.) age of 54.3 (2.7), were compared to 15 healthy age, sex and BMI matched, controls. Anthropometric characteristics (BMI and waist-to-hip ratio (WHR)), blood pressure, basal GH, IGF-I, fasting glucose, fasting insulin, HbA1c, lipid levels, ApoA1, ApoB, hs-CRP, fibrinogen, PAI-1, t-PA and circulating thrombomodulin levels were measured in all study participants. Insulin resistance (IR) was calculated by HOMA and, in ten subjects who had undergone an oral glucose tolerance test, insulin sensitivity was also estimated using Matsuda index.
Results
Patients with GH deficiency exhibited a marginally increased WHR and had significantly higher fasting insulin levels, fasting glucose-to-insulin ratio, HbA1c, total-chol, LDL-chol and triglyceride levels, higher ApoB and lower HDL, compared to controls. IR did not differ by HOMA-IR, however, patients were less insulin sensitive than controls.
Fibrinogen levels and PAI-1 levels did not differ significantly, but t-PA was markedly increased compared to controls. Thrombomodulin levels were not affected.
Conclusions
A considerable number of risk factors including insulin sensitivity, lipid and lipoprotein levels and pro-thrombotic factors are affected in GH deficient adults. Studies addressing whether GH substitution results in decreased CVD morbidity and mortality are needed so therapy could be more vigorously implemented in such patients.

Increased serum levels of the Wnt antagonist Dickkopf-1 (DKK1) and impaired trabecular bone mineral density using QCT scan in acromegalic patients

Elena Valassi[1], Iris Crespo[1], Anna Aulinas[1], Eulalia Urgell[2], Jorge Malouf[3], Jaume Llauger[4], Ana Maria Marin[3], Betina Biagetti[5] & Susan M Webb[1]
[1]II-B Sant Pau and Department of Internal Medicine/Endocrinology, Hospital Sant Pau, UAB and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBER-ER, Unidad 747), ISCIII, Barcelona, Spain; [2]Department of Biochemistry, Hospital Sant Pau, Barcelona, Spain; [3]Department of Internal Medicine, Mineral Metabolism Unit, Hospital Sant Pau, Barcelona, Spain; [4]Department of Radiology, Hospital Sant Pau, Barcelona, Spain; [5]Department of Endocrinology, Hospital Vall d'Hebron, UAB, Barcelona, Spain.

Introduction
Acromegaly is associated with increased bone turnover and skeletal fragility. Although the GH/IGF1 system plays an important role in bone homeostasis, effects of GH excess on the Wnt signalling pathway are to be determined. Bone quantitative CT (QCT) provides a volumetric, tridimensional measure of bone mass at the trabecular and cortical level.
Aim
i) To compare volumetric bone density (vBMD) using QCT in patients with acromegaly vs gender-, age-, and BMI-matched controls; ii) to correlate it with the levels of Wnt antagonists, dickkopf factor-1 (DKK1) and sclerostin (SOST), in the same subjects.
Methods
Thirty-one acromegalic patients (17 (55%) men; 18 (58%) with active disease; mean age 48.2±7.5 years (range 28–65 years)) and thirty-two age-, gender- and BMI-matched controls underwent QCT scan using Mindways Software. Serum concentrations of DKK1, SOST, ß-crosslaps, procollagen type-1 amino-terminal propeptid (P1NP) and osteocalcin were also measured.
Results
vBMD of cortical total hip (CTH vBMD) and trabecular total hip (TTH vBMD) were lower in acromegaly than controls (CTH vBMD, 776±199.4 vs 937±346.4 mg/cm^3; $P<0.05$ and TTH vBMD, 121.4±20.6 vs 142.8±22.8; $P<0.01$). P1NP levels were lower (41.7±20.5 vs 51±21.2 ng/ml, $P<0.05$), while DKK1 levels were higher (33.7±12.9 vs 26±14.8 pmol/l, $P<0.05$) in acromegaly patients compared to controls. No intergroup difference in ß-crosslaps, osteocalcin and SOST levels was observed. A negative correlation between DKK1 and TTH vBMD ($r=-0.382$, $P<0.01$) was observed. A positive correlation between P1NP, ß-crosslaps, and SOST with CTH vBMD ($r=0.34$, $r=0.27$, $r=0.26$, respectively, $P<0.05$) was also observed. After multiple regression analysis, DKK1 and disease duration were independent, negative predictors of TTH vBMD ($R^2=0.335$, $P<0.05$), whereas female gender was an independent, positive predictor of CTH vBMD ($R^2=0.156$, $P<0.05$).
Conclusions
Acromegaly patients exhibit low vBMD on QCT. The Wnt signalling antagonist DKK1 may contribute to the skeletal fragility described in acromegaly.

Outstanding growth response to GH replacement therapy in three different cases of GH deficiency

Ljiljana Saranac[1], Zlatko Djuric[1], Ivana Markovic[2], Hristina Stamenkovic[1] & Dragoljub Lazarevic[1]
[1]Pediatric Clinic, Faculty of Medicine Nis, University of Nis, Nis, Serbia; [2]Institute of Radiology, University Clinical Centre Nis, Nis, Serbia.

Introduction
Growth response in GH deficient children during GH replacement therapy rarely fulfil our projections and patient's expectations. We here report three cases with outstanding growth response.

Case reports
First patient was diagnosed as gluten enteropathy in early childhood, but the diet didn't improve his growth. At age of 7 years the diagnosis of isolated GH deficiency (GHD) was established and GH substitution therapy introduced. Next 2 years his growth velocity increased to 10 cm/year. Routine head MRI revealed hypothalamic tumour. Severe growth failure in 8-years-old boy with history of purulent meningitis in toddler period and head trauma at age of 6. MRI discovered congenital pituitary abnormality (pituitary hypoplasia and ectopic posterior pituitary). Combined substitution therapy improved his height from −3S.D. to +0.67S.D. An empty sella syndrome was diagnosed in short obese boy with delayed puberty. At diagnosis his height of 148.8 cm was −1.88S.D. (P3). During 4 years of combined therapy he achieved height of 184 cm (P90), +1.28S.D.
Conclusion
Mechanisms of excellent growth response in these GH deficient children certainly include concomitant hypogonadism, but somatostatin deficiency may also be considered.

Introduction
High affinity binding of pasireotide for both sst_2 and sst_5 leads to its enhanced efficacy in treatment of acromegaly but results in decreased secretion of insulin, incretins (GLP-1 and GIP) and, to a lesser extent, glucagon. Metformin may be a good option in patients with acromegaly experiencing hyperglycaemia with pasireotide as it improves GLP-1 secretion. We analysed data from a 12-month, Phase III, randomised study in medically naïve patients with acromegaly to better understand the effects of antidiabetic agents used during pasireotide treatment.
Methods
Patients were randomised to pasireotide LAR 40 mg/28 days ($n=176$) or octreotide LAR 20 mg/28 days ($n=182$) for 12 months. Patients ($n=57$) randomised to pasireotide who were not receiving antidiabetic medication at baseline and who initiated such medication during the study were included in this analysis. Three groups were analysed: patients receiving i) metformin alone; ii) metformin + another oral antidiabetic (OAD); and iii) insulin ± OAD.
Results
Metformin was the most commonly initiated antidiabetic; metformin alone ($n=24$), metformin + another oral antidiabetic (OAD; $n=19$) and insulin ± OAD ($n=10$). Mean (S.D.) fasting plasma glucose (FPG) and HbA1c at baseline were 94.7 (13.0) mg/dl and 5.8% (0.4%) for metformin alone, 99.7 (12.8) mg/dl and 5.8% (0.4%) for metformin + another OAD, and 106.7 (19.7) mg/dl and 6.1% (0.5%) for insulin ± OAD. Mean (S.D.) FPG values at month 3 were 131.0 (37.2), 153.2 (41.6) and 170.0 (88.6) mg/dl, and at month 12 were 126.7 (17.4), 132.6 (25.0) and 137.1 (31.7) mg/dl in the three groups. HbA1c values were 6.6% (0.5%), 7.0% (1.0%) and 8.7% (1.9%) at month 3, and 6.6% (0.7%), 6.7% (0.6%) and 7.2% (1.2%) at month 12.
Conclusions
At month 12, patients treated with metformin monotherapy or in combination with OAD agents had a mean HbA1c that met the ADA/EASD goal of <7%. Metformin-based OAD therapy proved effective in hyperglycaemia associated with pasireotide in patients with acromegaly.

Analysis of the aetiology of hypopituitarism: the results from double centre study

Mustafa Caliskan[1], Mehtap Navdar Basaran[2], Selvihan Beysel[1], Muyesser Sayki Arslan[1], Bekir Ucan[1], Mazhar Muslum Tuna[2], Erman Cakal[1], Dilek Sensoz Berker[2], Serdar Güler[2,3] & Tuncay Delibasi[1,4]
[1]Department of Endocrinology and Metabolism, Diskapi, Teaching and Research Hospital, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Numune Teaching and Research Hospital, Ankara, Turkey; [3]Faculty of Medicine, Hitit University, Corum, Turkey; [4]School of Medicine (Kastamonu), Hacettepe University, Ankara, Turkey.

Introduction
Hypopituitarism is commonly acquired in adult life and its main causes are pituitary tumors and/or their treatments, empty sella syndrome and etc.
Patients and methods
A double centre, cross-sectional database study was performed in Turkish population for last 10 years to investigate the etiology of hypopituitarism. One-hundred forty nine patients were included (53% female and 47% male) with a mean age of 47.9 ± 15.6 years (ranging from 19 to 83 years). Patients were classified by the causes of hypopituitarism as pituitary tumors (due to direct effect of the pituitary tumors and/or their treatments), extra-pituitary tumors, and non-tumoural causes.
Results
It was found that the most common etiology of pituitary dysfunction was due to non-tumoural causes (48.9%) among all patients (Table 1). According to the subgroup analysis of the causes of hypopituitarism, the most common cases with more than 10% frequencies were prolactinomas, non-secretory adenomas, idiopathic, and empty sella (Table 1). In terms of the type of hormonal deficiencies, FSH/LH deficiencies was the most common hormonal deficit (93.9%). In 70.4% of the patients, four anterior pituitary hormone deficiencies (FSH/LH, ACTH, TSH and GH) were present.

Table 1 Subgroup analysis of the frequencies of hypopituitarism in all patients (*n*, number of patients; (%), frequency).

Aetiology	*n* (%)
Pituitary adenomas	62 (41.6%)
Prolactinomas	13 (8.7%)
Acromegaly	2 (1.3%)
Cushing	3 (2%)
Gonadotrophinomas	1 (0.7%)
Thyrotropinomas	1 (0.7%)
Non-secretory adenomas	42 (28.2%)
Extra-pituitary tumors	13 (8.7%)
Non-tumoural causes	
Idiopathic	13 (8.7%)
Sheehan's syndrome	59 (39.6%)
Apoplexia	2 (1.3%)
Total	*n*=149

Note: Frequencies over 10% were represented in bold.

Conclusion
Although non-secretory pituitary adenomas were the most common cause of hypopituitarism in male patients, Sheehan's syndrome was the leading cause of hypopituitarism in female patients.

A case of idiopathic granulomatous hypopysitis that was initially treated as a prolactinoma

Ismail Emre Arslan, Mehmet Muhittin Yalcin, Nuri Cakir, Alev Eroglu Altinova, Ilhan Yetkin, Müjde Aktürk, Fusun Balos Toruner & Metin Arslan
Endocrinology and Metabolism Department, Gazi University Faculty of Medicine, Ankara, Turkey.

Idiopathic granulomatous hypophysitis is a very rare inflammatory disease of the pituitary gland. Primary hypophysitis represents a difficult diagnostic challenge because it can imitate pituitary adenomas clinically and radiologically. The diagnosis is usually made histologically by hypophysectomy. We herein present a rare case of idiopathic granulomatous hypopysitis diagnosed primarily by pituitary biopsy.
Case
A 50-year-old female patient presented with headache, visual loss and menstrual irregularities over the preceding year. At her first visit at another hospital, TSH level was normal but prolactin level was high (PRL: 115 ng/ml). In her visual field examination, a near total defect on right eye and a peripheral visual field defect on left eye were detected. Pituitary MRI revealed a $17\times9\times12$ mm macroadenoma extending to optic chiasm. Cabergoline therapy was started. When she applied to our clinic 3 months later, pituitary MRI demonstrated a 6 mm microadenoma? and her vision complaints were disappeared; but hypocortisolism and secondary hypothyroidism were detected. Replacement therapies were started and cabergoline was stopped. This unexpected development of pituitary insufficiency necessitated a re-evaluation of MRI screenings. Because our decision was in favor of a possible hypophsitis, trans-sphenoidal pituitary biopsy was performed. Pituitary biopsy demonstrated non-necrotising granulomatous hypophysitis. Possible secondary causes were investigated and no evidence was found. The final diagnosis was idiopathic granulomatous hypophysitis. We decided to follow-up the patient and replacement therapies were continued. The patient had no further complaints.
Conclusion
Idiopathic granulomatous hypophysitis, which is a very rare disease, diagnosed by pituitary biopsy is the main characteristic of our remarkable case. In patients with pituitary insufficiency, considering hypophysitis is a crucial clinical decision especially if they have specific radiological findings because it is highly possible to treat these patients medically and avoid hypophysectomy.

Transsphenoidal surgery of pituitary adenomas in 491 clinical cases: the retrospective single-centre study

Robertas Knispelis[1], Birutė Žilaitienė[1,2], Martyna Ramančiuckaitė[3], Rasa Verkauskienė[1], Kęstutis Šinkūnas[4], Rimantas Žalinkevičius[2] & Arimantas Tamašauskas[4,5]
[1]Department of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [4]Department of Neurosurgery, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [5]Institute of Neurosciences, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction
The number of studies on the incidence and outcomes of surgical treatment for pituitary adenomas is still limited, despite that pituitary tumours are one of the most frequent intracranial tumours.
The aim of this study
To evaluate clinical features of transsphenoidaly operated pituitary adenomas (PA) and perioperative results of the treatment.
Materials and methods
This is a retrospective single institution study of 491 patients. Data were collected from medical records of patients operated during the period 1995–2014 at the Hospital of Lithuanian University of Health Sciences due to functioning and non-functioning micro or macroadenomas. The series consisted of 357 (64, 91%) female and 193 (35, 09%) male patients, with a mean age of 49.95 ± 16. 4 year (range 18–85 year).
Results
The study included 227 non-functioning and 264 functioning adenomas: 103 were GH, 122 prolactin (PRL), 32 ACTH and seve TSH secreting adenomas. Female patients were significantly younger than male patients ($P<0.$ 02). Gross total resection as ascertained by surgeon just after the operation was achieved in 92 (40.71%) cases of non-functioning adenomas, 62 (64.58%) cases of GH, 64 (55.17%) cases of PRL, 24 (85.71%) cases of ACTH, and 3 (42. 86%) cases of TSH secreting adenomas. According to the size the non-functioning tumours were significantly large than functioning adenomas. Tumour type and size directly influenced surgical outcome. The highest possibility for total tumour removal was detected in the case of ACTH secreting adenomas ($P<0.001$) and lowest in non-functioning adenomas ($P<0.001$). Surgical intraoperative rupture of membrane selle turcique and liquorrhea occurred in 16.51% and no major intraoperative complications were observed.
Conclusion
Our centre data confirm effectiveness and safety of transsphenoidal surgery for PA and the best prognosis for ACTH secreting PA.

Pharmacokinetic and pharmacodynamic analyses of pasireotide LAR from a randomised, phase III study in patients with inadequately controlled acromegaly

Guoxiang Shen[1], Christelle Darstein[2], Karina Hermosillo Reséndiz[1] & Ke Hu[1]
[1]Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, USA; [2]Novartis Pharma AG, Basel, Switzerland.

Introduction
A 24-week, PhIII, randomised study (PAOLA) demonstrated superior efficacy of pasireotide long-acting release (PAS-LAR; 40 and 60 mg) vs continued treatment with octreotide LAR 30 mg or lanreotide Autogel 120 mg (15.4%, 20.0% vs 0%) at providing biochemical control (GH <2.5 μg/l and normalized IGF-1) in patients with acromegaly inadequately controlled on first-generation somatostatin analogues. Results from PK/PD analyses of PAS-LAR are reported here.
Methods
Relationship between PAS plasma concentration/efficacy endpoints (GH and IGF-1) and PAS exposure/safety (FPG, ECG, and liver function tests) were analysed. Dose-proportionality was explored and possible covariate effects were determined using linear mixed-effects models.
Results
A steady-state PAS concentration was achieved following three consecutive monthly injections. PAS exposures were approximately dose proportional for the tested dose range (40–60 mg). Gender, age, and baseline total bilirubin levels were statistically significant PK covariates for PAS concentration but without clinically significant impact. A clear exposure-response relationship was observed between PAS concentration and efficacy endpoints. Estimated maximum GH and IGF-1 suppression (mean $\pm$ S.E.M.) was $83.0\pm6.5\%$ and $67.1\pm5.8\%$, respectively. Estimated effective concentration of PAS to suppress GH to 2.5 μg/l was 12.3 ± 3.3 ng/ml; to suppress IGF-1 to $1\times$ULN required higher PAS concentration (42.3 ± 16.6 ng/ml). These results were aligned with clinical finding of higher response rate for GH vs. IGF-1 with 40 and 60 mg (40 mg: 35.4% vs 24.6%; 60 mg: 43.1% vs 26.2%). A 1.5-fold increase in PAS trough concentration (40–60 mg dose) was associated with a 54, 44, and 51% increase in the odds of GH+IGF-1, GH and IGF-1 responses, respectively; corresponding increase in the odds of having hyperglycaemia was only 36%.
Conclusions
A positive relationship between PAS exposure and efficacy supported the clinical observations of higher GH and IGF-1 response rates with higher dose (60 mg vs 40 mg). These results are aligned with the clinical findings of a positive benefit/risk profile for PAS-LAR treatment in this patient population.

Pituitary apoplexy in GH-deficient adults treated with GH – a KIMS database retrospective study

Serban Radian[1], Peter J Jönsson[2], Cecilia Camacho-Hübner[3], Beverly M K Biller[4], Michael Buchfelder[5], Ann-Charlotte Åkerblad[3] & Márta Korbonits[1]
[1]William Harvey Research Institute, Queen Mary University of London, London, UK; [2]Pfizer Health AB, Sollentuna, Sweden; [3]Endocrine Care, Pfizer Inc., New York, New York, USA; [4]Massachusetts General Hospital, Boston, Massachusetts, USA; [5]Department of Neurosurgery, University of Erlangen-Nürnberg, Erlangen, Germany.

Background
Pituitary apoplexy (PitApo) has significant associated-morbidity and its management is not yet standardised.
Aim
To describe prevalence and characteristics of PitApo patients in GH deficient (GHD) patients compared with two control populations.
Patients and methods
Patients with 'infarction-apoplexy' GHD aetiology code were identified from Pfizer International Metabolic Database (KIMS). Baseline characteristics, GH dosage and 1-year response to GH replacement of PitApo patients were compared with non-functioning pituitary adenoma (NFPA, $n=3828$) and Sheehan's syndrome ($n=495$) control groups.
Results
We identified 151 PitApo patients (0.96% of 15.809 GHD patients), including eight PitApo reported as adverse events during KIMS. Median age at GHD diagnosis was lower in PitApo than NFPA (47.8 vs 51.8 years, $P<0.01$) and higher than Sheehan's patients (42.5 years, $P<0.001$). Gender distribution was similar in PitApo and NFPA groups (68.2% vs 60.8% males). There were no differences in dose between groups regardless of oestrogen use. The proportion of GH-naïve/semi-naïve patients with normal IGF-I after 1 year of GH replacement was similar between PitApo and NFPA (80.4% vs 82.5%) and lower in Sheehan's (57.8%, $P<0.0001$ vs PitApo). Median IGF-I SDS 1-year increase was similar in PitApo and NFPA (1.61 vs 1.92) and higher in Sheehan's (2.59, $P<0.05$ vs PitApo). Mean age/gender-adjusted serum total cholesterol decreased from baseline in PitApo (-0.76 mmol/l) vs NFPA (-0.32 mmol/l, $P<0.05$) and Sheehan's patients (-0.19 mmol/l, $P<0.05$), while LDL- and HDL-cholesterol changes did not differ. AGHDA-QoL-score reduction (indicating improved QoL) was similar in PitApo and NFPA (-4.33 vs -3.76 points) and higher than Sheehan's patients (-1.58 points, $P<0.01$ vs PitApo).
Conclusions
In this large cohort of patients with pituitary apoplexy, representing $<1\%$ of GHD patients overall, GH dose and treatment effects were comparable to NFPA controls, except for greater reductions in serum lipids, while Sheehan's controls attained normal IGF-I less frequently and their QoL improved less.
Disclosure
KIMS is sponsored by Pfizer, Inc. SR is a Marie Curie IEF postdoctoral fellowship recipient (grant no. 303006/2011).

Psychological and neurocognitive evaluation in patients with pituitary adenoma

Elisa Sala[1,2], Barbara Zarino[3], Elena Malchiodi[1,2], Elisa Verrua[1,2], Giulia Carosi[1,2], Marco Locatelli[3], Paolo Rampini[3], Giorgio Carrabba[3], Anna Spada[1,2] & Giovanna Mantovani[1,2]
[1]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [2]Endocrinology and Diabetology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]Unit of Neurosurgery, Fondazione IRCCS C Granda Ospedale Maggiore Policlinico, Milan, Italy.

Reduced health-related quality of life (HRQoL) and impairment in neurocognitive functions are a possible complaint in patients with pituitary adenoma. Psychiatric comorbidities in Cushing's disease are well known. However recent studies showed HRQoL reduction and psychiatric symptoms in patients with pituitary disease with or without hormonal excess. Aim of this study is to analyse HRQoL, psychiatric symptoms and neurocognitive functions in patients with pituitary adenomas, with either Cushing's disease or non-functioning pituitary adenoma (NPFA) before and after surgery. Through three validated questionnaires (SF-36, BDI-II, MMPI-II) and an interview with a psychologist, we assessed HRQoL, psychiatric symptoms and neurocognitive functions in 20 adult patients (age 49.6 ± 11.4, M/F = 12/8) harboring pituitary tumors (ten Cushing's disease and ten NPFA, macro/micro = 12/8). We conducted a baseline measurement before transphenoidal surgery as well as after 12 months. All Cushing's patients were in remission at the follow-up visit and pituitary deficiencies, when present, were adequately substituted. 20 healthy subjects, age- and sex-matched, were analysed as controls. Regarding HRQoL, patients with NFPA did not show significant differences compared to controls. On the contrary, patients with Cushing's disease had significantly lower HRQoL than NFPA and controls in all scales of SF-36 questionary, both at baseline and at follow-up. At follow-up NFPA patients showed an improvement in all scales while patients with Cushing improved only in role-physical and general health ones. Furthermore, BDI-II and MPI-II scales showed a significant increase of depression ($P=0.045$) and social inversion ($P=0.031$) in the Cushing's group. Lastly, both groups of patients, without any difference, showed a significant impairment in all neurocognitive functions tests at baseline compared to controls. At follow up, though, the difference had disappeared. According to the literature, this study confirms that Cushing's disease leads to a much larger impact on HRQoL and psychiatric comorbidities, with significant improvement after treatment but without a complete remission, probably due to irreversible changes in neural function. Interestingly, however, neurocognitive impairment is present and appears in all patients with pituitary tumors, independently of hormone secretion.

Macroprolactinomas invasive and its response to treatment in women. Cali - Colombia cohort study

Paula Andrea Velásquez[1,2], Adriana Mayor[1,2] & Alin Abreu[1]
[1]Centro Medico Imbanaco, Cali, Valle del Cauca, Colombia; [2]Universidad Libre, Cali, Valle del Cauca, Colombia.

Background
Orolactin-producing tumours are the most frequent pituitary tumours, representing 40% of these tumours, with an annual incidence of 6–10 cases/million. $<10\%$ are macroprolactinomas, which vary by age and gender, with female to male ratio of 10:1, however, less diagnosed in this population group.
Objective
To describe clinical features and therapeutic response of 30 women with invasive macroprolactinoma.
Methods
Follow a cohort of 30 patients was performed, aged 18–47 years, in Imbanaco Endocrine Clinic Medical Center in Cali, Colombia, between 2002 and 2012. Demographic and clinical characteristics were analysed; signs, symptoms, hormone levels, surgery and complications. Univariate analysis to estimate proportions and measures of central tendency was performed according to the nature of the variable. Treatment success was defined as a decrease in time macroprolactinomas size, measured by NMR and decrease in serial serum prolactin. Parametric tests were used to compare serum prolactin and tumor size Fisher Snedecor's F was applied.
Results
The mean age was 35 years, and BMI 28. The symptoms were; 96.7% headache, menstrual disorders, 90, 80% hipopituarismo, visual disorder 76.7% decreased libido 73.3% Galactorrhoea/asthenia 70%, infertility 60, 30% unilateral amaurosis. Trans-cranial 16.7, 43.3% trans-sphenoidal surgery, 23% of patients started with bromocriptine, of these 10% used it as monotherapy, 13% remaining, cabergoline should start. 86% received only cabergoline. Regarding complications presented 20% empty sella, 3.3% rinoliquia. With statistically significant differences ($P<0.0001$) measurements at 6 and 12 months in the three diameters relative to the benchmark, like serum prolactin.
Conclusion
Interventions Patients were successful in 100% of cases.

Trial design of phase IIIb, open-label, single arm study to evaluate efficacy and safety of pasireotide LAR in patients with inadequately-controlled acromegaly despite treatment with first-generation somatostatin analogues

Monica R Gadelha[1], Alberto M Pedroncelli[2], Albert Kandra[2], Karina Hermosillo Reséndiz[3] & Anna Maria Colao[4]
[1]Division of Endocrinology, Medical School and Hospital Universitário Clementino Fraga Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [2]Novartis Pharma AG, Basel, Switzerland; [3]Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, USA; [4]Dipartimento di Medicina Clinica e Chirurgia, Università Federico II di Napoli, Naples, Italy.

Introduction
The present study is designed to evaluate the efficacy and safety of pasireotide-long-acting release (LAR) in patients with acromegaly inadequately controlled after ≧3 mo treatment with the maximal approved doses of first-generation SSAs.
Methods
Phase IIIb, multicentre, single-arm, open-label study.
Patients
Adults (N∼112) with inadequately controlled acromegaly (mean GH > 1 μg/l and IGF-1 > 1.3xULN) despite receiving octreotide-LAR (30 mg/40 mg depending on the country) or lanreotide-ATG (120 mg) for ≧3 mo.
Design
Run-in phase (≧3 mos): patients on octreotide-LAR 30 mg despite the availability of the 40 mg dose at the time of screening will enter a run-in receiving three injections of octreotide-LAR 40 mg/28 day. Core phase (wk0-36): starting dose of pasireotide-LAR: 40 mg/28 day. GH and IGF-1 evaluated every 12 week and dose increased to 60 mg/28 day in uncontrolled patients (mean GH > 1.0 μg/l and/or IGF-1 > ULN) if no tolerability issues. Dose will remain unchanged in biochemically controlled patients. Dose decrease is permitted for safety reasons. During the extension phase (wk36–72), concomitant medications used to treat acromegaly are allowed if patients are uncontrolled on pasireotide 60 mg/28 day. Safety and tolerability will be assessed throughout the study.
Endpoints
Primary: proportion of patients with GH < 1 μg/l and IGF-1 < ULN at wk36; supporting analyses for primary endpoint will be performed in two patient subgroups by mean GH level at screening (GH: 1–2.5 μg/l, GH > 2.5 μg/l). Secondary: change in mean GH (five-point profile over a 2-h period), IGF-1xULN from study baseline to wk36; proportion of patients overall and by mean GH level at screening with GH < 1 μg/l and IGF-1 < ULN at wk12 and 24; GH < 1 μg/l alone, IGF-1 < ULN alone at wk12, 24 and 36, safety and health-related quality of life.
Conclusions
This study will evaluate efficacy and safety of pasireotide-LAR in patients with inadequately controlled acromegaly after ≧3 mo treatment with maximal approved doses of first-generation SSAs. In particular, a new patient population with GH 1–2.5 μg/l not studied in the PAOLA study will be evaluated.

Thyrotropinoma – not just hyperthyroidism

Edyta Gurgul, Maria Gryczynska, Adam Maciejewski, Aleksandra Klimowicz, Dagny Lapinska & Marek Ruchala
Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland.

Thyrotropinoma is a very rare cause of hyperthyroidism. In October 2014 a 41-year-old male patient was examined for anaemia and diarrhoea. Abdomen CT scan, gastroscopy, colonoscopy and parasite tests did not reveal any abnormalities. The patient had lost 18 kg 7 years ago and his weight had been stable since then (BMI 21.3 kg/m^2). The laboratory tests revealed high TSH, normal fT_4 and low cortisol level. The patient referred to our department presented with diarrhoea, velvet skin, loss of facial, chest, axillary and pubic hair; he admitted occasional heart palpitations. The results of insulin tolerance test showed secondary adrenal insufficiency. Other laboratory results were: TSH 13.56 μIU/ml (no increase in TRH stimulation test), fT_3 12.57 pmol/l, fT_4 55.55 pmol/l, low FSH, LH, DHEA-S, testosterone, GH and IGF-1 levels. Pituitary MRI demonstrated a solid intra- and suprasellar pituitary macroadenoma (25 mm) with sphenoid and cavernous sinus invasion and optic chiasm dislocation. Thyroid ultrasound showed low echogenicity of thyroid gland. Densitometry revealed osteoporosis. Diarrhoea resolved on gluten-free diet (suspected coeliac disease). ASCA antibodies were positive (suspected Crohn disease). The gastroenterological diagnosis has not been clearly stated. We introduced octreotide injections every 4 weeks, hormonal replacement and osteoporosis therapy. TSH, fT_3 and fT_4 still remain above upper limit of normal. Control pituitary MRI will be performed in February 2015 and the patient will be qualified for neurosurgical treatment. We conclude that clinical image of thyrotropinoma may be confusing due to coincident symptoms of pituitary deficiency and potential concomitant diseases. Optimal diagnosis and treatment require a multidisciplinary approach.

Introduction
The PAOLA study in patients with inadequately-controlled acromegaly ($n = 198$) demonstrated superior efficacy of pasireotide long-acting release (LAR; 40 mg/60 mg) in biochemical control (GH < 2.5 μg/l and normalized IGF-1) vs continued treatment with octreotide LAR 30 mg/lanreotide Autogel 120 mg (15.4% and 20.0% vs 0%). Here we report preliminary data from the extension phase of PAOLA at wk28.
Methods
Pasireotide-LAR (40 mg/60 mg) patients who were biochemically controlled at wk24 (core phase) continued with the same double-blind pasireotide LAR dose whereas uncontrolled patients started open-label pasireotide LAR 60 mg. Uncontrolled patients in the active-control group (octreotide LAR/lanreotide Autogel) patients crossed over to open-label pasireotide LAR 40 mg. Key efficacy endpoints at extension wk28 were i) proportion of patients with biochemical control ii) proportion of patients with GH < 2.5 μg/l or normal IGF-1 alone. Safety and tolerability were evaluated.
Results
A total of 173 patients entered the extension (pasireotide LAR 40 mg, $n = 57$; pasireotide LAR 60mg, $n = 54$ by randomised dose; crossover, $n = 62$). The preliminary analysis at wk28 in all patients achieving that time point, including early discontinuation showed that the proportion of patients with i) biochemical control was 18.4% (9/49), 33.3% (15/45), and 20.0% (10/50) ii) GH < 2.5 μg/l was 38.8% (19/49), 46.7% (21/45), and 42.0% (21/50); normal IGF-1 was 32.7% (16/49), 37.8% (17/45), and 24.0% (12/50), in the pasireotide LAR 40 mg-, pasireotide LAR 60 mg-, and crossover arm, respectively. Safety findings were consistent with the ones in the core phase; most common adverse events were hyperglycaemia, diabetes mellitus, cholelithiasis, and diarrhoea.
Conclusions
The preliminary data in patients achieving wk28 indicate that pasireotide LAR maintained biochemical control during the extension in patients with inadequately-controlled acromegaly; ∼20% of the active-control patients achieved biochemical control after crossing over to pasireotide in the extension.

No new safety signals were identified during the extension. These findings suggest that pasireotide LAR is a viable, long-term treatment option for patients with acromegaly.

Ongoing, open-label, multicenter, expanded-access study demonstrating the safety and efficacy of pasireotide sc in patients with Cushing's disease

Luiz R Salgado[1], Günter K Stalla[2], Tania Longo Mazzuco[3], Eliza B Geer[4], Alberto M Pedroncelli[5], Moncy Ye[6], Albert Kandra[5] & Padiporn Limumpornpetch[7]

[1]University of São Paulo Medical School, São Paulo, Brazil; [2]Department of Internal Medicine, Endocrinology and Clinical Chemistry, Max Planck Institute of Psychiatry, Munich, Germany; [3]Health Sciences Centre, Universidade Estadual de Londrina, Londrina, Brazil; [4]Icahn School of Medicine at Mount Sinai, New York, New York, USA; [5]Novartis Pharma AG, Basel, Switzerland; [6]Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, USA; [7]Prince of Songkla University, Hat Yai, Thailand.

Background

Pasireotide (Signifor®), a multireceptor-targeted somatostatin analogue, was initially approved in Europe and the USA in 2012 for treating adult patients with Cushing's disease for whom surgery is not an option/has failed. This 'expanded-access' study allowed patients to receive pasireotide until regulatory approval was obtained in their country, and collected further safety/efficacy data. Here we report an interim analysis of this ongoing study.

Methods

Adult patients with confirmed Cushing's disease were enrolled; all had mean 24-h UFC > ULN. Patients initiated pasireotide at 600/900 μg sc bid; dose could be increased or decreased in 300 μg increments to a minimum of 300 μg for tolerability issues/sustained UFC normalization, or to a maximum of 900 μg. Patients remain in the study until pasireotide becomes commercially available in their country or 31/12/15, whichever occurs first. The primary objective was to assess the safety of pasireotide; changes in UFC and clinical signs/symptoms in patients with available measurements at weeks 12, 24 and 48 were evaluated as secondary objectives.

Results

As of 31/7/14, 97 patients enrolled (mean age 42.2 ± 12.8 years). Median exposure to pasireotide was 23.6 weeks (range 1–131). 22 patients (22.7%) are still on study and 29 (29.9%) have completed; 46 (47.4%) discontinued: primary reasons were AEs ($n=16$), unsatisfactory therapeutic effect ($n=13$), consent withdrawal ($n=13$) and other ($n=4$). Most AEs were mild/moderate; most common: nausea ($n=48$; 49.5%), diarrhoea ($n=46$; 47.4%), hyperglycaemia ($n=38$; 39.2%). At weeks 12, 24 and 48: 35/71 (49.3%; 95% CI 37.2–61.4), 24/49 (49.0%; 34.4–63.7) and 11/27 (40.7%; 22.4–61.2) patients had UFC < ULN; 40/71 (56.3%; 44.1–68.1), 26/49 (53.1%; 38.3–67.5) and 11/27 (40.7%; 22.4–61.2) had UFC decrease ≥50% from baseline. Improvements were observed in signs/symptoms, including facial rubor, supraclavicular/dorsal fat pads, striae and bruising.

Conclusions

This study provides further evidence that pasireotide effectively decreases UFC levels and improves clinical signs/symptoms, with a generally favourable safety profile, in patients with Cushing's disease.

Is there a role for the 24 h GH profile in the assessment of acromegaly?

Robert D'arcy, Patrick Bell, Hamish Courtney, David McCance, Steven Hunter & Karen Mullan

Regional Centre for Endocrinology and Diabetes, Royal Victoria Hospital, Belfast, UK.

Recent Endocrine Society guidelines advocate IGF-1, random GH and nadir GH after oral glucose tolerance test (OGTT) for assessment in acromegaly. In our regional centre the 24 h GH profile has also been used partly because of changing IGF-1 assay methodology but also because of concerns that IGF-1 may not adequately reflect partial therapeutic success. We evaluated 58 GH profiles in 35 patients from April 2008 to November 2012 when both GH and IGF-1 assays remained unchanged. Samples were drawn every 2 h from 0800 to 0800 (13 time points) and matched with OGTT and IGF-1. In 20 patients paired profiles were available pre and 3 month postoperatively. Correlation between the mean 13 and five point (0800–1600) profile was strong ($r=0.98$, $P<0.01$). Correlations between the mean 13 point profile and nadir GH on OGTT and IGF-1 were also moderate-strong ($r=0.96$, $P<0.01$ and $r=0.65$, $P<0.01$ respectively). Preoperatively there was full concordance between 0800 GH and IgF-1 and GH profiles. Six patients had discordant results postoperatively (high 0800 GH ≥1 μg/l; normal IGF-1). Three of these had a 13 point mean of <1 μg/l. In the five patients with high 0800 GH (≥20 μg/l) preoperatively reductions in GH postoperatively were considerable (88–99%) and in one patient mean GH was <1 μg/l. In these five patients IGF-1 was not normalised being modestly reduced (34-64%) and in one patient, elevated by 33%.

Conclusions

GH profiling is not necessary in assessing the majority of patients with acromegaly if there is confidence in the local IGF-1 assay. When undertaken, a five point profile is adequate. In patients with high 0800 GH values profiling may more adequately reflect therapeutic effect than IGF-1. Further work is needed to explore the role of the GH profile in stratifying patients with discordant IGF-1 and GH results postoperatively.

Cone beam computed tomography reveals altered trabecular bone structure in acromegaly

Andrea Giustina[1], Gherardo Mazziotti[1], Michele Maddalo[2], Filippo Maffezzoni[1], Stefano Frara[1], Ivan Zorza[2], Pierantonio Soldini[2], Francesco Doglietto[3] & Roberto Maroldi[2]

[1]Endocrinology, University of Brescia, Brescia, Italy; [2]Radiology, University of Brescia, Brescia, Italy; [3]Neurosurgery, University of Brescia, Brescia, Italy.

Over the last years, there has been evidence that acromegaly may cause skeletal fragility with high risk of vertebral fractures. The diagnostic approach to this complication is still a matter of uncertainty, since DXA measurement of bone mineral density (BMD) does not provide reliable information on fracture risk in acromegaly. The cone beam computed tomography (CBCT) technique offers three-dimensional images for the radiographed area with the advantage to use non-dedicated equipments as compared to the peripheral Quantitative Computed Tomography. The aim of this study was to investigate whether a non-dedicated CBCT system may provide information on the skeletal abnormalities caused by acromegaly. Twenty-two patients with acromegaly (12 females, ten males; mean age 62 years, range 25–72) and 16 healthy control subjects (six females and ten males; mean age 59 years, range 25–68) were studied using high resolution CBCT system (Newtom 5G; QR, Verona, Italy) at the distal radius. All acromegaly patients were also evaluated for DXA BMD at lumbar spine, total hip, femoral neck and distal radius. Patients with acromegaly showed lower trabecular bone volume fraction (BV/TV) ($P=0.001$) and mean trabecular thickness (Th.mean) ($P=0.001$) and greater mean trabecular separation (Sp.mean) ($P=0.01$), without significant difference in cortical thickness ($P=0.47$) as compared to the control subjects. In acromegaly patients, the duration of active disease significantly correlated with BV/TV (r: −0.69; $P=0.001$), Th.mean (r: −0.46; $P=0.05$) and Sp.mean (r: 0.47; $P=0.04$). In acromegaly patients, the BMD at distal radius significantly correlated with cortical thickness ($r=0.56$; $P=0.007$), whereas the BMD at either skeletal site was not significantly correlated with the trabecular parameters. In acromegaly patients, the distal radius CBCT reveals significant alterations of physiological trabecular bone structure which may be responsible for their high risk of fragility fractures even in the presence of normal BMD.

Cabergoline test as a predictor for long term therapy management of hyperprolactinaemia

Andra Caragheorgheopol[2], Iuliana Busila[1], Ruxandra Dobrescu[2], Adriana Gogoi[2] & Corin Badiu[1,2]
[1]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania; [2]'C.I.Parhon' National Institute of Endocrinology, Bucharest, Romania.

Objective
To determine if the response to one single dose of 0.5 mg cabergoline (CAB) can be used as predictor for choosing personalized therapy of hyperprolactinaemia. Although CAB is a selective, long half-life D2-receptor agonist some patients proved to be resistant with minimum to no response in serum prolactin and tumour shrinkage, even after a few months of treatment.
Patients and methods
A dose of 0.5 mg CAB was administered orally to a number of 53 naive patients, in a prospective interventional study. Based on hyperprolactinaemia two groups were selected: the first group of 38 patients with prolactinoma and a second group of 15 patients with other causes of hyperprolactinaemia, who served as control. In the prolactinoma group all cases were prospectively evaluated, starting a maintenance phase with 2–3 mg cabergoline twice a week for at least 6 months. This second phase allowed us to divide the prolactinoma group into sensitive and resistant cases: 31 proved to be sensitive and seven resistant to CAB, when comparing the results of serum prolactin dosage and tumour shrinkage on CT/MRI scan. The main test consists of a first phase when a single dose of CAB is administered and the serum prolactin is measured at basal, 12 and 48 h comparing these results. For a more complete understanding and analysis of linkage mechanism the plasma CAB levels were also measured using a mass-spectrometry based method. The instrumental analysis was performed on a HPLC tandem mass-spectrometer in the multiple-reaction monitoring method (MRM).
Results
CAB determined prolactin decrease in both sensitive and resistant cases but with a significant difference. In sensitive prolactinoma the decrease showed to be from 2781 to 1099 ng/ml at 12 h (which means almost with 60%, $P=0.001$), 1075.1 ng/ml at 24 h and 843.63 at 48 h. The highest decrease was registered at 12 h after CAB administration. In resistant prolactinomas, the decrease went from 3675.7 ng/ml basal value to 2043 ng/ml at 12 h, 1679.71 at 24 h and 1586.6 ng/ml at 48 h (which means lower than 45% in the first 12 h). In the control group the decrease was also much smaller. In the follow up time: one patient with small response at CAB test proved to be long-time therapy responsive and another one with prolactin decrease on CAB test, proved to develop partial response in long time treatment. Meanwhile, CAB pharmacokinetics showed the highest value at 12 h, which was 9.50 pg/ml, with 6.44 pg/ml at 24 h and 4.73 pg/ml at 48 h.
Conclusions
CAB test can provide information about the sensitivity to treatment for a better future management and good results, which is allowing patients to receive personalized therapy in adapted method and time duration. Anyway, further studies with larger study population should be done in order to completely understand all possible determinants of a better or a more accurate therapy response.

Renal function in acromegaly

Christine Pichl, Sylvère Störmann, Matthias Pichler & Jochen Schopohl
Klinikum der Universität München, Medizinische Klinik und Poliklinik IV
Mailing adress: Ziemsenstraße 1, Munich, Germany.

Introduction
Acromegaly is a rare disease resulting from GH excess mostly due to pituitary adenomas. It is associated with changes of most organ systems and multiple comorbidities. The impact of GH and IGF-I excess on renal function in acromegaly is unclear.
Methods
We investigated 66 acromegalic patients from our outpatient clinic (32 female, 34 male, mean age 61.5 ± 12.9 years, women 10 years older than men). The renal function was assessed by blood and urine tests, ultrasound and blood-gas analysis.
Results
38 patients were considered biochemically controlled according to latest recommendations on criteria for cure of acromegaly (IGF-I in age- and gender-specific reference range, random basal GH <1 ng/ml). 12 patients were partially controlled (IGF-I up to 1.3 times elevated), 16 biochemically active. 61% of the patients have hypertension (68% of the controlled, 75% of the partially and 31% of the uncontrolled patients), 21% of the patients presented with diabetes mellitus, 11% have both. The distribution between the sexes was balanced. According to the Cystatin C formula ($GFR(CysC) = 77.24 \times \text{Cystatin C}^{-1,2623}$) 39 patients (59%) presented with reduced glomerular filtration rate (GFR $<$ 90 ml/min). 50% of the patients have a chronic kidney disease stage 2 (GFR 60–89 ml/min), 9% stage 3 (GFR 30–59 ml/min). Despite their higher age the median GFR of the female patients is 4 ml/min higher (82.4 vs 86.4 ml/min). The median GFR of hypertonic patients is 21.6 ml/min lower than in patients without hypertension (80.8 vs 102.4 ml/min). There is no significant difference between the GFR of controlled, partially and not controlled patients in our patients (81.9 vs 89.5 vs 84.1 ml/min).
Conclusion
We found a reduced renal function (GFR $<$90 ml/min) in 59% of acromegalic patients. The disease activity has no effect on GFR as determined by Cystatin C formula.

Successful treatment of huge pituitary macroadenoma secreting TSH and GH

Agnieszka Adamska, Agnieszka Zapora-Kurel & Maria Gorska
Department of the Endocrinology, Diabetology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland.

Introduction
The mixed tumor which secretes an excess of both GH and TSH causing acromegaly and hyperthyroidism is rare. The main problem is the late diagnosis, especially in men, even 10 years after the occurrence of the first symptoms.
Case report
A 53-year-old men, was admitted to the our department, with complaints of excessive sweating and enlargement of the hands. His medical history included arterial hypertension. Past medical history revealed thyroidectomy 20 years ago. Physical examination showed typical signs of acromegaly and nodules in both lobes of the thyroid gland. Performed laboratory test revealed elevated plasma concentrations of the PRL levels: 79.52 (0–29 ng/ml), IGF1: 593 (87–267 ng/ml) and lack of the suppression of GH after 75 g glucose (6.67 ng/ml). Additionally, we observed central hyperthyroidism: fT_4: 3.09 (0.7–1.48 ng/ml), fT_3: 17.49 (1.45–3.48 pg/ml) and TSH level: 6.095 (0.35–4.94 mU/ml) with normal anti-TPO: 0.4 (0–4.1 ng/dl). Diagnosis was confirmed by dynamic testing with TRH. An ultrasound scan of the thyroid showed a multinodular goitre. MRI revealed a large pituitary macroadenoma measuring $5 \times 6 \times 6$ cm with left cavernous and sphenoid sinus invasion, with compression of the optic chiasm, the third ventricle as well as the brainstem. Firstly, patient was treated with thiamazol, octreotide LAR and bromocriptine during 6 months. Then, he proceeded twice to the transsphenoidal resection of the pituitary macroadenoma with consecutive partial reduction of the tumor mass. After neurosurgery laboratory signs of hyperthyroidism resolved but serum GH was still elevated. Currently, the patient is under octreotide LAR therapy.
Conclusions
We presented an unusual case with a huge pituitary macroadenoma secreting TSH and GH who was successfully treated with transsphenoidal adenomectomy. This case showed that despite of symptoms and size of mixed tumour, diagnosis could be missed for the long time. On the other hand, the proper preparation for surgery, lets avoid the complications during the perioperative period.

Management of Cushing's disease: single centre experience

Mirsala Solak[1], Ivana Kraljevic[1], Tina Dusek[1], Ante Melada[2], Marcel Marjanovic Kavanagh[3], Vjerislav Peterkovic[2], David Ozretic[4] & Darko Kastelan[1]
[1]Department of Endocrinology, Center of Neuroendocrinology Zagreb, Zagreb, Croatia; [2]Department of Neurosurgery, Center of Neuroendocrinology Zagreb, Zagreb, Croatia; [3]Department of Otorinolaringology, Zagreb, Croatia; [4]Department of Radiology, University Hospital Center, Zagreb, Croatia, Zagerb, Croatia.

Introduction
Cushing's disease (CD) is an uncommon condition of excess endogenous glucocorticoids caused by ACTH secreting pituitary corticotroph adenoma.

The purpose of this study is to review therapeutic outcomes and comorbidity of patients with CD in a single centre.
Methods
We conducted a retrospective study of 33 patients with CD undergoing transsphenoidal surgery from January 2007 to February 2014. (27 female and six male, median age 38 years, range 18–71 years). The diagnosis of Cushing's syndrome was established on the basis of the patient's history, characteristic clinical features and laboratory data, including elevated 24-h urinary free cortisol (UFC) level, lack of serum cortisol suppression after suppression tests (1-mg overnight dexamethasone suppression test and/or 2 mg-2 days dexamethasone suppression test) and elevated midnight cortisol level. In 28/33 patients tumor was visualised on MR of sellar region, while in five it was diagnosed using an inferior petrosal sinus sampling.
Results
Ten patients had macroadenoma, the remaining 23 had microadenoma. Twenty-one patients (63.6%) had hypertension, 17 (51.5%) dyslipidemia, while 7 (21.2%) had type 2 diabetes or Impaired Glucose Tolerance. Median follow-up period was 58.3 months. Remission after transsphenoidal surgery was achieved in 78.8% of patients, while seven patients failed to achieve disease remission. They were treated with second-line treatment modalities (second operation, radiotherapy, bilateral adrenalectomy and/or ketoconazole). One patient rejected all treatment modalities after surgery.
Conclusion
Cumulative remission after all treatment modalities was achieved in 93.9% patients. Two female patients had recurrence of hypercortisolism. The results of our Centre are comparable to leading centers in the world.

Post-operative serum cortisol levels as predictors of recurrence in Cushing's disease

Diana Martins[1], Daniela Guelho[1], Isabel Paiva[1], Carla Baptista[1], Nuno Vicente[1], Luís Cardoso[1], Diana Oliveira[1], Margarida Balsa[2] & Francisco Carrilho[1]
[1]Endocrinology, Diabetes and Metabolism Department of Coimbra Hospital and University Centre, Coimbra, Portugal; [2]Endocrinology, Diabetes and Nutrition Department of Baixo Vouga Hospital Centre, Aveiro, Portugal.

Introduction
Cushing's disease (CD) is characterized by increased secretion of ACTH often as a result of a pituitary adenoma. The surgical success rates after transsphenoidal pituitary surgery (TSS) range from 53 to 96% in different centres. Postoperative cortisol levels have been proposed as the standard criteria for prediction of surgical remission however, this variable is subject of a variety of interferences.
Objectives
Evaluate the potential of post-transsphenoidal pituitary surgery cortisol levels to predict surgical remission and recurrence of CD.
Methods
Retrospective cohort study of patients with clinical and biochemical diagnosis of CD, submitted to TSS and followed in our centre between 1977 and 2013 ($n=84$). Patients who lost follow-up or with insufficient data on their personal records were excluded ($n=51$). Statistical analysis: SPSS(21).
Results
Thirty three patients, 29 (87.9%) women, with a median age of 33 years were included. All patients underwent TSS as first treatment option and were followed postoperatively during a median period of 8 (1–28) years. Eighteen (57.8%) patients achieved disease remission after the first treatment, 11 (33.3%) presented recurrence and 3 (9.1%) patients had persistent disease. Post-operative morning cortisol levels were lower in cured patients than in patients with recurrent or persistent disease (5.3 vs 8.1 vs 16.1 μg/dl, respectively, $P<0.05$). It was also observed an inverse correlation between morning serum cortisol levels and time free of disease ($r=-0.81$, $P<0.01$). We verified that cortisol levels at midnight were significantly different in the immediate post-operative evaluation than in the evaluation at 1 month and a half (5.30 ± 7.58 μg/dl vs 4.20 ± 6.84 μg/dl, $P<0.01$) . However both evaluations of midnight cortisol correlated significantly with the number of recurrences ($P<0.01$).
Conclusions
Serum cortisol levels can be a predictor of recurrence risk and also influence in time free of disease. However, midnight serum cortisol levels can fluctuate significantly in time.

Endocrine manifestations of Langerhans cell histiocytosis

Luis Cardoso[1], Leonor Gomes[1,2], Dírcea Rodrigues[1,2], Carolina Moreno[1,2], Daniela Guelho[1], Nuno Vicente[1], Margarida Balsa[3], Diana Martins[1], Diana Oliveira[1] & Francisco Carrilho[1]
[1]Department of Endocrinology, Diabetes and Metabolism, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [2]Faculty of Medicine, University of Coimbra, Coimbra, Portugal; [3]Department of Endocrinology, Centro Hospitalar do Baixo Vouga, Aveiro, Portugal.

Introduction
Langerhans cell histiocytosis (LCH) is a rare disorder characterized by proliferation/accumulation of cells phenotypically similar to skin Langerhans cells. Clinical presentation and aggressiveness are very heterogeneous, from benign to disseminated forms that cause significant morbi-mortality, particularly endocrine failures.
Case 1: A 15-year-old Caucasian woman presented with a 14-month history of headaches, secondary amenorrhea. She reported polyuria and polydipsia in the last 2 years. Secondary evaluation revealed hypogonadism hypogonadotrophic, central hypothyroidism, and a 1 cm suprasellar lesion. Surgical excision of the lesion was performed, though histologic examination was inconclusive, and pan-hypopituitarism developed after surgery. Radiotherapy was prescribed due to persistent disease. Two years later, biopsy of recurrent vulvar ulcers revealed HCL. Subsequent studies showed active disease in the vulvar region, thyroid and hypothalamic–pituitary axis, which remitted after several cycles of vulvar radiotherapy, and systemic chemotherapy with prednisolone, methotrexate, and vinblastine (PDN/MTX/VBA).
Case 2: A 37-year-old Caucasian man presented with a 6-month history of otalgy, otorrhea, weight loss, and skin brown maculo-papular rash. He reported polyuria and polydipsia in the previous five years. Secondary evaluation revealed pan-hypopituitarism and a suprasellar mass of 2 cm. Temporal bone biopsy revealed HCL. Patient was treated.
Case 3: A 60-year-old Caucasian woman presented with 6-month history of jaw pain and weight loss. Secondary evaluation revealed polyostotic HCL and the patient was treated with zoledronic acid. Three years later the patient complained of headaches, polyuria, and polydipsia. Complimentary evaluation revealed diabetes insipidus, hypogonadism hypogonadotrophic, central hypothyroidism, and pituitary stalk enlargement. All patients required permanent hormonal substitution for the failed HPA sectors.
Conclusion
All cases described had hypothalamo-pituitary axis involvement with pituitary failure. The dominant manifestation was diabetes insipidus. If not treated promptly LCH may have a considerable morbi-mortality with permanent endocrine failures, that require proper hormonal substitution. Relapses may occur and appropriate follow-up is recommended.

High BMI in female patients with prolactinomas

Irena Ilovayskaya, Alexander Dreval, Yulia Krivosheeva, Irina Chikh & Galina Stashuk
Moscow Regional Research and Clinical Institute N.A. M.F. Vladimirskiy, Moscow, Russia.

We analysed BMI of 270 female patients: 148 with hyperprolactinaemia (non-tumoural hyperprolactinaemia, $n=46$; microadenomas, $n=56$; and macroadenomas, $n=46$), 55 with isolated central hypogonadism, 67 with hypopituitarism. Additionally, 53 healthy women of reproductive age and 51 postmenopausal women were examined. In patients with hyperprolactinaemia median prolactin levels were 1547 (1124; 2185), 1490 (1050; 2280), and 3100 (1790; 18840) mE/l, accordingly ($P=0.002$). Median BMI in hyperprolactinaemic women was elevated (25 (23; 34.5) kg/m^2) but this parameter varied in dependence of hyperprolactinaemia type: BMI was 22.5 (20; 23) kg/m^2 in non-tumoural hyperprolactinaemia, 23 (22; 34.5) kg/m^2 – in microprolactinomas and 32 (26; 35) kg/m^2 – in macroprolactinomas ($P=0.023$). There was no significant correlation between BMI and prolactin levels; however, there was a positive correlation between BMI and prolactinoma volume ($r=0.49$, $P=0.015$). BMI in women with nontumoral hyperprolactinaemia did not differ from healthy women (21 (20; 23.5) kg/m^2, $P=0.8$) and women with isolated central hypogonadism (22.2 (20; 23.8) kg/m^2, $P=0.6$). BMI in women with microprolactinomas was significantly higher than in healthy women and in non-tumoral hyperprolactinaemia ($P=0.03$) however was comparable with hypopituitary patients (24 (22.7; 27.3) kg/m^2, $P=0.33$) and postmenopausal women (24.4 (23.2; 27.1) kg/m^2, $P=0.35$). The highest BMI was noted in patients with macroprolactinomas and

it was significantly greater than BMI in other hyperprolactinaemic and non-hyperprolactinaemic subgroups ($P<0.001$ for all). Thus, we conclude that hyperprolactinaemia *per se* is not a risk factor for obesity in women. Prolactin-secreting pituitary lesions lead to the higher rate of increased BMI, and macroprolactinomas are more powerful risk factor for obesity than physiological menopause or hypopituitarism.

Study of the prevalence and related factors in the withdrawal of medical treatment macroprolactinomas

Lorena Suarez Gutierrez[1], Maria Galiana Rodriguez Caballero[2], Cecilia Sanchez Ragnarson[2], Nuria Valdes García[2], Laura Cacho García[2] & Edelmiro Menendez Torre[2]
[1]Hospital of Cabueñes, Gijón, Spain; [2]University Hospital of Asturias, Oviedo, Spain.

Introduction
The prolactinoma is the most common functioning pituitary tumour. There are few long-term studies on the optimal duration of treatment with dopamine agonists prolactinoma to ensure healing without recurrence after stopping the medication and do not provide a consensus on it or on withdrawal criteria treatment.
Objectives
To establish the prevalence of withdrawal of treatment macroprolactinomas and evaluate criteria prolactinoma cure medical treatment and analysing the possible factors involved.
Methods
Retrospective study of 77 patients diagnosed and treated for prolactinoma in the Service Endocrinology of University Hospital of Asturias, from 1982 to 2012. Only 56 patients were treated exclusively with dopamine agonists and the rest were excluded. Of these 40 patients continue with treatment and 16 patients were withdrawn from treatment (eight men and eight women) after verifying the suppression of prolactin (PRL) levels and the disappearance of the pituitary mass. In 28.6% removal treatment and 44.6% could meet criteria.
Results
The withdrawal of treatment was on average after 11.01 ± 7.36años (2.26–26.8) normalization of prolactin. After removal medical treatment was resumed in 50% patients at 1, 6, 12, and 60 months respectively. The cause of restarting treatment was in all the elevation of plasma PRL levels. No significant differences between withdrawal and not withdrawn for age, sex, prolactin levels presuspension, initial tumour size, type of response, and dose of agonist withdrawal.
Conclusions
Following the withdrawal of treatment with dopamine agonists after an average of 10 years under normal PRL and almost complete tumour shrinkage was reintroduce 50% of the patients in our series. Re-introduction why treatment was in all cases prolactin elevation. No tumour regrowth in any of the control images. We observed no relation to either the initial size nor PRL figures presuspension or other predictors by the limited sample size.

The effect of gonadotropin treatment on insulin resistance and cardiovascular risk factors in patients with idiopathic hypogonadotropic hypogonadism

Yasin Simsek[1], Kenan Guclu[2], Gulden Baskol[2] & Fahri Bayram[1]
[1]Department of Endocrinology, Erciyes University, Kayseri, Turkey; [2]Department of Biochemistry and Clinical Biochemistry, Erciyes University, Kayseri, Turkey.

Introduction
Idiopathic hypogonadotropic hypogonadism (IHH) is a rare disorder characterised by delayed or absent sexual maturation and infertility associated with inappropriately low gonadotropin and sex steroid levels. Insulin resistance (IR) is defined as an impaired biologic response to both endogenous and exogenous insulin. IR is a common precursor to the development of glucose intolerance, including diabetes, hypertension, and cardiovascular disease. Dyslipidaemia, apolipoprotein B-100 (ApoB-100), homocysteine, ApoA1, and high sensitive C-reactive protein (hsCRP) are another risk factors on coronary artery disease. We aimed to to look at the role of gonadotropin replacement treatment in development of IR and other cardiovascular risk factors in patients with IHH.
Materials and methods
Twenty-four male patients with untreated IHH were enrolled into the study. IR was calculated by the homeostasis model assessment of IR (HOMA-IR) form. Plasma glucose, insulin, hsCRP, homocysteine, ApoA1, ApoB-100, LDL-cholesterol (LDL-C), HDL-cholesterol (HDL-K), triglyceride (TG), total cholesterol (TC) levels were measured in fasting blood samples, and biochemical and hormonal analyses were performed for all study participants before and after treatment.
Results
Before and after gonadotropin replacement, HOMA-IR were 3.12 ± 1.44 and 1.98 ± 1.48; LDL-C levels were 110.8 ± 33.7 and 91.8 ± 27.6 mg/dl respectively. There was a statistically significant difference between HOMA-IR ($P=0.001$) and LDL-C levels ($P=0.004$). However, there was no statistically significant differences among other parameters ($P>0.05$).
Conclusions
Gonadotropin replacement can significantly improve patients' insulin sensitivity and decrease serum LDL-C levels. Therefore, gonadotropin replacement may prevent developing diabetes mellitus and cardiovascular diseases in future.

Clinical features and treatment outcomes of resistant acromegaly patients: a single-centre study

Özgür Demir, Asena Gökçay Canpolat, Berna Imge Aydoğan, Çağlar Keskin, Şule Canlar, Mustafa Şahin, Rifat Emral, Sevim Güllü, Vedia Tonyukuk Gedik, Ali Riza Uysal & Demet Çorapçioğlu
Department of Endocrinology and Matabolism, Ankara University Faculty of Medicine, Ankara, Turkey.

Introduction
Disease control in acromegaly can be achieved by surgery, medical treatment, and radiotherapy either alone or in combination. The acromegaly patients whom tumour shrinkage cannot be provided or growth hormone levels do not decrease under multiple treatment modalities are designated as resistant acromegaly. We aimed in our study to evaluate the clinical features of resistant acromegaly patients and determine their responds to different treatment modalities.
Methods and results
47 acromegaly patients were enrolled between 2007 and 2015 in this study. 18 of patients (ten men and eight women) were accepted as resistant acromegaly according to their clinical course. The median age, median tumour size and mean IGF1 levels at diagnosis were found 36.5 (28–62), 21 mm (12–70), and 1184 ± 567 ng/ml respectively. The mean numbers of their operation and radiation were found 2 (0–3) and 1 (0–1). Of these 18 procedures, 15 were transsphenoidal procedures and three involved transfrontal surgery. Histological evaluation revealed exhibition of sparse granular staining in eight patients. Long acting somatostatin analogue therapy dose was increased in three patients. Cabergoline (0.5–2 mg/week) and pegvisomant therapy were added to their somatostatin analogue therapy in five and ten patients respectively. The mean follow-up was 18 ± 4 months. There were no difference found between these tree treatment modalities. IGF1 normalisation was achieved overall in 94% of resistant acromegaly patients.
Discussion
Resistance to traditional treatment options in acromegaly represents 25% of whole cases. We found a similar ratio as 39% in our case series. Resistant group was found to be diagnosed at younger age, with greater dimensions of tumour and found to have more sparse granular staining compatible with literature. We could not find any differences between IGF1 levels. It is also a debate as whether which treatment option is suitable for resistant patients.

A rare case of GH deficiency: mucolipidoses type II/III

Elena Braha[1,2], Ioana Armasu[2], Cristina Rusu[1], Daniela Raileanu[3], Adina Manolachie[2], Georgiana Constantinescu[2], Mirela Puiu[2], Roxana Stefan[2] & Carmen Vulpoi[2]
[1]Department of Genetics, University of Medicine and Pharmacy 'Gr.T. Popa', Iasi, Romania; [2]Department of Endocrinology, University of Medicine and Pharmacy 'Gr.T. Popa', Iasi, Romania; [3]County Hospital, Botosani, Romania.

Introduction
Mucolipidoses II/III (ML) are rare autosomal recessive lysosomal storage disorders (incidence: 1/325 000 live births). They have overlapping clinical phenotypes with mucopolysaccharidosis disorders and include growth retardation, facial dysmorphism, skeletal abnormalities, respiratory and heart diseases, hepatosplenomegaly and abdominal hernias. There is no specific treatment and the management has been limited to supportive care.
Case presentation
A Manolachie aged 18, boy of an young non-consanguineous apparently healthy couple, in evidence of the Genetics Department for mucopolysaccharidosis type I, was first addressed to the Endocrinology Department at the age of 14 years 4 months for investigations of growth retardation. The clinical examination revealed short stature (-4 S.D.), 'elf' facies, limited extension and abduction of the upper limbs with bilateral tendon retraction of the fingers and also in the radiocarpal and elbow joints, decreased mobility of the spine and waddling walk with wide support base; no signs of pubertal onset. Wrist radiography revealed delayed bone age of $\sim$6 years. Somatotropic axis investigations revealed low IGF1 (62.4 ng/ml, $n=220$–972, GH $=0.42$ ng/ml, without stimulation at the arginine test: GH $=2.75$ ng/ml) pleading for GH deficiency. Since there were not known contraindications, GH replacement therapy was started with an initial dose of 0.035 mg/kg per day and biannual reassessments were performed. After 4 years of treatment the medium growth rate was 0.42 cm/month and no side effects were reported. The last wrist radiography revealed delayed bone age (11 years and 6 months) permitting treatment continuation. At the last evaluation the enzymes α-iduronidase, iduronate-2-sulfatase, arylsulfatase B, β-galactosidase could be assessed and were indicative of MLV II/III.
Conclusions
Corroborating the clinical phenotype, biological data and evolution, this case can be included in MLV III. We haven't found in the literature any case of MLV III treated with GH replacement therapy. In our case the treatment was effective and improved the patient's quality of life.

Performance of early cortisol measurements post transphenoidal surgery in predicting ACTH sufficiency as assessed by dynamic testing

Christopher McAlpine[1], Aikaterini Theodoraki[1], Anne Dawnay[1], Neil Dorward[2], Joan Grieve[2] & Stephanie Baldeweg[1]
[1]University London College Hospital, London, UK; [2]National Hospital For Neurology and Neurosurgery, London, UK.

Background
After pituitary surgery patients require HPA axis assessment, that is achieved with postoperative cortisol measurements and, in selected patients whose post-operative cortisol measurements are inconclusive, with the insulin tolerance test (ITT) and the glucagon stimulation test (GST).
Aim
We aimed to assess the performance of the day 2/3 post-operative cortisol in predicting the HPA axis sufficiency as assessed by the ITT and the GST.
Methods
Retrospective review of all pituitary surgical records done in 2004–2014 in a tertiary centre.
Results
71 patients met the inclusion criteria, out of which 41 (57.7%) had an ITT and 30 (42.3%) a GST. 0900 h cortisol measurements on day 2/3 postoperatively did not differ between the patients having an ITT or a GST (353 ± 188 vs 348 ± 194, P 0.85). Peak cortisol measurements post dynamic testing were 549 ± 218 for ITT and 458 ± 241 for GST. ROC curve analysis showed that day 2/3 postoperative cortisol of $\leq$142 nmol/l was 100% (84–100%) sensitive in detecting patients that would fail the ITT, with 31% (14–56%) specificity, and a cut-off of $\geq$470 nmol/l was 94% (69–100%) specific in identifying patients with ACTH sufficiency with 32% (17–52%) sensitivity. When applying the same cut-offs in GST, a day 2/3 cortisol of $\leq$142 nmol/l was 93% (62–100%) sensitive in detecting patients that would fail the GST, with 28% (12–51%) specificity, and a cut-off of $\geq$470 nmol/l was only 78% (54–91%) specific in identifying patients with ACTH sufficiency with 50% (26–75%) sensitivity.
Conclusion
After pituitary surgery a day 2/3 postoperative cortisol of $\leq$142 nmol/l detects all patients with ACTH insufficiency, and a cortisol of 470 nmol/l excludes ACTH insufficiency.

Acquired male hypogonadotropic hypogonadism in a type 2 diabetes patient revealing empty sella

Hela Marmouch[1,2], Tasnim Slim[1], Fadia Boubaker[1], Sondes Arfa[1], Sameh Graja[1,2], Hanene Sayadi[1,2], Manel Jmal[1,2] & Ines Khochtali[1,2]
[1]Department of Internal Medicine–Endocrinology, Monastir, Tunisia; [2]Faculty of Medicine, Monastir, Tunisia.

Introduction
Empty sella in male patients is a very rare situation. It could be diagnosis in acquired male hypogonadotropic hypogonadism or hypopituitarism.
Case report
A 55-year-old type 2 diabetes male was referred to our hospital with erectile dysfunction (ED). He has three children. His secondary sex characteristics, sexual function, and ejaculation were previously normal but for the last 3 years he had ED. His genital stage was Tanner V, and pubic hair stage was Tanner III. There were no varicoceles. The diabetes was poorly controlled (Hb1Ac $=9\%$). His hormonal data were LH 1.1 mIU/ml (normal: 2–8 mIU/ml), FSH 1.8 mIU/ml (2–12 mIU/ml), testosterone 1.2 ng/ml (3–7 ng/ml), and FT_4 13 pmol/l (10–20 pmol/l). The rate of PSA was normal. Magnetic resonance imaging of the head revealed slight depression of the diaphragma sellae, indicating an 'empty sella'. We diagnosed acquired hypogonadtropic hypogonadism related empty sella. A replacement androgen therapy was introduced. Twelve months after hormone replacement therapy, the ED wasn't disappear but the quality of life of this patient was better.
Discussion
ED is common in type 2 diabetes men poorly controlled. It may reveal endocrine dysfunction such as acquired functional male hypogonadotropic hypogonadism (MHH). Pituitary MRI is frequently normal.
Conclusion
In this observation, we report a common situation in type 2 diabetes patient which revealed a rare case of acquired MHH due to empty sella. Pituitary MRI is interesting in acquired MHH and can reveal multiples others endocrine deficiency.

Early postoperative basal cortisol level as good predictor of hypothalamic–pituitary–adrenal axis function after transsphenoidal surgery for pituitary tumours

Tanja Skoric Polovina[2], Mirsala Solak[2], Ivana Kraljevic[2], Tina Dusek[1,2], Maja Baretic[2] & Darko Kastelan[1,2]
[1]Zagreb University School of Medicine, Zagreb, Croatia; [2]University Hospital Center Zagreb, Zagreb, Croatia.

Accurate assessment of the hypothalamic–pituitary–adrenal (HPA) axis is important for the appropriate management of patients with pituitary tumours after transsphenoidal surgery. The aim of our study was to evaluate the clinical relevance of the early postoperative basal cortisol level in assessing postoperative HPA axis function. We performed a retrospective analysis of 68 patients (male:female $=36:32$, age 59.5 years, range 21–77) treated by transsphenoidal surgery between September 2011 and October 2014 at our centre of neuroendocrinology (44 nonfunctioning pituitary adenoma, 15 somatotrophinomas, five symptomatic Rathke's cleft cysts bigger than 15 mm, three craniopharyngeomas, and one macroprolactinoma resistant to medical therapy). Patients with Cushing's disease were excluded as well as patients with preoperative HPA insufficiency. Early postoperative basal cortisol levels (measured on the second postoperative day) and a Synacthen stimulation test (performed 10–12 weeks after the operation with a peak cortisol level of $>$550 nmol/l considered as normal response) were analyzed to assess HPA axis function during follow-up. We found that basal cortisol level of $\geq$249.5 nmol/l measured on the second day after the operation is a sensitive and accurate predictor of normal postoperative HPA axis function, with a sensitivity of 87.8%, and a specificity of 52.6%. Our data suggest that early postoperative cortisol level of $\geq$249.5 nmol/l predicts distant, normal postoperative HPA axis function following transsphenoidal surgery.

A case of adrenal crisis secondary to ipilimumab-induced autoimmune hypophysitis

Anna Todd & Athinyaa Thiraviaraj
Altnagelvin Area Hospital, Londonderry, UK.

A 42-year-old man undergoing ipilimumab therapy for stage IV metastatic melanoma presented after his third dose with vomiting, abdominal pain, hypotension, and pyrexia. He was treated as a presumed line sepsis. Four days prior to admission, thyroid function test showed T_4 of 7.9 pmol/l and TSH 0.02 mU/l and he was treated with levothyroxine. A pituitary profile was carried out on admission and the results were as follows, cortisol was 24 nmol/l, testosterone <0.2 nmol/l, LH 1.5 U/l, FSH 5.1 U/l, and prolactin 135 mU/l. Pituitary profile had been normal at start of treatment. Acting on the above results he was commenced on hydrocortisone and clinically improved rapidly. CT brain found no abnormality in the pituitary region. MRI showed an atrophic pituitary with homogenous enhancement, normal stalk and a preserved posterior pituitary bright spot. Given the finding of new pan-hypopituitarism he was treated as an adrenal crisis secondary to ipilimumab related autoimmune hypophysitis, despite lack of pituitary or stalk enlargement on imaging. There is no consensus in the literature on how to manage ipilimumab related hypophysitis. Some centres advocate high dose i.v. or oral steroids, while other centres feel that steroids do not affect the outcome. Our patient was treated with high dose i.v. methylprednisolone therapy followed by a rapidly reducing dose of oral prednisolone therapy. He had symptomatic improvement from this, but continues to demonstrate pan-hypopituitarism at assessment 3 months after treatment. This case describes adrenal crisis secondary to immune related hypophysitis caused by ipilimumab and management of it with i.v. methylprednisolone. Frequency of immunotherapy for treating solid organ tumours is increasing and clinicians need to be aware of these life threatening side effects and their treatment.

Glucose homeostasis alterations in Cushing's disease: epidemiology, anthropometric assessment and the role of family history of type 2 diabetes

Przemyslaw Witek[1], Joanna Witek[2,3], Grzegorz Zielinski[3], Marlena Blazik[4] & Grzegorz Kaminski[1]
[1]Department of Endocrinology and Isotope Therapy, Military Institute of Medicine, Warsaw, Poland; [2]Diabetes Outpatient Clinic, Institute of the Mother and Child, Warsaw, Poland; [3]Department of Neurosurgery, Military Institute of Medicine, Warsaw, Poland; [4]Paediatric Outpatient Clinic, Warsaw, Poland.

Introduction
Cushing's disease (CD) leads to glucose homeostasis alterations, obesity, unfavorable changes in body composition and cardiovascular complications.
Aim of study
i) Prospective evaluation of the frequency of pre-diabetes and diabetes. ii) Assessment of insulin resistance (IR) indices in CD. iii) Analysis of the influence of family history of type 2 diabetes (T2D) on the anthropometry in CD.
Methods
The study group included 47 patients with CD (37 women and ten men, aged 43.1 ± 14.6). Waist and hip circumferences, BMI, and body fat content were recorded. Glucose and insulin levels during an oral glucose tolerance test (OGTT) were assessed. HOMA-IR, QUICKI, and Matsuda indices were calculated. Patients previously diagnosed with diabetes were examined exclusively for fasting glucose and HbA1c.
Results
Sixteen patients (34%) had diabetes, another 18 (38.3%) had pre-diabetes. Hypertension was confirmed in 37 patients (78.7%). Mean total fat content was 34.52 ± 10.64 kg and trunk fat was 17.49 ± 5.18 kg. Mean BMI was 30.9 ± 6.6 kg/m^2. Obesity was confirmed in 23 patients (48.9%) and overweight in 17 (36.2%). In patients with hypertension trunk fat was higher than in the normotensive group (18.38 ± 4.87 kg vs 14.25 ± 5.2 kg, $P<0.05$). Positive family history of T2D was found in 15 patients (32%). It was associated with a greater hip circumference (114.37 ± 17.84 cm vs 102.81 ± 9.6 cm, $P<0.05$) compared to those without T2D in the family history. Matsuda and QUICKI indices were higher in patients without concomitant glucose homeostasis alterations than in patients with pre-diabetes (4.01 ± 2.04 vs 2.08 ± 0.92, $P=0.001$ and 0.338 ± 0.034 vs 0.311 ± 0.024, $P=0.01$ respectively). There was no significant difference with regards to HOMA-IR (2.78 ± 1.44 vs 5.33 ± 4.82, $P=0.08$).
Conclusions
i) Glucose homeostasis alterations were observed in 70% of patients with CD. ii) We confirmed the association between the presence of arterial hypertension and trunk fat content. iii) The family history of T2D may be associated with a higher risk of obesity in CD. iv) Matsuda index contrary to HOMA-IR may be a more sensitive marker of IR in CD.

Cushing's disease: reversibility of glucose homeostasis alterations and improvement in insulin resistance indices following a successful, transsphenoidal surgery

Joanna Witek[1,2], Przemyslaw Witek[3], Grzegorz Zielinski[2], Marlena Blazik[4] & Grzegorz Kaminski[3]
[1]Diabetes Outpatient Clinic, Institute of the Mother and Child, Warsaw, Poland; [2]Department of Neurosurgery, Military Institute of Medicine, Warsaw, Poland; [3]Department of Endocrinology and Isotope Therapy, Military Institute of Medicine, Warsaw, Poland; [4]Paediatric Outpatient Clinic, Warsaw, Poland.

Introduction
Cortisol excess in Cushing's disease (CD) leads to glucose homeostasis alterations and increased cardiovascular risk.
Aim of the study
i) To assess the reversibility of glucose homeostasis alterations and dynamics of inflammatory and coagulation parameters after the successful transsphenoidal surgery (TSS) for CD. ii) Analysis of the early improvement in insulin resistance (IR) indices following TSS.
Methods
The group consisted of 26 patients (22 women and four men; aged 41.5 ± 13.3) with early remission of CD. Anthropometric parameters, glucose, and insulin levels during an oral glucose tolerance test (OGTT), HbA1c, hsCRP, fibrinogen, and D-dimers were assessed prior to, and 3 months after TSS. HOMA-IR, QUICKI, and Matsuda indices were calculated. Patients previously diagnosed with diabetes were assessed exclusively for fasting glucose and HbA1c.
Results
Four patients (15.4%) had been diagnosed with diabetes prior to CD confirmation. Five patients (19.2%) were diagnosed with diabetes based on OGTT results prior to surgery. Ten patients (38.5%) were diagnosed with impaired glucose tolerance. A significant decrease in OGTT parameters was confirmed: fasting blood glucose (95.9 ± 17.4 mg/dl vs 83.8 ± 13.4 mg/dl, $P<0.05$), mean blood glucose (155.4 ± 34.1 mg/dl vs 117.3 ± 21.6 mg/dl, $P<0.0001$), 60-min glucose (182.6 ± 45 mg/dl vs 135.8 ± 30.6 mg/dl, $P<0.001$), and 120-min glucose (161.5 ± 52.2 mg/dl vs 118.7 ± 33.9 mg/dl, $P<0.05$). The Matsuda index and QUICKI improved significantly (2.8 ± 1.8 vs 5.2 ± 3.6, $P<0.01$ and 0.32 ± 0.03 vs 0.35 ± 0.04, $P<0.05$ respectively). Three months after TSS decrease in BMI and reduction in waist and hip circumference were not significant. No differences were observed with regards to mean, fasting and 120-min insulin levels, HbA1c, HOMA-IR, hsCRP, D-dimers, and fibrinogen.
Conclusions
i) Three months following successful TSS for CD significant decrease in fasting, mean and 120-min OGTT glucose levels could already be seen. ii) The Matsuda index and QUICKI might be more sensitive IR indices in the early postoperative period compared to commonly used HOMA-IR. iii) To demonstrate improvement in anthropometric parameters, insulin levels during OGTT, inflammatory and coagulation parameters, a longer follow-up may be required.
Disclosure
The studies were partly supported by the grant of Military Institute of Medicine No. 1/8807(258)/2013.

Post-operative ACTH and cortisol values and its correlation with long-term clinical features in Cushing's disease

Celia Rios Perez[1], Carmen Fajardo Montañana[1,2], Pablo Abellan Galiana[3,4], Pedro Riesgo Suarez[1], Jose Gomez Vela[1], Carlos Messeguer Escriva[1], Enrique Molla Olmos[1], Gisela Alaman Laguarda[1], Jose Luis Llacer Ortega[1] & Jose Piquer Belloch[1,2]
[1]Facultad de Medicina, Universidad Católica San Vicente Martir (UCV), Valencia, Spain; [2]Hospital Universitario de La Ribera, Alzira, Spain; [3]Hospital General Universitario, Castellon, Spain; [4]Facultad de Medicina, Universidad CEU Cardenal Herrera, Castellon, Spain.

Introduction
It has been described that early post-operative cortisol value <2 μg/dl might predict long-term remission while ACTH value has been less described.
Objective
To study early post-operative ACTH and cortisol levels in Cushing's disease patients as predictor factor of long-term remission.
Patients
61 consecutive patients (12 men/49 women), mean age 42.6 years (17–86 years) undergoing transphenoidal hypophysectomy for Cushing's disease from 2005 to 2014 in our hospital. Mean followed-up period 32.1 ± 23.6 months. Post-operative ACTH and cortisol were measured, without replacement treatment, every 4–6 h. We study early clinical features, hormone values, radiological images, histological and surgical findings and clinical outcome at the end of the follow-up period.
Results
54 patients (88.5%) met clinical criteria for remission (97.3% micro, 77.7% macro, and 66.6% without MRI). Total surgical adenoma removal was performed in 86% patients (except six partial resections and two hemihypophysectomy based on cathetherism result). After initial surgery, post-operative serum cortisol was undetectable (<2 μg/dl) in 40 patients (27 micro, ten macro, and three without MRI). Recurrence was observed in 12/54 (22.2%) of the patients, 19.3 ± 12.2 months after achieving disease-remission, with a higher ACTH nadir value after surgery (25.9 ± 15.6 pg/ml vs 9.9 ± 8.8 pg/ml; $P=0.005$) and a long time to achieve cortisol nadir <2 μg/dl (58.9 ± 24.4 months vs 40 ± 20.6 months; $P=0.044$), while there were not differences in cortisol nadir value, adenoma size, sex, and age between recurrence and remission patients.
Conclusions
Intraoperative identification and selective removal of the pituitary adenoma, even if they were not identified by preoperative MRI, correlated with initial clinical remission in our patients. Early post-operative cortisol and ACTH measurements (without hormonal therapy replacement) have a prognostic value. Cortisol level <2 μg/dl has a curative predictive value in patients with Cushing's disease while a higher ACTH value after surgery and a long time to achieve cortisol nadir can predict recurrence.

EP832

Who needs pre-operative medical blockade for Cushing's disease?

Elisabeth Trapp, Julia Prague & Ben Whitelaw
King's College Hospital, London, UK.

The definitive treatment for Cushing's disease is curative surgery. Patients with severe disease burden will likely require pre-operative medical blockade to reduce the risk of peri- and post-operative complications. The threshold for deciding when to medically block excess cortisol is currently based on clinical judgment. Expert centres may use a different criteria to determine this. There is no widely adopted tool for evaluating the clinical severity of Cushing's disease.
Methods
We retrospectively identified 30 consecutive patients diagnosed with Cushing's disease who proceeded to transphenoidal surgery. Using the Sonino Cushing's severity index (CSI) we then retrospectively calculated each patient's clinical severity disease score by reviewing their medical notes.
Results
All 30 patients (100%) had sufficient information documented in their medical records to enable retrospective calculation of their CSI score (mean 5.8, range 0–10). Twenty-three percent (7/30) received pre-operative medical blockade. Of the seven patients who received blockade: five received metyrapone alone, one ketoconazole alone, and one received both metyrapone and ketoconazole. The mean duration of blockade was 14 weeks (range 2–30). The mean CSI of patients deemed to need pre-operative blockade was 7.9 compared to 5.2 in the patients who were deemed to not need prior optimisation ($P=0.017$). Only one of 18 patients (6%) with a CSI <7 was prescribed blockade. Six of the 12 patients (50%) with a SCI in the range ≥ 7 received medical blockade.
Conclusion
We report our recent practice which shows that patients with a CSI of <7 are very unlikely to require pre-operative medical blockade. However, CSI of 7–9 will often be an indication for blockade and CSI of ≥ 10 is highly likely to be an indication. As such this scoring system with these associated cut off values could easily be utilised in clinical practice to guide medical decision making and facilitate comparison outcomes between expert centres.

Sarcoidosis in a 53-year-old women followed for a refractory thyroid carcinoma: a misleading association

Philippe Thuillier, Nathalie Roudaut, Véronique Kerlan & Sonnet Emmanuel
CHRU BREST, Brest, France.

Sarcoïdosis is a relatively frequent systemic disease of unknown origin. Prevalence is about 4.7–64 in 100 000. We report the case of a 53-year-old woman followed in our institution since 2007 for a thyroid carcinoma. In 2010, she was diagnosed refractory thyroid carcinoma because of a high thyroglobulin assay (477 μg/l) without uptake on post-therapeutic (^{131}I) whole body scan. Thereafter, the story is marked by the appearance in 2011 of multiple cervical and mediastinal lymph nodes, pulmonary and bones lesions. Bones lesions were treated with surgery, additive radiation therapy and cementoplasty. Between 2011 and 2013, we observed pulmonaries lesions progression with an aspect of lymphangitic carcinomatosis. In early 2013, morphologic evaluation showed the appearance of multiple lymph nodes (hepatic hilum, inguinal bilaterally). Biologically, we noted a slight increase of thyroglobulin assay (711 μg/l). In May 2013, a tyrosine kinase inhibitor, Sorafenib 400 mg twice a day was started. Six months later, a therapeutic evaluation was performed. TEP–TDM showed a majoration of mediastinal, abdominal, and inguinal lymph nodes and pulmonary lesions uptakes (SUV max 12.8) and an intense splenic uptake. Biologically, thyroglobulin assay remained paradoxically stable (673 μg/l). Because of this atypical presentation for a thyroid metastasis disease (lymphangitic carcinomatosis, unusual splenic metastasis, and stable thyroglobulin assay) and past history of breast cancer, a biopsy of a left inguinal lymph node was finally performed. Histological analysis demonstrated an aspect of epitheloid cell granuloma reaction with no caseous necrosis. This aspect was consistent with the diagnosis of sarcoidosis. Sorafenib was discontinued and a corticotherapy was started, enabling an improvement of respiratory symptoms. TEP–TDM performed in April 2014 showed a disappearance of all lymph nodes, pulmonaries, and splenic uptakes. In conclusion, sarcoidosis should be considered in case of atypical thyroid metastatic disease, when presentation is consistent with this diagnosis.

What are the delays in the management of thyroid cancer?

Dave F N Fung & Sebastian Aspinall
North Tyneside General Hospital, Newcastle, UK.

Introduction
This audit aims to evidence the compliance of our practice with guidelines on the management of thyroid cancer. This may help to promote quality improvement in areas where there is substandard clinical care and service provision.
Method
In this retrospective study, patients diagnosed with thyroid cancers at our unit between 2009 and 2014 were identified. Electronic records were examined to establish the dates of referral, clinic attendance, investigations, and treatment, allowing us to determine whether patients received timely assessment and treatment. The quality of our ultrasound reporting and inadequacies of cytological assessment were also documented. A comparison was made against standards as proposed by the British Thyroid Association.
Results
There were 37 cases of thyroid cancer. 18 patients presented with a symptomatic thyroid nodule, five as incidental radiological findings and 14 as incidental pathological findings. Of the 23 cases with suspicious thyroid nodules, 11 were

not seen in clinic within 2 weeks of referral and eight did not have first definitive treatment within 62 days. The mean time to their diagnostic fine-needle aspiration (FNA) was 32 days. Of the 30 ultrasound scans completed, 23 were performed prior to Endocrine Clinic. However, none of these reports included all suggested features for risk stratifying thyroid nodules. Of the 41 FNA performed, 12 yielded inadequate specimens. The mean time to a repeat FNA was 104 days.
Conclusion
There was a considerable proportion of inadequate FNA specimens and thyroid nodules were poorly classified on ultrasound reporting. This may be why there was a significant lag period to a diagnostic FNA with subsequent delays to management. We recommend ultrasound assessment for risk stratification of all thyroid nodules and that this is clearly reported. In addition, any inadequate specimens should have a repeat FNA urgently under ultrasound guidance.

EP835

Ectopic ACTH secretion by metastatic medullary thyroid carcinoma

Faiza Qari
King Abdulaziz University, Jeddah, Saudi Arabia.

A 45-year-old male known case of sporadic medullary thyroid carcinoma with metastasis to lymph nodes and bone. He underwent total thyroidectomy and modified neck dissection and external radiation in 2003. He was admitted with MTC which was progressive with rising calcitonin from 9000 to 40 000 μg/l. He underwent urgent tracheostomy and assessed by ENT and found to have bilateral vocal cord palsy. Patient improved; however on further assessment he was found to have severe proximal muscle weakness and he is unable to stand from sitting position.

Hormonal assay	Patient
ACTH	61 pg/ml
Serum cortisol (am)	↑ 1089 nmol/l
Serum cortisol (pm)	↑ 1004 nmol/l
24 h U for free cortisol	562 nmol/l
Dexamethasone suppression test	No suppression

Radiological investigations
Pituitary MRI is normal. MRI spine thoracic show multiple bony mets with no cord compression. Bilateral inferior petrosal sinus sampling (IPSS) for ACTH levels. CRH + vasopressin stimulation: ACTH 117 – max response 127 nmol/-cortisol 1003 – max response 1045 nmol/l.
Discussion
The diagnosis is ACTH-dependant Cushing's syndrome. The most likely the underlining cause of this condition in this patient is due to ectopic ACTH secretion by metastatic medullary thyroid carcinoma.

Thyroid malignancy concurrent with hyperthyroidism: variations with thyroid status and age

Nadeesha Nawarathna[1], Navam Kumarasinghe[1], Deepthika Chandrasekara[1], Shamali Balasooriya[2], Aruna Shaminda[1] & Ranjith Senevirathne[1]
[1]Teaching Hospital, Kandy, Sri Lanka; [2]University of Peradeniya, Peradeniya, Sri Lanka.

Introduction
Thyroid malignancy associated with hyperthyroidism is considered rare. Retrospective studies have shown the incidence of thyroid malignancy in hyperthyroid patients to be low (0.7–8.5%). To assess the clinical relevance of this association, thyroid status in a cohort of patients with thyroid malignancy were analysed.
Method
Thyroid malignancies diagnosed histologically in 56 patients, over a 18-month period beginning from April 2013, in a single surgical unit at Teaching Hospital Kandy were included. Preoperative patient details and progression of thyroid status were asessed with TSH, free thyroxine, and free triiodothyronine levels.
Results
Amongst 56 patients papillary carcinoma was diagnosed in 44 (78.6%), follicular carcinomas in 7 (12.5%), and 5 (8.9%) with medullary and anaplastic carcinomas. 12 (21.4%) were males and 44 (78.6%) were females. 20 (35.7%) were <40 years, 29 (51.8%) were between 40 and 59 years and 7 (12.5%) were above 59 years. Cross tabulation of type of carcinoma with gender revealed likelihood ratio of 6.908, significance $P=0.032$. Biochemically 12 (21.4%) were hyperthyroid. Out of them 5 (41.7%) had primary hyperthyroidism and 7 (58.3%) had secondary hyperthyroidism. Mean age of euthyroid patients was 43.77 years (S.D. 10.574) and hyperthyroid patients was 53.25 years (S.D. 16.057). Independent samples *t*-test is -2.446, two tailed significance $P=0.018$. When cross tabulate thyroid status with age group likelihood ratio was 9.640, significance $P=0.008$.
Conclusion
Papillary carcinoma is seen more among females. Among the patients with thyroid carcinomas, those with biochemically proven hyperthyroidism were more among the older age group than those who were euthyroid. Hence, careful evaluation of elderly hyperthyroid patients to select the most suitable therapeutic approach is justified.

Comparable ablation outcome between second and third ablation doses of 30 mCi radioactive iodine (^{131}I) in patients with papillary thyroid cancer

Khaled Salman[1], Safwan Zatary[2], Shereen Wagieh[3], Maha Abd-El Kareem[4], Yasser Mohammad[4], Sherif Abd-El Razek[5] & Manal Al-Ezzi[3]
[1]Nuclear Medicine Department, King Abdulla Medical City (KAMC), Mekka, Saudi Arabia; [2]Endocrinology Department, King Abdulla Medical City (KAMC), Mekka, Saudi Arabia; [3]Nuclear Medicine Department, King Abdulla Medical City (KAMC), Jeddah, Saudi Arabia; [4]Nuclear Medicine Department, Cairo University Hospital, Cairo, Egypt; [5]Assuit University Hospital, Assuit, Egypt.

Introduction
Complete ablation of residual thyroid tissue in patients with papillary thyroid cancer decreases locoregional recurrence, distant metastases and cancer death. No single group achieved 100% complete ablation post first ablation dose with variable successful complete ablation rate. In patients who failed to achieve complete ablation a reablation dose is recommended to have complete ablation outcome. Post second ablation dose some patients still have small residual thyroid tissue in the neck, that warrants small third ablation dose of ^{131}I to achieve complete ablation.
Aim
The aim of the current study is to compare ablation outcome post 30 mCi ablation dose of ^{131}I used as a second and as a third ablation dose.
Patients and methods
Retrospective analysis of data of 372 patients with papillary thyroid cancer confined to the thyroid gland referred post total thyroidectomy for ^{131}I ablation was performed. All received first ablation dose of 100 mCi of ^{131}I. Presence of residual thyroid tissue in follow-up ^{131}I whole body scan (WBS) with elevated unsuppressed serum thryoglobulin (Tg) level indicate incomplete ablation outcome. Those patients received 30 mCi of ^{131}I reablation on outpatient basis. Patients post second ablation dose with small residual thyroid tissue in the neck seen in follow-up ^{131}I WBS 6–9 months post second ablation dose with elevated serum Tg level received a third ablation dose of 30 mCi. Follow-up WBS and Tg level were performed 6–9 months post third dose to assess ablation outcome.
Results
Complete ablation rate post first dose was reported in 249 patients (66.9%). Out of the remaining 123 patients complete ablation was achieved post 30 mCi second ablation dose in 89 patients (72.4%) with an overall complete ablation post two doses achieved in 338 patients (90.9%). A third ablation dose of 30 mCi was given to the remaining 34 patients. Complete ablation was reported in 26 patients (76.5%), with statistically insignificant difference ($P>0.05$) between complete ablation outcome using 30 mCi as a second or as a third ablation dose. Successful complete ablation post three doses of ^{131}I (total dose of 160 mCi) was achieved in 364 patients (97.8%).
Conclusion
Complete ablation outcome rate between second and third ablation doses of 30 mCi of ^{131}I are comparable with no statistically significant difference.

Well-differentiated thyroid cancer: the Philippine General Hospital experience

Tom Edward Lo, Abigail Uy & Patricia Deanna Maningat
Philippine General Hospital, Manila, Philippines.

Well-differentiated thyroid carcinoma (WDTC) is the most common thyroid malignancy. Although, associated with good prognosis, it may have a highly recurrent and fatal outcome in selected groups of patients. Filipinos in particular were reported to be the ethnic group with the highest incidence of thyroid cancer in several studies. Thyroid cancer among Filipinos were also observed to be more aggressive and recurrent in nature. This paper aims to describe the experience of a Philippine Tertiary Care Centre in managing patients with differentiated thyroid cancer. This is a retrospective cohort study of 723 patients diagnosed with WDTC (649 papillary and 79 follicular). We evaluated clinic–pathologic profile, ultrasound features, management received, clinical course, tumour recurrence, and eventual outcome during a mean follow-up period of 5 years. Mean age at presentation was 43 ± 13 for papillary thyroid cancer (PTC) and 44 ± 13 for follicular thyroid cancer (FTC). Majority of both PTC (63.2%) and FTC (54.4%) presented initially as stage 1. Greater FTC cases (12.7% vs 3.7%) presented with distant metastases with lung and bone being the most common. Nodal metastases at presentation were frequent among PTC (29.9% vs 7.6%). Majority of cases received complete thyroidectomy, subsequent radioactive iodine therapy and TSH suppression therapy which led to disease free state. Excluding patients with distant metastases at presentation, recurrence rates for papillary and follicular thyroid cancer were 30.1 and 18.8% respectively. Recurrences for PTC and FTC frequently occurred within 15–16 months from the initial post-surgical radioactive iodine therapy. PTC among Filipinos presents at a younger age, larger tumour size, higher distant metastases at presentation and a higher recurrence rate suggesting a more aggressive and recurrent behaviour for this type of thyroid malignancy. FTC among Filipinos also presents at a younger age and a higher recurrence rate but appears to behave similarly with other racial groups.

EP839

Risk factors for recurrence in Filipinos with well-differentiated thyroid cancer

Tom Edward Lo, Abigail Uy & Patricia Deanna Maningat
Philippine General Hospital, Manila, The Philippines.

The incidence of recurrent well-differentiated thyroid cancer (WDTC) continues to rise as better imaging test and more sensitive monitoring improves disease surveillance. Despite its excellent prognosis, increasing morbidity from recurrent diseases continues to affect long-term outcome of most patients leading to higher medical cost and poorer quality of life. Filipino ethnicity in particular was reported to have the highest incidence of thyroid cancer with a highly aggressive and recurrent nature. This paper aims to identify associated risk factors for recurrence among Filipinos with WDTC. This is a retrospective cohort study of 723 patients diagnosed with WDTC seen at Philippine General Hospital (PGH). Study population was divided into groups based on presence or absence of recurrence. Recurrence was considered if the patient had clinical, biochemical or radiologic evidence of cancer remnants after surgery. Multivariable logistic regression analyses were used to determine significant predictors of recurrence. 214 (32.9%) patients with papillary thyroid cancer (PTC) and 23 (29.1%) patients with follicular thyroid cancer (FTC) developed recurrence within a median interval of 13 months and 26 months from thyroidectomy respectively. Age >45 (HR $=1.44$), multifocality of cancer (HR $=1.43$), nodal involvement (HR $=4.0$) and distant metastases at presentation (HR $=2.78$) were the risk factors identified to negatively impact the risk of recurrence for PTC. Follicular variant histology (HR $=0.60$)) and post-surgical radioactive iodine ablation therapy (HR $=0.31$) were protective factors for PTC recurrence. Distant metastases at presentation (HR $=19.4$) and post-surgical radioactive iodine ablation therapy (HR0.41) were identified for FTC recurrence. Lymph node metastases at presentation was the most important predictor of recurrence in PTC while it was distant metastases at presentation for FTC recurrence. Identified recurrence factors for WDTC among Filipinos in this study will be helpful in guiding the intensity of their treatment strategies and long-term thyroid cancer surveillance aimed to reduce future morbidity and mortality.

Follicular variant of papillary thyroid carcinoma: an intermediate clinical entity

Tom Edward Lo, Abigail Uy & Patricia Deanna Maningat
Philippine General Hospital, Manila, The Philippines.

Follicular variant papillary thyroid cancer (FV-PTC) appeared to be the most common subtype representing between 9 and 22.5% of all PTC cases. With the dramatic increase in thyroid cancer incidence, FV-PTC has also been increasingly diagnosed in recent times. Despite its high incidence, the clinical behaviour, prognosis and outcome of FV-PTC remains controversial and challenging for most physicians. This study aims to compare the disease characteristics of FV-PTC with Classic-PTC and FTC in a single institution in the Philippines. This is a retrospective cohort study of 606 thyroid cancer patients diagnosed as C-PTC ($n=440$), FV-PTC ($n=87$) or FTC ($n=79$) by biopsy. Different clinical variables of three groups were then compared using a univariate logistic regression analysis. FV-PTC and C-PTC presented similarly with higher rates of multifocality (25.3% and 22.7% vs 7.6%) and bilateral involvement (20.7% and 17.1% vs 6.3%) as compared to FTC. C-PTC (37.7%) presented with high nodal involvement at presentation while both FV-PTC (8.1%) and FTC (7.6%) presented with less nodal metastases. Distant metastases was observed highest among the FTC (12.7%) group followed by FV-PTC (5.8%) and rarely in C-PTC (3.4%). Majority of patients underwent complete thyroidectomy and post-surgical radioactive iodine ablative therapy with similar rates across the groups. Recurrence rate was observed to be highest among C-PTC (39.4%) while FV-PTC (18.4%) had the lowest recurrence rate. FV-PTC resulted in almost 50% reduction (HR $=0.4934$; P value $=0.007$) in recurrence risk as compared with C-PTC. Mortality rate was highest among FTC (2.5%) group while FV-PTC (0%) and C-PTC (0.5%) had a similarly low mortality rate. FV-PTC represents a major sub-type of PTC that represents an intermediate entity between C-PTC and FTC. Although it behaves clinically like FTC presenting with lower lymph node metastases and higher distant metastases than C-PTC, its long-term survival and prognosis is quite similar with that of C-PTC. Treatment recommendations for C-PTC and FTC can be applied to FV-PTC cases.

FNAC and frozen section correlation with definitive histology in thyroid diseases

Nithianantha Mayooran, Paeder Waters, Michael Kerin & Denis Quill
University Hospital Galway, Galway, Ireland.

Introduction
The ability to diagnose thyroid cancers pre-op or intra operatively by Fine needle aspiration cytology (FNAC) or frozen section (FS) leads to the delivery of appropriate one stage surgical management. We aim to study the concordance and discordance of FNAC and FS with final histology in thyroid pathologies.
Methods
All thyroid procedures from 2007 to 2011 ($n=423$), involving FNAC and or Frozen Section (FS) in their management pathway were included. FNAC ($n=159$) were classified in a five tier system (non-diagnostic, benign, atypical, suspicious or malignant). FS ($n=128$) were classified as inconclusive, benign, suspicious or malignant. FNAC and FS were correlated with final histopathology.
Results
Out of 159 FNAC 72 (40.8%, PPV 92.8%) showed correlation with final histology. 61 (38.3%) were reported undetermined as Atypical ($n=23$), follicular neoplasm ($n=27$) or suspicious for malignancy ($n=11$). Within 61 undetermined FNAC there were 25 malignancies (40.6%) detected in final histology. Frozen sections; 104 out of 128 showed correlation (81.2%, PPV 99.0%). 15 false negative and one false positive FS were noted. Out of six suspicious FS; four showed benign pathology and two showed malignancies. There were two inconclusive FS showed malignancies in histology.
Conclusion
In conclusion, until now FNAC is considered as the best modality to triage the thyroid nodule pre operatively. Atypical and follicular neoplasm cytology categories warrants further clinical assessment and close follow ups when appear benign. The intra operative frozen sections are helpful to perform a one stage operation for suspicious thyroid lesion. This study also highlights the recognised limitation of intra operative frozen section analysis of thyroid neoplasia.

Clinical features, demographic, staging and prognostic factors in patients with microcarcinoma papillary thyroid

Rodriguez Ortega, Roldan Mayorga, Diaz Perez, Laínez López, Lopez Pérez & Rebollo Perez
Complejo Hospitalario Huelva, Hospital Juan Ramón Jiménez, Huelva, Spain.

Introduction
Papillary microcarcinomas tirodieos (MCT) are tumours less than or equal to centimeter size, mostly indectectables in the clinic and found incidentally after a thyroidectomy performed for another reason, management is under discussion and its prevalence is increased ~30%, it is believed that the increased use of thyroid ultrasound.
Review
16 patients with MCT in a province of southern Spain and evaluate the clinical and prognostic variables of our patients. Mostly women 15/1, age 44–74 years X 50. Most MCT found are incidental finding in Total thyroidectomy (TT) euthyroid BMN 13/16, other causes of surgery: Graves' disease 1/16 and 1/16 parathyroid adenoma. Hyperthyroidism 2/1. Histologically since, given the size average 4.4 mm, only one case of multifocality without capsular most or vascular invasion. In two cases has been extended thyroidectomy were no outbreaks of MCT. The capsular invasion and follicular variety associated with increased vigilance in our patients. They have only received 2/16 I131, the most aggressive. In terms of gender, our only case man is what has been presented with worse prognosis and clinical aggressiveness from the start. Our series is small, the follow-up time is short, but data obtained corroborate published prognostic factors, the most important gender, multifocality and lymphadenopathy. 2. The heterogeneity of this tumour requires us to individualise the approach, and close monitoring based on prognostic factors, to indicate the different strategies.

Clinical significance of BRAF (V600E) mutation in papillary thyroid microcarcinoma

Jisun Park & Hye Kyung Shim
Inje University Haeundae Paik Hospital, Busan, Republic of Korea.

Objective
The purpose of this retrospective study was to correlate BRAF (V600E) mutation with clinicopathological characteristics in papillary thyroid microcarcinoma (PTMC).
Methods
We reviewed the clinical records of patients who were operated for a papillary thyroid microcarcinoma (PTMC) between May 2011 and October 2012 in Inje University Haeundae Paik Hospital. We investigated the prevalence of the BRAF (V600E) mutation, and relations between the presence of BRAF (V600E) mutation and clinicopathological characteristics (age, sex, tumour size, multiplicity, lymph node status and extrathyroid tissue invasion).
Results
Total 137 patients were included; 121 (88.3%) were female and 16 (11.7%) were male patients, aged from 22 to 74 years (mean age, 46.4 years). Median tumour size was 0.56 cm, ranging from 0.10 to 0.95 cm. The BRAF (V600E) mutation was identified in 82 patients (59.9%). Sixty patients (43.8%) had capsular invasion and 32 (23.4%) presented with some kind of extrathyroidal invasion of the tumour. Thirty-six patients had lymph node metastases; 32 (23.4%) to the central neck and 4 (2.9%) to the lateral neck. Three of four patients (75%) with lateral neck node metastases had BRAF (V600E) mutation, although this was not statistically significant. No statistically significant association was found between the BRAF (V600E) mutation and clinicopathological characteristics (age, sex, tumor size, multiplicity, lymph node status, capsular invasion and extrathyroid tissue invasion) of PTMC.
Conclusion
There was no significant association between the BRAF (V600E) mutation and any of the clinicopathological characteristics. However, we have noted that the prevalence of lateral neck node metastases was more frequent in patients with BRAF (V600E) mutation than those with WT BRAF, but this trend was not statistically significant.

Follicular and papillary carcinoma in a subject with Graves' disease having aggravated orbitopathy following remnant ablation

Umut Mousa[1], Hasan Sav[1], Osman Koseoglulari[1] & Sebnem Aydin[2]
[1]Department Of Endocrinology and Metabolism, B Nalbantoglu Hospital, Nicosia, Cyprus; [2]Department of Nuclear Medicine, B Nalbantoglu Hospital, Nicosia, Cyprus.

Introduction
The risk for thyroid malignancy is higher in subjects with Graves' disease particularly papillary thyroid cancer (PTC). However, coincidence of both PTC and follicular thyroid cancer (FTC) in these subjects is rare. In this case report we present a subject with Graves' disease with a pathological diagnosis of PTC and FTC having aggravated orbitopathy following remnant ablation.
Case report
A 53-year-old subject was referred to our Endocrinology outpatient clinic with symptoms of retro bulbar pain and having TSH levels <0.05 (0.25–5.0 μIU/l) and FT4 67.3 pmol/l (10.6–19.4). The TSH receptor antibody level was 44 U/l (>9 (+)). She was negative for thyroglobulin and thyroid peroxidase antibodies. The thyroid ultrasound was reported as being compatible with thyroiditis with no visible thyroid nodule. Methimazole was initiated. 2 months after initiation of the anti-thyroid drug her eye pain increased in intensity and periorbital edema occurred. Total thyroidectomy was decided as the treatment option and early postoperatively her eye symptoms resolved. The pathology report was surprising. It was compatible with a 3 cm follicular carcinoma and a 3 mm papillary carcinoma follicular variant in the left lobe together with lymphocytic thyroiditis despite the ultrasound revealing no visible nodule. She received 100 mCi radioactive iodine for remnant ablation and glucocorticoid prophylaxis therapy was initiated. The patient lost contact and did not comply with the glucocorticoid treatment. 3 months after the radioiodine the patient admitted with diplopia, bilateral exophthalmos, chemosis, periorbital edema, spontaneous retro bulbar pane and pain on down gaze. Orbita MRI revealed bilateral thickening in the superior and lateral rectus muscles. She recently received pulse glucocorticoids therapy (7 gm in 10 weeks) and will receive orbital radiotherapy.
Discussion
Although occult microPTC is frequently observed in the thyroidectomy material of subjects with Graves' disease, it was surprising to visualize a 3 cm tumor pathologically but not radiologically. This could be explained by the very heterogeneous parenchyma masking the tumor. Aggravation of orbitopathy can be observed following remnant ablation for thyroid cancer in these subjects and glucocorticoid prophylaxis should be considered.

EP845

Malignancy risk of thyroid nodules with repeated 'atypia of undetermined significance/follicular lesion of undetermined significance' diagnosis

Berrin Cetinarslan[1], Alev Selek[1], Emine Kivrakoglu[2], Zeynep Canturk[1], Ilhan Tarkun[1], Duygu Temiz[2] & Zeynep Akyay[1]
[1]Department of Endocrinology, Kocaeli University, kocaeli, Turkey; [2]Department of Internal Medicine, Kocaeli University, kocaeli, Turkey.

Introduction
'Atypia of undetermined significance/follicular lesion of undetermined significance' (AUS/FLUS) is a heterogeneous diagnostic thyroid fine needle aspiration biopsy (FNAB) category. AUS/FLUS is comprised of cases that cannot be definitively diagnosed as benign, suspicious for/consistent with neoplasm, suspicious for malignancy or malignant. The recommended management strategy for these cases is to perform a repeat FNAB after an appropriate time course. Although the estimated risk of malignancy for AUS/FLUS is reported 5–15%, there is growing evidence in the literature that suggest higher incidence of malignancy for this category The purpose of this study is to estimate the malignancy risk of repeated AUS/FLUS diagnosis of thyroid fine needle aspiration biopsies.
Methods
We report retrospective analyses of 56 cases with repeated AUS/FLUS diagnosis among 5396 thyroid FNABs. The demographic data and histologic follow-up were evaluated in the study. Histological outcome was categorised as benign, malignant or well-differentiated tumors of uncertain malignant potential (WDT-UMP).
Results
Initial AUS/FLUS diagnosis was 5.2% of our FNAB series. Among these 63 (22%) of were diagnosed again as AUS/FLUS on repeated FNAB. Seven patients were lost during follow-up. Among 56 cases with a repeated diagnosis of

AUS/FLUS, histologic follow-up revealed 28 (50%) benign outcome, 23 (41%) malignant outcome and 5 (9%) WDT-UMP outcome. The mean age was similar in both malignant and benign groups.
Discussion
The malignancy risk of AUS/FLUS category in thyroid FNABs was higher than anticipated in Bethesda System. The malignancy risk was reported up to 43% even with single biopsy in some studies. In current study the risk was 41% in repeated AUS/FLUS diagnosis. The reported malignancy rate of follicular neoplasm or suspicious for a follicular neoplasm (FN/SFN) was 15–30%, for whom surgery is recommended management. Therefore, the management strategy of AUS/FLUS should also be revised as the malignancy rate was same or even higher than FN/SFN.

Association of calcium-stimulated calcitonin values with pathological findings following total thyroidectomy

Georgios Papadakis, Ioannis Keramidas, Eleni Triantafillou, Foteini Kanouta, Theodora Pappa, Victoria Kaltzidou, Athanasia Tertipi, Gino Vecchini, Despoina Papadouli & Anastasios Pappas
Metaxa Cancer Hospital, Piraeus, Greece, Greece.

Background and objectives
Medullary thyroid carcinoma (MTC) originates from thyroid C-cells and is a calcitonin (CT) secreting tumour with aggressive behaviour. Surgery is recommended in all patients with basal or calcium-stimulated CT values of 100 pg/ml or higher due to the high probability of MTC. The objective of this study was to investigate the utility of calcium stimulation test for CT in order to distinguish MTC from C-cell Hyperplasia (CCH) preoperatively and to examine the histological findings of thyroidectomy in patients with peak stimulated CT >100 pg/ml.
Patients and methods
A total of 52 patients with thyroid nodules and basal CT levels between 6 and 100 ng/l had a positive calcium stimulation test (peak CT >100 ng/l) and underwent total thyroidectomy.
Results
patients (35%) were diagnosed with MTC and 34 (65%) with CCH. 20 patients (38%) had a differentiated carcinoma of follicular origin (DTCf) coexistent with either MTC or CCH. Calcium-stimulated calcitonin levels >452 ng/l had the optimal sensitivity and positive predictive value for differentiating MTC from CCH.
Conclusion
A large percentage of MTC may be identified by peak stimulated CT levels >100 pg/ml preoperatively, but overlapping calcitonin levels between MTC and CCH reduce the accuracy of the test. Remarkably, many patients with peak stimulated CT levels >100 pg/ml harbour a DTCf. A probable association between C-cell disease and DTCf needs further examination.

Primary thyroid lymphoma: a heterogeneous disease and presentation of two different cases

Eleni Triantafillou, Georgios Papadakis, Ioannis Keramidas, Konstantinos Moustakas, Georgios Tsakonas, Paraskevi Manitarou, Aspasia Drosou, Olympia Tzaida, Athanasia Tertipi, Ioannis Tzaves, Aikaterini Megalakaki & Anastasios Pappas
Metaxa Cancer Hospital, Piraeus, Athens, Greece.

Background
Primary thyroid lymphoma (PTL) is a rare thyroid malignancy. Nevertheless, it frequently presents diagnostic and therapeutic challenges. We describe two patients with PTL with different clinical presentation/clinical picture and outcome.
Patients and methods
Two female patients underwent total thyroidectomy, the first, a 67-year-old female patient, because of nodular goitre and the second, a 79-year-old female patient, because of a large, painless thyroid mass accompanied by severe obstructive symptoms of the upper respiratory and gastrointestinal track.
Results
Histology of the first patient revealed lymphocytic thyroiditis and a small focus of previously unsuspected PTL, coexistent with an occult papillary thyroid carcinoma (PTC). The PTL was an incidental finding and 2 years after thyroidectomy she is free of disease without any further treatment. Histology of the second patient confirmed the clinical suspicion of PTL and established the diagnosis of a diffuse large B-cell lymphoma. Although she underwent standard chemotherapy, she died four months later.
Conclusions
PTL may have an aggressive and lethal course on the one end of the spectrum and the other one may be quite indolent. Our two cases confirm the heterogeneous nature of PTL.

False-positive uptake of radioiodine WBS in a patient with papillary thyroid cancer due to a vertebral hemangioma

Eleni Triantafillou, Foteini Kanouta, Georgios Papadakis, Ioannis Tzaves, Evgenia Panagiotidi, Erasmia Trivizaki, Victoria Kaltzidou, Athanasia Tertipi, Aspasia Drosou & Anastasios Pappas
Metaxa Cancer Hospital, Piraeus, Athens, Greece.

Introduction
Diagnostic and post-therapy radioiodine whole body scan (WBS) is used in the follow-up of differentiated thyroid carcinoma (DTC) for the detection of local recurrence or remote metastasis. We report a case of false-positive uptake of radioiodine WBS.
Case report
A 37-year-old female patient underwent subtotal thyroidectomy for multinodular goitre and histology revealed multifocal papillary thyroid carcinoma, of follicular type with three foci of major diameter 1.35 mm. Post-operative radioiodine uptake of 24 h was 2.7% and thyroglobulin (Tg) levels were 35 ng/ml. Neck ultrasound was negative for pathologic lymph nodes and chest X-ray was unremarkable. An ablation dose of 70 mCi radioiodine was administered and the post-therapy WBS demonstrated multiple thyroid remnants on the anterior cervical region, increased uptake on the anterior upper mediastinum and a third large focus in the middle of the chest most evident on the posterior views suggesting vertebral metastatic involvement. Chest CT scan, cervical and mediastinal MRI were negative. In the 99Tc-bone scan a small focus of increased uptake was observed at the 8^{th} thoracic vertebrae with no other pathologic findings of the skeleton. MRI of the spine showed a high intensity pathologic signal in the 8^{th} thoracic vertebrae with a major frontal diameter of 14.6 mm, which is most likely attributed to an atypical hemangioma and not to metastatic disease, in line with the rather mild elevation of Tg levels. Bone metastases in DTC are known to cause higher Tg concentrations, usually >100 ng/ml.
Discussion
Vertebral hemangiomas are common and radioiodine uptake by a vertebral hemangioma in a patient with DTC has been reported in the literature in very few cases. These false positive results may mislead the physician to the presence of distant metastasis and erroneously change the stage of the disease and the therapeutic approach.

Recurrent bone metastasis of follicular thyroid carcinoma with unknown primary site

Ji Oh Mok[1], Chong Hwa Kim[2], Sung Rae Kim[3], Seung Hee Yu[4] & Kiyoung Lee[4]
[1]Soonchunhyang University Bucheon Hospital, Bucheon, Republic of Korea; [2]Sejong General Hospital, Bucheon, Republic of Korea; [3]The Catholic University of Korea Bucheon ST.Mary's Hospital, Bucheon, Republic of Korea; [4]Gachon University Gil Hospital, Incheon, Republic of Korea.

Introduction
Occurrence of follicular thyroid carcinoma (FTC) is limited almost within thyroid gland, but distant metastasis is discovered uncommonly as first presentation. We experienced a rare case about recurrent bone metastasis of FTC with unknown primary site.
Case report
A 58-year-old woman complained about back pain for 3 years. A 5 cm sized mass in right 8th posterior rib was discovered and performed resection. The result of pathology was bone metastasis of FTC. Thirty four years ago, she underwent right thyroidectomy because of benign nodule. Thyroid USG shows no specific findings on remained left lobe of thyroid gland, but PET-CT presents increased uptake in the left thyroid gland, bilateral hilar and mediastinal regions, and right 8th rib. Left thyroid gland was removed totally, but primary FTC wasn't discovered in left lobe. After operation, she received radioactive iodine (RAI) ablation with 100 mCi. However, recurrent bone metastasis of right 8th posterior rib was found in PET-CT at 6 months after surgery. Repeated operation was performed for the lesion of right rib and pathological finding shows the same results as the first operation. Because of repeated bone metastasis and increased Tg level, she was ablated four times totally with 550 mCi and underwent recurrent operations for bone metastasis of right rib. One year later, metastasis of left temporal bone was found newly and removed surgically with cranioplasty. The result of pathology was a metastasis of FTC such as the previous result. Currently, the patient is followed up in the outpatient department for conservative treatment.
Conclusions
With unknown primary site, recurrent bone metastasis of FTC is a rare case and should be treated with appropriate therapy because of poor prognosis. We report a case about recurrent bone metastasis of FTC managed with repeated operation and RAI ablation.

EP850

BRAF V600E positive papillary thyroid carcinoma is associated with suspicious ultrasound features

Julia Sastre-Marcos[1], Florentino Del Val-Zaballos[1], Claudia Cortes-Muñoz[1], Yolanda Campos-Martin[1], Sonsoles Aso-Manso[1], Ignacio Jaen-Diaz[2], Almudena Vicente-Delgado[1] & Jose Lopez-Lopez[1]
[1]Complejo Hospitalario de Toledo, Toledo, Spain; [2]Centro de Salud de Buenavista, Toledo, Spain.

Aims
To study if BRAF V600E mutation in thyroid fine needle aspiration (FNA) is associated with specific ultrasound (US) characteristics.
Patients and methods
From 2010 to 2014 we reviewed patients with thyroid nodules with the following inclusion criteria: US guided FNA of the nodule and molecular testing for BRAF V600E on the FNA. BRAF mutation was detected using fluorescence melting curve. An expert on US, blinded to the BRAF status reviewed US examinations and recorded the sonographic characteristics for each nodule. Six US characteristics were collected: margins, echogenicity, halo, nodular vascularization, calcifications and cystic or solid composition. US findings were classified into three categories: probably benign, indeterminate o suspicious. Demographic and clinical characteristics were also analysed. Univariate (χ^2 and student's *t*-test) and multivariate analysis were carried out.
Results
patients were studied (85, 6% women), mean age 52 years. 79 patients showed BRAF V600E mutations on FNA (29, 2%). BRAF-positive patients were younger (48.5 ± 16.0 vs 53.6 ± 16.1 years, $P < 0{,}05$) and with different gender distribution (men 21.5% vs 11.5%, $P < 0.05$). BRAF-positive nodules showed at least one malignant US characteristics in 89.9% vs 49.5% in BRAF-wild type nodules ($P < 0.001$). BRAF-positive nodules were classified as suspicious in 63.3% and as probably benign in 10.1%. BRAF-negative nodules were classified as suspicious in 24% and probably benign in 50, 5% ($P < 0.001$). By multivariate analysis, micro-macrocalcifications (OR 3.8 CI95% 1.8–8.0, $P < 0.001$) and hypoechogenicity (OR 2.7 CI95% 1.2–6.2, $P < 0.05$) were independently associated with the presence of BRAF V600E mutation.
Conclusion
Suspicious US characteristics are highly associated with BRAF positive FNA. Routine cervical US and molecular testing can contribute to improve preoperative risk classification of papillary thyroid cancer.

Mixed medullary and papillary thyroid carcinoma – a case report

Emel Senol[1], Peyker Temiz[2], Yamaç Erhan[3] & Zeliha Hekimsoy[1]
[1]Medical Faculty, Department of Internal Medicine, Division of Endocrinology and Metabolism, Celal Bayar University, Manisa, Turkey; [2]Medical Faculty, Department of Pathology, Celal Bayar University, Manisa, Turkey; [3]Medical Faculty, Department of General Surgery, Celal Bayar University, Manisa, Turkey.

Thyroid cancers are divided into two main subgroups according to their embryonic origin: papillary cancer, the most common histologic type, seen in 75–80%, and medullary cancer, seen in 5–10% (sporadic or as a component of multiple endocrine syndrome). Because of the different phenotypic characteristics of these two cancers, it's unusual for them to present simultaneously. Since 1980, only a few cases of simultaneous papillary and medullary thyroid cancer have been reported. Medullary thyroid cancer may have follicular or papillary components, but it's very rare to see mixed medullary and papillary thyroid cancer in a single nodule (< 2 cm). In this article, we review the characteristics of one of our patients with mixed medullary and papillary thyroid cancer. A 59-year-old woman with a history of autoimmune hepatitis and primary biliary cirrhosis, was evaluated for a 16$\times$ 12 mm thyroid nodule in her right lobe. Finding medullary carcinoma by fine needle biopsy, she underwent total thyroidectomy with central lymph node dissection. Histopathologic examination of the tissues revealed 'thyroid medullary carcinoma fields meshed with papillary carcinoma sections'. Both medullary and papillary carcinoma components were confirmed immunohistochemically. The main component of the mixed tumour was medullary carcinoma. The patient will be followed up in our Endocrinology and Metabolism Clinic. The incidence, histopathological structures, treatment, and follow up of papillary and medullary thyroid carcinomas are different. The presence of medullary thyroid carcinoma mandates further investigation to see whether other components of MEN syndromes are present, and to evaluate other family members for similar problems. The prognosis of papillary carcinoma is better than medullary thyroid cancer. The recurrence and mortality rates of medullary cancer are higher, in direct proportion to the size of the primary lesion. Mixed thyroid carcinomas are rare and are difficult to diagnose preoperatively by fine needle biopsy alone.

Testosterone and pituitary hormones levels in thyroid cancer males patients

Eugen Luchytskiy, Vitaliy Luchytskiy, Galina Zubkova, Victoriya Rybalchenko, Valentyn Markov & Sergiy Gulevatyy
SE 'Institute of endocrinology and metabolism named after V.P. Komissarenko National Academy of Medical Science of Ukraine', Kyiv, Ukraine.

The high pprevalence of thyroid cancer among the male population of Ukraine during the active reproductive age (over 25 years) makes it reasonable to study the effect of the disease on testicular function. The purpose of work was to examine the state of androgen levels and pituitary hormones in men with thyroid cancer.
Design and methods
The study involved 14 male patients aged from 21 to 40 years, with thyroid cancer. The control group were 46 healthy men aged from 20 to 45 years. All patients underwent determination of serum levels of total testosterone (tT), luteinising hormone (LH), *follicle-stimulating hormone* (FSH) and prolactin before surgery and one month after.
Results
The study of pituitary hormones and testosterone in surveyed patients showed that the average concentration of pituitary hormones in male patients with thyroid cancer before and after surgical treatment was not significantly different from that of the control group and were within the normal vibrations. Average levels of LH were 5.7 ± 1.2 IU/l before surgery and 6.0 ± 1.1 IU/l after ($P > 0.5$), and do not differ from control group (4.6 ± 0.4 IU/l). Average FSH levels were 6.5 ± 1.1 IU/l before surgery vs 5.5 ± 1.8 IU/l ($P > 0.5$), as well 5.3 ± 0.5 IU/l in controls. The average levels of tT in men with thyroid cancer had trend to decrease after thyroidectomy from (16.4 ± 0.5) nmol/l to (15.6 ± 0.4) nmol/l ($P = 0.05 < 0.1$). However, these parameters were within normal fluctuations euhonadal men and did not differ significantly from that of the control group (19.1 ± 1.7) nmol/l.
Conclusion
These data confirm that short-term failure of the thyroid gland is not pronounced adverse effect on testicular testosterone production.

Detection of somatic oncogene alterations in FNA samples of cold nodules and 3 years follow-up of patients in Hungary

Bálint Tobiás[1,3], Bernadett Balla[1,3], P János Kósa[1,3], István Takács[1], Zsolt Nagy[1], Péter Horváth[1], Balázs Járay[2], Eszter Székely[2], Roland Istók[2], Tamás Székely[2] & Péter Lakatos[1]
[1]1st Department of Internal Medicine, Semmelweis University, Budapest, Hungary; [2]2nd Department of Pathology, Semmelweis University, Budapest, Hungary; [3]Pentacore Laboratory, Budapest, Hungary.

Cold nodules are one of the most common findings on scintigraphic examinations of the thyroid gland. About 5–10% of these nodules turn out to be histologically malignant. Our aim was to examine some somatogenetic alterations associated with thyroid cancer in FNA samples of the thyroid. These alterations included single nucleotide mutations (BRAF, HRAS, NRAS, KRAS) and genetic translocations (RET/PTC1, RET/PTC3, PAX8ex7/PPARgamma, PAX8ex9/PPARgamma). The SNPs were tested by real-time PCR with fluorescence melting curve analysis and the rearrangements were detected by Taqman probe-based quantitative real-time PCR. We have analysed 779 consecutive FNA samples and followed up the patients 3 years long. In the examined 779 samples, we found different genetic alterations (39 BRAF, 23 NRAS, 9 HRAS, 1 KRAS mutations and 1 RET/PTC3 rearrangement). After 1 year follow-up by histology, 52 cases (6.8%) were classified as malignant, from which we identified genetic alterations only in 40 (5.1%). (specificity 93.3%, sensitivity 46.2%, negative predictive value 96.0%, positive predictive value 32.9%) In two years follow-up group ($n=504$) by histology, 30 cases (6.0%) were classified as malignant, from which we identified genetic alterations in 26 (5.2%). In three years follow-up group ($n=250$) by histology, 13 cases (5.2%) were classified as malignant, from which we found genetic alterations in 14 (5.6%). No PAX8/PPARgamma rearrangements were demonstrated in the 779 samples. These data are not in complete accordance with published information. This fact might be due to several factors including the differences in iodine supply in different geographical areas.

Primary thyroid lymphoma: an ominous and commonly forgotten association with Hashimoto's thyroiditis

Cherng Jye Seow[1], Davin Ryanputra[2], Tian Ray Lai[1], Chin Ee Ong[1], Minyang Chow[1], Grace Lum[1], Claire Min-Li Teo[1] & Zhiguang Ng[1]
[1]Tan Tock Seng Hospital, Singapore, Singapore; [2]Yong Loo Lin School of Medicine, Singapore, Singapore.

Introduction
Primary thyroid lymphoma (PTL) is rare and constitutes 2–5% of thyroid malignancies. The risk however increases with background Hashimoto's thyroiditis. (HT) We report a patient with HT complicated by thyroid lymphoma and did a literature review on this topic.
Case presentation
A 61-years-old Chinese lady with background HT on levothyroxine presented with an enlarging goitre of 6 months duration. There was weight loss of 3–4 kg, but no fever or night sweats. Examination showed an enlarged, non-tender thyroid gland with no palpable cervical lymph node. US showed a lobulated heterogeneous mass measuring $5.5\times3.2\times2.9$ cm with internal vascularity. FNAC was suspicious for a lymphoma. CT neck, thorax and abdomen showed a $6.7\times7.0\times4.1$ cm mass with possible infiltration through the left lateral tracheal wall and encasement of the left common carotid artery. There was no significant lymphadenopathy. Referral to the oncologist was made.
Discussion
PTL has an estimated annual incidence of two cases per million and almost all are of B-cell origin. It affects middle-aged to older individuals, predominantly women. Most are diagnosed with stage I disease and the most common histologic subtype is diffuse large B-cell lymphoma. The likelihood of developing thyroidal lymphoma is 40–80 times greater in patients with chronic thyroiditis. Proposed mechanisms include prolonged antigenic stimulation in the setting of autoimmune thyroiditis leading to lymphomatous transformation or malfunction of the somatic hypermutation process, a phenomenon called aberrant somatic hypermutation process, which is regarded as a mechanism of lymphomagenesis. Treatment comprises different modalities depending on histologic subtype and stage of disease.
Conclusion
The diagnosis of PTL should be considered in a rapidly growing goiter especially in the background of HT. Early detection may result in improved survival.

Vitamin-D neutralising CYP24A1 gene expression in thyroid fine-needle aspiration biopsy samples

Bernadett Balla[1], Péter Horváth[1], Bálint Tobiás[1], Gabriella Győri[2], Balázs Járay[3], János Kósa[1,4] & Péter Lakatos[1,4]
[1]PentaCore Laboratory, Semmelweis University, Budapest, Hungary; [2]Department of Radiology and Oncotherapy, Semmelweis University, Budapest, Hungary; [3]2nd Department of Pathology, Semmelweis University, Budapest, Hungary; [4]1st Department of Internal Medicine, Semmelweis University, Budapest, Hungary.

Objectives
We previously published the result of CYP24A1 gene expression in one hundred, solely papillary thyroid carcinoma (PTC) compared to its own tumour free control from the same patient. We report an increase in CYP24A1 gene transcription in more than half of analysed PTCs. Elevated CYP24A1 protein expression was also observed in the cancerous tissue section compared to peritumoural normal thyroid tissue. In the present study we aimed to examine CYP24A1 gene transcription in thyroid fine-needle aspiration biopsy (FNAB) specimens and follow up the patients for 2 years.
Methods
The gene expression analyses of 42 thyroid FNABs were carried out by Taqman probe-based quantitative real-time RT-PCR. The somatic mutation states of BRAF, NRAS, HRAS, KRAS oncogenes as well as ELE1/RET and CCDC6/RET rearrangements were also tested. Genomic DNA and total RNA were isolated from each sample using Roche High Pure kits.
Results
Eight males and 34 females participated in the study. The mean age was 51.43 years. Cytology results of 28 FNABs were benign and 14 were malignant. Within the malignant specimens 13 papillary and 1 follicular type carcinoma were recognised. Altogether, 6 BRAF (rs113488022) mutations, 1 ELE1/RET translocation were detected in the malignant FNAB samples and one benign biopsy carried HRAS (rs28933406) mutation. CYP24A1 gene expressions were noticed only in five FNAB samples diagnosed with PTC. We could not determine CYP24A1 specific mRNA in the benign samples. During the follow up period we identified malignant transformation in three cases from the 28 initially cytological benign FNABs. In all of these three cases PTC were certified.
Conclusion
It is well established, that CYP24A1 gene activity is elevated in various cancers including thyroid carcinoma might be to protect tumour tissue from the anti-proliferative and pro-apoptotic effects of 1.25-vitamin D3. Our results show that changes of CYP24A1 gene expression have no predictive value in precancerous states of thyroid and it could not help to complete the diagnosis of FNAB cytology.

Brain metastases of thyroid carcinoma: a report of two cases and review of the literature

Ahmed-Ali Leila, Fedala Nora Soumeya & Chentli Farida
Department of Endocrinology, Metabolic Disease Bab El Oued Hospital, Algiers, Algeria.

Introduction
Brain metastases of thyroid carcinomas are rare (0.1–5%) according to the literature data. They generally occur in a context of metastatic spread which has a serious impact on survival. We report two cases and will review the literature data.
Observations
Case 1: 57-year-old patient monitoring for papillary thyroid carcinoma in its solid form trabecular classified T4N0M1with lung metastases. Following a neurological symptoms of tonic-clonic type of the left arm cerebro-spinal MRI revealed a 20 mm right parietal lesion and cerebellar lesion 4 mm. The rest of the staging finds multiple hepatic nodules probably metastatic. Up-take scan after radioiodine therapy was positive in cervical, brain and lung. thyroglobulin rates are increased to 3050 ng/ml.
Case 2: 11-year-old patient with a vesicular thyroid carcinoma with multiple secondary metastases: brain, lung, bone, pancreas, liver. The histological study of parietal localization confirmed his thyroid origin. Up-take scan after radioiodine therapy was positive especially in brain. thyroglobulin levels are increased to 8000 ng/ml.
Conclusion
Patients with thyroid carcinoma metastatic to the brain appear to have a relatively short survival time compared with other patients with thyroid carcinoma,

although this survival time is significantly longer than that noted with other solid tumour metastases to the brain. Early detection is important and specific treatment (radioiodine therapy) and standard treatments (surgery, Whole Brain Radiation Therapy) can improve their prognosis.

Aggressive papillary thyroid cancer with rare morphological features: a case report

Umut Mousa[1], Osman Koseoglulari[1], Sebnem Aydin[3], Minel Ozen[2], Hasan Sav[1] & Varol Esatoglu[4]
[1]Department of Endocrinology and Metabolism, B Nalbantoglu Hospital, Nicosia, Cyprus; [2]Deparment of Pathology, B Nalbantoglu Hospital, Nicosia, Cyprus; [3]Deparment of Nuclear Medicine, B Nalbantoglu Hospital, Nicosia, Cyprus; [4]Department of General Surgery, B Nalbantoglu Hospital, Nicosia, Cyprus.

Introduction
Papillary thyroid cancer (PTC) is the most frequently observed type of thyroid cancer. It usually shows favorable prognosis although some aggressive pathological subtypes have been defined. In this case report we present an aggressive form of PTC with previously non defined histological features.
Case report
At initial evaluation the subject presented with a mass in the neck. Neck ultrasonography (USG) revealed a 49×23 mm hypo echoic nodule in the left lobe and multiple lymphadenopathies adjacent to the left thyroid lobe being suspicious for malignancy. The nodule had irregular edges and was hyper vascular in power doppler imaging (PDI). The patient underwent total thyroidectomy and ipsilateral central lymph node dissection. The pathology report was compatible with papillary thyroid cancer (PTC) and Hashimoto's thyroiditis. The tumour was composed of 30–35% insular, 10% Tall-Cell and 55% anaplastic cells. The tumour was 45mm in size and showed pericapsular soft tissue invasion. Immunohistochemistry was positive for Thyroglobulin, TTF-1, NSE, Pan SK and CK 19. And negative for CEA, Calcitonin, chromogranine and synaptophysin. Ki 67 proliferation index was 5–6%. PET CT revealed multiple metastases in the liver, lungs, thoracic and lumbar vertebra. The patient is actively receiving chemotherapy at the Medical Oncology department in our hospital.
Result
Although PTC generally shows favourable prognosis the histomorphological features are variable and may not suit one of the previously defined PTC subtypes. Such cases as the one defined may clinically advance like anaplastic thyroid cancer.

The evaluation of sex hormone receptors in papillary thyroid cancer as an additional tool in the post-operative risk stratification and in the pre-gravidic counselling of women with persistent disease

Laura Fugazzola[1,5], Simone De Leo[1,2], Michela Perrino[1,2], Stefania Rossi[3], Delfina Tosi[4], Valentina Cirello[5], Carla Colombo[1,2], Gaetano Bulfamante[3,4], Leonardo Vicentini[6] & Guia Vannucchi[1]
[1]Endocrine Unit, Fondazione IRCCS Ca' Granda, Milan, Italy; [2]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [3]Division of Pathology, San Paolo Hospital, Milan, Italy; [4]Department of Health Sciences, University of Milan, Milan, Italy; [5]Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy; [6]Endocrine Surgery Unit, Fondazione IRCCS Ca' Granda, Milan, Italy.

Thyroid cancer is highly prevalent in women aged 15–44 years, suggesting that in females the fertile age could be regarded as a risk factor. Consistently, in the last decades epidemiological and experimental findings indicated a possible role of oestrogens in the development and progression of differentiated thyroid tumours. We studied the expression of oestrogen receptor α (ER α) and Progesteron receptor (PR) in 182 female and male patients with papillary thyroid cancer (PTC) and correlated it to clinical and molecular features. ER α and PR expression was found in 66.5 and 75.8% of patients respectively, and significantly correlated with larger tumour size and with the presence of metastatic neck lymph-nodes at diagnosis. Interestingly, the occurrence of the 'receptor conversion' phenomenon, already reported to have a negative prognostic effect in breast cancer, has been demonstrated for the first time in thyroid tumours. Indeed, almost all the ER α positive primary tumours analysed had ER α negative metastatic lymph-nodes. $BRAF^{V600E}$ mutation was detected in 23.2% of the tumours, with a higher prevalence in larger tumours and in those with a stronger ER α or PR staining. Finally, the follow-up of a woman with persistent PTC during pregnancy, highlighted the role of oestrogens in the progression of the disease. In conclusion, the expression of ER α and PR is frequent in PTC tumour tissues and it is significantly associated with a more aggressive presentation. Although their expression did not seem to influence the outcome of the disease, the evaluation of sex hormone receptors could be an additional tool in the post-operative risk stratification and might be useful in the pre-gravidic counselling of fertile women affected with persistent thyroid cancer.

Concomitant papillary thyroid cancer and graves' disease: an ominous association

Davin Ryanputra[1] & Cherng Jye Seow[2]
[1]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [2]Tan Tock Seng Hospital, Singapore, Singapore.

Background
Papillary thyroid carcinoma (PTC) in patients with background Graves' disease (GD) has been associated with a higher risk of post-operative tumour recurrence. We present a case and review the literature for possible explanations.
Case presentation
A 55-year-old gentleman with GD treated with carbimazole presented 1 year after initial diagnosis with a 3 cm palpable thyroid nodule. Fine needle aspiration cytology (FNAC) was suggestive for malignancy. A total thyroidectomy with prophylactic central-compartment neck dissection was done-stage 3 papillary thyroid cancer (T3N0M0); size of tumour: 4.7×2×2 cm. There was no lymphovascular invasion or features of aggressive histology. He received 150 millicurie of 131-radioactive iodine (RAI) and was started on high dose L-thyroxine, keeping thyroid stimulating hormone (TSH) suppressed. Thyroid-stimulating hormone receptor antibody (TRAb) levels was positive at 3.3 IU/L (NR: <1). 2 years post operatively, a follow-up neck ultrasound revealed prominent lymph nodes. FNAC was positive for malignancy. There were no distant metastases. He had neck dissection followed by RAI.
Discussion
Neoplastic cells of differentiated thyroid cancer, like normal thyroid cells, express functional receptors for TSH. Thyroid stimulating antibodies might play a role in stimulating thyroid cancer growth, invasiveness and angiogenesis by up-regulating vascular endothelial growth factor, placenta growth factor, and their receptors. The antibodies have also been shown to initiate cellular proliferation by suppressing mitochondrial reactive oxygen species levels, preventing apoptosis. Apart from that, different growth factors that probably are produced by the over-stimulated (by TRAb) and hypervascularised thyroid could also affect the growth and metastases of thyroid cancer in patients with GD. Interleukins four and ten, locally produced in thyroid glands affected by GD, also have a strong anti-apoptotic effect on malignant thyrocytes.
Conclusion
A high index of suspicion for tumour recurrence in patients with PTC and concomitant Graves' disease is necessary.

Rise in incidence of differentiated thyroid cancer in the south of Spain

Florentino Carral[1], Gema Ruiz[2], Raquel Tinoco[2], Julio González-Outon[4], Vicente Vega[3], Maribel Robles[3], Ana Isabel Jiménez[1], Concepción García[1] & Carmen Ayala[1]
[1]Endocrinology Department, Puerto Real University Hospital, Puerto Real, Cádiz, Spain; [2]Internal Medicine Department, Puerto Real University Hospital, Puerto Real, Cádiz, Spain; [3]Surgery Department, Puerto Real University Hospital, Puerto Real, Cádiz, Spain; [4]Clinical Information Department, Puerto Real University Hospital, Puerto Real, Cádiz, Spain.

Background
Recent studies have shown that the incidence of differentiated thyroid cancer (DTC) is increasing.
Objective
Evaluate the incidence of DCT in a center of the south of Spain for the last 15 years and analyse the clinical and morphological factors related to DTC.

Methods
We reviewed the series of patients undergoing thyroid surgery at our hospital over a 15-year period and identified patients with DTC. Patients were divided in three periods: 2000–2004, 2005–2009 and 2010–2014 and incidence rates were calculated. The variables gathered were age, sex, date of diagnosis, clinical presentation, hormonal status and cytology, size, morphology and extension of the tumour.
Results
patients with DTC were diagnosed. A significant increase in the number of DTC was shown in the period ranging from 2010 to 2014 (105 cases; 17.1% of the surgeries) compared to 71 cases between 2005 and 2009 (14.2% of interventions) and 48 cases between 2000 and 2004 (9.8% of interventions) ($P<0.001$). Incidence rates also increased from 3.7 (2000–2004 period) to 4.8 (2005–2009 period) and 6.8/1 00 000 habitants (2010–2014 period) ($P<0.001$) and this trend was found in both genders. The incidence was 3.1 times higher in women than in men and the most frequent morphology was papillary carcinoma (90.6%). No differences were found in the prevalence of microcarcinoma, extrathyroidal extension, lymph node involvement or distance metastases in the analysed periods.
Conclusions
We report a similar rise in the incidence of DTC in the south of Spain to the overall reported in the international literature.

Our experience in the treatment of Thyr3 and Thyr4 nodules

Elisa Bertocchi, Paolo Del Rio, Lorenzo Viani, Annarita Totaro & Mario Sianesi
General Surgery and Organ Transplantation, University Hospital of Parma, Parma, Italy.

Introduction
The Bethesda System 2010 introduced six diagnostic categories and divided follicular proliferation in two risk classes: Thyr3 and Thyr4. In literature about 5–15% of Thyr3 nodules are malignant and the risk of malignancy for Thyr4 is closer to 15–30%. We have analysed our cases surgically treated in recent years.
Materials and method
We have prospectively categorised into a dedicated database patients submitted to thyroidectomy at OU General Surgery and Organ Transplantation, University Hospital of Parma, from January 2012 to December 2014. The following data were recorded: age, sex, cytological category and histological examination.
Results
patients were submitted to total thyroidectomy for suspected or definite diagnosis of differentiated thyroid cancer (DTC). In 145 cases cytological categories were Thyr3 (48 patients: 43 females and five males; average age 50.3 years) and Thyr4 (97 patients: 79 females and 18 males; average age 49.7 years). In 16 patients with Thyr3 (33.3%)and in 40 patients with Thyr4 (42.85%) nodules were malignant.
Conclusion
In our area the percentage of thyroid nodules is high; the incidence of malignant nodule in females is closer to 18 cases/1 00 000 person-years. This element explains the higher incidence of malignancy of Thyr3 and Thyr4 nodules in our series compared to data in the literature.

Anaplastic thyroid carcinoma: The failure of conventional therapy but the real promise of targeted therapy

Paul Lennon[1], Sandra Deady[2], Marie-Louise Healy[1], John Kinsella[1], Conrad Timon[1] & James Paul O'Neill[3]
[1]St. James's Hospital, Dublin, Ireland; [2]National Cancer Registry, Cork, Ireland; [3]Royal College of Surgeons, Ireland, Dublin, Ireland.

Introduction
Anaplastic thyroid cancer is a devastating disease with median survival between 1.2 and 10 months. The disease accounts for as little as 0.9–1.6% of total thyroid cancer cases, but may account for up to half of all thyroid cancer mortality. The aim of our study is to evaluate the prognostic factors and outcomes of patients diagnosed with anaplastic thyroid cancer in Ireland and review emerging treatments for this disease.
Methods and design
A retrospective analysis of the National Cancer Registry in Ireland was undertaken, for patients with a diagnosis of anaplastic thyroid cancer between 2000 and 2010. Patient, tumour, and treatment characteristics were recorded. The Kaplan–Meier method was used to determine overall survival and factors predictive of outcome were determined by univariate and multivariate analysis by cox regression using Stata 13 software.
Results
Of a total of 64 patients, 40 were female and 24 were male. The median age was 69, and 27.5% of patients had distant metastases at diagnosis. The overall median survival was 2.3 and the 6 months, 1, 2, and 5 year overall survival was 23.4, 12.5, 6.25, and 4.69% respectively. On univariate analysis age, gender, metastases at diagnosis, surgery, radiotherapy, and multimodality treatment were statistically significant indicators of prognosis, and metastases at diagnosis remained statistically significant on multivariate analysis. A review of the7741 patients in the literature revealed a median survival of 3.67 months.
Conclusions
The British and American Thyroid associations (BTA/ATA) have comprehensive guidelines on the management of ATC. However due to the rapidity of onset of the tumour, few patients benefit substantially from aggressive conventional treatments, and survival has not changed over a period of 40 years. Personalised therapeutic approaches based on the use of targeted therapy may be the best hope to improve treatments for patients with ATC.

Polymorphisms of cdkn1b gene may influence hereditary medullary thyroid carcinoma aggressiveness

Raquel Bueno Barbieri[1], Lucas Leite Cunha[1], Natassia Elena Bufalo[1], Danilo Villagelin[1,3], Lígia Vera Assumpção[1], Rui Monteiro Maciel[2], Janete Maria Cerutti[2] & Laura Sterian Ward[1]
[1]University of Campinas – UNICAMP, Campinas/SP, Brazil; [2]Federal University of São Paulo – UNIFESP, Sao Paulo/SP, Brazil; [3]Pontificia Universidade Católica de Campinas – PUCC, Campinas/SP, Brazil.

Despite the importance of the Ret receptor, it is clear that other signal transduction pathways, tyrosine kinase receptors, and tumours suppressor genes are involved in MTC tumorigenesis and progression. Differences in the clinical behaviour of patients harbouring the same Ret mutations may be related to these other genes. Alterations of genes involved in the G1 phase of the cell cycle, including the cyclins, CDKs and CDK inhibitors, are common events in neoplastic development of a series of different types of tumours. The role of key cell cycle regulations genes in hereditary medullary thyroid cancer (HMTC) is still largely unknown. In order to evaluate the influence of inherited polymorphisms of CDKN1B (rs2066827, rs34330), CDKN2C (rs12885) and CDKN2A (rs11515) genes in the pathogenesis of HMTC, we used TaqMan SNP genotyping to examine 138 HMTC patients. All patients were previously genotyped for RET gene and mutations are: 81 in codon 533 3 in codon 618 1 in codon 609 51 in codon 634 and two patients in codon 804.
A multivariate logistic regression analysis demonstrated that CDKN1B (34330) gene polymorphism inheritance was related to HMTC aggressiveness. Wild type (CC) rs34330 CDKN1B patients presented larger tumours (1.4 ± 1.38 cm) than polymorphic (TT) patients (0.6 ± 0.65 cm; $P=0.044$). In the same way, wild type (CC – 29.3 ± 15.6 years) rs34330 CDKN1B gene patients are younger than heterozygous patients (CT – 42.1 ± 18.2 years; $P=0.029$). We were unable to find any other association between the profile of the CDKN1B (rs2066827), CDKN2C (rs12885) and CDKN2A (rs11515) genes and patients' clinical or pathological characteristics. This study is first to investigate the association of CDKN1B, CDKN2C and CDKN2A polymorphisms and the aggressiveness to HMTC and suggests that profiling cell cycle genes may help define the risk and characterize HMTC aggressiveness, hence identifying patients who could benefit of a closer follow-up.

A cavernous angioma-mimicking case of solitary bone and brain metastasis of the columnar cell variant of papillary thyroid carcinoma

Mikyung Kim, Namkeong Kim, Yeyeon Lee, Nanhee Cho & Hyesoon Kim
Keimyung medical school, Daegu, Republic of Korea.

Background
Thyroid carcinoma has increased annually. Papillary thyroid carcinoma (PTC) is the most common thyroid malignancy and thought to have favourable prognosis. Distant metastases are common in lungs and bones. However, brain metastases are rare and its prognosis is unfavourable. Here we reported a case of solitary brain metastases of PTC mimicking cavernous angioma in a 76-year-old woman patient.
Methods
We collected her data retrospectively.
Results
A 76-year-old woman presented memory disturbance for 3 months. On physical examination, there was a 5 cm sized mass without tenderness in sternum. The brain magnetic resonance image showed a lobulated lesion with a mixed signal core surrounded by low intensity rim in right frontal lobe that was not enhanced in contrast image suitable for a cavernous angioma with haemorrhage. There was a mass with necrosis in the manubrium on chest computed tomography (CT) but no abnormality in abdomen CT. We did craniotomy for tumour removal and manubrium mass biopsy in the same day. In pathological finding, brain and manubrium revealed metastatic carcinoma consistent with primary in thyroid. For investigation of thyroid cancer, we did a neck ultrasonography and it demonstrated 1 cm sized hypoechoic nodule with coarse calcification in the left isthmus. As a result of fine needle aspiration on left thyroid nodule, pathology showed a classic PTC and BRAF mutation was positive. The patient refused thyroidectomy and expired 9 months later due to pneumonia and sepsis.
Conclusion
Brain metastases with PTC mimicking cavernous angioma is extremely rare. It makes us cautious that even small PTC could occur as distant metastasis.

DOI: 10.1530/endoabs.37.EP864

Incidental papillary thyroid carcinoma prevalence in benign multinodular goitre: data from Northern Portugal

Maria Teresa Pereira, André Couto de Carvalho, Cláudia Freitas & Fátima Borges
Division of Endocrinology, Diabetes and Metabolism, Centro Hospitalar do Porto, Porto, Portugal.

Introduction
Incidental papillary thyroid carcinoma (PTC) in patients undergoing thyroidectomy for benign multinodular disease is a well-recognised finding. Its true prevalence remains uncertain and shows great variability between studies, ranging from 7–25%. Our purpose was to review the prevalence of PTC in thyroid glands removed for benign nodular disease at a Northern Portuguese tertiary hospital.
Methods
From December 2012 to December 2014, the histological reports of patients treated surgically for benign nodular thyroid disease were reviewed. We excluded patients with thyroid hyperfunction and those with any suspicious cytological findings (*Bethesda category* $\geq$III). Data regarding demographics and pathological findings were retrieved.
Results
patients were included in the analysis, with a mean age of 55 ± 15 years; 87% were females. The overall prevalence of malignancy (PTC) found was 15.8% (95% CI, 11.4–21.5%). There were no statistically differences between PTC and benign groups regarding patient's age and gender. The pathological tumour size ranged between 1 and 55 mm (median 8 mm). Most cases of PTC were microcarcinomas (19 in 32, 59.4%), with a median diameter of 4 mm (range, 1–9 mm). In respect to macrocarcinomas (13 in 32, 40.6%), the median tumour diameter was 35 mm (range, 11–55 mm). In seven patients (22%), the tumour was multifocal and in one patient (3%) vascular invasion was documented. The most common variants of PTC found were classical and follicular with 59.4 and 37.5% respectively.
Conclusions
In our series, microscopic PTC prevalence in patients undergoing thyroid surgery for benign euthyroid disease seems to be similar to the previously described. These high rates of pathological incidental thyroid carcinomas should be taken into account and drive appropriate diagnostic and therapeutic approaches.

Serum Galectin-3 in papillary thyroid cancer: preliminary results

Andra Caragheorgheopol[1,2], Sorina Schipor[1,2], Dana Manda[1,2], Ana-Maria Stefanescu[1,2], Dumitru Ioachim[1,2] & Corin Badiu[1,2]
[1]National Institute of Endocrinology 'C. I. Parhon', Bucharest, Romania; [2]University of Medicine and Pharmacy 'Carol Davila', Bucharest, Romania.

Background
There are only few reports regarding the role of serum galectin-3 (Gal-3) as an early biochemical marker in thyroid carcinoma.
Aim
To evaluate the potential overexpression of Gal-3 in sera from patients with confirmed diagnosis of papillary thyroid carcinoma (PTC).
Patients and methods
We retrospectively investigated serum Gal-3 in 40 patients referred to the surgical department for thyroidectomy. Sera were collected before surgery. We measured sera of 40 patients (mean age 48.79 ± 14.15 years): 32 women (82.5%) and seven mens (17.5%). Patients were divided in four groups, based on histopathological stage: nodular goitre, PTC1, PTC2, PTC3/4. Gal-3 was measured by Elisa (Abcam, UK); sensitivity 0.12 ng/ml, intra-assay cv 6.4%, inter-assay cv 11.4%. The study was approved by Ethics Committee of the Institute.
Results
patients showed different PTC stages at histopathological exam, as follows: 10 PTC1, 10 PTC2 and 11 PTC3/4, respectively; nine patients were diagnosed with benign nodular goitre. We found a significant difference between cancer and non-cancer patients (median Gal-3 – 8.427 ng/ml vs 4.402 ng/ml, $P = 0.019$), between PTC3/4 patients and those with nodular goitre (median Gal-3 – 9.069 ng/ml vs 4.402 ng/ml, $P = 0.0097$), and between PTC1 and goitre patients (median Gal-3 – 8.751 ng/ml vs 4.402 ng/ml, $P = 0.047$). In our study, we noticed higher values vs reference ranges in nodular goitre group (mean 5.046 (2.28–7.81) ng/ml vs 0.54 (0–2.28) ng/ml, $P < 0.0001$). However, serum Gal-3 did not discriminated between different PTC stages. Intra-assay cv% in our hands was 3.57%.
Conclusion
Serum Gal-3 might be considered as an early circulating tumour marker in thyroid cancer. Our preliminary data showed no association of serum Gal-3 with tumour aggressiveness.

The two tyrosine kinase inhibitors, CLM29 and CLM3, have antineoplastic activity in primary cultures from anaplastic thyroid cancer obtained from fine needle aspiration

Silvia Martina Ferrari[1], Poupak Fallahi[1], Concettina La Motta[2], Gabriele Materazzi[3], Francesca Ragusa[1], Francesca Limongi[1], Ilaria Ruffilli[1], Federico Da Settimo[2], Paolo Miccoli[3] & Alessandro Antonelli[1]
[1]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy; [2]Department of Pharmacy, University of Pisa, Pisa, Italy; [3]Department of Surgical, Medical, Molecular Pathology and Critical Area, University of Pisa, Pisa, Italy.

Anaplastic thyroid cancer (ATC) is one of the most lethal endocrine malignancy, with a mean survival of about 6 months. Until now, the most effective therapy for ATC comprises a multimodal treatment protocol, including surgery, chemotherapy (doxorubicin and cisplatin), and hyperfractionated accelerated external beam radiotherapy, with a median patient survival of 10 months. A possible increase in the effectiveness of the treatment could be achieved testing the sensitivity of 'primary anaplastic thyroid cancer cells' (pATC) from each subject to different drugs, in this way avoiding the administration of inactive therapeutics to these patients. Here, we tested the *in vitro* antineoplastic effect of the two new 'pyrazolo (3,4-d) pyrimidine' compounds (CLM3, CLM29) in pATC obtained both from

biopsy (biop-pATC), or from fine needle aspiration (FNA-pATC), from five patients. We evaluated different concentrations of both compounds (1, 10, 30, and 50 μM). A significant reduction of proliferation was evidenced in FNA-pATC, or biop-pATC, cells by WST-1 assay (a 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazolium bromide, used in the MTT assay) with respect to the control, especially with CLM29, while slightly with CLM3. Furthermore the percentage of apoptotic cells in FNA-pATC, or biop-pATC, cells was increased dose-dependently by both compounds. Our results show no significant differences in sensitivity to CLM29 or CLM3 between the tested ATC cells from FNA, or biopsy.We conclude that: 1) primary FNA-pATC cells have a sensitivity to tyrosine kinase inhibitors (TKIs) agents quite similar to that observed in biop-pATC cells, and for this reason the use of primary FNA-pATC cells to conduct the *in vitro* tests could reduce the time needed for biopsy; 2) CLM29 and CLM3 reduce cell growth, increasing the percentage of apoptotic cells in ATC; 3) the possibility to test sensitivity to different TKIs in each patient could increase the efficacy of treatments, avoiding the administration of ineffective drugs.

Role of miR-26a in follicular thyroid carcinoma

Erica Gentilin[1,2], Elisa Ortolan[1], Teresa Gagliano[1], Carmelina Di Pasquale[1], Simona Falletta[1], Roberta Rossi[1], Katiuscia Benfini[1], Federico Tagliati[1], Ettore Degli Uberti[1,2] & Maria Chiara Zatelli[1,2]
[1]Department of Medical Sciences, University of Ferrara, Ferrara, Italy; [2]LTTA, Laboratorio per le Tecnologie delle Terapie Avanzate, Ferrara, Italy.

Follicular thyroid carcinoma (FTC) is the second most common thyroid malignant epithelial tumor. It is clinically asymptomatic, usually represented by a single nodule, less often multiple, with origin from thyroid follicular epithelial cells. Despite its well-differentiated characteristics, FTC may develop distant metastases through hematogenous dissemination. The molecular alterations involved in the pathogenesis of follicular neoplasia are not completely known. Recent studies have demonstrated the importance of miRNAs, small non-coding nucleic acids that regulate gene expression at post-transcriptional level. It is well known that the expression profile of miRNAs is altered in follicular thyroid carcinoma. To date, the aftermaths of deregulated expression of miRNAs in the FTC have not been clarified. In order to investigate the molecular mechanisms involved in thyroid tumorigenesis, we evaluated the effects of miR-26a modulation in a human FTC cell line. We observed that miR-26a is significantly down-regulated in FTC-133 cells as compared to a thyroid normal cell line, NTHY-ORI. Our results demonstrated that miR-26a does not directly regulate Protein Kinsae C Delta (PRKCD), a known target of this miRNA, but influences its levels. PRKCD is a regulator of caspase-mediated apoptosis, vascular endothelial growth factor (VEGF)-mediated cell proliferation and iodide uptake *via* sodium iodide symporter (NIS). We observed that miR-26a up-regulation increases PRKCD and NIS protein levels as well as caspase activity, but does not influence VEGF secretion. These results support the hypothesis that miR-26a may influence thyroid differentiation processes and nay represent a therapeutic target for future innovative therapy in advanced radio-refractory disease.

A rare case of an off midline thyroglossal duct cyst papillary thyroid carcinoma

Melania Balas[1], Ioana Golu[1], Daniela Amzar[1], Mihaela Vlad[1], Emilia Ianes[2], Alis Dema[3] & Ioana Zosin[1]
[1]Department of Endocrinology, University of Medicine and Pharmacy V. Babes, Timisoara, Romania; [2]Department of Oral and Maxillofacial Surgery, University of Medicine and Pharmacy V. Babes, Timisoara, Romania; [3]Department of Morphopathology, University of Medicine and Pharmacy V. Babes, Timisoara, Romania.

Introduction
Papillary thyroid carcinoma can be found very rarely in a thyroglossal duct cyst (TDC) (1%), this cancer variant being the most common type. Although, most of the TDC develop in the midline of the thyroglossal duct (∼70%), some cysts occur off midline, within 2 cm of the midline.
Case presentation
The female patient of 34-year-old presented at the Maxillofacial Surgery Department in October 2014, with a right submandibular painless neck mass at about 1.5 cm of the midline. The lump was discovered by the patient during pregnancy and increased in size gradually, reaching 2.5 cm at 5 months after birth. The clinical examination did not reveal any pathological aspects of the thyroid, nose, nasopharynx, or cervical lymph nodes. The ultrasound of the swelling revealed a pseudosolid mass near the hyoid bone, with thick capsule (4 mm), microcalcifications, and internal vascularity. The post-contrast computed tomography (CT) showed a 28/23 mm right submandibular mass, with complex heterogeneous composition, thick capsule, several microcalcifications in the solid component, no adenopathies, and no surrounding infiltration. After the mass was removed, histological examination established the diagnosis of papillary thyroid carcinoma. Subsequently, the evaluation of the thyroid gland (ultrasound, functional tests, and scintigraphy) detected no abnormalities. Up to now, the patient (still breastfeeding) has been closely monitored by clinical examination and thyroid ultrasound. Suppressive thyroxine treatment will be taken further into discussion.
Discussion and conclusions
As TDC in adults presents variable sonographic and CT appearance, the diagnosis poses sometimes difficulties. Moreover, the diagnosis can be hampered by the unusual off line location of the TDC. The management of the TDC carcinoma is still controversial, the recommendations ranging from only Sistrunk procedure to total thyroidectomy, followed by radioiodine and suppressive thyroxine treatment, or only suppressive doses of thyroxine.

Chemotherapy effectiveness in the treatment of non-medullary well-differentiated thyroid cancer: a systematic and case review

Ana Albero[1], Esther Martín[2], Alberto Torres[3], Teresa García[1], Natividad Gonzalez[3], María de Carmen del Alamo[1], Luis de la Cruz[1] & Tomás Martín[3]
[1]Department of Oncology, Hospital Virgen Macarena, Seville, Spain; [2]Andalusian Agency for Health Technology Assessment, Seville, Spain; [3]Department of Endocrinology and Nutrition, Hospital Virgen Macarena, Seville, Spain.

Introduction
Nowadays, use of chemotherapy in well-differentiated non medullary thyroid cancer, locally advanced stage and/or with radioiodine-refractory metastases is considered of scanty value. However, in the last 40 years was not published any phase III study nor a systematic review of its use in clinical setting.
Methods
A systematic literature search was performed in databases such as Medline and Embase, among others. Two independent reviewers analysed the articles selected full text, made a critical reading and extracted results using forms designed specifically. A qualitative synthesis of the results was performed and the accumulated data were calculated.
Results
A total of 509 references were found. Sixteen studies involving 473 patients published were included. Thirteen studies showed individual response data to treatment. Finally, 179 patients treated with different chemotherapy alone or in combination were identified. The overall response rate (IR) was 27% (0–57%), with a 4% of patients showed a complete response (CR) and clinical benefit (CB) in 60% (14–100%). Eight studies reported data response relative to histologic subtype. The IR for the 37 cases with papillary cancer was 24% (0–50%) and 32% (5% CR) (0–100%) of 56 with follicular cancer. However, data must be interpreted carefully due to the risk of bias detected. Unlike modern studies a performance status >2 was described in about 40% of patients. Five individual studies published survival data from 54 patients with advanced CDT: the median survival was estimated at 18 months (95% CI 0–37.5), with significant differences between patients treated before 2000 vs those treated later (7 months vs 41 months, $P<0.00$).
Conclusion
There are insufficient data to evaluate the effectiveness of chemotherapy in patients with advanced non-medullary thyroid cancer, although, it seems to have some efficacy, therefore, it could be necessary to be tested in well-designed studies vs or in combination with new therapies.

Other malignancies accompanying differentiated thyroid cancer in Turkish Cypriots: a single-centre study

Sebnem Aydin[2], Umut Mousa[1], Osman Koseoglulari[1] & Hasan Sav[1]
[1]Department of Endocrinology and Metabolism, B Nalbantoglu Hospital, Nicosia, Cyprus; [2]Department of Nuclear Medicine, B Nalbantoglu Hospital, Nicosia, Cyprus.

Introduction
The aim of this study was to determine the frequency and types of accompanying malignancies in Turkish subjects with differentiated thyroid cancer (DTC) residing in the northern region of Cyprus.
Subjects and methods
We retrospectively analysed 567 subjects with a diagnosis of DTC in the Departments of Endocrinology and Nuclear Medicine.
Results
Four hundred and forty-eight (79%) were females and 119 (21%) were males. A total of 17 subjects (2.9%) had an accompanying second malignancy other than DTC. Sixteen were females (94.2%) and one was male (5.8%). The mean age was 46.3 years for subjects with DTC being the only malignancy and 54.76 years for those with accompanying malignancies ($P<0.05$). Out of these 17 subjects 14 had classical papillary thyroid cancer (PTC), two had PTC follicular variant, and one had follicular thyroid cancer. All subjects received radioactive iodine for remnant ablation. The secondary malignancies were breast cancer in nine subjects (52.9%), endometrium cancer in two subjects (11.7%) and acute lymphoblastic leukemia, Hodgkin lymphoma, lung cancer, malignant melanoma, and gastrointestinal stromal tumour in one subject each. In 11 subjects DTC developed secondarily, in five subjects DTC developed first and in one subject DTC and the other malignancy developed synchronously.
Conclusion
The rate of accompanying malignancies in DTC was 2.9%. Classical PTC was the most frequent tumour type accompanying other malignancies (82.3%). DTC was observed four times higher in female subjects compared to male subjects. The role of gender was higher in those with accompanying malignancies. The most frequently observed accompanying malignancy was breast cancer leading by far. Only five subjects had developed a malignancy after the diagnosis of DTC and 12 subjects had a diagnosed malignancy before DTC. Thus we believe the role of RAI remnant ablation for secondary malignancy development is none or minimal.

DOI: 10.1530/endoabs.37.EP871

Role of thyroglobulin as a predictor of the evolution of disease in differentiated thyroid cancer

Betina Biagetti, Carles Zafón, Amparo García-Burillo, Mónica Velasco, Gabriel Obiols, Joan Castell & Jordi Mesa
Vall d'Hebron Hospital, Barcelona, Spain.

Aim
Investigate, in patients with differentiated thyroid cancer (DTC) if thyroglobulin (Tg) values, immediately before and six months post radioiodine ablation are good predictors of disease progression.
Materials and methods
Basal Tg values (Tg-B) and rhTSH stimulated Tg (Tg-S) before ablation (0) and 6 months later (6) from 142 DTC patients, with post-surgical ablation therapy between 2003 and 2009 with a follow up of 5 years, were analysed.
Results
After a 5-year follow up, 121 patients (85.2%) were free of disease (FD), 15 patients (10.6%) had evidence of disease (ED) and six had died (4.2%). A Tg-B-0 <0.2 ng/ml. was present in 39 patients (27.5%), only one (2.5%) has ED because of positive antibodies and only one (2.5%) needed retreatment. In contrast: a Tg-B-0 >0.2 ng/ml, was present in the 103 patients (72.5%), 21 patients (20.4%) had ED and 27 (26.2%) needed retreatment A Tg-S-0 <1 ng/ml was found in 34.8% only one (2.6%) was ED and only one (2.6%) required retreatment. However, 65.2% of patients had these value >1 ng/ml, of which 22.5% was considered ED and 26.7% have required retreat. At 6-month when Tg-B-6 ablation >0.2 ng/ml, 40% was ED and 46.7% required retreatment and when Tg-S-6-ablation >1 ng/ml, 56% was ED, and 67% required retreatment in 5 years follow up.
Conclusion
Tg basal value at the time of ablation has a high specificity and sensitivity for predicting disease progression. Stimulated Tg at that time does not add predictive value At 6-month high levels of Tg value predicts evidence of disease in 5 years follow up.

Clinical and biological differences between incidental and non-incidental papillary thyroid microcarcinomas

Miguel Paja[1], Eider Etxebarria[1], Ma Teresa Gutiérrez[2], Amaia Expósito[2], Maddalen Dublang[1], Amelia Oleaga[1], Maite Pérez de Ciriza[1] & Aitziber Ugalde[3]
[1]Endocrinology Department, Hospital Universitario de Basurto, Bilbao, Basque Country, Spain; [2]Endocrine Surgery Department, Hospital Universitario de Basurto, Bilbao, Basque Country, Spain; [3]Pathology Department, Hospital Universitario de Basurto, Bilbao, Basque Country, Spain.

The clinical significance and potential morbidity of papillary thyroid microcarcinomas (PTMC) is discussed. Particularly the differences between those PTMC identified postoperatively in histological examination (incidentals), and those diagnosed preoperatively (non-incidentals). We retrospectively analysed differences in clinical presentation and course after treatment in these two groups. The study population consisted of 199 patients with PTMC who underwent surgery from 2000 to 2014. Eight patients preoperatively diagnosed of lateral compartment lymph node metastasis (LNM) were excluded, as they were considered suffering a more advanced disease. We compared characteristics, and outcomes between both groups. There were 118 incidental and 73 non-incidental PTMC. Patients with Incidental PTMC were older (55.7 years vs 50.8 years; $P=0.01$), have smaller tumours (4.3 mm vs 7.9 mm; $P=0.001$) and lower preoperative TSH (1.87 vs 3.06; $P=0.001$). Incidence of serological or histological evidence of autoinmunity was not different between both groups. Multifocal disease (46.8% vs 29.8%; $P=0.02$) and extracapsular invasion (25.6% vs 4%; $P<0.001$) were most frequently reported in non-incidental neoplasms. One hundred and sixteen out of 122 patients treated with radioiodine had at least 1 year of follow-up (62 incidentals and 54 non-incidentals). One year after radioiodine, eight incidental cases didn't reach remission criteria (undetectable stimulated thyroglobulin and normal high-resolution cervical ecography). Three of them persisted with biochemical disease 1, 2, and 3 years passed, one patient is waiting for surgery to identified cervical adenopathy, two achieved remission after ganglionar surgery plus more radiodine and two without additional treatment. There were two non-incidental patients without remission 1 year after ablation, both without structural disease, persistent 1 and 6 years passed. There was one biochemical relapse after initial remission in the non-incidental group. In our series, incidental and non-incidental PTMC showed differences at presentation, but similar biological behavior in the follow-up after treatment. Remnant disease is more often seen in incidental carcinomas after ablation.

Differentiated thyroid cancer: tendency changes from 1970 to 2012 in the southwest of Spain

Antonio Jesús Martínez Ortega[1], Elena Navarro González[1], Raquel Guerrero Vázquez[1], Ana de los Reyes Romero Lluch[1], José Manuel Martos[2] & Ignacio Cuenca Cuenca[3]
[1]Endocrinology Department, Virgen del Rocío University Hospital, Seville, Spain; [2]Endocrine Surgery Department, Virgen del Rocío University Hospital, Seville, Spain; [3]Nuclear Medicine Department, Virgen del Rocío University Hospital, Seville, Spain.

There is a specific unit specialised in treating differentiated thyroid cancer (DTC) at the Endocrinology Department from a hospital the southwest of Spain that attends patients from two different provinces. Owing to environmental pollution, one of them has higher incidence of cancer.
To evaluate the changes in the clinical presentation of DTC over time and analyse possible differences between patients from the two provinces, we designed a descriptive retrospective study, including all DTC cases admitted from January 1970 to March 2014. Quantitative variables are expressed as median (interquartile range). All the results were standardized using specific population records from the National Institute for Statistics for each time period.
Results
Total population 1289 (255 males/1034 females). Age at diagnosis: 43 years (33–55); 82.2% were papillary thyroid cancer (PTC) while 17.5% were follicular thyroid cancer (FTC). We found a progressive increase in PTC since 1970, more marked from 1996 to the present in both sexes (mainly between 21 and 65 years at diagnosis), in tumours >1 cm (T1b-T4), as well as papillary microcarcinoma, following the same trend. A similar pattern was observed in FTC. There were no differences regarding unfavourable histological subtypes. In the 1970's, PTC and

FTC tended to be >4 cm and/or with extrathyroid extension, N1 and M1, in comparison with the current presentation (<4 cm, limited to the thyroid and N0 M0). In patients from the most polluted province we detected a non-significant slightly higher percentage of high-risk tumours (8.85% vs 7.55%) without any other differences.

Conclusion

DTC clinical presentation has shifted from high-risk tumours at diagnosis (1970's and 1980's) to a low-risk profile (T1-3, N0, and M0) in the last years, with a steadily increase in the number of cases per year, mainly PTC. Men have a tendency to have higher risk tumours than women.

Thyroid cytology–biopsy correlation

Inmaculada Gavilán-Villarejo[1], Laura Larrán-Escandón[1], Isabel Mateo-Gavira[1], Pilar Roldán-Caballero[1], Cristina López-Tinoco[1], Diego Martínez-Parra[2], Eduardo Vallejo-Roca[3] & Manuel Aguilar-Diosdado[1]
[1]Endocrinology, Puerta del Mar Hospital, Cádiz, Spain; [2]Pathological Anatomy, Puerta del Mar Hospital, Cádiz, Spain; [3]Radiology, Puerta del Mar Hospital, Cádiz, Spain.

Background

Fine-needle aspiration (FNA) biopsies are the cornerstone of preoperative evaluation of thyroid nodules, but FNA diagnostic performance has varied across different studies. We conducted a study to evaluate the effectiveness of ultrasound guided FNA in the thyroid nodule and to review the correlation between cytopathology and histopathology.

Methods

Prospective FNAs were collected from 332 patients who underwent thyroid surgery between 2008 and 2013. The cytological sample was assessed by a single consultant pathologist and was classified as inadequate, non-neoplastic, neoplastic, or indeterminate. The histology were classified as non-neoplastic (benign), neoplastic (malignant). Sensitivity, specificity, positive predictive value, and negative predictive value were calculated.

Results

The mean age was 51.65 ± 13.40 years, 279 (84%) were women. The average size of nodules was 3.35 ± 1.41 cm. Multinodular goiter presented with dominant nodule 239 (72%) patients and 93 (28%) single nodule. Cytology analysis showed 216 (66.3%) benign, 86 (26.4%) indeterminate, and 24 (7.4%) malignant. One hundred and ninety-seven (59.3%) patients underwent total thyroidectomy. From this population indeterminate cytology rate were 75 (87.2%) benign and 11 (12.6%) malignant histopathology. The FNAs had a sensitivity of 84.62%, specificity of 99.07%, positive predictive value of 91.67%, and negative predictive value 98.15%.

Conclusions

Ultrasound-guided FNA provides important information for the diagnosis and the preoperative evaluation of thyroid nodules. The low rate of false-positive and false-negative results suggests that it might be enough for surgical planning for thyroid nodule.

Simultaneous occurrence of different follicular neoplasms within the same thyroid gland: a retrospective study

Sefika Burcak Polat[1], Dilek Arpaci[2], Aylin Kilic Yazgan[3], Husniye Baser[1], Mehmet Kilic[4], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Endocrinology and Metabolism Department, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey; [2]Enocrinology and Metabolism Department, Karaelmas University Hospital, Zonguldak, Turkey; [3]Pathology Department, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey; [4]General Surgery, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey.

Introduction

Neoplasms of the thyroid gland are classified according to the cell that it originates and commonly they originate from follicular or parafollicular C cells. The most common differentiated thyroid cancers (DTC) are papillary and follicular carcinomas. Coexistence of two different histological types of primary follicular thyroid neoplasm is a rare condition. There are previous reports of concomitant medullary and papillary thyroid cancers. However, there is scarce data about the simultaneous two different histological types of primary follicular thyroid tumors and this is the first study on that subject.

Method

From January 2007 to September 2014, our institutional database was reviewed for patients who underwent thyroid surgery for various indications. Medical records and cytopathology reports of those patients were examined retrospectively. Simultaneous neoplasms of follicular origin were noted.

Results

A total of 3700 patients were operated. Histopathological examination result was benign in 2686 (73%) patients while it was malignant in 1014 (27%) patients. Among the patients with the diagnosis of DTC only 20 (1.9%) had accompanying second neoplasia within the same thyroid gland. PTC had thyroid capsule invasion in seven patients (35%) while capsule was intact in 13 (65%). In 17 (85%) patients there wasn't vascular invasion whereas in three patients (15%) vascular invasion was detected in PTC. Second neoplasm was follicular carcinoma in ten patients, Hürthle cell carcinoma in two patients, Hürthle cell adenoma in five patients, and follicular adenoma in three patients.

Conclusion

Such simultaneous tumors may be part of a familial tumour syndrome or an unidentified novel gene mutation playing role in the pathogenesis of more than one type of tumor. Based on the current evidence the synchronous occurrence of those neoplasms in a given patient is likely coincidental in the literature. Further study is required using a larger patient population with standardised genetic characterisation.

Thyroid Imaging Reporting and Data System (TIRADS) can reduce the needed number of FNA

Dana Stoian[1,5], Mihnea Derban[2], Florian Varcus[3], Bogdan Timar[6] & Mihaela Craciunescu[4]
[1]Department of Obstetric Gynecology, Victor Babes University of Medicine, Timisoara, Romania; [2]Department of Pathology, Victor Babes University of Medicine, Timisoara, Romania; [3]Department of Surgery, Victor Babes University of Medicine, Timisoara, Romania; [4]Department of Microbiology, Victor Babes University of Medicine, Timisoara, Romania; [5]Center for Elastography, Timisoara, Romania; [6]Department of Medical Informatics, Victor Babes University of Medicine, Timisoara, Romania.

The prevalence of solid thyroid nodules is very high in the general population. Appropriate selection of cases for surgery is the most important task, when evaluating nodules. The present study wants to see if the use of Thyroid Imaging Reporting and Data System (TIRADS) could decrease the number of needed FNAB procedures.

Material and method

174 nodules evaluated by conventional ultrasound and real time elastography, with linear multifrequency probe, Hitachi Preirus Machine, Hitachi, Inc. Prospective all nodules were classified by TIRADS system: ecogeneity (risk = inhomogeneity), margins (risk = irregular margins), shape (risk = irregular shape, taller than wide), calcification (risk = micro calcifications), lymph node (risk = presence), and increased strain (color map 4, 5, increased strain ration). TIRADS 4A, 4B, and 5 cases were referred also to FNAB. All 174 cases were operated and pathology report was obtained.

Results

Cancer was certified in 29 of the 174 operated thyroid nodules. The number of required punctions would be in 169 cases, if we consider the AACE guidelines. If we apply the TIRADS system (all 4A, 4B, and 5 TIRADS nodules) in selecting the cases for FNAB, the number would decrease significantly up to 74 nodules. The diagnostic quality of TIRADS is very high: using the ROC method, the AUC = 0.95761, confidence limit of 0.8424–0.989 (95% LCL and 95% UPL). The sensitivity and specificity in diagnostic of cancer was excellent: diagnostic sensitivity, 86.20% with high specificity, 97.24%, with the best accuracy of 95.40%.

Conclusion

Using TIRADS system, the correct evaluation of the majority of the thyroid nodules is achieved.

Female male ratio in thyroid cancer

Sevilay Ozmen[1], Ilknur Calik[1], Aynur Arslan[1], Ozge Timur[2], Hakan Sevimli[2], Ayse Carlioglu[3], Senay Arikan Durmaz[3], Ali Kurt[1] & Fazli Erdogan[1]
[1]Department of Pathology, Training and Research Hospital, Erzurum, Turkey; [2]Department of Internal Medicine, Training and Research Hospital, Erzurum, Turkey; [3]Department of Endocrinology, Training and Research Hospital, Erzurum, Turkey.

Aim
402 patients who were admitted and FNA was done in the Endocrinology Clinic at EBEAH were enrolled in this study. 340 (85%) of them were females and 62 (15%) of them were males. The age range was between 16 and 82. There weren't any statistical differences in age between both sexes. Thyroid cancer is reported to constitute $<2\%$ of cancers in humans. At the same time, it is the most lethal endocrine malignancy. In the literature it is stated that 3% of all cancers in women and 1% of all cancers in men is thyroid cancer. Papillary thyroid carcinoma is the most common malignant neoplasm of thyroid, it generates $\sim$80% of all thyroid cancers.
Results
340 of the examined 402 cases were female and cytopathological results of 303 (89.11%) were benign, 37 (10.88%) were malignant. A total of 62 male patients, 55 (88.70%) were benign, 7 (11.29%) were malignant. Totally 358 cases were reported as benign, 44 cases were reported as malignant. Of the 37 patients who were female, 26 had malignant papillary carcinoma, eight had papillary microcarcinoma, and three had follicular carcinoma. Of the seven male cases which were histopathologically reported as malignant, four had papillary carcinoma, two had papillary microcarcinoma, and one of them was reported as a well-differentiated neoplasm of uncertain malignant potential. When the results of FNAB were analysed according to the gender distribution, there wasn't any statistically significant difference. The results of FNAB were reported as benign in 89.11% of female and 88.70% of male patients. The positive assessment in terms of malignancy were 10.88% in females and 11.29% in males. Although, some malignancies are more common in women and some in men, thyroid malignancies can develop at any gender. In this study which includes 402 cases there was no significant difference in terms of gender. And these findings are very close to the values reported in the literature.

Histhopathological verification of atypia of undetermined significance in Bethesda system

Sevilay Ozmen[1], Ilknur Calik[1], Ahmet Erkan Bilici[1], Ozge Timur[2], Ayse Carlioglu[3], Senay Arikan Durmaz[3], Fazli Erdogan[1] & Ali Kurt[1]
[1]Department of Pathology, Training and Research Hospital, Erzurum, Turkey; [2]Department of Internal Medicine, Training and Research Hospital, Erzurum, Turkey; [3]Department of Endocrinology, Training and Research Hospital, Erzurum, Turkey.

The pathologist cannot easily decide some thyroid fine-needle aspiration biopsy (FNA) into the benign, suspicious, or malignity and this condition are reported as 'atypia of undetermined significance' (AUS) or 'follicular lesion of undetermined significance' in the Bethesda system. Diagnosis of AUS of a thyroid nodule is leaved an endocrinologist as well as the patients in a difficult situation. However, the risk of malignancy at AUS is $\sim$5–15%. Our aimed to this study is to determined histhopathological verification of atypia of undetermined significance according to Bethesda system.
Materials and methods
Results of FNA were used totally in 402 patients with nodular goitre from our hospital records from 2012 to 2014. Twenty people (19 women and one man) out of this study population were diagnosed AUS. All the patients had undergone total or subtotal thyroidectomy. We retrospectively re-evaluated postoperative biopsy results and compared with those histhopathological diagnoses.
Results
It was found that postoperative biopsy results of the patients who were diagnosed AUS were adenomatous hyperplasia (5%, $n=1$), nodular goitre (65%, $n=14$), papillary carcinoma (5%, $n=1$), Hashimoto's thyroiditis (15%, $n=3$), and microfolliculary adenoma (5%, $n=1$).
Conclusions
Our finding demonstrated that AUS category substantially indicated to benign cellular change. This date was found in accordance with prediction of Bethesda system. Therefore, a repeated FNA should be performed after an appropriate period of time. The factors including follicular lesion in part suspicious follicular neoplasia, existence of lymphoid cell, hypocellularity and artefact of sample preparation may lead to misdiagnosis of malignity in patients with AUS.

EP880

A pitfall of thyroid fine-needle aspiration biopsy results

Sevilay Ozmen[1], Ilknur Calik[1], Emre Akarsu[1], Ozge Timur[2], Ayse Carlioglu[3], Hakan Sevimli[2], Senay Arikan Durmaz[3] & Ali Kurt[1]
[1]Department of Pathology, Training and Research Hospital, Erzurum, Turkey; [2]Department of Internal Medicine, Training and Research Hospital, Erzurum, Turkey; [3]Department of Endocrinology, Training and Research Hospital, Erzurum, Turkey.

Introduction and aim
Bethesda system for thyroid cytopathology has been widely used recently. Approximately 3–7% of thyroid fine-needle aspiration (FNA) biopsy is considered as malign. Suspicious or malign nodules should likely to be resected. Aim of this study is to confirm the diagnosis of malign or suspicious for malignity according to Bethesda classification in patients with nodular goitre after thyroidectomy.
Materials and methods
Results of FNA in totally 402 patients with nodular goitre were achieved from our hospital records. All of the patients had undergone totally or subtotals thyroidectomy. We re-evaluated retrospectively biopsy results postoperatively. We compared their preoperative FNA results.
Results
We described totally five patients whom FNA were malignity but results of postoperative biopsy were benign. We found false positive results as one 38-year-old patient with follicular adenoma, one 50-year-old patient with papillary thyroid cancer, and three patients (44.6 ± 8.7 years) with suspicious for papillary thyroid cancer.
Conclusions
The malignity risk in classification of suspicious for malignity and malignity according to Bethesda reporting system is 60–75 and 97–99% respectively after thyroidectomy. Our findings demonstrate that our false positive results are lower than reported Bethesda classification in medically literature. Hyperplastic adenomatoid nodule, follicular adenoma, well-differentiate follicular carcinoma and papillary carcinoma follicular variant have several characteristic features in common. Therefore, difficulty of these lesions in pathologically evaluation may lead false positive results.

Histopathology results of follicular neoplasia according to Bethesda classification in thyroid fine-needle aspiration biopsy

Sevilay Ozmen[1], Ilknur Calik[1], Ebru Sener[1], Ozge Timur[2], Ayse Carlioglu[3], Hakan Sevimli[2], Senay Arikan Durmaz[3] & Ali Kurt[1]
[1]Department of Pathology, Training and Research Hospital, Erzurum, Turkey; [2]Department of Internal Medicine, Training and Research Hospital, Erzurum, Turkey; [3]Department of Endocrinology, Training and Research Hospital, Erzurum, Turkey.

Introduction and aim
Interpretation of follicular neoplasia classification according to Bethesda system in thyroid fine needle aspiration biopsy is very different among pathologist. A number of definition including 'follicular lesion', 'follicular proliferation', 'follicular lesion of undetermined significance', and 'follicular neoplasia' were used in terminology. A clearly discrimination between nodular goitre, follicular adenoma, and follicular carcinoma cannot lack due to same cytomorphologic features. Approximately 15–30% of case of follicular neoplasia in thyroid fine-needle aspiration biopsy (FNA) is considered as malignity. Aim of this study is to confirm with histopathological diagnosis after thyroidectomy in patients with follicular neoplasia according to Bethesda classification.
Materials and methods
Results of FNA in totally 402 patients with nodular goitre were achieved from our hospital records from 2012 to 2014 years. All the patients had undergone totally or subtotal thyroidectomy. We retrospectively re-evaluated postoperatively biopsy results.
Results
We described ten patients whom diagnosis of FNA were follicular neoplasia but results of postoperative biopsy were found adenomatous nodule ($n=1$),

'adenomatous nodule and chronic lenfocytic thyroiditis' ($n=1$), 'papillary carcinoma', 'follicular variant ($n=2$)', 'nodulary goitre' ($n=4$), 'adenomatous nodule-Hürthle cell variant ($n=1$)', and 'well-differentiated follicular neoplasia'.
Conclusions
Our finding demonstrated that descriptive criteria of folliculary neoplasia in FNA substantially point out hyperplastic proliferation rather than neoplasia.

The rare intracellular RET mutation p.S891A in a Turkish family with hereditary medullary thyroid carcinoma

Caglar Keskin & Sevim Gullu
Department of Endocrinology and Metabolic Disease, Ankara University Faculty of Medicine, Ankara, Turkey.

Introduction
Medullary thyroid carcinoma (MTC) could be familial in 30% of cases. Here, we report a family of FMTC with rarely seen RET p.S891A mutation.
Case presentation
A 49-year-old man presented with a single nodule in the left lobe of thyroid. Thyroid ultrasonography (US) showed a nodule and pathological cervical lymph nodes. There was no relevant family history. Fine-needle aspiration cytology (FNAC) of the nodule was consistent with a diagnosis of medullary thyroid carcinoma. Serum calcitonin level was 906 pg/ml (reference range 0–18) and the other laboratory tests, parathyroid hormone level and 24-h urine catecholamine levels were normal. An extensive RET molecular analysis identified the rare intracellular RET p.S891A mutation. Then the patient underwent total thyroidectomy and bilateral neck dissection. Histopathology revealed medullary thyroid carcinoma pT1bN1bM0 with capsular and lymphovascular invasion and lymph node metastases. Serum calcitonin and carcinoembryonic antigen levels measured 3 months after the surgery was 569 pg/ml and 12 ng/ml respectively. During the follow-up there was progressive rise in calcitonin and CEA levels. No distant metastases were detected. Since there were cervical pathological lymph nodes he was planned to have revision operation. RET p.S891A mutation was also detected at his daughter. She was completely asymptomatic and baseline serum calcitonin level was normal. Calcium stimulation test showed no marked increase in CT levels therefore prophylactic thyroidectomy was postponed.
Conclusions
We reported a patient who presented all characteristic features of sporadic MTC but extensive molecular analysis revealed rarely seen intracellular RET p.S891A mutation and his daughter had same mutation. RET genetic screening is very important tool for the preclinical diagnosis and early treatment of unsuspected affected family members.

Aggressive medullary thyroid cancer in a homogenous population

Paul Lennon[1], Sandra Deedy[2], Andrew Green[3], John Kinsella[1], Conrad Timon[1], James Paul O'Neill[4] & Marie-Louise Healy[1]
[1]St. James's Hospital, Dublin, Ireland; [2]National Cancer Registry, Cork, Ireland; [3]National Centre for Medical Genetics, Dublin, Ireland; [4]Royal College of Surgeons, Dublin, Ireland.

Introduction
Medullary thyroid cancer arises from the calcitonin-secreting parafollicular C cells and consists of a spectrum of disease that ranges from extremely indolent tumours, where patients may survive for many years with a large tumor burden, to aggressive types associated with a high mortality rate. The objective of our study is to evaluate the prognostic factors and outcomes of patients diagnosed with medullary thyroid cancer in a homogenous population, and to examine the tissue sample of patients diagnosed with MTC for mutations in the RET proto-oncogene from the same period.
Methods and design
A retrospective analysis of the National Cancer Registry in Ireland was undertaken, for patients with a diagnosis of medullary thyroid cancer between 1998 and 2007. The Kaplan–Meier method was used to determine overall survival and factors predictive of outcome were determined by univariate and multivariate analysis by Cox regression using STATA 13 Software.
Results
Forty-six patients were diagnosed with MTC, 55.8% were females and 44.2% were males. A median age of 52was found. The overall median survival was 6.32 years and the 1- and 5-year overall survival was 88.37 and 62.79% respectively, with a 10-year survival calculated at 48.63%. On univariate analysis age, stage and surgical intervention were statistically significant indicators of prognosis. T stage and age remained statistically significant indicators of prognosis on multivariate analysis. Two patients with no history of MEN syndromes or family history of MTC had RET proto-onocogene mutations.
Conclusions
Our patient cohort was substantially older than what is commonly seen in the literature. There was a very low pick up of RET mutations in sporadic MTC in our patient cohort, and along with relatively poor outcomes, this suggest that further studies of this population may allow us to identify aggressive variants of medullary thyroid cancer.

Simultaneous occurrence of medullary and papillary thyroid microcarcinomas: case report

Krisztian Sepp[1], Eva Csajbok[1], Sandor Magony[1], Laszlo Tiszlavicz[2], Balint Tobias[3], Attila Patocs[4] & Zsuzsanna Valkusz[1]
[1]First Department of Medicine, University of Szeged, Szeged, Hungary; [2]Department of Pathology, University of Szeged, Szeged, Hungary; [3]First Department of Internal Medicine, Semmelweis University, Budapest, Hungary; [4]Second Department of Internal Medicine, Semmelweis University, Budapest, Hungary.

Thyroid cancers represent ~1% of new cancer diagnoses. Thyroid malignancies are divided into papillary carcinomas (80%), follicular carcinomas (10%), medullary carcinomas (5–10%), anaplastic carcinomas (1–2%), and other rare tumours (primary thyroid lymphomas and primary thyroid sarcomas). The main therapeutic options are surgery (mainly total thyreoidectomy), radioiodine treatment, levothyroxine therapy (TSH suppression dose), others (external beam irradiation, chemotherapy, and tyrosine kinase receptor inhibitors). A medical investigation was started with a 60-year-old male patient due to palpable thyroid nodules. The ultrasonography revealed nodules in the isthmus and in both thyroid glands (diameter: 4.0, 2.7, and 2.0 cm) without lymphadenopathy, the fine-needle aspiration didn't show any malignant suspect cytological sign. The patient was euthyroid, the calcitonin level was elevated (38.5 pg/ml, normal: −9.6). Because of the suspicion of medullary cancer we recommended total thyroidectomy. The postoperative histology showed papillary microcarcinoma in the left lobe nodule and medullary microcarcinoma in the right lobe nodule with no affected lymph nodes. Levothyroxine therapy was started at substitutional dose, there was no radioiodine treatment. Now the patient has undetectable calcitonin level and low human thyreoglobuline level (<1 ng/ml) with normal anti-human thyreoglobuline rate without any sign of recurrence or metastasis. Genetic screening was performed: it is negative for RET mutation, the other markers are processing. In our case a simulataneous occurrence of medullary and papillary thyroid microcarcinomas were detected in different nodules of the thyroid gland, the genetic screening is in process. In the literature <80 similar cases were reported (none in Hungary). Owing to the rarity of the occurrence we are reporting our interesting case.

The utility of basal serum thyroglobulin measurement, using a highly sensitive immunoassay, in the follow up of patients treated for differentiated thyroid cancer

Nigel Glynn[1], Anne Marie Hannon[1], Lauren Schneekloth[1], Ciara De Buitleir[1], Martina Morrin[2], Frank Keeling[2], Clare Faul[3], Mary Leader[4], Arnold D K Hill[5], William Tormey[6], Diarmuid Smith[1], Chris J Thompson[1] & Amar Agha[1]
[1]Department of Endocrinology, Beaumont Hospital and RCSI Medical School, Dublin, Ireland; [2]Department of Radiology, Beaumont Hospital and RCSI Medical School, Dublin, Ireland; [3]Department of Radiation Oncology, Beaumont Hospital and RCSI Medical School, Dublin, Ireland; [4]Department of Histopathology, Beaumont Hospital and RCSI Medical School, Dublin, Ireland; [5]Department of Surgery, Beaumont Hospital and RCSI Medical School, Dublin, Ireland; [6]Department of Chemical Pathology, Beaumont Hospital and RCSI Medical School, Dublin, Ireland.

Introduction
TSH-stimulated serum thyroglobulin (Tg) is used as a sensitive marker for the detection of early recurrence or residual disease following treatment for differentiated thyroid cancer (DTC). However, stimulated Tg, using TSH or thyroid hormone withdrawal, is either costly or cumbersome for patients.
Aim
To compare the performance of basal T_4 suppressed, with stimulated Tg measurement, in the follow up of patients treated for DTC.
Methods
We retrospectively reviewed patients treated for DTC at our institution between September 2011 and September 2014. Data recorded included patient demographics, surgical pathology, and imaging results as well as biochemical parameters. Tg was measured by a highly sensitive immunoassay with a functional sensitivity of 0.1 ng/ml. A stimulated Tg >2 ng/ml was considered significant. Patients with an elevated anti-Tg antibody titre were excluded.
Results
46 stimulated Tg measurements were performed in 41 patients – TNM stages 1 and 2=33 patients; stages 3 and 4=8 patients. Of the 31 tests in which the basal Tg was <0.1 ng/ml, only one (3%) had a stimulated Tg >2 ng/ml; none had radiological evidence of recurrent or residual disease. If the basal Tg was 0.1–0.5 ng/ml, stimulated Tg was >2 ng/ml in 33% of cases.
Conclusion
Undetectable basal Tg measurement, using a highly sensitive Tg assay, together with negative neck imaging, are highly reassuring for remission following treatment for DTC.

The introduction of endocrinology–radiology MDT meeting significantly reduced inadequacy rates of thyroid fine-needle aspiration in a University Teaching Hospital

Mohamed Ahmed[1], Michael Jeffers[2], John Feeney[3], Pardeep Govender[3], Mark Sherlock[1] & James Gibney[1]
[1]Department of Endocrinology, The Adelaide and Meath Hospital Incorporating the National Children's Hospital (AMNCH), Tallaght, Dublin, Ireland; [2]Department of Histopathology, The Adelaide and Meath Hospital Incorporating the National Children's Hospital (AMNCH), Tallaght, Dublin, Ireland; [3]Department of Radiology, The Adelaide and Meath Hospital Incorporating the National Children's Hospital (AMNCH), Tallaght, Dublin, Ireland.

Introduction
A weekly endocrinology–radiology multidisciplinary (MDT) meeting has been recently introduced in our hospital to discuss indications and suitability of thyroid nodules for fine-needle aspiration (FNA). In a recent 5 years retrospective audit, 80% of thyroids FNAs were performed under ultrasound (US) guidance in our institution with an overall inadequacy (Thy1) rate of 11.1%.
Objectives
The aim of this study was to assess whether such an intervention can improve percentage of FNAs done under US guidance and reduce inadequacy rates.
Methods
A retrospective review of all computerised meeting records held in 2013. Cytological outcomes for those undergone FNA were obtained from pathology laboratory system.
Results
216 thyroid cases were discussed at our MDT meetings between January and December 2013, of those, FNA was recommended in 118 (54.6%), follow-up US thyroid in 39 (18%), and further images (mainly isotope uptake) in 28 (13%) cases. FNA was not indicated in 31 (14.3%) of cases most of them were small (<1 cm), stable, or hot nodules. 113 thyroid nodules were aspirated following MDT discussion. All FNAs (100%) were performed under US guidance with pathology in attendance to review adequacy of samples. The cytology outcomes were as follows: Thy1 (non-diagnostic) in six (5.3%) cases, Thy2 (benign) in 97 (85.8%) cases, Thy3 (follicular lesion/neoplasm) in seven (6.2%) cases, Thy4 (suspicious for malignancy) in one (0.9%), and Thy5 (malignant) in two (1.8%) cases. Inadequacy rate for FNAs performed following discussion at MDT was significantly lower (5.3%) compared to the overall inadequacy rate of 11.1% reported in the previous audit period ($P<0.05$).
Conclusion
The introduction of endocrinology–radiology MDT resulted in a 52.3% reduction of thyroid FNA inadequacy rate. This MDT proved to be a cost effective intervention in reducing inadequacy rate, hence further costs. All thyroid nodules should be discussed at such meeting to assess suitability for FNA.

Value of neutrophil to lymphocyte ratio in predicting malignancy in thyroid nodules diagnosed as follicular neoplasm on cytology

Neslihan Soysal-Atile[1], Nuray Can[2], Sibel Güldiken[3], Hüseyin Çelik[3], Atakan Sezer[4], Dogan Albayrak[4] & Armagan Tugrul[3]
[1]Endocrinology Department, Tekirdag State Hospital, Tekirdag, Turkey; [2]Pathology Department, Trakya University Faculty of Medicine, Edirne, Turkey; [3]Endocrinology Department, Trakya University Faculty of Medicine, Edirne, Turkey; [4]General Surgery Department, Trakya University Faculty of Medicine, Edirne, Turkey.

Aim
It is well known that there is a strong relationship between chronic inflammation and tumorigenic process. The cytological diagnosis of follicular neoplasm (FN) carries a 20–30% risk of malignancy for thyroid nodules. In this study, we aimed to evaluate whether preoperative neutrophil to lymphocyte ratio (NLR) is a predictive factor for malignancy in thyroid nodules diagnosed as FN on cytology.
Materials and methods
A total of 139 patients with FN who were treated by surgery were enrolled. Preoperative demographic and laboratory findings, USG characteristics and final pathological results were assessed retrospectively.
Results
86.3% of the patients are females ($n=120$) and 13.7% are males ($n=19$). The overall malignancy rate of FN cytology was 44.5% ($n=62$). There was no significant difference in NLR between the benign and malign groups (NLR= 2.12 ± 1.05 and 1.98 ± 0.92, respectively, $P=0.496$). When USG features were evaluated, hypoechogenicity and irregular margins was found associated with malignancy risk ($P=0.006$).
Conclusion
Our study showed no association between NLR and malignancy risk in thyroid nodules diagnosed as FN on cytology. The NLR is used as a readily available and inexpensive biomarker of inflammation. Many studies emphasised the increased NLR is associated with poor prognosis and adverse survival in various solid tumors including differentiated thyroid tumors. But we concluded NLR is not useful in predicting malignancy risk of thyroid nodules diagnosed as FN on cytology.

Accuracy of fine-needle aspiration of the thyroid in a University Teaching Hospital

Mohamed Ahmed[1], Michael Jeffers[2], John Feeney[3], Pardeep Govender[3], Mark Sherlock[1] & James Gibney[1]
[1]Department of Endocrinology, The Adelaide and Meath Hospital Incorporating the National Children's Hospital (AMNCH), Tallaght, Dublin, Ireland; [2]Department of Histopathology, The Adelaide and Meath Hospital Incorporating the National Children's Hospital (AMNCH), Tallaght, Dublin, Ireland; [3]Department of Radiology, The Adelaide and Meath Hospital Incorporating the National Children's Hospital (AMNCH), Tallaght, Dublin, Ireland.

Background
Thyroid fine-needle aspiration (FNA) is a safe, valuable and cost effective procedure and is now regarded as the investigation of choice for preoperative assessment of thyroid nodules. The reported sensitivity of thyroid FNA varies from 65 to 98% and the specificity from 73 to 98%.
Aim
The aim of this study was to assess the accuracy of this procedure correlating cytology with histological outcomes, and to audit our practice against standard recommendations and published literature.
Methods
The cytological diagnoses of all thyroid FNA biopsies performed during the 5 years period (2008–2012) were retrieved retrospectively from the Pathology Laboratory Information System.
Results
567 thyroid FNAs were performed on 433 patients. The cytological diagnoses were as follows: Thy1 (non-diagnostic) in 63 (11.1%) cases, Thy2 (benign) in 424 (74.8%) cases, Thy3 (follicular lesion) in 54 (9.5%) cases, Thy4 (suspicious for malignancy) in nine (1.6%), and Thy5 (malignant) in 17 (3%) cases. Of 63 cases which were non-diagnostic, 25 had a repeat sampling, and of those a diagnostic aspirate was achieved in 84% ($n=21$) of cases. 80% of FNAs were performed under US guidance with onsite cytopathology evaluation, and the inadequacy rate was significantly lower in the US guided FNA compared to the free-hand aspirates (8.7% vs 15.7%, respectively, $P<0.05$). 111 patients had either partial or total

thyroidectomy, of which 69 (62.2%) were benign and 43 (37.8%) were malignant nodules. The sensitivity and specificity for detecting neoplasia were 87.5 and 83% respectively.
Conclusions
Thyroid FNA is a reliable and accurate procedure in triaging patients with thyroid nodule for surgery. Our findings are consistent with the standard recommendations and published literature. The use of US guided FNA coupled with onsite evaluation by pathologist should be the standard practice in all cases of thyroid nodules referred for FNA in order to reduce inadequacy rate and improve accuracy.

Pleural metastasis of papillary thyroid carcinoma: case report and review of literature

Ahmed-Ali Leila, Fedala Nora Soumeya & Chentli Farida
Department of Endocrinology and Metabolic Disease, Bab El Oued Hospital, Algiers, Algeria.

Introduction
Papillary thyroid carcinoma (PTC) has generally good prognosis, and distant spread is rare. Common sites of distant metastasis are lung parenchyma and bone. Pleural metastasis is less common (0.6%), and most cases have been detected because of pleural effusion. Malignant pleural effusion is a poor prognostic factor among patients with PTC. We report a case of pleural metastasis of PTC proved by pleural biopsy.
Case report
A 62-year-old man was referred to our unit for pleural effusion and lung metastases which pleural biopsy showed the thyroid origin. He had undergone total thyroidectomy. Histopathological examination revealed a multifocal thyroid papillary carcinoma (PT3NXM2). Up-take scan after radioiodine therapy was positive in cervical and lungs. After pathological diagnosis, the serum thyroglobulin level was 6090 ng/ml. The rest of the staging (cerebro spinal MRI and bone scan) came back without abnormalities.
Conclusion
Pleural metastases of thyroid carcinomas are rare and usually occur in a context of metastatic spread. Their specific management is difficult because of the recurrent nature of the effusion. The median survival duration after pleural effusion development is reported to be <1 year, and most reported cases have had poor prognoses.

Sentinel lymph node biopsy in medullary thyroid carcinoma: a pilot study

Radan Dzodic[1,2], Nada Santrac[2], Merima Oruci[2], Ivan Markovic[1,2], Igor Djurisic[2], Marko Buta[2] & Gordana Pupic[3]
[1]Medical School, University of Belgrade, Belgrade, Serbia; [2]Surgical Oncology Clinic, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia; [3]Department of Pathology, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia.

Introduction
Serum calcitonin levels (sCT) in medullary thyroid carcinoma (MTC) correlate with the tumour size and disease progression. Lymph node (LN) metastases can be verified even in sCT lower than 100 pg/ml. The extent of LN dissection has not yet been standardised. The aim of this pilot study was to show our experience with sentinel lymph node (SLN) biopsy of jugulo-carotid chain (JCC) in selection of patients with MTC for modified radical neck dissection (MRND).
Materials and methods
Following protocols of our institution, all patients with confirmed thyroid carcinoma on intraoperative frozen section analysis undergo total thyroidectomy, central neck dissection, and SLN biopsy of JCC. SLN biopsy is performed after peritumoral injection of 1%-methylene blue dye (0.2–0.5 ml), and frozen section examination follows, in order to make decision on further MRND. For this study, we have selected 13 patients treated surgically from year 2007 to 2015 due to suspect MTC with increase of sCT, clinically and ultrasonically verified thyroid tumour and 'clear' regional lymph nodes. Inclusion criteria for this pilot study were sCT lower than 1000 pg/ml and subcentimetre tumour size. All patients had uni- or bilateral SLN biopsy of supraomohyoid regions (II–III). Besides these blue stained SLNs, we have removed surrounding LNs of II and III region in order to obtain more precise definite pathological evaluation of LNs.
Results
In dissected central LNs, metastases were not verified. All SLNs were identified as benign, both on frozen section and definite pathological analysis, thus there were no false negative results. Besides SLNs, all LNs extirpated from II to III regions were benign on definite pathology reports. On postoperative check-ups, all sCT were in the normal range, patients suffered no complications of thyroid surgery and none have disease relapses. The SLN biopsy method's accuracy is 100%.
Conclusion
This pilot study is the first reported experience with SLN biopsy of JCC in MTC using methylene blue dye. SLN biopsy can be precisely used for intraoperative assessment of lateral neck compartment. It enables adequate surgery for patients with subcentimetre MTC and sCT under 1000 pg/ml, avoiding unnecessary prophylactic MRND.

Papillary thyroid carcinoma in children: 33 years of experience of a single institution in Serbia

Marko Buta[1], Ivan Markovic[1,2], Milovan Matovic[3,4], Nada Santrac[1], Igor Djurisic[1], Zorka Milovanovic[5], Gordana Pupic[5] & Radan Dzodic[1,2]
[1]Surgical Oncology Clinic, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia; [2]Medical School, University of Belgrade, Belgrade, Serbia; [3]Department of Nuclear Medicine, Clinical Center of Kragujevac, Kragujevac, Serbia; [4]Medical School, University of Kragujevac, Kragujevac, Serbia; [5]Department of Pathology, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia.

Background
Well-differentiated thyroid carcinoma in children is rare but it shows aggressive behaviour. Gross lymph node metastases and distant metastases are common on first clinical presentation.
Patients and methods
During 33 years (1981–2014) at the Institute of Oncology and Radiology of Serbia 24 children were operated due to papillary thyroid carcinoma. Mean age was 12.6 (range 7–16) years. At the time of diagnosis 12.5% patients had lung metastases. Total thyroidectomy or completion of thyroidectomy was performed in all cases followed with central neck dissection and frozen section examination of the jugulo-carotid compartments. Median follow-up was 10.1 (range 2.0–29.4) years.
Results
pT1a tumours were found in 12.5%, pT1b in 25%, pT2 in 20.83%, pT3 in 25%, and pT4 in 16.67%. All patients had papillary thyroid carcinoma. Multifocal tumours were found in 79.17% and capsular invasion in 83.33%. Lymphonodal metastases in either central or lateral neck compartments were found in 75% of patients. Median DFI has not been reached and overall survival rate was 100%.
Conclusion
Papillary thyroid carcinoma in children is characterised with high rate of loco-regional aggressiveness, multifocality, capsular invasion, lymph node metastases, and distant metastases at the time of diagnosis. Extensive surgical approach should be performed in both primary and recurrent disease in young patients with well-differentiated thyroid carcinoma in order to achieve loco-regional disease control and long disease free survival.

DOI: 10.1530/endoabs.37.EP891

Lymphonodal metastases in incidental thyroid microcarcinomas verified by sentinel lymph node biopsy of jugulo-carotid chain

Merima Oruci[1], Ivan Markovic[1,2], Nada Santrac[1], Igor Djurisic[1], Marko Buta[1], Gordana Pupic[3], Dusica Gavrilovic[4] & Radan Dzodic[1,2]
[1]Surgical Oncology Clinic, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia; [2]Medical School, University of Belgrade, Belgrade, Serbia; [3]Department of Pathology, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia; [4]Institute for Oncology and Radiology of Serbia, Data Center, Belgrade, Serbia.

Introduction
The aim of this study was to determine frequency of lymphonodal metastases in jugulo-carotid chain (JCC) and central neck compartment in incidental thyroid

microcarcinomas (ITMC), as well as to examine whether sentinel lymph node (SLN) biopsy of JCC is an accurate technique to select patients with true positive, but clinically and ultrasonically negative lymph nodes, for modified radical neck dissection (MRND).
Materials and methods
Out of all patients operated in our Institution from 2004 to 2013 for multinodal goitre, Hashimoto's thyroiditis, adenomas, Graves' disease or increase of serum calcitonin concentration, for the purpose of this study, we have selected 117 who had ITMC and were surgically treated with total thyroidectomy (lobectomy in only one patient), sampling or complete dissection of central lymph nodes and SLN biopsy in JCC. As a standard procedure, SLN mapping was performed with 0.2 ml of 1% methylene blue dye injected just beneath thyroid gland capsule. SLNs were examined by frozen section and if positive, additional MRND was done. Hystopathological analysis showed 108 papillary, six medullary, and three combined papillary and medullary thyroid microcarcinomas <1 cm in diameter.
Results
Multicentric carcinomas were recorded in 39.32% of patients. In patients with lymphonodal metastases (24.79%), JCC metastases were found in 7.69% and central in 20.51%. Specificity and sensitivity of method are 100 and 57.14%, positive and negative predictive values are 100 and 97.3%. Method's accuracy is 97.39%.
Conclusion
Data showed high percentage of metastases in central neck compartment. SLN biopsy is a method more precise than clinical examination and ultrasonography in detection of ITMC lateral lymphonodal metastases in N0 patients. Using SLN biopsy for intraoperative assessment of lateral compartment one can avoid unnecessary MRND, as well as prevent under-treatment of patients with good prognosis. In addition, this method helps optimizing ablative radioiodine treatment.

Thyroid cancer arises in 5% of patients referred from primary care to a high-resolution thyroid clinic

Isabel Mancha Doblas[1], Carmen Maria Cortes-Salazar[2], Jose Carlos Fernandez-Garcia[1] & Francisco Tinahones[1]
[1]Endocrinology Department, Virgen de la Victoria University Hospital, Malaga, Spain; [2]Badolatosa Primary Care Centre, Seville, Spain.

Objective
To evaluate the prevalence of thyroid cancer in patients with suspected thyroid nodule referred from primary care.
Methods
Retrospective cohort study which included patients with suspected thyroid nodule referred from primary care to a high-resolution thyroid nodule clinic. Demographic and clinical characteristics were collected, all patients underwent thyroid ultrasound and subsequently, a fine-needle aspiration (FNA) was performed if thyroid nodules were >1 cm of diameter of if there was evidence of risk factors for thyroid carcinoma (in accordance with American Thyroid Association guidelines).
Results
987 patients were included in this study. After performing thyroid ultrasound the presence of a thyroid nodule was detected in 79.5% of patients (785 nodules) with a mean nodule diameter of 2 ± 1.15 cm. FNA was performed in 585 nodules (74.5% of all nodules). 11.8% of all cytological samples had suspected malignancy and 2.1% were malignant. Referral for surgery was required in 23.2% of patients (mainly because of nodule size or suspected malignancy). Malignancy was confirmed in 5.6% of thyroid nodules.
Conclusions
The prevalence of thyroid cancer in this cohort of patients from primary care is 5.6%. Thus, approximately one out of 20 thyroid nodules referred from primary care to a high-resolution thyroid clinic is proven to be malignant.

Miliary tuberculosis mimicking papillary thyroid cancer metastasis

Adem Gungor[1], Naile Gokkaya[1], Arzu Bilen[2] & Habib Bilen[1]
[1]Faculty of Medicine, Department of Internal Medicine, Division of Endocrinology and Metabolism, University of Ataturk, Erzurum, Turkey; [2]Faculty of Medicine, Department of Internal Medicine, University of Ataturk, Erzurum, Turkey.

Introduction
Papillary thyroid carcinoma (PTC) is the most frequently occurring subtype of thyroid differentiated cancers. PTC frequently metastasizes to the cervical lymph node region and metastasis rate of approximately 20–90% is available when diagnosed. Distant metastasis are usually the lungs, bone and brain metastases. Furthermore rarely the adrenal gland, skeletal muscle, ovaries, submandibular gland, sphenoid sinuses, liver and pancreatic metastases can be occurred. PTC's lung metastases can manifest as nodular, local or generalized lymphadenopathy, pleural effusion and miliary multiple metastases. Miliary metastases are extremely rare.
Case
A 40-year-old man was referred to Department of Pulmonary Diseases for complaints of cough with expectoration, dispnea and chest pain. Chest x-ray revealed miliary pulmonary lesions which was confirmed on computed tomography (CT) analysis. Because of clinical suspicion of miliary tuberculosis, bronchoscopic biopsy was performed. The papillary thyroid cancer metastasis was diagnosed in histological examination. Since the histological diagnosis was PTC, we checked the thyroid gland. Ultrasound examination of thyroid gland showed 10×15 mm hypoechoic solid nodule with micro calcification. The diagnosis of PTC was verified with cytological examination *via* ultrasound guided thyroid fine needle aspiration. Because of these findings total thyroidectomy was performed. Microscopically, this nodule was diagnosed PTC (hurtle cell variant) with capsular and lenfovascular invasion. After treatment with iodine 131 was planned patient was discharged.
Conclusion
Although PTC is known relatively lingering disease, the early metastases can be occurred before When diagnosis of PTC is established. Metastatic PTC may appear radiograhpically as solitary or multiple nodules and rarely diffuse micronoduler and reticular. So because of these paterns while evaluating the miliary lesions of lung the metastases of PTC must be come to mind.

Analysis of thyroid cancer mortality between 1975 and 2011 in Andalusia, Spain

Ana R Romero-Lluch[1,2], Elena Navarro-González[1,2], M Cruz Almaraz-Almaraz[2], Jorge Díaz-Alemán[2], M Ángeles Gálvez-Moreno[2], Inmaculada Gavilán-Villarejo[2], Tomás Martín-Hernández[2], Carolina Sánchez-Malo[2], Elena Torres-Vela[2] & Francisco Viciana-Fernández[3]
[1]Virgen del Rocio University Hospital, Seville, Spain; [2]Thyroid Cancer working group, Andalusia, Spain; [3]Institute of Statistics and Cartography, Andalusia, Spain.

Introduction
The incidence of thyroid cancer (TC) is low, but rising over time. Some studies point to a possible increase in mortality rate (MR) from this cancer in certain areas of Spain and Andalusia. Our purpose was to analyse the TC mortality in Andalusia and study how it has changed in the last years. We also analysed differences by age, sex, and geographic area.
Methods
All deaths from TC were collected between January 1, 1975 and December 1, 2011. These deaths were classified by age, sex, and province. Data were obtained from the mortality register of the Andalusian Statistics and Cartography Institute and from the Regional Ministry of Health. We calculated specific MR standardized by the direct and indirect method (standardized mortality ratio-SMR-) for all Andalusia and for each province.
Results
Between 1975 and 2011, 1199 TC deaths were registered in Andalusia (62.1% women). In these 37 years the MR has not changed significantly. The MR is higher in women (0.5–1 deaths/100 000 population-year) than in men (0.4–0.7 deaths/100 000 population-year); however, it has remained stable in both genders over time. Mortality increases exponentially with age, ranging MR from 0.02–0.1 deaths/100 000 population-year at 1930s up to 2–5 deaths/100 000 population per year at 1980s. Mortality is higher in men than in women up to 1940s, remains equal in both sexes between 1940s and 1970s and is higher in women over 1970s. There are small differences when comparing mortality in the Andalusian provinces. The SMR for whole Andalusia is 1. A SMR >1 indicates that there are more deaths observed than expected, as occurs in Seville, Granada, Cádiz and Huelva. Córdoba, Jaén, Almería and Málaga have a SMR <1.
Conclusions
Mortality from TC in Andalusia has remained stable over the last 37 years. There are differences in mortality in the Andalusian provinces. It is necessary to analyse the factors involved.

Lymphocytic thyroiditis and differentiated thyroid cancer – challenges in follow-up

Diana Oliveira[1], Cristina Ribeiro[1], Maria João Martins[2], Sandra Paiva[1], Miguel Melo[1], Carolina Moreno[1], Daniela Guelho[1], Nuno Vicente[1], Luís Cardoso[1], Diana Martins[1] & Francisco Carrilho[1]
[1]Endocrinology, Diabetes and Metabolism Department, Coimbra Hospital and University Centre, Coimbra, Portugal; [2]Department of Pathology, Coimbra Hospital and University Centre, Coimbra, Portugal.

Introduction
Chronic lymphocytic thyroiditis (LT) is a very common condition, and its coexistence with papillary thyroid carcinoma has often been reported. Analytical and echographic challenges must be kept in mind in the follow-up of patients with both these disorders.
Case report:
We present the case of a woman with a history of multinodular goitre who underwent left thyroidectomy and isthmectomy at the age of 43, with the histopathological finding of papillary microcarcinoma associated with nodular hyperplasia and LT. Her follow-up included regular cervical and thyroid ultrasound and thyroglobulin (Tg) and antithyroglobulin autoantibodies (TgAbs) measurements. The remaining right thyroid lobe had a micronodular appearance on ultrasound; TSH was in the normal range; TgAbs were positive; Tg was undetectable. After 8 years of follow-up, ultrasound revealed a suspicious cervical lymph node. A fine-needle aspiration biopsy (FNAB) was performed, with the Tg concentration of FNAB washout liquid being 36 ng/ml and cytology revealing aspects of metastasis from papillary thyroid carcinoma. She underwent completion thyroidectomy and lymph node dissection. Histopathology revealed a 12 mm papillary carcinoma in the right thyroid lobe, with extension to perithyroidal adipose tissue. The patient was subsequently admitted for radioiodine remnant ablation.
Conclusions
In patients with thyroid papillary microcarcinoma who have had only partial thyroidectomy and are positive for TgAbs, neither Tg nor TgAbs can be used reliably; regular careful ultrasound evaluation is essential in the follow-up of these patients. On the other hand, due to known alterations in thyroid gland structure, LT may cause diagnostic performance of thyroid ultrasound to be inferior in detecting suspicious nodules. This case report brings attention to the different difficulties found in the follow-up of patients with coexisting LT and thyroid papillary carcinoma.

DOI: 10.1530/endoabs.37.EP896

EP897

RET M918T-exon 16 mutation in subjects with sporadic medullary thyroid cancer (sMTC)

Darko Katalinic[1], Miljenko Solter[2] & Nora Nikolac[2]
[1]University Hospital Centre Zagreb, Zagreb, Croatia; [2]University Hospital Centre Sisters of Charity, Zagreb, Croatia.

Medullary thyroid cancer (MTC) is a form of thyroid carcinoma which originates from the calcitonin-secreting neuroendocrine parafollicular cells of the thyroid. It accounts for 5–10% of all thyroid cancers, and it mostly occurs as a sporadic entity (sMTC), but a familial pattern is also possible. Somatic mutations of RET are reported in 20–80% of sMTCs. The majority of MTCs harbour a RET M918T-exon 16 mutation. In sporadic MTCs the RET gene is mutated in codon 918, where a methionine is substituted to a threonine. This transformation of RET gene promotes uncontrolled cell proliferation and tumoural development. The objective of this study was to assess the occurrence of MTC and co-occurring RET M918T mutation in the sample of Croatian population. A nonisotopic polymerase chain reaction (PCR) based single strand conformation polymorphism analysis and heteroduplex gel electrophoresis method was used to screen DNA extracted from 34 formaldehyde fixed and paraffin embedded sMTC specimens of the patients for M918T mutation in RET exon 16. Results were compared with the disease phenotype and clinical findings. A germline methionine/threonine point mutation at codon 918 of the RET tyrosine kinase domain was identified in 21 patients (61.7%) (16 females (76.1%) and five males (23.8%), aged 62–78 years). The first data about RET M918T mutational status in the sample of Croatian population with MTC shows that the incidence of RET exon 16 mutation is within generally valid limits. However, all subjects with RET M918T mutation had more aggressive phenotype and worse cancer-specific survival. These data should be confirmed on a larger study group in prospective studies in order to determine whether RET M918T mutation contribute to progression of sMTC. All obtained results could serve in selection of patients for RET-inhibitors therapy with vandetanib and cabozantinib and as predictive biomarkers the same therapy.

Cytological variants of papillary thyroid carcinoma: clinical presentations according with the presence of BRAF mutation

Amelia Oleaga[1], Eider Etxeberría[1], Laura Calles[1], Fernando Goñi[1], Elena Fuertes[2], Maite Pérez de Ciriza[1], Aitziber Ugalde[2] & Miguel Paja[1]
[1]Endocrinology Department, Universitary Basurto Hospital, Bilbao, Spain; [2]Pathology Department, Universitary Basurto Hospital, Bilbao, Spain.

Introduction
BRAF(V600E) mutation has received great attention to improve risk stratification in patients with PTC. Its prognostic value in the different Cytological variants (CytV) of PTC is not well established. The aim of this study was to investigate differences in clinicopathological features according to CytV, among patients harbouring the mutation.
Methods
We evaluated 102 patients with pathological diagnosis of PTC. All of them underwent total thyroidectomy and radioiodine ablation, 87 central lymph node (LN) dissection (67 prophylactic, and 18 lateral neck dissection as well. DNA was extracted from neoplastic cells and BRAF mutation was detected by PCR and sequencing. Analysis included histological subtype, age, multifocality (MF), extrathyroidal extension (EET), LN metastases (LNMx), LNratio (LNR) (number of positive LN divided by the total amount of dissected nodes) and clinical remission(CR) after 1 year of initial treatment (stimulated thyroglobulin (Tg) undetectable, no presence of Tg antibodies and negative cervical ultrasound).
Results
patients harboured BRAF mutation (45,1%). According to CytV: 27/38 (71%) classic variant (CV), 3/33 (9%) follicular variant (FV) and 16/25 (64%) mixed forms (MV). In mutation carriers mean age was 47 years in CV, 58 in FV and 60 in MV. MF was present in 59% of CV, 66% FV, 50% MV. EET was found in 51% of CV, 33% FV, 33% MV. The rate of central LNMx was 85% in CV, 37%MV and no patients in FV. The LNR was 22.4% in CV, and 6.1% in MV. CR was achieved in 15 out of 20 evaluated patients with CV and all the 11 with MV.
Conclusions
In our series BRAF mutation is more prevalent in CV of PTC as it has been described previously, and at a younger age. We also emphasise the high prevalence of LNMx and the higher LNR found in patients with CV tumours. Given the prognostic value of BRAF mutation, these results confirm the more benign behaviour of FVPTC.

EP899

Incidence and peculiarities of thyroid cancer in patients with type 2 diabetes mellitus

Tetyana Yuzvenko & Volodymyr Pankiv
Ukrainian Scientific and Practical Center of Endocrine Surgery, Transplantation of Endocrine Organs and Tissues of the Ministry of Health of Ukraine, Kiev, Ukraine.

Diabetes mellitus is a risk factor for cancer, specifically of breast, endometrium, bladder, liver, colorectum, and pancreas. The pathophysiology of how diabetes contributes to cancer growth or development is an area of active investigation. The aims is to study the frequency and morphological features of thyroid cancer in patients with type 2 diabetes mellitus (DM).
Materials and methods
The study involved 45 patients with thyroid cancer and type 2 DM. 980 patients with thyroid cancer who underwent treatment at the surgical department of the Ukrainian Scientific and Practical Center of Endocrine Surgery for the period from 2010 to 2012 years. The examination included the study of patients' complaints, measurement of blood glucose profiles, glycated hemoglobin, immunoreactive insulin (IRI), C-peptide, HOMA-IR index, lipid profile, ultrasound of thyroid and abdominal organs. In addition conducted fine needle aspiration of thyroid nodules before surgery, pathological examination after surgical treatment, the determination of interleukin-6 (IL-6). We studied the incidence of thyroid cancer in the general population of Ukraine. Statistical data were processed using Microsoft Excel. Results are expressed as the mean $\pm$ standard error indicators ($M \pm m$).
Results
The mean age of patients with type 2 DM and thyroid cancer was 59.2 ± 2.7 years, duration of DM (from the time of diagnosis) – 7.1 ± 1.3 years, body mass index (BMI) – 31.7 ± 2.6 kg/m^2. All patients established insulin resistance (IRI level was 31.26 ± 2.81 μ/l, HOMA-IR index – 14.57 ± 2.31). The frequency of type 2 DM among all patients treated with thyroid cancer is 4.6%. Among patients with thyroid cancer and type 2 DM were mostly women (32; 71.1%). Most patients had papillary thyroid cancer (37; 82.2%) than follicular one. Among the total

population of Ukraine thyroid cancer had been diagnosed in 39 042 patients, representing 74.8 per 100 000. At the same time among the inhabitants of Kiev incidence of thyroid cancer reaches 3039 (177.5 per 100 000). Obviously that the presence of DM is associated with an increased risk development of thyroid cancer. The number of newly diagnosed patients with thyroid cancer in Ukraine increase and in 2011 was 2984, or 6.5 per 100 000 of population, but in some regions, for example, in Kiev and the Kiev region, the incidence is respectively 12.9 and 12.2 per 100 000 of population.

Conclusion

Patients with DM have a higher incidence of thyroid cancer compared with the general population. The frequency of type 2 DM among patients with thyroid cancer is 4.6% with a predominance of women (71.1%). Most patients had the papillary thyroid cancer (82.2%) than follicular one.

Concomitant thyroid nodules in primary hyperparathyroidism

Mustafa Sahin, Gozde Sengul aycicek, Demet corapcioglu, Rifat emral, Sevim gullu, Murat Faik erdogan, Vedia Tonyukuk Gedik, Nilgun Baskal & Ali Riza Uysal
Ankara University, Ankara, Turkey.

Objectives

Coexisting thyroid nodules affect the treatment choice for PHPT. We aimed to evaluate the incidence of concomitant thyroid nodules in patients with primary hyperparathyroidism and to investigate the relationship between thyroid nodule volume, thyroid gland volume and thyroid nodules with clinical and laboratory parameters.

Materials and methods

This study was carried out at Ankara University Endocrinology and Metabolism Department. 183 patients with biochemically confirmed primary hyperparathyroidism and 30 patients with no any other co morbidities, as a control group, were evaluated. USG images, FNAB results, clinic and laboratory parameters of patients were reviewed from medical data.

Results

Thyroid nodules were higher in the PHPT patients ($P<0.001$). Six of the patients had papillary thyroid carcinoma and one had follicular neoplasia. Patients with thyroid nodules had higher 25-OH vitamin D levels ($P=0.026$). Thyroid volume was positively correlated with BMI ($P=0.001$ $r=0.272$), fasting glucose ($P=0.22$ $r=0.173$) and negatively correlated with TSH ($P=0.01$ $r=-0.194$). Number of nodules and nodule volume were positively correlated with creatinine ($P=0.036$ $r=0.158$) and negatively with GFR ($P=0.018$ $r=-0.179$). Also nodule volume was positively correlated with 25-OH vitamin D level ($P=0.04$ $r=0.154$). In regression analyses thyroid volume was found to be in relation with creatinine, HDL, 24 h urinary calcium and phosphorus; number of nodules with age, creatinine, GFR, BMI, HDL, 25-OH vitamin D, albumin and 24 h urinary calcium. The patients with malignancy had higher T4 lower TSH and better lumbar *T*-scores. But we couldn't find any relationship between 25-OH D levels, glucose levels and malignancy.

Conclusion

Thyroid nodules are more common in patients with primary hyperparathyroidism compared to normal group and considerable number of patients with nodules has thyroid cancer. Decreased GFR seems to be related with this increased incidence. Preoperative evaluation of thyroid gland with USG prevents missing thyroid disease especially a malignancy and unnecessary re-operative surgery.

Differentiated thyroid carcinoma in geriatric patients: a single centre experience with 7 years of follow-up

Mesut Ozkaya[1], Umut Elboga[2], Ayten Eraydın[1] & Y Zeki Celen[2]
[1]Department of Endocrinology, Gaziantep University, Gaziantep, Turkey; [2]Department of Nuclear Medicine, Gaziantep University, Gaziantep, Turkey.

Introduction

We evaluated the characteristics of differentiated thyroid carcinoma in geriatric patients and factors that influenced long-term survival in this retrospective study design. Among 1188 patients with differentiated thyroid carcinoma who were treated at our institution over the past 7 years, 144 patients were identified who were age 65 years or older(age range:65–88 years) at the time of their initial diagnosis. This study conducted a retrospective analysis of the patients and factors that influenced long-term survival of these 144 patients, who had a median follow-up of 5.5 years (range, 2–7 years).

Results

There were 105 female patients and 39 male patients (female to male ratio, 2.6:1). 86 tumours were papillary, 48 tumours were follicular, and ten tumours were Hurthle cell carcinoma. One hundred 11 (77%) of patients presented with a thyroid mass, and 104 (72.9%) of tumours pathologic stage were T3 or T4. Lymph node disease was evident at presentation in 66 (45.8%) of patients, and distant metastases were documented at diagnosis in 35 (24.3%) of patients. 122 (84.7%) patients underwent total thyroidectomy, and the remaining patients underwent biopsy only. Radioiodine was administered to 108 (75%) patients. The specific survival rates were 93, 90, and 86% at 2, 5, and 7 years follow up respectively. Multivariate analysis showed that the presence of metastases was the most important independent prognostic factor for survival. Survival was greatest in patients with tumours <1 cm in diameter, characterized by the absence of extraglandular spread and lymph node.

Conclusion

Differentiated thyroid carcinoma appears more aggressive in geriatric patients. A large proportion of tumors showed extrathyroid spread and distant metastases. This may justify a more aggressive surgical strategy with possible prophylactic lymphadenectomy, in addition to ablative therapy with iodine and suppressive therapy with levothyroxine.

Evodiamine inhibits human thyroid cancer cells *in vitro* and *in vivo*

Ying-Ray Lee[1], Chieh-Hsiang Lu[2], Yi-Sheng Chang[1], Shu-Hsin Chen[1] & Yi-Wen Liu[3]
[1]Translational Medicine Center, Chiayi Christian Hospital, Chiayi City, Taiwan; [2]Division of Endocrinology and Metabolism, Department of Internal Medicine, Chiayi Christian Hospital, Chiayi City, Taiwan; [3]Department of Microbiology, Immunology and Biopharmaceuticals, College of Life Sciences, National Chiayi University, Chiayi City, Taiwan.

Thyroid cancer is the most prevalent cancer among endocrine malignancies. In clinically, surgical resection combined with radioactive iodine therapy has been proved effective in treating differentiated thyroid cancer, including papillary and follicular thyroid cancers (FTC). However, patients with incurable differentiated thyroid cancer (DTC), poorly differentiated thyroid cancer (PDTC) and anaplastic thyroid cancer (ATC) exhibit worse prognosis. Therefore, a novel and effective treatment is urgently needed to deal with the current treatment. Evodiamine is one of the important components isolated from Chinese herb Wu-Chu-Yu, and has been demonstrated to contribute on anti-inflammatory effects, anti-angiogenesis, anti-tumor growth, anti-invasive and metastatic activities, and up-regulating apoptosis. In the present study, we examined the effects of evodiamine in FTC, PDTC and ATC cells, respectively. Evodiamine inhibited cellular proliferation and the colonies formation of FTC, PDTC and ATC cells. Cell cycle arrest at G2/M phase was found in all of the cells during evodiamine treatment. Moreover, caspase-dependent apoptosis in these cells was also revealed under evodiamine treatment. In addition, autophagy induction was also found in evodiamine treated human thyroid cancer cells. Finally, we verified the effects of evodiamine on anti-human thyroid cancers in a xenograft nude mice model. Our results demonstrate that evodiamine induces cell cycle arrest, caspase-dependent apoptosis and autophagy leading to inhibit proliferation of multiple types of human thyroid cancer cells. We suggest that evodiamine could be a chemo-therapeutic candidate for human thyroid cancers.

Familial non-medullary thyroid cancers tend to be more bilateral and have more capsular invasion compared to non-familial ones

Dilek Yazici[1], Yersu Kapran[2], Onur Demirkol[3], Tarik Terzioglu[4], Serdar Tezelman[5] & Faruk Alagol[1]
[1]Section of Endocrinology and Metabolism, Koç University Medical School, Istanbul, Turkey; [2]Department of Pathology, American Hospital, Istanbul, Turkey; [3]Department of Nuclear Medicine, Koç University Medical School, Istanbul, Turkey; [4]Department of General Surgery, American Hospital, Istanbul, Turkey; [5]Department of General Surgery, Koç University Medical School, Istanbul, Turkey.

Introduction
Currently, about 5–15% of non-medullary thyroid cancers (FNMTC) are considered to be of familial origin. These are either syndrome-associated tumours or non-syndromic tumours. The aim of the study was to determine the clinical, pathological and biochemical characteristics of FNMTC compared to non-familial ones with a follow-up of 10 years.
Methods
Among FNMCT followed by a single physician, 62 patients with papillary cancer were screened retrospectively.
Results
(40.3%) patients had either one or more of their first-degree relatives with papillary cancer. Age (48.1 ± 15.1 years vs 45.3 ± 13.1 years), female/male ratios (20/5 vs 29/8) and age at diagnosis (44.1 ± 12.1 yrs vs 39.4 ± 10.9 years) were similar. Bilateral tumours (7/25 vs 5/32, $P=0.01$) and capsular invasion (11/25 vs 9/28, $P=0.004$) were more frequent in FNMTC compared to non-familial ones. Maximum tumour diameter (0.9 ± 0.6 cm vs 1.3 ± 1.0 cm) was comparable. Multicentricity (8/25 vs 8/37), lymph node metastasis (5/25 vs 6/37), vascular invasion (5/25 vs 5/37 patients), number of patients being operated more than once (4/25 vs 8/37 patients), having radioiodine therapy (10/25 vs 13/37), having classical tumour subtypes (11/25 vs 15/37) were comparable among groups. Postoperative thyroglobulin (0.48 ± 1.02 vs 0.65 ± 1.48) and TSH levels (0.16 ± 0.26 vs 0.25 ± 0.45) at 1st and (0.31 ± 0.44 vs 0.44 ± 0.76 thyroglobulin and 0.02 ± 0.03 vs 0.32 ± 0.69 TSH) 5th year follow-up were comparable. When patients with two cases ($n=20$) and more than two cases in family ($n=5$) were compared, all above mentioned parameters were similar among groups.
Conclusion
In conclusion, FNMTC tends to be more bilateral and has a higher rate of capsular invasion compared to non-familial ones.

Adjuvant radioiodine (RAI) treatment reduces the risk of relapse in low advanced differentiated thyroid carcinoma (DTC)

Jolanta Krajewska, Michal Jarzab, Agnieszka Czarniecka, Aleksandra Kukulska, Daria Handkiewicz-Junak, Zbigniew Wygoda, Zbigniew Puch, Ewa Paliczka-Cieslik, Jozef Roskosz & Barbara Jarzab
M.Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice, Poland.

The routine use of adjuvant RAI treatment in low-risk DTC remains controversial due to the lack of unequivocal evidences of its effectiveness in radically operated subjects. The aim of the study was a retrospective evaluation of long-term outcomes of combined DTC treatment to evaluate the impact of adjuvant RAI therapy in the low risk group. Primary hypothesis was: 'if adjuvant RAI treatment was unnecessary, a delay in RAI administration would have no impact on long-term outcomes'.
Material and methods
The study group consisted of 510 DTC patients, staged pT1b-T4N0-N1M0. Total thyroidectomy was carried in all subjects and followed by RAI therapy. On the basis of initial DTC stage and postoperative stimulated serum thyroglobulin (Tg) level 272 patients were classified as a low risk group (T1–T3, N0Nx and Tg $<$ 10 ng/ml), 90 as high risk (stimulated Tg >30 ng/ml), whereas 148 remaining constituted an intermediate risk group. Median follow-up was 12.1 years (range 1.5–15.2).
Results
To properly assess the efficacy of adjuvant RAI therapy all groups were divided depending on time of RAI administration. Next, subjects treated with RAI up 9 months after DTC diagnosis were compared to subgroups treated later: within 9–24 and >24 months. In the low risk group, patients treated with RAI up to 9 months, showed no recurrences, whereas among those, treated 9–24 months and >24 months after diagnosis, the risk of recurrence were 5.5 and 7.1%, respectively ($P=0.035$). There was no significant time depending difference in both intermediate and high risk groups.
Conclusion
Adjuvant RAI therapy, administered within a short time period after the operation significantly reduces the risk of cancer recurrence in the low advanced DTC. We believe that the exclusion of low risk patients from RAI therapy, suggested by the ATA and European guidelines, is not justified.

Efficacy and safety of an outpatient low radioide dose for remnant thyroid ablation in low risk papillary thyroid carcinoma (PTC)

Gabriel Obiols, Amparo García-Burillo, Carles Zafon, Joan Castell & Jordi Mesa
Hospital Vall d'Hebron, Barcelona, Spain.

In PTC, radioiodine required dose for thyroid remnant ablation is uncertain. Recent works show that low doses may be sufficient for low risk patients.
Aim
To evaluate the efficacy and safety of thyroid remnant ablation in patients with low-risk PTC by using 1100 MBq (30 mCi) outpatient doses.
Materials and methods
Twenty-five patients (24 women, 55 years-old mean age, range 34–77) referred for ablation of postsurgical thyroid remnants diagnosed with low-risk PTC (pT1-T2, N0, M0) were studied. After total thyroidectomy, an outpatient ablation was performed with 1100 MBq of ^{131}I under rhTSH stimulation with strict radiation protection measurements and dosimetry control at home environment. Whole body scan (WBS) and SPECT-CT were performed on the fifth day. Control of therapeutic efficacy was performed at 6 months, using WBS and SPECT-CT with ^{123}I after stimulation with rhTSH. Basal and post-stimulated thyroglobulin levels were determined in both studies. Ablation was considered successful when no abnormal activity was observed in WBS and SPECT-CTs and when basal/stimulated thyroglobulin levels were under 1 and 2 ng/ml, respectively.
Results
All 25 patients showed thyroid uptake without uptaking adenopathies in the WBS and SPECT-CTs performed on the fifth day after administration of ^{131}I. In 23/25 patients (92%) a successful ablation at 6-month efficacy control was achieved. One patient (5.1 ng/ml stimulated Tg) was re-treated with a new dose of 30 mCi and a second patient (2.3 ng/ml stimulated Tg) spontaneously normalised her basal and stimulated Tg levels at the 18-month control. Dosimetry on family members showed exposure levels of <0.2 mSv.
Conclusion
The postsurgical outpatient treatment with an activity of 1100 MBq is safe for the family environment and cost-effective in a great majority of patients with low-risk PTC.

Wide screening of RET proto-oncogene in Iranian medullary thyroid carcinoma patients: 13 years study

Mehdi Hedayati[1], Marjan Zarif Yeganeh[1], Sara Sheikholeslami[1] & Fereidoun Azizi[2]
[1]Research Institute for Endocrine Sciences, Cellular and Molecular Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Research Institute for Endocrine Sciences, Endocrine Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran.

Introduction
Thyroid cancer is the most common endocrine cancer and medullary thyroid carcinoma (MTC) is one of the most malignant thyroid tumours which occur in both hereditary (25%) and sporadic (75%) forms. Mutations of the RET proto-oncogene in MTC development have been well demonstrated. The aim of the study was to investigate the mutational spectrum of exons 3, 5, 8, and 10–18 of RET proto-oncogene in MTC patients.

Material and methods
This retrospective study has been started since 2001 in Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, and Tehran, Iran. 399 participants, including 233 patients (176 sMTC, 40 FMTC, eight MEN2A, four MEN2B, five pheochromocitoma), and 166 relatives were evaluated. Genomic DNA was extracted by the standard Salting Out/ProteinaseK method and Mutation detection was performed through direct DNA sequencing. Sequence analysis was performed by Chromas Software version 2.3.
Results
Totally, in 233 patients (131 female, 102 male) and 166 relatives (91 female, 75 male), 82 mutations were identified in RET main exons, including 10, 11, and 13–16. Furthermore, 282 single nucleotide polymorphism (SNP) were found in exons 3, 13, and 14. Interestingly, G691S SNP and S904S SNP were 100% in linkage disequilibrium in 131 patients and 87 relatives. The most common mutation in our population were C634Y and C634R (4%) whereas C618R, C618S, C620G, L887L mutations had rare allele frequency (0.3%). Moreover, R886Q mutation was detected in exon 15 in two members of a family affected with MTC for the first time.
Discussion
Exon 11 and after that exon 10 were the most frequently mutated exons of *RET* proto-oncogene in MTC patients in Iranian population. As about half of patients with the hot spot mutations had the G691S/S904S haplotype simultaneously, further analysis needs for clarifying the effect of multiple risk alleles in MTC development.

Ratio of lymph node aspiration washout thyroglobulin levels to whole blood and serum washout thyroglobulin levels in patients with differentiated thyroid carcinoma: a new approach for standardisation of measurements and increased accuracy

Cevdet Aydin[1], Didem Ozdemir[1], Muhammed Sacikara[1], Sefika Burcak Polat[2], Aylin Kilic Yazgan[3], Seyda Turkolmez[4], Eda Demir Onal[2], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Department of Endocrinology and Metabolism, School of Medicine, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Ataturk Education and Research Hospital, Ankara, Turkey; [3]Department of Pathology, School of Medicine, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey; [4]Department of Nuclear Medicine, School of Medicine, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey.

Introduction
High values of fine needle aspiration washout thyroglobulin (FNA-Tg) are diagnostic for metastatic lesions of thyroid cancer. However, there is not a consensus on cut-off for high Tg level. The most important confounding factor for FNA-Tg is inability to calculate Tg per unit volume because residual aspiration material in the needle cannot be known exactly. Another problem is possible contamination of whole blood during lymph node aspiration. In this study, we aimed to determine a more accurate and standardised parameter for FNA-Tg.
Methods
Ultrasonographically suspicious 155 lymph nodes in 120 patients with histopathologically confirmed differentiated thyroid cancer and suspicious for malignancy/malignant thyroid nodule FNA result in cytology were evaluated. Tg was measured in samples obtained by aspiration (FNA) and non-aspiration (FNNA) biopsy. The highest value obtained by these methods from the same lymph node was defined as FNB-Tg. Simultaneous venous blood sample was taken. Tg was measured from whole blood and serum washouts which were obtained by using syringes and needles identical to ones used for lymph node biopsy.
Results
Data of 16 lesions in 14 patients who underwent lymp node dissection were analysed. FNNA-Tg, FNB-Tg/whole blood washout-Tg, FNB-Tg/serum washout-Tg, FNB-Tg/serum Tg were significantly higher in malignant lymph nodes compared to benign ones. Areas under the ROC curve for FNNA-Tg, FNNA-Tg/whole blood washout-Tg, FNNA-Tg/serum washout-Tg were statistically significant for the discrimination of benign and malignant lymph nodes. Best cut-off values for FNNA-Tg and FNB-Tg were 15.86 and 31.8 ng/ml. respectively. Among ratios, best cut off values to discriminate benign and malignant lymph nodes were 5.44 for FNB-Tg/whole blood washout-Tg and 3.95 for FNB-Tg/serum washout-Tg.
Conclusion
Determining ratio of FNB-Tg to whole blood washout-Tg and/or serum washout-Tg might be a promising method for increasing accuracy and providing standardization of lymph node aspiration to detect malignant lymph nodes.

The risk of thyroid cancer (TC) in a thyroid nodule on the basis of a tertiary reference TC center experience

Aleksandra Blewaska[1], Aleksandra Sygula[1], Ewa Chmielik[2], Ewa Stobiecka[2], Ewa Zembala-Nozynska[2], Agnieszka Czarniecka[3], Aleksander Sacher[3], Jolanta Krajewska[1], Aleksandra Kukulska[1] & Barbara Jarzab[1]
[1]Nuclear Medicine and Endocrine Oncology Department, M.Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice, Poland; [2]Tumor Pathology Department, M.Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice, Poland; [3]The Oncologic and Reconstructive Surgery Clinic, M.Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice, Poland.

A global TC risk in a single thyroid nodule is rather small and ranges between 1 and 11%. However, taking into consideration Bethesda System for Reporting Thyroid Cytopathology TC risk varies between distinct categories: 0–3, 5–15, 15–30, 60–75 and 97–99% for Bethesda class II–VI, respectively. However, these values may differ in a centre, specialized in TC. Therefore, the aim of this study was to evaluate the TC risk in patients referred to a tertiary reference TC centre.

Material
282 thyroid nodules were involved into a retrospective analysis. Fine needle aspiration biopsy (FNAB) was performed in all cases and followed by surgery regardless of the results of FNAB. Next, histopathological findings were compared with FNAB results.
Results
According to FNAB 26.9% thyroid nodules were classified as benign (Bethesda II), 28.7% as malignant (Bethesda VI), while 23.8% as indeterminate (Bethesda III + IV + V). Among indeterminate nodules 3/67 were diagnosed as Bethesda III, 23/67 as follicular neoplasm (Bethesda IV), whereas 41/67 were suspicious for malignancy (Bethesda V). For 20.6% remaining tumours the FNAB result was nondiagnostic (Bethesda I). TC was diagnosed by histopathological examination in 171 tumours (60.6%), among them in 21/76, 39/67, 81/81 and 30/58 preoperatively classified as benign indeterminate, malignant and nondiagnostic, respectively. 96 nodules were benign in histopathology, while for 15 others no data were available. Finally, the risk of TC evaluated on the basis of aforementioned data was 27.6% for benign nodules, 39.1% for follicular neoplasm, 70.7% for nodules suspicious for malignancy and 100% when tumour were classified as malignant. Surprisingly, TC was confirmed after surgery in 51.7% with nondiagnostic FNAB.
Conclusions
The risk of TC in thyroid nodules referred to specialised thyroid cancer center is substantially higher than in routine practice. Thus, more careful procedures, including molecular markers are necessary to state a proper diagnosis and start the treatment on time.

Thyroid cancer in Ireland: a 10-year review of the National Cancer Registry

Paul Lennon[1], Sandra Deedy[2], Marie-Louise Healy[1], John Kinsella[1], Conrad Timon[1] & James Paul O'Neill[3]
[1]St James's Hospital, Dublin, Ireland; [2]National Cancer Registry Ireland, Cork, Ireland; [3]Royal College of Surgeons, Ireland, Dublin, Ireland.

Introduction
The increased incidence of thyroid cancer is driven mainly by a large increase in papillary thyroid cancer (PTC). The number of patients that succumb to the disease has remained stable. The aim of our study is to analyze the incidence and mortality of thyroid cancer in Ireland.
Methods and design
A retrospective analysis of the National Cancer Registry was undertaken, between 1st of January 1998 and the 31st December 2007. The Kaplan–Meier method was used to determine overall survival using Stata 13 software.
Results
A total of 949 patients were diagnosed, 781 (82.2%) were well-differentiated thyroid cancers (papillary 565, follicular 177, Hurtle cell 39) whilst there were 44 medullary thyroid cancers and 61 anaplastic thyroid cancers. The female to male ratio was 3:1, with a median overall age of 47. This was significantly lower in women at 45, then men at 52 ($P = 0.0000$). The incidence of thyroid cancer increased from 1.43/100 000 to 3.61/100 000. This increase was in the mainly attributed to PTC, rising from 0.63 to 2.46/100 000. The number of deaths from the disease remained stable at 0.63–0.59/100 000. There was no survival difference between those under going total thyroidectomy vs thyroid lobectomy for PTC (hazard ratio 0.868, 95% CI 0.598–1.26, $P = 0.457$).
Conclusions
These results correlate with studies that demonstrate that although an increase in incidence of thyroid has been found, the number of patients dying from the disease has remained stable. This emphasises the need for a new treatment paradigm of risk stratification in order to ensure maximum benefit for the patient.

Fine needle aspiration cytology, do cytology technicians make the difference?

Ricardo Capitao, Catarina Moniz, Catarina Sararaiva, Rute Ferreira, Clotilde Limbert, Marlene Carriço, Maria Carvalho, Claudia Linares, Diamantina Branco, Sancia Ramos, Isa Martins, Jose Duraes & Carlos Vasconcelos
Centro Hospitalar Lisboa Ocidental, Lisbon, Portugal.

Introduction
The fine needle aspiration cytology (FNAC) of thyroid nodules is the procedure of choice in the diagnostic approach of nodular thyroid disease. Despite showing a sensitivity of 83% and a specificity of 92%, many of the results are non-diagnostic. One of the factors that can contribute to this number is the proper procedure of the smear.
Objective
To compare the FNAC's results in our team with and without the contribution of an expert Cytology Technician (CT).
Methods
All FNACs results (based on Bethesda classification) were registered in the period of 2 consecutive years in our hospital. The results were distributed between two groups: – Group A: 01/01/2013 to 31/12/2013 without CT support. Group B: 01/01/2014 to 31/12/2014 with CT support.
Results
The total of FNACs obtained was 3107 (1538 in Group A and 1569 in Group B). Benign lesions were the most frequent diagnosis in both groups. A statistical relationship between the presence of a CT and the Bethesda classification in the evaluation of FNACs was obtained (χ^2 test, $P < 0.001$). There were also a significantly more nodules with a non-diagnostic result in the Group A (χ^2 test, $P < 0.001$) than in Group B (33% vs 25% respectively). The Benign lesions and follicular Neoplasm were significantly more frequent in Group B (59.1 and 1.5%) when compared to Group A (53.0 and 0.6%), (χ^2 test, $P < 0.001$ for benign lesions; $P < 0.05$ for follicular neoplasms). There was no significantly difference in the results of atypia of undetermined significance, suspicious for malignancy and malignant with or without CT.
Conclusions
The presence of a CT had an impact on results of FNAC, diminishing the number of non-diagnostic results and increasing the results of benign lesions and follicular neoplasms.

Proprotein convertase subtilisin/kexin type 9 (PCSK9), soluble lectin-like oxidized ldl receptor 1 (SLOX-1) and ankle brachial index in short term overt hypothyroidism

Cigdem Ozkan[1], Mujde Akturk[1], Alev Eroglu Altinova[1], Ethem Turgay Cerit[1], Ozlem Gulbahar[2], Mehmet Muhittin Yalcin[1], Nuri Cakir[1] & Fusun Balos Toruner[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Gazi University, Ankara, Turkey; [2]Department of Biochemistry, Faculty of Medicine, Gazi University, Ankara, Turkey.

Cardiovascular deleterious effects of short term hypothyroidism are not well known. We aimed to investigate proprotein convertase subtilisin/kexin type 9 (PCSK9), soluble lectin-like oxidized LDL receptor 1 (sLOX-1) and ankle brachial index (ABI) in patients with thyroid cancer with short term overt hypothyroidism due to thyroid hormone withdrawal (THW). Twenty-one patients who require radioactive iodine (RAI) ablation or RAI scan and thirty-six age, sex, BMI similar euthyroid healthy control subjects were enrolled into this study. Patients were evaluated both in subclinical thyrotoxic period when they were on suppressive levothyroxine therapy and overt hypothyroidism period due to THW for four weeks. Serum PCSK9, sLOX-1, lipid levels and ABI were measured in patient and control groups.Total cholesterol, LDL cholesterol, triglycerides and Apo B levels were increased in short term overt hypothyroidism compared to control group ($P < 0.001$). Patients with short term overt hypothyroidism had significantly increased PCSK9 levels compared to control group ($P < 0.001$). PCSK9 levels were also found to be increased before THW when compared to control group ($P = 0.004$). sLOX-1 levels were not different between patients with short term overt hypothyroidism and control group ($P = 0.27$). ABI was found to be significantly decreased in patients with short term overt hypothyroidism compared to control group ($P = 0.02$). In conclusion, we found increased PCSK9 and decreased ABI which may contribute to the undesirable metabolic and vascular changes in thyroid cancer patients with short term overt hypothyroidism due to THW.

Objective
Thyroid incidentaloma is a common endocrinological disorder. Current literature regarding the risk of thyroid cancer in incidentalomas found in patients with non-thyroid cancer is limited. The aim of the present study was to investigate the frequency of thyroid malignancy in thyroid incidentalomas detected in patients with non-thyroid cancer.
Methods
The database of 287 thyroid nodules from 161 patients with a history of non-thyroid cancer followed between 2008 and 2014 were retrospectively evaluated.
Results
From 287 thyroid nodules, 69.7% had a benign final cytology. Thyroid cancer detected in one nodüle while follicular neoplasia detected in four nodules, atypia of unknown significance (AUS) detected in ten nodules, hurthle cell neoplasia detected in five nodules and suspicious for malignancy detected in six nodules according to fine needle aspiration biopsy results. Metastasis of the non-thyroid cancer to the thyroid gland were detected in four nodules. Twenty seven nodules from 15 patients were removed with surgery. There were three malignant nodules found after surgery (one papillary, one follicular and one medullary cancer). In addition to these three thyroid cancers, two patients with benign nodules had co-incidental thyroid cancer detected after surgery. Finally, 11.1% of thyroid nodules which underwent thyroid surgery had malignant histopathology except co-incidental and metastatic cancers.
Conclusion
The frequency of thyroid malignancy seems not to be substantially increased in incidental thyroid nodules detected in patients with non-thyroid cancer when these patients were evaluated in nodule-based approach.

Differentiated thyroid cancer: assessment of clinical practice in a tertiary referral centre

Patrick Owens[1], Aoife Lowery[1], Denis Quill[1], Marcia Bell[2] & Michael Kerin[1]
[1]Department of Surgery, University Hospital Galway, Galway, Ireland; [2]Department of Endocrinology, University Hospital Galway, Galway, Ireland.

International best practice guidelines provide well-defined recommendations for the management of differentiated thyroid cancer (DTC) measuring ≤ 1 cm, > 4 cm and for those with defined risk factors. However, the extent of surgery and requirement for radioiodine remnant ablation (RRA) are less clearly defined for tumours 1–4 cm in size. Guidelines recommend a 'personalised decision making' approach for this cohort, with therapeutic decisions based on patient preference, recurrence risk and multi-disciplinary discussion. This study aims to assess adherence to guidelines and investigate treatment patterns in the 'personalised decision making' cohort for thyroid cancers in an Irish tertiary referral centre. A random subset of 97 patients treated for DTC between 2009 and 2014 were assessed. Data were obtained from a prospectively maintained thyroid cancer database. 92 out of 97 patients (95%) were managed in accordance with guidelines (Table 1). Out of those whose management did not adhere to guidelines, three were over treated with total thyroidectomy, while two were under treated with lobectomy only. 28 patients (29%) had tumour characteristics requiring 'personalised decision making', of which 26 underwent total thyroidectomy rather than lobectomy. Similarly for RRA, 39 out of 41 patients (95%) in the 'personalised decision making' group were treated with radioactive iodine.

Table 1.

	Patients (%)	Adherence to guidelines (%)
Total cohot:	97 (100)	92 (95)
≤ 1 cm	17 (18)	14 (82)
1–4 cm	61 (63)	61 (100)
> 4 cm	19 (20)	17 (89)
Multifocal	40 (41)	38 (95)
Lymphovascular invasion	21 (22)	20 (95)
Capsular invasion	21 (22)	21 (100)

These data suggest that management of thyroid cancer at our institution closely adheres to guidelines, with a trend towards more aggressive management in those where personalised decision making is required.

Graves' disease and papillary/insular thyroid cancer in a large compressive goitre

Mara Carsote[1,2], Anda Dumitrascu[2], Dana Terzea[2,5], Andreea Geleriu[2], Dan Peretianu[3], Daniela Alexandrescu[2,4], Corina Chirita[6], Radu Iorgulescu[5], Andrei Goldstein[2] & Catalina Poiana[1,2]
[1]C. Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; [3]SCM Povernei Medical Centre, Bucharest, Romania; [4]St John Hospital, Bucharest, Romania; [5]Monza Oncoteam Hospital, Bucharest, Romania; [6]Anima Medical Centre, Bucharest, Romania.

Introduction
The association between autoimmune thyroid disease and thyroid cancer is a dynamic field regarding the prevalence data and the common pathogenic background.
Aim
We report a sixth decade women case with a 1 year history of Graves' disease that was discovered with an aggressive differentiated thyroid carcinoma.
Case report
M.E. 56-year-old female has a 10 months history of daily medium dose of thyamazolum which was well tolerated (she presented with mild features of hyperthyroidism). The personal and family medical history is negative. On admission, she accused compressive symptoms for the last 2 months. The TSH was 1.59 μUI/ml. The eye examination showed values of 17 mm for proptosis. The cervical computed tomography pointed a large left thyroid nodule of 4.5 by 7.28 cm, with multiple microcalcifications associating a mass effect over the trachea (the minimum diameter of 1.71 by 1.7 cm at the level of clavicles). The eye exam showed values of 17 mm for exophthalmometria. The calcitonin was normal (of 0.857 pg/ml) , as well as antithyreoperoxidase antibodies (of 14 U/ml). The total thyroidectomy and lymph neck resection was performed. A papillary thyroid carcinoma (oxifile type) with insular and compact areas was found (of 6 cm), together with vessel invasion (T3N1Mo). The immunohistochemistry pointed a Ki67 of 15%. The 131 iodine therapy was added to the levothyroxine suppressive therapy.
Conclusion
The finding of a follicular cells cancer in a thyroid underling an autoimmune process is a rare event, yet new data reveals that the two diseases maybe more than incidental, possible by sharing common mechanisms.

Differentiated thyroid carcinoma prevalence in the Graves' disease; Akdeniz University experience

Mustafa Kemal Balci, Birsen Unsal Koyuncu, Safiye Arık, Cumhur Arıcı, Ramazan Sarı & Hasan Ali Altunbaş
Akdeniz University Medical Faculty, Antalya, Turkey.

Objective
The frequency of differentiated thyroid cancer in the Graves' disease are controversial. The aim of this study was to evaluate the frequency of thyroid cancers in patients operated because of Graves' disease.

Subjects and methods
Sixty-six patients in whom thyroidectomy was performed because of Graves' disease between 2001 and 2012 were evaluated retrospectively. Patients who had received radioactive iodine treatment and external irradiation treatment in the neck region and who had had thyroid surgery previously were not included in the study.
Results
Thyroid nodule was absent in 17 (25.8%) of 66 Graves' patients. There was one thyroid nodule in 17 (25.8%) patients, two thyroid nodules in 13 (19.7%) patients, three thyroid nodules in 13 (19,7%) patients, four thyroid nodules in 4 (6.1%) patients, and five and over in 2 (3%) patients. Thirteen (19.7%) patients had thyroid cancer in the s patients. The rate of thyroid cancer was 17.6% ($n=17$) in the Graves' patients who had no nodule, whereas it was statistically not different from other graves patients with nodules. The risk of thyroid cancer didn't increased significantly in the presence of nodule.

Association of papillary thyroid cancer with thyroid autoimmunity

Gesthimani Mintziori, Fotini Adamidou, Zoe Eustathiadou, Athanasios Panagiotou, Panagiotis Anagnostis & Marina Kita
Department of Endocrinology, Ippokratio General Hospital, Thessaloniki, Greece.

Introduction
Although the association between thyroid autoimmunity and papillary thyroid carcinoma (PTC) is supported by clinical studies, evidence to their pathophysiologic link and causal relationship is lacking. Moreover, there is a paucity of data regarding the association of thyroid autoimmunity with the less common types of differentiated thyroid cancer (DTC). The aim of the current paper was to investigate the association of autoimmunity and PTC vs follicular or medullary thyroid cancer.
Methods
We conducted a retrospective, registry-based study in the Department of Endocrinology, Ippokratio General Hospital, Thessaloniki, Greece. Patients with histologic evidence of DTC that were pre-operatively screened for thyroid autoimmunity during the last 5 years were included in the study. Patients with known cancer-related syndromes (patients with autoimmune polyglandular syndrome or multiple endocrine neoplasia) were excluded from the analysis. Thyroid autoimmunity was defined as presence of positive anti-TPO and/or anti-Tg antibodies. Statistical analysis was performed with the use of IBM SPSS 20.
Result
Sixty-five patients with thyroid cancer were assessed (12 men and 53 women). Their mean age was 51 ± 2 years. Out of 65 patients, 54 patients had PTC, six had follicular cancer and five patients had medullary cancer. When patients with PTC were compared with patients with follicular or medullary cancer, the prevalence of thyroid autoimmunity was higher in patients with PTC in comparison with patients with other types of thyroid cancer (43% vs 9% respectively, $P=0.035$), independently of TSH concentrations.
Conclusion
This small retrospective study demonstrates that patients with PTC demonstrate significantly higher prevalence of thyroid autoimmunity, in comparison with other types of DTC. Further study into this differential association may provide insights for better prevention and management of PTC.

Evaluatıon of recurrence risk in differentiated thyroid cancer after treatment

Mustafa Koçak[1], Rahman Koseoglu[1], Bircan Sönmez[2], Serdar Türkyilmaz[3], Ismail Dogan[2], Halil Onder Ersoz[1] & Cihangir Erem[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Karadeniz Technical University, Trabzon, Turkey; [2]Department of Nuclear Medicine, Faculty of Medicine, Karadeniz Technical University, Trabzon, Turkey; [3]Department of General Surgery, Faculty of Medicine, Karadeniz Technical University, Trabzon, Turkey.

Introduction
The aim of this study was to validate the American Thyroid Association (ATA) risk of recurrence staging system (2009).
Methods
Retrospective analysed 300 adult (239 women, 61 men) differentiated thyroid cancer patients followed for a median of 57 months (range 38–97).
Results
ATA risk stratification of patients according to the system 54.7% low-risk, 39.7% moderate risk, and 5.7% were in the high risk group. The responses of patients to treatment; 79.7% very well to treatment, 11% acceptable, 9.3% of the showed that the response is missing. In 21% of patients follow-up of persistent or recurrent disease in the last case was detected. Initial treatment responses based on the persistent structural or recurrent disease adapted risk estimation in low risk group not treated very well responsive 7.3% from 2.9%, intermediate-risk group and the treatment very good responders and 14.3% from 5.3%, higher risk group and 70.5% in those who respond very well to therapy than was seen in 60%. In this study the first 2 years treatment criteria follow-up of disease status of being considering the low risk group treated very well not respond, intermediate-risk group, stimulated thyroglobulin <1 ng/ml or treatment very good response of the high-risk group is suppressed Tg$<$ 1 ng/ml of being, at the end of follow-up showed that disease estimated to be more powerful.
Conclusion
According to ATA risk classification, initially recurrent/persistent disease was found to be a useful system to predict. However, only adapted to the risk of follow-up the patient's entire life does not change during the initial risk estimates also showed that not be done. Tailored to each patient, to achieve dynamic and full of risk assessment, risk prediction system response to treatment is needed to conclude that the combination of the variables.

Primary squamous cell carcinoma of the thyroid: a rare type of thyroid cancer

Pinar Sisman[1], Ahmet Bilgehan Sahin[2], Hande Peynirci[1], Ozen Oz Gul[1], Soner Cander[3], Erdinc Erturk[1] & Canan Ersoy[1]
[1]Uludag University Medical School Department of Endocrinology and Metabolism, Bursa, Turkey; [2]Uludag University Medical School Department of Internal Medicine, Bursa, Turkey; [3]Sevket Yilmaz Training anr Research Hospital Clinic of Endocrinology and Metabolism, Bursa, Turkey.

Introduction
Primary squamous cell carcinoma (PSCC) of thyroid is a rare type of thyroid malignancies because thyroid gland lacks squamous epithelium. It is seen in $<1\%$ of all thyroid malignancies. During last 30 years only about 90 cases were published. PSCC is an aggressive tumour as well as rare.
Case report
We present a 60-year-old female who had been followed up for multiple nodules in thyroid in our outpatient clinic for 2 years. Her serum free thyroxine (fT_4), free triiodothyronine (fT_3) and TSH levels were 0.9 ng/dl, 1.8 pg/ml, and 3.8 μIU/ml, respectively Her first fine needle aspiration cytology (FNAC) was benign. During follow-up because of sonographic features of nodul in left lobe, we performed the second FNAC which was suspicious for malignancy. Then total thyroidectomy was performed. In histopathological examination, well differentiated squamous cell carcinoma was revealed. Lymphovascular invasion was not seen. After surgery there was no increased glucose metabolism on F-18-fluorodeoxyglucose positron emission tomography. 21 months have passed after surgery and she had no complaint. She is going on the follow-ups.
Conclusion
PSCC of thyroid is rare but aggressive malignancy comparing with other thyroid cancers. FNAC is important for diagnosis like other types. It seems complete surgical eradication of tumour is the main treatment in PSCC of thyroid. But to achieve this, early and accurate diagnosis is important.

Series of cases a descriptive study of management of metastatic medullary thyroid cancer

Eyvee Arturo Cuellar Lloclla, Mariana Tome Fernandez Ladreda, Guillermo Martinez de Pinillos Gordillo, Mariola Mendez Muros, Juan Manuel Garcia de Quiroz, Ignacio Fernandez Peña, Fernando Garcia Perez, Ignacio Fernandez Lopez, Margarita Rivas Fernandez, Juana Hidalgo Amat & Maria Victoria Cozar León
Hospital Virgen del Valme, Seville, Spain.

Introduction
There are new therapies indicated in medullary thyroid cancer (MTC) based on different molecular targets, that appear to be effective in some cases with advanced disease, although many are still under investigation.
Material and methods
We retrospectively evaluated five cases of medullar thyroid advanced carcinoma that later were referred to Oncology Department for Chemotherapy treatment.
Results
Five patients (mean age 52 ± 18.8 years) were evaluated. All cases were sporadic and stage IV at diagnosis. Four cases had undergone total thyroidectomy and cervical lymphadenectomy. three patients had metastases at diagnosis, the other two patients persistent with local disease after surgery. The average value of calcitonin prior to the oncology evaluation was 3072.6 ± 3789.6 pg/ml (382–8600 pg/ml) and CEA 576.5 ± 856.9 ng/ml (13.23–2075 ng/ml). Threeout of five patient received chemotherapy (Vandetanib). The average decrease in calcitonin and CEA in treated patients was 1350 ± 2448.8 pg/ml (−240 to 4170 pg/ml) and 1862.3 ± 1009.1 (−275 to 1714 ng/ml). None of them showed advanced disease on different imaging studies, and two of them had mild radiological improvement. Two untreated patients had showed a mean increase of calcitonin and CEA of 377 pg/ml and 10.3 ng/ml; in both cases the radiologic stability of the disease remained in time. Only one patient had cutaneous toxicity with Vandetanib.
Conclusions
Patients with Vandetanib had certain laboratory and radiologic improvement, although more investigation of the long-term efficacy would be necessary. In our study, patients with asymptomatic metastatic MTC disease had persisted with radiologic and analytical stability despite not chemotherapy applied. These data are consistent with current recommendations about not to treat patients with these characteristics.

Identification of high-risk patients with incidental papillary microcarcinomas of thyroid helps in deciding appropriate management

Naveen Siddaramaiah, Mamatha Devaraj, Satish Artham & Sathyajith Nag
South Tees Hospitals NHS Foundation Trust, Middlesbrough, UK.

Papillary microcarcinoma (PMC) of thyroid is being increasingly detected following thyroid surgery for various reasons. The management of incidental PMC, not clinically or radiologically evident, is not well defined often leading to over treatment. Identifying risk factors for recurrence could help in administering appropriate management.
Aims and methods
To review the incidence of PMC and management locally. Retrospective review of case notes of patients diagnosed with papillary carcinoma over 9 years (2006–2014).
Results
$n = 113$, of which 30 were PMC (26.5%). Female = 23. Mean age: 49 years. Lump in the neck was the commonest initial presentation. Patients had one FNAC on an average (Thy3 to Thy5 $n = 11$). Nine patients with suspicious or diagnostic cytology or non-thyroidal surgeries were excluded. 21 patients had incidental PMC (total thyroidectomy $n = 7$, lobectomy $n = 14$). Five patients underwent completion thyroidectomy and further foci of PMC were found in three of them. Eight out of 21 patients were found to have risk factors such as size (6–10 mm), multifocality, and extrathyroidal spread. Five of eight patients had initial total thyroidectomy. Three underwent hemithyroidectomy followed by completion thyroidectomy. Completion thyroidectomy was done in one patient (MEN1) without risk factors for incidental PMC in thyroid tissue attached to parathyroid specimen. Five of 21 patients received radioiodine ablation following surgery ($n = 4$ with risk factors, $n = 1$ oncocytic neoplasm). 19 patients received post-operative hormonal therapy including eight with risk factors. TSH level was aimed at 0.1–0.4 mU/l. Complete suppression of TSH was noted at various stages during follow up in four of these 19 patients (21%).
Conclusion
Incidence of PMC in this cohort is in keeping with published literature. Identifying risk factors for local or regional recurrence is helpful in optimising management of incidental PMC. This could avoid unnecessary overtreatment with extensive surgery or RAI ablation or TSH suppression.

DOI: 10.1530/endoabs.37.EP921

EP922

Incidence of intrathyroid location of parathyroid glands and description of their characteristics compared to extrathyroid ones

Nick Michalopoulos[1], Efterpi Margaritidou[2], Efstathios Kotidis[1], Konstantinos Sapalidis[1], Ioannis Kanellos[1] & Kalliopi Pazaitou Panayiotou[2]
[1]3rd Department of Surgery, Aristotle University of Thessaloniki, AHEPA University Hospital, Thessaloniki, Greece; [2]Department of Endocrinology, Endocrine Oncology, Theagenio Cancer Hospital, Thessaloniki, Greece.

Introduction
Total thyroidectomy (TT) is a safe and effective operation. The most frequent complication after TT is hypoparathyroidism. Surgical trauma, devasculisation of parathyroid glands and inadvertent parathyroidectomy have been identified as the main causes resulting in postoperative hypocalcaemia. The objectives of this study are to investigate the incidence of intrathyroid parathyroid glands (ITPGs) in a large cohort and to clarify their histological characteristics.
Patients and methods
This is a retrospective study of two specialized centers in thyroid diseases. The medical records of patients with thyroidectomy were reviewed. Patients who underwent lobectomy or near total thyroidectomy, intentional parathyroidectomy during TT for concurrent parathyroid diseases, lymph node dissection and patients with inadequate data were excluded from the study. Patients were divided into two groups: those with (P group) and those without parathyroidectomy (non-P group). According to the location of the dissected parathyroid gland the P-group was sub-divided in ITPGs or extrathyroid parathyroid glands (ETPGs). Morphological characteristics of ITPGs were compared with the corresponding characteristics of the ETPGs in a case control way.
Results
4500 patients with TT were included. 605 of them were excluded from the study. Inadvertent parathyroidectomy (IP) was presented in 424 cases (10.89%). Intrathyroid parathyroid glands were presented in 68 cases (1.75%). There was a trend of ITPGs being smaller in size compared to ETPGs ($P = 0.067$). Cystic degeneration was presented in ITPGs ($P = 0.01$). Other histological characteristics, including weight were similar in intra and extra parathyroid glands. Presence of clinical hypocalcaemia was similar in all groups.
Conclusions
The incidence of ITPGs in our cohort is 1.75%. Surgical removal of ITPGs does not increase the presence of clinical hypocalcaemia and should be consider a minor complication of TT. Patients should be informed prior to TT about the possible presence of ITPGs and, therefore, their probable accidental removal.

Histopathological results of suspicious nodules in the patients with Hashimoto thyroiditis

Sevilay Ozmen[1], Ilknur Calik[1], Yusuf Can[1], Ozge Timur[2], Ayse Carlioglu[3], Hakan Sevimli[2], Senay Arikan Durmaz[3], Esref Kabalar[1] & Kenan Cadirci[2]
[1]Department of Pathology, Erzurum, Training and Reserch Hospital, Turkey; [2]Department of Internal Medicine, Training and Reserch Hospital, Erzurum, Turkey; [3]Department of Endocrinology, Training and Reserch Hospital, Erzurum, Turkey.

Introduction and aim
The most endocrinologists in routine practice are used to Bethesda classification for evaluation of thyroid nodule in fine needle aspiration biopsy (FNA). It is accepted that FNA biopsy is an accurate diagnostic and gold standard test. However, false-positive diagnosis may sometimes occur as a patient with a 'malign' lesion is found incorrectly rather than an actually benign lesion on histological examination. Hashimoto's thyroiditis probably is the most common cause of false-positive cytology. The aims of present study evaluate retrospectively postoperatively biopsy results in patients with Hashimoto disease have a thyroidectomy.
Materials and methods
Results of totally 29 patients with Hashimoto thyroiditis achieved from our hospital records. All of the patients had undergone totally or subtotals thyroidectomy. We re-evaluated retrospectively biopsy results postoperatively. We compared their preoperative FNA results.
Results
We detected 24.1% papillary thyroid cancer in seven patients (mean age 45.5 ± 11.9 year), 44.8% nodular goitre in 13 patients (mean age 45.8 ± 4.9 year), 13.7% adenomatous nodule in four patients (mean age 43.5 ± 14.4 year), 3.4% hurtle cell adenoma in one patient with 56 years old. But, 14% in four patients with Hashimoto thyroiditis (mean age 41.5 ± 13.1 year) were redundantly operated due to atypia of undetermined significance in FNA.
Conclusions
Although Hashimoto disease is a benign diagnosis, its misclassification as atypia of undetermined significance in FNA accounts for some false-positive errors. The cytopathologists can frequently be interpreted as atypia of undetermined significance instead of Hashimoto's thyroiditis. Therefore, result of atypia of undetermined significance in FNA may lead unnecessarily concern among with the endocrinologists. More importantly, our results demonstrated that high papillary thyroid cancer rate was found postoperatively in suspicious nodules evolved background Hashimoto thyroiditis.

The evaluation of demographic features and histopathological results in patients with reoperative thyroid surgery

Fatma Neslihan Cuhaci[1], Husniye Baser[2], Cevdet Aydin[1], Aylin Kilic Yazgan[3], Seyda Turkolmez[4], Mehmet Kilic[5], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Department of Endocrinology and Metabolism, Yildirim Beyazit University Faculty of Medicine, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Ataturk Education and Research Hospital, Ankara, Turkey; [3]Ataturk Education and Research Hospital, Department of Pathology, Ankara, Turkey; [4]Department of Nuclear Medicine, Ataturk Education and Research Hospital, Ankara, Turkey; [5]Department of General Surgery, Ataturk Education and Research Hospital, Ankara, Turkey.

Introduction
Reoperative surgery for thyroid disease is rare. It is sometimes indicated for nodular recurrence after partial surgery for initially benign thyroid disease or for a completion total thyroidectomy when a final diagnosis of thyroid cancer is confirmed on a permanent section of a partially removed thyroid gland. We aimed to investigate the demographic features and reoperation indications in patients with reoperative thyroidectomy.
Methods
Thirty-six patients reoperated between 2008 and 2011 were included into the study. Demographic features, indications of reoperation and histopathological results of patients were evaluated retrospectively.
Results
After reoperative thyroidectomy, the results of histopathological evaluation of 24 patients were malignant (19 papillary thyroid carcinomas, three follicular thyroid carcinomas, one Hurthle cell neoplasm and one neoplasm with undetermined malignant potential) while 12 patients were benign. Of 36 patients, 11 (30.5%) went to reoperation due to giant thyroid nodule (>4 cm), 5 (13.9%) due to ≥2 nondiagnostic fine needle aspiration biopsy (FNAB), 3 (8.3%) due to toxic multinodular goitre, 5 (13.9%) due to malignant cytology, 2 (5.6%) due to suspected malignancy, 2 (5.6%) due to suspicion for a follicular neoplasm, 3 (8.3%) due to follicular lesion of undetermined significance, 1 (2.8%) due to atypia of undetermined significance, 1 (2.8%) due to suspected Hurthle cell neoplasm and 3 (8.3%) due to cytology of cellular adenomatoid nodule and ultrasonography suggesting malignancy.
Conclusion
Thyroid surgery may lead to regional scars and some degree of fibrotic process. This may result in problems in collecting thyroid FNAB samples and assessing cellular abnormalities. Our study findings demonstrated that histopathological evaluation of 14 patients whose cytological results showed no malignancy, was consistent with malignancy. We consider that decision for reoperative thyroidectomy should not be made with cytological findings, but patients' symptoms and ultrasound findings should also be taken into account.

A case of primary hypothyroidism initially presenting with massive pericardial effusion

Mahmut Apaydin[1], Selvihan Beysel[1], Taner Demirci[1], Erman Çakal[1] & Tuncay Delibasi[1,2]
[1]Department of Endocrinology and Metabolism, Diskapi Yildirim Beyazit Teaching and Research Hospital, Ankara, Turkey; [2]Department of Internal Medicine, School of Medicine (Kastamonu), Hacettepe University, Ankara, Turkey.

Introduction
Although pericardial effusion is a common finding in primary hypothyroidism, massive pericardial effusion or pericardial tamponade are rare. Herein, we describe a newly diagnosed case of primary hypothyroidism initially presenting with massive pericardial effusion.
Case report
A 64 years old male patient attended to the emergency unit with worsening dyspnea over the past 1 month. ECG showed a low voltage QRS wave. Chest X-ray showed increased cardio-thoracic index. No infiltration observed in the lung parenchyma. Massive pericardial effusion diagnosed by Echocardiography and ejection fraction was measured 60%. Pericardiocentesis was performed and a total of 2800 cc of fluid was evacuated. Complete blood count, rutine biochemical tests and erythrocyte sedimentation rate were normal. No bacterial growth was observed in pericardial fluid samples and cytological examination revealed no findings suggesting malignancy. Also, adenosine deaminase level was normal and no growth occurred in Lowenstein-Jensen medium. Rheumatoid factor, antinuclear antibody profile, and viral markers (HIV and HBsAg) were negative. Thyroid function tests were as follows: TSH >150 mIU/l (*n*: 0.5–4.7), fT_4 0.2 ng/dl (*n*: 0.8–1.7), fT_3 1.2 pg/ml (*n*: 1.8–4.6 pg/ml), antiTPO and antiTG negative. There were no findings in ultrasound examination of the thyroid gland. Consequently, a diagnosis of primary hypothyroidism was made and replacement treatment was initiated with 50 μg/day of levothyroxine with gradual dose titration. Follow-up examination after 6 months was normal and no pericardial effusion detected by echocardiography.
Conclusion
Massive pericardial effusion is a rare complication of hypothyroidism and patients frequently exhibit other signs and symptoms of hypothyroidism before the development of pericardial effusion. However, in the patient described herein, initial presentation involved massive pericardial effusion associated with dyspnea. Physicians should keep in their mind that massive pericardial effusion might precede overt symptoms of hypothyroidism.

Usefulness of Body Adiposity Index % in comparison to body composition analyser parameters among patients with and without autoimmune thyroid diseases hospitalised on Endocrinology Department-preliminary report

Aneta Koszowska[1,2], Justyna Nowak[1,2], Anna Bronczyk Puzon[2,4], Karolina Kulik Kupka[5], Anna Dittfeld[3] & Barbara Zubelewicz Szkodzinska[2]
[1]Doctoral Study in the School of Pharmacy with the Division of Laboratory Medicine in Sosnowiec (Medical University of Silesia in Katowice), Katowice, Silesia, Poland; [2]Department of Nutrition-Associated Disease Prevention; Faculty of Public Health, Bytom, Silesia, Poland; [3]Doctoral study in the School of Medicine with the Division of Dentistry in Zabrze (Medical University of Silesia in Katowice), Bytom, Silesia, Poland; [4]Doctoral Study in the School of Health Care in Katowice (Medical University of Silesia in Katowice), Katowice, Silesia, Poland; [5]Doctoral study in the School of Public Health (Medical University of Silesia in Katowice), Katowice, Silesia, Poland.

Introduction
Anthropometric parameters such like BMI aren't suitable enough for each type of figure and leads to misinformation about body composition. Body Adiposity Index (BAI) is suggested as an alternative for BMI.
Aim
The aim of the study was to compare the usefulness of BAI in context to body composition parameters.
Materials and methods
The BAI index was calculated for 86 patients according to previously described formula. The patients were divided into three examined groups: autoimmune thyroid disorders (including Hashimoto disease, Graves Basedow disease) (AITD) ($n=40$), non autoimmunological diseases of thyroid gland like thyroid goiter (non AITD) ($n=16$), and controls without thyroid dysfunction ($n=30$). The body analysis was done in the morning in light clothes by specialist equipment with Medical Device Directive. Spearman's rank correlation was used. The collected data were statistically analysed, $\alpha=0.05$.
Results
The mean age in group with autoimmune thyroid diseases AITD was 46.5 ± 15.97, BAI $34.33\pm7.29\%$, the mean of age in group with non autoimmunological diseases was 43.75 ± 17, 81, BAI $34.03\pm6.25\%$ among patients without thyroid diseases the mean age was 28.17 ± 9.78, BAI $30.38\pm5.22\%$. In each group BAI correlates with parameters obtained from body analyzer. Strong positive correlation was observed between BAI and % amount of body fat in group of patients with AITD ($r=0.86$, $P=0.0000$), non AITD ($r=0.713$, $P=0.0001$), patients without thyroid diseases ($r=0.84$, $P=0.0000$). Positive correlations were also observed in each groups between BAI and free fatty mas, muscle mass ($P<0.05$). Strong negative correlation was observed between BAI and % of body fat in each group ($P<0.05$).
Conclusions
BAI could be useful tool for evaluation of patients percentage amount of fat. Moreover BAI could be used when patient weighing is difficult because the body mass is not used in formula. BAI as a new marker should be validated for proper use.

Health-related quality of life is reduced in treated primary hypothyroidism and with lower fT_3/fT_4-ratio

Hannah C M van Loon, Hanneke J C M Wouters, Anneke Muller Kobold, Sandra N Slagter, Thera P Links, Melanie M van der Klauw & Bruce H R Wolffenbuttel
University of Groningen, University Medical Center Groningen, Groningen, The Netherlands.

Introduction
Despite adequate treatment with LT_4 monotherapy, many patients with primary hypothyroidism still report complaints, as this treatment can not exactly imitate the endogenous homeostasis. We examined whether the different domains of HR-QOL were affected by the existence of a thyroid disorder and use of LT_4 substitution, and whether a lower ratio of free triiodothyronine (fT_3)–free thyroxine (fT_4) could predict lower HR-QOL.
Methods
A total of 16 631 participants from the population-based LifeLines Cohort Study, of Western European descent and with normal TSH values (0.4–4.5 mU/l), were evaluated; 368 of them used LT_4 monotherapy. TSH, fT_4 and fT_3) were measured with electrochemiluminescent immunoassay on the Roche Modular E170 Analyzer. HR-QOL was assessed using the Short Form-36 questionnaire.
Results
Mean ($\pm$s.d.) age was 51 ± 13 years and BMI 26.9 ± 4.7 kg/m^2 in the LT_4 users, vs 43 ± 13 years and 25.5 ± 3.8 kg/m^2 in the non-users; 90% of LT_4 users were females. We observed considerably higher fT_4 and lower fT_3 levels in LT_4 users, with the fT_3/fT_4-ratio being 25% lower in LT_4 users, despite similar TSH levels in both groups. 50% of LT_4 users had a fT_3/fT_4-ratio which was below the 2.5th percentile of euthyroid individuals. LT_4 users reported poorer HR-QOL, the largest reduction was observed in physical functioning, bodily pain, general health and vitality. In the non-users, those in the lowest tertile of the fT_3/fT_4-ratio reported a significantly lower HR-QOL in the domains physical functioning, bodily pain, and general health compared to participants in the middle and highest tertile.
Conclusion
Patients treated with LT_4 monotherapy for primary hypothyroidism report low HR-QOL. In subjects not using LT_4, a lower fT_3/fT_4-ratio was associated with more impairments in HR-QOL.

Assessment of vitamin D (25-OH vitamin D_3) concentration among patients with and without autoimmune thyroid diseases hospitalised on Endocrinology Department-preliminary report

Aneta Koszowska[1,2], Justyna Nowak[1,2], Anna Bronczyk Puzon[2,3], Anna Dittfeld[4], Karolina Kulik Kupka[5], Agata Kulpok[6] & Barbara Zubelewicz Szkodzinska[2]
[1]Doctoral Study in the School of Pharmacy with the Division of Laboratory Medicine in Sosnowiec (Medical University of Silesia in Katowice), Katowice, Silesia, Poland; [2]Department of Nutrition-Associated Disease Prevention; Faculty of Public Health, Bytom, SIlesia, Poland; [3]Doctoral Study in the School of Health Care in Katowice (Medical University of Silesia in Katowice), Katowice, Silesia, Poland; [4]Doctoral Study in the School of Medicine with the Division of Dentistry in Zabrze (Medical University of Silesia in Katowice), Katowice, Silesia, Poland; [5]Doctoral Study in the School of Public Health (Medical University of Silesia in Katowice), Katowice, Silesia, Poland; [6]Department of Endocrinology, Country Hospital, Piekary Slaskie,Silesia, Poland.

Introduction
Vitamin D is important for proper functioning of all body tissues. Receptors for vitamin D are also presence in thyroid gland. It's open questions how this vitamin could modulate the thyroid function.
Aim
The aim of the study was assess the concentrations of vitamin D as well as antiTPO level among patients with thyroid dysfunction hospitalised on Endocrinology Department.
Materials and methods
The study was conducted among 86 patients, which were divided into three groups: Autoimmune Thyroid Disorders AITD (including Hashimoto disease, Graves Basedow disease) ($n=40$), non autoimmunological diseases of thyroid gland (e.g. thyroid goitre) ($n=16$), and persons without thyroid dysfunction ($n=30$) as control group. The Kruscal Wallis test and Spearman rank correlation were used. The collected data were statistically analysed, $\alpha=0.05$.
Results
The mean age in group with autoimmune thyroid diseases AITD was 46.5 ± 15.9, mean of antiTPO was 316.79 ± 303.94 IU/ml, vitamin D $18{,}53\pm9{,}17$ ng/ml. The mean of age in group with non autoimmunological diseases was 43.75 ± 17.81, antiTPO 0.63 ± 1 IU/ml, vitamin D 18.3 ± 7.42 ng/ml and among patients without thyroid diseases the mean age was 28.17 ± 9.78 and antiTPO 0.57 ± 0.98 IU/ml, vitamin D 16.54 ± 5.51 ng/ml. The statistical significance difference was observed between groups according to age ($P=0.0000$) and antiTPO level ($P=0.0000$), the statistical difference wasn't observed between vitamin D concentration in analysed groups. In all group of 86 patients positive correlation between age and antiTPO level was observed ($P=0.00003$). Obesity was most frequently observed among patients with AITD. The vitamin D deficiency defined as level below 20 ng/ml was observed among 71% all of hospitalized patients.
Conclusions
Screening of thyroid function should be done among patients with overweight, obesity and also among patients over 40. Vitamin D deficiencies should be diagnosed and corrected according to guidelines recommended in Central Europe.

Renal involvement in Graves' disease patients treated with Benzylthiouracyl

Ibtissem Oueslati[1], Amel Melki[1], Hayet Kaaroud[2], Ibtissem Ben Nacef[1], Nadia Mchirgui[1], Karima Khiari[1] & Néjib Ben Abdallah[1]
[1]Department of Endocrinology, Charles Nicolle University Hospital, Tunis, Tunisia; [2]Department of Nephrology, Charles Nicolle University Hospital, Tunis, Tunisia.

Introduction
Renal complications in Graves' disease are rare and may be related either to the disease itself or secondary to antithyroid drugs.
Methods
We report seven cases of renal damage in patients with Graves' disease treated with Benzylthiouracyl collected over a period of 14 years.
Results
There were seven women with a mean age of 37.86 ± 14.25 years (19–61 years). Six patients developed renal vasculitis associated with ANCA. The signs were dominated by renal proteinuria and renal failure noted in all cases and associated with hematuria in five cases. The lung involvement was the most common extrarenal manifestation occurred in four patients (alveolar hemorrhage in two cases, lymphocytic alveolitis in one case and pleurisy in 1 case). The benzylthiouracyl was discontinued in four patients still under treatment. Corticosteroid therapy was used alone or in combination with cyclophosphamide in all cases. Plasmapheresis sessions were made during the alveolar hemorrhage. A complete remission was obtained in one case and incomplete remission in two cases. The other three patients required chronic hemodialysis. One patient died of sepsis. The seventh patient developed a nephrotic syndrome with hypertension and hematuria related to membranous glomerulonephritis. In this patient, the etiology was not found. Complete remission of nephrotic syndrome was achieved with corticosteroids.
Conclusion
The possibility of renal impairment in Graves' disease requires monitoring to detect urinary abnormalities in order to early initiate therapy and improve patient's outcome.

Indications and outcomes of repeated thyroid fine-needle aspirations: a retrospective evaluation from a tertiary centre

Sevde Nur Firat, Ozlem Turhan Iyidir, Mehlika Isildak, Cüneyd Anil, Nazli Kirnap Gursoy, Asli Nar & Neslihan Bascil Tutuncu
Department of Endocrinology and Metabolism, Baskent University Hospital, Ankara, Turkey.

Introduction
Fine needle aspiration (FNA) is the first-line diagnostic test for evaluating thyroid nodules. This test can effectively distinguish between neoplastic and non neoplastic nodules. The Bethesda System suggest that thyroid nodules with non diagnostic (ND), atypia/follicular lesions of undetermined significance (A/FLUS) aspiration should undergo repeat sampling. We aimed to investigate the clinical validity of repeated FNA in the management of patients with thyroid nodules in our institution.
Methods/design
In this study we evaluated 668 nodules of 529 patients who undergone repeated sampling in Başkent University Hospital between 2000 and 2014.
Results
The majority of patients were female ($n=421$, %79.6). The mean age of patients was 60.1 ± 14.5 years. First evaluation revealed that 467 (89.9%) of nodules were benign, 180 (26.9%) were non diagnostic and 21 (3.1%) were A/FLUS). Enlargement of the nodule (%27.9) was the most common indication for a repeated sampling followed by non-diagnostic cytology (%26.9). Re-aspiration altered the initial diagnosis in 84.4% and 66.7% of the non-diagnostic and (A/FLUS) patients but only in 10.7% of patients with a benign cytology the initial diagnosis was changed. We evaluated the outcome of patients whose initial and repeated cytological diagnosis are non diagnostic and A/FLUS (Table 1). Outcome data was obtained 23 (65.7%) of these patients.

Table 1 Outcome data of patients with initial and repeated diagnosis of non diagnostic and A/FLUS.

FNA1–FNA2	Surgery	Repeated biopsy
ND-ND ($n=28$)	Nodular hyperplasia-6	Benign-7
	Papillary thyroid ca-2	ND-1
A/FLUS ($n=7$)	Nodular hyperplasia-5	Benign-2

FNA, fine needle aspiration; ND, non-diagnostic; A/FLUS, atypia/follicular lesions of undetermined significance.

Conclusion
Repeat FNA is useful in cases whose initial diagnosis is non diagnostic or A/FLUS, but repeated aspiration for patients with an initial benign examination appears to not increase the expected likelihood of a malignant cytology.

The efficacy of radioiodine therapy in patients with non-toxic nodular goitre with large cold nodule

Saeid Abdelrazek[1], Piotr Szumowski[1], Katrzyna Siewko[2], Janusz Mysliwiec[1], Malgorzata Szelachowska[2] & Marcin Garkowski[1]
[1]Department of Nuclear Medicine, Medical University of Bialystok, Bialystok, Poland; [2]Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland.

Most of the patients with the benign cold nodule refuse surgical operation. Radioiodine therapy (RIT) is the choice for these patients. The aim of our study was to evaluate the efficacy of radioiodine therapy to reduce thyroid volume in patients with cold nodule by the use of two doses of radioiodine.
Methods
We treated 40 patients with non-toxic nodular goitre with large cold nodule, aged 18 and 48 years; initial 24 h radioiodine uptake (RAIU) was ranged between 18–45%, and thyroid volume ranged between 48 and 120 ml, effective half-life was more than 3 days at the time of treatment. Malignant changes were excluded in all nodules by fine needle aspiration biopsy. The activity dose was calculated by the use of Marinelli's formula and ranged between 280 and 800 MBq. Thyroid ultrasonography, and thyroid scan with RAIU at 24 was done before and after 6 and 12 months of RIT. Follow up control was done every 6 weeks.
Results
After 6 months RIT in all the patients the large cold nodule changes to hot nodule. In 13 patients the size of the thyroid gland decrease to 48%, and no need for the second dose of radioiodine therapy. 27 patients received second dose of RIT to decrease the nodule which was cold and turned to hot after the first dose. After 12 months of the second dose of radioiodine a mean thyroid volume reduction of 56% was achieved. After 12 months of RIT euthyroidism persist in 52% of patients, and hypothyroidism develop in 48% of patients.
Conclusions
Radioiodine is non-invasive, safe and cost effective method of therapy for reduction of large non-toxic goitre even with cold nodule. The reduction of the cold nodule and the thyroid volume, were due to well accurate measurement of administered activity, relatively high effective half-life and well-organised follow up.

Fibromyalgia in patients with euthyroid Hashimoto's thyroiditis

Muge Bilge[1], Mine Adas[2], Muyesser Nergiz Yanmaz[3] & Aysen Helvaci[1]
[1]Okmeydani Education and Research Hospital, Internal Medicine, Istanbul, Turkey; [2]Okmeydani Education and Research Hospital, Endocrinology, Istanbul, Turkey; [3]Kemerburgaz University, Rheumatology, Istanbul, Turkey.

Introduction
The aims of this study are to evaluate fibromyalgia (FM) in patients with euthyroid Hashimoto's throiditis (HT) and whether antithyroperoxidase antibody (TPOAb) positivity is associated with the FM.
Methods
We have studied 167 patients with HT and 83 healthy controls followed in our hospital. Single researcher took the history and did physical examination including manual tender point examination according to Manuel Tender Point Survey instructions. For the diagnosis FM, 2010 American College of Rheumatology Classification Criteria for the FM was used. Thyroid assessment was done by free T_4, free T_3, TSH, antithyroglobulin antibody (TgAb) and TPOAb. Patients were excluded from the study if they had any other serious disease, and if there was any history of drug use that interferes with the symptoms of FM.

Results
FM was found in 40% (67 out of 167 patients) of in HT patients, in 7% (six out of 83 healthy controls, $P<0.001$) of controls. The average age was significant higher in patients with FM than controls (43.78±10.48 years vs 40.43±10.52 years, $P=0.02$). TSH (2.97±2.03 vs 2.20±1.33, $P=0.001$), TPOAb (240.92±268.6 vs 197.05±288.14, $P=0.006$) and TgAb levels (300.68±528.79 vs 153.76±411.51, $P=0.003$) where notable higher in patients with FM, according to patients without FM. Widespread pain index, symptom severity scale and tender point examination showed no significant difference between the patient and control group. On the other hand widespread pain index, symptom severity scale and tender point examination showed a positive correlation with TSH (r: 0.184, $P=0.004$; r: 0.204, $P=0.001$; r: 0.167, $P=0.009$, respectively). Also TgAb showed positive correlation with symptom severity scale (r: 0.168, $P=0.02$). İncreasing age in patients with HT showed positive relationship with widespread pain index and tender point examination($r=0.193$, $P=0.012$ and $r=0.170$, $P=0.02$ respectively).
Conclusion
In our study, euthyroid HT patients showed significantly higher prevalence of FM, as compared to healthy control. This finding support thyroid autoimmunity may influence the development of FM, but the evidence which support that FM is related to autoimmune aetiology is not clear, and FM severity may not be affected by the presence of thyroid autoantibody.

False positive post RAI scan in a subject with papillary thyroid cancer secondary to urine contamination

Sebnem Aydin[2], Nafiye Direktor Ozmen[3], Umut Mousa[1], Osman Koseoglulari[1] & Hasan Sav[1]
[1]B Nalbantoglu Hospital Department of Endocrinology and Metabolism, Nicosia, Cyprus; [2]B Nalbantoglu Hospital Department of Nuclear Medicine, Nicosia, Cyprus; [3]B Nalbantoglu Hospital Department of Internal Medicine, Nicosia, Cyprus.

Introduction
Radioactive iodine (RAI) for remnant ablation and post RAI scanning are very frequently employed modalities in differentiated thyroid cancers (DTC). Radioactive iodine is secreted into physiological secretions such as tears and urine. In this case report we present a case who received RAI for DTC with a surprising post RAI scan compatible with multiple metastases.
Case report
A 53-year-old male subject underwent total thyroidectomy and ipsilateral lymph node dissection after being diagnosed as papillary thyroid cancer (PTC) via fine needle aspiration cytology (FNAC). He received 150 mCI of RAI due to lymph node metastases. His stimulated thyroglobulin level (Tg) was 33.3 ng/ml and was positive for anti thyroglobulin antibodies. In the post RAI scan we visualized suspicious metastases in the thyroidal area together with the mid abdominal, proximal right femoral, mid left femoral and distal left tibia areas. The metastatic findings were untypical and were localized anteriorly. Also the patients' general situation was fine so we planned a bone scan and PET CT to confirm these findings. Both bone scans and FDG PET was negative for metastases. The subjects' socioeconomic status and personal hygiene was very low thus we suspected these findings were secondary to urine contamination. Six months later he underwent a whole body scan which was negative for metastases. His stimulated Tg was 1.16 ng/ml and anti Tg was positive during the scan.
Discussion
Post RAI scanning is a very important technique for determining metastases in subjects with DTC. Contamination with body fluids can cause false metastatic findings in which other radiological methods and personal history can aid the physicians in making a decision.

Smoking associated with TSH receptor antibody and serum IL17A elevation in hyperthyroid Graves' disease

Ildikó Molnár[1], Ilona Bohaty[2] & Éva Somogyiné-Vári[1]
[1]EndoMed, Immunoendocrinology and Osteoporosis Centre, Debrecen, Hungary; [2]Regional Centre of Hungarian National Blood Transfusion Service, Debrecen, Hungary.

Th17 cells represent newly discovered CD4+T cells producing predominantly IL17A cytokines, which are involved in inflammations and autoimmune diseases. Elevated IL17 levels were demonstrated in thyroid autoimmunity and the activity of Graves' ophthalmopathy. The relationship among IL17A, anti-thyroid antibodies, smoking, and clinical activity score of ophthalmopathy was investigated in hyperthyroid Graves' disease. One hundred and thirty-eight patients, 62 with Graves' disease (25 with ophthalmopathy, 33 with hyperthyroidism, and 17 have daily smoking), 38 with Hashimoto's thyroiditis and 38 healthy controls were investigated. Serum IL17A levels were measured with ELISA; thyroid hormones, anti-thyroid antibodies in a fully automated way, but TSH receptor antibodies with RIA. IL17A serum levels were higher in Graves' patients than those in Hashimoto's thyroiditis and controls (5.28±3.8 with or 5.43±3.62 ng/ml without ophthalmopathy vs 3.65±2.22 ng/ml, $P<0.04$ or $P<0.01$, respectively, for Hashimoto's thyroiditis and vs 2.83±0.73 ng/ml, $P<0.0001$ and 0.004 respectively for controls). Smoking increased IL17A levels in comparison with nonsmoking patients in hyperthyroid Graves' patients after thyrostatic therapy (2.92±1.44 ng/ml vs 10.46±7.18 ng/ml, $P<0.04$). TSH receptor antibody positive and hyperthyroid smoking patients showed significantly higher IL17A and TSH receptor antibody levels than those who were nonsmoking (3.59±2.28 ng/ml vs 7.24±5.42 ng/ml, $P<0.02$ for IL17A and 9.07±9.39 U/l vs 22.52±11.48 U/l, $P<0.01$ for TSH receptor antibodies). No relevant elevation in IL17A levels was connected to clinical activity score of ophthalmopathy. The results highlight the role of IL17A levels in hyperthyroid Graves' disease. Smoking can play as an aggravating factor in IL17A and TSH receptor antibody elevation.

Evaluation of acoustic voice analysis in patients with subclinical thyrotoxicosis

Taner Demirci[1], Mehmet Uyar[2], Emel Tatar Çatallı[3], Mustafa Çalışkan[1], Bekir Uçan[1], Dilek Demiral[2], Müyesser Sayki Arslan[1], Mustafa Özbek[1], Mehmet Hakan Korkmaz[3] & Tuncay Delibaşı[1,4]
[1]Department of Endocrinology and Metabolism, Dişkapi Yildirim Beyazit Teaching and Research Hospital, Ankara, Turkey; [2]The Audiology–Speech Impediment Unit, Dişkapi Yildirim Beyazit Teaching and Research Hospital, Ankara, Turkey; [3]Department of Otolaryngology, Ministry of Health, Dişkapi Yildirim Beyazit Teaching and Research Hospital, Ankara, Turkey; [4]Department of Internal Medicine, School of Medicine (Kastamonu), Hacettepe University, Ankara, Turkey.

Introduction
The relationship between hyperthyroidism and voice disorders has not been identified before. The aim of this study was to investigate the changes in the acoustic values in patients with subclinical thyrotoxicosis.
Methods
In this study, acoustic voice analysis was evaluated in a total of 115 cases. Sixty of 115 individuals (18 men and 42 women) had subclinical thyrotoxicosis, aged between 18 and 65 years, and all had no history of laryngeal surgery, no vocal complaints. These patients were compared with the control group consisting of 55 cases (18 men and 37 women) with similar characteristics. Acoustic and perceptual analyses are the most commonly used method in the assessment of voice quality. Kay CSL 4300 unit was used for acoustic voice analysis and as the operating parameters, F0 (fundamental frequency), Jitter, Rap (relative average perturbation), Shimmer, noise-to-harmonic ratio (NHR), and voice turbulence index (VTI) values were evaluated. The results were evaluated using the Mann–Whitney U statistical method.
Results
The performed acoustic analysis showed that mean values of the investigated parameters in patients were Jitter (%) 1.18, Shimmer (%) 4.00, Rap (%) 0.70, F0 (Hz) 209.85, VTI 0.05, and NHR (dB) 0.14. In the control group, the analyzed parameters were the following: Jitter (%) 0.96, Shimmer (%) 3.16, Rap (%) 0.57, F0 (Hz) 207.86, VTI 0.05, and NHR (dB) 0.12. There was no statistically significant difference between the control group and patients ($P>0.05$).
Conclusions
In our study, it was concluded that the moderate increase in thyroid hormones doesn't affect the voice quality. Effect on the voice quality of the excess of thyroid hormones, such as clinical thyrotoxicosis was not evaluated. Therefore, further studies are needed to interpret the relationship between thyroid hormone and voice quality.

Transient pulmonary hypertension in patients with Graves' disease

Hela Marmouch, Fadia Boubaker, Sondes Arfa, Tansim Slim, Hanene Sayadi, Manel Jmal & Ines Khochtali
Department of Internal Medicine and Endocrinology, Faculty of Medicine, Monastir, Tunisia.

Introduction
Hyperthyroidism produce changes in cardiac contractility, blood pressure, and systemic or pulmonary vascular resistance. In almost all cases these cardiovascular changes are reversible when the underlying thyroid disorder is recognised and treated. Pulmonary hypertension (PAH) has been associated with thyroid dysfunction, but primarily with hyperthyroidism. The vast majority of patients with this form of PAH are usually older with toxic multinodular goitre. The aim of this study was to determine the clinical correlates of PAH in patients with Graves' disease (GD).
Methods
Our study is retrospective one concerning patients with GD referred for echography before using any treatment. PAH has been diagnosis when pulmonary artery systolic pressure was elevated.
Results
Among 22 consecutive patients with GD referred for echocardiography, six patients (27.32%) had PAH measured by continuous-wave Doppler echocardiography (pulmonary artery systolic pressure >35 mmHg). The patients with PAH had significantly higher pulmonaryvascular resistance (PVR), cardiac output, and TSH receptor antibody (TRAb) compared to those without. Pulmonary artery systolic pressure may had a good correlation with TRAb, but was not related to free T_4. All this patients have a reversible pulmonary hypertension after treatment.
Discussion
In addition to the effect of thyroid hormone on the cardiovascular system, autoimmune-mediated pulmonaryvascular remodelling may play a role in Graves' disease-linked elevated pulmonary artery systolic pressure. An autoimmune process inducing endothelial damage with GD may play a key role. Future studies should focus on discovering the immunogenetic overlap between autoimmune thyroid diseases and PAH.
Conclusion
Study highlights the importance of considering hyperthyroidism as a cause of idiopathic PAH, and demonstrates the potential reversibility of its complications. At present, thyroid function tests should be considered in the investigation of all patients.

Side effects of steroid therapy in Graves' orbitopathy: comparison of two different protocols: parenteral vs combined parenteral and oral

Biljana Beleslin, Jasmina Ciric, Mirjana Stojkovic, Slavica Savic, Slavica Ciric, Tijana Lalic, Tanja Nisic, Milos Stojanovic & Milos Zarkovic
Clinic for Endocrinology, Medical School, Clinical Center of Serbia, University of Belgrade, Belgrade, Serbia.

Introduction
Glucocorticoids (GCs) are the treatment of choice for moderate-to-severe and active Graves' orbitopathy (GO), but optimal treatment is still undefined as serious side effects are great concern of GC therapy. The aim of the present study was to evaluate tolerability and safety of two different treatment protocols.
Methods
Consecutive patients were divided according to the protocol of GC therapy into two groups: combined intravenous and oral GC therapy (combined GC group, 66 patients, 49 ± 10 years), and only intravenous GC therapy (IVGC group, 66 patients, 50 ± 11 years, $P=$NS). Combined GC therapy included 500 mg of methylprednisolone in 500 ml of saline solution for 2 alternative days, followed by oral prednisone tapering dose that was repeated each month for the next 5 months. Cumulative dose was 10.2 g. IVGC therapy included infusions of 500 mg of methylprednisolone for the first 6 weeks, and then infusions of 250 mg for the remaining 6 weeks. Cumulative dose was 4.5 g.
Results
Combined GC therapy induced significantly more side effects in comparison to IVGC (49/66, 74% vs 28/66, 42%, $P<0.001$), including weight gain of >3 kg (55% vs 22%, $P<0.001$), hirsutism in female patients (49% vs 4%, $P<0.001$), myalgias (33% vs 0%, $P<0.001$), sleeplessness (17% vs 2%, $P=0.004$), and urinary infections (15% vs 3%, $P=0.03$). Increase in total cholesterol (42% vs 35%) and development of diabetes (8% vs 3%) was also more prevalent without reaching statistical significance ($P=$NS). Considering serious side effects two patients in combined GC group developed herpes zoster infection and pulmonary tuberculosis, whereas one patient in IVGC group had myocardial infarction during IVGC therapy.
Conclusion
Side effects were more prevalent in the combined group, as a consequence of higher cumulative dose, longer duration of therapy (6 months vs 3 months), and treatment schedule. Careful monitoring during GC therapy in patients with GO is mandatory in both treatment protocols.

Isolated cutaneous findings of systemic lupus erythematosus due to propylthiouracil

Gamze Erfan[1], Kaan Tasolar[1], Meltem Öznur[2] & Murat Yılmaz[3]
[1]Dermatology, Tekirdag, Turkey; [2]Pathology, Tekirdag, Turkey; [3]Endocrinology and Metabolism, Tekirdag, Turkey.

Propylthiouracil (PTU), used to treat thyroid dysfunctions such as Graves' disease, rarely induces lupus-like syndrome. A 52-year-old woman developed dermatological findings of systemic lupus erythematosus with malar rash, photosensitivity and discoid lupus erythematosus-like lesions, after 3 weeks of exposure to the drug. ANA and anti-dsDNA were positive. Skin biopsy of face revealed vacuolar changes in basal layer and lymphoid infiltration in perivascular region of dermis. No other organ involvement was diagnosed. PTU treatment was stopped and with oral prednisolone 40 mg daily, in 3 weeks she had resolution of lesions. The patient has no skin lesions in 2-month follow-up. This is a report of isolated skin findings of lupus-like syndrome with positive serologies and without any other organ involvement. The physicians should be aware of this rare but potentially serious, possible adverse effect of PTU.

Seasonality in paediatric Graves' disease compared to the general population: impact of month of birth: a national study

Tiago Nunes da Silva, Bernardo Dias Pereira, Henrique Vara Luiz, Ana Catarina Matos, Maria Carlos Cordeiro, Luisa Raimundo & Jorge Portugal
Hospital Garcia de Orta – Endocrinologia e Diabetes, Almada, Portugal.

Paediatric Graves' disease (PGD) is an uncommon autoimmune disorder with a multifactorial origin. Although, in some autoimmune endocrinophaties the seasonality of month of birth (MOB) distribution differed from the general population, this association has not been study in PGD. The aim of this work was to analyse the impact of seasonality of MOB on PGD incidence in Portugal.
In 2013, the Portuguese Paediatric Society of Diabetes and Endocrinology undertook a national multicentric study of the PGD (153 cases). We compared the distribution of MOB within this study with the Portuguese population (data from the National Institute of Statistics). Since, the mean age at diagnosis was 11 years, we restricted the study period up to 2001 to correct for that variation (125 cases). Statistical analysis was performed with STATA Software, version 12.0. Walter and Elwood method was used because it takes into account the population at risk. A total of 125 cases of PGD born between 1983 and 2001 were recorded (75% females) compared to 2 271 523 births (49% females). Among PGD, the percentage of observed to expected births did not differ across the 12 months ($P=0.8$). Nevertheless, the smoothed birth-month estimates demonstrated a non-significant (NS) excess of births from September to April, and a deficit from May to July. The evaluation of the subgroup with higher TRABS titters at diagnosis (50 cases with TRABS ten times the upper limit of normal), did not show a higher incidence compared to the Portuguese population ($P=0.7$).
This was the first population-based study that analysed the impact of seasonality of MOB in the incidence of PGD. Despite a trend to a higher incidence of PGD in children born between September and April, no uniform seasonal pattern of MOB in PGD was observed in this sample of the Portuguese population. We thank the Portuguese Paediatric Society of Diabetes and Endocrinology for allowing the study data to be used in this work.

Late onset of amiodarone-induced thyrotoxicosis causing pharmacoresistant atrial fibrillation with subsequent development of serious heart failure

Monika Nývltová, Karolína Drbalová, Patrik Jarkovský, Miroslav Vodák, Petr Krejcí & Miroslav Zavoral
Central Military Hospital, Prague, Czech Republic.

Amiodarone is a potent and among cardiologists still very popular anti-arrhythmic drug. This case report describes severe course of amiodarone-induced thyrotoxicosis (AIT) which is one of the most serious side effects of the treatment. The patient (J S born in 1950) was first hospitalised in June 2012 for atrial fibrillation with rapid ventricular response and tachycardia-induced cardiomyopathy with a decreased ejection fraction (EF). Thyroid hormones were normal at that time and electric cardioversion was successfully performed and following echocardiography showed improving EF. Attending cardiologist added to the medication amiodarone which was after <6 months discontinued for symptomatic corneal deposits. The second hospitalisation for the same reason was in September 2013. According to laboratory findings, ultrasonography and scintigraphy we diagnosed a destructive type of amiodarone-induced thyrotoxicosis more than half a year after the withdrawal of this drug! We started treatment with combined antithyroid medication at higher doses (including parenteral forms of administration) and corticosteroids. The atrial fibrillation was resistant to standard doses of β-blockers even in combination with digoxin. However, despite the normalisation of thyroid hormones the patient had to be after 33 days of treatment moved to ICU with a serious heart failure. After administration of levosimendan, diuretics and after an electric cardioverison was carried out, the clinical condition began to improve. We had decided for a total thyroidectomy and afterwards we started a substitution therapy with levothyroxine. Recurrence of atrial fibrillation in October 2014 was without any major concern quickly solved by pharmacological cardioversion with amiodarone. Nowadays, the amiodarone treatment was discontinued, the patient keeps sinus rhythm and a radiofrequency ablation is planned. This case report draws attention to the risk of developing a serious AIT even after a long time since discontinuation of administering amiodarone.

Ultrasonography-guided fine-needle aspiration biopsies of thyroid nodules: single-centre experience

Salim Susuz[1], Nur Kebapci[2], Emine Dundar Kasapoglu[3], Mahmut Kebapci[4], Özge Cevikalp[5], Belgin Efe[2] & Aysen Akalin[1]
[1]Internal Medicine Clinic, Afyonkarahisar State Hospital, Afyonkarahisar, Turkey; [2]Endocrinology and Metabolism Division, Osmangazi University Medical School, Eskisehir, Turkey; [3]Pathology Division, Osmangazi University Medical School, Eskisehir, Turkey; [4]Radiology Division, Osmangazi University Medical School, Eskisehir, Turkey; [5]Statistic Division, Osmangazi University Medical School, Eskisehir, Turkey.

In the present study, we aimed to investigate the efficiency of ultrasound-guided fine-needle aspiration biopsy in our clinic. Totally, 701 patients followed at Department of Endocrinology, Faculty of Medicine, Eskisehir Osmangazi University with nodular thyroid disorder were included in this study during January 2000 and January 2011. Ultrasound-guided thyroid fine-needle aspiration biopsy was performed in these 701 cases at Interventional Radiology Department. Throid nodules were evaluated in terms of size, echo quality, peripheral halo, and calcification. The biggest diameter was determined measuring three dimensions of nodule. If multiple nodules were found in a patient, TFNAB was performed from the biggest dominant nodule. The result of US-TFNAB was insufficient in 11.7% of patients. US-TFNAB was reported as benign in 79.3% of patients, suspected malignant in 4%, malignant in 3.9% and suspected follicular neoplasm in 1.1%. When suspected follicular neoplasm and suspected malignancy cases were included into malignant group, the malignancy ratio based on US-TFNAB was 9%. 146 of 701 cases were operated (20.8%), 19 cases (2.7%) didn't accept the surgery. According to histopathology results of operated patients, 66 patients were malignant and 80 were benign (Table 1). No significant gender difference was determined for benign or malignant histopathology results ($P>0.05$).
When all cases with suspected follicular neoplasm, suspected Hürthle-cell neoplasm, suspected malignancy and suspected papillary carcinoma were included into malignancy group, the sensitivity was 79.4%, specificity was 83.8%, overall accuracy rate was 81.8%, positive predictive value was 80.6%, and negative predictive value was 82.7%.
A clinical assessment performed an experienced clinician, US-guided TFNAB performed by an experienced radiologist and pathologic evaluation by a cytopathologist is a team work which will achieve success to identification of malignant thyroid nodules in all patients with nodular thyroid.

The evaluation of TSH-receptor antibody in hyperthyroid patients treated with surgery or radioactive iodine

Ahmet Dirikoc[1], Fatma Neslihan Cuhaci[1], Husniye Baser[2], Cevdet Aydin[1], Oya Topaloglu[1], Mehmet Kilic[3], Seyda Turkolmez[4], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Yildirim Beyazit University, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Ataturk Education and Research Hospital, Ankara, Turkey; [3]Department of General Surgery, Ataturk Education and Research Hospital, Ankara, Turkey; [4]Department of Nuclear Medicine, Ataturk Education and Research Hospital, Ankara, Turkey.

Introduction
Radioactive iodine (RAI) therapy is widely used in the treatment of hyperthyroidism especially in patients with Graves' disease (GD), toxic multinodular goitre (TMNG), and toxic adenoma. RAI may lead to worsening of the autoimmunity with the elevation of TSH-receptor antibody (TRAB). In this study, we aimed to compare the effects of surgery or RAI treatment on TRAB.
Methods
Hyperthyroid patients were divided into three groups; patients in group 1 ($n=23$) had GD conducted to RAI, in group 2 ($n=18$) had TMNG referred to RAI, and group 3 ($n=12$) had GD who underwent to surgery. Before and 12 months after RAI and surgery, sera were collected and analysed for the presence of TRAB.
Results
In group 1, there were eight patients (34.8%) before treatment and 14 patients after treatment with TRAB positivity ($P=0.311$). In group 2, before treatment there were two patients (11.1%) with TRAB positivity, whereas after treatment there were four patients (22.2%) ($P=0.423$). In group 3, TRAB positivity were in six patients (50%) and in one patient (8.3%) before and after treatment respectively ($P=0.296$). However, there was no difference in TRAB positivity between groups 1 and 3 before treatment ($P=0.383$), TRAB positivity was statistically higher in group 1 than group 3 at 12 months of treatment ($P=0.003$). There was no difference between groups 1 and 2 before treatment ($P=0.080$). TRAB positivity was significantly higher in group 1 than group 2 at 12 months of the treatment ($P=0.013$).
Conclusion
RAI treatment can induce autoimmunity in patients with TMNG similar as in patients with GD. We observed similar ratios of TRAB positivity in patients with GD and TMNG before and 12 months after treatment. Whereas 12 months after the treatment, we demonstrated higher TRAB titres in GD patients treated with RAI than underwent to surgery.

Dynamic thiol/disulfide homeostasis in patients with autoimmune subclinical hypothyroidism

Ihsan Ates[1], Mustafa Altay[1], Fatma Meric Yilmaz[2,3], Canan Topcuoglu[2], Salim Neselioglu[3], Özcan Erel[3] & Nisbet Yilmaz[1]
[1]Department of Internal Medicine, Ankara Numune Education and Research Hospital, Ankara, Turkey; [2]Department of Biochemistry, Ankara Numune Education and Research Hospital, Ankara, Turkey; [3]Department of Biochemistry, Medical Faculty, Yildirim Beyazit University, Ankara, Turkey.

Objective
To investigate dynamic thiol/disulphide homeostasis in autoimmune subclinical hypothyroidism.
Materials and methods
48 patients with newly diagnosed subclinical hypothyroidism due to Hashimoto's thyroiditis and not yet on any treatment and 48 healthy subjects without any known disease were enrolled. Thiol/disulfide homeostasis (native thiol(-SH)–disulphide(-S-S-) exchanges) was measured in both groups with new method developed by Erel and Neselioglu. The half of the difference between total thiol (-SH + -S-S-) and -SH concentrations gave the -S-S- bond amount.
Results
In patients with subclinical hypothyroidism, -SH level and -SH/(-SH + -S-S-) ratio was found to be lower than that of the control group. -S-S- level ($P=0.004$),

-S-S-/-SH ($P=0.001$), and -S-S-/(-SH+-S-S-) ($P=0.001$) ratio was higher in patients with subclinical hypothyroidism as compared to that of the control group. A positive correlation was found between anti-TPO and anti-Tg levels and -S-S-/-SH ve -S-S-/(-SH+-S-S-) levels while a negative correlation was found with -SH/(-SH+-S-S-) level.
Conclusions
Thiol/disulfide homeostasis was found to have a tendency towards -S-S- formation in patients with subclinical hypothyroidism and thyroid autoantibodies were correlated positively with thiol oxidation. Abnormal thiol/disulfide homeostasis in patients with Hashimoto's thyroiditis, is whether a cause or a consequence, may be illustrated by using thiol-containing drugs and following autoantibody levels. The efficacy, dose and duration of thiol drugs may be monitored easily, effectively, quickly and cheaply by the method developed by Erel and Neselioglu.

EP944

Is oxidative stress an effective risk factor in the development of overt hypothyroidism in Hashimoto's thyroiditis?

Ihsan Ates[1], Mustafa Altay[1], Fatma Meric Yilmaz[2], Canan Topcuoglu[2], Nisbet Yilmaz[1] & Serdar Guler[1]
[1]Department of Internal Medicine, Ankara Numune Education and Research Hospital, Ankara, Turkey; [2]Department of Biochemistry, Ankara Numune Education and Research Hospital, Ankara, Turkey; [3]Department of Endocrinology and Metabolism, Ankara Numune Education and Research Hospital, Ankara, Turkey.

Objective
We aimed to investigate the effects of oxidative stress in the pathhogenesis and progression of thyroiditis in patients with Hashimoto's thyroiditis whose aetiopathogenesis includes environmental and genetic factors.
Methods
80 patients (40 euthyroid and 40 subclinical hypothyroidism) older than 18 years with newly diagnosed Hashimoto's thyroiditis and not yet on any treatment were enrolled. Patients were followed up for 9 months. Blood sample was drawn at diagnosis for thyroid function tests and oxidative stress parameters. Total antioxidant status (TAS), total oxidative status (TOS), paraoxonase 1 (PON1), arylesterase, and total thiol (total SH) were measured by colorimetric method. The ratio of serum TOS level and TAS level gave the oxidative stress index. TSH, free thyroxine (fT_4), anti-thyroid peroxidase (anti-TPO), and anti-thyroglobulin (anti-Tg) were measured by ECLIA method.
Results
Total SH level was found to be higher in the euthyroid group as compared to the subclinical hypothyroidism group ($P=0.019$). TAS, TOS, OSI, PON, and arylesterase levels were similar in the two groups ($P>0.05$). At 9 months of follow-up, overt hypothyroidism developed in 14 patients. Patients with overt hypothyroidism tended to have significantly higher average TOS and OSI levels at diagnosis ($P<0.001$) and significantly higher anti-Tg and anti-TPO levels at hypothyroidism development ($P<0.05$) than those who did not develop overt hypothyroidism. Multivariable Cox regression analysis showed TSH level (HR = 1.348, $P<0.001$), fT_4 level (HR = 0.481, $P=0.017$), and OSI ratio (HR = 2.349, $P<0.001$) to be independent predictors for the development of overt hypothyroidism in euthyroid patients and those with subclinical hypothyroidism.
Conclusion
Higher levels of autoantibodies and oxidative stress in patients developing overt hypothyroidism shows that oxidative stress plays a major role in the pathogenesis and progression of autoimmune thyroiditis.

Does treatment with levothyroxine sodium decrease oxidative stress in Hashimoto's thyroiditis?

Ihsan Ates[1], Mustafa Altay[1], Fatma Meric Yilmaz[2], Nisbet Yilmaz[1] & Serdar Guler[1]
[1]Department of Internal Medicine, Ankara Numune Education and Research Hospital, Ankara, Turkey; [2]Department of Biochemistry, Ankara Numune Education and Research Hospital, Ankara, Turkey; [3]Department of Endocrinology and Metabolism, Ankara Numune Education and Research Hospital, Ankara, Turkey.

Background
In Hashimoto's thyroiditis, chronic inflammation and autoimmunity increases oxidant radicals and cause oxidative stress. However, the effect of levothyroxine therapy on the oxidant and antioxidant systems is not known in overt hypothyroidism. Therefore, we sought to investigate the effect of levothyroxine sodium therapy on oxidative stress in patients with Hashimoto thyroiditis and overt hypothyroidism.
Materials and methods
36 patients (nine males and 27 females) with a diagnosis of Hashimoto's thyroiditis and overt hypothyroidism older than 18 years and not yet on any therapy were enrolled. Blood samples were taken at diagnosis and after 6 months following treatment with levothyroxine for measurements of TSH, free thyroxine (fT_4), anti-thyroid peroxidase (anti-TPO), anti-thyroglobulin (anti-Tg), and oxidative stress parameters. TSH, fT_4, anti-TPO, and anti-Tg levels were measured using the ECLIA method. Total antioxidant status (TAS), total oxidative status (TOS), paraoxonase 1 (PON1), aryesterase, and total thiol (total SH) levels were measured using the colorimetric method. Oxidative stress index (OSI) was obtained from the ratio of TOS and TAS levels.
Results
TSH, anti-TPO, and anti-Tg levels decreased after treatment ($P<0.05$) while fT_4 level increased ($P<0.05$). TAS level increased after treatment (1.5 ± 0.2 vs 1.7 ± 0.3, $P=0.030$) while TOS level decreased (6.5 ± 1.9 vs 4.4 ± 1.3, $P=0.012$). OSI ratio also decreased after treatment (4.3 ± 2.3 vs 2.7 ± 1, $P=0.003$). Total SH level increased after treatment (442.8 ± 63.8 vs 470.3 ± 30.1, $P=0.034$), but no significant change was observed in arylesterase and log(PON) levels.
Conclusion
Levothyroxine treatment was found to have positive effects in terms of thyroid antibodies and oxidative stress parameters in patients with Hashimoto's thyroiditis. More studies are needed to understand whether this effect of levothyroxine is due to increase of antioxidant molecules and induction of enzyme synthesis or reduction of inflammation.

Concomitant Graves' disease and primary hyperparathyroidism: case report

Ramazan Cosar[1], Isilay Kalan Sari[2,3] & Senay Arikan Durmaz[3]
[1]Department of Internal Medicine, Faculty of Medicine, Kirikkale University, Kirikkale, Turkey; [2]Department of Endocrinology and Metabolic Diseases, Burdur State Hospital, Burdur, Turkey; [3]Department of Endocrinology and Metabolic Diseases, Faculty of Medicine, Kirikkale University, Kirikkale, Turkey.

Introduction
Hyperthyroidism is associated with asymptomatic hypercalcaemia due to increased calcium mobilization from bone and catecholamine metabolism. Hypercalcaemia secondary to hyperthyroidism coexist with decreased or normal parathyroid hormone level. We reported case of 30-year-old man who suffered from Graves' disease and primary hyperparathyroidism.
Case report
A 30-year-old male patient was admitted to our hospital suffered from palpitation, heat intolerance and sweating. He had blood pressure of 130/90 mmHg, heart rate of 102 beats/min, and temperature of 36.6 °C. He had warm and moist skin. Blood tests showed TSH <0.03 μU/l, fT_3 14.34 pg/ml, and fT_4 3.91 pg/ml. Other results: anti-TPO 229 IU/ml, TRAbs 0.73 U/l, serum calcium 11.05 mg/dl, inorganic phosphorus 3.61 mg/dl, iPTH 85.9 pg/ml, and 25-OH vitamin D_3 31.8 ng/ml. The 24-h collected urine showed creatinine clearance of 132 ml/min and calcium excretion of 428 mg/day. Other laboratory parameters were largely within normal ranges. Ultrasonography revealed enlarged thyroid gland with inhomogeneous pattern. Scintigraphy of the thyroid gland was consistent with Graves' disease. Scintigraphy of the parathyroid glands revealed parathyroid adenoma. Patient was treated with propylthiouracil 300 mg/day and propranolol 20 mg twice a day. Treatment successfully controlled sympathetic symptoms. When he became euthyroid, serum calcium, and parathyroid hormone was still elevated. Subtotal thyroidectomy and parathyroidectomy was performed. The follow-up investigations showed normalisation of serum calcium and parathyroid hormone.
Conclusion
Constant hypercalcemia after treatment of hyperthyroidism may indicate concomitant hyperparathyroidism if iPTH level is not reduced. It should be considered that; slightly or moderately elevated iPTH levels in hypercalcaemia coexists with hyperthyroidism, may suggest hyperparathyroidism. Ultrasonography, scintigraphy, and ultrasound guided fine-needle biopsy of parathyroid

gland lesions can be used for differential diagnosis. Avoiding from repeated operations and complications; the best treatment is combined resection of thyroid and parathyroid gland when concomitant parathyroid adenoma is determined.

Measurement of epicardial adipose tissue (EAT) thickness in subclinical hypothyroid patients and to determine the relationship between EAT and abdominal/visceral fat mass

Dilek Arpaci[1], Aysel Gurkan Tocoglu[1], Sabiye Yilmaz[2], Sumeyye Korkmaz[1], Hasan Ergenc[1], Huseyin Gunduz[2], Nurgul Keser[2] & Ali Tamer[1]
[1]Department of Internal Medicine, Sakarya Education and Research Hospital, Sakarya University, Sakarya, Turkey; [2]Department of Cardiology, Sakarya Education and Research Hospital, Sakarya University, Sakarya, Turkey.

Background
Subclinical hypothyroidism (SH) is defined as high TSH accompanied with normal free thyroxine (FT_4). SH has found to be associated with cardiovascular disease (CVD) and increased mortality. Epicardial adipose tissue (EAT) is now considered to be a new noninvasive measurement method used for the early detection of CVD susceptibility. EAT has vasocrine and paracrine actions which lead to CVD. We aimed to evaluate measurement of EAT and to detect relationship between EAT and abdominal/visceral fat mass in patients with SH.
Material and methods
This study included 41 patients with SH and 35 healthy controls (matched in age and gender). Demographic data (age, gender, BMI, fat mass (FM), abdominal FM, visceral FM, waist circumstance (WC), hip circumstances (HC), systolic and diastolic blood pressure) and laboratory results (fasting plasma glucose (FPG), LDL cholesterol (LDL-c), HDL cholesterol (HDL-C), triglycerides (TGs), FT_4, TSH, and anti-TPO) were recorded. EAT was measured with transthoracic echocardiography.
Results
Fat mass, BMI, WC, and WC/HC ratio, visceral and abdominal fat mass were higher in the study group than the control group ($P<0.05$). While there were no differences in terms of FPG ($P=0.780$), there were significant differences regarding LDL-C and TGs between the two groups ($P=0.002$ and $P=0.026$ respectively). Serum TSH and anti-TPO levels were found higher and FT_4 level was lower in the study group than the control group ($P<0.05$). Although, there were significant differences in terms of BMI, FM, abdominal and visceral FM, WC, HC, WC/HC ratio, LDL-C, and TG, there were no differences in EAT between the two groups. Mean EAT was 4.61 ± 0.06 mm in the study group and 4.51 ± 0.07 mm in the control group ($P=0.532$). While positive correlation was found between EAT and demographic parameters and serum TG levels ($P<0.05$), no correlation was found between EAT and TSH, FT_4, LDL-C, and anti-TPO level ($P>0.05$).
Conclusion
Despite EAT has been playing an important role in predicting subclinical atherosclerosis in SH, this study could not support this. In our opinion, more studies with more number of patients are needed to claim that.

DOI: 10.1530/endoabs.37.EP947

High circulating levels of SICAM-1 and SVCAM-1 in patients with Hashimoto's thyroiditis

Aysenur Ozderya[1], Kadriye Aydin[1], Sule Temizkan[1], Semra Dogru Abbasoglu[2], Pervin Vural[2] & Yuksel Altuntas[3]
[1]Department of Endocrinology and Metabolism, Kartal Dr Lutfi Kirdar Training and Research Hospital, Istanbul, Turkey; [2]Department of Biochemistry, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey; [3]Department of Endocrinology and Metabolism, Sisli Etfal Training and Research Hospital, Istanbul, Turkey.

Objective
Elevated levels of the soluble adhesion molecules, sICAM-1 and sVCAM-1 reflect chronic inflammatory state. Increased levels of sICAM-1 and sVCAM-1 were demonstrated in various autoimmune thyroid diseases with abnormal thyroid function, but their clinical significance is undefined, especially in the euthyroid patients with Hashimoto's thyroiditis (HT). Increased levels of soluble adhesion molecules are also associated with components of the metabolic syndrome like diabetes mellitus, insulin resistance and obesity, and beyond thyroid dysfunction, HT is believed to affect metabolic parameters. Accordingly, in the present study we aimed to analyze sICAM-1 and sVCAM-1 levels in HT, their relation with thyroid autoimmunity and glucose metabolism markers in HT.
Methods
Eighty euthyroid patients with HT, and age- and BMI-matched 80 control participants were enrolled. Serum sICAM-1, sVCAM-1, free triiodothyronine (fT_3), free thyroxine (fT_4), TSH, thyroid peroxidase antibody (anti-TPO), thyroglubulin antibody (anti-TG), fasting blood glucose, insulin, lipid levels, and homeostatis model assessment for insulin resistance (HOMA-IR) were assessed in all participants.
Results
Patients with HT had significantly higher levels of sICAM-1 and sVCAM-1 than controls (both $P<0.001$) as well as glucose metabolism parameters. Correlation analysis revealed that both sICAM-1 and sVCAM-1 were significantly positively correlated with TSH, glucose, anti-TG, and anti-TPO; while sVCAM-1 was correlated with fasting insulin, HOMA-IR, HDL-C positively and with TG negatively in whole study group. However, these relations were not present when patients and controls were analyzed separately. Regression analysis demonstrated that sICAM-1 was related with anti-TPO and sVCAM-1 was related with both anti-TPO and anti-TG.
Conclusion
sICAM-1 and sVCAM-1 levels were significantly elevated in HT and correlated closely with thyroid autoimmunity. Moreover, soluble adhesion molecules, specifically sVCAM-1 had a strong relation with metabolic parameters in HT.

Elevated neutrophil/lymphocyte ratio in patients receiving any replacement therapy with euthyroid Hashimoto

Havva Keskin[1], Yasemin Kaya[4], Kenan Cadirci[2], Cuneyt Kucur[5], Elif Ziypak[2], Eda Simsek[2], Hakan Gozcu[2], Senay Arikan[3] & Ayse Carlioglu[2]
[1]Medeniyet University, Istanbul, Turkey; [2]Erzurum Training and Research Hospital, Erzurum, Turkey; [3]Kirikkale University, Kirikkale, Turkey; [4]Ordu University, Ordu, Turkey; [5]Dumlupinar University, Kutahya, Turkey.

Introduction
Neutrophil lymphocyte rate (NLO), which is obtained from peripheric blood and used as mathematical rates of lymphocyte numbers, is accepted as available and practical indicator of systemic inflammation existence. We aimed to search NLO between Hashimoto's thyroids patients who have autoimmune thyroid and also include an aetiopathogenesis auto-inflammatory process, and healthy control group with this study.
Method
59 patients who have been diagnosed as Hashimoto's thyroiditis, euthyroid and receive any treatment, 53 people who have no in point of age, BMI among them, totally 112 people have been incorporated to the study. The average age of patients has been counted as 33.8 ± 12.8 years and the average age of control group has been counted as 30.1 ± 12.4 years. Statistically significant difference couldn't be determined ($P=0.1$).
Results
As a result of this study; patient group NLO has been founded as 4.0 ± 0.7 and healthy group NLO has been founded as 2.0 ± 0.1. Statistically significant difference has been determined ($P=0.01$). While statistically significant difference hasn't been determined between healthy group and patient group in point of white blood cell count (7.9 ± 0.3 and 7.4 ± 0.2, $P=0.1$) among neutrophil (5.5 ± 0.3 and 5.4 ± 1.1, $P=0.9$), the difference has been determined in point of lymphocyte values (2.04 ± 0.1 and 3.1 ± 0.5, $P=0.05$). Positive correlation has been determined between NLO and CRP ($r=0.6$, $P<0.0001$), thyroid peroxidase immune body level and ($r=0.3$, $P<0.001$), anti-thyroglobulin immune body level and ($r=0.3$, $P=0.006$), white blood cell count and ($r=0.4$, $P<0.001$) and also between neutrophil level and NLO ($r=0.265$, $P=0.007$), neutrophil and lymphocyte count ($r=0.776$, $P<0.001$).

Discussion
Present symptoms show that NLO values have statistically significant increased in euthyroid Hashimoto's thyroiditis in comparison with healthy control group and it is seen that it correlated with autoantibody level which is used for the diagnosis of disease. In these results, we think that systemic inflammatory process is important in Hashimoto's thyroiditis aetiology.

Radioiodine treatment of Graves' disease: dose–response analysis

Jitka Cepkova, Ioannis Svilias, Eva Krcalova & Jiri Horacek
University Hospital Hradec Kralove, Charles University in Prague, Hradec Kralove, Czech Republic.

Introduction
Despite more than 60 years' experience with radioactive iodine ^{131}I (RAI) treatment of Graves' disease (GD) about the most appropriate dosing regime is still controversial. The objective of our research was to analyse the outcome of RAI therapy in our cohort of patients.
Methods
Retrospectively, we analysed 603 patients with GD (500 women and 103 men, mean age 51.5 ± 12.7 years) treated with RAI. According to recommended practice in Czech Republic, most patients came with at least 1-year history of the disease, in the first or next relapse. Their antithyroid medication was withdrawn 3–4 days before RAI administration. The treatment was considered successful if patients were euthyroid or hypothyroid on follow-up.
Results
Total efficacy of RAI treatment was 74% in 6 months and 88% in 12 months. We divided our cohort into three subgroups according the adjusted dose (adjusted to thyroid volume and 24-h RAI accumulation): i) in the first group ($n=120$) with adjusted dose 0.5–5.0 MBq/g the success rate was 54% in 6 months and 72% in 12 months, ii) in the second group ($n=239$) with adjusted dose 5.1–8.4 MBq/g it was 71 and 86%, and iii) in the third group ($n=244$) with adjusted dose 8.5–77.2 MBq/g it was 86 and 96% respectively. Median adjusted dose in the second group was 6.8 MBq/g. In the detailed analysis of the third group, any further dose increase over 8.5 MBq/g did not result in higher cure rates. In patients with higher thyroid volume ($P<0.001$) and higher disease activity (i.e. higher fT_3, fT_4, TSHR-Ab, and 24-h RAI accumulation as well as suppressed TSH), there was an increased risk of treatment failure. The therapy efficacy was not dependent on sex ($P=0.580$) and age ($P=0.578$).
Conclusion
With adjusted dose of 8.5 MBq/g, very reasonable efficacy was attained. In patients with smaller gland and lower disease activity it was possible to administer lower adjusted dose, ~6.5–7 MBq/g.

Serum H-FABP levels in patients with overt hypothyroidism

Esra Tutal[1], Mustafa Ozbek[1], Muyesser Sayki Arslan[1], Oya Topaloglu[1], Taner Demirci[1], Melia Karakose[1], Mustafa Caliskan[1], Ilknur Ozturk Unsal[1], Askin Gungunes[1], Evrim Cakir[1], Bekir Ucan[1], Nujen Colak Bozkurt[1], Gulfer Ozturk[2], Mustafa Sahin[3], Erman Cakal[1] & Tuncay Delibasi[1,4]
[1]Department of Endocrinology and Metabolism, Diskapi Teaching and Research Hospital, Ankara, Turkey; [2]Department of Biochemistry, Diskapi Teaching and Research Hospital, Ankara, Turkey; [3]Department of Endocrinology and Metabolism, School of Medicine, Ankara University, Ankara, Turkey; [4]Department of Internal Medicine, School of Medicine (Kastamonu), Hacettepe University, Ankara, Turkey.

Aim
Overt hypothyroidism affects mostly women with an increased prevalence in individuals by age. Hypothyroidism is associated with accelerated atherosclerotic cardiovascular diseases, possibly caused by the higher incidence of hyperlipidemia, insulin resistance, hypertension which all are associated to hypothyroidism. Heart-type fatty acid binding protein (H-FABP) is specific for cardiomyocytes and a sensitive marker of myocardial injury. The purpose of this study is examining the effect of hypothyroidism on H-FABP levels and carotid artery intima–media thickness (CIMT) level.
Methods
We measured serum H-FABP levels in 33 patients with overt hypothyroidism and age, gender, and BMI-matched 39 control subjects. All participants underwent high-resolution B-mode ultrasonography in order to measure CIMT.
Results
Serum levels of H-FABP were not found significantly different in the patient group in comparison with the controls (1515.87 ± 2143 pg/ml vs 953 ± 416 pg/ml, $P=0.15$ respectively). CIMT was significantly higher in the patient group than in the control group (0.53 ± 0.08 mm vs 0.48 ± 0.05 mm, $P<0.05$). However, the HOMA-IR and fasting insulin levels did not differ between the two groups ($P>0.05$).
Conclusion
Based on the results of this study, H-FABP seems not a useful marker while detecting preclinical atherosclerosis in patients with overt hypothyroidism but CIMT might be useful to detect early atherosclerosis.

Evaluation of geriatric patients with hyperthyroidism treated with radioactive iodine-131

Umut Elboga[1], Mesut Ozkaya[2], Mustafa Basibuyuk[1], Ayten Eraydin[2] & Y Zeki Celen[1]
[1]Department of Nuclear Medicine, Gaziantep University, Gaziantep, Turkey; [2]Department of Endocrinology, Gaziantep University, Gaziantep, Turkey.

Introduction
In this study, we aimed to evaluate radioiodine (RAI) treatment efficacy in geriatric patients with hyperthyroidism.
Design
Patients older than 65 years who received RAI treatment were included via retrospective data analyses. Eighty-two patients with hyperthyroidism (average age: 69.9 years, age range: 64–81 years) who received RAI treatment and then followed up for at least 6 months were included in the study. Patients' clinical and laboratory results were analysed retrospectively. Euthyroid or hypothyroid status at the end of the year after treatment was deemed to be a response to treatment.
Results
Nineteen patients were men (average age: 68.3 years, age range: 64–75 years), the 63 were women (average age: 71.3 years, age range: 65–81 years). According to thyroid ultrasound or physical examination findings, 13 patients had diffuse thyroid hyperplasia, the other patients had non diffuse hyperplasia (nodular or multinodular). RAI treatment was given to the patients once or twice, or three times if necessary. In first RAI treatment, average 12.7 mCi, in second, average 15.1 mCi, and in third, average 20.7 mCi were given orally. 41 (50%) patients were euthyroid, 19 (23.1%) were hypothyroid, and 22 (26.9%) were thyrotoxic. Success rate of RAI treatment was 73.1%. The highest success rate was obtained in geriatric patients who have diffuse thyroid hyperplasia. Serious side-effects were not observed in our patients.
Conclusion
We observed approximately similar success rates with the reported results in RAI treatment of geriatric patients with hyperthyroidism and also side effects of RAI treatment were low. We believe that RAI treatment should be first choice for treatment of hyperthyroidism in geriatric patients, because it is easy to perform and its side effects are very low.

Safety and efficacy of rapid thyroid blockade with Lugol's iodine in the pre-surgical management of Graves' thyrotoxicosis

Azmi Mohammed, W Elsaify, Rasha Mukhtar & Sath Nag
The James Cook University Hospital, Middlesbrough, UK.

Introduction
A significant number of patients are intolerant of anti-thyroid drugs (ATD) and thyroidectomy remains the only treatment option available to patients who decline radioiodine as definitive therapy. As patients with poorly controlled thyrotoxicosis are at risk of developing thyroid storm, optimal pre-operative control of hyperthyroidism is essential. Rapid thyroid blockade (RTB) with the contrast agents sodium ipodate and iopanoic acid were attractive treatment options but these agents are no longer available for routine use.
Aims
To explore the safety and efficacy of rapid thyroid blockade with Lugol's iodine in the pre-surgical management of Graves' thyrotoxicosis.
Method
Lugol's iodine (0.2 ml three times a day) was administered to six patients with Graves' thyrotoxicosis who were resistant to treatment with the conventional ATD, carbimazole, and propylthiouracil. Treatment was started 10 days prior to planned thyroid surgery. TSH at baseline and subsequent fT_4 and fT_3 were measured at fixed intervals prior to thyroidectomy.
Results
All patients were female; mean (S.D.) pre-treatment fT_4 and fT_3 levels were 30.1 pmol/l (8.12) and 8.8 pmol/l (5.9) respectively. Mean nadir fT_4 and fT_3 levels after treatment were 16.2 and 4.4 pmol/l respectively. Mean percentage fT_4 reduction was 45.2% and mean percentage fT_3 reduction was 40.4%. fT_4 and fT_3 dropped at an average rate of 7.6 pmol/l per day. Mean absolute reductions in fT_4 and fT_3 levels were13.9 and 4.4 pmol/l respectively. All patients were biochemically euthyroid preoperatively. The mean time to normalise fT_4 was 3.8 days (S.D. 1.72). On patient experienced transient adverse effects with Lugol's iodine.
Conclusion
In this pilot study, Lugol's iodine was effective in rendering patients biochemically euthyroid prior to planned thyroidectomy. The long-term safety and efficacy of crash thyroid blockade with Lugol's iodine needs to be assessed in a larger cohort of patients.

Higher titre of TSH receptor antibody was associated with better responsiveness of thyroid hormone to antithyroidal drug in Graves' disease

Hoonsung Choi[1] & Won Sang Yoo[2]
[1]Department of Internal Medicine, Kangwon National University Hospital, Chuncheon-si, Republic of Korea; [2]Department of Internal Medicine, Dankook University Hospital, Cheonan-si, Republic of Korea.

Introduction
Antithyroidal drug (ATD) therapy is considered as choice of treatment for Graves' disease; however, the response of treatment varied between patients. Although several studies reported risk factors for relapse after initial treatment, there were few studies for the responsiveness during early treatment period.
Method and design
We reviewed 94 patients with Graves' disease and used their initial TSH receptor antibody (TSHRAb) titre and consequent free T4 levels during follow up periods. Drug responsiveness was defined as the correlation coefficients between decreasing rates of free T4 levels and exposed dose of ATD. We analysed and compared the coefficients of each patient according to clinical characteristics and TSHRAb titre.
Results
The mean age of subjects was 47.1 ± 15.4 years old and male patients were 26 (28%). The mean titre of initial TSHRAb was 19.1 ± 14.0 IU/L. Although the correlation coefficients did not showed significant association with age group (≤ 40, $41 \sim 60$, $60 <$) and sex, higher titre of TSHRAb was associated with better responsiveness (-0.13 ± 0.10 vs. -0.16 ± 0.16 vs. -0.22 ± 0.13, respectively in three groups (≤ 10, $10.1 \sim 20$, $20 <$)). We could also observe significant correlation between the consequent TSHRAb titre and the responsiveness.
Conclusion
Our results suggest the possible usage of TSHRAb titre to decide the optimal initial ATD dose and its adjustment in early treatment periods.

Shear-wave elastography in diagnostics of primary hyperparathyroidism – new application of the method

Adam Stangierski, Kosma Wolinski, Ewelina Szczepanek-Parulska & Marek Ruchala
Department of Endocrinology, Metabolism and Internal MedicinePoznan University of Medical Sciences, Poznan, Poland.

Introduction
Shear wave elastography (SWE) is a reliable, objective and reproducible technique in sonographic assessment of tissue stiffness. It is considered to be an improvement of conventional ultrasonographic examination. It was demonstrated to be useful in the diagnosis of many thyroid disorders, such as thyroid cancer, Hashimoto's thyroiditis or Graves' disease. The aim of our study was to check if SWE can be supportive in the diagnosis of primary hyperparathyroidism.
Materials and methods
43 patients referred for the surgery due to primary hyperparathyroidism were included. In all cases presence of parathyroid adenoma was confirmed by histopathology. Control group consisted of 322 benign thyroid nodules in 98 patients referred for surgery. Maximal elasticity (E_{max}) of each lesion was recorded.
Results
Mean E_{max} value for parathyroid adenomas was 14.4 kPa with S.D. 17.1 kPa; median was 11.1 kPa. For benign thyroid lesions mean E_{max} was equal to 57.3 with S.D. = 60.6, median = 36.2 kPa. The difference was statistically significant ($P =$). E_{max} of the parathyroid adenomas was inversely correlated with PTH level ($P = 0.04$, $r = -0.32$).
Conclusions
Parathyroid adenomas turned out to be significantly and distinctly more elastic than benign thyroid lesions – median values of the stiffness differed over three times. SWE can be a useful supportive method in the diagnosis of such lesions. Presence of very soft lesions, localised typically near the rear wall of the thyroid may arouse suspicion of primary hyperparathyroidism and hinting further diagnostic, such as measurement of PTH, calcium and phosphate serum concentrations.

The role of antithyroglobulin, antiperoxidase and anti-TSH autoantibodies in amiodarone induced thyrotoxicosis or amiodarone induced hypothyroidism (a two-center study)

Agata Czarnywojtek[1,2], Malgorzata Zgorzalewicz-Stachowiak[3], Marta Fichna[1], Kosma Wolinski[1], Maria Teresa Plazinska[4], Adam Stangierski[1], Pawel Gut[1], Izabela Miechowicz[5], Hanna Komarowska[1], Rafal Czepczynski[1], Leszek Krolicki[4] & Marek Ruchala[1]
[1]Department of Endocrinology, Metaboilsm and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; [2]Department of Pharmacology, Poznan University of Medical Sciences, Poznan, Poland; [3]Department of Health Prophylaxis, Laboratory of Medical Electrodiagnostics, Poznan University of Medical Sciences, Poznan, Poland; [4]Nuclear Medicine Department, Medical University of Warsaw, Warsaw, Poland; [5]Department of Computer Science and Statistic, Poznan University of Medical Sciences, Poznan, Poland.

Purpose
In the recent study it has been reported, that elevated serum concentrations of TSH receptor (TSH-R), antithyroglobulin (Tg), antiperoxidase (TPO) autoantbodies (Abs) may be observed in the subjects treated for amiodarone induced thyrotixicosis (AIT) type I, decreased in type II of AIT, or changed in amiodarone induced hypothyroidism (AIH). This study was done to analyse the changes of Tg-Abs, TPO-Abs and TSH-R-Abs titer in euthyroid, hyperthyroid (AIT), and hypothyroid (AIH) patients.
Methods
The study consisted of 217 patients diagnosed in the Chair and Department of Endocrinology, Metabolism and Internal Medicine, Poznan, and 63 patients treated in the Department of Nuclear Medicine, in Warsaw, Poland between January 2003 and December 2014. Titer of serum TPO-Abs, Tg-Abs, TSH-R-Abs were analyzed retrospectively, in euthyroid patients with the history of hyperthyroidism prior to re-administration of amiodarone (group A), patients with AIT who discontinued AM therapy (group B), patients with AIT chronically treated with AM (group C), and hypothyroid patients (AIH, group D).

Results
Statistically significant differences were observed in serum Tg-Abs values between groups: A and B ($P=0.001$), A and D ($P=0.001$), B and D ($P=0.01$), A and C ($P=0.001$), B and C ($P=0.001$). In case of serum level of TPO-Abs, we found statistically significant differences between groups: A and C ($P=0.05$), B and C ($P=0.001$), C and D ($P<0.05$). Serum TSH-R-Abs were not elevated in any of the studied groups, and the titers did not differ between patients with AIT and AIH. TPO-Abs and Tg-Abs were in normal ranges in all groups.
Conclusion
Normal or slightly decreased titer of TPO-Abs, Tg-Abs, TSH-R-Abs were observed in all studied groups. Observed statistically significant differences were not clinically relevant. Discontinuing or continuing amiodarone therapy had no influence on the titer of autoantibodies.

Rho/Rho-kinase gene expressions in Graves' disease and Hashimoto's thyroiditis

Suzan Tabur[1], Serdar Oztuzcu[1], Elif Oguz[2], Mesut Ozkaya[1] & Abdullah Tuncay Demiryurek[1]
[1]Gaziantep University, Gaziantep/Sahinbey, Turkey; [2]Harran University, Sanliurfa/Yenisehir, Turkey.

Introduction
Autoimmune thyroid diseases result from a dysregulation of the immune system leading to an immune attack on the thyroid. Autoimmune thyroid diseases, which include Graves' disease (GD) and Hashimoto's thyroiditis (HT), are characterised by lymphocytic infiltration of the thyroid parenchyma. The mechanisms that trigger the autoimmune attack to the thyroid are not entirely known. The aim of this study was to investigate the possible contribution of Rho/Rho-kinase gene expressions in GD and HT.
Methods
A total of 47 patients with GD, 41 patients with HT, and 42 healthy control subjects with similar age and sex were included to this study. mRNA from blood samples was extracted, and real time polymerase chain reaction on the BioMark HD dynamic array system (Fluidigm, South San Francisco, CA) was performed for the Rho/Rho-kinase gene expressions. For calculation of the significance of differences in gene expressions, the Mann–Whitney *U*-test was used.
Results
Gene expression analysis showed that RHOC, RHOF, RAC1, and ROCK1 mRNA contents in leukocytes were markedly depressed, and RHOH gene was up-regulated in both GD and HT patients when compared to the control groups ($P<0.05$). Although CDC42 gene expression was decreased in GD, it was augmented in HT. Additionally, RHOQ, RHOU, RHOV, RHOBTB1, RHOBTB3, and RAC3 expressions were significantly suppressed in HT ($P<0.05$). There was also decrease in ROCK2 gene expression in HT ($P<0.05$). No marked changes were noted in RHOA, RHOB, RHOD, and RND3 (RHOE) genes in GD and HT groups.
Conclusion
In conclusion, to the best of our knowledge, these results are the first to demonstrate the contribution Rho/ROCK gene expressions in GD and HT. Our data showed that these gene expressions may contribute to the pathology of GD and HT.

Survey on the steroid dose for patients with subacute thyroiditis in a Korean tertiary hospital

Won Jun Kim[1], Sangmo Hong[2], Myoung Sook Shim[1] & Jin Yeob Kim[1]
[1]Department of Endocrinology and Metabolism, University of Ulsan College of Medicine, Gangneung Asan Hospital, Gangneung, Republic of Korea; [2]Department of Endocrinology and Metabolism, University of Hanyang College of Medicine, Hanyang Guri Hospital, Guri, Republic of Korea.

Introduction
Subacute thyroiditis (SAT) is most common cause of painful thyroiditis. Although prednisolone at 40 mg/d has been preferred as initial dose for moderate to severe SAT, there have also been other recommendations as 25–60 mg/day in many reports. We retrospectively assessed the effect of steroid dose on the SAT.
Methods
We examined 132 patients with SAT who visited our endocrinology clinic at least three times between January 2005 and December 2012. We excluded patients without high ESR level, steroid prescription, and follow-up within 6month after resolution. Final number of subjects was 63. The outcome in the group with initial steroid dose less than 30 mg ($n=22$, 34.9%) was compared with that with 30 mg or more ($n=41$, 65.1%).
Results
The mean age of the total patients was 48.2 years. The incidence was most prevalent from September to November (40%, $n=26$). The mean of initial prednisolone dose was 30.2 mg, while tapering steroid dosage for the mean duration of 7.6 weeks. Six patients (9.5%) have relapsed within 6 months. The clinical outcome in the group with less dosage was not significantly different from that in the group with more dosage, such as total administration period ($P=0.804$), the recurrence rate ($P=0.423$), TSH ($P=0.826$), free T4 ($P=0.072$), ESR ($P=0.079$), 99 m-Technisium thyroid scan uptake ($P=0.185$). Although no serious side effect was observed, three cases of epigastric discomfort and swelling was reported in higher dosage group.
Conclusion
In our study, the initial dosage for the treatment of SAT with less than 30mg appeared as effective as 30 mg or more. Relapse of SAT seemed not dependent on the initial dose of prednisolone.

Difficulties in the interpretation of urinary iodine excretion in pregnant women

Zsuzsanna Szanto[1,2], Attila Csiszer[3], Zsuzsanna Croitorescu[4] & Imre Zoltan Kun[5]
[1]Department of Endocrinology, University of Medicine and Pharmacy, Tirgu-Mures, Romania; [2]Clinical Department of Endocrinology, Clinical Hospital Mures County, Tirgu-Mures, Romania; [3]Regional Center of Public Health, National Institute of Public Health, Tirgu-Mures, Romania; [4]Central Laboratory, Clinical Hospital Mures County, Tirgu-Mures, Romania; [5]Doctoral School, University of Medicine and Pharmacy, Tirgu-Mures, Romania.

Introduction
The urinary iodine excretion (UIE) from fasting morning urine sample is a good epidemiologic indicator for iodine state, used in populational groups (school-children, pregnant women) at risk to develop iodine deficiency disorders. It is not adequate to evaluate individual iodine intake. In pregnant women, especially with chronic autoimmune thyroiditis, it is important to estimate iodine state.
Objectives
To evaluate the individual iodine state in pregnant women comparing UIE from morning and 24-hours urine samples.
Material and methods
24-h UIE was determined in 23 pregnant women, and the values expressed in μg/l and μg/g-creatinine were compared to each other. Morning UIE was additionally assessed in 11 women, and compared to the 24-hours UIE levels.
Results
The mean 24-hours UIE was 157.64 ± 69.50 μg/l, with 44% lower than 273.53 ± 121.76 μg/g-creatinine ($P=0.0003$, 95% CI=56.96–174.80). The individual values expressed in μg/l and μg/g-creatinine were in concordance in most of the cases (87%), both being normal or both being reduced. In three women (13%) the 24-hours UIE in μg/l suggested iodine deficiency, while the values in μg/g-creatinine indicated normal iodine intake. In the 11 pregnant women the mean morning UIE was 155.36 ± 75.87 μg/l, similar with the 24-hours UIE μg/l (156.7 ± 60.69), but with 30.4% lower than the 24-hours UIE μg/g-creatinine (225.29 ± 86.74, $P=0.0578$). In nine cases (81.8%) all the three UIE values (morning UIE, 24-hours UIE μg/l, 24-hours UIE μg/g-creatinine) indicated concordantly iodine deficiency or normal iodine intake, in the other two (18.2%) the different UIE suggested different iodine state.
Conclusions
Important differences were observed between the morning UIE, 24-hours UIE in μg/l, 24-hours UIE in μg/g-creatinine, however the interpretation of these were mostly in concordance (87%). In 13% the results could not clearly show iodine

state. Project no. 34/2013 financially supported by the internal research grants from the University of Medicine and Pharmacy Tirgu-Mures, Romania.
Disclosure
This work was supported by the Internal Research Grants of University of Medicine and Pharmacy Tirgu Mures, Romania (grant number 34/2013).

Surgical and pathological changes after radiofrequency ablation of thyroid nodules

Chiara Dobrinja[1], Stella Bernardi[2], Bruno Fabris[2], Rita Eramo[1], Petra Makovac[1], Gabriele Bazzocchi[3], Fabrizio Zanconati[2] & Fulvio Stacul[3]
[1]General Surgery, Cattinara Teaching Hospital, Trieste, Italy; [2]Department of Medical, Surgical, and Health Sciences, University of Trieste, Trieste, Italy; [3]Radiology Unit, Maggiore Hospital, Trieste, Italy.

Background
Radiofrequency ablation (RFA) is an effective technique for the treatment of symptomatic benign thyroid nodules. It is not known to what extent RFA may affect thyroid surgery and/or histological diagnosis.
Materials and methods
patients were treated with RFA and then followed for 2 years. RFA was performed on 64 symptomatic Thy2 nodules and on six symptomatic Thy3 nodules, without atypical cells nor BRAF or NRAS mutations, in surgically high-risk individuals or patients unwilling to undergo surgery. Volume reduction was evaluated at 1, 3, 6, 12, and 24 months after the procedure. Two Thy3 nodules regrew after the procedure, and the patients accepted to undergo a total thyroidectomy. Here we present how RFA has affected their operation or the final pathology of the surgically removed nodules.
Results and conclusions
RFA is effective for the treatment of Thy2 nodules. RFA should not be used for the treatment of Thy3 nodules, as it only delays surgery in case of malignancy. One session of RFA does not affect subsequent thyroid surgery and/or histological diagnosis.

Serum total sialic acid levels in overt and subclinical hypothyroid patients and its relationship with atherosclerotic risk factors

Mustafa Altay[1], Mehmet Ayhan Karakoç[1], Nuri Çakır[1], Etem Turgay Cerit[1], Müjde Aktürk[1], Canan Yılmaz Demirtaş[2], Neslihan Bukan[2] & Metin Arslan[1]
[1]Gazi University Medical Faculty, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Gazi University Medical Faculty, Clinical Biochemistry, Ankara, Turkey.

Objective
Serum total sialic acid(SA) concentration is assessed as an up to date risk indicator of atherosclerosis and cardiovascular diseases.
Methods
It was aimed to investigate about how SA levels are effected in overt or subclinical hypothyroidism (SH) and how it's associated with other atherosclerosis risk factors because there is no study about these topics, though SA is intensively studied in recent years.
Patients
Sixty newly diagnosed treatment-naive hypothyroid patients (35 subclinical and 25 overt) and 30 euthyroid individuals were included in the study. Fasting blood samples were taken and SA, serum homocystein and hsCRP was measured in addition to routine biochemical measurements and carotid artery intima media thickness (CIMT) measurements were performed.
Results
Diastolic blood pressure, CIMT, Total-C, LDL-C, TG levels were significantly increased in patients. Other atherogenesis related measurements such as systolic blood pressure, uric acid, hsCRP and homocystein levels were also increased in patients, but not statistically significant. Serum total SA levels were higher in hypotyroid patients compared to controls but the difference was not statistically significant. In patients' group positive correlation between CIMT and SA was determined as it was between SA and uric acid.
Conclusions
Interesting result of our study is the positive relationship between SA and CIMT which is revealed for the first time. The existence of correlation between SA and some indicators like CIMT, hsCRP and uric acid in hypothyroid group suggests that it can be an atherogenesis indicator in hypotyroid patients.

Lifestyle intervention reduces TPO antibody level in euthyroid patients: a retrospective cohort study

Liang Chen, Jian Kuang, Jianhao Pei, Hongmei Chen, Zhong Chen, Zhongwen Li, Huazhang Yang, Xiaoyin Fu, Long Wang & Zhijiang Chen
The First Division of Endocrinology, Guangdong Academy of Medical Sciences, Guangdong General Hospital, Guangzhou, China.

Objective
To investigate the impact of lifestyle intervention on elevated thyroid peroxidase (TPO) antibody levels in outpatients with normal thyroid function.
Methods
A retrospective cohort study was performed to observe and evaluate euthyroid patients with excessive TPO antibodies that presented to the authors' hospital between March 2013 and October 2014 for routine medical examinations. The subjects were randomly divided into the lifestyle intervention group and the control group. Lifestyle interventions, including diet improvement and adequate sleep, were instituted immediately following the medical examination for 12–24 weeks. Both groups had patients taking either selenium supplements or Chinese herbal medicines. The difference between the two groups in TPO antibody level was compared after lifestyle intervention.
Results
The TPO antibody level decreased by 30% in the intervention group and only 5% in the control group ($P<0.05$).
Conclusion
Increased TPO antibody level is often related to autoimmune thyroid disorders and inflammation, including conditions such as toxic goitre or autoimmune thyroiditis. The present cohort study demonstrated that lifestyle intervention can effectively improve early-stage thyroid disorders.

Beware Carbimazole induced agranulocytosis in amiodarone induced thyrotoxicosis: recovery with Filgrastim

James O'Hare, Alwin Sebatian & Liam Casserly
Department of Medicine University Hospital Limerick, Limerick, Ireland.

Agranuloctosis is a rare and serious complication of Carbimazole. (risk $<1/10^6$ of population/year. It is associated with higher doses. We report two cases over 1 year in patients exposed to amiodarone.
Case 1: A 63 year old man with ischemic cardiomyopathy had been treated with amiodarone for atrial fibrillation for 3 years. 6 months after stopping he developed symptomatic thyrotoxicosis and started on carbimazole 60 mg per day. Thyroid T^c uptake was low. (Probable type 1 or mixed amiodarone thyrotoxicosis AIT). 3 months later he presented with sepsis and a neutrophil count of 0.010×10^9/l and was treated with Filgrastim and antibiotics. Granulocytes rose $>1.000\times10^9$/l on day nine of treatment Thyrotoxicosis resolved after 3 months on prednisolone and a short course of potassium perchlorate.
Case 2: A 72 year old female with atrial fibrillation, diabetes and ES renal disease previously on amiodarone for 2 years developed symptomatic thyrotoxicosis and treated with carbimazole 60 mg per day on a reducing regime. 2 months later she developed agranulocytosis and sepsis: neutrophil count: 0.010×10^9/l. Probable type 2 AIT induced thyrotoxicosis. She was treated with Filgrastim and antibiotics.Neutrophil count rose over 1.000×10^9 after 6 days. She became euthyroid after prednisone therapy.
Risk for carbimazole induced agranulocytosis may be do the combination of high doses and older age predisposing these patients to agranulocytosis. Because of the cross reactivity of antithyroid drugs treatment of thyrotoxicosis is particularly difficult with the risk of thyroid storm during sepsis. Amiodarone induced thyrotoxicosis can be slow to respond to antithyroid drugs and higher doses are often necessary. Both our patients had accelerated recovery with Filgrastim. We advise caution with high antithyroid drug doses in amiodarone induced thyrotoxicosis and suggest considering combined therapy early.

Elevated TSH (in upper limit of normal) and insulin resistance

Mustafa Boz, Cuneyt Muderrisoglu, Esma Altunoglu, Feray Akbas, Fusun Erdenen & Hayri Polat
Istanbul Training and Reseach Hospital, Istanbul, Turkey.

Introduction
Level of TSH respond to fluctuations in serum free (FT_4) but remain in a very narrow individial range. Thyroid function tests are intrinsically linked to variables of insulin resistance and endothelial function. It is possible that underlying factors lead simultaneously to increased serum TSH, insulin resistance, even within current normal TSH levels.
Description of methods and design
We aimed intestigate the patients with upper limit TSH and insulin resistance in patients of our out-patients clinics of endocrinology where they were adressed for obesity. Serum insulin, C-peptide and TSH Levels were measured by chemiluminescence method on advia centour XP and HbA1C measured by immune – inhibition on Advia 2400 chemistry system (Siemens Healtcare Diagnostics Inc).
Results and conclusion
Some characteristics of study group (means $\pm$S.D.) (totaly 152 patients): age (years): 49.7$\pm$14.8, systolic blood pressure (mm/Hg): 128.8$\pm$19.2, diastolic blood pressure (mm/Hg): 78.3$\pm$9.6, fasting blood glucose (mg/dl): 110.3$\pm$48, HbA1C (%): 5.74$\pm$1.35, insulin (μU/ml): 12.2$\pm$11.4, C-peptide (ng/ml): 3.04$\pm$1.71, TSH (μIU/ml):2.56$\pm$2.7, FT_4 (ng/ml): 1.28$\pm$0.47, weight (kg): 84.5$\pm$18.7, BMI (kg/m^2): 32.2$\pm$7.5, circumference of waist (cm): 98.9$\pm$16.3, WHR (waist/hip ratio): 0.87$\pm$0.07. When we divided into two group according to TSH levels. We found hyperinsulinemia ($P<0.04$), elevated C-peptide levels ($P<0.01$), and WHR ($P<0.04$) in the second group. This findings could justify the increased risk for insulin resistance associated disorders, such as cardiovascular disease, observed in patients with high TSH levels.

Hypothyroidism and platelet parameters evaluation: a preliminary study

Francesco Scavuzzo, Maria Ludovica Genna, Gianluca Nastri, Domenico Serino & Raffaele Volpe
Cardarelli Hospital, Naples, Italy.

According to the findings of recent epidemiological research, thyroid complaints are among the most frequent endocrine illnesses in Italy. Being positively correlated to MPV, the mean platelet volume, in subjects with hypothyroidism, it has been hypothesised in literature that TSH can have a probable prothrombotic effect. The mean platelet volume (MPV), PCT (plateletcrit), PDV (platelet distribution width) and P-LCR (platelet large scale ratio) indicate the dimensions of platelet circulating uniformity.
Aim
The study seeks to evaluate whether platelet indicators can undergo alterations in individuals affected by subclinical and clinical hypothyroidism.
Materials and methods
Between September and December 2014, 60 individuals of both sexes between 18 and 45, all unaffected by other pathologies, were enrolled: 20 with hypothyroidism, 20 with subclinical hypothyroidism and 20 controls. These consented to give peripheral venous blood samples for a complete emochromocitometric examination so as to determine platelet indicators, FT_3, FT_4, TSH thyroid hormones. The PT, APTT coagulative parameters and fibrinogen I levels of the single parameters were statistically evaluated with parametric analyses (l *t*-test of Student) and linear mixed model.
Results and considerations
Evaluation of the findings yielded that the P-LCT and PCT remained unaltered. Neither were in a state of conclamed hypothyroidism or sub-clinical hypothyroidism (*P*-value P-LCT$=$0.36 and 0.38, *P*-value PCT 0.75 and 0.40 respectively). However, the MPV and PDW seemed to undergo statistically significant modifications in patients with subclinical hypothyroidism (*P*-value 0.0000199–0.0159) and in patients with conclamed hypothyroidism (*P*-value 1.152 and 8.012), thus reflecting a hypothetical increase of thrombotic risk in such patients. With a view to being able to use the MPV and PDW as useful and affordable cardiovascular illness risk evaluation parameters, it is hoped that research upon more numerous sample populations may be forthcoming.

Decreased ultrasound echogenity as a thyroid hypofunction marker

Dragan Dimic, Milena Velojic Golubovic, Milica Pesic & Sasa Radenkovic
Clinical Center Nis, Clinic of endocrinology, Nis, Serbia.

Objectives
The value of ultrasound in functional disorders can be significant. That is why the question arises on the use of ultrasound examination of thyroid gland and its echogenity as a screening method in early detection of disfunctions, primarily subclinical and clinical forms of hypothyreosis.
Methods
Testing included 328 patients. All examinees underwent ultrasound examination of thyroid gland, the blood was taken for determination of FT_4, TSH, TPOab andTGab. The patients were divided into two groups. Group A with normal echogenity of thyroid gland tissue, and B with decreased echogenity. Group B was divided into two subgroups, B1 with a mildly decreased and B2 with significantly decreased echogenity.
Results
TPO antibodies, TSH and TG antibodies positivity and their mean values in group B are significantly higher, as well as in subgroups B1 and B2, in relation to group A, $P<0.001$. In group A only two examinees (1%) were indicated with subclinical hypothyreosis. In group B the sublinical hypothyreosis was indicated in 21, while the clinical hypothyreosis was indicated in eight examinees. 29 (25%) suffered of thyroid gland altered function. In subgroup B1 eight examinees were indicated with subclinical and two with clinical hypothyreosis. Ten examinees (11%) suffered of altered thyroid function. In group B2 the subclinical was found in 13 examinees, while the clinical hypothyreosis was found in 6. 19 examinees (76%) suffered of altered thyroid function.
Conclusion
The ultrasound screening of thyroid gland plays important role in early detection of thyroid disfunction, i.e. sublinical and clinical hypothyreosis. Decreased ultrasound echogenity represents the significant marker of altered thyroid gland function. In these persons we have determined the high percentage of subclinical and clinical hypothyreosis frequency.

Immunohistochemical expression of Claudin-1 in Hashimoto's thyroiditis and Graves' disease patients

Tatjana Zake[1], Sandra Skuja[1], Katrina Pekarska[1], Valerija Groma[1], Ilze Konrade[1] & Regina Kleina[2]
[1]Riga Stradins University, Riga, Latvia; [2]Riga Eastern Clinical University Hospital, Riga, Latvia.

Introduction
Autoimmune thyroid diseases, including Graves' disease (GD) and Hashimoto's thyroiditis (HT), are complex diseases combining genetic susceptibility and environmental encounters leading to the breakdown of immune tolerance. The relationship between thyroid cancer (TC) and HT has been proven (Guarino *et al.* 2010), and the antibody specific association has been demonstrated (Azizi *et al.* 2014). Overexpression of claudin-1 appears to be an early finding in TC.
Aim
To estimate expression of claudin-1 in the thyroid tissue of patients with HT and GD assessed by immunohistochemistry.
Materials and methods
Patients presenting 17 cases of HT, 7 of GD, and 11 cases of ordinary colloidal goiter with normal thyroid function were enrolled in this study. Immunohistochemical staining was performed using an anti-claudin-1 antibody. The expression levels were calculated semiquantitatively.
Results
Claudin-1 showed a circumferential membranous staining pattern in thyroid follicular epithelial cells. Positive claudin-1 expression (staining in $>5\%$ of the cells) was observed in 27 out of 35 cases (77.1%). The highest claudin-1 mean expression level was observed in HT patients, although six out of 17 cases showed negative claudin-1 expression. The mean claudin-1 expression level in HT and GD thyroid cells was calculated as 1.65$\pm$0.63 and 1.22$\pm$0.19 respectively, whereas, in control group it was estimated as 1.58$\pm$0.44. Only eight out of 35 cases (22.9%) showed claudin-1 positivity in $>50\%$ of the cells (score 4); six of which presented with HT and 2 – with colloidal goitre.
Conclusion
These results demonstrate that HT and GD patients display different junction protein expression patterns. The overexpression of claudin-1 in HT when compared to control tissues and GD patients may be interpreted similarly to overexpression of claudins in epithelial-derived cancers, including TC, however,

molecular mechanisms by which claudins affect tumourigenesis remain largely unknown.

The effect of thyroid hormone replacement on treatment schedule

Mahmut Apaydin[1], Selvihan Beysel[1], Seyfullah Kan[1], Bekir Ucan[1], Esra Tutal[1], Taner Demirci[1], Mustafa Caliskan[1], Muhammed Kizilgul[1], Mustafa Ozbek[1], Erman Cakal[1] & Tuncay Delibasi[1,2]
[1]Department of Endocrinology and Metabolism, Diskapi Yildirim Beyazit Teaching and Research Hospital, Ankara, Turkey; [2]Department of Internal Medicine, School of Medicine (Kastamonu), Hacettepe University, Ankara, Turkey.

Introduction
Levothyroxine sodium (LT_4) is widely used thyroid hormone to treat hypothyroidism. It is generally recommended to take it in the morning and hungry. Several studies about timing of thyroid hormone administration have shown different effects on TSH and FT_4. The aim of this study is to determine the effects of timing of LT_4 administration on TSH and the clinical outcomes.
Method
The study group includes 65 patients with primary hypothyroidism who take a minimum dose of 50 mg levothyroxine sodium 30 min before the breakfast. Whether their serum TSH is within the laboratory reference range (0.5–5.75 mIU/l) has been examined. We have suggested the patients to take LT_4 at bed time instead in the morning and the patients have been observed for 3 months. Five patients have been excluded from the study for several reasons. At the end of the study parameters such as TSH, FT_4, lipid levels, BMI and clinical outcomes have been evaluated.
Results
Compared to the morning intake, LT_4 was taken at bedtime were an increase in free T_4 level of $0.06 + 0.20$ ($P = 0.025$) and an increase in body weight of $0.76 + 1.53$ ($P < 0.001$). The TSH levels have shown no significant difference between morning and bedtime intake of LT_4 ($P > 0.05$). When the clinical outcomes are evaluated, night sweating in ten patients (% 16.7; $P < 0.001$) and in eight patients (13.3%; $P < 0.001$)) increase in appetite have been observed.
Conclusions
Our study showed that use of LT_4 in the morning and at night had similar effects on serum TSH. However, bedtime intake of LT_4 has resulted in increase of sweating, appetite and weight.

Estimation of iodine intake in pregnant women living in Northern Ireland using a validated food frequency questionnaire

Paul McMullan[1,2], Lesley Hamill[2], Jayne Woodside[2] & Karen Mullan[1]
[1]Belfast Health and Social Care Trust, Belfast, UK; [2]Queen's University, Belfast, UK.

Adequate iodine intake during pregnancy is required for the production of thyroid hormones and brain development in the foetus. Recent evidence has suggested re-emergence of mild iodine deficiency in the UK but there are few studies that have specifically looked at iodine intake in pregnant women. Current World Health Organisation recommendation is for 250 μg per day intake of iodine in pregnancy and the following are good sources of dietary iodine: 1 pint milk (~140–220 μg); one egg (~20 μg) and 100 g white fish (~115 μg). A cross-sectional survey was carried out to assess iodine intake amongst pregnant women (n = 145) living in Northern Ireland (NI). Iodine intake was estimated from a validated iodine specific food frequency questionnaire (FFQ). This 18 item semi-quantitative FFQ estimated iodine intake over the preceding two months and was repeated in 67 women during the second trimester and 36 in the third trimester. 70% of women consumed ≤½ pint (280 ml) milk per day although milk consumption increased with each trimester ($P < 0.01$). Egg consumption did not change significantly through pregnancy (18% none; 23% one egg/week). White fish intake was low with 77/145 (53%) eating fish never or ≤1 per month. Only 2/145 (1.4%) consumed white fish >1 per week. In the first trimester 76/143 (53%) women were taking an iodine containing supplement and this decreased through pregnancy ($P < 0.05$). The results suggest that pregnant women living in Northern Ireland have low intake of foods known to be rich sources of iodine. Only 53% of women took an iodine containing supplement during the early stages of pregnancy. The UK has no salt or food iodination programme and so public health messaging along with early ante-natal education is key to improving dietary intake of iodine at this important stage in foetal development.

Iodine status of school girls living in Northern Ireland cities: a cross-sectional survey

Paul McMullan[1,2], Lesley Hamill[2], Jayne Woodside[2] & Karen Mullan[1]
[1]Belfast Health and Social Care Trust, Belfast, UK; [2]Queen's University, Belfast, UK.

Iodine deficiency is the most common cause of preventable mental impairment worldwide. Recent evidence suggests the re-emergence of mild iodine deficiency in the UK possibly due to changing farming practice. A recent multicentre survey in the UK reported that 68% of school girls were iodine deficient with the lowest levels seen in Northern Ireland (NI). Unlike many countries, the UK does not have a salt or food iodination programme. A cross-sectional survey of 264 schoolgirls, aged 14–15 years of age, was carried out in Belfast and Derry/Londonderry as the initial part of an Island of Ireland wide survey (seven centres). These are the two largest cities in NI and both located on the coast. Belfast is more southern with a latitude of 54.583 vs 54.998. Participants were surveyed in spring and winter months to look for seasonal differences. Urinary iodine levels were measured from morning spot urine samples using a standardised Sandell-Kolthoff colorimetry method. World Health Organisation defines deficiency as follows: mild 50–99 μg/l; moderate 20–49 μg/l; severe <20 μg/l. Median urinary iodine level was 119.1 μg/l (IQR 78.3–166.3). Ninety participants had mild deficiency (34%) while 14 had moderate deficiency (5.3%) and none surveyed had severe deficiency. There was no significant difference in urinary iodine level between spring and winter seasons and no difference between the two cities. Therefore of the schoolgirls surveyed in NI 39% were iodine deficient. These results are in keeping with the previous UK survey and completion of the study in the other five geographical areas will enable a clearer understanding of the extent of this public health issue.

Introduction
Molecular testing play increasingly a significant role in pre-operative diagnosis of nodular goiter, as standard methods may not give conclusive decision in choosing optimal treatment approach. BRAF gene mutations are often discovered in the cytological specimens among the patients with papillary thyroid cancer. The aim of the study was to assess the incidence of *BRAF* T1799A mutation in cellular specimens derived from fine needle aspiration biopsy (FNAB) of thyroid nodules.

Material/methods
85 women with nodular goiter were enrolled into the study. Using hormonal tests, autoantibodies and ultrasound, both hormonal thyroid dysfunction and autoimmune process were excluded. All the patients underwent FNAB of revealed nodules. We analyzed genomic DNA isolated from the thyroid lesions and peripheral blood. Standard methods of real-time amplification detection (real-time PCR) were used to analyze BRAF mutation, with the use of specific starters surrounding the mutated site.
Results
We found BRAF T1799A mutation in thyroid specimens of 6 (7.05%) subjects. In five of them, benign nature of the thyroid nodules was confirmed by FNAB of the lesions. This procedure was non-diagnostic in one subject and histopathology post-operative assessment confirmed papillary thyroid cancer.
Conclusion
The presence of BRAF mutation in FNAB cytological specimens of benign thyroid nodules may be useful to evaluate the risk of malignancy, support the diagnosis and choose treatment options of nodular goitre.

Pentraxin 3 levels in patients with Hashimoto disease

Unsal Aydin, Cavit Culha, Aynur Aktas, Muge Keskin, Muge Ozcan, Anara Karaca, Tulay Omma, Nese Ersoz Gulcelik, Gonul Koc & Yalcin Aral
Department of Endocrinology and Metabolism, Ankara Training and Research Hospital, Ankara, Turkey.

Pentraxin 3 (PTX3) is produced from several cell types in case of inflammation. PTX3 has been investigated in several autoimmune diseases. As Hashimoto disease is an autoimmune disease of thyroid, we investigated the role of PTX3 levels in patients with Hashimoto disease.
Objective
The aim of this study was to investigate the relationship between PTX3 and autoimmune thyroiditis.
Methods
The study subjects were classified as four groups. Group 1: Control group included 42 euthyroid healthy women with negative autoantibody. Group 2 included 27 euthyroid women with positive autoantibody. Group 3 included 46 subclinic hypothyroid women with positive autoantibody (TSH 5–10 mU/L). Group 4 included 39 hypothyroid women with positive autoantibody (TSH >10 mU/L). PTX3 values were measured with ELISA method.
Results
No significant difference was found for PTX3 level between patients with autoimmune thyroiditis and control group. The highest PTX3 level was determined in fourth group. There was a positive relation between PTX3 and TSH level in all groups. There was also a positive correlation between PTX3 and cortisol level.
Conclusion
This is the first study investigating the relationship between PTX3 and autoimmune thyroid disease. Although PTX3 levels were positively associated with TSH levels, we couldn't find any difference in PTX3 levels between our groups.

Morphological and functional alterations of thyroid gland during treatment with tyrosine kinase inhibitors in advanced renal cell carcinoma

Laura Rizza[1], Elisa Giannetta[1], Emilia Sbardella[1], Rosa Lauretta[1], Daniele Gianfrilli[1], Andrea Lenzi[1], Flavia Longo[2] & Andrea M Isidori[1]
[1]Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy; [2]Department of Clinical Oncology, Sapienza University of Rome, Rome, Italy.

Background
Sunitinib (SUN) is a novel oral multitarget tyrosine-kinase inhibitor (TKI) that has demonstrated its efficacy in the treatment of metastatic renal cell carcinoma (mRCC). The thyroid dysfunction is one of the most common side effects of SUN. The mechanisms inducing thyroid dysfunction are still poorly understood.
Aim
Identify the incidence, severity, ultrasonographic changes and pattern of response of thyroid function tests during treatment with SUN.
Methods
This ongoing prospective observational study to date has completed the evaluation of 25 mRCC patients: ten women (59 ± 18 years) and 15 men (65.5 ± 7 years). 5/25 patients received LT_4 replacement therapy and 11/25 had thyroid nodules at enrollment. SUN was administered at daily dose of 50 mg (schedule 4/2). Thyroid function tests were assessed at baseline and at week-4 and -6 of each cycle, ultrasound at baseline and after the first and the third SUN cycle.
Results
we observed an increase in TSH values, most frequently after the second cycle of SUN (mean-TSH 17.05 ± 43.56 μUI/ml) and in older men (mean-TSH 91.95 ± 106.4 μUI/ml. TSH rose above normal range (0.35–4.94 μUI/ml) only in patients which were not on LT_4 replacement at enrollment. Half of untreated patients had an TSH elevation requiring LT_4 replacement after the first cycle; all of them required a further dosage increase after the second cycle. No dose-adjustment was needed in patients already on LT_4 at enrollment. In all patients, a volumetric reduction of thyroid lobes occurred at week-6. Ultrasound at week-18, detected the appearance of a hypoechoic solid nodule in one patient and a volumetric increase of pre-existing nodules in two other patients.
Conclusion
SUN is associated with thyroid functional and morphological changes occurring rapidly, within few weeks, in most but not all patients. Distinct individual patterns of response to TKI are identified allowing a better prognosis and management.

Thyroid autoimmunity may effect on mean platelet volume

Isılay Kalan[1], Senay Arıkan Durmaz[1], Seyma Yavuz[2], Ayse Carlıoglu[3], Ramazan Cosar[2] & Aydın Cıfcı[2]
[1]Kırıkkale Unıversıtesı Tıp Fakultesı Ic Hastalıkları Anabılım Dalı, Endokrınolojı ve Metabolızma BD, Kırıkkale, Turkey; [2]Kırıkkale Unıversıtesı Tıp Fakultesı Ic Hastalıkları Anabılım Dalı, Kırıkkale, Turkey; [3]Kırıkkale Unıversıtesı Tıp Fakultesı Dermatolojı Anabılım Dalı, Kırıkkale, Turkey.

Aim
Mean platelet volume (MPV) is considered a new indicator of atherosclerosis. Activated platelets and subclinical inflammation predispose to create for atherosclerotic heart disease. Larger platelets are metabolically more active than smaller ones and have more protrombotic potential. We have recently demonstrated that MPV levels in Hashimoto's patients tend to be higher than healthy controls even if in euthyroid state. In present study we aimed to investigate a relationship between MPV and autoimmune thyroid disease.
Materials and method
patients with Hashimoto thyroiditis (HASH) (58 euthroid Hashimoto thyroiditis (EHASH) (mean age 43.4 ± 12.4 year)) and 42 hypothyroid (HPHASH) (mean age 46.7 ± 15.5 year)) and 81 patients with Graves disease (GD) (mean age 38.8 ± 13.5 year) who referred our endocrinology outpatient clinic due to high thyroid autoantibodies as antithyroid peroksidase (Anti-TPO) and/or antithyroglobuline (Anti-Tg) and/or TSH receptor antibody were included in the study. 57 (age-matched 46.4 ± 11.6 year) euthyroid control subjects were taken into the study. All study population were evaluated by hormonal and platelet parameters.
Results
Serum Anti-TPO levels in all study groups (EHASH, HPHASH, GD) were significantly higher than those control subjects ($P=0.01$, $P=0.0001$, $P=0.0001$ respectively). The MPV in patients with EHASH, HPHASH, GD were also found significantly higher than control group ($P=0.046$, $P=0.044$, $P=0.002$ respectively). No statistically significant differences were found between the other parameters such as the platelet count, platelet distribution width and plateletcrit. We found that MPV increased independently of presence of age, sex and TSH in chronic autoimmune thyroid diseases ($\beta=0.074$, $P=0.007$). There was a significant correlation between MPV and anti-TPO levels ($r=0.145$, $P=0.027$).

Discussion
Our findings suggest that change of autoimmunity in thyroid gland in patients with chronic autoimmune disease may be effect on MPV level as well as tend to create cardiovascular risk because of large platelets have more metabolically active.

Body composition after treatment of subclinical hyperthyrodism

Diana Boj-Carceller[1], Alejandro Sanz-París[1], Johanna Espejo-Niño[2], Paloma de Castro-Hernández[1], Marta Monreal-Villanueva[1], Diego Alvarez-Ballano[1] & María Dolores Abós-Olivares[2]
[1]Department of Endocrinology and Nutrition, Hospital Universitario Miguel Servet, Zaragoza, Spain; [2]Department of Nuclear Medicine, Hospital Universitario Miguel Servet, Zaragoza, Spain.

Background
Subclinical hyperthyroidism (SHT) is associated with harmful effects on cardiovascular system, bone metabolism and progression to clinical hyperthyroidism. Loss of weight is a common fact in patients with clinical hyperthyroidism and of particular relevance in elderly patients, who are vulnerable to sarcopenia.
Objective
To assess changes in body composition after radioiodine therapy for SHT due to toxic nodular goitre.
Subjects and methods
Prospective controlled cohort study. Patients with persistent SHT due to toxic nodular goitre received a single fixed dose of ^{131}I (555 MBq). A control group was established with patients who preferred to delay treatment. Body composition (lean mass, fat mass and bone mineral content) was determined by dual-energy X-ray absorptiometry (DEXA) at baseline and 12 months after.
Results
Twenty-nine patients were studied (age 69.5±11.5; 75.9% women; BMI 27.1±5.7 kg/m^2; serum thyrotropin (TSH) 0.20±0.21 μUI/ml; serum free thyroxine (T_4) 1.01±0.19 ng/dl), 17 belonging to the treatment group and 12 to the control group. Study groups were comparable. No longitudinal changes in body composition were noted in either group, except for a trend to gain fat mass. However, when individuals with age >65 years were selected, only patients who received radioiodine therapy showed a significant increase in body weight (from 64.1±10.0 to 66.9±9.2 kg), BMI (from 27.3±4.8 to 28.7±4.5 kg/m^2), fat mass (from 26.1±8.5 to 27.8±7.9 kg), lean mass (from 36.3±0.4 to 37.4±0.4 kg) and skeletal muscle mass index (SMI) (from 6.0±0.6 to 6.3±0.6 kg/m^2).
Conclusions
Treatment of SHT seems to have positive effects on body composition in subjects older than 65 years. Weight gain reflects increases in both fat and lean mass.

Efficacy of two different L-thyroxine formulations in dyspeptic patients with subclinical hypothyroidism

Danilo Ribichini[1], Berardino Vaira[2] & Renato Pasquali[1]
[1]Alma Mater University of Bologna, Endocrinology Unit S.Orsola-Malpighi Hospital, Bologna, Italy; [2]Alma Mater University of Bologna, Internal Medicine Unit S.Orsola-Malpighi Hospital, Bologna, Italy.

Levo-thyroxine (LT_4) formulations are available on tablets (TAB) or liquid solution (SOL). LT4 TAB absorption could be affected by several gastric diseases as Helicobacter pylori (HP) infection or chronic atrophic gastritis (CAG), instead no data are available on absorption of the LT_4 SOL in these conditions. The aim of the study was to compare the efficacy of TAB or SOL LT_4 formulations in patients with dyspeptic syndrome (DS) and subclinical hypothyroidism (SH) due to chronic autoimmune thyroiditis. 20 naïve patients (15 females, 5 males, 27 to 55 years), with DS and SH were included. All were firstly investigated by esophageal gastric duodenal endoscopy and urea-breath test and divided in: group A n=4 patients had HP infection; group B: n=4 with CAG; group C: n=6 with simple gastritis and n=6 with no organic alterations. LT_4 treatment was randomly (TAB or SOL) started at a fixed dose (1.5 μg/kg per day); TSH and FT_4 were assessed at T_0, T_3 and T_6 months of treatment. On group A HP eradication was performed at the 3rd month. In all groups, no difference in basal TSH levels were shown within patients assigned to different treatments (group A: TSH_{tab}=10.1±1.8, TSH_{sol}=9.6±2.2; group B: TSH_{tab}=7.1±1.2, TSH_{sol}=6.9±2.1; group C: TSH_{tab}=7.9±1.7, TSH_{sol}=8.1±2.1). At T_3, TSH values on group A (before eradication of HP) significantly decreased on patients treated with SOL, while on group B and C, equally decreased without difference within two formulations (group A: TSH_{tab}=7.8±2.6 vs TSH_{sol}=3.1±1.8, P<0.001; group B: TSH_{tab}=2.4±1, TSH_{sol}=2.6±1.2; group C: TSH_{tab}=1.7±1.4, TSH_{sol}=2.5±1.6). At T_6, TSH levels on group A (after eradication of HP) were in the normal range with no significant changes within two formulations; on group B and C, TSH levels were normal without significant difference within two formulations (group A: TSH_{tab}=2.5±2.6 vs TSH_{sol}=3.6±1.8, P=ns; group B: TSH_{tab}=3.5±2.2 vs TSH_{sol}=2.1±1.8, P=0.093; group C: TSH_{tab}=1.9±2.1, TSH_{sol}=2.0±1.7). In each groups, no differences were shown on FT_4 values within two formulations. In conclusion this preliminary report suggests that LT_4 TAB or SOL are equally efficient to treat SH in dyspeptic patients without gastric alterations or with simple gastritis or CAG, while LT_4 SOL seems to be more efficient than TAB in patients with HP infection, independent of its eradication.

Clinical case of amyloid goitre due to idiopathic AA-amyloidosis

Dmitry Pasechnik[1,2], Elena Sinelnik[2], Natalya Volkova[1] & Maria Porksheyan[1]
[1]Rostov State Medical University, Rostov on Don, Russia; [2]Rostov Regional Hospital No. 2, Rostov on Don, Russia.

Introduction
Amyloid goitre is a rare cause of thyroid enlargement, especially as a reason of fast growth. Here we present unusual case of idiopathic AA-amyloidosis as a cause of rapidly growing goitre.
Clinical case: Patient 36-year-old presented with complaints of shortness of breath and deglutitive problems during 2 months. His medical history was notable for nephrotic syndrome due to AA-amyloid nephropathy and chronic hepatitis C that were diagnosed 8 years ago. At that time in order to determine the cause of AA amyloidosis, there were performed extensive laboratory evaluation, the results of which turned out barren of definitive diagnosis. The pathogenic and symptomatic treatment of nephrotic syndrome was prescribed. 3 years later he was diagnosed with terminal stage of chronic kidney disease, and chronic haemodialysis was started. Physical examination revealed considerably enlarged thyroid gland, and ultrasound was performed. The volume of gland was 163 ml, and there were detected three lesions about 2.5 cm in diameter. The results of thyroid ultrasound, which was performed because of screening for hyperparathyroidism 6 months ago, were normal. In order to determine the nature of lesions there was done fine-needle biopsy, the results of which were consistent with macro-microfollicular goiter. The thyroid function was normal (TSH 0.93 mU/l). Since there were objective signs of upper airway obstructive symptoms, there were performed thyroidectomy. Microscopically, the stroma contained deposits of amorphous material characteristic of amyloid. These deposits stained with Congo red and were apple green in colour when examined microscopically under polarised light. Immunohistochemical staining patterns were consistent with AA amyloid. There was extensive fat cell metaplasia in the thyroid interstitium.
Conclusion
The differential diagnosis of rapid thyroid enlargement should include amyloid goitre nevertheless the type of enlargement (in our case it was not typical diffuse manner) and amyloidosis duration if it is present.

Pseudothrombocytopenia improved with antithyroid treatment in Graves' disease: a case report

Mehmet Muhittin Yalcin[1], Fusun Balos Toruner[1], Emre Arslan[1], Alev Altinova[1], Zubeyde Saygili[2], Sena Aksoy[2], Mujde Akturk[1], Zeynep Arzu Yegin[3] & Nuri Cakir[1]
[1]Gazi University Faculty of Medicine Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Gazi University Faculty of Medicine Department of Internal Medicine, Ankara, Turkey; [3]Gazi University Faculty of Medicine Department of Hematology, Ankara, Turkey.

Thrombocytopenia can be seen rarely in Graves disease (GD). In this report we present a case of pseudothrombocytopenia in a 21-year-old woman who had hyperthyroidism due to GD. A 21-year-old female admitted to our clinic with symptoms such as hair loss, anxiety, nervousness and tremor in hands. Considering her symptoms, thyroid function tests were evaluated to screen for presence of hyperthyoidism. Her TSH level was low while free T_3 and free T_4 levels were elevated. There was no nodules seen in her thyroid ultrasonography. An increased radioiodine uptake was found in thyroid gland. Her thyroid receptor antibody (TRAB) was positive. In the light of all these results, GD was diagnosed. Before antithyroid treatment, a complete blood count and liver function tests were ordered. All the tests were normal except low platelet count. She had no bleeding history. Test was reordered using a citrate-containing tube and platelets were found low again. Aggrevated platelets were seen in peripheral smear showing that decreased platelet level was due to pseudothrombocytepenia. There was no history of herbal drugs,medicine or any other cause of pseudothrombocytopenia. Methimazole treatment was started. One month after therapy, thyroid function tests came back to normal levels, and TRAB turned to be negative. Interestingly platelet count were turned to be normal in blood tests using both EDTA-containing and citrate-containing tube. Repeated peripheral smear did not contain any aggregation of platelets. Pseudothrombocytopenia was described in only a few case reports in the active phase of some autoimmune diseases like systemic lupus eritamatosis. Our case is the first report of pseudothrombocytopenia in GD. We think that normalisation of platelet count after successful antithyroid treatment is important in the evaluation of these patients.

Ogilvie's syndrome and myxoedema crisis: a case report

David Barbosa[2], Sara Freire[1], Nádia Simas[1], João Barreira[1], Emília Velhinho[1] & Glória Nunes da Silva[1]
[1]Serviço de Medicina 3, Centro Hospitalar de Lisboa Norte, Lisbon, Portugal; [2]Serviço de Endocrinologia, Diabetes e Metabolismo, Centro Hospitalar de Lisboa Norte, Lisbon, Portugal.

Introduction
Ogilvie's syndrome (acute colonic pseudo-obstruction) is a syndrome in which the clinical features resemble those of mechanical obstruction with massive colonic dilatation, in the absence of any demonstrable evidence of such an obstruction in the intestine. The exact pathophysiology of intestinal pseudo-obstruction remains to be elucidated. Current theories continue to suggest the idea of an imbalance in the autonomic nervous system. The initial therapy remains conservative with supportive measures (*Nil Per Os*, nasogastric decompression, correction of fluid, electrolyte and metabolic disorders, reduction or discontinuance of drugs that inhibit gastrointestinal motility, and treatment of infections), followed by neostigmine, decompressive colonoscopy and finally surgery if signs of ischemia, abdominal sepsis, or perforation are present.
Case presentation
A 51-year-old Caucasian female patient with a past medical history of hypothyroidism with poor adherence to therapy presented with symptoms of abdominal colic pain, distension and obstipation, associated with nausea, puffiness of the eyes, and adynamia. At observation the abdomen was distended, with normal bowel sounds, diffusely painful to palpation but without signs of peritoneal involvement. There was no altered mental status. Laboratory tests revealed increased creatinine and creatine kinase levels, normocytic normochromic anaemia, hypokalaemia, and normal glycaemic levels. Thyroid profile and ultrasonography were suggestive of primary hypothyroidism. Tomography images were consistent with Ogilvie's syndrome with proximal colonic dilatation until a cut off at the sigmoid, without any structural lesion visualised. The colonoscopy performed was normal. The patient underwent hormone replacement therapy, as well as supportive measures, evolving with progressive clinical and radiological improvement after a few days.
Conclusion
This case illustrates a rare association between myxoedema crisis and Ogilvie's syndrome and the importance of prompt recognition and treatment of reversible medical causes, after excluding mechanical large bowel obstruction.

Effect of L-thyroxine on left ventricular function in subclinical hypothyroidism

Valentina Velkoska Nakova[1], Brankica Krstevska[2], Elizabeta Srbinovska Kostovska[3] & Gordana Pemovska[4]
[1]Clinical Hospital, Shtip, Macedonia; [2]University Clinic of Endocrinology, Diabetes and Metabolic Disorder, Skopje, Macedonia; [3]University Clinic of Cardiology, Skopje, Macedonia; [4]University Clinic of Cardiology, Skopje, Macedonia.

Introduction
Thyroid hormone deficiency can lead to the impairment of cardiac function. Whether subclinical hypothyroidism (ScH) is a risk factor for left ventricular (LV) dysfunction is controversial. Aim of the study was to assess whether ScH is associated with LV systolic and diastolic dysfunction and it's reversibility after treatment with L-thyroxine.
Material and methods
Twenty-seven consecutive patients with newly diagnosed ScH underwent laboratory analyses (TSH, fT_4, fT_3, anti-TPO, and anti-Tg antibodies), and a complete two-dimensional echocardiography study.
Results
Analysed patients has the following characteristics: age 41 ± 12 years, TSH 8.5 ± 2.7 mU/l before treatment, and TSH 2.07 ± 0.9 mU/l after an average follow-up period of 7.2 ± 1.9 months. Compared to baseline measurements, after 5 months euthyroid stage the duration of the A wave was shorter (112.18 ± 17.2 ms vs 112.18 ± 17.2 ms, $P < 0.01$), and the longitudinal global strain was higher ($-19.55 \pm 2.3\%$ vs $-20.07 \pm 2.7\%$, $P < 0.05$). Free T_4 positively correlated with E/A ratio ($r = 0.42$, $P < 0.05$) and fT_3 negatively correlated with DT ($r = -0.50$, $P < 0.05$). Univariant regression analysis showed a statistically significant independent effect of TSH on the E/e' lat, E/e' average, LVED vol, LA, and LA area.
Conclusion
Subclinical hypothyroidism is associated with systolic and diastolic LV dysfunction, as well as reducing global longitudinal LV systolic function. These alterations may be reversed by L-thyroxine.

Is there any effect of the treatment on mean platelet volume in patients with hypothyroidism and hyperthyroidism?

Yildiz Okuturlar[1], Aliye Soylu[2], Enver Tekin[1], Meral Mert[3], Ozlem Harmankaya[1] & Abdulbaki Kumbasar[1]
[1]Department of Internal Medicine, Bakirkoy Dr. Sadi Konuk Education and Research Hospital, Istanbul, Turkey; [2]Department of Gastroenterology, Bakirkoy Dr. Sadi Konuk Education and Research Hospital, Istanbul, Turkey; [3]Department of Endocrinology and Metabolism, Bakirkoy Dr. Sadi Konuk Education and Research Hospital, Istanbul, Turkey.

Introduction
Mean platelet volume (MPV) which is part of a complete blood count measures the platelet size. There are many studies in the literature that it is an indicator of platelet function in thrombotic and inflammatory diseases. However, the number of studies about changes in MPV after treatment in thyroid disease is very limited. In this study, we aimed to reveal the MPV change with treatment in patients with hypothyroidism and hyperthyroidism.
Materials and methods
After approval from the ethics committee 400 patients (mean age: 51.24 ± 13.62) were retrospectively examined. Two groups were created as 200 patients (21 males and 179 females) with hypothyroidism and 200 patients (26 males and 174 females) with hyperthyroidism. Regularly followed up patients having no other

inflammatory acute and chronic disease and without malignancy were included in the study. Before and after treatment in the outpatient follow MPV and TSH values were compared.
Results
TSH level is found 9.54 and 2.18 μIU/ml pre-treatment and post-treatment period respectively ($P<0.001$) in hypothyroid patients. Pre-treatment TSH level is 0.09 μIU/ml and also post-treatment level is 0.62 μIU/ml ($P<0.001$) in hyperthyroidism group. There is significant difference between MPV values before and after treatment in hypothyroidism and hyperthyroidism group and also MPV values increased in both groups after treatment ($P=0.001$).
Conclusion
It is known that MPV decreases in inflammatory events and MPV increases with regression of inflammation. Those results of hypothyroidism which is in group of autoimmune thyroid diseases can be interpreted in terms of the presence of inflammation. The reason for the changes in MPV in our study can be explained in terms of the effect of the treatment of inflammatory period.

Co-occurrence of Graves' disease and immune thyrombocytopenia: a case report

Mehmet Muhittin Yalcin[1], Emre Arslan[1], Fusun Balos Toruner[1], Alev Altinova[1], Mujde Akturk[1], Burak Dumludag[2], Munci Yagci[3], Ilhan Yetkin[1] & Metin Arslan[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Gazi University, Ankara, Turkey; [2]Department of Internal Medicine, Faculty of Medicine, Gazi University, Ankara, Turkey; [3]Department of Hematology, Faculty of Medicine, Gazi University, Ankara, Turkey.

Also cytopenies can be established in the evaluation of Graves' disease (GD), isolated thrombocytopenia is very rare. Here, we present a case of immune thrombocytopenia incidentally found in the evaluation of GD. A 48-year-old female was admitted to our hospital with palpitation and anxiousness. The thyroid function tests were concordant with thyrotoxicosis. She had two subcentimetre nodules in the right thyroid lobe. Thyroid gland had increased iodine uptake. And thyroid scan showed a diffuse hyperactive thyroid gland. GD was diagnosed. She had isolated thyrombocytopenia in her complete blood count (37 000/μl). She had no history of bleeding, chronic illness, medication, or herbal drugs. Peripheral smear was concordant with platelet count. Her haemoglobin level was normal. Antinuclear antibody was negative. Immune thrombocytopenia was diagnosed. As she had platelet levels above 20 000/ml we decided to initially start methimazole therapy without steroid therapy. In the first month of methimazole therapy, platelet counts were defined between 25 000 and 45 000/μl. But 6 weeks after methimazole therapy, when her free T_4 and free T_3 levels were in the normal range, her platelet count began to decrease. Prednisolone treatment was initiated for immune thrombocytopenia. Platelet count rapidly increased to normal levels. Steroid therapy gradually tapered and stopped after two months. Four months after discontinuing steroid treatment, she is now euthyroid with methimazole therapy, and her platelet count is fluctuating between 100 000 and 120 000/μl.
Discussion
There were only a few case reports describing co-occurrence of GD and immune thrombocytopenia. A hypothesis of cross reaction between antithyroid antibodies and platelet epitopes were discussed. Although some literature supported this hypothesis, others did not. In our case report methimazole treatment was failed for improving platelet count despite successful normalisation of free thyroid hormone levels.

Insulin resistance and low folate levels are associated with hyperthyroidism in Graves' disease

Celestino Neves[1], César Esteves[1], João Sérgio Neves[1], Oksana Sokhatska[2], Miguel Pereira[1], Carmo Palmares[2], Camila Dias[3], Davide Carvalho[1], Luís Delgado[2] & José Luís Medina[1]
[1]Endocrinology Service, Faculty of Medicine, São João Hospital, University of Porto, Porto, Portugal; [2]Immunology Department, Faculty of Medicine, São João Hospital, University of Porto, Porto, Portugal; [3]Department of Biostatistics and Medical Informatics, Faculty of Medicine, São João Hospital, University of Porto, Porto, Portugal.

Objective
To evaluate the interrelationships between thyroid function, insulin resistance, lipid profile, homocysteine, C-reactive protein (CRP), folic acid, and vitamin B12 levels, in Graves' disease (GD).
Methods
We recorded thyroid function tests, BMI, insulin resistance markers, lipid profile, homocysteine, CRP, folic acid, and vitamin B12 levels, in 104 subjects with GD in the first cycle of treatment with methimazole, 94% of whom were female. The subjects were classified into two groups: 49 patients were included in the hyperthyroid group (fT_3 >3.71 pg/ml and/or fT_4 >1.48 ng/dl, and TSH <0.35 UI/ml) and 55 in the euthyroid group. Statistical analysis was performed with Mann–Whitney *U* test, logistic regression, and Pearson's correlations test. Results are expressed as median and percentiles (25–75). A two-tailed *P* value <0.05 was considered significant.
Results
Significantly higher levels of TRAb (UI/ml) were found in the hyperthyroid patients (3.2 (1.5–12.1) vs 1.1 (0.5–2.0), $P<0.001$). The levels of folate (ng/ml) and WBISI were significantly lower in the hyperthyroid group (5.1 (3.6–6.5) vs 6.9 (5.1–9.4), $P=0.001$ and 4.39 (2.49–6.15) vs 5.50 (4.08–7.79), $P=0.015$). Across all patients, TSH levels were positively correlated with folate ($r=0.240$, $P=0.021$), HISI ($r=0.217$, $P=0.046$), and WBISI ($r=0.356$, $P=0.001$) and negatively correlated with TRAb ($r=-0.461$, $P<0.001$), HOMA-IR ($r=-0.218$, $P=0.045$), and IGI ($r=-0.313$, $P=0.004$). The levels of fT_3 and fT_4 were positively correlated with HOMA-IR ($r=0.284$, $P=0.008$ and $r=0.261$, $P=0.016$) and negatively correlated with HISI ($r=-0.283$, $P=0.009$ and $r=-0.261$, $P=0.016$) and WBISI ($r=-0.233$, $P=0.032$ and $r=-0.260$, $P=0.016$). Negative correlations were also found between fT_3 levels and QUICKI ($r=-0.281$, $P=0.009$) and between fT_4 levels and HDL-C ($r=-0.198$, $P=0.046$). In the hyperthyroid group we found significant correlations between fT_3 and Lp(a) ($r=0.367$, $P<0.05$). In the euthyroid group we found negative correlations between fT_3 and vitamin B12 ($r=-0.358$, $P<0.01$).
Conclusion
We found that patients with higher levels of TRAb and insulin resistance had a higher risk of being hyperthyroid in Graves' disease. On the other hand, patients with higher folate levels had a lower risk of being hyperthyroid.

Urinary iodine concentrations in pregnant women with gestational and pregestational diabetes mellitus

Hana Vitkova[1], Katerina Anderlova[1,2], Veronika Radimerska[1], Jan Kratky[1], Tomas Fait[2] & Jan Jiskra[1]
[1]Third Department of Medicine, General University Hospital and First Faculty of Medicine, Charles University in Prague, Prague, Czech Republic; [2]Department of Obstetrics and Gynecology, General University Hospital and First Faculty of Medicine, Charles University in Prague, Prague, Czech Republic.

Introduction
Urinary iodine concentration (UIC) can reflex recent changes in iodine status and serve as a sensitive marker of current iodine intake. The cut-off value of UIC was determined as the level lower than 100 μg/l. Adequate median urinary iodine for iodine intake in pregnancy is 150–249 μg/l. The aim of this study was to map the situation of iodine intake in pregnant women with pregestational and gestational diabetes and to explore relationship with thyroid function.
Methods
We have measured UIC in 252 pregnant women screened positive for pregestational or gestational diabetes in second trimester of pregnancy. Currently, serum levels of autoantibodies against thyroid peroxidase (TPOAb) and thyroglobulin (TgAb), TSH, and free thyroxine (FT_4) were determined.
Results
Median UIC was 90.90 μg/l (range 20–4725 μg/l). In 222/252 (88.1%) women UIC was lower than 150 μg/l (median 85.70 μg/l) and in 151/252 (59.9%) was lower than 100 μg/l. UIC in the range appropriate with mild iodine deficiency (50–149 μg/l) was measured in 195/252 (76.2%) women and 27 (10.7%) values were found in the range of moderate deficiency (20–49 μg/l). Any value of UIC was lower than 20 μg/l. In nine women were measured levels in the adequate range for pregnant women (150–249 μg/l). In 21 women (8.3%) was UIC higher than 249 μg/l (median 305.1 μg/l). In women with the UIC <150 μg/l was found significantly higher serum TSH in comparison to them with UIC ≥150 μg/l (1.866 mIU/l vs 2.079 mIU/l, $P<0.001$).

Conclusion
In total 88.1% of women screened positive for gestational or pregestational diabetes were iodine deficient in second trimester of pregnancy and had slight elevation of serum TSH as compared to them with sufficient iodine intake.

Beware false positive lymph node biopsies in patients with chronic lymphocytic thyroiditis

Lorelei Salazar & Angelos Kyriacou
Salford Royal Foundation Trust, Greater Manchester, UK.

A 40-year-old lady who was 4 months *postpartum*, presented with clinical and biochemical features consistent with post partum thyroiditis associated with neck swelling. She had a family history of autoimmune thyroid disease. She underwent ultrasound guided fine-needle aspiration (FNA) biopsy which was reported as Thy3f and listed for diagnostic hemithyroidectomy. She presented to us for a second opinion. She was on replacement therapy and the anterior neck swelling has resolved. Thyroid antibodies were negative. Thyroid ultrasound was repeated showing a diffusely lobular thyroid consistent with background thyroiditis with associated lymphadenopathy. The isthmus 'thyroid nodule' that was previously biopsied was noted to be extrathyroidal isthmus lymph nodes in close proximity to the thyroid. Patient was discussed in a multidisciplinary meeting (MDT) with confirmation that the original cytology was reflective of lymphocytic thyroiditis. She was advised that surgery was not indicated but she will be actively monitored clinically.
Sonographic features of chronic lymphocytic thyroiditis (CLT) include the following: hypoechoic and heterogeneous, pseudomicronodular ('swiss cheese' or 'honeycomb' pattern), pseudomacronodular, profoundly hypoechoic, developing fibrosis, hyperechoic, and speckled. Pseudomicronodular appearances may be confused with a multi-nodular goitre. With the pseudomacronodular pattern the area of inflammation is larger. The skilled sonographer need to be able to appreciate both these patterns as they may be misinterpreted for thyroid nodules. Reactive lymph nodes are almost universally found in CLT; they are commonly found in the pretracheal and paratracheal region as well as at levels III and IV. Given the higher prevalence of papillary thyroid cancer in CLT, such lymph nodes need to be distinguished from malignant lymph nodes using the same sonographic criteria as per patients without CLT. Isthmus lymph nodes can be mistaken for thyroid nodules given their close proximity to the thyroid potentially leading to unnecessary investigations and treatment.

Propylthiouracil induced anti-neutrophil cytoplasmic antibody-associated vasculitis with skin lesions and granulocytopenia

Seher Tanrikulu, Burak Ince, Özlem Soyluk Selcukbiricik, Sakin Tekin, Ferihan Aral & Refik Tanakol
Division of Endocrinology and Metabolism, Department of Internal Medicine, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey.

Propylthiouracil (PTU) is a widely used drug, and can cause drug-induced vasculitis which is characterized by inflammation and cellular infiltration of small vessels and presence of anti-neutrophil cytoplasmic antibodies (ANCA). We report a case of perinuclear antineutrophil cytoplasmic antibody-associated vasculitis developed during treatment with PTU for Graves' disease. A 58-year-old woman admitted to the Emergency Department with painful necrotic lesion at her right ear and left arm for 15 days. Ear lesions were considered as ecthyma gangrenosum in an ENT clinic 10 days ago and anti-pseudomonal treatment had begun but no ameloriation observed. Her medical history was significant for type 2 diabetes for 12 years and Graves' disease for 4 years. There had been a similar lesion at her left ear 6 months ago resulted with auto-amputation. She had been using PTU 100 mg/day and pre-mixed insulin injection twice a day. We found non-tender, mobile cervical lymphadenopathies, enlarged liver and spleen together with ear lesions in physical examination. Her laboratory tests revealed normal thyroid function, leukopenia, neutropenia and normochrom normocytic anaemia, high CRP and sedimentation with p-ANCA and anti-MPO positivity. Biopsy of the affected skin revealed leukocytoclastic vasculitis. As additional tests excluded systemic vasculitis, propylthiouracil-induced vasculitis was diagnosed. Propylthiouracil was discontinued and the skin lesions disappeared, granulocytopenia has revealed over time without the need of any specific therapy.
Conclusion
Physicians and also the patients should be aware of the major adverse reactions of anti-thyroid drugs.

Haemorrhagic thyroid cyst after breathing exercise

Abbi Lulsegged[1], Mufaddal Moonim[2] & Rose Ngu[2]
[1]Kings College Hospital NHS Foundation Trust, Farnborough, Kent, UK; [2]Guys and St Thomas NHS Foundation Trust, London, UK.

A 40-year-old gentleman was referred with sudden onset discomfort in the neck associated with the development of a lump. Earlier that morning he had carried out breathing exercise known as surya krishna at 0600 h and noticed the lump 3 h later whilst shaving. Thyroid USS showed a right-sided thyroid cyst, aspiration of which yielded haemorrhagic contents. FNA of the solid component of the wall did not reveal any malignant cells. The fluid re-accumulated with pressure symptoms including a gritty discomfort when talking, pain and heaviness in this region. Repeat scan did not reveal any significant changes in the appearance of the thyroid cyst. Surya krishna is a breathing exercise lasting 30–60 min with times of hyperventilation and other times of slow breathing. He recalled experiencing pins and needles, numbness and tingling with the hyperventilation but felt energetic at the end of the session. However, at the beginning of the session there is an emphasis placed on breathing through the throat and he remembered exerting a certain pressure in the throat region when doing this. We hypothesise that the pressures involved during the breathing exercises may have been sufficient to cause haemorrhaging within a thyroid nodule. The authors have seen two other cases presenting in a similar manner.

Levothyroxine therapy in comparison: fixed vs alternating dosage in subclinical hypothyroidism

Renato Pastore[1], Amalia Cannuccia[2] & Frontoni Simona[1,2]
[1]Ospedale S. Giovanni Calibita, Fatebenefratelli, Isola Tiberina, Roma, Italy; [2]Department of Systems Medicine, Tor Vergata University, Roma, Italy.

Introduction
Oral levothyroxine (L-T_4) is the standard treatment for hypothyroidism and serum TSH represents the best marker for assessing the proper L-T_4 dose. The absorption and bioequivalence of different commercial L-T_4 preparations might be variable. The aim of this study is to compare the efficacy of L-T_4 using alternating doses vs fixed ones.
Methods
Fifty-eight patients with primary hypothyroidism receiving L-T_4 therapy. The inclusion criteria were as follows: i) age range between 23 and 75 years and ii) patients with subclinical hypothyroidism (TSH level between 2.5 and4.5 mU), treated with L-T_4 oral solution at alternating dosages on consecutively days (75 μg/100 μg, group O) or soft capsules (88 μg/day daily, group T), for at least 6 months. The exclusion criteria were as follows: i) pregnancy or lactation; ii) patients with chronic diseases, such as cardiac (coronary disease or arrhythmias), pulmonary, gastrointestinal (malabsorption disorders), and renal disorders or malignancy; and iii) medications that could interfere with L-T_4 absorption.
Results
According to ANOVA for repeated measure with treatment (T vs O group) as between-subjects factor and time (baseline, 45, 90, and 180 days) as within-subjects factor, a significant interaction treatment×time was found ($F=3.673$, Greenhouse-Geisser df = 1.9, 184.6, $P=0.028$), indicating two different trends of

TSH in T and O groups. Contrast analysis (each time vs baseline) showed a stronger TSH decrease after soft capsules at 180 days (O group 2.17±0.55 and T group 1.67±0.59).
Discussion
Our preliminary observation seems to show a possible greater efficacy of L-T_4 at fixed dosage vs alternating and consecutive dosage, as suggested by significant greater decrease of TSH levels in group T. This finding could be related to an improving of adherence to L-T_4 therapy at fixed dosage. Treatment at alternating dosage on consecutive days may not always be accurate. However, prolongation of follow-up is needed to confirm our data.

The relationship between vitamin D deficiency and thyroid autoimmunity in Graves' disease

Tuğba Arkan
Kocaeli Derince Education and Research Hospital, Kocaeli, Turkey.

Context
Graves' disease (GD) is the most common cause of hyperthyroidism. It occurs more commonly amongst women, smokers and patients with other autoimmune diseases or a family history of thyroid autoimmunity. Peak incidence occurs between 40 and 60 years of age but any age group may be affected. Vitamin D deficiency has been reported to link with a variety of autoimmune diseases. However, the relationship between the thyroid autoimmunity in GD and vitamin D deficiency is unclear.
Objective
We aimed to investigate the association of vitamin D and TSH receptor antibody levels (TRab) with GD.
Design and setting
This was a cross-sectional study conducted in education and research hospital. A total of 67 patients with GD (30 men and 37 women) along with 53 age-matched non-GD controls participated in the study.
Main outcome measures
TSH, free triodothyronine (FT_3), free thyroxine (FT_4), thyroid peroxidase antibody (TPOAb) and thyroglobulin antibody (TGAb), thyrotrophin receptor antibody (TRAb), parathyroid hormone (PTH), calcium, and 25-hydroxyvitamin D (25(OH)D) levels were measured.
Results
25(OH)D levels were significantly lower in the GD group, compared with non-GD control group ($P<0.001$). 25(OH)D levels was inversely correlated with TRab levels ($r=-0.38$, $P<0.001$). However, our results did not show a correlation between the levels of 25(OH)D and the levels TPOAb, TGAb, FT_3, FT_4, and TSH. The levels of PTH in serum were increased in TRAb positive GD patients compared to control subjects ($P<0.001$). Logistic regression analysis results indicated that 25(OH)D levels were not a significant risk factor for developing GD.
Conclusion
In patients with GD, low vitamin D status might be cause of increased titres of TRAb, suggesting a possible link between vitamin D status and increased thyroid autoimmunity in GD.

Thyroid hormone resistance: a case report

Pinar Sisman[1], Hande Peynirci[1], Ozen Oz Gul[1], Soner Cander[2], Esra Nur Bulbul[3], Erdinc Erturk[1] & Canan Ersoy[1]
[1]Department of Endocrinology and Metabolism, Uludag University Medical School, Bursa, Turkey; [2]Clinic of Endocrinology and Metabolism, Sevket Yilmaz Training and Research Hospital, Bursa, Turkey; [3]Department of Internal Medicine, Uludag University Medical School, Bursa, Turkey.

Classic thyroid hormone resistance (THR) occurs per every 400 000 live birth. THR should be considered along with TSH-producing adenomas when normal or high levels of TSH not consistent with hyperthyroidism is present. A 45-year-old female patient who was operated three times for multinodulary goitre had been treated with L-thyroxine. Mamillary biopsy had performed after detection of mass localized in right breast by mammography performed during regular follow-up, then right radical mastectomy was performed due to the diagnosis of ductal carcinoma. In thyroid USG examination, it was found that there were three to four nodules in right thyroid lobe sized 9×6.5 mm and nodules with hypoechoic solid-nature which largest of them was 16×11 mm in left thyroid lobe. In addition, there were also ovoid-shaped lymph nodes with fatty hiluses in both cervical lymphoid chains as two of them (largest one sized 26×5 mm) in right zone 3 and three of them (largest one sized 25×6 mm) in left zone 3. Thin needle aspiration biopsy was performed on thyroid nodules and cervical lymph nodes. Results were benign. Cella magnetic resonance imaging (MRI) was performed with diagnosis of secondary hyperthyroidism after detection of elevated TSH, fT_3, and fT_4 levels in thyroid tests. In cella MRI, it was found that there was an adenoma sized 11×9×10 mm in hypophysis gland. Other anterior hypophysis hormones were normal. There were no eyesight pathology. L-thyroxine treatment was ceased due to the euthyroid status of the patient. During tests performed for excluding THR, it was found that alfa subunit (ASU) level was in normal range (0.35) and molar ASU/TSH ratio was below 1. These results were consistent with THR. Then, TRH stimulation test was planned. TSH levels at 0, 15, 30, 45, and 60 min after TRH administration were obtained. It was observed that there was an extensive response consistent with THR in TSH levels with TRH test (TSH at 0 min: 8 mIU/ml, TSH at 15 min: 57 mIU/ml, TSH at 30 min: 76 mIU/ml, TSH at 45 min: 75 mIU/ml, and TSH at 60 min: 67 mIU/ml). Hypothyroidism symptoms were not observed in follow-up without medication. Adenoma size had not been changed in control sella MRI. Anterior hypophysis hormones were in normal range. Patient was enrolled in follow-up with the diagnosis of THR and non-functional hypophysis adenoma. In clinical practice, differentiation between TSH-secreting adenomas and THR is quite difficult. Predominance of hyperthyroidism symptoms and presence of macroadenoma in hypophysis make the possibility of TSH-secreting adenoma more convincing. However, most of the patients are asymptomatic. Considerable elevations in TSH levels increase the possibility of TSH-secreting adenoma although thyroid function tests are mostly same in both of these pathologies. TRH stimulation test is the most valuable test for diagnosing. Its sensitivity and specificity were reported as 90% and 80–90% respectively. In conclusion, THR should be considered before diagnosing as TSH-secreting adenoma in patients evaluated for secondary hyperthyroidism and identified with hypophysis adenoma.

Relationship of thyroid function and central obesity

Lina Zabuliene[1,2], Agne Petrenaite[3], Ieva Minkeviciute[3] & Jurgita Urboniene[4]
[1]Clinics of Rheumatology, Traumatology – Orthopaedics and Reconstructive Surgery, Faculty of Medicine, Vilnius University, Vilnius, Lithuania; [2]Antakalnio Outpatient Clinic, Vilnius, Lithuania; [3]Faculty of Medicine, Vilnius University, Vilnius, Lithuania; [4]Infectious Diseases and Tuberculosis Hospital, Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania.

The objective of the study was to investigate association between BMI, waist circumference, and measures of thyroid function among euthyroid adult women.
Material and methods
We analysed retrospective data of 119 euthyroid women participating in Lithuanian screening and prevention program for patients with high cardiovascular risk at Vilnius Antakalnio Outpatient Clinic from Jul 2013 to Dec 2013. Glucose, lipid profile, TSH, and fT_4 tests and ultrasound of thyroid gland records were investigated and thyroid gland volume was calculated using formula: thyroid volume = height × width × depth × correction factor (as 0.524).
Results
Mean patients age was 57.04±4.56, BMI 28.86±5.53 kg/m^2, waist circumference 88.40±12.24 cm, TSH 1.81±0.92 mIU/l, fT_4 12.84±2.89 pmol/l, and mean thyroid gland volume 14 464.46±6453.74 mm^3. 36.1% of women were obese and 41.2% overweight. Mean TSH and thyroid volume did not differ between groups of obese, overweight and normal weight women. TSH inversely correlated with thyroid gland volume ($r=-245$, $P=0.044$), fT4 ($r=-0.471$, $P=0.042$), and positively correlated with waist circumference ($r=0.210$, $P=0.036$) and BMI ($r=0.184$, $P=0.045$). After adjusting for age, presents of diabetes and dyslipidaemia significant positive association was observed between TSH and waist circumference ($B=0.17$, $P=0.029$).

Conclusions
We found that measures of overall and central adiposity were associated with higher circulating levels of TSH in euthyroid women. Although, weight loss and weight gain are well-known consequences of overt thyroid dysfunction, our results suggest that, within the euthyroid range, excess body weight and especially central obesity may induce changes in thyroid hormone levels.

Ultrasonographic and cytopathological characteristics of thyroid nodules in Graves' disease

Cuneyd Anil, Nazli Gulsoy Kirnap, Ozlem Turhan Iyidir, Sevde Nur Firat & Neslihan Bascil Tutuncu
Faculty of Medicine, Baskent University, Ankara, Turkey.

Introduction
The risk of malignancy has often been reported to be more frequent in Graves' disease (GD) than non-autoimmune thyroid nodules. However, frequency of thyroid nodules, diagnostic yield of fine-needle aspiration (FNA), and their potential for bearing malignancy in GD are still debatable issues. We aimed to determine the prevalence, ultrasonographic and cytological features, and the rate of malignancy outcome of thyroid nodules in a group of patients with GD.
Methods
This was a single center retrospective study. All patients with GD followed up in the Outpatient Clinic of Department of Endocrinology between 2008 and 2013 were included. Thyroid hormone, thyroid autoantibody, TSH receptor antibody (TRAb) levels of all cases during diagnosis were recorded. Basic ultrasonographic data, cytological results of every nodule which underwent fna, and the histopathological data were also recorded.
Results
175 cases (132 females) with mean $\pm$ S.D. age 45.9 $\pm$ 15.8 were included. 58.8% of the whole group were TRAb positive. 81.1% ($n=142$) of the patients were treated with anti-thyroid drugs. 14.3% ($n=25$) were finally treated with radioactive iodine with a median (min–max) dose of 12 mCi (5–20). 40% ($n=70$) of the cases had totally 134 thyroid nodules. The median (min–max) value of maximum diameter of thyroid nodules was 10.0 (3–54) mm. 14.8% of the nodules owned microcalcifications. 23% ($n=28$) nodules underwent FNA. Cytopathology revealed that 24 were benign, two were indeterminate, and the last two were non-diagnostic, both of which were also eventually benign in repeat aspirations. The indeterminate nodules went to surgery, which turned out to be benign. Eight additional patients underwent surgery for ablative purposes; only one turned out to be malignant, which was incidental.
Conclusion
Nodular goitre is prevalent in GD. Diagnostic yield of fna may not be so low; malignancy rates do not seem to be high in this group of patients.

Thyroid disorders in patients with type 2 diabetes mellitus

Ayhan Zengi[1], Serap Unal Tilki[3] & Timur Kose[2]
[1]Endocrinology and Metabolism, Isparta State Hospital, Isparta, Turkey; [2]Biostatistic, Ege University, Izmir, Turkey; [3]Internal Medicine, Isparta State Hospital, Isparta, Turkey.

Aim
Increased thyroid volume and thyroid dysfunction (TD) in diabetics have been reported. The aim of this study is to investigate the prevalence of thyroid disorders in patients with type 2 diabetes mellitus in formerly iodine deficient area.
Methods
We included 131 (73 females and 58 males) diabetics without a history of previous thyroid disease and symptoms. The demographic, medical and clinical data, laboratory results (fasting plasma glucose (FPG), HbA1c, lipid profile, TSH, free thyroxine (fT_4), and free triiodothyronine (FT_3)) were recorded. The result of thyroid function was classified as subclinical hyperthyroidism (Sc-hyper) (TSH $\leq$0.5 mIU/l, FT_4 and FT_3: normal), euthyroidism (TSH: 0.5–4, FT_4 and FT_3: normal), and subclinical hypothyroidism (Sc-hypo) (TSH: 4.1–9.9, FT_4 and FT_3: normal). All participants were evaluated by thyroid ultrasonography (US) and thyroid volume (TV) were calculated by standard formula.
Results
There is a significant difference between females and males with respect to age, smoking habit, and BMI. No significant differences were found between two groups with respect to diabetes duration, FPG, HbA1c, lipids levels, and thyroid function. Sc-hyper, euthyroidism, and sc-hypo were detected in 15 (11.4%), 107 (81.7%), and 9 (6.9%) patients respectively. US findings except TV were similar in two groups. Although, TV was higher in males than females, the diameter of dominant nodule was not different. In all patients, the frequencies of normal US, multinodular goitre (MNG), nodular goitre (NG), diffuse goitre (DG), and thyroiditis with or without nodule were 24 (18.3%), 51 (38.9%), 27 (20.6%), 10 (7.6%), and 19 (14.6%) respectively.
Conclusion
The most common thyroid disorder in diabetics is hypothyroidism. Although, the prevalence of thyroid dysfunction in our patients is concordant with previous results, sc-hyper is more prevalent than sc-hypo. According to our results, 81.7% of diabetics had thyroid gland abnormality by US. In light of these results, all diabetics should be evaluated for thyroid disorders.

The occurrence of newly diagnosed thyroid diseases during 13 years follow-up

Monika Buziak-Bereza[1,2], Malgorzata Trofimiuk-Muldner[1,2], Maciej Kolodziej[2] & Alicja Hubalewska-Dydejczyk[1,2]
[1]Chair and Department of Endocrinology, Jagiellonian Univesity Medical College, Krakow, Poland; [2]Endocrinology Department, University Hospital in Krakow, Krakow, Poland.

The increase in thyroid disease frequency has been observed recently. It may be attributed to the changing iodine status, endocrine disruptors, as well as better availability of ultrasound and laboratory tests. The aim of the study was to assess the occurrence of newly recognized thyroid diseases during long-term follow-up.
Material and methods
Study was carried out in 2010–2012 in Krakow area. It included 266 patients aged 23–81 years (168 females and 98 males) out of 548 subjects with no thyroid diseases detected during previous survey (1997–1999). In each patient thyroid ultrasound was performed, and TSH, FT_4, and ATPO levels were assessed.
Results
During 13 years primary hypothyroidism requiring treatment with levothyroxine was detected in 29 subjects (10.9%). In additional 13 cases subclinical hypothyroidism was recognised (4.9%). Elevated titer of ATPO antibodies was detected in 40 subjects (15%). Two subjects had already been treated with radioactive iodine due to hyperthyroidism. The new case of hyperthyroidism was diagnosed in one person during the survey. In two subjects thyroidectomy had been performed during 13 years preceding the study (including one case of differentiated thyroid cancer). In 112 (42.8%) of studied persons (45.5% of females and 38.1% of males) nodular goiter was recognized: solitary nodule in 19.1% and multinodular goiter in 23.7%. In one male papillary thyroid cancer was detected.
Conclusions
During about 10-year follow-up new thyroid pathology may be detected in up to 50% of studied population.
Disclosure
This work was supperted by Jagiellonian University Medical College grant.

EP995

E-selectin in women with autoimmune thyroiditis and the relationships with metabolic syndrome

Lucyna Sieminska[1], Beata Kos-Kudla[1], Bogdan Marek[1], Mariusz Nowak[1], Dariusz Kajdaniuk[1], Wanda Foltyn[1], Krzysztof Walczak[2] & Artur Borowski[3]
[1]Department of Pathophysiology and Endocrinology, Medical University of Silesia, Katowice, Poland; [2]Regional Railway Hospital, Katowice, Poland; [3]The Silesia Urology Centre Urovita, Chorzow, Poland.

Autoimmune thyroiditis (AIT) is characterised by infiltration of the thyroid by lymphocytes and other immune cells. Autoantibodies to thyroid-specific antigens:

thyroglobulin (TG) and thyroperoxidase (TPO) are also produced. The penetration of inflammatory cells into target organ is regulated by cytokines and adhesion molecules expressed on thyroid endothelial cells. E-selectin is one of the selectin family, and is responsible for interaction between leukocytes and endothelium and facilitates the accumulation of inflammation cells in thyroid gland. It is suggested that chronic inflammation and endothelial dysfunction can lead to increased cardiovascular risk and metabolic syndrome (MS) in AIT.
Aim
To investigate whether AIT is associated with elevated serum levels of E-selectin; to examine relationships between E-selectin, thyroid function, and different risk factors – components of MS.
Materials and methods
Two hundred and fifty-eight postmenopausal, euthyroid women were enrolled into the study. In 76 women AIT was recognised as the presence of elevated at least one of thyroid antibodies (TPO-Abs and TG-Abs) and the presence of typical thyroid sonography. One hundred and eighty-two women without AIT were control group. Anthropometric measurements were conducted (BMI and WHR) and blood pressure was measured. In all subjects were assessed: lipid profile, glucose, TSH, fT_4, TPO-Ab, TG-Ab, and E-selectin concentrations. Thyroid ultrasound scan was performed. The diagnosis of MS was performed using AHA/NHLBI criteria.
Results
When we compared AIT women and control group there were no differences in serum E-selectin concentrations. E-selectin was higher in MS for the two groups, but the prevalence of MS was similar. When we analysed all studied women, E-selectin positively correlated with BMI, WHR, and negatively with cHDL and fT_4. AIT was associated with elevated TSH.
Conclusions
In our study E-selectin was increased in metabolic syndrome, in relationships with obesity, visceral adiposity and lower fT_4, but was not related to thyroid autoimmunity.

Ultrasound-guided fine-needle aspiration biopsy is an efficient diagnostic tool in thyroid nodules

Ioana Armasu[1], Delia Ciobanu[2], Andra Istrate[3], Ioana Vasiliu[4], Lidia Ionescu[5], Cristina Preda[1], Voichita Mogos[1] & Carmen Vulpoi[1]
[1]Department of Endocrinology, University of Medicine and Pharmacy 'Gr.T. Popa', Iasi, Romania; [2]Department of Morphopathology, University of Medicine and Pharmacy 'Gr.T. Popa', Iasi, Romania; [3]Department of Internal Medicine, University of Medicine and Pharmacy 'Gr.T. Popa', Iasi, Romania; [4]Department of Physiology, University of Medicine and Pharmacy 'Gr.T. Popa', Iasi, Romania; [5]Department of General Surgery, University of Medicine and Pharmacy 'Gr.T. Popa', Iasi, Romania.

Introduction
Thyroid nodules are commonly encountered in clinical practice, the main diagnostic problem being the benign or malignant nature of the nodules. Fine-needle aspiration biopsy (FNAB) is a standard diagnostic test for evaluating thyroid nodules. Several studies have showed that the use of ultrasound guidance (US-FNAB) improves the diagnostic accuracy of aspiration biopsies in comparison with palpation guidance (P-FNAB) alone.
Patients and methods
We performed a retrospective study to compare the efficacy of US-FNAB of thyroid nodules with that of P-FNAB. Study group included patients referred to Endocrinology Department for assessment of thyroid nodular disease who underent FNAB by palpation from 2000 to 2001 and under echoguidance in 2009–2012. In order to avoid differences due to nodules size we have selected only palpable nodules in both groups. Thyroid examinations, ultrasound imaging, and aspiration biopsies were performed by the same endocrinologist. Histopathologic and cytologic diagnoses were compared for patients who were operated.
Results
Study sample consisted of 403 patients. P-FNAB was performed in 106 patients (of which 32 underwent thyroidectomy), and US-FNAB in 297 patients (58 operated). Excepting for moderate local pain in some cases, no adverse effects were noticed. Cytologic diagnostic accuracy rate was 83.87 and 90.19% for P-FNAB and US-FNAB respectively. With use of ultrasound guidance, sensitivity (85.71% for US-FNAB and 50% for P-FNAB), positive predictive value (60% vs 40%), and negative predictive value (97.56% vs 92.3%) were increased significantly and the false-negative rate was significantly reduced (14.28% vs 50%).
Conclusions
FNAB is an essential diagnostic tool in the management of thyroid nodules. US-FNAB improved the cytologic diagnostic accuracy, sensitivity, and positive predictive value and reduced the false-negative rate in comparison with P-FNAB. Therefore, practice guidelines should universally recommend US-FNAB in the management of thyroid nodules, permitting an accurate preoperatory diagnostic and avoiding numerous unnecessary surgical interventions.

Two cases with primary thyroid lymphoma developed on the basis of Hashimoto's thyroiditis

Hande Peynirci[1], Pinar Sisman[1], Cigdem Aksu[2], Ozen Oz Gul[1], Soner Cander[3], Erdinc Erturk[1] & Canan Ersoy[1]
[1]Department of Endocrinology and Metabolism, Uludag University Medical School, Bursa, Turkey; [2]Department of Internal Medicine, Uludag University Medical School, Bursa, Turkey; [3]Department of Endocrinology and Metabolism, Sevket Yilmaz Training and Research Hospital, Bursa, Turkey.

Introduction
Primary thyroid lymphomas are rare cancers and account 1–5% of all thyroid cancers and 3% of all extranodal non hodgkin lymphomas (NHLs). We aimed to present cases of thyroid lymphoma encountered in our clinic.
Case 1: A 54-year-old female patient admitted with pain and swallow on the cervical region. In ultrasonographic (USG) thyroid examination, it was found that both thyroid lobes were very large with routh parenchyme consistent with chronic thyroiditis; also there was a solid nodule 23 mm in diameter in left side. In fine-needle aspiration biopsy (FNAB) of thyroid, there were suspicious findings strongly indicating lymphoid hyperplasy. Patient underwent total thyroidectomy. Pathology results were consistent with extranodal (MALT type) marginal zone lymphoma. There were no pathologic findings implicating systemic involvement; patient is still followed-up.
Case 2: A 40-year-old female patient admitted with hypothyroidism. In USG examination of thyroid, it was found that thyroid parenchyme was extensively heterogeneous and there were multiple nodules. FNAB findings were reported as Hashimoto's thyroiditis and papillary carcinoma. Patient underwent total thyroidectomy and pathology results were considered as morphologic and immunephenotypic findings consistent with extranodal (MALT type) marginal zone lymphoma. Patient underwent radiotherapy. She is in remission and still followed-up.
Discussion
Primary thyroid lymphomas are rare cancers. Hashimoto's thyroiditis has been found 94% of the primary thyroid lymphoma cases. MALT lymphoma of thyroid has best prognosis with 100% of 5-year survival expectancy. Early diagnosis is important.

Factors affecting the efficacy of radioiodine therapy in patients with Graves' disease

Magdalena Pogwizd, Agata Baldys-Waligorska, Dorota Pach, Monika Buziak-Bereza & Alicja Hubalewska-Dydejczyk
Department of Endocrinology, Medical College, Jagiellonian University, Krakow, Poland.

Introduction
In treating hyperthyroidism in Graves' disease (GD) patients with 131-iodine, the optimum activity of radioiodide is yet to be established. We analysed factors affecting the efficacy of ^{131}I radiotherapy in GD patients.
Materials and methods
The analysed group consisted of 362 (80.9% females and 19.1% males) GD patients, of median age 53 (min: 14 and max: 85) years. GD was diagnosed from clinical features, laboratory tests, thyroid USG, and scintigraphy. All patients with orbitopathy (GO) received glucocorticoids to prevent GO exacerbation. Focal lesions were observed in 164 (84% females and 16% males) patients. ^{131}I was applied for the first time in 85.4% of patients; 45.8% received ^{131}I more than once; 6.1% of all patients received it on first onset of hyperthyroidism, while 48.1% received it on first recurrence. The activity delivered was based on clinical

status, thyroid USG-established volume and 24-h ^{131}I uptake. Ranges of ^{131}I activity applied were: up to 555, 555–800, and above 800 MBq. Six months post ^{131}I treatment euthyroidism or hypothyroidism were stated in 72% of patients.
Results
The median thyroid volume was significantly larger in men (30 ml (18.95–52.75)) than in women (24 ml (16.1–37)) ($P=0.006$). No significant differences in efficacy related to ^{131}I activity applied were stated six months post treatment. In the group of patients treated with lower (<555 MBq) or higher (555–800 MBq) ^{131}I activity, 76 or 68.5% of patients, respectively, were effectively cured. Presence of focal lesions did not affect the efficacy of ^{131}I treatment either. In the group of 28 GO patients significant increase of hTRAB level was observed. *De novo* GO occurred in 1.9% of patients.
Conclusions
The efficacy of ^{131}I treatment in GD patients evaluated after 6 months was negatively affected by larger thyroid volumes and by anti-thyroid medication.

Descriptive analysis of a series of 1567 thyroidectomies in Castilla La Mancha and its association with thyroid cancer

Enrique Castro[1], Sandra Herranz[5], Manuel Delgado[2], Dulce Calderón[4], Jose Joaquin Alfaro[3], Julia Sastre[1] & Florentino Del Val[1]
[1]Hospital Virgen de la Salud, Toledo, Spain; [2]Hospital General Ciudad Real, Ciudad Real, Spain; [3]Hospital General de Albacete, Albacete, Spain; [4]Hospital Virgen de la Luz, Cuenca, Spain; [5]Hospital Universitario, Guadalajara, Spain.

Introduction
We wanted to analyse the descriptive variables of a series of 1567 thyroidectomy patients between 2010 and 2013 and its association with malignancy in our series.
Material and methods
Retrospective, multicentre study done by review of the medical records of 1567 patients who became thyroidectomy between 2010 and 2013 in eight sanitary areas. This is an analysis of clinical and demographic variables.
Results
The percentage of women/men was 82%/18%. The mean age was 51.8 years (S.D. 15). For the following variables, median and IC range were: time tracking: 1 year (0–3); number of visits 3 (2–6); number of scans performed 1 (1–3); and cytological studies 1 (1–2). 60.9% of patients had a family history of thyroid disease. Thyroid cancer in the family: 3.3% of cases (52 patients). Goitre/nodule was incidental in 30.8% of cases. The reasons for surgical indications were: cytological findings (33.1%); size without compressive symptoms (26%), ultrasound findings (13.5%), compressive symptoms (11.9%); hyperthyroidism 11.6% (4.3% for Graves' disease); growth (9.9%) express wish of the patient (5.5%); lymphadenopathy (3.8%); hardness (1.1%); previous neck irradiation (0.4%); and recurrent nerve injury (0.3%).
Conclusions
In a multivariate analysis to predict malignancy were significant variables with OR: male sex 1.44 (1.023–2.05) ($P=0.037$); family history of thyroid cancer: 2.43 (1.23–4.8) ($P=0.010$); cytology as surgical indication 3.15 (2.29–4.33) ($P=0.000$); growth as an indication 2.1 (1.23–3.5) ($P=0.006$); non-existence of compressive symptoms 1.92 (1.13–3.29) ($P=0.017$); no size criterion as indication 1.66 (1.13–2.45) ($P=0.011$); no hyperthyroidism 4.06 (1.8–9) ($P=0.001$); and no incidental finding 1.46 (1.03–2.07) ($P=0.03$).

Incidence of autoimmune thyroid disorders following treatment with pegylated interferon therapy for HCV infection among Egyptian patients

Salah Eldin Shelbaya, Makboul Khaled Mahmoud, Mona Mohamed Abdelsalam, Zaki Doaa Zakaria & Manar Alshahawey Alsayed Ghazy
Faculty of Medicine, Ain Shams University, Cairo, Egypt.

Introduction
Egypt has an epidemic of HCV. Interferon (IFN) is the drug of choice for treatment induces autoimmune thyroiditis. The biochemical characteristic of the autoimmune thyroid disorder is the presence of autoantibodies against thyroid peroxidase and thyroglobulin. Chemokine ligand 10 (CXCL10) is an IFN inducible chemokine involved in the autoimmune thyroid disease.
Aim
To assess the incidence of autoimmune thyroid disorder following treatment with IFN and if we can predict its development.
Method
40 patients with chronic HCV participated and received IFN for 6 months. Liver function (ALT and AST), HCV–PCR, FT_3, FT_4, TSH, anti-thyroid peroxidase (ATPO) antibodies, anti-thyroglobulin antibodies, and CXCL10 all done before and after 6 months of treatment.
Results
At the end of the study, patients divided into three groups according to their response to IFN therapy and developing of thyroid dysfunction. Group A: 24 patients (60%) responded to Interferon and their liver enzymes and PCR turned normal without developing thyroid dysfunction. Group B: ten patients (25%) didn't respond to IFN and their liver enzymes and PCR still elevated, without developing thyroid dysfunction. Group C: six patients (15%) had elevated thyroid antibodies after 6 months of treatment, but responded to IFN and became PCR negative. At the beginning of the study: group C had higher ATPO ($P=0.06$) and ATG in comparison with A and B ($P=0.09$). The lowest level of PCR ($P\leq0.01$) and CXCL10 in comparison with A and B ($P\leq0.01$). After therapy: group C showed elevation of ATG ($P\leq0.01$), and ATPO level ($P\leq0.01$) in comparison with A and B. Groups A and C showed marked decrease in CXCL10 level in comparison with B ($P\leq0.01$).
Conclusion
15% of the participants developed thyroid dysfunction after IFN therapy. They had high normal level of thyroid antibodies and lower CXCL10 before treatment.

EP1001

Does vitamin D differ among the different thyroid states? A pilot study in Egyptian patients

Mohamed Fahmy Abdelaziz, Salwa Seddik Hosney, Mona Mohamed Abdelsalam, Alyaa Ahmed Alsherbeny & Yassmin Yehia Rashwan
Faculty of Medicine, Ain Shams University, Cairo, Egypt.

Introduction
Vitamin D plays an essential role in calcium homeostasis and bone metabolism, immune modulation, and control of other hormonal systems. Vitamin D deficiency is also common for many reasons. On the other hand, thyroid diseases have widespread systemic manifestations including their effect on bone metabolism.
Aim
To assess vitamin D status among Egyptian patients with different thyroid states: euthyroid, hypothyroid, or hyperthyroid states.
Subjects and method
45 participants (39 females and six males) were divided into three groups: Group 1: (15) euthyroid subject, group 2: (15) hyperthyroid subjects, and group 3: (15) hypothyroid subjects. Diseases and drugs that affect vitamin D were excluded. History taking including dietary habits, sun exposure and clothes and full examination was done. Serum 25-hydroxy vitamin D level by ELISA, ionised calcium, phosphorus, alkaline phosphatase, TSH, free T_3, and free T_4 were assessed.
Results
The study showed high incidence of vitamin D deficiency among all groups. 21 subjects (45.6%) had vitamin D deficiency (<30 nmol/l), 24 subjects (52.1%) had insufficiency (30–75 nmol/l), and one subject (2.7%) had vitamin D sufficiency. 25-hydroxy vitamin D was significantly different between groups with the level of 25 ± 15.78 nmol/l in group 1, 42.88 ± 20.03 nmol/l in group 2, and 28.46 ± 20.03 nmol/l ($P<0.05$). 60% in group 1, 50% in group 2, and 33.3% in group 3 had sufficient sun exposure with no significant difference between the three groups ($P=0.8$). Nearly 80% were veiled with no significant difference between the three groups ($P=0.2$). No difference between groups as regard sufficient dietary vitamin D ($P>0.05$). There was no significant difference between groups as regard serum ionised calcium and phosphorus and alkaline phosphatase ($P>0.05$).
Conclusion
Vitamin D was deficient in the different status of thyroid function. Assessment of vitamin D and replacement might be recommended in patient with thyroid disorder.

Prevalence of thyroid dysfunction in Spain: diabetes study

Sergio Valdés[1], Cristina Maldonado-Araque[1], María José Tapia[1], Ana Lago[1], Vidal Perez-Valero[1], Albert Goday[2], Luis Castaño[3], Edelmiro Delgado[4], Joan Vendrell[5], Gemma Rojo-Martínez[1] & Federico Soriguer[1]
[1]Hospital Regional de Málaga, Málaga, Spain; [2]Hospital del Mar, Barcelona, Spain; [3]Hospital de Cruces, Baracaldo, Spain; [4]Hospital Central de Asturias, Oviedo, Spain; [5]Hospital Universitario Joan XXIII, Tarragona, Spain.

Introduction
Thyroid dysfunction is a common health problem. Its prevalence may vary in different populations, and in Spain, it has not been sufficiently studied. The aim of this study was to evaluate the prevalence of thyroid dysfunction (clinical and subclinical) in our country.
Materials and methods
The diabetes study is a national, cross-sectional, population-based survey. Target population: the entire Spanish population >18 years. Sample: >5000 subjects in 112 clusters. Participation: 57%. Variables: clinical, demographic, and lifestyle survey, physical examination and blood sampling. Study period: 2008–2010. Specific variables for this study: the concentration of TSH, FT_4, FT_3, and TPOab antibodies was determined by chemiluminescence (Roche) in 4530 subjects. Iodine concentration was measured in an isolated urine sample by the Benotti technique.
Results
The prevalence of treated hypothyroidism, untreated subclinical hypothyroidism and untreated clinical hypothyroidism were 4.2% (95% CI 3.6–4.9%), 4.6% (95% CI 4.0–5.2%), and 0.3% (95% CI 0.1–0.5%) respectively. The prevalence of hyperthyroidism was 0.8% (95% CI 0.6–1.1%) and the prevalence of positive thyroid autoimmunity (TPO >50 IU/ml) and 7.5% (95% CI 6.7–8.3%). All thyroid disorders were more prevalent in women than in men: hypothyroidism (total) 13.3% (12.0–14.6%) vs 4.8% (3.8–5.7%), hyperthyroidism 1.1% (0.7–1.4%) vs 0.6% (0.3–1.0%), and positive thyroid autoimmunity 10.8% (9.6–12.1%) vs 4.1% (3.2–5.0%) respectively. Hypothyroidism was associated with the presence of positive anti-TPO antibodies ($P<0.001$) and elevated urinary iodine levels ($P<0.001$).
Conclusions
We report for the first time the prevalence of thyroid dysfunction in a representative sample of the Spanish population.

Presentations and outcome of thyroiditis from an Outpatient Clinic of Endocrinology

Muhammad Shahid, Saeed Mahar & Shiraz Shaikh
Liaquat National Hospital, Karachi, Pakistan.

Background
Thyroiditis is 'the disorder in which there is inflammation of the thyroid gland'. If diagnosed earlier have often good chances of recovery. Limited data is available related to this problem from low income countries and hence there is delay in the diagnosis and management of this important disorder. The objective of the study was to assess the clinical presentations and early outcome of patients presenting with thyroiditis in a tertiary care hospital.
Design/methods
This case series was conducted from December 2013 to September 2014. Patients between 18 and 70 years of age with acute onset of thyroiditis confirmed on thyroid scan or clinical judgment in cases of contraindication of thyroid scan presenting to the out patient services was included in the study. Pregnant females, psychiatric illnesses, those patients having other chronic illnesses were excluded from the study. Patients were followed for 6 months.
Results
A total of 26 patients with thyroiditis attended the endocrine clinic. Mean age of patients was 41.2 ± 11.12 years. There were 18 (69.2%) females. Clinical presentations (signs) were fever (65.4%), tender neck (23.1%), goitre (19.2%), localised tenderness in neck, and palpable lymph nodes (26.9%). Major symptoms reported were sore throat (69.2%), weight loss (38.5%) whereas upper respiratory tract infection, thyroid pain, tremor, sweating and fever of unknown origin in 26.9% cases. All the patients had raised ESR. Low TSH <0.4 was seen in 88.5 and 57.7% had raised free T_4 >1.8. Complete recovery was seen in 88.5% patients while 11.5% had early hypothyroidism.
Conclusion
Fever and sore throat were the main presenting features of thyroiditis patients. ESR was raised in all patients. Majority of patients had complete recovery with appropriate management.

Association between fibromyalgia and thyroid autoimmunity

Nooshin Shirzad[1,2], Shafieh Movassaghi[3], Hoda Karmostaji[3], Fatemeh Esfahanian[2], Mahboobeh Hemmatabadi[2] & Mostafa Qorbani[1]
[1]Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Endocrinology and Metabolism Research Institute, Tehran, Iran; [2]Endocrine Research Center, Valiasr Hospital, Tehran University of Medical Sciences, Tehran, Iran; [3]Rhomatology Research Center, Valiasr Hospital, Tehran University of Medical Sciences, Tehran, Iran.

Fibromyalgia is a disorder characterised by fatigue, generalised body pain and cognitive symptoms, and the aetiology has not been clearly described. Because similar symptoms are frequently found in Hashimoto's thyroiditis and there is not an optimal response to the treatment of hypothyroidism, the aim of this study is to determine the prevalence of fibromyalgia in patients with Hashimoto's thyroiditis, to explain the symptoms and to select the appropriate treatment. This cross-sectional study used the 'case study' method and included 100 euthyroid patients with Hashimoto's thyroiditis that were referred to the rheumatology clinic of Imam Khomeini hospital in 1392. Patients who met the inclusion criteria underwent a physical examination according to ACR 2010 criteria for fibromyalgia. Data collection and analysis was performed using SPSS 22 software. The mean age of the patients was 38.7 ± 11.58 years, and 7% of patients were male. The prevalence of fibromyalgia was 5%. No significant correlation was found between fibromyalgia patients and other variables such as age, gender, marital status, menopause, education, duration of Hashimoto's thyroiditis, Anti-TPO and TSH levels, and also no correlation was found between the severity of fibromyalgia and these variables. The prevalence of fibromyalgia was not higher than the normal population; thus, musculoskeletal symptoms could not be justified only with fibromyalgia. According to the low number of samples and lack of information on the prevalence of the disease in Iran, further studies using a larger population are recommended.

A case report of Hoffmann's syndrome

Ziynet Alphan Uç[1] & Süheyla Gorar[2]
[1]Usak, Government Hospital, Usak, Turkey; [2]Antalya, Training and Research Hospital, Antalya, Turkey.

Introduction
Hoffman's syndrome is a rare form of hypothyroid myopathy characterised with muscle hypertrophy, stiffness and wakefulness.
Case report
A 43-years-old woman admitted to our hospital with a complaint of fatigue and progressive muscular weakness with cramps and myalgia started 3 months before.Thyroid gland examination was normal. On neurological examination she had proximal and lower limb muscle weakness(3/4) and hyporeflexia. Her calf muscles was hypertrophic.Laboratorial investigation reveals increased serum levels of muscular enzymes, dislipidemia severe hypothroidism. Electromyography (EMG) muscles revealed low amplitude and short duration motor unit action potentials (MUAPs) with early recruitment suggestive of a myopathic disorder. The patient was diagnosed of having severe hypothyroidism with Hoffman syndrome. L-thyroxine treatment was started (100 μg per day) and dose was elevated 150 μg per day after 2 weeks later. After 1 month therapy her hypothyroid symptoms reduced, pseudohypertrophy of the calf muscles regressed, muscle enzymes were reduced.
Discussion
The characteristic features of Hoffman's syndrome include localised or generalised hypertrophy of muscles in addition to muscle weakness, stiffness, cramps and pain as compared to the classic symptoms of hypothyroidism.The CPK is the best biochemical marker of myopaties. Mild to moderate elevation of serum CPK level is seen in 70–90% patients with hypothyroidism indicative

of muscle involvement but does not correlate with the severity of weakness. The clinical presentation and biochemical features might make it a bit difficult for the physician to differentiate it from polymyositis or muscle dystrophies. Hoffman Syndrome has good prognosis if diagnosed earlier and treated appropriately.This case report shows that Hoffman syndrome, though a rare presentation of hypothyroidism has a good prognosis with timely diagnosis and appropriate management. In the differential diagnosis of myopathy with pseudo-hypertrophy, Hoffmann's syndrome should be considered. It is an infrequent cause of myopathy, with good prognosis.

Successful treatment with radiotherapy in a patient who developed severe Graves'-like ophthalmopathy after treatment with pegylated interferon Alpha-2a for hepatitis C

Carmen Acosta-Calero[1], Claudia Arnas-Leon[1], Ruth Carmona-Vigo[2], Francisco Javier Martinez-Martin[1] & Pedro Conrado Jimenez-Santana[3]
[1]Endocrinology Department, Hospital Universitario de Gran Canaria Dr. Negrin, Las Palmas de Gran Canaria, Spain; [2]Radiation Oncology Department, Hospital Universitario de Gran Canaria Dr. Negrin, Las Palmas de Gran Canaria, Spain; [3]Internal Medicine Department, Hospital Universitario de Gran Canaria Dr. Negrin, Las Palmas de Gran Canaria, Spain.

Introduction
Interferon treatment for hepatitis C has been associated with Graves'-like thyroiditis, developing in rare instances severe ophthalmopathy. The usual management is interferon withdrawal and high-dose corticosteroids, but it may interfere with the resolution of hepatitis. Hereby we report a case successfully treated with radiotherapy, which in our knowledge has never been previously reported.
Case report
A 52-year-old woman was diagnosed of chronic hepatitis C (serotype 1) and began treatment with pegylated Interferon Alpha-2A (Pegasys, 180 μg weekly) and ribavirin (1200 mg per day), After a year, she achieved clinical, biochemical and virological remission and the treatment was withdrawn. In the last month of antiviral treatment, the patient reported symptoms of hyperthyroidism, eyelid swelling and diplopia. TSH was suppressed and free T_4 was 2.27 ng/dl. Tc-99 m scintigraphy showed irregular uptake with cold areas. The ultrasonography showed multinodular goiter, and the FNAC was reported as chronic lymphocitic thyroiditis (benign). An orbitary CT scan showed prominent enlargement of muscle and retroorbitary fat with exophthalmos. The ophthalmologist recommended high-dose corticosteroid pulses, but we were concerned about the risk of hepatitis recurrence. The patient received standard metimazol treatment for hyperthyroidism and bilateral retro-orbital irradiation with a total dose of 10 Gy fractionated in 1 Gy once a week over 10 weeks. After the seventh session, the diplopia remitted and the patient is presently asymptomatic.
Conclusions
Retroorbitary radiotherapy should be considered as an alternative treatment for Graves'-like ophthalmopathy associated to interferon treatment, avoiding the need for high-dose corticosteroids which may result in hepatitis recurrence.

Hypothyroidism in clinical practice

Faiza Qari
Kauh, Jeddah, Saudi Arabia.

Hypothyroidism is the most common endocrine disease that was seen in the clinical practice especially for family. What issues about hypothyroidism should be covered in clinical practice? A 36-year-old woman who was diagnosed with hypothyroidism 3 years ago tells her endocrinologist that she wants to conceive in the next year. She was treated with LT_4, 0.1 mg per day. Her last serum TSH was 0.7 mIU/l. She is instructed to notify her endocrinologist as soon as she finds out that she is pregnant so that a serum TSH level can be checked. Her menstrual period is 1 week late, a home pregnancy test is positive, and her serum. TSH level is 1.9 mIU/l.
Conclusions
The clinical issues were addressed by clinical scenario followed by questions and stressed on the important clinical points.

EP1008

Graves' disease with autoimmune haemolytic anemia

Randa Salam, Nagwa Ramadan & Fatma Gaber
Cairo University, Cairo, Egypt.

Introduction
Haematologic involvement is not uncommon in Graves' disease. Autoimmune haemolytic anaemia is occasionally reported in patients with other autoimmune illnesses. However very rarely reported in Graves' disease.
Case report
We report a 19-year-old female with reactive arthritis, Graves' disease and autoimmune haemolytic anaemia while under treatment with methimazole. Physical examination: Under built female BMI 17, Blood pressure was 110/70, heart rate 100 min., respiratory rate 16 min, temperature 37.6, jaundice, pallor, no cervical, supraclavicular, epitrochlear, axillary, or inguinal lymphadenopathy. The thyroid gland mildly enlarged not nodular no thrill or bruit, proptosis, no lid-lag, or tremor. Lungs were clear and the heart rhythm was regular, accentuated S1, pulmonary component of S2 ejection systolic murmur over the cardiac base no click, or gallop. The abdomen was soft and non-tender, with the liver edge not palpable; the spleen was palpable 3 cm below LF costal margin, joint pain affecting both knees with limitation of movement.
Investigations
Haemoglobin 4.4 g/dl, MCV 107.2, platelet count 193 000, WBC count 4 000, reticulocyte count 23.3%, Bilirubin 4.0 mg/dl (direct 0.4), LDH 311 U/l, positive comb test, ESR;128, ANA negative. Abdominal sonar mild splenomegaly, normal echo cardiography. The patient was started on prednisone 1 mg/kg with rapid improvement in her anaemia and jaundice. 11 days after admission haemoglobin improved to 10.0 g/dl. The prednisone was tapered off over 3 months with continued stable haemoglobin levels and no evidence of recurrent haemolysis.
Conclusion
We report a case of concurrent reactive arthritis, Graves' disease, and autoimmune haemolytic anaemia. Yersinia enterocolitica infection could theoretically cause both reactive arthritis and Graves' disease, although we cannot prove this connection in our patient's case which improved dramatically on steroids.

Successful treatment of hypothyroidism with rectal thyroxine can be achieved with variable dose response: a case report

Muhammad Naeem Durrani, Najmul Islam, Nanik Ram & sarwar Malik
Aga Khan University Hospital, Karachi, Pakistan.

Introduction
Hypothyroidism is a common endocrine disorder worldwide. Its treatment is with oral thyroxine, but when this route cannot be utilised then intravenous thyroxine is an alternate but not available in some countries so rectal thyroxine administration can be used but clinical experience is lacking.
Case report
This is a case of a 55-years-old Pakistani male known case of hypothyroidism since July 2007 and was maintaining normal TSH and FT_4 level on thyroxine 125 μg per day. He was diagnosed as recurrent laryngeal carcinoma and planned to undergo change of tracheostomy and feeding gastrojejunostomy surgery. As he was unable to take oral referred for hypothyroid medical optimisation prior to surgery. On presentation he was constipated, lethargic had tracheostomy and was on total parental nutrition and not taking his thyroxine for last one month. His TSH was >150uIU/ml and FT_4 was 0.44 ng/dl. As the intravenous thyroxin was not available was started on rectal suppository of thyroxin 250 μg per day. The dose of rectal thyroxine gradually increased to 500 μg per day and his TSH level dropped to 8.83 uIU/ml and FT_4 level raised to 1.29 ng/dl and patient underwent successfully for gastrojejustomy and started him on thyroxine 125 mcg per day through gastrojeunostmy tube and maintaining normal TSH and FT_4 level.
Conclusion
Patients with hypothyroidism can be managed with rectal thyroxine responses are variable as in our case required four times the oral dose.

EP1010

1 year response rate to 10 mCi radioactive iodine (I131) in patients with relapsed Graves' disease

Khaled Salman[1], Safwan Zatary[2], Shereen Wagieh[3], Tarek Munshy[1], Maha Abd-El Kareem[4], Yasser Mohammad[4] & Manal Al-Ezzi[3]
[1]Nuclear Medicine Deparmetnt, King Abdulla medical City (KAMC), Mekka, Saudi Arabia; [2]Endocrinology Department, King Abdulla medical City (KAMC), Mekka, Saudi Arabia; [3]Nuclear Medicine Department, King Abdulla Medical City (KAMC), Jeddah, Saudi Arabia; [4]Nuclear Medicine Department, Cairo University Hospitals, Cairo, Egypt

Introduction
Failure of medical treatment in patients with primary diffuse toxic goitre (Graves'disease) was reported in around 50% of patients and can occur few months after cessation of therapy. Radioactive I131 therapy is a good therapeutic alternative that can be used safely in patients with relapsed Graves' disease and achieve good response rate with hypothyroisdism representing the main side effect.
Aim
The aim of the current study is to asses one year response rate to 10 mCi of I131 in patients with relapsed Graves' disease post failure of medical treatment patients and methods: 33 patients who had transient control of clinical manifestations with normal thyroid hormonal profile post at least 12 months of continuous proper dose of of neomercazole therapy were included. This was followed by variable period of disease control (range: 7–19 months). After a mean period of 13.4 ± 5.5 months with no thyrotoxic clinical manifestations and more importantly normal thyroid hormonal profile during follow up, all patients had clinically and biochemically confirmed thyrotoxic state with a diagnosis of relapsed primary diffuse toxic goiter (relapsed Graves' disease). All presented for I131 therapy post failure of medical treatment and confirmed relapse. They received 10 mCi of I131 on out patient basis. Patients were followed up for 1 year to assess response to I131 therapy.
Results
14 patients (40.4%) developed clinical hypothyroidism that was confirmed biochemically 3 months post I131 therapy. 1 year post 10 mCi of I131 both clinical and biochemical data showed overt hypothyroid state in 21 patients (63.6%). One patient (3%) with subclinical hypothyroidism was diagnosed by thyroid function tests with no clinical symptoms. Normal thyroid function tests with no clinical manifestations of recurrence were reported in eight patients (24.4%). Considering both hypothyroid and euthyroid states as successful response to I131 therapy, so the overall successful response rate post 1 year of 10 mCi of I131 therapy is 91%. Failure of response to 10 mCi of I131 with a need for a second I131 dose was reported in only three patients (9%).
Conclusion
10 mCi of I131 is a good therapeutic choice in patients with relapsed Graves' disease with an overall response rate 1 year post I131 therapy of 91%. Hypothyroidism occurs as early as 3 months post therapy in around 40% of patients, increasing to 66.6% by the end of first year after therapy.

EP1011

Correlation of midkine levels in serum and thyroid nodules with histopathological, haematological and radiological variables

Fatih Kuzu[1,2], Dilek Arpaci[1,2], Ayfer Altas[2], Gürkan Haytaoglu[2], Murat Can[3], Figen Barut[4,5] & Taner Bayraktaroglu[1,2]
[1]Faculty of Medicine, Department of Internal Medicine, Division of Endocrinology and Metabolism, Bulent Ecevit University, Zonguldak, Turkey; [2]Faculty of Medicine, Department of Internal Medicine, Bulent Ecevit University, Zonguldak, Turkey; [3]Faculty of Medicine, Department of Biochemistry, Bulent Ecevit University, Zonguldak, Turkey; [4]Faculty of Medicine, Department of Pathology, Bulent Ecevit University, Zonguldak, Turkey; [5]Faculty of Medicine, Department of Biostatistics, Bulent Ecevit University, Zonguldak, Turkey.

Aim
To evaluate serum (SMK) and nodular (NMK) midkine levels in thyroid nodules and explore its relevance to ultrasound feature/pathological results.
Methods
A total of 80 patients (56 women, 24 men) with thyroid nodules were included in this prospective study. Hemograms, thyroid function tests, fine needle aspiration biopsies, ultrasonographic evaluation were routinely made. In addition, levels of SMK and NMK were measured. Any possible correlations between SMK, NMK and biochemical or radiological variables under investigation were sought.
Results
The average age of study group was 51.9 ± 14.4. Both SMK and NMK were found to be higher in hypoechoic nodules with an irregular border and absent halo. Serum MK levels were significantly higher in nodules containing microcalcifications than the macrocalcification or without calcification ($P = 0.001$). Serum MK levels were high in patients with differentiated thyroid carcinoma, compared to patients with follicular adenoma or nodular hyperplasia. Serum MK levels seemed to correlate with nodular MK levels ($r = 0.54$, $P < 0.001$).
Conclusion
Results of the current study showed that both SMK and NMK were indicators of highly malignant/suspicious thyroid cytopathology and also correlate well with sonographic features of thyroid malignancy. We suggest that Midkine may serve as a novel biomarker in conjunction with the cytopathological results in preoperative assessment of thyroid nodules.

DOI: 10.1530/endoabs.37.EP1011

EP1012

Correlation of VEGF, VEGFR-1 levels in serum and thyroid nodules with histopathological and radiological variables

Gurkan Haytaoglu[1,2], Dilek Arpaci[1,2], Fatih Kuzu[1,2], Ayfer Altas[1], Murat Can[3], Figen Barut[4], Firuzan Kokturk[5], Sevil Uygun Ilikhan[1] & Taner Bayraktaroglu[1,2]
[1]Department of Medicine, Department of Internal Medicine, Bulent Ecevit University, Zonguldak, Turkey; [2]Faculty of Medicine, Department of Internal Medicine, Division of Endocrinology and Metabolism, Bulent Ecevit University, Zonguldak, Turkey; [3]Faculty of Medicine, Department of Biochemistry, Bulent Ecevit University, Zonguldak, Turkey; [4]Faculty of Medicine, Department of Pathology, Bulent Ecevit University, Zonguldak, Turkey; [5]Faculty of Medicine, Department of Bioistatistics, Bulent Ecevit University, Zonguldak, Turkey.

Aim
To evaluate serum and intranodular vascular endothelial growth factor (VEGF) and vascular endothelial growth factor receptor-1 (VEGFR-1) level thyroid nodules and explore its relevance to ultrasound feature/pathological results.
Methods
A total of 80 patients (62 women and 18 men) with thyroid nodules were included in this prospective study. Thyroid function tests, fine needle aspiration biopsies, ultrasonographic and scintigraphic evaluation were routinely made. In addition, levels of serum and intranodular VEGF, VEGFR-1 were measured. Any possible correlations between serum and intranodular VEGF, VEGFR-1 and biochemical or radiological variables under investigation were sought.
Results
The average age of study group was 54.1 ± 13.3. Average BMI was 27.6 ± 4.2 kg/m^2. There were no statistically significant differences between sVEGF; nVEGF; nVEGFR-1 based on gender ($P > 0.005$). But serum VEGFR-1 in male was higher than women ($P = 0.045$). Although nVEGFR-1 was significantly higher in normal BMI patients compared with the obese patients; ($P = 0.02$); there were no differences sVEGF, sVEGFR-1 and nVEGFR-1. There were no significant differences between sVEGF; nVEGFR-1; sVEGFR-1 and nVEGFR-1 levels ($P > 0.05$) according to number of nodules (single and multinodular), benign and malignant ultrasonographic features (large nodules >4 cm; microcalcifications; intranodular hypervascularity; irregular border; hypoechoic structure; incomplete thick halo; regional lympadenopathy). When we grouped patients according to the thyroid status; sVEGFR-1 and nVEGFR-1 levels were higher in hyperthyroid patients than euthyroid patient ($P < 0.05$ and $P = 0.003$). In addition, nVEGFR-1 level was higher in hypothyroid patient than thyroid patients. ($P = 0.016$). There were no significant differences sVEGFR-1; nVEGFR-1 and nVEGF levels between the groups according to scintigraphic sign. But sVEGF was found higher in hyperactive nodules than others. sVEGF, sVEGFR 1, nVEGF, nVEGFR1 levels had no significant differences according to thyroid nodule size; ($P > 0.05$). There were no significant differences between sVEGF; sVEGFR-1; nVEGF and nVEGFR-1 levels between malignant/suspicious cytology and benign cytology ($P > 0.05$). Both sVEGFR-1($r = 0.29$; $P = 0.008$) and nVEGF levels inside nodule ($r = 0.29$; $P = 0.01$). Was significantly raised with increasing age. nVEGFR-1 was decreased with increasing BMI ($r = -0.32$; $P = 0.004$). There was no relationship between nodule size and sVEGF; nVEGF; sVEGFR1; nVEGFR1 ($P > 0.05$).
Conclusion
As a result; in our study we showed a relationship between sVEGF; nVEGF; sVEGFR-1; nVEGFR1 levels; and age; gender; BMI; hyperthyroidism. The number of malignant or suspicious groups were very small in our study, which is the limitation of this study. Studies which has more number of patients are required to evaluate it.

EP1013

Iodine nutrition status among neonates in Uttarakhand, India (for ESE Young Investigator Award)

Neha Sareen[1,2], Umesh Kapil[2] & Vanisha S Nambiar[1]
[1]Department of Foods and Nutrition, The Maharaja Sayajirao University of Baroda, Vadodara, India; [2]Department of Human Nutrition, All India Institute of Medical Sciences, New Delhi, India.

Introduction
Iodine deficiency (ID) is an endemic health problem in Uttarakhand State. ID leads to mental retardation, deaf mutism, squint, dwarfism, spastic diplegia, neurological defects and congenital anomalies. Iodine nutrition status amongst neonates can be assessed by estimating thyroid stimulating hormone (TSH).
Objectives
Current study aimed to assess iodine nutrition status among Neonates in Uttarakhand, India, a known endemic region for ID.
Methodology
Three districts, namely Udham Singh Nagar (USN), Nainital (N) and Pauri Garhwal (PG), were selected. In each district, all Hospitals/CHCs catering to the population for obstetric services were identified and enlisted. Six hospitals per district were selected keeping in view of operational feasibility. The 450 births occurring in these Hospitals/CHCs during the 12 months of study period were included for estimation of TSH. Total of 2013 neonates (649 from Udham Singh Nagar, 670 from Nainital and 694 from Pauri Garhwal) were studied. Umbilical cord blood samples of neonates were collected on filter paper and analyzed for TSH by sandwich enzyme-linked immunosorbent assay. WHO (2007) reported that a $<3\%$ frequency of TSH concentrations above 5 mIU/l in samples collected 3–4 days after birth indicates iodine sufficiency in a population.
Results
We found that 55.3% (USN), 76.4% (N) and 72.8% (PG) of the neonates had TSH levels of more than 5 mlU/l, thus indicating ID in the population studied. No statistically significant difference of gender on the TSH levels was observed.
Conclusion
Iodine deficiency continues to be a public health problem in Uttarakhand, India.
Disclosure
Indian Council of Medical Research, New Delhi (vide letter No: 5/9/1025/201 1-RHN).

EP1014

Prevalence of short stature in juvenile hypothyroidism and the impact of treatment in tertiary care centre

Sukriti Kumar[1] & Manish Gutch[2]
[1]SGPGI, Lucknow, India; [2]LLRM Medicalcollege, Meerut, India.

Background
Juvenile hypothyroidism is very common problem in developing part of world, and produces various skeletal manifestations and one of them is short stature and it is the most common reason for referral to endocrinologist. It has very wide etiology and one of them is hypothyroidism, which needs special attention, as the treatment impact of thyroxin replacement has favourable outcome.
Aim and objectives
To study the prevalence of juvenile hypothyroidism, to study the various radiological manifestation of juvenile hypothyroidism and to study the impact of treatment on short stature.
Materials and methods
Out of total 900 patients, 87 patients found to be of juvenile hypothyroidism were enrolled in the study that were 6–18 years of age with newly diagnosed or on follow in the OPD of Department of Endocrinology and Metabolism over a period of $1\frac{1}{2}$ years were evaluated clinically and by laboratory tests. Serial assays of TSH, T_4, T_3 and skeletal X-rays were done and clinical and radiological outcome of patients were analysed.
Statistical analysis
Data were analysed by SPSS version 17 and were presented in the values of mean, median, and percentages. The P-value of <0.05 was considered significant.
Results
The mean age of diagnosis of juvenile hypothyroidism was 11.2 years, and the females had twice the incidence than that of males, the mean TSH value were 118 μIU/ml while T_4 and T_3 were very low. Marked improvement in the anthropometry was seen in comparison to the initial assessment which was well correlated with the normalisation of the TSH level and the X-ray of the bone. The maximum impact of hypothyroidism was on delayed bone age.
Conclusion
Juvenile hypothyroidism, constituent about 10% of total hypothyroid patients and it is more common than congenital hypothyroidism. The presentations may be varied including short stature, spondylolisthesis, delayed bone age and irregular ossification of the epiphyses. Prompt recognition of the findings can lead to early and effective treatment, and improving the skeletal defects.

The role of circulating sTWEAK in the pathogenesis of Hashimoto's thyroiditis and its relationship with other cytokines: a pilot study

Mustafa Altay[1], İhsan Ateş[2], Fatma Meriç Yılmaz[3], Canan Topçuoğlu[3], Mustafa Kaplan[4] & Fatma Aybala Altay[5]
[1]Department of Endocrinology and Metabolism, Keçiören Education and Research Hospital, Ankara, Turkey; [2]Department of Internal Medicine, Numune Education and Research Hospital, Ankara, Turkey; [3]Department of Biochemistry, Ankara, Numune Education and Research Hospital, Turkey; [4]Department of Gastroenterology, Yüksek ihtisas Education and Resarch Hospital, Ankara, Turkey; [5]Dışkapı Education and Research Hospital, Ankara, Turkey.

Objective
We aimed to investigate the role of sTWEAK in the pathogenesis of Hashimoto's Thyroiditis (HT) and its relationship with IL-12, IL 17-A and TGF-β1.
Methods
Serum TSH, FT_4, anti-TG and anti-TPO were measured and thyroid USG was performed to both group. In addition serum samples were collected and sTWEAK, IL 17-A, IL-12 and TGF-β1 were measured.
Patients
Six patients (20 patients were euthyroid, 20 patients were subclinical hypothyroidism and other 20 were overt hypothyroidism), who were newly diagnosed with HT and did not receive any treatment, and 20 patients with no known disease as the healthy control group were included in the study.
Results
The HT group had lower levels of sTWEAK and TGF-β1, but had higher levels of IL-12 and IL 17-A as compared to the control group. Of these, only the difference between IL 17-A levels reached the statistical significance (2.1 (1.1–10.7) vs 1.8 (1.2–2.3)) $P<0.001$). The overt hypothyroidism group had significantly higher levels of IL-12 than those of other groups. All of the subgroups had significantly higher levels of IL 17-A than those of control group. sTWEAK was negatively correlated with IL 17-A in the overt hypothyroidism.
Conclusions
We achieved data that support the role of IL-12 and IL17-A in the pathogenesis of HT but did not find significant differences between the sTWEAK level and the groups. Also, no significant relationship was identified between the sTWEAK level and either the thyroid autoantibodies or the cytokine levels of other pathways. Further studies are needed to present the effect of sTWEAK level on the autoimmune diseases.

EP1016

Serum selenium levels in euthyroid nodular thyroid diseases

Davut Sakiz[1], Ahmet Kaya[2] & Mustafa Kulaksizoglu[2]
[1]Necmettin Erbakan University Meram Medical Faculty Internal Medicine, Konya, Turkey; [2]Department of Endocrinology and Metabolism, Necmettin Erbakan University Meram Medical Faculty, Konya, Turkey.

Introduction
Thyroid gland is susceptible for nodulation. It is not clear which mechanism is responsible for the growth of only some follicular cells resulting in nodule formation. Selenium deficiency may a risk factor in the development of thyroid nodules. The aim of this study was to investigate the relationship between selenium levels in patients with euthyroid nodular thyroid diseases.
Design
Euthyroid 70 patients with solitary thyroid nodule, euthyroid 70 patients with more than one nodule healthy 60 patients without thyroid nodule were included in the study. Venous serum samples were stored at -80 °C and studied at the same day by spectrometric method.
Results
Selenium levels of patients with multiple thyroid nodules, solitary nodules and patients without nodules respectively were 57.3 ± 1.76 μg/l; 58.7 ± 1.80 μg/l and 57.6 ± 1.71 μg/l. The mean serum selenium level of all patients included in the study was 57.92 ± 14.43 μg/l. Serum selenium levels were minimally higher in men, although statistically significant difference was not observed. In our study,

significant relationship between serum selenium levels and nodular thyroid disease was not seen.
Conclusion
Our study was done in a iodine sufficient area. Mean serum selenium levels were lower compared to other studies in Turkey. This condition can be associated with the low selenium content of the soil. Nodular thyroid disease shows multifactorial features. Besides iodine deficiency additional factors such as selenium deficiency can be responsible for the increase of nodule formation. Further studies should be done to assess the role of selenium in the thyroid nodule formation.

Technique of story-telling in Patient care with reference to endocrine surgery

Sabaretnam Mayilvaganan, Naval Bansal & Saroj Mishra
Sanjay Gandhi Postgraduate Institute of Medical sciences, Lucknow, India.

Background
In the modern day busy clinical practice the communication between patient/relative and care giver is at minimal level. The patients and relatives feel apprehensive when advised about the surgical/interventional treatment. In such situation they feel the need of detail information from the care givers which on many occasions is not available. Story telling is such a technique of health communication made out in common man language which can be made animated and interactive using virtual characters and can operate in a virtual environment eliminating the need of health professionals. We intended to study the efficacy of storytelling technique on patients undergoing Hemithyroidectomy for benign cytology.
Methods
A story of a lady (cartoon version) aged 25 years with a benign thyroid nodule who underwent uneventful Hemithyroidectomy is depicted in this movie including the history, clinical examination, investigations, counseling and the operative procedure and the running time of the animation movie is four minutes. For developing this movie, high end graphic computer work station and various multimedia authoring tools like Adobe Flash, Photoshop, Captivate, Maya and Final Cut Pro were used. The story was shown to patients with clinically solitary thyroid nodules who were provisional candidates for surgery in the outpatient department.The patients filled in the evaluation of Multimedia animation questionnaire at the time of discharge.
Result
20 patients filled the questionnaire. 19 found the movie useful and their remaining questionnaire was analyzed. Mean age was 35.45 ± 12.8 years.15 (75%) were females. All patients were euthyroid. The mean weight was 40.80 ± 20.79 gm. The final histopathology was colloid in majority. In the questionnaire, the mean score for improved understanding of the disease was 73.9 ± 14.7 ($P=0.003$), better organization of treatment was 78.6 ± 13.1 ($P=0.000$), stimulated interest in the relatives was 70.8 ± 15.8 and saved unnecessary discussion with the consultant was 55.5 ± 7.8.
Conclusion
Story telling is a useful tool in health communication. With widespread availability of high speed internet and affordable mobile computing devices such kind of information can be of use to the patients and relatives in decision making and also saves valuable time of the treating consultant. Future studies with larger numbers are needed.

Adiponectin and gut hormones in thyroid dysfunction: a new concept (PFG axis)

S Ali Emami[1], Mehdi Hedayati[1] & M Reza Nazem[2]
[1]Cellular & Molecular Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Department of Clinical Biochemistry, School of Medicine Tarbiat Modares University, Tehran, Iran.

Background
Integration between fat tissue, gastrointestinal tract, and the brain has attracted scientific interest in recent years. Thyroid hormones influence carbohydrate mechanisms *via* its interaction with adipocytokines and gut hormones. *Adiponectin*, *ghrelin* and *obestatin* play important roles in metabolism regulation. TSH receptors have been reported to be present in adipose tissue. Moreover, gut peptides signal to their functional cognate receptors on adipocytes. Nonetheless, the limited number of studies assessing the link between thyroid, gut hormones and adipokines have yielded conflicting results.
Aim
The objective of this study was to examine the associations between adiponectin, ghrelin and obestatin in patients with thyroid dysfunction. Furthermore, there might be a cross talk between them.
Methods
This study was performed on 72 subclinical hypo- and hyperthyroids, and 33 healthy euthyroid subjects. Serum concentrations of adiponectin, ghrelin, obestatin, TSH, free T_3 and free T_4 were measured by ELISA, ECLIA, IRMA and RIA methods.
Results
Serum levels of adiponectin were decreased in hypothyroids and increased in hyperthyroids (11.91 ± 5.02 and 15.13 ± 5.88 ng/ml, respectively) than the controls (12.73 ± 5.19 ng/ml, $P<0.05$). Ghrelin and obestatin values were lower in hypothyroids (320 ± 81 and 44.3 ± 11.7 ng/l respectively), and higher in hyperthyroids (750 ± 289 and 71.1 ± 27.3ng/l, respectively), compared to the controls (487 ± 110 and 58.5 ± 10.3 ng/l respectively, $P<0.05$). We found a negative correlation between TSH and adiponectin ($r=-0.42$, $P<0.05$). In addition, ghrelin and obestatin showed strong correlations with TSH ($r_{gr}=-0.53$, $r_{ob}=-0.59$; $P<0.001$). Also, strong correlations were observed between adiponetin and gut hormones ($r_{gr}=0.75$, $r_{ob}=0.69$; $P<0.001$).
Conclusion
Our findings show adiponectin and gut hormones are significantly affected by thyroid dysfunction. Additionally, these hormones are noticeably correlated with each other. Hence, we would like to consider a new regulatory concept, as a novel axis (*Pituitary-Fat-Gut axis*).

A case of unilateral Graves' disease

Baris Cansu, Bengur Taskiran & Tatiana Bahceci
Yunusemre State Hospital, Eskisehir, Turkey.

Introduction
Thyroid hemiagenesis is a congenital developmental disorder. Most cases are euthyroid although hyperthyroidism, hypothyroidism, and malignancy may develop. We present a case of hemiagenesis with Graves' disease.
Case
A 45-year-old female patient was admitted to the endocrinology ward due to nausea and diarrhoea. She had hyperthyroidism for 1 year. She did not have any family member with thyroid disease. She was already on propylthiouracil therapy. She did not bear signs of Graves ophthalmopathy. Thyroid function tests revealed a TSH level of 0.01 μU/ml (0.35–4.94), free T_4 1.80 ng/dl (0.7–1.48), free T_3 3.82 pg/ml (1.71–3.71). TSH receptor antibody, antithyroid peroxidase antibody, and anti-thyroglobulin antibody were all positive. Left lobe and isthmus were invisible on ultrasound. Right lobe was $44 \times 18 \times 12$ mm in size with heterogenous hypervascular paranchyme echogenicity containing no nodules. Thyroid scan using 5 mCi ^{99m}Tc showed increased homogenous tracer uptake in the right lobe (6.7%). Isthmus, pyramidal lobe, and left lobe were not visualised. The patient was diagnosed with thyroid hemiagenesis and Graves' disease. The dose was readjusted and RAI therapy was planned.
Conclusion
In case of unilateral increased uptake on scintiscan Graves' disease with hemiagenesis must be kept in mind in the differential diagnosis of autonomus solitary adenoma, postinflammatory atrophy of thyroid in Hashimoto's disease, focal or unilateral subacute thyroiditis, and primary or metastatic carcinoma. It is prudent to do thyroid ultrasound along with scintigram.

Evaluation of oxidative stress in patients with euthyroidism and with subclinical hypothyroidism

Şati Sena Yildiz, Sibel Serin, Gülçin Güngör Olçüm & Sema Basat
Ümraniye Research and Education Hospital, Istanbul, Turkey.

Objective
There is not sufficient data about oxidative stress in euthyroid Hashimoto (EH) and subclinical hypothyroid Hashimoto (SHH) disease. We studied oxidative stress with more oxidative stress tests in EH and SHH patients and assessed whether there is an association betweeen Hashimoto disease and PON1 phenotype.
Materials and method
35 EH and SHH patients and 38 control was included to the study. Comprehensive biochemistry, routine blood analysis, total antioxidant status (TAS), total oxidant status (TOS), oxidative stress index (OSI), arilesterase (ARE) paraxonase (PON), lipid hidroperoxide (LOOHs) were measured, and PON1 phenotype was determined.
Results
The levels of TOS and OSI increased significantly in patients with EH and SHH when compared with the control group (for TOS $P=0.005$, $P=0.004$; for OSI $P=<0.001$, $P=<0.001$, respectively). The level of ARE activity increased closely significant in patients with EH, and increase significantly in patients SSH patients when compared with the control group ($P=0.059$, $P=0.024$ respectively). The levels of PON, TAS, LOOHs are similar in the control group. Hashimoto's patients also have found that PON1 phenotype distribution similar to the control group (P: 0.303).
Conclusion
TOS, OSI and ARE were found to be increased in EH patients; however TAS, paraoxonase and LOOHs were similar to the control group. Increased OSI is related to increase in TOS in Hashimoto patients, because TAS was found to be similar to the controls. In EH and SHH patients, ARE activity, which is an indicator of molecular concentration of PON 1 enzyme, was found to be increased. On the other hand paraoxonase activity was similar to the control group, due to its consumption during the process of reducing the elevated LOOHs as a result of the increase in TOS. Consequently lipid peroxidation was found to be at a similar level with the controls. Oxidative stress parameters and biochemical values are similar in EH and SHH patients. In the PON1 phenotyping we performed, no PON1 phenotype creating predisposition to Hashimoto disease was detected.

Circulating levels of irisin is elevated in patients suffering from hypothyroidism and obesity in Hashimoto's thyroiditis: original article

İhsan Ates[1], Mustafa Altay[1], Canan Topçuoğlu[2], F Meriç Yılmaz[2] & Guvenç Toprak[1]
[1]Department of Internal Medicine, Ankara Numune Education and Research Hospital, Ankara, Turkey; [2]Department of Biochemistry, Ankara Numune Education and Research Hospital, Ankara, Turkey.

Background and objectives
Our objective in this study was to discover the relationship of irisin hormone, which acts on adipose tissue and the metabolism as thyroid hormones, with the thyroid functions and the obesity secondary to thyroid disease.
Methods
A total of 74 patients were included in the study, of the patients, 37 were newly diagnosed with Hashimoto's thyroiditis dependent hypothyroidism but not received a treatment yet, and the remaining 37 were healthy volunteers with no known disease. Serum TSH, free thyroxin (fT_4), anti-thyroglobulin (anti-TG) and anti-thyroid peroxidase (anti-TPO) were measured and thyroid ultrasonography was performed to both group. The serum irisin levels were measured using the commercially available ELISA kit.
Results
The hypothyroidism group had higher levels of irisin compared with the control group (2.77 ng/ml vs 2.15 ng/ml respectively; $P=0.017$). The hypothyroidism group had higher median levels of irisin in the obese patients than those in the control group (3.10 ng/ml vs 2.10 ng/ml relatively; $P=0.013$). The irisin level was negatively correlated with the age in the entire population and patients with hypothyroidism (r: -0.255, $P=0.028$; $r=-0.346$, $P=0.036$ respectively). The irisin level was positively correlated with the TSH ($r=0.247$, $P=0.034$) but negatively with the fT_4 ($r=-0.316$, $P=0.006$) in the entire population. Obesity, fT_4 and irisin level were identified to be independent predictors in the diagnosis of hypothyroidism in the multivariable logistic regression analysis.
Conclusions
To the best our knowledge, this study is the first in literature to identify that obesity, irisin level and fT_4 level are independent risk factors on hypothyroidism.

The relationship between oxidative stress and thyroid autoantibodies in patients with Hashimoto's thyroiditis

İhsan Ates[1], F Meriç Yılmaz[2], Mustafa Altay[3], Nisbet Yılmaz[3] & Serdar Güler[1]
[1]Department of Endocrinology and Metabolism, Ankara Numune Education and Research Hospital, Ankara, Turkey; [2]Department of Biochemistry, Ankara Numune Education and Research Hospital, Ankara, Turkey; [3]Ankara Numune Education and Research Hospital, Ankara, Turkey.

Background
The relationship between Hashimoto's thyroiditis (HT) and oxidative stress (OS) has been investigated in several studies that have included a limited number of patients, the findings have not been conclusive, which indicates that additional research that investigates parameters of OS in larger patient populations is needed. As such, this dissertation study aimed to determine the levels of parameters of OS and their relationship with thyroid antibodies in HT patients in the euthyroid, subclinical, and overt hypothyroidism stages.
Methods
This study included 93 treatment-naïve HT patients aged >18 years and 31 healthy volunteer controls with no known disease. TSH, sT_4, anti-TPO, and anti-Tg were measured via ECLIA, and serum total antioxidant status (TAS), total oxidant status (TOS), total thiol (total-SH), paraoxonase (PON), and arylesterase were measured via the colorimetric method.
Results
The TOS level and OS index (OSI) were higher in the overt hypothyroidism group than in the other group, whereas TAS, total-SH, and arylesterase levels were lower in the overt hypothyroidism group than in the other groups. Total-SH level was similar in the control and subclinical hypothyroidism groups, but was higher in the euthyroid group than in the control and subclinical hypothyroidism groups. The log (PON) and PON/HDL levels were higher in the control group than in all three patient groups. There weren't any significant differences in the log (PON) or PON/HDL levels between the three patient groups. There was a negative correlation between the anti-TPO level, and TAS, log (PON), and PON/HDL level, and between the total SH and anti-Tg levels. Overt hypothyroidism was an independent predictor of the level of all oxidative stress parameters, except for total-SH.

Conclusion
This study examined numerous parameters of OS according to HT stages. The findings provide a general picture of how OS might be affected by thyroid hormone and thyroid autoantibody levels in patients with HT.

The relationship between procalcitonin and thyroid autoantibodies in patients with Hashimoto's thyroiditis

İhsan Ates, Ali Öncül, Mustafa Altay & Canan Topçuoğlu
[1]Department of Internal Medicine, Ankara Numune Education and Research Hospital, Ankara, Turkey; [2]Departmen of Biochemistry, Ankara Numune Education and Research Hospital, Ankara, Turkey.

Background
Procalcitonin (PCT) is often an increased acute phase reactant in the bacterial infection-related inflammation, and its serum level is reported elevated in several autoimmune disease. However, the level of PCT and its relationship with autoimmunity remain unknown in Hashimoto's thyroiditis (HT). Our objective was to investigate the serum levels of PCT and its association with autoantibodies in patients with euthyroid HT.
Methods
A total of 80 participants, 40 patients were newly diagnosed with euthyroid HT and 40 healthy volunteers with no known disease. Thyroid function tests and thyroid autoantibodies are analyzed in hormone laboratory with Electro-chemiluminescence immunoassay. The serum levels of PCTwere measured by ELISA kit.
Results
Hashimoto's thyroiditis patients had higher median PCT levels than those of the control group (34.3 pg/ml vs 27.8 pg/ml respectively; $P=0.037$). In the entire population and HT group, the PCT level was positively correlated with systolic and diastolic blood pressures (the entire population; r: 0.320, $P=0.004$; $r=-0.267$, $P=0.017$; HT; r: 0.355, $P=0.025$; $r=0.420$, $P=0.007$). PCT and TPO levels were identified to be an independent predictor in diagnosis of HT in the multivariate logistic regression model. An increase of one unit in the PCT level increased the risk for HT by 1.478 times and an increase of one unit in the anti-TPO level increased the risk for HT by 1.164 time when the other risk factors were kept constant.
Conclusion
Procalcitonin being the independent predictor of HT, as indicated in the multivariate regression analysis, suggests that PCT could be a hormone associated with the autoimmunity. Extensive and further researches are needed in this field.

Mimic the symptoms of thyroid disorders in pregnant women

Sima Nazarpour[1], Fahimeh Ramezani Tehrani[2], Masoumeh Simbar[1], Maryam Tohidi[3], Fereidoun Azizi[3] & Hamid Alavi Majd[4]
[1]Department of Reproductive Health and Midwifery, Faculty of Nursing and Midwifery, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Reproductive Endocrinology Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [3]Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [4]Department of Biostatistics, Faculty of Paramedicine, Shahid Beheshti University of Medical Sciences, Tehran, Iran.

Introduction
The prevalence of these disorders in pregnant women is relatively high and may affect mother and foetus adversely if they are not evaluated and treated appropriately. Therefore, their diagnosis and treatment is very important. On the other signs and symptoms of thyroid disease can often be masked by the physiologic changes of pregnancy and are not found. The aim of this study was to evaluate the physiological symptoms similar to thyroid disorders and their incidence in pregnant women without thyroid disorders.
Materials and Methods
This study is a population based cross sectional study. A total number of 1600 pregnant women were selected with population based cluster method in prenatal care centres. After questioning the women about the symptoms of thyroid disease and relevant clinical examination, blood samples were taken for thyroid tests and serum T_4, TSH, T3 uptake and TPOab were measured.
Result
63.5% of the participants in this study had normal thyroid function. The prevalence of overt hypothyroidism and hyperthyroidism were 3.8 and 0.8%, respectively and 29.8% of patients had subclinical hypothyroidism. 64.0% of pregnant women without thyroid dysfunction had one or more of the symptoms of thyroid disorders. 24.3% of them had one or two symptoms and 41.5% of them have three or more of the symptoms of thyroid disorders in pregnancy. Most symptoms was laziness and drowsiness (30.3%), followed by fatigue (20.3%). 2.2% of pregnant women have goitre and the symptoms were minimal.
Discussion
The correct planning in order to evaluate and diagnose thyroid disorders during pregnancy is important. Understanding the value and interpretation of thyroid function tests during normal pregnancy is necessary to discriminate between anticipated changes, pathological changes appear.

An unusual clinical presentation of subacute thyroiditis in a patient with Hashimoto thyroiditis

A Serap Yalin[1], Erdem Turemen[1], Mithat Biyikli[1], Omer Aydiner[2], Ozgur Sarica[2], Saime Ramadan[3] & Kezban Berberoglu[4]
[1]Division of Endocrinology and Metabolism, Anadolu Medical Center, Istanbul, Turkey; [2]Department of Radiology, Anadolu Medical Center, Istanbul, Turkey; [3]Department of Pathology, Anadolu Medical Center, Istanbul, Turkey; [4]Department of Nuclear Medicine, Anadolu Medical Center, Istanbul, Turkey.

Hashimoto thyroiditis (HT) is the most common cause of hypothyroidism. Subacute thyroiditis (SAT) is an uncommon disease with characteristic clinical features. Co-existence of HT and SAT is very rare and diagnosis can be challenging.
Case
A 42-year-old woman with HT and multinodular goitre under levothyroxine sodium (LT_4) therapy admitted to internal medicine clinic with 1 month history of anterior neck pain radiating to jaw. Thyroid function tests (TFT), erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were normal. Neck ultrasonography (NUS) revealed a hypovascular focal area in right lobe (RL) which could be consistent with thyroiditis. However, NUS showed an increase in the size of focal area a week later. She was referred to endocrinology clinic for differential diagnosis (DD). Complaints were consistent with SAT, however TFT, ESR and CRP were normal. LT_4 was stopped due to the possibility of thyrotoxicosis in SAT and to perform thyroid scintigraphy (TS). She was anxious and had another NUS by her own will 12 days later. NUS reported further progression of area in RL, and formation of a new area in left lobe (LL) with a suspect of thyroid lymphoma (TL). TS revealed decreased LL activity and increased background activity. DD included three rare situations: TL, painful HT and SAT co-existing with HT. Clinical presentation was consistent with SAT, however no inflammatory response and thyrotoxicosis developed. TL is more prevalent in HT but rarely painful. However, rapid progression of NUS findings suggested lymphoma possibility. We performed fine needle aspiration biopsy (FNAB) to exclude TL. FNAB demonstrated giant cells compatible with SAT. During 6 months of follow up thyrotoxicosis was not observed and thyroid stimulating hormone increased gradually. LT_4 was initiated again. She refused steroid therapy. HT, an autoimmune disease, can alter the course of SAT and FNAB may be required for DD.

Association between thyroid specific genotypic variation and phenotypic expression of dyshormogenetic goitre and Hashimoto's thyroiditis in children and adolescents: a South Indian experience

B Ramesh, Verma B Aparna, R Vijayaraghavan, Bhargav P Ramakanth & B Rajesh
[1]Mediciti Institute of Medical sciences (MIMS), Hyderabad, India; [2]MIMS, Hyderabad, India; [3]Saveetha University, Chennai, India; [4]Endocare Hospital, Vijayawada, India; [5]MIMS, Hyderabad, India.

Background
Thyroid disorders are the commonest endocrine disorder after diabetes in most of the populations worldwide. Though, hypothyroidism is extremely common in children, there is acute scarcity of genetic studies leading to improper screening and treatment protocols in developing countries. The aim of this ambitious study was to screen for NIS, DUOX2 and TPO mutations in south Indian children and adolescent patients with dyshormogenetic goiter (DH) and Hashimoto's thyroiditis (HT) and to define the relationships between NIS, DUOX2 and TPO genotypes and clinical phenotypes.
Material and methods
Blood samples were collected from 20 patients with dyshormogenetic goiter (DH) and Hashimoto's thyroiditis (HT). Genomic DNA was extracted from peripheral blood leucocytes. PCR and direct sequencing were used to analyse for NIS, DUOX2 and TPO genes. Detailed clinical, biochemical and follow-up data were recorded in a structured proforma. Subjects with hypothyroidism were treated with thyroxine replacement. Detailed genetic analysis with 142 SNP (single nucleotide peptides) and eight sets of primers were done.
Results
The age of the cohort was 11 ± 4.5 (5–17) years. F:M ratio was 17:3. The type of hypothyroidism was overt and subclinical in 14 and six patients respectively. Family history of hypothyroidism was present in seven patients (35%). Genetic analysis shows that heterozygous NIS mutations were seen in five children with HT and in two children with DH. A homozygous mutation was picked up in a child with HT. No mutations were found in DUOX and TPO genes.
Conclusions
NIS gene mutations appears to be most prevalent mutations in HT and DH amongst South Indian children in this study. The iodine deficiency and ethnic factors may be responsible for this pattern. Further studies are needed to characterise hypothyroid phenotypes in children.

Evaluation of unknown thyroid disorders in nursing home people

Ferit Kerim Kucukler, Yasin Simsek & Serdar Güler
Department of Endocrinology, Hitit University, Corum, Turkey.

Introduction
The prevalence of thyroid diseases increase with age. Mostly, they are undiagnosed. The lack of overt clinical appearance of hypo-hyperthyroidism in elder people increases the need for an attentive clinician to suspect and investigate for their presence. Thyroid dysfunctions, especially subclinics, are more frequently seen in older populations, have been linked to increased morbidity and mortality. Therefore, elderly people should evaluate in terms of thyroid functions.
Materials and methods
Hundred and ninety-two participant were enrolled in the study, 108 of them from the selected nursing home and 84 of them were living in their own home. All of the participants were evaluated in terms of thyroid functions, thyroid ultrasonography and osteoporosis.
Results
The nursing home participant (NP) group had 89.8% euthyroid, 3.7% subclinical hypothyroidism, 0.9% overt hypothyroidism, 0.9% overt hyperthyroidism and 4.6% subclinical hyperthyroidism, in household participants (HP) group's rates were 83.3, 9.5, 0.0, 0.0 and 7.1% respectively. NP group had 64.2%, HP group had 78.3% thyroid nodule. NP group's osteoporosis ratio was 34.7%, HP group's was 22.95.
Conclusions
There was no statistical difference between two groups in terms of distribution of thyroid dysfunction, thyroid nodules and osteoporosis.

Thyroid switching and D727E polymorphism

Mustafa Altay[1], Murat Dağdeviren[2], Gülsüm Biten Güven[3] & Derun Taner Ertuğrul[1]
[1]Department of Endocrinology and Metabolism, Keçiören Education and Research Hospital, Ankara, Turkey; [2]Department of Internal Medicine, Keçiören Education and Research Hospital, Ankara, Turkey; [3]Department of Clinical Microbiology, Keçiören Education and Research Hospital, Ankara, Turkey.

Introduction
Graves' disease and Hashimoto's hypothyroidism are common thyroid diseases. However, occurrence of both clinical disorders one after the other in the same patient, is not common.
Case report
In this article, we presented two hypothyroid patients who developed clinical thyrotoxicosis during levothyroxine treatment. Both patients were treated with levothyroxine for a long time. Due to occurrence of clinical hyperthyroidism, levothyroxine treatments of the both patients were terminated. Although unmedicated follow-up for about 6 weeks period, recovery from thyrotoxicosis wasn't observed. Both of the patients were positive for TSH receptor antibody.
Results
They were diagnosed as Graves' disease on the basis of clinical signs, laboratory findings and imaging techniques, thus antithyroid treatment was initiated. In both cases, TSH receptor gene sequence analysis was performed, and in both of the patients D727E homozygous polymorphism was obtained.
Conclusions
In hyperthyroid cases with the history of hypothyroidism, switching between hypothyroidism and hyperthyroidism should be kept in mind and due to D727E polymorphism, and the other TSH receptor gene mutations, if it is possible genetic analysis should be performed.

Relationship between thyroid function tests and all-cause mortality in patients on peritoneal dialysis: a prospective analysis

Juan J Díez[1], Sara Romero-Perez[2], María A Bajo[3], Pedro Iglesias[1], Cristina Grande[4], Gloria Del Peso[3], Rosario Madero[5], Marta Ossorio[3] & Rafael Selgas[3]
[1]Department of Endocrinology, Hospital Universitario Ramón y Cajal, Madrid, Spain; [2]Department of Nephrology, Hospital Universitario del Sureste, Madrid, Spain; [3]Department of Nephrology, Hospital Universitario La Paz, Madrid, Spain; [4]Department of Biochemistry, Hospital Universitario La Paz, Madrid, Spain; [5]Department of Biostatistics, Hospital Universitario La Paz, Madrid, Spain.

Background
Alterations in thyroid function tests results in patients on peritoneal dialysis (PD) might represent a risk factor for cardiovascular disease (CVD) and mortality.
Objective
To investigate the relationship of serum TSH, free thyroxine (FT_4), and triiodothyronine (T_3) concentrations with incident CVD and mortality in PD patients.
Methods
Prospective study including all patients attending our PD unit between 2003 and 2012 who had remained at least for 3 months in the PD program. All patients were followed until death, exit of PD program, loss of follow-up, or census date (September 2012). Survival time was estimated by the Kaplan-Meier method. Unadjusted and multivariate Cox regression models were used to assess the effects of several variables on the risk of death.
Results
From 169 subjects included in our program, 139 (81.8%) were euthyroid, 4 (2.4%) had overt hypothyroidism, and 26 (15.4%) had subclinical hypothyroidism. Patients in the first tertile of T_3 (<0.91 ng/ml) had a higher percentage of CVD events during follow-up (10.9%) than those in the second (0.91–1.10 ng/ml, 1.9%) and third tertiles of T_3 (>1.10 ng/ml, 1.9%, $P<0.05$). All-cause mortality was higher in patients in the first tertile of T_3 (20%) in comparison with patients in the second (3.8%) and third tertiles (5.6%, $P<0.05$). Kaplan-Meier analysis showed that median survival time for all-cause mortality were significantly lower in patients in the first tertile of T_3 ($P=0.013$). Unadjusted Cox regression analysis showed an increase in the risk of death in patients in this tertile (HR, 4.3; 95% CI, 1.48–12.45, $P=0.007$). In the multivariate (adjusted) analysis, this risk of death remained significant (HR, 3.14, 95% CI, 1.05–9.43, $P=0.041$).

Conclusions
Thyroid function tests alterations are associated with long-term incidence of CVD and mortality in uremic patients undergoing PD. In particular, low T_3 levels are significantly related to all-cause mortality in this population.

EP1031

Role of regulatory T cell and CTLA-4 gene as risk factor relapse in Graves' disease

Fatimah Eliana[1] & Pradana Suwondo[2]
[1]YARSI University, Jakarta, Indonesia; [2]University of Indonesia, Jakarta, Indonesia.

Introduction
Graves' disease (GD) management in Indonesia are generally preceded by administration of antithyroid drugs. Antithyroid drug delivery requires a long time to achieve remission, even more than 50% of patients who had remission can recur after antithyroid medication is stopped. The purpose of this study was to determine the role of CTLA-4 gene and regulatory T cells against recurrence in patients GD in Indonesia.
Methods
The study was conducted using a case-control in 144 patients GD, comparing patients who relapse and recurrence. Definition of relapse if the patient is declared remission after antithyroid treatment for at least 18 months, but relapsed after 12 months of antithyroid medication is stopped. Examination of CTLA-4 gene polymorphism of exon1 by the method of PCR RFLP, and the number of regulatory T cells was checked by flow cytometry.
Results
Research shows that patients with GD have higher risk of relapse if they have family history (P 0.01), degree two of ophtalmopathy (P 0.011) and enlargement of the thyroid gland exceeded the lateral edge of the sternocleidomastoideus muscle (P 0.044). GD patients with polymorphisms of CTLA-4 gene exon1 genotype GG and GA have higher risk of relapse than the AA genotype (P 0.003 and OR6.545). The number of regulatory T cells in patients with relapsed is lower than non-recurrence ($P<0.005$). GD patients with the G allele in the gene CTLA-4 exon1 has had lower regulatory T cells than the A allele ($P<0.005$).
Conclusion
The risk of relapse in patients with GD can be determined prior to administration of antithyroid therapy based on clinical factors, genetics and immunology.

Iodine supplementation to pregnant women is scarcely available in Brazil

Danilo Villagelin[1,2], Laura Ward[2], Roberto Santos[1], Douglas Tiago[1], Giovana Azevedo[1], Sarah Zolio[1] & Joao Romaldini[1]
[1]Pontificia Universidade Católica de Campinas, Campinas, Brazil; [2]University of Campinas, Campinas, Brazil.

Introduction
A woman's iodine requirements increase substantially during pregnancy to ensure adequate supply to both mother and fetus. The deficiency of this element may cause several maternal-fetal repercussions. For this reason, iodine supplementation for pregnancy has been recommended and the World Health Organization (WHO) commends an iodine urinary concentration at a median UIC 150–249 μg/l. As in many other countries around the world, there is evidence of iodine deficiency among Brazilian pregnant women. In fact, a recent study identified UIC below 150 μg/l in 57% of the pregnant women investigated. Iodine supplements availability have not yet been evaluated in the country and our objective was identify the availability of dietary supplements for pregnant women in Brazil and verify the amount of iodine present on them, correlating it with the new global recommendations.
Methods
We used our national health electronic system (Anvisa's Bulário Eletrônico) to investigate the nutritional information of dietary supplements used by pregnant women through their package insert. Further, we contacted the pharmaceutical industries and consulted the Brazilian Dictionary of Pharmaceutical Specialties (DEF) 2012–2013.
Results
There are, currently, 23 dietary supplements for pregnant women in use. Based on daily iodine intake recommended by American Thyroid Association, European Thyroid Association and WHO (minimum of 150 μg/day), 52.2% out of these products contain no iodine; 13.0% contain insufficient amounts of iodine (1–149 μg); and only 34.8% contain the recommended quantity of this element.
Conclusion
Despite salt iodination, recent data indicate that at least half of Brazilian pregnant women present iodine insufficiency, reinforcing the need of iodine supplementation during the prenatal period. However, the present study indicates that just one third of the commercially available dietary supplements currently used by Brazilian pregnant women contain the internationally recommended daily iodine intake.

Is there any effect of the treatment on MVP in patients with hypothyroidism and hyperthyroidism?

Yildiz Okuturlar[1], Aliye Soylu[2], Enver Tekin[1], Meral Mert[3], Serdal Cakmak[2], Ozlem Harmankaya[1] & Abdulbaki Kumbasar[1]
[1]Department of Internal Medicine, Bakirkoy Dr Sadi Konuk Education and Research Hospital, Istanbul, Turkey; [2]Department of Gastroenterology, Bakirkoy Dr Sadi Konuk Education and Research Hospital, Istanbul, Turkey; [3]Endocrinology and Metabolism, Bakirkoy Dr Sadi Konuk Education and Research Hospital, Istanbul, Turkey.

Introduction
In this study, we aimed to reveal the mean platelet volume (MPV) change with treatment in patients with hypothyroidism and hyperthyroidism.
Materials and methods
Two groups were retrospectively evaluated as 200 patients (21 male, 179 female) with hypothyroidism and 200 patients (26 male, 174 female) with hyperthyroidism. Before and after treatment in the outpatient follow. MPV values were compared.
Results
There is significant difference between MPV values before (8.8fL(6.1–12.1), 8.78fL (6.7–13)) and after (9.1fL (7–14), 9fL(6–12)) treatment in hypothyroidism and hyperthyroidism groups respectively and also MPV values increased in both groups after treatment ($P=0.001$).
Conclusion
The reason for the changes in MPV in our study can be explained in terms of the effect of the treatment on inflammatory period.

Triiodothyronine is independently associated with metabolic syndrome in euthyroid middle-aged subjects

Hye Jeong Kim[1], Hyeong Kyu Park[1], Dong Won Byun[1], Kyoil Suh[1], Myung Hi Yoo[1], Jae Hyeon Kim[2], Yong-Ki Min[2], Sun Wook Kim[2] & Jae Hoon Chung[2]
[1]Soonchunhyang University Hospital, Soonchunhyang University College of Medicine, Seoul, Republic of Korea; [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

Background
Recent studies have shown associations of thyroid hormone levels with metabolic syndrome (MetS) among euthyroid individuals, though there have been some inconsistencies. We evaluated the relationships between thyroid hormones and MetS in euthyroid middle-aged subjects in a large cohort.
Methods
Retrospective analysis of 13 496 euthyroid middle-aged subjects who participated in comprehensive health examinations was performed. Subjects were grouped according to TSH, total triiodothyronine (T_3), total thyroxine (T_4), and T_3–T_4 ratio quartile categories. We estimated the odds ratios (OR) for MetS according to thyroid hormone quartiles using logistic regression models, adjusted for potential confounders.
Results
Twelve percent ($n=1664$) of the study subjects had MetS. Higher T_3 levels and T_3– T_4 ratio were associated with unfavorable metabolic profiles, such as higher BMI, systolic and diastolic BP, triglycerides, fasting glucose and HbA1c, and lower HDL cholesterol. The proportion of participants with MetS increased across the T_3 quartile categories (P for trend <0.001) and the T_3–T_4 ratio quartile categories (P for trend <0.001). The multivariate-adjusted OR (95% CI) for MetS in the highest T_3 quartile group was 1.249 (1.020–1.529) compared to the

lowest T_3 quartile group, and that in the the highest T_3–T_4 ratio quartile group was 1.458 (1.141–1.863) compared to the lowest T_3–T_4 ratio quartile group, even after adjustment for sex, age, body fat percentage, smoking, and HOMA-IR.
Conclusions
Serum T_3 levels and T_3–T_4 ratio are independently associated with MetS in euthyroid middle-aged subjects. Longitudinal studies are needed to define this association and its potential health implications.

Hypothyroidism related to blocking TSH receptor antibodies after allogenic haematopoietic stem cell transplantation

Kanza Benomar[1], Catherine Massart[2], Leonardo Magro[1], Anne Sophie Parent[1], Michèle D'Herbomez[1], Ibrahim Yacoub-Agha[1], Jean Louis Wemeau[1] & Marie Christine Vantyghem[1]
[1]Department of, Endocrinology and Metabolism, Biology, Blood Diseases, Lille University Hospital, Lille, France; [2]Department of Biochimy and Hormonology, Rennes University Hoispital, Rennes, France.

Besides total body irradiation and immunosuppressive drugs, massive iodine supply and stress might participate in thyroid dysfunction, described in 50% of allo-HSCT. We report on a rare case of hypothyroidism related to blocking TRAb. A 55-year-old man was admitted for asthenia, dyspnea, myalgia, 8 kg-weight gain, constipation, dry skin, hoarse voice, recent deafness. He had moon face without any goiter. He had received, 1 year before, an unrelated 9/10 human leukocyte antigen matched allo HSCT for acute myeloid leukemia after chemotherapy including antilymphocyte serum and had achieved full female donor chimerism. He developed an acute graft-vs-host disease (GvHD) grade II 1 month post-transplantation treated with ciclosporine. Laboratory tests showed high blood cholesterol (3.53 g/l–*n*: 1.5–2.4), triglycerides (2.70 g/l–*n*: 0.3–1.50), CPK (2623U/l–$n<195$), TSH (99 mUI/ml; $n>3.5$) levels as well as antithyroperoxidase (179 U/ml; $n>5$) and TSH receptor antibodies (TBII: 102 U/l; $n<1$) levels with undetectable FT_4 and anti-thyroglobulin antibody. The functional study of TBII confirmed high blocking (TRAbs 92%; $n<30$) and low stimulating (TSAbs 58%; $n<125$) activities. The immunophenotype showed a lymphopenia with an increased CD4+(48.7%; *n*:38–46) and low CD8+(28%; *n*: 31–40) percentages. Indeed, the development of autoimmune hypothyroidism is frequent post allo-HSCT and requires regularly monitoring of TSH, given the difficulty of diagnosis in patients whose complaints can easily be attributed to the causal disease or GvHD. Immunological dysregulation during T-cell engraftment may also favour hyperthyroidism, sometimes preceded by a hypothyroid episode related to blocking TBII, called immune reconstitution syndrome. This rare and delayed syndrome has been reported in children post allo-HSCT (Sinha Thyroid 2013) or HIV (Sheikh AIDS 2014) treatment and coincided with a rapid expansion in naïve and total CD4. TSAbs and TBAbs have been shown to have similar characteristics (high affinity and similar binding epitopes on the TSH-R; morgenthaler JCEM 2007). The occurrence of 'switching' emphasizes the need for careful patient monitoring and management.

Prevalence of hypothyroidism in a large series of adult thalassemic patients

Raffaella Radin[1], Leila Danesi[1], Alberto Ambrogio[1], Elena Cassinerio[2], Laura Zanaboni[2], Maria Domenica Cappellini[2], Marina Baldini[2], Maurizio Poggi[3], Chiara Ottaviani[3], Vincenzo Toscano[4], Marco Zavattaro[5], Francesco Cavagnini[6], Luca Persani[7] & Massimo Scacchi[8]
[1]IRCCS, Istituto Auxologico Italiano, Milan, Italy; [2]Cà Granda Foundation Ospedale Maggiore Policlinico, Milan, Italy; [3]II Faculty of Medicine, Sapienza University of Rome, Rome, Italy; [4]Sapienza, University of Rome, Rome, Italy; [5]Università del Piemonte Orientale 'A. Avogadro', Novara, Italy; [6]Istituto Auxologico Italiano IRCCS, Neuroendocrinology Research Laboratory, Cusano Milanino, Italy; [7]Department Medical Sciences and Community Health, IRCCS Istituto Auxologico Italiano, University of Milan, Milan, Italy; [8]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy.

Hypothyroidism has been traditionally described as a frequent endocrine complication of thalassemic children: in these patients hypothyroidism is mainly of primary origin and not linked to autoimmunity (Mariotti *et al*., Pediatr Endocrinol Rev 2011). Fewer data are available on the prevalence and nature of this complication in adult age thalassemia. Therefore, we elected to evaluate thyroid function and autoimmunity in a large series of adult patients.
Study
Ninety-five adult thalassemic subjects (48 women and 47 men, mean age 38.1 ± 6.9 years) underwent assessment of thyroid function (fT_3, fT_4 and TSH) and thyroid autoimmunity (anti-thyroid peroxidase and anti-thyroglobulin antibodies). Serum ferritin was also measured in all patients, who were regularly taking iron-chelating drugs. Hormone deficiencies other than hypothyroidism were adequately replaced.
Results
Thirty-one patients (32.6%), 16 men and 15 women, aged 39.5 ± 6.7 years, turned out to be affected by hypothyroidism. Two of them had previously undergone-thyroid surgical removal for multinodular goitre and carcinoma, respectively. The stratification by age of the other hypothyroid subjects disclosed a prevalence of 25% (2/8) among those aged 20–30, 27% (10/37) among those aged 30–40, and 36% (16/44) among those aged 40–50. No hypothyroid patients displayed anti-TPO or anti-TG antibodies. No cases of secondary hypothyroidism were observed. Mean serum ferritin was not significantly different between hypothyroid and euthyroid thalassemic subjects (1067.7 ± 664.5 vs 868.0 ± 743.5 ng/m, NS, respectively).
Comment
Hypothyroidism, primary in all cases, was highly prevalent in our series, being present in one third of the patients. This endocrine complication was equally distributed among genders and its prevalence appeared to progressively increase with age. Since measurement of serum ferritin expresses an estimation of the current degree of iron overload and not its evolution within the clinical history of patients, our data cannot rule out a contribution of secondary hemosiderosis to the pathogenesis of hypothyroidism in thalassemia.

Thyroidectomy: analysis of 184 cases in a single centre

Gema López Gallardo, Francisco Javier Gómez Alfonso, Julia Silva Fernández, Álvaro García Manzanares, Inés Rosa Gómez & María López Iglesias
Mancha Centro General Hospital, Alcázar de San Juan, Spain.

Aim
To evaluate whether differences exist in terms of patient, radiological, tumour characteristics and surgical complications between malignant and benign thyroidectomy.
Materials and methods
184 correlatives cases of thyroidectomy during the period from October 2011 to October 2013 are analysed. Patient, ultrasound, tumour and complication characteristics are compared. Categorical data are reported as percentages. Characteristics between the two groups are compared using a Student's *t*-test for continuous variables and a Fisher's exact test or a χ^2 test for categorical variables.
Results
A female: male ratio of 5:1 (157 women: 28 men) is found with eight malignant cases (28.6%) in men and 35 (22.3%) in women. Malignancy is associated with family cancer history (RR: 0.3 (0.183–0.143)), and larger tumour size with benignity. Benignity nodules are 1, 21 cm larger than malignity nodules (*P*: 0.00 (0.474–1.567). No statistically significant differences in terms of age, mean operative time, mean postoperative hospital stay and surgical complications are found.
Conclusions
The nodule size is not an accurate predictor of thyroid cancer. Malignant thyroidectomy is not associated with more surgical complications or post-operative hospital stay.

IL-2, IL-4, IL-5, IFN-γ and TNF-α levels in Turkish patients with Hashimoto's thyroiditis

Guzin Fidan Yaylali[1], Bedia Guleryuz[2], Fulya Akin[1], Sebahat Turgut[3], Senay Topsakal[1], Melek Tunc Ata[3] & Mukaddes Mengen Dalyanoglu[3]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Pamukkale University, Denizli, Turkey; [2]Department of Internal Medicine, Faculty of Medicine, Pamukkale University, Denizli, Turkey; [3]Department of Physiology, Faculty of Medicine, Pamukkale University, Denizli, Turkey.

Background
Hashimoto's thyroiditis (HT) is one of the most common autoimmune thyroiditis that characterised by lymphocytic infiltration and thyroid hormonal disturbances. Genetic and environmental factors play a role in etiology of the disease, but genetic factors are most common. In this study, we investigated the association between Hashimoto's thyroiditis and IL-2, IL-4, IL-5, TNF-α and IFN-γ levels.
Methods
We performed a case–control study that included 139 cases with HT (50 euthyroid, 50 subclinical hypothyroid, 39 overt hypothyroid patients) and 50 healthy control. Subjects were collected from Endocrinology Clinic of Pamukkale University in Turkey. Serum levels of glucose, insulin, PTH, Ca, phosphorus (P), alkaline phosphatase (ALP) were measured and IL-4, IL-5, TNF-α, IFN-γ analysis were performed with ELISA.
Results
IL-2, IL-4, TNF-α and IFN-γ levels were significantly higher in Hashimoto's thyroiditis patients, there were no significant differences between the groups regarding IL-5 levels. There were no significant differences detected in PTH, ALP and Ca levels.
Conclusion
Because of the HT is an inflammatory disease significantly high IL-2, IL-4, TNF-α and IFN-γ level were observed in HT. Practitioners should take into consideration IL-2, IL-4, TNF-α and IFN-γ levels in HT diagnosis. These inflammatory markers may have an important role in the pathogenic pathway in HT.

Descriptive analysis of the histopathological findings of a series of 1567 thyroidectomies

Dulce Ma Calderón[1], Manuel Delgado[2], Enrique Castro[3], Jose Joaquín Alfaro[4], Gema López[5], José López[3] & Jaime Aranda[1]
[1]Hospital Virgen de la Luz, Cuenca, Spain; [2]Hospital General de Ciudad Real, Ciudad Real, Spain; [3]Hospital Virgen de la Salud, Toledo, Spain; [4]Hospital General de Albacete, Albacete, Spain; [5]Hospital La Mancha Centro, Alcázar de San Juan, Spain.

Introduction
We wanted to analyse the pathology results of thyroidectomies performed in the hospitals of Castilla La Mancha (Spain) between the years 2010 and 2013, inclusive.
Material and methods
A retrospective, multicentre, descriptive study of the histopathological results of the 1567 thyroidectomies performed in the hospitals of the eight health districts in our region between the years 2010 and 2013.
Results
The histopathological results were benign in 1124 cases (colloid goiter/adenomatous 42.7%, follicular adenoma 9.7%, Hurthle cell adenoma 2.7%, Graves' disease 2.6%, lymphocytic thyroiditis 7.7%, thyroiditis de Quervain 0.1%, thyroid cyst 0.4%, normal thyroid 0.4%, and other 5.6%) and malignant in 402 cases (papillary microcarcinoma 7.5%, macropapillary carcinoma 14.9%, follicular 1.5%, medullar 1.3%, anaplastic carcinoma 0.1%, parathyroid carcinoma 0.1%, and other 0.3%), and unknown in 2.6% of cases.
Conclusions
During the years 2010–2013,1567 thyroidectomies were performed in the hospitals of Castilla La Mancha. In 1124 cases (71.7%) the histopathology was benign and in 402 cases (25.6%) malignant. The most common tumour was papillary carcinoma.

Sensitivity and specificity of thyroid cytology in the diagnosis of malignancy: results of a series of 1567 thyroidectomies

Dulce Ma Calderón[1], Sandra Herráiz[2], Julia Sastre[3], Abel González[4], Belén Fernández[4], Miguel Angel Valero[5] & Miguel Aguirre[4]
[1]Hospital Virgen de la Luz, Cuenca, Spain; [2]Hospital Universitario de Guadalajara, Guadalajara, Spain; [3]Hospital Virgen de la Salud, Toledo, Spain; [4]Hospital General de Ciudad Real, Ciudad Real, Spain; [5]Hospital Nuestra Sra. del Prado, Talavera de la Reina, Spain.

Introduction
Sensitivity and specificity of thyroid cytology in our series of thyroidectomies were evaluated.
Material and methods
A retrospective, multicentre study of 1567 thyroidectomies performed in the eight hospitals of Castilla La Mancha (Spain) during the years 2010–2013.
Results
The cytological results were benign in 37.6% of cases, malignant or suspicious of malignancy in 17.3% (10 and 7.3% respectively). In 4.1% of cases the cytology was atypical or indeterminate and in 12.5% follicular proliferation/follicular lesion. There were 8% non-diagnostic cytologies. In patients whose prequirúgical FNA was nondiagnostic, 20.6% had a carcinoma. Overall, 25.6% of patients had thyroid carcinoma. The sensitivity and specificity of suspicion of malignancy or malignant thyroid cytology for the diagnosis of malignancy was 75.8 and 90.3% respectively. There were 3.5% false positive and 4.5% false negative results.
Conclusions
Thyroid cytology is the diagnostic technique of choice for the study of thyroid nodule. The results in terms of sensitivity, specificity and nondiagnostic cytology in our series are acceptable.

EP1041

Surgical treatment of thyroid disease: descriptive analysis and histopathology of a series of 92 cases

Dulce Ma Calderón[1], Jaime Aranda[1], José Mondéjar[2], Mubarak Alramadan[1], David Martín[1] & José Pérez[1]
[1]Hospital Virgen de la Luz, Cuenca, Spain; [2]Universidad de Castilla La Mancha, Cuenca, Spain.

Introduction
Retrospective study of patients undergoing thyroid surgery at the Hospital Virgen de la Luz, Cuenca (Spain) during the years 2010–2013.
Material and methods
We evaluated data of 92 patients basically with nodular thyroid disease, who were studied and treated in our hospital.
Results
Our series is made up of 92 patients (25% men and 75% women) with an average age of 52 years. The most common form of presentation (47.8%) was recent emerging thyroid nodule, having less than a year. In 19 cases (20.6%) it was found incidentally, mainly by ultrasound. In most cases, 58 (63%), monitoring prior to surgery was $\leq$1 year. Ultrasound findings showed mostly mixed multiple nodules (32.6%). The results of cytology were nondiagnostic in 7.6%, 35.9% benign, atypical 2.2%, 9.8% follicular proliferation, suspicious of malignancy 6.5%, and 10.9% malignant. In 25 cases (27.1%) was not done FNA. In 86.9% thyroid function was normal. Total thyroidectomy was performed in 78.3%, in 20.6% hemithyroidectomy and bilateral subtotal thyroidectomy in 1.1%. Surgery was performed in 65% of cases by the most experienced surgeon. The pathology was benign in 70.6% and malignant in 29.3% cases.
Conclusions
The most common presentation in our thyroid disease amenable to surgical treatment is emerging thyroid nodule. In 20.6% of cases it was an incidental finding. Total thyroidectomy was the technique of choice (78.3%). 29.3% of the cases presented a thyroid carcinoma.

Iodine nutritional status among adolescent girls in Uttarakhand State, India

Umesh Kapil
All India Institute of Medical Sciences, New Delhi, India.

Introduction
Iodine is an essential micronutrient. Iodine deficiency (ID) among adolescent girls could lead to ID amongst the newborns as they are the future mothers. Uttarakhand state is a known endemic region for ID.

Objective
The present study was conducted with an objective to assess the iodine nutritional status amongst adolescent girls in districts: Udham Singh Nagar (USN), Nainital (N), and Pauri (P) of Uttarakhand state.
Methods
In each district, 30 clusters (schools) were identified by utilising population proportionate to size (PPS) cluster sampling methodology. In each school, 60 girls (12–18 years) attending the schools were included. A total of 5430 girls from USN (1823), N (1811), and P (1796) were studied. Clinical examination of thyroid of each girl was conducted. From each cluster, on the spot urine and salt samples were collected from 20 girls.
Results
Total goitre rate (TGR) was found to be 6.8% (USN), 8.2% (N), and 5.6% (P) respectively. Median urinary iodine concentration (UIC) levels were 250 μg/l (USN), 200 μg/l (N), and 183 μg/l (P) indicating adequate iodine status amongst the study population. The percentage of families consuming salt with iodine content of <15 p.p.m. were 59.5 (USN), 44.0 (N), and 46.7 (P) percent.
Conclusion
Findings of the present study documented that adolescent girls had adequate iodine nutritional status in three districts of Uttarakhand.

Ultrasonographical features and cytological findings of thyroid nodules in patients with Hashimoto's thyroiditis

Didem Ozdemir[1], Fatma Dilek Dellal[2], Husniye Baser[2], Aylin Kilic Yazgan[3], Seyda Turkolmez[4], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Department of Endocrinology and Metabolism, School of Medicine, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Ataturk Education and Research Hospital, Ankara, Turkey; [3]Department of Pathology, Ataturk Education and Research Hospital, Ankara, Turkey; [4]Department of Nuclear Medicine, School of Medicine, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey.

Introduction
It is unclear whether ultrasonographic (US) findings and fine-needle aspiration biopsy (FNAB) results of nodules accompanied with Hashimoto's thyroiditis (HT) are affected by the presence of thyroiditis or not. In this study, we compared US features and cytological results of nodules in patients with and without HT.
Methods
Patients who underwent FNAB in our clinic were evaluated prospectively. Nodules in patients with and without HT were categorised as groups 1 and 2 respectively. Cytological results were classified as benign, atypia of undetermined significance/follicular lesion of undetermined significance (AUS/FLUS), follicular neoplasia suspicion, malignancy suspicion, malignant, and nondiagnostic.
Results
181(35.5%) patients with HT and 329 (64.9%) without HT were included in the study. There were totally 800 nodules, 288 (36%) in group 1 and 512 (64%) in group 2. Ultrasonographically, presence of hypoechoic halo and marginal irregularity were similar in two groups ($P=0.12$ and $P=0.20$ respectively). Microcalcification was present in 11.8% of nodules in group 1 and 20.3% in group 2 ($P=0.002$). Macrocalcification was detected in 19.5 and 23.8% of nodules in groups 1 and 2 respectively ($P=0.01$). 30.6% of nodules in group 1 was hypoechoic, 66.3% was isoechoic, and 3.1% was hyperechoic. In group 2, 40.2% was hypoechoic, 58.4% was isoechoic, and 1.4% was hyperechoic ($P=0.01$). Solid texture was observed in 78.1% of nodules in group 1 and 62.3% of nodules in group 2 ($P<0.001$). Cytological results were as follows; in group 1, 78.1% benign, 2.4% AUS/FLUS, 0.3% malignancy suspicion, 1.7% malignant, and 14.6% nondiagnostic; in group 2, 81.4% benign, 2.3% AUS/FLUS, 0.4% follicular neoplasia suspicion, 1.0% malignancy suspicion, 1.4% malignant, and 13.5% nondiagnostic ($P=0.78$).
Conclusion
Suspicious US features such as microcalcification, macrocalcification and hypoechoic appearance are found with a lower prevalence in nodules accompanying HT. Cytological results were similar in patients with and without HT.

EP1044

Usefulness of the assessment of thyroid blood flow as a predictor of relapse of Graves' disease

Agustín Angel Merchante[1], Lourdes García-Blasco[2], Susana Pérez[1], Amparo Fabra[2], Pilar Cubells[1] & Carlos Sánchez[2]
[1]University General Hospital of Castellón, Castellón de la Plana, Spain; [2]University General Hospital of Valencia, Valencia, Spain.

Objective
We investigated the clinical usefulness of thyroid blood flow measurement by colour-flow Doppler ultrasonography in predicting relapse of Graves' disease (GD).
Patients and methods
In 30 euthyroid GD patients, (eight males and 23 females), aged 17–68 years (mean 43.8 ± 12.8), after at least 1 year of treatment with anti-thyroid drug (ATD) and just before its withdrawal, we evaluate with colour-flow Doppler ultrasonography the colour-flow Doppler mapping (the amount of flow was classified on four point scale, 0–3) and we calculate, in pulsed Doppler mode, the peak systolic velocity in the inferior thyroid artery (ITA–PSV). All ultrasound examinations were performed by the same endocrinologist expert in thyroid ultrasound using a duplex Doppler apparatus (Logic Scan 64, B-Side Medical System) with an 8 MHz linear array probe. Clinical data was collected and measurements of TSH, serum free thyroxine, and TSH receptor antibodies were performed. GD relapse was defined as an increase in the serum level of FT_4 to above the normal upper range and suppression of serum TSH in 18 months after removal of ATD. Mann–Whitney *U* test and Fisher's exact test were used for statistical analysis. The sensitivity and specificity were calculated using a 2×2 table.
Results
In relapse group ($n=14$, 47%) ITA–PSV was significantly higher than in the non-relapse group ($n=16$), (48.5 ± 17.7 cm/s vs 32.6 ± 9.5 cm/s, $P=0.01$). For prediction of GD relapse, the best cut-off value was 35 cm/s for ITA–PSV. Sensitivity was 71%, specificity 87%, positive predictive value 83%, and negative predictive value 78%. All patients with grade 3 in colour-flow Doppler mapping ($n=3$) had an early relapse of GD (before the first 6 months).
Conclusions
Colour-flow Doppler mapping study and measurement of ITA/PSV in euthyroid GD patients immediately before withdrawal of ATD may assist in the prediction of GD relapse.

The effect of anti-TNF therapy on thyroid function in patients with inflammatory bowel disease

Stavroula A Paschou[1], Fotios Kothonas[2], Alexandros Myroforidis[2], Vasiliki Loi[1], Olympia Karayianni[1], Androniki Poulou[2], Konstantinos Goumas[2] & Andromachi Vryonidou[1]
[1]Department of Endocrinology and Diabetes, Hellenic Red Cross Hospital, Athens, Greece; [2]Department of Gastroenterology, Athens, Greece.

Introduction
Inflammatory bowel disease (IBD) has been associated with various disorders of thyroid function. Many of these patients are now treated with biological agents targeting on TNF-a.
Aim
To investigate thyroid function in patients with IBD and the potential effect of anti-TNF therapy.
Patients and methods
We studied 41 patients with IBD (25M/16F, 36.4 ± 11 years), without any known thyroid disorder. Eighteen patients (9M/9F, 33.6 ± 8.8 years) were on anti-TNF therapy for more than 1 year, while 23 patients (16M/7F, 38.7 ± 12.5 years) were treated with azathioprine and mesalazine (Aza/Mes). Nine patients from the second group were then treated with anti-TNF and studied again 6 months later. We assessed thyroid function by measuring T_3, FT_4, TSH, anti-TG, and anti-TPO levels.
Results
One patient presented with clinical and one with subclinical hyperthyroidism. Thyroid auto-antibodies were positive in 12.2% (one anti-TG and four anti-TPO). Patients from the anti-TNF group had reduced levels of FT_4 (1.09 ± 0.15 ng/dl vs 1.38 ± 0.9 ng/dl, $P=0.042$), with no differences in T_3 levels (1.8 ± 0.28 nmol/l vs 2.02 ± 1.7 nmol/l) and TSH (1.76 ± 0.8 mIU/ml vs 1.58 ± 0.9 mIU/ml, $P>0.05$). The percentage of patients with positive thyroid auto-antibodies were lower in the

anti-TNF group, 5.6% (1/18) vs 17.4% (4/23), but without statistical significance ($P>0.05$). In patients who were treated for 6 months with anti-TNF, we found statistically significant reduction in FT_4 (1.24 ± 0.26 ng/dl vs 1.11 ± 0.16 ng/dl, $P=0.048$), without changes in T_3 (1.5 ± 0.43 nmol/l vs 1.8 ± 0.2 nmol/l) and TSH (1.82 ± 1.28 mIU/ml vs 1.68 ± 0.96 mIU/ml), in all comparisons $P>0.05$. There was no change regarding thyroid auto-antibodies.
Conclusions
Patients with IBD showed high percentage of thyroid autoimmunity, while the functional thyroid disorders presented were clinical and subclinical hyperthyroidism. Treatment with anti-TNF resulted in reduced levels of FT_4, without changes in T_3, TSH, and thyroid auto-antibodies.

Hypo- and hyperthyroidism: causes of hepatic dysfunctions

Lencu Codruta[1], Iacob Adrian[1], Lencu Monica[2] & Georgescu Carmen[1]
[1]Department of Endocrinology, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania; [2]4th Medical Clinic, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania.

Background and aims
The aim of this study is to analyse the serum markers of liver function and the morphological hepatic changes (by ultrasound) in hypo- and hyperthyroidism.
Methods
The study included 59 patients with hypothyroidism: subclinical disease 14 patients and clinically manifest disease 45 patients, and 30 patients with hyperthyroidism. All patients underwent serum liver function tests: alanine aminotransferase (ALT), aspartate aminotransferase (AST), total bilirubin (Bt), gamma-glutamyl transpeptidase (GGTP), alkaline phosphatase (SAP), and ultrasound monitoring of the liver. The results were compared to those of a control group of 30 patients with the same age and sex parameters.
Results
In hypothyroidism, increased ALT levels were found in 35.60% of the patients, and nonalcoholic fatty liver disease (NAFLD) was present in 37.30% of the patients; there was an inversely proportional linear correlation with a high statistical significance between free T_4 vs ALT, free T_4 vs AST and a directly proportional correlation between TSH vs ALT, TSH vs AST, and TSH vs GGTP. In hyperthyroidism, the prevalence of liver test changes in the patients was as follows: ALT and AST 23.3%, Bt 36.6%, GGTP 36.6%, SAP 53.3%; NAFLD 33.3%; the linear regression model evidenced a directly proportional correlation between free T_4 and the liver parameters, with a significance for Bt, SAP, and GGTP.
Conclusions
It is recommended to monitor the liver function of all patients with thyroid dysfunctions at the time of diagnosis (pre-therapy) and during the evolution of the disease under therapy.

TPOAb as an autoimmune response or index of thyroid hypofunction in breast cancer?

Peter Smyth[1,2], E W M McDermott[1] & N J O'Higgins[1]
[1]UCD, Dublin, Ireland; [2]NUI (G), Galway, Ireland.

The observed association between thyroid disorders and breast cancer has provoked many investigations. One area where there is some, although far from universal, agreement is the finding of an increased prevalence of anti-thyroid autoantibodies in breast cancer patients compared to controls. Whether this is a feature of a generalised autoimmune response to breast cancer, or provoked by the enzyme thyroid peroxidase acting as an autoantigen, remains unclear. In this study we looked at thyroid antibodies in terms both of their positivity, either detectability or elevation, and their relationship to serum TSH in patients with breast cancer ($n=907$) compared to 179 postmenopausal controls. TPOAb detectability was defined as >2.0 and <20.0 kIU/l; and positivity >20.0 kIU/l. TPOAb was undetectable (≤ 2.0 kIU/l in 82.1% of controls compared to 51.8% of breast cancers; $P<0.001$). Detectable TPOAb values were (controls 3.9%; breast cancer 24.5%; $P<0.001$); elevated values (controls 14.0%; BrCa 22.9%; $P<0.01$). In the case of elevated TPOAb serum TSH was >4.0 mU/l in 61.5% of BrCa compared to 20.0% of controls. Interestingly, both TPOAb positivity and detectability were increased in BrCa patients (33.1 and 24.0%), even when TSH was within the upper 50% of the reference range (2.1–4.0 mU/l). Comparable values for controls were 11.0 and 4.8% respectively ($P<0.001$ in both cases). Thus a tendency towards higher TSH applied to patients with BrCa who had either detectable or elevated TPOAb. This finding suggests that even the marginally detectable TPOAb levels described in this study may represent more than so called 'assay noise'. They indicate, on the basis of serum TSH distribution, that TPOAb positivity may be associated with a subtle thyroid dysfunction which we and others have suggested may be beneficial in terms of breast cancer outcome.

Menstrual disturbances in thyroid dysfunction

Gökçen Güngör[1], Zeliha Hekimsoy[2], Derya Öz[2], Pinar Alarslan[2], Ogün Hatiboglu[2] & Bilgin Özmen[2]
[1]Department of Internal Medicine, Medical Faculty, Celal Bayar University, Manisa, Turkey; [2]Division of Endocrinology and Metabolism, Department of Internal Medicine, Medical Faculty, Celal Bayar University Manisa, Turkey.

Introduction
Thyroid hormones play an important role in achieving and maintaining reproductive functions. Thyroid dysfunction affects the menstrual cycle and often leads to menstrual irregularity. We prospectively investigated untreated female patients presenting to our Endocrinology and Internal Medicine outpatient clinics.
Material and methods
All the patients were of reproductive age and were newly diagnosed with thyroid dysfunction. After a detailed history (including menstrual history) was taken, TSH, fT_3, fT_4, anti-Tg, and anti-TPO levels were measured and thyroid ultrasound was performed in all. Thyroid functional status was determined by measurement of TSH, fT_3, and fT_4. Patients were subdivided into the following groups: overt hypothyroidism (54 patients), subclinical hypothyroidism (106 patients), overt hyperthyroidism (50 patients), subclinical hyperthyroidism (55 patients), and euthyroid patients (Hashimoto's thyroiditis/nodular goiter, 220 patients). Women with normal routine laboratory and imaging studies were classified as controls. Thus, 485 patients and 108 healthy controls were evaluated.
Results
Among patients with overt hypothyroidism, the most frequent menstrual disorders were hypermenorrhea, menorrhagia, oligomenorrhea, and polymenorrhea. Hypermenorrhoea was significantly more common (33.3%) than in controls (5.6%) ($P<0.05$). Among hypothyroid patients, hypermenorrhoea was more common (35%) in those with severe hypothyroidism (TSH >50 μIU/ml) than in those (16.5%) with mild hypothyroidism (TSH 5–10 μIU/ml) ($P<0.05$). The prevalence of menstrual disturbances in the other groups of thyroid dysfunction patients was not significantly different than that of controls.
Conclusion
Thyroid function influences the menstrual cycle and affects reproductive activity, fertility, and pregnancy outcomes. For these reasons, investigation of thyroid function in women with abnormal menstrual activity should be performed.

Brain, mood and cognition during treatment initiation in mild hypothyroidism

Eva Maria Quinque[1], Stefan Karger[2], Katrin Arélin[1,3], Matthias L Schroeter[1,4], Jürgen Kratzsch[5] & Arno Villringer[1,4]
[1]Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany; [2]Clinic for Endocrinology and Nephrology, University Hospital, Leipzig, Germany; [3]Leipzig Research Center for Civilization diseases, University of Leipzig, Leipzig, Germany; [4]Clinic for Cognitive Neurology, University Hospital Leipzig, Leipzig, Germany; [5]Institute for Laboratory Medicine, Clinical Chemistry and Molecular Diagnostics, University Hospital Leipzig, Leipzig, Germany.

In the present study, we investigated neural alterations in newly diagnosed patients with mild hypothyroidism due to Hashimoto's thyroiditis alongside mood and cognition as well as changes with treatment initiation. Animal studies and first studies of human brain metabolism using radioactive tracers suggest neural involvement in affective and cognitive symptoms of hypothyroidism. Here, we introduce non-invasive magnetic resonance imaging (MRI) techniques that allow the analysis of both brain structure and functional connectivity between brain regions and may thus help identifying neural correlates of hypothyroid symptoms. Nine patients and nine healthy matched control subjects (mean age 42 ± 5 vs 38 ± 8 years; one male each) underwent structural and resting-state functional 3T MRI scanning and comprehensive neuropsychological testing before and 3 months after treatment initiation. Voxel-based-morphometry was used to investigate grey matter density and resting-state functional MRI to analyse the connectivity of brain regions known to be involved in hypothyroidism such as the hippocampus, the amygdala and the anterior cingulate cortex. Treatment restored thyroid hormone levels to the reference range, though the overall effect was small (mean $\pm$ s.d. TSH (mU/l): pre 6.1 ± 1.2; post 3.4 ± 1.2). Patients reported significantly higher symptom load, reduced well-being and mental health compared to the control group before but not after treatment initiation. We did not find cognitive impairment or neural alterations even before treatment and no change with treatment. The observed mood alterations could not be related to brain structure or function. The attempt to relate initial treatment effects in mild hypothyroidism to changes in brain structure and function did not produce positive results. Given the small sample size and the mildness of the hypothyroidism, we cannot exclude a false negative finding regarding cognition and brain data. We still want to share the data to avoid publication bias and have thus made them available here for use in meta-analyses: http://neurovault.org/collections/169/.

Thyroid function in healthy pregnant women in iodine excessive area

Yoon Young Cho, Dong Ik Cha, Jae Hyeon Kim, Jae Hoon Chung & Sun Wook Kim
Samsung Medical Center, Seoul, Republic of Korea.

Background/aims
Maternal subclinical hypothyroidism has been reported to be associated with risks of adverse pregnancy outcomes such as fetal loss and possible fetal neurodevelopmental deficit. However, current guidelines seem to overestimate subclinical hypothyroidism in pregnant women in some regions. Therefore, we aim to evaluate trimester-specific reference range of serum TSH for pregnant women in Korea and whether maternal subclinical hypothyroidism affects perinatal outcomes.
Methods
This is a prospective, observational study conducted in Samsung Medical Center between April 2012 and September 2013. Total 348 pregnant women who visited obstetrics for antenatal check-up were enrolled. Women with previous thyroid diseases or medications, positive for autoantibodies, multifetal gestation were excluded.
Results
Mean values of serum TSH in the first, second and third trimester were 1.22, 1.65 and 1.69 mIU/l respectively. Reference intervals (2.5%, 97.5%) of serum TSH in each trimesters as follows; 0.04–4.07, 0.09–4.85 and 0.32–6.07 mIU/l, respectively. According to current guidelines, 25.5% of subjects in the first trimester were diagnosed as subclinical hypothyroidism, 12.9% in the second trimester and 12.3% in the third trimester, respectively. Additionally, perinatal outcomes of these women were not different with that of subjects with normal TSH value.
Conclusions
Upper limit of reference value of serum TSH is much higher in Korean pregnant women than that of current guidelines and needs to be modified. Perinatal outcomes are favorable in pregnant women with subclinical hypothyroidism and further studies are needed to clarify long-term neurodevelopmental outcomes of offspring.

Seaweed derived gaseous iodine: a source of iodine intake in coastal communities?

Peter Smyth[1,2], Robert Burns[2], Michael Casey[1], Maria Andersson[4], Karen Mullan[3] & Colin O'Dowd[1]
[1]NUI(G), Galway, Ireland; [2]UCD, Dublin, Ireland; [3]QUB, Belfast, UK; [4]ETH, Zurich, Switzerland.

This communication tests the hypothesis that iodine (I2) gas or iodine oxides released from seaweeds previously shown to enhance atmospheric iodine adjacent to seaweed hotspots, may through being inspired by respiration, supply a significant fraction of daily iodine requirements. This could assume importance in a country such as Ireland where iodised salt availability is $<5\%$. Iodine intake was assessed by measuring urinary iodine (UI) excretion using a dry ashing technique with Sandell Kolthoff colorimetry. Urine samples were obtained from schoolchildren ($n=167$) and adult ($n=481$) populations living in coastal areas, including those residing beside a seaweed hot spot, and inland areas of Ireland. Despite dietary iodine intake not varying significantly between inland and coastal communities, the median UI values in the inland areas was 72.5 μg/l (range 58–102 μg/l); coastal areas with limited seaweed growth 70.8 μg/l; seaweed hot spot 145 μg/l. The % of individual readings suggestive of iodine deficiency (<50 μg/l) were greatest in inland areas 27.9 vs 14.3% in limited seaweed growth areas. The lowest proportion of UI values <50 μg/l (3.6%) was observed in the population living beside the seaweed hot spot. Not surprisingly, the greatest number of UI values >150 μg/l (45.6%) was observed in the seaweed hot spot region. In contrast, relatively few higher UI values (>150 μg/l) occurred in the other regions (range 3.6–11.6%). It is postulated that the most infrequent evidence of iodine deficiency recorded near seaweed hotspots may be the result of atmospheric iodine compensation for inadequate dietary iodine intake through respiration in coastal areas and may assist in maintaining normal thyroid function even when dietary intake is apparently deficient.

Percutaneous ethanol injection as a first line treatment of cystic thyroid nodules: experience after its introduction in a university hospital

Jordi L Reverter, Nuria Alonso, Isabel Ordoñez, Maribel Cuadrado, Lucia Cano, Dídac Mauricio & Manel Puig Domingo
Endocrinology and Nutrition Department. Germans Trias i Pujol University Hospital, Badalona, Spain.

Objectives
To evaluate the efficacy, safety and patient's pain perception of percutaneous ethanol injection treatment (PEIT) as an alternative to surgery in symptomatic thyroid cysts.
Patients and methods
Thirty consecutive patients (mean age: 46 ± 10 years; 82% women) with symptomatic thyroid cysts relapsed after drainage were included. In all cases, cytology prior to treatment, maximum cyst diameter and volume were determined. PEIT was conducted using the established procedure, and the volume of fluid removed and pain perceived by the patient were assessed. In each procedure, the volume of alcohol instilled was <2 ml. After follow-up, final cyst diameter and volume were determined and the persistence of symptoms was assessed by questionnaire.
Results
Mean symptom duration was 10 ± 20 months. All the cases had a benign cytology. A single session of PEIT was required to complete the procedure in 45% of patients two in 31% and three in 13%. Mean initial maximum cyst diameter was 3.5 ± 1.0 cm and mean extracted liquid volume 61 ± 36 ml. During PEIT, 39% of patients experienced virtually no pain, 43% mild pain and 17% moderate pain. No complications of PEIT were observed. After 9 ± 3 months follow-up, cysts were reduced more than 70% in volume in 86.3% of patients, more than 80% in 61.9% and more than 90% in 42%. Final mean maximum cysts diameter was 1.3 ± 0.6 cm. With respect to cosmetic complaints or local symptoms of compression, PEIT-treated patients presented an initial score of 22 ± 8 and 13 ± 5 after treatment ($P<0.05$) and 47% of cases reported a score of 10 (absence of symptoms).
Conclusions
In our experience, percutaneous ethanol injection has prove to be an effective, safe and well-tolerated first-line treatment of symptomatic thyroid cysts.

Soft gel capsule vs liquid thyroxine formulation at breakfast: the results of 'TITI' study

Ilenia Pirola, Anna Maria Formenti, Alessandra Cristiano, Linda Daffini, Elena Gandossi & Carlo Cappelli
Department of Clinical and Experimental Sciences, Endocrine and Metabolic Unit, Clinica Medica, University of Brescia., Brescia, Italy.

Levothyroxine (l-T_4) is the mainstay of treating hypothyroidism. Despite the 'classic' tablet formulation of l-T_4, pharmaceutical industries have recently introduced other formulations such as liquid and a soft gel capsule in a few countries. Recent studies have shown a better absorption of these formulations compared with the traditional tablet bypassing the pH-depending dissolution phase and less suffering the binding by sequestrants in the intestinal lumen. Our preliminary data of the 'TICO' study, a double-blind, placebo-controlled trial aimed to evaluate the efficacy of oral liquid l-T_4 assumed at breakfast, seems to demonstrate that oral liquid thyroxine makes no difference to the thyroid hormonal profile (TSH, fT_4 and fT_3) regardless assumed before or during breakfast. Based on these preliminary data, we have conducted the 'TITI' (Tirosint® vs Tiche®, Ibsa farmaceutici Italia) study in order to verify the thyroid hormonal profile of patients assuming l-T_4 in soft gel capsule during breakfast. We have enrolled 30 (25/5 female/male, 47.1 ± 11.9 years old) euthyroid patients on stable liquid l-T_4 therapy assumed during breakfast. According to the study design all patients switched the liquid formulation to soft gel capsule maintaining the same dosage and the usual breakfast. After 6 weeks TSH, fT_4 and fT_3 values were re-tested. At the end of the study no differences to TSH serum (2.61 ± 1.44 vs 2.23 ± 1.16 mIU/l, $P = 0.269$), fT_4 (10.43 ± 1.25 vs 9.91 ± 1.26 pg/ml, $P = 0.120$) and fT_3 (2.71 ± 0.39 vs 2.88 ± 0.31 pg/ml, $P = 0.068$) were observed among the patients whether assuming liquid or soft gel capsule at breakfast. In conclusion, we have clearly demonstrated that l-T_4 soft gel capsule can be taken at breakfast without difference from liquid formulation, facilitating compliance to l-T_4 replacement therapy.

The association between sick euthyroid syndrome and hs-CRP in obese patients without comorbidities

Şakir Özgür Keşkek[1], Tayyibe Saler[1], Sinan Kırım[1], Özlem Kurşun[1], Süleyman Ahbab[2], Mehmet Bankir[1] & Ömer Arif Pamuk[1]
[1]Internal Medicine Clinic, Adana Numune Training And Research Hospital, Adana, Turkey; [2]Internal Medicine Clinic, Haseki Training And Research Hospital, Istanbul, Turkey.

Inflammation has been shown in obese patients in previous studies. Sick euthyroid syndrome is an expected condition in case of inflammatory diseases. In this study, we aimed to investigate the frequency of sick euthyroid syndrome in obese patients without comorbidities and evaluate the association between obesity and inflammation. A total of 390 subjects were enrolled in this case-control study. The study group consisted of 200 obese patients without comorbidities and the control group consisted of 190 healthy subjects. Thyroid function tests, fasting glucose, insulin, serum lipids, complete blood count, erythrocyte sedimentation rate and hs-CRP levels of all patients were measured. Blood pressures, waist circumference, body mass index were reported. Groups were compared according to the hs-CRP levels and the frequency of sick euthyroid syndrome. The association between hs-CRP and sick euthyroid syndrome was evaluated. The groups were matched in terms of age and sex ($P = 0.082$, 0.186 respectively). There was statistically significant difference between the groups according to the frequency of sick euthyroid syndrome ($P < 0.001$). There was a correlation between the levels of FT_3 and hs-CRP in obese patients with sick euthyroid syndrome ($P = 0.006$). In this study, we have found an association between sick euthyroid syndrome and obesity. Moreover, we have found a correlation between sick euthyroid syndrome and hs-CRP level. These results showed that obesity (without any comorbidities) is an inflammatory disease and has systemic effects which lead to sick euthyroid syndrome ($P = 0.006$). In this study, we have found an association between sick euthyroid syndrome and obesity. Moreover, we have found a correlation between sick euthyroid syndrome and hs-CRP level. These results showed that obesity (without any comorbidities) is an inflammatory disease and has systemic effects which lead to sick euthyroid syndrome.

Efficacy and safety of radiofrequency ablation performed by an endocrinologist for large benign thyroid nodules

Tae Hyun Kim, Seok Ho Seo & Soonho Kim
Kwangju Christian Hospital, Gwang ju, Republic of Korea.

Background
Radiofrequency ablation has recently been used for the treatment of benign thyroid nodules, with outstanding results. However, in most related studies, smaller nodules (< 2 cm) were included and the procedure was usually performed by a radiologist or surgeon. Therefore, this study evaluated the efficacy and safety of radiofrequency ablation for nodules > 2 cm performed by an endocrinologist with several years of experience performing fine-needle aspiration cytology.
Methods
This study was a cross-sectional analysis of 111 patients who received radiofrequency ablation between April 2010 and July 2013; 73 patients with 75 nodules > 2 cm in diameter with at least 6 months of follow-up examinations were included.
Results
The mean follow-up period was 11.5 months. The mean nodule volume decreased from 17.0 ± 15. ml preoperatively to 6.0 ± 8.5 ml postoperatively, with a mean volume reduction of 69.7%. There were no major complications, and only one patient (1.3%) presented with a minor complication (haemorrhaging of the thyroid parenchyma).
Conclusions
Radiofrequency ablation is a safe method for reducing the size of large benign thyroid nodules and is not associated with any major complications.

DOI: 10.1530/endoabs.37.EP1055

EP1056

Prediction of the size of benign thyroid nodules and an analysis of associated factors

Seok Ho Seo, Tae Hyun Kim & Soonho Kim
Kwangju Christian Hospital, Gwang Ju, Republic of Korea.

Background
Most thyroid nodules are benign therefore, they are commonly only monitored. Only a few studies are available on the natural progression/regression of benign thyroid nodules, and large-scale studies on the subject are non-existent. So we identify factors that affect the size of benign thyroid nodules and to predict the potential nodule size through a model.
Methods
Between January 2001 and December 2011, 2,469 benign thyroid nodules (1,564 patients) were diagnosed through fine needle aspiration. After excluding 505 nodules for which either the volume was unknown or percutaneous ethanol injection or radiofrequency ablation had been performed, 1,964 benign thyroid nodules (1,261 patients) were selected for the retrospective analysis in our study.
Results
The nodules with increased size overtime involved a longer follow-up period than the nodules with decreased size. The proportions of females and cystic portion were relatively high. For the thyroid nodules with increased size, we analysed the potential influencing factors. Our analysis results indicate that larger nodule volume, extended follow-up period, and high cystic proportion were all positively associated with increased nodule size.
Conclusion
Controlling for all other potential variables, the thyroid nodules tended to grow at a rate of approximately 0.034 cm^3 per year in the group with continually growing nodules. The model used in our study may offer helpful insight in determining an optimal treatment schedule for benign thyroid nodules.

Investigation of GLP-1 and GIP levels change in patients with hyperthyroidism before and after treatment

Duygu Kalkan Cira, Sabahat Ozdem & Ramazan Sari
School of Medicine, Akdeniz University, Antalya, Turkey.

The main hormones responsible for the incretin effect are GIP and GLP-1. Thyroid hormones accelerate the absorption of glucose from the intestine, increase the release of glucose from glycogen stores and affect the hepatic

demolition of insulin. We aimed to assess incretin levels in patients with hyperthyroidism before and after thyroxine therapy. Total 24 subjects (12 hyperthyroid and 12 controls) were enrolled in the study. Oral glucose tolerance test was performed in patients with 75 g glucose. Glucose, insulin, C-peptide, GLP-1 and GIP levels were measured at 0, 30, 60, 90, and 120th minutes. Tests were repeated after providing euthyroidism in patients with hyperthyroidism. Basal glucose level was higher in hyperthyroidism group when compared control group ($P=0.03$). There was no statistically significant difference between groups in terms of temporal GLP-1 and GIP response for oral glucose load. Peak GLP-1 level was reached at 60 minutes and GIP was at 90 min in both groups. GLP-1 and GIP measurements did not change before and after the treatment in the hyperthyroidism group. Peak GLP-1 level was reached at 60th minutes in hyperthyroidism group before the treatment but it was reached at 30th minutes after providing euthyroidism. Peak GIP-1 level was reached at 90th minutes in hyperthyroidism group before the treatment but it was reached at 60th minutes after providing euthyroidism. These findings suggest that total incretin response for oral glucose load in patients with hyperthyroidism might be preserved. However, peak incretin responses are changed after providing euthyroidism.

Liquid vs tablet levo-thyroxine formulation in de novo treatment of hypothyroidism in patients with Hashimoto's thyroiditis: tolerability and changes in quality of life

Marilena Sidoti[1] & Massimo Giusti[1,2]
[1]Centro Diagnostico Priamar, Savona, Italy; [2]Dipartimento di Medicina Interna, Università di Genova, Genoa, Italy.

Several levo-thyroxine (L-T_4) formulations are now available. However, scientific societies discourage the use of generic L-T_4 owing to its uncertain bioavailability in comparison with brand L-T_4. Recent literature data suggest that using a liquid formulation of brand L-T_4 improves the management of hypothyroidism. However, it is not clear whether patient satisfaction improves on liquid (LI) L-T_4, as patients may initially be reluctant to switch from their tablet (TA) formulation to a 'new' (LI) L-T_4. The aim of this study was to evaluate efficacy, tolerability and quality of life (QoL) changes in Hashimoto's thyroiditis patients who began de novo L-T_4 treatment for sub-clinical or overt hypothyroidism. Patients were randomized to LI ($n=15$) or TA ($n=16$) L-T_4 formulation (IBSA Farmaceutici). After 6 months, they switched from one formulation to the other. Clinical and hormonal data were collected at the baseline and after 1 (1st titration), 6 (crossover), 7 (2nd titration) and 12 (end of study) months. Hypothyroid symptoms were scored on the Billewiciz scale (BS); subjective satisfaction and QoL were evaluated by means of a visual analogic scale (VAS) and the ThyPRO inventory. On randomization, sex distribution (85% females), median age (59 years), thyroid volume (8 ml), blood pressure (systolic 120 mmHg; diastolic 80 mmHg) heart rate (70 bpm) and concomitant therapies (1 drug on average), but not BMI (TA 26.7 ± 1.3 kg/m^2, LI 22.7 ± 0.8 kg/m^2; $P=0.02$), were similar between groups. BS scores (LI 3.8 ± 0.4; TA 2.7 ± 0.4; $P=0.06$), fT_3, fT_4 (LI 7.7 ± 0.7 pg/ml; TA 9.1 ± 0.6; $P=0.1$) and TSH (LI 21.5 ± 8.4 mIU/l; TA 11.0 ± 2.5 mIU/l) were not statistically different. ThyPRO scores did not differ between groups at the baseline. In both groups, L-T_4 treatment was begun at a dosage of 50 μg/day. Before the 1st titration, sevne women (LI 27% TA 19%) withdrew their consent and dropped out. After titration, the dosages were similar in both groups (LI 46.1 ± 4.1 μg per day, TA 55.8 ± 3.0 μg per day). On crossover, clinical data remained unchanged between groups and BMI was still significantly lower ($P=0.003$) in LI (23.6 ± 0.9 kg/m^2) than in TA (26.0 ± 1.2 kg/m^2) subjects. On L-T_4 treatment, BS scores decreased in both groups (LI 2.4 ± 0.4, TA 1.3 ± 0.4; $P=0.1$). No differences were noted between groups in terms of VAS (LI 8.4 ± 0.4, TA 8.1 ± 0.4) or laboratory data. A reduction on all ThyPRO scales was noted in both groups. To improve median TSH levels (LI 3.6 mIU/l, TA 3.3 mIU/l) after crossover and 2nd titration, L-T_4 dosages were increased in 43% and 29% of patients on LI and TA L-T_4, respectively. Intention-to-treat analysis revealed similar median BS (LI 3, TA 2.0) and VAS (LI 8, TA 7.5) scores and median TSH (LI 6.1 mIU/l, TA 6.0 mIU/l) levels at the end of the study. After 12 months of L-T_4 treatment, 60% of subjects required a further increase in L-T_4 dosage, in both formulations, to adequately control hypothyroidism. At the end of the study, only the ThyPRO scales 'eyes', 'anxiety' and 'cosmetic complaints' had improved less on LI than on TA therapy. In conclusion this protocol was burdened by a high number of drop-outs; the number of data available may therefore constitute a limitation to the study. Both LI and TA L-T_4 formulations displayed similar efficacy. However, dosages need to be carefully increased when treatment for the control of hypothyroidism is started de novo. The tolerability of LI and TA L-T_4 proved similar and QoL improved in all patients on therapy.

Serum Galectins are increased in patients with Graves' disease hyperthyroidism

Ana M Ramos-Leví[1,2], Ana Serrano[1], Miguel A Sampedro-Núñez[1], Alicia Vicuña[1], Ana Rodríguez-Muñoz[1], Rebeca Martínez[1], Hortensia De la Fuente[2,3] & Mónica Marazuela[1,2]
[1]Department of Endocrinology and Nutrition, Instituto de Investigación Princesa, Hospital Universitario Princesa, Madrid, Spain; [2]Universidad Autónoma de Madrid, Madrid, Spain; [3]Department of Immunology, Instituto de Investigación Princesa, Hospital Universitario Princesa, Madrid, Spain.

Introduction
Patients with autoimmune thyroid disease (AITD) exhibit aberrant immune-regulatory mechanisms. Galectins (Gal) are a family of glycan-binding proteins, which have been involved in immune regulation. However, the association of Gal with AITD remains unknown. In this study, we evaluated serum Gal-1 and Gal-9 in patients with AITD.
Methods
Peripheral blood samples from 31 patients with Graves' disease (GD) (14 with untreated hyperthyroidism, nine euthyroid with treatment, eight with iatrogenic hypothyroidism), 26 Hashimoto's thyroiditis (HT) (20 hypothyroid, six euthyroid with treatment), 12 non-GD hyperthyroid patients (NG) and 24 healthy controls were studied. Serum levels of thyroid hormones, thyroid antibodies (Ab), Gal-1 and Gal-9 were measured on the same day (FT4 by RIA; TSH, Tg-Ab, TPO-Ab and TSHR-Ab by immunoradiometric assays; Gal-1 and Gal-9 by ELISA). Patients were grouped according to clinical diagnosis and thyroidal status.
Results
Serum Gal-1 (ng/ml) and Gal-9 (pg/ml) were significantly increased in GD (3.756 and 8.582 respectively), HT (3.085, 9.188) and NG (2.822, 8.983), in comparison to controls (1.508, 7.323), $P<0.05$. No significant differences in Gal levels were found between the first three groups. Patients with hyperthyroidism (both GD and NG) had higher Gal-9 levels than euthyroid AITD patients, although there were no differences in Gal-1. In fact, in GD, we observed a direct correlation between Gal-9 and FT4 ($r=0.517$, $P=0.006$), and an inverse correlation between Gal-9 and TSH ($r=$-0.478, $P=0.007$). We did not find an association between Gal-9 and Ab levels in either group of AITD, although an association between Gal-1 and TPO-Ab levels was found in HT ($r=$-0.512, $P=0.038$). Antithyroid treatment reduced Gal-1 levels in patients with GD.
Conclusions
Galectins may be involved in the severity and pathogenesis of AITD, and could potentially be used as a diagnostic and therapeutic marker.

Paraoxonase and arylesterase levels in autoimmune thyroid diseases

Hakan Korkmaz[1], Suzan Tabur[1], Mesut Özkaya[1], Elif Oguz[2], Nurten Aksoy[3] & Ersin Akarsu[1]
[1]Faculty of Medicine, Department of Internal Medicine, Division of Endocrinology, Gaziantep University, Gaziantep, Turkey; [2]Faculty of Medicine, Department of Pharmacology, Harran University, Sanliurfa, Turkey; [3]Faculty of Medicine, Department of Clinical Biochemistry, Harran University, Sanliurfa, Turkey.

Objective
The aim of this study was to evaluate paraoxonase-1 (PON1) *activities and its association with oxidative stress status in* autoimmune thyroid disease (AITD).
Materials and methods
Patients with 25 Hashimoto thyroiditis (HT) and 25 Graves' disease (GD) and 27 healthy controls were enrolled in the study. Blood samples were obtained in euthyroid period and 3 months after the initiation of medical treatment. *S*erum samples from AIT diseases and healthy control group were analysed for paraoxanose (PON), arylesterase (ARE) activities, lipid hydroperoxide (LOOH) and total free sulfhydryl (–SH) levels.
Results
The preoperative PON and –SH levels of the patients with AIT were significantly lower compared to those of the control group ($P<0.001$, for each), while LOOH levels were significantly higher ($P<0.001$, for each). There was no significant difference between the patients with AIT and the healthy control groups in terms of ARE levels ($P>0.05$). PON levels showed a positive correlation with –SH ($r=0.522$, $P<0.001$) and a negative correlation with LOOH ($r=-0.487$, $P<0.001$).

Conclusion
Serum PON levels is decrease in patients with AIT, and serum PON is positively correlated with –SH, a well known antioxidant, and negatively correlated with LOOH, an oxidant.

Reference values of TSH, FT_4 and FT_3 in a cohort of pregnant women in the north of Spain

David Ruiz Ochoa[1], María Piedra León[2], María del Carmen Baamonde Calzada[1], Fátima Mateos García[2], Azucena Setién Rodriguez[3], Cristina Temprano Marañon[3], Laura Gutierrez Chicote[4], Raquel Zubeldia Valdés[3], Rosa Nuria Secadas López[1], Sonia Ojugas Zabala[3], Mercedes Álvarez del Campo[3], Aurora Otero García[3], Iñigo Tejado Elviro[1] & Jose Antonio Amado Señaris[2]
[1]Sierrallana Hospital, Cantabria, Spain; [2]Marques de Valdecilla Universitary Hospital, Cantabria, Spain; [3]Department of Family Medicine, Health Care Center Area IV, Cantabria, Spain; [4]Department of Family Medicine, Health Care Center Area III, Cantabria, Spain.

Introduction
As soon as pregnancy is established, various physiological changes occur in maternal thyroid economy. Due to that, the reference limits of thyroid parameters used for the general population are no longer valid to diagnosis thyroid dysfunction during pregnancy.
Methods
We included 266 pregnant women, with no thyroid disorders and resident in Cantabria, a region in northern Spain. They were questioned about iodized salt and iodine supplements intake and blood samples for TSH, FT_4 and FT_3 were obtained in the first and third trimester of gestation and for TPO abs and Tg abs in the first trimester.
Results
Eighteen patients (6.76%) were TPO abs or Tg abs positive. Iodized salt was consumed by 39.8% in the first trimester and by 83.5% in the third ($P<0.01$) and iodine supplement by 70.7% in the first and 91.2% in the third ($P<0.01$). Reference values, expressed as median and 2.5 and 97.5 percentiles were: TSH 1.67 μUI/ml (0.27–4.16), FT_4 1.06 ng/dl (0.86–1.31), FT_3 2.97 pg/ml (2.42-3.65) in the first trimester and TSH 1.92 μUI/ml (0.57–4.01), FT_4 0.89 ng/dl (0.70–1.08), FT_3 2.85 pg/ml (2.24–3.51) in the third trimester. If we exclude TPO abs or Tg abs positive women from the analysis, reference values were: TSH 1.63 μUI/ml (0.27–4.13), FT_4 1.06 ng/dl (0.86–1.31), FT_3 2.97 pg/ml (2.42–3.64) in the first trimester and TSH 1.92 μUI/ml (0.65–3.95), FT_4 0.88 ng/dl (0.7–1.07), FT_3 2.85 pg/ml (2.27–3.53) in the third trimester. Difference between the first and third trimester were significant for TSH, FT_4 and FT_3 in both groups. The small group of women with positive TPO abs or Tg abs, presented a higher TSH in the first trimester compared with women without antibodies: TSH 2.23 μUI/ml vs 1.63 μUI/ml ($P=0.031$). No significant difference was found for TSH, FT_4 or FT_3 in relation to the consumption of iodized salt or iodine supplement, except a significantly higher FT_3 in the third trimester between women who take iodine supplements compared to women who did not ($P=0.045$).
Conclusions
Method-and gestation-specific reference ranges are needed to avoid misdiagnosis of thyroid function during pregnancy. Pregnant women with positive TPO abs or Tg abs show higher levels of TSH in the first trimester compared with women without antibodies.

Serum prolactin and macroprolactin levels in pregnancy and association with thyroid dysfunction and thyroid autoimmunity

Metin Guclu[1], Soner Cander[1], Sinem Kiyici[1,3], Ebru Vatansever[2], Arif Bayram Hacihasanoglu[1] & Gürcan Kisakol[1]
[1]Department of Endocrinology, Sevket Yilmaz Research and Education Hospital, Bursa, Turkey; [2]Department of Biochemistry, Sevket Yilmaz Research and Education Hospital, Bursa, Turkey; [3]Department of Internal Medicine, Sevket Yilmaz Research and Education Hospital, Bursa, Turkey.

Aim
To assess the contribution of macroprolactin (macroPRL) to high serum prolactin (PRL) levels and association of prolactin and macroprolactin levels with thyroid status and thyroid autoimmunity during pregnancy.
Methods
Pregnant women ($n=138$) who had undergone a thyroid-stimulating hormone (TSH) screening during the first trimester of pregnancy enrolled in the study. Serum prolactin, macroprolactin, TSH, FT4, FT3, and thyroid autoantibodies were studied. Selected patients were divided into three groups; group 1 euthyroidsm (n 40: TSH between 0.1 and 2.5 μIU/l), group 2 hypothyroidism (n 54: TSH$\geqq$2.51 μIU/l), and group 3 hyperthyroid (n 44: TSH$\leq$0.09 μIU/l). The level of TPOAb $\geqq$35 U/ml has been considered as antibody positive. Polyethylene glycol (PEG) precipitation method was used for detection of macroprolactin and the percentage of monomeric prolactin recovery (monoPRL%) after PEG treatment 40% or less is considered as macroprolactinaemia.
Results
Macroprolactinaemia was found only in two patients (1.4%). One of these patients was euthyroid while the other one was hypothyroid and basal prolactin levels in these patients were 400 and 403 ng/ml respectively. Due to small number of macroprolactinaemia, percentage of their monoPRL recovery was used to compare prolactin homogeneity in other patients. Referring to the whole patients; there was no correlation between PRL, macroPRL or monoPRL% with thyroid hormone status and thyroid antibodies ($P>0.05$). A positive correlation was observed between the serum levels of PRL with TSH ($P=0.014$ and $r=0.219$), while negative correlation was found with FT4 ($P=0.011$ and $r=-0.227$).
Conclusions
There were no significant contributions of macroprolactin to prolactin levels during pregnancy. The levels of prolactin showed strong homogeneity and no correlation were found with thyroid dysfunction and thyroid autoimmunity at that time. This uncertainty persisted when correlation analyses done with monoPRL % instead of macroPRL. Eventually we couldn't find any relationship between thyroid hormones and antibodies with prolactin types in terms of molecular size.

The effect of vitamin D on thyroid autoimmunity

Yasin Simsek[1], İlkay Cakir[2], Ferit Kerim Kucukler[1], Halit Diri[3], Murat Baglıcakoglu[1] & Serdar Guler[1]
[1]Endocrinology Department, Hitit University, Corum, Turkey; [2]Endocrinology Department, Bagcilar Goverment Hospital, Istanbul, Turkey; [3]Endocrinology Department, Mus, Mus Goverment Hospital, Turkey.

Introduction
Although, vitamin D (vit D) mainly regulates calcium and phosphate metabolisms, its deficiency may also contribute to the development of some carcinomas, autoimmune, and cardiac diseases. Vit D deficiency has been defined to correlate with increased autoimmune disease such as type 1 diabetes mellitus, rheumatoid arthritis, autoimmune thyroid diseases (AITD). Previous studies suggested that patients with AITD had lower vit D levels when compared with healthy controls. Moreover, vit D supplements were found to prevent the development and progression of autoimmune disorders such as type 1 diabetes mellitus and multiple sclerosis. Thus, we aimed to assess the effect of vit D on thyroid antibody titers in patients with AITD.
Materials and methods
Twenty-four participants were enrolled into the study. All of the participants were diagnosed with AITD and vit D deficiency. We assayed the serum anti-thyroid peroxidase (anti-TPO) and anti-thyroglobulin (anti-Tg) antibody levels before and a month after the vit D replacement. The daily dose of the vit D replacement was 2000 International Units (I.U).
Results
The AITD induced disorders in participants were as following: subclinical hypothyroidism: 66.6%, subclinical hyperthyroidism: 8.3%, overt hypothyroidism: 12.5%, and overt hyperthyroidism: 12.5%. Mean vit D level was 13.1$\pm$1.2 ng/ml. Before and after vit D replacement, anti-TPO titers were 276.6$\pm$42.7 IU/ml, 257.1$\pm$40.1 IU/ml ($P<0.001$); and anti-Tg titers were 371.9$\pm$64.3 IU/ml, 269.3$\pm$36.4 IU/ml ($P<0.001$) respectively. There was a statistically significant decrease in the anti-TPO and anti-Tg levels after the vit D replacement.
Conclusions
Vit D supplements seem to reduce thyroid antibody titers which play the main roles in the development and progression of AITDs. Therefore, vit D therapy may be used in the treatment of patients with AITD, particularly those with vit D

deficiency. Further studies are needed to assess the role of vitD replacement therapy in the treatment of autoimmune diseases.

Endocrine involvement in systemic amyloidosis.

Ibtissem Oueslati[1], Nadia Khessairi[1], Ibtissem Ben Nacef[1], Nadia Mchirgui[1], Karima Khiari[1], Hayet Kaaroud[2] & Néjib Ben Abdallah[1]
[1]Department of Endocrinology, Charles Nicolle University Hospital, Tunis, Tunisia; [2]Department of Nephrology, Charles Nicolle University Hospital, Tunis, Tunisia.

Introduction
Systemic amyloidosis leads to functional compromise of various organs through infiltration of these tissues by amyloid protein.
The aim of this study was to determine the endocrine disorders in patients with systemic amyloidosis.
Methods
During the period from 1975 to 2006, we collected 580 patients with renal amyloidosis confirmed by histological exam. We selected 123 patients with hormonal exploration. 55 patients had thyroid function tests and 68 patients had adrenal function tests.
Results
There were 85 males and 38 females with a mean age of 49.6 ± 18 years.
Seventeen patients had primary hypothyroidism (30.9%) and ten patients had primary adrenal insufficiency (14.7%). The diagnosis of hypopituitarism was established in 18 patients with a central hypothyroidism in 14 cases and an adrenocorticotropic hormone deficiency in four cases. None of the patients had a simultaneous achievement of two pituitary abnormalities but one patient had TSH deficiency associated with adrenal insufficiency. Goiter was observed in nine patients with hypothyroidism in four cases.
All patients with adrenal insufficiency, ten patients with low TSH and five cases of goiter had AA amyloidosis.
Conclusion
Endocrine disorders such as hypothyroidism and adrenal deficiency were frequent in renal amyloidosis. Therefore their screening is necessary for an early treatment to improve patient's prognosis.

Amyloid goitre as the first manifestation of systemic amyloidosis

Ibtissem Oueslati, Hana Ben Hadj Hassen, Ibtissem Ben Nacef, Nadia Mchirgui, Karima Khiari & Néjib Ben Abdallah
Department of Endocrinology, Charles Nicolle University Hospital, Tunis, Tunisia.

Introduction
Thyroid gland may be asymptomatically involved in most patients with secondary systemic amyloidosis. However, clinically detectable amyloid goiter is quite rare; often it is seen in patient with kidney involvement. We report one case of amyloid goitre without kidney manifestation.
Case report
A 30-year-old male diagnosed with bilateral bronchiectasis since 1992 was admitted with rapidly growing goiter associated with dysphagia for solids, change in voice, weight loss and dyspnea. The goitre was nodular large and hard. The rest of the examination was normal. His thyroid function tests were normal, antithyroglobulin and antimicrosomial antibodies were negatives. As he had signs of compression, total thyroidectomy was performed without complication. Histological exam showed type AA amyloid throughout the gland. Labial biopsy was positive for type AA amyloid. Evolution was favorable and 2 years later proteinuria was still negative.
Conclusion
We report perhaps, a new case of amyloid goitre without renal manifestation in the course of secondary amyloidosis. A preoperative diagnosis of amyloid goiter must be considered in patients with thyromegaly who have a predisposing risk factor for developing amyloidosis.

A questionnaire on quality of life identifies Graves' ophthalmopathy patients who deserve more attention

Danilo Villagelin[1,2], Heloisa Nogueira[1], Ana Claudia Gomes Sandrin[1], Rebeca Carbinatto[1], Jakeline Gioyanetti[1], Larissa Campos[1], Roberto Santos[1], Natassia Bufalo[2], Joao Romaldini[1] & Laura Ward[2]
[1]Pontificia Universidade Católica de Campinas, Campinas, Brazil; [2]GEMOCA – Laboratory of Cancer Molecular Genetics, University of Campinas, Campinas, Brazil.

Introduction
Graves' ophthalmopathy (GO) varies from minor changes to visible face disfigurement which may compromise the visual capacity and the aesthetics of the patient. These deformities affect the quality of life in both functional and emotional senses. There are some questionnaires designed to evaluate the patient's health, quality of life and relationship with a specific disease. The use of these questionnaires is recommended to improve the quality of care and, mainly, to identify patients who are in need of psychological support. However, they need to be validated in each country.
Methods
We evaluated 140 consecutive Brazilian GD patients investigating the severity of their ophthalmopathy (Clinical Activity Score), and quality of life, according to the questionnaire on quality of life in Graves' ophthalmopathy (GO-QoL).
Results
The patients were divided in two groups according their initial CAS. Group 1 (CAS 0 or 1), $n = 108$, and group 2 (CAS > 2), $n = 32$. There were no differences in age, duration of disease and gender between the groups. However, group 1 had better results concerning the score of total visual functioning ($P < 0.005$) and the score of total appearance ($P < 0.0001$); patients in group 2 were more affected on simple tasks such as moving around the house ($P < 0.05$), walking outdoors ($P < 0.005$), reading ($P < 0.05$), watching TV ($P < 0.005$). In addition, this group had a worse score on self-confidence ($P < 0.0001$) and felt hindered from doing something they wanted to do because of GO ($P < 0.05$).
Conclusion
GO significantly affects the quality of life and the use of the GO-QoL questionnaire permitted to identify patients who deserve specific attention.

Graves' disease and HIV infection: bad response to antithyroid drugs due to interaction with HIV therapy

Catarina Moniz[1], Maria José Campos[2] & Carlos Vasconcelos[1]
[1]Endocrinology Department, Hospital de Egas Moniz, CHLO-EPE, Lisbon, Portugal; [2]Infectiology Department, Hospital de Egas Moniz, CHLO-EPE, Lisbon, Portugal.

Graves' disease is one of the multiple autoimmune diseases that have been reported in HIV-infected patients. With the upsurge of highly active anti-retroviral therapy (HAART) the incidence of autoimmune diseases in HIV-infected patients is increasing, especially after immune reconstitution. We present a male, 51-year-old, who started complaining with anxiety, sudoresis and palpitations. The laboratory workout revealed hyperthyroidism: TSH <0.02 μU/ml (0.46–4.68), FT4 28 pmol/l (10.0–28.2), FT3 13.7 pmol/l (4.26–8.10). The patient started propylthiouracilo 100 mg per day and was referred to the Endocrinology Department. He had Mitral Insufficiency and HIV-1 infection. He was on HAART since 2007 with emtricitabin, tenofovir, atazanavir and ritonavir. The etiologic study disclosed Graves disease with TRAbs level 45.3 U/l (<1). We changed propylthiouracilo for thiamazole. During follow-up most of the time it wasn't possible to achieve euthyroidism. We offered other therapeutic options (Iodine-131 or surgery) but the patient rejected them. On the 23rd month of thiamazole therapy the patient was icteric and blood workout revealed hyperbilirubinemia (total bilirubin 8.1 mg/dl), FT4 48.1 pmol/l and FT3 18.7 pmol/l. We discussed these results with the Infectiology Department and hyperbilirubinemia was interpreted as an atanavir adverse effect. Boosted atazanavir (with ritonavir) was replaced by rilpivirine and we maintained the same dosis of thiamazole (15 mg per day). 6 weeks later he had normal total bilirunin (0.64 mg/dl) and normal/low thyroid hormones: FT4 9.45 pmol/l and FT3 6.05 pmol/l. Both atazanavir, ritonavir and thiamazole are metabolized in cytochrome P450. In this case the interaction resulted in decreased benefit of thiamazole and explains why it was so difficult to attained euthyroidism. To the best of our knowledge this is the first time the interaction between atazanavir and thiamazole is reported.

Plasma visfatin/pre-B-cell colony enhancing factor levels in hypothyroid patients and relationship of these levels with thyroid autoimmunity and atherosclerosis

Bekir Ucan[1], Nur Kebapci[2], Sema Uslu[2], Mehmet Kara[2], Belgin Efe[2] & Setenay Oner[2]
[1]Ministry of Health, AIBU Izzet Baysal Medical Faculty Training and Research Hospital, Bolu, Turkey; [2]Osmangazi University Medical Faculty, Eskisehir, Turkey.

Visfatin/pre-B-cell enhancement factor is an adipocytokine, which is found in the visceral fat tissue and enhances the growth of precursor of B cells through showing synergy with IL7 and stem cell factors. Other cytokines released from the adipose tissue are TNFα and IL6, which has been shown to be related with pathogenesis of insulin resistance, diabetes, dyslipidaemia, inflammation, and atherosclerosis. Our aim was to determine the relationship of plasma visfatin/pre-B-cell colony enhancing factor levels with thyroid autoimmunity and atherosclerosis. The study was performed randomly on 35 patients (32 women/three men, mean age 43.8 ± 9.6 years) diagnosed with Hashimoto's thyroiditis and 18 healthy controls (17 women/one men, mean age 43.3 ± 5.2 years) attending our outpatient clinic between June 2009 and January 2010. Before therapy anthropometric levels, carotid intima–media thickness (CIMT), serum anti-Tg, anti-TPO, hsCRP, homocystein, lipo(a), ApoA, ApoB1, β-2 microglobulin, insulin, glucose, visfatin, IL6, TNFα, oxidized-LDL levels, and lipid profile was measured. Plasma visfatin oxidised LDL, IL6, and TNFα levels did not differ from the control group before and after therapy in hypothyroid patients, statistically. The cardiovascular risk factors like systolic and diastolic blood pressure, HOMA-IR index, triglyceride, Apo B and ApoB/ApoA, homocystein, β-2 microglobulin, and CIMT were found to be elevated in the patients. Ox-LDL, cholesterol, homocysteine, and proteinuria levels were positively correlated with anti-Tg levels. Conclusionally, we think that non-traditional CVD risk factors are elevated in hypothyroid Hashimoto's thyroiditis patients and as a atherosclerosis indicator CIMT increase accompanies it and anti-Tg antibody is a bridge between autoimmunity and atherosclerosis.

EP1071

Could thyroid replacement therapy not be enough to reduce oxidative stress in hypothyroid patients with Down' syndrome? A cohort study

Emanuele Rocco Villani[1], Graziano Onder[1], Angelo Carfì[1], Francesco Pagano[1], Sebastiano Raimondo[2], Chantal Di Segni[2], Andrea Silvestrini[3], Elisabetta Meucci[3] & Antonio Mancini[1]
[1]Department of Internal Medicine and Geriatrics, Catholic University of Sacred Heart, Rome, Italy; [2]Division of Endocrinology, Department of Medical Sciences, Catholic University of Sacred Heart, Rome, Italy; [3]Institute of Biochemistry and Clinical Biochemistry, University of Sacred Heart, Rome, Italy.

Hypothyroidism and autoimmune thyroiditis are common in patients with Down' syndrome (DS), leading to common prescription of thyroid replacement therapy. On the other hand, thyroid function is involved in oxidative stress (OS) mechanisms. DS is a well-known high OS condition because several genes involved in OS mechanisms map on chromosome 21 and coenzyme Q10, lipophilic antioxidant, could be more correlated with hypothyroidism than TSH in DS people. To investigate relationships among thyroid function, OS and replacement therapy, we enrolled 26 adults with DS (ten males) aged 18–64. Fourteen were under thyroid replacement therapy with levothyroxine. A fasting blood plasma sample was collected at 0900 h and TSH (NR 0.30–2.80 μUI/l), fT_4 levels and total antioxidant capacity (TAC) were evaluated. TAC was evaluated with colorimetric method, using the system metamyoglobin–H_2O_2 and the chromogen ABTS; the latency time (LAG, s) in the appearance of ABTS radical proportional to antioxidant content of the system. Patients were classified in two groups: i) patients under thyroid replacement therapy (14/26) and ii) patients without replacement therapy (12/26). Among the first group, 57% (8/14) of patients were euthyroid (mean ± s.d. TSH 3.01 ± 3.27), whilst 42% (5/12) were hypothyroid in the second group (mean TSH 2.39 ± 1.09). TAC was lower in the first group (62.50 ± 14.64) than in the second group (74.17 ± 12.40), regardless of TSH level. These data confirm hypothyroidism as a high OS condition and suggest that replacement therapy alone could not be enough to establish normal TAC levels in hypothyroid patients. Further studies will be necessary to evaluate whether a supplementation with antioxidants should be considered in DS hypothyroid patients, due to the competence of two causes of high oxidative stress in those patients. It could also be necessary to evaluate whether non-DS hypothyroid patients under thyroid replacement therapy show higher OS levels.

Hypothyroidism and the haemodialysis patients: it is a matter for discussion

Mohammed Aljefery
Merjan Teaching Medical City, Hilla, Babylon, Iraq.

149 haemodialysis chronic renal failure (CRF) patients on haemodialysis (HD) program of 4 h/three times a week investigated for thyroid gland function and try to answer the question: is the thyroid function abnormality affect the response of the haemodialysis CRF patients response to recombinant human erythropoietin (rHuEPO)? We compare the results of the thyroid gland markers; T_3, T_4, and TSH (which tested by minividus technique) of the patients with the packet cell volume (PCV) values of the patients and showed if the haemodialysis CRF with hyper or hypothyroidism affect the response of the patients to the rHuEPO and if there are differences in the values of the PCV between the groups of the patients after fixed the duration and the times of the HD session and the same dose and route of the rHuEPO. The results analysed statistically and discussed and from that we can concluded there are hyporesponsiveness of the rHuEPO in patients with CRF and hypothyroidism in haemodialysis and for this reason we advise to search any haemodialysis patients for thyroid function.

The changes of thyroid function after coronary angiography in Koreans

Dong Sun Kim[1], Jung Hwan Park[1], Yeon-Ah Sung[2] & Kyu Chang Won[3]
[1]Department of Internal Medicine, College of Medicine, Hanyang University, Seoul, Republic of Korea; [2]Department of Internal Medicine, College of Medicine, Ewha Womans University, Seoul, Republic of Korea; [3]Department of Internal Medicine, College of Medicine, Yeungnam University, Gyeongbuk, Republic of Korea.

Background
The risk of iodine-induced thyrotoxicosis is increased in patients with Graves' disease and multi nodular goiter with thyroid autonomy. At same time, hypothyroidism can develop after iodine exposure in patients with Hashimoto's thyroiditis. But, there are no studies about the influence of iodine containing contrast media on thyroid function in iodine excessive area. This study was done to evaluate the changes of thyroid function after coronary angiography (CAG) with/without percutaneous coronary intervention (PCI) (CAG ± PCI) in Koreans with excessive iodine intake.
Methods
56 subjects with normal thyroid function who admitted for CAG ± PCI were enrolled. Levels of TSH and free thyroxine (FT_4) in serum were measured before CAG ± PCI and at 1 and 12 weeks after CAG ± PCI.
Results
There was no statistical significance of levels of TSH measured between before CAG ± PCI and at 1 and 12 weeks after CAG ± PCI. Levels of FT_4 were not changed before and after CAG ± PCI, but mild increase of FT_4 was observed at 1 week after CAG ± PCI. Larger amount of iodine containing contrast media for PCI did not change the thyroid function either. Among the 56 subjects, three patients were newly diagnosed as subclinical hypothyroidism at 1 week after CAG with PCI. Among the three patients, one patient remained subclinical hypothyroidism at 12 weeks after CAG with PCI.
Conclusion
There were no changes of thyroid function after CAG in Koreans with normal thyroid function. Mild elevations of FT_4 levels at 1 week after CAG ± PCI was showed, but it normalised at 12 weeks after CAG ± PCI. This suggests that there was no significant effect of iodine containing contrast on thyroid function.

Clinical and social concerns in treated patients with primary hypothyroidism in Basrah: a cross sectional study

Haider Ayad Yassin Yassin, Alaa Khattar Musa Musa & Abbas Ali Mansour
Basrah College of Medicine, Basrah, Iraq.

Background
Despite available treatment for hypothyroidism, levothyroxine replacement therapy in a biochemically appropriate dose does not necessarily relieve patients' symptoms and complaints. The aim of the study was to evaluate the concerns of patients treated with hypothyroidism and to correlate these concerns with different patient characteristics and thyroid biochemical control.
Method
One hundred and eighteen treated primary hypothyroid patients attending Al-Faiha Diabetes Endocrine and Metabolism Center (FDEMC) in Al-Basrah were entering a questionnaire designed to capture personal, anthropometric, biochemical, and clinical data. Twenty-four concerns were questioned to the patients who score these concerns on a four point Likert scale.
Results
The most scored patients' concerns were fatigue, neuropathic pain, lack of weight loss, cold intolerance, breathing problems, and swallowing problems. No statistically significant relations were existed between these concerns and TSH control, except for a high TSH group which were highly likely to have concerns of feeling sick (OR: 0.27, 95% CI 0.54–2.0, $P=0.001$), neuropathic pain (OR: 0.4, 95% CI 0.17–1.6, $P=0.01$), cold intolerance (OR: 0.35, 95% CI 0. 0.3–1.7, $P=0.005$), and hair problems (OR: 0.26, 95% CI 0.6–2.1, $P<0.0001$). While they were less likely to have concerns about lack of weight loss (OR: 8.7, 95% CI -2.9 to -1.3, $P<0.0001$) and permanent medication (OR: 2.7, 95% CI -1.8 to -0.35, $P=0.003$) than in normal TSH patients where these concerns scored more and significantly. A significant correlation existed between duration of the hypothyroidism and patients' concerns of swelling of the hands and feet ($R=0.7$, $P<0.0001$), memory problems ($R=0.4$, $P<0.0001$), hearing disturbance ($R=0.38$, $P<0.0001$), and hair problems ($R=0.3$, $P=0.001$). Age significantly affect patients concerns of memory problems ($R=0.6$, $P<0.0001$), swelling of the hands and feet ($R=0.4$, $P<0.0001$), and hearing disturbance ($R=0.37$, $P<0.0001$). Positive correlation was present between LDL cholesterol level and patients' concerns of cold intolerance ($R=0.3$, $P=0.001$), hair problems ($R=0.28$, $P=0.003$), feeling sick ($R=0.2$, $P=0.02$), and neuropathic pain ($R=0.18$, $P=0.04$). The total cholesterol level also showed a positive correlation with patients' concerns of cold intolerance ($R=0.3$, $P=0.001$), hair problems ($R=0.25$, $P=0.01$), neuropathic pain ($R=0.22$, $P=0.01$), and fatigue ($R=0.2$, $P=0.04$).
Conclusion
We cannot rely on the TSH level alone as a marker of optimal treatment outcome in patients with primary hypothyroidism because it does not reflect the concern status of the patients.

Ultrasonographical and cytological features of exophytic thyroid nodules: do exophytic nodules pretend to be malignant?

Fatma Dilek Dellal[1], Husniye Baser[1], Didem Ozdemir[2], Aydan Kilicarslan[3], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Department of Endocrinology and Metabolism, Ataturk Education and Research Hospital, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, School of Medicine, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey; [3]Department of Pathology, School of Medicine, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey.

Aim
Exophytic nodule refers to a nodule that sticks out of the normal thyroid boundary/outline. Other definition is a nodule with an acute angle between the lesion and adjacent thyroid capsule. In the literature, one study reported that thyroid nodules with exophytic configuration showed a high malignancy rate. We aimed to compare ultrasonographical features and cytopathologic results of exophytic and non-exophytic thyroid nodules.
Material and method
Thirty-four exophytic and 34 non-exophytic thyroid nodules in which fine-needle aspiration biopsy was indicated throughout 3 months were evaluated prospectively. Mean nodule size was similar in two groups (18.83 ± 8.71 and 15.28 ± 7.57 mm, $P=0.173$). The ratio of presence of peripheral hypoechoic halo and marginal irregularity was also similar in both group ($P=0.512$ and $P=0.153$ respectively). Microcalcification was present in 21.4 and 29.4% of exophytic and non-exophytic nodules respectively ($P=0.424$). Macrocalcification was detected in 4.5% of exophytic and 11.8% of non-exophytic nodules ($P=0.111$). 47.6% of exophytic nodules was hypoechoic and 52.4% was isoechoic. 47.1% of non-exophytic nodules was hypoechoic and 52.9% was isoechoic. Color flow Doppler pattern was defined as non-vascular, peripheral, central, or of mixed type and was similar in both groups ($P=0.138$). Cytopathologic results of exophytic nodules were 75% benign, 4.3% follicular lesion or atypia with undetermined significance, 2.3% suspicious for malignancy, 2.3% malign, and 15.9% non-diagnostic. In non-exophytic group, 79.4% was benign and 20.6% was non-diagnostic ($P=0.497$).
Conclusion
Exophytic configuration of thyroid nodules was rarely investigated as a possible predictive feature for malignancy in the literature. In this study, we did not find any difference in terms of ultrasonographical features and cytological results between exophytic and non-exophytic thyroid nodules. However, more comprehensive studies are needed to clarify any possible relation between exophytic configuration and malignancy.

Dynamics of thyroid function tests during antiviral treatment of hepatitis C

Olga Nechaeva, Alexander Dreval, Maria Matsievich, Maria Petrachenkova, Kseniya Kokina & Pavel Bogomolov
Moscow Regional Research Clinical Institute, Moscow, Russia.

Aim
To estimate the frequency of changes in thyroid function on the background of antiviral therapy in patients with chronic hepatitis C.
Material and methods
The retrospective group was consists of 204 patients (mean age 35.5 ± 8.4 years) with HCV genotype 3a, who took the antiviral therapy course with pegylated

interferon and ribavirin during 24 weeks. The patients were divided for two groups: 86.3% (176) had a sustained virological response (SVR), 13.7% (28) did not reach the SVR. SVR was defined as undetectable HCV RNA level at weeks 4–12. The groups were matched only by sex, because of the mean age of patients with SVR was statistically significant younger (32.3±7.2 years) than patients without SVR (40.63±8.66 years).

Results

Among 204 patients, TSH, fT_4, and TPOAb levels were analysed in 66 patients before and after treatment. 92.4% (61) subjects had TSH level between 0.4 and 4.0 mIU/l with normal fT_4. 7.6% (5) subjects had subclinical hypothyroidism. Although, absolute levels of TSH, fT_4, and TPOAb were not significantly different before and after treatment, however, after course number of people with normal TSH level decreased to 71.2% (47), and in 28.8% (19) patients thyroid dysfunction was diagnosed. Most of them became hypothyroid and Graves' disease manifested only in one case. In patients with normal function tests before treatment there was no difference in levels of fT_4 in groups with SVR+ and SVR− and there was the significant difference in levels of TSH and TPOAb: the lower the value of TSH and TPOAb was before treatment, the more marked presence of SVR was determined.

Conclusion

Antiviral treatment can caused a statistically significant change in the thyroid function in 21.2% patients. The levels of TSH and TPOAb before treatment may be a predictor of SVR. Another study are necessary for confirming this fact.

Nondiagnostic fine-needle aspiration biopsy results: our clinic experience

Sevilay Ozmen[1], Ilknur Calik[1], Ebru Sener[1], Esref Kabalar[1], Ozge Timur[2], Hakan Sevimli[2], Ayse Carlioglu[3] & Senay Arikan Durmaz[3]
[1]Department of Pathology, Training and Research Hospital, Erzurum, Turkey; [2]Department of Internal Medicine, Training and Research Hospital, Erzurum, Turkey; [3]Department of Endocrinology, Training and Research Hospital, Erzurum, Turkey.

Adequacy of thyroid fine-needle aspiration (FNA) is generally defined by the thyroid follicle cells, amount, and quality of colloid. Samples priorly should be evaluated for adequacy. A set of qualifying criteria are specified in Bethesda system to remove subjectivity from the adequacy assessment. Each sample prepared from a thyroid FNA should be monitored at least six follicles cell groups containing at least ten cells. In addition to these criteria of assessing the adequacy, the quality of preparation is also very important. Follicular cells should able to observe, the blood or clots should not cover the preparation and painting should be made fine. Our clinic evaluation results of FNA biopsy (FNAB) are reported as non-diagnostic for 69 patients; 54 females and 13 males. All the patients reported as non-diagnostic were operated without re-biopsy. As these patients evaluated after operation 57 of them; 44 females and 13 males diagnosed as nodular goitre (81.5%), four adenomatous hyperplasia (7%), one diffuse hyperplasia (1.8%), one papillary carcinoma (1.8%), three follicular adenoma (5.4%), and one Hürthle cell adenoma (1.8%). Patients with non-diagnostic FNAB results evaluated after operation with histopathological preparations and reported 96.4% benign and 3.6% malignant. Most of the nodules with non-diagnostic/inadequate FNAB evaluated as benign. These results bring a question to mind; should these patients operated immediately? As Bethesda's clinical approach, patients with non-diagnostic FNAB should be re-aspirated after 3 months. To avoid false positive results depending on regeneration, there must be at least 3 months between two aspirations. We believe such an approach would protect patients from unnecessary surgery.

EP1078

False negatives and reasons: Erzurum Research and Training Hospital Pathology Department experience

Sevilay Ozmen[1], Ilknur Calik[1], Senay Erdogan[1], Ozge Timur[2], Hakan Sevimli[2], Ayse Carlioglu[3], Senay Arikan Durmaz[3] & Fazli Erdogan[1]
[1]Department of Pathology, Training and Research Hospital, Erzurum, Turkey; [2]Department of Internal Medicine, Training and Research Hospital, Erzurum, Turkey; [3]Department of Endocrinology, Training and Research Hospital, Erzurum, Turkey.

Fine-needle aspiration biopsies (FNAB), adequate for examination, reported as benign re-evaluated with histopathological samples. 61 patients, 52 females and nine males re-evaluated. 41 of them reported as benign. 20 of the patients, seven females and three males reported as papillary carcinoma. Six of the papillary carcinomas were single focus, two muiticentric, and 12 papillary microcarcinoma. Six of the eight patients malignant lobe was different from the lobe that FNA was made. Multicentric malignancy was detected in two cases. Malignant FNA diagnosis forms 4–8% of all thyroid FNAs, as in literature. Most of them are papillary thyroid carcinoma (PTC). In fact PTC cytopathological features are quite obvious, at the level of diagnostic. Patients diagnosed PTC with FNAB showed PTC at the rate of 96–100% with histopathological samples. However, false-negative value was 32.78% in our patients under observation. This value is over the false-negative rate ranging between 1 and 21.3% stated in the literature. However, the results of the histopathological report with the results of cytopathological reports examined in detail the majority of the cases with false-negative study (60%) constitute papillary microcarcinoma. This finding suggests that PTC is overlooked with FNAB. Our false-negative rates are compatible with the literature as PTC excluded. Another reason for our false-negative value is the patchy distribution of PTC in the same nodule. As a result, FNAB accompanied with ultrasound, should be applied to all solid, hypoechoic nodules and nodules with microcalcification. Also, because of the presence of PTC showing a patchy distribution in a single nodule, multiple biopsies should be taken from more than one areas, from the large nodules seen sonographically suspicious.

Multiple disease associations in autoimmune polyglandular syndromes

Anna Dabrowska[1], Agnieszka Zwolak[1,2] & Jerzy Tarach[1]
[1]Chair and Department of Endocrinology, Medical University of Lublin, Lublin, Poland; [2]Chair of Internal Medicine, Department of Internal Medicine in Nursing, Medical University of Lublin, Lublin, Poland.

Introduction

Autoimmune polyglandular syndromes (APS) are a heterogeneous group of disorders characterised by autoimmune activity against endocrine and non-endocrine organs. APS type depends on the combination of the diseases (APS1, APS2, and APS3).

Methods

The study was conducted in 89 patients (70F and 19M) with APS aged mean 50.00±14.80 years, treated at Endocrinology Department between 2003 and 2015. We analysed clinical manifestations, results of laboratory tests and imaging to determine the components of APS.

Results

The most common syndrome was APS3 (69.66%). 24.72% of patients had APS2, only five subjects (5.62%) suffered from APS1. Autoimmune thyroid disease was found in 84.27% of cases, i.e. Hashimoto's thyroiditis (58.43%) and Graves's disease (25.84%), and in 100, 86.36, and 82.26% of APS1, APS2, and APS3 cases respectively. Type 1 diabetes had been diagnosed in 61.80% of participants (in 20.00, 27.27, and 77.42% of APS1, APS2, and APS3 cases respectively). Besides patients with APS2, all subjects with APS1 were treated due to Addison's disease which was found in 29.21% of APS patients. Other problems such as: vitiligo (17.98%), psoriasis (12.36%), Addison-Biermer anemia (10.12%), alopecia areata (5.62%), asthma (3.37%) and in individuals – rheumatoid arthritis, myasthenia gravis, coeliac disease, ulcerative colitis, and autoimmune hepatitis were observed. In APS1, three to six diseases were noted, mostly the coexistence of Addison's disease and hypoparathyroidism. Two to three diseases were found in APS2. Schmidt's syndrome was determined in 63.64% of patients with APS2, Carpenter syndrome only in two cases. The most common diseases in APS2 were: Hashimoto's disease, type 1 diabetes, Graves's disease (72.73, 27.27, and 13.64% respectively). In APS3, two to four diseases were found. Type 1 diabetes, Hashimoto's disease, and Graves' disease were the most common disorders (77.42, 50.00, and 32.26% respectively). The most common coexistence in APS3 was type 1 diabetes with Hashimoto's disease.

Conclusions

Although, some diseases occur more frequently than others, it should be remembered about various APS components during follow-up such patients.

Intraocular pressure, corneal, and retinal thickness in patients with euthyroid autoimmune thyroiditis

Fatma Neslihan Cuhaci[1], Husniye Baser[2], Nagihan Ugurlu[3], Fatma Yulek[3], Reyhan Ersoy[1], Nurullah Cagil[3] & Bekir Cakir[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Yildirim Beyazit University, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Ataturk Education and Research Hospital, Ankara, Turkey; [3]Department of Ophthalmology, Ataturk Education and Research Hospital, Ankara, Turkey.

Introduction
Ocular changes and ocular symptoms may be encountered in patients with hypothyroidism and hyperthyroidism. However, the data concerning the effects of thyroid disorders on intraocular pressure (IOP), central corneal thickness (CCT), and retinal thickness (RT) are very rare. Here, we aimed to evaluate the alterations in IOP, CCT, and RT in patients with euthyroid autoimmune thyroiditis (AIT).
Methods
Twenty-five subjects with euthyroid AIT were included into the study. The patients were compared with age and sex-matched 40 healthy subjects. A detailed ophthalmologic examination including the IOP, CCT, and RT was performed in both groups.
Results
There was no statistically significant difference in mean right RT, left RT, right CCT, and left CCT between two groups ($P>0.05$ for all parameters). Also, no significant difference was found between groups concerning right and left IOP ($P>0.05$ for all parameters). In patients groups, left RT was significantly higher in patient with TSH >2.5 μIU/ml than those of TSH <2.5 μIU/ml (294.85 ± 23.58 μm vs 261.50 ± 21.70 μm, $P=0.003$). A positive correlation was observed between left RT and TSH levels ($r=0.269$, $P=0.033$). No significant correlation was found between free triiodothyronine levels, and right CCT, right RT, right IOP, left CCT, left RT, and left IOP levels ($P>0.05$ for all parameters). Also, free tetraiodothyronine levels were not significantly correlated with right CCT, right RT, right IOP, left CCT, left RT, and left IOP levels ($P>0.05$ for all parameters).
Conclusion
An increase in IOP in Graves' ophthalmopathy is a well-known entity. In literature, hypothyroidism seems to cause a reversible increase in CCT and IOP. In this study, we observed no significant difference between groups concerning IOP, CCT, and RT. So, further studies with larger sample size are needed to evaluate IOP, CCT, and RT in patients with euthyroid AIT.

Should fine-needle aspiration biopsy perform all of nodules in patients with nodular goitre?

Sevilay Ozmen[1], Ilknur Calik[1], Hilal Balta[1], Ozge Timur[2], Ayse Carlioglu[3], Hakan Sevimli[2], Senay Arikan Durmaz[3] & Ali Kurt[1]
[1]Department of Pathology, Training and Research Hospital, Erzurum, Turkey; [2]Department of Internal Medicine, Training and Research Hospital, Erzurum, Turkey; [3]Department of Endocrinology, Training and Research Hospital, Erzurum, Turkey.

Introduction and aim
Fine-needle aspiration (FNA) biopsy has become widely accepted as a reliable method for diagnosis of malign thyroid nodule. In our study we aimed to review results of thyroid FNA biopsy to be performed by same endocrinologist and compared to their histopathological results after thyroidectomy.
Materials and methods
This retrospective study was done at the department of pathology for a period of 2 years from 2012 to 2014. The 401 patients applied to our Endocrinology Department due to solitary or multinodular goitre was included the study. Ultrasonography guide was used in all of FNA. FNA findings according to Bethesda classification were compared with corresponding histopathology findings, obtained with thyroidectomy specimens.
Results
After thyroidectomy, we determined that eight women (mean age 50.7 ± 6.8 years) of 401 patients with nodular goitre had papillary thyroid cancer in a cross thyroidal lob which FNA was not made, although finding of FNA was benign at one thyroid lob which FNA was made. Moreover, multicentric papillary thyroid cancer was found in two of them after thyroidectomy.
Conclusions
Our landmark finding point out that FNA should be performed all of suspicious nodule rather than dominant nodule. On the other hand multicentric papillary thyroid cancer are still a problem, although, FNA is widely used for evaluate cytology of nodules.

EP1082

Hyperthyroidism in Internal Medicine Services in Spain (2005–2012)

Sandra Duran[1], Judith Lopez[2], Ana Ortolá[1], Irene Crespo[1], Teresa Ruiz Gracia[1], Manuel Mendez[1], Karla Nuñez[1] & Javier Marco[1]
[1]Hospital Clinico San Carlos, Madrid, Spain; [2]Hospital Universitario de Canarias, San Cristobal de la Laguna, Spain.

Introduction
The prevalence of hyperthyroidism in patients admitted in Internal Medicine at Spanish hospitals is 0.8%. Proper diagnosis and management of HTD in these patients is still a challenge and therefore, the analyses of the factors involved in the prognosis and survival is of interest.
Methods
Data from the minimum-data-set (MDS) of Spanish National health System were collected during 2005–2012 from discharged patients of Internal Medicine with HTD diagnosis. A bivariate analysis was performed in order to detect differences in the mortality rate, median age, median hospital stay, readmission rate and comorbidities among HTD and non HTD (NHTD) patients. A logistic regression analysis was performed using as dependent variable in-hospital mortality and sex, mean age, adjusted comorbidities measured by the Charlson's index and HTD as independent variable. χ^2 and Student's t-test were performed. SPSS22.
Results
A total of 32 515 out of 3 952 018 (0.8%) cases of HTD were found with a 66% of women vs 47.1% in NHTD ($P<0.001$). Mean age was 77 (S.D. 12.71) years vs 72 (S.D. 17.06) in NHTD. Atrial fibrillation was more common in HTD (41% vs 22%; $P<0.001$), and heart failure was more frequent in HTD (33% vs 21%; $P<0.0001$). The mortality rate in HTD was lower than in NHTD (8% vs 10%; $P<0.001$). In the logistic regression analyses adjusted by age, sex, and Charlson's corimbility index, HTD was found to be an independent factor to prevent mortality in inpatients OR 0.69 (CI: 0.66–0.74; $P<0.0001$).
Conclusions
HTD patients admitted to Internal Medicine wards have a lower mortality than NHTD. The frequency of women, atrial fibrillation and heart failure was higher in the HTD group. It is still unknown why HTD patients show lower mortality during admission. Perhaps other clinical and therapeutical factors, which have not been assessed through this retrospective study, have been involved with the hospital prognosis.

EP1083

The prevalence of hyponatraemia and mortality in lung cancer patients

Ankit Jain, Alam Salma, Sophie Mascall, Shobhit Baijal, Joyce Thompson & Jayadave Shakher
Birmingham Heartlands Hospital, Birmingham, UK.

Aim
To estimate the prevalence and clinical significance of hyponatraemia in patients with lung cancer.
Methods
The data were obtained from Hospital Registry. The serum sodium (SNa) on diagnosis was used for statistical comparisons. Normonatraemia is defined as SNa 135–144 mmol/l, hyponatraemia <135 mmol/l, and hypernatraemia >145 mmol/l. The data was analysed for small cell (SCLC), non-small cell (NSCLC) and unknown group where histological diagnosis was not possible due to clinical reasons. Data analysis by STATA, version 12.1.
Results
The study population was 314 (57.3% males and 42.7% females). There were 16.4% SCLC, 60.1% NSCLC, and 23.5% unknown group. The sex distribution in SCLC – 52.9% males and 47.1% females, NSCLC – 59.4% males and 40.6% females, and unknown – 56.2% males and 43.8% females. The mean age in SCLC $69.1+10.2$, NSCLC $69.7+9.7$, and unknown $70.3+13.8$ ($P=0.84$). The overall incidence of hyponatraemia, SNa <135 mmol/l was 37.6%. The incidence of hyponatraemia was higher in SCLC than other two groups but not statistically significant ($P=0.09$) (SCLC 49.0%, NSCLC 33.2%, and unknown 41.1%).

Analysis according to severity of hyponatraemia between groups. Normonatraemic (135–144) 60.5%, mild (130–134) 21.7%, moderate (120–129) 15.3%, severe (<120) 0.6%, and hypernatraemia (≥145) 1.9%. Distribution of hyponatraemia among groups were as follows: SCLC mild 27.5%, moderate 21.6%, and severe 0% ; NSCLC: mild 19.8%, moderate13.4%, and severe 0%. The risk of death within 30 days was 43% higher in the hyponatraemic group than the normonatraemic, not statistically significant. Normonatraemia 37.9%, hyponatraemia 46.6%, and odds ratio (95% CI) 1.43 (0.90–2.28); $P=0.13$. The risk of death within 30 days in the mild and moderate groups increased by 46 and 27% respectively compared to normonatreamia but not statistically significant. Within 30 days – normonatremia 117/190 (61.6%), mild 36/68 (52.9%), moderate 27/48 (56.3%), and severe 0/2. Odds ratios: normonatraemia 1.00, mild 1.46 (0.83–2.55), $P=0.19$; moderate 1.27 (0.67–2.42), $P=0.46$, and severe NA.

Conclusions

Hyponatraemia is a negative prognostic indicator in lung cancer patients. Further studies are needed to see whether correction of hyponatraemia has any survival benefit.

Disclosure

The presenting author has received educational grant from Otsuka.

Somatostatinoma in patient with neurofibromatosis 1 – case report

Violetta Rosiek[1], Magdalena Londzin-Olesik[1], Anna Zemczak[1] & Beata Kos-Kudla[2]

[1]Department of Endocrinology, School of Medicine with the Division of Dentistry, Medical University of Silesia, Katowice, Poland; [2]Department of Endocrinology, School of Medicine with the Division of Dentistry, Chair of Pathophysiology and Endocrinology, Medical University of Silesia, Katowice, Poland.

Introduction

We present a rare case of 49-year-old patient with neurofibromatosis type I and somatostatin-secreting pancreatic neuroendocrine neoplasm. World literature describes about 30 cases of duodenal somatostatinoma in NFI1 and 1/3 of these cases with metastases to the lymph nodes or liver.

Case report

In October 2013 patient was operated in emergency due to gastrointestinal tract obstruction. During the procedure inoperable head of pancreas tumour, closing duodenum was confirmed. Gastrojejuniostomia was performed, specimens from pancreas tumour were taken. Neoplasm tissue wasn't found in the examined specimens in the histopathological examination. In June 2014 core biopsy pancreas tumour was performed under control CT which resulted in discovering neuroendocrine neoplasm G2. Afterwards in 30th September 2014 patient was operated (using the method of Whipple's). Diagnosis well-differentiated neuroendocrine neoplasm G2, Ki-67 5% was confirmed (positive somatostatin reaction/expression in immunohistochemical test). In abdominal CT 17th December 2014 local recurrence and metastases to liver and lymph nodes have been identified. Stomachaches, weight loss and loose stools (4/day) since October 2014 were appeared. Evaluated concentrations of neuroendocrine markers (CgA, insulin, gastrin, serotonin and 5-hydroxyindoleactic acid) were in reference ranges. Determination of serum somatostatin level was impossible. Due to symptomatic and metastatic characters neuroendocrine neoplasm patient was treated with the somatostatin analogue. Clinical improvement (weight stabilization, diarrhea withdrawal) was observed.

Conclusion

Somatostatin-secreting pancreatic neuroendocrine neoplasm occurs very rarely and affects patients with neurofibromatosis type I. Somatostatin analogues in neuroendocrine neoplasm treatment resulted in great effectiveness.

Insulinoma: a multicentre and retrospective analysis of the Spanish experience during three decades

Pedro Iglesias[1], Christian Lafuente[1], María Angeles Martín Almendra[2], Antonio López-Guzmán[3], José Carlos Castro[4] & Juan José Díez[1]

[1]Department of Endocrinology, Hospital Ramón y Cajal, Madrid, Spain; [2]Department of Endocrinology, Hospital Virgen de la Concha, Zamora, Spain; [3]Department of Endocrinology, Hospital Nuestra Señora de Sonsoles, Avila, Spain; [4]Department of Endocrinology, Hospital General, Segovia, Spain.

Objective

To characterise insulinoma diagnosed and treated in the period 1983–2014 in various hospitals in Spain.

Methods

Inclusion criteria were the presence of biochemical and morphological criteria compatible with insulinoma and/or histologic demonstration of tumour.

Results

Twenty-nine patients (23 women (79.3%); mean age 48.7±17.4 years (range, 16–74)) were recruited. In 26 (89.7%) cases the tumor was sporadic and the rest (3 women, 10.3%) was presented in the context of multiple endocrine neoplasia (MEN 1). There were 3 (10.3%) multiple insulinomas, one associated with MEN and 2 (6.9%) sporadic malignant insulinomas. The majority ($n=18$, 62.1%) showed fasting hypoglycaemia, about a third (31%) both postprandial and fasting hypoglycaemia and 6.9% postprandial hypoglycaemia only. Time to reach nadir of glucose (37.3±6.5 mg/dl) in the fasting test was 9.0±4.4 h, with maximal insulinaemia of 25.0±20.3 mcU/ml. Abdominal CT detected insulinoma in 75% of patients. Twenty seven (93.1%) patients underwent surgery (enucleation, 18 (66.7%) and subtotal pancreatectomy was performed in 9 (33.3%) patients; mean tumour size was, 1.7±0.7 cm). Surgery achieved cure in the majority ($n=24$, 88.9%) of patients.

Conclusion

Insulinoma is usually a benign, small and solitary tumour, affecting predominantly women aged 45–50 years which is habitually located with abdominal CT. Open surgery by enucleation is the most commonly used surgical technique achieving a high cure rate.

Psoriatic patients have not an increased risk of polycystic ovary syndrome-results of a retrospective study

Gina Botnariu[1], Daniel Cioloca[1], Catalina Holban Cioloca[1], Anca Chiriac[2,3] & Alexandru Florescu[1]

[1]University of Medicine and Pharmacy 'Gr. T. Popa', Iasi, Romania; [2]Apollonia University, Iasi, Romania; [3]Nicolina Medical Center, Iasi, Romania.

Objective

There are a few studies regarding the relationship between psoriasis and polycystic ovary syndrome (PCOS).

The aim of present study was to identify the prevalence of PCOS in patients with psoriasis.

Material and methods

A retrospective study has been performed upon 1236 patients diagnosed with psoriasis (male 54.13%, female 45.87%) during 2004–2011. The prevalence of polycystic ovary syndrome (PCOS) has been quantified.

Results

Out of the 1236 patients diagnosed with psoriasis, 669 were men (54.13%) and 567 (45.87%) women, 533 women of reproductive age with psoriasis. PCOS was diagnosed in eight patients, representing 1.5% of female patients of reproductive age with psoriasis.

Conclusion

Although previous data have suggested a higher prevalence of PCOS in women with psoriasis one, our data does not support the correlation. Limitations of present study: no healthy age and body mass index (BMI)-matched controls.

Case report of successfully treated congenial hyperinsulinism in Armenia

Gayane Bayburdyan & Yelena Aghajanova

Yerevan State Medical University, Yerevan, Armenia.

Introduction

Congenital hyperinsulinism is the most common cause for recurrent hypoglycaemia in neonates and infants. Uncontrolled hypoglycaemia leads to seizures and long-term cerebral damage. Herein, we report a case of congenital hyperinsulinism (persistent hyperinsulinaemic hypoglycaemia of infancy, nesidioblastosis) and review of the relevant literature regarding on the aetiology, pathogenesis, clinical and pathological features, diagnosis and treatment of this disorder.

Case report
A term male newborn with a birth weight of 2900 g, delivered vaginally without complications, presented with tonic-clonic seizures and hypoglycaemia of 0.5 mmol/l (normal range 1.7–2.8 mmol/l) on the second day of life. Intravenous infusion of 12.5% glucose solutions at a rate of 10–17 mg/kg and dexamethazone 0.8 mg/kg were given to maintain a stable blood sugar level. The plasma insulin level was 32.3 μU/ml (normal values 2.6–24.9 μU/ml) and blood sugar level was between 0.5 and 7.2 mmol/l on day 30 of his life. These results suggest nesidioblastosis, or persistent hyperinsulinaemic hypoglycaemia of infancy (PHHI). To confirm the diagnosis, the diagnostic laparoscopy was performed. During the surgery, enlarged hyperplastic Langergance islets were visualised, patient was subjected to a pancreatectomy with resection of 50% pancreatic gland. Pathological analysis was consistent with insulinoma.
Conclusions and follow up
Congenital hyperplasia and dysplasia of pancreatic islet cells and a focal adenomatous hyperplasia was diagnosed by pathological analysis of surgical material, as well as clinical presentation. At present time, the patient is 3 years old, maintains euglycaemia with fractionated feeding and has a normal psychomotor development. This is the first case of diagnosis and successful treatment of congenital hyperinsulinism in Armenia.

Hodgkin's lymphoma presented as goitre: case report

Iva Jakubikova[1,2], Jan Cap[1,2] & Filip Gabalec[1,2]
[1]4th Department of Internal Medicine, University Hospital in Hradec Kralove, Hradec Kralove, Czech Republic; [2]Charles University Faculty of Medicine in Hradec Kralove, Hradec Kralove, Czech Republic.

Introduction
Lymphomas account for <5% of thyroid malignancies. The vast majority of them are non-Hodgkin's lymphomas (NHL), especially mucosa-associated lymphoid tissue lymphomas (MALT) and diffuse large B-cell lymphomas (DLBCL). However, Hodgkin's lymphoma affecting thyroid gland is very rare. Worldwide has been reported <50 cases so far and we describe another one.
Case report
A 22-year-old woman was referred to our department of endocrinology for a rapid enlargement of thyroid gland. Prior short therapy of corticosteroids soothed the growth, but after its cessation the goitre enlarged causing dysphagia, dry cough and stridor. The patient also suffered with night sweats and intermittent fever. Both physical and ultrasound examination found unilaterally large hypoechoic right thyroid lobe, deviating trachea to the left and at least two suspicious supraclavicular lymph nodes along the right sternocleidomastoid muscle. According to laboratory the patient was euthyroid, thyroid antibodies were negative, no significant changes in blood count. Elevated was lactate dehydrogenase (LDH 6 μkat/l), C-reactive protein (CRP 53 mg/l), erythrocyte sedimentation rate (ESR 76 mm/first hour). The fine-needle aspiration cytology (FNAC) was highly suspicious of lymphoma, but the flow cytometry did not prove any abnormal population of lymphocytes consistent with non-Hodgkin's lymphoma. Therefore a diagnostic excision from the right thyroid lobe was performed. Final diagnosis of classical Hodgkin's lymphoma, nodular sclerosing subtype was established. The department of haematology classified our patient for advanced stage IIB + E (extranodal involvement). The patient was treated with six cycles of eBEACOPP chemotherapy, reaching total remission according to PET/CT scan, further radiotherapy was not indicated.
Conclusion
Hodgkin's lymphoma of thyroid is rare, rapid growth can mimic primary thyroid carcinoma, FNAC can mimic thyroiditis, lacking diagnostic Reed-Sternberg cells. Flow-cytometry is not helpful in Hodgkin's disease. A biopsy is usually necessary to confirm the right diagnosis.

To be or not to be a primary hepatic neuroendocrine tumour

Ioana Maria Lambrescu[1,2], Sorina Martin[1,3], Cristina Blaga[3], Luminita Cima[1,2] & Simona Fica[1,3]
[1]Endocrinology Department, Carol Davila University of Medicine and Pharmacy, Eroii Sanitari Avenue 8, 050474, Bucharest, Romania; [2]PhD Student in the Project, Sectorial Operational Programme Human Resources Development (SOPHRD) Contract Number POSDRU/159/1.5/S/141531, Bucharest, Romania; [3]Endocrinology Department, Elias Hospital, Marasti Avenue 17, 011461, Bucharest, Romania.

Introduction
Primary hepatic neuroendocrine tumours (PHNTs) are a very rare medical entity. Usually, the liver represents the preferential site for metastasis. Large sized, singular nodules are the usual presentation of PHNTs. We report a patient with PHNTs at 4 years of tumour free follow-up.
Case presentation
A 45-year-old Caucasian female who presented with nausea, vomiting, diarrhoea, accompanied by diffuse abdominal pain, was found to have on contrast enhanced computer tomography an encapsulated liver mass measuring 7/8.5/9 cm, which contained multiple daughter cysts separated by a matrix. In this context, the initial diagnosis was of an Echinococcus cyst. The patient underwent an uneventful left atypical hepatic resection. The resected specimen displayed a centrally brown–greyish solid cystic tumour measuring 8 cm, outlining a heavily vascularized cell proliferation with trabecular and band disposition and a homogenous growth pattern. The result of the immunohistochemical stain was diffusely positive in the tumour cells for chromogranin, synaptophysin and neuron specific enolase with 2–4% nuclear reactivity for Ki-67 index. Postoperatory, the specific neuroendocrine markers (serum Chromogranin A and 24-h-urinary 5-hydroxyindolacetic acid) were within the normal range. The patient underwent In^{111} DTPA-octreotid scan, that showed no regions that were somatostatin receptor positive, and the PET scan with 5HTP could not find any suspicious lesions. The patient is now at 4 years of follow-up with no local recurrence or distant metastasis.
Conclusions
We report a case of primary PHNT in an adult female presenting with abdominal pain and diarrhoea, at 4 years of follow up with no signs of recurrence. We think that PHNT is an over-diagnosed medical entity, as most cases in English literature are incompletely documented, which makes it hard to establish the exact percentage of this type of tumour. In order to exclude an occult primary neuroendocrine tumour, thorough long-term investigations are required.

Benign and malignant thyroid disease in patients with acromegaly

Irina Tenu[2], Antonia Kiraly[2], Ileana Duncea[1,2], Ana Valea[1,2], Alina Silaghi[2] & Cristina Ghervan[1,2]
[1]Department of Endocrinology, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; [2]Endocrinology Clinic, Cluj County Clinic Emergency Hospital, Cluj-Napoca, Romania.

Introduction and purpose
Acromegaly is characterised by a chronic increase of GH and IGF-1 levels that may induce various clinical symptoms and multisystem comorbidities. The purpose of this study is to evaluate the type and frequency of thyroid disease most often associated with acromegaly patients.
Material and methods
We conducted a retrospective observational study analysing the data from the observation charts of 77 patients with acromegaly (58 females and 19 males), with a mean age of 54 years, evaluated between July 2007 and July 2014 in the Endocrinology department. The recorded data were: acromegaly status, sonographic thyroid morphology, thyroid function, and pathological data after surgical cure. The statistical analysis was conducted using Microsoft Excel 2010.
Results
The acromegaly status was active for 49% of the patients, controlled in 37%, and cured in 14%. 96% of the patients were treated, the most common combination being surgical treatment + radiotherapy + medication (39%). Thyroid disease was diagnosed in 54 patients (70.12%). Nodular goiter had the highest prevalence rate (27.27%), followed by Hashimoto's thyroiditis (12.98%) and thyroid cancer (10.38%). The occurrence of thyroid pathology was almost equal in women (70.68%) and men (68.42%). Thyroid disease was most frequent for the ≥60 years old age range, while acromegaly was most frequent in the 40–50 years old range. Other malignant diseases were diagnosed in 5% of the patients.
Conclusions
Thyroid disease is a frequent complication of acromegaly, with nodular goiter having the highest prevalence rate. In terms of malignant pathology, in our study, thyroid cancer had the highest prevalence rate (10.38%). This indicates the need for a systematic evaluation in order to achieve an early diagnosis.

Mutation in CDKN1B 3′-UTR region in a patient with acromegaly and primary hyperparathyroidism

Elizaveta Mamedova, Natalia Mokrysheva, Ekaterina Pigarova, Elena Przhiyalkovskaya, Evgeniy Vasiliev, Lyudmila Rozhinskaya & Anatoliy Tiulpakov
Endocrinology Research Center, Moscow, Russia.

Introduction
Multiple endocrine neoplasia type 4 (MEN4) is a rare disorder, caused by inactivating mutations in *CDKN1B* gene that encodes $p27^{kip1}$ cyclin-dependent kinase inhibitor. To date nine different germline *CDKN1B* mutations have been described in patients with clinical features of multiple endocrine neoplasia type 1 (MEN1) negative for *MEN1* mutations (MEN1 phenocopies).
Case report
We present a female 54 y.o. with clinical features of MEN1: active acromegaly due to GH-producing pituitary macroadenoma after two consecutive neurosurgical interventions (transcranial and transsphenoidal) with remaining tissue in left cavernous sinus, requiring treatment with long-acting somatostatin analogues; mild primary hyperparathyroidism with ultrasound signs of superior right parathyroid adenoma; multinodular colloid goiter; extirpation of uterus and ovaries for adenomatous endometrial polyp, multinodular fibromyoma and endometrioid cyst; right mammary gland resection for benign lesion. Genetic testing for *MEN1* germline mutation was negative. Genomic DNA from a blood sample of this patient together with ten other MEN1 phenocopies underwent high-throughput sequencing on the Ion Torrent Personal Genome Machine (Life Technologies) using a custom-designed AmpliSeq panel for the sequencing of a variety of genes, including *CDKN1B*, which could be responsible for the development of MEN1 phenocopies. We revealed a heterozygous mutation in 3′-UTR g.3897G>T (c×8G>T) in *CDKN1B* gene, which was *in silico* tested with free web-based application for disease-causing potential of DNA sequence alterations MutationTaster, detecting splice site alterations. Further *in vitro* studies are needed to confirm, whether this mutation alters protein function.
Conclusions
To our knowledge, we describe the first mutation in 3′-UTR of *CDKN1B* in a patient with MEN1 phenocopy.

EP1092

Analysis of current indications to bilateral adrenalectomy

Maria Kurowska, Joanna Malicka, Agnieszka Zwolak & Jerzy S Tarach
Department of Endocrinology, Medical University, Lublin, Poland.

Introduction
Bilateral adrenalectomy (BA) is rarely applied as a therapeutic procedure. It serves as a life-saving treatment in patients with persistent Cushing's disease after an ineffective pituitary surgery or in ectopic ACTH production. Other indications for BA are: bilateral adrenocortical adenomas, congenital adrenal hyperplasia and bilateral phaeochromocytoma in patients with hereditary paraganglioma-phaeochromocytoma (PPS/PGL) syndromes. It is also a procedure of choice in bilateral adrenal metastases. The aim of the study was to determine the indications to BA in patients hospitalized in our ward between 2001 and 2012.
Material and methods
12 patients (7F; 5M) aged 19–72 years. Studies were based on retrospective analysis of medical records.
Results
Patients were divided into three groups. Group 1:7 patients (4F; 3M) with bilateral phaeochromocytoma (MEN2 syndrome – four patients, PPS/PGL-1 patient, von Hippel – Linadu – one patient, one woman with sporadic bilateral phaeochromocytoma). Among three patients from group 2 the indications to BA were adrenal metastases of renal clear cell carcinoma in two and a metastasis to one adrenal gland coexisting with adenoma of the other in one case. Group 3: two women with Cushing's disease. One of them was operated 31 years earlier propter corticotroph microadenoma and the second – because of atypical pituitary macroadenoma refractory to radiation, neurosurgical and pharmacological treatment. Patients with congenital disorders (six), Cushing's disease (two) and one with metastasis and adenoma, underwent synchronous bilateral or two-stage adrenal surgery. Female with sporadic bilateral phaeochromocytoma was operated twice at interval of 10 years and two patients with adrenal metastases at intervals of 3–4 years. Two patients died after a year and 3 years due to the progression of the underlying disease. The remaining are still alive (from 2 to 31 years after surgery).
Conclusions
Currently, the prevalent indication to BA is bilateral phaeochromocytoma, mostly in the course of underlying hereditary neoplasmatic syndrome.

EP1093

Audit of adrenal tumours at Vilnius University Hospital Santariskiu Klinikos (VUHSK): 4 year results

Zydrune Visockiene[1,2] & Milda Girdziute[2]
[1]Vilnius University, Vilnius, Lithuania; [2]Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania.

The aim of study was to make a retrospective audit of diagnostic approach of symptomatic and asymptomatic patients with adrenal tumours diagnosed at VUHSK from 2010 to 2013.
Methods
Cases coded as D35.0; D44.1; E27.0; E27.5; E27.8; E27.9 according to ICD-10 classification were retrieved from database. Electronic data capture system was used to collect information.
Results
There were 527 (123 men, 404 women) patients, age 62.5±11 years, diagnosed with adrenal tumours from 2010 to 2013: 281 patient had symptoms: hypertension – 91.1%, episodic elevations of blood pressure – 34.5%, hypokalaemia – 18.1%, 246 patients had no symptoms. There were 71.5 and 94.7% of tumours found incidentally in symptomatic and asymptomatic groups respectively. Suspicion of hormonal hypersecretion and proper diagnostic approach was used only in 80 (28.5%) of symptomatic patients. Symptomatic patients were assessed for hormonal activity as compared to asymptomatic: aldosterone – 64.8 vs 43.9%, renin – 54.4 vs 30.1%, metanephrine/normetanephrine or adrenaline/noradrenaline – 61.2 vs 22.0% ($P<0.001$ for all), cortisol – 39.2% in both groups, comprehensive analysis – 14.6 vs 6.5% ($P=0.003$). Computed tomography confirmed diagnosis in 93% of cases in both groups; with larger tumors in asymptomatic compared to symptomatic patients (24.7±14.0 vs 22.5±14.4 mm, $P=0.02$).
Non-secreting tumours were diagnosed in 81.4 vs 94.8%, aldosteroma – in 10.3% vs 1.2%, phaeochromocytoma – in 6.8 vs 0.8% ($P<0.001$ for all), carcinoma – in 1.1 vs 0.4%, $P=0.378$ comparing symptomatic and asymptomatic groups respectively. There were 45% of secreting tumours in symptomatic patients for whom proper diagnostic approach was used based on symptoms.
Conclusions
The proportion of patients having adrenal tumours with and without symptoms is similar. Although hormonal assessment should be performed in all patients, clinical symptoms should urge the doctor for comprehensive assessment as the prevalence of secreting tumours is the highest in symptomatic patients for whom proper diagnostic approach was used to clarify the diagnosis.

Plasma chromogranin A and chromogranin B concentrations in untreated patients with mid gut carcinoid and their biochemical response to octreotide

Lee Armstrong, Teresa Rea, Brian Johnston & David McCance
Belfast HSCT, Belfast, UK.

We measured chromogranin A (CgA) and chromogranin B (CgB) in 36 patients, recently confirmed to have a midgut carcinoid tumour (MGC), prior to the commencement of octreotide treatment. Blood samples were taken before and after a bolus injection of 50 μg octreotide. There were 21 males, 15 females, age range 28–76 median 61 years.
Basal CgA, expressed as times the upper limit of normal (ULN) ranged from 333.3 to 0.5 ULN. Basal CgB ranged from 33.7 ULN to zero (undetectable). Of 36 patients, 21 had highly elevated basal CGA (> X5 ULN), ten had moderately elevated CGA (X2–X5 ULN) and five patients had normal or marginally raised

CgA. Nine patients had CgB > X2 ULN, four patients had elevated CgB up to X2 ULN and 23 had normal CGB. All patients with elevated CgB also had raised CgA. Fourteen of 29 patients with raised basal CgA showed a significant (>20%) decrease in CgA 60 min after octreotide injection. Three showed an increase of >20%. The remaining patients showed no significant change. Seven of 11 patients with a high basal CgB showed a decrease >20% 60 min post injection. It is generally observed that very high CgA concentrations before treatment begins may indicate advanced stage of disease and therefore poor prognosis. A lack of response may also predict a poor prognosis. However, good biochemical response to bolus octreotide may indicate a good future response to treatment. CgB was performed to assess its usefulness as a supplementary diagnostic test in neuroendocrine tumour patients with normal CgA. We did not observe any patients with raised CgB only according to the supplied kit reference range.

Endoscopic ultrasound features of familial vs sporadic pancreatic neuroendocrine tumours: a single-centre retrospective study

Gianluca Tamagno[1], Vanessa Scherer[1], Alberto Caimo[2], Simona R Bergmann[1] & Peter H Kann[1]
[1]Division of Endocrinology and Diabetology, University Hospital – Philipp's University, Marburg, Germany; [2]Faculty of Economics, University of Lugano, Lugano, Switzerland.

Introduction
Pancreatic neuroendocrine tumours (pNETs) can either occur in patients with a familial syndrome, like multiple endocrine neoplasia type 1 (MEN-1), or being sporadic. In the last decade, endoscopic ultrasound (EUS) has become one of the first-line investigations for the characterisation of pNETs. The ultrasonographic features of a pNET might differ depending on the familial vs sporadic pathogenesis of the tumour. Therefore, the EUS findings might help and direct the accurate definition of a pNET with a possible impact on the most appropriate diagnostic and therapeutic management of pNET patients.
Patients and methods
In this single-centre retrospective study, we have reviewed the EUS characteristics of 131 pNETs from 38 MEN-1 patients and 14 pNETs from 13 sporadic disease patients at the time of their first EUS assessment. The patients attended consecutively our institution over a 5-year-time period. With the goal of defining the EUS features of MEN-1 vs sporadic pNETs, we have analysed the most relevant morphological and ultrasonographic aspects of the tumours and compared the findings between the two patient groups.
Results
Patients with MEN-1 are more likely to present with multiple (3.4 vs 1.1 tumours/patient) and bigger (21.6 vs 7.5 mm) pNETs in comparison to those with sporadic disease. There is no statistical difference with regard to morphology, definition of the margins, and vascularization of the pNETs between the two groups. However, pNETs appear to be significantly more heterogeneous in patients with MEN-1 than in those with sporadic disease.
Conclusion
In patients with MEN-1 pNETs tend to be more numerous, bigger, and more heterogeneous than in patients with sporadic disease. EUS can help with the precise characterization of a pNET, including the definition of ultrasonographic features which can distinguish a familial vs sporadic disease.

Thyroid carcinoma in relation to gender and age in patient who were treated with total thyroidectomy for different thyroid disorders

Entela Puca[1], Kadir Burak Koza[1], Emiljana Huti[1], Sonila Bitri[1], Edmond Puca[2] & Agron Ylli[2]
[1]American Hospital 2, Tirana, Albania; [2]UHC Mother Teresa, Tirana, Albania.

Aim of the study
Thyroid cancer comprises the most common endocrine malignancy and a variety of studies have examined the incidence of carcinomas in n thyroid disorders. Objective of the present retrospective study was the assessment of the possible influence of age and gender parameters in the presence of thyroid carcinoma in a patient who underwent total thyroidectomy.
Material and methods
We studied 107 patients (96 females/11 males) underwent total thyroidectomy because of nodular goitre in our Department. The classification of patients in both genders was conducted in the following age-groups: a = 16–39 years, b = 40–59 years, c = > 60 years. Thyroid specimens were histopathologically examined at our Pathology Department for the establishment of the final diagnosis of benignity or malignancy. Thyroid cancer cases were categorized in relation to gender and age group.
Results
40 patients (37.3%) were diagnosed with carcinoma (rate females:males 9:1), while 67 patients (62.7%) were free of malignancy. The incidence of thyroid cancer in male subjects was 36.5% (4/11). The respective cancer frequency in female subjects was 37.5 0% (36/96). The incidence of carcinoma per age group was in males: a = 3/4;75%, b = 0 and c = 1/5; 20%. In females it was respectively: a = 13/27; 48.1%, b = 20/51; 39.2%, c = 3/18; 16.62%.
Conclusions
We found the highest prevalence of thyroid carcinomas among the females. Age-specific rates of thyroid carcinoma were higher among women than men across all age groups. In males groups there was a high incidence in the age group 20–39 years and >60 years. Total thyroidectomy appears to be the therapeutic method of choice in men with indication of surgical removement of a goitre which belong to the above age groups. Contrarily, there was a high incidence in women age group 15–39 with a pick 40–59 years.

The sensitising action of a TIM16 inhibitor towards chemotherapeutic agents in human breast cancer cells depends on TIM16 expression

Teresa Gagliano[1], Federico Tagliati[1], Eleonora Riva[1], Denise Zerbini[1], Silvia Sambugaro[1], Erica Gentilin[1], Simona Falletta[1], Katiuscia Benfini[1], Carmelina Di Pasquale[1], Claudio Trapella[2], Severo Salvadori[2], Ettore degli Uberti[1] & Maria Chiara Zatelli[1]
[1]Section of Endocrinology, Department of Medical Sciences, University of Ferrara, Ferrara, Italy; [2]Department of Chemical and Pharmaceutical Sciences, Univeristy of Ferrara, Ferrara, Italy.

TIM16 a component of the translocase complex TIM23 of the mitochondrial inner membrane is encoded by the Magmas gene. Magmas was found to be over-expressed in human pituitary adenomas. Silencing Magmas in ACTH secreting rat pituitary adenoma cells enhances sensitivity to pro-apoptotic stimuli. Moreover, Magmas overexpression protects GH secreting rat pituitary adenoma cell lines towards apoptosis. Recently, we found that compound 5, a TIM16 inhibitor, is not cytotoxic but enhances the proapoptotic effects of staurosporine by reducing mitochondrial membrane potential (MMP) activation in a medullary thyroid carcinoma cell line, suggesting that compound 5 may be useful for cancer treatment in association with chemotherapeutic drugs. Since breast cancer (BC) displays high chemoresistance, the aim of our study was to investigate Magmas expression in human breast cancer cell lines and to verify whether compound 5 could increase the effects of a chemotherapeutic agent, such as Doxorubicin in these cells. As an *in-vitro* model we used three human breast cell lines: MCF7 and MDA-MB231 carcinoma cell lines and MCF12A normal breast cell line. We found that Magmas protein is highly expressed in the MCF7 cell line as compared to MDA-MB231 and MCF12A cells.
Our data show that treatment with compound 5 did not influences cell viability in the three cell lines, while Doxorubicin decreases this parameter by 20–30%. Only in MCF7 cells co-treatment with compound 5 enhances by 15–20% the antiproliferative effects of Doxorubicin, measured as cell viability and BrDU incorporation. MitoTox Glo assay shows that in MCF7 cells the enhancing effects of compound 5 on Doxorubicin action are due to mitochondrial toxicity. In summary, these data suggest a role for the use of compound 5 as a sensitising agent for chemoresistant breast cancer expressing high levels of TIM16.

Differential gene expression between primary and secondary hyperparathyroidism

Shih-Ping Cheng, Chien-Liang Liu, Jie-Jen Lee, Han-Hsiang Chen & Chih-Jen Wu
MacKay Memorial Hospital and Mackay Medical College, Taipei, Taiwan.

The pathophysiology differs significantly between primary and secondary hyperparathyroidism. Whole exome sequence analysis of parathyroid adenomas showed few somatic variants. The underling mechanisms of the occurrence of sporadic primary hyperparathyroidism remain largely unknown. In this study, we analysed the differences in gene expression between primary and secondary hyperparathyroidism to explore potential functional alterations. Total RNA was extracted from tissues obtained during parathyroidectomy. Gene expression microarray and bioinformatic pathway analysis were performed. Parathyroid tissues were classified in an unsupervised manner into primary and secondary clusters. Parathyroid adenomas showed higher expression of cell adhesion molecules. On the contrary, secondary hyperparathyroidism exhibited upregulation of complement/coagulation cascades and mTOR signalling pathway. In conclusion, our study demonstrates that different pathophysiology led to differential gene profiling in hyperparathyroidism. The results from pathway analysis may have diagnostic and therapeutic implications.

Surgical correlation of thyroid nodules categorised as potential follicular neoplasms in core-needle biopsy (CNB)

Miguel Paja[1], Rosa Zabala[2], Igone Corta[2], Amaia Expósito[4], Laura Calles[1], Aitzol Lizarraga[1] & Aitziber Ugalde[3]
[1]Endocrinology Department, Hospital Universitario de Basurto, Bilbao, Basque Country, Spain; [2]Radiology Department, Hospital Universitario de Basurto, Bilbao, Basque Country, Spain; [3]Pathology Department, Hospital Universitario de Basurto, Bilbao, Basque Country, Spain; [4]Endocrine Surgery Department, Hospital Universitario de Basurto, Bilbao, Basque Country, Spain.

In our centre we use CNB for routine study of thyroid nodules since 2005. Four diagnostic categories for CNB's results have been standardised: insufficient; benign; follicular proliferation (FOL), including follicular and oncocytic neoplasms; and malignant. Diagnosis of FOL was defined according to the presence of microfollicular patterned biopsies with scant or absent colloid, sometimes with minimal pleomorphism or discrete nuclear changes. This category could be equivalent to AUS/FLUS and FN/SFN, III and IV categories in BSRTC, encompassing undetermined diagnosis leading to surgical evaluation. We review surgical results in operated patients. A series of 166 patients (33 men), mean age, 52.8 years (SD 14.5) from 3750 CNBs (207 FOL; 5.5%) all of whom underwent surgery, from October 2005 to December 2014 were retrospectively analysed. They included 102 diagnosed as pure follicular lesions and 64 as oncocytic FOL. The false-positive rate, unnecessary surgery rate, and malignancy rate for the CNB patients according to the final diagnosis following surgery were evaluated. In surgical specimens 32 patients (19.3%) had non-neoplasms (unnecessary surgery), all of which were nodular adenomatous hyperplasia. The remaining 134 nodules were true neoplasms, 31 (18.7%) malignant. Malignant included 16 follicullar carcinomas, 13 papillary carcinomas. one medullary carcinoma and one poor-differentiated thyroid carcinoma. In 23 cases there were incidentally discovered papillary carcinomas (1–12 mm of size) in the same or contralateral lobe of the biopsied lesion. From 102 adenomas, 17 carried an incidental PTC (16.7%). Globally, there were 54 carcinomas with a CB of FOL (32.5%). CNB shows good/fine precision in diagnosing follicular neoplasms, but as FNA, fail to distinguish adenomas from carcinomas, with a malignancy rate around 20%. We remark the frequent association of benign neoplasm (adenomas) with malignant lesions in the same thyroid (16.7%), supporting surgical treatment when this CB diagnosis is obtained.

Emotional state in men and women with acromegaly after pituitary adenomas

Lina Lasaite[1], Robertas Knispelis[2], Jurate Lasiene[2] & Lina Barsiene[2]
[1]Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Clinic of Endocrinology, Clinical Hospital of Lithuanian University of Health Sciences, Kaunas, Lithuania.

Adult patients with acromegaly after pituitary adenomas usually have emotional problems, impaired quality of life. Objective was to detect possible differences of emotional state between patients with acromegaly after pituitary adenomas and healthy age- and sex-matched controls and to outline possible gender-specific differences.

Patients and methods

12 males (age 49.6±10.2 years) and 29 females (age 51.5±9.5 years) with acromegaly after pituitary adenomas; 12 control males (age 44.7±14.6 years) and 29 control females (age 50.4±12.7 years). Average duration since diagnosis of acromegaly was 7.1±8.9 years. Emotional state (domains of tension-anxiety, depression-dejection, anger-hostility, vigour-activity, fatigue-inertia, confusion-bewilderment) was evaluated using Profile of Mood States (POMS).

Results

Anger-hostility was significantly lower in men with acromegaly than in control men (9.5±5.0 vs 14.8±7.5, $P=0.039$). In women with acromegaly tension-anxiety (9.3±5.9 vs 4.5±6.0, $P=0.005$) was significantly higher than in control women. No significant differences in emotional state was detected betweeen men and women with acromegaly and between men and women in the control group, only some statistical trends. In acromegalic patients there was statistical trend for men to have higher vigour activity (16.8±4.8 vs 13.8±5.2, $P=0.060$) than women; in age- and sex-matched controls there was statistical trend for men to have higher anger-hostility (14.8±7.5 vs 9.7±5.7, $P=0.061$) than women.

Conclusion

Men with acromegaly after pituitary adenomas have lower anger-hostility level and women with acromegaly after pituitary adenomas have higher tension-anxiety level than age- and sex-matched controls.

Von Hippel–Lindau disease: report of two cases

Anna Dabrowska[1], Jerzy Tarach[1] & Agnieszka Zwolak[1,2]
[1]Chair and Department of Endocrinology, Medical University of Lublin, Poland, Lublin, Poland; [2]Chair of Internal Medicine and Department of Internal Medicine in Nursing, Medical University of Lublin, Poland, Lublin, Poland.

Introduction

Von Hippel–Lindau (VHL) disease is a rare autosomal dominant syndrome (1/36 000 live births) with highly penetrance that predisposes to the development of benign and malignant, highly vascularised tumours in many organs.

Case reports

Two women with VHL, without family history of VHL, were admitted to Department of Endocrinology for checkups. The diagnosis was made based on genetic tests.

Patient A

A 53-year-old woman, after partial right adrenalectomy in 1976 and total left adrenalectomy in 1979 due to bilateral pheochromocytoma. At present, she has no hypertension and typical symptoms of adrenal insufficiency. Hormonal tests revealed normal concentrations of serum cortisol and 24 h urinary cortisol in the presence of elevated serum ACTH that may indicate low adrenal reserve. The administration of hydrocortisone (10–20 mg/day) was recommended, in case of stress. The levels of serum chromogranin-A, dopamine and noradrenaline as well as 24 h urinary methoxycatecholamines were in normal range. All body scintigraphy and abdomen CT scan did not show phaeochromocytoma recurrence.

Patient B

A 44-year-old woman, with right retina haemangioblastoma leading to blindness, after resection of cerebellum haemangioblastoma (with right hemiparesis and imbalances) and clear-cell carcinoma of the left kidney, with renal cysts. At present, she has no hypertension. Hormonal tests revealed normal concentrations of serum ACTH and cortisol and 24 h urinary cortisol as well as serum chromogranin-A, dopamine, noradrenaline, urinary 5-HIAA. Abdomen CT scan showed hepatic vascular malformations and two pancreatic tumours. In head MRI

scan, the lesions: in right frontal lobe and in right eyeball were found. Somatostatin receptor scintigraphy confirmed increased radioisotope accumulation in pancreas and in right orbit. We excluded phaeochromocytoma. The diagnosis of pancreatic NETs, without hormonal activity, was made and the surgery is considered. Moreover, stereotactic radiotherapy for brain lesion was recommended.
Conclusions
Some manifestations of VHL cause that endocrine care is needed to optimize patients' treatment.

Enucleation of pancreatic proinsulinoma: case report

Ana Pires Gonçalves[1], Rui Almeida[2], Hercilia Martins[3], Madalena Lourenço[4], Jorge Pereira[5], Bruno Peixe[6], Ana Rita Clara[2], Conceição Viegas[2], Ana Marta Nobre[7], Sílvia Silva[7], Jorge Paulino Pereira[7] & Mário Lazaro[2]
[1]Internal Medicine Service – Endocrinology's Division – CHAlgarve, Faro, Portugal; [2]Internal Medicine Service – CHAlgarve, Faro, Portugal; [3]Clinical Pathology Service – CHAlgarve, Faro, Portugal; [4]Day Hospital Nurse – CHAlgarve, Faro, Portugal; [5]Radiology Service – CHAlgarve, Faro, Portugal; [6]Gastroenterology Service – CHAlgarve, Faro, Portugal; [7]Hepato-pancreato-biliary Surgery Division – Hospital Curry Cabral, Faro, Portugal.

Introduction
Functional islet β-cell tumours represent 1–2% of all pancreatic neoplasms. Diagnosing this type of tumour is often challenging because they present with unspecific clinical features overlapping more common syndromes. Diagnosis involves expensive testing, so, establishing whipple's triad and excluding causes of exogenous hyperinsulinaemia is crucial before initiating investigation.
Objective
To report a rare case of a proinsulinoma.
Case report
A 47-year-old woman was sent to the endocrinology department for evaluation of suspected spontaneous hypoglycaemia. There were no relevant antecedents. For 2 years she had had adrenergic/neuroglicopenic symptoms that relieved after ingestion of carbohydrate. She had gained 20 kg/2 years. Fractionated-diet, excluding simple carbohydrates, failed to improve symptoms. The patient was taught how to use a glucose meter to measure capillary blood glucose (BMT) and instructed to do a diary, that include meals content and BMT during symptoms. Study revealed hypoglycaemias (BMT (50 mg/dl) without a predictable pattern. Laboratorial investigation confirmed endogenous hyperinsulinism secondary to autonomous proinsulin secretion. A study with CTscan-with-contrast, ultrasound and ecoendoscopy, showed a single oval nodule with 17×13 mm. Given the nodule to be unique and with very suggestive features of proinsulinoma, it was decided not to perform aspiration cytology. The patient started treatment with diazoxide while waiting for surgery. In September of 2014, she underwent a tumour enucleation, without complications. The histopathological study confirmed a low-grade neuroendocrine tumour. In the postoperative period symptoms/hypoglycaemia resolved and there was no hyperglycaemia or diabetes mellitus.
Conclusion
The work-up of fasting hypoglycaemia is crucial because a wrong diagnosis can lead to unnecessary pancreatectomy or a missed pancreatic tumour. Localisation is challenging so imaging studies should only take place once the diagnosis has been established. Highly specific serum insulin assay can difficult the diagnosis. An enucleative approach minimises the risk of developing post-operative diabetes, leading to a favourable prognosis.

Morphological features and functional activity of parathyroid adenomas

Yuri Aleksandrov, Dmitryi Oralov & Sergey Pamputis
Yaroslavl Medical University, Yaroslavl, Russia.

Study for morphological and hormonal changes in the parathyroid glands in 35 patients with primary hyperparathyroidism was carried out. Post-mortem material (five bodies) used to control. All patients had primary hyperparathyroidism and elevated levels of parathyroid hormone and ionized calcium in serum. Morphometric study evaluated the cellular structure (chief and oxyphil cells) and calculated the ratio of the basic elements of parathyroid cells (nucleus, cytoplasm) and stroma (collagen fibres, blood vessels). The correlation between hormonal and morphological parameters calculated using the methods of variation statistics. Levels of PTH had significant variation range from 96 to 2665 pg/ml ($X=734$, 6 pg/ml), as well as the volume of parathyroid adenomas – from 0.3 up to 31.5 cm 3 ($X=5.1$ cm^3). A direct relationship is between the level of PTH and a relative density of nuclear component parenchyma ($r=0.56$; $P=0.009$). A feedback is between PTH and a relative density of parathyroid cells cytoplasm ($r=-0.56$; $P=0.012$). There is no correlation between the level of PTH and the average number of cellular elements in the field of view ($r=0.27$; $P=0.26$). In parathyroid adenomas smaller than 1 cm^3 of correlation between levels of PTH and the increase in the size of the tumour is not ($r=0.25$; $P=0.47$). In parathyroid adenomas larger than 1 cm^3 PTH level increases with tumour volume ($r=0.55$; $P=0.01$). There is no direct correlation between level of PTH and specific morphological changes in the parathyroid glands. Secretion of parathyroid hormone depends on the intracellular and the structural changes in parathyroid adenomas. Significantly changes are correlate with the size of the tumour.

Adult-onset nesidioblastosis causing hyperinsulinaemic hypoglycaemia: diagnosis and treatment challenge: a case report

Daniel-Tudor Cosma[1], Alina Silaghi[2,4], Nicolae Rednic[3,4], Sorin Barbu[3,4], Carmen Georgescu[2,4] & Ioan Andrei Veresiu[1,4]
[1]Diabetes, Nutrition and Metabolic Diseases Clinical Center, Cluj-Napoca, Cluj, Romania; [2]Endocrinology Clinic, Cluj-Napoca, Cluj, Romania; [3]Railways Clinical Hospital, Cluj-Napoca, Cluj, Romania; [4]Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Cluj, Romania.

Nesidioblastosis is defined as a diffuse proliferation of primitive pancreatic islet cells budding from ductal epithelium. This condition can cause hypoglycaemia in infants as a result of mutations in the sulfonylurea receptor or in the anatomically linked potassium channel. In adults, this disease occurs independently from these genetic mutations.
Case report
A 41-year-old male was referred to our center via emergency room with suspicion of an insulinoma after an episode of loss of consciousness with a glycemia (G) of 24 mg/dl. Further questioning revealed three similar episodes in 2012. At admission: altered general status with retrograde amnesia, dry skin and mucous membrane and deep tenderness in the epigastrum, pulse 65 b/min. The 72 h fast was stopped for symptomatic hypoglycaemia with high insulinaemia. Imaging studies were normal excepting endoscopic ultrasound which revealed a pseudolobular aspect in the pancreas tail and body. The patient was guided to a surgical clinic with dietetic recommendation and phenytoin 200 mg/day for insulinoma localization and surgical treatment. His was admitted into the surgical clinic after 3 weeks from the previous hospitalization with only two moderate hypoglycaemic episode under phenytoin treatment. The short octreotide test was interrupted due to symptomatic hypoglycaemia confirming the lack of tumour somatostatinoma receptors. Exploratory laparotomy was performed with intraoperative ultrasonography which exhibited two tumors in the pancreas tail and body. A subtotal spleno-pancreatectomy was performed. Microscopic view was consistent with nesidioblastosis and no tumour was found. The patient remains euglycaemic 10 months post-operatively.
Discussions
Nesidioblastosis is a rare cause of adult hypoglycaemia. Pre-operative differentiation from insulinoma is difficult, but mandatory when imaging studies are negative. New diagnostic tools like ^{18}F-DOPA PET scan or selective arterial calcium stimulation with hepatic venous sampling (unavailable in our country) could help establishing the diagnosis.

Pituitary apoplexy

Dhiaeddine Bellarbi, Said Azzoug, Leyla Rabehi, Brahim Terki & Farida Chentli
Endocrinology and Metabolic diseases department Bab El Oued hospital, Algiers, Algeria.

Introduction
Pituitary apoplexy is a rare endocrine emergency characterized by the sudden onset of severe headaches, vomiting, visual abnormalities and pituitary dysfunction secondary to an acute hemorrhage or infarction within a pituitary adenoma.
Subjects and methods
We report a retrospective study from 2000 to 2014 of 23 cases with pituitary apoplexy. Their mean age was 38.7±14.8 years, with a male to female ratio of 2:1.
Results
Apoplexy revealed an unknown adenoma in 74%. 48% were prolactinomas, 22% were GH-secreting adenomas and 30% were non functioning adenomas. The commonest presenting symptoms were frontal and retro-orbital headaches in 92%, visual impairment in 78%, vomiting in 43% and ocular nerves palsies mainly the third nerve palsy in 40% with diplopia and ptosis. Fever, meningeal irritation signs, rhinorrhea and epistaxis were reported in 8%. Predisposing factors were diabetes in 31%, bromocriptine use in 22%, antithrombotic medication in 4.3% and pregnancy in 4.3%. Pituitary imaging showed macroadenomas in all cases. These macroadenomas invade the optical chiasma in 87%, the cavernous sinuses in 48%, the sphenoidal sinus in 39% and have multidirectional extension in 22%. Areas of intratumoral hemorrhage were evident on MRI in 94%. Endocrine evaluation showed at least one hormone deficiency in 92%. Gonadotroph deficiency was present in 78%, corticotroph deficiency in 70% and thyrotropic deficiency in 61%. After the apoplexy episode 40% of GH-secreting adenomas normalized their GH–IGF1 levels and 27% of prolactinomas normalized their prolactin levels. Six patients were treated with high dose glucocorticoids with complete neuro-ophthalmological recovery in 67%.
Conclusion
Pituitary apoplexy is a rare life-threatening clinical syndrome caused by infarction or hemorrhage within a pituitary adenoma, once diagnosed a multidisciplinary team approach is mandatory in order to improve the outcome of this condition.

Relationship between thrombotic markers, insulin resistance and thyroid volume in women with prolactinoma

Ayten Oguz[1], Dilek Tuzun[1], Murat Sahin[1], Elif Inanc[2], Irem Gokalp[2], Didem Atay[2], Hakan Demir[2] & Kamile Gul[1]
[1]Department of Endocrinology and Metabolism, Kahramanmaras Sutcu Imam University, Faculty of Medicine, Kahramanmaras, Turkey; [2]Department of Internal Medicine, Kahramanmaras Sutcu Imam University, Faculty of Medicine, Kahramanmaras, Turkey.

Aim
Hyperinsulinaemia is frequent finding in patients with hyperprolactinemia and has associations with thyroid volume. In this study, we evaluated the association between thrombotic markers, insulin resistance, CIMT, and thyroid volume in female patients with prolactinoma.
Material and methods
38 women with prolactinoma and 24 healthy women were included to the study. We evaluated anthropometric, biochemical, hematologic and hormonal parameters as well as thyroid volume (TV) and CIMT in prolactinoma patients (before treatment) and controls. Insulin resistance was calculated using the HOMA-IR.
Results
Mean age, BMI, TSH, mean platelet volume (MPV) and platelet distribution width (PDW) levels were similar between groups ($P>0.05$). HOMA-IR, platelet counts, prolactin, insülin levels, CIMT and tiroid volume was were significantly higher in prolactinoma group ($P<0.05$). While there was positive correlation between prolactin levels and insulin levels, platelet counts, CIMT and triglyceride levels ($P=0.04$, $r=0.23$; $P=0.01$, $r=0.32$; $P=0.02$, $r=0.28$; $P=0.01$, $r=0.31$, respectively), there was no significant correlation between prolactin levels and TV, MPV, PDW, and HOMA-IR ($P>0.05$). There was statistically significant positive correlation between TV and HOMA-IR, insulin levels, platelet counts and CIMT ($P=0.00$, $r=0.45$; $P=0.00$, $r=0.43$, $P=0.00$, $r=0.35$, respectively).
Conclusion
Hyperprolactinemia has been implicated in the pathogenesis of obesity and glucose intolerance and is reportedly associated with an impaired metabolic profile. Additionally, elevated PRL levels may increase the risk of developing atherothrombotic events via the activation of platelets. Thyroid volume has been found to be associated with age, anthropometry, smoking, iodine status and hyperinsulinaemia. Additonally, growth hormone and growth factors have been shown to affect TV. In our study, we determined relationship between TV and insulin resistance, platelet count, and CIMT in patients with prolactinoma. So we think that, insulin resistance and thrombotic factors may be responsible for change in thyroid volume in patients with prolactinomas.

Gastrointestinal stromal tumour in a patient with multiple endocrine neoplasia type 1

Murat Sahin[1], Ayten Oguz[1], Dilek Tuzun[1], Ilhami Taner Kale[2], Cansu Yilmaz Cabioglu[3], Muharrem Bitiren[4], Safa Ersen Ganidagli[3], Tugba Yilmaz[3] & Kamile Gul[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [2]Department of General Surgery, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [3]Department of Internal Medicine, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [4]Department of Pathology, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey.

Introduction
Multiple endocrine neoplasia type-1 (MEN-1) is an autosomal dominant disorder MEN-1 diagnosis is established as the occurrence of two or more MEN-1 associated tumour or one MEN-1 associated tumour in a patient that have 1 MEN-1 family member or positive MEN-1 genetic mutation. MEN-1 associated tumours usually involve the parathyroid glands, anterior pituitary and enteropancreatic cells but many other tumours may be seen. In this report, we presented a gastrointestinal stromal tumour (GIST) in a patient with MEN-1.
Case
A first degree relative of a patient that has MEN-1 was hospitalised to our clinic for screening MEN-1 related tumours. The patient has stomach ache for 6 months and a history of gastric surgery for perforation 9 years ago. In his family history one brother was diagnosed as MEN-1 (parathyroid adenoma, Cushing's disease, gastric neuroendocrine tumour, pancreatic mass and positive MEN gene mutation) and other siblings are under evaluation for MEN-1 associated tumours. In physical examination palpation of abdomen revealed a mass in epigastrium and other findings were normal. Laboratory results were as follow; calcium 10.8 mg/dl (8.4–10.2), phosphor 1.7 mg/dl (2.4–5.4), cortisol 23.88 μg/dl (5–23), prolactine 19.7 ng/ml (3–23), IGF1 152 ng/dl (11–836), TSH 1.57 μIU/ml (0.4–4.2), fT_4 0.91 ng/dl (0.8–2.7), gastrin 57.2 pmol/l (6.2–54.8), insulin 6.92 μIU/ml (6–27) and cortisol after low dose dexamethasone suppression test 1.45 μg/dl. Parathyroid ultrasound showed a hypoechoic solid mass in posterior of the left thyroid lobe, suggestive for parathyroid adenoma. Abdomen CT showed a 112×73 mm solid mass. General surgery performed a biopsy and pathologic examination revealed a GIST.
Conclusion
GISTs are neoplasms arising from connective tissue located in the gastrointestinal wall. GISTs are uncommon neoplasms for MEN-1 syndrome and only a few cases are reported. It is not clear whether GISTs are coincidental or there is a role of MEN-1 gene mutation in these tumours.

The micropenis: about a series of 30 patients

Hakima Abes[1], Nora Soumeya Fedala[1], Ali El Mahdi Haddam[2], Leyla Ahmed Ali[1], Farida Chentli[1] & Djamila Meskine[2]
[1]Bab El Oued Hospital, Algiers, Algeria; [2]Bologhine Hospital, Algiers, Algeria.

Introduction
Micropenis is defined as a stretched penile length of <2.5 S.D., which can be diagnosed from birth to adolescence. It is idiopathic or associated with a chromosomal abnormality, hypogonadism, pituitary abnormality or a complex malformation syndrome. The therapeutic management of this disease should be early to get a favorable response and absence of impact objective. Clarify the clinical and etiological aspects of micropenis of patients followed.
Population, methodology
We made a retrospective study of the cases of patients with micropenis collected in 26 years. A clinical examination and oriented paraclinical exploration has been made.
Results
30 patients were identified (18 children and adolescents between 2–18ans and 12 adultes between 21–44 years). The average age at the consultation is 15 years in children, 30 adults. It is isolated in 50% diagnose at an average age of 13, 5 years in children. In half of the cases, it is associated with other genital abnormalities who did reveal: it in children: cryptorchidism 12 (40%) diagnosed at 5 years (only on at birth) lifts testicles: 2 (6%), hypospadias 1 (3%). The reason for consultation was the signs of hypogonadism in adults in all cases. Aetiological, it is due to a central hypogonadism (40%), GH deficiency (7%) and gonadal dysgenesis (3%). 50% of cases are idiopathic. In half of cases micropenis children (mainly idiopathic and pituitary) responded favourably to androtardyl and GHR in the case of GH deficiency. The younger children (<6 years) responded best.
Discussion and conclusion
The absence of systematic examination of the external genitalia at birth and ignorance of these abnormalities explain the delay in diagnosis and ineffectiveness of treatment. Progress height-weight and hairiness induced by the treatment did not reconsider the treatment against the benefit obtained.

EP1109

Papillary thyroid carcinoma in a patient with MEN 1 syndrome

Alina Dumitru, Diana Paun, Adina Dragomir, Mihaela Nistor, Georgiana Taujan & Constantin Dumitrache
National Institute of Endocrinology C. I. Parhon, Bucharest, Romania.

Introduction
MEN1 is a rare syndrome characterised by hyperplasia or neoplasm of the parathyroid glands, pituitary, pancreas or duodenum and can associate, less frequently, phaeochromocytoma, thymic or bronchial carcinoids, multiple lipomas, cutaneous angiofibromas and thyroid adenomas.
Case report
A 47-year-old woman with MEN1 presenting parathyroid recurrent adenomas, a pituitary prolactin-growth hormone cosecreting macroadenoma, associated with an incidentall papillary thyroid microcarcinoma. The patient had a primary hyperparathyroidism treated 12 years ago, diagnosed after she was treated for a coraliform lithiasis. 2 years after, a secondary amenorrhea followed, caused by pituitary prolactin secreting macroadenoma, and a dopamine agonist was started. She didn't present for the follow ups for 10 years, when another kidney stone was discovered. Laboratory results show hypercalcaemia and increased PTH, with normal TSH and free thyroxine levels. She had a total thyroidectomy and parathyroidectomy. Besides the two parathyroidian adenomas, the histopathological examination revealed a papillary thyroid microcarcinoma. 1 year after, she was admitted in our service. Having a MEN1 patient, we had to continue the investigation. We found a slightly increased PTH level with normal calcaemia most probably secondary to the vitamin D insufficiency. The pituitary check-up showed a 1.01/1.03 cm adenoma with increased prolactin level and surprisingly increased IGF1 levels. Additionally, the patient had no signs or symptoms suggesting a pancreatic-duodenal involvement (no hypoglycaemia, insulin and gastrin in normal range). The next steps are the genetic analysis for MEN1 gene and the treatment for the pituitary macroadenoma.
Conclusion
This case underline the different phenotypic presentation of MEN1. Our patient had the classical presentation hypercalcaemia but she doesn't associate duodenoenteropancreatic NETs, the second most common endocrine manifestation in MEN1 syndrome. Additionally, the pituitary adenoma cosecrete prolactin and growth hormone. As we found in literature, the papillary thyroid carcinoma is probably incidental.

EP1110

Breast cancer and gonadal axis in postmenopausal and premenopausal women: impact of obesity

Rym-Ikram Mehaoudi[1], Karima Assas[1], Nawel Lazdam[1], Saida Adane[2] & Yacine Soltani[1]
[1]Faculty Of Biological Sciences, Laboratory of Biology and Physiology of Organisms, Endocrinology Team, USTHB, Algiers, Algeria; [2]Department of Oncology, Central Military Hospital, Ain Naadja, Algiers, Algeria.

Introduction
Breast cancer is one of the diseases causing the most deaths in women worldwide. Obesity, especially in postmenopausal women is a definite risk factor due to hormonal imbalance mainly to the levels of circulating oestrogen. The aim was to record levels for some gonadal axis hormones in breast cancer treated obese women.
Patients and methods
81 women aged between 21 and 80 years 54 are diagnosed with breast cancer (BC) during postmenopausal (PoBC) and premenopausal (PrBC) under different treatments, and 27 pre and postmenopausal women constitute the control groups (PrC and PoC). BMI lipidaemia, inflammatory status established by agglutinated plasma C-reactive protein (CRP) test, plasma LH, FSH, oestradiol, DHEA-S, androstenedione, prolactin, and testosterone were estimated by RIA.
Results
Obesity is predominant in PoBC group with 50 vs 35% in PrBC. while overweigh-obese women group represents 72% of PrBC and 83% PoBC groups respectively. Obesity in PoBC patients was mainly associated to dyslipidaemia, including significant increase in plasma total cholesterol, LDL-c, TG and HDL-c decrease. FSH increase in PrBC (126.3%; $P=0.01$) and decrease in PoBC (3.8%) was concomitant to DHEA-S fall in PrBC (42.8%; $P=0.037$) and increase in PoBC (51.3%; $P=0.031$) vs control groups. Whereas LH and estradiol increased concomitantly in PrBC (14.9 and 13.8%), but decreased (40.5 and 3.8%) in PoBC, testosterone was significantly reduced in regrouped PrBC and PoBC patients (24.2%; $P=0.04$). while androstenedione and prolactin fall of 17.5 and 11.9% respectively in regrouped PrBC and POBC patients.
Discussion conclusion
Obesity is confirmed as breast cancer risk factor in postmenopausal women. The sensitivity to hormone therapy appear to be more efficient in PoBC women with BMI$\leq$30 compared to PrBC patients, and reveal their efficiency to decrease plasma oestradiol, leading to activate positive feedback mechanism on LH and FSH secretion.

Neuroendocrine tumours observed in endocrinology

Mounia Safer[1], Nora Soumeya Fedala[1], Ali El Mahdi Haddam[2], Leyla Ahmed Ali[1], Farida Chentli[1] & Djamila Meskine[2]
[1]Bab El Oued Hospital, Algiers, Algeria; [2]Bologhine Hospital, Algiers, Algeria.

Introduction
Neuroendocrine tumours or TNE form from cells of the endocrine and neurological system at any point in the body and are characterised by their ability to secrete hormones and express protein markers. They are often benign, but some are malignant and can easily metastasise.
Objective
To describe the clinical, paraclinical and scalable of TNE endocrinology observed outside medullary carcinoma and phaeochromocytoma.
Population, methodology
Retrospective study of cases of patients with NETs collected in 26 years. All patients have benefited from a clinical, hormonal balance, specific morphological investigation and postoperative follow-up.
Results
16 cases were observed. They represented by endocrine pancreatic tumours ($n=10$, 62.25%) and carcinoids ($n=6$; 37.5%). The mean age at diagnosis was 43 ± 15 years (7–78 years) and sex ratio 1H/2F. 66.6% of pancreatic secreting tumours and revealed by an endocrine syndrome (60% insulinoma, 6.6% secrete TCT) and 33.3% non-secreting tumours discovered during abdominal pain. Average tumour size was 24 ± 0.4 mm (1 ± 0.4 cm: insulinoma and 7 ± 1 cm other PET). 46% are malignant (size$>$ 2 cm; 13% insulinoma; 33% others), 26% are metastatic, and 50% are well differentiated. The carcinoid are located at

rectum (*n*:2),intestinal (*n*:1), thymus (*n*: 1) and lung (*n*:6). They are malignant, well differentiated with slow evolution. All patients were successfully operated completed by a antisécrétoirs treatment or chemotherapy (10%). No recurrence or deaths were observed.

Discussion and conclusion

NET are rare in endocrinology. They dominate the gastrointestinal system. They are often secreting and malignant tumours with slow-growing and generally good prognosis. Their medical management requires a multidisciplinary team and a long term follow up.

EP1112

Vitamin D and breast cancer

Ifigenia Kostoglou-Athanassiou[1], Eustathia Papageorgiou[2], Athanasios Armakolas[2] & Michael Koutsilieris[2]
[1]Department of Endocrinology, Red Cross Hospital, Athens, Greece; [2]Department of Experimental Physiology, Medical School, University of Athens, Athens, Greece.

Introduction

The anticancer action of vitamin D is currently considered one of its main properties. The main actions of vitamin D are related to the regulation of calcium levels and the normal function of the musculoskeletal system. However, its anticancer action is currently in the focus of research interests.

Aim

The aim was to study the effect of vitamin D on MCF-7 human breast cancer cells *in vitro*.

Methods

The effect of 1,25 $(OH)_2D_3$ (Sigma-Aldrich) at an initial concentration of 200 nM on MCF-7 human breast cancer cells was studied *in vitro*. MCF-7 human breast cancer cells were incubated for 48 h at a temperature of 37 °C with progressively decreasing concentrations of $1,25(OH)_2D_3$. MCF-7 cells were also incubated with progressively decreasing concentrations of $1,25(OH)_2D_3$ (the initial concentration of $1,25(OH)_2D_3$ being 200 nM) in the presence of the antimitotic agent docetaxel 50 nM.

Results

A mild inhibition of the proliferation of human breast cancer cells MCF-7 was observed after 48 h incubation with $1,25(OH)_2D_3$. After simultaneous incubation with $1,25(OH)_2D_3$ and docetaxel intense inhibition of the proliferation of MCF-7 breast cancer cells was observed.

Conclusions

In conclusion, a mild inhibitory effect of $1,25(OH)_2D_3$ on the proliferation of MCF-7 human breast cancer cells was observed, while the antimitotic agent docetaxel had intense inhibitory effect on their proliferation. These findings are in agreement with the expression of VDR (Alimirah *et al.*, Mol Cell Biochem, 2010), the vitamin D receptor, in breast cancer cells.

EP1113

The effect of melatonin on MCF-7 breast cancer cells in vitro

Ifigenia Kostoglou-Athanassiou[1], Eustathia Papageorgiou[2], Athanasios Armakolas[2] & Michael Koutsilieris[2]
[1]Department of Endocrinology, Red Cross Hospital, Athens, Greece; [2]Department of Experimental Physiology, Medical School, University of Athens, Athens, Greece.

Introduction

It has been reported that blind women with disturbed melatonin secretion have a lower incidence of breast cancer. A higher incidence of breast cancer has been reported in women in shift work, in which lower nocturnal melatonin secretion is observed. The anticancer action of melatonin is currently the focus of research interest.

Aim

The aim was to study the effect of melatonin on MCF-7 breast cancer cells *in vitro*.

Methods

The effect of melatonin (Sigma-Aldrich) at an initial concentration of 1nM on MCF-7 human breast cancer cells was studied *in vitro*. MCF-7 human breast cancer cells were incubated for 48 h at a temperature of 37 °C with progressively decreasing melatonin concentrations. MCF-7 cells were also incubated for 48 h with progressively decreasing melatonin concentrations in the presence of the antimitotic agent docetaxel 50 nM.

Results

The proliferation of MCF-7 human breast cancer cells was significantly inhibited by melatonin. The antimitotic agent docetaxel significantly inhibited the proliferation of MCF-7 cells. The simultaneous incubation of MCF-7 cells with melatonin and docetaxel had a synergistic inhibitory effect on their proliferation.

Conclusions

In conclusion, it appears that melatonin exerts an inhibitory effect on the proliferation of breast cancer cells *in vitro*. These findings should be confirmed in other cell lines and are in agreement with findings of other researchers having shown the presence of the melatonin receptor MT1[1] on the cell surface of breast cancer cells.

The effect of melatonin on pC3 prostate cancer cells *in vitro*

Ifigenia Kostoglou-Athanassiou[1], Eustathia Papageorgiou[2], Athanasios Armakolas[2] & Michael Koutsilieris[2]
[1]Department of Endocrinology, Red Cross Hospital, Athens, Greece; [2]Department of Experimental Physiology, Medical School, University of Athens, Athens, Greece.

Introduction

Melatonin is an indole being produced by the pineal gland and secreted mainly during the night. Melatonin is involved in the regulation of biological rhythms. The hormone possesses antioxidant action and is thought to be involved in the protection of the organism from the development of malignant tumors. Melatonin has been found to have anticancer action *in vitro* as is has been observed to inhibit the proliferation of cancer cells *in vitro*.

Aim

The aim was to study the effect of melatonin on PC3 prostate cancer cells *in vitro*.

Methods

The effect of melatonin (Sigma–Aldrich) at an initial concentration of 1nM on PC3 prostate cancer cells *in vitro* was studied. PC3 cells were incubated *in vitro* for 48 h at a temperature of 37 °C with progressively decreasing melatonin concentrations. PC3 cells were also incubated for 48 h with progressively decreasing melatonin concentrations in the presence of the antimitotic agent docetaxel 50 nM.

Results

The proliferation of PC3 prostate cancer cells was significantly inhibited by melatonin. In the simultaneous presence of melatonin and docetaxel the inhibitory effect on the proliferation of PC3 cells was very significant.

Conclusions

In conclusion, it appears that melatonin has an inhibitory effect on the proliferation of prostate cancer cells *in vitro*. These findings need to be confirmed in various other cancer cell lines and are in agreement with other research findings having shown the anticancer effect of melatonin. It appears that the modern way of life which disturbs the biological rhythms controlled by the cycle of light and inadvertently exposes the human organism to light during the night may contribute to carcinogenesis.

Multifocal insulinomas (insulinomatosis) in GLP-1-receptor PET/CT

Stefan Jenni[1], Kwadwo Antwi[2], Melponemi Fani[2], Damian Wild[2], Tobias Heye[3], Beat Gloor[4], Aurel Perren[5] & Emanuel Christ[1]
[1]Departement of Endocrinology, Diabetes and Clinical Nutrition, Inselspital, University Hospital, University of Bern, Bern, Switzerland; [2]Division of Nuclear Medicine, University of Basel Hospital, Basel, Switzerland; [3]Clinic of Radiology and Nuclear Medicine, University of Basel Hospital, Basel, Switzerland; [4]Division of Visceral Surgery, University Hospital of Bern, Inselspital, Bern, Switzerland; [5]Institute of Pathology, University of Bern, Bern, Switzerland.

Introduction
Apart from occurring sporadically, insulinoma within the framework of multiple endocrine neoplasia 1 (MEN-1) is well known. The rare presence of multifocal insulinomas has recently been assigned a separate entity (insulinomatosis). The difficulty of localising insulinomas may be improved by GLP1-receptor imaging. Case report A 48-year-old woman had been treated for suspected epileptic seizures for 2 years (lamotrigine). During another such episode low blood glucose (BG) was detected. During fasting she was unaware of hypoglycaemia (BG 2.3 mmol/l), endogenous hyperinsulinism was established. With a history of treated prolactinoma (operation, quinagolid) – and slightly elevated calcium levels MEN-1 was considered. ^{68}Ga-DOTA-Exendin-4 PET/CT and MRI revealed a major lesion located directly left to the pancreatic head (8×13 mm) and smaller lesions in the tail (max. 5 mm). After pretreatment with diazoxid/prednisolone surgery was proposed. Intraoperatively, granular pancreatic tissue was palpated mainly located in the left side up to the head of the pancreas – matching with the increased uptake in GLP-1R imaging. As intraoperative ultrasound did not confirm a focal lesion, left-sided pancreatectomy was performed. Histologically the major lesion proved to be insulin-positive, however 37 more small adenoma, mainly with insulin staining were detected establishing the diagnosis of insulinomatosis. The postoperative course was complicated by a peripancreatic abscess and recurrence of asymptomatic mildly low BG levels. Genetic testing (MEN-1) is pending.
Conclusions
i) GLP-R imaging is useful in benign insulinomas and might be useful in the context of MEN-1 in order to separate insulin secreting neuroendocrine tumours (NET) from other secreting and non-secreting NETs, ii) GLP-1R imaging showed positive lesions in the case of insulinomatosis. However, most of the lesions were too small to be detected by ^{68}Ga-DOTA-Exendin-4 PET/CT. iii) Clinical and biochemical work-up of this patient suggests that insulinomatosis occurred in the context of MEN-1 that – if confirmed – would be a new association.

Expression analysis of potentially MEN1-targeting microRNAs in sporadic and MEN-1 syndrome associated parathyroid adenomas and hyperplasias

Vince Kornél Grolmusz[1,2], Katalin Borka[3], Katalin Balogh[1], Anna Szentpéteri[1], Csaba Dékány[3], András Kiss[3], Zsuzsanna Valkusz[4], Miklós Tóth[1], Anikó Somogyi[1], János Horányi[5], Károly Rácz[1,6] & Attila Patócs[2,6]
[1]2nd Department of Medicine, Semmelweis University, Budapest, Hungary; [2]'Lendület' Hereditary Endocrine Tumours Research Group, Hungarian Academy of Sciences – Semmelweis University, Budapest, Hungary; [3]2nd Department of Pathology, Semmelweis University, Budapest, Hungary; [4]1st Department of Medicine, University of Szeged, Szeged, Hungary; [5]1st Department of Surgery, Semmelweis University, Budapest, Hungary; [6]Molecular Medicine Research Group, Hungarian Academy of Sciences – Semmelweis University, Budapest, Hungary.

Background and aim
Primary hyperparathyroidism (PHPT) is a frequent endocrinopathy among postmenopausal women, leading to hypercalcaemia, osteoporosis and nephrolithiasis. PHPT may represent the first manifestation of certain familial syndromes. Among these, multiple endocrine neoplasia syndrome type 1 (MEN-1) caused by germline mutation of *MEN1*, the gene encoding menin, is the most frequent. Additionally, somatic mutations of *MEN1* and microRNAs silencing *MEN1* have also been proposed to be involved in sporadic parathyroid tumourigenesis. Our aim was to determine if there is a difference in expression of potentially *MEN1*-targeting microRNAs between MEN-1 syndrome associated and sporadic PHPT tissues.
Materials and methods
In silico analysis was performed to detect microRNAs potentially targeting *MEN1*. Immunohistochemical analysis of menin and Ki67 was performed in 16 MEN-1 associated and 41 sporadic PHPT tissues. RNA was isolated from formalin-fixed, paraffin-embedded PHPT tissues and microRNA expression analysis of six chosen microRNAs was performed using predesigned TaqMan probes for quantitative PCR. *MEN1* status was determined by Sanger sequencing. Statistical analysis was performed using IBM SPSS Statistics Software.
Results
All MEN-1 associated as well as 12 (29.3%) sporadic PHPT tissues lacked nuclear menin expression on immunohistochemical analysis. MicroRNA analysis revealed that hsa-miR-24 and hsa-miR-28 levels were elevated in sporadic PHPT tissues compared to those measured in MEN-1 associated tissues ($P=0.011$ and $P=0.019$, respectively).
Conclusions
Elevated levels of microRNAs potentially targeting *MEN1* detected in sporadic PHPT tissues might contribute to the silencing of menin during sporadic parathyroid tumourigenesis.

Vitamin D and prostate cancer

Ifigenia Kostoglou-Athanassiou[1], Eustathia Papageorgiou[2], Athanasios Armakolas[2], Vlasia Aroni[2] & Michael Koutsilieris[2]
[1]Department of Endocrinology, Red Cross Hospital, Athens, Greece; [2]Department of Experimental Physiology, Medical School, University of Athens, Athens, Greece.

Introduction
Vitamin D is a hormone related to calcium homeostasis and normal function of the musculoskeletal system. Recently, the extraskeletal actions of vitamin D are the focus of scientific interest. The hormone is thought to possess anticancer properties, these properties being especially related to cancer of the prostate.
Aim
The aim was to study the effect of vitamin D on PC3 prostate cancer cells *in vitro*.
Methods
The effect of $1,25(OH)_2D_3$, $25(OH)D_3$, $1\alpha(OH)D_3$ and paricalcitol at initial concentrations of 200, 40, 20 and 20 nM, respectively, on PC3 prostate cancer cells was studied *in vitro*. PC3 cells were incubated for 48 h at 37 °C with progressively decreasing concentrations of $1,25(OH)_2D_3$, $25(OH)D_3$, $1\alpha(OH)D_3$ and paricalcitol. Experiments were also performed with $1,25(OH)_2D_3$ at concentrations of 500 nM and 1 μM. PC3 cells were also incubated with progressively decreasing concentrations of $1,25(OH)_2D_3$, the initial concentration being 200 nM, in the presence of the antimitotic agent docetaxel 50 nM.
Results
The proliferation of PC3 prostate cancer cells was not affected by $25(OH)D_3$, $1\alpha(OH)D_3$ and paricalcitol. High concentrations of $1,25(OH)_2D_3$ mildly inhibited PC3 proliferation whereas lower concentrations had no effect. The proliferation of PC3 cells was inhibited in the presence of both $1,25(OH)_2D_3$ and docetaxel.
Conclusions
In conclusion, $25(OH)D_3$ and analogues of vitamin D had no effect on the proliferation of PC3 prostate cancer cells. However, relatively high concentrations of the active hormone $1,25(OH)_2D_3$ was shown to inhibit PC3 cells proliferation. It appears, that vitamin D may possess anticancer properties especially related to prostate cancer.

Oestrogen- and progesterone-receptors may play a role in the pathogenesis of gastroenteropancreatic neuroendocrine tumours

Nadine Zimmermann[1], Georg Brabant[2], Nehara Begum[3] & Christoph Thorns[1]
[1]Institut für Pathologie, Universität zu Lübeck, Lübeck, Germany; [2]Medizinische Klinik 1, Universität zu Lübeck, Lübeck, Germany; [3]Klinik für Chirurgie, Universität zu Lübeck, Lübeck, Germany.

A positive expression of oestrogen-receptors has recently been demonstrated in pancreatic neuroendocrine tumours as well as in non-neoplastic islet-cells. This prompted us to systematically analyse the expression of both oestrogen and progesterone receptors in a series of GEP neuroendocrine tumours. We analysed

oestrogen- and progesterone-receptor in 69 foregut GEP, 25 midgut GEP and seven hindgut GEP. Namely, the foregut GEP included 53 pancreatic NET. All tumour samples were evaluated by to pathologist and a consensus immunoreactivity score according to Remmele (0–12) was assigned. An immunoreactivity score ≥ 2 was regarded as positive. According to the definition above 17% of the samples were oestrogen-receptor and 46% were progesterone-receptor positive. When we compared pancreatic NET to all other GEP-NET as well as to foregut, midgut and hindgut NET, the expression of oestrogen-receptor did not differ significantly between the groups. However, expression of the progesterone-receptor was more frequently expressed in pancreatic NET than in the other GE-NET (81% vs 8%, $P<0.0001$). This difference remained statistically significant, when pancreatic NET were compared to foregut NET (81% vs 13%, $P<0{,}0001$), to non-pancreatic midgut NET (81% vs 8%, $P<0{,}0001$) and to hindgut NET (81% vs 14%, $P=0{,}0039$). To evaluate the potential role of oestrogen/progesterone receptors in metastasis we evaluated biospies of 83 metastases from 45 cases. Oestrogen-receptor expression was rare (IRS ≥ 2 in three nodal metastases of pNET and four nodal metastases of non-pNET). In contrast, progesterone-receptor expression was found in only one nodal metastases of non-pancreatic origin, but 15 metastases of pNET stained positive for the progesterone receptor. In summary, our data indicate a potential role of progesterone-receptor expression in the metastatic process and its determination may help to identify the primary in cases of NET-metastasis of unknown primary.

Audit of patients with multiple endocrine neoplasia type 1 (MEN1): screening of pancreatic neuroendocrine tumours (pNETs), parathyroid tumours and pituitary adenomas

Ma Pyeh Kyithar[1], Lisa Cullen[2], Chun Lee[2], Niall Swan[2], Justin Geoghegan[2], Stephen Skehan[2], Rachel Crowley[1,2], Donal O'Shea[1,2] & Dermot O'Toole[2]
[1]Endocrinology Department, St Vincent's University Hospital, Dublin, Ireland; [2]Neuroendocrine Tumour Service, St. Vincent's University Hospital, Dublin, Ireland.

Introduction
Patients with MEN1 have increased morbidity and mortality compared to those patients with sporadic NETs. No genotype-phenotype correlation is described and age-related clinical penetrance surpasses 50 and 90% by 20 and 40 years, respectively. The aim of the audit was to compare the screening programme for MEN1 patients with MEN1 clinical guidelines.
Methods
Case notes of MEN1 patients attending a tertiary NET-multidisciplinary team (MDT) in Ireland were reviewed. All patients attending the NET-MDT have gastrointestinal hormone, parathyroid, pituitary profiles, endoscopic and imaging studies according to guidelines (NIH 2012, Brandi *et al*. 2001; 86: 5658–71).
Results
Of 13 patients with MEN1 (11 kindreds), 85% ($n=11$) had confirmed *MEN1* mutations and two had clinical or familial MEN1. 69% were referred to NET-MDT for screening due to known *MEN1* mutations, 15% for family screening, 8% for management of pNETs and 8% for screening due to primary hyperparathyroidism and acromegaly. Prior to NET-MDT assessment, 46% did not have endoscopic/radiology studies to screen for pNETs and none of the patients had CT/MRI thorax to screen for thymic/bronchial NETs. Mean age referred to NET-MDT was 41.5 ± 12.2 years. Mean age at endoscopic/radiological screening for NETs (prior to/at NET-MDT) was 37.1 ± 14.3 years. Mean age at diagnosis of NETs was 34.9 ± 14.3 years. On screening of 13 patients at NET-MDT, the following new diagnoses were made: eight pNETs, seven duodenal/gastric NETs, two primary hyperparathyroidism, three pituitary adenomas and four adrenal adenomas. Family screening has been performed in 8/11 families: a further seven family members were identified with *MEN1* mutations and will attend NET-MDT for screening. Genetic screening of other families is proceeding.
Conclusion
Endoscopic/radiological screening of NETs occurred at later age than recommended by current guidelines. Surveillance methods were also largely at variance with guidelines. Referral to a dedicated MDT has identified a significant number of previously unrecognised neuroendocrine pathologies.

EP1120

The prevalence of benign and malignant neoplasms in the patients with acromegaly

Adam Stangierski, Kosma Wolinski, Edyta Gurgul & Marek Ruchala
Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland.

Introduction
Acromegaly is a relatively rare endocrine condition caused by GH oversecretion by pituitary adenoma. Its most frequent complications include cardiovascular and respiratory system diseases with high tendency of neoplastic transformation and increased risk of benign and malignant tumors. The aim of this retrospective study was to assess the prevalence of benign and malignant neoplasms in patients with acromegaly.
Materials and methods
We have searched the medical documentation of patients treated in our medical center from the years 2004–2013. The prevalence of benign and malignant neoplasms was analysed basing on the latest available records of particular patients.
Results
We have identified 180 patients with acromegaly (108 women, 72 men). The mean age at the time of last available assessment was 52.5 years (S.D. 12.2, median – 54.0). The most common neoplastic comorbidity was observed in the thyroid -140 patients (77.8%) – 110 patients with multinodular goiter (MNG) (61.1%) or resection of MNG in the past medical history. Adrenal adenomas were diagnosed in nine subjects (5%), prostate hyperplasia in six (8.3% of males), and polyps of the colon in 1.7% of all individuals. Among malignancies, the most common were thyroid cancer ($n-11$, 6.1%), breast cancer ($n=5$, 4.6% of women with acromegaly) and colonic cancer ($n=4$, 2.2%).
Conclusions
Patients with acromegaly present increased risk of neoplastic transformation, especially in the thyroid, adrenals, gastrointestinal tract and prostate. Among malignancies, thyroid, breast and colonic cancer were the most frequent. According to our results, active screening for potential malignancies should be an important part in the management of acromegaly.

Identification of human SST2 somatostatin receptor domains involved in receptor internalization and signaling in pancreatic neuroendocrine tumors

Valeria Cambiaghi[1], Eleonora Vitali[1], Giovanna Mantovani[2], Anna Spada[2], Erika Peverelli[2] & Andrea Lania[1,3]
[1]Laboratory of Cellular and Molecular Endocrinology, IRCCS Clinical and Research Institute Humanitas, Rozzano, Italy; [2]Endocrine Unit, Department of Clinical Sciences and Community Health, Fondazione IRCCS Ospedale Maggiore Policlinico, University of Milan, Milan, Italy; [3]BIOMETRA Department, University of Milan, Neurosurgery Department, IRCCS Humanitas Clinical Institute, Rozzano, Italy.

Somatostatin exerts its inhibitory effects on hormone secretion and cell proliferation via five receptors subtypes (SST1-SST5). After agonist binding, receptor residues mainly located in the carboxyl terminal (CT) and in the third intracellular loop (IC3) are phosphorylated and β-arrestins are recruited to drive SSTRs internalization.
Aim of the study is to characterize the intracellular mechanisms responsible for SST2 internalization and identify the molecular determinants mediating its intracellular signaling in pancreatic neuroendocrine QGP1 cell line. To this purpose we created SST2 receptor mutants, the first lacking 20 aminoacids in CT portion (del349), the second a IC3 mutant with a point mutation (Ser-245-Ala) in a phosphorylation site. We evaluated SST2 mutants ability to associate with β-arrestins and to internalize after SST2 selective somatostatin analog stimulation (BIM23120). In cells transfected with the SST2 IC3 mutant, no differences in β-arrestins recruitment and receptor internalization were observed after SST2 activation in comparison with cells bearing wild type SST2. Conversely, the truncated SST2 failed to recruit β-arrestins and to internalize after BIM23120 incubation. Then, we analyzed the effect of BIM23120 on cell proliferation, cyclin D1 expression and ERK1/2 phosphorylation in the presence of either IC3 mutant and truncated SST2. As expected, BIM23120 induced a reduction in cell proliferation ($-30\pm7\%$, $P<0.01$ vs untreated) and in CD1 expression ($-23\pm8\%$, $P<0.001$ vs untreated) in SST2 wild type QGP1 transfected cells, this effect being completely lost in the presence of both SST2 mutants. To further

analyze the antiproliferative actions of SST2, we analyzed the effects of SST2 activation on ERK1/2 phosphorylation and we found the both SST2 mutants fail to affect ERK1/2 phosphorylation status after BIM23120 incubation. Taken together these data suggest that: i) CT region is crucial for β-arrestins/SST2 interaction and SST2 internalization; ii) antiproliferative intracellular signaling mediated by SST2 require the integrity of both CT and IC3 domains.

The evaluation of the effectiveness and safety of transarterial embolisation of to the liver metastasised neuroendocrine tumours

Sophie van Dijk, Margot Tesselaar, Wieke Verbeek, Marc Meier & Warner Prevoo
The Netherlands Cancer Institute, Amsterdam, The Netherlands.

Abstract
Transarterial embolisation (TAE) is an effective treatment for liver metastases from neuroendocrine tumour (NET). It reduces arterial blood flow to the tumour resulting in ischemia and necrosis. In this single centre retrospective study the effectiveness and safety of TAE was evaluated.
Patients and methods
30 patients with histological confirmed gastro-entero-pancreatic NET with liver metastases were investigated. Tumour response, decline in symptomatic carcinoid syndrome, the overall survival and adverse events were evaluated in the whole population.
Results
Among 30 patients (15 male) 47 TAE procedures were performed. The median age was 61.5 years. The primary NET site is ileum in 16 patients (53.3%), colon in 6 patients (20%), pancreas in one patient (3.3%), lung in one patient and unknown in six patients. 18 patients (60%) received surgery for their primary NET prior to TAE. 22 patients (73.3%) were also diagnosed with extrahepatic metastases. The number of patients with a decrease in liver tumour on CT were significantly higher when liver involvement before TAE was $<50\%$. 29 patients (96.7%) received octreotide treatment prior to TAE. The median time from diagnosis to first TAE was 36.5 months. There was a significant decrease in chromogranin A both 1 and 3 months after TAE ($P=0.001$ and $P=0.017$, resp.). 80.9% of the cases had a decrease of neuroendocrine liver metastases after TAE. 26 patients had carcinoid syndrome of which 88% had a decrease in clinical symptoms at 1 month follow up. This was 69.6% at 3 months follow up. Liver functions assessed 1 and 3 months after TAE were compared to baseline values. Bilirubin shows a significant decrease at 1 month. Alkaline phosphatase is significantly higher after both 1 and 3 months. γGT is significantly higher at 1 month. ASAT, ALAT and LDH show no significant differences. Two patients had major TAE related complications. No TAE related death occurred. The overall survival at 1 year follow up is 86.7%, which is not statistically different compared to the overall survival of the group of patients who had a second or third TAE.
Conclusion
Transarterial embolisation is a relative safe treatment for to the liver metastasized NET which can be done multiple times within one patient. It reduces carcinoid syndrome and shows a significant reduction in tumour marker. Radiological decrease rate is significantly higher with patients who have less tumours in the liver.

Evaluation of routine basal serum calcitonin measurement for an early diagnosis of medullary thyroid carcinoma

Entela Puca[1], Kadir Burak Koza[1], Emiljana Huti[1], Sonila Bitri[1], Albana Daka[1], Edmond Puca[2] & Agron Ylli[2]
[1]American Hospital 2, Tirana, Albania; [2]UHC Mother Teresa, Tirana, Albania.

Background
Medullary thyroid carcinoma (MTC) is characterised by a high concentration of serum calcitonin. Routine measurement of serum calcitonin concentration has been advocated for detection of MTC among patients with nodular thyroid diseases. The aims of our study were to identify medullary thyroid cancer (MTC) in its earliest stages by screening patients with basal calcitonin measurements and to determine whether basal serum calcitonin measurements should be a part of our routine evaluation of a nodular goitre.
Subject and methods
We performed routine measurement of basal serum calcitonin levels from 151 patients (male 30 and female 121 with nodular goitre. The average age was 47 years old (range 19–76).
Results
Patients with FNAC or ultrasound suspicious of any kind of thyroid carcinoma and patients with elevated basa calcitonin level underwent surgery. Three patients (1.9%) had elevated basal serum calcitonin levels ranging between 129 and 7493 pg/ml. FNAC was suggestive of MTC in two from three patient with elevated calcitonin. MTC was confirmed in all patients, with elevated calcitonin. Differentiated thyroid carcinoma, mostly papillary, was confirmed at histology in 40 subjects. The prevalence of MTC, diagnosed by serum CT measurement among 136 patients with nodular thyroid disease was high: 1.9% of all thyroid nodules and 7% of all thyroid carcinomas. Serum CT measurement was superior to FNAC in suggesting the diagnosis of MTC.
In conclusion, calcitonin measurement is an effective method for the diagnosis of MTC. It is superior to FNAB for diagnosis of MTC. High basal serum calcitonin levels increase the chance of curative therapy by diagnosing it in the early stages.

Evaluation of metabolic syndrome in patients with primary hyperparathyroidism

Mustafa Caliskan[1], Muyesser Sayki Arslan[1], Esra Tutal[1], Selvihan Beysel[1], Melia Karakose[1], Mahmut Apaydin[1], Ozgur Ozcelik[1], Muhammed Kizilgul[1], Nujen Colak Bozkurt[1], Erman Cakal[1], Mustafa Ozbek[1] & Tuncay Delibasi[1,2]
[1]Department of Endocrinology and Metabolism, Diskapi Teaching and Research Hospital, Ankara, Turkey; [2]Hacettepe University, School of Medicine (Kastamonu), Ankara, Turkey.

Aims
Primary hyperparathyroidism (PH) has been reported to be associated with increased insulin resistance, hypertension, dyslipidemia and cardiovascular inflammatory markers. The aims of this study were to evaluate the rate of metabolic syndrome (MS) and effect of parathormone, calcium and phosphorus levels to MS components in PH subjects.
Methods
One hundred and fifty one subjects, 23 men and 128 women, aged 53 ± 11.2 years with newly diagnosed PH were recruited from our outpatient clinic. All subjects underwent measurements of height, weight, waist and hip. Metabolic variables were obtained after an overnight fasting. MS was diagnosed using the Adult Treatment Panel III criteria (ATP III).
Results
The rate of the MS (76/151, 50.3%) was higher to that reported in the general Turkish population (36.6%). 15.2% ($n=23$) of patients had diabetes mellitus and 72.8% ($n=110$) of patients had hypertension. Serum levels of glucose and

Table 1 Demographic parameters in studied group.

Age	53 ± 11.2
Sex (M/F)	23 M/128 F
Glucose (mg/dl)	95.2 ± 17.1
Triglyceride (mg/dl)	152.1 ± 73
Calcium (mg/dl)	11.9 ± 0.67
Phosphorus (mg/dl)	2.6 ± 0.47
Parathormone (mg/dl)	253.6 ± 256.9
Metabolic syndrome (%)	50.3
Diabetes mellitus (%)	15.2
Hypertension (%)	72.8
Obesity (%)	52.3
Overweight (%)	35.7

triglyceride were 95.2±17.1 and 152.1±73 mg/dl, respectively. The rate of obesity, overweight was 52.3 and 35.7% respectively. There were no significant differences between the levels of calcium, phosphorus and parathormone levels (11.16±0.8 vs 11.01±0.6 mg/dl, 2.59±0.45 vs 2.63±0.48 mg/dl, 259.6±238 vs 247.5±276 mg/dl respectively) according to MS presence (Table 1).

Conclusion

Based on the results of this study, the rate of the MS in PH was found to be higher than that reported in the general Turkish population. Metabolic control must be considered in the clinical management of patients diagnosed PH.

Mitotane directly interacts with lipid membranes and alters membrane structure and dynamics

Peter Müller[1], Stephan Theisgen[2], Andreas Schirbel[3], Silviu Sbiera[3], Ivan Haralampiev[1], Martin Fassnacht[3,4], Daniel Huster[2] & Matthias Kroiss[3,4]

[1]Humboldt University, Berlin, Germany; [2]Institute of Medical Physics and Biophysics, Leipzig, Germany; [3]University Hospital Würzburg, Würzburg, Germany; [4]Comprehensive Cancer Center Mainfranken, Würzburg, Germany.

Context

Mitotane (1,1-dichloro-2-[o-chlorophenyl]-2-[p-chlorophenyl]ethane) is the only drug approved for treatment of adrenocortical carcinoma (ACC). Mitotane counteracts both tumor growth and tumoural steroid hormone production but treatment is severely hampered by unfavorable pharmacokinetics and serious side effects. Mitotane is a lipophilic compound and treatment emergent alterations of lipid metabolism are frequently observed. This raises the question whether mitotane directly interacts with lipids.

Objective

To investigate the impact of mitotane on lipid membranes using biophysical techniques.

Methods

We used nuclear magnetic resonance (NMR), electron spin resonance (ESR) and fluorescence spectroscopy as well as fluorescence microscopy to determine whether mitotane interacts with lipid membranes. We aimed at determining the impact of mitotane on membrane structure and dynamics by assessing its influence on membrane integrity and on the formation of lateral membrane domains in lipid vesicles (large unilamellar vesicles, giant unilamellar vesicles).

Results

We demonstrate that mitotane intercalates into lipid membranes. This binding influences the mobility of spin-labeled lipids within membranes and disturbs membrane integrity in a dose-dependent manner. The presence of cholesterol in the membrane appears to modulate these effects.

Conclusion

Mitotane directly binds to and interacts with lipid membranes thereby altering membrane structure and dynamics. This interaction may contribute to the biological effects of mitotane impacting both on efficacy and adverse effects.

EP1126

Oestrogen metabolism by steroid sulphatase and 17β-hydroxysteroid dehydrogenases promotes colorectal cancer proliferation via the G-protein coupled oestrogen receptor

Lorna Gilligan, Habibur Rahman, Anne-Marie Hewitt, Angela Taylor, Dion Morton & Paul Foster

University of Birmingham, Birmingham, West Midlands, UK.

Colorectal cancer (CRC) is the third most common cancer worldwide with incidence expected to rise. Although not traditionally viewed as a hormonal cancer, evidence suggests peripheral synthesis of active oestrogens worsens prognosis. Oestrogen metabolising enzymes include steroid sulphatase (STS), which desulphates oestrogens into their active forms, and 17β-hydroxysteroid dehydrogenases (17βHSD), which are estrogen oxidoreductase enzymes. We have previously shown STS activity is increased in human CRC compared to matched-normal tissue. However, the impact of this increased oestrogen de-sulphation on CRC proliferation is unknown. Furthermore, the expression and activity of 17βHSD-1, 17βHSD-7 and 17βHSD-12, all of which reduce the less active oestrone (E_1) to the more potent oestradiol (E_2), have not been fully examined in CRC. Thus, this project investigated the proliferative effects of E_1 and E_2 treatment and overexpression of STS in CRC cell lines. Additionally, how these cell lines metabolised oestrogen was analysed using a novel uPLC-MS/MS technique. Protein and mRNA expression of 17βHSDs capable of reducing E_1–E_2 were examined in human CRC tissue and cell lines. Oestrogen (E_1 and E_2) and STS overexpression increased proliferation of the CRC cell line HCT116. Proliferation also increased in response to G1, a G-protein-coupled estrogen receptor 1 (GPER) agonist. LC-MS/MS indicated HCT116 cells reduced E_1–E_2 most likely catalysed by 17βHSD-12. In human CRC 17βHSD-1 was not expressed, however 17βHSD-7 and -12 expression was significantly elevated ($P<0.0005$) compared to matched normal tissue. GPER was also found to be expressed in the colon. Together these findings suggest the majority of human CRC escalate intratumoural E_2 concentrations through STS and 17βHSD-12. This local oestrogen rise likely acts through GPER to augment tumour proliferation. Therefore, STS, 17BHSD-12 and GPER inhibitors may benefit many CRC patients.

Expression of ghrelin and somatostatin systems components in pancreatic neuroendocrine tumours and their relationship with clinical-histological characteristics

Aura D Herrera-Martínez[1], Manuel Gahete[2], Rafael Sánchez-Sánchez[3], Teresa Caro Cuenca[3], Raquel Serrano Blanch[4], Raúl Luque[2], María A Gálvez Moreno[1] & Justo Castaño[2]

[1]Department of Endocrinology and Nutrition, Hospital Universitario Reina Sofía, Cordoba, Spain; [2]Department of Cell Biology, Physiology and Immunology, Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Hospital Universitario Reina Sofía, University of Córdoba, Campus de Excele, Cordoba, Spain; [3]Department of Pathology, Hospital Universitario Reina Sofía, Cordoba, Spain; [4]Department of Medical Oncology, Hospital Universitario Reina Sofía, Cordoba, Spain.

Pancreatic neuroendocrine tumors (PNETs) are uncommon neoplasms from the endocrine pancreas, whose incidence is recently rising. Unfortunately, an advanced stage is often found at diagnosis; thus, identification of new molecular diagnostic, prognostic, and therapeutic markers is required. Ghrelin and somatostatin/cortistatin systems are two multifunctional regulatory complexes widely distributed throughout multiple tissues, including the pancreas, where they exert diverse (patho)physiological actions; and alterations in these systems can be associated to development/progression of various cancers. Here, we aim to evaluate expression levels of ghrelin and somatostatin systems components in PNETs and explore their putative relationship with histological/clinical patient features. Namely, an observational retrospective study with 28 PNET patients was performed by collecting clinical/histological characteristics and measuring expression levels of ghrelin and somatostatin/cortistatin systems components, by quantitative-PCR, in formalin-fixed paraffin-embedded PNET samples ($n=25$; 52.2% G2, 43.5% G1 and 4.3% G3) and in control adjacent non-tumoral tissues. Mean age was 55±14 years (57.1% females); 21.1% of cases were diagnosed incidentally, 42.1% were functioning tumors and 40.7% had metastasis at diagnosis. Tumour diameter associated negatively to vascular invasion ($P<0.05$) and necrosis ($P<0.05$). Somatostatin receptor (sst) subtypes-1 and -2, cortistatin and ghrelin O-acil-transferase enzyme were overexpressed in PNETs compared to control-tissues ($P<0.01$). Presence of skin lesions at diagnosis was correlated to sst3 expression ($P<0.05$). sst1 expression was negatively associated with vascular invasion ($P<0.05$). Ghrelin-receptor was negatively associated with nerve invasion ($P<0.01$). Mortality was associated to metastasis ($P<0.05$), relapsed disease ($P<0.05$) and somatostatin expression. Interestingly, there was a trend for mortality and sst3 expression to be associated ($P=0.08$). Our results indicate that the majority of ghrelin and somatostatin systems components are expressed in PNETs, where some of these components

display specific associations with clinical-histological parameters, which may help to better understand PNETs pathophysiology and to identify novel molecular targets with potential prognostic and/or therapeutic value for PNETs patients.

A unique case of hyperparathyroidism-jaw tumour syndrome due to a previously unreported pathogenic duplication mutation of CDC73 gene

Pawel Bogusz[1], Elizabeth Mae McConnell[2], Vivienne McConnell[3] & Marian Korda[4]
[1]Registrar in Diabetes and Endocrinology, Craigavon Area Hospital, Craigavon, Co Armagh, UK; [2]Consultant Endocinologist, Craigavon Area Hospital, Craigavon, Co Armagh, UK; [3]Consultant in Genetic Medicine, Belfast City Hospital, Belfast, CoAntrim, UK; [4]Consultant ENT Surgeon, Craigavon Area Hospital, Craigavon, Co Armagh, UK.

Hyperparathyroidism-jaw tumour syndrome (HPT-JT) is a rare autosomal dominant condition characterized by primary hyperparathyroidism (<90%) as a result of parathyroid adenoma or carcinoma (10–15%), ossifying fibromas of mandible and maxilla (30–40%), renal lesions (20%) most commonly cysts and benign and malignant uterine tumours and caused by germline CDC73 pathogenic gene mutations. Currently only 200 cases reported in medical literature. His management has proved more difficult which may be associated with this novel CDC73 pathogenic gene mutation. A 31-year-old man presented with polydipsia, fatigue, corrected calcium of 4.3 and PTH 147. USS and CT neck revealed a left inferior parathyroid adenoma, confirmed by exploration. Histology showed disruption of the capsule with fibrous tissue extending into the lesion at one pole although no overt malignancy. A few months later he had recurrence of symptoms, further hypercalcaemia and a right inferior parathyroid adenoma was excised. Genetic testing detected a novel pathogenic duplication mutation of CDC73 gene leading to premature termination of translation. He presented a third time with hypercalcaemia. No adenoma was identified on imaging however he declined selective venous PTH sampling. His case was extensively discussed with multiple specialists with differing opinions as to total parathyroidectomy +/− auto transplantation. Patient elected for total parathyroidectomy and no auto transplantation due to his germline CDC73 pathogenic gene mutation and 10–15% risk of parathyroid carcinoma development. This unique case illustrates consideration of genetic testing in primary hyperparathyroidism under 45 years, with challenges in rarity and management including implications for biopsy and surgical intervention, multisystem lifelong screening of proband and relatives which is recommended from 5 to 10 years and availability of predictive genetic testing for the familial CDC73 gene mutation. This indicates a significantly more complex case where previous literature has been unable to guide on management and may help advise other endocrinologists.

Extremes in hyperparathyroidism: management of parathyroid carcinoma

Lidia Radomir[2], Daniel Mihai[2], Simona Jercalau[2] & Corin Badiu[1,2]
[1]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania; [2]'C.I.Parhon' National Institute of Endocrinology, Bucharest, Romania.

Background
Parathyroid carcinoma (PC) is a rare cause of primary hyperparathyroidism (PHPT), accounting for <1%, with an equal gender distribution and an average age of diagnosis in the fifth decade of life. The diagnosis of PHPT is based on the laboratory finding of high levels of immunoreactive PTH in the presence of severe hypercalcaemia. The only potentially curative treatment for PC is surgery. Early surgery is the most important factor for optimal outcome.

Methods
This case series is based on a multidisciplinary review of four patients with parathyroid cancer, describing their therapeutic management and follow-up. Imagistic evaluation was performed by ultrasound (US), computed tomography scan (CT), magnetic resonance imaging (MRI), positron emission tomography (PET) and Technetium-99m sestamibi scintigraphy, for detecting the primary tumour, its local extent and remote metastases.
Results
Between 2008 and 2014 four patients were diagnosed with PC in our clinical department, three men and a woman, with a mean age of 50 years ± S.D. 13.22 (range 38–68). None had family history of hyperparathyroidism or hormonal disorders suggesting multiple endocrine neoplasia. All had severe hypercalcaemia (15.3–19.4 mg/dl) and elevated PTH levels ranging from 15 to 45 times above normal value. Tumor size ranged from 3.2 to 7 cm; two of them had thyroid gland invasion and one thymic invasion. Three patients underwent parathyroidectomy with hemithyroidectomy and one underwent parathyroidectomy with thymectomy and cervical dissection. Schulte stage at diagnosis was between II and IV, while all were classified as high risk. Conformational radiotherapy of the tumor bed was used in two cases. Cinacalcet treatment was tried in one case and chemotherapy regimen in another, without significant improvement. Three patients had local recurrence and the time from the initial surgery to recurrence ranged from 1 month to 1 year.
Conclusion
Parathyroid carcinomas are rare endocrine cancers, with high relapse rate and poor prognosis. Multidiscplinary approach requires detailed imaging, skilled surgeons, endocrinologist and oncologist.

PATZ1 downregulation promotes proliferation and migration in Ras-driven thyroid transformation

Michela Vitiello[1], Teresa Valentino[1], Marta De Menna[2], Paola Francesca[1], Gabriella De Vita[2] & Monica Fedele[1]
[1]Institute of Experimental Endocrinology and Oncology – CNR, Naples, Italy; [2]Department of Molecular Medicine and Medical Biotechnology – DMMBM, Naples, Italy.

Thyroid cancer is one of the most frequent malignancies of the endocrine system, and its incidence is predicted to become the fourth leading cancer diagnosis by 2030. Among thyroid carcinomas, anaplastic thyroid cancer (ATC) is the most aggressive and lethal tumor, which grows very rapidly, invades adjacent tissues and metastasizes, causing death in 1 year from diagnosis. We recently showed that in thyroid cancer PATZ1 expression is downregulated compared to normal thyroid and is further downregulated in follicular (FTC), poorly differentiated (PDTC) and ATC compared to the papillary (PTC) histotype, suggesting PATZ1 downregulation may be involved in late steps of thyroid tumor progression. Consistently, restoration of PATZ1 expression in thyroid cancer cell lines inhibited cellular migration *in vitro* and partially reverted the epithelial–mesenchymal transition *in vivo*. In order to investigate the upstream signaling causing PATZ1 downregulation during thyroid transformation we previously employed an inducible cellular system, in which the oncogenic Ras^{V12} could be induced by tamoxifen in FRTL-5 rat thyroid cells, causing complete malignant transformation towards an undifferentiated phenotype. In this cell system, as well as in FRTL-5 cells stably expressing the Ras^{V12} oncogene, we identified miR-29b as a miRNA specifically upregulated, which targets and downregulates PATZ1 expression downstream of Ras. This is consistent with previous studies showing that in PTC, where PATZ1 is less downregulated, Ras mutations are hardly detected, while in FTC, PDTC and ATC, where PATZ1 is more strongly downregulated, mutations in Ras genes are more frequently found. Here we identify a fundamental role for downregulation of PATZ1 in driving rat thyroid cell transformation by oncogenic Ras. Indeed, PATZ1 overexpression inhibits proliferation and migration of Ras-transformed cells, suggesting that its downregulation is required for Ras-induced thyroid carcinogenesis. Overall, our work demonstrated that PATZ1 is a pivotal regulator acting downstream of miR29b to suppress thyroid cell transformation driven by oncogenic Ras, highlighting a new potential therapeutic target to fight highly malignant thyroid cancer.

Inhibitor of apoptosis protein livin/BIRC7 in adrenocortical tumours

Barbara Altieri[1,2], Silviu Sbiera[1], Silvia Della Casa[2], Sonja Steinhauer[1], Vanessa Wild[3], Guido Fadda[4], Michaela Bekteshi[1], Andreas Rosenwald[3], Alfredo Pontecorvi[2], Martin Fassnacht[1], Bruno Allolio[1] & Cristina L Ronchi[1]
[1]Endocrine and Diabetes Unit, Department of Internal Medicine I, University Hospital of Wuerzburg, Wuerzburg, Germany; [2]Division of Endocrinology and Metabolic Diseases, Institute of Medical Pathology, Catholic University, Rome, Italy; [3]Department of Pathology, University of Wuerzburg, Wuerzburg, Germany; [4]Division of Anatomic Pathology and Histology, Catholic University, Rome, Italy.

Introduction
Adrenocortical tumours comprise frequent adenomas (ACA) and rare highly malignant carcinoma (ACC). Livin/ML-IAP/BIRC7 is a member of the inhibitors of apoptosis proteins family, which are involved in tumorigenesis, mostly through the inhibition of caspase-3. Aim of the study was to evaluate the expression of livin/BIRC7 in normal and neoplastic adrenal glands.
Methods
The mRNA expression of *BIRC7,* its isoforms *livin α* and *livin β,* and *caspase-3* was evaluated by qRT-PCR in 84 fresh-frozen tissues (34 ACC, 25 ACA, 25 normal adrenal glands=NAG), including 19 paired samples of tumour and surrounding NAG. Additionally, livin protein expression was assessed by western blot analysis (WB) in 14 paired samples (eight ACA, six ACC) and by immunohistochemistry in 127 paraffin-embedded tissue sections (67 ACC, 45 ACA, 15 NAG). The relationship with several histopathological and clinical data was also evaluated.
Results
BIRC7 mRNA expression was similar between ACAs (0.01 ± 0.01) and NAG (0.01 ± 0.02), but significantly higher in ACCs (0.06 ± 0.12, $P<0.005$ vs both ACA and NAG), the isoform β was more expressed than α in all the subgroups. Comparable results were obtained with WB. The *caspase-3* was higher in ACA (0.024 ± 0.012) than in ACC (0.017 ± 0.011, $P=0.05$) and NAG (0.018 ± 0.011, $P=0.03$). Livin cytoplasmatic immunostaining was relatively homogeneous (79.5% of more than 50% positive cells). Livin protein expression was higher in ACC than ACA and NAG (mean ± S.D. H-score: 1.72 ± 0.7 vs 1.58 ± 0.5 vs 1.33 ± 0.6, respectively; $P=0.09$), being even higher in ACC samples coming from first surgery ($n=53$, 1.8 ± 0.7) than in those coming from recurrence ($n=8$, 1.25 ± 0.5) or distant metastasis ($n=6$, 1.5 ± 0.5) ($P=0.0001$). No significant correlation was observed with the histopathological and clinical data, including overall survival.
Conclusion
Our study demonstrates that livin/BIRC7 is specifically over-expressed in ACCs, suggesting that it may be involved in adrenocortical tumorigenesis. BIRC7 could represent a novel marker for malignancy and a potential target for therapeutic approaches in ACC.

High-dose treatment with somatostatin analogues in neuroendocrine tumours

Roberta Modica[1], Valeria Ramundo[1], Francesca Marciello[1], Vincenzo Marotta[1], Genoveffa Pizza[1], Anna Chiara Carratù[1], Chiara de Luca di Roseto[1], Pasqualina Buonomano[1], Carla Giordano[2], Francesco Trimarchi[3], Annamaria Colao[1] & Antongiulio Faggiano[1]
[1]Department of Clinical Medicine and Surgery, Section of Endocrinology, Federico II University, Napoli, Italy; [2]Department of Internal and Specialistic Medicine, Endocrinology, University, Palermo, Italy; [3]Department of Clinical and Sperimental Medicine, Endocrinology, University, Messina, Italy.

Somatostatin analogs (SSA) effectively control symptoms in neuroendocrine tumours (NET), besides showing antiproliferative activity. In progressive or metastatic NET, increasing SSA dose or shortening the dosing interval are common clinical practice, though empirical. Aim of this study is to evaluate efficacy and safety of high-dose SSA treatment in patients with progressive disease under standard SSA dose. Twenty-one patients (median age 56.8 years) with NET of different origin were retrospectively identified among 118 patients under SSA therapy. All 21 patients were treated with SSA high dose schedule treatment, after disease progression under standard dose. The median follow-up was 22.3 months (range 4–76). High dose schedule included octreotide LAR in 15 patients (73%) and lanreotide Autogel in 6 (27%). Progression free survival was significantly higher with high-dose treatment compared with standard dose (32 vs 8 months, $P<0.05$). Partial objective tumour response was recorded in one patient (5%), stabilisation in 10 (47.5%) and progression in 10 (47.5%). Among 16 patients who were symptomatic under standard dose, complete clinical response was obtained in 1 (6%), partial response in 9 (57%). Side effects were abdominal discomfort (5%), asymptomatic gallstones (5%) and type 2 diabetes mellitus (5%). High-dose SSA treatment in progressive NET is still effective in patients refractory to standard SSA doses. No additional toxicity is observed compared with standard dose.

Craniopharyngioma audit, single centre experience

Jehangir Abbas, Philip Kane & Vijayaraman Arutchelvan
The James Cook University Hospital, Middlesbrough, UK.

Objectives
Craniopharyngioma is a benign tumour of the suprasellar region that is associated with increased morbidity and mortality in comparison to other causes of hypopituitarism. We aimed to establish the mode of presentation, investigations, treatment outcomes, mortality and subjective improvement in patients with craniopharyngioma in a single institution over 10 years.
Design
Retrospective case notes review of patients with Craniopharyngioma on endocrine register between 2000 and 2010. Clinical records of eligible patients were reviewed and information regarding clinical presentation, medical and surgical management and post treatment outcomes were extracted and collated.
Results
Symptoms at presentation: the commonest presenting symptoms were headache (79%) and visual impairment (75%). Other symptoms were vomiting (27%), cognitive dysfunction (3.4%), weight gain (34.4%), reduced conscious level (3.4%), poor energy level (68.9%), somnolence (13.7%), loss of libido (13%) and polyuria (13.7%).
Surgical outcomes
Gross total resection was achieved in 41.3% but was curative in only 20%. The remaining 80% required further surgical and/or radio therapeutic intervention. Reduction in tumour size was achieved in 86% of patients. CSF leak was 18% post surgical intervention. Visual field were fully recovered in only 27.8% and partially recovered in 26% of patients after surgery and radiotherapy. Endocrine out comes: multiple pituitary hormone deficiency evolved in all patients over time, the commonest were hypothyroidism (79%) and ACTH deficiency (72%). Other deficiencies were gonadotrophins (45%), diabetes insipidus (41%), and GH def (14%). Although neurocoagnitive, psychological and behavioural problems were noted for some patients, only 20% of patients were formally assessed.
Subjective improvement in condition
It was assessed by follow up clinic letters that 59% patients have reported improvement in their condition but 18% of these patients got worse after intervention.
Mortality
All cause mortality was 31%. Tumour related mortality was 25%.
Conclusions
Craniopharyngioma is associated with significant long-term morbidity. Attention to an integrated care pathway that includes standardised neurocognitive and psychological and behavioural assessment would facilitate early appropriate intervention and support leading to an improved quality of life of patients with craniopharygioma.

Gonadotropin releasing hormone antagonist treatment induces cell cycle arrest in gonadal somatic cell and adrenocortical tumours

Milena Doroszko[1], Marcin Chrusciel[1], Ilpo Huhtaniemi[1,3], Jorma Toppari[1,2] & Nafis Rahman[1,4]
[1]Department of Physiology, Institute of Biomedicine, University of Turku, Turku, Finland; [2]Department of Pediatrics, University of Turku and Turku University Hospital, Turku, Finland; [3]Department of Surgery and Cancer, Imperial College London, Faculty of Medicine, London, UK; [4]Department of Reproduction and Gynecological Endocrinology, Medical University of Bialystok, Bialystok, Poland.

We have earlier shown that treatment with gonadotropin releasing hormone antagonist blocked adrenocortical tumour progression through gonadotropin suppression in inhibin α/SV40 T-antigen (inhα/Tag) transgenic (TG) mice. Hereby, we investigated the molecular mechanisms underlying the GnRH antagonist (Cetrorelix acetate; GnRH-a) treatment induced potential antitumor effects on gonadal somatic cell and adrenocortical tumors *in vivo* and *in vitro*. *In vitro* treatment with 10 μM GnRH-a significantly decreased cell viability and proliferation of murine KK1 (granulosa cell), BLT1 (Leydig cell), Cα1 (adrenocortical), all three lines originating from inhα/Tag mice tumors, compared to respective non-treated controls. Flow cytometric analysis revealed a cell cycle arrest at G1 phase in all treated cell lines. We treated *in vivo* 6-mo-old inhα/Tag mice bearing gonadal or 6.5-mo-old mice bearing adrenal tumors for 21 days, with either 3 mg/kg b.w./48 h i.p. of GnRH-a or vehicle. Treatments revealed a significant reduction of tumor burden in all types of tumours with GnRH-a treatment vs vehicle treated group. Our results suggest that GnRH-a treatment, besides blocking the release of gonadotropins, may also directly induce tumour cell death.

Genotype-phenotype correlations in a series of patients with von Hippel-Lindau disease in one single tertiary centre

Raluca Maria Furnica, Nicolas Janin & Dominique Maiter
Cliniques Universitaires Saint-Luc, Brussels, Belgium.

Background
Von Hippel-Lindau (VHL) disease is an autosomal dominant inherited tumour syndrome with an important phenotypic variability. Genetic testing for VHL is simple and accurate.
Objective
In this study, we investigated the relationships between genotype and phenotype in a series of patients with different VHL gene mutations.
Method
This was a retrospective analysis of the clinical and molecular characteristics of 15 VHL patients followed between 1965 and 2012 at the Cliniques Universitaires Saint-Luc. Patients were divided into two groups in order to investigate possible differences in tumour risk and age of onset. Group 1 included six patients with missense mutations, while group 2 comprised nine patients with nonsense mutations ($n=7$), gene deletion ($n=1$) or gene insertion ($n=1$).
Results
The mean age at onset of symptoms was 20.6 ± 9.1 years. Retinal (27%) and CNS haemangioblastomas (27%) were the most frequent initial presentations. In three cases (20%), the initial presentation was a phaeochromocytoma. The cumulative occurrence was 93% for cerebellar haemangiomas (mean age 28.7 years), 67% for retinal haemangiomas (mean age 25.8 years), 47% for renal cancer (mean age 38.2 years), 53% for phaeomochromocytoma (mean age 27.1 years), 53% for multiple pancreatic cysts (mean age 31.8 years) and 33% for pancreatic neuroendocrine tumours (mean age 34.8 years). Eleven different VHL mutations were found: nine mutations in unrelated VHL patients and two mutations in two different kindreds. Patients from group 1 tended to have more frequently a phaeochromocytoma (4/6, 66,7%) than patients from group 2 (4/9, 44,4%), while patients from group 2 tended to have more frequently a endolymphatic sac tumour (3/9, 33,3%) than patients from group 1 (0/6). When we compared prevalence and age of onset of the other types of tumours, we did not find significant differences between the two groups.
Conclusions
In our study there was no significant difference in the phenotype of patients with missense vs nonsense gene alterations.

Clinical characteristics and survival of patients with adrenocortical carcinoma: a single centre experience

Valentina Elezovic, Djuro Macut, Milan Petakov, Sanja Ognjanovic, Tatjana Isailovic, Bojana Popovic, Ivana Bozic Antic, Tamara Bogavac, Dusan Ilic & Svetozar Damjanovic
Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia.

Adrenocortical carcinoma (ACC) is rare malignancy associated with limited treatment options and poor prognosis. The aim of this study is to review clinical characteristics and survival of patients with ACC in single centre. We retrospectively analysed 60 patients (37 female and 23 males) with pathologically confirmed ACC who were treated at our institution between January 2005 and December 2014. Staging was performed according to European Network Study of Adrenal Tumours (ENS@T) criteria. The median age at diagnosis was 49.0 years (range 14–74), mean tumour size was 11.3 cm (range 3.1–30 cm) and median follow up duration was 34 month (range 3–179). Patients with hormone secreting ACC (43%) mainly presented with isolated Cushing's (20%), or combined with hyperandrogenism (18%) and 57% of patients had non-functioning tumour. The series included 47% low-stage tumours (three stage I, 25 stage II) and 50% high-stage tumours (no stage III, 30 stage IV). At the time of diagnosis 33% of patients had metastasis. Surgical resection was performed in 90% of patients (73% had adrenalectomy, 15% tumour debulking). At 34 patients the median Weiss score was 6 (range 3–8); proliferation index Ki67 index $>10\%$ was in 20/27 patients (median 23.5%, range 2–65%). Up to January 2012 all patients received adjuvant mitotane treatment after surgical resection, and after that date only those with potential residual disease (R1/Rx resection) or with Ki-67 $>10\%$. Since august 2013, plasma mitotane and metabolites levels were measured regularly using HPLC in our institution. Twenty four percent of patients received chemotherapy (EDP 80%, EP 10%, 5FU-DTC-ADM 10%). Median overall survival was 106 months (95%CI 17–194) with 5 year overall survival 53% (76% in stage II, 33% in stage IV). Median disease free survival was estimated 14 months (95%CI 8–20). We presented the overall survival of ACC patients in Serbia, our 10 years' experience.

Effects of cyberknife radiotherapy treatment of pituitary adenomas

Soraya Puglisi[1], Oana Ruxandra Cotta[1], Alfredo Conti[2], Antonio Pontoriero[3], Erika Messina[1], Adriana Albani[1], Francesco Ferrau[1], Marta Ragonese[1], Maria Luisa Torre[1], Flavio Angileri[2] & Salvatore Cannavo[1]
[1]Department of Clinical and Experimental Medicine – Endocrinology, University of Messina, Messina, ME, Sicily, Italy; [2]Department of Neurosciences – Neurosurgery, University of Messina, Messina, ME, Sicily, Italy; [3]Department of Imaging and Biomorphological Sciences – Radiotherapy, University of Messina, Messina, ME, Sicily, Italy.

Introduction
CyberKnife (CK) is an emerging treatment for pituitary tumours (PT) resistant to other therapies.
Patients and methods
We report long-term CK effect on endocrine function and tumour volume in 20 PT patients (11M/10F, mean age 58.6 ± 14.4years). Twelve patients harboured a non functioning adenoma, 2 an ACTH, 5 a GH (one case of TSH co-secretion) and 2 a PRL-secreting PT. Before CK nine patients had normal while 11 presented impaired pituitary function. CK was used as first line treatment in three cases. The mean follow-up period was 21.16 ± 16.35 months (range, 2–90 months).
Results
MRI demonstrated tumour shrinkage in 50% of patients. Tumour increase was evident only in two cases. Pituitary function impairment occurred in three of the nine patients with previous normal pituitary function who developed isolated deficiency in two cases and multiple deficiencies in 1. Among six patients with previously multiple or isolated hypopituitarism, two became panhypopituitary and one developed a new deficit.
Conclusions
CK treatment for PT is safe and effective, ceasing tumour growth in 90%, and inducing tumour shrinkage in 50% of cases. Nevertheless, impairment of pituitary secretion was demonstrated in 30% of cases with previously intact pituitary function and in 50% of already hypopituitary patients.

Real-time shear wave elastography in the evaluation of parathyroid adenomas

Mihaela Vlad, Ioana Golu, Daniela Amzar, Melania Balas, Ioana Zosin & Ioan Sporea
Victor Babes University of Medicine and Pharmacy, Tmisoara, Romania.

Real-time shear wave ultrasound elastography (SWE) is a new technique, which evaluates elasticity and stiffness of the different structure.
Aim
To determine the values of the elasticity index (EI) measured by SWE in parathyroid gland adenomas and to compare with those of normal thyroid tissue.
Subjects and methods
We studied 50 cases (F/M = 42/8), ten with primary or tertiary hyperparathyroidism, diagnosed by specific tests, and 40 healthy volunteers. In all the patients with hyperparathyroidism, parathyroid adenomas were detected by using ultrasound and at least another imaging technique. In six cases surgical removal of parathyroid adenomas was performed and the pathological results confirm the diagnosis. For each parathyroid lesion two or three elastographic determinations were performed and a mean value was calculated and expressed in kilopascals (kPa). In healthy volunteers, thyroid parenchyma was evaluated, by performing three elastographic determinations for each thyroid lobe. A mean value was calculated and expressed in kPa. All the measurements were performed with an Aixplorer system (Supersonic Image, Inc. France), using a linear high-resolution transducer 15–4 MHz.
Results
In ten patients with primary or tertiary hyperparathyroidism, 11 parathyroid adenomas were evaluated by SWE. The mean EI for parathyroid lesions was 9.2 ± 4.8 kPa (4.2–18.2). In healthy volunteers the mean EI was similar in the right and left thyroid 19.9 ± 6.6 kPa vs 19.3 ± 6.6 kPa, $P = 0.69$, respectively. The statistical analysis indicates that the mean EI assessed by SWE in parathyroid adenomas was significantly lower than in nearby normal thyroid parenchyma: 9.2 ± 4.8 kPa vs 19.6 ± 6.2 kPa, $P < 0.0001$.
Conclusion
This new technique can evaluate the EI of parathyroid adenomas, which was significantly lower than EI of normal thyroid parenchyma. This preliminary study indicates that the determination of EI by SWE might be a new method that can help in preoperative localisation of parathyroid adenomas.

Neuroendocrine tumor European patient experience: results from the first global NET patient survey – a collaboration between the International Neuroendocrine Cancer Alliance and Novartis

Kjell Öberg[1], John Leyden[2], Grace Goldstein[3], Maia Sissons[4] & Teodora Kolarova[5]
[1]Uppsala University Hospital, Uppsala, Sweden; [2]The Unicorn Foundation, Mosman, New South Wales, Australia; [3]The Carcinoid Cancer Foundation, Inc., White Plains, New York, USA; [4]NET Patient Foundation, Hockley Heath, UK; [5]APOZ and Friends, Sofia, Bulgaria.

Background
NETs are a rare heterogeneous group of malignancies, often with a delayed diagnosis. Although diagnosis of NETs is increasing (due in part to greater awareness), little has been published on the NET patient experience. We present data on the EU NET patient perspective.
Methods
In 2014, 1928 NET patients from >12 countries, including EU ($n = 763$: Belgium, Bulgaria, France, Germany, Norway, UK, other EU countries (not specified by respondents)), participated in a survey on the NET patient experience conducted by Hall & Partners on behalf of INCA/Novartis and funded by Novartis. Comparisons were significant at $P < 0.05$.
Results
EU patient-reported NET types included gastrointestinal/pancreatic (GI/pNETs, 53%/27%), lung/thymus (11%), and other/unknown (13%). Most patients reported G1/G2 (67%) functional disease (44%); GI NETs were more likely than pNETs to be low grade (G1: 50% vs 32%) and functional (58% vs 23%). 63% of NETs had metastasized at diagnosis (significantly greater for GI/pNETs (71%/62%) than lung NETs (37%)). 41% reported fair/poor health, and 72% said NETs had a negative impact on their lives, including overall energy levels (70%) and emotional health (60%). Having NETs made patients feel anxious/worried (46%) and concerned (44%). Patients made numerous lifestyle adjustments, including dietary changes (GI/pNET, 54%/55%; lung NET, 34%) and increased travel (47%)/related spending (41%) for medical appointments. 87% of respondents not working ($n = 163$) stopped due to NETs; 30% of retirees ($n = 295$) had to stop working earlier than planned. Patients felt well supported by their medical team, particularly endocrinologists (78%), nuclear medicine specialists (75%), and oncologists/nurses (74%/74%). Patients believed more awareness of NETs (38%), information regarding how to manage disease/treatment-related symptoms (37%/33%), and increased access to NET-specific treatments/medical teams (37%/36%) would help them live better with NETs.
Conclusion
This large global NET patient survey demonstrated a substantial impact of NETs on EU patients and identified areas for improvement.

Vitamin D receptor and progesterone receptor expression in papillary thyroid carcinoma

Maria Yavropoulou[1], Gregory Panayotou[3], Konstantina Topouridou[1], Anastasia Panteliadou[1], Georgia Karayannopoulou[2], Thomas Zaraboukas[2], Apostolos Goropoulos[4], John Yovos[1] & Kaliopi Pazaitou[3]
[1]Department of Endocrinology and Diabetes, AHEPA University Hospital, Thessaloniki, Greece; [2]Department of Pathology, School of Medicine Aristotle University of Thessaloniki, Thessaloniki, Greece; [3]Department of Endocrinology and Endocrine Oncology, Theagenion Cancetr Hospital, Thessaloniki, Greece; [4]Department of Endocrine Surgery, St Luke's Hospital, Thessaloniki, Greece.

Background
Vitamin D receptor (VDR) and progesterone receptor (PR) expression have been described before in papillary thyroid carcinoma but data regarding association of this expression with tumour histological characteristics are scarce.
Materials and methods
Formalin-fixed, paraffin-embedded specimens from adult patients with papillary thyroid carcinoma (PTC), who underwent total thyroidectomy from 2009 to September 2012 were retrieved. Data regarding tumour size and aggressiveness were recorded. Real-time quantitative RT-PCR and immunohistochemistry was used to characterise the expression of VDR and PR in thyroid follicular cells of the PTC.
Results
A total of 32 thyroid carcinoma specimens were used in the final analysis. Eighteen cancer specimens (56%) overexpressed VDR and 11 of them ($n = 34\%$) overexpressed PR compared to adjacent normal thyroid tissue. Co-expression of the two receptors was found in seven specimens (22%). Expression of PR but not VDR was significantly associated with the tumour size ($r = 0.645$, $P = 0.007$).
Conclusion
VDR is overexpressed in the majority of patients with papillary thyroid carcinoma, compared to normal thyroid tissue. However, the potential role of this receptor in the histological behaviour of PTC remains to be elucidated. Expression of progesterone receptor may be associated with a less favourable prognosis of this tumour type.

Genotype–phenotype analysis in patients with medullary thyroid carcinoma: a single centre experience

Tatjana Isailovic, Gordana Rodic, Djuro Macut, Milan Petakov, Sanja Ognjanovic, Valentina Elezovic, Bojana Popovic, Ivana Bozic Antic, Tamara Bogavac, Dusan Ilic & Svetozar Damjanovic
Clinic for Endocriology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia.

Introduction
Medullary thyroid carcinoma (MTC) is a malignant neoplasm derived from the parafollicular cells of the thyroid gland. Approximately 25% of them are caused by germline mutations of the *RET* gene, presenting as a part of FMTC, MEN2A or MEN2B syndrome.
Design of the study
We analysed 213 consecutive patients with MTC (142 females, 71 males, age 6–78, mean 45 years), treated in a single centre from 2004 to 2014. Direct DNA sequencing for detection of mutation in coding region of *RET* exons 5, 8, 10, 11, and 13–16, was performed in all patients.

Results
Mutations in *RET* protooncogene were found in 89 (41.8%) MTC patients (age 3–72, mean 37.7 years) and their 33 unaffected relatives (age 10– 70, mean 40 years), comprising 38 different families. FMTC was diagnosed in 37 (41.6%), MEN2A in 47 (52.8%), MEN2B in 5 (5.6%) of MTC patients. A total of 15 different mutations were found. Cys634Phe, Cys634Arg and Val804Met were the most frequent mutations in MTC patients (21.3, 20, and 19.1%, respectively), but the most predominant one among all analyzed patients was Tyr791Phe (29/122 patients, 23%). However, only 9 (31%) of these patients were diagnosed with MTC. The rest of the patients were asymptomatic, or with different renal and auditory abnormalities. Polymorphisms of the *RET* protooncogene were found in 101 (47.4%) of MTC patients. The type or the number of detected polymorphisms did not influence clinical presentation, calcitonin level, or the outcome of the disease.
Conclusion
A higher prevalence of inherited MTC was found in our group of patients than in other studies. The prevalence of different types of mutations among MTC patients is similar as previously reported. However, in contrast to the European studies, an unusually high prevalence of Tyr791Phe mutation was found among our carriers.

TFF3 and *TIMP3* – the candidate marker genes for differentiation diagnosis of follicular cell-derived thyroid tumours

Karolina H Czarnecka[1], Michał Kusiński[2], Maja Kacprzak[1], Dorota Pastuszak-Lewandoska[1], Monika Migdalska-Sęk[1], Ewa Nawrot[1], Daria Domańska[1], Justyna Kiszałkiewicz[1], Krzysztof Kuzdak[2] & Ewa Brzeziańska-Lasota[1]
[1]Department of Molecular Bases of Medicine, I Chair of Internal Medicine, Medical University of Lodz, Lodz, Poland; [2]Department of Endocrine, General and Vascular Surgery, Chair of Endocrinology, Medical University of Lodz, Lodz, Poland.

The search for new differentiating biomarkers in follicular-cell derived thyroid tumors (FCDT), especially for the FNAB with underdetermined cytology, is an important scientific task. Disturbed expression of tumor suppressor genes plays important role in thyroid carcinogenesis. In this study we focused on epigenetic mechanism influencing on trefoil factor 3 (TFF3) and tissue inhibitor of metalloproteinases 3 (TIMP3) expression.
Aim of the study
Evaluation of *TFF3* and *TIMP3* promoter hypermethylation and gene expression as candidate biomarkers in differentiating diagnosis of FCDT neoplasms.
Material
Thyroid neoplasms and matching macroscopically unchanged tissues (control) from 86 patients with preoperative FNAB diagnosis: 'follicular neoplasm'/PTC. Final diagnosis: FA ($n=9$), PTC ($n=35$), FTC ($n=9$) and NG ($n=33$).
Methods
DNA bisulfite conversion, followed by promoter methylation level evaluation in methylation specific PCR, Methylation Index (MI) calculation. mRNA expression level (RQ) measured by real-time PCR using Low Density Arrays. The results (MI, RQ) were correlated with the clinicopathological features.
Results
TIMP3 MI value correlates with RQ ($P=0.029$) and increase with patients age. *TIMP3* MI and RQ are higher in woman vs men ($P=0.016$). *TIMP3* MI value was significantly higher in follicular lesions (FTC/FA), than in NG and PTC ($P=0.049$). *TIMP3* expression was the highest in FA, the lowest in FTC, RQ values don't correlate with methylation pattern. *TFF3* MI value revealed the opposite correlation to *TIMP3* – low MI in FTC/FA. In PTC *TFF3* MI correlates with RQ level ($P=0.01$). The significant correlations among *TIMP3* and *TFF3* MI levels and among their expressions were observed ($P=0.00008$ for MIs, $P=0.00$ for RQs). In women positive correlation between MIs and RQs for *TIMP3* and *TFF3* were found ($P=0.0004$, $P=0.00$ resp.). RQ values regarding pTNM groups reversely correlate with MI for both genes ($P>0$).
Conclusions
The increased *TIMP3* MI values in FA/FTC, and *TFF3* in PTC suggest that can be regarded as promising biomarkers for FCDT distinguishing. Our research indicates that simultaneous analysis of methylation profile and expression level of *TIMP3* and *TFF3* may be diagnostically useful. Further studies are needed.

EP1143

A case series of etomidate use in ACTH ectopic syndrome in endocrine neoplasms

Georgios Boutzios, Georgios Nikolopoulos, Krystallenia Alexandraki, Maria Kaltsatou, Maria Chrysochoou, Marina Tsoli & Gregory Kaltsas
Endocrine Unit, Department of Pathophysiology, University of Athens, Medical School, Laiko Hospital, Athens, Greece.

Introduction
Etomidate is an imidazole derivative which inhibits several enzymatic steps (11β-hydroxylasey, 17β-hydroxylase, 17,20-lyase, cholesterol side-chain cleavage). Intravenous etomidate at sub-anaesthetic doses remains an important option when i.v. administration is required for rapid treatment of severely ill patients with hypercortisolaemia (Cushing's syndrome, CS) and is almost always very effective.
Case series
A 49-year-old woman with left adrenocortical carcinoma (T4N1M1, stage IV during ENSAT2008, Ki-67: 15%) and CS, relapsed 6 months after surgical removal of the primary tumour while she had received chemotherapy and adrenolytic therapy. Recurrence involved new liver metastases and an increase in cortisol values with recurrence of CS. She received 2.4 mg/h of etomidate intravenously for 7 days; serum cortisol (F) and 24-h urine cortisol concentrations (UFC) decreased (pre-treatment F: 1456.5 μg/dl, post-treatment F: 613.8 μg/dl, pre-treatment UFC: 773.5 mg/24 h, post-treatment UFC: 615 mg/24 h). The patient died because of sepsis one month later. A 72-year-old man with atypical lung neuroendocrine neoplasm (NEN) (T1aNxMx,Ki-67: 4–7%) and ectopic secretion of ACTH (ACTH: 78.7 pg/ml) had surgical removal of the primary tumour followed by chemotherapy and somatostatin analogues. He had disease recurrence 6 years later. He was treated with metyrapone and ketoconazole without adequate control of CS (pre-treatment-UFC: 709 mg/24 h, post-treatment-UFC:416 mg/24 h). Etomidate was administered at a dose of 3–3.3 mg/h intravenously and hypercortisolaemia was controlled (pre-treatment-F: 44 μg/dl, post-treatment-F: 23 μg/dl). A bilateral adrenalectomy was performed to control hypercortisolaemia. A 51-year-old woman with medullary thyroid carcinoma (T3NxM1, stage IV), liver metastases and ectopic secretion of ACTH (ACTH: 153 pg/ml, F: 74 μg/dl) underwent thyroidectomy without resolution of CS. She received etomidate intravenously at a dose of 2.6 mg/h with a decrease in cortisol levels (pre-treatment-F: 273.8 μg/dl, post-treatment-F:79.2 μg/dl). The patient died because of a septic shock 2 days later.
Conclusion
Etomidate may be used as first-line treatment in severely ill patients with CS. However, it needs to be very carefully monitored, because of sedation that may be apparent in higher doses, and adjustments should be made with regards to renal failure and stressed situations such as sepsis.

Differentiated thyroid carcinoma arising from or associated with struma ovarii: a report of two cases

Lavinia Vija[1], Andrei Goldstein[1], Daniela Neamtu[1], Mariana Purice[1], Florin Alexiu[1], Doina Piciu[3] & Corin Badiu[1,2]
[1]Nuclear Medicine Department, 'C.I. Parhon' National Institute of Endocrinology, Bucharest, Romania; [2]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania; [3]'Ion Chiricuta' Oncology Institute, Cluj-Napoca, Romania.

Introduction
Struma ovarii is a rare condition which elicited considerable interest because of its many unique features like its relationship to teratoma and differentiated thyroid cancer. The most common thyroid carcinomas to arise in struma ovarii are papillary and follicular.
Objectives
We describe two patients with differentiated thyroid carcinoma originating from malignant struma ovarii.
Results
Our index patient is a 32-year-old woman with well differentiated follicular carcinoma who developed peritoneal dissemination and appendix tumoural infiltration of a follicular variant of papillary thyroid carcinoma arising from an ovarian teratoma. There was no thyroid carcinoma within thyroid tissue (total thyroidectomy). Whole body scintigraphy (WBS) with therapeutic activity of I-131 (two sessions; cumulated activity: 300 mCi) revealed disseminated pulmonary and bone metastases with a complete response after radioiodine therapy. The second patient is a 49-year-old woman presenting with bone pain revealing bone follicular thyroid carcinoma metastases on biopsy; total

thyroidectomy with lymphadenectomy was performed revealing a follicular thyroid carcinoma T3N1bM1. Two years later, ovarectomy revealed a malignant struma ovarii. Surgical spinal decompression and resection of several vertebral metastases as well as seriate adjuvant radioiodine therapy (279 mCi I-131) were performed. WBS revealed high uptake on cervical lymph node and disseminated pulmonary and skeleton metastases justifying the pursue of radioiodine therapy.
Conclusions
Vascular invasion of the thyroid carcinoma within struma ovarii was not identified in any of the cases; however, disseminated metastases were identified. Mechanisms still need to be searched for. At present, treatment for patients with thyroid carcinoma within ovarian malignant struma ovarii comprises resection of the extraovarian tumoral tissue with subsequent thyroidectomy followed by radioactive iodine ablation.

Mitotane treatment for metastatic Leydig cell tumour

Vasileios Chortis[1], Nicholas Johal[1], Michael Cullen[2], Irina Bancos[1], Peter Guest[2], Emilio Porfiri[2] & Wiebke Arlt[1]
[1]Centre for Endocrinology, Diabetes and Metabolism, University of Birmingham, Birmingham, UK; [2]University Hospital Birmingham, Birmingham, UK.

Introduction
Testicular leydig cell tumours (LCTs) are rare stromal tumors often associated with androgen excess. Metastatic malignant LCTs typically show resistance to radiotherapy and cytotoxic chemotherapy, calling for alternative management options. Here we describe our experience with treatment of two patients with metastatic LCTs with the adrenolytic drug Mitotane.
Patients/methods
Case 1: A 51-year-old patient presented with a 6 month history of restlessness, aggressiveness, insomnia, facial plethora and increasing body hair growth, 15 years after successful orchidectomy for malignant LCT. Imaging by computed tomography revealed disseminated metastatic deposits. Biochemical work-up revealed severe androgen excess as the cause of his signs and symptoms, with a plasma testosterone of 93 nmol/l and a 20-fold rise in urinary excretion of active androgen metabolites (androsterone and etiocholanolone), as well as high urinary cortisol. *Case 2:* A 65-year-old patient presented with disseminated disease 3 years after orchidectomy for LCT. This was also associated with steroid hormone excess, including high testosterone (104 nmol/l) and oestradiol. Both patients were commenced on palliative chemotherapy with mitotane.
Results
In both cases, introduction of mitotane led to prompt control of the underlying hormonal excess, with a precipitous decrease in circulating testosterone and oestradiol levels, diminution of the excretion rate of all urinary androgen metabolites and substantial inhibition of the conversion of testosterone to dihydrotestosterone, as demonstrated by serial urine steroid profiling by gas chromatography/mass spectrometry. Clinically, this resulted in a rapid alleviation of the debilitating clinical symptomatology of hyperandrogenism. Radiologically, stabilisation of the rapidly progressive disease was documented on follow-up imaging for 6 months in case 1, while partial response was noted in case 2.
Conclusions
Mitotane can be an effective treatment option for patients with functional metastatic LCTs, offering prompt palliation of the distressing symptoms of hormone excess and, in some cases, disease stabilisation.

EP1146

Patients with multiple endocrine neoplasia type 1 (MEN1) have late progression and long survival despite the presence of disseminated disease: the experience of a referral centre in Greece

Georgios Boutzios, Krystallenia Alexandraki, Eleftherios Chatzellis, Maria Chrysochoou, Marina Tsoli, Maria Kaltsatou, Georgios Nikolopoulos, Panagiotis Moschouris & Gregory Kaltsas
Endocrine Unit, Department of Pathophysiology, University of Athens, Medical School, Laiko Hospital, Athens, Greece.

Introduction
Multiple endocrine neoplasia type 1 (MEN1) is a genetic disorder involving mainly parathyroid tumours, pancreatic neuroendocrine neoplasms (pNENs) and pituitary tumours. In the present study we have registered demographic, clinical, imaging, pathological characteristics, therapeutic options, response to treatment and overall outcome of patients with MEN1.
Methods/design
35 patients with MEN1 registered in our data base have been studied (14 females, mean age on diagnosis 39 years; range: 15–64), followed during the period 2004–2014. The primary sites, the presence of functional syndrome, and metastatic foci have been registered. TNM system has been used for staging and proliferation index Ki-67 for grading. The therapeutic management and the outcome have been also registered.
Results
24 (68.6%) patients were the index cases. 19 (54.3%) had a positive gene mutation while 5 (14.3%) did not have the mutated gene. 22 (62.9%) patients had a pituitary adenoma and 31 (88.6%) had hyperparathyroidism. All patients but one suffered from pNENs. 11 (32.4%) patients had a functional syndrome. Metastatic liver deposits were found in 6 (17.6%) patients. In the first diagnosis, 21 (61.9%) neoplasms were found in stage 1, 3 (8.5%) in stage 2, 4 (11.9%) in stage 3 and 6 (17.7%) in stage 4. 14 (41.2%) patients had surgical removal of the neoplasms. The other systemic or local therapies that the patients received as monotherapy or in combination as first line treatment are as following: somatostatin analogues ($n=5$), chemotherapy ($n=1$), neoplasm-targeted molecular therapy ($n=1$), radionucleotides ($n=2$), chemoembolization ($n=1$). In the last follow-up of the present analysis 3 (8.6%) patients died of their disease out of the 24 under current follow-up: two with grade 1 pNEN and one grade 2 pNEN.
Conclusion
The present registry implies that the majority of the patients with MEN1 have late progression and long survival despite the presence of disseminated disease, confirming the necessity of specific therapeutic and diagnostic options following the guidelines as well as their management from referral centers under multidisciplinary teams.

Expression of shorter isoforms of retinoblastoma interacting zinc-finger protein in seminoma tissues

Valentina Rossi[1], Caterina De Rosa[2], Ciro Abbondanza[2], Erika Di Zazzo[1,3], Bruno Montcharmont[3] & Antonio Agostino Sinisi[1]
[1]Dpt Scienze Cardiotoraciche e Respiratorie, Second University of Napoli, Napoli, Italy; [2]Dpt Patologia Generale, Second University of Napoli, Napoli, Italy; [3]Dpt Scienze per la Salute, University of Molise, Campobasso, Italy.

The full-length retinoblastoma interacting zinc-finger protein (RIZ), codified by ten exons, has tumour suppressive and differentiating properties and is known to be a downstream effector in classical oestrogen target tissue. In many normal and malignant tissues alternative splicing isoforms, RIZ1 and RIZ2, frame-shift mutations and/or exon deletions have been found, but their oncogenic role is still debated. Although the presence of RIZ1 in the testis has been described, in gonadal tumours the relative expression of two isoforms, the presence of gene product variants has not been investigated yet. Aim of this study was to evaluate RIZ expression in normal and malignant testis. We analysed five seminomas, four non-seminomas and four control testis tissue samples. RNAs were extracted on frozen samples and RIZ expression measured by semi-quantitative and quantitative Real time RT-PCR using RPS28 as housekeeping gene. In order to identify the presence of different length variants, we analysed the transcripts of the head exon1 and of the tail exons 9 and 10.
Results and discussion
RIZ transcript was found in all samples analysed. Moreover, exon 9-transcript levels were higher than C-terminal conventional tail exon 10 level, absent in one seminoma sample. Thus, the balance of head and tail exon transcript levels revealed a greater expression of a shorter RIZ gene isoform in seminomas vs non-seminomas and health testis samples. Our data suggest that shorter RIZ isoforms, prevalent in malignant testes, may exert a potential oncogenic and de-differentiating role in male gonad.

EP1148

Succinate dehydrogenase B associated bladder paragangliomas

U Srirangalingam[2], A Banerjee[1], E George[3], M Druce[1], M Waterhouse[1], S L Chew[1], J Peters[1], P Patki[1], A J Kumar[1], D Berney[1], A Sahdev[1], W M Drake[1] & S A Akker[1]
[1]St Bartholomew's Hospital, London, UK; [2]Royal Free Hospital, London, UK; [3]Queen Elizabeth Hospital, King's Lynn, UK.

Objective
Succinate dehydrogenase B (SDHB) germline mutations are associated with predominantly extra-adrenal paraganglioma (PGLs) and high rates of metastatic disease. Bladder paragangliomas are a rare form of chromaffin cell tumours arising from the bladder wall. The aim of the study is to highlight the preponderance of bladder paragangliomas associated with SDHB gene mutations.
Design
Retrospective case series.
Patients
Five of eight subjects (62.5%) subjects with bladder paragangliomas found to have SDHB mutations. Subjects were seen at St Bartholomew's and associated hospitals, between 1989 and 2013.
Measurements
Basic demographics, disease characteristics, genetics, clinical outcomes.
Results
Genetic testing confirmed germline SDHB mutations. Median age at first diagnosis was 24 years (range 18–68). 60% of patients presented with micturition related symptoms of catecholamine excess. Plasma and/or 24-h urine catecholamines/metanephrines were raised in 4/5 (80%) subjects. A positive family history was apparent in 2/5 (40%). Surgical resection was undertaken in four subjects and one subject awaits surgery. Histopathological or radiological analysis confirmed extension through the lamina propria in 4/5 (80%) subjects. Distant metastatic disease developed in 2/5 (40%) subjects within 4 years of the initial tumour diagnosis. A non-invasive 5.4 mm bladder paraganglioma was identified and excised at an early stage through the SDHB surveillance program. One subject died from metastatic disease 6 years after the initial diagnosis.
Conclusions
The bladder is a 'hot-spot' for SDHB associated paragangliomas linked with high rates of invasive disease. Intensive surveillance regimes, with a focus on the bladder can allow early identification and treatment of potentially aggressive disease.

DOI: 10.1530/endoabs.37.EP1148

EP1149

Excision of phaeochromocytoma and paraganglioma involving the great vessels

U Srirangalingam[2], K Gunganah[1], L Parvanta[1], K Metcalfe[1], G M Besser[1], A Sahdev[1], H S Flora[1], S Bhattacharya[1], R Carpenter[1], S Akker[1], S J Edmondson[1] & W Drake[1]
[1]St Bartholomew's Hospital, London, UK; [2]Royal Free Hospital, London, UK.

Objective
The aim of the study was to describe the surgical management of phaeochromocytomas and paragangliomas which lie in close proximity to or involve the great vessels including the aorta and vena cava.
Design
Retrospective case-series. Patients: five subjects undergoing surgical excision of either a phaeochromocytoma or paraganglioma involving the great vessels seen at St Bartholomew's Hospital, UK (2004–2013).
Measurements
Clinical presentation, genetic mutations, tumour location, catecholamine secretion, pre-, intra- and post-operative course.
Results
Of the five subjects (age range 16–60 years), three had thoracic paragangliomas located under the arch of the aorta, one had an abdominal paraganglioma in which preoperative imaging was unable to delineate that the tumour was invading the aorta and one had a massive phaeochromocytoma invading the IVC. Three of the four subjects tested had predisposing germline mutations. All subjects had alpha and β adrenergic blockade prior to surgery. The thoracic paragangliomas were excised following cardiopulmonary bypass and aortic transection to access the tumours. The abdominal paraganglioma invading the aorta was resected with part of the aorta to clear disease and required insertion of an aortic Dacron graft. The phaeochromocytoma invading the IVC was resected en bloc with the right kidney with a venotomy to extract to resect the tumour nodule invading the IVC. Only one subject experienced an early post-operative complication, which was managed conservatively, and all subjects made a good recovery from surgery.
Conclusion
Excision of phaeochromocytoma and paraganglioma involving the great vessels is high-risk surgery and should be undertaken in a tertiary referral centre within a multidisciplinary setting. Subjects require comprehensive radiological and biochemical assessment. Meticulous pre-operative preparation and appropriate intra- and post-operative back-up are essential. In some cases radiological imaging is unable to resolve the tumour anatomy and extent pre-operatively and direct visualisation of the tumour may be the only way to clarify the surgical strategy, Pre-operative knowledge of the genetic predisposition may influence surgical management.

EP1150

A one-stop multi-disciplinary VHL clinic: patient benefits and feedback

S O'Toole[1], L McAndrew[1], W Drake[1] & U Srirangalingam[2]
[1]St Bartholomew's Hospital, London, UK; [2]Royal Free Hospital, London, UK.

Introduction
Von Hippel-Lindau (VHL) syndrome is a complex multi-organ disorder with significant associated morbidity and mortality. Patients see multiple specialities and have many clinic appointments which can significantly disrupt their lives. In 2012 the St Bartholomew's VHL multi-disciplinary clinic was set up. It consists of an amalgamated one-stop clinic for patients and their families when all relevant specialities are seen in one sitting. The major aims were to: i) provide a more cohesive service and maximise patient benefit from appointments; ii) consolidate clinical experience and expertise in the management of VHL.
Methods
Analysis of medical records from 2000 until the present day for all VHL patients cared for at St Bartholomew's Hospital, London. A prospective patient questionnaire was completed by patients attending the clinic.
Results
27 VHL patients (15 male) are under the care of St Bartholomew's Hospital; 18 (66.7%) attend the multi-disciplinary clinic. 21 completed questionnaires were returned. The mean number of hospital attendances per patient per year was 3.34. This was significantly less after the introduction of the multi-disciplinary clinic (3.59 vs 2.50, $P < 0.05$). All but two patients attended hospital less frequently after the introduction of the multi-disciplinary clinic. Patient feedback was positive. All respondents thought a one-stop clinic was a good idea and 95% preferred to be seen at the same time as their family. Recurring comments included the benefits of combined consultations and the time saved. The vital role of the specialist nurse was highlighted. Reported downsides were limited and centred on the organisation of the consultation.
Discussion
An amalgamated one-stop multi-disciplinary VHL clinic is practical and reduces hospital appointments whilst being well received by patients. In addition the physical bringing together of all interested parties (both patient and medical) allows for improved communication and truly shared decision making.

Progesterone is a potent substance which inhibits the migration of ovarian cancer cells by reducing epithelial-mesenchymal transition via progesterone receptor-dependent pathway

So-Ye Jeon & Kyung-Chul Choi
Laboratory of Biochemistry and Immunology, College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Ovarian carcinoma (OC) is the most deadly and leading cause of cancer death occurring in the female reproductive tracts. Several factors involved in ovarian carcinoma remain poorly defined and the therapy for OC is limited. Epidemiological data strongly suggest that endogenous and exogenous steroid hormones may play important roles in ovarian carcinogenesis. One of the primary steroid hormones, progesterone (progesterone), offers protection against ovarian carcinogenesis. We predicted that progesterone would inhibit the migration of

BG-1 ovarian cancer cells by reducing epithelial-mesenchymal transition (EMT) as well as the growth of cancer cells. First, we investigated the expression of progesterone receptors in ovarian cancer cells with RT-PCR. Next, we determined a proper concentration of progesterone, 17β-estradiol (E_2; a positive control), and Mifepristone (anti-progesterone receptor agent) through MTT assay. We confirmed that progesterone reduced the ovarian cancer cell viability in a dose-dependent manner, which was inhibited by Mifepristone. Also, the migration of ovarian cancer cells was reduced by the treatment of progesterone in comparison with negative and positive control groups. Additionally, the alteration of EMT markers such as vimentin was examined at mRNA and protein levels by using reverse-transcription (RT)-PCR and western blot. The expression of Vimentin was reduced in the treatment of progesterone while the expression of its reverse transition marker E-cadherin was increased. These results indicate that progesterone can inhibit the migration of BG-1 ovarian cancer cells by reducing EMT. Further studies using *in vivo* xenografted mouse models will be needed to predict that progesterone significantly inhibits the growth of ovarian cancer without any virulent effects on the animals. Consequently, the present results represent that progesterone is a potent substance which inhibits the growth of human ovarian cancer cells and metastasis. Therefore, this hormone therapy may be a clinically effective tool for the treatment of human ovarian cancer. A case of TSH secreting pituitary adenoma with Evans' syndrome

Toshiro Seki[1], Atsushi Yasuda[1], Natsumi Kitajima[1], Masami Seki[2], Masayuki Oki[1], Atsushi Takagi[1] & Masafumi Fukagawa[1]
[1]Tokai University School of Medicine, Kanagawa, Japan; [2]Seirei Numazu Hospital, Shizuoka, Japan.

Introduction

To the best of our knowledge, there is no case report of Evans' syndrome associated with TSH secreting pituitary adenoma (TSHoma).

Case report

A 30-year-old woman was admitted to near hospital due to purpura and ecchymoses on her limb and body and epistaxis. A hematologic disease was suspected and she was referred to our hospital. The diagnosis of Evans' syndrome was made on the bases of idiopathic thrombocytopenic purpura (ITP) and autoimmune haemolytic anaemia (AIHA). Physical examination showed acromegalic features. She had the history of malocclusion and thyroid gland enlargement 4 years prior to admission. Endocrinological tests suggested syndrome of inappropriate secretion of TSH (SITSH) and magnetic resonance imaging (MRI) of the brain demonstrated a pituitary tumor. An oral 75-g glucose tolerance test revealed impaired glucose tolerance, but GH was not suppressed by high serum glucose. Initial studies suggested that this patient had hyperthyroidism due to TSH secreting pituitary adenoma and the adenoma concomitantly secreted GH.

Conclusions

Recently, several cases of Evans' syndrome associated with hyperthyroidism by autoimmune thyroid disease such as Graves' disease suggest that these two conditions may have a common immunological background. In our case, hyperthyroidism is due to TSHoma. Thus, it is suggested that thyroid hormone excess itself promote autoimmunity in Evans' syndrome The early treatment for hyperthyroidism is necessary in TSHoma because there is the possibility that normalisation of thyroid hormone may prevent the development of Evans' syndrome.

EP1153

Recurrent hyponatremia in woman with undiagnosed postpartum pituitary insufficiency

Maria Kurowska, Joanna Malicka, Agnieszka Zwolak & Jerzy S Tarach
Department of Endocrinology, Medical University, Lublin, Poland.

Introduction

Hyponatremia occurs in 33–69% of women with postpartum pituitary necrosis. The aim of the study was to present a patient in whom recurrent hyponatremia was one of the dominant symptoms of postpartum anterior pituitary hormones deficiency.

A case report

55-year-old woman with a diagnosis of Sheehan syndrome established 19 years after the last labor complicated by massive bleeding due to uterine atonia. The first symptoms of pituitary insufficiency were the lack of lactation and secondary amenorrhea. In addition, the patient complained of weakness, fatigue, psychomotor retardation, depressed mood, dizziness, hypotension including orthostatic hypotension, flushing, loss of appetite, abdominal pain, recurrent episodes of nausea and vomiting, weight loss. She observed dry skin, loss of pubic and axillary hair, loss of eyelashes and eyebrows and recurrent infections of the urogenital system. Over the last few years she was hospitalised for recurrent hyponatremia (Na 115–125 mmol/l) many times. The hormonal measurements were: ACTH = 32.5 pg/ml; cortisol circadian rhythm = 2.6–1.3 μg/dl; daily urine cortisol excretion = 6 μg/day; DHEAS < 3.0 μg/dl (normal range: 25.9–460.2); PRL = 3.5 ng/ml; LH = 1.5 mIU/ml; FSH = 5.03 mIU/ml; estradiol < 12.0 pg/ml; GH < 0.1 ng/ml; IGF-1 = 10 μg/l (normal range: 50–184); fT_4 = 6.6 pmol/l; fT_3 = 1.1 pmol/l; TSH = 2.36 mIU/l. Ultrasound examination showed the 8.5 ml thyroid gland with normal echogenicity. MRI revealed partial empty sella syndrome with small (7 × 3 mm), symmetric pituitary with normal morphology of the signal.

Conclusion

Recurrent hyponatremia may be one of the dominant symptoms in the patient with long-lasting and unrecognised pituitary insufficiency after a pathological labour.

A case report of Langerhan cells histiocytosis – the need for a good transition care

Ana Margarida Balsa[1], Margarida Bastos[2], Carolina Moreno[2], Daniela Guelho[2], Luís Cardoso[2], Nuno Vicente[2], Diana Martins[2], Diana Oliveira[2], Márcia Alves[1], Joana Guimarães[1] & Francisco Carrilho[2]
[1]Serviço de Endocrinologia, Diabetes e Nutrição do Centro Hospitalar do Baixo Vouga, Aveiro, Portugal; [2]Serviço de Endocrinologia, Diabetes e Metabolismo do Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal.

Introduction

Langerhan Cells Histiocytosis (LCH) is a rare heterogeneous idiopathic clinical entity involving clonal proliferation of Langerhan cells that may infiltrate most commonly bone, skin, lymph nodes or lungs. It affects mainly children between 5 and 15 years. The most common endocrine manifestation is diabetes insipida.

Clinical case

The authors describe a case of a 19-year-old female patient, admitted in the Transition Follow-up of the Endocrinology Department of Coimbra's Hospital and Universitary Center. In her past medical history, at the age of 15 months she presented with rash, fever and distended abdomen. Complementary diagnosis exams showed anemia and hepatosplenomegaly and the first bone marrow examination reached the diagnosis of Kala-Azar but the directed treatment did not show clinical improvement. A new bone marrow exam was conducted with a final diagnosis of LCH. After 17 years over the diagnosis, two recurrences and 27 chemotherapy courses she was now referred to Transition Follow-up. On admission she showed no sign of recurrent disease, no anterior-pituitary disfunction, the maintenance of pituitary stalk thickening at MRI and diabetes insipida, treated with desmopressin.

Discussion

Since it affects mostly children, the majority of published literature about HCL concerns pediatric patients. Our patient reached adulthood and now we face the challenge of planning the future follow-up, concerning the risks of recurrence of the primary disease and the consequences and long-term effects of the treatment of a childhood cancer.

Case report: adrenal phaeochromocytoma presenting with ileus, renal vein thrombosis and pulmonary embolism

Ray Lai, Daphne Lee, Huiling Liew, Timothy Peng Lim Quek & Cherng Jye Seow
Department of Endocrinology, Tan Tock Seng Hospital, Singapore, Singapore.

Introduction
We report a patient who presented with presumed intestinal obstruction, and was subsequently diagnosed with an adrenal phaeochromocytoma associated with venous thromboembolism. We review the literature and discuss underlying mechanisms for these uncommon manifestations.
Case presentation
A 56-year-old man with background untreated hypertension presented with abdominal distension, vomiting, breathlessness and haemoptysis. Heart rate (HR) was 126/min and blood pressure (BP) 159/95 mmHg at presentation. CT scan of the abdomen revealed dilatation of a long segment of small bowel, with a transition point at the distal jejunum. A heterogeneous 4.6×4.5×4.9 cm left adrenal mass with associated renal vein thrombosis and left lower lobe segmental pulmonary embolism was noted. Emergent exploratory laparotomy and bowel decompression followed. Intra-operatively, no mechanical cause for intestinal obstruction was identified. Post-operatively, he had uncontrolled hypertension and tachycardia, with BP up to 200/120 mmHg, and HR up to 120–140/min. Urinary catecholamines were ten times above the normal range, confirming the diagnosis of left adrenal phaeochromocytoma. Ga-68 DOTA-TATE PET-CT did not reveal any evidence of metastatic disease. Anticoagulation was started and patient was optimised medically before laparoscopic left adrenalectomy was performed.
Discussion
These uncommon initial manifestations can be explained by a state of catecholamine excess. Ileus occurs due to suppression of gastrointestinal peristalsis. Catecholamines exert a direct effect on primary and secondary haemostasis, and adrenergic infusions have been shown *in vivo* to increase fVIII activity, vWF antigen, tPA activity, and platelet activation and aggregation. Both arterial and venous thromboses have been reported in the literature. Overall, these are relatively uncommon and also likely under-reported phenomena in patients with phaeochromocytoma. A greater awareness of these associations will enable clinicians to avoid missing a potentially catastrophic diagnosis.

Phaeochromocytoma and hypoglycaemic fits: a case report

Ivar Følling[1,2], Anne Lise Olsen[1], Ingrid Nermoen[1,2] & Per Medbøe Thorsby[3]
[1]Department of Endocrinology, Akershus University Hospital, Nordbyhagen, Norway; [2]University of Oslo, Oslo, Norway; [3]Hormone Laboratory, Oslo University Hospital, Oslo, Norway.

Introduction
Phaeochromocytomas often induce hyperglycaemia. Few cases are reported with hypoglycaemic fits. The mechanism is unknown. Our findings may indicate a mechanism.
The patient
A 37 year old female had a phaeochromocytoma, with typical characteristics: attacks of headache, nausea and sweating. High blood pressures, up to 237/134. Electrocardiogram indicated ischemia, normal coronary arteries on dynamic CT, normal Echo-Doppler heart examination. HbA1c 6.6%. Fasting glucose 8.8 mmol/l. Plasma metanephrine and normetanephrine, and 24-h-urine adrenaline and noradrenaline were 9, 5, 21, and 3 times upper reference value. MR: phaeochromocytoma (45 mm) in right adrenal. MIBG-scintigraphy: no extra-adrenal signal. In addition to this typical presentation she developed frequent fits with hunger, lethargy and visual disturbances, blood glucose 1.8–3.9 mmol/l, induced by sweet meals. A sweet meal challenge gave blood glucose 1.8 mmol/l, and simultaneously high C-peptide and insulin (1012 and 47 pmol/l). Pre-operative alphablockade with doxazosin normalised blood pressure and abolished headache, nausea and sweating, while her hypoglycemic fits persisted. β-blocker was intended because of moderate tachycardia and electrocardiographic abnormalities, and considered safe when alphablockade was effective. However, after the first tablet of pranolol 20 mg, she developed a severe attack with hypertension, pallor, headache, vomiting and Takotsubo-cardiomyopathy. The attack was curbed with intravenous nitroglycerin. After removal of her tumour she has been healthy, with normal blood glucose values and without hypoglycemic fits.
Discussion
Normally alphaadrenergic stimulation of β-cells inhibits, while βadrenergic stimulation increases insulin secretion. Three findings may indicate that her catecholamines have caused abnormal βadrenergic stimulation of insulin release: persistence of hypoglycemic fits after alphablockade; unusual response to the small βblocker dose, suggesting an abnormal βadrenergic tone; no fits postoperatively.
Conclusion
Our pheochromocytoma patient had the rare variant with hypoglycemic fits. They were hyperinsulinaemic, possibly caused by excessive βadrenergic stimulation of insulin secretion.

EP1157

An uncommon complication of post trans-sphenoidal surgery for pituitary adenoma

Hiang Leng Tan & Kurien John
Weston General Hospital, Weston-Super-Mare, UK.

Introduction
The commonest complications post trans-sphenoidal surgery is diabetes insipidus and the development of anterior pituitary hormone deficiencies. Other complications include meningitis, CSF leak, visual deterioration, haemorrhages and transient hyponatremia. We present a case of pituitary abscess 6 months post pituitary surgery who presented with viral meningitis and panhypopituitarism.
Case report
A 55-year-old lady presented with a 3 weeks history of tiredness, headache, visual disturbances and pyrexia. She had an uncomplicated trans-sphenoidal adenomectomy surgery (TSA) for TSH and GH secreting adenoma 6 months previously. She had evidence of pan hypopituitarism with a peak cortisol response of a short synacthen test of 280 nmol/l at 30 min, adrenocorticotropic hormone level of <5 ng/l, low gonadotrophin, low free T_3 and inappropriately normal thyroid-stimulating hormone. A lumbar puncture was done showing evidence of viral meningitis. Initial magnetic resonance imaging (MRI) of pituitary showed evidence of likely recurrence of her pituitary adenoma. However, due to the presence of pyrexia and viral meningitis a MRI pituitary with contrast was subsequently performed. This confirmed evidence of multiloculated pituitary abscess with optic chiasm compression. She was commenced on intravenous hydrocortisone, thyroxine, intravenous acyclovir and antibiotics and transferred to a neurosurgical centre for drainage of the abscess.
Conclusion
Pituitary abscess is a rare complication post transphenoidal surgery. Mortality is high and high index of suspicion is important as early surgical drainage is required for definitive treatment. In a patient with hypopituitarism and a sellar mass, pituitary abscess should be borne in mind if there are systemic signs of infection especially in a patient post pituitary surgery. When suspecting this condition, a MRI with contrast enhancement must be performed to look for evidence of ring enhancing lesion typical of abscess.

Polyglandular autoimmune syndrome type 2 (Schmidt's syndrome)

Faiza Qari
King Abdulaziz, Jeddah, Saudi Arabia.

A 58-year-old Saudi female presented with fatigue, dizziness and generalised skin hyper-pigmentation. She was diagnosed as Hashimoto's hypothyroidism. She was diagnosed recently to be diabetic and her blood sugar was controlled with insulin. She reached menopause at the age of 36 years.

Lab results	Patient	Reference
FT_4	15;pmol/l	12–22
TSH	36 uIU/l	0.27–4.2
Antithyroglublin AB	1:1600	
Corisoal at 8.00	3.6 ug/dl	8–23
ACTH	850 pg/mL	20–80

BPis 90/60 mm/Hg sitting and 70/50 mm/Hg standing. Generalised hyperpigmentation of the skin. Diagnosis is polyglandular autoimmune syndrome type 2 (Schmidt's syndrome) was made on the basis of concomitant Hashimoto's hypothyroidism; premature ovarian failure; Addison's disease; IDDM.

Sellar plasmacytoma masquerading as pituitary macroadenoma – a case report

Antonela Sabati Rajic[1], Matevž Škerget[2] & Sarah Gomezelj[3]
[1]Department of Endocrinology, University Medical Centre Ljubljana, Ljubljana, Slovenia, [2]Department of Hematology, University Medical Centre Ljubljana, Ljubljana, Slovenia, [3]Medical Faculty, University of Ljubljana, Ljubljana, Slovenia.

A 49-year-old male presenting with acute onset strabismus on left lateral gaze was admitted to the Endocrinology Department. The CT scan showed a 35×40×25 mm tumor mass, presumed to be a pituitary macroadenoma, in the sellar region which extended into the sphenoidal sinus, clivus, posterior ethmoidal cells, petrous part of the temporal bone and towards the nasopharynx. A MR scan of the head also revealed that the mass displaced the anterior pituitary gland and the infundibulum upwards. The MRI result was not typical for pituitary macroadenoma and raised the possibility of another tumour. A biopsy was performed and a specimen of the sphenoidal sinus mass was obtained. The histological examination revealed that the tumor was a moderately differentiated plasmacytoma with restriction to kappa light chains and a serum proteinogram showed a disturbance in the κ/λ ratio with a raise in the free κ light chains. A radiographic skeletal survey showed a suspect lesion of the 8th thoracic vertebra. Endocrinological assessment revealed indirect hyperprolactinaemia, secondary hypothyroidism and insufficiency of the pituitary-gonadal axis. After beginning the treatment with bortezomib and dexamethasone as well as radiotherapy, the patient's pituitary-adrenal axis also became insufficient. Plasmacytoma in the sellar region is very rare. There have been 33 cases reported in the literature insofar, but the number is even lower for cases where the sellar region was the first and/or only site of occurrence without prior diagnosis of multiple myeloma. The majority of sellar plasmacytomas described were diagnosed only after surgical treatment, whereas ours is the second case so far where the diagnosis was made prior to any surgical intervention in a patient without pre-existing multiple myeloma. It is also uncommon for plasmacytoma of the sellar region to present with a disturbance of the pituitary-peripheral axis, besides hyperprolactinaemia.

EP1160

Pituitary apoplexy case caused by Hanta virus ınfection

Semra Ayturk[1], Ahmet Bilal Genc[2], Selcuk Yaylacı[2], Oguz Karabay[3], Ali Tamer[2] & Mehmet Celik[1]
[1]Faculty of Medicine, Department of Endocrinology, Trakya University, Edirne, Turkey; [2]Department of Internal Medicine, Sakarya Education and Research Hospital, Sakarya, Turkey; [3]Faculty of Medicine, Department of Infectious Diseases and Clinical Microbiology, Sakarya University, Sakarya, Turkey.

Pituitary apoplexy (PA) is a rare but life-threatening medical emergency. Common predisposing factors include closed head trauma, blood pressure alterations, history of pituitary irradiation, cardiac surgery, anticoagulation, treatment with dopamine agonists, pituitary stimulation testing, and pregnancy. Hantaviruses belonging to the Bunyaviridae family are a group of rodent- or insectivore-borne single-strand ribonucleic acid (RNA) viruses. In humans, hantaviruses can cause haemorrhagic fever with renal syndrome or cardiopulmonary syndrome. About one third of the patients may occur bleeding in the brain, conjunctiva or gastrointestinal tract. Pituitary hemorrhage due to pituitary insufficiency have also been reported. We report the case of a patient, who the 62-years-old man was admitted to the emergency department with complaints of fever, severe headache and confusion. There was no disease in his history. He had not taken any medication or had bleeding disorder prior to this presentation. Leukopenia, thrombocytopenia, elevated liver enzymes and creatinine and panhypopituitarism was detected in laboratory investigations at intensive care. The patient underwent hemodialisis and stress-dose methylprednisolone was started. Because of fever, acut renal failure and thrombocytopenia etiology were thought to be viral infections. Serum sample of the patient was sent to National Reference Virology Laboratory for IFA and immunoblot test which revealed hantavirus IgM and IgG antibodies. Hantavirus seropositivity was determined by two tests. Magnetic resonance imaging revealed sella and suprasellar mass (22×23×30 mm) with evidence of acute hemorrhage and diagnosed as PA. The patient underwent transsphenoidal surgery. Histopathologic examination showed signs of recent bleeding. 12 months after surgery, the patient with persisten hypopituitarism is given steroid, L-thyroxine and testosterone treatment. Thus, physicians should suspect PA in a patient with hemorrhagic fever who develops a rapid onset of severe headache, even in a patient without a known pituitary adenoma.

EP1161

Pasireotide - the last treatment option in Cushing's disease - case report

Corina Galesanu[1,2], Adrian Condrea[2], Dan Niculescu[2], Alexandru Florescu[1], Catalin Buzduga[1,2], Liliana Moisii[1,2] & Vasile Ciubotaru[3]
[1]University of Medicine and Pharmacy 'Gr.T.Popa', Iasi, Romania; [2]University Hospital 'Sf.Spiridon', Iasi, Romania; [3]University Hospital 'Bagdasar-Arseni', Bucharest, Romania.

Introduction
The most common cause of Cushing's disease is ACTH secreting tumours of the pituitary gland. It is associated with high morbidity and mortality. Pasireotide, a potential therapy, has a unique, broad somatostatin-receptor–binding profile, with high binding affinity for somatostatin-receptor subtype 5.
Case report
We present the a 40-years-old man diagnosed in 2005 with Cushing's Disease for which a left adrenalectomy was performed (pathology report: diffuse and nodular adenomatous hyperplasia). In January 2006 given the persistence of hypercortisolism and the adenomatous hyperplasia in the right adrenal gland (49/29 mm), surgery was performed on this location also. After surgery, evolution was not good, the signs and symptoms of Cushing's Disease persisted, the urinary cortisol levels were very high and and for this Ketoconazole treatment (200 mg×3 per day) was initiated. Another surgery was performed on the left adrenal gland (CT showing a 1.5 cm nodule). Until 2008 the blood and urinary cortisol levels remain upper limit under Ketoconazole therapy. High ACTH and pituitary microadenoma require transsphenoidal surgery to practiced and which has proved to be ineffective. Another surgery is required which manages to normalize the ACTH and cortisol levels until 2012. Re-growth of ACTH requires begun the treatment with cyproheptadinum 4 mg (6/4 cp per day). When admitting of July 2014 ACTH and cortisol values are maintained above the limit: ACTH = 177 pg/ml, Cortisol = 15 μg/dl, UFC = 1753 nmol per day, and the MRI showing the pituitary microadenoma. We decide to start the treatment with Pasireotide (0.6 mg×2 per day) with a 2 months follow up (in October) when ACTH and cortisol have been normalized.
Conclusions
In our patient's case Pasireotide was the last and the only option, because the other proved inefficient in time. The significant decrease in cortisol levels in patients with Cushing's disease who received pasireotide supports its potential use as a targeted treatment for corticotropin-secreting pituitary adenomas.

Lump it or leave it & bilateral adrenal macronodular hyperplasia: Case report and clinical insights

Namson S Lau & Nadia Manzoor
Liverpool Hospital, Sydney, New South Wales, Australia.

Clinical case
MG was a 57-year-old female when first referred to endocrinology for investigation of adrenal incidentaloma. Relevant medical history included poorly controlled hypertension on two agents, dyslipidaemia and history of minimal trauma fracture. Baseline labs (including 24 h urine collection) were unremarkable as was clinical examination (exception hypertension). Cortisol levels on two 1 mg Dexamethasone suppression tests failed to suppress. Dedicated CT adrenal study showed bilateral adrenal hyperplasia: left gland was largest. A diagnosis of bilateral adrenal macronodular hyperplasia with subclinical Cushings' syndrome was made. Further investigations showed high grade osteoporosis and normal results for aberrant receptors (TRH, GnRH, mixed meal and postural changes) and Short Synacthen test with 17-OH-P levels. Adrenal vein sampling was

performed that confirmed diagnosis. Immediate progress included continued hypertension now needing three agents; moderate weight gain and new minimal trauma vertebral fracture. Following discussion with MG regarding diagnosis and its associated complications (metabolic syndrome and osteoporosis), the treatment options of medical management of complications and monitoring vs medical treatment vs surgery, she elected for medical management and monitoring. Follow-up CT adrenal studies showed interval increasing size in both glands, persistent osteoporosis despite bisphosphonate treatment and moderate weight gain. Hypertension and dyslipidaemia were controlled. 4 years following initial diagnosis, MG elected for surgery and successfully underwent a laproscopic posterior extra-peritoneal left adrenalectomy. Post-operatively she does not require glucocorticoid therapy and reduced dosages of hypertensive medications. She continues to be followed up by endocrinology.

Discussion

This case highlights the challenges in recognising and managing bilateral adrenal macronodular hyperplasia and its complications. The natural history of the condition, role of investigations including for CAH and receptor testing, the value of adrenal venous sampling, imaging options and medical and surgical treatment options will all be explored.

DOI: 10.1530/endoabs.37.EP1162

EP1163

Clinical nonsecreting pituitary macroadenoma managed by cabergoline: anybody, anytime?

Amalia Ioana Arhire[1], Elena Iuliana Pascu[1], Simona Fica[1,2] & Carmen Gabiela Barbu[1,2]
[1]Elias University Hospital, Bucharest, Romania; [2]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania.

Introduction

Therapeutic management of clinical nonsecreting pituitary adenomas with ophthalmological manifestations is certainly limited to surgery unless IHC from previous intervention could bring up new data.

Case report

A 16-year-old patient was admitted in February 2014 in our Endocrinology Department for short stature (−3.5 S.D.), in the context of an iatrogenic pituitary insufficiency. 7 months before, he had been diagnosed with pituitary macro-adenoma of 36/24/30 mm which invaded the sphenoidal sinus anteriorly and had a contact with the optic chiasm, causing left cecity. He undergone frontal adenomectomy, with a ACTH and TSH deficit that were currently substituted. Clinically: short stature (149.9 cm, −3.5 DS), underweight, BP=95/60 mm/Hg, Tanner stage P3G3, left temporal hemianopsia.Biologically: low IGF1 (−3 DS), maximum stimulated GH 0.226 during insulin induced hipoglicemia, normal testosterone, LH=1.9, normal ACTH, TSH and prolactin. The pituitary MRI showed an adenoma of 3.2/3.56/3.4 cm, the hand X-ray showed a bone age similar to the chronological age, with open growth cartilages and the visual field a left temporal hemianopsia. According to the family's choice not to reoperate, we decided to start the treatment with cabergoline as the adenoma had IHC prolactin, LH, FSH, TSH and GH staining. We started with a dose of 1 mg/week and progressively increased the dosage up to 3 mg/week, with visual field evaluation every 1–2 months and MRI after 6 months. The left hemianopsia improved and was stable for 3–5 months, the MRI showed no evolution, but after 6 months the patient developed right hemianopsia and nausea, so surgery was recommended.

Conclusion

Cabergoline treatment of nonsecreting tumors with IHC staining for D2 receptors is a new strategy with optimist results in recent studies; however, close monitoring is mandatory during the treatment in order to identify non-responders and assure an individualised therapeutic decision.

EP1164

Catecholamine-induced cardiomyopathy: pitfalls in diagnosis and management

Yaasir Mamoojee, Satish Artham, Wael Elsaify & Sath Nag
The James Cook University Hospital, Middlesbrough, UK.

Introduction

Cardiomyopathy as the initial presentation of phaeochromocytoma (PCA) is uncommon. Diagnostic workup and perioperative management may be challenging within this context. We report three cases of PCA presenting with cardiomyopathy to illustrate the pitfalls in diagnosis and management. None of the patients had typical adrenergic symptoms of catecholamine excess and all patients were well established on beta-blockers on presentation. All three patients had an adrenalectomy and a PCA was confirmed on histology.

Cases: Patient A: A normotensive 56-year-old male with dilated cardiomyopathy, was found to have an incidental longstanding right adrenal nodule. Plasma and urine metadrenaline levels were raised during decompensated heart failure and improved with treatment. However, a subsequent increase in metadrenaline levels was noted despite clinical and echocardiographic improvement of cardiac function. MIBG and Octreotide scans were both negative but CT of the right adrenal with wash out studies showed indeterminate characteristics. Patient B: A 66-year-old male was referred with a right adrenal mass. Previous investigations revealed severe left ventricular impairment and non-flow limiting coronary disease. Plasma and urine metadrenalines were raised and asymmetrical adrenal uptake was noted on an MIBG scan. Patient C: A 61-year-old female with type 1 Neurofibromatosis presented with Takotsubo cardiomyopathy. Fractionated metadrenaline levels were raised and a MIBG avid left adrenal lesion, corresponding to a left adrenal mass on CT scan, was found.

Conclusions

Interpretation of fractionated metadrenaline levels in the context of established cardiomyopathy is difficult as cardiac failure of any aetiology generates an adrenergic response. Screening all patients with idiopathic cardiomyopathy for catecholamine excess is highly likely to generate false positive results. However, a high index of suspicion should prompt further investigations of patients with idiopathic cardiomyopathy for occult an PCA. Peer reviewed guidelines are required to guide the investigation and management of suspected catecholamine-induced cardiomyopathy.

EP1165

Histiocytosis, a rare cause of hypopituitarism. Langerhans cell histiocytosis and Erdheim–Chester disease, two case reports of pituitary deficiency

Václav Hána, Mikuláš Kosák & Václav Hána
Third Medical Department, 1st Faculty of Medicine Charles University and General Faculty Hospital in Prague, Prague, Czech Republic.

Introduction

Langerhans cell histiocytosis (LCH) is a rare disease with incidence of 1–2 adults per milion/year. Pituitary function is affected in 30% of cases presenting almost always with diabetes insipidus. Other deficiencies such as GH, FSH+LH, TSH and ACTH follow. Erdheim–Chester disease is a rare Non-LCH described in several hundreds of cases in the world so far, with the pituitary function involvement in similar frequency as in LCH.

Case 1

A 36-year-old man has been treated for diabetes insipidus, central hypogonadism and severe GH deficiency of unknown origin since 2006. In 2014 MRI showed a hypothalamic lesion with involvement of pituitary stalk and other small lesions around IV. ventricle. PET/CT revealed maxillary and mandible lesions with adjacent soft and lymphatic tissue involvement. A biopsy from recently discovered scalp lesions, previously described as [foliculitis capitis] in the scalp, proved LCH. Otitis externa was another manifestation of LCH.

Case 2

A 42-year-old man has been diagnosed with isolated diabetes insipidus. MRI showed an infiltration of hypothalamus and pituitary stalk. Biopsy from suspicious papule on the arm did not reveal LCH as CD1a and S100 stains were negative. Additional PET/CT scan showed a multifocal bone involvement. The clavicle biopsy was in agreement with the skin papule biopsy and diagnosed an Erdheim–Chester disease.

Conclusions

Histiocytosis should be considered in case of a diabetes insipidus with/without other pituitary deficiency and hypothalamic lesion. Other organs such as bones, skin, lungs, lymphatic tissue and others can also be involved and PET-CT scan can reveal it. A biopsy from the extrapituitary lesion can lead to the diagnosis.

EP1166

A rare case of primary empty sella syndrome and growth hormone excess in a patient with neurofibromatosis type 1

Pascu Elena Iuliana[1], Epure Mihaela[1], Arhire Amalia Ioana[1], Martin Sorina[1,2] & Fica Simona[1,2]
[1]Endocrinology Department, Elias Emergency Hospital, Bucharest, Romania, [2]Endocrinology Department, Carol Davila University of Medicine and Pharmacology, Bucharest, Romania.

Introduction
Neurofibromatosis type 1 (NF1) is the most common type of NF, and accounts for about 90% of all cases. Primary empty sella syndrome (ESS) results from herniation of arachnoid mater into the pituitary fossa. Since it has been demonstrated that the small anterior pituitary size reflects loss of neurofibromin expression in the hypothalamus, leading to reduced GHRH, pituitary GH and IGF1 production, we agree that IGF1 and GH increased in our patient can be challenging.
Case report
We report the case of a 33-year-old woman, diagnosed in childhood with NF1, with a single spontaneous menstrual cycle at 14 years, secondary amenorrhea and oestroprogestative substitution treatment ever since, diagnosed with primary ESS, hydrocephaly and central ventricular system malformation at 18 years. Physical examination revealed six café au lait macules on the trunk and neck, multiple cervical, supraclavicular and upper thorax plexiform neurofibromas. Blood pressure was 115/100 mm/Hg, without orthostatic hypotension. The fluid intake was normal. She had no hystory of head trauma, pregnancy or childbirth. Lab tests:IGF1 = 413 ng/ml (115–307 ng/ml) ACTH = 12.6 pg/ml, TSH = 0.893 μIU/ml, FT4 = 0.851 ng/dl, TPOAb < 10 UI/ml ($n < 35$), PTH = 46.5 pg/ml, 0800 h serum cortisol = 12.9 μg/dl, plasmatic metanephrines = 15.1 pg/ml ($n < 90$), plasmatic normetanephrines = 35.8 pg/ml ($n < 180$). Oral glucose tolerance test showed unsuppressed GH on glucose load (nadir GH = 1.710 ng/ml). Thyroid, breast, abdominal and pelvic ultrasound were normal. Bone densitometry: z-score spine = −2.5 s.d. Pituitary MRI:empty sella without pituitary microadenoma. We consider that this is either infarction of a pituitary microadenoma or ectopic secretion of GHRH requiring further evaluation.
Conclusion
ESS is a rather frequent neuroradiological finding in the general population and can be associated with hypopituitarism. GH deficiency is more common in patients with NF. Since this rare case presents a young patient with NF, ESS and an uncommon excess of GH, careful evaluation, diagnosis and follow-up appears to be essential.

Gonadotrophin secreting pituitary adenoma with hypersecretion of testosterone and testicular enlargement

Murali Ganguri[1], Naveen Aggarwal[1], Alistair Jenkins[2], Abhijit Joshi[3], Colin Saysell[3] & R A James[1]
[1]Department of Endocrinology, Royal Victoria Infirmary, Newcastle upon Tyne, UK; [2]Department of Neurosurgery, Royal Victoria Infirmary, Newcastle upon Tyne, UK; [3]Department of Pathology, Royal Victoria Infirmary, Newcastle upon Tyne, UK.

Gonadotroph pituitary adenomas are common but majority of them are classified as non-functional as they do not lead to features of hormonal excess. Functional gonadotroph adenomas are rare and there are only few small series or individual case reports about these.
Case report: 45-year-old gentleman presented with headaches, progressive visual failure and complaint of excessive tiredness. He had normal libido and had an 8-year-old child. On examination, he had bitemporal hemianopia and bilaterally enlarged testes (>40 ml bilaterally). His MRI showed a large pituitary macroadenoma (35 × 29 × 26 mm) with suprasellar extension and displacing the optic chiasma. His blood results showed high normal haemoglobin of 180 g/l (130–180) with borderline high haematocrit of 0.51 l/l (0.40–0.50). Sex hormone profile was as follows: LH: 10.5 IU/l (3.0–13); FSH: 15.7 IU/l (1.3–9.2); Testosterone: 43.4 nmol/l (9–25); free Testosterone 1257 pmol/l (215–760); Sex Hormone Binding Globulin 26 nmol/l (15–48). Alpha sub-unit was also elevated at 2.55 IU/l (NR < 1.0). His thyroid functions were as follows: TSH: 7.61 mU/l (0.3–4.7), FT_4: 6.0 pmol/l (9.5–21.5); FT_3: 2.7 pmol/l (3.5–6.5). Prolactin was mildly high at 982 mIU/l (0–450). GH and IGF1 were normal at 0.13 μg/l and 14 nmol/l (7–28) respectively. His baseline cortisol was low at 75 nmol/l. He was started on Dexamethasone and Levothyroxine and underwent trans-sphenoidal pituitary adenomectomy. He made an uneventful recovery apart from transient diabetes insipidus. The histology was consistent with pituitary adenoma with scattered FSH positive cells and very rare LH positive cell. In the post-operative period, his LH, FSH & Testosterone levels were 0.7 IU/l, 3.0 IU/l and <1.0 nmol/l respectively. His visual fields also improved significantly. He is continuing on steroids and levothyroxine. The patients reported earlier had either high testosterone levels or testicular enlargement. The authors could not find any case report of a patient with both, high testosterone level and testicular enlargement, secondary to functional gonadotrophinoma.

Adrenal cevernous hemangioma

Miomira Ivovic[1,2], Vladan Zivaljevic[1,2], LJiljana Marina[1], Svetlana Vujovic[1,2], Milina Tancic-Gajic[1,2], Zorana Arizanovic[1], Dragana Rakovic[1] & Dragan Micic[1,2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Disease, Clinical Center Serbia, Belgrade, Serbia; [2]Belgrade University School of Medicine, Belgrade, Serbia.

Adrenal hemangioma is a rare adrenal tumour usually presented as incidental finding in asymptomatic patients. Due to its radiographic features sometimes it's difficult to differentiate them from other malignant lesions. We present a 55-years-old men admitted to our department with adrenal incidentaloma size 5 × 4 cm confirmed by MSCT scan. Active phaeochromocythoma was excluded by normal urinary catecholamines. Endocrine evaluations revealed normal midnight cortisol, with post 1mg-DST cortisol suppression and normal basal ACTH. PRA and Aldosteron were in normal range with normal ALD/PRA ratio. According to MSCT tumour had some malignant neoplastic features. Surgery was performed. Intraoperative findings showed adrenal tumour about 5 cm sizes without signs of local infiltration or lymphadenopathy. Tumour was completely removed with adrenalectomy. Pathophysiology showed cavernous and partially capillary hemangioma with hyperplasia of the rest of adrenal gland. 6 months later patient was retested and results show normal function of the left adrenal gland. Most of adrenal cavernous hemangioma was non-functional and surgical removal was the right choice of therapy. They should be also the part of differential diagnosis of adrenal incidentaloma.

Oncocytic adrenal cortical adenoma presenting as Cushing's syndrome: an exceptional clinical entity

Maria Molina Vega, Araceli Muñoz Garach, Silvia Maraver Selfa, Ana Gomez Perez, Isabel Cornejo Pareja, Cristina Diaz Perdigones, Isabel Mancha Doblas & Francisco Tinahones Madueño
Hospital Clinico Universitario Virgen de la Victoria, Malaga, Spain.

Introduction
Oncocytomas are tumours composed by oncocytes, cells with granular and eosinophilic cytoplasm filled with mitochondria. It is a neoplasm that can arise in several organs (more commonly described in the kidney, salivary gland and thyroid). Oncocytoma arising in the adrenal gland is a rare finding. Most of them are benign and non-functioning and are detected incidentally. However, functional adrenal oncocytomas presenting as Cushing's syndrome and phaeochromocytoma have been reported.
Case report
55 years old woman with progressive weight gain in the last year. Medical history: smoker, arterial hypertension, dyslipidemia, gastroesophageal reflux disease and past infection with the hepatitis B virus. She had developed edema of her face, abdomen and ankles and had frequent headaches. Physical examination: truncal and centripetal obesity, thin extremities with muscle atrophy, plethoric moon face, echymoses and hirsutism. Blood pressure: 120/85 treated with losartan 50 mg/24 h, amiloride hydrochlorothiazide 5/50 mg/24 h and atenolol 50 mg/24 h. Laboratory evaluation: fasting blood glucose 86 mg/dl, total cholesterol 218 mg/dl, HbA_{1c} 6.3%, TSH 0.96 μIU/ml, serum cortisol (0800 h) 22 μg/dl (5–25), serum cortisol (after 1 mg overnight dexamethasone suppression) 10 μg/dl, serum cortisol (after 0.5 mg dexamethasone every 6 h for 48 h suppression) 27 μg/dl, urinary free cortisol repeatedly reased (593, 388 μg/24 h), ACTH 1 pg/dl, rest adrenal hormonal profile normal. Computed tomography: 2.2 cm mass in the right adrenal gland. From these findings, the final diagnosis for this patient was Cushing's syndrome and we decided laparoscopic right adrenalectomy. Histopathology: adrenal adenoma with encapsulated oncocytoma without capsular invasion. The patient is receiving glucocorticoid replacement

therapy 6 months after the surgery with progressive reduction. She is waiting to see clinical and analytical evolution to suspend such treatment.
Conclusion
Adrenocortical oncocytoma, although extremely rare, should be considered in the differential diagnosis in adrenal masses. They are usually non-functional and benign but few cases are functioning tumours and may cause Cushing's syndrome. To make a correct diagnosis, biochemical, clinical and histological features must be analysed together.

Adrenal insufficiency revealing pseudotumorale surrénale tuberculosis

Samir Ait Abderahmane, Meriem Bensalah, Yamina Aribi, Lila Brakni, Samia Ouldkablia & Zahra Kemali
Central Hospital of Army, Algiers, Algeria.

Adrenal tuberculosis was first described by Thomas Addison in 1855, Isolated adrenal tuberculosis is rare and between represents 1–2% of the aetiologies of adrenal masses called expired incidentalomas. We report the case of a related Addison's disease is a progressive adrenal tuberculosis which could benefit from exploration and a tomography monitoring on anti tuberculosis treatment. Patient aged 35 years presented himself to medical emergency with clinical surgical nickname, the diagnosis of adrenal insufficiency decompensation was made. Our patient underwent adequate replacement therapy, with correction of electrolyte disturbances. The aetiological investigation concluded in adrenal tuberculosis on the basis of arguments. History of pulmonary tuberculosis treated, melanodermia gradual onset, progressive weight encrypted fall has 16 kg in 3 years, TA figures tend to decline, Malaise hypoglycemic with difficulty fasting month of Ramadan. TST positive tuberculin 25 mm.La chest X-ray shows pulmonary tuberculosis effects and abdominal CT shows bilateral adrenal hypertrophy presence of multiple nodules that larger situated right 21 mm major axis. After a treatment based TB established for 6 months, a radiological objective control complete disappearance of radiological lesions surrenalien. Un base cortisol is collapsed income 89 ng/l. In light of this observation we update on this rare disease. Adrenal tuberculosis can be discovered on the occasion of the setting evidence of adrenal mass was the initial phase of bacillary disease, there adrenal hypertrophy before the appearance hormonal insufficiency.

Three cases of successful pregnancy outcomes after different methods of therapy in women of acromegaly apart from remission of the disease

Natalia Molitvoslovova[1], Andrey Grigoriev[1], Yuri Trunin[2] & Olga Oleynik[1]
[1]Endocrinology Research Center, Moscow, Russia; [2]Burdenko Neurosurgery Institute, Moscow, Russia.

Reports of pregnancy in acromegalic women are uncommon.
Case 1: Patient K., 25-year-old., 01/04/2008 – transsphenoidal adenomectomy in connection with active acromegaly (GH/OGTT – 47.2–64.0–38.0–29.6–28.7 ng/ml; macroadenoma 19×14×12 mm with compression of optic chiasm). Postoperative remission of the disease, recovery of menstrual function without additional therapy. At the end of August 2008 the patient became pregnant, in the beginning of June 2009 – childbirth. After 6 months – the second successful pregnancy. The both children are wellbeing till now.
Case 2: Patient Yas.,32-year-old., 24/02/2005 – partial transsphenoidal adenomectomy without remission due to spreading macroadenoma into left cavernous sinus around ICA. After surgery patient received additional therapy with SSA (Somatulin 30 mg twice a week till 2006, then Sandostatin LAR 40 mg in combination with cabergoline 1 mg a week) without cure of the disease: IGF1 is not low then 770 ng/ml (62–280). 03/04/08 – radiotherapy ('Novalis'), 22 G. After 1 year – spontaneous pregnancy. Due to severe headache in view of active disease patient independently continued therapy with Sandostatin LAR 40 mg during all period of pregnancy. In the beginning of March 2010 – childbirth. The boy is wellbeing till now.
Case 3: Patient P., 30-year-old. Primary infertility during 10 years. Two-fold partial transsphenoidal adenomectomy (in 1998 and 2001) without remission due to macroadenoma with supra-infra-latero-cellar extension. In 2002 – conventional gamma-therapy, 50 G. In one year after radiotherapy – active acromegaly (GH-25 ng/ml, IGF1 – 690 ng/ml) and spontaneous pregnancy with successful outcome. The boy is wellbeing till now. After childbirth SSA therapy have been initiated.

An unusual cause of central diabetes insipidus

Paraskevi Kazakou, Frederic Vandergheynst, Bruno Couturier, Nicolas Dumarey, Daniel Van Gansbeke, Agnieszka Pozdzik, Sandrine Rorive & Agnes Burniat
Erasme Hospital, Brussels, Belgium.

Introduction
In 30–50% of cases central diabetes insipidus (CDI) is idiopathic. Other causes include tumours, pituitary surgery, cranial trauma or infiltrative diseases. Long-term medical follow-up is crucial given that idiopathic CDI can be the earliest sign of an evolving process (inflammatory or tumoural).
Case report
We report the case of a 23-year-old woman who presented with isolated polydipsia and polyuria. The diagnosis of isolated CDI was established. Magnetic resonance imaging of the pituitary gland showed thickening of the pituitary stalk and loss of normal hyperintense signal of the posterior pituitary on T1-weighted images. A ^{18}F-FDG PET/CT revealed a tumour-like lesion in the right kidney which was confirmed by a renal contrast-enhanced ultrasonography (CEUS). Granulomatous with polyangiitis (GPA) was suspected on the basis of associated maxillary sinus hypermetabolism on PET/CT and plasmatic anti-MPO ANCA positivity. Strikingly, urinalysis and renal function were normal. Furthermore sinus biopsy revealed no granulomatous inflammation. Ultrasound control performed six months later showed that the right renal mass had doubled in diameter and demonstrated new lesions in the left kidney. Renal function and urinary sediment still remained normal. Finally, US-guided biopsy of the right renal tumour revealed granulomatous inflammation consistent with the diagnosis of GPA.
Conclusions
GPA is an ANCA-associated systemic vasculitis which classically affects the upper and lower respiratory tracts and kidneys. Pituitary involvement is very rare. Renal impairment is usually characterised by glomerulonephritis with hematuria and/or proteinuria leading to progressive renal failure. Only 16 cases of GPA with renal pseudotumours have been reported. To our knowledge this is the first case combining CDI and subsequent bilateral renal tumours in the setting of GPA. This affection should be considered in the differential diagnosis of CDI. Early diagnosis and initiation of treatment could minimize the risk of irreversible pituitary function loss.

Longest survival with central diabetes insipidus; more than 30 years without and 25 years with desmopressin treatment

Didem Ozdemir[1], Sefika Burcak Polat[1], Yunus Halil Polat[1], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Department of Endocrinology and Metabolism, School of Medicine, Yildirim Beyazit University, Ataturk Education and Research Hospital, Ankara, Turkey; [2]Department of Internal Medicine, School of Medicine, Yildirim Beyazit University, Ataturk Education and Research Hospital, Ankara, Turkey.

Introduction
Diabetes insipidus (DI) is a disease characterized by excessive thirst, polydipsia and excess diluted urine caused by insufficiency of antidiuretic hormone or renal resistance to its effect. Although it is generally a benign condition, severe hypernatremia and hypertonicity may cause death if water loss is not compensated.
Case report
A 72-years-old man admitted to our clinic for routine control. In medical history, he told that when he was about 9 years, polyuria and polydipsia had started and he was diagnosed to have DI when he was 17 years old in 1959. At that time, he was told to drink water as much as possible since there was not any drug available in our country. He had been drinking about 15–16 l of water in those years. About 25 years ago, desmopressin became available in our country and the patient had started desmopressin treatment. From then on, polyuria and polydipsia had

resolved and the dosage was progressively increased to 3×20 mcg/day. He did not have any other chronic disease except hypertension regulated with amlodipin. In laboratory examination, serum sodium was 141 mmol/l, potassium 4.1 mmol/l, urinary density 1014, serum osmolality 291 mlOsm/l and urinary osmolality 486 mlOsm/kgwater. His anterior hypophysial hormones were normal and magnetic resonance imaging revealed a normal hypophysial gland with a height of 4.3 mm.

Conclusion

To our knowledge, the longest follow-up time reported in studies or case reports including patients with central DI in the literature does not extend beyond 30 years. Our patient has the longest survival of more than 55 years of which 30 years passed without any medical treatment. This is supportive for the fact that loss of urine can be compensated and water balance can be maintained as long as thirst mechanisms work and water intake is provided.

EP1174

Positive MIBG scan in a patient with adrenal failure secondary to lymphoma: a coexistent paraganglioma or false positive involvement?

Didem Ozdemir[1], Sefika Burcak Polat[1], Betul Asan[2], Aydan Kilicarslan[3], Sabire Y Aksoy[4], Seyda Turkolmez[4], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Department of Endocrinology and Metabolism, School of Medicine, Yildirim Beyazit University, Ataturk Education and Research Hospital, Ankara, Turkey; [2]Department of Internal Medicine, School of Medicine, Yildirim Beyazit University, Ataturk Education and Research Hospital, Ankara, Turkey; [3]Department of Pathology, School of Medicine, Yildirim Beyazit University, Ataturk Education and Research Hospital, Ankara, Turkey; [4]Department of Nuclear Medicine, School of Medicine, Yildirim Beyazit University, Ataturk Education and Research Hospital, Ankara, Turkey.

Introduction

We report stage IV B cell lymphoma in a patient presenting with adrenal failure and an intraabdominal mass which imaging techniques were suggestive for paraganglioma.

Case report

A 71-years-old woman admitted to our emergency clinic with severe fatigue and stupor. She was diagnosed to have primary adrenal failure since serum ACTH was 229 pg/ml and cortisol response to 250 µg co-syntropin was 6.17 µg/dl. In abdominal MRI, bilateral adrenal enlargement and a 35×31 mm paraaortic lesion consistent with paraganglioma (heterogenous, markedly increased contrast uptake, milimetric cystic foci) were detected. ^{123}I-MIBG showed diffuse uptake in the lesion. 24 h urine metanephrin, normetanephrin and VMA levels were moderately increased. She did not have persistent or intermittent hypertension. During investigation for the cause of adrenal failure, multiple mediastinal and hilar lymph nodes (24×7 mm the biggest) were observed in thoracal CT and a lesion of 94 mm destructing cortex of left iliac crest and extending to soft tissue was detected in pelvic MRI. 18F-FDG PET/CT confirmed high uptakes with high SUVmax indexes in the lesion inferior to the left adrenal gland, bilateral adrenal glands, paravertebral and mesenteric lymph nodes, intestinal serosal surfaces and left iliac crest. A CT-guided biopsy was taken from the lesion surrounding iliac crest and the histopathological result was high grade B cell lymphoma infiltration. Rituximab-CHOP chemotherapy treatment was started.

Conclusion

To our knowledge, coexistent paraganglioma and lymphoma was not reported in the literature previously. However, since we did not have histopathological confirmation, false positive MIBG uptake secondary to lymphoma could not be excluded. Although ^{123}I-MIBG is known to have a sensitivity of 77–90% and specificity of 88–99% for localizing paragangliomas, lymphoma might be one of the causes of false positivity in addition to some other rare causes such as angiomyolipoma.

DOI: 10.1530/endoabs.37.EP1174

EP1175

Synacthen induced phaeochromocytoma crisis, an unusual presentation

Ali Aldibbiat[1], Murali Ganguri[1], RD Bliss[2] & Andy James[2]
[1]Department of Endocrinology, Royal Victoria Infirmary, Newcastle Upon Tyne, Tyne and Wear, UK; [2]Department of Endocrine Surgery, Royal Victoria Infirmary, Newcaslte upon Tyne, UK.

75 male was referred to endocrine service with incidental pituitary macroadenoma measuring 4.2×3.1×3.3 cm noted on MRI-C-Spine done for ankylosing spondylitis with Atlanto-axial joint instability. He had reduced secondary sexual characteristics and left quadrantanopia. Endocrine studies confirmed thyrotroph and gonadotroph failure but normal lactotroph and HPA axis. He underwent trans-sphenoidal tumour resection followed by external beam radiation due to tumour residuum. His quadrantanopia resolved completely and he was started on annual pituitary assessment. 2 years later he developed palpitations and collapsed following Synacthen injection for short Synacthen test (SST). He made full recovery and initial work up demonstrated no clear cause. A repeat SST 6 month later resulted in palpitations and near collapse. An evolving history of frequent episodes of palpitations and sweating accompanied by headache over the previous months was noted, which raised suspicion of pheochromocytoma. Plasma metanephrines then were marginally elevated (metadrenaline 1140 (80–510) pmol/l, normetadrenaline 3833 (120–1180) pmol/l). This rose further in the following 3 months (metadrenaline 3008 pmol/l, normetadrenaline 5387 pmol/l) and 24 urine analsysis demonstrated raised indices to creatinine (metadrenalines/creatinine 1.14 (0–0.3) umol/mmol, normetadrenaline/creatinin 0.76 (0–0.35) umol/mmol). CT-abdomen demonstrated a suspicious L-adrenal mass measuring 4.5×4.3 cm. MIBG scan showed uptake in the region of L-adrenal consistent with a neuroendocrine tumour. Alpha-blockade was established and patient later underwent L-adrenalectomy. Histopathology confirmed pheochromocytoma. Metanephrines normalised post-operatively but SST demonstrated inadequate adrenal response. He is currently on glucocorticoid replacement and annual pituitary assessment. This case demonstrates synacthen-induced pheochromocytoma crisis. There are several case reports of exogenous glucocorticoid-induced pheochromocytoma crises but no reports of Synacthen/ACTH-induced crisis were found. The likely mechanism is the effect of glucocorticoid surge secondary to synacthen stimulation leading to augmented effect on enzymes involved in catecholamine biosynthesis and release, e.g. phenylethanolamine N-methyltransferase (PNMT).

Ectopic ACTH-secreting pituitary adenomas located in the sphenoid sinus: an overview

Philip C Johnston[1], Laurence Kennedy[1], Robert J Weil[2] & Amir Hamrahian[1]
[1]Department of Endocrinology, Diabetes and Metabolism, Cleveland Clinic, Cleveland, OH, USA; [2]Department of Neurosurgery, Cleveland Clinic, Cleveland, OH, USA.

Background

Ectopic pituitary adenomas are defined by the presence of adenomatous pituitary tissue outside the sella and distinctly separate from the pituitary gland. Ectopic ACTH-secreting pituitary adenomas (EAPAs) are a rare cause of Cushing's syndrome. Detecting these radiologically can prove difficult, in part, due to their typically small size and unpredictable anatomical location.

Aim

We reviewed the current literature on all previously reported EAPAs within the sphenoid sinus.

Results

Twenty cases of EAPAs have been reported in the literature to date. In most cases, ectopic ACTH pituitary adenomas within the sphenoid sinus will manifest with symptoms of hormonal excess, have an obvious sphenoid sinus mass on pre-operative imaging and will demonstrate resolution of hypercortisolism after surgical excision if located and removed.

Conclusions

In ACTH-dependent Cushing's syndrome, if, despite comprehensive testing, the source of excess ACTH remains occult (including negative work up for ectopic ACTH syndrome) thought should be given to the possibility of the patient harbouring an EAPA. Careful review of the neuroimaging to identify potential lesions, especially when pituitary imaging is not conclusive, is imperative. In the context of negative 'MR' imaging, the presence of EAPAs should be considered. Appropriate investigation and resection of such lesions may prevent unwarranted hypophysectomy, radiotherapy and/or adrenalectomy and result in long term and persistent remission.

EP1177

Cushing's disease and co-existing phaeochromocytoma

Philip C Johnston[1], Pablo Recinos[2], Laurence Kennedy[1] & Amir Hamrahian[1]
[1]Department of Endocrinology, Diabetes and Metabolism, Cleveland Clinic, Cleveland, OH, USA; [2]Department of Neurosurgery, Cleveland Clinic, Cleveland, OH, USA.

Clinical presentation
We report a 46 year old female who presented with a 1 year history of bruising, thin skin and weight gain. In addition; she reported flushing of her chest, heat intolerance, palpitations and abdominal pain. On clinical examination she appeared cushingoid, blood pressure was elevated at 160/98 mm/Hg.
Investigations
Biochemical investigations indicated ACTH-dependent Cushing syndrome: 24 h UFC 300 μg (0–50), ACTH 119 pg/ml (8–42); midnight salivary cortisol 950 ng/dl (<100). MRI pituitary demonstrated a sellar lesion; 14×9×9 mm suggestive of a pituitary macroadenoma. To investigate the symptoms of flushing and palpitations, plasma fractionated catecholamines and metanephrines were performed and were elevated; norepinephrine 822 pg/ml (80–520), epinephrine <10 pg/ml (10–200), dopamine <20 pg/ml (0–20), normetanephrine 1250 pg/ml (18–101), metanephrine 34 pg/ml (12–67). CT abdomen revealed a lipid poor right adrenal mass measuring 17×36 mm with Hounsfield units of 47, consistent with a phaeochromocytoma.
Management
The patient started phenoxybenzamine and subsequently uptitrated the dose for three weeks prior to elective adrenalectomy. A robotic right trans-abdominal lateral adrenalectomy was performed without complications, histology confirmed phaeochromocytoma. One month post-adrenalectomy plasma fractionated catecholamines and metanephrines were normal. The patient continued to be hypercortisolemic post-op. 6 weeks after adrenal surgery transsphenoidal resection of the pituitary mass was performed, the histology revealed an adenoma which was diffusely positive for ACTH, it did not stain with any other anterior pituitary hormones. At 3 months post-pituitary surgery, she had normal plasma metanephrines and 24 h UFC levels with no visible residual disease on pituitary MRI.
Discussion
Phaeochromocytoma is associated with excess morbidity and mortality if undiagnosed, it was therefore fortuitous that this diagnosis was made prior to pituitary surgery. Clinicians should be alert to the about rare association of phaeochromocytoma in patients with clinically significant pituitary adenomas, and pursue further work up if clinically indicated.

DOI: 10.1530/endoabs.37.EP1177

EP1178

Cushing's disease from an ectopic parasellar adenoma

Philip C Johnston[1], Laurence Kennedy[1], Amir H Hamrahian[1] & Robert J Weil[2]
[1]Department of Endocrinology, Diabetes and Metabolism, Cleveland Clinic, Cleveland OH, USA, [2]Department of Neurosurgery, Cleveland Clinic, Cleveland, OH, USA.

Background
Most cases of Cushing's disease originate from the pituitary, rarely the source of excess ACTH is from an ectopic pituitary adenoma.
Case
A 34-year-old woman had a 12-month history of a labile mood, weight gain, easy bruising, irregular menses and hypertension, she appeared cushingoid. Biochemical investigations demonstrated hypercortisolism: 24 h urine-free cortisol 520.7 μg (4–50), ACTH 152 pg/ml (8–42); midnight salivary cortisol 510 ng/dl (<100), 0800 h serum cortisol 28.5 mcg/dl (6.5–26) after a 1 mg overnight dexamethasone suppression test (DST). There was a 70% suppression of cortisol after an overnight high dose (8 mg) DST, and a 50% increase in ACTH during a corticotropin releasing hormone (CRH) test. MRI of the sella revealed an atypical enhancing mass (0.7×0.9×0.5 cm) lying above the pituitary gland, the pituitary gland was normal. Transsphenoidal exploration without inferior petrosal sinus sampling (IPSS) was undertaken. A lesion located wholly in the suprasellar intracranial space, with its inferior aspect lying on but not transecting the diaphragm sella, was removed. No tumour was identified within the sella or pituitary. Pathology revealed a pituitary adenoma, with ACTH immunopositivity. At 6 months follow-up she remains in remission, with preservation of anterior pituitary function.
Discussion
Various locations of ectopic pituitary adenomas have been reported, including the sphenoid sinus, nasopharynx, intracavernous sinus. Ectopic pituitary tumours have been proposed to arise mainly from pituitary rest cells from the embryonic remnants of Rathke's pouch, from aberrant migration of pituitary cells or from neoplastic transformation of the pharyngeal pituitary. They can be difficult to diagnose because of their small size and unusual locations.
Conclusion
In patients with Cushing's disease, careful preoperative review of sellar imaging is imperative. These ectopic tumours are not always visible on imaging, and may explain why some patients with Cushing's disease have residual hypercortisolism after hypophysectomy.

Two cases of observation of teenagers after prostatectomy volume transnasal pituitary education followed by recombinant growth hormone therapy Dzhintropinom (Eurofarm)

Mukhlisa Shakirova[1,2], Yulduz Urmanova[1,2] & Shakhlo Babakhodgaeva[1,2]
[1]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan; [2]The Center of Endocrinology, Tashkent, Uzbekistan.

Purpose
To examine two cases of teenagers after transnasal removal of pituitary volume of education followed by recombinant growth hormone therapy Dzhintropinom (Eurofarm).
Materials and methods
During the period of 2014 in the department of paediatric endocrinology and neuroendocrinology RSNPM Endocrinology Center MoH (Tashkent), we examined two male patients, including the patient F., 2.5 g of a craniopharyngioma, and the second patient For 15 years with inactive pituitary adenoma. Patients underwent the following range of studies, including clinical, biochemical blood tests and urine tests, radioimmunoassays hormonal methods of blood tests (prolactin, IGF1, GH, TSH, ACTH, LH, FSH, free testosterone, cortisol, thyroxine), ECG, ultrasound genitals and others. All patients underwent MRI of the pituitary gland. Both patients in 2013 was carried out surgery – transnasal pituitary prostatectomy. In both postoperative patients developed panhypopituitarism: diabetes insipidus, GH deficiency (0.03 nmol/ml at a rate of greater than 2 nmol/l), IGF1 (<35 ng/ml), and hypogonadotropic hypogonadism and short stature patient K. 15 l. In this regard, both patients were assigned to hormone replacement therapy, which included desmopressin, levothyroxine, and genetically engineered growth hormone Dzhintropin (Eurofarm). The latter was assigned based 0.033 ug/kg per day, daily, subcutaneously, in the evening, in the forearm, within 6–8 months.
Results
Based on the investigations, it was found that both patients showed a positive trend during therapy Dzhintropinom, namely significantly increased basal and stimulated (with sample klofellinom) levels of growth hormone. Furthermore, there was a noticeable improvement in the dynamics of growth of the body, namely an average of 6 months to 6 cm.
Conclusions:
patients (children and adults).

The case of a combination of pituitary hypoplasia and achondroplasia have a child (boy 6 years old)

Feruza Khodgaeva, Yulduz Urmanova, Shakhlo Babakhodgaeva & Nazira Rikhsieva
Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan.

Purpose
To describe the case of a combination of pituitary hypoplasia and achondroplasia have a child (boy).
Material and methods
Under our outpatient observation is a boy Abdulahatov S., born in 2008, lives in Samarkand. From history: The child was born in the closely related parents' marriage (sisters' children). Height at birth 50 cm, weight 3000 g, cried and took the breast immediately. Psycho-motor development – late. Constantly under the supervision of a paediatrician, getting a massage. Addressed to the endocrinologist for the first time in 2014. In RSSPMC Endocrinology MoH patients underwent the following range of studies, including clinical, biochemical studies - complete blood count, radioimmunoassay methods hormonal blood tests (prolactin, IGF1, GH, TSH, cortisol, thyroxine), ECG, ultrasound of internal organs, pituitary MRI, X-ray of hand and spine.
Results and discussion
According to parents, the patient complains of stunting, trouble walking. On examination it was found: objective: Growth 103, 5 cm, weight – 29 kg. Growth Deficit – 20 cm, underweight – 9 kg. Pubertal status: Ah0Rh0, testis 3.0×3.0 ml, penis length of 1.0 cm. On the side of hormonal studies: STG – 1.4 mIU/l (normal in children aged 5–16 years 2.1±0.53 mIU/l, St. T_4 – 124 nmol/L (60–160), TSH – 1.9 mIU/l (normal 0.17±4.05), IGF1 – 101 nmol/l. MRI sella (from 01.12.2014 g) was discovered pituitary hypoplasia: height 0.1 cm anteroposterior size – <0.4, width – up to 0.4 cm. On radiographs of the hand (from 02.12.2014 was): bone age from 3 to 24 months, the appearance of a violation of the sequence of points of ossification. Growth areas are open, narrowed, shortening of the phalanges. Cystic fibrosis? Gipohondroplaziya? On radiographs of the spine (from 02.12.2014 city). S-shaped scoliosis of the spine. Dysplasia of both hips, thighs complicated dislocation on both sides. Thus, on the basis of the foregoing, the clinical diagnosis was exhibited: est. Achondroplasia. Sop. Pituitary hypoplasia. OSL. Growth retardation and skeletal development. S-shaped scoliosis of the spine. Dysplasia of both hips, thighs complicated dislocation on both sides. Patient was recommended to hormone replacement therapy: levothyroxine 50, genetically engineered growth hormone, and thyroid medications, calcium, vit D3. The patient was recommended consultation and treatment and also a podiatrist.
Conclusions
Patients with achondroplasia recommended MRI of the pituitary to identify possible hypo – or aplasia pituitary; 2) In the presence of hypopituitarism in patients with achondroplasia need appropriate hormone replacement therapy.

EP1181

Atypical teratoid rhabdoid tumor as a form of presentation of pituitary apoplexy

Maria Belen Ojeda-Schuldt, Laura Larrán-Escandón, Isabel Mateo-Gavira, Francisco Javier Vilchez-López, Inmaculada Gavilán-Villarejo & Manuel Aguilar-Diosdado
Department of Endocrinology, University Hospital Puerta del Mar, Cádiz, Spain.

Introduction
Even though pituitary apoplexy usually occurs in the context of a pituitary adenoma, it can also occur over other tumours, which is less common in adulthood and has faster growth and aggressiveness. It can also produce clinical, analytical and even radiological indications that are indistinguishable from a pituitary adenoma with ischemic and/or haemorrhagic events.
Case report
A 43-year-old female, with no medical history of interest except hypertension, had headaches for a period of 3 months, as well as vomiting, diplopia and left ptosis prior to admission. An image of a sellar pituitary tumour, measuring 20× 23 mm with suprasellar growth (with obliteration of the parasellar tank and cavernous sinus) compressing the optic chiasm was seen by magnetic resonance imaging confirming the presence of invasive pituitary macroadenoma with subacute bleeding. Analytical data showed hyponatremia and hypopituitarism with partial data. A tumour resection by transsphenoidal approach was perfomed, suspecting pituitary apoplexy. The hystopathological finding indicated rhabdoid tumour/teratoid atypical (WHO grade IV). The evolution was satisfactory until the ninth postoperative day when the patient started with a headache, vomiting and impaired level of consciousness. A CT scan was performed and confirmed a large isointense mass of about 7.2 cm in temporal and frontal rights lobes and suprasellar region, collapsing the right lateral ventricle. The patient finally died at 27 days after surgical intervention.
Conclusion
Teratoid/atypical rhabdoid tumor is an aggressive malignant tumour of the central nervous system that usually occurs in children younger than 3 years of age and has a poor prognosis despite chemotherapy and/or radiotherapy.

17 α hydroxylase enzyme deficiency with hyperaldosteronism

Ilkay Kartal, Gonca Incemehmet Tamer & Hasan Hüseyin Mutlu
Medeniyet University, Goztepe Training and Research Hospital, Istanbul, Turkey.

Background
Congenital adrenal hyperplasia (CAH) resulting from 17 α hyroxylase enzyme deficiency (17OHD) is a rare autosomal recessive disorder. More than 150 cases were reported in the literature. Patients with 17OHD were reported to have hypoaldosteronism.
Case
A 16-year-old female referred to endocrinology outpatient clinic from family medicine department with the absence of a secondary sexual characteristics and primary amenorrhea. On physical examination she had no pubic or axillary hair. She has tanner stage I breast development and female external genitalia. Her height was 158 cm, weight 51 kg and blood pressure was 155/90 mm/Hg. Her karyotype was 46XX and bone age was nine years. Initial laboratory tests showed that serum glucose, urea, creatinin, sodium levels were normal; potassium level was low. Serum levels of 17 α hydroxyprogesterone (17-OHP), dehydroepiandosterone sulphate (DHEA-S), androstenodione, cortisol, plasma renin activity (PRA), oestradiol (E2) were low and serum aldosterone, adrenocorticotropic hormone (ACTH), deoxycorticosterone (DOC), luteinizing (LH), follicle stimulating hormone (FSH) was high (Table 1). All aldosterone and PRA values were obtained in upright position. Abdominal MRI showed rudimetary uterus and a nodullary development in the left adnexial area suggestive for ovary. The adrenal gland did not show significant adrenal hyperplasia and there was no mass lesion. Her blood pressure (110/80 mm/Hg) and potassium (3.9 mEg/l) became normal after beginning hydrocortisone tablet 10 mg in the morning, 10 mg at noon and 5 mg in the evening. Subsequently the patient was started on cyclic oestrogen for maturation of secondary sex characteristics. At the following visit we show that breast development was started but her blood pressure was 180/100 mm/Hg. Her potassium level was 3.4 meq/l we raised the total hydrocortisone dose to total 30 mg per day and added 25 mg sprinolactone. Few days later her self monitoring blood pressure results were between 160/100–140/90 mm/Hg. Amlodipin 10 mg was started. Few days later blood pressure became normal. At the last visit her blood pressure was 120/80 mm/Hg serum potassium (3.9 meq/l), aldosterone (194 pg/ml), PRA (0.762 ng/ml/h).

Table 1 Baseline biochemical and hormonal test results

Potassium (meq/l)	2.9	3.5–5.2
PRA upright (ng/ml/saat)	<0.2	0.2–6
Aldosteron upright (pg/ml)	385.45	20–220
ACTH 0800 h (pg/ml)	106	10–46
Cortisol 0800 h (μg/ml)	1.75	6.2–19.4
DHEA-S (μg/ml)	6.33	25–250
DOC (ng/dl)	250	4–12
17-OHP (ng/dl)	4.63	31–217
Total testosteron (ng/dl)	6.33	10–70
LH (mIU/ml)	34	follicular:2.12–10.89 luteal:1.20–12.86
FSH (mIU/ml)	89	follicular:3.85–8.78 luteal:1.79–5.12
E2 (pg/ml)	<20	follicular:27–122 luteal:49–291

Discussion
Patients with 17OHD have been reported to have hypoaldosteronism. We report a different variant of 17OHD with increased aldosteron and decreased renin production. We reviewed the literature and found at least 17 cases of 17OHD with normal aldosterone and 18 cases with elevated aldosterone levels.

The explanation for that is salt retaining due to volume expansion effects of the high concentrations of DOC, with consequent transcriptional down regulation of aldosterone synthase. The mechanism of normal and high aldosterone levels remains unclear. One explanation for this different aldosterone levels can be the cross reaction of the antisera for aldosterone measurement. Beckman Coulter radioimmunoassay kit was used for aldosterone measurement in this case.The antibody used in this kit is highly specific for aldosterone. According to the direction of use of this kit; low reactivities were obtained with several molecules (corticosterone, 18-OH corticosterone, etc). Patients who have been regulary exposed to animals or received immunotherapy or diagnostic procedures utilizing immunoglobulins or immunoglobulin fragments may produce antibodies that interfere with immunoassays; but there was no suspicion of having these antibodies in our patient. At the last visit her self-monitoring blood pressure results, serum potassium, aldosterone and PRA levels were all in normal limits as a result of hydrocortisone, sprinolactone, amlodipin treatment. We terminated cycling oestrogen use for four weeks before these tests because oestrogen, progesterone replacement may also interact with steroidogenesis. We thought that the radioimmunoassay in this study is reliable. Although the cross reaction possibility remains. Cases of 17OHD with hyperaldosteronism could be a variant of 17 OHD and could be genetically determined.

Laryngeal carcinoma in acromegalic patients: a rare case

Gamze Akkus, Mehtap Evran, Murat Sert & Tamer Tetiker
Cukurova University, Adana, Turkey.

Introduction
Acromegaly is a very rare disease with persistent GH secretion due to excessive release of liver IGF1. The risk of malignancy, particularly colon cancer, is increased in acromegalic patients. But no evidence is found in the literature associated increasing of laryngeal carcinoma in acromegalic patients. We aimed to present this case that laryngeal carcinoma should be considered in acromegaly by the clinicians.
Case report
A 51-year-old male patient was diagnosed as acromegaly due to pituitary macroadenoma with the expansion of the suprasellar area localisation in flood. He was operated the right pterional craniotomy at December 2003. Postoperatively he was given the 28×200 cGy doses of radiotherapy linear treatment because of residual mass lesion in screening control MRI. He was medicated somatostatin analogues without cured by radiotherapy. In 2011, he admitted to our clinic with hoarseness and left ventrikuler mass extending was found by direct laryngoscopy. Polypoid soft tissue mass with narrowing the air column of the left vocal cord was detected by simultaneously neck CT. Biopsy revealed squamous cell carcinoma. Total laryngectomy with left lateral neck dissection was performed. Malignancy was not detected in PET CT which made of re-staging. Colonoscopy and endoscopy was performed and two polyps were found. As a result of pathology has been reported hyperplastic changes.
Conclusions
The elevated GH and IGF1 levels lead to a wide range of cardiovascular, respiratory diseases and malignancy also. A strong association between acromegaly and colon cancer and thyroid cancer has been highlighted. We could not find any data which acromegaly and in terms of laryngeal cancer association. However the laryngeal mucosa epitelium has been proven by the observational studies. We presented a case of a acromegaly patient who had a larynx carcinoma. Also clinicians should be aware that managing patients with acromegaly can occur other malignancy.

Psychotropic medication – endocrine consequences

Georgiana Cristina Taujan, Diana Loreta Paun, Mihaela Nistor, Alina Maria Dumitru, Adina Simona Dragomir & Constantin Dumitrache
National Institute Of Endocrinology C.I.Parhon, Bucharest, Romania.

Given the increasing incidence in psychiatric pathology, adverse reactions of psychotropic medications, especially the metabolic and endocrine side effects, are encountered more frequently in clinical practice. We present the cases of two female patients with psychiatric pathology, in whom the specific treatment was accompanied by significant endocrine adverse reactions, making the tumoural differential diagnosis very difficult. The first case is of a patient aged 61 years, known with schizophrenia from the age of 27 years and treated for many years with valproic acid, who presented to our clinic for severe virilising syndrome, with a total serum testosterone of 9.2 ng/ml, rising the suspicion of ovarian or adrenal carcinoma. The second case is of a female patient aged 24 years, diagnosed with depressive disorder, in whom treatment with escitalopram and valproate was accompanied by amenorrhea-galactorrhoea syndrome and severe hyperprolactinaemia of 224 ng/ml (more specific for a macroprolactinoma). The pituitary CT scan revealed a microadenoma of 0.4/0.4 cm, generating important issues regarding differential diagnosis. Although endocrine side effects are often not life threatening and are less frequent than neurological side effects, such as sedation, extrapyramidal syndrome and anticholinergic disorders, recognising and correcting them is the key to successful therapy and ensures compliance of the patient with psychiatric pathology.

EP1185

Acromegaly due to McCune-Albright syndrome

Tatiana Borodich[1], Larisa Dzeranova[1], Ekaterina Pigarova[1], Zhanna Belaya[1], Elena Przhiyalkovskaya[1], Maxim Kutin[2], Alexander Vorontsov[1], Victoria Vladimirova[1], Elena Averkieva[1] & Liudmila Rozhinskaya[1]
[1]Endocrinology Research Centre, Moscow, Russia;
[2]Burdenko Neurosurgical Research Institute, Moscow, Russia.

A 27-year-old male patient during past 10 years noted a gradual change in his appearance, but began to seek a medical attention only 1.5 years ago due to reduced vision. Hormonal tests from March 2013 revealed marked elevation of GH to 106 mIU/ln (ref. values <20), and IGF1 to 567 ng/ml (121–336), decrease in testosterone levels to 1.91 ng/ml (3–12), with cortisol, LH, FSH, PRL, TSH values within the reference range; MRI of the brain showed a 4×7 mm adenoma of the anterior part of the pituitary, CT brain scan with contrast described poliostic dysplasia of the skull bones. From September 2013 octreotide depot injections therapy was initiated 10 mg per 28 days, with further increase to 20 mg per 28 days. In January 2014 levels of GH and IGF1 were still high in spite of medical treatment – 119 mIU/l and 1033 ng/ml respectively. In Apr 2014, at admission to Endocrinology Research Centre at the age of 27 years the patient was 205 cm tall and weighed 124 kg (BMI 29.5 kg/m^2). 'Café au lait' pigmentation of the skin was noted at the chest, back, and abdomen. His facial features were acromegaloid with sloped towered skull. Lab tests confirmed the presence of the active acromegaly (GH – 117 mIU/l, IGF1 – 1412 ng/ml), brain MRI with contrast showed a marked increase in the size of previously described adenoma (17×23×14 mm), and progression of the fibrous dysplasia (predominantly hypointense on T1) of the skull base, parietal, temporal bones, scales of the frontal and occipital bones, hypopneuma-tization of frontal sinus and ethmoidal labyrinth, narrowing of the internal and the external auditory canals on the left. All these symptoms allowed us to suspect a McCune-Albright (MAS) syndrome. The progressive clinical course of the disease, insensitivity to octreoride treatment was the basis for the choice of further surgical treatment despite the pronounced fibrous dysplasia of the skull base. In Oct 2014 at Burdenko Neurosurgical Research Institute the patient underwent endoscopic endonasal removal of tumor using navigation BrainLab. Postoperatively levels of GH and IGF1 decreased to – 27 mIU/l and 856 ng/ml, visual function had markedly improved. He was then followed on depo octreotide injections 30 mg per 28 days and cabergoline 2 mg per week with later dose adjustments.
Conclusions
The treatment of acromegaly in the setting of MAS is characterized by multiple challenges that require the participation of a team of experienced endocrinologists and neurosurgeons.

EP1186

Spontaneous pneumocephalus associated with a giant craniopharyngioma

Vasiliki Daraki[1], Efrosini Papadaki[2], Nikos Zampoulakis[1], Evangelia Mamalaki[1], George Kalikakis[1] & Stathis Papavasiliou[1]
[1]Department of Endocrinology, Diabetes and Metabolic Diseases, University Hospital of Crete., Heraklion, Greece; [2]Department of Radiology, University Hospital of Crete., Heraklion, Greece.

Introduction
Pneumocephalus is defined as the presence of air within the cranial cavity. It is usually associated with neurosurgical procedures but can also be caused by craniofacial trauma, infections and tumours of the skull base and rarely can occur spontaneously. Neoplasms involving the pituitary fossa are unusual causes of spontaneous pneumocephalus.
Case report
A 39-year-old man presented in the emergency department with significant visual loss, headache and rhinorrhoea. He had no previous history of head trauma or medical illnesses. He complained for increasing fatigue, headache and progressive loss of libido for the last 20 years. On physical examination his height was normal but he had low blood pressure and orthostasis. Optical field examination revealed preservation of central vision only. Initial laboratory examinations showed anaemia. All measured pituitary hormones were low except prolactin. The patient was diagnosed with panhypopituitarism. In the emergency department the patient brought with him a skull radiograph lateral view which showed air in the intracranial cavity. He underwent a brain MRI. A midline large space-occupying inhomogeneous mass was seen, extending and filling the suprasellar cistern, pituitary fossa and sphenoid sinus. It was characterised by cystic lesions separated by thin diaphragms and filling by fluid of increased signal intensity on T2 due to increased protein concentration. Haemorrhagic elements were demonstrated inside the solid contents at the left part of the mass. The aforementioned characteristics were indicative of a giant craniopharyngioma. The patient underwent neurosurgical debulking of the tumour and evacuation of the air collection. He was placed in replacement therapy with marked improvement Histological examination confirmed the diagnosis of craniopharyngioma.
Conclusion
Although extremely rare, spontaneous pneumocephalus should be considered as a possible diagnosis in patients with large pituitary lesions, rhinorrhoea and non-specific neurological manifestations. Early treatment of this potentially life-threatening disorder improves surveillance of these patients.

EP1187

Late diagnosis, early response - or the story of a smile

Roxana Novac & Nicoleta Rosu
Emergency Hospital, Moinesti, Romania.

We present the case of a 33-year-old male who addresses an endocrinology service for the first time in May 2014 for marked asthenia, drowsiness, muscular aches, and a delay in growing. The physiological exam showed difficulties in communicating and relation with the others based on his own negative image of himself, lack of self- trust, auto-isolation tendency, state of depression. We raised the suspicion of a panhypopitutarism confirmed by the lab exams that describe a somatotrope, tireotrope, corticotrope and gonadotrope deficit. The patient doesn't associate diabetes insipidus. In this conditions the patient associates a delay of bone age that is of approximately 14 years with a height at -1 S.D. for adult age (height velocity the last 2 years as declared was approximately 15 cm per year) and also a poor bone mass density z-score $= -1.8$. The IRM showed an empty sella. We initiated treatment with prednisolone on which the blood pressure raised till 110/70 mm/Hg, thyroid hormones and testosterone to complete his bone grow after which we will be placing him on growth hormone substitution for adults. After 6 months of treatment his general estate improved: his blood pressure raised, hair and skin improved, started puberty, but what was amazing were the changes in his emotional area, so the repeated physiological exam showed improved self-image, absence of depressive estates, increased capacity of communication, relating availability and most of all … the appearance of a smile.

EP1188

Ipilimumab-induced hypophysitis in cancer patients

Christian Lafuente[1], Karina Arcano[1], Fernando Guerrero[2], A Marengo[2], I Peiró[2], Ainara Soria[1], Juan José Diez[1], Carlos Villabona[2] & Pedro Iglesias[1]

Context
Ipilimumab is a human monoclonal antibody against cytotoxic T lymphocyte antigen-4 (CTLA-4), which enhances stimulation of cytotoxic T lymphocytes, resulting in an immune response against the tumour. This drug-induced hyperactivity of the immune system can lead to serious adverse effects including endocrine disorders such as autoimmune hypophysitis, thyroiditis and adrenal insufficiency.
Objective
To report our experience on ipilimumab-induced hypophysitis (IIH) in patients with advanced cancer.
Results
Four patients (three men (75%); aged 67.5 ± 8.7 years (range, 59–75)) with advanced cancer (three melanomas and one prostate cancer) were recruited. The clinical presentation of IIH was similar in all cases regardless of the underlying tumor. IHH developed after 12–19 weeks of starting treatment, usually between two and four ipilimumab cycles. Main symptoms were fatigue ($n=3$) and headache ($n=2$), nausea ($n=2$) and vomiting ($n=2$). IIH was associated with partial or total hypopituitarism in three cases. Pituitary hormone deficiencies most frequently affected were corticotrophin (ACTH, $n=3$), thyrotropin (TSH, $n=3$) and gonadotropins (FSH and LH, $n=3$). Two patients showed prolactin and growth hormone deficiencies. One patient did not develop any pituitary hormone deficiency although magnetic resonance imaging (MRI) of the pituitary showed morphologic changes of hypophysitis. MRI study showed enlarged pituitary in three patients. All patients were treated with high steroid doses ($>0,5$ mg/kg per day of prednisone or equivalent). After 28 months (range, 22.2–35.4) of follow-up, three patients remained with steroid hormone replacement therapy and two patients with replacement doses of levothyroxine. One patient recovered thyroid function.
Conclusion
IIH is an immune-related adverse event that can compromise the patient's life because of the possibility of development of adrenal and thyroid insufficiency in a high percentage of patients. Glucocorticoids are the treatment of choice. Hormone replacement therapy is indicated according to hormone deficiencies. Patients receiving immunomodulatory therapies should be closely monitored by baseline and follow-up hormone assessment.

A case report of two sibling with untreated congenital adrenal hyperplasia

Basak Karbek[1], Ayten Eraydın[2], Ozcan Ozbag[1] & Mesut Ozkaya[2]
[1]Gaziantep Doktor Ersin Arslan Hospital, Gaziantep, Turkey; [2]Medical Faculty, Gaziantep University, Gaziantep, Turkey.

Introduction
The term congenital adrenal hyperplasia (CAH) encompasses a group of autosomal recessive disorders, each of which involves a deficiency of an enzyme

involved in the synthesis of cortisol, aldosterone, or both. Deficiency of 21-hydroxylase, resulting from mutations or deletions of CYP21A, is the most common form of CAH, accounting for more than 90% of cases.
Case report
Two female siblings were referred to endocrine clinic with the complain of amenorrhea and hirsutism. İn their medical history; The elder sister presented to the paediatrics team at 4 years old with progressive enlargement of the clitoris, acne, muscular built and labioscrotal hyperpigmentation. There was no history of salt-losing crisis or hypoglycaemia. A diagnosis of CAH was made. The younger sister at 2 years old, presented with clitoral enlargement and acne. Similar investigations were performed and the diagnosis of CAH was confirmed. Both sisters were started on hydrocortisone upon diagnosis. Clitoral reduction and vaginal reconstruction surgery was performed for both sisters soon after the diagnosis. Although the seriousness of the illness was explained to their parents, replacement therapy were interrupted by them due to difficult social and economic status of the family, who lived for many years without basic medical care. 15 years later, at the age of 19 and 17; they were seen at the endocrine clinic. On physical examination, they were noted to have a short stature with body height of 1.48 and 1.52 cm. Physical examination revealed extreme virilisation. They were observed marked hirsutism, male type pubic hair, deepening of the voice, cliteromegaly, without breast development and primary amenorrhea. Hormonal analysis showed significantly elevated serum levels of 17-OHP (416, 513 nmol/l) and serum testosterone (30, 49 nmol/l). Mutational analysis of the CYP21A2 gene by multiplex ligation-dependent probe amplification and by polymerase chain reaction (PCR) followed by direct DNA sequencing showed homozygotes I172N mutation.
Discussion
Here we present two sisters with classic simple virilising form of 21-OHD with homozygotes I172N mutation diagnosed infancy who virilised after interruption of the glucocorticoid replacement therapy. If replacement therapy was discontinued, like our cases, there were serious consequences; risk of life, virilisation, change in psycho-social orientation.

Phaeochromocytoma and Cushing syndrome: a rare association

Abdelkefi Cherifa, Haouat Emna, Kandara Hajer, Hbaili Nadia, Ben Salem Hachmi Leila & Ben Slama Claude
National Institute of Nutrition, Tunis, Tunisia.

Introduction
Phaeochromocytoma and Cushing syndrome are two uncommon endocrine conditions. The association of these two conditions is very rare and not well elucidated. We report an association of a phaeochromocytoma with an ACTH-dependant Cushing syndrome.
Case report
A 32-years-old female patient was admitted in the endocrine department for paroxysmal hypertension diagnosed in the immediate post partum period. She reported sweating and palpitation crises occurring with hypertensive peaks. Her blood pressure on treatment (calcic inhibitor and central antihypertensive) was 95/70. Clinical examination didn't reveal any evidence for Cushing syndrome. Laboratory findings showed hypokalaemia at 3.8 meq/l with a hyperkaliuresis. CT-scan revealed a 34×34 mm homogenous right adrenal mass. Urinary metanephrines were very high confirming phaeochromocytoma. Cortisol after low dose dexamethasone suppressing test (LDDST) was 60 nmol/l confirming the diagnosis of Cushing syndrome. ACTH was 39 ng/l and cortisol was suppressed by high dose dexamethasone test. Pituitary MRI was normal. The patient had an endoscopic adrenalectomy. Histology concluded to phaeochromocytoma. After surgery, hypertension and hypokaliaemia disappeared. Urinary metanephrines became normal and cortisol was suppressed by LDDST.
Conclusion
This is a rare case of phaeochromocytoma with a paraneoplasic ACTH secretion causing a subclinical Cushing syndrome.

Coexistence of ovary tumour, congenital adrenal hyperplasia and triple translocation involving chromosome 9,11 and 12: Initial steps of defining new syndrome?

Sami Akbulut[1], Senay Arikan Durmaz[2], Timur Tuncali[3] & Nilgun Sogutcu[4]
[1]Department of Surgery, Diyarbakir Education and Research Hospital, Diyarbakir, Turkey; [2]Department of Endocrinology and Metabolism, Erzurum Region Education and Research Hospital, Erzurum, Turkey; [3]Faculty of Medicine, Department of Genetics, Ankara University, Ankara, Turkey; [4]Department of Pathology, Diyarbakir Education and Research Hospital, Diyarbakir, Turkey.

Introduction and aim
Congenital adrenal hyperplasia (CAH) is rare autosomal recessive disease. CAH due to 21-hydroxylase deficiency accounts for 95% of cases. We aim to define in this report 59-year-old woman with simple virilizing type CAH who diagnosed granulosa cell tumour and I172N mutation in the CYP21A as well as triple translocation involving chromosome 9p, 11p and 12p at first time in the literature.
Case report
A 59-year-old woman was applied to our clinic complained with abdominal pain and distension. She had irregular menstrual cycle per 3–4 month and hypomenorrhoea. She had gone through the menopause at 40 years old. She had never become pregnant. In physical examination her breast tissue had not developed and virilism was determined (modified Ferriman Galvey score >16). A palpable solid mass was detected in the right of abdomen. Ambiguous genitalia, clitoramegaly and hyperpigmentation were found. In computerized tomography giant ovarian mass in mesentery tissue was viewed. The mass (3500 g) was removed with the right tubo-ovarian structures. The granulosa cell tumour was diagnosed by the immunohistochemical examination. The high serum concentration of 17-OH progesteron measured at baseline and after 250-μg bolus of synthetic ACTH. In genetic analysis, we screened for six point mutations, large deletions, and noncommon mutations using restriction fragment length polymorphism (RFLP) methods, PCR, and sequencing of CYP21 gene respectively. The patient was detected to be homozygote for the I172N mutation. In addition, 50% of the metaphases examined had triple translocation (t(9; 11; 12)) between chromosomes 9p, 11p and 12p.
Conclusion
The I172N mutation in the CYP21A accompanied with t(9;11;12) translocation did not define previously in patients with CAH. This mutation may be sign of a new syndrome or a co-insidans that triggered to granulose cell tumour.

Case report: an acromegalic patient presented with dysphagia

Feyzi Gokosmanoglu, Cigdem Tura Bahadir, Elif Kilic Kan & Aysegul Atmaca
Ondokuz Mayis University, Samsun, Turkey.

Introduction
Acromegaly is a chronic disease characterized by prognatism, frontal bossing, coarsened facial features, enlarged hands and feet due to overproduction of growth hormone (GH) generally by a pituitary adenoma. Here, we aimed to present an acromegalic patient presented with retropharyngeal hypertrophy first time in the literature.
Case report
65-year-old female patient had been referred to our department from otorhinolaryngology outpatient-clinic, where she had admitted with sensation of something stuck in throat for 2 years, upon finding overgrowth in uvula and orophayrngeal structures. She had symptoms of sweating, overgrowth in hands, feet, nose and lips. She had type 2 diabetes mellitus and hypertension history. Physical examination revealed coarsened facial features, deepened nasolabial folds, prognatism, tongue and oropharynx hypertrophy. Her blood glucose level was 173 mg/dl, IGF1 level was 929 ng/dl (normal range: 94–166 ng/dl) and GH level was 4.2 ng/dl. The lowest GH level during growth hormone suppression test was 3.8 ng/dl. Levels of other pituitary hormones were normal. Head and neck

magnetic resonance imaging (MRI) revealed expansion of orofacial bones and hyperthropy of the retropharyngeal soft tissue. MRI of pituitary gland revealed a 8×6 mm microadenoma with well defined boundaries in the pituitary gland. The patient was diagnosed with acromegaly and consulted with neurosurgery department regarding surgery.
Discussion
Acromegaly is a condition that should be considered in cases of soft tissue hyperthrophy in oral cavity, teeth occlusions, diastema and teeth prosthesis discrepancies.

A rare case of adrenal histoplasmosis presenting as adrenal insufficiency and hypogonadism following a visit to bat caves

Gideon Mlawa[1], Mahesh Deore[2] & Saiji Nageshwaran[1]
[1]St Georges Hospital, London, UK; [2]Darrent Valley Hospital, Dartford, UK; [3]St Georges Hospital, London, UK.

Background
Histoplasmosis is an opportunistic fungal infection that commonly affects immunocompromised individuals. Histoplasmosis may be asymptomatic or may present with progressive systemic manifestations (pulmonary or disseminated). We present a case of a 76 year old immunocompetent man presented to hospital with 8 weeks history of general malaise and lethargy, intermittent night sweats, a productive cough, weight loss of 2.5 stones in two months and low grade fever. He had completed two courses of antibiotics with no resolution of his symptoms. He reported no history of tuberculosis contacts. Significant history was of travel to Malaysia and a visit to bat caves 2 years prior to the onset of symptoms. On admission, he was haemodynamically stable and his initial blood tests were normal apart from raised CRP of 80 mg/l. Chest XRay was normal.CT of sinuses showed minimal mucosal thickening. CT chest, abdomen and pelvis revealed large bilateral adrenal heterogeneous masses measuring 6.1×4.5×3.7 cm on the right, and 6.4×6.2×4.3 cm on the left. Adrenal biopsy showed fungal spores on microscopy. He was started on antifungal therapy for likely adrenal histoplasmosis and discharged home. He was readmitted 2 months later with a GCS of 6/15, Temperature 38 °C, and hypotensive episodes. He had normal CT and MRI brain results, negative blood cultures and unremarkable CSF studies. Echocardiogram excluded the vegetations. He was treated with intravenous empirical antibiotics and hydrocortisone. He was continued on his antifungal therapy. Initial short synacthen test showed normal response, however he became more tired and hyperpigmented with a subsequent short synacthen test showing a suboptimal response $T0 = 333$ nmol/l, $T30 = 378$ nmol/l. He also developed primary hypogonadism subsequently, thought to be due to effect of antifungals or due to histoplasmosis itself.
Conclusion
Adrenal histoplasmosis is rare, especially in immunocompetent individuals and should be considered as a differential diagnosis in any patient presenting with bilateral adrenal masses, constitutional symptoms and suggestive history. Also one should be vigilant about possible side effects of antifungals e.g. hypogonadism in this case.

Differential diagnosis of low renin hypertension – pseudohypoaldosteronism type 2

Ieva Kalere[1,2], Ieva Tonne[1,2], Aivars Lejnieks[1,2] & Ilze Konrade[1,2]
[1]Riga East University Hospital, Riga, Latvia; [2]Riga Stradins University, Riga, Latvia.

Introduction
Pseudohypoaldosteronism type 2 (PHA2), also known as Gordon syndrome is a rare inherited form of low-renin hypertension associated with hyperkalaemia and hyperchloremic metabolic acidosis in patients with a normal glomerular filtration rate (GFR). PHA2 is the result of mutations in a family of serine-threonine kinases called with-no-lysine kinases (WNK) 1 and WNK4. These enzymes regulate electron channels in the aldosterone sensitive distal nephron, resulting in disrupted electron balance. PHA2 is a genetically and phenotypically heterogeneous entity, associated with high sensitivity to thiazides.
Case report
A 57 year old patient with anamnesis of treatment-naïve hypertension and *foramen ovale apertum* enclosed with occluder was admitted to the hospital for surgery due to adrenal mass – a typical adenoma found on abdominal CT 5 years ago with the diameter of 1.7 cm. Laboratory test results excluded Cushing syndrome, but primary hyperaldosteronism was not suspected due to persisting hyperkalaemia. Abdominal CT scan was repeated to evaluate the growth dynamics of the adrenal mass, revealing an enlarged left adrenal gland with a hypodense (9 HU) vascular mass 4.1 cm in diameter. Pre-operative testing revealed several laboratory abnormalities: hyperkalaemia 5.6 mmol/l (3.5–5.1) and hyperchloraemia 106 mmol/l (95–105), low plasma renin <0.5 μU/ml (4.4–46.1), normal aldosterone 95.8 pg/ml (25.2–392.0), normal GFR 100.5 ml/min, acidic urine pH 4.8 and decreased potassium excretion 23 mmol per day (25–125). Considering the findings of low renin hypertension with hyperkalaemia and normal GFR the diagnosis of PHA2 was established. The patient was started on antihypertensive treatment with thiazide diuretic and underwent left adrenalectomy. Histology conformed to hormonally inactive adrenocortical adenoma, Weiss score 2.
Conclusions
The current case demonstrates the challenges of differential diagnosis of low renin hypertension depicting the characteristic findings of PHA2. It should be noted that upon correct diagnosis this form of low renin hypertension is easily treatable with thiazide diuretics.

EP1196

The hidden liquorice: apparent mineralocorticoid excess caused by inadvertent exposure to liquorice root extract

Ailsa Maria Main & Ulla Feldt-Rasmussen
Faculty of Health Sciences, University of Endocrinology, Rigshospitalet, and University of Copenhagen, Copenhagen, Denmark.

Introduction
Excessive consumption of liquorice can cause endocrine symptoms of apparent mineralocorticoid excess (AME). This is usually caused by excessive consumption of liquorice-containing sweets and native liquorice root but the different chemical compounds in liquorice may also be used in many other products where it is considered an additive and therefore not explicitly declared.
Case
We here report a 21-year-old patient who exhibited severe symptoms of AME (oedema, spells of dizziness, headaches and peripheral paraesthesia as well as general and muscular fatigue) due to inadvertent excessive intake of liquorice. Blood samples showed low serum potassium (2.3–3.1 mmol/l, ref (3.5–4.6)) requiring potassium supplementation (40 mmol×2 daily) and high normal sodium (142–147 mmol/l, ref (137–145)). Measurement of 24 h urinary steroid metabolite excretion raised the suspicion of AME. Additional blood tests showed undetectable serum concentrations of aldosterone (<38 pmol/l, ref (50–360)) and renin ($<2*10^{-3}$ IU/l, ref (6–60)). Pituitary function (thyroid hormones, prolactin, IGF1, IGFBP3) was normal. No obvious endocrine cause of AME could be established and the patient re-evaluated all personal dietary products. Liquorice root was present in several herbal teas and sugar-free chewing gum that had been consumed daily in large amounts. Cessation of usage of these products resulted in complete recovery of AME-related symptoms.
Conclusions
Our case report revealed other potential sources of liquorice than sweets including industrial sweeteners and flavouring agents that could potentially cause clinical symptoms. Clinicians should thus extend their medical history to a broader range of consumer products when suspecting AME.

From erectile dysfunction to brain subependymoma: a case report

Tatjana Bacun[1,2], Aleksandar Kibel[1,3], Dunja Degmecic[4,5], Karin Zibar[6,7] & Roman Pavic[8,9]
[1]University Hospital Centre Osijek, Internal Medicine Clinic, Osijek, Croatia; [2]Faculty of Medicine, Department of Internal Medicine, University of Osijek, Osijek, Croatia; [3]Faculty of Medicine, Department of Physiology and Immunology, University of Osijek, Osijek, Croatia; [4]University Hospital Centre Osijek, Clinic of Psychiatry, Osijek, Croatia; [5]Faculty of Medicine, Department of Psychiatry, University of Osijek, Osijek, Croatia; [6]University Clinic Vuk Vrhovac, Zagreb, Croatia, [7]University Hospital Merkur, Zagreb, Croatia; [8]University Hospital of Traumatology, Zagreb, Croatia; [9]Faculty of Medicine, Department of Surgery, University of Osijek, Osijek, Croatia.

Introduction
Endocrinopathies are rare causes of erectile dysfunction and previously cases of hyperprolactinaemia and pituitary adenomas have been reported.
Case report
We present the clinical case of a 27-year old male, married for 4 years with no children, presented with possible infertility and erectile dysfunction which was previously interpreted as caused by a poor social and psychological situation in the family. After additional endocrinological (mildly elevated prolactin levels and reduced levels of testosterone) and radiological (skull X-ray, CT scan and MRI) an underlying subependymoma was discovered. The subependymoma was expanding in the sellar and suprasellar regions and pressing against the pituitary gland. The patient experienced occasional periorbital and temporal headaches, loss of appetite, general weakness. A Goldman perimeter test was consistent with bitemporal hemianopia. The resulting endocrine disorder caused the problems which were subjectively at first mainly manifested as erectile dysfunction. The patient underwent a left-sided supraorbital craniotomy and complete surgical removal of the tumor at the Department of Neurosurgery. The histopathology findings described a subependymoma (G II). One year after surgery, the patient was in good general condition, but with bitemporal hemianopia, with atrophy of the right optic nerve and complete loss of vision in his right eye, panhypopituitarism and impotence. Two years later, with hormone replacement therapy (desmopressin, hydrocortisone, levothyroxine, testosterone undecanoate) there was no sexual dysfunction.
Conclusions
The case is an educative example about the necessity to keep possible intracranial lesions in mind when starting the workup of a patient presenting with erectile dysfunction. It may be of broad clinical interest not only for endocrinologists, but for practitioners in various fields.

EP1198

Intestinal obstruction and bowel perforation as a presenting feature of a phaeochromocytoma

Izaskun Olaizola[1], Estela Elias[2], Ana Maria Chacon[1], Ismene Bilbao[1], Nerea Egaña[1], Cristina Garcia[1], Maite Aranburu[1], Tomas Matteucci[2], Alfredo Yoldi[1] & Miguel Goena[1]
[1]Hospital Universitario Donostia, Donostia San Sebastián, Gipuzkoa, Spain; [2]Hospital Bidasoa, Irún, Gipuzkoa, Spain.

Introduction
Phaeocromocytomas are a rare catecholamine secreting tumours that can present in multiple ways. The classic triad of symptoms consists of episodic headache, sweating, and tachycardia. Most patients do not have the three classic symptoms. Sustained or paroxysmal hypertension is the most common sign. Among less common symptoms and signs constipation has been described and few cases of megacolon and phaeochromocytoma have been published.
Case report
A 39 year-old man, with previous medical history of schizophrenia, autism and pulmonary tuberculosis with a partial left lobectomy, complained of abdominal pain of 3 days. An abdominal X-ray demonstrated dilated loops of small and large bowel with air-fluid levels in the upright position, abundant faecal remainders in the large bowel and faecaloma. Large bowel obstruction was suspected presenting an unfavorable evolution despite medical treatment. CT scan showed small and large bowel obstruction secondary to an intestinal malrotation with signs of sigmoid colon and rectum suffering and a left adrenal incidentaloma of 6 cm. An urgent surgical intervention was performed showing small bowel obstruction secondary to internal hernia secondary to dolichomegasigma and large bowel perforation with loculated abscess, performing sigmoidectomy, terminal colostomy and abscess exeresis. The postoperative evolution was good. The functionality of the adrenal incidentaloma was studied showing urinary metanephrines consistent with phaeochromocytoma. Treatment with phenoxybenzamine was started and left adrenalectomy was performed confirming the diagnosis of phaeochromocytoma. 1 year after the surgery he has not presented new episodes of bowel obstruction.
Conclusions
Intestinal obstruction is an important clinical condition that can present in association of phaeochromocytoma. Due to the risk of intervention in a patient previously not treated with alpha-blockade, if an adrenal incidentaloma is observed in a patient with intestinal obstruction, phaeochromocytoma should be ruled out in order to prevent. surgery complications.

EP1199

Spontaneous resolution of bilateral avascular necrosis of the femoral head following cure of Cushing's syndrome secondary to primary pigmented micronodular adrenal disease

Agnieszka Pazderska[1], Stephen Crowther[2], Pradeep Govender[3], Kevin C Conlon[4,6], James Gibney[1] & Mark Sherlock[1,5]
[1]Department of Endocrinology, Adelaide and Meath Hospitals, incorporating the National Children's Hospital, Tallaght, Dublin 24, Ireland; [2]Department of Pathology, Adelaide and Meath Hospitals, incorporating the National Children's Hospital, Tallaght, Dublin 24, Ireland; [3]Department of Radiology, Adelaide and Meath Hospitals, incorporating the National Children's Hospital, Tallaght, Dublin 24, Ireland; [4]Professorial Surgical Unit, Adelaide and Meath Hospitals, incorporating the National Children's Hospital, Tallaght, Dublin 24, Ireland; [5]Department of Endocrinology, Trinity College Dublin, Dublin, Ireland; [6]Department of Surgery, Trinity College Dublin, Dublin, Ireland.

Avascular necrosis is a rare presenting feature of endogenous hypercortisolism. The literature suggests that, if left untreated, complete collapse of the femoral head may ensue, necessitating hip replacement in up to 70% of patients. The majority of described patients with avascular necrosis due to endogenous hypercortisolaemia were treated surgically.
Case report
A 36-year-old female, investigated for right leg pain, reported rapid weight gain, easy bruising and secondary amenorrhea. She had abdominal adiposity with violaceous striae, facial plethora and hirsutism, atrophic skin, ecchymosis and proximal muscle weakness. Spinal imaging showed L4/L5 disc herniation, fractures of L1 and multiple ribs. Investigations confirmed cortisol excess (cortisol post low dose 48-h dexamethasone suppression test 807 nmol/l; 24-h urinary free cortisol 1443 nmol (normal $<$290 nmol)). ACTH was $<$5.0 pg/ml. CT demonstrated subtle left adrenal gland hypertrophy. Post left adrenalectomy hypercortisolaemia persisted. Histology revealed primary pigmented micronodular adrenal disease. Post-operatively right leg pain worsened and left leg pain developed, affecting mobility. MRI showed bilateral femoral head avascular necrosis, which was not surgically treated at this point. She underwent right adrenalectomy and commenced steroid replacement. Within 4 months of surgery her leg pain resolved and she could ambulate freely. Repeat MRI showed marked improvement in high signal intensity in both femoral heads, consistent with spontaneous healing of avascular necrosis.
Conclusion
We report a case of a 36-year-old woman with Cushing's syndrome due to primary pigmented nodular adrenocortical disease, presenting with symptomatic avascular necrosis of both hips. This was managed conservatively from an orthopaedic perspective. Following cure of hypercortisolaemia, the patient experienced an excellent functional and radiological recovery. She remains symptom-free 4 years post adrenalectomy. This case is the first to report a favourable outcome over long-term follow up of a patient with bilateral avascular necrosis of the hip which reversed with treatment of endogenous hypercortisolaemia.

EP1200

New onset Graves' disease as a cause of an adrenal crisis in an unrecognised empty sella

Hela Marmouch[1,2], Tasnim Slim[1], Fadia Boubaker[1], Sondes Arfa[1], Hanene Sayadi[1,2], Manel Jmal[1,2] & Ines Khochtali[1,2]
[1]Department of Internal Medecine-Endocrinology, MONASTIR, Tunisia; [2]Faculty of Medecine, MONASTIR, Tunisia.

Introduction
A 66-year-old woman was admitted as an emergency with vomiting, hypotension and serum cortisol of 0.92 microg/dl indicative of adrenal failure. She was found to be hyperthyroid (fT_4 = 72 pmol/l).
Case report
She had hypotension (blood pressure 80/40 mm/Hg) She was fit and well till the age of 65. Endocrine assessment revealed deficiency in ACTH-cortisol, growth hormone, and gonadotropin, as well as low-normal fT_4. On the day of his emergency admission he looked ill and dehydrated, though was fully conscious and cooperative. Heart rate was 110 beats/min (sinus rhythm), blood pressure 85/60 mm/Hg. There were no obvious features of infection, but there was marked tremor and thyroid bruit. She received treatment with intravenous fluids and hydrocortisone. Administration of large dose of methimazole (40 mg per day)

resulted in gradual decrease in fT_4. Pituitary MRI showed empty sella. The patient was found to have increased titre of antithyroperoxidase (anti-TPO) and anti-TSH receptor (anti-TSHR) antibodies (2100 IU/l (ref. range <40) and 3.7 IU/l (ref. range <1.0), respectively). She was referred for radioactive iodine treatment. Iodine uptake scan performed prior to radioiodine administration confirmed uniformly increased iodine uptake consistent with Graves' disease.
Discussion
We encountered a patient with unrecognised adrenocortical disease due to empty sella, in whom development of Graves' hyperthyroidism caused an adrenal crisis. Empty sella syndrome in this case can be related to autoimmune hypophysitis.
Conclusion
Our case illustrates coexistence of hypopituitarism and clinically significant autoimmune thyroid disease. The presence of hypopituitarism does not preclude the development of autoimmune thyrotoxicosis.

DOI: 10.1530/endoabs.37.EP1200

EP1201

Klinefelter syndrome with portal vein aneurysm: case report

Isilay Kalan Sari[1], Ramazan Cosar[2], Sevda Yilmaz[3] & Hüseyin Demirci[4]
[1]Department of Endocrinology and Metabolic Diseases, Burdur State Hospital, Burdur, Turkey; [2]Faculty of Medicine, Department of Internal Medicine, Kirikkale University, Kirikkale, Turkey; [3]Faculty of Medicine, Department of Radiology, Kirikkale University, Kirikkale, Turkey; [4]Faculty of Medicine, Department of Endocrinology and Metabolic Diseases, Turgut Özal University, Ankara, Turkey.

Introduction
Klinefelter syndrome (KS) is the most common chromosomal disorder characterized by clinical features of hypogonadism and infertility. Portal vein aneurysms are very rare clinic findings. Reported cases are increasing due to use of modern imaging techniques in clinic practise.
Case report
19-year-old man was admitted to our hospital with complaints of abdominal pain, nausea, and vomiting associated with eating. He was recently diagnosed with KS by chromosomal analysis, which was performed because of eunucoid appearance and gynecomastia. On physical examination, lungs were clear and heart beats were regular. No abdominal tenderness was found and no enlarged liver or spleen was palpated. Laboratory studies revealed: white blood cell counts, 6.600 mm^3; haemoglobin, 14.6 g/dl; AST, 18 U/l, ALT, 9 U/l; GGT 20 U/l; ALP 111 U/L; amylase 40 U/l; total bilirubin 1.47 mg/dl; FSH 52.62 mIU/ml; LH 23.11 mIU/ml; total testosterone 3.28 ng/ml; oestradiol 21.59 pg/ml. An abdominal ultrasound scan showed 23 mm anechoic, saccular expansion in the left branch of portal vein. There were no features of thrombosis, portal hypertension, chronic liver disease, pancreatic mass or pancreatitis. No aneurysmal change was noted in arterial tree and there were no pathological findings in other intraabdominal organs. Monophasic, turbulent venous flow was detected in aneurysmal dilatation by Doppler ultrasonography. Esophagogastroduodenoscopy was performed and revealed pangastritis. Abdominal pain was attributed to gastritis.
Conclusion
Portal vein aneurysms are rare presences and are usually asymptomatic. Portal vein thrombosis is a severe complication of PVA and can result in intestinal ischemia or intestinal infarction. Early diagnosis and initiation of therapy is important. It is well known that KS is associated with an increased risk of venous thrombosis include portal vein thrombosis. So, it is important to follow up the patient for the risk of portal vein thrombosis. For asymptomatic patients regular clinic follow-up will be sufficient.

DOI: 10.1530/endoabs.37.EP1201

EP1202

Exaggerated cortisol response in heterozygous carriers with a mutation in the melanocortin-2 receptor (MC2R) gene

Ma Pyeh Kyithar[1], Andrew Green[2], Claire Hughes[3], Nuala Murphy[4] & Maria Byrne[1]
[1]Endocrinology Department, Mater Misericordiae University Hospital, Dublin, Ireland; [2]National Centre for Medical Genetics, Our Lady's Hospital, Crumlin, Dublin, Ireland; [3]Barts and the London School of Medicine, London, UK; [4]Children's University Hospital, Dublin, Ireland.

Introduction
Familial glucocorticoid deficiency (FGD) is a rare autosomal recessive disease characterised by ACTH resistance and isolated glucocorticoid deficiency. Mutations of ACTH receptor, known as melanocortin-2 receptor (MC2R), and melanocortin-2 receptor accessory protein (MRAP) account for approximately 25 and 15 to 20% of cases respectively. To date there is no strong evidence that heterozygous carriers have abnormal cortisol secretion.
Case
We studied a pedigree with a MC2R mutation where the index case presented with severe hypoglycaemia at three years of age in 1970s and was subsequently diagnosed with adrenal insufficiency. Of eight siblings, two brothers died as neonates, with hindsight due to adrenal insufficiency and a third brother was diagnosed with adrenal insufficiency when he presented comatose at two months and remained profoundly handicapped and later died. The index case was found to have a homozygous missense mutation c.221G$>$T, leading to p.S74I (substitution of serine with isoleucine at position 74) in the MC2R gene. We studied three of her siblings with the heterozygous S74I mutation in the MC2R gene. The mean age of heterozygous carriers was 31.3 ± 2.5 years. They had generalised slightly tanned skin, but no significant hyperpigmentation. They were normotensive and had no symptoms suggestive of glucocorticoid deficiency. Short synacthen testing with 250 µg tetracosactide in heterozygous carriers showed baseline ACTH levels of 53.7 ± 31.9 ng/l (normal range <46 ng/l), 0 min cortisol levels of 506 ± 168 nmol/l, 30 min cortisol levels of 952 ± 85 nmol/l, and 60 min cortisol levels of 953 ± 36 nmol/l.
Conclusion
The study of heterozygous MC2R mutation carriers demonstrated slightly elevated baseline ACTH levels with a relatively high baseline cortisol level and an exaggerated cortisol response to synacthen test. These findings suggest there is no evidence of glucocorticoid deficiency despite elevated ACTH levels in heterozygous carriers with MC2R mutations.

EP1203

Pituitary enlargement in pregnancy presenting with visual field defects and interesting imaging

Hsiu Lye Yap, Maura Moriarty, Edouard Mills, Ana Pokrajac & Thomas Galliford
West Hertfordshire Hospitals NHS Trust, West Hertfordshire, UK.

We report a rare case of a patient presenting with headaches and almost complete bilateral hemianopia during her third trimester of pregnancy. This lady presented with headaches and vomiting 2 years prior, with a pituitary MRI initially reporting an acute pituitary haemorrhage. This time, due to progression of her visual field defects, it was decided in a multidisciplinary meeting to perform a Caesarean section at 37 weeks and start Cabergoline post-operatively, as the patient did not plan to breast-feed. She had a raised prolactin in keeping with pregnancy, but the rest of her pituitary profile was normal. Upon reviewing her initial pituitary MRI and subsequent imaging at a later date, it was noted that the patient had a bulky pituitary gland, but the signal characteristics on MRI remained unchanged, which brought the original diagnosis of pituitary haemorrhage into question. It was therefore felt that this was either a proteinaceous developmental cyst or persisting blood products on serial imaging. This pituitary abnormality in combination with physiological pituitary gland enlargement in pregnancy is likely to have caused chiasmal compromise and visual field defects in this patient. Since her delivery, she has had repeat MRI imaging, which showed regression in the size of her pituitary gland with no compression of the optic chiasm. She was gradually weaned off the cabergoline. There is no evidence of any endocrine dysfunction. However, the patient still reports some persisting visual defects, which are unaccounted for in view of her most recent pituitary imaging. She has been referred on for neuro-ophthalmic assessment. This case also demonstrates the importance of multi-specialty management in a complex patient to achieve a satisfactory outcome. The patient has been strongly advised to avoid future pregnancies, as it is likely that she will get chiasmal compression once again.

EP1204

Familial SDHC mutation associated with prolactin/gh-secreting pituitary adenoma and paraganglioma

Mohammed Barigou[1], Alexandre Buffet[1,2], Antoine Bennet[1], Pascal Pigny[3], Laurent Bellec[4], Philippe Caron & Delphine Vezzosi[1]
[1]Department of Endocrinology, Metabolic Diseases and Nutrition, CHU Larrey, Toulouse, France; [2]INSERM UMR 970, Centre de recherche Cardiovasculaire à l'HEGP, Paris, France; [3]Centre de Biologie-Pathologie du CHRU de Lille, Lille, France; [4]Urology Department, CHU Rangueil-Toulouse, Toulouse, France.

Introduction
SDH genes mutations are associated with hereditary phaeochromocytoma and paraganglioma syndromes. We describe the case of a patient with SDHC related familial paraganglioma and pituitary adenoma.
Case
A 65-year old man consulted for an incidentally discovered 7 cm abdominal mass on CT-scan, lateral to the right kidney, invading inferior vena cava, associated to a retroperitoneal adenomegaly and a lesion on the body of L2 vertebra with spinal MRI aspect of metastasis. All these lesions showed hypermetabolism on 18F-FDG PET. Continuous blood pressure monitoring, plasma catecholamines and their methoxylated metabolites were normal. Chromogranine A was four times normal (Normal range <100 µg/l). Total right adrenalectomy, lumbo-aortic lymphadenectomy and nephrectomy were performed. Vertebral metastasis was treated by radiofrequency. Histopathology of the primary tumor confirmed the diagnosis of paraganglioma with 2% mitotic index. During follow-up, erectile dysfunction developed. Endocrine evaluation revealed partial hypogonadotropic hypogonadism (testosterone 214 ng/dl Normal: (280–820), LH 2.2 mUI/ml, FSH 2.5 mUI/ml) with hyperprolactinaemia (470 ng/ml, normal value <19 ng/ml) and elevated IGF1 level (214 ng/ml, normal: 41–196 ng/ml). OGTT confirmed GH hypersecretion. MRI showed a T_2 hyperintense pituitary adenoma of $15\times$ 17 mm with left cavernous sinus extension without optic compression. We retained the diagnosis of PRL/GH-secreting pituitary adenoma and started dopamine agonist plus somatostatin analogue treatment. Genetic analysis revealed an new mutation on SDHC gene on exon 4 c239-242dupGTGC. The same mutation was found in his siblings (son, daughter and the grandson). His son had a non-secreting pituitary microadenoma, without pituitary abnormalities in the daughter. Work-up for paraganglioma was negative in siblings.
Conclusion
This case suggests that SDHC gene mutations could be related to pituitary adenomas occurrence in association with paraganglioma syndromes, but more studies should be conducted to define the pathogenic pathways of this relationship.

Bilaterally slipped capital femoral epiphysis in growth hormone–deficient patient: osteosynthesis also needs the oestrogen epiphyseal fusion- case report

Dragan Tesic[1], Milena Mitrovic[1], Jovan Vlaski[2], Svetozar Damjanovic[3] & Vera Popovic[3]
[1]Clinic for Endocrinology, Diabetes and Metabolic Disturbances, Novi Sad, Serbia; [2]Department of Pediatrics, Novi Sad, Serbia; [3]Institute for Endocrinology, Belgrade, Serbia.

Introduction
Growth without growth hormone is seen also in patient with craniopharyngioma. We just speculate what anabolic factors might be involved in this process. However, oestrogen through its receptors lead to epiphyseal fusion. In this case report we would like to present the patient with bilateral slipped femoral epiphysis (SFE) and interventions made at tertiary health care level.
Case report
20-years-old female, operated from craniopharyngioma when was 10 year, bogy height 167 cm, body weight 71.8 kg, not regularly on levothyroxine 50 gr, in December 2013 presented as pain in right hip, on X-ray SFE, and osteosynthesis was performed. In July 2013 similar clinical picture but on left side. Patient was sended at tertiary level. After multislice CT scanning same surgical procedure performed on left femur with three screws. Then patient was moved on endocrinology department. Clinically, according to sex characteristics, patient was Tanner I stage, without measurable values of growth hormone, insulin like growth factor I, gonadotropins and estrogens, insulinaemia 17.3 mU/l, blood glucose 4.5 mmol/l. On X-ray of the left hand skeletal age was 12 year. Estrogen therapy started with 0. mg etinil estradiol and after 5 months increased on 2 mg estradiol, 21 and 7 days pause. Skeletal age at 5 m, 10 m and 13 were 13 years 6 months, 14 year, 15–16 year respectively. Increased markers of bone resorption (cross laps) returned back into normal range. DEXA scan of lumbar spine was improved from – 3.2 T-score onto – 2.8 in just 6 month period. Body height was changed from 167.5 cm to on 171 cm and body weight from 67.5–80 kg.
Conclusions
After the operation of craniopharyngioma and growth without growth hormone we have to follow skeletal growth and on time introduce sex hormones. Later, in young adults we have to consider a small dosages of growth hormone to improve their body composition.

Effectiveness of octoreotide administration before surgery for GH-TSH co-secreting pituitary adenoma with thyrotoxicosis: a case report

Shihori Kimura[1], Osamu Isozaki[1], Izumi Fukuda[1], Satoshi Morimoto[1], Yasufumi Seki[1], Kaoru Yamashita[1], Noriyoshi Takano[1], Akiko Otsuki[1], Terumi Kaneshige[1], Kanako Bokuda[1], Daisuke Watanabe[1], Takashi Ando[1], Naomi Hizuka[1], Kosaku Amano[2], Takashi Komori[3], Yoshikazu Okada[2] & Atsuhiro Ichihara[1]
[1]Department of Medicine II, Tokyo Women's Medical University, Tokyo, Japan; [2]Department of Neurosurgery, Tokyo Women's Medical University, Tokyo, Japan; [3]Department of Pathology I, Tokyo Women's Medical University, Tokyo, Japan.

Introduction
TSH-secreting pituitary adenoma (TSHoma) sometimes brings on rare cause of hyperthyroidism because of its excessive TSH secretion. Though the first line of treatment for TSHoma is surgical removal of tumour, hyperthyroidism often causes perioperative thyroid storm. Here, we report a case of GH-TSH pituitary adenoma whose thyrotoxicosis was controlled by 5 days' octoreotide (OCT) subcutaneous administration before surgery.
Case report
A 47-year-old woman with hyperhidrosis and palpitation for these 7 years was admitted to our hospital. She also presented acromegalic change, such as the increase in size of finger rings and shoes. In endocrinological examination, serum levels of TSH, fT_4 and fT_3 were 1.500 µU/ml, 3.73 ng/dl and 8.06 pg/ml, and l GH and IGF1 were 10.31 ng/ml and 861 ng/ml. 75gOGTT did not suppress GH (nadir GH: 10.26 ng/ml). MRI demonstrated a pituitary adenoma of $18\times12\times$ 9 mm. GH-TSH co-secreting pituitary adenoma was suspected, and in order to prevent from perioperative thyroid storm, we scheduled OCT administration. Single OCT administration (50 µg) decreased serum TSH levels from 1.740 to 0.515 µU/ml and GH levels from 11.42 to 0.68 ng/dl respectively. Then, OCT (100 µg/day) was injected additionally for 5 days and serum fT_4, fT_3 and IGF1 levels decreased to 1.53 ng/dl, 2.65 pg/ml, and 350 ng/ml respectively before operation. Pituitary adenoma was completely and uneventfully removed *via* trans-sphenoidal-surgery and her all hormone levels were normalized without any medication.
Conclusion
A case of GH TSH co-secreting pituitary adenoma with thyrotoxicosis was reported. To prevent from perioperative thyroid storm, OCT administration should be recommended.

Cushing's syndrome secondary to aberrant hormone receptors in a patient with macronodular adrenal hyperplasia ACTH-independent

María Molina Vega, Jose Antonio Lopez Medina, Araceli Muñoz Garach, Isabel Cornejo Pareja, Cristina Díaz Perdigones, Ana Gómez Pérez & Francisco Tinahones Madueño
Hospital Universitario Virgen de la Victoria, Malaga, Spain.

Introduction
Cushing's syndrome (CS) due to macronodular adrenal hyperplasia ACTH-independent (MAHAI) is rare. Regulation of cortisol secretion by G-protein-coupled receptors (GPCRs) aberrantly expressed is frequently found in MAHAI. Various aberrant receptors have been reported, mostly: GIP, vasopressin, beta-adrenergic, LH/hCG and serotonin.
Case report
61 years old woman. Medical history: type 2 diabetes, hypertension, obesity, dyslipidaemia and severe sleep apnoea. Treatment: metformin, insulin, lyxisenatide, *irbesartan-hydrochlorothiazide, torasemide, diltiazem, acetyl salicylic acid and atorvastatin.* Physical examination: moon face, centripetal obesity, abdominal striaes and thin extremities. Laboratory evaluation: HbA_{1c} 8.4%, TSH 2.06 μIU/ml, serum cortisol: at 0800 h:17.2 μg/dl (5–25), overnight dexamethasone suppression (1 mg): 5.3 μg/dl, after 0.5 mg dexamethasone every 6 h for 48 h suppression: 5.03 μg/dl, after nocturnal 8 mg dexamethasone suppression: 5.7 μg/dl. Urinary free cortisol repeatedly normal (49.4 and 24 μg per day), salivary cortisol repeatedly raised (0.382 and 0.292 ng/ml). ACTH 2.83, others adrenal hormonal profile normal. With these findings, the suspected diagnosis was Cushing's syndrome. CT: adrenal glands enlarged with homogeneous hypodense nodules (3.3×2.6 cm right; 3.2×1.9 cm left). Because of the known association between MAHAI and aberrant GPCRs some tests were performed: posture test, standard mixed meal, LHRH (100 mg i.v.), metroclopramide (10 mg orally), glucagon (1 mg i.v.) and AVP (10 IU i.m.). Positive response (50% increase in plasma cortisol levels) in the standard mixed test and metroclopramide test (indicating serotonin and GIP aberrant receptors). Right adrenalectomy is planned.
Conclusion
In patients with MAHAI aberrant GPCRs can be identified. The detection of such aberrant receptors is necessary in all patients with MAHAI. Identification of these receptors can provide specific pharmacological treatment with or without adrenalectomy.

Complicated investigation of adrenal incidentaloma in a critically ill patient – a case study

Simona Kratochvílová[1], Petr Wohl[1], Lenka Hošková[2], Jirí Kettner[2], Jana Vrbská[2], Michal Kudla[3] & Jana Brunová[1]
[1]Institute for Clinical and Experimental Medicine, Diabetes Centre, Prague, Czech Republic; [2]Cardiology Department, Institute for Clinical and Experimental Medicine, Prague, Czech Republic;[3]Transplant Surgery Department, Institute for Clinical and Experimental Medicine, Prague, Czech Republic.

Adrenal incidentaloma is frequently encountered in endocrinological praxis, however in specific situations the proper investigation is almost impossible. A 60-years old patient was admitted to our intensive care unit with a myocardial infarction in cardiogenic shock requiring ionotropic support and intraaortic balloon counterpulsation. On account of ejection fraction 15–20% an urgent pretransplantation investigation was started. Abdominal ultrasound displayed a hypoechogenic structure 35×30 mm in the left suprarenal region and adrenal CT confirmed a low density mass 25×37 mm. Both aldosterone (886.8 ng/l) and plasmatic renin activity (PRA) (5.9 ng/ml/hod) were highly elevated but our patient was treated with interfering medication (furosemide and spironolactone). Plasma metanephrine levels were within normal limits despite of catecholamine support. The patient had no cushingoid features and ACTH level was normal, but dexametahsone test was falsely positive due to hyperactivation of stress axis and inadequate absorption of dexamethasone. When excluding phaeochomocytoma and malignancy the patient was indicated to urgent heart transplantation. 2 months after the operation, in patient already having normal cardiac function, hypertension and the tendency to hypokalaemia occurred. Elevated aldosterone and supressed PRA were detected. We confirmed the diagnosis of primary hyperaldosteronism by the saline infusion test: basal PRA 0.448 ug/l/hod and aldosterone 182 ng/l; supressed PRA 0.486 ug/l/hod; aldosterone 363 ng/l, the ratio aldosterone/PRA 40 (ng/dl/ng/ml/hod). We did not perform the renal veins cannulation because of the chronic immunosuppressive corticosteroid administration. Left adrenalectomy with histological evidence of adenoma resulted in normalization of blood pressure and potassium levels 6 months after the heart transplantation. An excessive secondary activation of the renin-angiotensin-aldosterone axis in the patient with severe heart failure completely superimposed the original primary hyperaldosteronism pattern.

An underactive hypothalamo-pituitary-adrenal axis in a shift worker with chronic fatigue syndrome

Ljiljana Marina, Svetlana Vujovic, Miomira Ivovic, Milina Tancic-Gajic, Zorana Arizanovic, Dragana Rakovic, Milos Zarkovic, Tijana Lalic, Marina Nikolic-Djurovic, Zvezdana Jemuovic & Dragan Micic
Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction
Chronic fatigue syndrome is characterised by a state of chronic fatigue that persists for more than 6 months and has no clear cause.
Case report
A 38-year-old male was referred to our Clinic due to chronic fatigue, unrefreshing sleep, substantial impairment in concentration, headaches and postexertional malaise lasting from 6 to 9 months for 9 years. As a mechanical engineer he was working in shifts 12 h day/24 h break/12 h night/72 h break for 9 years. Other than allergy to penicillin he denied any significant health issues. Complete blood count, liver and kidney function tests, basal gonadotropin, TSH, prolactin, ACTH, cortisol and testosterone levels were normal. Hepatitis B, C, HIV and anti nuclear antibodies were negative. Chest X-ray and abdominal ultrasound were normal. Psychiatrist excluded a psychiatric disorder. Standard and 1 μg Synacthen test showed inadequate peak cortisol 419 and 532 nmol/l respectively. Insulin tolerance test, with hypoglycaemia of 1.2 mmol/l in 30', showed inadequate peak responses of ACTH 25 ng/l in 30', cortisol 345 nmol/l in 60', prolactin 282 mIU/l and low normal growth hormone 22 mIU/l in 60'. Endocranium with hypothalamo-pituitary region MRI was normal. The patient was diagnosed with chronic fatigue syndrome (CFS). As we advised he stopped working in shifts and commenced a low-grade physical activity with cognitive – behavioural therapy. After 6 months he was complaint free with adequate cortisol levels in standard and 1 μg Synacthen test, 718 and 715 nmol/l respectively. After a year he was still complaint free with basal cortisol 570 nmol/l.
Conclusion
The cause of CFS in our patient was the long-term exposure to a stressor – shift work, which led to a circadian disruption, crashing adaptive mechanisms and leading to a disease.

A case of pleomorphic adenoma and acromegaly: a coincidence or a pathophysiological association?

Oya Topaloglu[1], Sefika Burcak Polat[2], Cemaleddin Oztürk[3], Murat Bavbek[4], Togay Muderris[5], Reyhan Ersoy[1] & Bekir Cakir
[1]Faculty of Medicine, Department of Endocrinology and Metabolism, Yildirim Beyazit University, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Atatürk Education and Research Hospital, Ankara, Turkey; [3]Department of Internal Medicine, Atatürk Education and Research Hospital, Ankara, Turkey; [4]Faculty of Medicine, Department of Brain Surgery, Yildirim Beyazit University, Ankara, Turkey; [5]Department of Otorhinolaryngology, Atatürk Education and Research Hospital, Ankara, Turkey.

Introduction
Acromegaly is a chronic disease caused by excessive secretion of growth hormone (GH), and as a result, of insulin-like growth factor-1 (IGF1). Although controversial, frequency of both benign and malignant neoplasm formation is thought to be increased in acromegalic patients. Pleomorphic adenoma is the most

common arising tumour from the parotid salivary gland. Here we report the case of a 33-year-old woman with acromegaly and also who presented with a swelling on the left neck and diagnosed as pleomorphic adenoma arising from parotid gland after excision of the tumour.
Case report
33-year-old woman admitted to the hospital complaining of a 2-week history of visual loss and headache. She also determined weight gain, menstrual irregularity, libido loss, galactorrhoea, and a slowly growing swelling on the left neck during the last year. Hypophyseal MRI revealed a mass of 20×32 mm occupying the sellae and invasing right cavernous sisternae and extending to the optic chiasm. Hormonal evaluation demonstrated that the patient had acromegaly and secondary hypothyroidism. Parotid ultrasound (US) revealed a 42×28×45 mm heterogenous, hypoechoic intraglandular lobulated solid mass occupying left parotid gland superficial lobe and extending to the deep lobe. Hypohpyseal adenoma was excised by transsphenoidal route and immunohistochemical analysis showed extensive GH positivity. She had residual tumour after the operation and somatostatin analogous therapy was started in the follow-up period. After eight months from the hypophyseal operation the parotid tumour was excised and pathology showed that it was a pleomorphic adenoma.
Conclusion
It seems that this is the first case of a coincidence between an acromegaly and pleomorphic adenoma of parotid gland in the English literature. We don't have still enough knowledge about an association between salivary gland tumours and acromegaly. If present or not this association must be evaluated with the further studies.

Primary hyperaldosteronism: case presentation

Rodica Petris[1], Constantin Dumitrache[1], Sorin Paun[2], Catalina Poiana[1], Roxana Ganescu[2], Mara Carsote[1] & Diana Paun[1]
[1]National Institute of Endocrinology C.I. Parhon, Bucharest, Romania; [2]Emergency Hospital Bucharest Floreasca, Bucharest, Romania.

Introduction
We should consider testing for primary aldosteronism in the presence of hypertension and hypokalaemia, resistant hypertension, onset of hypertension at a young age (<20 year), severe hypertension and whenever considering secondary hypertension.
Case report
We presented the case of a 38 years old woman who was admitted in the National Institute of Endocrinology C.I. Parhon Bucharest for the evaluation of high blood pressure. She has high blood pressure for 10 years (maximum value 190/100 mm/Hg) and she is on β blocker and angiotensin II receptor blockers. She has no other medical history and her blood pressure is still 150/80 mm/Hg on the antihypertensive drugs. She has heredocolateral antecedents of high blood pressure (her mother). After she has stopped for 4 weeks the antihypertensive drugs, we detected hypopotasemia (K: 2.9 nmol/l), normal serum natrium, and normal biochemia but high levels of serum aldosterone (121 ng/ml) and low levels of serum renin (2 μUI/ml) with plasma metanephrines and normetanephrines in the upper normal range and normal plasma cortisol with good response after 1 mg overnight dexamethasone suppression test. An adrenal computed tomography has been performed and we discovered a left adrenal mass of 1.2/0.9 cm. We have replaced the β blocker with Spironolactona (200 mg per day) and Aspacardin and on these medications she has high normal blood pressure and normal potassemia. The patient was transferred to the surgery where they performed laparoscopic adrenalectomy. 2 weeks after surgery she has normal blood pressure and normal natraemia and potassemia without medications.
conclusion
We presented the case of woman with primary hyperaldosteronism and although she has high blood pressure for 10 years and we have not expected that it would be entiraly coreccted after surgery, patient did not need any antihypertensive drugs after surgery.

Hyperprolactinaemia and breast abscess: is there a link?

Imen Rojbi, Emna Haouat, Hajer Kandara, Basma Saada, Leila Ben Salem Hachmi & Claude Ben Slama
National Institute of Nutrition, Tunis, Tunisia.

Introduction
Hyperprolactinemia is a common endocrine condition causing galactorrhoea. Breast abscess is a frequent complication of the post partum period and breast feeding but it rarely occurs out of these two situations. We report the case of a patient presenting with tumoural hyperprolactinaemia associated with a breast abscess.
Case report
A 34 years-old patient presented with galactorrhoea, spaniomenorrhoea and headache for six months. She had nothing special in her medical history and was not on drugs. She was the mother of two children aged eight and four. Prolactine assessment was made twice and confirmed the hyperprolactinaemia (Prolactine: 94 and 110 ng/ml). Pituitary MRI concluded to a pituitary microadenoma so that microprolactinoma was diagnosed and the patient put on dopaminergic agonists. 15 days later, the patient suddenly developed a painful mass of the left breast. Biologic assessment showed an inflammatory syndrome with hyperleucocytosis. The breast ultrasound examination revealed an abscess of 4 cm in the superior external quadrant, with no other abnormalities of the breast. The course of the abscess was good on antibiotics (Amoxicillin + clavulanic acid) and surgery was not indicated.
Conclusion
This case report highlights the fact that during pathological hyperprolactinaemia, the histology of the breast glands may be modified leading to a risk of developing breast abscess. This phenomenon is may be exactly the same than during breastfeeding. No other similar cases have been reported in the literature.

EP1213

5 years complete clinical remission after single adrenalectomy for severe occult ACTH-dependent Cushing's syndrome

Daniel Grigorie[1,2], Andra Caragheorgheopol[1], Dan Hortopan[1] & Alina Sucaliuc[1,2]
[1]National Institute of Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine, Bucharest, Romania.

Introduction
Complete long-term clinical remission in occult ectopic ACTH syndrome after a single adrenalectomy is unexpected.
Case report
5 year ago, a 54-year-old man was admitted because of resistant HTA, multiple severe vertebral fractures, muscle weakness and cushingoid features of at least 1 year. Adrenal tests were diagnostic of ACTH-dependent Cushing'syndrome: ACTH = 263 pg/ml, high plasma (62 μg/dl) and urinary free cortisol (UFC = 1256 μg per day) with no suppression after both low-dose (cortisol = 40.12 μg/dl; UFC = 255.36 μg per day) and high-dose dexamethasone (cortisol = 32.95 μg/dl; UFC = 1193.2 μg per day). A pituitary MRI showed no identifiable tumour. CTs of the thorax and abdomen and a ^{18}-FDG-PET CT scan failed to identify a possible tumour. A right adrenal laparoscopic adrenalectomy was performed. 1 mo postsurgery ACTH decreased to 79.8 pg/ml and cortisol was 16.7 μg/dl, non-suppressible with low dose DXM (7.37 μg/dl); low testosterone, 25OHD normalised, and bone turnover markers increased significantly (osteocalcin 10 ×). As clinical improvement was significant the patient declined the second adrenalectomy. 10 mo postsurgery all cushingoid features disappeared and the patient was in very good clinical condition with mild HTA and normal blood chemistries as he is now. Adrenal tests were performed annually: they fluctuated, with serum cortisol/UFC normal or high normal but nonsuppressible (or paradoxically increased); ACTH also was around 100 pg/ml. BMD increased progressively for 5 year (32% at the FN). 2 years ago a CT scan revealed a small pulmonary nodule (10 mm) but a SMS (^{111}-indium-pentetreotide) scan was negative; the nodule was stable on recent CT. We wait for the patient consent to operate the pulmonary nodule.
Conclusion
The case shows an unexpected rapid and complete clinical remission of a severe occult ectopic Cushing' syndrome. The abnormal cortisol feed-back persisted for the duration of follow-up.

EP1214

Aberrant expression of serotonin receptors in an aldosterone- and cortisol-producing adenoma

Maria Lytrivi[1], Denis Brisbois[1], Bernard Corvilain[1], Pieter Demetter[1], Camilo Garcia[3], Valerio Lucidi[1], Rodrigo Moreno-Reyes[1], Stella Vudu[1], Celine Duparc[2], Julien Wils[2], Herve Lefebvre[2], Estelle Louiset[2] & Natacha Driessens[1]
[1]Erasme University Hospital, Brussels, Belgium; [2]INSERM, U982, University of Rouen, Mont-Saint-Aignan, France; [3]Jules Bordet Institut, Brussels, Belgium.

Introduction
Aberrant expression of serotonin receptors has been described to be involved in the pathophysiology of both aldosterone-producing and cortisol-producing adrenal adenomas.
Case report
A 46-year-old woman was referred for evaluation of severe hypertension associated with hypokalaemia. Primary aldosteronism with concurrent subclinical Cushing's syndrome was diagnosed. A CT-scan identified a lesion of 4 cm in the right adrenal gland and a second lesion of 1 cm in the left adrenal gland, both displaying benign imaging phenotype. Following dexamethasone suppression, we explored the potential aberrant expression of serotonin receptors in the adrenal cortex by intravenous administration of metoclopramide, a serotonin type 4 receptor (5-HT_4-R) agonist. This led to abnormal cortisol increase and physiological response of aldosterone in peripheral blood. Adrenal venous sampling was then performed in basal conditions and after metoclopramide stimulation. An increase in cortisol level was observed in the left adrenal vein after stimulation. ^{131}I-19-Iodocholesterol scintigraphy showed intense radiotracer uptake in the right adrenal mass and weak uptake in the contralateral mass. Right laparoscopic adrenalectomy was performed. Histological examination revealed an adrenocortical adenoma. *In vitro*, cultured adrenocortical cells derived from the tumoural tissue exhibited aldosterone and cortisol co-secretion. Administration of 5-HT or metoclopramide to the cells induced a dose-dependent increase in cortisol production. These effects were inhibited by concomitant administration of the 5-HT_4-R antagonist GR113808. Incubation of tumour tissue fragments with 5-HT induced a significant increase in aldosterone production which was abrogated in the presence of GR113808. These data were suggestive of aberrant expression of 5HT_4-R in the tumoural tissue.
Conclusion
We report a rare case of an aldosterone- and cortisol-co-producing adenoma in a patient with severe hypertension and bilateral adrenal masses exhibiting an abnormal plasma cortisol response to metoclopramide. *In vitro* studies revealed enhanced sensitivity of the tumour tissue to 5-HT indicative of illicit expression of 5-HT_4 receptors.

EP1215

'Idiopathic'- the truly unknown or yet another hiding place for autoimmunity? A case of central diabetes insipidus in a young woman with Hashimoto thyroiditis

Alexandra Nila[1], Cristina Serbanescu[1], Mihaela Epure[1], Minodora Betivoiu[1], Sorina Martin[1,2] & Simona Fica[1,2]
[1]Endocrinology Department, Bucharest, Elias Emergency Hospital, Romania; [2]Endocrinology Department, Carol Davila University of Medicine and Pharmacology, Bucharest, Romania.

Introduction
Central diabetes insipidus is a rare, chronic disease characterized by polyuria and polydipsia due to a partial or total vasopressin deficiency (hypothalamic – neurohypophysial system damage). The aetiology can be familial (autosomal dominant inheritance, X-linked recessive traits; mutation of the vasopressin – neurophysin II genes), secondary (tumours, infections, infiltrative diseases, trauma, vascular lesions) and idiopathic (10–30%).
Case report
We present the case of a 24 year-old female who presented in our clinic for a polydipsia- polyuria syndrome (10 l per day) with a sudden onset 3 months prior her admission. She had a family history of Hashimoto thyroiditis and Diabetes Mellitus type 1, and a personal history of Hashimoto thyroiditis with hypothyroidism for which she had been taking treatment with L-thyroxine for almost 1 year. Physical examination: overweight (BMI 28 kg/m^2), blood pressure 120/95 mm/Hg, heart rate 108 bpm, no signs or symptoms of pulmonary disease. She had no modifications in circadian rhythm or appetite, normal menstrual cycle, no history of head trauma, pregnancy or childbirth. Lab tests: routine investigations and inflammatory markers were normal, endocrinological testing revealed a normal anterior pituitary function and a balanced hypothyroidism substitution (TSH = 3.01 μIU/ml, fT_4 = 1.47 ng/dl). The water deprivation test and ADH value when the test ended (< 1 ng/l) were suggestive for central diabetes insipidus. Hypothalamic-pituitary MRI with contrast showed no pathological modifications except for the absence of the physiological posterior pituitary bright spot. The patient received long-term oral desmopressin treatment and her fluid intake and output normalised.
Conclusion
Central Diabetes Insipidus is rare chronic disease, even rarer in the case of young adults. When no familial or secondary cause of vasopressin deficiency is feasible, vascular lesions and autoimmune processes must be taken in consideration before labelling it as 'idiopathic'. In this particular case, given the personal and familial history of autoimmune diseases, despite the non-suggestive MRI findings, anti-pituitary and vasopressin-cell autoantibodies should be determined as an attempt to look even further and truly define a diagnosis.

ARMC5 mutation in a family with Cushing syndrome due to bilateral macronodular adrenal hyperplasia

Teresa Rego[1], Fernando Fonseca[1], Ana Agapito[1], Stéphanie Espiard[2], Karine Perlemoine[2] & Jérôme Bertherat[2]
[1]Endocrinology Department, Curry Cabral Hospital, Lisbon, Portugal; [2]Endocrinology Department, Hôpital Cochin, Paris, France.

Introduction
Bilateral macronodular adrenal hyperplasia (BMAH) is a rare aetiology of Cushing syndrome. Familial clustering suggests a genetic cause that was recently confirmed, after identification of inactivating germline mutations in *armadillo repeat containing 5* (ARMC5) gene.
Clinical case
A 70 years old female admitted due to femoral neck fracture in May 2014, presented central obesity, rubeosis and hypertension. Laboratory work up revealed: ACTH < 5 pg/ml; urinary free cortisol (UFC) – 532 ug per day (ref.v. – 20–90); serum cortisol after DST – 21 ug/dl; Abdominal MRI: enlarged nodular adrenals (right – 55 × 54 × 30 mm; left – 85 × 53 × 35 mm). She was submitted to bilateral adrenalectomy and histology confirmed cortical nodular hyperplasia (adrenal weight: right – 62 g; left – 151 g). In 2006 this patient's 39 years old daughter had been observed by one of the authors. She presented severe clinical hypercortisolism and ACTH < 5 pg/ml; UFC – 204 ug per day; serum cortisol after DST – 16.2 ug/dl; Abdominal CT scan showed bilateral enlarged nodular adrenals with maximal axis of 15 cm for both. Bilateral adrenalectomy was performed (adrenal weight: right – 68 g; left – 104 g) and pathology revealed cortical nodular hyperplasia. In this familial context of severe bilateral disease, genetic study was preformed. Leucocyte DNA genotyping identified in both patients a ARMC5 mutation in exon 1 c.172_173insA p.158Nfs*44.
Comments
The clinical cases herein described have an identical phenotype with severe hypercortisolism and huge adrenal glands, but different ages on diagnosis. Current knowledge of inheritance of this disease, its insidious nature and the well known deleterious effect of hypercortisolism favour genetic study of other family members. Since ARMC5, a tumoral supressor gene, is expressed in many organs and recent findings suggest an association of BMAH and meningeoma, a watchful follow-up is required.

EP1217

Successful pregnancy outcome in recurrent phaeochromocytoma: a clinical case report

Evelina Praneviciene[1], Birute Zilaitiene[2,3], Lina Barsiene[3], Lina Radzeviciene[2,3], Tomas Birzietis[4] & Rasa Verkauskiene[2,3]
[1]Faculty of Medicine, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Department of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [4]Department of Obstetrics and Gynaecology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction
Phaeochromocytoma in pregnancy is very rare and potentially dangerous situation for mother and foetus. Failure to diagnose this condition or suboptimal management can be disastrous for mother and/or foetus, because of raised catecholamine levels.
Case
A 22-year-old pregnant woman (8 weeks' gestation) with hypertension and a suspected recurrence of phaeochromocytoma was referred to the Endocrinology Department in March 2014. The pregnancy was unplanned. In physical examination her height – 176 cm, weight – 74 kg, blood pressure and pulse were 156/90 mmHg and 92 beats/min respectively. Laboratory investigations: metanephrin 0.42 nmol/l (0–0.456), normetanephrin >16.38 nmol/l (0–0.1037), potassium 3.4 mmol/l (3.8–5.3), plasma renin activity (PRA) 16.81 ng/l (1.6–14.7), aldosterone (ALD) 633 ng/l (35–300), with normal ALD:PRA ratio, chromogranin A 361.18 μg/l (0–100). From her medical history it was already known that she underwent right adrenalectomy due to pheochromocytoma in March 2012. 6 months later increased blood preassure till 160/100 mmHg was observed. On abdominal CT scan (June 2013) – right adrenal gland removed, several $\sim 1.1 \times 1.0$ cm lymph nodes are visible, left adrenal gland structural, without any additional masses in it. Metanephrin and normetanephrin tests indicated significantly elevated catecholamines levels. Unfortunately abdominal MRI (August 2013, September 2014) and MIBG scans (October 2013, February 2014) did not reveal possible source of catecholamines hyperproduction as well. Genetic testing results were negative. Hypertention during first trimester was treated with Labetalol 600mg/day, Metildopa 1000 mg per day, potassium chloride 1500 mg per day. Phenoxybenzamine hydrochloride was added later on and titrated till 100 mg per day in order to reach satisfactory blood pressure control. In September 2014 the patient had uncomplicated delivery of a healthy boy (weight – 2890 g, height – 47 cm, Apgar score 9–9) *via* Caesarean section. She is breast-feeding and continues Labetalol 900 mg per day for hypertension control. Further investigations are planned to identify localization of phaeochromocytoma.
Conclusion
This case illustrates that adequate medical management in the case of phaeochromocytoma predispose the successful pregnancy outcome.

Rare aetiology for primary adrenal failure: ACTH resistance

Ioana Hristov[2], Simona Gherasim[2], Ana Hreniuc[2], Maria Christina Ungureanu[1,2], Cristina Preda[1,2], Carmen Vulpoi[1,2], Voichita Mogos[1,2] & Letitia Leustean[1,2]
[1]University of Medicine and Pharmacy 'Gr.T.Popa', Iasi, Romania; [2]Universitary Hospital St Spiridon, Iasi, Romania.

Introduction
ACTH resistance syndromes are rare, autosomal and genetically heterogeneous diseases that include familial glucocorticoid deficiency and triple A syndrome. These are characterised by early onset of primary adrenocortical insufficiency associated with hypoglycaemia, convulsions and skin pigmentation.
Case report
We present the case of primary adrenal failure in a boy diagnosed at the age of four, during a decompensation episode with hypoglycaemia and hyponatremic convulsive episode. Adrenal functional evaluation revealed: low cortisol with suboptimal ACTH response-Synacthen (cortisol T60 = 17.6 ng/dl) and very high ACTH >1500 pg/ml. Glucocorticoid and mineralocorticoid treatment improved the clinical and biologic status (normal natremia and glycaemia). The aetiological evaluation for this adrenal insufficiency included: negative anti-adrenal antibodies, normal long chain fatty acids, negative tuberculosis testing, normal 17-OH progesterone and normal pituitary (MRI) and normal adrenal aspect (CT). This profile suggests a possible diagnosis of ACTH resistance syndrome. Molecular analysis for the ACTH receptor gene (MC2R) and its associated protein (MRAP) is needed for confirming this diagnosis. Clinical aspect is particular: no skin hyperpigmentation (high ACTH >1500)-suggesting a possible melanocyte receptor deficiency (MC1-R). This ACTH resistance diagnosis seems to be associated with alacrima (Shirmer test confirmed low lacrimal secretion) but no achalasia symptoms were objectified.
Discussion
Several mutations have been found to affect the ACTH-R gene and results in different effects on receptor function. Given the ACTH resistance on multiple receptor locations: MC1-R, MC2-R (adrenal insufficiency, absence of hyper pigmentation) we suspect a co-factor mutation. Molecular analysis of DNA for MC2R, MRAP, and AAAS genes in literature shows that about 50% of FGD has unknown genetic cause. Recently, it was shown that MC2R interacts with Nup50, a nuclear pore complex protein, suggesting that this interaction could be a novel mechanism of action of ACTH receptor.

Autoimmune hypophysitis: from pituitary expansion to empty sella: description of four cases

Giulia Marconcini[1], Isabella Lupi[1], Luca Manetti[1], Mirco Cosottini[2], Claudio Urbani[1], Enio Martino[1], Claudio Marcocci[1] & Fausto Bogazzi[1]
[1]Department of Experimental Medicine, University of Pisa, Pisa, Italy; [2]Department of Neuroscience, University of Pisa, Pisa, Italy.

Four patients with autoimmune hypophysitis were followed since the diagnosis of the disease. All presented with severe headache, decreased libido, astenia. Case 1 and 3 presented polyuria and polydipsia. At MRI pituitary was enlarged, with high gadolinum uptake and stalk enlargement.
Case 1, male 41 years. MRI volume: AP 13 mm, CC 7 mm. Hormonal assessment: central hypothyroidism, hypoadrenalism, hypogonadism, normal GH and IGF1, hyperprolactinemia, central diabetes insipidus. Pituitary biopsy: severe lymphomonocitic infiltrate. Case 2, male 54 years. MRI volume: AP 13.5 mm, CC 7.7 mm. Hormonal assessment: central hypothyroidism, hypoadrenalism, hypogonadism, GH deficiency, hyperprolactinemia. Case 3, male 74 years. MRI volume: AP 9 mm, CC 7 mm. Hormonal assessment: panhypopituitarism, central diabetes insipidus. Pituitary biopsy: rich IgG4 lymphomonocitic infiltration. Case 4, female 35 years. MRI volume: AP 16 mm, CC 7 mm. Hormonal assessment: panhypopituitarism, hyperprolactinemia. All patients were treated by oral prednisone therapy (starting dose: 40 mg/day gradually tapered over 6 months) and followed with regular hormonal exams and pituitary MRI. At the last outpatient visit: Case 1 (6 years AR): recovery of gonadic and thyroid function, GH deficiency, adrenal insufficiency and diabetes insipidus remained unchanged. MRI: shrinked pituitary (AP 8 mm, CC 4 mm). Case 2 (1 year AR): complete recovery of adrenal function, persistence of hypogonadism and GH deficiency, subclinical hypopthyroidism. MRI: shrinked pituitary (AP 11 mm, CC 2.5 mm). Case 3 (6 years AR) persistence of panhypopituitarism and diabetes insipidus. MRI: shrinked pituitary (AP 6 mm, CC 4 mm). Case 4 (1 year AR) complete recovery of pituitary function. MRI: normal pituitary volume (AP 12 mm, CC 4 mm).
Conclusion
Glucocorticoid treatment is effective in improving pituitary function and pituitary mass. Over the years new hormonal defects may appear along with pituitary shrinkage: empty sella might be the outcome of autoimmune hypohysitis. (abbreviations: AR, after remission; AP, antero–posterior diameter; CC, cranio-caudal diameter).

Occurrence of liver failure in post-surgery hypopituitaric patients

Valentina Lo Preiato, Danilo Ribichini, Margherita Baccini, Renato Pasquali & Uberto Pagotto
Endocrinology Unit, Sant'Orsola-Malpighi Hospital, Alma Mater University, Bologna, Italy.

Multiple pituitary hormone deficit and hypothalamic obesity are common complications after brain surgery for childhood tumors. Despite adequate replacement hormone therapy, obesity develops equally, but liver failure is not usually described. In this study, four subjects who had undergone surgery for brain tumors involving the peri-hypothalamic area when they were nursing or as youths (9 months, 6 years, 9 years and 20 years). They were referred to our Unit when they were 19, 23, 23 and 31 years old, respectively. One of this patients had a pilocytic astrocytoma, two of these patients had a craniopharyngioma, and the last a third ventricle germinoma. One patient underwent radiotherapy and

chemotherapy after surgery and another one received four transphenoidal or transcranial surgical operations. All patients developed panhypopituitarism, but only two had taken in childhood and adolescent age adequate hormone replacement therapies since brain damage. Since the other two patients came to our observation, adequate hormonal replacement therapy was proposed. All patients developed obesity (BMI 39.2–46.6 kg/m^2) or overweight (BMI: 27.1). The two patients adequately treated for hypopituitarism after surgery, developed a fatty liver when they were 16 and 21 years old respectively. In both cases, steatosis progressively evolved into cirrhosis after 2 years. One of these patients also developed a hepatic-pulmonary syndrome and underwent liver transplant at the age of 25 years. In the two patients with inadequate or absent hormone replacement therapy, a diagnosis of cirrhosis was concomitant with the first appropriate endocrinological care during hospitalization for liver failure. The analysis of these four cases shows that pediatric peri-hypothalamic surgery may be associated with very severe hepatic clinical features, induced by mechanisms not yet known, regardless of hormone replacement therapy. It is therefore very important to start a careful follow-up of these patients from childhood for early detection of possible liver failure.

EP1221

Two treatment patterns of thyrotropinomas with over 3-year follow-up

Mihail Coculescu & Madalina Vintila
Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
Thyrotropinomas are rare pituitary tumours. Neurosurgery is considered the first-line treatment, followed by medical therapy with somatostatin analogues or radiotherapy.
Case reports
We present two cases of thyrotropinomas with different therapeutic approaches. Case 1: A 63-year old man presented with severe thyrotoxicosis. Biochemical evaluation showed inappropriate TSH secretion (TSH = 7.5 mU/l, FT_4 = 45.5 pmol/l); computed tomography revealed a pituitary macroadenoma (2.37/2.56 cm). The patient underwent preoperative lanreotide and antithyroid drugs preparation before trans-sphenoidal tumour removal. Immunohistochemistry showed a pure thyrotropinoma. After neurosurgery, he had complete disease remission without any antithyroid medication and no signs of recurrence after 7-year follow-up. However, he developed postoperative gonadotropin deficiency. Case 2: A man, 36-years, with total thyroidectomy for thyroid follicular adenoma presented with high TSH (15 mU/l) although he received daily 100 μg of levothyroxine and serum thyroid hormones were in high-normal concentrations (total T_4 = 11 μg/dl). Adding T_3 (20–30 μg/day) to T_4 treatment, TSH was still high (between 41 and 18.4 mU/l for FT_4 between 1.28 and 2 ng/dl), showing inadequate TSH secretion. Pituitary MRI revealed a 1.62/1.45/1.6 cm mass. Acute octreotide test showed decreasing of TSH from 22.4 to 0.53 μU/ml with no change in serum T_4 and T_3 levels. The patient refused surgery and received chronic treatment with long-acting octreotide, 20 mg/month. Along 3-year follow-up he had good biochemical response (TSH between 4.35 and 2.87 mU/ml while normal T_4 and T_3 levels under substitution) and ~25% reduction of tumor dimensions (1.21/0.92/1.29 cm). Whenever octreotide was stopped, inappropriate TSH secretion relapsed.
Conclusions
Neurosurgery is the treatment of choice in thyrotropinomas but when surgery is refused somatostatin analogues are an efficient alternative for long-time disease control.

Glucocorticoid resistance syndrome: case report

Ana Carolina Neves, Fernando Fonseca & Ana Agapito
Endocrinology Department, Curry Cabral Hospital – CHLC, Lisbon, Portugal.

Introduction
Glucocorticoid resistance syndrome (GRS) is a rare familial or sporadic condition, caused by mutations in glucocorticoid receptor gene. It is characterised by generalised partial resistance of target tissues to cortisol action and compensatory elevation of ACTH with subsequent hypersecretion of cortisol, mineralocorticoids and androgens. Its clinical spectrum is broad and it may occur with high blood pressure (HBP) metabolic alcalosis, hypokalaemia and virilisation.
Case report
A 19-year-old black male was referred to Endocrinology department due to HBP diagnosed at 14 years old and elevated ACTH. He had delayed psycomotor development and epilepsy since childhood. There was no history of precocious puberty. His height, weight and blood pressure were 1.70 m, 52 kg and 139/95 mmHg, respectively. No signs or symptoms of deficiency or excess of glucocorticoids, hyperandrogenism or other causes of HBP were present. Complementary exams excluded adrenal enzymatic deficiency, primary aldosteronism, phaeochromocytoma and renovascular disease as aetiology of HBP. Pituitary–adrenal axis evaluation revealed: ACTH 158 pg/ml (ND-46), cortisol(s) 08/24 h 21.9/1.8 μg/dl, cortisol (u) 102.5 μg/24 h (20–90); low-dose dexamethasone suppression test (DST): cortisol(s) 19.8 μg/dl; high-dose DST: cortisol(s) < 1.0 μg/dl. DNA analysis revealed a frameshift mutation c.2159_2160delAA, in heterozigoty in the *NR3C1* gene, not yet described in the literature. Genetic study of relatives has not been done yet, since they live abroad.
Conclusions
The clinical spectrum of GRS is broad, ranging from severe to asymptomatic forms and the biochemical profile varies, depending on the severity of the defect in the signal transduction of glucorticoids. Persistent elevated urinary cortisol and ACTH with no clinical signs of hypercortisolism in this hypertensive young man led us to suspect of GRS. Diagnosis was confirmed by the finding of a not yet described mutation of *NR3C1* gene.

Bilateral adrenal haemorrhage: a rare complication of anti phospholipid syndrome

Sriranganath Akavarapu & Yee Michael
Imperial College NHS Trust, London, UK.

Introduction
Bilateral adrenal haemorrhage is a rare potentially life-threatening event that occurs either in traumatic or non traumatic conditions. We present a rare case report of bilateral adrenal haemorrhage due to anti-phospholipid antibody syndrome.
Case report
A 54 year old Iranian origin male presented with abdominal pain and collapse. His past history includes unprovoked DVT 6 months ago and off the warfarin recently. CT abdomen showed bilateral Adrenal haemorrhage. Early morning cortisol was 54. He was subsequently treated with i.v. hydrocortisone, antibiotics, fluids and made a good recovery. He had further admission within 1 week of discharge with chest pain and hypotension due to acute myocardial infarction. Coronary artery angiogram was normal. Further investigation showed positive ANA and lupus anticoagulant positive. He was discharged on oral hydrocortisone and warfarin. The diagnosis of anti phospholipid antibody syndrome was confirmed after repeat lupus anticoagulant positive at 3 months with satisfactory clinical and biochemical criteria.
Discussion and conclusion
Acute adrenal insufficiency due to bilateral adrenal haemorrhage is a rare manifestation of APS. Prompt treatment with steroids needed to achieve favourable outcome.

Cushing's disease in a patient with complicated varicella

Ana Saavedra[1,2], Sandra Belo[1,2], Maria Manuel Costa[1,2], Claudia Nogueira[1,2], Paula Freitas[1,2], Ana Santos[4], Lurdes Santos[4] & Davide Carvalho[1,2]
[1]Department of Endocrinology Diabetes and Metabolism, Centro Hospitalar S. João, Porto, Portugal; [2]Faculty of Medicine, University of Porto, Porto, Portugal; [3]Instituto de Investigação e Inovação em Saúde, University of Porto, Porto, Portugal; [4]Department of Infectious Diseases, Centro Hospitalar de São João, Porto, Portugal.

Introduction
Immunossupression is a possible consequence of hypercortisolism, putting these patients in a state of increased risk of infections.
Case report
Female, 19 years old. In July 2014 she seek for medical care because she became feverish and developed an erythematous rash on her face/trunk with subsequent widespread to the entire body. She was admitted in the ICU with the diagnosis of severe varicella with acute cholestatic hepatitis and confluent necrosis of coagulative type. The patient presented full moon face (more prominent over the last 2 months), truncal obesity starting after menarche (at 10 years old), hirsutism and menstrual irregularities/secondary amenorrhea. Physical examination also showed bruises and reddish purple striae. During hospitalisation she presented hypertension, hyperglycaemia (HbA1c 6.7%) and hypokalaemia. After treatment with antiviral/antibacterial drugs and the resolution of the acute infection, she was evaluated for the suspicion of Cushing's syndrome, which was confirmed based on: high levels of serum cortisol; high 24 h urine free cortisol (300.1 μg/day); two increased late-night salivary cortisol assays (1.150 μg/dl; 0.961 μg/dl); cortisol after 1-mg overnight dexamethasone suppression test (DST) – 23.0 μg/dl; and cortisol after 2 day low-dose DST – 15.1 μg/dl. As she had high basal ACTH levels (14.7 pg/ml), it was performed a 2 day high-dose DST test (end cortisol – 3.8 μg/dl). Then it was performed a pituitary MRI, which reveals a 'lesion in the right half of the pituitary gland compatible with a microadenoma', thus confirming the diagnosis of Cushing's disease.
Discussion
This clinical case emphasizes the importance of considering hypercortisolism as a condition capable of inducing immunosuppression, which may result in the development of serious infections and, therefore, these severe clinical situations should raise this diagnostic possibility.

EP1225

Anaesthesia during petrosal sinus sampling and possible interference with ACTH levels

Margaret Keil, Maya Lodish, Charalampos Lyssikatos, Jaikrit Bhutani, Elena Belyavskaya & Constantine Stratakis
National Institutes of Health- NICHD, Bethesda, Maryland, USA.

Background
General anaesthesia and surgical intervention in humans are known to affect the function of the hypothalamic–pituitary–adrenal axis (HPA). In the literature there are conflicting reports about the effect of propofol, a commonly used intravenous anaesthetic agent, on HPA function.
Case reports
We report two males (11 and 12 years) with ACTH-dependent Cushing syndrome (CS) who underwent inferior petrosal sinus sampling (IPSS) with general anaesthesia. ACTH was measured from bilateral petrosal and peripheral sites at baseline and after administration of corticotrophin releasing hormone (CRH). Anaesthetic agents used included: propofol infusion (pt A: 7.8 mg/kg; pt B: 29 mg/kg), fentanyl, and midazolam. ACTH results from IPSS were atypical for both patients (i.e. no stimulation of ACTH (peripherally) and overall low values of ACTH). Since the ACTH results precluded scheduling of transsphenoidal surgery, the IPSS procedures were repeated. Results of the 2nd IPSS showed appropriate stimulation of peripheral and central ACTH levels and peripheral to central ratios consistent with Cushing disease (CD) in both patients. Anaesthetic agents used included single dose propofol at induction (~50 min prior to sampling) (pt A: 1.8 mg/kg; pt B: 1.4 mg/kg), fentanyl, and midazolam. Subsequently, both patients underwent TSS for removal of corticotropinoma which was confirmed at histology; they remain in remission of hypercortisolemia to date.
Conclusion
Historically, propofol has been shown to have direct antisteroidogenic effects on adrenal cells and to be a weak inhibitor of adrenal steroidgenesis, compared to etomidate. However, the two cases presented provide a novel insight about a possible interaction of propofol and ACTH. These cases suggest a possible short-term inhibition of ACTH secretion by propofol and highlight the importance of future research. A better understanding of the interaction of propofol with ACTH may be of vital importance in the intra- and post-operative management of patients as well as in diagnostic endocrine testing that involves anaesthesia.

A case of IgG4 related hypophysitis in a Caucasian female

Anne Marie Hannon[1], Saket Gupta[1], Dave Slattery[1], Karen McGurran[1], Brendan Kinsley[2], Moshen Javadpour[3], Francesca Brett[4] & Amar Agha[1]
[1]Department of Diabetes and Endocrinology, Beaumont Hospital, Dublin, Ireland; [2]Department of Diabetes and Endocrinology, Mater Misericordiae Hospital, Dublin, Ireland; [3]Department of Neurosurgery Beaumont Hospital, Dublin, Ireland; [4]Department of Neuropathology, Beaumont Hospital, Dublin, Ireland.

IgG4 related hypophysitis is a recently described entity belonging to the IgG4 related diseases. It is characterised by markedly elevated serum IGG4 levels and tissue infiltration by IgG4 positive plasma cells. To date, 34 cases of IgG4 related hypophysitis have been described but only a handful were in women or biopsy proven. We describe a case of a 58 year old woman who presented with transient headache. She also complained of polyuria and nocturia. She had a thyroidectomy for treatment of hyperthyroidism 10 years previously. MRI pituitary revealed a pituitary mass with marked diffuse stalk thickening. Dynamic evaluation of her anterior pituitary function revealed raised prolactin and severe GH deficiency. An 8-h water deprivation test showed partial diabetes insipidus. Ferritin, serum ACE, β-HCG, alphafetoprotein, autoimmune screen and ANCA were negative. Chest and abdominal imaging and breast mammography showed no malignancy. A transsphenoidal pituitary biopsy showed evidence of hypophysitis with fibrosis and increased number of histologically benign plasma cells and >10 positive cells per HPF on IgG4 immunocytochemistry, which is highly characteristic of IGG-4 related hypophysitis. Her plasma IgG4 level was normal. She was determined to have IgG4 related hypophysitis as per the criteria proposed by Leporati *et al*. in 2011. She was commenced on glucocorticoids and is due for a follow up MRI in 6 months. IgG4 related hypophysitis is a rare disorder, which was first described in 2004 based on clinical data. Of the 34 cases recorded in the literature, 29 were men and five were women. The majority of documented cases have been from Japan. While initial case reports were of more severe disease, more recently there have been case reports of patients with milder variants, with one patient reported with normal pituitary function. Accurate diagnosis is essential, as previous reported cases have shown improvement with glucocorticoid therapy. This case illustrates that when an enlarged pituitary gland/stalk is detected, IgG4 hypophysitis should be considered in the differential diagnosis regardless of pituitary function and serum IgG4 level.

Difficulties of acromegaly treatment in young patients: clinical case

Alexandru Florescu[1,2], Andra Sandru[1], Adrian Condrea[1], Liliana Moisii[1,2] & Corina Galesanu[1,2]
[1]Spitalul Sfantul Spiridon, Iasi, Romania; [2]Universitatea de Medicina si Farmacie GR. T. Popa, Iasi, Romania.

Transsphenoidal surgery still appears to be the best option for most of the patients with GH secreting adenomas. In many cases the biochemical cure targets are not reached and the patient needs adjuvant therapy. Alternatives include medical therapy with somatostatin analogues, GH-receptor antagonists and dopamine agonists. These drugs can be used alone or in combination. Radiation therapy with conventional fractionated photons or radiosurgery with proton beam could also be

effective in some cases. We present the clinical case of a 32 year old man, who first came to us in October 2008 due to acral enlargement of hands and feet, prognatism and fatigue. He had a GH level of 52 µg/l and an IGF1 level of 839 ng/ml at the time of diagnosis. After 6 months of therapy with Octreotide (Sandostatin LAR) 20 mg/28 days both of them decreased (IGF1 by 70% and GH by 80%).This treatment was maintained for 2 years, with the persistence of high levels of IGF1 (X 2009- 677 ng/ml, VIII- 767 ng/ml), but with the decrease of the tumour and the levels of GH. In august 2011 the patient underwent transsphenoidal surgery (difficult to perform due to severe bleeding and anatomical abnormalities), followed one month later by Gamma Knife. At that point he developed partial pituitary insufficiency (thyreotrop and gonadotrop), hypertension and impaired fasting glucose, for which he started medical treatment. From january 2012 he received again somatostatin analogues (the starting dose was octreotide 20 mg every 28 days for 6 months, followed by 30 mg/28 days) without the normalisation of IGF1 (X 2012-631 ng/ml, VI 2013-403 ng/ml). Because the IGF1 levels were still elevated the dose of octreotide was increased at 40 mg/28 days and GH receptor antagonists (Pegvisomant) was associated (III 2014 10 mg/day s.c.). The following IGF1 levels are still high (V 2014-493 ng/ml, VII 2014 -587 ng/ml, XII 2014-541 ng/ml). The particularity of the case is represented by the age of the patient and by the fact that throughout a relative short period of time he received the latest available therapy in acromegaly.

Successful systemic treatment of Xanthoma disseminatum with cyclophospamide: an interesting case with endocrine and gastrointestinal involvement

Reyhan Ersoy[1], Sefika Burcak Polat[1], Karabekir Ercan[2], Berna Ogmen[1], Huseyin Ustun[3], Osman Ersoy[4] & Bekir Cakir[1]
[1]Endocrinology and Metabolism Department, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey; [2]Radiology Department, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey; [3]Pathology Department, Ataturk Education and Research Hospital, Ankara, Turkey; [4]Gastroenterology Department, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey.

Introduction
Xantoma disseminatum (XD) is a rare non-Langerhans cell histiocytosis (NLCH) which is often resistant to treatment. In this report, we presented a case with extensive cutaneous, hypothalamohypophysial, cerebral and gastrointestinal system involvement, which responded well to cyclophosphamide.
Case
A 16-year-old female patient admitted to our hospital with the complaints of amenorrhoea, weight gain, polidipsia, poliuria, yellow-brownish papular lesions on the cervical, periorbital, axillary and genital regions. Lesions first appeared 18 months ago and increased in amount and size in time. Hormonal evaluation was done including dynamic tests and secondary hypothyroidism, hypogonodothropic hypogonadism, GH deficiency and central diabetes insipidus were detected. Pituitary MRI demonstrated a mass 15×8 mm in diameter at hypothalamohypophysial tract together with multiple cerebral lesions. Her visual and neurologic examination was normal. A biopsy was performed on skin and duodenal lesions and the result of pathologic analysis was coherent with NLCH. In the light of those findings, she was diagnosed with XD. Hormonal replacement therapies for hypothyroidism, hypogonadism and DI were initiated. For hypothalamic mass and skin lesions 60 mg/day methyl prednisolone was started and its dosage was gradually reduced to maintenance dose of 4 mg/day. MRI screening performed at 6th month of therapy didn't show any regression in mass sizes. Hence, medical therapy was changed with cyclophosphamide 100 mg/day. No complete remission was achieved but significant regression in cutaneous, hypothalamohypophysial, cerebral and gastrointestinal lesions was obtained in 24 months. No side-effects were noticed related with cyclophosphamide. The skin lesions did not relapse after discontinuation of cyclophosphamide.
Conclusion
The coexistence of XD with hypopituitarism is a rare condition. There are various systemic treatments such as radiotherapy, cryotherapy, corticosteroids, and antiblastic chemotherapy but no single treatment is universally successful. In rare cases complete remission was obtained with low-dose oral cyclophosphamide in adults as it occurred in our case.

Hyponatremia in secondary adrenal insufficiency after transsphenoidal surgery for pituitary adenoma: case report

Gordana Pemovska[1], Tatjana Bajraktarova Prosheva[2] & Sasha Jovanovska Mishevska[1]
[1]University Clinic of Endocrinology, Diabetes and Metabolic Disorders, Skopje, Macedonia; [2]Clinical Hospital, Shtip, Macedonia.

Introduction
Hyponatremia is rarely reported as a delayed complication of transsphenoidal resection of pituitary adenoma. Severe hyponatraemia can cause potentially fatal conse-quences.
Material and methods
A 34 year old patient was admitted as an urgent case at the Clinic of Endocrinology, with symptoms and signs of Addisonian crisis (dizziness, headaches, nausea, vomiting, hypotension), with muscular weakness and muscle aches, tingling hands and confusion. It was a pa-tient diagnosed with acromegaly due to STH secreting macroadenoma, with onset of symptoms 10 days after transsphenoidal pituitary surgery for macroadenoma.
Results
The biochemical analyses showed se-vere hyponatremia (Na = 116, 118, 122, 136 mmol/l). There were no hormonal dysfunctions de-tected in the pituitary–thyroid and pituitary–gonadal axis, values of STH were 1.6 ng/ml. Because of expressed slow mental process, disorientation and somnolence brain KT was made, showing reduction in the ventricular system, flattened gyri and loss of sulci suggesting cerebral oedema. The con-dition of the patient improved after the correction of hyponatremia with hydrocortisone therapy.
Conclusion
Postoperative hyponatremia after transsphenoidal surgery is more common than previously reported and may lead to fatal complications. Therefore, all patients should undergo serum electrolyte level monitoring regularly for at least 1 or 2 weeks after transsphenoidal surgery.

Cushing's disease in a 7-year-boy due to corticotroph cell hyperplasia

Rosemary Dineen[1], Karen McGurren[1], Mohsen Javadpour[2], Colm Costigan[3] & Amar Agha[1]
[1]Department of Endocrinology, Beaumont Hospital, Dublin, Ireland; [2]Department of Neurosurgery, Beaumont Hospital, Dublin, Ireland; [3]Department of Paediatric Endocrinology, Our ladys hospital for Sick Children, Crumlin, Dublin, Ireland.

Introduction
Cushing's disease (CD) is very rare in children and is invariably caused by a corticotroph adenoma. However, corticotroph cell hyperplasia has only been convincingly shown in two previous cases of paediatric Cushing's disease. We report the case of a 7-year-old boy with Cushing's disease caused by coticotroph cell hyperplasia.
Case report
Our patient presented with a 10-month history of obesity, hirsutism and growth retardation. His height was 2.5S.D. below the mean and his weight was over 98th percentile for age. Examination revealed a cushingoid facies, central obesity, striae and hirsutism. Biochemical assessment showed raised 24-h urine free cortisol and mid-night salivary cortisol with failure to suppress serum cortisol following low dose dexamethasone. Baseline 0900 h ACTH level was elevated. A peripheral CRH test showed a brisk rise in ACTH and cortisol consistent with Cushing's disease. Pituitary MRI was normal. Bilateral inferior petrosal sinus sampling with CRH stimulation showed a central-peripheral gradient >3:1 at 10-min post-CRF confirming the diagnosis of pituitary dependent Cushing's. The patient underwent endoscopic transphenoidal pituitary exploration. Abnormal tissue was resected from the left side of the pituitary. Histopathology revealed no adenoma but intense immunostaining for ACTH consistent with corticotroph hyperplasia. On the fourth post-operative day, am serum cortisol level was 39 nmol/l indicating early remission. Three months post-operatively he remained hypocortisolaemic on hydrocortisone with significant clinical improvement.
Conclusion
This case illustrates that paediatric Cushing' disease may be caused, albeit very rarely, by cortricotroph hyperplasia. Careful follow-up in necessary as the recurrence rate of this entity is not known.

Phaeochromocytoma patient successfully treated after seven myocardial infarctions

Krzysztof Marczewski[1,2], Iwona Ciuba[1], Andrzej Kleinrok[1,2], Tomasz Romanowicz[1] & Dorota Boniek-Poprawa[1,2]
[1]Pope John Paul II Regional Hospital, Zamosc, Poland; [2]Zamosc University of Management and Administration, Zamosc, Poland.

Introduction
Although pheochromocytoma with fatal myocardial infarction has been described over 50 years ago, diagnostics focused on catecholamine secretion is not a routine procedure post myocardial infarction.
Case report
A 49-year-old man, previously healthy, was admitted to the hospital in June 2003, with severe pulmonary oedema. Myocardial infarction was diagnosed on the basis of an increase in markers of myocardial necrosis. There was also found a significant hyperglycaemia and ketoacidosis. Coronary angiography, has not confirmed the changes in the vessels. Due to respiratory failure patient had to be mechanically ventilated. There was even a short-term cardiac arrest. After intensive treatment his status had improved and the patient left the hospital in a stable condition, require two antihypertensive drugs and insulin. In the following years (until 2012) patient has a six NSTEMI. In none of the subsequent coronary angiography important atherosclerotic lesions are visualised. The patient frequent suffered from angina and anxiety. In January 2012 in the left adrenal gland was found in the ultrasound focal lesion, confirmed in tomography as 34 mm high density lesion (50jH) with contrast retention. Hormonal diagnostics allowed diagnose adrenal pheochromocytoma. Surgery was delayed for seven and until now the last heart attack (07/05/2012). After the preparation of alpha-blocker, the patient was successfully operated on 05/09/2012. Removal of phaeochromocytoma resulted not only normalisation of blood pressure and the disappearance of the from the coronary symptoms but allowed the metabolic control and improve the patient's mental state. Currently, the patient is at a good physical and mental condition, treated with a small dose of ramipril, nebivolol and metformin.
Conclusion
The diagnosis of phaeochromocytoma is difficult, although this may change substantially fate of people affected by them. An important clue may be inadequate response to typical treatment.

Primary hyperaldosteronism by Conn's syndrome: clinical case discussion

Claudia Coelho, Ana Margarida Monteiro, Vera Fernandes, Selma B Souto, Fernando Manso & Olinda Marques
Hospital de Braga, Braga, Portugal.

Introduction
Primary hyperaldosteronism (PA) is a disturbance caused by the autonomous production of aldosterone by the adrenal gland. The most frequent causes are due to bilateral supra-renal gland hyperplasia and aldesterone producing adenoma. It is most frequent amongst women aged between 30 and 50 years of age. It is clinically characterised by hypertension (HTN), resistant to therapy. Hypokalaemia, which is known as a 'classical marker' is found in less than a third of the patient and is followed by inespecific symptoms (muscle pain/weakness, polydipsy, polyuria, nocturia and parathesia). Diabetes mellitus (DM) can also be found in some cases.
Clinical case
A 55-year-old woman referred from internal medicine due to a adenoma on her right supra-renal gland with hypertension and hypokalaemia. The patient has been hypertensive for the past 16 years with the hypertension being resistant to therapy despite being on four antihypertensives (loasatran/hydrochlorothiazide 100 mg/25 mg, carvedilol 25 mg and spironolactone 50 mg). All tests were normal, except a high aldosterone/renin ratio (17.86). The patient was also diagnosed with DM and started on metformin. She was also given KCl for her hypokalaemia. A salt-loading test was carried out that confirmed the diagnosis of HP. (aldosterone 0–35.94; 4 h 56.18 ng/dl). The patient was subjected to a right sided adrenalectomy without complications leading to normokalaemia 48 h after surgery. The aldosterone/renin ratio also normalised. The patient is now able to maintain a normokalaemic state and she only needs 10 mg/day of lercanidipine to control her blood pressure.
Discussion
Due to the resistant hypertension before the age of 40 and the lack of experience with or unsatisfactory results obtained by catheterising supra-renal veins the surgical option was chosen in this case. We would like to highlight the importance of monitoring potassium levels on a weekly basis during the first month post-surgery due to the risk of transient hipoaldosteronism. With this patient we noticed an improvement in the blood pressure profile during the first month after the surgery. As described in the literature, an improvement or normalisation of hypertension can happen 1–6 months post surgery. However, due to the patient's long standing hypertension it is unlikely that this will normalise.

Acute renal failure in a patient with hypopituitarism and rhabdomyolysis

Malgorzata Kaluzna, Katarzyna Piatek, Katarzyna Ziemnicka, Jerzy Sowinski & Marek Ruchala
Department of Endocrinology, Metabolic Diseases and Internal Medicine, Poznan University of Medical Science, Poznan, Poland.

Introduction
Hyponatremia can be a life-threatening emergency. Severe hyponatremia may occur in patients with hypopituitarism and secondary adrenal insufficiency and hypothyroidism. The acute decompensation of pituitary insufficiency can also lead to accompanying rhabdomyolysis and acute renal failure (ARF).
Case report
A 67-year-old woman complaining of general fatigue, dizziness, nausea, feeling cold and numbness of limbs and tongue was admitted to the emergency room. Neurological consultation was made and computer tomography (CT) showed probably old, single, hypodensic ischemic lesion of 6 mm in diameter localized subcortically in the left frontal lobe. Pale skin, loss of axillary hair and scarce pubic hair were found on inspection. The patient's past medical history was unremarkable and she had not taken drugs permanently. The patient gave birth to three, menopause occurred at the age of 52. Initial laboratory studies have shown severe hyponatremia (Na 116 mmol/l) resistant to the symptomatic treatment. Rhabdomyolysis and acute renal failure developed in the patient. Rhabdomyolysis was diagnosed on the base of elevated liver enzymes, CK-MB, CPK, and creatinine. The patient was admitted to the Department of Endocrinology. Diagnosis of complete pituitary insufficiency was made on the basis of hormonal profiles. Magnetic resonance imaging (MRI) of the pituitary has shown a very small pituitary gland. Our patient recovered after hydrocortisone and levothyroxine substitution and nephrology treatment. Due to the rhabdomyolysis and ARF the patient required appropriate hydration and a single hemodialysis treatment.
Conclusions
The diagnosis of hypopituitarism in hyponatremic patients can be overlooked and may have grave consequences. Severe hyponatremia and acute renal failure may be the leading symptoms of acute decompensation of pituitary insufficiency. Appropriate hormonal substitution with alert nephrological monitoring and management (including renal replacement therapy if necessary) are crucial in case of acute pituitary decompensation and accompanying complications treatment.

Hemangiopericytoma associated hypoglycaemia and concomitant secondary adrenal insufficiency

Sinem Kiyici, Figen Topyildiz, Bunyamin Polat & Ahmet Hunuk
Department of Internal Medicine, Sevket Yilmaz Education and Research Hospital, Bursa, Turkey.

Introduction
Hemangiopericytomas (HPC) are rare vascular tumours that may be associated with hypoglycaemia. Here we report a case of HPC with multiple metastases, accompanying severe recurrent hypoglycaemia due to the combination of different aetiologies.
Case report
A 21 year-old woman was hospitalised due to loss of consciousness. The patient has been diagnosed as HPC by tibia mass biopsy 1 year ago. Tumour embolization was made several times. On admission, serum glucose was 42 mg/dl and serum insulin and C-peptide levels were suppressed. GH and cortisol response to hypoglycaemia were found insufficient. Basal ACTH was below 5 pg/ml. IGF2 was 25 ng/ml (normal range 116–358 ng/ml) and IGF2 was 823 ng/ml (normal range 288–736 ng/ml). The IGF2/IGF1 ratio was 32.9 (normal range <10), which indicates unregulated production of IGF2. Thorax and abdomen CT imaging demonstrated multiple metastatic lesions in the liver, lung, abdominal cavity, pelvis and bone. MRI revealed a microadenoma in the pituitary gland. In this case, we suggest that hypoglycaemia was associated with the combination of adrenal insufficiency secondary to deficient ACTH secretion, abnormal production of IGF2 and diminished hepatic glucose production due to the liver metastases. Because of recurrent severe hypoglycaemic attacks, a continuous glucose infusion was required to maintain normoglycaemia. Prednisolone 40 mg/day was started and a dramatically quick response was observed. Hypoglycaemic attacks were resolved immediately and 20 mg/day prednisolone was needed as maintenance therapy to prevent recurrent hypoglycaemia.
Conclusions
HPC associated hypoglycaemia is a paraneoplastic syndrome usually related with excessive production of IGF2 or partially processed forms of pro-IGF2. Hypoglycaemia can also develop by combinations of different factors such as adrenal insufficiency that we observed in the present case. The possibility of other factor must also take into consideration evaluating and treating the hypoglycaemic attacks in patients with mesenchymal tumours.

DOI: 10.1530/endoabs.37.EP1234

EP1235

An unusual case of possible cyclic Cushing's disease in a young man with Klinefelter syndrome

Thea Christoffersen[1], Anne Elisabeth Jarløv[1], Anders Juul[2], Lars Poulsgaard[3], Aase Krogh Rasmussen[1] & Ulla Feldt-Rasmussen[1]
[1]Department of Medical Endocrinology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; [2]Department of Growth and Reproduction, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; [3]Department of Neurosurgery, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark.

Introduction
Cyclic Cushing's syndrome (CS) is a rare disorder, characterised by alternating periods of normo – and hypercortisolism.
Case report
An 18-year-old young man was followed at the Department of Growth and Reproduction due to Klinefelter and received androgen replacement since the age of 12. As he was shifted to i.m. injections his liver enzymes increased and liver damage due to androgen replacement was suspected. A liver biopsy showed steatosis and, accordingly, androgen replacement was paused. However, the medical history revealed 20 kg weight gain, abdominal striae and mental changes, leading to evaluations for CS. Initial tests showed elevated UFC levels of 213, 238 and 397 nmol/day (ref: 12–150) and borderline abnormal 1 mg dexamethasone suppression test (DST). Over the following months, equivocal test results challenged the clinicians. Repeated long DSTs were normal, UFC levels were fluctuating and, subsequently, a peripheral CRH test showed more than 50% rise in ACTH. Finally, MRI demonstrated a 5 mm hypointense mass in the pituitary gland and an inferior petrosal sinus sampling showed a pituitary-to-peripheral ACTH-response >5, which led to the diagnosis of Cushing's disease. Two years after first CS suspicion a transsphenoidal adenomectomy was performed. Unfortunately, histology did not reveal signs of an adenoma and during the following years he presented with clinical CS features. He resumed androgen replacement to rule out androgen deficiency as responsible for the symptoms, and liver function tests were unrelated to this. Repeated DSTs showed normal suppression of cortisol despite several elevated UFCs. Thus, the cyclic manifestation of Cushing's had, very likely, relapsed. The patient had side effects to all possible registered medical therapies for Cushing's and refuses another neurosurgical procedure.
Conclusions
This case illustrates how overlapping symptoms of cyclic CS and hypogonadism due to lack of androgen replacement further hamper diagnosis and management of cyclic CS.

EP1236

Accelerated sarcopenia as an initial manifestation of Cushing's disease

Lakshminarayanan Pichaipillai, Mohit Kumar, Sivatharshya Pathmanathan, Denise Tiong & Claire Higham
Department of Endocrinology, Christie Hospital, Manchester, UK.

Introduction
Cushing's syndrome usually presents with a phenotype including central obesity, striae, hypertension and diabetes. We report a case of Cushing's syndrome presenting in an atypical manner.
Case
A 73 year old lady was referred to neurology with a year's history of progressive limb wasting, weakness and recurrent falls. The neurology team diagnosed accelerated sarcopenia. Investigations included CK (normal), EMG (suggested myopathic process), nerve conduction studies (no evidence of large fibre neuropathy) and muscle biopsy (atrophic change compatible with on-going neurogenic process). She had a 4-year history of hypertension and type 2 diabetes and morning cortisol was 750 nmol/l. Clinical features included progressive weight loss, immobility, severe muscle wasting and friable skin with extensive bruising and breakdown. Endocrine investigations (18 months post initial presentation) revealed: UFC 1227 nmol/24 h, midnight salivary cortisol 45.1 nmol/l, non-suppressed cortisol following LDDST at 493 nmol/l, normal potassium and ACTH 18 ng/l. Cushing's syndrome secondary to ectopic ACTH from a malignancy was considered due to the severe clinical features. Initial MRI pituitary was normal. CT whole body showed no evidence of malignancy. Dynamic pituitary MRI revealed area of reduced signal within the pituitary-likely microadenoma. A diagnosis of Cushing's disease was made and patient was started on metyrapone. On metyrapone 1 g tds her mean cortisol on day curve done by mass spectrometry was 390 nmol/l. Antihypertensives and metformin were discontinued. Concurrent intensive physiotherapy lead to the regaining of limited mobility.
Conclusion
Cushing's disease can rarely present with severe atypical clinical features that can mimic pathology of various systems, on this occasion accelerated sarcopenia, warranting neurological investigations. It is important to consider and recognise this condition early in order to prevent extreme phenotypes, where regaining full recovery may be prolonged or unattained.

Grossly elevated plasma metanephrine levels due to midodrine, an α1 receptor agonist, in a patient presenting with postural orthostatic tachycardia syndrome

George Farah[1], Ashley Grossman[1], Abbi Lulsegged[2] & Nick Gall[2]
[1]Oxford University Hospitals NHS trust, Oxford, UK; [2]King's College Hospital NHS Foundation Trust, London, UK.

While phaeochromocytomas are rare tumours, their identification is essential to avoid morbidity and mortality; their biochemical identification is crucial. Plasma and 24 urinary metanephrines are used as first line investigations, with plasma metanephrines increasingly used first due to its simplicity and high sensitivity/specificity. False positive results, however, can be as high as 20%, particularly secondary to medications; their exclusion is essential to avoid unnecessary imaging and operation. However, most interfering factors cause elevation of less than fourfold above the normal range. In our case, we show the effect of midodrine- an α1 receptor agonist- in causing grossly elevated plasma, but not urinary, metanephrine. 41-year old lady was referred to our endocrine clinic in

Oxford with a possible phaeochromocytoma. She had 6-year history of dizziness and syncope, initially diagnosed with vasovagal syncope, but latterly diagnosed with postural orthostatic tachycardia syndrome (POTS). Her symptoms were episodes of dizziness, shortness of breath, nausea, headaches, with or without loss of consciousness. Her cardiovascular investigations showed sinus tachycardia and hypotension associated with her symptoms. As part of investigations, plasma metanephrines were assessed and were grossly abnormal: plasma metanephrine $>$ 25 000 pmol/l and normetanephrine of 1758 pmol/l. Her medications included midodrine 7.5 mg 3 h, bisoprolol and slow sodium. Doxazosin, an α1-adenoceptor antagonist, had recently been added following the above results. There was no relevant family history, and examination was unremarkable. Investigations included a repeat plasma metanephrines which showed similar results. However, 24-h urinary metanephrines, PTH, thyroid function and pituitary profile were normal, as was adrenal CT scan. Midodrine was then withheld for a week, and plasma metanephrines levels became normal. Doxazosin was subsequently stopped. Most reported drug interference with metanephrine levels cause mild to moderate elevation, due to a variety of mechanisms. We highlight the massive interference in plasma metanephrines assay by the α-adrenoceptor agonist midodrine.

Adrenal crisis due to steroid withdrawal

Muhammad Ridhwaan Salehmohamed[1,2], Martin Cuesta[1,2] & Chris Thompson[1,2]
[1]Academic Department of Endocrinology and Diabetes Metabolism, Beaumont Hospital, Dublin, Ireland; [2]Royal College of Surgeons in Ireland, RCSI, Dublin, Ireland.

Introduction
Hen corticosteroids are utilised for their anti-inflammatory properties, adreno-cortical atrophy may result. Abrupt steroid withdrawal or intercurrent illness can precipitate acute adrenal crisis. We report two cases of adrenal crisis which resulted from withdrawal of immunosuppressive steroid therapy.
Case report
i) A 74-year-old gentleman was admitted with hypotension (BP 80/40), severe hyponatremia (Na:118 mmol/l) and acute renal failure (Creat 470 mmol/l). Despite i.v. fluids, hypotension (70/46) and renal failure (Creat 610) deteriorated; dialysis was recommended. Endocrinology consultation, for hyponatremia, elicited a drug history of prednisolone 5 mg daily for rheumatoid arthritis. The patient was treated with i.v. hydrocortisone 100 mg i.v. qds, with rapid recovery of BP (134/80), and plasma sodium (137 mmol/l). Further history revealed that prednisolone had been withheld during 48 h of bowel preparation for colonoscopy, after which the patient vomited and became delirious. The patient was unaware of 'sick day rules' and had no medicalert bracelet. ii) A 76-year-old lady was admitted for knee arthroscopy. Post operatively her plasma sodium dropped from 142 to 119 mmol/l. BP fell to 102/58 mmHg. An endocrinology consult for hyponatraemia documented that she was on prednisolone 5 mg daily for rheumatoid arthritis, but had run out of tablets 3 days prior to her admission. She had no i.v. hydrocortisone cover for anaesthesia. Random cortisol was $<$30 nmol/l. A diagnosis of adrenal crisis due to steroid withdrawal was made. She rapidly responded to i.v. hydrocortisone, and plasma sodium rose to 130 mmol/l over 36 h. The patient was unaware of 'sick day rules' and had no medicalert bracelet.
Conclusion
The case studies illustrate the vulnerability to adrenal crisis in patients on long-term immunosuppressive steroid. Patients on immunosuppressive steroids should be as aware of sick day rules as endocrine patients on adrenal replacement therapy.

EP1239

A cystic lesion of the adrenal gland mimicking hydatid cyst

Faten Hadj Kacem[1], Mouna Ammar[1], Ayman Maalej[2], Nesrine Cheikrouhou[1], Nadia Charfi[1] & Mohamed Abid[1]
[1]Department of Endocrinology, Sfax, Tunisia; [2]Imaging Department, Sfax, Tunisia.

Introduction
Adrenal cystic lesions are uncommon and mostly identified incidentally during radiological investigations or at surgery for unrelated reasons. Its incidence varies between 0.064 and 0.18%. Adrenal cysts are classified as endothelial cysts, pseudocysts, epithelial cysts, and parasitic cysts.
Case report
A 45-year-old female with a past medical history of systemic hypertensive disease for 2 years, presented with recurrent abdominal pain during the last 3 months. Abdominal ultrasonography (US) showed a multicystic mass in the right adrenal region. The CT scan revealed a hypo-dense, multicystic mass measuring 6$\times$5 cm in the right adrenal bed, with slightly mural enhancing after administered with contrast medium and calcifications of the cystic wall. The pictures obtained were very evocative of hydatid cyst. Hydatid serology was negative. An adrenal evaluation was performed and was within normal limits. On the basis of these findings, surgical excision was carried out. The histopathological diagnosis was a cystic lymphangioma in the right adrenal gland.
Conclusion
Cystic adrenal lymphangiomas are very rare, benign vascular lesions. Imaging can character-ize the cystic nature of these lesions. However, it sometimes fails to establish a specific diag-nosis preoperatively. So definite diagnosis relies on Histologic and immunohistochemical examination. Lymphangiomas must be kept in mind in the clinical and radiologic differential diagnosis of cystic adrenal lesions.

Pituitary state during conservative treatment of prolactinomas

Anna Gusova
Scientific Research Institute of Neurosurgery n.a. N.N. Burdenko, Moscow, Russia.

Prolactinomas are the most common hormone-secreting pituitary tumors. They have good response for conservative treatment. In the time of diagnosis large pituitary tumors unrarely can cause hypopituitarism. We have two cases of partially or totally recovery of hypopituitarism in consequence of effective dopamine agonists use. The 24-years man with large prolactinoma (prolactin 52 times higher) and laboratory markers of panhypopituitarism had total recovery in 1 year of cabergoline treatment. The dramatic shrinkage of prolactinoma was observed and the last one was the secondary hypothyroidism which disappeared. The second case is 52 years old man with macroadenoma and ten times higher prolactin. He also has hypogonadism, secondary hypothyroidism and moderate hypocorticoidism (according to laboratory tests). Cabergoline, thyroxine and cortisone were administered. In 1 year despite of tumor shrinkage and prolactin normalisation, testosteron level was still undetected which was qualified as unreversible secondary hypogonadism and testosterone injection were administered. At the same time serum cortisol was at normal-low level and therapy was continued. In one more year the serum cortisol was even more high and the patient reported that he avoided to take cortisone with no consequence as for well-being. He also informed that after several testosterone injection in routine regimen the testosterone level was abnormally high so he discontinued the therapy. After laboratory tests gonadal function was found partially restored with testosterone level slightly lower than lower limit of normal, the level of cortisol was medium-high, but thyroid function remained impaired. Therefore, in case of large prolactin-secreting tumor which leads to hypopituitarism, there is still a chance of at least partially restoring of pituitary function when there is any positive size-dinamic. Our patients didn't have heavy symptoms of hypopituitarism (exept hypogonadism) and was instructed about frequence and expectance from laboratory testing. The thyroid function was the hardest to restore.

Pituitary apoplexy in Cushing's disease after a standard low-dose dexamethasone suppression test

Mouna Mezoued, Djamila Meskine & Amine Habouchi
Obologhine Hospital, Algiers, Algeria.

Introduction
Pituitary apoplexy is caused by an infarction or a haemorrhage in a pituitary adenoma manifesting in acute headaches, consciousness impairment, endocrine features, and moderate to severe visual loss, with chiasmal syndrome or oculomotor palsies.

Case report
We describe here a case of a 25 years old woman, followed in our institute for a Cushing disease, and who underwent a pituitary apoplexy 24 h after a standard low-dose dexamethasone suppression test. In fact our patient presented a clinical outcome of a intra cranial hypertension, made of headache, vomiting associated to a loss of visual field and oculomotor palsies. MRI demonstrated classical signs of apoplexia. Patient was treated by cortico-therapy for one week with no response, leading to a surgical management. After what we could rapidly appreciate an improvement in the visual symptoms.
Conclusion
The clinical picture of pituitary apoplexy is characterized by the sudden onset of oculomotor palsy or blindness with acute headaches and even consciousness impairment. A functional and vital risk is present because of acute hypopituitarism. This emergency diagnosis is confirmed by tomodensitometry or magnetic resonance imaging. The association of hormone substitution and tumour transsphenoidal resection commonly leads to a positive outcome and visual improvement.

DOI: 10.1530/endoabs.37.EP1241

EP1242

Hypopituitarism after miscarriage: a case report

Ana Margarida Monteiro, Marta Alves & Olinda Marques
Department of Endocrinology, Hospital de Braga, Braga, Portugal.

Introduction
Sheehan's syndrome (SS) is a cause of partial or total hypopituitarism that occurs after postpartum pituitary infarction, in the context of serious bleeding and/or hypotension. With the advancement of obstetric care, it has become a rare disease in developed countries, but its prevalence may be underestimated. Clinical presentation is dependent on the severity of hormonal deficits, is often nonspecific and many women may be asymptomatic for years. These reasons contribute to a delay in diagnosis and in treatment of a significant cause of morbidity and mortality in affected women.
Clinical case
We report a case of a 32 years old woman sent to endocrinology consultation because of hypogonadotropic hypogonadism. Past history: menarche at 11 years with regular cycles, two pregnancies, a normal delivery without complications (17 years) and a miscarriage at 8 weeks gestation (28 years). After the miscarriage, she was hospitalised with anaemia and needed blood transfusions. She's amenorrhoeic since the miscarriage. Currently, she's asymptomatic and desires another pregnancy. On physical examination, highlight for a low BMI (17 kg/m^2). Analytically, FSH 1.08 mUI/ml (2.5–10.2), LH $<$0.07 mUI/ml (1.9–12.5), oestradiol 63.89 pmol/l (71.6–529.2), TSH 1.43 μUI/ml (0.358–3.74), FT_4 0.75 ng/dl (0.76–1.46), prolactin 4.67 ng/ml (2.8–29.2), cortisol 13.6 μg/dl (4.3–22.4), ACTH 19.7 pg/ml ($<$46), somatomedin 110 ng/ml (115–307), testosterone $<$10 ng/dl (14–76), normal DHEAS and androstenedione. Insulin induced hypoglycaemia reveals normal response of cortisol and GH. Pituitary MRI revealed a concave gland with lower dimensions than expected for her age. She was treated with levothyroxine 50 μg/day and oriented to assisted reproductive consultation.
Discussion
The patient presented corresponds to a case of hypopituitarism due to probable pituitary infarction after abortion. We emphasise the importance of the evaluation of pituitary function in women with childbirth history associated with significant blood loss, even several years after the episode.

Acromegaly caused by atypical pituitary adenoma

Maria Manuel Costa[1,4], Ana Saavedra[1,4], Lígia Castro[2], Margarida Basto[5], Josué Pereira[3], Eduardo Vinha[1] & Davide Carvalho[1,4]
[1]Department of Endocrinology, Diabetes and Metabolism, Centro Hospitalar São João, Porto, Portugal; [2]Pathology, Centro Hospitalar São João, Porto, Portugal; [3]Neurosurgery, Centro Hospitalar São João, Porto, Portugal; [4]Faculty of Medicine, University of Porto, Porto, Portugal; [5]Neuroradiology, Centro Hospitalar São João, Porto, Portugal.

Introduction
Atypical pituitary adenomas have higher risk of aggressive behaviour in particular by the higher growth, local invasion and high risk of recurrence after surgery. In acromegaly the resistance to somatostatin analogues may be another manifestation of these adenomas since higher levels of Ki-67 are associated with poor response to therapy.
Case report
A 41-year-old woman presented to our consult with history of headaches, growth of the hands, hyperhidrosis, carpel tunnel syndrome and enlargement of the lips with 3 years of evolution. She also mentioned complaints of neck pain and reported an episode of visual changes that reversed spontaneously. Hormonal evaluation revealed the following alterations: IGF1 1687 μg/dl (64–336), GT basal 25.6 ng/ml ($<$8) and a lack of GH suppression to $<$1 ng/ml on oral glucose tolerance test. Pituitary MRI revealed pituitary lesion with 24 mm craniocaudal diameter and 5 mm transverse diameter with invasion of the cavernous sinus. She was submitted to transsphenoidal resection. Tumour pathology showed diffuse expression of GH, prolactin multifocal expression and absence of expression of other pituitary hormones. Ki-67 labelling index was 8%. Sparse representation of p53.
Conclusion
Atypical pituitary adenoma. The MRI repeated 3 months after surgery showed persistence of tissue attributable to residual tumour invading the right cavernous sinus. The patient began treatment with somatostatin analogues. This is a case of acromegaly with several predictors of a possible failure of response to somatostatin analogues: young age, elevated levels of GH and IGF1 at diagnosis, macroadenoma with invasive growth and Ki-67 labelling index of 8%. In the presence of cases of atypical adenomas a multidisciplinary team of endocrinologists, neurosurgeons, pathologists and oncologists must work together in attentive and personalised follow-up of the patient in order to prevent disease progression.

EP1244

Slipped upper femoral epiphysis: a rare clinical manifestation of MEN2: a case report

Laura Slattery, Jayne Doherty, Donal O'Shea, Malachi McKenna & Rachel Crowley
Department of Endocrinology, St Vincent's University Hospital, Dublin, Ireland.

Introduction
Multiple endocrine neoplasia type 2 (MEN2) comprise a group of heritable disorders that result from mutations in the RET proto-oncogene on chromosome 10. MEN2 is sub classified into MEN2A and MEN2B; these syndromes are characterised by the development of tumours at multiple sites. MEN2A is characterised by medullary thyroid cancer, phaeochromocytoma, and primary parathyroid hyperplasia.
Description/case presentation
The index case is a 49 year old female with a recent diagnosis of right phaeochromocytoma on screening for known MEN2A. Her mother had a parathyroidectomy, a partial thyroidectomy and bilateral phaeochromocytoma. The index case had a total thyroidectomy in 1980 at which time C cell hyperplasia was noted. Diagnosis was confirmed by RET oncogene mutation analysis. She has three children who are MEN2A positive and are undergoing screening. Her daughter was diagnosed with a phaeochromocytoma in 2006 with a subsequent unilateral adrenalectomy. There is also a family history of slipped upper femoral epiphysis; she had a unilateral SUFE in her teens prior to her diagnosis of MEN2A. Her daughter underwent surgery for bilateral SUFE at the age of 11 and 12. SUFE is the most common hip disorder affecting the adolescent population; there are believed to be multiple aetiological factors. In the literature, SUFE has been attributed to endocrine pathologies including hypogonadism and panhypopituitarism, deranged parathyroid hormone function and hypothyroidism. Both the index case and daughter were slim and had no history of trauma therefore atypical for SUFE.
Discussion/conclusion
We postulate that changes in parathyroid hormone or fluctuations in T_4 level in response to replacement during adolescence may have contributed to the development of SUFE in this family. Patients with MEN2A may be particularly vulnerable to this disorder because of their young age at the time of endocrine disturbance. This has not been reported previously in the literature.

Simultaneous diagnosis of Graves' hyperthyroidism and adrenal insufficiency

Ifigenia Kostoglou-Athanassiou[1], Ervin Kostakis[1], Alexandros Dermentzoglou[1] & Eleni Xanthakou[2]
[1]Department of Endocrinology, Red Cross Hospital, Athens, Greece; [2]Endocrinologist, Sparti, Greece.

Introduction
Patients with autoimmune diseases are known to develop other autoimmune conditions. Adrenal insufficiency of autoimmune etiology is known to coexist with autoimmune diabetes mellitus, Hashimoto's thyroiditis and vitiligo. However, Graves' disease in the context of adrenal insufficiency of autoimmune etiology is rare.
Aim
The aim was to describe the case of a patient who presented with fatigue and was diagnosed to have hyperthyroidism and adrenal insufficiency of autoimmune aetiology.
Case report
A patient, male aged 25 years presented with fatigue, tachycardia and weight loss. He was found to have high free T_4 levels and TSH 0.001 mU/l. Antithyroid drugs were administered. However, the patient complained of continuing fatigue and weight loss. He had dark colored skin. However, when his photos were compared to older ones it appeared that his skin had a darker color. Morning cortisol and ACTH were measured. Cortisol was found to be very low and ACTH high. Cortisol was administered along with antithyroid medications and the patient improved. TSH receptor antibodies were positive and anti-adrenal antibodies were also positive. On clinical examination as well on ultrasonography the patient had no evidence of Graves' ophthalmopathy.
Conclusions
Autoimmune diseases may coexist with other autoimmune conditions, which develop usually sequentially. However, even in young patients, the simultaneous development of more than one endocrine autoimmune conditions cannot be excluded, and it should be included in the differential diagnosis, especially if symptoms persist.

Fatigue as the presenting symptom of multiple endocrine neoplasia of type 2A

Nurdan Gul, Ayse Kubat-Uzum, Gulsah Yenidunya-Yalin, Refik Tanakol & Ferihan Aral
Division of Endocrinology, Department of Internal Medicine, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey.

Clinical spectrum of phaeochromocytoma syndromes are very heterogeneous. Sometimes life threatening hypertensive attacks may be the presenting symptom or the clinical picture may be subtle that a nonspecific symptom like fatigue can lead to diagnosis. We herein present two phaeochromocytoma cases with distinct clinical features.
Case 1
A 20-year-old female patient admitted to emergency department with blurred vision and headache. She experienced headache for 3 years and once she had a seizure and lost consciousness for 4 h. During the course blurred vision recurred and examination revealed papilledema and retinal haemorrhage. Thorax CT-angiography performed for a presumptive diagnosis of Takayasu's arteritis revealed a 3.5-cm right adrenal mass, and she was referred to our endocrinology clinic. She was hypertensive, and urinary catecholamines were very high. She had no family history of phaeochromocytoma and work-up for hereditary syndromes were negative. After preoperative preparation, she was successfully operated. Histopathological examination was compatible with phaeochromocytoma.
Case-2
30-year-old male patient was evaluated by his family physician because of fatigue. He was anxious as his father died of metastatic brain cancer. His laboratory evaluation revealed slightly elevated carcinoembryonic antigen. Endoscopic examination of the gastrointestinal tract was normal, but abdominal ultrasound showed 6-cm pancreatic and adrenal mass lesions, and MRI showed bilateral adrenal mass. His blood pressure was 130/90 mmHg. He did not have a history of hypertension, but he described occasional headaches. His urinary catecholamines were very high. Calcitonin level was 34.8 ng/ml. He underwent bilateral adrenalectomy, and pathologic examination confirmed phaeochromocytoma. RET protooncogen was positive, and total thyroidectomy revealed multifocal medullary thyroid cancer.
Conclusion
Even fatigue can be the presenting symptom of MEN2A, and clinical picture does not correlate with the extent of disease in phaeochromocytoma syndromes.

Ectopic ACTH syndrome due to a pancreatic neuroendocrine tumour: a case report

Juan Marti[1], Elena Zubillaga[1], Yenifer Bocangel[1] & Alfredo Yoldi[2]
[1]Hospital Zumarraga, Zumarraga, Spain; [2]HUD, Donosti, Spain.

The ectopic secretion of corticotropin from no pituitary tumours causes ~10–20% of cases of Cushing's syndrome. Enteropancreatic neuroendocrine carcinoma represents a rare cause of ectopic ACTH syndrome.
Case
A 51 years-old woman without past medical history was admitted by gain weight, facial oedema 4 months previous. Physical examination: BP 167/124, cardiac rate 49 bpm, facial oedema, troncular obesity. No others abnormalities. Laboratory test. Glucose 148 mg/dl. Kaliemia 2.8 mEq/l. Cortisol 102 µg/dl, FCU 4000 µg/24 h, chromogranin A 526 ng/ml, indolacétic acid 6.8 mg/24 h. Nocturnal cortisol 132 µg/dl, ACTH: 427 pg/ml. Nuggent test. Cortisol 129 µg/dl. Suppression with 8 mg of dexamethasone: cortisol basal 141 µg/dl, post 146 µg/dl, ACTH basal 577 pg/ml post 586 pg/ml. CT scan revealed a pancreatic mass of 30×20 mm and enlargement of adrenal glands. PET scan displayed abnormal accumulations of fluorodeoxyglucose in pancreatic area, distribution at multiple sites in the liver and enlargement of both adrenal glands. Surgical procedure was carry out, and large pancreatic tumour with multiples hepatic metastasis were observed. Pancreatectomy and splenectomy was carry out. Hystopatologycal study showed pancreatic neuroendocrine tumour, positive to cromogranin, sinaptofisine and CKAE1-AE3, Ki 67 up 50%, with lymph nodes and liver metastasis of neuroendocrine tumour. Surgical treatment of adrenal gland was discarded. Treatment with ketoconazole and metyrapone was initiated without improvement and mifepristone was added, lowering cortisol levels, however, outcome was unfavourable and patient died 3 months after diagnosis by respiratory distress and complications of Cushing's syndrome.
Discussion
Patients with pancreatic neuroendocrine carcinoma represent a rare cause of ectopic ACTH syndrome. A typical Cushingoid appearance is less frequent in ectopic ACTH syndrome. Treatment of ectopic ACTH syndrome is excision of the primary tumour. However, curative surgery is successful in only 30–47%. If the tumour cannot be resected, bilateral adrenalectomy offers effective permanent treatment. Medical cortisol inhibitors include ketoconazole, metyrapone.

EP1248

Bullous pemphigoid induced by vildagliptin

Bengur Taskiran[1], Bahattin Erdogan[2], Canan Solak Sisman[2] & Guven Baris Cansu[1]
[1]Yunus Emre State Hospital, Eskisehir, Turkey; [2]Eskisehir State Hospital, Eskisehir, Turkey.

Introduction
Bullous pemphigoid (BP) is an uncommon chronic, autoimmune, and subepidermal disease. It can be associated with drugs, u.v. irradiation, and X-ray therapy. There is a number of reports on bullous pemphigoid (BP) induced by DPP-IV inhibitors (vildagliptin, sitagliptin, saxagliptin). The enzyme DPP-IV degrades glucagon like peptide 1 (GLP-1), which is a potent stimulator of insulin production and secretion. DPP-IV (CD26), present as a cell surface molecule on immune cells, also plays an important costimulatory role in immune activation. We present a case of BP induced by vildagliptin.
Case report
A 59-year-old male patient who was diagnosed type 2 DM had initial HbA1c level of 12.90%. Initial therapy with premix biphasic aspart insulin bid was switched to metformin and vildagliptin 50/1000 mg combo pill bid after A1c level dropped to 5.7% at 9 months of insulin therapy, Five months after vildagliptin was started, tense vesicles 8–10 in number with an erythematous base developed over forearms and cruris. Histologic examination of lesions yielded BP. Oral antidiabetics was discontinued. He was followed up with diet alone. He did not

adhere to the therapy of oral flantadin and azathioprine and topical steroid. But the lesions regressed spontaneously after cessation of antidiabetics. Clobetasol propionate cream bid was continued. A1c was 5.7% 5 months after discontinuation of vildagliptin and metformin.

Conclusions

In the literature onset of BP lesions took 10 days to 2 years. Mostly the patients were on combo therapy with metformin. The lesions improved dramatically after cessation DPP-IV inhibitors avoiding necessity for systemic treatment for BP. Elder males predominate. This is the first case of BP induced by DPP-IV inhibitors in Turkey.

EP1249

Adjustment disorder and hypertensive episodes associated with cross-sex treatment with testosterone

Claudia Arnas-Leon[1], Francisco Javier Martinez-Martin[1,2], Carmen Acosta-Calero[1] & Esperanza Perdomo-Herrera[3]
[1]Hospital Doctor Negrin, Las Palmas De Gran Canaria, Spain; [2]Clinica San Roque, Las Palmas De Gran Canaria, Spain; [3]Cap Escaleritas, Las Palmas De Gran Canaria, Spain.

Introduction

Testosterone treatment in female-to-male transsexuals has been associated with worsened cardiovascular risk factors, acne, male-pattern baldness and more rarely with the onset of hypertension. Another frequent side effect of the treatment is aggression proneness -but rarely actual aggression- and increased libido.

Case report

We present the case of a 17-year old transsexual patient referred for initiation of testosterone treatment. A low initial dose (20 mg daily as a topical gel) elicited acne and mild transient mood changes (increased libido, occasional aggressive ideation) without blood pressure elevation. These symptoms improved after the first month. Three months later, after increasing the dose to 40 mg, the patient presented bouts of anger, aggression proneness, and coincidentally headache and hypertensive episodes. Secondary hypertension was ruled out and an ambulatory blood pressure monitoring showed blood pressure peaks up to 192/113 mmHg, with tachycardia up to 123 bpm and a mean activity blood pressure of 138/87 mm Hg. The patient was diagnosed of adjustment disorder, received short-course psychotherapy and testosterone was withdrawn. After one month, the mood disorder had abated, without new episodes of headache and hypertension. A second ambulatory blood pressure monitoring showed no hypertensive peaks with a mean activity blood pressure of 124/71 mmHg. According to the patient's wishes, low-dose testosterone treatment was reinstated with a scheduled slow dose progression; So far, the patient remains asymptomatic and normotensive.

Conclusions

Our patient suffered hypertensive episodes in the context of an adjustment disorder associated with testosterone treatment. Withdrawing testosterone resolved both the adjustment disorder and the hypertensive episodes. We consider that the increased blood pressure was not a direct consequence of testosterone, but an indirect result mediated by untoward psychological reactions of the patient.

EP1250

Submandibular ectopic thyroid with normally located thyroid gland

Mahmut Sinan Yılmaz[1], Semra Ayturk[2], Mehmet Güven[1] & Fatma Husniye Dilek[3]
[1]Department of Otolaryngology, Medical Faculty of Sakarya University, Sakarya, Turkey; [2]Department of Endocrinology and Metabolism, Trakya University Faculty of Medicine, Edirne, Turkey; [3]Department of Pathology, Medical Faculty of Sakarya University, Sakarya, Turkey.

Ectopic thyroid is a rare developmental anomaly of the thyroid gland which is defined as the presence of thyroid tissue at a site other than the pretracheal area. Nearly 1–3% of all ectopic thyroids are located in the lateral neck. Simultaneous submandibular ectopic thyroid tissue presenting with a functional orthotopic thyroid gland is extremely rare. A 37-year-old woman was admitted to our outpatient clinic with a cervical mass existing for 3 years. On physical examination, a painless, uniformly bounded, mobile, soft, nearly 3×4 cm mass was observed in the right submandibular region. A detailed systemic examination did not reveal any abnormality. Ultrasonography of the neck demonstrated a solid mass of $34\times36\times26$ mm, including cystic areas and showing significant blood flow, localized in the right submandibular region. Her thyroid gland was in a normal location and had normal parenchyma. Thyroid function tests confirmed euthyroidism and she had no anti-thyroperoxidase or antithyroglobulin antibodies. Ultrasonographyguided fine needle aspiration biopsy was non-diagnostic. Cervical magnetic resonance imaging revealed a $35\times41\times26$ mm lobulated mass showing contrast agent involvement in the right submandibular region and a normal orthotopic thyroid gland. The patient underwent excision of the submandibular mass under general anaesthesia. The histopathological examination of the mass revealed thyroid gland tissue with nodular hyperplasia. She was symptom free and euthyroid over the next year and there was no evidence of recurrence. Ectopic submandibular thyroid tissue is an extremely rare event that poses both diagnostic and management problems. However, physicians should be aware of the possibility that a submandibular mass could be ectopic thyroid tissue.

EP1251

Four osteopoikilosis cases detected in a family

Semra Ayturk[1], Ahmet Bilal Genç[2], Selcuk Yaylacı[2], Serdar Savas Gul[3], Ali Tamer[2] & Mehmet Celik[1]
[1]Department of Endocrinology, Faculty of Medicine, Trakya University, Edirne, Turkey; [2]Department of Internal Medicine, Sakarya University Educational and Research Hospital, Sakarya, Turkey; [3]Department of Nuclear Medicine, Sakarya University Educational and Research Hospital, Sakarya, Turkey.

Osteopoikilosis (OPK) is a rare benign sclerotic bone dysplasia. It is inherited in an autosomal dominant pattern. There is no exact evidence of its aetiology and pathogenesis. Usually, it is an asymptomatic disease and the diagnosis is made incidentally from radiographs which show multiple, small, well-defined, variably shaped and widely distributed sclerotic areas over the skeleton. We report a family with OPK. A 22 years old woman was admitted to outpatient clinic with complaints of right hip pain and fatigue for 2 years. Clinical examination was unremarkable. The patient did not have any other co-morbidity. Her laboratory and biochemical parameters were within normal limits. Numerous small round, symmetric sclerotic bone foci were detected at her pelvic radiographs. Similar lesions involving femoral head, acetabulum, sacroiliac joints, distal femur, proximal tibia as well as carpal and metacarpal bones were noted on detailed skeletal survey of the patient. Bone scintigraphy for whole body with Tc-99m was normal. Because of the radiological findings are diagnostic for OPK, family members were screened. We learned that the patient's mother and father had died. Four asymptomatic siblings were examined and three of them (two male and one female) were found to have OPK. A follow-up program was made for them. This disorder does not require any treatment and its complications are rare. However, there may be rarely associated bone tumors (such as osteosarcoma) that require follow-up. OPK is a diagnosis that should be kept in mind to avoid misdiagnosis, particularly with regard to cancer metastasis. OPK is a benign disease and invasive diagnostic procedures as well as aggressive treatment modalities should be avoided.

EP1252

Euthyroid Graves' ophthalmopathy in a patient with long-term amiodarone treatment

Minodora Betivoiu[1], Sorina Martin[1,2], Alexandra Nila[1] & Simona Fica[1,2]
[1]Endocrinology Department, Elias Hospital, Bucharest, Romania; [2]Endocrinology Department, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Introduction

Ophthalmopathy, the most common extrathyroidal manifestation of Graves' disease, occurs in 5% of cases in the absence of hyperthyroidism. Amiodarone, an iodine-rich antiarrhythmic drug, influences thyroid function, causing thyrotoxicosis or hypothyroidism, but its effect on thyroid autoimmunity is still a matter of debate.

Case report
We report the case of a 58-year-old woman, suffering from non-sustained ventricular tachycardia, treated inconstantly with amiodarone for 27 years. Thyroid function was normal until January 2014 when she developed amiodarone induced hypothyroidism (TSH = 24 mUI/l) with negative thyroid autoantibodies anti-Tg = 0.1 UI/ml (<4), anti-TPO = 1.0 UI/ml (<20), and substitutive therapy with L-thyroxine 50 μg/day was started. Three months later the patient stopped L-thyroxine at a TSH = 0.16 mUI/l. Subsequent evaluation in August showed normal thyroid function (TSH = 3.4 mUI/l). In October she was referred to our Department for periorbital oedema, increased tearing, diplopia, mild conjunctival injection. The laboratory tests showed euthyroidism (TSH = 3.88 mUI/l), negative anti-Tg and anti-TPO antibodies, positive TRAb = 6.8 UI/l (<1). Thyroid ultrasound was normal. The eye examination revealed a clinical activity score of 4, decreased left eye motility, vertical diplopia and Hertel exophtalmometer measurements were 15 mm on the right and 17.5 mm on the left eye. The orbital CT-scan showed thickening of the left eye inferior and medial rectus muscle. The patient was treated with six pulses of intravenous methylprednisolone, 250 mg once a week, but after the third pulse she developed symptomatic bradycardia. The cardiologist recommended to stop amiodarone. The remaining pulses were well tolerated, with improvement of the eye symptoms.
Conclusion
In our case this variable thyroid status and the occurrence of euthyroid Graves' ophthalmopathy (GO) sustain the finding that in susceptible individuals amiodarone may precipitate thyroid autoimmunity due to its cytotoxic effect with a greater release of thyroid antigens. Patients with euthyroid GO need regular follow-up, because the eye involvement may develop before the appearance of clinical or laboratory signs of hyperthyroidism.

Squamous cell thyroid carcinoma, the importance of early diagnosis and treatment

Isabel M Cornejo-Pareja[1], Silvia Maraver-Selfa[1], Jorge García-Alemán[1], M Victoria Ortega-Jiménez[2], Araceli Muñoz-Garach[1], Ana M Gómez-Pérez[1], María Molina-Vega[1], Cristina Díaz-Perdigones[1], Isabel Mancha-Doblas[1] & Francisco Jose Tinahones-Madueño[1]
[1]Department of Endocrinology and Nutrition, Virgen de la Victoria, Málaga, Spain; [2]Department of Pathological Anatomy, Virgen de la Victoria, Málaga, Spain.

Introduction
Squamous cell thyroid carcinoma is a very rare malignant epithelial tumour. It presents as rapid growth cervical mass, may affect neighbour structures and sometimes metastasizes other parts of the body. It's often associated with previous goiter history and occasionally with autoimmune thyroiditis. It can appear pure, as a component of undifferentiated carcinoma, or combined with differentiated carcinoma areas (papillary or follicular).
Case report
A 31 years old woman, with goiter family history (mother and paternal aunt). Without any previous history or cervical radiotherapy. She presented an anterocervical lump, without compressive discomfort. Physical examination: multinodular goitre (MNG) grade 2. Neck ultrasound: bilateral MNG with endothoracic projection and left prevalence with 3 cn dominant nodule. Biochemistry: TSH 1 μUI/ml. Ultrasound-guided FNA: colloid nodule with cyst formation. X-ray chest: left-extrinsic tracheal mark. Because of nodule size and endothoracic projection, we decided total thyroidectomy. Histopathology: colloid nodules with peripheral areas of squamous metaplasia, including nuclear atypia area, mitosis and p53 expression suggestive of squamous carcinoma transformation, the tumour doesn't exceed the capsule, there were no lymphatic or vascular infiltration. Extension post-surgery, we apply for a thyroid ultrasound with suggestive image of scar tissue in left thyroid bed and PET-CT was negative. Oncology Service examined our case, no adjuvant treatment was recommended. Currently, three years after surgery, the patient remains free of disease.
Conclusion
Squamous cell thyroid carcinoma is an aggressive tumour, usually lethal. It requires rapid diagnosis. The best option of treatment is radical surgery, only possible if early diagnosis, as in our case. The use of postoperative external radiotherapy or adjuvant chemotherapy should be considered because of the high rate of local recurrence of these tumours.

EP1254

A rare case of triple parathyroid adenoma with hyperparathyroidism occurring at a young age

G Gonca Oruk[1], Mehmet Haciyanli[2], Melike Bedel Koruyucu[3], Ebru Rüksen[4], Ozlem Gur[2], Cengiz Tavusbay[2], Husnu Yilmaz[1] & Baris Pamuk[1]
[1]Division of Endocrinology and Metabolism, Ataturk Training and Research Hospital, Izmir Katip Celebi University, Izmir, Turkey; [2]Department of Surgery, Ataturk Training and Research Hospital, Izmir Katip Celebi University, Izmir, Turkey; [3]Ataturk Training and Research Hospital, Ankara Yildirim Beyazit University, Ankara, Turkey; [4]Deparment of Nuclear Medicine, Ataturk Training and Research Hospital, Izmir Katip Celebi University, Izmir, Turkey.

Lesions causing primary hyperparathyroidism (PHP) can be summarised as solitary adenoma (80–85%), multiglandular hyperplasia (15%), parathyroid carcinoma (1%). While double adenomas are identified in 2–15% of the patients which are operated for PHP, triple adenomas are very rare. The case is presented because in the recent years patients who are admitted to the hospital with intense bone complaints are very unusual and multiple adenomas are also seldom. 22 years old female patient was admitted to orthopaedics outpatient clinic with symptoms of severe pain with activity and mass at proximal area of left femur. During evaluation calcium and parathyroid hormone (PTH) levels were discovered to be high. Calcium: 11.8 mg/dl, phosphorus: 2.2 mg/dl, alkaline phosphotase (ALP): 1275 U/l, PTH: 2754 pg/ml, 24 h urine calcium: 288 mg/day, BUN: 5 mg/dl, creatinine: 0.41 mg/dl, 25 (OH) D Vitamin: 3.2 μg/l. Thyroid doppler ultrasonography revealed a 20×17×7 mm mass at the right lobe of the thyroid and at the caudal region of this lesion a 13×11×9 mm mass, also a 36×22×23 mm lesion at the left lobe of the thyroid continuing to the mediastinum consistent with right and left-sided parathyroid adenomas. 20 mCi Tc-99m MIBI SPECT images demonstrated hyperdense activity only at the left side. Before the operation the patient was screened for multiple endocrine neoplasia because of her young age, results were negative. After the operation three parathyroid adenomas were discovered and PTH and calcium levels regressed to 10 pg/ml and 8.4 mg/dl respectively. Usually PHP is expected to occur at later stages of life, but PHP should also be kept in mind in patients with serious bone complaints, high calcium and PTH levels. Early diagnosis and appropriate treatment can be prevent morbidity and mortality related with PHP.

DOI: 10.1530/endoabs.37.EP1254

EP1255

A case of Gitelman syndrome with normomagnesemia: do detailed history and basic laboratory tests provide correct diagnosis?

Yumi Harano, Yurika Akiyama, Kazufumi Honda & Hiroko Arioka
St Luke's Medical Center, Tokyo, Japan.

Introduction
Gitelman syndrome (GS) is autosomal recessive disorder, characterised by hypokalemia, hypomagnesemia, metabolic alkalosis and low urinary calcium excretion. We report a case with final diagnosis of GS using the DNA analysis, presented with severe hypokalemia but normomagnesemia.
Case report
A 47-year-old Japanese male presented to our hospital because of severe hypokalemia in the annual health check-up. Severe hypokalemia was pointed out in the previous check-up, but he was reluctant to be investigated. He was totally asymptomatic and had no history of muscle weakness, palpitation and syncope. He denied the use of any medication including laxative and diuretics. He was normotensive and no growth retardation. The laboratory test revealed that the serum potassium was 1.7 mEq/l but he had no hypomagnesemia. His 24 h-urinary calcium excretion, 75 mg/day, was not so impaired. We analysed his genetic mutation by direct DNA sequencing. As a result, he had two genetic mutations on SLC12A3 which encoded the thiazide-sensitive NaCl cotransporter. These genetic mutations are found in the majority of GS patients. We established a final diagnosis of GS based on his history and genetic mutations.
Discussion and conclusion
To make a diagnosis of GS, many aetiologies should be excluded. Especially, Bartter syndrome is an important genetic disorder to distinguish. Especially, type III Bartter syndrome has similar features with GS, adult-onset, no growth retardation, preserved renal function and similar electrolyte abnormalities. To evaluate serum magnesium and urinary calcium excretion were important for the differential diagnosis. In this case, the serum magnesium was normal and urinary calcium excretion was not decreased. This case didn't have classical features

of GS. To identify the genetic mutation is very important to establish a diagnosis of GS. When the laboratory findings are not typical for GS, direct DNA sequencing can be useful test to distinguish with Bartter syndrome.

EP1256

Clinical features and surgical approach of thyroid pathology in patients over 65 years

Mihai Radu Diaconescu[1], Ioan Costea[1], Mihai Glod[1], Mirela Grigorovici[1] & Smaranda Diaconescu[2]
[1]IVth Surgical Clinic. 'Gr T Popa' University of Medicine and Pharmacy, Iasi, Romania; [2]Vth Pediatric Clinic 'Gr T Popa' University of Medicine And Pharmacy, Iasi, Romania.

Introduction
The significant increase in the average lifespan of the general population lead to a proportional enhancement in the prevalence of benign and malignant thyroid conditions and equally the number of surgeries for this pathology.
Patients and method
In a personal series of 464 thyroid disorders undergoing surgery over two decades we recorded 51 patients (21.5%) aged over 65 years of which 11 (2.4%) having over 75 years. Demographic, clinical and diagnostic characteristics of these cases were together with indications, management practice and outcome.
Results
There have been recorded 33 females and 18 males ($R=1/1$) with clinically, laboratory and histologically confirmed diagnosis in which were 22 (multi) nodular goitres (47%) among 16 six plunging goitres some with compressive phenomena, 18 (35.2%) – two Basedow diseases, nine multinodular toxic goitres and seven toxic adenomas and also nine thyroid carcinomas (17.6%) of which six were differentiated and three anaplastic tumours. Thirty-four total or near-total thyroidectomies of which three with cervical lymphadectomy and 17 conservative exercises were performed. There were not postoperative deaths but we recorded two cases each of prolonged hypocalcaemias, recurrent laryngeal nerve paresis and one recurrence. In all benign cases we obtained a stable in time cure while in obtained in four papillary tumours.
Discussions
Our series as well as literature data emphasises out of increased prevalence of thyroid geriatric disorders underling peculiarities related of sometimes delayed occurrence and prolonged evolution, atypical or imprecise symptomatology with less conclusive bioassays, coexistence of burdensome comorbidity all of them with direct consequences of a possible surgical sanction. In terms of clinical and lesional aspects outside thyroid nodules and especially micro-nodules that can accommodate any substrate, hyperthyroidism are more often (multi)nodular and they have mostly atypical manifestations, ophthalmopathy and hyperkinetic syndrome being sometimes replaced by an 'apathetic' presentation with weight loss and predominantly cardiovascular syndrome j arrhythmia and cardiac failure. Finally thyroid carcinomas have increased aggressiveness, accelerated evolution, higher incidence of anaplastic forms. Principles of thyroid surgery in the elderly are the same with those adopted at younger ages also taking into account the pathological load of the subjects and its mandatory preoperative correction.
Conclusions
Despite some difficulties in diagnostic and additional risks related to comorbidity benign and malignant pathology installed in patients over 65 years, may benefit of all types of conservative or radical thyroidectomies in terms of strict monitoring individualised in each case.

DOI: 10.1530/endoabs.37.EP1256

EP1257

Incidental papilar carcinoma and large goitre in extremely obese patient with excessive daytime sleepiness

Milina Tancic-Gajic[1], Svetlana Vujovic[1], Miodrag Vukcevic[2], Miomira Ivovic[1], Ljiljana Marina[1], Zorana Arizanovic[1] & Dragan Micic[1]
[1]Faculty of Medicine, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, University of Belgrade, Belgrade, Serbia; [2]Faculty of Medicine, University Clinical Hospital Center Bezanijska Kosa, University of Belgrade, Belgrade, Serbia.

Introduction
In adults, the most common cause of obstructive sleep apnoea is obesity. Other causes are anatomical craniofacial bony abnormalities, neurologic syndromes, alcohol and sedatives use, hypothyroidism, acromegaly and rarely thyroid goitre. Untreated obstructive sleep apnoea can lead to serious complications, including cardiovascular diseases, accidents, and premature death.
Case report
A 56-year-old patient was referred to a pulmologist due to excessive daytime sleepiness. Patient has primary hypothyroidism adequately treated with a constant daily dose of levothyroxine (L-T_4). The scores for the Epworth sleepiness scale was 18. The severe obstructive sleep apnoea (OSA) was confirmed by polisomnography (Respironics Alice 5): apnoea-hypopnea index (AHI) was 32.6/h. Spirometry showed a restrictive pattern related to obesity. Due to primary hypothyroidism and obesity examination by an endocrinologist was advised. Patient was extremely obese - BMI 45.3 kg/m^2 with neck of 50 cm in circumference and large goitre. Ultrasonography of the neck revealed a large goitre with significant retrosternal propagation and some thyroid nodules. Volume of the right lobe was 120 ml, whereas the volume of the left one was 92 ml with a tracheal compression. Due to large goitre a total thyroidectomy was conducted. Pathohistology report was showed chronic lymphocytic thyroiditis and papilar carcinoma with diameter of 1.8 cm in the left lobe. The patient postoperatively received therapeutic dose (3.7 GBq) of ^{131}I. There were no significant changes of the patient's weight. Six months after the surgery polysomnography was repeated. A mild form of OSA (AHI 12.3/h) was present.
Conclusion
Thyroid cancer coincided with large goitre which was an additional cause together with extreme obesity for OSA. In obese patients with excessive daytime sleepiness, additional endocrine causes of OSA should be considered.

A rare cause of syndrome of inappropriate antidiuretic hormone

Mutlu Niyazoglu[1], Esra Hatipoglu[2], Burcugul Kaya[1] & Sadi Gundogdu[3]
[1]Division of Endocrinology, Department of Internal Medicine, Istanbul Research Hospital, Istanbul, Turkey;
[2]Division of Endocrinology, Department of Internal Medicine, Edirne Government Hospital, Edirne, Turkey; [3]Division of Endocrinology and Metabolism, Department of Internal Medicine, Cerrahpasa Medical School, University of Istanbul, Istanbul, Turkey.

Introduction
Acute intermittent porphyria (AIP) is an autosomal dominant disorder resulting from partial deficiency of the haeme biosynthetic enzyme porphobilinogen deaminase.
Case report
A 17-year-old female presented with progressive abdominal pain. She had history of recurrent abdominal pain and darkening in urine colour. She was on lansoprazol and metaclopramide, initiated 2 days earlier. She did not have additional personal or relevant family history. Physical examination did not reveal any pathologic finding.
Laboratory findings were as following: glucose: 84 mg/dl (N: 74–106), urea: 14 mg/dl (N: 17–43), creatinin: 0.6 mg/dl (N: 0.5–0.9), sodium: 103 mmol/l (N: 136–146), potasium: 3.6 mmol/l (N: 3.55.1), chloride: 76 mmol/l (N:101109), ALT: 21 U/l (N: 035), CK: 281 U/l (N: 0145), triglyceride: 46 mg/dl (N: 0–150), total protein: 6.9 g/dl (N: 6.6–8.3). In urine sediment erythrocyte was 11 p/Hpf (N: 0–2), leucocyte was 60 p/Hpf (N: 0–2), and nitrite was (+). Search for euvolemic hyponatraemia was initiated. Sodium in spot urine was 95 mmol/l, urine osmolarity was 490 mOsm/kg and plasma osmolarity was 230 mOsm/kg. TSH was 3.1 IU/ml (N: 0.3–5.6) and basal morning cortisol level was 34 μg/dl (N: 6.7–22.6). She was diagnosed with syndrome of inappropriate ADH. Plasma Na level was gradually increased up to 133 mmol/l with infusion of %0.3 NaCl solution. Chest X ray, cranial MRI and abdominal ultrasonography did not reveal any abnormality. Based on her history of periodic abdominal pain and dark urine porphyria was suspected. Porphoblinogen in 24-h urine sample was 19.7 mg/24 h (N: 0–1.6) and total porphyrin was 646 μg/24 h (N: 0–100). She did not have any cutaneous lesions. With the laboratory findings and her personal history she was diagnosed with inappropriate ADH syndrome secondary to AIP. The acute attack of AIP was taken under control with glucose loading and antibiotherapy for urinary tract infection.
Conclusion
It is important not only to treat syndrome of inappropriate ADH, but also to address any underlying condition. Diagnosis and management of AIP can be challenging and close monitoring for complications is needed.

Introduction
High-resolution ultrasound (US) allows the location of large parathyroid adenomas. These tumours should be however differentiated from thyroid nodules. For the confirmation of the parathyroid adenoma, we propose US-guided fine-needle aspiration biopsy (FNAB) of suspected nodules, with additional parathyroid hormone (PTH) analysis in the washout of the aspirate (PTH-FNA).
Case report
A 51-year old woman with recently installed menopause and a history of kidney lithiasis and fragility fractures attended our hospital for the investigation of a multinodular goitre. The measurement of bone mineral density assessed by dual X ray absorptiometry showed that the patient was severely osteoporotic, with lowest score on distal 1/3rd of the radius. Despite the presence of complications, the high PTH level (281 pg/ml) was accompanied by only marginally increased serum calcium (10.1 mg/dl). This discrepancy may be explained by the co-existence of D hypovitaminosis (11 ng/ml). Ultrasound investigation revealed the presence of a multinodular goitre containing five nodules, one of them showing features suggestive for a large parathyroid adenoma. We measured high PTH levels only in the FNAB washout from the suspected parathyroid adenoma, but not in that extracted from the largest of the other thyroid nodules. The patient was submitted to total thyroidectomy due to compressive complaints and excision of the parathyroid adenoma. Immediately after surgical intervention, the PTH levels normalised. Histology confirmed pre-surgical localization of the parathyroid adenoma and revealed that one of the thyroid nodules contained an *in situ* papillary carcinoma.
Conclusion
PTH-FNA is a reliable and possibly a more accurate and faster method than additional imaging techniques to localise a large parathyroid adenoma in patients with concomitant thyroid nodules.

Hypercoagulable state: an evidence of linkage with hyperthyroidism

Kunjang Sherpa, Robin Maskey, Prahlad Karki, Deebya Raj Mishra, Denish Peeyush & Naveen Pandey
B.P. Koirala Institute of Health Sciences, Dharan, Nepal.

Introduction
Hyperthyroidism is not a widely recognised association with Venous thromboembolism (VTE). However, Several previous studies suggest that hyperthyroidism represent a potential hypercoagulable and hypofibrinolytic state, which may contribute to the increased risk of thromboembolism.
Case report
A 39-year-old lady presented with Swelling over bilateral lower limbs for 1 month, Palpitation for 1 month. She had history of swelling over neck for last 13 years and protrusion of bilateral eye for 13 years, history of increased sweating, anxiety, and weight loss of about 10 kg in last 6 months. On examination patient had staring appearance, atrial fibrillation, She also had pallor, bilateral exophthalmos ('NO SPECS'-2), Diffuse goiter bilateral and non pitting pedal edema with hyperpigmented plaques over dorsum of leg and foot. Investigation revealed thyroid function test- TSH = <0.05 mIU/l, $fT_3 = 29.8$ pmol/l, $fT_4 = >100$ pmol/l and anaemia (haemoglobin of 9 mg/dl). Venous Doppler ultrasound (USG) revealed presence of an echogenic thrombus in bilateral lower limb extending into femoral vein in right side and up to popliteal vein in left side and USG neck showed diffusely enlarged thyroid gland with heterogenous echotexture with increased vascularity. The patient was treated with antithyroid drugs,anticoagulants, and β-blockers. The patient improved clinically with normalization of thyroid function.

Taken with permission

Conclusion
Our case report reinforces the available evidence on the possible role of overt hyperthyroidism as VTE risk factor. It seems worthwhile to measure thyroid hormones in patients with unprovoked venous thromboembolic event and in contrarily the diagnosis of venous thromboembolism should be considered in patients with hyperthyroidism, particularly if additional prothrombotic risk factors are present.

Atypical subacute thyroiditis

Guzin Fidan Yaylali[1], Zeynep Dundar Ok[2], Mehmet Sercan Erturk[1], Fulya Akin[1] & Senay Topsakal[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Pamukkale University, Denizli, Turkey; [2]Department of Internal Medicine, Faculty of Medicine, Pamukkale University, Denizli, Turkey.

Introduction
A diagnosis of subacute thyroiditis (SAT) is readily suspected when patients present with a particular set of typical clinical and laboratory characteristics. We present a patient with atypical SAT who had no neck pain but presented with fever, and weight loss; had thyrotoxicosis with normal 99mTc uptake, and needed higher doses of steroids to resolve.
Case report
A 57-year-old man presented with a fever (39 °C) of 2 month-duration. Physical examination was unremarkable. Laboratory analysis revealed WBC: 10 550 K/ul, hemoglobin: 10 g/dl, erythrocyte sedimentation rate: 102 mm/h, C-reactive protein: 17 (<0.5) and normal renal, hepatic function tests. Hepatitis and human immunodeficiency virus serologies were negative. Toxoplasmosis, Epstein-Barr virus, and cytomegalovirus IgM and IgG titers were negative. Blood and urine cultures were also negative. Serum protein electrophoresis showed no abnormality compatible with multiple myeloma. Computed tomography of the neck, thorax and abdomen showed jugular, mediastinal, parailiac and retroperitoneal lymph nodes in nonpathological size. Biopsy of a lymph node showed lymphoid hyperplasia. Transthoracic echocardiography did not show any finding compatible with infective endocarditis. TSH: 0.412 IU/ml (0.2–4.2), fT_3: 14 pg/ml (2.8–4.3), fT_4: 0.9 ng/dl (1.04–1.65), anti-TPO: 16 (0–34), anti-TG: 32 IU/ml (0–115), TSH receptor antibody: 0.4 U/l (<1.8), thyroglobulin: 14 ng/ml (0.83–68). Thyroid ultrasonography did not show any nodules. Thyroid scintigraphy showed normo-active, diffuse hyperplastic thyroid gland. Methimazole and propranolol were initiated. But his fever did not resolve until 60 mg of methylprednisolone was given with the diagnosis of SAT. After steroid treatment, fT_3 levels decreased which had increased previously with methimazol.
Conclusion
This case presented atypically in that he had no neck pain but was diagnosed with SAT while being worked up for the fever of unknown origin. Interestingly, he had normo-active thyroid gland and his fT_3 levels increased to very high levels in disproportion to his fT_4 levels. Higher doses of steroids were needed to resolve his fever and normalize his fT_3 levels. This report illustrates that the diagnosis and treatment of SAT can sometimes be difficult.

New treatments of diabetes: a promising alternative to bariatric surgery in obese patients

M Mar Roca-Rodríguez, Isabel Mancha-Doblas, M José Picón-César, Ana María Gómez-Pérez, Isabel Cornejo-Pareja, María Molina-Vega, Cristina Díaz-Perdigones, Gabriel Olveira-Fuster & Francisco J Tinahones
Department of Endocrinology, Virgen de la Victoria and Regional Hospitals, Malaga, Spain.

Introduction
New treatments of diabetes improve global metabolic status beyond glycemic control and achieve weight reduction in many patients.
Case reports
We described four case reports to show GLP-1 agonists and dapaglifozin effects on metabolism and weight in patients with type 2 diabetes and obesity.
Case 1 (Liraglutide)
A 48-year-old man, hypertension, type 2 diabetes and extreme obesity. Baseline visit: treatment enalapril 20, acetylsalicylic acid 100, metformin 850. Weight 191 kg, BMI 60.9 and HbA1c 6.6%. After 4 months under treatment with liraglutide: weight 158 kg, BMI 50.4 and HbA1c 5.3%.
Case 2 (Exenatide lar)
A 58-year-old man, type 2 diabetes and extreme obesity. Baseline visit: weight 141 kg, BMI 50 and HbA1c 6.7%. After 4 months under treatment with metformin 850 and exenatide lar: weight 133 kg, BMI 47 and HbA1c 6%. After 10 months under treatment with metformin 850 and exenatide lar: weight 127 kg, BMI 44.9 and HbA1c 5.5%.
Case 3 (Lixisenatide)
A 52-year-old woman, hypertension, type 2 diabetes and extreme obesity. Baseline visit: treatment metformin 850, simvastatin 20, losartan 100, atenolol 50. Weight 138 kg, BMI 55.4 and HbA1c 9%. After 4 months under treatment with metformin 850 and lixisenatide: weight 133 kg, BMI 47 and HbA1c 6%. After 10 months under treatment with metformin 850 and lixisenatide: weight 125 kg, BMI 48.8 and HbA1c 5.7%.
Case 4 (Dapaglifozin)
A 64-year-old man, type 2 diabetes, dyslipidaemia and grade 1 obesity. Baseline visit: treatment metformin 850 and simvastatin 40. Weight 106 kg, BMI 34.2 and HbA1c 8.8%. After 5 months under treatment with dapaglifozin: weight 93.6 kg, BMI 31.8 and HbA1c 6.6%.
Conclusion
GLP-1 agonists and dapaglifozin got ssignificant improvement of anthropometric parameters and glycaemic control in patients with type 2 diabetes and obesity. They were safety and well tolerated, and could represent a promising alternative to bariatric surgery.

EP1263

Graves' disease in a mediastinal mass presenting after total thyroidectomy for nontoxic multinodular goitre

Filipe Cunha[1,2], Elisabete Rodrigues[1,2], Joana Oliveira[1,2], Luís Vinhas[3] & Davide Carvalho[1,2]
[1]Serviço Endocrinologia, Diabetes e Metabolismo do Centro Hospitalar São João, Porto, Portugal; [2]Faculdade de Medicina da Universidade do Porto, Porto, Portugal; [3]Serviço de Cirurgia Geral do Centro Hospitalar São João, Porto, Portugal.

Introduction
Thyrotoxicosis after total thyroidectomy (TT) is mostly iatrogenic. Rarely, an hyperfunctional thyroid remnant or ectopic tissue may be the cause. We report a case of Graves's disease in a mediastinal thyroid mass presenting 7 years after TT for nontoxic goitre.
Case report
A 67-year-old woman presented with palpitations, fatigue and weight loss. She had a history of TT for nontoxic multinodular goitre at the age of 60 without any signs of malignancy on microscopic examination. She was medicated with levothyroxine 100 μg/day since the surgery without follow-up. She was tachycardic and had no cervical mass nor eye involvement. The TSH levels were suppressed (0.000 μU/ml) and the free T_4 (3.22 ng/dl) and free T_3 (8.46 pg/ml) increased. No mediastinal enlargement nor trachea deviation on chest roentgenogram. Levothyroxine treatment was stopped but patient showed no improvement on free T_4 or free T_3 10 days later. Thyroglobulin was increased: 294 mg/ml. Cervical ultrasound revealed no thyroid remnant. Anti-TSH receptor antibodies were high (19.7 U/l). Corporal scintigraphy demonstrated increased intrathoracic radioiodine uptake. CT scan confirmed a 60×40 mm mediastinal mass. Methimazole 10 mg/day was started. Three months later her thyroid function was normal and she was submitted to surgical resection. Microscopic examination showed thyroid tissue with no signs of malignancy.
Conclusions
Although thyrotoxicosis after TT is mostly due to excessive supplementation, true hyperthyroidism may be the cause. The presence of thyroid tissue after TT in our patient may correspond to a remnant or an ectopic thyroid tissue that became hyperfunctional in the presence of anti-TSH receptor antibodies.

Severe hyponatremia in the course of autoimmune polyglandular syndrome type 2 of atypical clinical picture

Maria Kurowska, Joanna Malicka, Jerzy & Stanisław Tarach
Department of Endocrinology, Medical University, Lublin, Poland.

Introduction
Severe hyponatremia defined as the blood sodium concentration below 115 mmol/l is rarely recognised in the course of autoimmune polyglandular syndrome type 2 (APS t.2). The aim of the paper is to present the female patient with severe hyponatremia preceding the diagnosis of APS t.2 of atypical clinical picture.
Case report
A 54-year-old woman with the diagnosis of psoriasis established 10 years earlier and treated for psoriatic arthritis from 7 years. She was admitted to the emergency ward because of persistent vomiting, hyponatremia = 111 mmol/l and hyperkaliemia = 5.4 mmol/l. For several months she observed increasing fatigue, hypotension, recurrent abdominal pain, loose stools, increased appetite for salt, progressive darkening of the skin and weight loss of 12 kg/6 months. Her ACTH level was 857.3 pg/ml; blood cortisol in the morning was: 3.7; 1.6 μg/dl and in the evening: 2.7, 1.7 μg/dl. Lack of adrenal response after stimulation with Synacthen and normal adrenal CT image were confirmed. 21-hydroxylase autoantibodies were negative (1: <10). FT_4-32.2 pmol/l; FT_3-16.2 pmol/l; TSH <0.004 mIU/l. Antibodies antiTPO-4659 U/ml; antiTG-391 U/ml, TRAb-1.8 U/ml. USG revealed 12 ml thyroid gland with numerous, hypoechogenic, small (4 mm) areas in both lobes. The diagnosis of primary adrenal insufficiency with concomitant autoimmune thyroid disease with hyperthyroidism in a patient with psoriatic arthritis was established. Summary. Psoriatic arthritis and thyroid disease with thyrotoxicosis are rare components of APS type 2 and hyponatremia occurs more frequently in patients with concomitant hypothyroidism.
Conclusion
Severe hyponatremia in our patient could be the result of a significant increase in demand for cortisol caused by thyrotoxicosis and the lack of opportunity to increase its production by the adrenal cortex.

EP1265

Diabetes mellitus in a patient with Leri–Weill dyschondrosteosis

Didem Ozdemir[1], Sefika Burcak Polat[1], Nagihan Bestepe[1], Saliha Ozbek[2], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Department of Endocrinology and Metabolism, School of Medicine, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey; [2]Department of Internal Medicine, Endocrinology and Metabolism, School of Medicine, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey.

Introduction
Leri–Weill dyschondrosteosis (LWD) is a rare autosomal dominant dyschondrosteosis characterised by Madelung deformity and mesomelic dwarfism. Majority of cases are associated with haploinsufficiency of the short-stature homeobox-containing (SHOX) gene. Here we report a patient with LWD and diabetes mellitus (DM).
Case report
A 31 years old man applied with polyuria and polydipsia. He did not have any chronic disease. In family history, father had type 1 and mother had type 2 DM. His height was 146 cm and weight was 62 kg, with a BMI of 29.1 kg/m^2.

Laboratory investigation revealed a fasting blood glucose of 298 mg/dl, HbA1c 13.4%, insulin 8 μU/ml (2.6–24.9), C-peptide 1.65 ng/ml (0.1–3.6). AntiGAD, anti-insulin and islet-cell antibodies were negative. Intensive insulin treatment was started. The result of genetic analysis made to determine cause of short stature about 1.5 years ago was 45,X,-Y[5]/46,X,der(Y)t(Y;Y)(p11.2;q11.21). There was deletion in the SHOX gene of Y chromosome. He had bilateral Madelung deformity which is an epiphyseal growth plate disturbance characterized by shortened and bowed radii and ulnae leading to dorsal dislocation of the distal ulna. Thus, he was diagnosed to have LWD.
Conclusion
Haploinsufficiency of the SHOX gene which is located on the pseudoautosomal region of both the X- and Y-chromosomes is a cause of short stature in various clinical conditions including LWD. There are previous reports indicating inverse association between height and diabetes, and showing increased prevalance of gestational DM in patients with short stature. In the literature, clinical features of LWD is limited to skeletal anomalies and short stature. This is the first report of DM in a patient with this syndrome. Although, it is probable that this might be just a coincidence, we think possible association between impaired glucose metabolism and syndromes related with short stature needs further investigation.

EP1266

Hyponatraemic encephalopathy induced by single dose of indapamide

Naik Haya & Karim Noordally
Eastbourne Hospital, East Sussex, UK.

Introduction
Hyponatraemia is the most common of electrolyte abnormalities. There are numerous factors which may directly cause or contribute to hyponatraemia, including dehydration, concomitant cardiac/hepatic/renal disease, and certain medications, such as diuretics. Hyponatraemia may cause a range of symptoms, depending on the speed and severity of the deficiency. Mild hyponatraemia (>115 mmol/l), can causes malaise, nausea and vomiting. Significant hyponatraemia, $[Na^+]<115$ mmol/l, manifests with confusion, seizures, and ultimately coma. Chronic, 'asymptomatic' hyponatraemia has been shown to cause gait disturbances, falls and neurocognitive impairment.
Case
A 76-year-old lady was brought into A&E, having been found collapsed at home. GCS was 6/15.She was confused and agitated. She was euvolaemic, and had normal blood glucose. CT-head showed no acute intracranial abnormality. Laboratory work up showed a profound hyponatraemia, Na^+108. Prior to this admission, her sodium levels were within normal ranges. Full-body CT scan, which showed no neoplastic cause for her hyponatrameia. Her past medical history also included asthma, IHD, and primary hypothyroidism. She was smoker, although she denied any new respiratory symptoms, or weight loss. She reported having commenced indapamide for hypertension one day prior to presentation.
Laboratory work
$K+4.2$ mmol/l; corrected calcium 2.13 mmol/l, TSH 9.9 mU/l, FT_4 18 pmol/l. Her urinary osmolality was 475 mOsm/kg; urinary $[Na^+]$ was 27; serum osmolality, 236, serum cortisol was 761 nmol/l. Indapamide was stopped and she was put onto fluid restriction, with a strict input/output chart. She had regular $[Na^+]$ checks, which showed gradual improvement in the hyponatraemia: 108 mmol/l on day 0, 111 mmol/l on D1, 120 mmol/l on D2, 127 mmol/l on D3. She was notably less confused and agitated on discharge, and, when reviewed in clinic a 4 weeks later, her symptoms had resolved entirely. More recent biochemistry shows normal sodium.
Conclusion
Diuretics are associated with hyponatraemia. However this is the first reported case of hyponatraemia and encephalopathy after single dose of indapamide.

EP1267

Noninfectious but genetic bilateral neck swelling

Capraro Joel, Nagel Wolfgang, Clerici Thomas, Stöckli Sandro, Brändle Michael & Bilz Stefan
Kantonsspital St.Gallen, St.Gallen, Switzerland.

Introduction
We describe a case of a 32 year old woman with bilateral carotid body tumours as initial finding of a paraganglioma syndrome type 1.
Case
A 32-year old previously healthy mother was referred because of bilateral neck swelling, presumably lymphadenopathy, associated with recurrent upper respiratory tract infections during the past year. Cervical ultrasound raised the suspicion for bilateral carotid body tumours which were confirmed by MR-imaging and a subsequent DOPA-PET-CT, which showed no evidence for multifocality or metastases. Plasma metanephrines including methoxytyramine were within the normal range and although a family history was negative, the genetic work-up revealed a SDHD mutation (paraganglioma syndrome typ 1). Because of mass effects and the patients wish, resection of the right sided tumour has been scheduled.
Discussion:
HNPGLs are rare tumours (incidence 1:30 000 – 100 000) derived from extraadrenal chromaffin cells and 95% arise from the parasympathic nervous system, typically the carotid body (glomus caroticum), jugular bulb (glomus jugulare) and different branches of the vagal nerve (glomus vagale, glomus typanicum). Plasma methoxytyramine may be elevated (1/3 of cases), normally they are clinically nonsecretory and present because of their mass effects. Around 35% are associated with a genetic defect, with SDHD-mutations accounting for $>50\%$, SDHB for 20–35% and SDHC for 15% (extraordinary SDHAF2). The inheritance pattern is autosomal dominant for SDHx mutations, but in SDHD and SDHAF2 maternal imprinting is postulated. Malignancy is rare (3.5%) although metastases occur up to 20 years after initial diagnosis. Staging is performed by functional imaging with ^{18}F-DOPA- or ^{68}Ga-DOTATATE-PET-CT, anatomical imaging with CT and/or MRI gives a better locoregional resolution. Surgical resection may be associated with significant morbidity especially caudal cranial nerve injury. Radionuclid-therapy or radiotherapy/-surgery must be evaluated as alternatives. Genetic counselling and testing is mandatory due to the high rate of germline mutations and familial disease.

EP1268

Hypercalcaemia; a silent indolent course?

Ruth Casey, Larissa Higgins, Aoife Lowery, Michael Kerin & Conal Dennedy
Galway University Hospital, Galway, Ireland.

A 83-year-old lady presented to hospital with a one week history of malaise, dyspnoea and chest pain. Her admission bloods revealed a markedly elevated calcium of 4.16 mmol/l. Further investigations revealed a PTH of >5000 ng/l. Clinically the patient had poor dentition which had developed over the past 3 years and a history of episodic abdominal pain and constipation. For investigation of primary hyperparathyroidism, she had an ultrasound neck, which revealed an enlarged 8 cm left parathyroid gland. She was initially managed with intravenous bisphosphonate, i.v. fluids and i.v. furosemide, once intravascularly volume replete. As part of her initial workup, she underwent a CT pulmonary angiogram. This revealed acute subsegmental pulmonary emboli, a cystic pancreatic lesion, sequelae of previous pancreatitis, nephrolithiasis and possible medullary sponge kidney. Swift surgical referral was sought because of concern of possible parathyroid carcinoma. Once her calcium was optimised and the patient was medically fit, a minimally invasive parathyroidectomy was carried out. Surgical dissection included a sliver of the left thyroid lobe to ensure clear surgical margins with the aforementioned suspicion of a parathyroid carcinoma. The high risk of hungry bones was anticipated and the patient was given vitamin D by intramuscular injection pre operatively and a bed was booked in the high dependency unit post operatively to facilitate an arterial line and frequent close monitoring of ioinsed calcium levels. Fortunately the patient only required four intravenous infusions of calcium. Within five days of her surgery the patient was discharged. The histology revealed a parathyroid adenoma with no suspicious or mitotic features. This case acts a reminder that although primary hyperparathyroidism is often considered a benign entity, life-threatening hypercalcaemia can develop and requires urgent management. It highlights the multi-systemic sequelae that can occur with chronic hypercalcemia and reminds us that parathyroid carcinoma although rare, must always be considered when markedly elevated levels of parathyroid hormone and hypercalcaemia are encountered.

The association between Graves' disease and thyroid cancer: coincidence or causality? Case report

Stefana Bilha[1,2], Ionut Repede[3], Alina Gatu[1,2], Radu Danila[4], Cristian Velicescu[4], Voichita Mogos[1,2] & Dumitru D Branisteanu[1,2]
[1]Endocrinology Clinic, 'Sf. Spiridon' Clinical Emergency Hospital, Iasi, Romania; [2]Department of Endocrinology, University of Medicine and Pharmacy 'Gr. T. Popa', Iasi, Romania; [3]Department of Endocrinology, 'Sf. Pantelimon' Hospital, Focsani, Romania; [4]Surgery Clinic III, 'Sf. Spiridon' Clinical Emergency Hospital, Iasi, Romania.

Introduction
Graves' disease (GD) has been related to a higher incidence of thyroid cancer. Thyroid nodules found in GD seem to have a higher risk for malignancy. The prognosis of thyroid cancer may be aggravated by the association with GD.
Case report
We present the case of N.I, a 56-year-old woman diagnosed with multinodular goitre and overt hyperthyroidism for which therapy with carbimazole 40 mg/day was started. She was referred to our Endocrinology Department 2 months later for follow-up. She complained of important weight loss, palpitations, fatigability and recent swelling of the neck. Clinical examination revealed a painless large goitre and mild exophthalmia. Laboratory findings still showed subclinical hyperthyroidism (TSH = 0.013 μUI/ml – normal range 0.4–4 and FT_4 = 0.957 ng/dl – normal range 0.89–1.76). TSH antibodies (TSAb) were present in high titres and GD diagnosis was established. Thyroid ultrasound revealed a large conglomerate mass with microcalcifications in the left lobe on the background of a hypoechoic, hypervascular goitre. FNAB from the nodule revealed cytology highly suspicious of malignancy. Total thyroidectomy was performed and histopathology report showed invasive papillary thyroid carcinoma follicular variant and typical findings of GD. After surgery, the patient underwent radioactive iodine (^{131}I) therapy. The post-therapy whole-body radioiodine scan showed remnant thyroid tissue and multiple iodine-avid lung metastases. Thyroglobulin levels remained abnormally elevated, making the patient a candidate for an additional radioactive iodine administration.
Conclusions
This is a rare case of simultaneously diagnosed GD and thyroid carcinoma. The tumour had a rather invasive and aggressive phenotype, in contrast to histopathology and in accordance with studies proposing GD as a negative prognostic factor in thyroid cancer. We suggest managing patients with thyroid cancer and GD according to high-risk protocols. We recommend a closer ultrasound follow-up for nodules in GD and the performance of FNAB when nodules are found.

EP1270

Severe hypocalcaemia and hypomagnesaemia secondary to omeprazole

Claire Min-Li Teo, Timothy Peng Lim Quek & Shaikh A K K Abdul Shakoor
Tan Tock Seng Hospital, Singapore, Singapore.

Introduction
Proton pump inhibitors (PPIs) are commonly prescribed drugs. We report a case of severe hypocalcaemia secondary to omeprazole-induced hypomagnesaemia.
Case report
A 85-year-old Chinese man with stage 4 chronic kidney disease was admitted to our hospital in Jun 2014 with vomiting and weakness. On admission, he was severely hypocalcaemic (adjusted calcium 1.37 mmol/l (RI: 2.15–2.58)) and hypomagnesaemic (Mg 0.1 mmol/l (RI: 0.7–1.0)). Serum phosphate and 25-OH vitamin D levels were normal. Intact PTH done after normalisation of serum magnesium showed secondary hyperparathyroidism (intact PTH 61.0 pmol/l (RI: 0.8–6.8)). An inpatient endocrinology referral was made for persistent hypocalcaemia. Review of his medical records revealed initiation of omeprazole in 2010 for peptic ulcer prophylaxis when he was prescribed short course prednisolone for gout. Omeprazole was continued after prednisolone cessation. Severe hypomagnesaemia and hypocalcaemia was also noted during two previous admissions to another hospital in Nov 2013 and Jun 2014. Calcium levels were normal between hospitalisations but magnesium levels were not rechecked.
In view of the possibility of omeprazole induced hypomagnesaemia and hypocalcaemia, omeprazole was stopped and changed to famotidine. With electrolyte replacement and a short course of calcitriol, serum calcium normalised within 4 days and remained normal at follow-up with calcium carbonate 1.25 g bd (as a phosphate binder) and no magnesium supplementation.
Conclusion
Severe hypomagnesaemia with hypocalcaemia is a rare side effect of PPI use. PPI use may alter intestinal absorption of magnesium, resulting in hypomagnesaemia, which then in turn impairs PTH secretion and action, causing hypocalcaemia. Correction of magnesium levels by stopping the PPI and aggressive magnesium replacement is hence essential before correction of the hypocalcaemia can be achieved. It is therefore important to have a high index of suspicion for this potentially life threatening side effect in patients on omeprazole presenting with hypocalcaemia.

EP1271

Late-diagnosed primary hyperparathyroidism resulting in loss of kidney and advanced osteoporosis

Malgorzata Jacewicz, Anna Zielinska, Anna Poplawska-Kita, Malgorzata Szelachowska & Maria Gorska
Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland.

Introduction
The report describes the case of a late-diagnosed primary hyperparathyroidism in the patient, who developed catastrophic renal complications and such advanced osteoporosis, that hungry bone syndrome occurred after removal of parathyroid adenoma.
Case report
A 63-year-old woman with long-lasting nephrolithiasis was admitted to the hospital due to high PTH discovered in a routine laboratory testing. She had undergone left-side nephrectomy 2 years before admission due to hydronephrosis. In the last year she lost 5 kg and suffered from asthenia, joint-pain and recurrent infections of the urinary tract. Laboratory tests during hospitalisation confirmed significantly raised PTH (2070 pg/ml), ALP (1047 IU/l), total calcium, and ionized serum calcium (3.26 and 1.91 mmol/l respectively). Also, anaemia (Hb, 8.8 g%) was observed and serum creatinine was substantially deteriorated (2.12 mg/dl, GFR 19 ml/min). Calcium (92.4 mg) and phosphate (367 mg) urine excretion in 24 h collection and 25(OH)D3 (17 ng/ml) were under normal range. Neck ultrasonography demonstrated multinodular goitre (thyroid function tests were normal). The biggest nodule was in the right thyroid lobe, it was hypoechogenic and had 20×16×24 mm diameter. 99mTc-sestamibi scintigraphy detected abnormal lower right parathyroid gland. DXA osteodensitometry showed advanced osteoporosis (−4.8 S.D. lumbar and −3.6 S.D. femoral neck *T*-score). During the parathyreoidectomy rapid decrease of serum PTH was observed (to 150 pg/ml). Two months postoperatively patient developed hypocalcaemia (1.93 mmol/l) and again high level of PTH (946 pg/ml). The diagnosis of hungry bone syndrome was made. The treatment with vitamin D, calcium supplementation, and alendronate sodium was started, which resulted in a gradual decrease in PTH and normalization of serum calcium.
Conclusion
In each case of nephrolithiasis the probability of hyperparathyroidism should be checked, otherwise it can lead to irreparable damages of human organism.

Acute thyroiditis due to nocardia associated to thyrotoxicosis

Isabel Torres-Barea[1], Rosa Márquez-Pardo[1], Gloria Baena-Nieto[1], Francisco J Vilchez-López[2], Manuel Cayón-Blanco[1], Lourdes García-García-Doncel[1] & Rosario López-Velasco[1]
[1]Hospital de Jerez, Jerez de la Frontera, Spain; [2]Hospital Puerta del Mar, Cádiz, Spain.

Introduction
Acute thyroiditis is an uncommon illness that exceptionally presents with thyrotoxicosis. Differential diagnosis mainly includes subacute thyroiditis. Nocardia asteroides is an opportunistic pathogen, with the majority of infections occurring in immunocompromised patients, as the delay in diagnosis due to negative blood cultures makes it potentially letal.

Case report
We present a case of acute thyroiditis due to Nocardia that presents with thyrotoxicosis in a patient with diabetic nephropathy that received a kidney cadaveric transplantation. A 44-year-old woman with diabetic nephropathy had a cadaveric renal transplant. About 3 months later, she presented neck pain accompanied by fever, dysphagia, enlargement of thyroid gland and thyrotoxicosis. These findings together with image tests were consistent with subacute thyroiditis. However, worsening of symptoms despite usual treatment and the finding of an abscess in the ultrasonography study made us formulate the possibility of an acute thyroiditis. Fine-needle aspiration of the abscess and drainage were performed and Nocardia asteroides was isolated in the fluid culture. Owing to abscess persistence despite of drainage and specific antibiotic therapy surgical thyroidectomy was made.
Conclusions
Acute thyroiditis due to Nocardia is exceptional, with only six published cases in the literature, none of them presenting with thyrotoxicosis. It is the second known case of Nocardia thyroiditis in a patient with solid transplant organ, being the rest in patients under corticosteroids treatment. Nocardiosis is typically regarded as an opportunistic infection occurring in immunocompromised hosts and is it to be taken into account in these patients.

Adrenal embolisation in severe ectopic Cushing: unusual case and extraordinary measures

Ismene Bilbao, Luisa Antuñano, Izaskun Olaizola, Ana Chacon, Estela Elias, Nerea Egaña, Cristina Garcia, Maite Aranburu, Alfredo Yoldi & Miguel Goena
Hospital Universitario Donostia, San Sebastian, Spain.

Introduction
Pancreatic ACTHomas have a poor prognosis with severe and rapidly progressive clinical courses, influenced by hypercortisolaemia thus whenever possible, control of the cortisol levels should be obtained to reduce complications. We report the use of adrenal embolisation in a case of a life threatening paraneoplastic Cushing.
Case
A 51-year-old woman with a negative past medical history complained of general weakness. Cushing's syndrome was suspected on the basis of hypokaliaemia, new onset hyperglucaemia and metabolic alkalosis found in the laboratory tests run on admission. She had no Cushingoid features except mild plethora. The suspicion was confirmed by high levels of urinary free cortisol, serum cortisol and ACTH, a lack of circadian rhythm of serum cortisol, and a low (1 mg) and high dose (8 mg) overnight of dexamethasone tests that failed to suppress. CT and whole body PET scan showed 2×3 cm mass in the pancreas tail. She underwent the excision of the pancreatic mass and pathology confirmed the neuroendocrine nature of the tumour. Cushingoid features were more obvious and liver metastases were observed so treatment with ketokonazol was started, initially decreasing cortisol levels, but refractory hypercortisolemia recurred although dose was increased and metopirone added. The patient became psychotic so mifepristone was commenced, but she continued to deteriorate. It was therefore decided that an attempt should be made for bilateral adrenalectomy, but the patient was unfit for surgery so a bilateral adrenal embolectomy was performed. A week after the procedure her condition improved and the urinary cortisol levels lowered. Unfortunately the patient died soon after due to a multiorganic failure.
Conclusions
Aggressive attitudes to control cortisol levels are necessary to reduce comorbidities in ectopic Cushing. This case shows that adrenal embolectomy might be of some use when the patient has become unfit for surgery and in whom medical therapy has failed.

Primary hyperparathyroidism in pregnancy

Hanna Komorowska, Barbara Brominska, Maciej Biczysko, Bartosz Luftmann, Wojciech Pienkowski & Marek Ruchala
University of Medical Sciences in Poznan, Poznan, Poland.

Introduction
Hyperparathyroidism during pregnancy is a serious problem. Appropriate management is a matter of debate. We would like to present cases in which, PHP was diagnosed in completely different circumstances, though end up with various pregnancy outcomes.
Case report
First patient was 29-year-old women in 21th week of her second pregnancy admitted to our ward due to suspected relapse of Graves' disease and possible adrenal dysfunction. She presented with weakness, abdominal pains, vertigo in 7th week of pregnancy. During hospitalisation, previous suspicions were ruled out. Unexpectedly, we discovered elevated concentration of total calcium. After thorough examination, we confirmed a diagnosis of hyperparathyroidism. Owing to biochemical deterioration she was operated in 24th gestation week. The women gave birth to a healthy baby girl in 40th week of gestation. Second patient was 28-year-old women admitted to Outpatient Endocrinology Clinic due to hypercalcaemia. Medical history revealed miscarriage in 9th week. During pregnancy which she lost, calcium levels were very high. On the day of visit neck ultrasonography depicted a hypoechoic region which could be consistent with enlarged parathyroid gland. She was operated. Frozen section pathology and intraoperative PTH assay confirmed diagnosis of parathyroid adenoma and curative procedure.
Conclusion
Presented cases highlight the importance of controlling calcium-phosphate balance in pregnancy. Decisions concerning method of treatment PHP are difficult. When conservative procedures are introduced, mother and her child should remain under strict control. On the other hand operation during pregnancy is hazardous. Our experience gives a novel insight into that complicated problem. Taking into account possible adverse effect of PHP on health of both women and fetus there are growing evidence pro surgery, regardless of gestational age.

Thyroid tuberculosis mimicking carcinoma: case report

Samir Ait Abderrahmane, Yamina Aribi, Zoubir Sellal, Merieme Bensalah, Leila Brakni, Samia Ouldkabli & Zahra Kemali
Central Hospital of Army, Algiers, Algeria.

Tuberculosis of the thyroid gland occurs rarely, and should be considered in the diagnosis of nodular lesion of the thyroid gland. We report the case of a 44-year-old woman admitted for therapeutic management of a suspected goiter appeared at 2 months of hospitalisation and quickly increasing in volume in a few days, she had a goiter clinically type 2, firm, homogeneous, without palpable nodules in it, hardly moving with swallowing movements with slight dysphagia without signs of thyroid dysfunction. Cervical ultrasound: found a suspicious mass in the right thyroid lodge. FNA of cervical mass found the CPE side for a very granulomatous thyroiditis DeQuervain IDR A Tuberculin had regained energy. The patient received a total thyroidectomy before the signs of malignancy on ultrasound. Histology was in favor of a histopathology of thyroid and thyroid localization soft tissue died a Caseo folliculaire.mise tuberculosis TB treatment with good clinical course.
Conclusions
Thyroid tuberculosis is a rare disease, which can take various forms, especially you must think in TB endemic area, the diagnosis is histological and/or bacteriological. Treatment is primarily medical, based on a combination of anti tuberculosis. Preoperative diagnosis of thyroid tuberculosis is important because of the availability of medical treatments and the limited role of surgery.

Case report: superior vena cava syndrome secondary to intrathoracic goitre

Bruno Francisco García-Bray[2,3], Nieves Cruz Felipe-Pérez[1], Ricardo Darias-Garzón[1], Benigno Rivero-Melián[1] & Ignacio Llorente-Gomez de Segura[1]
[1]Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain; [2]Orden Hospitalaria San Juan de Dios, Santa Cruz de Tenerife, Spain; [3]Hospital Quirón, Santa Cruz de Tenerife, Spain.

Introduction
We introduce a case involving the appearance of superior vena cava syndrome secondary to intrathoracic goitre. We discuss the diagnosis, prognosis and treatment applied to this pathology.
Case report
A 67-year-old woman who presents respiratory distress, cough, and weight loss. After physical examination and a chest radiography showing a mass that occupied the upper and middle right lung lobes, a neoplasm is suspected and at first, palliative radiotherapy is indicated. Chest and abdomen CT are done before treatment and an intrathoracic goitre is diagnosed. Following this finding, surgical treatment is performed.
Conclusions
When a superior vena cava syndrome is diagnosed, additional tests should be performed to discover the real aetiology of the syndrome, which in this case corresponds to a giant intrathoracic goitre. Thyroid function tests and imaging techniques such as ultrasound or CT are indicated in these cases. The treatment of choice of the intrathoracic goitre is surgical removal, especially in cases where compression of adjacent structures is present.

Clinical and hormonal characteristics of a series of patients affected by inappropriate TSH syndrome: insights into the differential diagnosis

Sefika Burcak Polat, Cevdet Aydin, Mina Gulfem Kaya, Neslihan Cuhaci, Reyhan Ersoy & Bekir Cakir
Endocrinology and Metabolism Department, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey.

Introduction
Normal or elevated TSH level in the presence of elevated T_4 is defined as 'inappropriate TSH syndrome'. Two main clinical conditions that can lead that syndrome are TSH-secreting adenoma (TSHoma) and resistance to thyroid hormone (RTH). Making the correct diagnosis is crucial in order to decide the most appropriate treatment option. Herein we presented clinical and laboratory data of seven patients who were hospitalised for the differential diagnosis of the two clinical entities.
Method
Our database was reviewed for the patients diagnosed with inappropriate TSH syndrome at our hospital between 2010 and 2014. After exclusion of the other rare causes of inappropriate TSH syndrome, seven patients who were hospitalised for the differential diagnosis of TSHoma and RTH were included in this report.
Result
Age of the patients was changing between 20 and 52 years. Clinically two patients were asymptomatic, three had tachycardia and weight loss and one had goitre. Final diagnosis was RTH in four patients, TSHoma in two and unequivocal in one. Two patients diagnosed with TSHoma were operated and had positive staining with TSH. Both of the TSHoma cases had macroadenoma on pituitary MRI and visual field defect while two of four patients with RTH had microadenoma. Alpha-subunit/TSH molar ratio was above 1 in all patients diagnosed with TSHoma while it exceeded 1 in two patients with the final diagnosis of RTH. TRH stimulation test revealed a blunted response in all patients with TSHoma and a positive response (increase $>100\%$) was observed in all with THR. TSH was suppressed after T_3 suppression test in all patients with the final diagnosis of RTH.
Conclusion
Differential diagnosis of RTH and TSHoma can be a clinical challenge and requires complex hormonal tests and imaging methods. Since incidental pituitary tumours are not rare, presence of an adenoma should not rule out diagnosis of RTH.

Autoimmune polyglandular syndrome: case report series

Raluca Nan[1], Cristian Guja[1,2], Andra Caragheorgheopol[1,3], Dana Manda[3], Gabriela Radulian[1,2] & Madalina Musat[1,3]
[1]University of Medicine and Pharmacy 'Carol Davila', Bucharest, Romania; [2]National Institute of Diabetes, Nutrition and Metabolic Disease 'Prof. Dr. N. Paulescu', Bucharest, Romania; [3]National Institute of Endocrinology 'C.I. Parhon', Bucharest, Romania.

Introduction
The polyglandular autoimmune syndromes (PAS) are rare conditions characterised by the failure of several endocrine glands sometimes associated with other non-endocrine autoimmune diseases. There are four categories of PAS: PAS-I includes at least two out of: mucocutaneous candidiasis, hypoparathyroidism and adrenocortical failure. PAS-II comprises of Addison's disease, autoimmune thyroid disease and/or type 1 diabetes (Carpenter's syndrome). PAS-III is defined by the presence of other autoimmune disorders than Addison's disease and hypoparathyroidism, while PAS IV includes non-endocrine autoimmune disorders and Addison's disease, but not hypothyroidism.
Case reports
We present three cases of a larger series of PAS type II/III. The first case is of a 55-year-old woman, who was diagnosed with PAS-II (Addison's disease, autoimmune thyroiditis and latent autoimmune diabetes in adults). The second case is of a 42-old man, so far diagnosed with Basedow's disease, type 1 diabetes and vitiligo. The third case is of a 22-year-old woman, diagnosed with type 1 diabetes mellitus and primary hypothyroidism so far. The occurrence of autoimmune diseases can continue in the latter two cases, therefore PAS-III could evolve into PAS II.
Conclusion
We emphasise the importance of screening for PAS after the first autoimmune disease is diagnosed. The key to successfully managing patients with PAS is to identify and treat their disorders early before complications occur. This may be achieved by early screening for autoantibodies or subclinical endocrine failure. Patients should be educated to comply with the lifelong medical surveillance and encourage their family members to be screened for autoimmune diseases as about 50% of patients with PAI II have siblings with autoimmune diseases.

Similia similibus curentur: a novel treatment approach in endocrinology?

Regina Streuli[1,2], Lea Slahor[2], Lukas Burget[2], Christoph Henzen[2] & Stefan Fischli[2]
[1]Division of Endocrinology, Diabetes, Osteology and Metabolism, Departement of Medicine, Kantonsspital, 9007 St. Gallen, Switzerland; [2]Division of Endocrinology, Diabetes and Clinical Nutrition, Departement of Medicine, Luzerner Kantonsspital, 6000 Luzern 16, Switzerland.

Introduction
Hyperinsulinaemic hypoglycemia after gastric bypass surgery is a rare but probably underestimated complication. The mechanisms leading to hypoglycemia are complex and incompletely understood and involve several factors: A part from decreasing insulin resistance, caloric restriction and alteration of nutrient delivery, enhanced secretion of insulin and incretins (GLP1 and GIP), altered physiology of other hormones and dysregulation of counterregulatory effectors seem to play a major role. Treatment strategies include nutritional counselling with carbohydrate restriction and various medical treatments. Partial pancreatectomy is reserved for severe treatment-refractory cases.
Case report
A 53-year-old woman presented with postprandial hypoglycemia and neuroglycopenia 3 years after Roux-en-Y gastric bypass. A CGMS over 1 week demonstrated several hypoglycemic episodes typically occurring 2–3 h after meals. Endogenous hyperinsulinism was documented in a mixed meal test which was stopped after 2 h when the patient had severe neuroglycopenic symptoms and a plasma glucose of 1.9 mmol/l. ^{18}F-DOPA-PET showed diffuse uptake within the pancreas but no focal enhancement. Despite carbohydrate restriction the patient continued to have neuroglycopenic symptoms. Diazoxide was begun but had to be withdrawn due to side effects. After discussion of other treatment options, the patient was started on liraglutide (Victoza) which was titrated to a dose of 1.2 mg daily. Frequency and severity of postprandial hyperinsulinemic hypoglycemia decreased markedly and neuroglycopenia resolved completely.
Conclusions
GLP1 analogues might be a new treatment option for hyperinsulinaemic hypoglycemia after bariatric surgery. However, the exact mechanism of action remains to be elucidated. It can be assumed that a stimulation of glucagon secretion with concurrent inhibition of insulin secretion in low blood glucose

states by GLP1 analogues partly explains the stabilising effect on glucose metabolism in these patients. Nevertheless, further studies are needed.

EP1280

The use of omega-3 free fatty and medium chain triglycerides in combination with GLP1 and SGLT2 in the management of obesity and severe refractory hypertriglyceridaemia

Yusniza Yusoff[1], Yong Sy Liang[1], Foo Geong Taat[1] & Khoo Kah Lin[2]
[1]Hospital Tengku Ampuan Rahimah, Klang, Selangor, Malaysia; [2]Pantai Medical Center, Kuala Lumpur, Malaysia.

Hypertriglyceridaemia and obesity are common encounter in diabetic patients. It is often refractory to conventional treatment especially those with a very high triglyceride (TG) levels. The institution of medium chain diet (MCT) and fish oil in addition to the liraglutide and SGLT2 and conventional insulin has rendered significant and a satisfactory triglyceride, and glucose level as well as weight reduction. We would like to illustrate a case of 35 years old lady with a different treatment modality apart from the current general approach in managing obesity and hypertriglyceridaemia. There was marked reduction in HbA1c, 12.1–9.2% within 2 months. This is accompanied with weight reduction of 6 kg within four months. While the triglyceride levels steadily decreasing from 32.3 to 3.18 mmol/l and remained so throughout the treatment. There was no side effect observe at this period of treatment.

Multiple endocrine organ failure due to amyloidosis

Feyzi Gokosmanoglu, Cigdem Tura Bahadir, Elif Kilic Kan & Aysegul Atmaca
Ondokuz Mayis University, Samsun, Turkey.

Introduction
Amyloidosis is characterised by accumulation of amorph and proteinous substance in several tissues and organs. Thyroid, adrenal, and pituitary insufficiencies may rarely be observed due to accumulation of these substances. Here, we present a case to point out this rare condition.
Case report
A 19-year-old male patient admitted with complaints of swelling in the neck, abnormality in thyroid hormone levels and fatigue. He had been diagnosed with familial Mediterranean fever at the age of 5. At 13 years old, he had renal insufficiency due to amyloidosis and had undergone renal transplantation. Physical examination revealed systemic arterial blood pressure of 90/60 mmHg, pulse rate of 72 beats/min. Thyoid gland was found to be diffuse palpable (grade 2), secondary sex characteristics development was defined as stages 2–3. In laboratory evaluation, TSH level was elevated, FT_4 level was decreased, anti-TPO and anti-TG were negative. He had primary adrenal insufficiency and hypogonadothrophic hypogonadism. ACTH and GnRH stimulation tests were in concordance with primary adrenal failure and hypogonadothrophic hypogonadism. Thyroid ultrasonography revealed that right thyroid lobe was $24\times23\times54$ mm and left thyroid lobe was $17\times21\times52$ mm in diameters. Isthmus was 5.5 mm in diameter and there was heterogenic echogenity in thyroid parenchyma. Doppler ultrasonography revealed grades 1–2 increased thickness in thyroid parenchyma. Thyroid fine needle aspiration biopsy revealed homogenous eosinophyllic accumulation which was stained histochemically with congo red and methyl violet between thyroid follicullar cells. Pituitary magnetic resonance imaging was normal. In the light of these findings the patient was diagnosed with amyloid goitre, primary adrenal insufficiency, and partial pituitary insufficiency. Prednisolone 5 mg/day, levothyroxine 50 μg/day, and testesterone enanthate 125 mg every 3 weeks were administered.
Conclusions
Systemic amyloidosis may be accompanied with amyloid accumulation in thyroid gland as well as adrenal and pituitary insufficiencies. Thus, endocrinologic evaluation is necessary in these patients.

DOI: 10.1530/endoabs.37.EP1281

EP1282

Gynaecomastia in a patient with von Recklinghausen's disease (neurofibromatosis type 1)

Ekaterina Sorkina[1], Liubov Machekhina[2], Aliy Asanov[1] & Konstantin Makhinov[1]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russia; [2]Endocrinology Research Center, Moscow, Russia.

Introduction
Neurofibromatosis type 1 (NF1), also known as von Recklinghausen's disease, is the most common type of NF and one of the most frequent human genetic diseases. Gynaecomastia due to pseudoangiomatous stromal hyperplasia (PASH) in patients with NF1 is quite a rare complication but still it should be differentiated from gynecomastia caused by other conditions.
Clinical case
A 30-year-old man, previously diagnosed with NF1 at the age of 19, was first consulted in the Endocrinology department of MSMU in March 2014. He complained bilateral enlargement of breasts, painful feeling in them, weight loss, reduction of libido, muscle weakness, back pain and pain in the legs, diarrhoea. Physical examination: height 165 cm, weight 42.5 kg, BMI 15.7 kg/m^2, strong reduction of subcutaneous fat, breasts enlarged, painful while palpated; loss of facial hair, multiple neurofibromas in supraclavicular, axillary, and parotid areas. Laboratory analysis: serum creatinine 50.8 mmol/l (62.0–115.0), prolactin 136 mIU/ml (47–135), macroprolactin 61 mIU/ml, estradiol 97 pmol/l (0–146), testosterone 9.7 nmol/l (8.4–28.7), and leptin 0.9 ng/ml (2–5.6). DXA: generalized osteoporosis (Z-criteria -3.2 to -3.8), Total body quantitation: total fat tissue 9.9%. Immunological tests of specific antibodies in celiac disease: negative. Brain MRI: no signs of a pituitary adenoma. Breasts US: gland tissue hyperplasia, ducts are not dilated, no cysts or tumours were detected. Mediastinum lymph nodes biopsy: neurofibromas. Spine CT, MRI: multiple neurofibromas. Neurologic status: Multiple compressive-ischemic mononeuropathies of upper and lower limbs, distal assymetric tetraparesis, neuropathic pain syndrome, crampy. Pain syndrome is treated successfully with pregabalin 375 mg/day and amitriptyline 0.05 mg/day. A bilateral mastectomy was performed at June 2014. Osteoporosis is treated with zoledronic acid and combined preparations of calcium and vitamin D3.
Conclusion
We report our experience of gynecomastia and hyperprolactinaemia in a patient with NF1. Though these are rare complications of the disease, if found, such patients should undergo complex examination to exclude other causes of this state, which can worsen the course of their primary disease.

Petrified ears associated with Schmidt's syndrome

Ana Valea[1,2], Andra Morar[2], Maria Breaban[2], Florica Tomesc[2], Adina Terec[2], Iulia Iacob[2], Dan Dumitru Pop[2], Alina Silaghi[2] & Cristina Ghervan[1]
[1]University of Medicine and Pharmacy Cluj-Napoca, Cluj-Napoca, Cluj, Romania; [2]Endocrinology Department, Cluj-Napoca, Cluj, Romania.

Introduction
Bilateral calcification of auricular cartilage is an uncommonly reported condition. The aetiology of this phenomenon is still unclear. Petrified ears have seldom been described in association with endocrinopathies such as adrenal insufficiency, hypothyroidism, diabetes mellitus, and acromegaly.
Case report
We present the case of a 42 year-old male patient, diagnosed with Addison's disease at the age of 14, currently undergoing treatment with prednisone 10 mg/day, with low compliance and therefore repeated episodes of adrenal crisis throughout the years. At the age of 42 he was diagnosed with hypothyroidism due to Hashimoto's thyroiditis and treatment with levothyroxine 25 μg/day was initiated. Physical examination revealed hyperpigmentation of the skin, lipoma of the posterior chest wall, markedly rigid auricular cartilages that were difficult to fold manually, with no evidence of hearing impairment. CT scan confirmed bilateral calcification of the auricular cartilages.
Conclusions
A long history of poorly controlled adrenal insufficiency (in this case more than 25 years) and the presence of primary hypothyroidism seem to be precipitating factors for auricular calcification.

EP1284

Two cases of bullous pemphigoid induced by vildagliptin

Asli Dogruk Unal, Ozlem Tarcin, Gulsen Tukenmez Demirci, Ebru Demiralay, Ayse Tulin Mansur, Semsi Yildiz & Nilgun Guvener Demirag
Baskent University Hospital, Istanbul, Turkey.

Background
Bullous pemphigoid is an autoimmune blistering disease that commonly arise in elderly with increased risk for mortality and morbidity. The aetiology of this disease is not entirely clear, although a few cases have been described with dipeptidyl peptidase IV inhibitors.
Case 1
A 81-year-old man presented with bullous pemphigoid after 28-month treatment with repaglinide, vildagliptin, and metformin. The patient's condition didn't improve with local treatment with clobetasol. The patient was started on methylprednisolone and azathiopurine but skin lesions sustained. Remission was achieved only after withdrawal of gliptin.
Case 2
A 64-year-old man treated with insulin glargine, insulin aspart, and vildagliptin for 12 months presented with bullous pemphigoid on skin and laryngeal mucosa. After discontinuation of vildagliptin skin lesions were resolved but laryngeal involvement continued. Mucosal lesions were resolved after methyprednisolone and azothiopurine treatment.
Conclusion
In the literature, there have been few cases descibed with gliptins. The exact mechanism has not been known but believed to be modified immune responses. These reports support the risk of bullous pemphigoid in patients exposed to gliptins. The difference of our cases from the literature is mucosal involvement and remission of our cases only with immunosuppressive agents.

DOI: 10.1530/endoabs.37.EP1284

EP1285

Hashimoto's thyroiditis with subclinical hypothyroidism, but severe growth delay in a prepubertal boy

Emilia Ghita, Alina Andreea Gatu, Voichita Mogos & Dumitru Branisteanu
Department of Endocrinology, University of Medicine and Pharmacy 'Gr.T. Popa', Iasi, Romania.

Hashimoto's thyroiditis is an autoimmnune condition most common in females but can be also found in children with a prevalence of 1.2%. When is associated with hypothyroidism, the growth delay is an important, but late symptom. We present the case of a 12-year-old boy presenting with small height for age (123 cm, < -3 S.D.), important weight gain and fatigue. He was the only child from parents of average height and had normal weight at birth (3300 g). Growth delay was not obvious until 2–3 years ago, when the child remained the shortest in the class, growing at a pace of < 2 cm/year. Although with an IQ above average, the patient had mild features of hypothyroidism. Clinical supposition was confirmed by laboratory investigation: $fT_4 = 0.3$ ng/ml (normal 0.9–1.9 ng/ml) and TSH = 35 mIU/l (normal 0.4–6 mIU/l). Etiological diagnosis of atrophic Hashimoto's thyroiditis was set by high titers of anti-peroxidase antibodies – 326 U/l (positive when > 50 U/l) and small, hypoechogenic, avascular thyroid gland. Therapy with 100 μg/day L-thyroxine and daily rGH injections (0.035 mg/kg per day) was initiated, with spectacular catch-up growth of 30 cm in 2 years (153 cm at 13 years, -0.8 S.D., corresponding to adult parental height). Hashimoto's thyroiditis is a frequent disease in adult women, but seldomly encountered in prepubertal boys. Normal intellect, relatively harmonious development and the presence of the thyroid gland excluded the hypothesis of an undiagnosed congenital myxoedema in our case. Diagnosis was mainly set by severe growth delay. Catch-up growth under thyroid hormone substitution does not completely restore height handicap in long-standing hypothyroidism, therefore the association of GH therapy may be beneficial, as in our case.

EP1286

A case of childhood autoimmune polyglandular syndrome type 1

Aysegul Alpcan[1], Bilge Eris[2], Senay Arikan Durmaz[3], Aydin Cifci[2] & Isilay Kalan[3]
[1]Kirikkale Yuksek Ihtisas Hospital, Kirikkale, Turkey; [2]Department of Internal Medicine, Kirikkale, Turkey; [3]Department of Endocrinology and Metabolism, Kirikkale University, Kirikkale, Turkey.

Autoimmune polyendocrine syndromes (APS) are rare groups of diseases with autoimmune failure of at least two endocrine glands. In general, APS1 first occurs with candidiasis. Hypoparathyroidism generally presents until 10 years of age, and adrenal insufficiency around 20 years. We aim to this report a young girl is presented with early onset APS1 first presenting with adrenal insufficiency.
Mucocutaneous candidiasis on the oral mucosa, and ectodermal dystrophic changes in her nails attracted attention in an 18-year-old girl in asthenic appearance who attended the Endocrinology Outpatient Clinic for malaise and failure to thrive. No hyperpigmentation was detected on the skin and mucosa on physical examination because she took corticosteroid treatment. Pubertal development was accordant with Tanner stage 5.Other systemic examinations were normal. It was learned from her anamnesis that malaise, loss of appetite, darkening in skin colour, and changes in the nails were first detected and investigated at a Paediatrics outpatient clinic she attended when she was 6 years old. As much as learned from her records at that time, her height and weight were consistent with her age, turgor was decreased, the skin was dry, there were marking, shape and color changes in the hand nails, candidiasis and skin hyperpigmentation were detected. As PTH was 2.83 pg/ml (15–65), ACTH was 1250 pg/ml (7.2–63.3), and basal cortisol was 1 μg/dl (6.2–19.4), and there was no response to Synacthen stimulation test. Adrenal insufficiency, hypoparathyroidism, and candidiasis were detected and the patient was diagnosed for APS1.
Conclusion
APSs clinically include a quite broad group of diseases. When one type of endocrinological disease is detected in a patient, the patient should be tested for complete blood count, electrolytes, hormonal levels, and antibodies for other diseases once every 3 years.

EP1287

Propylthiouracil-induced hepatotoxicity in Graves' disease: a case report

Hela Marmouch[1,2], Sondes Arfa[1], Tesnim Slim[1], Fadia Boubaker[1], Hanene Sayadi[1,2], Manel Jmal[1,2] & Ines Khochtali[1,2]
[1]Department of Internal Medicine–Endocrinology, Monastir, Tunisia; [2]Faculty of Medicine, Monastir, Tunisia.

Introduction
Propylthiouracil-induced severe hepatotoxicity is a relatively rare occurrence, with very few cases reported in the literature. The management of this complication in pregnancy can be a challenge because of the effects of the various treatment options on the foetus.
Case presentation
We report a case of hyperthyroidism in a 28-year-old woman that occurred at 20 weeks gestation. This situation was due to Graves' disease. Propylthiouracil treatment was used. The following of the pregnancy doesn't shows any side effects. 15 days after delivery, she has a vomiting and fatigue. Check list show elevated ALAT = 1000 UI/l. This liver toxicity has been managed by stopping this medication. After 4 days, ALAT romain to normal rate.
Conclusion
This case illustrates a rare complication of treatment with a presumed safe drug during pregnancy followed by adverse maternal outcomes due to the hepatotoxicity treatment.

Combined treatment with sitagliptin and vitamin D in a patient with latent autoimmune diabetes of adulthood

Eleni Rapti, Athanasios Mousiolis, Maria Grammatiki, Maria Yavropoulou, Pantelis Zebekakis, Michail Daniilidis & Kalliopi Kotsa
University General Hospital of Thessaloniki AHEPA, Thessaloniki, Greece.

Objective
To report a case of a patient diagnosed with latent autoimmune diabetes of adulthood (LADA) based on clinical presentation and positive glutamic acid decarboxylase antibodies (GAD-abs) that converted to antibody negative diabetes after combined treatment with sitagliptin and vitamin D.
Methods
A 31-year-old male presented at the emergency room with symptoms of polyuria, polydipsia, and weight loss. Blood glucose was 300 mg/dl with mild ketonuria and HbA1c was 9.6%. The patient had a family history of autoimmune disorders. Declining insulin therapy he was initially treated with gliclazide and metformin. Owing to the patients poor glycemic control a GAD-abs titer measurement was performed and the results came back positive at 32 U/ml (NV <5 U/ml), so a LADA diagnosis was established. Other blood tests came back normal except from a low 25-OH-vitD level of 11 ng/ml (NV >30 ng/ml). Declining insulin therapy, he was advised to discontinue gliclazide and a combination of metformin 850 mg/sitagliptin 50 mg twice daily along with vitamin D supplementation (2000 IU/day) was prescribed.
Results
At follow-up visits, his HbA1c was 6.1% at 6 months and 5.4% at 11 months. His GAD-abs level declined by 86% within normal range at 4.2 U/ml. Two years later, receiving the same treatment, he has negative GAD-abs, his HbA1c is 5.2% and he maintains an excellent glycaemic profile.
Conclusion
Both vitamin D analogues and dipeptidyl peptidase 4 (DPP4) inhibitors have been shown to improve β-cell function and attenuate autoimmunity in type 1 diabetic mouse models. To our knowledge this is the first case that combined treatment with sitagliptin and vitD in a patient with LADA reverted the phenotype and preserved an excellent glycaemic control without the use of insulin 24 months after diagnosis.

A rare case of papillary thyroid carcinoma and MALT thyroid lymphoma in the setting of Hashimoto's thyroiditis

Nada Santrac[1], Merima Oruci[1], Marko Buta[1], Igor Djurisic[1], Emilija Golubovic[1], Gordana Pupic[2] & Radan Dzodic[1,3]
[1]Surgical Oncology Clinic, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia; [2]Department of Pathology, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia; [3]Medical School, University of Belgrade, Belgrade, Serbia.

Introduction
Papillary thyroid carcinoma (PTC) is the most common thyroid malignancy (80%), while primary thyroid lymphomas (PTL) occur in only 0.6–5% of cases. A significant number of PTCs, as well as PTLs, arise in the setting of Hashimoto's thyroiditis (HT), however the simultaneous occurrence of these two malignancies is extremely rare.
Case report
We present a 34-year-old female patient with thyroid MALT lymphoma and coexisting papillary microcarcinoma (PMC) in the setting of HT in the contralateral lobe that was admitted to our Institution for thyroid surgery. Patient had no compressive symptoms or lymphoma-related symptoms. Physical and ultrasonical examination in our Institution showed euthyroid multinodal goitre with pre-laryngeal medial neck mass (position of pyramidal lobe) and negative regional lymph nodes. Additionally, patient had increased antibodies' level. Preoperative fine-needle aspiration biopsy of pyramidal lobe tumour showed HT. Patient was submitted to total thyroidectomy with sentinel lymph node biopsy of jugulo-carotid regions after 1%-methylene blue dye injection. Histopathology analysis showed MALT lymphoma in the right lobe and HT with incidental PMC in the left lobe. Lymph nodes were diagnosed as benign, with reactive sinus histiocytosis. Postoperative whole body scintigraphy with radioiodine 131 was negative and substitutional-suppressive therapy with levothyroxine was initiated. Complete multidisciplinary diagnostic evaluation for MALT lymphoma was performed with confirmation of PTL stage IE, thus no further therapy was conducted. Ten months after surgery, presented patient is without recurrence.
Conclusions
Optimal management of coexisting PTC and MALT lymphoma depends on stage of both diseases at the initial presentation. In patients with HT, attention should be focused on frequent concomitant PTCs and possible occurrence of lymphomas, thus total thyroidectomy represents a therapy of choice.

Nephrogenic syndrome of inappropriate antidiuresis secondary to an activating mutation in the arginine vasopressin receptor AVPR2

Andrew S Powlson[1], Benjamin G Challis[1], Alice Lagnado[1], David J Halsall[2], Robert K Semple[1] & Mark Gurnell[1]
[1]Metabolic Research Laboratories, Institute of Metabolic Science, University of Cambridge, Cambridge, UK; [2]Department of Clinical Biochemistry, Addenbrooke's Hospital, Cambridge, UK.

Case history
A 38-year-old man was referred with a 12-month history of recurrent bouts of transient hyponatraemia (serum sodium ranging from 115 to 125 mmol/l). Citalopram, which he was taking for depression, was discontinued, but the episodes continued.
Initial investigations
Whilst symptomatic, and clinically euvolaemic, his biochemical profile was consistent with a syndrome of inappropriate antidiuresis (SIAD): sodium 124 mmol/l, potassium 4.5 mmol/l, glucose 6 mmol/l, urea 4.7 mmol/l, creatinine 76 μmol/l, serum osmolality 268 mOsm/kg, urine osmolality 652 mOsm/kg, and urine sodium 154 mmol/l. A contemporaneous anterior pituitary profile, including short Synacthen test, was normal, as were urinary porphobilinogens. Head, chest, and abdominal CT were unremarkable.
Laboratory studies
A water load test was arranged: after 4 h he had excreted just 15% of a 20 ml/kg oral load (normal range 78–82%) and his serum sodium fell from a baseline of 134 mmol/l to a nadir of 125 mmol/l (serum osmolality 266 mOsm/kg and urine 808 mOsm/kg), consistent with inappropriate antidiuresis. Despite this, his AVP levels were profoundly low (0.4–0.9 pmol/l) throughout the test, indicating a nephrogenic syndrome of inappropriate antidiuresis. Sanger sequencing of *AVPR2* revealed a missense mutation (X-linked) in a highly conserved arginine residue in the second intracellular loop (R137C). The mutant receptor exhibits constitutive activity when compared with its WT counterpart in transient transfection assays.
Discussion
Confirmed cases with activating mutations in AVPR2 causing nephrogenic SIAD are rare, with only sixteen cases reported worldwide since the syndrome was first described in 2005. However, this disorder may be underdiagnosed, based on historical reports of AVP levels in unexplained hyponatraemia. The ability to find a definitive cause in this case has provided validation to our patient, given a rational for preventative management with fluid restriction, and allows the potential for family screening.

EP1291

Nephrotic syndrome due to membranous nephropathy as the cause of rising TSH levels or primary hypothyroidism as the cause of nephrotic syndrome? A case report

Sohini Patel[2], Nirav Gandhi[1,2] & Jayadave Shakher[1]
[1]Birmingham Heartlands Hospital, Birmingham, UK; [2]University of Birmingham, Birmingham, UK.

We present a case of a 52-year-old man with a past medical history of primary hypothyroidism on treatment, presenting with elevated TSH levels, suggesting inadequate thyroxine (T_4) replacement. The patient was managed with 200 μg of T_4 for 14 years with no compliance issues. TSH levels failed to normalise despite increasing the dose of T_4. In addition to elevated TSH levels the patient noted progressive leg swelling and associated shortness of breath over the preceding 12 months. Examination revealed bilateral pitting oedema up to the abdomen and elevated blood pressure (175/103 mmHg). Initial blood results demonstrated a low albumin of 21 g/l, down from a previous 44 g/l with urinalysis confirming marked proteinuria ($+3$) in addition to blood ($+2$). Subsequently, nephrotic syndrome was investigated as a probable cause. Twenty-four hour urinary protein was raised at 12.42 g (normal <0.15 g). A kidney biopsy was performed which demonstrated membranous glomerulonephritis. The nephrotic syndrome was

symptomatically managed on frusemide 40 mg b.d. and ramipril 10 mg o.m. The proteinuria improved with reduction of peripheral oedema and stabilization of TSH levels. There are numerous causes of elevated TSH levels in a primary hypothyroidism patient on T_4. One of the less commoner causes is nephrotic syndrome, characterized by oedema, hypoalbuminaemia and proteinuria. Increased glomerular permeability results in loss of thyroxine-binding globulin (TBG) and free T_3/T_4. As a result, the pituitary–hypothalamic axis responded by increasing TSH production to compensate for reduced serum T_3/T_4. This elevation of TSH is not responsive to increasing doses of exogenous T_4 due to urinary loss of TBG. Management is of the underlying nephrotic syndrome. It is important to recognise that many hormones are protein based, as are their carrier molecules calling for a closer analysis of symptoms on presentation of elevated TSH.

Clinical case: gender identity disorder as an aetiology of hypothalamic amenorrhoea

Natalia Volkova, Maria Porksheyan & Saida Kanaeva
Rostov State Medical University, Rostov on Don, Russia.

Hypothalamic amenorrhoea is a diagnosis of exclusion, frequent cause of which are medications or psychiatric disorders (bulimia/anorexia). Here we present a case, when its aetiology was gender identity disorder. A 18-year-old girl presented with absence of menses during last year. Menses began at the age of 14 and were regular till age of 16, when she moved to another city. She was seen by gynaecologist because of amenorrhea, and evaluation was performed: FSH 4.6 mU/ml (1.37–9.9), LH 7.2 mU/ml (1.68–15.0), oestradiol 20 pg/ml (68–606), total testosterone 0.5 nmol/l (0.38–1.97), TSH 2 mU/l (0.4–4.0), prolactin 570 mU/l (109–557), and US, multifollicular ovaries. 'Ovarial hypofunction' was established, and vitaminotherapy was prescribed without any effect. She appealed to different specialists, however, definitive diagnosis wasn't established. At the age of 17, menses were recovered spontaneously and stopped again in 6 months. Patient had not taken OC, weight remained stable. Physical examination revealed BMI 19 kg/m^2, hirsute number 0, breast development Tanner 5. Hormonal test results were in reference range, hCG was negative. Talking with patient, our attention was drawn by her hysterical behaviour, because she told about herself as an asexual being. Thereby, she appealed to psychiatrist, and diagnosis of gender identity disorder was established. It was interesting to note that her menses recovered at that time, when she fell in love and felt as a woman. Taking into consideration absence of pregnancy, excluded endocrine causes of amenorrhea, no history of OC, no excess or insufficient food intake, spontaneous menses recover during normal identity, there was established diagnosis of hypothalamic amenorrhoea, and psychiatric treatment was recommended. In case of amenorrhoea, body weight changes, and careful inspection are needed while suspicion of bulimia/anorexia. It is also needed to pay attention to patient's speech, which may be a clue to diagnosis of gender identity disorder as a cause of hypothalamic amenorrhea.

Multiple endocrine neoplasia type 2A in a Turkish family presented with nonspesific symptoms

Dilek Tuzun[1], Ayten Oguz[1], Murat Sahin[1], Ilhami Taner Kaleli[2], Sevgi Bakaris[3], Mustafa Saygin Deniz[4], Cansu Yilmaz Cabioglu[4] & Kamile Gul[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [2]Department of General Surgery, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [3]Department of Pathology, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [4]Department of Internal Medicine, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey.

Introduction
Multiple endocrine neoplasia type 2A (MEN2A) is a complex autosomal dominant inherited syndrome characterized by medullary thyroid carcinoma (MTC), phaeochromocytoma, and primary parathyroid hyperplasia (PPH). In patients with only one or two clinical features, identification of a germline rearranged in transfection (RET) mutation or the identification of the clinical features of MEN2A in other first degree relatives is required to make the diagnosis. We present the case of a family with MEN2A syndrome, diagnosed with the complaint of abdominal pain.
Cases
Index case was the brother – OS – aged 28 years and was admitted to the hospital with the complaint of abdominal pain. There was no pathology in his medical history and physical examination. In radiologic examination; bilateral adrenal adenoma, multinodular goitre (MNG) and PPH was detected. Fine-needle aspiration cytology (FNAC) revealed MTC. And then operated for MTC, phaeochromocytoma, and PPH. Genetic analysis showed RET gene mutation in 634codons. His father was died from myocardial infarction 5 years ago. Upon that all family members were investigated for MEN. Second case (brother, GS, aged 27 years), third case (sister, AK aged 32 years), and fourth case (sister, LK, aged 22 years) had also MNG in thyroid USG examination, PPH and FNAC revealed MTC. Operations also decided for them. Biochemical and hormonal parameters of cases are as shown in Table 1.

Table 1

	Case 1, OS	Case 2, GS	Case 3, AK	Case 4, LK	Normal reference range
PRA	5,82	11	21.07	42	0.7–3.3 ng/ml per h
PAC	2.37	0.78	4.46	4.68	7–30 ng/dl
Normetanephrine (urine)	1054	3401	1120	1227	88–444 μg/day
Metanephrine (urine)	3211	14527	1831	3108	52–341 μg/day
Cortisol	15	15	18	22	5–25 μg/dl
TSH	2.2	1.18	2.86	0.9	0.4–4 IU/ml
DHEAS	215	150	148	155	35–560 μg/dl
Calcitonin	622	132	40	698	<18.2 pg/ml (men) and <11.5 pg/ml (women)
Parathormone	145	91	87	121	10–65 pg/ml
Calcium	11.5	11	10.3	10.4	8.4–10.2 mg/dl
Albumin	4.2	4.3	4.3	4.7	3.5–5.2 g/dl
Phosphor	2.6	3.6	4.1	3.7	2.4–5.4 mg/dl
1 mg overnight DST cortisol	1.3	0.9	1.4	1.31	<1.8 μg/dl

PRA, plasma renin activity; PAC, plasma aldosterone concentration; DST, dexamethasone suppression test.

Discussion
MEN2A is the most prevalent form and presents with MTC in 95% of cases, bilateral pheochromocytoma in 50% of the cases and primary hyperparathyroidism in 25% of cases. Bilateral adrenal adenoms determined at a young age should be investigated interms of MEN syndrome. Also, in our index case bilateral adrenal adenoms were incidentally detected. In light of the association between certain familial syndromes and patients diagnosed with pheochromocytomas at a young age should be screened with genetic testing for a RET mutation.

Cervical paraganglioma ultrasonographically mimicking parathyroid adenoma: a case report

Selvihan Beysel[1], Mustafa Caliskan[1], Muyesser Sayki Arslan[1], Melia Karakose[1], Esra Tutal[1], Seyfullah Kan[1], Muhammed Kizilgul[1], Mahmut Apaydin[1], Erman Cakal[1], Mustafa Ozbek[1] & Tuncay Delibasi[1,2]
[1]Department of Endocrinology and Metabolism, Diskapi, Teaching and Research Hospital, Ankara, Turkey; [2]School of Medicine (Kastamonu), Hacettepe University, Ankara, Turkey.

Introduction
Paragangliomas are neuroendocrine tumors arising from extra-adrenal chromaffin cells. Paragangliomas of the head and neck frequently originate from the paraganglionic system including the carotid bifurcation, middle ear and the ganglion nodosum of the vagus nerve. However, of paragangliomas of the head and neck, only 1–3% secrete hormones and majority are non-functional. Here, we describe a case of non-functional paraganglioma confused with parathyroid adenoma ultrasonographically.

Case
A 45-year-old female patient attending to our department with difficulty in swallowing was found to have a palpable mass lesion in the right lower cervical region. A neck ultrasound showed a hypo-echoic, solid lesion without increased vascularity (15×18×24 mm) adjacent to the capsule of the lower pole of the thyroid lobe. She was euthyroid and had normal calcium and parathyroid hormone levels. Its location adjacent to the thyroid capsule suggested a non-functional parathyroid lesion. Thus, a technetium sestamibi scanning did not demonstrate any activity uptake consistent with a parathyroid lesion. Also a neck exploration was performed for differential diagnosis. Encapsulated solid nodule was confirmed a benign paraganglioma by histopatologic examination. Hormonal profile revealed a serum menanephrine of 0.37 nmol/l (*n*: 0.08–0.51), serum normetanephrine of 1.24 nmol/l (*n*: 0.12–1.18), urinary menatephrine of 78.29 µg/day (*n*: 52–341), and a urinary normetanephrine of 221.8 µg/day (*n*: 88–444). Thus, a diagnosis of non-functional paraganglioma was established, and further radiological imaging did not reveal paragangliomas at other sites.
Conclusion
Herein, we reported a case of cervical non-functional paraganglioma located at the neck that can be confused with a parathyroid adenoma ultrasonographically. In normocalcaemic patients with normal parathyroid hormone levels, a diagnosis of cervical paraganglioma should also be considered due to its ultrasonographic similarity to parathyroid lesions.

EP1295

Concurrent mediastinal parathyroid carcinoma and parathyroid adenoma

Mustafa Caliskan, Selvihan Beysel[1], Esra Tutal[1], Bekir Ucan[1], Taner Demirci[1], Seyfullah Kan[1], Mahmut Apaydin[1], Muhammed Kizilgul[1], Guleser Saylam[2], Erman Cakal[1], Mustafa Ozbek[1] & Tuncay Delibasi[1,3]
[1]Department of Endocrinology and Metabolism, Diskapi Teaching and Research Hospital, Ankara, Turkey; [2]Department of Otorhinolaryngology, Diskapi Teaching and Research Hospital, Ankara, Turkey; [3]School of Medicine (Kastamonu), Hacettepe University, Ankara, Turkey.

Introduction
While mediastinal parathyroid carcinoma is a rare entity by itself, multiglandular coexistence of parathyroid carcinoma and adenoma represents an extremely rare condition. Herein, we report such a rare presentation of multiglandular parathyroid neoplasm with an ectopic carcinoma in the mediastinum and adenoma on the right side of neck in a patient with persistent primary hyperparathyroidism (PHP).
Case report
A 38-year-old female patient who initially presented with nephrolithiasis and osteopenia was subsequently diagnosed as having PHP. Tc-^{99m}-methoxybutylisonitrile scintigraphy showed no parathyroid lesions, while a neck ultrasound determined the presence of a solid hypoechoic nodular lesion (4×4×8 mm) at the postero-inferior aspect of the right thyroid lobe. Following bilateral surgical neck exploration, existence of a parathyroid adenoma was revealed. However, due to the persistence of hypercalcaemia postoperatively, a single photon emission computed tomographic examination showed a mass lesion in the anterior mediastinum and no lesion in the neck region. A second surgical procedure was performed and histopathological examination revealed the presence of a mediastinal parathyroid carcinoma with evidence of invasion in the capsule and surrounding adipose tissue, without metastatic lymph nodes. At 1-year of follow-up there was no hypercalcaemia. The chest computed tomography failed to demonstrate any lesions in the mediastinum and neck region.
Discussion
To our knowledge, only four cases have been described in the literature with concurrent occurrence of multiglandular parathyroid adenoma and carcinoma, with all cases having the multiglandular parathyroid carcinoma localised in the neck. This is the first patient who had coexistent ectopic mediastinal parathyroid carcinoma and parathyroid adenoma in the neck with persistent PHP.
Conclusion
Concurrent occurrence of ectopic mediastinal parathyroid carcinoma and parathyroid adenoma may be result in significant diagnostic challenges for the clinicians. Multiple diagnostic studies appear to be required and essential for the identification of multiple parathyroid glands in patients with persistent PHP.

Radioguided excision of occult metastatic lesion in thyroid carcinoma: a safe technique for previously operated neck in two patients

Teresa Martins, Teresa Azevedo, Jacinta Santos, Fernando Rodrigues, Eugenia Rovira, Sofia Oliveira, João Neto, António Neves, Patricia Gilde & Carlos Cruz
Portuguese Institute of Oncology, Coimbra, Portugal.

Introduction
Intraoperative identification of neck lesions in patients who have undergone previous neck surgery is particularly difficult, because of operative scarring and distorted anatomy. Radioguided occult lesion localisation (ROLL) involves the preoperative intratumoral ultrasound-guided injection of a radioactive tracer. In the present study, we investigated the efficacy of roll in two patients with papillary thyroid cancer (PTC) who underwent previous neck exploration.
Material and methods
This study included two patients with recurrent/persistent PTC who have previously undergone operation. Patient 1: female, 65 years with PTC (T1bN1bM0) previously operated in 2010 with recurrence in the central neck (nodule with 9×7 mm). A fine-needle aspiration (FNA) cytology with FNA thyroglobulin (Tg) measurement was performed and confirmed the diagnosis of malignancy; patient 2: male, 50 years with PTC (T4aN1bM0) previously operated four times with three nodules in the central neck with 9, 7, and 6 mm. The largest nodule was submitted to FNA cytology confirming recurrence. In both patients ^{99m}TC-labeled macroaggregated albumin was injected directly into each lesion under US guidance 90 min before surgery. Scintigraphy was performed 30 min after injection to visualize the focally increased uptake of radiotracer. Intraoperative lesion detection was performed with gamma probe by identifying areas of maximum radioactivity.
Results
In patient 1 the lesion was identified and excised but in the patient 2 only two lesions were identified and excised. Histopathological examination confirmed recurrence of PTC in all of the nodules excised. In patient 1 serum Tg dropped from 15 to <2 ng/ml but in patient 2 Tg didn't drop significantly and in the follow-up persisted a 7 mm nodule in the central neck.
Discussion
The Roll technique was efficient and safe in the perioperative identification of recurrent thyroid cancer in the central neck. This technique might help decrease the complications rates associated with reoperation.

Familial hypocalciuric hypercalcaemia: case report

Ana Carolina Neves[1], Teresa Rego[1], Branca Cavaco[2], Fernando Fonseca[1] & Ana Agapito[1]
[1]Endocrinology Department, Curry Cabral Hospital – CHLC, Lisbon, Portugal; [2]Molecular Pathobiology Investigation Unit, Portuguese Oncology Institute, Lisbon, Portugal.

Introduction
Familial hypocalciuric hypercalcaemia (FHH) is a rare genetically heterogeneous disorder, with 3 variants described. An inactivating mutation in the calcium sensor receptor (CASR) gene causes the subtype 1, which represents 65% of the cases.
It is charaterised by hypercalcaemia and hypocalciuria with normal or elevated PTH. FHH is generally assymptomatic and treatment is not needed. Differential diagnosis with primary hyperparathyroidism (PHPT) is crucial and based on calcium-creatinine clearance ratio (CCCR), which, when under 0.02 points to the diagnosis of FHH. Genetic test is necessary for confirmation.
Case report
An assymptomatic 16-year-old girl was referred to Endocrinology Department due to hypercalcaemia. Family history of several malignancies was present. Her mother died at 39 years old from hepatocellular carcinoma, her maternal-aunt at 13 from sarcoma and her maternal cousin at 18 from ovarian carcinoma. Laboratory work-up: Ca 11.5 mg/dl (8.8–10.4); P 3.1 mg/dl (2.5–4.5); Ca(u) 92 µg/24 h (20–90); PTH 32 pg/ml (10–70); creatinine 0.7 mg/dl; and CCCR 0.007. DNA sequence analysis of *CASR* gene identified a frameshift mutation in exon 7, (c.1945delG), in heterozigoty, not previously described. Her father and half-brother had normal Ca and PTH levels. Some months later, patient maternal grandmother was observed for multinodular goitre and laboratory work-up

revealed Ca 11.9 mg/dl, P 3.1 mg/dl, PTH 93 pg/ml, 25OHD3 21.8 ng/ml (30–100), and Ca(u) 86 mg/24 h. Genetic study confirmed the same mutation.
Conclusions
FHH is a benign condition that must be considered in the differential diagnosis of hypercalcaemia with normal or elevated PTH. CCCR is used to distinguish it from PHPT, however the definitive diagnosis demands genetic study, in order to avoid needless parathyroidectomy. In this family, a novel mutation in *CASR* gene was identified.

EP1298

It is a link between Hashimoto encephalopathy and CLIPPERS syndrome?

Krzysztof Marczewski[1,2], Iwona Ciuba[1], Bozena Jarosz[3] & Dorota Boniek-Poprawa[1,2]
[1]Pope John Paul II Regional Hospital, Zamosc, Poland; [2]Zamosc University of Management and Administration, Zamosc, Poland; [3]Department of Neurosurgery and Pediatric Neurosurgery, Medical University of Lublin, Lublin, Poland.

Introduction
Different forms of brain damages in endocrine disease are relatively common. Recently the Hashimoto encephalopathy is more frequent recognised and successfully treated. The diagnosis criteria and treatment options however are still under discussion. On the other hand in neurology are described new pathologic entities, which can occurred also by endocrine patients.
Case
In September 2009 by the 66 years old women with type 2 diabetes and metabolic syndrome was diagnosed hypothyroidism in course of autoimmune thyroiditis with moderately elevated antithyroid antibodies. The hypothyroidism was successfully treated with levothyroxine, but in December 2012 patient was admitted with cognitive decline and impaired mobility. In CT brain metastases are described but the primary focus are not founded. In brain biopsy was found inflammatory infiltration from the T and B lymphocytes and macrophages, reactive gliosis and loss of myelin. After steroids, initially as pulses of 1 g methylprednisolone and then oral prednisonum (60 mg with subsequent reduction) clinical status was improved and in MRI we observed brain damage regressions until almost complete in November 2013. In May 2014 when attempting to further reduce the dose of steroids visual loss occurred on the right eye. The vision returned after pulses of methylprednisolone, which we have repeated in subsequent months. The patient is currently in a stable condition on oral 25 mg prednisone. Diabetes and hypothyroidism are treated effectively. She sees and moves quite well, although she had a depressed mood.
Comments
We have serious doubts regarding the diagnosis. The clinics including a strong dependence on steroids would speak rather for Clippers syndrome, but we cannot exclude pathology associated with thyroiditis, despite the relatively low titre of antibodies. Therefore, we would like to introduce our problem, to the European Endocrinologists in hope for comments and advice.

Graves' orbitopathy coursing with hypothyroidism: a case-report

Ana Saavedra[1,2], Joana Menezes Nunes[1,2], Elisabete Rodrigues[1,2,3], Sara Ribeiro[4], Victor Leal[4] & Davide Carvalho[1,2]
[1]Department of Endocrinology Diabetes and Metabolism, Centro Hospitalar S. João, Porto, Portugal; [2]Faculty of Medicine, University of Porto, Porto, Portugal; [3]Instituto de Investigação e Inovação em Saúde, University of Porto, Porto, Portugal; [4]Department of Ophthalmology, Centro Hospitalar de São João, Porto, Portugal.

Introduction
Graves' orbitopathy is usually associated with Graves' Disease, which is typically characterized by hyperthyroidism and goiter. However, in rare situations, Graves' disease can also present with hypothyroidism and orbitopathy.
Case report
Male, 38 years old, followed by his ophthalmologist for thyroid orbitopathy (exophthalmos right > left and conjunctival hyperaemia since 1 year ago) associated with asthenia, tiredness and weight gain. He was referred to endocrinology consultation because he presented TSH elevated (62.75 μUI/ml, reference values (RV): 0.35–4.94) with normal FT_4 0.70 ng/dl (RV: 0.70–1.48) and normal FT_3 2.95 pg/ml (RV 1.71–3.71) and high levels of anti-thyroid and TSH-receptor autoantibodies (TRAbs) (5.2 U/l (RV: 0–1.8)). Thyroid ultrasonography showed a gland with normal dimensions, heterogeneous and pseudonodular texture, suggesting thyroiditis. The patient denied any previous treatment. He started therapy with levothyroxine and the dose was increased as needed. It was accompanied by improvement of hypothyroid symptoms. Six months later, he had normal TSH and TRAb's = 3.9 U/l (RV: 0–1.8). A year after starting therapy, symptoms reappeared and analytically he presented again with hypothyroidism (TSH = 14.71; FT_3 and FT_4N) and TRAB's levels > 40.0 U/l.
Discussion
It has been described in literature different types of TRAbs, which are capable of inducing two distinct clinical syndromes: thyroid-stimulating autoantibodies and TSH-blocking autoantibodies. In this patient with Graves's orbitopathy, a predominance of blocking type TRAbs vs stimulatory type may be a possible explanation for the presence of hypothyroidism. Although, we can't exclude the possible contribution, at least at some degree, from the gland's destruction (suggested by high titres of anti-peroxidase/anti-thyroglobulin autoantibodies and the findings suggestive of thyroiditis in ultrasound). Thus, the determination of TRAbs subtype is of particular interest in these less common forms of presentation of thyroid autoimmune pathology.

Incidental thyroid cancer in a subcentimetric nodule with benign ultrasound criteria in a patient with Graves' disease

Enalda Demaj, Endri Ahmeti, Marjeta Kermaj, Violeta Hoxha, Gerond Husi, Thanas Fureraj, Dorina Ylli & Agron Ylli
Department of Endocrinology, University Hospital Center 'Mother Theresa', Tirana, Albania.

Introduction
A thyroid nodule discovered in a patient with Graves' disease (GD) should be evaluated and managed according to guidelines. A subcentimetre incidental thyroid cancer founded in a patients with GD, without high-risk history, without suspicious sonographic (US) features has not been reported yet.
Clinical case
A 40-year-old female patient, presented to our hospital with symptoms of thyrotoxicosis. On physical examination heart rate was 120 b.p.m., blood pressure of 130/90 mmHg, with a nontender thyroid gland, with murmurs on auscultation, without nodules on palpation. No exophtalmos or skin changes were noted. The patient was under treatment with methimazole 5 mg twice daily and β blocker, since 7 months. Laboratory investigations showed AST: 93 U/l, ALT: 156 U/l (*n*: < 40 U/l). Thyroid function tests revealed free T_3: 22.52 pg/ml (*n*: 2–4.4), free T_4: 63.04 ng/dl (*n*: 10.6–19.4), and TSH: 0.003 μUI/ml (*n*: 0.35–4.94). TRAbs: 1.8 UI/ml ($n < 1$). A thyroid ultrasound detected a diffuse enlargement with diffuse hypervascularity of thyroid, with a hyperechoic rounded nodule measuring 9 m ÷ 6.4 mm in the left lobe (with regular borders, with halo, without microcalcifications) and a hypoechoic right lobe. A scintigraphy showed a increased diffuse uptake, suggestive of GD. Fine-needle aspiration biopsy (FNAB) was not performed. Our patient underwent a total thyroidectomy after 2 months, in a euthyroid state. Histopatological examination of the thyroid gland showed a focus of papillary microcarcinoma, follicular variant, lying into the nodule detected on US.
Conclusions
Thyroid cancer occurs in GD patients with a frequency of 2% or less. We referred a case of incidental thyroid cancer in a Graves' disease with no malignant ultrasound features. We conclude that the presence of benign nodules on ultrasonographic examination does not reduce the risk of malignancy. We recommend a FNAB in all nodules detected on ultrasound in Graves' disease and early total thyroidectomy in these cases.

Late onset of a rare autoimmune association: coeliac disease and Hashimoto's thyroiditis; hormonal and metabolic implications

Mirela Puiu[1], Radu Popa[2], Elena Gologan[3], Felicia Crumpei[4], Ioana Armasu[1], Ioana Vasiliu[1], Adina Manolachie[1], Cristina Preda[1] & Carmen Vulpoi[1]
[1]Department of Endocrinology, University of Medicine and Pharmacy 'Gr.T.Popa', Iasi, Romania; [2]Department of Vascular Surgery, University of Medicine and Pharmacy 'Gr.T.Popa', Iasi, Romania; [3]Department of Gastroenterology, University of Medicine and Pharmacy 'Gr.T.Popa', Iasi, Romania; [4]Department of Radiology and Medical Imaging, University of Medicine and Pharmacy 'Gr.T.Popa', Iasi, Romania.

Introduction
Several autoimmune determinations have been reported in association with autoimmune thyroidits (AIT). While the classical correlations with other endocrine or general autoimmune diseases like pernicious anemia or vitiligo are frequent and well defined, there are fewer data on other rarer associations, as with celiac disease (CD). In the absence of typical clinical symptoms this association may be overlooked, as in the case we present.
Case presentation
DM, 64 years old female patient, with three recent episodes of persistent diarrhea and weight loss, having negative bacteriologic and imagistic investigations (gastric endoscopy with antral biopsy, colonoscopy, and abdominal CT), was oriented to the Endocrine Department for hypothyroidism associated with severe diselectrolemia. On admission she presented asthenia, hypoanabolic syndrome (BMI 17.5 kg/m^2) and inferior limb edema. Biological data confirmed autoimmune thyroiditis with hypothyroidism (TSH = 27 μUI/ml, fT_4 = 0.7 ng/dl, ATPO > 1000 UI/ml, and ATg > 3000 UI/ml), inflammatory syndrome, severe vitamin D deficiency (< 3 ng/ml), and severe metabolic disturbances (hypoalbuminemia, hypokaliemia, hyponatremia, hypocalcemia, and acidosis). Markers for digestive neoplasia and NET were negative. Other investigations revealed osteoporosis and profound venous thrombosis with decreased tolerance to cumarinic anticoagulants (INR 7.32) which imposed heparinotherapy. Coeliac disease was suspected, sustained by positive antigliadin antibodies. Patient refused doudenal biopsy. Substitutive L-T_4 treatment, vitamin D supplementation and gluten-free diet was started, with rapid and persistent improvement of the general status and biological data.
Conclusion
Undiagnosed CD associated with TAI may determine severe metabolic disturbances due to the vicious circle of malabsorbtion. Low L-T_4 absorbtion impose attentive substitution dosage. Most of guides do not recommend systematic search of CD in TAI however, since, as in our patient, CD may be paucisymptomatic and/or with late manifestation, we believe that it may be useful to search it, if not in all AIT patients at least in those with metabolic disturbances.

Malignant ectopic thyroid tissue with distant metastasis: a case report

Shehla Tabassum, Najmul Islam, Saulat Hasnain Fatimi, Mubasher Ikram, Arsalan Ahmed & Maseehuz Zaman
Aga Khan University, Karachi, Sind, Pakistan.

Introduction
Ectopic thyroid tissue is the most common form of thyroid dysgenesis. But primary malignant transformation in ectopic thyroid tissue is quite a rare entity, with follicular malignancy being the dominant form at ectopic sites. Very infrequently, malignant ectopic thyroid tissue can present with metastasis to lymph nodes. But we report a case of malignant ectopic thyroid tissue over manubrium sterni with distant metastasis.
Case presentation
A 42-year-old Pakistani female presented with gradually increasing swelling on anterior aspect of manubrium sterni for last 6 months. She had no goitre and was clinically and biochemically euthyroid. Rest of systemic exam was also unremarkable. CT chest showed a circumscribed soft tissue density mass arising from sternum, measuring 3.9×3.9 cm, causing erosions of anterior, right lateral and posterior walls of sternum. Trucut biopsy of the sternal mass proved it to be thyroid tissue with follicular differentiation and occasional mitotic figures. Multiple nodules were also noted in thyroid gland in US neck. She underwent total thyroidectomy and excision of ectopic thyroid tissue over manubrium sterni. Extensive histopathological examination of primary thyroid gland showed benign nodular hyperplasia with no evidence of malignancy. Ectopic thyroid tissue showed minimally invasive follicular thyroid carcinoma with tumor size of 3.2×2.3 cm. Her postoperative 21-day biochemical profile showed TSH 22.345 μIU/ml (0.4–4.2), serum thyroglobulin 88.3 ng/ml, and anti-TG antibodies < 20.0 IU/ml. Based on the histopatholigical diagnosis, she went through 30 mCi RAI-131 ablation. The post-ablative whole body scan showed good uptake of ablative dose over thyroid bed and evidence of multiple well-defined rounded areas of abnormally increased tracer accumulation over mid and lower dorsal spine, lumbar region and right iliac bone, representing bone metastasis. It was followed by MRI spine which showed foci of metastatic deposits in T1–T3 and L2 vertebral bodies and abnormal signals showing post-contrast enhancement in superior mediastinum with invasion of medial ends of both clavicles, more marked on right side. So patient was found to have malignant ectopic thyroid tissue with distant bone metastasis.
Conclusion
We describe the first case of its kind having malignant ectopic thyroid with metastasis to spine and ilium. Such cases may impose difficulties in their treatment decisions.

Medullary thyroid carcinoma in multiple endocrine neoplasia 2A: a therapeutic challenge

Luis Cardoso[1], Dírcea Rodrigues[1,2], Gracinda Costa[2,3], Carolina Moreno[1,2], Daniela Guelho[1], Nuno Vicente[1], Margarida Balsa[4], Diana Martins[1], Diana Oliveira[1] & Francisco Carrilho[1]
[1]Department of Endocrinology, Diabetes and Metabolism, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [2]Faculty of Medicine, University of Coimbra, Coimbra, Portugal; [3]Department of Nuclear Medicine, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [4]Department of Endocrinology, Centro Hospitalar do Baixo Vouga, Aveiro, Portugal.

Introduction
Medullary thyroid carcinoma (MTC) occurs in a hereditary pattern in 25% of cases. Virtually all patients with multiple endocrine neoplasia 2A (MEN2A) develop MTC. MTC aggressiveness and natural history varies according to the *RET* mutation. Prophylactic thyroidectomy may cure and/or prevent metastatic disease in most cases.
Case report
A 27-year-old man with past history of colostomy at 5 months of age for Hirschsprung disease and total thyroidectomy at age of 14 years old for the genetic diagnosis of MEN2A (C620R *RET*). Patient's underwent genetic study when his mother was diagnosed with MTC and a germline mutation in *RET* gene (C620R) was identified. Patient's post-operative histological diagnosis revealed two MTC foci of 1 and 0.3 cm. Patient was lost to follow-up at the age of 16. In the last year he reported low back pain radiated to right thigh. MRI showed a 9×5×8 cm mass in the right iliac bone and lesion biopsy was compatible with MTC metastasis. ^{68}Ga-DotaNoc PET showed uptake in the thyroid area, left parapharyngeal region, high density of somatostatin receptors in the left cervical region and right iliac bone. Biochemical analysis revealed thyroglobulin of < 0.2 ng/ml (1.6–60.0), calcitonin of 60.428 pg/ml (< 10), and CEA of 1.947 ng/ml (< 5.4). Patient underwent bilateral cervical lymph node dissection and subtotal resection of iliac metastasis. Histological examination confirmed MTC metastasis. Patient underwent a cycle of 200 mCi of ^{177}Lu-DotaTate, though low radionuclide uptake motivated its withdrawal. Patient showed increased uptake of ^{123}I-MIBG and treatment with ^{131}I-MIBG was started (154 mCi).
Conclusion
CMT is the first manifestation of MEN2A. As shown in this case the age of prophylactic thyroidectomy is of decisive importance to the prognosis. Tumour somatostatin receptors heterogeneity may be responsible for different responses to radionuclides. The treatment of metastatic disease is challenging due to the poor response to systemic therapy and/or radiotherapy.

Coexistent medullary and papillary thyroid carcinomas

Betül Ekiz-Bilir[1], Neslihan Soysal-Atile[1], Zehra Dagli[2] & Ufuk Coskunkan[3]
[1]Endocrinology Department, Tekirdag State Hospital, Tekirdag, Turkey; [2]Pathology Department, Tekirdag State Hospital, Tekirdag, Turkey; [3]General Surgery Department, Namik Kemal University, Tekirdag, Turkey.

Papillary thyroid cancer (PTC) is the most frequent thyroid tumour. Medullary thyroid cancer (MTC) however, is very rare. We report a case of coexistent

medullary and papillary carcinomas in two different foci in a patient with family history of TPC in a first-degree relative.
Case
A 65-year-old female was examined for multinodular goiter (MNG). She had a family history of thyroid papillary carcinoma in her elder sister. Free T_4, free T_3, and TSH levels were within normal limits. Neck ultrasound (US) displayed solid, hypo-echoic nodules >3 cm at the both lobes of the thyroid gland. The results of fine-needle aspiration cytology (FNAC) of the both nodules were benign. Patient preferred surgery because of the nodule size and positive family history. Histopathology results revealed MTC which is 4 mm in diameter in the right lobe and PTC follicular variant 12 mm in diameter in the left lobe. Postoperative calcitonin was 56 pg/ml and CEA was in normal limits. Completion thyroidectomy and lymph node dissection also performed. No residue was detected by post-operative neck US. Neck and chest CT and liver MRI which were performed for MTC metastasis were all negatives. RET protooncogen mutation was negative unless $BRAF^{V600E}$ mutation was positive. Patient's younger sister was also examined for MNG. Thyroid US displayed solid, hypoechoic nodules >2 cm in both lobes. FNAC of nodules were reported as suspicious for PTC. Patient underwent total thyroidectomy and central lymph node dissection and diagnosed as PTC on both lobes.
Discussion
FNAC is the most accurate method for evaluating thyroid nodules. False negative rate of FNAC is about 5%, so malignancy risk of benign results should be kept in mind especially with a positive family history of thyroid carcinoma in a first-degree relative. We presented a coincidental coexistence of MTC and PTC case to point to this risk.

Virilisation due to a Leydig cell tumour of the ovary: diagnostic and therapeutic challenges

Ruxandra Dobrescu[2], Cristian Poalelungi[1], Iuliana Ceausu[1], Dan Hortopan[2] & Corin Badiu[1,2]
[1]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania; [2]'C.I.Parhon' National Institute of Endocrinology, Bucharest, Romania.

Introduction
Severe hirsutism and virilisation, especially if occurring later in life and with rapid onset, should prompt the search for rare but potentially threatening causes such as an androgen secreting ovarian or adrenal tumour.
We present the case of a 47-year-old woman referred to our clinic with obesity, severe hirsutism, alopecia, acne, and deepening of the voice that appeared insidiously 2 years ago, along with amenorrhoea which she interpreted as menopause. Laboratory testing revealed polycythemia, impaired glucose tolerance, normal thyroid, IGF1, 17OH- progesterone, baseline ACTH, cortisol, and DHEAS levels with adequate suppression of cortisol after low dose ($2\times$ 2 mg). Dexamethasone suppression testing (LDDST) excluding an adrenal hypersecretion. She had severe hyperandrogenism – total testosterone $=$ 6.38 ng/ml which increased paradoxically after LDDST (7.57 ng/ml) and normal gonadotropins and oestrogens (LH $=2.63$ mUI/ml, FSH $=5.59$ mUI/ml, and oestrogen $=86$ pg/ml) reflecting either androgen induced amenorrhea in premenopause, or testosterone mediated gonadotropin suppression after menopause. CT scans of the abdomen and pelvis and the ultrasound evaluation of the uterus and ovaries showed normal morphology – raising suspicion of ovarian hyperthecosis. The patient initially postponed surgery, so a short trial of GnRH agonist was attempted (triptorelin 0.1 mg s.c./month) with a small decrease in testosterone to 5.65 ng/ml after 1 month, further proving its ovarian origin. A repeat ultrasound showed a 1.94/1.65 cm mass in the right ovary, suggesting an androgen-secreting ovarian tumour. The patient underwent bilateral oophorectomy and total hysterectomy and the pathology report confirmed a benign Leydig cell tumour of the ovary. Testosterone levels normalized immediately post-surgery (0.30 ng/ml) and after 6 months the hirsutism and alopecia were significantly improved, haemoglobin levels normalized, but the obesity persisted and diabetes mellitus was diagnosed.
Conclusion
Although, typically large, Sertoli–stromal ovarian tumours can occasionally be small enough to avoid detection even by high-resolution imaging; in the presence of virilisation the differential diagnosis includes ovarian hyperthecosis. In either situation bilateral oophorectomy is recommended after the end of childbearing years.

Takotsubo cardiomyopathy associated with levothyroxine over-replacement

Ana Margarida Balsa[1], Raquel Ferreira[2], Rosa Dantas[1] & Joana Guimarães[1]
[1]Serviço de Endocrinologia, Diabetes e Nutrição do Centro Hospitalar do Baixo Vouga, Aveiro, Portugal; [2]Serviço de Cardiologia do Centro Hospitalar do Baixo Vouga, Aveiro, Portugal.

Background
Takotsubo cardiomyopathy (TC) is characterised by acute, transient left ventricular apical ballooning precipitated by emotional or physiologically stressful stimuli and has been previously associated with Graves' disease based on few clinical reports. More recently, the association with exogenous thyrotoxicosis and radioiodine-induced thyroiditis has also been described. Iatrogenic hyperthyroidism on patients under levothyroxine replacement therapy for hypothyroidism had never been reported as a cause of TC. The authors describe two female patients with TC associated with levothyroxine over-replacement.
Case description
A 74- and 48-year-old female patient, medicated with levothyroxine (2.27 and 1.85 μg/kg respectively) for autoimmune thyroiditis was both admitted on our emergency room with precordial pain. The first had an ECG with ST-segment elevation in the anterior precordial leads, and the latter had sinus tachycardia with deep T-wave inversion and QT interval prolongation. Further investigation revealed a mild elevation of cardiac biomarker levels, severe apical hypokinesis but no significant coronary lesions on catheterisation. The suppressed TSH levels were only demonstrated on the cardiac intensive care unit: 0.21 and 0.07 mIU/l (0.35–5.50) respectively. Both patients showed improvement of the apical hypokinesis on the discharge echocardiogram and normalisation of cardiac biomarker levels. Levothyroxine dose was reduced.
Commentary
This case report emphasizes the importance of correct dose adjustment on patients under levothyroxine replacement therapy and stresses that TSH should be determined in patients presenting with acute coronary syndrome and typical finding of TC.

EP1307

Conversion of autoimmune hypothyroidism to hyperthyroidism with thyroid eye disease

Maura Moriarty, Edouard Mills, Hsiu L Yap & Arif Hamda
Department of Endocrinology, Watford General Hospital, Watford, UK.

We report the case of a 41-year-old lady who developed severe thyroid eye disease on a background of long standing hypothyroidism. She had been diagnosed with autoimmune hypothyroidism 15 years previously with positive TPO antibodies. She had been successfully maintained on levothyroxine replacement since then. She presented with a four year history of progressive eye swelling, gritty eyes and diplopia. On examination she was found to have active thyroid eye disease with restriction of extra-ocular movement, proptosis and diplopia. In addition her thyroid function tests showed suppressed TSH indicating probable over replacement with thyroid hormone. Her levothyroxine dose was weaned and eventually discontinued. She proceeded to have a course of steroids with some reduction in her visual symptoms. Unfortunately, she developed significant symptoms of thyrotoxicosis off thyroid replacement. Thyroid uptake scan showed generally increased uptake in the right lobe with no evidence of a nodule on ultrasound. TSH receptor antibodies at this time were strongly positive. Unfortunately her eye disease relapsed and she required orbital decompression surgery to which she had a good functional and cosmetic response. Thyroid function normalised rapidly on carbimazole and she was able to discontinue treatment after nine months. Following a period where she was biochemically euthyroid TSH levels have begun to rise again. We postulate that this lady had TSH receptor antibodies which were variably stimulating or blocking the TSH receptor as an underlying cause for her presentation. This case highlights the need to consider thyroid eye disease in a patient presenting with visual symptoms and a history of autoimmune thyroid disease. It also illustrates the need to have a high index of suspicion for possible conversion of

hypothyroidism to hyperthyroidism in a patient rather than attributing the biochemical abnormality solely to over replacement with thyroid hormone.

EP1308

Pulmonary neuroendocrine tumour presenting with thyroid gland metastasis: a case report

Cristina Corina Pop Radu
University of Medicine and Pharmacy, Tirgu Mures, Romania.

Introduction
Neuroendocrine tumours (NET) represent ~20% of all primary neoplasms of the lung. Histologic confirmation is important for treatment and prognosis determination. NET are classified according to four subtypes in the lung: typical carcinoid tumour (TC), atypical carcinoid tumour (AC), small cell carcinoma (SCC), and large cell neuroendocrine carcinoma (LCNEC). TC is low-grade, AC is intermediate-grade, and SCC and LCNEC are high-grade malignancies.
Case report
A 57-year-old woman, affected by a cervical anterior tumour and a proliferative tissue below the glottis was referred to our Endocrinology Department from ENT service for a second opinion. An ultrasound scan of the neck showed a polynodular goitre with bilaterally lymph nodes enlargement with suspicious malignancy characters. She had undergone surgery for the cervical anterior mass and for the laryngeal biopsy. Histopathological examination results were consistent with a SCC; neoplastic cells showed immunoreactivity to synaptophysin, neuron specific enolase, and chromogranin. The serum levels of serotonin, cromogranin A, calcitonin, carcinoembryonic antigen, ACTH, PTH, TSH, and FT_4 were normal. Fine-needle aspiration biopsy of her left thyroid lobe nodule was performed and the cytopathological exam was compatible with a neuroendocrine tumour metastasis. Thoracic and abdominal computed tomography was normal at that moment. Chest CT revealed the primary pulmonary tumour at 6 months after presentation. The therapeutic option for advanced or metastatic NETs is mainly palliation of symptoms; options need to be individualised and, therefore, rely on the knowledge of multidisciplinary teams.

EP1309

Graves' disease and pregnancy

Imane Leghbir, Samia Ould Kablia & Meriem Bensalah
Central Hospital of the Army, Algiers, Algeria.

Introduction
Pregnancy for women with Graves' disease is at risk for the mother and the newborn. In fact neonatal hyperthyroidism is uncommon, often transient in the context of maternal Graves' disease (1% of children). Immediate treatment is essential for a good prognosis, prenatal treatment improves foetal and neonatal development.
Case report
We report the case of a patient, known for Graves' disease since 2006, treated initially with carbimazole for 18 months.She was in remission for 2 years, but in December 2013 as she relapse, she was treated by radio-iodine (one month before conception). She gave birth to a premature 31 SA, in 21 August 2014 with subclinical hyperthyroidism (TSH: 0.07 UI/ml and FT_4: 7.09 pg/ml). After 15 days the new born present an overt hyperthyroidism (TSH: 0.01 UI/ml and FT_4: 23.5 pg/ml) with TSI: 6.89 UI/l. The baby receives carbimazole for 2 months and became euthyroid.
Conclusion
Neonatal hyperthyroidism should be screened in all newborn from mother with Graves' disease treated by radical treatment (radio-iodine or thyroidectomy) because TSI freely cross the placental barrier and thus stimulate the thyroid of the newborn. Prognosis of neonatal hyperthyroidism mediated by anti maternal body is quite good as they disappear in 4–12 weeks after birth.

The Ehlers-Danlos syndrome and metastatic medullary thyroid carcinoma: a case report

Lina Zabuliene[1,2], Airida Audrone Bagdziuniene[3], Birute Burnyte[4], Ramunas Janavicius[5], Jurgita Urboniene[6] & Algirdas Utkus[4]
[1]Clinics of Rheumatology, Traumatology–Orthopaedics and Reconstructive Surgery, Faculty of Medicine, Vilnius University, Vilnius, Lithuania; [2]Antakalnio Out-Patient Clinic, Vilnius, Lithuania; [3]Centre of Endocrinology, Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania; [4]Department of Human and Medical Genetics, Faculty of Medicine, Vilnius, Lithuania; [5]Department of Molecular and Regenerative Medicine, Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania; [6]Infectious Diseases and Tuberculosis Hospital, Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania.

Introduction
The Ehlers-Danlos syndrome, classic type is a connective tissue disorder, characterized by skin hyperextensibility, abnormal wound healing, and joint hypermobility, due to *COL5A1* or *COL5A2* genes mutations. Multiple endocrine neoplasia, type 2A (MEN2A) is a syndrome defined by medullary carcinoma, phaeochromocytoma, hyperparathyroidism, and occasionally cutaneous lichen amyloidosis, because of mutations in *RET* proto-oncogene. *COL5A* and *RET* genes mutations are linked to conditions affecting the human integumentary system.
Case report
A 18-year-old Caucasian female was consulted by endocrinologist in February 2014. Her psychomotor development was normal. Since childhood she was very flexible. At age 12 she had hip luxation and underwent internal fixation with screws. Deformities of pelvis and lumbar spine, knee valgus deformity occurred. At 15 years juvenile epiphysiolisis was diagnosed. She underwent left knee osteosynthesis followed by peroneal and tibial nerves damage. In 2012 small thyroid nodule, subclinical hypothyreosis was diagnosed; 25 mg of levothyroxine were prescribed. In 2014 medullary carcinoma (size 0.4 mm) was diagnosed. Thyroidectomy and neck lymphnodectomy was performed. She received radiotherapy course. 2.5 weeks after surgery calcitonin level was 1557.2 ng/l (0.5–7.8). She has been taking levothyroxine 125 mg/day. Her mother has MEN2A and underwent surgery for parathyroid adenoma. Father has multinodular goitre. On examination: height 184 cm, long face, long palms and fingers, joints' hypermobility, scoliosis, widened atrophic scars, atrophic striae at the back, hyperelasticity of face and elbows skin, piezogenic papules. Abdominal ultrasound and CT: no pathological changes. Left shoulder CT: sclerotic proximal growth line of left humerus. Body CT: multiple lymphnodes, lungs, pelvis bones, and vertebrae metastases. Bone scan: active head, humerus, pelvis focuses. Genetics'. Ehlers-Danlos syndrome; *RET* gene mutation at 13th egzone (*Y791F* mutation), causing MEN2A syndrome.
Conclusions
If complicated growth and atypical phenotype is obvious, genetics' consultation is desirable. Coexistent thyroid pathology might be inherited too.

DOI: 10.1530/endoabs.37.EP1310

Takotsubo cardiomyopathy in a young woman with severe adrenal insufficiency and hypothyroidism

Aleksandra Kruszynska[1], Jadwiga Slowinska-Srzednicka[1] & Agata Popielarz-Grygalewicz[2,3]
[1]Department of Endocrinology, The Medical Centre of Postgraduate Education, Warsaw, Poland; [2]Department of Cardiology, Bielanski Hospital, Warsaw, Poland; [3]Department of Cardiology, Faculty of Physiotherapy, Warsaw Medical University, Warsaw, Poland.

Introduction
Acute cardiac insufficiency induced by stress (Takotsubo cardiomyopathy (TTC)) is a reversible cardiomyopathy induced by severe emotional stress or severe clinical conditions. It is characterised by transient left ventricular systolic dysfunction and electrocardiographic changes. This cardiomyopathy has been described in some severe neurological conditions and in patients with pheochromocytoma. To date, some cases of this cardiomyopathy have been described in patients with hyponatremia due to isolated secondary adrenal insufficiency or in a patient with both hypothyroidism and adrenal insufficiency. TTC has been known to be more prevalent in women (the role of sex and hormones is not yet well defined).
Case report
We present a case of a 43-year-old woman with hypopituitarism, probably due to autoimmune hypophysitis with secondary hypothyroidism, secondary adrenal

insufficiency, and hypogonadism as well as with primary hypothyroidism due to Hashimoto's thyroiditis. The patient was treated for primary hypothyroidism, but her general condition suggested adrenal insufficiency. On admission, her plasma cortisol was 0 μg/dl, so she was treated immediately with hydrocortisone. As a routine examination, echocardiography was performed revealing ampulla cardiomyopathy. Electrocardiography showed T wave inversion in almost all leads. Two weeks after treatment with hydrocortisone and thyroxine, an echocardiographic examination showed recovered left ventricular wall motion and improvement in the ejection fraction and electrocardiography was normal. This is, to our knowledge, the first report of TTC due to hypothyroidism and adrenal insufficiency with no hyponatremia, no evident hypoglycemia and no evident catecholamine overproduction.

Conclusions

Adrenocortical failure is considered to be one of the triggering factors for ampulla cardiomyopathy. All patients with severe adrenal insufficiency should be screened for cardiomyopathy and first-line treatment in these cases consists of proper steroid substitution and careful monitoring of cardiac function.

A rare association: primary hyperparathyroidism and thyroid papillary carcinoma: case report

George-Sebastian Zmău[1], Cristina Preda[1], Cipriana Stefanescu[2], Radu Danila[3], Delia Ciobanu[4], Iulia Crumpei[1], Alina Daniela Belceanu[1], Adina Manolachie[1] & Carmen Vulpoi[1]
[1]Department of Endocrinology, UMF 'Gr. T. Popa' Iasi, Iasi, Romania; [2]Department of Nuclear Medicine, UMF 'Gr. T. Popa' Iasi, Iasi, Romania; [3]Department of General Surgery, UMF 'Gr. T. Popa' Iasi, Iasi, Romania; [4]Department of Morphopathology, UMF 'Gr. T. Popa' Iasi, Iasi, Romania.

Introduction

Although, the relationship between pathological process of the parathyroid and thyroid is common, concurrence of primary hyperparathyroidism (pHPT) and papillary thyroid carcinoma (PTC) is extremely rare, probably because, unlike with medullary thyroid cancer, they have not a common embryologic origin. We present a case with this uncommon association.

Case report

A 67-year-old woman with multinodular goitre was addressed in endocrinology for persistent hypercalcaemia 11.24 mg/dl and hypophosphatemia 2.4 mg/dl. High PTH value (119 pg/ml (normal range 10–69 pg/ml) confirmed primary hyperparathyroidism. The neck ultrasound revealed a potential 0.4 ml parathyroid adenoma at the superior pole of the right thyroid lobe and a 6 ml nodular conglomerate with central necrosis in the left thyroid lobe. The ^{99m}Tc-sestamibi parathyroid scintigraphy revealed an area with increased uptake in the projection aria of the nodule described at ultrasonography. Owing to the nodular aspect of the contralateral lobe total thyroidectomy was performed and the histological examination diagnosed right superior parathyroid adenomatous hyperplasia and multicenter invasive papillary carcinoma in the left thyroid lobe with (pT3Nx-G1). Hyperparathyroidism was cured, with normal PTH and phosphocalcic parameters. For the invasice PTC radioiodine therapy was performed with complete remission from – cifra! – ani. She is no more on suppressive L-T_4, having low normal TSH and absent thyroglobulin.

Conclusion

Our case illustrates an extremely rare synchronous association of primary hyperparathyroidismn with thyroid carcinomas (with an incidence roughly estimated at 0.0023/100 000 person-years). In spite of its rarity, this coexistence of pHPT and PTC maybe not a random but a possible new pathology. The concurrence of both pathological processes can make the patient management complicated, because unrecognised thyroid cancer diagnosed at the histological examination implies surgical re-intervention.

Fainting matters: a case of an autoimmune polyglandular syndrome with an atypical involvement of the parathyroid gland

Ieva Ruza[1,2], Sabine Upmale[2], Justine Malina[2] & Inta Leitane[1]
[1]Riga Eastern Clinical University Hospital, Riga, Latvia; [2]Riga Stradins University, Riga, Latvia.

Introduction

The autoimmune polyglandular syndrome (APS) is characterised by the coexistence of at least two glandular autoimmune mediated diseases. We report a combination of an autoimmune thyroid disease, Addison's disease and an atypical involvement of the parathyroid gland.

Case report

A 73-year-old white woman was admitted to our clinic for evaluation due to recurrent syncopes during last 3 years, along with vertigo, cold sweats, and general fatigue, associated with prolonged standing. Three months ago she was diagnosed with chronic autoimmune thyroiditis and primary hypothyroidism, as well as a parathyroid gland adenoma. Head CT scan revealed basal ganglia calcinosis. The patient had lost 15 kg within the past year, during investigation orthostatic hypotensia was detected, no skin colour changes. Biochemical tests revealed low aldosterone, renin, calcium, free T_4 and mildly elevated creatinine serum levels. TSH was elevated, ACTH was high normal. She had low cortisol in 24 h urine and also in serum after insulin stress test. PTH level was normal, but coexisting hypocalcaemia and parathyroid gland adenoma must be taken into consideration. Antibody screen (ANA, thyroid peroxidase, and tranglutaminase) was negative. No substantial changes in other tests. No data on diabetes mellitus or malignancy was found. Diagnosis of primary adrenal insufficiency with glucocorticoid and mineralocorticoid deficiency, chronic autoimmune thyroiditis with primary hypothyroidism, hypocalcaemia, calcinosis of basal ganglia (possible Fahr's syndrome), parathyroid gland adenoma, secondary osteoporosis due to malabsorption, chronic kidney disease was made. Based on these findings we suggest the final diagnosis of type 2 autoimmune polyglandular syndrome. Treatment was continued with L-thyroxine and oral calcium, started with alphacalcidol, hydrocortisone, fludrocortisone. A substantial improvement of symptoms was seen in a control visit after 3 months.

Conclusion

We would like to stress the importance of investigation for autoimmune glandular diseases and electrolyte level in case of unexplained syncope.

Subacute thyroiditis due to seasonal influenza vaccination

Fatma Aybala Altay[1], Galip Güz[2] & Mustafa Altay[3]
[1]Department of Infectious Disease and Microbiology, Ankara Dişkapi Yildirim Beyazid Education and Research Hospital, Ankara, Turkey; [2]Department of Nephrology, Medical Faculty, Gazi University, Ankara, Turkey; [3]Department of Endocrinology and Metabolism, Keçiören Education and Research Hospital, Ankara, Turkey.

Introduction

Subacute thyroiditis due to vaccination is reported in only a few case reports. A peritoneal dialysis patient who experienced a repeating attack after a vaccination for influenzae while she was being followed and treated successfully for subacute thyroiditis is presented.

Case

A 28-year-old female patient who has been applying dialysis for nine years was seen in policlinic telling about upper respiratory tract infection 2 months ago and pain at her thyroid lodge for 3 weeks. Her thyroid was palpable and tender. She was diagnosed as subacute thyroiditis with high levels of ESR, CRP, TSH, anti-TG, TPO, and consistent ultrasonography findings. She was begun ibubrofen at 1800 mg/day in three divided doses after consulting with nephrology. She had recovered totally a week after and begun to follow up with levotyroxine 75 μg/day. She applied to hospital 3 months later with fatigue, fever, sore throat, dyspnea, pain, and swelling at her thyroid lodge again. USG showed a larger thyroid. ESR, CRP, anti-TG, and anti-TPO were much more higher. It was learnt that she had been vaccinated for influenza 3 weeks ago and began to suffer from gribal symptoms at the third day and pain and swelling of thyroid at the second week of vaccination. Her thyroid scintigraphy showed heterogenous and lower activity and her thyroid biopsy resulted as consistent with subacute thyroiditis. So the patient was diagnosed as subacute thyroiditis and ibubrofen was begun besides raising levothyroxine dose to 100 μg/day. Methyl prednisolone of 40 mg/day was added because there was no symptomatic improvement at the third day. The symptoms regressed after steroid in three days and recovered totally at the end of the first week. Steroid was stopped by gradually declining at the third week.

Discussion

Influenza like symptoms is known to develop after vaccination. This case is showing a rare condition due to vaccination to cause a subacute thyroiditis just like the virus can make.

Testicular pain as an initial complaint in patient with classic form of Klinefelter's syndrome: a case report

Svetlana Jelic[1,2], Aleksandra Jevic-Ivanovic[1] & Stanislava Zivkovic[1]
[1]Clinical Hospital Center Bezanijska Kosa, Belgrade, Serbia; [2]School of Medicine, University of Belgrade, Belgrade, Serbia.

Background
In spite of being the most frequent genetic form of male hypogonadism, Klinefelter's syndrome is not so rarely undiagnosed until adulthood. As the severity of manifestations in Klinefelter's syndrome is proportional to the number of additional X chromosomes, they seem less severe and aparent in its classic form, with a 47,XXY karyotype than in cases of this syndrome with mosaicism and other variants.
Case report
A 25-year-old male was refered for endocrinological evaluation by urologist because of the chronic testicular pain preventing effective testosterone replacement of already proven hypogonadism. The physical examination revealed normal height, long limbs, muscular weakness, and reduced or completely absent hair in the androgen-dependent regions. There are clinical signs of testicular dysgenesis. Hormone measurements were as follows: ACTH, 37.74 pg/ml; cortisol, 505.9 nmol/l; TSH, 1.81 μIU/ml; fT_4, 15.15 pmol/l; LH, 31.78 mIU/ml; FSH, 53.39 mIU/ml; free testosterone, 5.0 pg/ml; PRL, 519.9 mIU/l; and vitamin D, 21.25 ng/ml. MRI demonstrated a profound arachnoid recessus hustling the pituitary toward the dorsum of the sella turcica. Densitometry showed osteopenia with the L1–L4 *T*-score of −2.7 and the hip *T*-score of −2.1. Assessment of the karyotype point out to the classic, 47,XXY form of Klinefelter's syndrome and testosterone replacement was initiated with the close follow-up of its effects.
Conclusions
The case presented demonstrates a classical form of the Klinefelter's syndrome with not so classical presentation of testicular pain which halted the correction of proven androgen deficiency. Coexistant empty sella with hyperpolactinaemia demand further periodical reassessment.

Ectopic ACTH syndrome: diagnostic and therapeutic challenge

Katarzyna Piatek, Malgorzata Kaluzna, Katarzyna Ziemnicka & Marek Ruchala
Department of Endocrinology, Metabolic Diseases and Internal Medicine, Poznan University of Medical Science, Poznan, Poland.

Introduction
Rapid deterioration of health condition in patient with diagnosed neoplastic disease, especially metastatic one, requires consideration of cancer progression. However other rare severe complications can occur. In 0.6–0.7% patients with medullary thyroid cancer (MTC) the ectopic ACTH syndrome (EAS) is observed. Hereby, we present a case EAS in patient suffered from MTC.
Case report
A 37-year-old man was admitted to the Department of Internal Medicine in serious clinical condition with general fatigue and chest pain. Myocardial infarction has been excluded. Patient's past medical history was remarkable for MTC with numerous reoperations. Routine laboratory test showed *de novo* diabetes mellitus. Calcitonin serum level was 499.53 pg/ml (*n*: 0–10 pg/ml). Additional tests revealed severe hypercortisolaemia (cortisol level 2100 nmol/l; *n*: 0700–1000 h: 171–536 nmol/l). The patient was referred to the Department of Endocrinology for further diagnostics and treatment. ACTH level was 329.0 pg/ml ($n<60.0$). There was no suppression of cortisol secretion after 1 mg of dexamethasone. Magnetic resonance imaging (MRI) of the pituitary gland showed no signs of macro or microadenoma. Computer tomography (CT) of the chest revealed metastasis to the mediastinum lymph nodes. The adrenal glands in CT were normal size and shape. The EAS was diagnosed. Owing to the rapid deterioration of general condition despite of ketoconazole treatment, bilateral adrenalectomy was performed. The patient in severe condition was transferred to the Intensive Care Unit. Four reoperations were conducted due to the: internal bleeding, megacolon toxicum, faecal peritonitis and eventration. On the 41th day after first surgery the patient died due to sepsis.
Conclusions
The EAS is a rare condition in patients with MTC, but our patient's history should serve as a warning to actively seek of EAS in case of metastatic disease, especially in rapid health deterioration.

EP1317

Stress cardiomyopathy following radioactive iodine therapy: a case report

Anastasia Dimakopoulou, Karunakaran Vithian, David Ganon & Alan Harkness
Colchester Hospital, Essex, UK.

A 55-year-old female presented to the Endocrine Clinic with Graves' disease which was treated with carbimazole for 18 months. Her initial symptoms were facial sweating and dry lips on background of a multinodular goitre confirmed on thyroid ultrasound. TSH was <0.01 mU/l, free T_4 was 42.2, and free T_3 18 pmol/l. Thyrotoxicosis recurred in an attempt to taper down the dose of carbimazole and a decision was made to proceed with radioactive iodine treatment. Four days after radioiodine administration, our patient presented to the Emergency Department with chest tightness and dyspnoea. TSH was undetectable and free T_4 was 77.7 pmol/l. ECG was consistent with sinus tachycardia and borderline ST elevation in II/III leads. Troponin was elevated at 438 ng/l. Our patient was transferred to the local cardiothoracic center, where echocardiography revealed left ventricular ejection fraction of 30–35%. Coronary angiography showed no obstructive coronary disease. This is a case of stress cardiomyopathy which developed in the context of radiation thyroiditis. Complete recovery was achieved after treatment with propylthiouracil, ramipril, carvedilol, and a course of steroids. Six weeks later left ventricular function was noted to be normal on echocardiography and hypothyroidism was evident on thyroid function testing. This the second case of stress cardiomyopathy following radioactive iodine therapy reported in the literature, to the best of our knowledge. Left ventricular dysfunction is reversible in stress cardiomyopathy although patients can present quite unwell. High index of suspicion along with early thyroid testing may lead to successful treatment without unnecessary diagnostic investigations.

Is thymectomy a solution for myasthenia gravis associated with autoimmune thyroid diseases?

Ioana Vasiliu, Ioana Bodescu, Cipriana Stefanescu, Delia-Gabriela Ciobanu, Lidia Ionescu, Ionela Lacramioara Serban & Carmen Vulpoi
University of Medicine and Pharmacy, Iasi, Romania.

Myasthenia gravis (MG) and autoimmune thyroid diseases (AITD) may coexist and influence one another clinical expression. The opportunity of thymectomy in this association is controversial, since not all the studies have proven its efficacy. We report eight patients (one man and seven women) diagnosed with AITD (Graves' disease (GD) – five cases, Hashimoto's thyroiditis (HT) – three cases) and MG. The AITD diagnosis preceded (two cases), followed (three cases) or occurred simultaneously (three cases) with MG. In most cases thyroid disease had a good evolution with medical treatment. Four cases underwent thyroidectomy: one for intolerance to antithyroid drugs, two severe relapse of GD, and one for large nodular goitre with compression symptoms. All patients had imagistic investigation of thymus area: CT, scintigraphy with 99Tc-tetrofosmin. Treatment was started with anticholinesterase drugs (ACD). Thymectomy was performed in six cases either for tumoural aspect on imagery or inefficacy of ACD. Surgery was performed, on demand, in one case with normal imagery and stable evolution. Thymectomy in this particular case did not modify the evolution. Three cases with evolution of MG for <1 year, had an improvement of the myasthenia after thymectomy. One of them, the man, who associated three autoimmune diseases, had also an improvement of the HT. One case, with a 4 years evolution of MG and HT, had no improvement after thymus resection. Last case had an unfortunate evolution, with postsurgical death. The two cases, not operated, had a good evolution of AITD followed by an amelioration of the MG symptoms. The association of MG and AITD may influence one-another evolution. Generally, the amelioration of the thyroid dysfunction induces an improvement of MG. Thymectomy may improve the evolution of MG if performed in the first year of diagnostic. Longer evolution leads to irreversible alterations; therefore the myasthenic symptoms cannot be improved.

Polydipsia and polyuria, differential diagnosis in pregnancy

Esther Delgado[1] & Cristina Tejera[2]
[1]University Hospital of Badajoz, Badajoz, Extremadura, Spain; [2]University Hospital of Ferrol, Ferrol, Galicia, Spain.

Introduction
Gestational diabetes insipidus (GDI) is a rare endocrinopathy whose incidence is around four cases per 100 000 pregnancies. It is a potentially life threatening state. We present a case of a 39 year old with GDI.
Case report
A previously healthy 39-year-old woman in her 37th week of gestation presented dry oral mucosa with polydipsia and polyuria of 8 l over 24 h for approximately 2 month. The prenatal course of the pregnancy was uncomplicated until 35 weeks. Medical history was an appendectomy and she had on treatment of female infertility with *in vitro* fertilisation. On admission, well general condition, blood pressure 105/60 mmHg and 75 beats/min and saturating 99% on ambient air. The physical and gynaecological examinations were unremarkable. Laboratory studies revealed: serum sodium of 140 mEq/l, potassium 4.3 mEq/l, chloride 108 mEq/l, glucose 79 mg/dl, creatinine 0.7 mg/dl, calcium 8.2 mEq/l, total protein 5.9 gm/dl, FA 142 units/l, AST 584 units/l, and ALT 613 units/l. The serum osmolality was 294 mOsm/kg; and urine osmolality was inappropriately low. Other laboratory datas were normal. Water deprivation test and treatment with DDAVP confirmed diagnosis. Twelve hours after admission, she had a female infant by spontaneous vaginal delivery with APGAR scores were 8, 10 at 5, and 10 min, respectively. Laboratory evaluation of the infant was normal. Post-delivery, polydypsia and polyuria were resolved. GDI was resolved after delivery.
Conclusions
The diagnosis of gestational DI is often not diagnosed because polyuria in pregnancy is generally considered normal. We should suspect in patients with typical symptoms or with risk factor because sometimes, GDI can be associated with serious pathology like fatty liver of pregnancy and pre-eclampsia that might lead to foetal demise.

Hyperprolactinemia and Leydig cell tumor

Ana Margarida Monteiro, Marta Alves & Olinda Marques
Department of Endocrinology – Hospital de Braga, Braga, Portugal.

Introduction
Leydig cell tumors are the most common testicular sex cord stromal tumors. The most frequent clinical presentation is a testicular mass. However, they can present with endocrine manifestations, and gynecomastia is the most common presentation. Hyperprolactinemia can cause hypogonadotropic hypogonadism, and in males, is also a cause of gynecomastia.
Clinical case
A 24-years-old male was referred to our Endocrinology Department due to hyperprolactinemia and increasing bilateral breast volume with a year of evolution, without galactorrhoea, libido changes or erectile dysfunction. He had irrelevant medical past history, without medication, smoking, alcohol or illicit drug use. On physical examination, bilateral painful gynecomastia, without palpable nodules, skin changes or nipple retraction or galactorrhea. Testes were present, with no palpable nodules. Laboratory exams revealed normal testosterone and FSH, slightly low LH (1.43 mIU/ml (1.5–9.3)), high estradiol (206.02 pmol/l (<146.1)) (although normal in its first evaluation) and high prolactin levels (27.08/35.49/30.30 ng/ml (2.1–17.7)). TSH was normal and testicular tumour markers were normal. Breast ultrasound showed increased bilateral mammary glands, compatible with gynecomastia. The pituitary MRI showed an area of low uptake which could correspond to a microadenoma. He started bromocriptine 2.5 mg/day. In the scrotal ultrasound an isoechogenic nodule with 12 mm in the right testicle was observed. He was referred to the urology consultation. Scrotal RM confirmed the nodule in the right testicle. He was submitted to right partial orchiectomy guided by ultrasound, and histological examination revealed a Leydig cell tumor. He was oriented to plastic surgery to bilateral mastectomy. After surgery, we stopped bromocriptine use and pituitary MRI was normal. Currently, he has normal prolactin levels.
Discussion
Prolactinomas and Leydig cells tumors are possible causes of gynecomastia and hyperprolactinemia (in the last because of hyperestrogenism) making it sometimes a challenge the evaluation of prolactin levels in this context.

Can pericardial effusion be a manifestation of Graves' disease? An unusual case

George Besis[1], Nikolaos Kyriakakis[2] & Lakdasa D Premawardhana[3]
[1]Department of Cardiology, University Hospital of Wales, Cardiff, UK; [2]Leeds Centre for Diabetes and Endocrinology, St James's University Hospital, Leeds Teaching Hospitals NHS Trust, Leeds, UK; [3]Section of Endocrinology, Department of Medicine, Ysbyty Ystrad Fawr, Hengoed, UK.

Introduction
Graves' disease (GD) is associated with a number of cardiovascular complications, including rhythm disturbances, mitral valve prolapse, pulmonary hypertension and heart failure. Pericardial effusion in the context of GD has only been reported in a small number of cases.
Case
A 59-year-old gentleman presented with a 3-day history of dyspnoea and pleuritic chest pain. He had a previous history of GD 8 months ago, pulmonary embolism (PE), asthma, hypertension, obesity and was established on warfarin, following a second episode of PE, 4 weeks prior to this clinical event. Clinical examination revealed tachypnoea, tachycardia, raised JVP and bibasal crackles. Echocardiography showed a 2.9 cm pericardial effusion, compromising the right ventricular filling. 10 days prior to this admission, a previously echocardiogram had shown a smaller size pericardial effusion. TFTs showed suppressed TSH, elevated free T_4 at 34.7 pmol/l (reference range 9.2–21 pmol/l) and positive TSH receptor antibodies, compatible with relapsed GD. Other laboratory investigations showed acute kidney injury (eGFR 38 ml/min per 1.73 m^2) and elevated INR at 17.2, which was pharmacologically reversed. Interestingly, 10 days prior to admission the patient had normal renal function. Analysis of the pericardial fluid showed inflammatory cells. Microbiology and cytology investigations were unremarkable. A full body CT scan did not show evidence of neoplastic process. The patient was stabilised following pericardiocentesis and was commenced on Carbimazole 40 mg daily.
Conclusions
This is an unusual presentation of GD. The patient was investigated extensively, but no alternative cause for pericardial effusion was found. The presence of inflammatory cells in the fluid, suggests an inflammatory pericarditis. GD could have also been implicated in the pathogenesis of the patient's recent PE, given the thrombogenic tendency that hyperthyroidism is associated with. We therefore recommend that TFTs should be undertaken in patients presenting with unexplained pericardial effusion and equally patients with GD presenting with dyspnoea should undergo echocardiography.

EP1322

Concurrent hyperthyroidism and thyroid cancer – case presentations

Monica Livia Gheorghiu[1,2], Dumitru Ioachim[1], Bogdan Stanescu[1] & Daniel Brasoveanu[1]
[1]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; [2]C. Davila University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
The coexistence of hyperthyroidism and thyroid cancer is rare (below 2% of cases with hyperthyroidism). If this association predisposes to larger, multifocal or more aggressive cancer (especially in Graves' disease) is a matter of debate. We describe the clinical and hystopathological aspects and evolution in two patients with hyperthyroidism and thyroid cancer.
Patient 1, a 42-year-old woman, was diagnosed in 2008 with Graves' disease (overt hyperthyroidism, mild exophtalmos of the right eye, medium goitre with multiple nodules in the right lobe on ultrasound (1.1–1.7 cm, one 1.5 cm ill-delineated, hypoechoic, with small calcifications). TSH <0.03 mIU/l, high T_3 and T_4). She was treated with methymazole but lost to follow-up for 2 years. In 2011 she presents with overt hyperthyroidism and a large goiter, with a 4 cm 'cold' nodule in the right lobe with microcalcifications and internal vascularisation. She underwent total thyroidectomy and was diagnosed with multifocal papillary carcinoma: 3.3 cm in the right lobe, with capsular invasion, and 1.5 cm in the isthmus ('follicular variant'). No metastases have been detected. The patient has received a total of 150 mCi I131 and is disease-free at 2.5 years of follow-up.
Patient 2, a 56-years-old woman, was diagnosed at the age of 35 with a thyroid nodule and then at the age of 56 with subclinical hyperthyroidism, normal TPOAb and a toxic nodular goitre with a 2 cm nodule with peripheral calcification in the right lobe and a 4 cm 'hot' hypoechoic nodule of in the left lobe. She underwent

total thyroidectomy and was diagnosed with multifocal papillary thyroid carcinoma 'follicular variant': 2 cm in the right lobe, 0.1 cm in the isthmus and 0.2 cm in the left lobe. The large nodule in the left lobe was a follicular adenoma. No local metastases were found. The patient is planned to receive 100 mCi I131.
Conclusion
Although the occurrence of thyroid cancer in hyperthyroid patients is thought to be a rare event, the presence of a suspicious nodule in a hyperfunctioning thyroid should be carefully evaluated to exclude the presence of concurrent malignancy.

Gigantomastia with mastitis during pregnancy in a patient with well controlled thyroid and lupus disease – a case report

Julia Prague, Laura Geddes & Felicity Kaplan
East and North Herts NHS Trust, Hertfordshire, UK.

Introduction
Gigantomastia is a rare condition characterised by excessive benign breast tissue growth that is thought to be a result of elevated physiological levels of circulating hormones (e.g. pregnancy), or an increased sensitivity of the breast tissue to such hormones. Isolated reports describe some medical conditions as precipitants (e.g. systemic lupus erythematosus (SLE)) or drugs (e.g. cyclosporine). Many will proceed to surgical intervention to improve physical and/or psychological suffering.
Case report
A 39-year-old woman of normal weight conceived with *in vitro* fertilisation therapy after a salpingectomy for ectopic pregnancy. She had well controlled Graves' disease and SLE on medication. Shortly after her salpingectomy she noted a gradual increase in her breast size, correlating with her monthly cycle, from a brassiere cup size C to a size E at the time of embryo transplantation. During her pregnancy, her breast size continued to increase at such a rate that her brassiere size changed every 3 weeks. Empiric bromocriptine was started at 30 weeks gestation. At 33 weeks she required inpatient admission for mastitis and a urinary tract infection. At 34 weeks her ultrasound showed oligohydramnios, thought to be secondary to her excessive breast tissue, and so she underwent caesarean section. As she chose not to breastfeed bromocriptine was continued. She had an uneventful postoperative recovery and was discharged three days later. She suffered with two further episodes of mastitis within a month of delivery, and was wearing a size N brassiere that was too small for her. She proceeded to surgery with resection of 6.53 kg of breast tissue; histology confirmed benign proliferative change with no atypia.
Conclusion
Gigantomastia is generally a rare, benign condition but is especially disabling to the pregnant woman. Excellent outcomes are generally achieved with surgery. To our knowledge this is the first documented case in a patient with thyroid disease.

Turner's syndrome associated with idiopathic thrombocytopenic purpura

Zorana Arizanovic[1], Svetlana Vujovic[1,2], Milina Tancic-Gajic[1,2], Miomira Ivovic[1,2], Ljiljana Marina[1], Danijela Lekovic[3], Dragana Rakovic[1] & Dragan Micic[1,2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Disease, Clinical Center Serbia, Belgrade, Serbia; [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [3]Clinic for Hematology, Clinical Center Serbia, Belgrade, Serbia.

Introduction
Turner's syndrome (TS) or Ullrich-Turner's syndrome is genetic condition that affects only females. It is characterized by typical physical features and complete or part absence of one of the X chromosomes. Women with TS have been reported to be at increased risk of autoimmune diseases as compared with other women. Idiopathic thrombocytopenic purpura (ITP), isolated low platelet count (thrombocytopenia) with normal bone marrow and the absence of other causes of thrombocytopenia, is rarely described in patients with TS.
Case report
A 39-year-old female patient was admitted to our Clinic for endocrinological evaluation of primary amenorrhoea. Previously, in October 2012 and June 2013. She was admitted to clinic for haematology due to gingival bleeding, epistaxis and petehial bleeding. Haematological tests confirmed the diagnosis of Idiopathic thrombocytopenic purpura. Endocrinologist was consulted, because of amenorrhoea. Anamnestically, she was hospitalised at the age of 12 because of the short stature and oestrogen replacement therapy was initiated. She used sporadically, without further supervision. Karyotype was not determined. During hospitalisation in our Clinic, on physical examination, her external genitalia appeared as completely normal feminine structures with reduced pubic and axillary hair. Breasts were completely developed with missing nipples. Hormonal analysis showed menopausal values of gonadotropins and oestradiol (FSH = 54.7 IU/l; LH = 21.3 IU/l; E_2 = 29.4 pmol/l; $P < 0.44$ nmol/l; LTH = 515.7 mlU/l; T = 1.2 nmol/l; DHEAS = 2.5 gmol/l; 17 OH-P = 0.19 nmol/l, TSH = 3 mlU/l; fT_4 = 7.7 ng/l; TPO Ab = 32.8 U/ml). Cytogenetic analysis revealed a 45, XO, karyotype, which confirmed the diagnosis of Turner's syndrome. Estroprogesterone therapy was initiated. Regular menstrual bleeding appeared.
Conclusion
Very careful follow up of Turner's syndrome is necessary due to high incidence of cardiovascular diseases, autoimmune diseases and short life expectancy.

Exquisite case of coeliac disease in elderly patient with polyglandular autoimmune syndrome type III; a case report

Natia Katamadze
V.Iverieli Endocrinology, Metabology, Dietology Center 'ENMEDIC', Tbilisi, Georgia.

Introduction
The link between Celiac disease (CD) and type 1 diabetes mellitus is well known. CD is an autoimmune disorder which was considered as a disease of childhood. Now, we know that CD is life-long condition. It affects people of all ages and all body shapes. Screening for CD or type 1 diabetes is recommended in individuals already diagnosed with either disorder. When individuals have both diseases, type 1 diabetes is usually diagnosed first.
Objectives
Our aim is to demonstrate clinical case of CD in 40 years old woman and results of successful treatment of a Polyglandular Autoimmune Syndrome type IIIA (diabetes mellitus type 1, Hashimoto's Thyroiditis and Celiac diasease).
Design and methods
40 years old woman, who has had diabetes mellitus type 1 since the age of 6 years, attended our clinic as her glycemia was poor controlled. She had episodes of severe hypoglycemia and complained of weakness, weight loss, fatigue, diarrhea 4–5 watery stools daily. Laboratory analysis were performed. Thyroid function tests revealed primary hypothyroidism, Hashimoto's Thyroiditis. It was believed that she had chronic diarrhea due to her diabetes and Alpha Lipoic Acid, B vitamins, Actovegin was initiated. After 2 weeks occured swollen abdomen and edema of lower extremities. Abdomen Ultrasound showed rush peristalsis of intestines, no liquid was observed. Biochemical profile was within normal range. CD was suspected as a disease frequently associated with Polyglandular Syndrome Type IIIA. The diagnosis of CD was confirmed by Serologic test for AGA and the biopsy. Gluten free diet was advised. After 2 weeks her diabetes was better controlled. She has had no complaints of diarrhea.
Conclusion
CD screening is recommended in elderly patients with Diabetes Mellitus type 1 as well as in children.

DOI: 10.1530/endoabs.37.EP1325

TNF-α and adiponectin pathways are deregulated in endometria from obese women with polycystic ovarian syndrome

Lorena Oróstica[1], Isis Astorga[1], Víctor García[3], Cristian Poblete[1], Carmen Romero[1,2] & Margarita Vega[1,2]
[1]Laboratory of Endocrinology and Reproductive Biology, Faculty of Medicine, University of Chile Clinical Hospital, Santiago, Chile; [2]Department of Obstetrics and Gynecology, Faculty of Medicine, University of Chile Clinical Hospital, Santiago, Chile; [3]Faculty of Health Sciences, University of Antofagasta, Antofagasta, Chile.

Seventy percent of women bearing PCOS are obese; adiponectin and TNFα, as obesity markers, have a dual role in the sensitivity and action of insulin. Adiponectin (insulin sensitising) decreases, whereas, TNFα, IL6 (negative

regulators of insulin pathway) increases in obese-women. Moreover, TNFα decreases the transcript and protein levels of adiponectin. These changes could affect the normal energetic status in endometrium, tissue that exhibits abnormal insulin signalling in the PCOS condition (hyperandrogenic/hyperinsulinic environment). The aim of the present work was to evaluate molecules involved in TNFα (RTNFα 1 y 2, NFkB, p-IKK) and adiponectin (AdipoR1, AdipoR2, APPL1, TAK1, MEK1) signalling in endometria ($n=15$) from lean, Obese and Obese-PCOS women by western-blot, immunohistochemistry and real-time PCR. Also, the number of macrophages was evaluated by CD68 and plasma levels of adiponectin, TNFα and IL-6 were assayed by ELISA. No changes in serum TNF-α levels were observed, however, IL-6 levels increase in both Obese groups vs Lean ($P<0.01$). Adiponectin was lower in Obese-SOP ($P<0.01$). TNFα, its receptors and CD68 levels increase in Obese-PCOS vs other groups ($P<0.05$). Transcripts levels for adiponectin, TNFα/receptors and APPL1 were similar in the three groups of endometria. NFkB nuclear localization was higher in Obese-SOP vs the other groups ($P<0.05$) and activated IKK increased markedly in both groups of Obese vs Lean group ($P<0.0001$). Adiponectin protein levels (plasma and endometrial), AdipoR1, APPL1 and MEK1 were low in Obese-PCOS vs Lean group ($P<0.05$); TAK1 diminished in both Obese endometria ($P<0.05$). Consequently, there is an increased inflammatory environment in endometrium of Obese-PCOS women that could decrease adiponectin signalling, through the participation of TNFα, NFκB activation and/or IL-6 signalling; therefore, affecting insulin signalling under obesity, hyperandrogenic and hyperinsulinic conditions, compromising the energetic metabolism for normal endometrial function.

A case of multiple gas-forming pyogenic liver abscesses in diabetic patient

Hyoung Woo Lee, Ho Jin Kim, Jun Ho Lee, Jun Sung Moon, Ji Sung Yoon & Kyu Chang Won
Yeungnam University College of Medicine, Daegu, Republic of Korea.

Background
Gas-forming pyogenic liver abscess is an uncommon, life-threatening infection that is usually found in poorly-controlled diabetic patients. Here, we experienced a case of gas-forming pyogenic liver abscess in diabetes caused by Klebsiella pneumoniae.
Clinical case
A 77-year-old man with 25-year history of diabetes was admitted due to fever for 2 days. On the physical examination, right upper quadrant tenderness of the abdomen was present. Initial laboratory results were: WBC 29 030/mm^3 (Neutrophil 94.3%), C-reactive protein 19.21 mg/dl, Procalcitonin 12.3 ng/ml, BUN/Cr 52.7/2.16 mg/dl, AST/ALT 271/295 IU/l, T-Bil 1.78 mg/dl, serum glucose 448 mg/dl. Abdominal CT showed 1.5–4.4 cm sized multiple gas-forming liver abscesses. Even though culture was negative from drained pus, K.pneumoniae was identified at the blood. The patient was successfully managed with broad-spectrum antibiotics and percutaneous drainage.
Conclusion
The clinical outcome of gas-forming liver abscess appears to be fatal, therefore, an early aggressive therapeutic strategies, such as percutaneous drainage or surgical intervention are needed.

Remission of acanthosis nigricans in a teenager after treatment with metformin

Kyriaki Tsiroukidou[1], Ioanna Zografou[2], Theodora Griva[1], Athena Pyrpasopoulou[1], Maria Papagianni[1], Konstantina Kosta[1], Anastasios Vamvakis[1], Panagiota Karagianni[2] & Christos Sampanis[2]
[1]3rd Pediatric Department Hippokration General Hospital, Thessaloniki, Greece; [2]Diabetes Center Hippokration General Hospital, Thessaloniki, Greece.

Introduction
Acanthosis nigricans is a condition commonly associated with disorders characterised by insulin resistance. Data regarding the treatment of acanthosis nigricans are still insufficient.
Case report
A 10-year-old overweight girl (BMI = 24 kg/m^2) presented at the obesity outpatient clinic. Her family history was negative for metabolic syndrome. Clinical examination revealed extensive acanthosis nigricans involving the neck and armpit. Laboratory tests were normal except for HOMA-IR that confirmed insulin resistance (HOMA-IR = 14). The patient was started on hypocaloric diet and exercise without clinical improvement after 1 year. Acanthosis nigricans expanded involving neck, armpit and thorax, as insulin resistance increased (HOMA-IR = 28.6). Metformin at a dose of 1700 mg daily was added to the diet and exercise with good clinical response. Insulin resistance decreased significantly after 3 months (HOMA-IR = 5.85) and acanthosis nigricans regressed after one year of treatment.
Conclusions
Metformin may be an effective treatment option in some cases of acanthosis nigricans. Larger studies are necessary to establish the efficacy and safety of agents that reduce hyperinsulinaemia and insulin resistance in the treatment of acanthosis nigricans.

Functional analysis of four mutants of the V2 receptor

Beril Erdem[1], Angela Schulz[2], Emel Saglar[1], Torsten Schöneberg[2], Ferhat Deniz[3] & Hatice Mergen[1]
[1]Department of Biology, Faculty of Science, Hacettepe University, Ankara, Turkey; [2]Faculty of Medicine, Institute of Biochemistry, Leipzig University, Leipzig, Saxony; Germany; [3]Department of Endocrinology and Metabolism, GATA Haydarpasa Teaching Hospital, Istanbul, Turkey.

Diabetes insipidus is a disorder characterised by severe liquid-imbalance because of the inability to concentrate urine. Inactivating mutations in either arginine vasopressin receptor type 2 (AVPR2) or aquaporin 2 (AQP2) gene can cause congenital Nephrogenic diabetes insipidus (NDI). AVPR2 is a G protein-coupled receptor (GPCR) and is mainly expressed at the basolateral site of the kidneys collecting duct principal cells. Activation of this receptor by vasopressin is responsible for elevation of cAMP levels resulting in insertion of AQP2 water channels in the cell membrane of the collecting duct cells. In this study, four new mutations of AVPR2 gene (R68W, R67_G69del/G107W, V162A and T273M) were found in patients and were functionally analysed. For this purpose, all mutants were generated by a site-directed mutagenesis strategy. Both, total cellular expression and cell surface expression of mutant receptors were analysed in ELISA experiments. Also, cAMP accumulation and concentration response curves were determined for each mutant receptor. According to total ELISA results, all mutant receptors were synthesised comparable to WT receptor. However, cell surface expression was impaired for all mutants except of V162A. cAMP measurement for mutant and WT receptors revealed reduced Emax values for all mutants. For some mutants (R68W, R67_G69del/G107W and T273M) concentration response curves showed shifted EC50 values to higher vasopressin concentrations. In conclusion, we characterised four new AVPR2 mutations found in Turkish patients. Some mutations lead to shifted EC50 values by only one magnitude and treatment with higher amounts of AVP could be helpful for these patients to reduce high urine volumes and to restore kidney function.

Diabetes, obesity and psoriasis in a 60-year-old woman

José M Varela-Aguilar[1,2], Rosa García-Contreras[1], Ana Calzada-Valle[1], M Luz Calero-Bernal[1], Estefania Pererira-Díaz[1], Fidel Moreno-Verdejo[1], Abelardo Hurtado-Ganoza[1], Francisco Ruiz-Ruiz[1] & Enrique Calderón-Sandubete[1,2]
[1]Internal Medicine Service, Hospital Virgen del Rocío, Seville, Spain; [2]CIBER Epidemiologia y Salud Pública, Seville, Spain.

Psoriasis (PS) is a skin disease of immune T-cell mediated. It is well known that obesity is a risk factor for severity PS and PS is associated with the degree of overweight. In addition, patients with PS have increased risk of metabolic disorders such as diabetes mellitus (DM) and dyslipidaemia. All these processes are characterised by the presence of systemic chronic inflammation. Liraglutide, an agonist receptor GLP-1, is being used in the treatment of obesity and diabetes mellitus with excellent results both in glycaemic control and reduced body weight.

Case report

60-year-old woman with a history of type 2 diabetes, type II obesity (78 300 kg; BMI 38.39) and moderate psoriasis which was derived from primary care for poor glycaemic control (glycated Hb: 7.3%). Skin: injuries erythematous scaly plaques on back of hands, elbows, knees, trunk and scalp with PASI 5.8 and BSA 7% (Fig. 1).

Treatment was initiated with metformin 850 mg bid and liraglutide 1.2 mg/s, maintaining the same treatment for psoriasis came performing with topical corticosteroids and methotrexate. Three months after treatment change was revised in consultation objectifying optimal glycaemic control (HbA1c 6.1%), reduction of 8.5 kg in weight and improvement of skin lesions with PASI <3 and BSA 2% (Fig. 2).

Conclusions

The improvement in the weight reduction and improved glycaemic control as well as reduced secretion of proinflammatory cytokines placed the receptor agonists of GLP-1 in a special place for treatment of patients with T2DM and psoriasis. These features, which have yet to be demonstrated on a consolidated basis in clinical practice, can play a key role in the individualization of treatment of patients with T2DM.

Metformin and lactic acidosis: a potentially lethal relationship during intercurrent illness

Marjeta Kermaj[1], Enalda Demaj[1], Gerta Sinani[2], Violeta Hoxha[1], Gerond Husi[1], Armela Cuko[3] & Agron Ylli[1]
[1]University Hospital Center 'Mother Tereza', Tirana, Albania; [2]Hospital Center, Librazhd, Albania; [3]University Hospital Center 'Shefqet Ndroqi', Tirana, Albania.

Introduction

Metformin-associated lactic acidosis (MALA) is defined as a high anion gap metabolic acidosis with high circulating lactate levels and without hypoperfusion. It is associated with a mortality rate up to 50%.The reported frequency is 0.01–0.05/1000 patient-years, mostly in patients with predisposing factors (which affect its clearance or energy metabolism) such as altered renal function, congestive heart, hepatic and respiratory failure, concomitant medications (angiotensin II receptors antagonist), old age. We present a report of a patient with type 2 diabetes who was receiving long term treatment with metformin and developed severe metformin associated lactic acidosis after dehydration, which resulted in renal impairment and consequent accumulation of metformin. We want to remind of a potentially lethal adverse reaction of this drug.

Case report

Our patient was a 64-year-old Albanian woman with a 3 year history of type 2 diabetes mellitus (treated with metformin 850 mg/d) and hypertension (treated with losartan 50 mg/d). She presented to our emergency with acute renal, hepatic, circulatory failure and severe metabolic acidosis, after a week history of abdominal pain, vomiting (associated with poor oral intake) and dyspnoea. Her medication also compromised a 3 day history of clarithromycin for acute sinusitis. She took adequate supportive care, management of concurrent disease, correction of acidemia, acceleration of lactate metabolism, and interruption of the offending drug. Twenty-four hours later, full clinical recovery was observed, with return to a normal serum lactate level.

Conclusions

Our initial impression was that the multiorgan failure was due to a combination of factors, including poor oral intake and nephrotoxic agents. Dehydration in patients taking metformin can lead to MALA. Given that mortality metformin should always be discontinued in such a clinical scenario. This case illustrated the importance of stopping metformin treatment (even small dose) during intercurrent illness, especially dehydration.

Leg oedema: first sign of an ischemic leg which precipitated hyperosmolor hyperglycemic state in a newly diagnosed type 2 diabetes patient

Sushuma Kalidindi, Probal Moulik & Andrew Macleod
Royal Shrewsbury Hospital, Shrewsbury, Shropshire, UK.

Patients with diabetes are prone to peripheral vascular disease. We present the case of an 81 year old female, current smoker who presented to her general practitioner with a 3 day history of ankle oedema for which she received furosemide. She had a background of right above knee amputation due to peripheral vascular disease and essential thrombocythaemia. Five days after commencing furosemide, she developed increased lethargy and confusion. On arrival to hospital, her venous blood glucose was 32.8 mmol/l, ketones of 1.8 mmol/l and she wasn't acidotic. She was dehydrated with sodium of 159 mmol/l, urea of 9.5 mmol/l, creatinine of 43 μ/l. Calculated serum osmolality was 338 mOsmol/kg. Insulin infusion and fluids were commenced. HbA1c was 81 mmol/mol on admission, with no prior history of diabetes. She developed atrial fibrillation while inpatient requiring digoxin. She was found to have a pale, pulseless, cold, ischemic left leg and was considered to be a very high perioperative risk. After discussion with family, she was started on the palliation pathway. This is a rare presentation of acute leg ischemia in a patient with newly diagnosed diabetes. She likely had an ischemic left foot which was masked by leg oedema. Peripheral vascular disease patients, who keep their legs in a dependent position for comfort often present with considerable edema of the feet and ankles. Numerous factors could have contributed to the ischemia, including emboli from atrial fibrillation, essential thrombocythaemia and peripheral vascular disease. Conversely dehydration from HHS could have precipitated her atrial fibrillation.

Potential effects of endocrine disruption: reproductive tract abnormalities in a 4 years boy

Cosmina Rimbu[1], Lisandra Damian[1,2], Ramona Axinte[1], Cristina Preda[1,2], Voichita Mogos[1,2] & Maria Christina Ungureanu[1,2]
[1]Endocrinology Clinic, 'St Spiridon' Emergency Clinical Hospital, Iasi, Romania; [2]'Grigore T. Popa' University of Medicine and Pharmacy, Iasi, Romania.

Endocrine disrupting chemicals are substances, both natural and artificial to which we are all exposed, even in a low dose in our everyday life. Health effects attributed to endocrine disrupting compounds include immune dysfunctions, various cancers, neurological effects and behaviour disorders, reproductive problems, early puberty, etc. Over the past 50 years, an increase in urogenital tract abnormalities in males has been noted. We present a 4 year old boy case report, born at term, by caesarean section, addressed to the Endocrinology Department for micropenis, hypospadias and overweight. His mother was diagnosed with PCOS but she never took anti androgenic treatment before the patient was conceived; she is working in a paint factory. The first consultation revealed: micropenis: 3 cm (−2,5 DS), hypospadias, bilateral descended testicles and normal developed scrotum. Workup: normal pituitary function; DHEAS slightly increased, normal 17OH progesterone; normal abdominal, pelvic and testicular ultrasounds; normal karyotype. We took in consideration next diagnostic assumptions: i) late-onset 3 β-hydroxysteroid dehydrogenase deficiency: excluded – androstendione in limits. ii) 5 α reductase deficiency: hCG stimulation: DHT = 252 pg/ml – borderline values, testosterone/DHT = 12.77 infirm this diagnosis. iii) Androgen partial resistance: the patient has descended testicles; no genetic tests available in our country; good response after androgen treatment iv) Intersexuality due to endocrine disruptors. He received treatment with testosterone enanthate 50 mg at 3 weeks, for 3 months, and his penis increased: 5 cm; is scheduled for hypospadias correction intervention.
Conclusions
Endocrine disruptor pathology must always remain a diagnostic hypothesis in reproductive tract abnormalities in children.

Intentional massive overdose with aspart and glargine insulin: a case report

Daniel-Tudor Cosma[1,3], Alina Silaghi[2,3], Carmen Georgescu[2,3] & Ioan Andrei Veresiu[1,3]
[1]Diabetes, Nutrition and Metabolic diseases Clinical Center, Cluj-Napoca, Cluj, Romania, [2]Endocrinology Clinic, Cluj-Napoca, Cluj, Romania; [3]Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Cluj, Romania.

Intentional insulin overdose in diabetic patients is a rare critical situation. The severity is due to numerous neurological complications, electrolyte disturbances, liver and lung damage or death.
Case report
A 65-year-old male, with significant cardiac and pulmonary pathology, diagnosed with type 2 diabetes since 1996 and treated with glargine (70 U/day) and aspart (68 U/day) insulin is admitted to our centre via ER (emergency room) after an episode of severe hypoglycaemia after administration of 750 U aspart insulin and 280 U glargine insulin. He arrived in the ER 3 h after overdose with a glycaemic value of 47 mg/dl after 40 ml of 33% glucose and 250 ml of 10% glucose. At admission: altered general status, blood glucose 105 mg/dl, tachycardia, multiple injection sites across his abdomen, acanthosis nigricans on the right elbow. Labs exams revealed: hypertrygliceridaemia, hypocalcaemia, slightly elevated creatinine, A1c = 7.9%. An infusion of 20% glucose was begun at 83 ml/h. The glucose infusion rhythm and concentration was adjusted according to the glycaemic profile while maintaining values around 150 mg/dl, with a total duration of infusion of 61 h. Hypocalcaemia was corrected by i.v. administration of calcium gluconate. Electrolytes, phosphorus and magnesium remained within normal limits during hospitalization. Psychological and psychiatric evaluation diagnosed depression and emotional unstable disorder. To increase the insulin clearance i.v. Furosemide was given for 6 days. In the 5th day of hospitalization, we decided the conversion to oral therapy with metformin 2 g/day and sitagliptin 100 mg/day, with a good glycaemic control.
Discussions
Insulin overdose requires intensive and prolonged glycaemic monitoring to prevent recurrent hypoglycaemia due to an early cessation of i.v. therapy. The dose is not correlated with the severity of hypoglycaemia but with a prolonged hypoglycaemic risk higher than that deduced from the pharmacokinetics of insulin analogue administered. This case represents the largest overdose with this analogues treated only by glucose infusion.

Diabetes mellitus associated with optic atrophy, hepatomegaly, hypogonadism

Betul Cavusoglu[1], Suleyman Ahbab[1], Fatih Turker[1], Evrim Cakir[2], Hayriye Esra Ataoglu[1] & Mustafa Yenigun[1]
[1]Haseki Training and Research Hospital Internal Medicine Department, Istanbul, Turkey; [2]Haseki Training and Research Hospital Endocrinology and Metabolic Diseases Department, Istanbul, Turkey.

A 21-year old male with a 4 year history of tip 1 diabetes mellitus was admitted for diabetic ketoasidosis. The patient was on premixed insulin in two divided of 20 units. He had poor control of diabetes with no regular follow up. His height was 141 cm (3rd persentile), and weight was 36 kg (3rd percentile). These anthropometric findings demonstrated low-height for his age. His bone age was consisted with 16 years. Physical examination revealed moon face, hepatomegaly, short stature. The patient was prepubertal with tanner stage 2 for testicular and pubic hair development. Fundus examination revealed bilateral optic atrophy. Laboratory analysis were as following; Hb: 11.3 g/dl (11–16), hct: 37.7% (37–54), AST: 65 U/lt (50) ALT: 61 U/lt (50), urea: 67.5 mg/dl (17–43) creatinine: 0.72 mg/dl (0.67–1.17), C peptide: 0.01 ng/ml, basal serum cortisol: 18.8 µg/dl, FSH: 0.98 mIU/ml (1.37–19.26) LH: 0.98 mIU/ml (1.24–8.62), PRL: 3.18 ng/ml (2.64–13.13), total testesterone: 0.36 pg/ml (1.75–7.81). Ferritin and iron levels were lower for normal limits. His thyroid profile was within normal limits. Somatomedin-C level was 144 ng/ml (84–376). These findings revealed hypogonadotropic hypogonadism. Scrotal sonography was normal. Urine density was 1015 and mean urine volume was 1500 ml. Diabetes insipidus associated with DIDMOAD syndrome was not obtained. Pituitary MR was normal. The coexistence of growth retardation, pubertal delay, hepatomegaly, elevated transaminase levels, diabetes mellitus and optic atrophy has not been reported, yet. It was the first case of the literature.

EP1336

Severe osteoporosis as a presentation of concealed Swyer syndrome (pure gonadal dysgenesis)

James O'Hare[1] & Kevin Hickey[2]
[1]Department of Endocrinology and Obstetrics and Gynecology, University Hospital Limerick, Limerick, Ireland; [2]Department of Obstetrics and Gynecology, Univesity Hospital Limerick, Limerick, Ireland.

Swyer syndrome (pure gonadal dysgenesis) is characterised by female phenotype with a 46 XY genotype due to a mutation of the sex determining region (SRY) gene on the y chromosome. A 28 year old presented with back pain after an accident and had a 2nd lumbar vertebral fracture and severe osteoporosis. The DEXA scan T score was −4.2. Procollagen Type 1 pro peptide and Osteocalcin levels were high. She had been in good health and denied any family illness. She was 180 cm tall and weighted 63 kg. Breasts were present though not fully developed. She had sparse pubic and axilliary hair. The external genitalia were normal. She had high gonadotropins and low oestrogen and testosterone levels. She had normal serum calcium, phosphate, parathyroid hormone, and vitamin D levels. coeliac and immunoglobulin screen was negative. She had no liver or renal disease. The patient reported menstruating from age 14. Genotype was 46XY -normal male. PCR analysis confirmed the SRY locus on the Y chromosome. MRI and ultrasound of pelvis showed a uterus, fallopian tubes, vagina and one streak gonad. Anti Mullerian factor was low. There is the first reported case of severe osteoporosis as the presentation of Swyer syndrome. It improved with a 29% increase in T score over 2 years with recombinant parathyroid hormone. She menstruated for the first time on cyclical oestrogen. She underwent gonadectomy for the risk of malignancy. Osteoporosis and tall stature were due to life long oestrogen deficiency.The patient later admitted she had concealed primary amenorrhoea for cultural reasons delaying early diagnosis and treatment.

DOI: 10.1530/endoabs.37.EP1336

EP1337

Recurrent severe symptomatic hyponatraemia induced by low-dose oral cyclophosphamide in a patient with ANA-related vasculitis

Rosemary Dineen[1], Agnieszka Pazderska[1], Ronan Mullan[2], James Gibney[1] & Mark Sherlock[1]
[1]Department of Endocrinology, Adelaide and Meath Hospital Incorporating the National Childrens Hospital, Tallaght, Dublin, Ireland; [2]Department of Rheumatology, Adelaide and Meath Hospital Incorporating the National Childrens Hospital, Tallaght, Dublin, Ireland.

Cyclophosphamide is an alkylating agent used in the treatment of malignant and autoimmune diseases. Severe hyponatraemia is a serious electrolyte disorder with life threatening neurological sequelae. We report a case of recurrent severe, symptomatic hyponatraemia that developed in a 61 year old female with systemic vasculitis and Sjogrens syndrome following low-dose cyclophosphamide.
Case report
A 61 year old lady, with ANA positive systemic vasculitis presented for her first cycle of low dose cyclophosphamide (12 mg/kg). She was prehydrated with 1 l of normal saline and drank 3 l of water for prophylaxis of haemorrhagic cystitis. 30 h post treatment her serum sodium fell from 135 mmol/l pre-treatment to 116 mmol/l with decreased GCS, requiring ITU admission. Her urinary sodium was 121 mmol/l, urine osmolality 347 mOsm/kg with a plasma osmolality of 240 mOsm/kg. She received hypertonic saline and recovered without neurological deficits after slow correction over 2 days. Four weeks later, she was admitted to hospital for careful monitoring, at her second cycle, she was again prehydrated. 24 h post treatment her sodium fell to 121 mmol/l with altered consciousness again requiring hypertonic saline. At her third cycle, she was not prehydrated and was commenced on a 1.5 l fluid restriction. Despite fluid restriction, her serum sodium fell from 135 to 129 mmol/l post therapy, without clinical features and corrected spontaneously.
Discussion
Patients receiving cyclophosphamide are at high risk of developing symptomatic hyponatraemia due to SIADH even at low doses of therapy. Cyclophosphamide may induce SIADH, by potentiating the renal actions of AVP. The combination of both increased ADH effect and excess water intake to prevent haemorrhagic cystitis can induce potentially life-threatening hyponatraemia. Clinicians need to be aware of this threat when encouraging large volume prehydration and diuresis with cyclophosphamide therapy. It is possible that pre-hydration with isotonic saline rather than oral water may minimise the incidence of this complication.

Polycystic ovary syndrome in women with type 1 diabetes mellitus: about three cases

Amira Djermane & Samia Ould Kablia
Central Hospital of the Army, Algiers, Algeria.

Introduction
Polycystic ovary syndrome (PCOS) is the most common endocrine disorder and is frequently associated with insulin resistance and type 2 diabetes mellitus. At present, women with type 1 diabetes mellitus (T1DM) are being treated with supraphysiological doses of exogenous insulin with the aim of providing a strict metabolic control. The prevalence of PCOS in women with T1DM varies depending on the diagnostic criteria employed and on the ethnicity of the population studied. In 2000 Escobar-Morreale *et al*., using National Institutes of Health (NIH) 1990 diagnostic criteria, reported a prevalence of 18.8%.
Design
We'll describe three profiles of PCOS in women (age 34, 31, 30 years old) with T1DM that is controlled by high dose of insulin. They have a normal level of SHBG. The PCOS is treated by modification in life style and metformin therapy.
Results
The physiopathology of PCOS in T1DM is unclear. It has been suggested that the use of exogenous insulin at high doses daily to treat T1DM may contribute to the development of PCOS by stimulating the synthesis of ovarian androgens. The normal levels of SHBG in T1DM (insulin concentrations at the portal vein are the main regulators of SHBG) explain both why the most sensitive serum marker of hyperandrogenism here is total testosterone levels, and the milder hyperandrogenic symptoms. The use of metformine permits a significant reduction in the insulin dose administered while providing an improvement in metabolic control.
Conclusions
Every effort must be made for the early detection and treatment of hyperandrogenic disorders in T1DM women because of the large prevalence of PCOS in these women. Future studies should evaluate the consequences of PCOS in women with T1DM and compare the different therapeutic options.

A case of Swyer syndrome with gonadoblastoma and dysgerminoma

Banu Sarer Yurekli[1], Nilufer Ozdemir Kutbay[1], Samim Ozen[2], Emin Karaca[3], Kamuran Acar[4] & Fusun Saygili[1]
[1]Endocrinology Department, Ege University Faculty of Medicine, Izmir, Turkey; [2]Pediatric Endocrinology Department, Ege University Faculty of Medicine, Izmir, Turkey; [3]Medical Genetics Department, Ege University Faculty of Medicine, Izmir, Turkey; [4]Pathology Department, Ege University Faculty of Medicine, Izmir, Turkey.

Aim
The Swyer syndrome belongs to a group of pure gonadal dysgenesis. Karyotype is 46,XY. Aberrations of chromosome Y or SRY gene mutation is present in 15–30% of cases. These patients have high gonadotropin levels and are classified as having hypergonadotropic hypogonadism. The Swyer syndrome in the female requires close followup because of the high risk of neoplastic transformation in the dysgenetic gonads. Herein we report a case of Swyer syndrome with gonadoblastoma and dysgerminoma.
Case
A 22-year-old woman was admitted to the Endocrinology Outpatient Clinic. Menarche age was 15 years old. Breast development was normal during pubertal period without using any oestrogen pill. After 1 year of regular menstrual period, irregular vaginal bleeding occurred. At the age of 18, a big mass was felt on abdomen. She had an abdominal operation for that mass and gonadoblastoma and dysgerminoma were diagnosed pathologically on the right ovary. After that pathologic diagnosis, karyotype study was performed and found as 46,XY. As the integrity of tumour capsule was destroyed, adjuvant chemotherapy was introduced. After chemotherapy, another abdominal operation was performed and gonadoblastoma was diagnosed on the left ovary. There was no laboratory examination regarding to gonadotropin and oestrogen levels before the operations. SRY positivity was present on left oopherectomy material. Phenotypically female paitent with 46, XY karyotype, Swyer syndrome was diagnosed. She was started estrogen/progesterone combination pill.
Discussion
This patient had the normal pubertal development without any delay. Because of this reason, we thought that the gonadoblastoma was hormone active most probably with oestrogen producing one. Unfortunately, we couldn't demonastrate this. Patients with gonadal dysgenesis and 46,XY karyotype should be referred for bilateral gonadectomy because of the high risk of neoplastic transformation. Oestrogen producing gonadoblastoma may mask gonadal dysgenesis and delay the diagnosis of this pathology.

EP1340

Brown cell tumour from parathyroid carcinoma

Jerome Barrera
Zamboanga City Medical Center, Zamboanga City, The Philippines.

Introduction
Parathyroid carcinoma is a rare cause of hyperparathyroidism. In most cases, hyperparathyroidism is caused by a single benign adenoma. The vast majority of the remaining cases are caused by parathyroid hyperplasia or multiple adenomas. We present here a case of a young Filipina who presented with multiple fractures on all extremities and bilateral parathyroid adenoma.
Case presentation
A 19-year-old Filipina presented with bone pains for 7 months associated with fatigue, anorexia, weight loss and muscle weakness. Subsequently, she had multiple fractures on all extremities and fixed hard masses on the left humerus and tibia. Her past medical and family histories were unremarkable.
Investigations
Corrected calcium was elevated at 15.4 mg/dl, Phosporus was decreased at. Intact PTH (iPTH) was extremely high at 2001 pg/ml (8.5–72.5). X-ray of the

extremities showed osteopenia, endosteal resorptive changes and multiple pathologic fractures. Bone biopsy revealed brown cell tumour/multifocal polyostotic giant cell tumour and negative for malignancy). Ultrasonography of the neck revealed parathyroid adenoma inferiorl of left thyroid gland measuring 2.3×1.1×1.0 cm. Ultrasound-guided FNAB revealed findings consistent with parathyroid carcinoma. She was hydrated and was given diuretic to control the severe hypercalcaemia. She underwent 3½ gland parathyroidectomy with en-bloc left thyroid lobectomy. Intraoperative findings showed a left mass with non well-circumscribed borders invading the capsule and local tissues and a right mass. Serum Calcium and iPTH immediately after OR decreased to 12.8 and 211.8 pg/ml respectively. Further reduction was noted after 24 h of surgery (iPTH, 48 pg/ml; Corrected Calcium: and 9.2 mg/dl).

Discussion/conclusion

Parathyroid carcinoma is a rare malignancy of the parathyroid glands. These tumours usually secrete parathyroid hormone, thereby producing hyperparathyroidism, which is usually severe. Surgery with en-bloc resection is the initial therapy, but when the tumour is no longer amenable to surgical intervention with intent to cure, treatment becomes focused on the control of hypercalcaemia.

An aggressive malignant insulinoma: a case report

Bugra Oztosun[1], Yildiz Okuturlar[1], Meral Gunaldi[2], Ozlem Soyluk[3], Meral Mert[3], Samet Sayilan[1], Mehmet Orman[1] & Ozlem Harmankaya[1]
[1]Department of Internal Medicine, Bakirkoy Dr Sadi Konuk Education and Research Hospital, Istanbul, Turkey; [2]Department of Medical Oncology, Bakirkoy Dr.Sadi Konuk Education and Research Hospital, Istanbul, Turkey; [3]Department of Endocrinology and Metabolism, Bakirkoy Dr Sadi Konuk Education and Research Hospital, Istanbul, Turkey.

Introduction

Insulinomas are rare pancreatic islet cell tumours with an incidence of four cases per million per year. About 10% of all insulinomas are malignant. We here examined an insulinoma with aggressive driving in a young male patient with severe hypoglycaemia in the emergency room.

Case report

34-year-old male patient was admitted to the emergency department with the blurring of consciousness. Blood glucose was 19 mg/dl, consciousness tends to sleep, non-cooperative and disoriented. Continuous dextrose infusion was required and the patient's laboratory tests results: aspartate aminotransferase (AST) 132 U/l, alanine aminotransferase (ALT) 225 U/l, γ glutamyltransferase (GGT) 504 U/l, alkaline phosphatase (ALP) 315 U/l, albumin 3.7 g/dl, total bilirubin 3.3 μg/dl, direct bilirubin 1.9 μg/dl, respectively. When the dextrose infusion interrupted, the blood glucose was 32 mg/dl whereas insulin level was 110 μIU/ml (n=0.1–29.1 μIU/ml) and C-peptide level was 5.6 ng/ml (n=0.9–4.3) respectively. Serum chromogranin A level was 158 ng/l (n: 27–94). Magnetic resonance imaging (MRI) revealed a mass in the pancreatic uncinate process level ~40×41 mm in size. Multiple nodules in different sizes were observed in the left and right lobe of the liver. Biopsy made from fine needle aspiration in pancreatic mass was consistent with neuroendocrine tumours. Tru-cut biopsy made from liver lesions revealed the tumour infiltration. In immunohistochemical studies of tumor, synaptophysin and chromogranin were positive diffuse, KI 67: 7%, CK 7 (+) (weak), CK 20 (−), respectively. Somatostatin receptor type 2 activity in all the liver lobes, multiple lymph nodes and right third rib was detected in Gallium-68 positron emulsion tomography. Metastatic malignant insulinoma was diagnosed with existing findings. In-operable patient, while local and systemic treatment was planning, died because of liver failure.

Conclusion

In the literature a small number of malignant insulinoma patients were treated successfully with different local and systemic treatment. However, we did not have a chance to have local and systemic treatment since the patient died within a month.

VIPoma: an unusual cause of electrolyte disturbance

Diana Boj-Carceller, Diego Álvarez-Ballano, María Eugenia López-Valverde, Leticia Pérez-Fernández, Beatriz Lardíes-Sánchez, Isabel Azcona-Monreal, Alejandro Sanz-Paris & Javier Acha-Pérez
Department of Endocrinology and Nutrition, Hospital Universitario Miguel Servet, Zaragoza, Spain.

Introduction

Vasoactive intestinal peptide-producing tumours (VIPomas) represent a rare type of neuroendocrine tumour whose incidence is 1 in 10 million per year. Most are located in the pancreas. They cause diffuse watery (secretory) diarrhoea, hypokalaemia and achlorhydria and also appear as an uncommon cause of hypercalcaemia.

Case report

A 69-year-old female with previous diagnosis of a 'non-functioning' neuroendocrine pancreatic tumour (2005) with liver metastasis (2009) was admitted for weakness and severe hypokalaemia. She had been admitted for hypercalcaemia a few months before. Her family history was a priori negative for MEN-1 affected. She complained of chronic watery diarrhoea that persisted with fasting (6–10 stools/day) in spite of multiple therapies (surgery, long acting somatostatin analogues, systemic chemotherapy and transarterial hepatic chemoembolization). Analysis showed: impaired fasting glucose (159 mg/dl), hypokalaemia (2.6 mEq/l), metabolic "acidosis" (pH 7.34, serum bicarbonate 15.1 mmol/l), hypophosphatemia (1 mg/dl), hypomagnesemia (1.6 mg/dl) and hypercalcaemia (until 15.3 mg/dl). Serum TSH, calcitonin, cortisol, PRL, glucagon, PTH-rp and 5HIAA were normal. PTH 23.8 pg/ml. 25-0H-vitamin D 35.6 nmol/l. CgA 115 ng/ml. VIP concentrations were high (>116 pmol/l, normal <30 pmol/l). Gastrin 149 pg/ml (13–115). An octreoscan showed known liver disease. There were no bone metastases. Immunohistochemistry was positive for somatostatin, synaptophysin and chromogranin A. Patient needed to be managed with high doses of supplements of potassium, magnesium, phosphorus, periodic i.v. bisphosphonates and a high salt intake. Recently, an essay of cinacalcet was added because of persistent hypercalcaemia.

Discussion

A clinical redefinition of diagnosis was made: VIPoma. Hypercalcaemia might be explained by the stimulatory effect of VIP on bone resorption. However, if normal feedback is intact, PTH concentrations should be low, whereas the patient described had a 'normal' PTH. We have observed a sustained response of calcium levels since cinacalcet introduction. 5% of VIPomas are in context of MEN-1.

Concomitance of pancreatic and neuroendocrine breast tumour – simple coincidence or not?

Iulia Crumpei[1], Alina Fadur[1], Adina Manolachie[1], George Zmau[1], Mihaela Anton[2], Constantin Volovat[3], Maria Christina Ungureanu[1] & Carmen Vulpoi[1]
[1]Depatament of Endocrinology, University of Medicine and Farmacy 'Gr. T. Popa', Iasi, Romania; [2]Departament of Endocrinology, Ragional Hospital, Bacau, Romania; [3]Departament of Oncology, Victoria Hospital, Iasi, Romania.

Introduction

Breast neuroendocrine carcinoma is a rare aggressive neuroendocrine tumour (NET) and the research on this subject is poor. Only seven studies were cited in the literature. Incidence in the population has not been reported, but the prevalence is under 0.1% of all breast carcinomas.

Case report

AV, 72, is hospitalised for bone pain and significant weight loss (15 kg in 2 months). Patient's previous history are: diabetes, hypertension, nodular goitre and suspected pulmonary sarcoidosis in 2011 treated 6 months with corticosteroids. In 2013 abdominal CT revealed in the pancreas an area of 21/20 mm at the isthmus. CA-50 was found negative 14 U/ml (n<25 IU/ml), without any further specific exploration until January 2014 when intense bone pain lead to spinal MRI and bone scintigraphy that objectified secondary dissemination at the lumbar-sacral level and dorsal vertebrae. Abdominal CT reevaluation described: an intraductal pancreatic lesion, secondary disseminations in the liver, spleen and bone. The appearance was suggestive for pancreatic NET, confirmed by high tumoural markers. From the patient's history, we found that she had a left breast fibroadenoma (2013-benign image on mammography). The breast ultrasound identified in the left breast multiple solid nodules with coarse calcifications. Breast cancer markers were increased ACE=31.5 ng/ml (n: 0–1.5), CA 15.3=160 IU/ml (n=0–38.4). A biopsy was performed from the lesion in the liver revealing metastasis of poorly differentiated carcinoma, immunohistochemical data showing carcinoma of the mammary gland with neuroendocrine features. The oncology evaluation staged the tumour in cT2N0M1, ECOG performance status 4 and recommended treatment with Sandostatin LAR, along with initiating treatment with zoledronic acid and aromatase inhibitors.

Conclusions

The peculiarity of the case is the association of a probably pancreatic neuroendocrine tumour with breast carcinoma with neuroendocrine features,

probably evolving for a long time in the past, which was initially considered and treated as sarcoidosis.

Endocrine assays in female patient with relapsing thymus cyst and myasthenia gravis

Mara Carsote[1,2], Dana Terzea[2,3], Ionela Baciu[1,2], Alexandra Mihai[2], Dan Peretianu[4], Florina Vasilescu[3], Mihaela Popescu[2], Raluca Trifanescu[1,2], Anda Dumitrascu[2] & Catalina Poiana[1,2]
[1]C.Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]C.I.Parhon National Institute of Endocrinology, Bucharest, Romania; [3]Monza Oncoteam Hospital, Bucharest, Romania; [4]SCM Povernei Medical Centre, Bucharest, Romania.

Introduction
The congenital cystic neck masses underlie various diagnosis including tymic cysts. Even they are an embryological defects, the adult onset might be seen. The aetiology is not clearly established. The malignant behaviour or infections are correlated to the cysts. Aim: we present a female case with a complicated history of cysts.
Case report
42-year old female is known with the following medical history. Seven years ago she was operated for a pericardia cyst. The computed tomography was normal after surgery until 2014 when she accused breathing difficulties. The computed tomography was performed and a tymic cyst was discovered (of 7 cm). Thoracotomy was chosen as procedure for the cyst: the cyst was partial evacuated during the procedure and then removed but the tymus was conserved. The pathological exam confirmed a simple tymic cyst, with no atipia. After surgery, the patient felt well for about 6 months when she accused again troubles in breathing, and also persistent asthenia. The computed tomography found again the tymic cyst of 4.89 by 4.1 by 6.4 cm, with no other thoracic or cervical anomalies. The patient was referred for an endocrinological check up. The blood pressure was 100 by 65 mmHg. The normal TSH (of 1.5 μUI/ml) was associated with negative thyroid antibodies. The morning plasma cortisol was of 19 μg/dl (normal levels <21 μg/dl). The calcium levels and parathormone, as well as basal plasma metanephrines/normetanephrines were also normal. The prolactin levels were mildly increased (of 28 ng/ml, normal levels <21 ng/ml). The patient was referred to neurological tests and myasthenia gravis was confirmed. A second procedure for the tymus cyst is soon to be done, including the entire organ resection.
Conclusion
The mildly increased prolactin levels are most probably associated to the thoracic surgery. The complete resection of the tymus is encouraged in case of cysts, especially large ones, because of relapse risk.

Oncogenic osteomalacia misdiagnosed as ankylosing spondylitis

Seher Tanrikulu[1], Burak Ince[1], Nurdan Gül[1], Samet Vasfi Kuvat[2], Ayse Kubat Uzum[1], Ferihan Aral[1] & Refik Tanakol[1]
[1]Department of Internal medicine, Division of Endocrinology and Metabolism, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Fatih, Turkey; [2]Istanbul Faculty of medicine, Plastic and Reconstructive Surgery, Istanbul University, Istanbul, Fatih, Turkey.

Oncogenic osteomalacia is a rare paraneoplastic syndrome, which can be associated with phosphaturic mesenchymal tumor or non-mesenchymal tumour. This tumour produces fibroblast growth factor 23 (FGF-23) that leads to subsequent hypophosphataemic osteomalacia. We, hereby present a patient with oncogenic osteomalasia who is misdiagnosed as ankylosing spondylitis. A 54-year old man with weakness, severe arthralgia involving pelvis, hip joints and lower extremities referred to the Rheumatology Department for the treatment of a suspected sero-negative spondiloarthritis and TNF-α inhibitor and glucocorticoid treatment had begun. Despite of 3 years of treatment, there was no relief of symptoms, and laboratory tests had shown hypophosphatemia (0.7 mg/dl) with low vitamin D and normal calcium, PTH levels, referred to Endocrinology clinic. Hypophoshataemia was resistant to oral phosphate replacement. Physical examination revealed a non-tender, mobile, 2 cm nodular lesion at right medial thigh. Magnetic resonance imaging showed an ovular 2.1×1.7 cm hypointense solid lesion with irregular borders in the soft tissue at right thigh. FDG-PET scanning showed high FDG uptake at the lesion, and no other hypermetabolic masses. We performed tumour resection and after an unremarkable post-operative course hypophospatemia resolved within 2 weeks. Histopathological evaluation showed extraosseos giant cell tumour with metaplastic bone cell formation. After surgical removal patient's symptoms have revealed and phosphorous levels became to normal levels. Oncogenic osteomalacia and ankylosing spondylitis, both can present with arthralgia, weakness, difficulty in walking. For the patients who have features suggestive of oncogenic osteomalacia, it is of crucial importance to perform a survey to detect the tumour or tumours responsible.

Stromal tumour revealing a multiple endocrine neoplasia type 1

Ennaifer Houda, Mchirgui Nadia, Ben Abdelghani Khaoula, Khiari Karima & Ben Abdallah Najib
Department of Internal Medicine A – Endocrinology-Charles Nicole University Hospital, Tunis, Tunisia.

Gastrointestinal stromal tumour (GIST) is now defined as a specific, KIT-expressing and KIT-signalling driven mesenchymal tumour of the gastrointestinal (GI) tract. We report a case of stromal tumour revealed by prolonged fever and skin lesions associated with primary hyperparathyroidism and pituitary adenoma.
Observation
We present the case of a 59-year-old patient admitted for prolonged fever with inflammatory syndrome and latte tasks cutaneous lesions. Abdominal ultrasound showed two intra abdominal masses of the left hypochondrium and inter-spleno kidney. Their scanno guided biopsy concluded to a double localisation of a gastro intestinal stromal tumour CKITT^{+}. The dermatological examination found a paraneoplastic dermatosis. The patient was put under Glivec 400 mg/day. A cervicothoracic CT discovered lung nodules. The colonoscopy found a juxta appendiceal tumour with multiple layered flat lesions which the biobsy concludes to a tubulo-villous adenoma with high-grade dysplasia. Hypercalcaemia 2.9 mmol/l is discovered. The diagnosis of primary hyperparathyroidism is confirmed by high PTH 217 pg/ml. A type 1 multiple endocrine neoplasia is evoked. A pituitary MRI found a micro pituitary adenoma. Hormonal exploration has concluded that it was a non-secreting adenoma. An abdominal CT scan finds a nodular hypertrophy of the left adrenal. The dosage of urinary Metanephrine was normal. This case illustrates the possible association of a stromal tumour with MEN1.

Gastrinoma with liver metastasis; is it always a bad news?

Sriranganath Akavarapu, Jayashekara Acharya, Parvathy Valsalakumari & Jeannie Todd
Imperial College NHS trust, London, UK.

Introduction
Gastrinoma is a rare neuroendocrine tumor and associated with liver metastasis in 20–40% of cases. We present a rare case report of a patient with stable liver metastasis due to gastrinoma for more than 35 years.
Case report
A 49 year old male is currently on our regular clinic follow up for the liver metastasis due to gastrinoma. His past history includes open laparotomy and resection of gastrinoma (Proven histologically) at the age of 12. During the surgery liver metastasis was noted. He was followed up in clinic until the age of 20. Later he presented with diarrhoea at the age of 38 and was started on Omeprazole 20 mg TDS. Currently he has no symptoms. Genetic study for MEN-1 syndrome is negative. Blood tests showed raised Gastrin levels of 450 ng/l while on Omeprazole. MRI of abdomen in 2014 showed three large liver lesions with largest lesion size of 7 cm. Gallium Dotate PET scan showed all lesions are metabolically active. Compared to previous CT scan in 2006 and 2010 no change in the liver metastasis size.
Discussion and conclusion
Presence of liver metastasis with gastrinoma generally indicates poor prognosis with some studies suggests 10-year survival rate of only 10–20%. However very indolent gastrinoma with liver metastasis is rare and could be managed conservatively.

The effect of self-administration of Ipstyl treatment on patients' lives: a qualitative study of patients with acromegaly

Henriette Brahe Hoei & Jonna Gintberg Jensen
Aarhus University Hospital, Aarhus, Denmark.

In 2014–2015, a study of patients' quality of life after training in self-management of monthly Ipstyl injections is implemented. These injections were previously given by their GPs. Inclusion criteria are described. Sample cuts across gender and age. Ten patients did not respond to mailed offers and 12 did not participate. The reason for this is only known to some of them. Six patients wanting training are invited to an introduction of self-management of Ipstyl and are informed that they can always turn to the department with questions related to self-management. Research interviews were conducted in connection with training. The Data Protection Agency approved the project, and the patients were informed of the rules for participation. An interview guide with validated questions was used, and qualitative interviews have so far been completed by two patients. Interviews of ~40 min were recorded and transcription carried out by the researcher. The patients' statements are categorised and analysed according to Steiner Kvale's analysis model's three operational levels i) the patient's self-understanding, which is a compressed image of the person's perception, ii) critical sense, a broader frame of reference than the patient's own opinion and iii) the theoretical level, providing a framework for interpretation of the meaning of statements (Kvale & Brinkmann 2009: 237ff.). The project's most spectacular preliminary findings are: i) Independence in planning GP consultation; ii) Positive experience of self-management procedure; iii) Self-determination of slow injection rate causing less pain at the injection site. Subsequent initiatives focus on optimising the quality of life of the 22 patients who currently do not want self-management. When they are admitted for their annual check-ups: they will be informed about the project's findings; training does not necessarily mean future self-management; spouses are allowed to participate in the introduction as well as in self-management.

Continuous subcutaneous hydocortisone infusion replacement treatement in adrenal insufficiency – how to start the hydrocortisone infusion

Katerina Simunkova[1], Nevena Jovanovic[2], Espen Rostrup[1], Paal Methlie[2], Marianne Øksnes[1], Roy Miodini Nilsen[4], Hanne Hennø[1], Mira Tilseth[1], Kristin Godang[3], Ana Kovac[1], Kristian Lovas[1] & Eystein Sverre Husebye[1]
[1]Departments of Clinical Science, University of Bergen, Bergen, Norway; [2]Department of Medicine, Haukeland University Hospital, Bergen, Norway; [3]Department of Endocrinology, Oslo University Hospital Rikshospitalet, Oslo, Norway; [4]Global Public Health and Primary Care University of Bergen, Bergen, Norway.

Many patients with primary adrenal insufficiency (Addison's disease) take extra doses of glucocorticoids before or during stressful events, but benefit has not been demonstrated. We aimed to test the effect of an extra dose of glucocorticoids on cardiorespiratory, hormonal and metabolic parameters in response to physical activity in a randomised placebo-controlled, 2-weeks cross-over, clinical trial (clinicaltrials.gov NTC01847690). Ten women with Addison's disease and ten female controls participated in the study. All underwent maximal incremental exercise testing. A stress dose of 10 mg hydrocortisone or placebo was given 1 h before exercise on two occasions. Blood samples were drawn before, and at 0, 15 and 30 min post exercise. The glycaemia was followed by continuous glucose monitoring for 24 h. The primary endpoints were oxygen uptake (O_2 uptake), maximal aerobic capacity (VO_2 max). Secondary outcomes were detailed ergometric parameters, and duration of exercise, post-exercise hypoglycaemic events and glycaemic variability, endocrine and metabolic responses to physical activity, and health status evaluated by questionnaires. VO_2max and duration of exercise were significantly lower in patients compared to controls and did not improve with the treatment. Stress-dosed hydrocortisone elevated serum cortisol significantly ($cortisol_{max}$ mean 671 nmol/l (s.d. 49) vs 204 nmol/l (s.d. 41), $P<0.0001$). After exercise the blood glucose and adrenaline levels were significantly lower, and free fatty acids slightly higher, in the patients than in the controls, irrespective of stress dose. No differences were found between the treatments in metabolic or hormonal parameters or quality of life after the exercise. In conclusion, patients did not obtain benefits from stress-dosed hydrocortisone during strenuous short-term exercise. And such dosing does not seem justified in this setting.

Offspring of nurses working on irregular shifts are more likely to be underweight and less likely to be obese compared with those working on a regular basis

Oya Adsiz Marasuna[2] & Umut Mousa[1]
[1]Department of Endocrinology and Metabolism, B Nalbantoglu Hospital Nicosia, Cyprus; [2]Department of Pediatrics, B Nalbantoglu Hospital, Nicosia, Cyprus.

Introduction
Like many other hospitals nurses work either on irregular shifts or on regular basis in our centre. Also their education levels differ among them. In this study we aimed to analyse some factors which may affect the children of female nurses' adiposity.
Subjects and methods
We included 100 children of female nurses on duty in our hospital. The ages ranged between 2 months and 17 years.
Results
According to standard BMI percentiles, 13 (13%) were underweight, 53 were normal weight (53%), 14 were overweight (14%) and 20 were obese (20%). Fifty seven were the first child (57%), 38 (38%) were the second and 5 (5%) were the third child. Sixty-eight children were born normally and 32 by caesarean section. Mothers of 42 children were working on regular basis compared with 58 working on irregular shifts. Out of the mothers of 13 underweight children 12 were working on irregular shifts and one on regular basis. Similarly out of the mothers of 20 obese children 12 were working on regular basis compared to eight on irregular shifts. These findings were statistically significant ($P=0.016$). Children's adiposity were also positively associated with snack habits ($P=0.003$). There was no association between children's adiposity and mothers' education level, fathers education level, fathers working status, duration of breast feeding, birth weight, children's gender, birth order, time of consumption of additional food and type of birth.
Conclusion
The main finding in our study was that underweight children were from mothers working on irregular shifts and that obese children were from mothers working on a regular basis. This could be attributed to irregular working hours leading to irregular and possibly insufficient family feeding. The mother is generally not with the child at feeding hours. These findings need to be clarified in larger scale studies.

EP1352

Pegvisomant home care programme leading to rapid IGF1 control likely improves quality of life

Els Rutten, Guy T'Sjoen, Bruno Lapauw, Charlotte Verroken & Els Feyen
Ghent University Hospital, Ghent, Belgium.

Background
Pegvisomant has demonstrated efficacy in attaining IGF1 normalisation in previously uncontrolled acromegalic patients. A home care programme improves treatment compliance.

Aims
Evaluation of home educational program and quality of life (Qol).
Methods
Multicentre observational study involving eight Flemish centres. Uncontrolled acromegalic out-patients were trained for daily subcutaneous pegvisomant injection at home by one specialist nurse during 2 h. Enhanced motivation was provided through regular follow-up visits on day 2, 3 and 7 (60′, and twice 45′, respectively) and 15′ phone calls at month 1, 1.5, 3, 4.5, 6, 12, 18, 24, 30 and 36. Preliminary results include IGF1 at baseline, 3, 4.5, 6, 12 and 18 months. Qol was assessed by Patient-Assessed Acromegaly Symptom Questionnaire (PAQ15).
Results
Eighteen patients were included. Associated treatments were long-acting somatostatin analogues ($n=15$): five patients were treated with octreotide LAR 30 mg monthly, four patients with lanreotide 90 mg monthly and six patients with lanreotide 120 mg monthly. In all participants, IGF1 decreased (sometimes needing dose adjustment of pegvisomant from 10 mg OD to 30 mg OD) and Qol improved significantly over time ($P<0.001$), based on decreased complaints of headache ($P=0.002$), perspiration ($P=0.001$), joint pain ($P=0.007$), fatigue ($P=0.023$) and soft tissue swelling ($P=0.001$). These improvements were durable and no drop-outs were observed Table 1.

Table 1

	Baseline ($n=18$)	3 months ($n=18$)	4.5 months ($n=12$)	6 months ($n=9$)	12 months ($n=11$)
IGF1 (ng/ml) (mean±S.D.)	464±262	221±103	282±236	249±167	217±136
	Baseline ($n=11$)	1 month ($n=18$)	6 months ($n=15$)	12 months ($n=10$)	18 months ($n=9$)
PAQ15 (0–8) (mean±S.D.)	11±7	7±6	6±6	6±5	3±3

Conclusion
Working with a specialist nurse may help to improve Qol by attaining rapid IGF1 normalisation, due to enhancing patients' compliance. PAQ15 score improved both on short and longer term.

Level of knowledge about work accidents and competencies among nursing students

Floreta Kurti[1,2], Vjollca Shpata[1,4], Klodiana Poshi[1,3], Brisilda Refatllari[1], Albana Gjyzari[1,5], Ermira Biu[1] & Tatjana Cina[1]
[1]Faculty of Medical Technical Sciencies, University of Medicine, Tirana, Albania; [2]Service of Gastrohepatology UHC Mother Theresa, Tirana, Albania; [3]Service of Endocrinology UHC Mother Theresa, Tirana, Albania; [4]Intensive Care Unit UHC Mother Theresa, Tirana, Albania; [5]Service of Nefrology UHC Mother Theresa, Tirana, Albania.

Aim
The aim of the study is to identify the current level of knowledge of nursing students at the end of their studies in the Master's degree about competence in general nursing, work accidents and competence of endocrine nurses in diabetes care.
Methods
We had 673 nursing students enrolled in the study. They were all students at the end of their study in the master's degree. 76% of the students were practicing nurses with more than 3 years of work experience. All the students fulfilled a very detailed anonymous questionnaire about work accidents, prevention and post exposure prophylaxis, as well as specific knowledge on tests in relation to normal and abnormal organ function.
Results
We had 108 males (15.7%) and 567 females (84.2%). Mean age of nursing students was 27.38±1.24. Out of 673 students, 580 of them (86.18%) report that they had at least one work accident during their work experience. 102 nursing students (15.15%) had good levels of knowledge about tests in relation to normal and abnormal organ function. Only 38 nursing students (4.75%) had expert level knowledge on the specialised field. Mean years of work experience is significantly higher in nurses with expert level knowledge's, and this is statistically significant, $P<0.05$.
Conclusion
Even after Master studies, the level of knowledge of nurses about prevention of work accidents, post-exposure prophylaxis and competency in special nursing fields is unsatisfactory. These results raise the need for the development of national standards in general nursing and the need for professional accreditation of skills and knowledge into practice. We should focus on work-based and lifelong learning plus supervisionn. Specialist nurses may achieve the expert status, in those competencies relevant to them, after 5 years and more in their specialty.
