INDEX OF AUTHORS

Prize Lectures and Biographical notes

European Journal of Endocrinology Prize Winner

The *European Journal of Endocrinology* Prize is awarded to a candidate who has contributed significantly to the advancement of the knowledge in the field of endocrinology through publication. Further information on the prize can be found at http://www.ese-hormones.org/prizes/eje.aspx. This year's recipient is Dr Robert Semple. The prize will be presented as part of the ECE 2015 opening ceremony where Dr Semple will deliver his lecture. Dr Semple will also write a review article based on this lecture to be published in the *European Journal of Endocrinology*.

Robert Semple, University of Cambridge, UK

Robert Semple is a Wellcome Trust Senior Research Fellow and Honorary Consultant Endocrinologist at the University of Cambridge, UK. He read Biochemistry and then Medicine at the University of Cambridge before internal medical posts in London. He returned to Cambridge for specialist training in Diabetes and Endocrinology, interrupted by doctoral studies with Prof Sir Stephen O'Rahilly, focussing on transcriptional regulation of adipose tissue metabolism.

For the past 12 years he has focussed on rare disorders of insulin action and growth. His research aims to identify novel genetic defects underlying insulin resistance and related conditions, both to accelerate diagnosis and to enhance treatment of affected patients, and to draw inferences, through physiological study of affected patients, about the pathobiology of common forms of metabolic disease. This work has played a key part in the establishment of a National Severe Insulin Resistance Service in Cambridge.

Dr Semple is also a fellow of Clare College, Cambridge, and Director of the Cambridge MB PhD programme.

The *European Journal of Endocrinology* Prize Lecture

Insulin Action in Common Disease: Too Much, Too Little, or Both?

Robert Semple, Wellcome Trust Senior Research Fellow and Honorary Consultant Endocrinologist, The University of Cambridge, Cambridge, UK

Insulin resistance is usually taken to mean a state in which insulin exerts a diminished blood glucose lowering effect. Insulin resistance is not a disease in itself, but is closely associated with pandemic diseases or tissue pathologies including type 2 diabetes, fatty liver, metabolic dyslipidemia, polycystic ovary syndrome and some cancers. It is also closely associated in the general population with obesity, and there is a widely prevalent view that obesity leads to insulin resistance, and that it is when compensatory hyperinsulinaemia starts to fail that diseases ensue. Nevertheless the idea has been promulgated since the 1980s that major components of the 'insulin resistance syndrome' are actually consequences of high levels of insulin exerting harmful effects on responsive tissues. In this talk known single gene forms of insulin resistance will be compared and contrasted with prevalent insulin resistance and with insulin deficiency in order to assess the relative importance in humans of lack of insulin action and, conversely, excessive insulin action in disease pathogenesis, with particular reference to fatty liver, dyslipidaemia, polycystic ovary syndrome and soft tissue overgrowth.

Geoffrey Harris Prize Winner UK

This prestigious prize is intended for established workers in the field of basic and clinical neuroendocrinology and is generously supported by Ipsen. This year's recipient is Prof. Carlos Dieguez. The prize will be presented as part of the ECE 2015 opening ceremony where Prof. Dieguez will deliver his lecture. Prof. Dieguez will also deliver two other lectures at future ESE scientific meetings. Further information can be found at http://www.ese-hormones.org/prizes/

Prof. Carlos Dieguez, Professor of Physiology, Scientific Director,
Center for Medical Research, University of Santiago de Compostela, Spain

Prof. Carlos Dieguez graduated in Medicine at the University of Santiago de Compostela in 1979. From 1981 to 1987 he completed his PhD and postdoctoral training under the supervision of M. Scanlon at the Department of Medicine, the Welsh National School of Medicine in Cardiff (UK). During this period the main focus of his research was related to the neuroendocrine control of TSH and GH secretion.

In 1988, he returned to the University of Santiago de Compostela where he is currently Professor of Physiology and Scientific Director of the Center for Medical Research. He has published over 450 research papers and reviews. His work has been focused in the neuroendocrine control of pituitary hormone secretion, energy balance and peripheral lipid metabolism.

His group maintains a large number of collaborations with different endocrine groups in Europe as well as being part of different consortiums funded by the EU (Diabesity, Neurofast, Reprobesity, Trans-in).

The Geoffrey Harris Prize Lecture

Understanding energy sensors, understanding neuroendocrine function

Carlos Dieguez, University Santiago de Compostela, Santiago de Compostela, Spain

The question on how cells, tissues and organisms are able to detect energy/nutrient availability has been the focus of research for many years. Data gleaned recently have identified different nutrient-sensing circuits implicated in the regulation of different homeostatic process. Furthermore, there has been a steady increase in our knowledge regarding the cellular and molecular mechanisms involved in nutrient detection and integration. In particular, this has allowed for a better understanding of the neural and endocrine circuits involved in nutrient and energy sensing and their adaptation to different metabolic needs in a tissue-specific manner.

Work carry out by different groups have uncovered the mechanism by which hypothalamic neurons sense nutrient bioavailability, with a relevant contribution of AMPK and mTOR among others, as sensors of cellular energy status. Interestingly, the orexigenic/anorexigenci effects of different neuropeptides and peripheral hormones appear to be mediated by an AMPK-driven regulation of hypothalamic lipid metabolism, and may involve also the modulation of mTOR signaling. Their integrative role in terms of energy homeostasis involved different mechanisms including regulation of food intake, energy expenditure or metabolic homeostasis at relevant target tissues. Furthermore recent developments has shown the involvement of central energy sensors in orchestrating the adaptative response of different hypothalamic-pituitary axis to changes in energy availability. This development helps to understand the interplay between peripheral signals and central neurotransmitters and neuropeptides in order to elicit a biological response at the whole organism.

Congenital Adrenal Hyperplasia (CAH): Mechanisms and management across the life span
PL4

Overhauling the pathophysiology and treatment of congenital adrenal hyperplasia across the lifetime

Richard Auchus
University of Michigan, Ann Arbor, Michigan, USA.

The most common form of congenital adrenal hyperplasia is 21-hydroxylase deficiency (21OHD). The treatment for classic (severe) 21OHD differs from treatment of most other types of adrenal insufficiency in that not only must one replace the glucocorticoid and mineralocorticoid deficiency but also attenuate the high adrenal-derived androgen production. In order to reduce the adrenocorticotropin (ACTH) driven androgen production, supraphysiologic doses of glucocorticoid and/or long-acting synthetic glucocorticoids are often used, to compensate for the short half-life of oral hydrocortisone. In particular, the early morning rise in ACTH and adrenal steroids is difficult to manage in 21OHD. Consequently, adults with 21OHD suffer from high rates of obesity, low bone density, and cushingoid features.
Several strategies have been employed recently to improve the control of androgen excess in 21OHD while limiting the dose of glucocorticoid to the physiologic replacement range. Modified-release forms of hydrocortisone have been developed to prolong its half-life, and hydrocortisone has been delivered via a continuous subcutaneous infusion system, to match the dosage and timing to the clinical need. Abiraterone acetate, the prodrug for the potent 17-hydroxylase/17,20-lyase (CYP17A1) inhibitor abiraterone, markedly lowered androgens in six adult women with 21OHD in a short-term study of 100–250 mg/day. The non-steroidal antagonist of the corticotropin-releasing factor receptor type 1 (CRFR1), NBI-77860, lowered ACTH and 17OHP in eight adult women with 21OHD. These therapies are all under further study to determine safety and efficacy in children and adults.
In addition, the pathways of androgen excess in 21OHD have been unclear, and the best biomarkers for diagnosis and titration of therapy are debated. Recent work suggests that the alternate or 'backdoor' pathway to dihydrotestosterone via 5α-reduced precursors significantly contributes to the androgen excess of infants with 21OHD. Specific 21- and 19-carbon steroids of adrenal origin might be better biomarkers of 21OHD than 17-hydroxyprogesterone and testosterone.

Insulin signalling and action
PL5

Interplay between genes and environment in insulin resistance and metabolic syndrome: the unique role of the gut microbiome

C Ronald Kahn, Siegfried Ussar & Shiho Fujisaka
Joslin Diabetes Center, Boston, Massachusetts, USA.

Both type 2 diabetes (T2D) and obesity are the result of a complex interaction between genes and environment, as well as complex interactions between the tissues of the body. The latter include effects of new adipokines released by fat that influence insulin action in other tissues of the body, as well as increasingly complex effects of the brain and adipose tissue on control of metabolism. Mouse models provide a powerful tool to investigate these interactions in disease pathogenesis. These studies have revealed new classes of insulin action and new mechanisms of tissue cross-talk in the pathogenesis of obesity and diabetes, as well as impact of genes, environment and the gut microbiome on disease pathogenesis. For example, we have previously shown that C57BL/6 mice (B6J) are susceptible to diet induced obesity, marked insulin resistance and metabolic syndrome, while 129S1 mice from Jax (here identified as 129J) are resistant to development of obesity and metabolic syndrome. Likewise, when challenged with genetically-induced insulin resistance, more than 90% of B6J mice develop diabetes, while $<5\%$ of 129J mice become diabetic. Genome-wide scanning indicates at least one of the genes involved in the difference in insulin resistance is the gene for PKCδ. Recently, we have extended this interaction between genes and environment using a unique experimental paradigm in which we have compared the responses of these two strains of mice from Jax to an almost isogenic strain of 129 mice from Taconic Farms (129T). Interestingly, while the 129J mice are resistant to this high fat diet challenge, 129T mice show a different phenotype, being susceptible to diet-induced obesity, but retaining normal insulin sensitivity. Thus, compared to B6J mice, the 129T mice represent a model of the 'healthy' obese. This phenotype however is related to environmental influences. Following 'normalization' of the environment by inbreeding these three strains of mice in our animal facility for several generations, the 129T mice lose their susceptibility to diet-induced obesity and became very similar to the obesity resistant 129J mice. Analysis of the composition of gut microbiota reveals profound differences in the relative amounts of bacterial species in the intestine between the three different commercial mouse lines and their environmentally-conditioned equivalents. The composition of the microbiome for each strain uniquely correlate with the genetic background, different diets and different environmental histories, i.e. the provenance, of these mice. These changes in microbiota are also associated with changes in production of the inflammatory mediators by the gut and to the production and secretion of gut hormones known to influence energy intake and metabolic homeostasis. When mice are treated with different antibiotics, the microbiome changes and this is associated with changes in insulin signaling and metabolism. Our study allowed us for the first time to unravel how diet, genetic background, as well as original housing conditions, each independently contribute in shaping the gut flora composition which will drive the susceptibility of mice to diet-induced obesity, which can be reprogrammed by exposing mice to new environmental factors.

Obesity and the skeleton

PL7

Obesity and the skeleton

Juliet Compston
Cambridge Biomedical Campus, Cambridge, UK.

Until recently obesity was believed to be protective against fractures as a result of higher bone mass and the protective effect of subcutaneous fat during falls. However, recent studies indicate that fractures in obese postmenopausal women and older men make a substantial contribution to the overall fracture burden in these populations. The effect of obesity on fracture risk is site-dependent, with protection against hip and wrist fractures but increased risk of ankle and lower leg fractures.

The pathophysiology of bone fragility in obese individuals has not been clearly established. Adipose tissue can produce adipokines and cytokines, many of which have adverse effects on bone. Increased intramuscular adipose tissue is likely to contribute to reduced muscle strength, reducing bone mass and increasing the risk of falls. Other potential pathogenetic factors include vitamin D insufficiency, secondary hyperparathyroidism and hypogonadism.

The evidence for efficacy of anti-osteoporosis medication in the obese is weak, since pivotal clinical trials have included relatively few obese individuals. There is some evidence that anti-resorptive medications may not be effective in reducing non-vertebral fractures in obese postmenopausal women. Further studies are needed to enable the development of effective strategies to reduce the growing fracture burden in the obese population.

Glucocorticoid action in health and disease

S1.1

Dietary regulation of cortisol production and metabolism in humans

Brian R Walker
University of Edinburgh, Scotland, UK.

The hypothalamic-pituitary adrenal (HPA) axis plays a key role in the metabolic response to stress, so it is to be anticipated that cortisol signalling might in turn be regulated by nutritional status. This regulation might operate either centrally, controlling ACTH and hence plasma cortisol, or peripherally, controlling metabolism of cortisol in target tissues.
Plasma cortisol levels are elevated during starvation in animals and a recent meta-analysis confirms that starvation elevates plasma cortisol also in humans, although the effect may be transient. Cortisol levels also rise transiently after meals in humans. It is usually assumed that these effects of starvation and feeding are mediated by central alterations in the HPA axis. However, using stable isotope steroid tracers and test meals with different macronutrient components, we demonstrated that enhanced peripheral regeneration of cortisol contributes substantially to the rise in plasma cortisol after consumption of carbohydrate but not fat. We further demonstrated acute up-regulation of 11β-HSD1 activity *in vivo* by insulin but not lipid infusions.
With chronic dietary manipulation in humans, however, a low carbohydrate diet induces up-regulation of 11β-HSD1, an effect which is mimicked by metformin administration, suggesting that hyperinsulinaemia may chronically down-regulate 11β-HSD1. Indeed, in obesity without diabetes 11β-HSD1 is down-regulated in liver. However, other factors may come into play in obesity, particularly up-regulation of adipose 11β-HSD1 induced by intra-adipose inflammation. A complex regulation of 11β-HSD1 by pathways involved in nutrient signalling appears to be species- and tissue-specific, e.g. Tith changes induced by PPAR agonists and growth hormone in mice not readily recapitulated in humans.
We conclude that both the HPA axis and peripheral regeneration of cortisol are influenced by nutritional status and dietary macronutrient content. Variations in glucocorticoid signalling may therefore contribute to adverse effects not only of total calorie excess, but also specific dietary components.

S1.2

Subclinical Cushing's syndrome and cardiovascular disease

Guido Di Dalmazi
Medizinische Klinik und Poliklinik IV - Klinikum der Universität München, Munich, Germany.

Subclinical Cushing's syndrome, defined as evidence of alterations of the HPA axis in patients without stigmata of hypercortisolism, is a frequent finding among patients with adrenal incidentalomas. It is well-known that this condition is associated with several co-morbidities, such as hypertension in 2/3 of the cases, diabetes in 1/3, and dyslipidemia, which impair the cardiovascular risk profile of those patients. Recently, different independent reports on the natural history of subclinical hypercortisolism have highlighted an association of this disease with severe cardiovascular outcomes. Specifically, during a long-term follow-up surveillance period, patients with subclinical hypercortisolism show an increased incidence of cardiovascular events, mainly coronary heart disease and stroke, with respect to patients with non-functioning adrenal incidentalomas. Interestingly, an even higher risk of cardiovascular diseases was reported in patients with increased cortisol secretion during follow-up. Moreover, patients with subclinical hypercortisolism also have a reduced survival rate than those with non-functioning tumors, mainly due to cardiovascular events and infectious complications. Increased cortisol levels were independently associated to the increased cardiovascular events and mortality of those patients. It is clear that the hypercortisolism driven by these tumors, although of mild entity, plays a pivotal role in contributing to the worsened cardiovascular profile, when sustained and prolonged for several years. However, although all these data together do not provide enough evidence that the surgical treatment is the best therapeutic option for all patients with subclinical hypercortisolism, they give clues on the existence of different subtypes of diseases that must be better stratified according to the cardiovascular risk and assigned to different follow-up strategies. In this context, randomized trials focused on the efficacy of surgery on cardiovascular outcomes, on one side, and pre-operative steroid profiling with mass spectrometry, on the other side, will be extremely useful in achieving a sub-classification of patients with subclinical hypercortisolism that could benefit from either medical or surgical treatment.

S1.3

11β-hydroxysteroid dehydrogenase type 1: substrate promiscuity, implications for local glucocorticoid activation?

Alex Odermatt
University of Basel, Basel, Switzerland.

11β-hydoxysteroid dehydrogenase type 1 (11β-HSD1) essentially catalyzes the conversion of the inactive endogenous glucocorticoid cortisone (11-dehydro-corticosterone in rodents) and the synthetic prednisone into the active cortisol (corticosterone in rodents) and prednisolone. The association of an elevated expression of 11β-HSD1 with metabolic disease has been extensively studied in humans and in rodent models. It is generally assumed that the effects that are observed upon modulating 11β-HSD1 function by pharmacological inhibition or genetic manipulation in transgene mouse models are glucocorticoid-dependent. However, 11β-HSD1 is a multi-functional carbonyl reductase involved in the hepatic metabolism of various non-steroidal xenobiotics. Besides, it has a role in the metabolism of neurosteroids, oxidized cholesterol and bile acids. In as much these alternative substrates might affect 11β-HSD1-dependent glucocorticoid activation can, so far, only be estimated from *in vitro* studies, and further investigations *in vivo* are needed.
A recent study in 11β-HSD1 deficient mice revealed elevated concentrations of circulating free bile acids, an effect that was more pronounced in global than liver-specific knockout mice. A reduced expression of the bile acid coenzyme A ligase Fatp5 suggested an impaired bile acid amidation and subsequently decreased conjugation. These effects of the lack of 11β-HSD1 activity seem to be glucocorticoid-independent because intra-hepatic corticosterone levels and glucocorticoid receptor target gene expression were not decreased in livers from liver-specific knockout mice. Furthermore, Fatp5 expression was not altered in mice deficient in hepatic glucocorticoid receptors.
Thus, the elucidation of glucocorticoid-independent functions of 11β-HSD1, such as its role in oxysterol and bile acid homeostasis, and the relevance for metabolic and immune disorders warrants further investigations.

DOI: 10.1530/endoabs.37.S1.3

Management of type 2 diabetes: State of the art

S2.1

Blood pressure management in Type 2 Diabetes Mellitus

Peter Rossing[1,2,3]
[1]Steno Diabetes Center, Gentofte, Denmark; [2]NNF Center for Basic Metabolic Research, University of Copenhagen, Copenhagen, Denmark; [3]Health Aarhus University, Aarhus, Denmark.

Hypertension is a major risk factor in type 2 diabetes both for cardiovascular and microvascular complications. It has been estimated that hypertension contributes to 41% of the attributable risk for mortality. Proper assessment of blood pressure, consideration of diurnal pattern, white coat and masked hypertension is important. Lifestyle factors should be addressed in the management, but in most patients pharmaceutical intervention is needed. The optimal intervention usually requires a combination of agents, particularly in patients with hypertension and renal complications, where three antihypertensive agents on average are used. Therefore selection of the optimal combination with best effect and least side effects are important, which requires attention to individual factors such as renal complications, history of cardiovascular events, fluid balance and electrolyte status. In addition attention to occurrence of side effects, as well as adherence to treatment regimen is important factors. Here consideration of the multifactorial intervention applied in type 2 diabetes is important. It is always a matter of discussion when to start treatment, as well as target blood pressure for treated individuals. Although targets have been declining for decades, to 130/80 mmHg, many of the most recent guidelines suggest a higher target blood pressure, such as 140/90, and probably as for glucose management, a need for a more individualised approach both regarding onset of treatment and target. This debate is fuelled by lack of clear evidence for the optimal target. Finally antihypertensive agents may play an important role in preventing the microvascular complications even in 'normotensive' subjects.

DOI: 10.1530/endoabs.37.S2.1

S2.2

Blood glucose management

Kåre Birkeland
Oslo University Hospital, Oslo, Norway.

Glucose lowering treatment in patients with type 2 diabetes aims at reducing hyperglycaemic symptoms, preventing acute hyperglycaemic crisis and delaying the onset and progression of microvascular complications. The impact of glucose control on cardiovascular complications remains uncertain, however, a modest benefit is likely to be present.
The cornerstones of treatment remain education, motivation and counseling on healthy eating behavior and moderate physical activity. As only a minor proportion of subjects will reach glycaemic targets with these measures alone, pharmacological antihyperglycaemic treatment is indicated in most patients. Despite non-convincing hard evidence, metformin is the first drug of choice for those who can tolerate it, starting with low dose and increasing slowly. When insufficient to control hyperglycaemia, sulphonylureas have been the drug of choice to combine with metformin for many decades. However, its use has been challenged by epidemiological and experimental studies of possible serious side effects, although recent reviews fail to show evidence of harm of second and third generation agents. DPP4-inhibitors that increase endogenous incretin responses have a favorable side effect profile, particularly less hypoglycaemia and weight-gain than SU, however to a considerable higher cost. Although some safety data from medium-time follow-up studies begin to emerge, we will have a lot more data from hard-endpoint studies in the next 1–2 years. SGLT2-inhibitors that increase urinary glucose (an energy) loss, also compare favorably to SU regarding hypoglycaemic risk and effects on body weight. However, we still await the results of the first end-point studies with these agents, and their use should be limited to patients that cannot tolerate other agents or have special needs. Despite several new classes of oral antihyperglycamic agents, injection therapies with insulin and/or the new GLP1-agonists is needed after many years of type 2 diabetes in a significant proportion of individuals. A single daily dose of basal insulin in a treat-to-target regimen in combination with metformin is usually the preferred start of injection therapy. It is easy to handle, relatively cheap and will often allow reaching glycaemic aims. However, it requires at least some blood glucose monitoring by the patient, it may result in weight gain and increase the risk of hypoglycaemia. The use of GLP1-agonists usually requires less BG monitoring, will reduce body weight 2–4 kg, and seldom give hypoglycaemia. However they are more expensive than insulin in most cases and there are lack of long-term outcome studies. The large and increasing number of antihyperglycaemic agents enable us to individualize treatment regimens, to maximize effects and minimize side effects and costs.

S2.3

PCSK9 antibodies for the treatment of hypercholesterolemia

Ioanna Gouni-Berthold
University of Cologne, Cologne, Germany.

Cardiovascular disease (CVD) is the leading cause of death worldwide accounting for more than 17 million deaths just in 2012. A major culprit for the development of CVD is an elevated low density lipoprotein (LDL) cholesterol (LDL-C) concentration. Despite statin therapy a high residual risk of cardiovascular events remains, especially since with the currently available treatment options only ~50% of high risk patients and ~20% of very high risk patients achieve their target LDL-C values of <100 and <70 mg/dl respectively. It is therefore clear that additional therapies are needed. The serine protease proprotein convertase subtilisin/kexin type 9 (PCSK9) binds to LDL receptor (LDLR) and directs it to lysosomes for intracellular degradation. This results in, decreased numbers of LDLR available on the hepatic cell surface to bind LDL particles and remove them from the circulation and therefore to a subsequent increase in circulating LDL-C concentrations. Since 2003, when the role of PCSK9 in LDL-C metabolism was discovered, there have been major efforts to develop efficient and safe methods to inhibit it. Amongst those, monoclonal antibodies against PCSK9 are the furthest in development, with multiple phase 3 trials already published and with cardiovascular endpoint trials currently underway. Two fully human monoclonal antibodies, evolocumab and alirocumab, have been extensively studied in a wide range of subjects, such as those with statin intolerance, as an add-on to statin therapy, as a monotherapy and in patients with familial hypercholesterolemia. PCSK9 antibodies result in a consistent and robust decrease in LDL-C plasma levels ranging from 40% to 70%, either on top of statins or as monotherapy. If the safety data from the on-going phase 3 trials remain as reassuring as the data available till now, PCSK9 antibodies will offer a novel, powerful therapeutic option to decrease LDL-C plasma levels and, hopefully, cardiovascular risk.

Non-classical causes of hypopituitarism (*Endorsed by Endocrine Connections*)

S3.1

TBI: whom to screen for hypopituitarism

Mark Hannon[1,2]
[1]St. Bartholomew's Hospital, London, UK; [2]Beaumont Hospital, Dublin, Ireland.

Traumatic Brain Injury (TBI) is a devastating neurological emergency, usually resulting in transient or permanent neurological dysfunction. It is the most common cause of death and disability in young adults in industrialised countries and is a major public health problem. Although anatomical pituitary damage following TBI was first recognised as long ago as 1918, evidence of hormonal dysfunction in both the acute and chronic phases following TBI had only been studied in detail over the last twenty years. There is now a rapidly growing evidence base showing that TBI may lead to both acute and long-term anterior and posterior pituitary dysfunction. However, it is often difficult to define what constitutes anterior pituitary damage in the acute period following TBI, as opposed to the acute adaptive hormonal changes which occur in most critically ill patients. Furthermore, given the huge numbers of patients who sustain a TBI, it is not possible to perform dynamic testing to screen for the presence of long-term hypopituitarism in all survivors of TBI. This talk aims to summarise the evidence base on the incidence of both acute and long term anterior and posterior pituitary dysfunction following TBI, and outline a pragmatic strategy to identify those who are most likely to benefit from dynamic pituitary testing.

Genetic causes of hypopituitarism

Thierry Brue[1,2]
[1]Aix-Marseille University, CNRS, CRN2M UMR 7286, Marseille, France; [2]Service d'Endocrinologie, Hôpital de la Conception, APHM, Marseille, France.

Genetic causes of anterior pituitary hormone deficiencies may result in combined or isolated pituitary hormone deficiencies. These disorders represent a heterogeneous group of rare diseases leading to defective function of specific pituitary cell types. Since the first description of POU1F1 human mutations, several other genetic defects of transcription factors have been reported with variable degrees of phenotype-genotype correlations. However to date, despite the identification of a growing number of genetic causes of isolated or multiple pituitary deficiencies, the etiology of most (80–90%) congenital cases of hypopituitarism remains unsolved. Identifying new etiologies is of importance as a post-natal diagnosis to better diagnose and treat the patients (delayed pituitary deficiencies, differential diagnosis of a pituitary mass on MRI…), and as a prenatal diagnosis to decrease the risk of early death (undiagnosed corticotroph deficiency for instance).
Some patients harbour a complex phenotype including anterior pituitary hormone deficiencies in association with extra pituitary abnormalities or malformations on MRI such as pituitary stalk interruption syndrome or midline defects. The transcription factors genes involved in these phenotypes (for instance LHX3, LHX4) are early expressed in regions that determine the formation of forebrain and related midline structures such as the hypothalamus and pituitary. Mutations in these genes are therefore characterized by marked phenotypic heterogeneity. Among more recently identified forms, the DAVID syndrome, an association of a deficit in adrenocorticotrophin with recurrent infections due to variable immunodeficiency was recently associated with NFKB2 mutations. In contrast, 'pure' endocrine phenotypes include anterior pituitary hormone deficiencies (progressive or not) with normal hypothalamo-pituitary morphology at MRI (regardless of the size of the pituitary gland) and no extra pituitary malformation. They are due to mutations of late-acting pituitary specific transcription factors. In such a context, PROP1 gene mutations remain the most frequently reported genetic defect.

S3.3

Drug induced hypopituitarism

Salvatore Maria Corsello
Catholic University School of Medicine, Rome, Italy.

Pituitary dysfunctions, reported as 'hypopituitarism' or 'hypophysitis', are relatively common side-effects induced by monoclonal antibodies (mAbs) inhibiting specific immune checkpoints. In particular, hypophysitis represents a distinctive side effect of CTLA4-blocking antibodies and is a new form of autoimmune pituitary disease.

In initial trials, the incidence of hypophysitis induced by anti-CTLA4-mAbs (ipilimumab and tremelimumab) varied considerably (0–17%) and seemed to be dose-dependent. Higher rate of hypophysitis (14%) is associated with the administration of ipilimumab in combination with bevacizumab, while, on the other hand, hypophysitis was not reported in patients treated with ipilimumab and pretreated with chemotherapy or radiotherapy, suggesting that the immune cell depletion induced by cytotoxic chemotherapy and radiotherapy may prevent mAbs induced pituitary dysfunctions. Tremelimumab has been reported to induce hypophysitis in 0–2.5% of patients.

Presenting symptoms of mAbs-induced hypophysitis are not specific, including headache, fatigue, weakness, while visual impairment may occur, but less frequently compared with classic lymphocytic hypophysitis (LH). At MRI a pituitary swelling can appear sometimes with thickening of the stalk. As in patients with classic LH, high-dose glucocorticoids are used to treat anti-CTLA4-hypophysitis, but pituitary hormone deficits may be prolonged or even lifelong, despite the prompt initiation of glucocorticoid therapy.

Moreover, cases of hypopituitarism have been attributed also to interferons (with or without ribavidin) in patients affected by hepatitis C. No cases of pituitary dysfunction were reported with lambrolizumab, a mAb against PD1.

In conclusion, hypophysitis and hypopituitarism represent possible side effects of anticancer drugs. This is a real recent knowledge, because until the advent of anti-CTLA4-mAbs, hypophysitis was never described in association with anticancer drugs. The precise mechanism of injury to the endocrine system triggered by these drugs is still to be fully elucidated but these conditions must be promptly recognized because they may be life-threatening.

Thyroid hormone and cardiovascular system

S4.1

Subclinical hypothyroidism and cardiovascular consequences in childhood

Mariacarolina Salerno
Department of Translational Medical Sciences, University Federico II, Naples, Italy.

The relationship between subclinical hypothyroidism (SH) and cardiovascular (CV) risk is still matter of debate. While the key-role of thyroid hormones in modulation of several atherosclerotic factors is well established, the mechanisms of TSH's action on CV system are still largely unknown.

In adults with SH a pattern of CV abnormalities (dyslipidemia, insulin resistance, endothelial and diastolic dysfunction) has been observed even in mild SH cases with TSH between 4.5 and 10 mU/L.

However, a positive effect of levo-thyroxine (L-T_4) therapy on CV morbidity and survival rates has not been clearly demonstrated although there are some evidence indicating an improvement in the lipid profile and left ventricular function.

It is well known that risk factors accelerating the development of atherosclerotic disease begins in childhood and may be predictive of CV risk in adulthood. Whether SH in children predisposes to adverse CV outcomes in adulthood is still unclear. Data on children are scanty and most of the studies are limited by the small number and the heterogeneity of the populations studied and by the presence of several confounding factors, as obesity and autoimmunity, making the evaluation of the direct impact of SH on CV risk difficult.

Recent data from a selected population of subjects with mild long-lasting idiopathic SH suggested that untreated SH children may develop a cluster of subtle metabolic abnormalities as increased abdominal adiposity and slight alterations in lipid profile and homocysteine levels. The clinical significance of these changes as early steps in initiation of atherogenesis is difficult to establish. Therefore, although further studies evaluating the long-term CV consequences of childhood-onset SH and the effect of L-T_4 therapy are still to be made, the evidences available suggest that these children should be carefully monitored for metabolic complications that may expose them to an higher risk of future CV diseases.

S4.2

Cardiovascular impact of thyroid hormone receptor mutations

Krishna Chatterjee
Institute of Metabolic Science, University of Cambridge, Cambridge, UK.

The actions of thyroid hormones (TH) are mediated by receptors (TRα1, TRβ1, TRβ2), encoded by separate genes (*THRA, THRB*), with differing tissue distribution. TRβ2 mediates negative feedback within the hypothalamic-pituitary axis, with TRβ1 being expressed in the liver & kidney; TRα1 predominates in the myocardium and skeletal muscle.

Resistance to Thyroid Hormone, usually due to heterozygous TRβ mutations (RTHβ), is characterised by elevated TH and non-suppressed TSH levels. Cardiac features include tachycardia and atrial arrhythmias; indices of myocardial contractility are in the hyperthyroid range. Marked cardiac hyperthyroidism in rare, homozygous RTHβ can lead to life-threatening cardiac failure. Management of cardiac features in RTHβ includes beta blockade, antiarrhythmics or lowering TH levels with triiodothyroacetic acid (TRIAC) therapy. It is not known whether raised cholesterol and triglyceride levels, hepatic steatosis and insulin resistance in RTHβ confers excess cardiometabolic risk, but TRβ-selective thyromimetics represent a rational approach to treatment of these metabolic abnormalities.

Recognised more recently, features of Resistance to Thyroid Hormone due to defective TRα (RTHα) include growth retardation, neurodevelopmental delay, skeletal dysplasia and constipation, but with near-normal thyroid function tests. The cardiovascular manifestations of this disorder include bradycardia and lower blood pressure; following thyroxine therapy, changes in these parameters and cardiac indices are blunted, reflecting myocardial resistance to hormone action.

The divergent phenotypes of RTHβ and RTHα highlight the relative importance of α and β receptor subtypes in mediating TH action in myocardium and other tissues.

S4.3

Cardiovascular actions of novel Thyroid Hormone metabolites

Carolin Höfig
Karolinska Institutet, Stockholm, Sweden.

Thyroid hormone (TH) is one of the key players in modulating cardiovascular function. The hormone increases heart rate and force of contraction by modulating cardiac gene expression, thereby providing a molecular explanation for the clinical correlation between hyperthyroidism and cardiovascular mortality. The talk will present current aspects of cardiovascular function mediated by newly discovered TH metabolites. Recent studies have shown that a single injection of 3-iodo-L-thyronamine (3-T1AM), a decarboxylated and deiodinated TH derivative, leads to rapid decreases in heart rate and cardiac output. Although 3-T1AM is rapidly converted to several metabolites *in vivo*, the strong acute pharmacological responses of bradycardia and negative inotropy were solely attributed to 3-T1AM, leaving potential contributions of downstream products untested (e.g. 3-iodothyroacetic (TA1) acid or N-acetyl-3-T1AM (NAc-3-T1AM). Our studies revealed that TA1, the main degradation product of 3-T1AM, lacks any cardiovascular effects in mice, and thus constitutes an important inactivation product of 3-T1AM. However, NAc-3-T1AM, which is produced in liver and WAT from 3-T1AM, significantly increases heart rate and blood pressure in mice and directly enhances contractility of primary cardiomyocytes. Both effects are blocked by the β-adrenergic antagonist timolol maleate, demonstrating that the actions of NAc-3-T1AM on cardiomyocytes require β-adrenergic receptors. Based on our findings, we identify NAc-3-T1AM as a unique endocrine TH metabolite, providing a previously unknown link between liver, WAT and cardiovascular function.

S5.2

Osteoporosis in ageing men

Dirk Vanderschueren
KU Leuven, leuven, Belgium.

Osteoporosis is still considered a postmenopausal disease. Nevertheless, about one out of three of all hip fractures occur in elderly men. Hip fractures in elderly men are also associated with considerable morbidity as well as excess mortality. However, the majority of men suffering from senile osteoporosis are still underdiagnosed and undertreated. In 2012 the endocrine society has therefore formulated practical clinical guidelines for the diagnosis as well as treatment of osteoporosis in men.

During this presentation, a clinical case history will be discussed and the practical use of these endocrine society guidelines illustrated. Similar to postmenopausal women, dual energy X-ray absorptiometry (DXA) should be used in order to diagnose osteoporosis in elderly men at risk for osteoporosis. In line with this recommendation, elderly men should have DXA screening following fractures. Some controversies with respect to use of DXA in men still exists with respect to reference values (male or female) as well as site of evaluation (femoral neck only or also, total hip and/or lumbar spine). The use of different diagnostic criteria for male osteoporosis may also identify different numbers of elderly men that are candidates for drug treatment. Secondary osteoporosis should also excluded in elderly men clinically as well as by laboratory testing Laboratory evaluation as proposed by the Endocrine society includes the measurement of serum testosterone. Besides prolonged use of glucocorticoids and alcohol excess, male hypogonadism remains one of the important cause of secondary osteoporosis. Unfortunately, recent studies show that even the majority of men with androgen deprivation still do not receive pharmacological treatment. The same holds true for men that experienced a hip fracture. Pharmacological treatment modalities for elderly men are similar to those used in postmenopausal women despites the limited number of studies in men that have used fractures as an endpoint. Men with low or borderline testosterone with a high fracture risk should also receive pharmacological treatment that prevent against fractures.

Beyond Phosphorus: multiple actions of FGF23

S6.1

FGF23: a cornerstone of phosphate/calcium metabolism

Justine Bacchetta[1,2]
[1]Paediatric Nephrology, Bron, France; [2]INSERM 1033 LYOS, Lyon, France.

Since its first description as a phosphaturic agent in the early 2000s, the Fibroblast Growth Factor 23 (FGF23) has rapidly become the third key player of phosphate/calcium metabolism with the two 'old' PTH and vitamin D.

FGF23 is a protein synthesized by osteocytes that has three main effects: hypophosphatemia (through an inhibition of phosphate reabsorption in the proximal tubule), decreased PTH levels and decreased 1–25 OH_2 levels (through an inhibition of 1α hydroxylase and an activation of 24 hydroxylase activity in the kidney). Off-targets of FGF23 have also been demonstrated, notably on cardiomyocytes and monocytes. The links between iron metabolism and FGF23 on one hand, and between FGF23 and bone mineralization on the other hand, seem also of importance, although still under investigation. The single-pass transmembrane Klotho protein, an anti-aging protein, is required *in vivo* for FGF23-mediated receptor activation, at least for its renal effects.

In human diseases, FGF23 can be deregulated, either in genetic diseases, either in acquired diseases. Four groups can be distinguished: diseases with primary increase of FGF23 levels (e.g., hypophosphatemic rickets or tumor-induced osteomalacia), diseases with primary decrease of FGF23 levels (e.g., hyperphosphosphatemic tumoral calcinosis), diseases with secondary increase of FGF23 levels (e.g., chronic kidney disease, CKD), and diseases with secondary decrease of FGF23 levels (e.g., VDR deficiency leading to vitamin D-resistant rickets).

This talk will give an overview of these recent data of phosphate/calcium physiology, as well as a description of the clinical conditions associated with FGF23 deregulation. As a conclusion, the future therapeutic perspectives in the field will be discussed.

S6.2

Target cell responses to FGF23

Reinhold Erben
University of Veterinary Medicine Vienna, Vienna, Austria.

Fibroblast growth factor-23 (FGF23) FGF23 is a bone-derived hormone which down-regulates renal proximal tubular phosphate reuptake and 1α-hydroxylase expression, the key enzyme for production of the vitamin D hormone, 1α, 25-dihydroxyvitamin D_3 ($1.25(OH)_2D$). The molecular mechanism of the phosphaturic action of FGF23 has recently been elucidated. FGF23 directly downregulates membrane expression of the sodium-phosphate cotransporter NaPi-2a in proximal tubular epithelium by serine phosphorylation of the scaffolding protein Na^+/H^+ exchange regulatory cofactor (NHERF)-1 through FGF receptor-αKlotho complex-mediated activation of extracellular signal-regulated kinase 1 and 2 (ERK1/2) and serum/glucocorticoid-regulated kinase-1 (SGK1). However, FGF23 not only targets renal proximal tubular cells, but also has distinct effects on the distal nephron, in bone, and possibly in the heart and in blood vessels. In renal distal tubules, FGF23 stimulates apical membrane abundance of TRPV5 and renal calcium reabsorption in a αKlotho dependent manner through a signaling cascade involving ERK1/2, SGK1, and with-no-lysine kinase-4 (WNK4). Because activation of WNK4 not only upregulates membrane transport of TRPV5 but also of the sodium-chloride co-transporter NCC, FGF23 also increases sodium reabsorption in distal renal tubules. Recent experimental evidence suggests that the calcium- and sodium-conserving function of FGF23 may be of pivotal importance in the pathophysiology of chronic kidney disease. In bone, we identified FGF23 as a strong transcriptional suppressor of alkaline phosphatase in osteoblastic cells, acting through FGF receptor-3 in a Klotho independent manner. Hence, FGF23 secreted from osteocytes may form an autocrine/paracrine feedback loop for the local fine-tuning of bone mineralization. Taken together, there is emerging evidence that FGF23 is not only a phosphaturic and vitamin D-regulating hormone, but rather a pleiotropic hormone with additional direct effects on calcium homeostasis, sodium homeostasis, blood pressure regulation, and bone mineralization.

Novel actions of FGF23

Myles Wolf
Northwestern University, Chicago, IL, USA.

The discovery that mutations in fibroblast growth factor 23 (FGF23) cause autosomal dominant hypophosphatemic rickets transformed our understanding of phosphate homeostasis in health and disease (White *et al. Nat Genet* 2000). Since then, the critical role of FGF23 in mineral metabolism in chronic kidney disease has been established (Larsson *et al. Kidney Int* 2003; Gutierrez *et al. J Am Soc Nephrol* 2005). Elevated FGF23 has emerged as the earliest alteration of disordered mineral metabolism in chronic kidney disease (Isakova *et al. Kidney Int* 2011). Several studies now demonstrate that elevated FGF23 is also a novel biomarker of risk for CKD progression, adverse cardiovascular outcomes and death among patients with chronic kidney disease (Fliser *et al. J Am Soc Nephrol* 2007; Gutierrez *et al. N Engl J Med* 2008; Isakova *et al. JAMA* 2011; Kendrick *et al. J Am Soc Nephrol* 2011; Jean *et al. Nephrol Dial Transplant* 2009). More recently, FGF23 was demonstrated to contribute mechanistically to development of left ventricular hypertrophy, which may underlie an important component of the association of elevated FGF23 levels with high risk of cardiovascular events (Faul *et al. J Clin Invest* 2011; Scialla *et al. J Am Soc Nephrol* 2013). These studies elevated FGF23 and disordered phosphate homeostasis from powerful

biomarker to novel mechanism of cardiovascular disease in chronic kidney disease. This session will describe the latest data on FGF23 in chronic kidney disease with specific emphasis on the role of FGF23 in cardiovascular disease.

Novel mechanisms of central weight regulation

S7.1

Nutritional regulation of hypothalamic inflammation

Julie A Chowen[1,2]
[1]Department of Endocrinology, Hospital Infantil Universitario Niño Jesús, Madrid, Spain; [2]CIBERobn, Instituto Carlos III, Madrid, Spain.

Hypothalamic inflammation has been the focus of an increasing number of studies in recent years as it is thought to underlie the pathogenesis of obesity-associated insulin resistance and type 2 diabetes. These studies have also highlighted the role of glial cells in metabolic control, due to the fact that both microglia and astrocytes are involved in central inflammatory processes. High fat diet (HFD)-induced obesity has been the most commonly used model for the analysis of this phenomenon, with the diet itself shown to play an important role as hypothalamic inflammation can occur even before significant weight gain is observed. Indeed, fatty acids (FAs) can directly activate glial cells and trigger neuroinflammation. However, this response differs depending on the FA involved, with some FAs possibly being protective. Moreover, not all obesity is induced by HFD intake. The hypothalamic inflammatory/gliosis response in animals that are obese or overweight due to genetic causes, early nutritional manipulations or high carbohydrate diets differs from that seen in HFD-induced obesity. This talk will focus on the advances in our understanding of the metabolic signals involved in hypothalamic inflammation/gliosis and how this might influence the development of secondary complications such as insulin and leptin resistance.

Regulation of hypothalamic development by maternal nutrition

Merly Vogt[1], Lars Paeger[2], Simon Hess[2], Sophie Steculorum[1], Susanne Neupert[2], Reinhard Predel[2], Peter Kloppenburg[2], Tamas Horvath[3] & Jens Brüning[1]
[1]MPI for Metabolism Research, Cologne, Germany; [2]Biocenter, Institute for Zoology, University of Cologne, Cologne, Germany; [3]Program in Integrative Cell Signaling and Neurobiology of Metabolism, Section of Comparative Medicine, Department of Obstetrics/Gynecology and Reproductive Sciences, Yale University School of Medicine, New Haven, CT, USA.

In light of the ever-increasing incidences of obesity and T2DM, development of novel therapeutic or preventative measures to combat these epidemics is of utmost importance. Identification of a causal relationship between an altered maternal metabolic homeostasis and an increased propensity for the unborn child to develop metabolic disorders throughout lifetime has shifted considerable amount of attention towards understanding the underlying cellular and molecular alterations. However, despite the multitude of studies already carried out in this field of research, to date we still know very little about the developmental alterations responsible for the increased propensity towards an impaired regulation of energy homeostasis.

By employing a thorough and physiological maternal high-fat diet (HFD) feeding paradigm in mice, we could demonstrate that nutritional and hormonal alterations specifically during lactation predispose the offspring for obesity and impaired glucose homeostasis. These metabolic defects are associated with malformations of the hypothalamic melanocortin circuitry in the offspring. Whereas the number and neuropeptide expression of anorexigenic proopiomelanocortin (POMC) and orexigenic agouti-related peptide (AgRP) neurons, electrophysiological properties of POMC neurons and posttranslational processing of POMC to the active neurotransmitter α-MSH remain unaffected in response to maternal HFD-feeding during lactation, the formation of POMC and AgRP projections to hypothalamic target sites is severely impaired. Moreover, abrogating insulin action in POMC neurons of the offspring prevents altered POMC projections specifically to the preautonomic paraventricular nucleus of the hypothalamus, restores pancreatic parasympathetic innervation and improves glucose-stimulated insulin-secretion in response to maternal overnutrition.

Taken together, these experiments reveal a critical developmental period of particular vulnerability towards altered maternal metabolic homeostasis. An abnormal developmental environment during exactly this period impairs hypothalamic neuronal projections at least in part by abnormal neuronal insulin signaling and thereby contributes to the increased propensity to develop obesity and impaired glucose homeostasis.

Hypothalamic tanycytes in metabolic regulation

Vincent Prevot
Inserm U1172, University of Lille, Lille, France.

The survival of an organism relies on its ability to promptly, effectively and reproducibly communicate with brain networks that control food intake and energy homeostasis. To achieve this, circulating factors of hunger and satiety reflecting nutrient availability must cross the blood-brain barrier (BBB) to reach effectors neurons. A defect in this process invariably leads to uncontrolled body weight. Here we will discuss the key role played in this process by a peculiar type of glial cells named tanycytes, which have their cell bodies lining the floor of the third ventricle and their endfeet contacting the pial surface of the brain. Recent studies indeed suggest that tanycytes, besides regulating hypothalamic BBB plasticity according to nutrient status, capture metabolic signals such as leptin from the bloodstream and transport them towards their cell body for release into the cerebrospinal fluid. Blockade of this conduit for peripheral metabolic factors into the brain of obese individuals is thought to contribute to the pathophysiology of central hormonal resistance.

The endocrine gut (*Endorsed by Endocrine Connections*)

S8.1

Gut microbiota and incretins

Patrice D Cani[1,2]
[1]Louvain Drug Research Institute, Université catholique de Louvain, Brussels, Belgium; [2]Walloon Excellence in Life sciences and BIO Technology, Brussels, Belgium.

The distal gut harbours microbial communities that outnumber our own eukaryotic cells. Over the last 15 years, our work has been devoted to examine the way by which gut microbiota interacts with nutrients and host physiology. We and others have suggested that cross-talks between gut microbiota and the host cells contribute to the regulation of energy, glucose and lipid homeostasis.

We described the concept of metabolic endotoxemia (increase in plasma LPS levels) as one of the triggering factors leading to the development of the metabolic inflammation and insulin resistance. Following this discovery, we found that the major factor involved in the development of metabolic endotoxemia observed upon obesity is related to the gut barrier function.

Bacterial metabolism of nutrients in the gut is able to drive the release of bioactive compounds (including short-chain fatty acids or lipid metabolites), which interact with host cellular targets to control energy metabolism and immunity.

We found in both rodents and humans that prebiotics, administration changed gut microbiota composition and activity.

In rodents, we found that specific change in the gut microbiota composition improves glucose tolerance, *via* GLP-1 dependent mechanisms and gut barrier *via* GLP-2 dependent mechanisms. More specifically, we found that prebiotics increased L-cells number and associated parameters (intestinal proglucagon mRNA expression, plasma GLP-1 and 2 levels).

Thus, although the clear mechanisms involved in the bacteria-host interactions are still under investigation, we found that the gut microbiota control enteroendocrine functions and cell differentiation.

Steroid hormone action in target tissues

S9.1

Tissue-specific sex steroid action: role of HSD17B-enzymes

Matti Poutanen
Institute of Biomedicine, University of Turku, Turku, Finland.

Recent data from us and others have evidently shown that steroid metabolism at the target tissues is a key determinant regulating the availability of high affinity ligands for steroid receptors. Thus, the serum concentrations of the steroids do not necessary mimic their target tissue concentrations in several physiological and pathophysiological settings. Accordingly, among the other steroid metabolizing enzymes, the expression of hydroxysteroid dehydrogenase- (HSD17B) enzymes catalyzing the conversion between 17-keto and 17-hydroxysteroids are expressed in various sex steroid target tissues. So far, among the various HSD17B enzymes the expression of HSD17B1, HSD17B2, HSD17B3, HSD17B5 (AKR1C3) and HSD17B6 has shown the strongest association with steroid metabolism in both preclinical models and clinical specimens. HSD17B1 and HSD17B2 enzymes are the ones with the strongest association with altered estrogen metabolism, and are, for example, differentially expressed in endometriosis lesions and in the eutopic endometrium. This results into an altered estradiol/estrone balance in the endometriosis, being one of the mechanisms promoting the growth of the lesions. Role of HSD17B1 in the activation of the sex steroids is also supported by multiple phenotypic alterations in the transgenic mice expressing the human HSD17B1, as well as by the data obtained in the HSD17B1 knockout (KO) mice. Similarly to that of endometriosis, novel routes for the local sex steroid synthesis in the castration resistant prostate cancer have been identified, and the strong intra-tumor androgen production is associated with up-regulation of HSD17B5 and HSD17B6 expression. However, especially the phenotypes of the KO mouse models have predicted also other metabolic roles for several other HSD17B enzymes, and thus, a critical evaluation of physiological role of all HSD17B-enzymes *in vivo* is essential. For example, HSD17B7 KO mice showed a role for the enzyme in cholesterol synthesis, and HSD17B12 and HSD17B13 KO mice indicated a role of the enzymes in lipid metabolism. In conclusion, novel HSD17B-enzyme dependent pathways for sex steroid synthesis and metabolism are emerging at target tissues, and provides new possibilities for the treatment of sex steroid-dependent diseases by HSD17B-inhibitors.

Steroid sulphatase and colon cancer

Paul Foster
University of Birmingham, Birmingha, West Midlands, UK.

Although not normally considered an oestrogen responsive tissue, compelling evidence now exists suggesting that the colon is responsive to oestrogenic effects. Results from the Women's Health Initiative demonstrated that post-menopausal women taking oestrogen and progestins as hormone-replacement therapy (HRT) had a 40% reduction in developing colorectal cancer (CRC). Intriguingly, patients taking oestrogen supplements at the time of CRC diagnosis presented a much more advanced disease stage. Thus, oestrogens are initially protective against CRC, but once developed oestrogens may drive CRC proliferations.

Therefore, the pre-receptor metabolism of oestrogens, namely through steroid sulphatase (STS) and the 17β-hydroxysteroid dehydrogenases (17βHSDs), and the oestrogen receptor status of colonic tissue, most likely influence the incidence and subsequent proliferation of CRC.

This presentation will examine the current evidence in support of oestrogenic effects on CRC initiation and development. It will highlight the importance of the peripheral synthesis of oestrogens by STS and 17βHSDs in CRC, and how this relates to oestrogen receptor status and proliferation.

AIRE in thyroid autoimmunity

Terry Smith
University of Michigan Kellogg Eye Center, Ann Arbor, Michigan, USA.

The autoimmune regulator protein (AIRE) is a critical component of thymic education which leads to immune tolerance. Its recent detection in extrathymic tissues has prompted inquiry into potential roles for this protein beyond the thymus. We have reported detecting AIRE in circulating CD34+ fibrocytes, monocyte progenitor cells that are involved in tissue reactivity and remodeling. These fibrocytes have been detected in orbital connective tissue from individuals

with thyroid associated ophthalmopathy and in thyroid tissue from patients with Graves' disease. Further, fibrocytes express functional TSH receptor, thyroglobulin, sodium iodide symporter, and thyroperoxidase. We therefore interrogated these cells for the expression of AIRE and found that both full length and truncated forms of the protein could be detected. When AIRE expression was knocked down with specific targeting SIRNAs, levels of all four thyroid associated proteins were substantially reduced. Analysis of fibrocytes from an individual with APS1 disclosed reduced levels of these proteins as well. These findings suggest that AIRE may play an important role in the expression of thyroid self-antigens outside the thyroid. It is possible that AIRE dependent expression of thyroid antigens by fibrocytes may be involved in the manifestations of Graves' disease such as thyroid associated ophthalmopathy.

Dissecting the function of autoimmune regulator (AIRE)

Pärt Peterson
University of Tartu, Tartu, Estonia.

AIRE gene is defective in autoimmune polyendocrinopathy candidiasis ectodermal dystrophy (APECED) disease. The disease usually starts in early childhood and is characterized by progressive autoimmune destruction of many endocrine and non-endocrine organs and, in addition, mucocutaneous candidiasis. An important characteristic is the presence of autoantibodies against multiple defined antigens. In most cases, these are tissue-specific proteins with important functions in the affected tissues and are identical to the self-antigens found in more common isolated autoimmune disorders such as type 1 diabetes and Addison's disease. AIRE is expressed in the thymus by medullary thymic epithelial cells, which express hundreds of tissue-specific antigens to eliminate self-reactive T cell clones during a process called negative selection. AIRE mutations result in defective expression of these autoantigens, ultimately causing a failure in negative selection and subsequent survival of self-reactive T cells. The exact mechanisms by which AIRE functions remain unclear. The presentation discusses recent findings in AIRE function and their implications to APECED pathogenesis.

Thyroid, selenium and autoimmunity

Lutz Schomburg
Institute for Exper. Endocrinology, Charite Berlin, Berlin, Germany.

The trace element selenium (Se) is unevenly distributed in our earth's crust causing regional differences in soil Se concentrations. Soil Se directly affects plant Se content and thereby animal and human Se intake. Besides intake, the actual health status and genotype modify Se metabolism and expression of selenoproteins, i.e., Se status. In order to assess the individual Se status, total blood Se concentration or two circulating selenoproteins are determined. According to these biomarkers, the majority of Europeans is Se-deficient while e.g. US Americans are sufficiently supplied. This does however not directly translate into an overt clinical phenotype. Nevertheless, several studies have indicated that a Se deficit predisposes to certain diseases. Importantly, some supplementation studies have yielded positive health effects in autoimmune thyroid diseases, but others have not. Only about half of the studies reported remarkable reductions in TPO autoantibodies or improved quality-of-life in Hashimoto's thyroiditis, and one supplementation trial of patients with mild Graves' orbitopathy reported positive effects on quality-of-life and eye disease symptoms – a promising finding which still needs to be replicated. But collectively, the data at hand do not yet advocate general Se supplementation as a therapeutic measure in thyroid autoimmunity. The situation is different when considering epidemiological studies implying that subjects with relatively low Se status have an increased risk for developing goiter, nodules, autoimmune thyroid diseases, infections, cancer and life-threatening complications once severely diseased. These findings – limited as they are – indicate that it appears prudent to avoid a Se deficiency by gentle measures, as successfully done on a population-wide scale in Finland since three decades. It is suggested that preventive biomarker-guided Se supplementation attempts should be considered as a promising health-supporting measure. The talk will raise the awareness for this topic and stimulate a discussion on the respective pros and cons.

Introduction

Pituitary gigantism is a rare disorder caused by GH-secreting lesions.

Aim

We studied gigantism for genetic defects.

Methods

We performed genome-wide analyses in 46 patients with gigantism and 248 patients with acromegaly.

Results

We detected a novel microduplication at chromosome Xq26.3 in two unrelated kindreds and 13 sporadic cases *de novo*. All patients had disease onset before five years of age and presented with mixed GH/prolactin-secreting macroadenomas and/or hyperplasia. All sporadic cases harbored non-recurrent duplications, whereas familial cases inherited the duplications from their mothers. Breakpoint junctions revealed microhomology, suggesting a replicative mechanism for their formation. Patients shared a common duplicated region of ~500 kb containing four protein-coding genes, of which only GPR101, a G-protein coupled receptor (GPCR) that activates cAMP signaling, was consistently over-expressed in patients' pituitary lesions. Low GPR101 expression levels were seen in non-duplicated GH-secreting tumors and in most normal adult human tissues, including the pituitary. On the contrary, high expression was observed in human fetal pituitary. Adult pituitaries of both rhesus monkey and rat expressed GPR101 but in different cell types. In the developing zebrafish embryo a strong and brain-specific GPR101 staining (including in the hypothalamus and pituitary) was seen.

Conclusions

We describe a new genomic disorder caused by Xq26.3 microduplications (X-LAG for X-linked Acro-Gigantism) and characterized by early-onset gigantism. This syndrome is likely caused by overexpression of GPR101, a dosage-sensitive GPCR that activates the cAMP pathway, whose mitogenic effects in pituitary somatotropes are well established. The brain is the major site of GPR101 expression across different species, although divergent species- and developmental stage-specific expression patterns are evident, especially concerning the pituitary. These differences might reflect the very different growth, development and maturation patterns among species. GPR101 may also be mutated in adult patients with acromegaly.

Unimolecular combination therapeutics for the treatment of obesity and type 2 diabetes

Matthias Tschöp
Helmholtz Zentrum München, Garching, Germany.

Emerging insights from recent advances in metabolic diseases research suggest that one or several patterns of multiple neuro-endocrine factors are necessary for sustained modulation of body fat or metabolism set points. Gut hormones appear to reside at the core of these master–key-like signaling patterns, as indicated for example by bariatric surgery research. Over the last 7 years, we have therefore tested a large series of combination therapies based on multiple gastrointestinal and adipocyte derived signals. Balanced single molecule peptide hormone based GLP1-glucagon and GIP-GLP1 co-agonists exhibited superior body weight loss and glucose metabolism benefits in mouse models of obesity and diabetes, as compared to any established mono-agonists. Preliminary translational data indicate efficacy of GIP-GLP1 co-agonists in non-human primates. Since co-infusion of a soluble and stable glucagon mono-agonist in parallel with GIP-GLP1 co-agonist treatment provided additional benefits, a series of single molecule GIP-GLP1-glucagon tri-agonists were generated and validated. These novel tri-agonists again showed unprecedented metabolic and body weight benefits in mouse and rat models of obesity and diabetes. In a parallel approach single molecule conjugates combining a peptide (e.g. GLP1) with a steroid (e.g. estrogen) were generated to maximize metabolic benefits and minimize potential toxicity by specifically targeting a subset of estrogen receptors in GLP1-receptor carrying cells. Such peptide carrier based targeting of a specific subset of nuclear hormone receptors was successful: Administration reversed hallmarks of the metabolic syndrome in diet induced obese and insulin resistant mice without causing any detectably side effects or toxicity. The above described novel single molecule approaches to polypharmaceutical therapeutics carry the potential to open new perspectives for the treatment of metabolic diseases such as diabetes and obesity.

Advances in phaeochromocytoma diagnosis and management (*Endorsed by the European Journal of Endocrinology*)

S12.1

Update on genetics of phaeochromocytoma/paraganglioma

Mercedes Robledo[1,2]
[1]Spanish National Cancer Research Center, Madrid, Spain; [2]ISCIII Center for Biomedical Research on Rare Diseases (CIBERER), Madrid, Spain.

Pheochromocytomas (PCC) and paragangliomas (PGL) are rare neuroendocrine tumours, located in the adrenal medulla (PCC) and in the intra-abdominal, thoracic or head and neck paraganglia (PGL). They have the highest heritability of all human neoplasms being a good example of diseases with underlying genetic heterogeneity. In this regard, at least 40% of PCC/PGL patients carry a germline mutation in one of the 16 genes described so far as related to the disease. In addition to the complexity of the genetics of PCC/PGL, we need to consider the role of somatic mutations, which to date, have been identified at least in 20–30% of tumors. The latter have been observed to occur not only in the same genes involved in heritable susceptibility, but also in new ones, which have thus recently emerged as key players in the sporadic presentation of these diseases. Despite of the increasing proportion of patients already explained by germline or somatic genetic defects, there are still patients with clinical indicators of hereditary disease (i.e. familial antecedents, multiple tumors and/or young age) without a molecular diagnosis, which are being actively investigated.
Genomic characterization has provided a robust way not only to identify molecular events associated with specific genotypes, but also diagnostic and prognostic markers. In fact, the new approaches have been responsible for the explosion of knowledge the scientific community is facing. In this regards, most of the latest PCC/PGL genes identified have been discovered after an integrative approach involving transcriptome, mirnome or methylome profiling and next generation sequencing.
The talk will review clinical features related to each of the PCC/PGL genes known so far, as well as new findings that point to the Krebs cycle genes as strong candidates to explain additional pheochromocytoma or paraganglioma cases.

S12.2

Current imaging of pheochromocytoma/paraganglioma

Henri Timmers
Radboud University Medical Centre, Nijmegen, The Netherlands.

After establishing a biochemical diagnosis, pheochromocytomas and paragangliomas can be localized using different imaging modalities. Appropriate imaging is critical for primary tumor localization, the detection of multiple primary tumors and the detection of metastases. This will guide the optimal choice between curative surgery and palliative treatment options.
First line anatomical imaging modalities for pheochromocytoma and paraganglioma imaging include computed tomography (CT) or magnetic resonance imaging (MRI). The specificity of these techniques is limited, however. Functional imaging is complimentary to anatomical imaging and provides specific information about the tumor's functional characteristics. Nuclear medicine scanning techniques include planar scintigrapy, single-photon emission computed tomography (SPECT) and positron emission tomography (PET). The most widely used radiotracers for pheochromocytoma and paraganglioma scintigraphy are (123I)-labeled metaiodobenzylguanidine (123I-MIBG) and 111In-DTPA-pentetreotide scintigraphy. They have long been considered as the 'gold standard' modalities. However, several studies have demonstrated the limitations of using 123I-MIBG scintigraphy alone in the staging of hereditary and metastatic pheochromocytoma/paraganglioma. The use of 123I-MIBG may lead to significant underestimation of metastatic disease. Novel PET tracers been proven to be very useful for the functional imaging of pheochromocytomas and paragangliomas. These include 6-(18F)-fluorodopamine (18F-FDA), 6-(18F)-fluoro-L-3,4-dihydroxyphenylalanine (18F-DOPA) and 2-(18F)-Fluoro-2-deoxy-D-glucose (18F-FDG). The performance of the different functional imaging modalities is largely determined by tumor location (adrenal pheochromocytoma and extra-adrenal paraganglioma *versus* head and neck paraganglioma), benign *versus* metastatic disease and the underlying hereditary syndrome. The main purpose of 123I-MIBG or somatostatin receptor based scintigraphy in a patient with metastases is to determine if internal targeted radiotherapy is an appropriate treatment choice. Current recommendations regarding the optimal functional imaging strategy for these tumors are made available as part of the Endocrine Society clinical practice guideline on pheochromocytoma and Paranglioma. Precise identification of the clinical context and genetic status of patients enables personalized use of functional imaging modalities.

Outcome of adrenal sparing surgery in heritable pheochromocytoma: the example of multiple endocrine neoplasia type 2

Frederic Castinetti
Department of Endocrinology, La Timone Hospital, Marseille, France.

With the early management of medullary thyroid carcinoma, multiple endocrine neoplasia type 2 has become an example of chronic disease with prolonged follow-up to look for pheochromocytoma diagnosis and appropriate management. In any genetic disease where pheochromocytoma can happen bilaterally, the surgery has long been based on bilateral adrenalectomy (even in the presence of a single pheochromocytoma), and as a consequence on a life long treatment for adrenal insufficiency. Progress has then been made by choosing unilateral adrenalectomy in case of unilateral pheochromocytoma, which now makes sense. Adrenal sparing surgery is probably another step in trying to improve the patients'

overall quality of life. It is a valuable option well described in patients with pheochromocytoma and Von Hippel Lindau's disease. Determining the interest of such a therapeutic approach implies to take into account the risk of recurrence, in comparison with the gain in terms of adrenal function. Moreover, assuming this risk of recurrence implies to characterize the potential of malignancy of hereditary pheochromocytoma, considering that already medullar hyperplastic tissue will remain after surgery. Data on MEN2 patients are scarce in the literature, usually based on a low number of patients, or a short-term follow-up, and this might explain why this approach is still not considered as the gold standard (when technically do-able).
Based on a large international consortium collecting data on 1210 patients with multiple endocrine neoplasia type 2, including more than 500 with pheochromocytoma, we determined the outcome of patients with adrenal sparing surgery in comparison with classical adrenalectomy. Our results emphasized the low rate of adrenal insufficiency, and a relatively low risk of recurrence after a median follow-up of 10 years after adrenal sparing surgery. Interestingly, the rate of recurrence was comparable in patients with classical adrenalectomy, whereas, as expected, the rate of adrenal insufficiency was highly superior with the classical approach. Adrenal sparing surgery is thus clearly a valuable therapeutic option, provided a prolonged and regular follow-up can be maintained (Castinetti et al., Lancet Oncology, 2014).

S13.2

Clinical consequences of low vitamin D status

Kevin Cashman
Vitamin D Research Group, School of Food and Nutritional Sciences and Department of Medicine, University College Cork, Cork, Ireland.

While there is still considerable debate as to what circulating 25-hydroxyvitamin D (25(OH)D) concentration may best represent low vitamin D status, it is clear that there is substantial evidence that the prevalence of vitamin D deficiency (serum 25(OH)D $<$25/30 nmol/l) and inadequacy ($<$50/75 nmol/l) is moderate and high respectively, across Europe. This has significant implications for human health throughout the lifecycle and may impact on healthy growth and development as well as successful aging for current and possibly future generations. The last two decades has seen an enormous increase in the number of peer-reviewed publications which describe associations between vitamin D status and non-skeletal health outcomes, many of which contribute majorly to the disease burden in Europe and beyond. These are in addition to the traditionally accepted key role for vitamin D in calcium metabolism and skeletal health. This presentation will summarize recent information on the prevalence of low vitamin D status in Europe and wider to provide a perspective. It will also very briefly highlight the impact of methodological considerations in relation to measuring vitamin D status. It will then overview the current and emerging potential health and disease consequences of low vitamin D status, along with some indication of the underpinning evidence-base, where possible. The presentation will finish by highlighting current guidelines for addressing low vitamin D status in patient care but also explore possible strategies by which vitamin D status at population-level might be improved. Prevention of low vitamin D status in patient groups and the general population should pay dividends to the European health-care systems.

Adipose tissue as an endocrine organ (*Endorsed by Endocrine Connections*)

S14.1

Adipose tissue turnover in humans

Kirsty Spalding
Karolinska Institute, Stockholm, Sweden.

Owing to the increase in obesity, life expectancy may start to decrease in developed countries for the first time in recent history. In humans the generation of fat cells (adipocytes) is a major factor behind the growth of adipose tissue during childhood. The factors determining the fat mass in adults, however, are not fully understood. Increased fat storage in fully differentiated adipocytes, resulting in enlarged fat cells, is well documented and thought to be the most important mechanism whereby fat depots increase in adults. Using a recently developed method, which is based on the incorporation of 14C from nuclear bomb tests into genomic DNA and molecules, we can now also analyse the turnover of adipocytes, their progenitor cells and lipid stores. Results from studies looking at adipocyte and lipid turnover in adult humans, in health and pathology, will be discussed. Understanding the dynamics of adipocyte and lipid turnover may shed new light on potential treatments for obesity.

S14.2

FGF1 and PPAR-γ in the Adipocyte

Johan Jonker
University Medical Center Groningen, Groningen, The Netherlands.

Survival requires the ability to adapt to cycles of feast and famine, yet the underlying mechanisms to maintain metabolic balance during extremes of nutrient excess remain poorly understood. We recently discovered that the classic growth factor FGF1 is induced in white adipose tissue (WAT) in response to high-fat-diet (HFD) and repressed during fastong, pointing to an unexpected metabolic function. Thus, FGF1 participates in both fed-state and fasted-state responses. In WAT, FGF1 is induced by HFD through a PPAR-γ dependent mechanism and thus is also responsive to PPARg drugs such as Actos and Avandia. Mice with a deficiency in FGF1, when challenged with a HFD, develop an aggressive diabetic phenotype, resulting from adipose that is unable to expand, which progressively becomes inflamed, fibrotic and necrotic and is simply unable to adapt to nutrient stress.
As loss of FGF1 by knockout results in a diabetic phenotype, we speculated that increasing FGF1 levels by direct injection in diabetic mice, could potentially have anti-diabetic effects. As a proteoglycan binding protein, endogenous FGF1 is normally locally restricted. Upon 'endocrinization' of FGF1 by simple injection into the body of obese diabetic mice we found potent glucose lowering and insulin sensitizing effects. Thus, more that 30 years after its discovery as a growth factor, 'endocrinization' of FGF1 in a diabetic mouse, uncovers a potent yet hidden insulin sensitizing activity with great potential as a new therapy in the treatment of metabolic disease.

DOI: 10.1530/endoabs.37.S14.2

S14.3

Manipulating adipose tissue sensitivity to glucocorticoid excess

Gareth Lavery
University of Birmingham, Birmingham, UK.

Glucocorticoids (GCs) have physiological actions in almost all tissues, classically mediated by the GC receptor. The potent effects of GCs upon metabolic phenotype are best exemplified in patients with circulating GC excess (Cushing's syndrome), who develop central (visceral) obesity, insulin resistance, myopathy, hypertension and in some cases overt type 2 diabetes (T2DM) and non alcoholic fatty liver disease (NAFLD). GCs are one of the most frequently prescribed class of medication, with 2–3% of UK and US populations currently receiving GC therapy. The clinical efficacy of GC therapy is not in doubt, but their 'cushingoid' side effects create significant morbidity and mortality and current prevention strategies to reduce the adverse metabolic consequences are limited. Tissue-specific availability of GC to bind and activate the GR is controlled by a series of pre-receptor regulatory enzymes. 11β-hydroxysteroid dehydrogenase type 1 (11β-HSD1) regenerates the active GC cortisol from inactive cortisone (corticosterone and 11-dehydrocorticosterone respectively in rodents) in adipose tissue, liver and muscle. Indeed, changes in GC availability, notably in adipose tissue, contribute significantly to the development of an adverse metabolic phenotype. Genetic and pharmacological inhibition of 11β-HSD1 in rodent and clinical studies improves the metabolic profile in obesity and T2DM models. This presentation will address how 11β-HSD1 contributes to promoting the unwanted metabolic aspects of GC excess and the 'cushingoid' phenotype often seen in patients taking GC therapy, with particular emphasis on adipose tissue specific GC effects. We propose that 11β-HSD1 inhibition may offer protection from a deleterious metabolic profile in the context of the GC excess state.

Puberty: new mechanisms

S15.1

Epigenetics of Female Puberty

Sergio Ojeda, Alejandro Lomniczi, Hollis Wright & Carlos Toro
Oregon National Primate Research Center/Oregon Health & Science University, Beaverton, OR, USA.

A prevailing concept regarding the mechanism controlling the timing of puberty proposes that GnRH release from the hypothalamus increases at puberty due to a loss of transsynaptic inhibition, accompanied by an increase in neuronal/glial excitatory inputs to GnRH neurons. Without negating the importance of this intercellular communication process, recent evidence suggests that a critical inhibitory/excitatory Yin-Yang mechanism regulating the advent of puberty is epigenetic in nature and affects the transcriptional activity of neurons involved in stimulating GnRH release (such as kisspeptin neurons). The repressive arm of this mechanism is provided by the Polycomb group (PcG) of transcriptional silencers, which prevents the premature initiation of female puberty by silencing the *Kiss1* gene in kisspeptin neurons of the arcuate nucleus (ARC) of the hypothalamus. At the end of juvenile development PcG proteins are evicted from the *Kiss1* promoter and the abundance of the PcG-catalyzed, 'repressive', histone modification H3K27me3 is reduced. The antagonistic counterpart of PcG-mediated gene silencing is provided by the Trithorax (TrxG) group of transcriptional activators. Like the PcG complex, TrxG genes are expressed in kisspeptin neurons of the ARC. Key TrxG proteins required for the synthesis of 'activating' histone marks (histone 3 di- and trimethylated at lysine 4) are recruited to the *Kiss1* promoter at the initiation of puberty and this correlates well with an increased abundance of the activating histone marks H3K4me3 and histone 3 acetylated at lysine 9 and 4 (H3K9, 14 ac) at the promoter. Both the PcG and the TrxG systems are, in turn) regulated by upstream repressors. Whereas PcG gene expression is inhibited by members of the POK (for POZ and Krüppel) family of transcriptional regulators, TrxG action is attenuated by zinc finger (ZNF) proteins that facilitate the demethylation of H3K4me2 *via* recruitment of a specific lysine demethylase (Kdm1a/LSD1) to the *KISS1* and *TAC3* promoters. The presence of this tight system of epigenetic regulation in *KISS1/TAC3* expressing neurons of the ARC suggests that a switch from epigenetic repression to activation within these neurons underlies the developmental process by which GnRH release is first kept in check before puberty, and then increases by late juvenile development to bring about the pubertal process. S15.2

GnRH development and function: lessons from semaphorins

Paolo Giacobini[1,2]
[1]Inserm, Laboratory of Development and Plasticity of the Neuroendocrine Brain, Jean-Pierre Aubert Research Centre, U1172, Lille, France;
[2]University of Lille, School of Medicine and Institut de Medecine Predictive et de Recherche Therapeutique (IMPRT-IFR114), Lille, France.

This talk summarizes recent studies analysing the contribution of specific guidance molecules named semaphorins in the development and adult function of gonadotropin-releasing hormone (GnRH) neurons. In vertebrates, the GnRH decapeptide regulates the secretion of luteinizing hormone and follicle stimulating hormone, which govern puberty onset, gametogenesis, and estrous cycling, from anterior pituitary gonadotropes. During embryonic development, these cells originate from the nasal placode and migrate to the hypothalamus apposed to olfactory-vomeronasal nerves.

Alterations either in the development of this system or in the secretion of GnRH are associated with reduction or failure of sexual competence. In order to understand the pathogenesis of human reproductive disorders, it is thus relevant identifying molecular pathways involved in the regulation of the GnRH system. The semaphorin proteins are one of the largest families of guidance cues, contributing to morphogenesis and homeostasis in a wide range of tissue types, including the brain. During embryonic development, several semaphorins are expressed in the olfactory-vomeronasal system and along the GnRH migratory route, prompting several groups of research to study their eventual involvement in the proper development of the GnRH and olfactory systems.

In recent years several studies have started to shed light on the role of semaphorins in the motility, survival and axonal plasticity of GnRH neurons.

This talk will review some of these studies, which provided insight into the sophisticated molecular mechanisms that allow for the spatiotemporal control of the responsiveness to semaphorins of developing GnRH neurons. Genetic data are also presented to show that some forms of reproductive disorders in humans are associated with mutations in specific classes of semaphorin family members.

Finally, some emphasis will be put on some recent studies, which started to shed light on the molecular mechanisms responsible for the progression of the estrous cycle in rodents and suggest that this phenomenon relies on the antagonistic effects of two semaphorins whose expression in the median eminence is periodically influenced by circulating sex hormones.

Genetic regulators of the timing of puberty

Ken Ong
University of Cambridge, Cambridge, UK.

The timing of puberty varies widely between individuals and in girls early puberty timing is associated with higher risks for adult obesity, type 2 diabetes (T2D), cardiovascular disease (CVD), breast cancer and all-cause mortality. Understanding the regulation of puberty timing therefore has relevance to disease pathogenesis as well as developmental and human biology. Large-scale genome-wide association studies have identified robust evidence for more than 100 independent genomic association signals associated with age at menarche, including overlap with genes that are disrupted in rare disorders of puberty. Such findings have implicated RNA-mediated gene silencing, histone regulation of gene activity, and retinoic acid-related nuclear receptors among novel mechanisms that regulate puberty timing. Menarche signals are enriched in imprinted gene regions and three imprinted loci (*DLK1/WDR25*, *MKRN3/MAGEL2*, and *KCNK9*) demonstrated parent-of-origin specific associations concordant with their known parental expression patterns; these findings indicate parental conflicts over the selective advantages of puberty timing. Recent findings provide evidence for a substantially shared genetic aetiology of puberty timing between males and females, and also indicate causal relationships between earlier puberty timing and higher BMI, T2D, and CVD, which are likely mediated by both BMI-related and BMI-independent mechanisms.

Pathogenesis of adrenocortical tumours

S16.1

Inherited tumour syndromes and adrenal cancer

Tobias Else
University of Michigan, Ann Arbor, MI, USA.

Adrenocortical carcinoma (ACC) is a rare endocrine cancer with a poor prognosis. Roughly 10–15% of all ACCs arise in patients with a predisposition to cancer development due to a germline mutation. Pediatric ACC is a well-described core malignancy of the Li Fraumeni syndrome tumour spectrum. More recently *TP53* mutations have also been found in adult ACC patients. In addition recent advances in clinical and molecular genetics have identified additional familial cancer syndromes, such as Lynch syndrome and Carney Complex, contributing to ACC development in adult patients.
Familial cancer syndromes can often be identified by obtaining a detailed family and personal history, and finding clues on physical exam. Identifying an underlying germline mutation in a patient with the diagnosis of ACC may impact treatment decisions, and allows for individual strategies for preventive surveillance regarding other associated tumours and for further family cascade screening. Due to the significant prevalence of familial cancer syndromes amongst patients with ACC, we recommend considering genetic counselling and a genetic work-up for all patients with ACC.

Role of steroidogenic factor-1 in the pathogenesis of adrenocortical tumours

Mabrouka Doghman[1,2] & Enzo Lalli[1,2]
[1]IPMC CNRS, Sophia Antipolis, France; [2]LIA NEOGENEX CNRS, Sophia Antipolis, France.

Steroidogenic factor-1 (SF-1, NR5A1) is a transcription factor that plays an essential role in the development of adrenal glands and gonads. Multiple level regulation of SF-1 activity is exerted by interaction with cofactors, post-translational modifications and epigenetic gene expression regulation. Our studies involving both cell lines and transgenic mouse studies showed that an increased SF-1 dosage activates adrenocortical cell proliferation and causes adrenocortical neoplasia. By employing multiple genomic approaches, we defined different levels of regulation in transcriptome, miRNome and more recently on regulome exerted by SF-1 dosage. We identified new functional interactions between SF-1 and neuron-restrictive silencer factor/RE1-silencing transcription factor (NRSF/REST) suggesting that SF-1 has a broader role than initially thought in regulating tissue-specific gene expression programs.
We showed that SF-1 dosage differentially regulates the expression of numerous and distinct genes, involved in a variety of biological processes, suggesting that fine regulation of SF-1 dosage is a critical determinant of its action during adrenal development, function and tumourigenesis.
We identified fetal and adult testis expressed-1 (FATE1), a cancer testis antigen (CTA), as a new dosage-dependent target of SF-1. CTAs are emerging as attractive targets for therapeutic cancer vaccines due to their expression in tumors but not in normal tissues except testis. Our recent studies aim to better understand the role of FATE1 in tumor cellular metabolism, mitochondrial morphology and signaling and in drug resistance, potentially important for the aggressive phenotype of adrenocortical carcinoma.
Our project aims to investigate the involvement of these new SF-1 target genes in adrenal pathophysiology to improve the diagnostic of ACC and in the future to develop innovative strategies for cancer treatment.

miRNA as biomarkers in adrenal cancer?

Peter Igaz
Semmelweis University, Budapest, Hungary.

MicroRNA (miRNA) are small RNA molecules involved in the posttranscriptional regulation of gene expression. Differential expression of miRNA has been described in several tumours. miRNA expression patterns can be used as markers of malignancy, as prognostic markers and even for the subclassification of tumours. miRNA markers can be especially useful for the diagnosis of tumours whose histological analysis is difficult such as adrenocortical cancer (ACC). Beside tissue miRNA, miRNA are also released into the circulation and these blood-borne circulating miRNA might have great potential as minimally invasive markers of malignancy. Several reports including ours have described potential tissue and circulating miRNA markers of ACC. The applicability of tissue miRNA as biomarkers is further extended due to their stability, and therefore formalin-fixed paraffin embedded tissue blocks can be used for miRNA analysis. Among tissue miRNA markers of malignancy, overexpressed miR-483-5p, the expressional difference of miR-503-miR-511 and underexpressed miR-195 are most promising showing high sensitivity and specificity values. Some miRNA markers might be exploited as prognostic markers, including miR-483-5p, miR-195, miR-503 and miR-210. Three studies to date have reported on circulating miRNA profiles in ACC. Overexpressed miR-483-5p, miR-100, miR-181b, miR-210 and miR-34a have been proposed as circulating miRNA markers of ACC. Circulating miR-483-5p and miR-195 might be exploited to distinguish aggressive and non-aggressive cancer forms. There are several technical problems associated with the analysis of circulating microRNAs that need to be overcome for their reliable use. miRNA expression patterns of aggressive and non-aggressive forms of ACC are different as established by next generation sequencing data. In conclusion, both tissue and circulating miRNA are promising biomarkers but most studies included only limited sample sets and there are significant differences among different studies. Sample size extension, the standardization of analytical approaches will be needed to confirm the suitability of miRNA markers in adrenal cancer.

Diabetes and bone (*Endorsed by the European Journal of Endocrinology*)

S17.1

Diabetes and osteoporosis – cause for concern?

Peter Vestergaard
Aalborg University Hospital, Aalborg, Denmark.

Background
Diabetes and osteoporosis are both frequent conditions, a link may thus put a substantial number of patients at risk of fragility fractures and the consequences of these such as pain, disability, and increased mortality. Skeletal fragility and osteoporosis may represent a hitherto overlooked complication of diabetes in line with say diabetic eye disease, diabetic nephropathy etc.
Findings
An increased risk of fractures has been observed in both type 1 and type 2 diabetes. In type 1 diabetes, a decreased bone density has been observed, while in type 2 diabetes, bone density may actually be increased. A discrepancy seemingly exists between bone density and fracture risk in diabetes, especially in type 2 diabetes. The increase in fracture risk has been observed at the hip, spine, and forearm as well as for overall risk of fractures. Especially the risk of hip fractures seems increased in type 1 diabetes, whereas the increase is less pronounced in type 2 diabetes. Hypoglycemia seems to play a minor role for the occurrence of fractures. The increase in fracture risk seemingly is related to diabetes *per se* and less so to complications (say falls related to diabetic eye disease).
Conclusions
An increased risk of fractures – in particular hip fractures, which may be associated with significant excess mortality and morbidity – may be present. The increase may be linked to skeletal frailty resulting from metabolic disruptions stemming from impaired glucose metabolism rather than from falls related to hypoglycemia or say reduced eye sight.

S17.2

Pathophysiology of diabetoporosis

Serge Ferrari
Geneva University Hospital, Geneva, Switzerland.

Both type 1 and 2 diabetes are associated with an increased fracture risk. Whereas in type 1 bone fragility is mostly explained by a lower peak bone mass and low bone turnover state, which is a common feature of several chronic and/or inflammatory diseases starting during growth, in type 2 diabetes there is not necessarily low bone mass, rather a higher aBMD related to overweight/obesity in

these subjects. To explain the increased propensity to fractures in this case, a higher risk of falls and decreased bone quality have both been advocated. The latter includes alterations in collagen crosslinks by advanced glycation end-products (AGEs) such as pentosidine; higher sclerostin levels associated with low bone formation; and microstructural alterations, particularly an increased cortical porosity. The molecular mechanisms relating glucose, fat and bone metabolism appear increasingly complex. They involve the transcription factor Ppar gamma, which promotes fat accumulation at the expenses of bone forming cells; Wnt-beta-catenin signaling; inflammatory factors, -i.e. interleukins-, and adipokines, -such as leptin and adiponectin-, that influence both insulin resistance and bone loss; and bone-derived molecules, including (undecarboxylated) osteocalcin and RANK Ligand, both recently found to regulate glucose metabolism. Moreover, genome wide association studies (GWAS) have started to unveil common genes that exert pleiotropic effects on the susceptibility to both diabetes and osteoporosis.

S17.3

Clinical management of fragile bone in type 2 diabetes

Eugene McCloskey
[1]University of Sheffield, Sheffield, UK; [2]CIMA, University of Sheffield, Sheffield, UK.

Given the increasingly accepted increase in fracture risk that occurs in patients with type 2 diabetes, a number of strategies need to be considered reflecting the multiple factors underlying the fracture risk. These comprise measures to improve falls risk, the avoidance of treatments that may be detrimental to skeletal health and the use of treatments to maintain or improve bone strength.

Older people with diabetes are at high risk of falls, recurrent falls and fractures. Risks factors for falls in older persons with diabetes include polypharmacy, muscle weakness, previous stroke, motor and sensory neuropathy, poor glycaemic control, hypoglycaemia, insulin use, cognitive dysfunction, orthostatic hypotension, and visual impairment. Lower HbA1c has been associated with higher risk of falls frail elderly people and hip fracture, especially in those treated with insulin. Falls risk should be assessed in all patients as many studies using techniques such as gait, balance, and strength training have shown reduced risk of falls for people with diabetes. No studies have shown a reduction in fracture risk. The significant side effect profile of thiazolidinediones includes concerns over an increase in the risk of fractures. This and other potential side effects has significantly decreased the enthusiasm for their use, despite their potential convenience in older people. The majority of the fractures have occurred in the limbs and guidance suggests that the risk of fracture should be considered in the care of patients, especially female patients, treated with such agents.

The evidence base for the use of agents developed for the treatment of osteoporosis in the setting of increased fracture risk in type 2 diabetes is lacking. The majority of studies have either excluded diabetes directly or indirectly by the requirement of low BMD at study entry. The decrease in bone turnover markers observed in type 2 diabetes raises a question mark over the use of antiresorptive therapies. Furthermore, post-hoc analyses of Phase 3 studies suggest that some anti-resorptive agents are less effective in the presence of a high BMI. In contrast, epidemiological studies suggest that diabetes does not seem to affect the fracture preventive potential of bisphosphonates or raloxifene.

New genetics of pituitary tumours (*Endorsed by the European Journal of Endocrinology*)

S18.1

A novel role for stem cells in the regulation of turnover in the postnatal pituitary

Cynthia Andoniadou
King's College London, London, UK.

Dysfunction in the mechanisms that regulate cell numbers in the pituitary gland can underlie hypopituitarism as well as the generation of tumours. Investigations into how these conditions arise has led to an interest in identifying mechanisms for correct maintenance of endocrine cells throughout life. Currently, the source and identity of signals promoting this maintenance in the postnatal pituitary are not known. We have previously shown that pituitary-specific disruptions in the WNT signalling pathway, a key developmental pathway often perturbed in disease including cancer, can lead to developmental anomalies and tumorigenesis. Here, we provide *in vivo* evidence that WNT signals promote the generation of new cells in the anterior pituitary. Using genetic lineage tracing in mouse we show that SOX2-expressing cells act as stem cells *in vivo*, able to differentiate into all hormone-producing lineages and contribute to organ homeostasis during postnatal life. However, SOX2-expressing stem cells are not the sole source of new endocrine cells at these stages, but complement contribution from more committed cell types. We find that committed cells responding to WNT signals are capable of proliferation and provide the majority of organ turnover. Unexpectedly, we uncover that SOX2-expressing stem cells act as critical regulators of this process through secreting WNT ligands promoting proliferation, thus influencing long-term physiological cell turnover in a paracrine manner. This represents a key step towards understanding the mechanisms controlling stimulation of new cell generation *in situ*, with an impact on future therapies for diseases of the pituitary gland.

Genetics of Cushings Disease

Martin Reincke
Medizinische Klinik und Poliklinik IV, Klinikum der LMU, München, Germany.

Cushing's disease is caused by corticotroph adenomas of the pituitary. To explore molecular mechanisms of endocrine autonomy, we recently performed exome sequencing of 10 corticotroph adenomas[1] identifying somatic mutations in the USP8 deubiquitinase gene in 4 of 10 adenomas. The mutations clustered in the 14-3-3 protein binding motif enhancing proteolytic cleavage and catalytic activity of USP8. Cleaved USP8 led to increased EGF receptor deubiquitination impairing its downregulation and sustaining EGF signaling. USP8 mutants enhanced promoter activity of the gene for proopiomelanocortin. Our data show that dominant mutations in USP8 cause Cushing's disease *via* activation of EGF receptor signaling. In a follow-up study we performed a retrospective, multicentric, genetic analysis of 134 functioning and 11 silent corticotroph pituitary adenomas using Sanger sequencing. Clinical data from these patients have been collected and examined within the context of the mutational status of USP8. Somatic mutations in USP8 were found in 48 (36%) adenomas from patients with Cushing's disease, but in none of the 11 silent corticotropinomas. The prevalence was higher in adults than in pediatric cases and in females than in males. Adults having USP8-mutated adenomas were diagnosed at an earlier age (36 vs 44 years) than those with wild-type adenomas. Future research will be directed towards therapeutic targeting of USP8 in corticotroph adenomas.

Metabolic dysfunction in PCOS

S19.1

Genetic determinants of metabolic dysfunction in PCOS

Jerome Strauss[1] & Jan McAllister[2]
[1]Virginia Commonwealth University, Richmond, Virginia, USA; [2]Pennsylvania State Hershey College of Medicine, Hershey, Pennsylvania, USA.

PCOS is a common disorder that is reported to affect 5–7% of women of reproductive age. Although there has been debate about the diagnostic criteria for

PCOS, hyperandrogenemia/hyperandrogenism, not explained by other causes, is a hallmark of the disorder, and it is included as an essential element in all 'consensus' diagnostic schemes. Studies on cultures of human theca cells derived from normal and PCOS women have demonstrated that PCOS theca secretes greater amounts of androgen than theca tissue or cells from regularly ovulating women. Increased *CYP17A1* (P450 17α-hydroxylase/17,20-lyase) gene expression in PCOS theca cells is associated with excess androgen production. Our previous molecular characterization of PCOS theca cells and normal theca cells from multiple individuals by microarray analysis and quantitative PCR established that normal and PCOS theca cells have distinctive molecular signatures, suggesting intrinsic (genetic) differences. A major milestone was achieved with the publication of a genome-wide association studies (GWAS) on Han Chinese, which identified eleven loci, including *DENND1A, a* finding that was subsequently validated in European populations. DENND1A is a clathrin binding protein found in coated pits, and which positions it to modulate cell surface receptor signal transduction. Using cultured human theca cells, we have shown that an isoform of DENND1A, V2, is over-expressed in PCOS theca cells compared to theca cells derived from ovaries of normally cycling women. V2 overexpression in PCOS may be the result of alternative splicing. Forced expression of V2 increases androgen production, and *CYP17A1* mRNA in normal theca cells, whereas knock-down of V2 expression reduces androgen secretion and *CYP17A1* mRNA in PCOS theca cells. Both humanized monoclonal antibodies against V2, and their Fab fragments, also reduce androgen production and *CYP17A1* mRNA when added to cultured PCOS theca cells. DENND1A V2 can be placed into a network of genes identified in the Chinese GWAS that can explain the hyperandrogenemia phenotype of PCOS.

S19.2

The role of androgens in PCOS-related insulin resistance

Michael O'Reilly[1], Jeremy Tomlinson[2], Robert Semple[3] & Wiebke Arlt[1]
[1]University of Birmingham, Birmingham, UK; [2]University of Oxford, Oxford, UK; [3]University of Cambridge, Cambridge, UK.

Insulin resistance and androgen excess are the cardinal features of polycystic ovary syndrome (PCOS). The severity of hyperandrogenism and metabolic dysfunction in PCOS are closely correlated but the underlying mechanisms are poorly understood. Aldoketoreductase type 1C3 (*AKR1C3*) is an important source of adipose androgen generation (converting androstenedione to testosterone) and we have postulated that it may have a critical role linking androgen metabolism and metabolic phenotype in PCOS.

Ten patients with PCOS, three with insulin receptor (INSR) mutations and ten control patients underwent oral DHEA challenge with concomitant adipose tissue microdialysis. Serum and adipose androgens, and adipose glycerol levels, were sampled every 30 minutes for 4 h. In parallel, adipose androgen generation (measured using LC/MS-MS), was studied using primary cultures of human adipocytes and the preadipocyte SGBS cell line. The impact of androgens upon metabolic adipocyte phenotype was assessed through measurement of adipose lipogenesis, free fatty acid uptake (FFA) and β-oxidation.

After oral DHEA, area under curve (AUC) for serum testosterone (T) was higher in PCOS patients than controls, but highest in patients with INSR mutations, suggesting enhanced *AKR1C3* activity. Adipose dihydrotestosterone (DHT) was detectable in adipose interstitial fluid and was higher in PCOS patients than controls. Furthermore, adipose tissue interstitial glycerol levels were decreased in PCOS patients. Subcutaneous adipose *AKR1C3* mRNA expression correlated strongly with BMI. In human adipocytes, insulin up-regulated *AKR1C3* expression and activity. T increased *de novo* lipogenesis, while both T and DHT increased FFA uptake and suppressed β-oxidation.

Hyperinsulinaemia may drive adipose androgen generation through increased expression and activity of AKR1C3, with consequences for adipocyte function, driving lipogenesis and increasing free fatty acid uptake. Resultant adipocyte hypertrophy could lead to increased insulin resistance, fuelling a vicious circle of hyperinsulinaemia, adipose androgen generation and increased lipid accumulation.

Endocrine consequences of childhood cancer treatment

S20.1

Reproductive function in cancer survivors

W Hamish Wallace
University of Edinburgh, Edinburgh, UK.

With increasing numbers of survivors from cancer at a young age the issue of fertility preservation has assumed greater importance. Female fertility preservation provides significantly different challenges to that for the male. Embryo freezing is now an accepted and well-established procedure in many centres, but is not available for children who do not have a partner. Cryopreservation using vitrification of mature oocytes has become increasingly successful, but requires the patient to go through a course of hormone stimulation and is therefore not appropriate for children and young girls. Ovarian tissue cryopreservation has the potential advantages of preservation of a large number of oocytes within primordial follicles, it does not require hormonal stimulation when time is short, and is appropriate for the pre-pubertal girl. Disadvantages include the need for an invasive procedure, and the uncertain risk of ovarian contamination in haematological and other malignancies. Ovarian tissue cryopreservation in adult women with later re-implantation has resulted in at least 39 live births worldwide. The number of re-implantations is unknown and this invasive approach to fertility preservation remains unproven and experimental in children and adolescents. The majority of young patients treated for cancer will have a window of opportunity for natural fertility if they survive their original cancer. We have published guidelines for patient selection in young female patients with cancer and in this lecture I will report our practise in a single centre that has offered fertility preservation since 1996 (Wallace *et al.*, *Lancet Oncology* 2014).

S20.2

Hypopituitarism in cancer survivors

Eva Marie Erfurth
Clinal Sciences, Medical Faculty of Lund University, Lund, Sweden.

Survival rates of childhood cancer have improved markedly and today more than 80% of those diagnosed with a pediatric malignancy will become 5-year survivors. Nevertheless, survivors exposed to cranial radiotherapy (CRT) are at particularly high risk for long-term morbidity, such as endocrine insufficiencies, metabolic complications and cardiovascular morbidity. Deficiencies of one or more anterior pituitary hormones have been described following therapeutic CRT for primary brain tumours, nasopharyngeal tumours, and following prophylactic CRT for childhood acute lymphoblastic leukemia (ALL). Studies have consistently shown a strong correlation between the total radiation dose and the development of pituitary deficits. Further, age at treatment and also time since treatment has strong implications on pituitary hormone deficiencies.

There is evidence that the hypothalamus is more radiosensitive than the pituitary and is damaged by lower doses of CRT. With lower doses of CRT (<50 Gy), the primary site of radiation damage is the hypothalamus and this usually causes isolated GH deficiency (GHD). Higher doses (>50 Gy), as were used in nasopharyngeal carcinomas, may produce direct anterior pituitary damage, which contributes to multiple pituitary deficiencies. The large group of ALL-survivors treated with CRT in the 80-90-ties has now reached adulthood and these survivors were treated mainly with 24 Gy and the vast majority of these patients suffer from GHD. Further, after long-term follow up we have recorded insufficiencies in Prolactin and TSH and proportion of these patients were also ACTH deficient. The more CRT sensitive hypothalamus causes neuroendocrine dysfunction, which means that the choice of GH test is crucial for the diagnosis of GHD.

Late effects of cancer treatment on cardiovascular risk

Francesco Felicetti[1,2]
[1]Transition Unit for Childhood Cancer Survivors, AOU Città della Salute e della Scienza, Turin, Italy; [2]Department of Medical Science, University of Torino, Turin, Italy.

In the last 50 years survival after childhood cancer has dramatically improved. However, childhood cancer survivors (CCS) are at risk for a considerable array of late effects arising from previous anti-cancer therapies. The excess mortality (compared with the general population) in CCS is mostly due to second neoplasms and cardiovascular diseases. Indeed, the cardiovascular system has been recognized as a highly sensitive target for damage by anti-cancer therapies. Early in the study of late effects, the anthracyclines were identified as a cause of late-onset myocardial dysfunction, with a dose-dependent mechanism. Moreover, radiotherapy was widely used in treatment protocols of several paediatric cancer (e.g. Hodgkin disease) but all components of the heart (pericardium, myocardium, valves and conduction system, as well as artery wall) are susceptible to ionizing radiations. Hence it follows that CCS treated with chest radiotherapy have a high risk of coronary artery disease, but also of valvular abnormalities, arrhythmias and stroke. Furthermore, several studies reported that CCS are more likely to have additional risk factors (dyslipidaemia, hypertension, diabetes). CCS, in general, are twice as likely to be hypertensive or diabetic as their siblings, with higher prevalence of these conditions in patients treated with abdominal radiotherapy or bone marrow transplantation. Obesity is a well known late effects in survivors of central nervous system tumours (due to hypothalamic damage or reduced physical activity). In conclusion, CCS need a long-term follow-up to manage this cardiovascular risk, in accordance with the growing evidences on this field and recommendations proposed by international cancer survivorship institutions.

S20.5

Secondary cancers in childhood cancer survivors

Raoul Reulen
University of Birmingham, Birmingham, UK.

Due to marked advances in curative therapy for childhood cancer – mainly the introduction of modern chemotherapy in the 1960s – the 5-year survival rate after childhood cancer has substantially improved over the last few decades from less than 30% in the 1960s to currently over 80%. As a result of these improved survival rates, a large and ever growing number of childhood cancer survivors have reached adulthood. A major concern following treatment of childhood cancer is the increased long-term risk of second primary cancers. Treatment with radiotherapy and – although to a lesser extent – specific chemotherapeutic agents have been associated with an increased risk of developing second primary cancers.
This presentation will provide an overview of the evidence from previous studies that have investigated the risks of second primary cancers in survivors of childhood cancer. Particular attention will be given to the extent to which the risks of second primary cancer varies by type of childhood cancer and to what extent the risk varies by attained age and time since childhood cancer diagnosis. More survivors are now reaching an age at which in the general population the risk of common cancer increases. This implies that even a small increased risk relative to that observed in the general population could lead to a substantial excess number of survivors of childhood being diagnosed with a second primary cancer. Understanding the long-term risks of second primary cancers is crucial because it provides a basis for counselling long-term survivors, planning future clinical follow-up and deciding on new treatment protocols with the ultimate aim of reducing the risks of developing second primary cancers without compromising the currently achieved 5-year survival rates.

Thyroid hormone in pregnancy

S21.1

Abstract unavailable.

DOI: 10.1530/endoabs.37.S21.1

S21.2

Consequences of maternal thyroid dysfunction for offspring

John Lazarus
Cardiff University, Cardiff, UK.

Treatment of hyperthyroidism with antithyroid drugs has recently been shown to have an effect on MMI/Carbimazole embryopathy at a specific early window in gestation. This has important implications for management.
There is agreement that untreated overt gestational hypothyroidism is associated with significant adverse obstetric and fetal/neonatal effects. Although there is also substantial evidence that gestational subclinical hypothyroidism (SCH) is associated with miscarriage, gestational hypertension, preterm delivery and decreased IQ in the offspring, there is a dearth of randomised studies in relation to maternal treatment in pregnancy. In addition there are recent data documenting significant ethnic variation in thyroid function in pregnancy which may affect the calculated incidence of SCH. The associated neuropsychological effects of SCH on the child now include behaviour disorders including ADHD and autism. Moreover, isolated hypothyroxinaemia (IH) is also associated with many of the adverse effects seen with maternal SCH and there is continuing debate as to whether this condition should be treated during gestation. Because of the uncertainties relating to outcomes following L-thyroxine therapy in SCH and IH the question of routine screening for thyroid function in early gestation is still controversial. Published guidelines on thyroid disease and pregnancy in general do not support screening despite the evidence that targeted case finding will miss more than 50% of women with thyroid dysfunction. Results of more randomised studies are awaited but several centres and endocrine societies are already committed to the screening strategy.

Thyroid hormone in brain development

Juan Bernal
Instituto de Investigaciones Biomedicas, CSIC, and Center for Biomedical Research on rare Diseases, Madrid, Spain.

Thyroid hormones (T_4 and T_3) have a major role in brain development, and their deficits during critical stages during the fetal and neonatal periods may cause profound intellectual and neuromotor deficits. A particular example is the X-linked Allan-Herndon-Dudley syndrome, caused by mutations of the cellular transporter for thyroid hormone MCT8 (SLC16A2). In this presentation I will first review the pathophysiology of thyroid hormone transport and metabolism in the brain, and the interaction between the main players, i.e., the transporters, the deiodinases, and the nuclear receptors. Then I will review how thyroid hormone (T_3) acts at the genomic level by regulating the expression of many genes. In particular I will present recent data from our laboratory using primary mouse cerebrocortical cells in culture that has permitted the identification of primary and secondary gene responses after T_3 addition. Genomic data indicate that the role of thyroid hormone is to facilitate the transition from a fetal pattern to a mature or adult pattern of gene expression.

Beta cell biology

S22.1

Noncoding genome function in pancreas development and disease

Jorge Ferrer
Imperial College, London, UK.

Most genetic mechanisms that are currently known to underlie developmental processes and human diseases are based on the analysis of a very small portion of the genome that encodes for protein-coding sequences. Novel sequence-based technologies, however, have recently disclosed that a major portion of the noncoding genome contains functional regulatory elements. It is thus reasonable to presume that the analysis of such elements can shed new light into developmental and cellular mechanisms, and uncover new causes of human disease. The elucidation of such defects will require knowledge of the genomic location of functional noncoding elements in disease-relevant cell types, as well as an in depth understanding of how they function. I will present data showing how transcriptional network maps and epigenomics of embryonic pancreatic cells can uncover novel cis-regulatory mechanisms of pancreas development, and will also present findings that use this knowledge to identify genetic causes of Mendelian forms of human diabetes. Further, I will discuss data indicating that non-coding genome variation can also contribute to the susceptibility for common forms of human diabetes.

Novel therapeutic targets in the β-cell

Thomas Mandrup-Poulsen[1,2]
[1]University of Copenhagen, Copenhagen, Denmark, [2]Karolinska Institute, Stockholm, Sweden.

Metabolic and inflammatory insults contribute to beta-cell failure and apoptosis, in part *via* the generation of reactive oxygen species (ROS). The pancreatic β-cell acquires sensitivity to the damaging actions of pro-inflammatory cytokines during differentiation, but the mechanisms underlying the differentiation-dependent sensitisation is unknown. By mRNA microarray of a cell-model of β-cell differentiation exposed to cytokines we identified a cluster of transcripts involved in metal-ion handling, including the divalent metal transporter DMT-1[1]. Cytokines up-regulated DMT-1 expression and iron import in β-cell-lines and islets. DMT-1 knock-down prevented cytokine-induced β-cell apoptosis. We generated an inducible β-cell specific DMT-1 knock-out (KO) mouse. Islets from these mice were protected from cytokine-toxicity *in vitro*, and glucose intolerance caused by both low-dose streptozotocin causing an autoimmune islet response but also by high-fat feeding was attenuated in DMT-1 KO mice. For this reason we have investigated whether FFA regulate β-cell and islet DMT-1 expression, iron import and ROS formation, and if DMT-1 KO prevented FFA induced islet secretory failure and apoptosis. The results of these studies will be presented. Elevated iron saturation conferred risk of diabetes development in large population studies[2]. This evidence suggests that pathways regulating iron handling may harbour novel therapeutic targets for anti-diabetic drugs.

Novel models of human pancreatic beta cells

Philippe Ravassard
ICM, CNRS UMR 7225, Paris, France.

Despite intense efforts over the past decades, human pancreatic beta cell lines with physiological insulin secretion have not been available. We have developed a robust transplantation model of fetal human pancreases that recapitulates pancreas development and combined such model with integrative lentiviral-mediated gene transfer. This resulted in production of human transgenic pancreases in which dynamic aspects of development can be studied. We thus forced expression of immortalizing transgene in developing human beta cells and were able to produce the first and only functional human beta cell lines. Importantly, such lines secrete insulin in response to glucose and are able to revert chemically induced diabetes in mice upon transplantation. Furthermore, we derived a conditionally immortalized human pancreatic β cell line using Cre-dependent reversible immortalization. After massive amplification immortalizing transgenes are removed resulting in proliferation arrest and dramatic enhancement of beta cell function. Altogether, these cells lines represent unique tools to study beta cell biology studies, for drug discovery and as preclinical model for cell replacement therapy.

Adrenal insufficiency: advances in diagnostics and therapy (*Endorsed by the European Journal of Endocrinology*)

S23.1

How to diagnose adrenal insufficiency in critical illness?

Eva Boonen
KU Leuven, Leuven, Belgium.

Critical illness represents a major challenge for the human body where an adequate stress response is indispensable for survival. Concomitantly high cortisol levels are observed and for a long time, an increased activation of the hypothalamic-pituitary-adrenal axis (HPA) was assumed to explain this hypercortisolism. Furthermore, insufficient activation of the HPA-axis during critical illness was described and referred to as 'relative adrenal insufficiency' or 'critical illness-related corticosteroid insufficiency' (CIRCI). These terms comprise insufficient adrenal cortisol production to match the level of stress due to a malfunctioning of the HPA-axis or a cortisol resistance of the peripheral tissues. Suggested diagnostic criteria were based on a landmark study by Annane *et al.* who identified a cortisol incremental response of <9 μg/dl after ACTH-injection and a baseline cortisol level >34 μg/dl as discriminative for increased risk of death. However, other investigators have not been able to replicate this. Furthermore, it remains debated whether CIRCI should be treated with exogenous glucocorticoids and with which doses. Indeed, randomized controlled studies generated conflicting results. The important lack of knowledge on the pathophysiology of CIRCI currently retains further improvement of diagnosis and treatment of CIRCI.

Recent novel insights have shown that cortisol metabolism was reduced which contributed to hypercortisolism, with limited increased cortisol production. The concomitant low ACTH levels, explained by negative feedback, could lead to an understimulation of the adrenal gland and negatively affect adrenal structure and function, given the crucial role of ACTH for adrenal gland maintenance. Predominantly in the prolonged phase of critical illness this could influence outcome and explain the increased incidence of adrenal failure in these patients. These findings represented a paradigm shift in our current understanding of HPA-axis regulation during critical illness and will redirect future research, underlining the urgent need for well-designed clinical trials.

Regenerative therapy in autoimmune Addison's disease

Simon Pearce
Newcastle University, Newcastle upon Tyne, UK.

It is obvious that adrenal cortex is plastic, with adrenal atrophy and functional hypoadrenalism during exogenous glucocorticoid therapy; yet adrenal hyperplasia and hyperfunction during stimulation from ACTH during Cushing's disease. This is owing to subcapsular adrenocortical stem cells that regenerate the zones of adult adrenal cortex throughout life.

We have performed a series of experimental medicine trials in order to explore the idea that autoimmune Addison's disease may therefore be remediable. These

studies have used either immunomodulation with B lymphocyte depletion therapy, high-dose ACTH analogue or both, in order to try to modify the natural history of the condition. In summary, there are a proportion of people (~20%) with both newly diagnosed and established autoimmune Addison's disease who have some degree of residual adrenal function. In a few people we have induced a durable, steroid medication-free remission of Addison's disease which has lasted from 6 months to as long as 4 years and ongoing. This opens a window for further regenerative medicine strategies to ameliorate adrenal failure in this patient group.

Cortisol measured in scalp hair as a monitoring tool for systemic cortisol levels

Elisabeth van Rossum
Erasmus MC, University Medical Center Rotterdam, Rotterdam, The Netherlands.

In recent years, scalp hair analysis had been successfully introduced as a novel biomarker for long-term cortisol levels. Traditionally used methods to measure cortisol (blood, saliva, urine) are complicated by the circadian rhythm and pulsatile way of cortisol secretion, as well as the influence of acute stress and day-to-day variation. In contrast to these short-term measurements, hair cortisol analysis allows to quantify the average cortisol production for a prolonged period of time ranging from 1 month to several months or even years, depending on the length of the hairs.

Hair analysis provides exciting new opportunities to study the influence of long-term cortisol exposure on a wide range of health outcomes and diseases. In this context, increased long-term cortisol levels have been associated to obesity, metabolic syndrome, cardiovascular diseases, psychiatric diseases and a wide variety of stress-related conditions. Also for endocrine diseases hair cortisol analysis has shown its value. Hair cortisol measurement has been shown to be a convenient, non-invasive tool to diagnose Cushing's syndrome with high sensitivity and specificity. Evidence is accumulating that this method can also be used for monitoring of hydrocortisone replacement therapy to improve its refinement. As hair grows on average one centimeter per month, scalp hair offers the unique opportunity to create historical timelines of long-term levels of cortisol. This facilitates the measurement of cortisol levels before and after an intervention or event using one single hair sample. In addition, in cases of cyclical Cushing's syndrome, retrospective hair analysis seems of great value to assist in diagnosing this rare disorder. In conclusion, hair seems a promising matrix to reliably measure cumulative cortisol levels over prolonged periods of time, yielding multiple clinical applications.

Androgens and disease progression in prostate cancer

S24.1

Leveraging circulating DNA studies to identify mechanisms of resistance to CYP17A1 inhibition

Gerhardt Attard
The Institute of Cancer Research and the Royal Marsden, London, UK.

CYP17A1 inhibition with abiraterone is an effective treatment for castration-resistance prostate cancer (CRPC), with significant improvements in survival, radiological progression free survival, pain, skeletal related events and other secondary end-points. However, resistance invariably develops. Due to mineralocorticoid excess, abiraterone is administered with glucocorticoids. Next-generation sequencing of circulating plasma DNA from CRPC offers an opportunity to monitor tumor genomic aberrations over the course of the disease and detect emergent changes that associate with resistance. Clones harboring resistance-conferring AR mutations emerge in ~20% of patients treated with abiraterone and exogenous corticosteroids. These mutations are activated by ligands that persist in abiraterone-treated patients, including by prednisolone or dexamethasone at clinically relevant doses and by progesterones, and confer a survival advantage. Often sub-clones with alternative genomic aberrations, including AR amplification, are also present suggesting multiple mechanisms co-exist that lead to re-activation of AR signaling. These data introduce a management paradigm requiring sequential monitoring of advanced prostate cancer patients with plasma and tumor biopsies to ensure early discontinuation of agents when they become potential disease drivers and identify therapeutic targets that will allow selection of the next best treatment.

Challenges in pituitary tumours

S25.1

Treatment with temozolomide in aggressive pituitary tumours with or without metastases

Gerald Raverot[1,2,3]
[1]Hospices Civils de Lyon, Lyon, France; [2]Université Lyon, Lyon, France; [3]INSERM U1028, Lyon, France.

Aggressive pituitary tumours, characterized by tumor recurrence and continued progression despite repeated treatments and pituitary carcinomas respond poorly to conventional therapies. The first reports describing the successful use of temozolomide (TMZ), an orally administered alkylating agent used to treat malignant gliomas, in the management of pituitary carcinomas were published in 2006. Following these single case reports small series of patients have detailed the successful use of TMZ, in the management of these pituitary tumours with an initial response in about 40–60% of cases some. Rapid tumour shrinkage or hormonal response to temozolomide treatment is usually observed within weeks after treatment initiation in responding patients. As a consequence, the lack of response after three cycles predicts further resistance to this treatment. Despite these encouraging results, complete tumour regression are exceptional, and secondary resistance are common during follow-up.

O6-methylguanine-DNA methyltransferase (MGMT), a DNA repair system involved in the cellular defence, represents the major mechanism of resistance to temozolomide. It has been suggested that MGMT expression may predict the tumour response to TMZ. Although results are conflicting among publication, it is accepted that low MGMT staining is associated with a high likelihood of treatment response. Owing to the rarity of the condition, contradictory published results, absence of prospective study and lack of other available medical treatments, MGMT status should probably not be taken as a reason to deny these patients the potential benefit of temozolomide. The expression of MLH1, MSH2, MSH6, three proteins of the DNA mismatch repair system, have been examined by IHC in three studies but these results are too preliminary and discordant to guide therapeutic options.

TMZ is not effective for all pituitary carcinomas or aggressive adenomas, and some tumours develop secondary resistance during follow-up. The development of new therapeutic options is therefore necessary. Some case reports suggest the need to associate temozolomide with other chemotherapeutic agents, while other preclinical and clinical studies suggest that new targeted therapies may be useful for controlling pituitary tumour growth.

Continuous glucose monitoring systems

Tadej Battelino[1,2]
[1]University Children's Hospital, Ljubljana, Slovenia; [2]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia.

Good metabolic control depends on the information of blood glucose concentration, routinely obtained with self-monitoring of blood glucose (SMBG). More frequent SMBG is associated with improved metabolic control. In the last decade, real-time continuous glucose monitoring (CGM) of subcutaneous glucose concentration became routinely available and is now introduced into day-to-day management helping people with diabetes make informed decisions on dosing, eating and engaging in physical activity.

Several randomised controlled trials (RCT) demonstrated a clinically meaningful reduction in glycated haemoglobin A1c with the use of CGM. A meta-analysis based on individual patients' data demonstrated that the reduction in A1c is most pronounced in patients with poor metabolic control and when CGM is used most of the study time. The reduction of A1c was significant when CGM was used with multiple daily injections (MDI) or continuous subcutaneous insulin infusion (CSII). In more recent RCTs, a reduction of A1c was associated with a concomitant reduction of time spent in hypoglycaemia.

CGM can be used with CSII combined in a single device. RTCs comparing sensor-augmenting insulin pumps (SAP) to MDI or CSII demonstrated a significant and clinically meaningful decrease in A1c. Moreover, a SAP can include an automated insulin delivery suspension on pre-selected low glucose threshold. This automated insulin delivery suspension feature was demonstrated in RCTs to reduce both hypoglycaemia and severe hypoglycaemia across all age groups of people with diabetes.

Finally, CGM can be used as a part of an artificial pancreas. RCTs using different algorithms for closed-loop insulin delivery based on CGM demonstrate both improvement in metabolic control and reduction in hypoglycaemia.

Currently available CGM systems still have quite a few technical limitations, related to the subcutaneous sensors, wireless connectivity, signal strength, accuracy and reliability. Further improvements are needed along with a continuous safety and quality surveillance for a sustained long term use of CGM that will empower people with diabetes for a more flexible, less burdensome and successful metabolic control.

S26.3

Artificial Pancreas

J Hans DeVries
Academic Medical Center at the University of Amsterdam, Amsterdam, The Netherlands.

The artificial pancreas or closed loop is the holy grail of diabetes technology. The concept has been around for decennia, but only as more or less accurate continuous glucose monitors became available some 10–15 years ago, patient related research could be initiated. The essential problem is the inherent delays in the loop. Insulin absorption, glucose uptake by the cell after activation of the insulin receptor and continuous glucose monitoring all take time. Once administered, insulin action will be notable for several hours after administration and if too much insulin infused, this can't be taken out of the body anymore. The efforts of the AP@home consortium, funded by the European Commission from 2010 to 2014, with ongoing activity in 2015, will be highlighted. It aimed at improvements in insulin absorption, closed loop control algorithms and continuous glucose monitoring. The name-giving aim of the consortium has been met; research is now completed and ongoing at the patient's home, under free-living conditions, while research had not progressed beyond the clinical research centre at the start of the project. Remaining obstacles before the artificial pancreas becomes available in clinical practice will be discussed.

Thyroid cancer: new development in diagnosis and treatment (*Endorsed by the European Journal of Endocrinology*)

S27.1

Central neck dissection: an important step forward in the management of thyroid papillary cancer

Antonio Sitges-Serra
Hospital del Mar, Barcelona, Spain.

Central neck dissection for papillary thyroid cancer (PTC) was initially proposed by Scandinavian authors in the late 70's on the following grounds: i) the common presence of obvious metastatic nodal disease in compartment VI; ii) compartment VI is the first step in lymph node dissemination of PTC; and iii) prevents cancer recurrence in the central neck leading to difficult reoperations. These same authors were also the first to suggest that thorough surgery for PTC would eliminate or substantially reduce the need for radioidine treatment. No one would argue today that in all patients with PTC the central compartment must be explored carefully and lymphadenectomy performed in all cases of macroscopic nodal involvement. Thus, therapeutic CND is out of question despite it is a quite challenging and extensive operation, often associated with locally advanced PTC, that may result in permanent hypoparathyroidism due to inadvertent parathyroidectomy and devascularization of the parathyroid glands.

Currently the controversy persists on the need to perform a prophylactic neck dissection in cases without macroscopic nodal involvement. We favor it on the following basis: i) half of the normal looking central nodes harbor PTC metastasis; ii) prevention of central neck recurrences; iii) better staging and progressive abandon of radioidine treatment; iv) few permanent complications if not bilateral and performed by experienced surgeons.

Because the rate of central lymph node metastasis increases with tumour size, we advocate to add routine CND to total thyroidectomy in all PTC >1 cm; preferentially bilateral if performed for therapeutic purposes and unilateral when performed prophylactically. In our hands, this optimized surgical approach has resulted in a low 9% recurrence rate after a mean follow-up of seven years in over

150 patients (mean T size 27 mm) with a 7.5 and 2.5% permanent hypopara rates for therapeutic and prophylactic CND respectively. All recurrences have occurred in the lateral neck (despite prior radioiodine treatment) and none in compartment VI. 30% of our patients were not treated with radioiodine; none of them has developed a recurrence.

Hormones and immunity in pregnancy

S28.1

Hormonal modulation of immune responses during pregnancy

Ana Claudia Zenclussen
Experimental Obstetrics and Gynecology, Medical Faculty, Otto-von-Guericke University, Magdeburg, Germany.

Pregnancy is a puzzling phenomenon for researches as it defies the rules of immunology. The immune system of a pregnant woman is able to both tolerate the foreign while being alert to possible harm. It is now known that paternal antigens expressed by the fetus are not ignored but actively tolerated by the maternal immune system. Pregnancy hormones may have a pivotal role on the modulation of immune cell functions. We have described the important participation of the pregnancy hormone human chorionic gonadotropin (hCG) in the regulation of immune responses during pregnancy. During this lecture, special emphasis will be put on the modulation of regulatory T cells and regulatory B cells. Data obtained from animal models as well as from patient's samples will be discussed.

S28.2

Sex hormones and B cells in pregnancy

Federico Jensen
Laboratory for Immunology of Pregnancy Center for Pharmacalogical and Botanical Studies (CEFYBO-CONICET-UBA), Buenos Aires, Argentina.

Mammalian pregnancy is characterized by tremendous changes and adaptations in the endocrine as well as in the immune system. Early in pregnancy, levels of female sex hormones, progesterone (P_4) and estradiol (E_2) produced by the corpora lutea (CL) significantly rise, promoting huge modifications of the uterine epithelium ensuring embryo implantation. Once the embryo is implanted, trophoblast cells produce and release increasing levels of human chorionic gonadotropin (hCG), which among other functions stimulates the CLs to continue producing progesterone. Simultaneously, the maternal immune system undergoes several adaptations; e.g., expansion of regulatory B and T cells, tending to 'accept' the presence of the semi-allogeneic fetus expressing foreign antigens.
These modifications and adaptations of the endocrine and immune system are not independent of each other but highly coordinated. Indeed, alongside with the above-mentioned functions, female sex hormones actively participate in the process of shaping immune cells toward a transient state of tolerance necessary for the maintenance of pregnancy.
B-lymphocytes are pleiotropic cells belonging to the adaptive arm of the immune system. Besides their well-known function as antibody-producing cells, B-lymphocytes can produce a broad variety of cytokines as well as present antigens to T cells, thus they have a central role in regulating an immune response. In this talk I will present and discuss different mechanisms of how female sex hormones influence and coordinate B cell functionality in the context of pregnancy.

S28.3

Vitamin D and pregnancy outcome

Nicholas Harvey
MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, UK.

Low concentrations of 25-hydroxyvitamin D, the major circulating storage form, are common in the general population. Over recent decades, there has been increasing evidence for a role of vitamin D in disease pathogenesis far beyond the musculoskeletal system. Thus, many studies have investigated whether low levels of circulating 25-hydroxyvitamin D have a detrimental effect on pregnancy outcomes, for both mother and offspring, and whether supplementation with vitamin D might ameliorate such effects. We comprehensively surveyed this literature in a recent systematic review, funded by NIHR HTA. Suggestive positive associations were observed between maternal 25-hydroxyvitamin D concentration/ vitamin D supplementation during pregnancy, and offspring birthweight, serum calcium concentrations and bone mass, with some evidence for a protective effect of maternal 25-hydroxyvitamin D concentrations on pre-eclampsia. Overall, though, there was insufficient evidence to recommend vitamin D supplementation in pregnancy for any single health outcome.
Such findings reinforce the need for high quality randomised control trials, such as the UK MAVIDOS Maternal Vitamin D Osteoporosis study, a multicentre, randomised, placebo-controlled, double-blind trial of 1000 IU/day vitamin cholecalciferol (D3) vs placebo from 14 weeks gestation till delivery of the offspring, in which the primary outcome is offspring DXA-measured bone mass, with pregnancy outcomes assessed as secondary endpoints. This study, which is currently in the analysis-phase, will test, in an interventional setting, earlier observations linking low maternal 25-hydroxyvitamin D concentration to reduced offspring bone mass, and gain valuable information regarding the role of vitamin D in pregnancy for other health outcomes.
Such a rigorous interventional approach is essential to enable research questions to be adequately answered, such that alterations to public health policy maybe confidently based on robust evidence.

Management of endocrine transition

Philippe Touraine
Department of Endocrinology and Reproductive Medicine, Hôpital Pitie Salpetriere, Paris, France.

Transition from pediatric to adult care is a challenging turning point for patients, physicians and health care system that need to be planned and adapted to each center. Endocrine conditions present some specific concerns at transition that need to be clarified to insure optimal care during adulthood. We had the opportunity to set up a network to evaluate transition process of patient with a chronic endocrine condition at the Department of Endocrinology and Reproductive Medicine of the GH Pitié-Salpêtrière, to establish basis of an optimal transition program and to improve follow-up of those patients presenting with rare diseases, including hypogonadotropic hypogonadism. Prospective and retrospective assessment of transition period was conducted through elaboration of standardized surveys that were sent or given for completion to targeted transition patients. Two categories of surveys were developed: i) one general survey addressing universal aspects of transition and ii) specific surveys exploring precise concerns for certain endocrine condition. Three chronic endocrinopathy, congenital adrenal hyperplasia, hypogonadotropic hypogonadism and growth hormone deficiency, have been kept for evaluation since they present specific challenges for both the patient and physician that need to be characterized. Answers where analysed and compared to actual recommendations for successful transition. Since the last decade, 273 patients in transition were listed in our department and 153 were kept for evaluation since they present one of the three endocrinopathy retains for assessment. A total of 73 subjects fulfilled both general and specific surveys. Over 80% of patients were satisfied about actual transition process in terms of organization, accessibility and medical care. Actual and optimal age felt by patients for transition correspond for most subjects (19.4 vs 18.4 years). Main concerns of patients about transfer have been identified. Finally, specific endocrine surveys allowed identification of psychological concerns, essentially around sexual life and fertility in patients with hypogonadotropic hypogonadism, that need to be address more systematically at first consultation. The present organisation allowed our medical team to improve transfer of pediatric patients and to identify the basis of a transition program tailored for our center and for each of the endocrine condition studied.

GH deficiency: the transition from childhood/adolescence to adulthood

Primus-E Mullus
Paediatric Endocrinology, Diabetology and Metabolism, University Children's Hospital, Inselspital, CH-3010 Bern, Switzerland.

Many children have been treated for the diagnosis of GH deficiency during childhood. Having reached final height, it was customary to stop the GH therapy. However, even though final height has been achieved, the adolescent 'child' is still in the transition phase as far as peak muscle and bone development are concerned. As this transition period is particularly challenging in adolescents that were treated with GH during childhood it is most important to redefine them correctly and find those who need lifelong substitution. Over the last years many studies have focused on this issues. In this presentation the our protocol to follow-up on these subjects/patients will be presented. In this review the specific focus is on the patients treated for childhood-onset GHD.

S29.4

Prader–Willi syndrome

Charlotte Höybye
Karolinska University Hospital, Stockholm, Sweden.

Prader–Willi syndrome (PWS) is a complex genetic disorder caused by the absence of normal activity in the paternally expressed genes from chromosome 15q11–q13. PWS is characterised by hyperphagia, muscular hypotonia, developmental and cognitive delays, behavioural problems and endocrine abnormalities. Obesity and short stature are common.

Endocrine deficiencies

The combination of the phenotype and reduced GH and IGF1 levels indicates a dysfunction in the GH/IGF1 axis. The degree of GH deficiency varies from mild to severe. GH treatment initiated during childhood normalises skeletal growth, improves body composition and optimizes mental and motor development. GH treatment with doses normalising IGF1 in adults with PWS improves body composition and to some degree quality of life (QoL) and physical fitness. GH treatment is safe but glucose metabolism must be continuously monitored especially in obese patients and in patients with heredity for diabetes, in addition to monitoring serum IGF-I and sleep related breathing disorders.

Incomplete sexual development is frequently seen in PWS. The majority has clinical and laboratory measurements demonstrating hypogonadism, which can be of both primary gonadal and hypothalamic origin. Sex-steroid treatment might be beneficial. Fertility has not been reported in PWS men while five pregnancies have been reported in PWS women.

Central adrenal insufficiency has been hypothesized to be responsible of an increased risk of sudden death in PWS. Available data indicate that some degree of central adrenal insufficiency may be part of PWS phenotype, although clinically relevant adrenal failure in PWS subjects appears to be rare. Adrenal insufficiency and hydrocortisone treatment should be considered whenever clinically indicated.

Hypothyroidism has been reported more frequently in children than in adults with PWS, and TSH and thyroid hormones should be followed regularly.

Conclusion

PWS in adults and children is associated with documented endocrine insufficiencies which should be monitored and treated.

S29.5

Management of endocrine transition: type 1 diabetes

Christina Kanaka-Gantenbein
University of Athens Medical School, Athens, Greece.

Transition from childhood through adolescence towards adulthood is a gradual process characterized by progressive independence, but also increased responsibility for health care. Specifically, for adolescents with chronic diseases, necessitating long-term medical care, the transition from pediatric to adult care is further characterized by the separation of the well-known environment of a Children's Hospital towards an adult health care system, mainly accompanied by a separation of the familiar health professionals' team to a new non-familiar one. For emerging young adults with diabetes the transition to adult care may have a direct negative impact on their glycemic control impairing their long-term prognosis and risk for micro- and macro-vascular complications. There is evidence for a high percentage of drop outs during transition that may further aggravate glycemic control of these young adults. Therefore, the transition to the adult care should be carefully prepared through a longer period of time that should be individualized according to the personality characteristics and psychosocial needs of each emerging adult. The transition should occur smoothly towards adult health care providers who might assure not only evidence-based medical care to young patients with diabetes but should also satisfy their psychosocial needs. Special attention should be laid for the early identification of specific patients' groups at risk, such as young women with diabetes and eating disorders or young men prone to delinquency or drug addiction. The transition of care should be carefully organized by the direct contact of the pediatric and the adult endocrinologist/diabetologist so that the patient realizes that there is a common attitude of the two health care providers. Moreover, an open option should be offered to the young adult to return to the pediatric care to discuss his experiences in the new environment before the care should be entirely transferred to the new health professionals' team.

How to manage hyponatraemia according to guidelines? The USA perspective

Joseph Verbalis
Georgetown University, Washington, District of Columbia, USA.

In 2013, a panel of international experts in hyponatremia published our recommendations for clinicians caring for patients with hyponatremia ('Diagnosis, Evaluation, and Treatment of Hyponatremia: Expert Panel Recommendations'). In 2014, a similar working group of experts from EU countries published their recommendations ('Clinical Practice Guideline on Diagnosis and Treatment of Hyponatraemia'). Despite reviewing the same evidence databases, these two groups independently proposed quite different recommendations. The major reason for the differences is divergent interpretation of evidence, notably the quality of the evidence for use of vasopressin receptor antagonists (vaptans) in SIADH. The EU group severely downgraded the quality of evidence of the vaptan clinical trials largely because they were industry sponsored. In addition, they relied upon meta-analyses of combined clinical trials of multiple vaptans, including those not licensed for use anywhere in the world. Our group chose to focus instead on the Phase III pivotal studies of only those vaptans that succeeded in gaining regulatory approval in Canada, EU, and US. Similar to the EMA, FDA and Health Canada, we felt the quality of the Phase III clinical trials for approved vaptans was high, with no need to downgrade the level of evidence for placebo-controlled, randomised trials. We believe that our recommendations represent a more practical guide to treating hyponatremia based on the strongest available evidence from well-constructed clinical trials, whereas the EU group inexplicably recommended therapies (e.g., urea, loop diuretics with NaCl supplementation) with relatively little evidence for either efficacy or safety based on small numbers of non-randomised studies. It is abundantly clear to everyone who treats hyponatremic patients that there is not 'one size that fits all'; rather therapy should be individualised to each patient's unique clinical situation. Within that context, to recommend against the use of any of the effective pharmacological therapies for hyponatraemia, as the EU guidelines group has done in contrast to our recommendations, represents a disservice to the patients we have the responsibility to care for in the best manner possible.

Management of prolactinoma

Dominique Maiter
Department of Endocrinology, UCL Cliniques St Luc, UCL, Brussels, Belgium.

Prolactinomas are the most common pituitary tumours with a prevalence varying from 0.3 to 0.5/1000 in the general population. This tumor has a large female predominance and a median age at diagnosis of 30 years. Prolactinomas in men are characterized by a larger size and a higher frequency of compressive symptoms, invasiveness, and resistance to therapy. Although the diagnosis of prolactinoma is often straightforward and the treatment strategy has been well defined in recent guidelines, new information has been provided over the past few years that may change the current management of these pituitary tumours. Moreover, several challenging issues in diagnosis and treatment still persist. As an example, the diagnosis of microprolactinoma is not always sufficiently well substantiated and this may lead to inappropriate prolonged treatment with a dopamine agonist. Also, the differential diagnosis of a large pituitary tumour with moderately elevated PRL concentrations remains sometimes difficult. The treatment of resistant and/or aggressive prolactinomas remains a challenge for the clinician, especially in young patients. Potential cardiac valve side-effects of long-term treatment with high doses of dopamine agonists should also be taken into account in the treatment strategy of such tumours. Management of prolactinoma in a young woman wishing to become pregnant, conditions of dopamine agonist withdrawal, or the place of transsphenoidal surgery are also still matters of debate. In this Meet-the-Expert session, illustrative clinical cases will be presented and diagnostic and therapeutic issues will be the subject of interactive discussion.

Management of thyroid eye disease

Georg Brabant[1] & Anja Eckstein[2]
[1]Experimental and Clinical Endocrinology, University of Lübeck, Lübeck, Germany; [2]Department Neuroophthalmology, Strabism and Oculoplasics, University Eye Hostpital Essen, Essen, Germany.

The diagnosis of TED is not always obvious and its management can be a challenging. Diagnosis as well as treatment should be performed in a multidisciplinary setting. Decision on treatment is based on a careful assessment of ophthalmological symptoms and the evaluation of the clinical activity of the disease using the clinical activity score. TED is classified into mild, moderate and sight threatening disease. An active inflammatory disease stage is followed by an inactive stage of incomplete remission in most of the patients. Periorbital swelling, proptosis, diplopia and lid retraction impair the quality of life of the patients severely. In the active state anti-inflammatory treatment is indicated. In milder stages a 6 months course of 200 µg Natriumselenid will suffice. In moderate TED i.v. steroids (cumulative dosage 4–5 g) in combination with orbital irradiation in cases with impaired motility are first choice. Off-label use of immunmodulatory medications (especially Rituximab 500–2000 g) may be considered if i.v. steroids do not suffice. All treatments have to be administered early enough before a fibrotic stage is reached. Inflammatory signs respond well, while impaired motility resolve only in one third of the patients and proptosis decrease only 1–2 mm. In rare cases sight threatening conditions like optic nerve compression, corneal ulceration, compartment syndrome with very high intraocular pressure develops and emergency decompression has to be performed. Persistent defects after maximal anti-inflammatory treatment can be successfully treated by surgery, when an inactive stable stage has been reached for at least 3 months and involve: decompression for proptosis reduction, muscle recession to correct diplopia and (finally) lid surgery. Anti-TSH-receptor-antibodies are specific for Graves' disease and are related to both the course of thyroid and orbital disease and can be used for treatment decisions. Generally, environmental factors like smoking needs to be omitted. Thyroid function should be rapidly normalized, primarily using thyrostatic drugs. Definite therapy with radioiodine may be associated with negative effects, particularly when no protection with co-administered steroids is used. Recent data suggest a positive influence of thyroid surgery on the outcome especially if total ablation is reached. Adjuvant therapy like artificial teardrops, dark glasses and prisms to compensate diplopia are important.

Central precocious puberty: management and long-term outcome

Juliane Léger
[1]Université Paris Diderot, Paris, France; [2]Hôpital Robert Debré, Paris, France.

CPP results from premature reactivation of the hypothalamo–pituitary–gonadal axis and pulsatile GnRH secretion, with a hormonal pattern similar to that of normal puberty. Recent studies have implicated the activation of Kisspeptin and its receptor and the inactivation of MKRN3 genes in CPP. MKRN3 gene defects are currently an identified genetic cause of paternally transmitted familial CPP, but such defects do not underlie maternally transmitted CPP and are rarely involved in sporadic forms. Premature sexual maturation is a frequent cause for referral. Clinical evaluation is generally sufficient to reassure the patients and their families, but premature sexual maturation may reveal severe conditions and thorough evaluation is therefore required to identify its cause and potential for progression, so that appropriate treatment can be proposed. If a non-progressive form of PP is suspected, it is recommended to wait a few months and then to reassess the patient, to avoid unnecessary treatment. CPP may be due to hypothalamic lesions or idiopathic in most cases, particularly in girls. It may have consequences for growth and psychosocial development. GnRH agonists (GnRHa) are the standard treatment for progressive CPP. Such treatment results in the regression or stabilization of pubertal symptoms, and decreases in growth velocity and bone age advancement. The factors affecting height outcome include initial patient characteristics and duration of treatment. After the cessation of GnRHa therapy, generally at an age of about 11 years, biological and clinical signs of puberty reappear within months, with most girls achieving menarche, with menstrual ovulation cycles, during the following year. PP associated with the presence of a hypothalamic lesion may progress to gonadotropin deficiency. The available data indicate that long-term GnRHa treatment does not seem to cause or aggravate obesity or have repercussions for body composition, bone mineral density and fertility. However, data concerning psychosocial outcomes are scarce.

Management of the transgender patient

Guy T'Sjoen
Ghent University Hospital, Ghent, Belgium.

Gender dysphoria (GD) is a condition in which a person experiences discongruency between their assigned sex and what they feel their genderidentity is. A person with gender dysphoria experiences persistently uncomfortable feelings about their birth gender (Diagnostic and Statistical Manual of Mental Disorders, Fifth edition (DSM-V) (American Psychiatric Association).
During the 'real life experience' hormonal treatment usually starts and applicants are required to live socially in the desired gender role before irreversible surgical reassignment is considered. Cross sex hormonal treatment is desired by trans persons to help them successfully live as a member of their identified gender. It is

clear that both in adults and adolescents the decision for starting hormonal treatment is not to be made by the endocrinologist. The mental health professionals (psychiatrists and/or psychologists), by preference working in a multidisciplinary Gender team, will guide these persons to make an informed decision about hormonal treatment. Eligibility criteria and readiness as described by WPATH's Standards of Care-7th version, should be evaluated. The goal of treatment in female-to-male trans persons is to induce virilization and to stop menses. The prinicipal hormone treatment is a testosterone preparation. In male-to-female trans persons oestrogen and anti-androgen treatment is provided. Treatment regimens are currently not standardised and include various forms of oestrogens, progestins, and/or (anti-) androgens as reported by different clinical centres. So far, no randomized intervention trials are available so treatment is largely experience-based. Options for fertility preservation should be discussed with the clients before hormonal intervention.

Appropriate care for transgender persons will lead to better outcome and should avoid unnecessary psychological pain, health risks (e.g. secondary psychiatric conditions or suicide), or self medication with inherent greater risk of complications.

Management of adrenal insufficiency

Stefanie Hahner
Department of Medicine I, Endocrinology and Diabetology, University Hospital Wuerzburg, Wuerzburg, Germany.

For a long time it has been assumed that patients with adrenal insufficiency (AI) can live without any restriction when receiving standard hormone replacement therapy.

However, recent evidence indicates that subjective health status (SHS) in patients with primary adrenal insufficiency is significantly impaired at least in a subgroup of patients and that mortality is increased compared to the general population.

The observation of impaired SHS holds true for patients with both primary and secondary AI and also for patients with congenital hyperplasia. It is reflected by a high proportion of occupational changes and restriction of leisure time activities. The non-physiological cortisol profile achieved by standard replacement strategies has been particularly claimed as main cause for the reduced SHS but also lack of further hormones like DHEA and epinephrine might be an underlying cause. Recent efforts aim at improving replacement strategies by mimicking a more physiological cortisol profile and to restore androgen deficiency and new therapeutic options have emerged.

The observation of increased mortality has led to more detailed studies demonstrating that adrenal insufficiency per se represents one of the most common causes of death in this patient population but also death from infectious disease and cardiovascular disease appears to be increased. Adrenal crisis is more frequent than suggested by earlier analyses, even in well educated patients. Both physical and psychological distress may precipitate adrenal crisis with infectious disease being the most frequent precipitating factor. The relative risk to die from infectious disease is largely increased, suggesting that many of these patients are not sufficiently treated resulting in adrenal crisis. Recent activities aim at an improved and standardized patient education and an improvement of awareness in health professionals.

In conclusion both, replacement strategies in chronic AI and prevention and treatment of adrenal crisis deserve particular attention and need to be further improved.

Acromegaly and cancer

Cesar Boguszewski
Sempr Fed Univ Parana, Curitiba, Brazil.

Experimental and epidemiological studies have implicated high serum GH and IGF1 levels as potential contributors to tumor progression by both endocrine and paracrine mechanisms. It is still a matter of debate, however, if the prevalence of cancer is increased in acromegaly, as this disorder, characterized by chronic GH and IGF1 hypersecretion, is also associated with elevated IGFBP3 levels, which has proapoptotic and anti-proliferative protective effects. On the other hand, non-endocrine mechanisms and epigenetic/genetic variations may favor the development of tumors in acromegaly. Currently, most investigators agree with the idea that acromegaly is associated with a modest increased risk for some types of tumors, especially colon and thyroid, and mainly in patients with active disease. Most guidelines have suggested a colonoscopy at diagnosis of acromegaly, because colonic neoplasia has been found in up to 19.3% of acromegalic individuals younger than 40 years in comparison with 4.4% of controls. The optimal follow-up is controversial, but as a general rule, patients with polyps or persistently active disease should repeat colonoscopy after 5 years, while in those with normal exam and controlled disease, every 10 years or according to the recommendations for the general population. Case–control studies and recent meta-analysis have demonstrated a high rate of nodular goiter and thyroid cancer in acromegaly, advocating for close surveillance by thyroid ultrasonography. This is not a consensus, however, and some guidelines only recommend a thyroid ultrasound for patients with a palpable thyroid nodule. In relation to other common tumors, as breast and prostate cancer, the prevalence does not seem to be increased in acromegaly and the patients should be followed in a similar way as the normal population. Some studies, however, have found an increased cancer-related mortality with these tumors in acromegalic patients.

Approach to the patient with dyslipidaemia

Alper Sonmez
Gulhane Military Medical Academy, Department of Endocrinology and Metabolism, Ankara, Turkey.

In clinical practice, dyslipidaemia defines the elevated plasma total cholesterol, LDL cholesterol or triglycerides or the decreased HDL cholesterol levels. In recent years however, new laboratory methods helped us understand that the functions of lipoproteins are more important than their amounts. Dyslipidaemia is one of the most important and correctable risk factors for the atherosclerotic cardiovascular diseases (CVD). The epidemiological data recurrently show a very significant linear relationship between the elevated cholesterol levels and the risk of CVD. Genetic background and age are the two major predictors of serum cholesterol levels. In the developed countries, with a considerable amount elderly people, more than half of the population have increased total cholesterol levels. Other important determinants of serum cholesterol and triglycerides are the eating habits and the presence of regular physical activity. The risk of dyslipidaemia is significantly increased in the modern populations with high caloric intake and low exercise capacity. The main problem with dyslipidaemia is the fact that it is mostly an asymptomatic metabolic disorder. Therefore, it is crucial for the primary care physicians to know when, where and how to search for and how to manage the patient with dyslipidaemia.

In a patient with dyslipidaemia, the medical history should be taken for the possible diseases or drugs, which may cause secondary dyslipidaemia. A family history of premature atherosclerosis is crucial as it may help us recognize familial dyslipidaemias. Also, the lifestyle of the patient, including history of smoking or alcohol intake and exercise habits should carefully be sought. Also, the presence of effort angina, dyspnoea or claudication intermittence should be searched in the systemic examination of the patient. In the physical examination, the body mass index and arterial blood pressures should be measured and the peripheral pulses should be checked. Also the eye and cutaneous findings of dyslipidaemia should

be searched during the physical examination. In order to rule out the secondary causes, fasting glucose levels, liver enzymes, creatine, urinary protein excretion and TSH levels should be seen in the laboratory evaluation process.

MTE 13: management of male osteoporosis

Dilek Gogas Yavuz
Department of Endocrinology and Metabolism, Marmara University School of Medicine, Istanbul, Turkey.

Osteoporosis in men is recently recognized as a major underestimated public health problem. In 2050, the incidence of hip fracture in men is expected to increase by 310% worldwide. After the age of 50, one out of three osteoporotic fractures are seen in men. Men suffering any major fracture have a higher mortality rate than women osteoporotic fractures. Screening is usually recommended in many guidelines above the age of 65 or 70 years and those younger aged with risk for osteoporosis. However, its relevance requires validation through prospective studies.

Fifty percent of the causes leading osteoporotic fractures in men are potentially treatable. Treatment decisions should be based on clinical evaluation, fracture risk assessment, diagnostic workup, and Bone mineral density measurements. Current Guidelines suggest initiating treatment in men over 50 with a history of hip or spine fractures and those with a *T*-score of -2.5 or below and men at high risk for fracture based on low BMD and/or clinical risk factors.Although it's less defined than women pharmacologic and nonpharmacologic management options exists for prevention and treatment of osteoporosis in men. Calcium consumption from dietary sources (with supplementation if necessary) along with appropriate vitamin D levels are recommended. Pharmacological agents approved for treatment of osteoporosis in men include the anti-resorptive drugs bisphosphonates (alendronate, residronate and zoledronic acid) and denosumab, the bone-forming agent teriparatide, and strontium ranelate. The evidence level for efficacy and safety of these drugs in men is still needs to be evaluated but recent data indicate that treatment effects of anti-osteoporotic drugs in men are very similar to what has been observed in the treatment of postmenopausal osteoporosis.

Growing body of evidence indicates of medical, economic and social impacts of male osteoporosis, currently only minority of men with high risk of fracture are detected and treated appropriately.

Medullary thyroid cancer

Thera P Links
Department of Endocrinology, University Medical Center Groningen, Groningen, The Netherlands.

Medullary thyroid cancer (MTC) is a rare disease accounting for about 5% of all thyroid cancers and can occur sporadically (75%) or as part of the familial syndrome multiple endocrine neoplasia type 2 (MEN 2). The hereditary forms are caused by a mutation in the 'rearranged during transfection' (RET) gene.

When a proven RET mutation is present carriers will be offered a prophylactic thyroidectomy. The timing of this prophylactic procedure is not completely clear for the choice between the risks of the complications of an early thyroidectomy versus the possible risk of disease development when delaying surgery is still difficult.

Most MTC patients present with an asymptomatic palpable solitary thyroid nodule and/or suspicious enlarged cervical lymph nodes. When diagnosed about 50% of the MTC patients show lymph node and 10% already have distant metastases. About 20% will die from progressive metastatic disease. The prognosis depends strongly on disease stage. The 10-year overall survival is 95% in patients with localized disease, and 75 and 40% in patients with respectively regional and metastasized disease

Tumour progression can be predicted by calcitonin and CEA doubling times and also ^{18}F-FDG-PET and ^{18}F-DOPA-PET are useful in guiding therapeutic steps in patients with MTC. The treatment for MTC is still a topic of discussion. American guidelines recommend total thyroidectomy, level VI and ipsilateral level II–V lymph node dissection when nodal involvement is suspected, while the British guidelines advocate bilateral selective lymph node dissection in T2–4 tumours or palpable lymph nodes in level VI and II–V. For metastatic disease local treatment options (radiofrequency ablation, radiotherapy) are available. Tyrosinekinase inhibitors show encouraging results, however no benefits on overall survival have yet been demonstrated.Several other different strategies for the treatment of MTC are currently being considered, many of which target downstream proteins of RET.

Meet the expert 17 (MTE17): management of Turner syndrome

Aneta Gawlik
Department of Pediatrics, Pediatric Endocrinology and Diabetes, School of Medicine in Katowice, Medical University of Silesia, Katowice, Poland.

The complete or partial absence of one of the two X chromosomes in a female with characteristic phenotype appearance entitles to Turner syndrome (TS) diagnosis. Monosomy of X chromosome (45,X) is prevalent, however some patients are mosaic and carry one or more additional cell lines, also with Y chromosome. The karyotype variability reflects the wide clinical spectrum of the syndrome. The prevalence of spontaneous puberty is 6% for 45,X and more than 50% for other karyotypes. Short stature affects almost 95% patients and like some of bone malformations results from SHOX haploinsufficiency. According to some studies, TS patients with X isochromosome present higher risk of autoimmune diseases (Hashimoto thyroiditis, celiac disease, inflammatory bowel diseases). In turn, ring X chromosome is associated with higher risk of mental retardation. Most of TS patients require multidisciplinary long-term care. It is worth to emphasize that all medical problems recognized during childhood should be followed-up into adulthood. A coordinated transition process from paediatric to adult health care is the key point to provide appropriate cure concerning hormone replacement therapy, cardiovascular disorders, hearing impairment, autoimmune disorders and bone health.

Primary hyperparathyroidism (Meet-the-Expert 18)

Alper Gürlek
Department of Endocrinology and Metabolism, Faculty of medicine, Hacettepe University, Ankara, Turkey.

Primary hyperparathyroidism (PHPT) is the third common disorder of the endocrine system. It reaches a peak incidence between ages 50–60. Biochemical screening has increased its incidence up to one per 1000 (USA), and most cases are presented with asymptomatic mild hypercalcemia. The most common cause in affected individuals is a functioning single parathyroid adenoma. In advanced cases, bones (brown tumours, osteitis fibrosa cystica) and the kidney (nephrolithiasis, nephrocalcinosis) as well as many organ systems may be affected by hyperparathyroidism and associated hypercalcemia. Concomitant vitamin D deficiency might mask hypercalcemia and if remains untreated, may exacerbate postoperative hungry bone syndrome and hypocalcemia.The biochemical diagnosis basicly depends on demonstration of elevated or inappropriately normal serum parathyroid hormone concentrations in a hypercalcemic patient. Guidelines for the management of asymptomatic hyperparathyroidism has been revised in recent years, the latest being issued in 2014. Based on these criteria, a patient with asymptomatic PHPT should be given to surgery if he/she fulfils one of the following: i) serum calcium exceeding 1.0 mg/dl (0.25 mmol/l) above the upper limit of normal range, ii). BMD by DXA:*T*-score < -2.5 at lumbar spine, total hip, femoral neck or distal 1/3 radius, iii) vertebral fracture by X-ray, CT, MRI or vertebral fracture assessment (VFA) iv)creatinine clearance <60 cc/min, v) 24 h urinefor calcium >400 mg/day and increased stone risk by chemical analysis, vi) presence of nephrolithiasis or

nwphrocalcinosis by X-ray, USG or CT, vii) age <50. The minimally invasive approach has recently gained popularity for parathyroidectomy. Various imaging techniques may be used to preoperatively localise the adenomas such as Tc99m-sestamibi SPECT CT, CT scan, MRI and ultrasonography. Intraoperative assessment of PTH is very useful to determine the success of such surgery. Patients who refuse or who are not good candidates for surgery may be followed by calcimimetic agent cinacalcet which is useful to reduce serum calcium level. Bisphosphonates are in widely used for patients in an attempt to increase BMD and reduce the risk of fragility fracture. If there is no intention to reduce calcium or increase BMD, the patient may be followed without any medication.

Assessing osteoporosis in the young adult

S Faisal Ahmed
University of Glasgow, Glasgow, UK.

Fragility fractures in the young individual are an uncommon clinical scenario and when faced with such a situation, appropriate assessment is required to ensure correct diagnosis of the underlying aetiology and to avoid unnecessary interventions. Although, primary causes of osteoporosis such as osteogenesis imperfecta are considered rare, this group of conditions has considerable phenotypic and genotypic heterogeneity and may be underdiagnosed. However, the majority of the young people with fragility fractures have a secondary cause as the underlying aetiology. This may include a range of chronic diseases and medications that can impact on bone turnover, modelling or bone mineral homeostasis. Given the increasing prevalence of young adults with childhood-onset chronic disease, it is likely that a higher number of people with such conditions will require an assessment of bone health in early adulthood. The diagnosis of osteoporosis in the young adult remains contentious. In growing children, interpretation of results and changes need to take into account the differences in stature, growth and pubertal development as well as the poor evidence that exists in this population for DXA BMD as a predictor of fractures. The ISCD recommends that people up to the age of 19 years should not be diagnosed with osteoporosis solely based on low BMD by DXA and has placed a greater focus on the presence of pathological fractures, especially vertebral, such that the diagnosis of vertebral fractures alone is indicative of osteoporosis in the younger individual regardless of DXA parameters. A stronger emphasis on vertebral morphometry, is therefore, becoming more routine in the assessment of osteoporosis. With technological advances in imaging as well as greater availability in the health care sector, it is also possible that identification of osteoporosis will reduce its reliance on techniques such as DXA in favour of other modalities that can provide a 'virtual bone biopsy' such as high resolution MRI or CT.

Responding to reviewer comments

Johannes Romijn
AMC, University of Amsterdam, Amsterdam, The Netherlands.

A statement attributed to Aristotle is: 'You can easily avoid criticism by saying nothing, doing nothing, and being nothing.' If you want to do research, apply for competitive grants and publish relevant scientific papers in competitive journals, criticism is a fact of life. There is also a positive twist to criticism: it is a major driving force to advance knowledge in science.

Frequently, the first reaction of authors to critical comments of reviewers is anger. Nonetheless, most reviewers involved in the review process are reasonable. They are intermediates between the authors and the editors. The authors like to publish in high ranking journals and the editors aim to accept papers with the highest potential for citations. In this respect authors and editors depend on each other.

In many cases the criticisms can be predicted in advance. Weaknesses in objectives, study design, methods, analyses, data acquisition, interpretation of results will frequently be identified by the reviewers. To prevent these comments, the authors should aim for high quality research from the start of the study. Ultimately, the comments of the reviewers frequently enable to improve the manuscript. It is important to address these comments in an elegant constructive way, precisely answering each comment in detail.

Open access

Jens Sandahl Christiansen
MEA, Aarhus University Hospital, Aarhus, Denmark.

Open access publishing provides authors with the highest possible visibility for their work, as articles are made freely available online to everyone. Many funding bodies and institutions around the world are adopting policies, which require their researchers to publish their work open access. Do you know how open access policies affect you, and how to comply? This talk will clarify what open access publishing means, including the difference between green and gold open access models and the various publishing licenses available. The difference between open access and hybrid journals will also be covered, the associated publication charges and what publishers are doing to provide authors with the options they require.

Drug addiction and the endocannabinoid system

Miriam Melis
Department of Biomedical Sciences, University of Cagliari, Monserrato CA, Italy.

Drug addiction is a brain psychiatric disorder, whose etiology involves interaction of inherited predispositions and environmental factors. Addictive drugs share the properties of being self-administered by laboratory animals, and of activating the brain reward circuitry, which stems from the ventral tegmental area (VTA) where dopamine (DA) cells are located. These neurons are involved in neural processing contributing to drug addiction and DA plays a crucial role as learning signal by changing the synaptic strength of neural circuits involved in action selection to optimize goal-directed behavior. Endocannabinoids serve as retrograde signaling molecules at many synapses in the brain, and regulate reward seeking by modulating DA signaling. In fact, endocannabinoids regulate different forms of synaptic plasticity in the VTA, exert a critical modulation of DA release and, ultimately, of the circuits within the limbic systems driving motivated behaviors. In this framework, evidence for the modulation of DA neuronal activity by endocannabinoids, which shape afferent neuronal activity in a short- and long-lasting fashion, in the context of vulnerability to drug addiction will be presented. Indeed, significant sex differences in cannabinoid self-administration displayed by Lister Hooded (LH) female and male rats, and of one of the few pairs of lines of rats selectively bred for their voluntary alcohol preference, that is Sardinian alcohol-preferring (sP) rat line represent two vulnerable phenotypes for Cannabis and alcohol dependence, respectively. Both vulnerable phenotypes share a dysfunctional form of endocannabinoid-mediated short-term synaptic plasticity at inhibitory afferents onto VTA DA neurons. This phenomenon does not depend upon differences in cannabinoid receptor number and/or function, but rather on the rate of endocannabinoid degradation. Thus, it appears that differences in equipment of the endocannabinoid system machinery might control specific sources of vulnerability for both cannabis and alcohol dependence.

Hypothalamo-pituitary-adrenal axis response and adaptation to repeated physical stress in professional athletes

Bojana Popovic[1], Dejana Popovic[2], Djuro Macut[1], Ivana Bozic Antic[1], Tamara Bogavac[1], Tatjana Isailovic[1], Valentina Elezovic[1], Sanja Ognjanovic[1], Dusan Ilic[1], Jadranka Antic[1], Milan Petakov[1] & Svetozar Damjanovic[1]
[1]Clinic for Endocrinology, Diabetes, and Metabolic Diseases, Clinical Centre of Serbia, Belgrade, Serbia; [2]Clinic for Cardiology, Clinical Centre of Serbia, Belgrade, Serbia.

Activation of hypothalamo-pituitary-adrenal (HPA) axis is a common feature of endocrine responses to stress, with cortisol secretion as an end product of this activation. Acute rise in cortisol level during stress is of utmost importance for metabolic adjustments, immune system adaptations, cardiovascular responses and muscle tissue remodeling. But since chronic hypercortisolism has many deleterious effects, scientific interest has started focusing around different biological models of chronic stress, and ways HPA axis adapts to this situation. Chronic dysregulation of HPA axis activity seems to be associated with the onset and course of several psychosomatic and psychiatric disorders, with most replicated findings in patients with major depressive disorder. Another model represents people with posttraumatic stress disorder (PTSD), with still controversial neurobiological findings. As opposed to models of adaptation to chronic psychological stress, our interest focuses on professional athletes, exposed to very specific pattern of physical stress. This model of stress is chronic but intermittent, and on a level of CNS perceived as harmless as opposed to different harmful psychological stressors. But being repetitive it provokes adaptations of many organ systems, with adaptations of cardiovascular system and body composition being well familiar as a common knowledge. Still, not much is known about HPA axis adaptation in professional athletes, but since this subpopulation is generally considered as healthy, it is speculated that whichever form of adaptation ensues, it should be protective long term. We analyzed two groups of professional athletes engaged in two different types of sport (mostly dynamic/aerobic vs mostly static/anaerobic). Our aim was to address their HPA axis adaptation by comparing responses to acute physical challenge to responses of sedentary subjects who were properly matched.

Why bariatric surgery should be considered as an option for obese patients

Carel le Roux
UCD, Dublin, Ireland.

Appetite can be better defined as hunger and fullness. Both of these change significantly after bariatric surgery. Gut hormones such as Peptide YY (PYY) and Glucagon like peptide-1 (GLP-1) are gastrointestinal peptides implicated in appetite control and glycaemic homeostasis. In non-obese individuals these satiety gut hormones may be attenuated. Given that PYY and GLP-1 are secreted from enteroendocrine L cells in the intestine, it is not surprising that manipulation of the gastrointestinal tract has been shown to alter their secretion; particularly when this intestinal manipulation is designed to aid weight reduction. PYY and GLP-1 dynamics are altered by bariatric surgery, with an improved secretory response to nutrient intake. However, there remains a debate regarding the mechanisms responsible for the alterations in PYY and GLP-1 dynamics. We will review the evidence for gut hormone dynamics after Roux-en-Y gastric bypass (RYGB), adjustable gastric banding (AGB), biliopancreatic diversion (BPD) and sleeve gastrectomy (SG), and make comparisons between modalities. In addition, we will review the potential mechanisms underlying theses dynamics, other molecules that may add to the 'incretin effect' and other possible roles for GLP-1 following bariatric surgery. In summary the evidence presented will make the case why if patients are eligible and are interested in bariatric surgery they should be encouraged to have surgery provided they can be supported long term within multidisciplinary teams.

Challenges in diagnosis, treating and managing patients presenting with hyponatraemia, polydipsia and polyuria: implications for nursing practice

Anne Marland[1] & Philip Yeo[2]
[1]Oxford University Trust Hospitals, Oxford, UK; [2]The London Clinic, London, UK.

Hyponatraemia, defined as a serum sodium concentration <135 nmol/l, is the most common disorder of body fluid and electrolyte balance encountered in clinical practice. Management of patients notoriously remains problematic and is associated with increased mortality, morbidity and length of hospital stay. The aim of this oral presentation will be to highlight and discuss new European guidelines in the diagnosis and treatment of patients with hyponatraemia. We will present patient case studies in which various clinical scenarios will be identified; this will include many of the different causes of hyponatraemia, consequent treatment and management.

Developing an effective abstract and poster presentation

Margaret Keil
NIH-NICHD, Bethesda, Maryland, USA.

Objectives
1. Discuss the criteria for clinical and research poster scientific abstracts.
2. Identify resources available to facilitate development of an effective abstract and poster presentation for the novice or experienced nurse.
3. List key components of a research abstract and poster and common errors to avoid.

Every year at the ECE conference someone will mention that they would like to present an abstract at ECE but they don't know how to get started, or can't seem to find the time to accomplish it. If this rings true for you, then this session will provide you with the groundwork to get started and identify methods to simplify the process. Plan to attend this session that will include an overview of writing an abstract and identification of resources to help facilitate your project. In addition, examples of research abstracts will be critiqued to identify strengths, common errors. The session will allow time to provide feedback to participants regarding their ideas for development of an abstract.

Research topic: identifying the needs of patients with Congenital Hypogonadotrophic Hypogonadism, implications for nursing practice

Andrew Dwyer
University Hospital Lausanne (CHUV), Lausanne, Switzerland.

Rare disease patients are frequently seen in endocrine clinic. These patients are not only faced with serious health challenges resulting from their chronic conditions, but often struggle with significant psychosocial impact. Understanding unmet patient needs and activating patients to become engaged participants in managing their condition are essential aspects for improving long-term outcomes for rare/chronic disease patients. Using the example of congenital hypogonadotropic hypogonadism (CHH) this presentation will review a nurse-led needs assessment that leveraged technology to reach dispersed rare disease patients. The identified shortfalls in care will be reviewed and discussed in the context of applicability to other endocrine disorders and will highlight targets for intervention for improving adherence to treatment, transitional care and quality of life. Discussion will include implications for nursing/multidisciplinary holistic care and will detail the community-based participatory research approach, mixed-methods research methodology, and helpful hints for those interested in applying these principles to other rare diseases/clinical settings.

Pre- and post-operative approaches for a patient with pheochromocytoma/paraganglioma

Karen Adams
Eunice Kennedy Shriver National Institute of Child Health and Human Development.

Patients with pheochromocytoma/paraganglioma need to be well-blocked or have their blood pressures well-controlled before surgery. After surgery, blood pressures should be closely monitored as well. This presentation will discuss pre-operative blockade, how to properly administer medications before surgery, and what to look for post-operatively in patients undergoing surgical resection of pheochromocytoma/paraganglioma.

Introduction
Germline inactivating mutations of the protein kinase A (PKA) regulatory subunit RIα (the *PRKAR1A* gene) cause primary pigmented nodular adrenocortical disease (PPNAD); other cyclic AMP (cAMP) signalling defects have been associated with bilateral adrenocortical hyperplasia (BAH), cortisol-producing adenoma (CPA) and related lesions. Recently, *PRKACA* somatic mutations were detected in single, sporadic CPAs in approximately 40% of patients with ACTH-independent Cushing syndrome (AICS) whereas germline copy-number gain (CNG) of the 19p13 *PRKACA*-locus was associated with micronodular BAH (iMAD) and PPNAD.
Methods
We studied 68 patients with AICS, 24 patients with CPA and 44 patients with BAH that did not have known germline *PRKAR1A* defects. The clinical characteristics of the patients were evaluated with genetic analysis.
Results
The hotspot somatic mutation (p.Leu206Arg, c.617T>G) in the *PRKACA* gene was identified in 3 of 25 CPAs. Ten of 44 patients with BAH had germline CNGat the 19p13 *PRKACA*-locus. In one of these cases, AICS with combined androgen production due to a PPNAD-like BAH that became clinically apparent during pregnancy, there was familial inheritance of the 19p13 CNG, which segregated with AICS in the affected members. There were specific dexamethasone-responses and histological features of the patients with somatic PRKACA defects; BAH due to 19p13 CNG was mostly micronodular but was not consistently PPNAD-like.
Conclusions
We conclude that both germline and somatic *PRKACA* defects are associated with specific clinical and histologic phenotypes. Their recognition may help in the earlier identification of these patients with AICS and in the case of hereditary BAH, the earlier recognition of carriers with 19p13 CNG may result in better patient outcome.

Functional study of ARMC5 (armadillo repeat containing 5), a new tumour suppressor gene involved in primary bilateral macronodular adrenal hyperplasia

ludivine Drougat[1], Stéphanie Espiard[1], Stéphane Doly[1], Stéphanie Rodriguez[1], Marthe Rizk-Rabin[1], Rossella Libé[1,2], Guillaume Assié[1,2], Stefano Marullo[1], Bruno Ragazzon[1] & Jérôme Bertherat[1,2]
[1]Institut Cochin, Université Paris Descartes, CNRS (UMR 8104)- Inserm, U1016, PARIS, France; [2]AP-HP, Hôpital Cochin, Department of Endocrinology, Center for rare adrenal diseases, PARIS, France.

Introduction
Primary bilateral macronodular adrenal hyperplasia (PBMAH) are adrenocortical tumors leading to adrenal Cushing's syndrome. Recently, our laboratory has identified the first gene predisposing frequently to PBMAH in adults, named ARMC5 (Armadillo Repeat Containing 5)1. The ARMC5-inactivating mutations identified in leucocyte and tumour DNA in PBMAH patients suggest that ARMC5 is a tumour suppressor gene. However, the mechanisms of action of ARMC5 remain unknown. The aim of this work is to understand both the biological role of ARMC5 protein and how mutations alter this function.
Methods
The human adrenocortical cells H295R were transiently transfected with expression vectors of WT or mutants ARMC5. The eight mutations studied (F700del, C657R, I664S, L754P, Y736S, R362L, R315W, L331P, C139R) have been identified in leukocyte or tumour DNA of operated PBMAH patients. After 8 and 14 h of transfection, apoptosis was analysed by flow cytometry and immunofluorescence analysis (cleaved caspase 3 staining). In parallel, co-immunoprecipitation experiments were carried out to identify partners of the ARMC5 protein by mass spectrometry.
Results
Cell overexpressing WT ARMC5 promptly undergo apoptosis compared to cells transfected with mutants ARMC5 that all lose the ability to induce apoptosis. We identified, by mass spectrometry, 16 proteins specifically interacting with WT ARMC5. These proteins are involved in the degradation of proteins, the redox system and the cAMP/PKA pathway including subunits of PKA. The interaction between ARMC5 and subunits of PKA were then confirmed by co-immunoprecipitations and BRET (Bioluminescence Resonance Energy Transfert) experiments.
Conclusion
These results confirm the role of ARMC5 in the regulation of apoptosis and the loss of this function by the mutants identified in PBMAH. By its binding with actors involved in the cAMP/PKA pathway, known to play an essential role in the adrenocortical function, ARMC5 seems to be a major factor in the adrenal cortex physiology and pathophysiology. 1- Assié et al., NEJM, 2014.

[$^{123/131}$I] azetidinylamide a novel radiotracer for diagnosis and treatment of adrenocortical tumours – from bench to bedside

Stefanie Hahner[1], Britta Heinze[1], Ken Herrmann[2], Andreas K Buck[2], Christina Blümel[2], Heribert Hänscheid[2], Joachim Brumberg[2], David Michelmann[1], Lukas Nannen[1], Martin Ries[1], Martin Fassnacht[1], Bruno Allolio[1] & Andreas Schirbel[2]
[1]University Hospital Wuerzburg, Dept of Medicine I, Endocrinology and Diabetology, Wuerzburg, Germany; [2]University Hospital Wuerzburg, Dept. of Nuclear Medicine, Wuerzburg, Germany.

Background
We have recently introduced [$^{123/131}$I]iodometomidate (IMTO) which selectively binds to the adrenocortical enzymes aldosterone synthase and 11ß-hydroxylase as SPECT tracer. IMTO has been proven to be useful for molecular adrenal imaging and radiotherapy in adrenal cancer (ACC). As IMTO is rapidly inactivated by endogenous esterases which may impair target tissue to background activity and therapeutic efficacy, >50 new IMTO derivatives have been designed and tested. For the new compound [$^{123/131}$I] azetidinylamide (IMAZA), comparable inhibition of CYP11B enzyme activity and a higher metabolic stability after incubation with liver microsomes was proven *in vitro* compared to IMTO.
Methods
IMAZA was subsequently analysed regarding its intracellular uptake in NCI-h295 cells and binding to mitochondrial membranes. *In vivo* biodistribution of [^{125}I] IMAZA was investigated in CD1 mice. Toxicity testing did not show toxic side effects at standard doses. In four patients with advanced ACC [^{123}I]MAZA or [^{131}I] MAZA was used for diagnostic evaluation of radiotherapy as a treatment option on a compassionate use basis and in three patients dosimetry and therapy was performed. Blood levels of tracer and metabolites were determined by radio-HPLC.
Results
In comparison to [^{125}I]IMTO, [^{125}I]IMAZA demonstrated higher uptake in adrenocortical cells and higher accumulation in the mitochondrial subfraction. In biodistribution experiments in CD1 mice, [^{125}I]IMAZA showed a higher, more selective and longer lasting adrenal uptake compared to [^{125}I]IMTO *in vivo*. Accordingly, first clinical data show higher metabolic stability in vivo with rapid clearance of unbound tracer. This significantly improved target to background ratios for [$^{123/131}$I]IMAZA resulting in highly improved imaging quality and calculated tumour doses up to 180 Gy in treated patients.
Conclusion
[$^{123/131}$I]azetidinylamide is a highly promising radiotracer for molecular adrenal imaging and radiotherapy of adrenocortical carcinoma. The highly specific and lasting uptake in the target tissue lead to superior imaging quality and therapeutic potential compared to IMTO.

^{11}C-metomidate PET-CT in primary aldosteronism: five possible indications for a non-invasive alternative to adrenal vein sampling

Andrew S Powlson[1], Olympia Koulouri[1], Elena Azizan[2], Carmela Maniero[2], Kevin Taylor[3], Franklin Aigbirhio[4], Brendan Koo[5], Heok K Cheow[6], John Buscombe[6], Mark Gurnell[1] & Morris J Brown[2]
[1]Metabolic Research Laboratories, Institute of Metabolic Science, University of Cambridge, Cambridge, UK; [2]Clinical Pharmacology Unit, University of Cambridge, Cambridge, UK; [3]Department of Clinical Biochemistry, University of Cambridge, Cambridge, UK; [4]Wolfson Brain Imaging Centre, University of Cambridge, Cambridge, UK; [5]Department of Radiology, Addenbrooke's Hospital, Cambridge, UK; [6]Department of Nuclear Medicine, Addenbrooke's Hospital, Cambridge, UK.

Background
Adrenal vein sampling (AVS) remains the gold-standard for distinguishing unilateral and bilateral disease in primary aldosteronism (PA). However, it is invasive, technically demanding, and may yield inconclusive or equivocal results. ^{11}C-Metomidate PET-CT (^{11}C-MTO-PET-CT) is a non-invasive alternative to AVS for localising unilateral aldosterone-producing adenomas (APAs).
Methods/patients
We report a retrospective analysis of 61 sequential patients with PA referred for ^{11}C-MTO-PET-CT in the three years since our original study (Burton *et al*., JCEM 2012). All had a definite/possible adenoma on previous CT/MRI *or* AVS suggesting lateralisation.
Results
^{11}C-MTO-PET-CT was unequivocally positive leading to a recommendation for surgery in 26/61 patients (42.6%). In all 12 cases operated locally to date (unilateral adrenalectomy), adrenocortical histology and CYP11B2 immunopositivity was confirmed, with biochemical cure of PA (normalisation of the aldosterone-to-renin ratio); six patients await adrenalectomy. In a further eight 'tertiary' referrals from elsewhere, lateralisation by ^{11}C-MTO-PET-CT led to a recommendation for adrenalectomy, but clinical outcome data is awaited. Finally, where multiple nodules co-existed, ^{11}C-MTO-PET-CT accurately identified the causative tumour (confirmed by cell-culture, gene-expression and genotyping).
Discussion
The 26 patients in whom unilateral disease was confirmed had one of five indications for ^{11}C-MTO-PET-CT: i) AVS technically unsuccessful (failure to cannulate one of the adrenal veins); ii) technically adequate AVS, but without clear lateralisation; iii) AVS not possible (unable to safely withdraw spironolactone or epleronone); iv) no clear-cut abnormality on cross-sectional imaging; and v) patient choice not to undergo AVS. ^{11}C-MTO-PET-CT was also valuable in providing strong evidence against lateralisation, especially in patients with a definite unilateral adenoma on CT/MRI, but no resolution by AVS. In conclusion, analysis of ^{11}C-MTO-PET-CT in 61 sequential patients supports its use as an adjunct/non-invasive alternative to AVS. In addition, we speculate that ^{11}C-MTO-PET-CT may facilitate non-surgical targeted nodule-specific ablation or selective surgical adenomectomy when multiple nodules are present.

Norepinephrine transporter as a predictive marker of response to PI3K/mTOR inhibition in phaeochromocytoma

Misu Lee[1,3], Iina Laitinen[2], Rickmer Braren[2] & Natalia S Pellegata[1]
[1]Helmholtz Zentrum München, Neuherberg, Germany; [2]Technische Universität München, Munich, Germany; [3]Yonsei University, Seoul, South Korea.

Currently, no effective medical therapy exists for inoperable phaeochromocytomas (PCCs). Thus, we investigated the antitumor potential of the dual PI3K/mTOR inhibitor NVP-BEZ235 against PCC *in vivo*. We employed a spontaneous model of endogenous aggressive PCCs (MENX rats), which closely recapitulate the human tumours. Administration of NVP-BEZ235 to MENX rats for 14 days inhibited proliferation (assessed by Ki67, NuSAP staining), vascularity (CD31, VEGFA), and induced apoptosis (active caspase 3) of PCCs *in vivo*. Diffusion weighted magnetic resonance imaging (DW-MRI) with calculated mean apparent diffusion coefficient (ADC) values pre- and post-therapy were determined and used as surrogate markers of tumour cellularity. ADC values were significantly increased after drug treatment ($P=0.0208$), further supporting a cytotoxic role of NVP-BEZ235 in PCC. Gene expression profiling (by RT-PCR arrays) of tumours from drug-treated and vehicle-treated rats showed that NVP-BEZ235 affects the expression of genes involved in cell death and survival, cell proliferation and motility. Among the genes down-regulated in NVP-BEZ235-treated vs vehicle-treated rat tumours was *Scl6a2,* encoding the norepinephrine transporter (NET), a common target of positron emitted tomography (PET) imaging of PCC. Specifically, we observed a dose-dependent reduction of both *Slc6a2* (by TaqMan) and NET (by immunohistochemistry) expression in rat PCCs following NVP-BEZ235 administration, which associated with decreased uptake of the radiolabeled norepinephrine analogue 18F-LMI1195 *in vivo*. To assess the relationship between NET levels and response to NVP-BEZ235, we generated a drug-resistant derivative of the MPC (mouse PCC) cell line. While incubation with NVP-BEZ235 reduced NET expression in MPC cells, no reduction was observed in the resistant derivative cells. This suggests that decreased NET expression associates with the ability of PCC cells to respond to PI3K/mTOR inhibition. Altogether, our data demonstrate that targeting PI3K/mTOR signalling is effective against PCCs and suggest that NET levels may represent a surrogate marker of therapy response to PI3K/mTOR inhibitors, which can be monitored by functional PET imaging.

Decanoic acid inhibits androgen production *in vitro* and *in vivo* by regulating HSD3B2: a promising drug candidate for the management of hyperandrogenism in polycystic ovary syndrome

Bao Hui Lee[1,2], Huey Min Tan[1], Yu Li[1], Zhiwei Zhang[1], Inthrani Raja Indran[1], Jun Li[1] & Eu Leong Yong[1]
[1]National University of Singapore, Obstetrics & Gynaecology, Singapore, Singapore; [2]National University of Singapore, NUS Graduate School for Integrative Sciences & Engineering, Singapore, Singapore.

Background
Polycystic Ovary Syndrome (PCOS) is an endocrine disorder characterized by hyperandrogenism in women, with a high incidence of insulin resistance. Decanoic acid (DA), a naturally occurring 10-carbon fatty acid, has been shown to improve insulin sensitivity and lipid profile in an *in vivo* model of diabetes without the induction of weight gain. However, the effects of DA on androgen production has not been explored.
Aim
The objective of this study was to evaluate the effects of DA on androgen production and regulation of steroidogenic enzymes *in vitro*and *in vivo*.
Methods
NCI-H295R human adrenocortical cells were used to assess the effects of DA on androgen production, gene and protein expression of the steroidogenic enzymes. In addition, an *in vivo* letrozole-induced PCOS rat model was used to assess if oral administration of glyceryl tridecanoate (GT), the triglyceride form of DA, may restore normal androgen production and alleviate the symptoms associated with PCOS.
Results
Our findings demonstrate that DA significantly inhibits gene and protein expression of HSD3B2, and androgen production in NCI-H295R cells in a dose-dependent manner. Notably, oral feed of the letrozole-induced PCOS rats with GT restored estrous cyclicity, reduced serum testosterone, and lowered fasting insulin.
Conclusion
Put together, this study has identified a natural compound, DA, as a promising drug candidate for the modulation of androgen biosynthesis. The inhibition of androgen biosynthesis by DA occurs, at least in part, via the suppression of HSD3B2, which codes for an essential enzyme in the steroidogenesis pathway. These results lay the platform for the development of DA for the management of hyperandrogenism and insulin resistance in PCOS.

[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases and Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [2]CHC Bezanijska kosa, Belgrade, Serbia; [3]IBISS, University of Belgrade, Belgrade, Serbia; [4]Clinic of Gynecology and Obstetrics, and Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [5]Institute of Physiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction

Lipid accumulation product (LAP) has been validated as good surrogate marker for the presence of metabolic syndrome (MetS) in general population. The aim of this study was to evaluate LAP in different PCOS phenotypes and to determine its association with MetS.

Methods

We evaluated 365 PCOS women (PCOS: $25.05 \pm 6.24 - \text{kg/m}^2$; 25.48 ± 5.21 years) diagnosed using ESHRE/ASRM criteria and 125 BMI-matched healthy women (controls: 25.41 ± 5.16 kg/m^2; 30.35 ± 5.62 years). PCOS group was divided into four phenotypes: a (anovulation (ANOV), hyperandrogenism (HA), polycystic ovary morphology (PCOM)), B (ANOV, HA), C (HA, PCOM) and D (ANOV, PCOM). MetS was defined according to NCEP ATP III definition. LAP was calculated using formula ((WC-58)$\times$triglycerides). ROC curve analysis was performed to determine associations of LAP and MetS.

Results

The prevalence of MetS in phenotypes/controls was as following: A: 20.8%, B: 27.5%, C: 17.5%, D: 5.3%, and in Controls: 6.4%. Phenotype D and Controls had lower ($P<0.05$) MetS prevalence than all other PCOS phenotypes. LAP was significantly lower ($P<0.05$) in phenotype D (19.11 ± 25.51) and Controls (25.33 ± 23.17) than in all other phenotypes (A: 35.37 ± 41.29, B: 48.74 ± 47.70, C: 32.55 ± 38.11). ROC curve analysis indentified LAP cut off value of 25.94 to be the most preferable for predicting MetS in PCOS by NCEP ATP III criteria (AUC$=0.95 \pm 0.01$ (95% CI 0.93–0.97), sensitivity: 98.5%, specificity: 76.1%). This cut off value had higher negative than positive predictive value for the whole PCOS group (99.5% vs 52%, respectively) and also for the phenotypes (A: 100% vs 54%; B: 100% vs 58%; C: 98% vs 48%; D: 100% vs 33%).

Conclusion

Lipid accumulation product represent a strong and simple surrogate marker for the diagnosing of MetS in all susceptible women with PCOS, and regarding their clinical phenotypes as well.

Restoration of fertility in hypogonadal LH receptor null background male mice by a constitutive active mutant FSH receptor

Olayiwola Oduwole[1], Hellevi Peltoketo[2], Ariel Poliandri[3], Laura Vengadabady[4] & Ilpo Huhtaniemi[1,5,]

[1]Imperial College London, London, UK; [2]Biocenter Oulu, University of Oulu, Oulu, Finland; [3]Queen Mary University of London, London; UK; [4]GlaxoSmithKline, London, UK; [5]University of Turku, Turku, Finland.

The gonadotropic hormones, LH and FSH are critical regulators of normal sexual functions including steroidogenesis and gametogenesis. Their essential role is underscored by the development of various hypogonadal phenotypes arising from genetic mutations. Constitutive activation of their cognate receptors also disturbs their function. We earlier showed that transgenic expression of an activating mouse *Fshr* mutant (*mFSHR*^{D580H}) in granulosa cells, under the anti-Müllerian hormone promoter, distorts ovarian function. Contrarily, transgenic males expressing this mutant in Sertoli cells were largely normal. To study further whether amplified FSH action affects spermatogenesis, we crossed the transgenic *Fshr* mutant males with Lhr deficient knockout (*Lhr*$^{-/-}$) mice, the homozygotes of which present with hypogonadism and infertility. The phenotype of the female litters from the crossbreeds largely mimicked those of *Lhr*$^{-/-}$ females. However, the double-mutant males presented with rescue of fertility, with normal testes size and spermatogenesis, and partially recovered seminal vesicles, but with delayed puberty, reflecting incomplete rescue of testosterone production. On attainment of full sexual maturity these mice sired litters similar to the wild-type (WT) littermates. Histologically, the testes of the adult mice partly mimicked those of *Lhr*$^{-/-}$ male mice with total absence of discernible Leydig cells in the interstitial space. In contrast, the seminiferous tubuli had normal diameter with full spermatogenesis. As expected, the Fshr, a Sertoli cell marker was upregulated in these mice, while the Leydig cell-specific genes, including Lhr and some key steroidogenic enzymes, were downregulated. Interestingly, treatment of these mice with the antiandrogen, flutamide had no effect on spermatogenesis, whereas it completely blocked spermatogenesis in the WT controls. Our findings demonstrate that excessive Fshr activation, in the absence of LH-stimulated Leydig cell function, and even without testosterone action, is able to restore and maintain spermatogenesis.

Background

During ageing, total testosterone (TT) declines and SHBG increases, resulting in a greater decline of free testosterone (FT) compared to TT. However, guidelines suggest using TT to diagnose androgen deficiency and to reserve FT only for men with borderline TT. We investigated if isolated low FT or isolated low TT was associated with androgen-related endpoints in healthy men.

Methods

3369 community-dwelling men, aged 40–79, were included. We assessed differences between men with both normal TT ($\geqq$10.5 nmol/l) and calculated FT ($\geqq$220 pmol/l) (referent), men with normal TT/low FT (group 1) and men with low TT/normal FT (group 2) by descriptive statistics and ordinal logistic regression adjusted for age, centre, BMI and comorbidities.

Results

2540 men had normal TT (18.4 ± 5.5 (mean$\pm$S.D.) nmol/l) and FT (326 ± 75 pmol/l). There were 261 men in group 1 (normal TT (14.2 ± 3.7 nmol/l), low FT (195 ± 22 pmol/l)) and 92 men in group 2 (low TT (9.6 ± 0.7 nmol/l), normal FT (247 ± 20 pmol/l)).

Compared to referent, men in group 1 were older and had higher SHBG, whereas group 2 was younger and had lower SHBG. BMI was higher in both groups. Men in group 1, but not group 2, were in poorer health and had lower haemoglobin. Regression analysis showed that men in group 1 had less frequent morning erections ($P=0.012$), more erectile dysfunction ($P<0.001$) and more physical symptoms (limited vigorous activity ($P=0.011$), walking 1 km ($P=0.026$) and bending ($P=0.005$)). Compared to referent, sexual and physical symptoms did not differ in group 2.

Conclusions
Independent of age, BMI and comorbidities, men with isolated low FT, but normal TT, have more androgen deficiency-related symptoms than men with normal TT and FT levels; whereas symptoms do not differ in men with isolated low TT. Not only total, but also FT levels should therefore be assessed in men with hypogonadal symptoms.

OC2.5

Bisphenol A-induced epithelial-mesenchymal transition was reversed with a phytoestrogen, genistein via oestrogen receptor and downregulation of transforming growth factor-beta signalling pathway

Ye-Seul Kim, Kyung-A Hwang & Kyung-Chul Choi
Laboratory of Biochemistry and Immunology, College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Epithelial–mesenchymal transition (EMT) is an important process appeared in tumour migration or progression, which is activated by 17β-estradiol (E_2). As a typical endocrine disrupting chemical (EDC), bisphenol A (BPA) has a potential to promote EMT and migration of oestrogen responsive cancers. On the contrary, genistein (GEN) as a phytoestrogen is known to have chemopreventive effects in diverse cancers. In the present study, the effects of BPA and GEN on EMT and migration of BG-1 ovarian cancer cells and the underlying mechanism were investigated. ICI 182,780, an oestrogen receptor (ER) antagonist, was co-treated with E_2 or BPA to BG-1 cells to identify the relevance of ER signalling in EMT and migration. As results, E_2 and BPA upregulated the protein expression of vimentin, cathepsin D, and MMP-2, but downregulated the protein expression of E-cadherin via ER signalling, suggesting that E_2 and BPA promoted EMT and cell migration related gene expressions. However, the increased protein expression of Vimentin, Cathepsin D, and MMP-2 by E_2 or BPA was reduced by the co-treatment of GEN. In a scratch assay, the migration capability of BG-1 cells was enhanced by E_2 and BPA via ER signalling pathway, but reversed by the co-treatment of GEN. In the protein expression of SnoN and Smad3, E_2 and BPA upregulated SnoN, a negative regulator of TGF-β signalling, and downregulated Smad3, a transcription factor in the downstream pathway of TGF-β signalling, suggesting that E_2 and BPA simultaneously lead the downregulation of TGF-β signalling in the process of induction of EMT and migration of BG-1 cells via ER signalling. On the other hand, the co-treatment of GEN reversed the down-regulation of TGF-β signalling by E_2 and BPA. Taken together, GEN suppressed EMT and migration capacities of BG-1 ovarian cancer cells enhanced by E_2 and BPA via ER signalling and the downregulation of TGF-β signalling.

Effect of GNAS transcript manipulation on human mesenchymal stem cells differentiation towards osteocyte cell lineage: insight into the pathophysiology of ectopic ossification in GNAS-related disorders

Francesca Marta Elli[1,2], Valentina Boldrin[1,2], Valentina Parazzi[3], Enrico Ragni[3], Paolo Bordogna[1,2], Anna Spada[1,2], Lorenza Lazzari[3] & Giovanna Mantovani[1,2]

Epi/genetic defects at the imprinted GNAS locus, that encodes the α subunit of the stimulatory G protein (Gsα), have been associated with a heterogeneous group of rare diseases, termed as Pseudohypoparathyroidism. Most GNAS-based disorders have the common feature of episodic *de novo* formation of heterotopic ossifications (HO) in subcutaneous tissues. The mosaic tissue distribution of HO suggests that pathogenesis involves an abnormal differentiation of precursor cells, and that GNAS defects provide a sensitized background, but the molecular mechanism is still under investigation. To date, investigations have been mainly conducted in mouse models, thus we have developed an *in vitro* human model from surgically removed samples of subcutaneous fat (adipose-derived mesenchymal stem cells, ADMSCs) to study the determinants underlying HO formation in GNAS-related diseases. The multilineage differentiation ability of ADMSCs was confirmed via biochemical assays, specific stainings and expression analysis of specific markers. We also determined the preservation of GNAS imprinting profile during cell culture and handling. Subsequently, cells were treated with siRNAs against Gsα-specific or non-specific GNAS transcripts, the efficiency of transfection (ranging from about 75% at day 4, up to about 50% at day 21) was evaluated, as well as the effect on cell differentiation toward osteoblasts. No significant differences due to different siRNA target sequences were observed. The increase of alkaline phosphatase activity reflected cell maturation and non-induced silenced cells displayed an intermediate phenotype between cells grown in control and inducing medium (Abs 405 nm at day 14: silenced $= 0.507 \pm 0.16$, control $= 0.076 \pm 0.01$, induced $= 0.861 \pm 0.13$, $P < 0.05$). Moreover, Gsα-deficient cells, although not able to completely differentiate and depose mineralized matrix, began to lay down few, interspersed and very small calcium deposits. Future experiments will expand our knowledge in molecular mechanisms underlying HO formation in GNAS-related disorders, in order to test pharmacological treatments against HO formation and progression.

The association of sclerostin serum levels with sclerostin expression in bone

Nathalie Bravenboer, Ruben Visser, Dirk Jan Mons, Angela Oostlander, Eveline Sohl, Hub van Essen, Renate de Jongh, Paul Lips, Annemieke Heijboer & Martin den Heijer
VU Medical Center, Amsterdam, The Netherlands.

Sclerostin is a major negative regulator of osteoblastic activity at tissue level. Serum sclerostin levels have been associated with bone mineral density and increased fracture risk. However, the relation between serum levels and expression on tissue levels is unknown. The aim of this study was to investigate this relationship. We used serum samples and bone biopsies from 26 patients that were available from a large randomised clinical trial, investigating with the effect of risedronate in patients with Crohn's disease and osteopenia (registered as NTR-163 Dutch Trial Register). Sclerostin expression in bone was detected using immunohistochemistry (mouse-human antibody, R&D systems). In cortical bone, sclerostin positive area was measured as a percentage from the total cortical area (NIS elements, Nikon). In trabecular bone, sclerostin expression is detected as number of positively stained osteocytes. Serum concentrations were determined by an enzyme-linked immunosorbent assay (Mesoscale discovery). We also assessed bone mineral density of the hip and lumbar spine with DEXA. Serum sclerostin was associated with the number of sclerostin positive trabecular osteocytes ($R = 0.54$, $P = 0.004$) but not with sclerostin positive area in cortical bone ($R = 0.07$, $P = 0.73$). Serum sclerostin levels and sclerostin expression in cortical bone as well as in trabecular bone showed positive correlations with bone mineral density of the spine. ($R = 0.55$, $P = 0.001$; $R = 0.38$, $P = 0.02$; $R = 0.35$, $P = 0.03$). With bone mineral density of the hip only the sclerostin positive area in cortical bone showed a correlation of 0.54 ($P = 0.0004$). We demonstrated that sclerostin levels in serum reflect the expression of sclerostin by osteocytes mostly in trabecular bone. Sclerostin expression in bone as well as sclerostin levels in serum are associated to bone mineral density, especially of the lumbar spine.

Klotho expression in long bones is critical for FGF23 production during renal failure

Jovana Kaludjerovic[1], Hirotaka Komaba[1], Tadatoshi Sato[1], Takenobu Ishii[1], Hannes Olauson[2], Tobias Larsson[2] & Beate Lanske[1]
[1]Harvard School of Dental Medicine, Boston, Massachusetts, USA; [2]Karolinska Institutet, Stockholm, Sweden.

Klotho (KL) is a type-I-membrane protein required for FGF23 to bind FGFR1 and modulate mineral ion homeostasis. Loss of either KL or FGF23 results in severe mineralisation defects. We recently found that membrane KL is expressed in osteoblasts and osteocytes, which are major sites of FGF23 syntheses. To investigate the role of bone-specific KL in mineral ion homeostasis and the progression of bone mineralisation defects in chronic kidney disease, we generated a mouse strain with limb-specific KL deletion using Prx1-Cre. No differences were seen in body weight, serum phosphate, FGF23, PTH, calcitriol or cortical bone volume between $KL^{fl/fl}$ and $Prx1\text{-}Cre;KL^{fl/fl}$ mice at 6, 16 or 24 weeks of age. However, as early as 6 weeks of age $Prx1\text{-}Cre;KL^{fl/fl}$ mice had lower trabecular bone volume and connectivity than $KL^{fl/fl}$ mice. To challenge the mice, we induced chronic kidney failure by feeding mice adenine diet for 8 weeks. At 16 weeks of age, all mice fed adenine diet had reduced body weight, kidney atrophy, high urea concentrations (80–120 pg/ml) and hyperphosphataemia, confirming the induction of renal failure. No differences in these parameters were seen between adenine fed $KL^{fl/fl}$ and $Prx1\text{-}Cre;KL^{fl/fl}$ mice. However, limbs of adenine fed $Prx1\text{-}Cre;KL^{fl/fl}$ mice did not respond with an increase in *Fgf23* mRNA expression that is characteristic of renal failure and was observed in adenine fed $KL^{fl/fl}$ mice. As such, adenine fed $Prx1\text{-}Cre;KL^{fl/fl}$ had significantly lower serum iFGF23 levels than adenine fed $KL^{fl/fl}$ mice, higher expression of renal 1α-hydroxylase, hypercalcaemia and severe kyphosis. To validate the results, findings were confirmed in 5/6 NTX $Prx1\text{-}Cre;KL^{fl/fl}$ mice. Therefore, our data is the first to show that limb-specific KL plays an important role in regulating mineral ion homeostasis and more importantly FGF23 production. This novel data suggests that Klotho expression in bone cells provides a sensor for the need of FGF23.

Introduction
It is known that patients with primary hyperparathyroidism (PHPT) have an increased cardiovascular morbidity and mortality. In our study, we aimed to investigate the cardiovascular risk factors in medically observed and operated PHPT patients.
Materials and methods
Twenty-nine medically observed (group A), 25 pre-operative (group B) and 23 post-operative (group C) patients with PHPT and 26 normocalcemic patients as control group (group D) were included to this study. Groups were assessed for flow mediated dilatation (FMD), carotid intima media thickness (CIMT), serum levels of sCD40L, hs-CRP and IL-8. Twelve patients with low levels of 25-hydroxy vitamin D (25OHD) in the medical treatment group were assessed in terms of these measurements before and 3 months after vitamin D replacement.
Results
Median FMD was 5, 5.1, 7.6 and 7.7% in groups A, B, C and D respectively. FMD measurement of group A was detected significantly lower than group C and D ($P=0.02$) and was similar with group B. FMD measurements of group B were also detected lower than group C and D but this did not reach to statistical significance. Results of CIMT measurement, serum sCD40L, IL-8 and hs-CRP levels showed no significant difference between groups. In 12 patients with low 25OHD within group A, FMD was increased to an average of 6.7% from 4.4% after vitamin D replacement ($P=0.04$).
Discussion
Endothelium-dependent vasodilatation was impaired in PHPT patients, particularly in medically treatment group, compared to control group. Vitamin D supplementation provide improvement in FMD measurements in medically followed PHPT patients with low 25OHD levels. The information that vitamin D replacement makes an improvement in endothelial dysfunction in PHPT patients with low 25OHD is a new contribution to the literature of our study.

Hypoparathyroidism is a rare endocrine deficiency due to inadequate amounts of parathyroid hormone (PTH) and is characterised by hypocalcaemia and hyperphosphataemia. Current management regimens with large amounts of oral calcium and active vitamin D do not adequately control mineral homeostasis and can lead to complications in many patients. The phase III REPLACE and RELAY clinical trials established the efficacy and safety of once-daily s.c. injection of recombinant human PTH, rhPTH(1-84). Here we present 3-year data from RACE, the open-label extension of REPLACE and RELAY. Patients received 25 or 50 μg/day rhPTH(1-84) with up-titration to 50, 75, or 100 μg/day if active vitamin D and oral calcium could be further reduced and serum calcium level remained at or above optimised baseline. Of 49 patients enrolled at 12 US centres (mean age 48 ± 10 years; 82% women; mean hypoparathyroidism duration 16 ± 12 years), 38 (78%) completed 36 months of rhPTH(1-84) as of September 30, 2014. 50% of patients (18/36) met the efficacy endpoint ($\geqq$50% reduction in oral calcium (or $\leq$500 mg/day), $\geqq$50% reduction in active vitamin D dose (or $\leq$0.25 μg/day), and albumin-corrected serum calcium $\geqq$1.87 mmol/l). Mean calcium and calcitriol doses were 2194 ± 1732 mg/day and 0.7 ± 0.4 μg/day, respectively, at baseline, and fell to 803 ± 1259 mg/day (–54%$\pm$80%) and 0.2 ± 0.3 μg/day ($-71\%\pm39\%$), respectively, at month 36. Albumin-corrected serum calcium levels were maintained (2.1 ± 0.2 mmol/l at both baseline and month 36). Serum phosphorus levels were uniformly lower than baseline (1.56 ± 0.19 mmol/l): mean change was -0.22 ± 0.29 mmol/l at month 36. Adverse events (AEs) were reported by 48 (98%) patients; most common AEs were hypocalcemia (35%), muscle spasms (29%), and nausea (27%). Serious AEs occurred in 9 (18%) patients; none were considered to be treatment related. This extension trial confirms the efficacy and safety of rhPTH(1-84) for an extended 3-year period.

Novel glucagon receptor antagonist peptides improve glycaemic control and partially protect against streptozotocin induced diabetes in mice

Finbarr O'Harte[1], Laura McShane[1,2] & Nigel Irwin[1]
[1]University of Ulster, Coleraine, N. Ireland, UK; [2]University of Central Lancashire, Lancashire, UK.

Glucagon receptor KO mice are resistant to the clinical manifestations of diabetes induced by streptozotocin (STZ) and retain normal glycaemic control and glucose tolerance. In the present study the effects of chronic (18 days) once daily i.p. administration of two different glucagon receptor antagonists (GRA); desHis[1]Pro[4]Glu[9]-glucagon (GRA-1) and its related acylated peptide desHis[1]Pro[4]Glu[9](Lys[12]PAL)-glucagon (GRA-2) were investigated in groups of male ($n=8$) high fat fed (45% fat) STZ-induced (125 mg/kg) diabetic mice. Food intake, body weight, blood glucose and plasma insulin were measured at regular intervals. At the end of the study period an oral glucose tolerance test, insulin sensitivity test and analysis of metabolic rate was performed. Terminal plasma glucagon concentrations and pancreatic insulin content were also measured. GRA-1 and GRA-2 showed no significant improvement in STZ-induced weight loss over the course of the study, however both peptides delayed STZ-induced glucose elevations ($P<0.05$) on day 3. No significant differences were found in non-fasting blood glucose on day 18 between the STZ-treated and both GRA treated groups. In comparison to STZ-treated controls (Area under curve $AUC_{0\text{-}60min}$ 749.5 ± 152.8): GRA-1 (530.2 ± 188.6) and GRA-2 (510.9 ± 184.9) significantly ($P<0.05$) improved oral glucose tolerance in STZ-induced diabetes, producing a 30% reduction in the overall glucose excursion. Both GRA-1 and GRA-2 significantly ($P<0.05$) enhanced the hypoglycaemic effects of insulin by 1.36-fold (Area above curve $AAC_{0\text{-}60min}$ 1471 ± 144.6) and 1.29-fold (1396 ± 112.8), compared with STZ-treated controls (1079 ± 165.5). Energy expenditure was also significantly increased ($P<0.001$) in both GRA treatment groups compared with STZ-treated controls. GRA-2 significantly enhanced ($P<0.001$) pancreatic insulin content (0.85 μg/g tissue) versus STZ-treated controls (0.02 μg/g; $P<0.001$). In conclusion, novel glucagon receptor antagonist peptides improved glycaemic control and partially protected against STZ-induced type 1 diabetes in mice.

Complement factor 5 deficiency leads to defective insulin receptor processing and severe systemic insulin resistance

Takuya Kikuchi, Dario A Gutierrez, Emily K Anderson-Baucum, W Reid Bolus, Merla J Hubler, Brian T Palmisano, Owen P McGuinness & Alyssa H Hasty
Vanderbilt University, Nashville, Tennessee, USA.

Activation of complement factor 5 (C5) produces the anaphylatoxin C5a and the proinflammatory cytolytic complex C5b-9. Recent studies have shown that C5a receptor (C5aR) deficiency leads to improved systemic and white adipose tissue (WAT) insulin sensitivity. This phenotype is considered to be due to the potent inflammatory potential of signalling through C5aR; however, the pleiotropic functions of C5 in inflammation and metabolism remain to be elucidated. We investigated the effect of C5 itself on systemic glucose tolerance and insulin sensitivity and found C5 to play a critical role in metabolic health. To determine the metabolic phenotype of C5 deficiency, we performed glucose tolerance tests and hyperinsulinaemic euglycaemic clamps using C5 deficient (C5D) and C5 sufficient (C5S) mice. Surprisingly, we found that C5D mice developed severe glucose intolerance and insulin resistance compared to C5S controls. Glucose uptake in muscle and WAT was lower in C5D mice. Conversely, C5S mice injected with C5a adenovirus showed improved insulin sensitivity and increased glucose uptake in muscle and WAT. We next sought to determine the mechanism for insulin resistance in C5D mice. We showed that expression and glycosylation of insulin receptor (InsR) was impaired in the liver, muscle, and WAT of C5D mice. Consequently, AKT phosphorylation following insulin stimulation was decreased in the liver of C5D mice. Insulin resistance in C5D mice was independent of obesity, inflammation, and leukocyte infiltration into WAT or liver. We tested the effect of C5 siRNA on HepG2 liver cells, which resulted in decreased total InsR protein levels and decreased insulin-stimulated AKT phosphorylation. Cumulatively, these results reveal a novel function of C5 on glucose tolerance and insulin sensitivity via InsR processing that is independent of immune cell infiltration, inflammation, and/or obesity.

Chronic, long-term administration of Vardenafil improves endothelial function and corrects hypogonadism in patients with type 2 diabetes mellitus. A longitudinal, prospective, randomized, placebo-controlled, double blind, clinical trial

Daniele Santi[1,2], Alessandro Guidi[2], Antonio Granata[2], Elisa Pignatti[3], Roberto Bozic[5], Stefano Zaza[6], Laura Roli[4], Tommaso Trenti[4], Cesare Carani[1] & Manuela Simoni[1,2]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences University of Modena and Reggio Emilia, Modena, Italy; [2]Azienda USL of Modena, Modena, Italy; [3]Center for Genomic Research University of Modena and Reggio Emilia, Modena, Italy; [4]Laboratory of clinical pathology and endocrinology, Azienda USL of Modena, Modena, Italy; [5]PerkinElmer, Milan, Italy; [6]LCMS Product Specialist. SHIMADZU Italia, Milan, Italy.

Background
Endothelial dysfunction leads to cardiovascular complications in type 2 diabetes mellitus (T2DM), through a reduction of nitric oxide (NO)-mediated relaxation. Phosphodiesterase-5 inhibitors (PDE5i) have hemodynamic effects, improving NO levels.
Aim
To investigate if long term, chronic treatment with the PDE5i Vardenafil improves systemic endothelial function in men with T2DM.
Methods
A longitudinal, prospective, investigator-started, randomized, placebo-controlled, double-blind, clinical-trial was carried out. 54 male patients affected by T2DM diagnosed within the last 5 years were enrolled. 26 and 28 patients were assigned by permuted block randomization to the verum and placebo-group, respectively. The study consisted of an enrollment phase, a treatment phase (24 weeks) (Vardenafil/placebo 10 mg twice-daily), and a follow-up phase (24 weeks). Parameters evaluated: International Index of Erectile Function (IIEF)-15, flow mediated dilation (FMD), intima media thickness (IMT), routine hematologic analyses. Serum testosterone (T) and its precursors were measured by liquid-chromatography tandem mass-spectrometry (LC-MS/MS). Gonadotropins were evaluated by ELISA.
Results
Only one serious adverse event was registered in the placebo group. The erectile function domain of IIEF-15 ($P=0.049$) improved after treatment. At the end of the treatment phase FMD significantly increased ($P=0.002$) while IMT ($P=0.003$), fibrinogen ($P=0.005$), white blood cells count ($P=0.018$) and Red cells Distribution Width ($P=0.028$) significantly decreased. FMD was significantly related to T serum levels ($P=0.002$), which significantly improved after Vardenafil treatment only in hypogonadal men ($T<10.4$ nmol/l) ($P=0.023$), without changes in gonadotropin serum levels. Smoking-habits, hypertension and glycemic control influenced the hemodynamic and inflammatory parameters.
Conclusions
This is the first double-blind, placebo-controlled clinical-trial in which T2DM men are chronically treated with Vardenafil for 6 months, and followed-up for 6 months after therapy-withdrawal. Chronically administered Vardenafil is safe and effective in T2DM patients and improves both tissue oxygenation and inflammatory markers, but this effect is lost after therapy withdrawal. For the first time, we demonstrate that chronic Vardenafil therapy improves T (measured by LC-MS/MS) in diabetic, hypogonadal men, an effect possibly due to improved microcirculation in the testis (EudraCT number 2009-014137-25).

Islet stellate cell isolated from Goto-Kakizaki rats affects β-cell function

Zilin Sun[1], Fengfei Li[1,2], Bijun Chen[1], Ling Li[1], Min Zha[1], Wei Xu[1], Shaoxia Zhou[3] & M G Bachem[3]
[1]Department of Endocrinology, Zhongda Hospital, Institute of Diabetes, Medical School, Southeast University, Nanjing, China; [2]Department of Endocrinology, Nanjing First Hospital, Nanjing Medical University, Nanjing, China; [3]Department of Clinical Chemistry, University Hospital Ulm, Ulm, Germany.

Background
Evidence suggests that pancreatic stellate cells (PSCs) are present in intra-/peri-islets in type 2 diabetes mellitus (T2DM). We isolated stellate cell from islets (ISC) of Goto-Kakizaki (GK) rats. Given these cells are intra-islets, which possibly affect the biological behavior of β-cell. This study was designed to determine the effects of ISC isolated from fibrotic islets of GK rats on β-cell function and survival.
Methods
ISC was isolated from islets of GK rats using the outgrowth method. We determined the genome-wide digital gene expression (DGE) profiles of ISC by DGE technology. Insulin-producing β-cell line were treated with ISC supernatant (SN). Then, INS-1 cell proliferation, apoptosis, and insulin production were measured.
Results
ISC grew out from cultured GK rat islets, with a triangular shape and large nucleus. These cells expressed α-smooth muscle actin (α-SMA), vimentin, and desmin. ISC genes expression was significantly overlapped with that of PSC. We also observed 1067 genes differentially expressed in ISC compared with PSC. The 5-ethynyl-2′deoxyuridine-positive INS-1 cells treated with ISC-SN were significantly decreased compared with control. Propidium iodide (PI)-positive INS-1 cells in ISC-SN groups were 2.6-fold higher than those in control groups. Caspase-3 activity was associated with increased PI-positive cells. INS-1 cells cultured with ISC-SN were significantly reduced than that in control groups.
Conclusions
ISC presented in fibrotic islet of GK rats might be a special PSC, which impaired β-cell function, proliferation and increased β-cell apoptosis.

Efficacy of mesenchymal stem cells transplantation on glycaemic profile in streptozotocin induced diabetic Wistar rat

Shobhit Bhansali, Vinod Kumar, Uma Nahar Saikia, Vivekanand Jha, Anil Bhansali & Pinaki Dutaa
PGIMER, Chandigarh, India.

Introduction
Bone marrow is an abundant source of adult stem cells that can differentiate into various cell types. Administration of mesenchymal stem cells (MSCs) in irradiated diabetic rat model has transiently shown to decrease blood glucose level. This study examines the effect of high dose and multiple injections of MSCs on glycaemic profile, their localisation and regeneration of islet in diabetic Wistar rat.
Methods
The study was carried out in male Wistar rats categorised into three groups ($n=6$, in each group); Group 1as control, group 2 STZ (50 mg/Kg) induced diabetic group and group 3 experimental group. 5-bromo-2-deoxyuridine (BrdU) labelled allogenic MSCs were injected in the non–irradiated diabetic rat of the experimental group through rat tail-vein. The blood glucose profile was subsequently monitored at regular intervals. Rats were sacrificed at day 45 and pancreas was examined for localization of BrdU labelled stem cells by immunofluorescence and islet-neogenesis by immunohistochemistry.
Results
There was a significant reduction in blood glucose level after administration of MSCs in the experimental group ($P<0.001$). The presence of BrdU labelled MSCs in islet suggested their localization in the pancreas. Co-expression of anti-BrdU and anti-insulin antibody indicated trans-differentiation/fusion into insulin producing cells evidenced by significant increase in total number of islet ($P=0.004$) and insulin positive cells ($P<0.0001$) in experimental group.
Conclusion
The MSCs administration in non-irradiated diabetic Wistar rat reduces hyperglycaemia and is accompanied by increased islet-neogenesis, possibly through trans- differentiation/fusion.

Maternal microbiota regulate glucocorticoids levels and placental development in mice

Maha Al-Asmakh[1,2], Lars Hedin[3] & Sven Pettersson[2]
[1]Qatar University, Doha, Qatar; [2]Karolinska Institute, Stockholm, Sweden; [3]Sidra Medical and Research Center, Doha, Qatar.

The gut microbiota contributes to postnatal development and maturation by influencing barrier functions of the intestinal wall, the development of the immune system, and the utilisation of nutrients. Recent studies have also implicated a role in the prenatal period since the maternal gut microbiota is altered during pregnancy with a potential role in the regulation of glucose homeostasis and protection against preterm birth. Using as a model system germ-free mice that have never encountered a live bacterium and pathogen-free mice that were reared in an environment free of monitored mouse pathogens, we demonstrated that lack of gut microbiota is associated with an altered hypothalamic-pituitary-adrenal axis (HPA) and impaired placental development. Germ-free (GF) mice displayed elevated serum glucocorticoids and reduced levels of glucocorticoid regulated insulin-like growth factor 2 (IGF2) and peroxisome proliferator-activated receptor (PPAR) β and γ compared to specific pathogen-free (SPF) dams, which correlated with an impairment of placenta development. Morphological analysis revealed reduced labyrinth size, inhibited vascularization and reduced expression of the tight junction proteins in the placenta from GF dams compared to SPF dams. Permeability test using a 1-kDa tracer showed an increased permeability in GF placental barrier. We conclude that the maternal microbiome can influence placental development and we propose that mammalian development, known to have the capacity to modulate placenta size and morphology to ensure the development of the growing offspring, is under the influence of the maternal microbiome, the forgotten organ.

Vitamin D decreases *in vitro* glucocorticoid sensitivity via down regulation of glucocorticoid receptor expression

Narjes Nasiri Ansari[1], Eliana Spilioti[1], Vasiliki Kalotychou[2], Geena Dalagiorgou[1], Paraskevi Moutsatsou[1], Athanasios Papavassiliou[1] & Eva Kassi[1,2]
[1]Laboratory of Biochemistry, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [2]National and Kapodistrian University of Athens, 1st Department of Internal Medicine, Medical School, Athens, Greece.

Introduction
Glucocorticoids (GCs) are used in the treatment of chronic inflammatory or autoimmune diseases. However, patients are often resistant to the GC effects. Response to GCs is triggered through glucocorticoid receptor (GR). An important regulator of GR activity is the *FKBP5*. FKBP5 binds to co-chaperones promoting a conformation with lower cortisol affinity. The number of GRs is another determinant of GC sensitivity; GR expression is regulated by the nuclear receptor co-repressor-1 (NCoR-1). An anti-inflammatory/immunomodulatory role of $1,25(OH)_2D_3$ has been demonstrated. We aimed to investigate the effect of $1,25(OH)_2D_3$ on the *in vitro* GC sensitivity.
Participants and methods
PBMCs were isolated from eight healthy women and incubated with dexamethasone for the last 48 h, with or without pre-incubation with $1,25(OH)_2D_3$ for 11 days. Co-incubation experiments with dexamethasone and $1,25(OH)_2D_3$ were also performed. *In vitro* GC sensitivity was assessed with dexamethasone-induced effects on GILZ mRNA expression (real-time PCR). FKBP5 and NCoR1 mRNA expression as well as GRα mRNA and protein expression (western blot analysis) were assessed. Intracellular distribution of GR was visualised by IF.

Results
After 11 days of culture, incubation of PBMCs with dexamethasone for the last 48-h resulted in 12-fold increase in GILZ-mRNA levels. When PBMCs were pre-incubated with $1,25(OH)_2D_3$, dexamethasone (last 48-h) induced a significant down-regulation of GILZ mRNA expression. When PBMCs were pre-treated with $1,25(OH)_2D_3$ for 11 days, dexamethasone (last 48-h) caused a significant down-regulation of GRα mRNA expression, confirmed at protein level. Treatment of PBMCs with $1,25(OH)_2D_3$, led to significant decrease in FKBP5 and NCoR1 mRNA levels. IF staining showed that vitamin D causes a GR translocation from nucleus to cytoplasm.
Conclusion
$1,25(OH)_2D_3$ decreased the *in vitro* glucocorticoid sensitivity in PBMCs isolated from healthy women. This effect is, at least in part, attributed to the reduction of GRα expression due to a mechanism that did not appear to implicate NCoR1 or FKBP5 expression. Moreover a $1,25(OH)_2D_3$-induced GR translocation from nucleus to cytoplasm is also involved. The mechanism through which vitamin D modulates response to glucocorticoids remains to be fully delineated.

Activators of AMP-activated protein kinase regulate adipocyte aldosterone secretion and mineralocorticoid receptor signalling
Anna White, Aurelie Nguyen Dinh Cat, Augusto Montezano, Ian Salt & Rhian Touyz
Institute of Cardiovascular and Medical Sciences, University of Glasgow, Glasgow, UK.

The increasing global prevalence of obesity requires urgent intervention to limit the anticipated surge of associated cardiometabolic morbidity and mortality. The energy sensor AMP-activated protein kinase (AMPK) is one proposed target for treating metabolic disorders and is downregulated in adipose tissue of obese insulin resistant individuals. Given the strong relationship between metabolic syndrome and overactivity of the renin-angiotensin-aldosterone system (RAAS) we investigated the role of AMPK in regulating adipocyte RAAS and mineralocorticoid receptor (MR) signalling. In vitro studies were carried out using differentiated 3T3-L1 (mouse) and SW872 (human) adipocytes. AMPK activators AICAR (1 mM) and A769662 (300 μM) were applied for 8 or 24 h. RT-PCR, immunoblotting and ELISA were used to assess effects on components of the renin-angiotensin-aldosterone system. Angiotensinogen, angiotensin II type 2 receptor and mineralocorticoid receptor mRNA levels were upregulated in differentiated adipocytes compared to undifferentiated fibroblasts. Aldosterone secretion by 3T3-L1 adipocytes and SW872 adipocytes was increased by 8 h of incubation with AICAR or A769662 respectively. Expression of Steroidogenic Acute Regulatory (StAR) mRNA was upregulated in accordance with aldosterone secretion along with associated down-regulation of MR mRNA and protein. Furthermore, we examined downstream MR targets serum and glucocorticoid-regulated kinase 1 (SGK1) and Lipocalin 2 which were both upregulated despite decreased MR. Interestingly, cells which produced aldosterone in response to AMPK activators exhibited a severe down-regulation of AMPK protein levels by 24 h. These data suggest that AMPK acts to control RAAS activity in adipocytes. We hypothesise that prolonged AMPK hyperactivation *in vitro* results in AMPK depletion allowing aldosterone secretion with subsequent increase in MR signalling. The upregulation of RAAS previously reported in obesity may be partially explained by the downregulation of AMPK related to excess nutrition.

Adipose tissue-specific androgen generation fuels an adverse metabolic phenotype in patients with polycystic ovary syndrome
Michael O'Reilly[1], Punith Kempegowda[1], Laura Gathercole[2], Angela Taylor[1], Iwona Bujalska[1], Jeremy Tomlinson[2] & Wiebke Arlt[1]
[1]University of Birmingham, Birmingham, UK; [2]University of Oxford, Oxford, UK.

Insulin resistance and androgen excess are the cardinal features of polycystic ovary syndrome (PCOS). The severity of hyperandrogenism and metabolic dysfunction in PCOS are closely correlated, but underlying mechanisms remain poorly understood. Aldoketoreductase type 1C3 (*AKR1C3*) is an important source of adipose androgen generation, activating androstenedione to testosterone (T). We postulated that *AKR1C3* plays a critical role linking androgen metabolism and metabolic phenotype in PCOS.
We undertook *in vivo* deep phenotyping in ten women with PCOS and ten age/BMI-matched controls. Patients underwent oral challenge with 100mg of the androgen precursor dehydroepiandrosterone, with serum sampling every 30 min for 4 h and concomitant adipose microdialysis. Serum and adipose microdialysate androgens were measured by LC/MS. In complementary *ex vivo* and *in vivo* studies, we investigated adipose androgen generation, employing primary cultures of human adipocytes and the preadipocyte cell line SGBS. The impact of androgens upon adipose lipid metabolism was assessed through measurement of *de novo* lipogenesis, free fatty acid uptake (FFA) and β-oxidation.
After oral DHEA, area under the curve for serum T was higher in PCOS patients than controls, suggesting enhanced *AKR1C3* activity. 5α-dihydrotestosterone (DHT) was detectable in adipose interstitial fluid and was higher in PCOS than controls. Adipose interstitial glycerol levels were reduced in PCOS patients. Subcutaneous adipose *AKR1C3* mRNA expression correlated strongly with BMI. In human adipocytes, insulin up-regulated *AKR1C3* expression and activity, while T increased *de novo* lipogenesis; both T and DHT increased FFA uptake and suppressed β-oxidation.
Here we provide integrated *in vivo, ex vivo*, and *in vitro* evidence that hyperinsulinaemia may drive adipose androgen generation through increased *AKR1C3* expression and activity. This may have consequences for adipocyte function by driving lipid accumulation. Resultant adipocyte hypertrophy in PCOS could lead to increased insulin resistance, fuelling a vicious circle of hyperinsulinaemia, adipose androgen generation and increased lipid accumulation.

Pituitary hormone secretion profiles in IGSF1 deficiency syndrome
Sjoerd Joustra[1], Ferdinand Roelfsema[1], Erik Endert[2], Bart Ballieux[1], Paul van Trotsenburg[2], Eric Fliers[2], Noortje Corssmit[1], Daniel Bernard[3], Wilma Oostdijk[1], Jan-Maarten Wit[1], Alberto Pereira[1] & Nienke Biermasz[1]
[1]Leiden University Medical Center, Leiden, The Netherlands; [2]Academic Medical Center, Amsterdam, The Netherlands; [3]McGill University, Montréal, Canada.

Context
Loss-of-function of immunoglobulin superfamily 1 (*IGSF1*) causes an X-linked syndrome of central hypothyroidism, macroorchidism, and variable prolactin deficiency, GH deficiency in childhood, delayed pubertal testosterone rise, and/or obesity. The clinical features advert towards a pivotal role for IGSF1 in the pituitary gland, but detailed knowledge on pituitary hormone secretion in this syndrome is lacking.
Objective
To study detailed 24 h spontaneous pituitary hormone secretion in patients with the IGSF1 deficiency syndrome.
Methods
We performed a 24 h sampling study with measurements every 10 min in eight IGSF1 deficient patients. Deconvolution, modified cosinor, and approximate entropy (ApEn) analyses were applied to quantify TSH, prolactin, and gonadotropin secretion rates, diurnal rhythmicity, and regularity of hormone release. Results were compared to matched healthy controls or (for TSH) patients with subclinical primary hypothyroidism (SCH).
Results
Compared to both healthy controls and SCH, IGSF1 deficient patients showed decreased pulsatile secretion of TSH with decreased disorderliness and absence of diurnal variation. Basal and pulsatile secretion of FSH was increased, while LH secretion was not different from healthy controls. For prolactin secretion, two phenotypes were observed, with absence of prolactin secretion in some and increased basal and total prolactin secretion in others.
Conclusion
The TSH secretion pattern is consistent with the previously proposed hypothesis of defective TRH signalling in IGSF1 deficiency, which is further supported by a decreased TSH response to TRH in patients, and the decreased expression of pituitary *Trhr* mRNA in *IGSF1* knock-out mice. However, the increased FSH and prolactin secretion, but normal LH secretion, in combination with the delayed puberty despite normal testicular growth, have been observed in untreated primary hypothyroidism, and provoke some novel hypotheses.

3,5-T2 might play a crucial role in the rodent heart

Julika Lietzow[1], Priyavathi Dhandapani[1], Wenke Jonas[2] & Josef Köhrle[1]
[1]Institut für experimentelle Endokrinologie, Charité – Universitätsmedizin Berlin, Berlin, Germany; [2]Department of Experimental Diabetology, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, Germany.

The endogenous thyroid hormone metabolite 3,5-diiodothyronine (3,5-T2) has attracted attention as a metabolically active substance modulating metabolism via classical thyroid hormone (TH) receptor-dependent and rapid plasma membrane, cytosolic and mitochondrial signaling pathways. Accordingly, 3,5-T2 has been proposed as a potential hypolipidaemic agent without inducing thyromimetic effects and is frequently used as illicit weight-reducing agent. The objective of the present study was to investigate 3,5-T2 effects on energy and lipid metabolism in a mouse model of diet-induced obesity. Adult male mice received either 3,5-T2 (2.5 μg/g bw) or saline i.p. over 28 days. Contrary to our expectations the heart weight strongly increased by 26 percent with 3,5-T2 treatment. Because only limited data are currently available about 3,5-T2 effects on heart, we started to investigate the potential role of 3,5-T2 in cardiac remodeling and hypertrophy. The results in 3,5-T2 exposed heart tissue indicate that 3,5-T2 modulates expression of TH responsive cardiac genes. The gene expression of Ca^{++}-ATPase (*Serca2a2*) was significantly increased while protein and gene expression of the Ca^{++}-ATPase inhibitor phospholamban was decreased. Interestingly, 3,5-T2 application enhanced transcript concentration of myosin heavy chain β (*Myh7*) and of the brain natriuretic peptide (*Nppb*) and reduced the mRNA concentration of TH receptor alpha (*Thra*) indicating a potential role of 3,5-T2 in activation of a cardiac fetal gene program and involvement of non-classical TH signaling pathways. To understand the molecular basis and to identify possible mechanisms we used the cardiomyocyte cell line H9c2. LC-MS/MS data reveal a preferential uptake of 3,5-T2 compared to classical thyroid hormones. Moreover, first findings in differentiated cardiomyoblasts show that 3,5-T2 (100nM) increased the gene expression of Ca^{++}-ATPase and β-MHC comparable to the in vivo data. In conclusion, our results suggest that 3,5-T2 treatment in mice alters expression of cardiac genes and might exert profound possibly adverse cardiac and cardiovascular effects.

Biological activity of novel thyroid hormone analogues: role of Na+ taurocholate cotransporting polypeptide in liver selectivity

Giulia Brigante[1,2], Bo Carlsson[3], Simone Kersseboom[4], Robin P Peeters[4] & Theo J Visser[4]
[1]Unit of Endocrinology and Metabolism, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Department of Medicine, Endocrinology and Metabolism and Geriatrics, Azienda AUSL of Modena, NOCSAE, Modena, Italy; [3]Karo Bio AB, Huddinge, Sweden; [4]Erasmus Medical Center, Rotterdam, The Netherlands.

Background
The interest in the potential effect of thyromimetics in lowering serum cholesterol is growing. Thyroid hormone actions on lipid metabolism are exerted in the liver and mediated by the T3 receptor TRβ1. The creation of molecules transported into hepatocytes by liver-specific transporters can increase the liver selectivity of thyromimetics. Sodium taurocholate co-transporting polypeptide (NTCP), a solute carrier protein primarily expressed on the basolateral membrane of hepatocytes, is particularly interesting.
Objectives
The role of NTCP in the liver preferential uptake of a series of new thyromimetics was analysed.
Methods
The compounds to test (KB141, KB5588, KB6628, KB6823, KB3488, KB3493, KB3495, KB4933, KB4956, KB5035, KB5160, KB5359, KB5525, KB5526, KB5866, KB6594, KB8038) were synthesised at Karo Bio AB. To explore the effect of NTCP on the nuclear availability of each compound, COS1 cells were co-transfected with TRβ1, NTCP, a construct coding for a TRE-dependent luciferase reporter and a control renilla reporter. Two days after transfection, cells were incubated for 24 h with 0.1–1000 nM of each compound. Incubation with the same concentrations of T3 was added as a control. The luciferase/renilla ratio was the measure of the compound transcriptional activity.
Results
Like T3, KB141, KB5588, KB3488 and KB6823 demonstrated no differences in transcriptional activity in the absence or presence of NTCP. KB6628, KB5035, KB5866, KB5160 and KB4956 showed a 1.5-fold higher activity in cells transfected with NTCP compared to cells transfected with empty pcDNA3 vector. KB3493, KB3495, KB5359, KB5525, KB5526, KB4933, KB6594 and KB8038 showed an even greater difference as they had no activity in the absence of NTCP and a fourfold higher activity in the presence of NTCP.
Conclusions
NTCP is an attractive transporter to target thyromimetics to the liver.

Different TSH suppressive effects of liothyronine combination according to Thr92Ala type 2 deiodinase polymorphism

Dong Yeob Shin, Kwang Joon Kim, Jiyeon An & Eun Jig Lee
Division of Endocrinology and Metabolism, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.

Introduction
Type 2 deiodinase (D2) catalyses intracellular T_3 production in several human tissues including pituitary gland, hence occupying an important role in the feedback regulation of TSH secretion. Although several previous researches have shown that Thr92Ala D2 polymorphism with decreased D2 enzymatic activity influences the levothyroxine dose requirement and the set point of the hypothalamus–pituitary–thyroid axis for postoperative TSH suppressive therapy in thyroid cancer patients, the clinical implications of D2 polymorphism and liothyronine replacement in thyroid cancer patients are still unknown.
Methods
The effect of liothyronine combination on TSH suppression according to Thr92Ala D2 polymorphism in 40 papillary thyroid cancer patients (20 males and 20 females; age 46.6±10.9 years, range 20–66) who were persistently unable to repress the serum TSH levels to less than 0.1 μIU/ml for at least 3 months despite the daily 2.0 μg/kg intake of levothyroxine were analysed. Total thyroidectomy with central compartment neck dissection and postoperative radioactive iodine ablation was performed in all patients at least a mean of 48.8±35.8 months before this study.
Results
In these patients, a decreased of mean TSH level was observed in all patients after 3 months of 12.5 μg liothyronine add on with 50 μg reduction of levothyroxine (3.18 vs 0.28 μIU/ml, $P=0.002$). After liothyronine combination, serum T_3 and free T_4 levels became more comparable to preoperative levels. Of the 40 patients, Ala/Ala homozygous genotype was observed in eight patients (20%), while WT and heterozygous type were observed in 15 (37.5%) and 17 (42.5%) patients, respectively. Preoperative serum free T_4 level was lower in Ala/Ala homozygous patients (0.98 vs 1.28 ng/dl, $P=0.006$). Ala/Ala homozygous patients displayed higher ratio of TSH level before and after liothyronine combination compared with patients carrying the Thr92 variant (X/Thr patients) (133.9±178.6 vs 25.5±41.5, $P=0.003$).
Conclusion
Thr92Ala D2 polymorphism is associated with liothyronine-dependent TSH suppressive intensity in athyreotic individuals. Thr92Ala D2 polymorphism analysis will be beneficial in predicting the effect of T_3 combination in thyroid cancer patients that are unable to achieve a full TSH suppression from levothyroxine mono-therapy.

The usefulness of determining the presence of BRAF (V600E) mutation in fine needle aspiration cytology of thyroid nodules cells

Aldona Kowalska[1], Janusz Kopczynski[2], Artur Kowalik[3], Danuta Gasior-Perczak[1], Iwona Palyga[1], Katarzyna Lizis-Kolus[1], Dariusz Waligorski[1], Dorta Szyska-Skrobot[1], Agnieszka Walczyk[1], Stefan Hurej[1], Agnieszka Chil[2], Renata Chodurska[3], Malgorzata Chlopek[3], Elzbieta Wypiorkiewicz[3], Ewelina Nowak[3] & Stanislaw Gozdz[4]
[1]Department of Endocrinology, Kielce, Poland; [2]Department of Neoplasm Pathology, Kielce, Poland; [3]Department of Molecular Diagnostics, Kielce, Poland; [4]Chemotherapy Clinic, Kielce, Poland.

Introduction
Fine needle aspiration cytology (FNACC) is the basic tool used in the diagnosis of thyroid cancer (TC) in nodular goitre. FNACC does not allow for the

establishment of a clear diagnosis in 15–30% of cases (mainly follicular lesions). Molecular biology techniques can be useful, allowing for the detection, in FNACC smears, of the known mutations involved in the oncogenesis.
Aim
To evaluate the usefulness of the detection of the BRAF mutation in FNAC in the early diagnosis of TC.
Material and methods
The study involved 1590 consecutive patients examined for 2 years and 2290 FNACC were performed. The FNAC results were classified according to the Bethesda system. In the case of the cytological results group 3,4,5 the molecular analysis was performed in order to detect BRAF mutation using the combination of Sanger sequencing, ASA-PCR and qPCR techniques. All the patients with BRAF mutation were operated on.
Results
Out of 2290 FNACC in groups 3,4,5 there were classified 106,29,12 respectively. Molecular analysis showed the presence of the BRAF mutation in a total of 12 cases (8.2%): three positive cytopathological results out of 106- in group 3; 0 out of 29 in group 4, and 9 positive out of 12- in group 5. Histopathological studies confirmed the presence of PTC in all the 12 patients with BRAF mutation present.
Conclusions
The presence of BRAF mutation in FNACC material is always associated with the presence of PTC, however from the clinical point of view the confirmation of the presence of mutations is of little help in early diagnosis. Revealing the BRAF mutation has resulted in a change of procedure only in the case of three patients, with cytological group 3, in the remaining nine cases from group 5 – the cytology procedure was enough to indicate those patients eligible for surgery.

Search for new candidate genes in RET mutation-negative families with hereditary medullary thyroid carcinoma using next generation sequencing

Eliska Vaclavikova[1], Sarka Dvorakova[1], Vlasta Sykorova[1], Josef Vcelak[1], Tereza Halkova[1], Petr Vlcek[2] & Bela Bendlova[1]
[1]Institute of Endocrinology, Dept. of Molecular Endocrinology, Prague, Czech Republic; [2]2nd Faculty of Medicine in Charles University and University Hospital Motol, Dept. of Nuclear Medicine and Endocrinology, Prague, Czech Republic.

Introduction
Hereditary medullary thyroid carcinoma (MTC) is associated with only one major cause – germline mutations in the *RET* proto-oncogene. The most of tested families with MTC is related to specific *RET* mutation, however, very small number of families left unresolved without the causing inherited mutation. New techniques of next generation sequencing give hope in finding the new candidate genes that could be involved in the pathogenesis of these MTC families.
Methods
We performed *RET* genetic screening in 870 individuals – 490 patients and 380 at-risk-relatives. The germline *RET* mutation was detected in 58 families (83% of familial and 7% of apparently sporadic MTCs). No mutation in all *RET* exons was found in six families with clinically supposed hereditary form of MTC (4 FMTC and 2 MEN2A phenotype). Six index patients of these families were analyzed using Trusight Cancer Sequencing Panel (Illumina) that targeted 94 genes associated with cancer. After exclusion of common single nucleotide polymorphisms, the data were focused on novel or rare non-synonymous variants in coding sequences and tested *in silico* (SIFT, PolyPhen) for possible damaging effect.
Results
Several promising variants in each patient have been identified in genes involved in key processes for cancer development such as repair genes. Considering SIFT and PolyPhen evaluation, the analysis has discovered very rare variants in genes *RHBDF2*, *XPA*, *MET* and *CHEK2*. The variants detected in *APC* and *EZH2* were previously investigated in association with other cancers. Three patients have a pathogenic polymorphism in *HNF1A*.
Conclusion
New candidate genes can represent genetic modifying factors or crucial genes in each family. Although detected alterations are promising, it is necessary to verify them in other affected family members.

Genetic screening of regulatory regions of pituitary transcription factors among patients with idiopathic pituitary hormone deficiencies

Joyce Schuilwerve[1], Melitza Elizabeth[1], Robin Peeters[1], Theo Visser[1], Anita Hokken-Koelega[2,3] & Laura de Graaff[1,3]
[1]Erasmus Medical Center, Rotterdam, The Netherlands; [2]Erasmus MC Sophia, Rotterdam, The Netherlands; [3]Growth Research Foundation, Rotterdam, The Netherlands.

Introduction
POU1F1 is a pituitary transcription factor, critical for differentiation of pituitary somatotrophs, thyrotrophs and lactotrophs. *POU1F1* expression depends on the presence of PROP1, which attenuates expression of transcriptional repressor *HESX1*. Previous mutation screening of *POU1F1* coding exons in our cohort of patients with combined pituitary hormone deficiency (CPHD) showed *POU1F1* mutations in only 1% of the families. We hypothesised that defects in the regulatory region of *POU1F1* might explain the phenotype of CPHD.
Patients and methods
We screened the regulatory regions of *POU1F1*, as well as those of *PROP1* and *HESX1* among 87 patients with CPHD (62M/25F). Since patients with *HESX1* mutations can initially present with IGHD only, we also screened 92 patients with IGHD (64M/28F). We compared genotype frequencies in our CPHD cohort with those found in controls from the 1000 genomes project and we studied *PROP1* and *POU1F1* promoter SNPs in relation to phenotypic data.
Results
We found a new variant in the *POU1F1* promoter. We are currently performing promoter-luciferase reporter assays, since *in silico* analysis of the new variant showed potential effects on promoter activity by creating a new binding site for several transcription factors. In addition, we found two known SNPs in the *POU1F1* promoter and six known SNPs in the *PROP1* promoter. We did not find any variant in the *HESX1* promoter. Rs148607624, a three nucleotide deletion in the *PROP1* promoter which has previously been associated with CPHD, showed a relation with IGF1 levels in our CPHD patients.
Conclusion
We screened the regulating regions of pituitary transcription factors *POU1F1, PROP1* and *HESX1* in our cohort of CPHD patients and found a new variant in the *POU1F1* promoter region. We will present detailed phenotypic data of the patient carrying the new variant. We will show the impact of the new variant on *POU1F1* promoter activity.

KLF4 in hypothalamus regulates leptin homeostatic effects through AgRP

Estrella Sanchez-Rebordelo[1], Monica Imbernon[1,3], Rosalia Gallego[2], Marina Gandara[2], Pamela Lear[1], Miguel Lopez[1,3], Carlos Dieguez[1,3] & Ruben Nogueiras[1,3]
[1]Department of Physiology of Santiago de Compostela, Instituto de Investigación Sanitaria, Santiago de Compostela, Spain; [2]Department of Morphological Sciences, School of Medicine, Insitituto de Investigación Sanitaria, University of Santiago de Compostela, Santiago de Compostela, Spain; [3]CIBER Fisiopatología de la Ovesidad y Nutrición (CIBERobn), Santiago de Compostela, Spain.

Introduction
Krüpel-like factor 4 (KLF4) is a zinc-finger-type transcription factor expressed in a range of tissues that plays multiple functions. KLF4 is expressed in neural stem cells and is critical to neuronal differentiation. Recent evidence suggests that KLF4 also plays an important role in the central regulation of energy balance. *In vitro* studies show that KLF4 is a transcriptional regulator of agouti–related protein (AgRP), essential to the hyperphagic response.
Description of methods/design
Sprague Dawley rats, WT and ob/ob mice. Stereotaxic microinjection of adenoviral and lentiviral expression vectors. Body composition, locomotor activity and indirect calorimetry. Leptin central pathway studies. Leptin sensitivity assays. Immunohistochemistry. Western blotting. Liver trygliceride content.
Results
We report that hypothalamic KLF4 represents a new transcription factor specifically modulating agouti-related protein (AgRP) expression *in vivo*.

Hypothalamic KLF4 colocalises with AgRP neurons and is modulated by nutritional status and leptin. Over-expression of KLF4 in the hypothalamic arcuato nucleus (ARC) induces food intake and increases body weight through the specific stimulation of AgRP, as well as blunting leptin sensitivity in lean rats independent of forkhead box protein 01 (FoxO1). Down-regulation of KLF4 in the ARC inhibits fasting-induced food intake in both lean and diet-induced obese (DIO) rats. Silencing KLF4, however, does not, on its own, enhance peripheral leptin sensitivity in DIO rats.

Conclusion

i) Hypothalamic KLF4 is regulated by leptin through both STAT3 and PI3K signalling pathways. ii) KLF4 over-expression in the ARC is sufficient to increase food intake and to blunt the anorectic action of leptin in a FoxO1-independent manner. iii) Leptin fails to inhibit hypothalamic KLF4 expression in DIO rats, while KLF4 does not on its own regulate HFD-induced peripheral leptin resistance.

Maternal distress associates with placental genes regulating foetal glucocorticoid exposure and IGF2: role of obesity and sex

Theresia Mina[1,4], Katri Räikkönen[2], Simon Riley[3,4], Jane Norman[3,4] & Rebecca Reynolds[1,4]

[1]Queen's Medical Research Institute, BHF Centre for Cardiovascular Sciences, University of Edinburgh, Edinburgh, UK; [2]Institute of Behavioral Sciences, University of Helsinki, Helsinki, Finland; [3]Queen's Medical Research Institute, MRC Centre for Reproductive Health, University of Edinburgh, Edinburgh, UK; [4]Queen's Medical Research Institute, Tommy's Centre for Maternal and Fetal Health, University of Edinburgh, Edinburgh, UK.

Introduction

Maternal distress, including poorer life satisfaction, increased anxiety and depression (A&D) symptoms, are worse in Severely Obese (SO) than lean pregnancy and may alter placental genes regulating foetal glucocorticoid exposure and placental growth. We hypothesised that the associations between increased maternal distress with changes in placental mRNA levels leading to a reduced placental barrier to maternal glucocorticoids, and altered placental IGF2, are more pronounced in SO pregnancy. We also considered any sex-specific effects.

Methods

Placental mRNA levels of genes regulating glucocorticoids including 11β-HSDs, NR3C1, NR3C2, ABC transporters, mTOR and IGF2 family were measured in term placental samples from 43 lean (BMI $\leq 25\ kg/m^2$) and 50 SO (BMI $\geqq 40\ kg/m^2$) women, in whom A&D symptoms were prospectively evaluated during pregnancy.

Results

The mRNA levels of genes with a similar role in regulating foetal glucocorticoid exposure were strongly inter-correlated (all $0.2 \leq \leq 0.7$, $P \leq 0.05$). Increased A&D symptoms associated with increased NR3C2 and IGF2 in both lean and SO group (all ≤ 0.3, $P \leq 0.05$). Increased maternal distress was associated with higher ABCB1 and ABCG2 mRNA levels in SO but lower ABCB1 and higher 11β-HSD1 mRNA levels in lean (all $P \leq 0.05$) suggesting a protective adaptive response in SO placentas. Increased maternal distress associated with reduced mRNA levels of ABCB1, ABCG2, 11β-HSD2, NR3C1and IGF2 in female placentas (all ≤ 0.29, $P \leq 0.05$), but not in males.

Conclusion

The observed sex differences in placental responses suggest greater vulnerability of female foetuses to maternal mood with potentially greater fetal glucocorticoid exposure and excess IGF2. Further studies are needed to test whether this translates to potentially greater negative outcomes of maternal distress in females in early childhood.

RF-amide-related peptide-3 (RFRP-3), the mammalian orthologue of the avian gonadotropin-inhibiting hormone (GnIH), has been proposed as major inhibitory signal for the reproductive axis, acting via the NPFF1 receptor (NPFF1R). In addition, RFRP-3 has been recently suggested to modulate feeding, with reported orexigenic actions; a function that might contribute to the integrative control of energy homeostasis and reproduction. However, characterisation of the metabolic effects of RFRP-3/GnIH signalling remains superficial and largely restricted to few pharmacological studies. As a means to address the putative physiological roles of GnIH/RFRP-3 signalling in the control of metabolic homeostasis, we report here the metabolic phenotyping of the first mouse line with constitutive inactivation of NPFF1R. Congenital elimination of NPFF1R did not alter adult body weight (BW) neither affected BW responses to high fat diet (HFD) in males. In contrast, NPFF1R null female mice tended to be slightly heavier and displayed exaggerated BW increases in response to obesogenic insults, such as HFD or ovariectomy. Conversely, NPFF1R KO males, but not females, fed on HFD showed perturbed glycaemic responses in glucose tolerance tests, even though basal glucose and insulin concentrations were not significantly different from WT levels. In addition, the patterns of food intake were affected in NPFF1R KOs of both sexes, with modest decreases in acute food intake and altered responses to leptin and ghrelin; feeding suppression following leptin administration was exaggerated in NPFF1R null mice, while the orexigenic responses to ghrelin were partially blunted in the absence of NPFF1R signalling. In sum, we provide herein the metabolic characterization of a mouse model of congenital elimination of the canonical receptor for GnIH/RFRP-3. While our data are compatible with a (modest) role of GnRH/RFRP-3 as orexigenic factor that mediates part of the effects of ghrelin on food intake, our study is the first to disclose the deleterious impact of the lack of NPFF1R signalling on BW and glucose homeostasis, which exaggerates the metabolic impact of concurrent obesogenic insults, such as HFD, in a sexually dimorphic manner.

Not so giants: mice lacking both somatostatin and cortistatin have high GH levels, but show no changes in growth rate or IGF-I levels

Raúl M Luque[1], Manuel D Gahete[1], Sergio Pedraza-Arévalo[1], Ana I Pozo-Salas[1], Fernando L-López[1], Luis de Lecea[3], José Córdoba-Chacón[1,2] & Justo P Castaño[1]

[1]Department of Cell Biology, Physiology and Immunology, Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Hospital Universitario Reina Sofía, University of Córdoba, Campus de Excelen, Córdoba, Spain; [2]Research and Development Division, Section of Endocrinology, Diabetes and Metabolism, Department of Medicine, Jesse Brown Veteran Affairs Medical Center, University of Illinois at Chicago, Chicago, Illinois, USA; [3]Department of Psychiatry and Behavioral Sciences, Stanford University, Stanford, California, USA.

Somatostatin (SST) and cortistatin (CORT) are two highly related neuropeptides involved in the regulation of several endocrine secretions. In particular, SST and CORT are two primary negative regulators of GH secretion. Consequently, SST or CORT knockout (KO) mice exhibit elevated GH levels; however, this does not lead to increased IGF-I levels or somatic growth, which has been suggested that

could be due to a compensatory mechanism between both peptides. In order to test this hypothesis, this study was designed to explore, for the first time, the consequences of simultaneously deleting endogenous SST and CORT by generating a double SST/CORT KO mouse model and exploring its endocrine and metabolic phenotype. Our results demonstrate that simultaneous deletion of SST and CORT induces a drastic elevation of endogenous GH levels, which, surprisingly, does not lead to increased growth rate or IGF-I levels, suggesting the existence of additional factors/systems that, in the absence of endogenous SST and CORT, could counteract GH-actions. Notably, elevation in circulating GH levels are not accompanied by changes in pituitary GH expression or by alterations in the expression of its main regulators (GHRH and ghrelin) or their receptors (GHRH-R, GHS-R or SST/CORT receptors) at the hypothalamic or pituitary level. However, although double SST/CORT KO male mice exhibit normal glucose and insulin levels, they have improved insulin sensitivity compared to control mice. Therefore, these results suggest the existence of an intricate interplay among the known (SST/CORT), and likely unknown, inhibitory components of the GH/IGF-I axis to regulate somatic growth and glucose/insulin homeostasis.

A role for vault particles as a marker for therapeutic effects against endocrine tumours

Constanze Hantel & Felix Beuschlein
Endocrine Research Unit, Medizinische Klinik and Poliklinik IV, Ludwig-Maximilians-University, Munich, Germany.

The vault complex, consisting of a major vault protein (MVP), two minor vault proteins (VPARP and TEP1) and small untranslated RNA molecules (vault RNAs 1–4), is considered the largest intracellular ribonucleoprotein particle. Although in recent years, vaults were believed to be involved in multidrug resistance, the exact function of this complex has remained unclear. Recently, we investigated the therapeutic applicability of a Tumour-Vascular-Disrupting Agent (ASA) in preclinical models for neuroendocrine tumours of the gastroenteropancreatic system (BON) and adrenocortical carcinoma (NCIh295R). Upon treatment we detected highly significant anti-tumoural effects in BON xenografts which were not evident in NCI-H295R. In an attempt to explain differences in therapeutic responsiveness, gene expression patterns within these tumours were investigated by a gene array. Subsequent analyses identified vault RNAs 1–3 as the most pronounced regulated transcripts in the tumour model showing therapeutic responsiveness. Quantitative real time PCR confirmed these results for ASA treated BON tumours (% of 100% controls; vault1: $2468.1 \pm 367\%$, $P<0.001$; vault2: $1922.5 \pm 235\%$, $P<0.001$; vault3: $901.3 \pm 119\%$, $P<0.001$) while no changes were detectable for the not-responding NCI-H295R-xenografts (% of 100% controls; vault1: $224.1 \pm 84\%$, $P>0.05$; vault2: $113 \pm 23\%$, $P>0.05$; vault3: $89 \pm 14\%$, $P>0.05$). Subsequently, we investigated NCI-H295R-xenografts which had been treated with two different chemotherapeutic regimens (EDP-M and LEDP-M). In this therapeutic setting treatment-dependent upregulation of vault RNAs could also be detected in NCI-H295R-tumors (% of 100% controls; vault1: EDP-M $296.3 \pm 44\%$, $P<0.001$; LEDP-M $243.5 \pm 16\%$, $P<0.001$; vault2: EDP-M $157.2 \pm 20\%$, $P>0.05$; LEDP-M $160.7 \pm 20\%$, $P>0.05$; vault3: EDP-M $241.2 \pm 55\%$, $P<0.001$; LEDP-M $118.9 \pm 16\%$, $P>0.05$). Further *in vitro* analyses revealed dynamic changes in vault RNA expression also upon blasticidin, doxorubicin, mitotane treatment and a significant increase in MVP protein levels upon TNF alpha treatment in BON cells. In summary, further investigation and modulation of vault particles might have potential to improve efficacy of anticancer drugs in endocrine tumours.

Role of microenvironment on neuroblastoma SK-N-AS SDHB silenced cell metabolism and function

Elena Rapizzi[1], Rossella Fucci[1], Elisa Giannoni[2], Letizia Canu[1], Susan Richter[3], Paolo Cirri[2] & Massimo Mannelli[1,4]
[1]Endocrinology Unit, Department Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; [2]Biochemistry Unit, Department Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; [3]Institute of Clinical Chemistry and Laboratory Medicine, Technische Universität Dresden, University Hospital Carl Gustav Carus, Dresden, Germany; [4]Istituto Toscano Tumori, Florence, Italy.

Solid tumours are very complex tissues comprising not only cancer cells, but also non-malignant stromal cells such as endothelial cells, fibroblasts, immune cells and extracellular matrix, forming the so called tumour microenvironment. In the last few years, it has become more and more evident the pivotal role of the tumour microenvironment in modulating cancer progression and metastasis. Tumour microenvironment has thus become a potential therapeutic target. To obtain an experimental model resembling the *in vivo* conditions of the succinate dehydrogenase B subunit (SDHB)-mutated paragangliomas (PGL), we evaluated the effects of SDHB silencing on metabolism and proliferation in the human neuroblastoma cell line (SK-N-AS), cultured alone or in association with human fibroblasts. Silencing, verified by Western Blot and densitometry analysis, caused a 70% decrease in protein expression, an almost complete loss of the complex specific enzymatic activity and a significant increase in HIF1α and HIF2α expression, thus resembling the *in vivo* tumor cell phenotype. When compared to wild type SK-N-AS cells, SDHB silenced cells showed an altered metabolism characterised by an unexpected significant decrease in glucose uptake and by an increase of lactate uptake. Moreover, silenced cells showed a significant increase in cell proliferation and metalloproteinase activity. When co-cultured with human fibroblasts, control cells showed a significant decrease in glucose uptake and a significant increase in cell proliferation vs their mono-cultured counterparts. These effects were even more strikingly evident in co-cultured silenced cells which showed a 70% decrease in glucose uptake and a 92% increase in cell proliferation vs their mono-cultured counterparts. Our data demonstrate, for the first time, that SDHB impairment causes a metabolic and functional derangement of neural crest-derived tumour cells and that microenvironment, here represented by fibroblasts, strongly affects their tumour metabolism and growth capacity.

We previously described aberrant expression of microRNAs belonging to the chromosome 19 cluster (C19MC) and the close miR-371-373 cluster in two-thirds of parathyroid carcinomas (PCas). Therefore, we investigated the involvement of the miR-371-373 cluster in parathyroid tumours, where miR-372 was the most consistently upregulated. miR-372 is known to be highly expressed in human

embryonic stem cells and definitely downregulated upon differentiation. Moreover, miR-372 promotes human somatic cell reprogramming. miR-372 was expressed at high levels (more than fourfold) in 48 out of 79 parathyroid tumours compared with the expression levels in normal parathyroid glands ($n=5$). miR-372 was expressed in more than 75% of both atypical parathyroid adenomas (PAds; $n=18$; 5.9 ± 0.8-fold, $P=0.003$) and PCas ($n=15$; 5.1 ± 1.1-fold, $P=0.01$) at levels significantly higher than those in typical PAds ($n=46$; 2.1 ± 0.7-fold). miR-372 overexpression in HEK293 and MCF7 cells significantly downregulated mRNA and protein levels of the cyclin inhibitor kinase CDKN1A/p21 and of the large tumour suppressor kinase 2 (LATS2). Similarly, *CDKN1A* and *LATS2* mRNA levels were significantly downregulated by the miR-372 overexpression in typical PAds-derived cells. miR-372 overexpression attenuated the Go/G1 checkpoint in the cell cycle, reducing the proportion of cells in the Go/G1 phase from 70 to 59%. Furthermore, miR-372 has been related with the 'stemness' Wnt/β-catenin signalling pathways. In 16 typical PAds we found that miR-372 levels were positively correlated with the nuclear β-catenin accumulation, investigated by western blot, and with the mRNA levels of the direct gene target of nuclear β-catenin transcriptional activity *AXIN2*. Nonetheless, in typical PAds-derived cells ($n=6$) miR-372 expression levels were not affected by lithium chloride-induced nuclear β-catenin accumulation. In conclusion, i) miR372 was aberrantly expressed in a subset of parathyroid tumours; ii) atypical PAds and PCas expressed miR-372 more frequently and at higher levels than typical PAds; iii) *CDKN1A/p21* and *LATS2* were targets of miR-372 inhibitory effects in PAds-derived cells; iv) miR-372 aberrant expression might impair Wnt/β-catenin pathway in parathyroid tumour cells.

The effects of peptides with oestrogen-like activity on cell proliferation and on energy metabolism in human derived tumour cell lines

Dalia Somjen[1], Sara Katzburg[1], Batya Gayer[2], Roni Kasher[3], Forune Kohen[2], Orli Sharon[1] & Naftali Stern[1]
[1]Institute of Endocrinology, Tel-Aviv Medical Center and the Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv 64239, Israel; [2]Department of Biological Regulation, The Weizmann Institute of Science, Rehovot 76100, Israel; [3]Department of Desalination and Water Treatment, Zuckerberg Institute for Water Research, The Blaustein Institutes for Desert Research, Ben-Gurion University of the Negev, Sede-Boqer Campus 84990, Israel.

Oestradiol-17β regulates diverse tissues and cells, both within and outside the reproductive system including human cancer cells. Currently used ERs agonists or antagonists are synthetic compounds prepared by structure modifications. Alternatively, peptide mimics of steroids would allow preparation of biased combinatorial libraries of chemical and biological origin, from which estrogenic peptides with tissue selective profiles can be selected. The phage-display peptide library may offer a suitable way to obtain peptides that mimic E2 biological activity. These libraries are diverse collections of random peptides displayed on the surface of filamentous phages, which can be screened for binding to a target molecule, such as an antibody or receptor. These combinatorial peptide libraries have not been used to isolate peptides that mimic the activity of organic compounds such as steroids. Here we report the development of peptides with oestrogen-like activity. We employed a novel approach utilizing a monoclonal antibody against oestradiol (mAb E2-15) to screen a 15-mer phage-display peptide library and to affinity select phage that interacted with mAb E2-15. Synthesis of such peptides resulted in the identification of a 15-mer linear peptide which interacted specifically with mAb E2-15. Incorporation of flanking -residues at the N-terminus and the C-terminus of the peptide, resulted with peptides recognized specifically mAb E2-15 and ERα. The peptides A44 (KAWFFE), A45 (KRAFFE), EMP-1 (VSWFFE), EMP-2, and cyclic peptide (23mer) stimulated DNA and CK in 'endocrine' and 'non-endocrine' human cancer cell lines. In ovarian cancer A2780, only EMP1 and EMP2 induced CK whereas 23mer inhibited it. In prostate cancer C4-24 CK was induced by all peptides tested. In colon cancer 320D, CK was induced by all except EMP2 and in adrenal carcinoma H295R all peptides except EMP1 stimulated CK. In A2780 DNA was stimulated by EMP1 and EMP2 but inhibited by A44 and mer23. In C4-24 and in 320D all peptides except EMP2 stimulated DNA. In H295R DNA synthesis was stimulated by all peptides except EMP1. All cells tested expressed ERα, ERβ and VDR to different levels. These mRNAs were variably affected by oestrogens. In conclusion, some of these peptides can be lead compounds for the effects on human cancer cells and might be targets for chemical modifications leading to development of inhibitors of growth of these cancer cells.

Oestrogen receptor α promotes prostate cancer progression through dual actions in both epithelia and stroma

Mitchell Lawrence[1], Ruth Pidsley[2], Stuart Ellem[1], Luc Furic[1], Shalima Nair[2], Hugh French[2], Aaron Stratham[2], Ola Larsson[3], Mark Frydenberg[1], John Pedersen[5], Grant Buchanan[4], Renea Taylor[1], Susan Clark[2] & Gail Risbridger[1]
[1]Monash University, Melbourne, Victoria, Australia; [2]Garvan Insitute of Medical Research, Sydney, New South Wales, Australia; [3]Karolinska institutet, Stockholm, Sweden; [4]University of Adelaide, Adelaide, South Australia, Australia; [5]Tissupath Pathology Services, Melbourne, Victoria, Australia.

In human prostate, Oestrogen receptor α (ERα) expression in the epithelium increases with tumour Grade and promotes proliferation involving classical genomic and rapid non-genomic signalling, as well as transcription regulation of non-coding RNA. Similarly, in the tumour stroma there is up-regulation of ERα, corresponding with declining AR, resulting in a higher ratio of ERα:AR with increasing Grade. Additionally, in prostate cancer-associated fibroblasts (CAFs) we reported an oestrogen-regulated gene expression signature and showed CXCL12 (SDF-1) was the most highly over-expressed gene. Functional assays showed that the CXCL12 secreted by CAFs recruits mast cells via CXCR4, with mast cells in turn expressing ERα, activated by oestrogen, and exhibiting altered pro-inflammatory chemokine/cytokine expression in response to oestrogen. To identify the mechanism regulating oestrogen gene expression in stroma, we examined patient-matched CAFs and normal prostate fibroblasts (NPFs) from prostatectomy specimens from a cohort of ten patients. We observed hypomethylation of the promoter of ESR1 gene (encoding ERα), which correlated with a higher ERα mRNA abundance in CAFs vs NPFs. To investigate if there was evidence of a broader role of epigenetic gene regulation, we used whole genome bisulphite sequencing to compile the first complete epigenome map of the human prostate tumour stroma. In addition to ESR1, there were >300 differentially methylated regions, including global hypomethylation and focal hypermethylation, in CAFs vs NPFs. Collectively, these data demonstrate that epigenomic changes in tumour stroma are a mechanism underlying the enduring functional differences between NPFs and CAFs. This includes epigenetically-regulated genes, such as ESR1, that are implicated in prostate cancer progression. These results warrant similar studies to determine if ERα is epigenetically regulated in epithelia, especially in advanced prostate cancer.

Effects of dexamethasone and adrenocorticotropin on circulating microRNA expression in humans

Ivan Igaz[1], Gabor Nyiro[2], Zoltan Nagy[3], Pal Perge[3], Miklos Toth[3], Karoly Racz[2,3], Peter Igaz[3] & Attila Patocs[4]
[1]Szent Imre Teaching Hospital, Budapest, Hungary; [2]Molecular Medicine Research Group, Hungarian Academy of Sciences and Semmelweis University, Budapest, Hungary; [3]Semmelweis University, Budapest, Hungary; [4]'Lendulet-2013' Hereditary Endocrine Tumors Research Group, Budapest, Hungary.

Objective
MicroRNAs are short non-protein coding RNA molecules involved in the regulation of numerous homeostatic processes via modulating gene expression. There are some data that the expression of microRNA might be modulated by hormones, but the interaction of hormones and circulating microRNAs of adrenocortical origin is mostly unknown.
Methods
The expression of six selected circulating microRNAs (hsa-miR-27a, hsa-miR-125b-2, hsa-miR-200b, hsa-miR-214, hsa-miR-483-5p, hsa-miR-503) was studied in plasma samples of ten individuals examined by 1 mg dexamethasone suppression test and another ten individuals stimulated by 250 μg tetracosactide (adrenocorticotropin). Total RNA was isolated from plasma samples and microRNA expression has been analysed by Taqman RT-qPCR normalized to cel-miR-39 as reference. The expression of hsa-miR-27a was also studied *in vitro* in NCI-H295R adrenocortical cell line.
Results
From the six circulating microRNAs selected for the *in vivo* study based on literature data showing their association to adrenocortical cancer or their responsiveness to hormonal stimuli in animal models, only circulating hsa-miR-27a proved to be significantly modulated *in vivo*: its expression was up-regulated by dexamethasone whereas it was suppressed by adrenocorticotropin. Expression of secreted *hsa-miR-27a* was significantly induced in culture supernatants of NCI-H295R cells, as well.
Conclusions
hsa-miR-27a expression is modulated by hormones of the hypothalamic-pituitary-adrenal axis both *in vitro* and *in vivo*. Dexamethasone induced secreted hsa-miR-27a both *in vitro* and circulating hsa-miR-27a *in vivo*. The expression of circulating hsa-miR-483-5p proposed as diagnostic marker for adrenocortical malignancy was not affected by dexamethasone or tetracosactide administration supporting its usefulness for the evaluation of malignancy of adrenocortical lesions.

Alternative pathway synthesis dominates androgen production in patients with congenital adrenal hyperplasia and is decreased by Chronocort® more than by conventional glucocorticoid therapy

Christopher Jones[1], Ashwini Mallappa[2], Nicole Reisch[3], Beverley Hughes[1], Donna O'Neil[1], Nils Krone[1], Martin Whitaker[4], David Eckland[4], Deborah Merke[2], Richard Ross[4,5] & Wiebke Arlt[1]

Suppression of excess androgen production poses a considerable clinical challenge in the management of patients with congenital adrenal hyperplasia (CAH). Whilst the major route of androgen synthesis in humans is the classic pathway via androstenedione and testosterone, the relative contribution of the alternative pathway originating from 17-hydroxyprogesterone to androgen excess in CAH has not been defined. Androgen effects of both pathways are elicited in androgen target tissues by the action of the most potent androgen receptor agonist, 5alpha-dihydrotestosterone (DHT). Here we carried out urinary steroid metabolome profiling by gas chromatography/mass spectrometry in conjunction with serum steroid analysis and clinical phenotyping in patients with CAH due to 21-hydroxylase deficiency. Our aim was to determine the extent to which the alternative androgen synthesis pathway contributes to DHT production in CAH and to examine the potentially differential impact of conventional and modified delayed glucocorticoid therapy.
In a cross-sectional study we analysed 24 h-urinary steroid excretion in 40 patients with CAH on conventional glucocorticoid replacement with hydrocortisone ($n=12$), prednisolone ($n=23$) and dexamethasone ($n=5$) in comparison to 80 sex- and age-matched healthy controls. CAH patients had significantly higher excretion of 5alpha-17HP, the signature metabolite of the alternative pathway, representing 0.97% of the 5alpha-reduced androgen pool in healthy controls, but 15.12% in patients with CAH. In an interventional study we treated 16 adults with classic CAH (eight females; age 29 ± 13 years; 12 salt-wasting, four simple virilising) with Chronocort, a modified and delayed release hydrocortisone preparation that mimics the physiological diurnal secretion profile of cortisol. Twenty-four hour urinary steroid excretion was analysed at baseline on conventional glucocorticoid therapy and after six months of Chronocort. Results revealed that Chronocort significantly reduced both the absolute amount and the relative percentage of 5a17HP (conventional HC 21.5% vs Chronocort 12.3%), concurrently exerting improved biochemical control with regard to overall and 5alpha-reduced androgen output.

Modelling the salivary cortisone to serum cortisol inter-relationship to predict serum cortisol under physiological conditions and after hydrocortisone

Miguel Debono[1], Robert Harrison[1], Brian Keevil[2], Martin Whitaker[3], Dena Digweed[3], Wiebke Arlt[3,4] & Richard Ross[1,3]
[1]University of Sheffield, Sheffield, UK; [2]University of Manchester, Manchester, UK; [3]Diurnal Limited, Cardiff, UK; [4]University of Birmingham, Birmingham, UK.

Introduction
Measuring serum cortisol to evaluate the normal circadian rhythm and adequacy of hydrocortisone replacement levels requires multiple readings; an expensive, cumbersome process. Conversely, salivary cortisone, a surrogate marker for free cortisol levels is non-invasive and well suited for out-patient settings. We hypothesised that salivary cortisone predicts circulating cortisol levels and can be used as an alternative marker of serum cortisol in a physiological setting or in patients on hydrocortisone replacement.
Methods
This was an observational study in 14 healthy male volunteers who had hourly serum cortisol measurements over 24 h in addition to salivary cortisol and cortisone measurements from 1500 h to 2200 h and from 0700 h to 1500 h; all measurements were carried out by liquid chromatography/tandem mass spectrometry. Relationships between serum and salivary cortisol/cortisone were assessed by individual correlation analysis and linear mixed effects modelling. A similar analysis was carried out after 20mg of oral and i.v. hydrocortisone given on different days after dexamethasone suppression.
Results
Correlation analysis (ρ), for the relationship between endogenous log-transformed salivary cortisone or salivary cortisol with serum cortisol rhythm, ranged from 0.96 to 0.99; $P<0.001$ and from 0.84 to 0.99; $P<0.001$, respectively. Salivary cortisone was superior to salivary cortisol (range R^2: 0.93–0.99 vs 0.71–0.97) in predicting circulating, serum cortisol. By fitting a mixed effects model to predict serum cortisol levels from salivary cortisone (predicted serum cortisol (nmol/l) = (13.57 + individual-specific random effects) × salivary cortisone (nmol/l)) correlation ρ and R^2 between measured and predicted serum cortisol were 0.91 and 0.82 under physiological conditions, 0.89 and 0.66 for 20 mg oral hydrocortisone and 0.93 and 0.72 for 20 mg i.v. hydrocortisone, respectively.
Conclusion
Salivary cortisone levels are strongly related to serum cortisol and repetitive measurements of salivary cortisone may be used to predict the serum cortisol rhythm and cortisol levels after hydrocortisone.

More than 2.5-fold increased risk for adrenal crises in patients with Addison's disease and the autoimmune polyglandular syndrome compared with secondary adrenal failure: German health insurance data 2010–2013

Gesine Meyer[1], Klaus Badenhoop[1] & Roland Linder[2]
[1]Division of Endocrinology, Department of Medicine 1, Goethe-University-Hospital Frankfurt, Frankfurt, Germany; [2]WINEG, Scientific Institute of the TK for Benefit and Efficiency in Health Care, Hamburg, Germany.

Introduction
Adrenal crises are potentially life-threatening complications in patients with adrenal insufficiency (AI). Our objective was to investigate the frequency of adrenal crises in patients with different forms of AI in the Techniker Krankenkasse (TK), one of the largest German Health Insurance providers, covering more than 12% of the German population.
Design
The Statutory Health Insurance (SHI) database of the TK was analysed for diagnostic codes over an observation period from 01.01.2010 to 31.12.2013. Adjusting data for age and sex, $n=11691$ diagnoses of AI were recorded and classified in primary ($n=4231$), respectively secondary ($n=7460$) AI. Additionally, the subgroup with autoimmune polyglandular syndrome (APS) comprising AI was defined ($n=1487$). A query for ICD-code E27.2 (adrenal crisis) was performed in these cohorts.
Results
In our cohort, we found a prevalence of 222/million for secondary and 126/million for primary AI. Adrenal crises were documented with a frequency of 4.8/100 patient years. Crises were significantly more frequent in patients with primary (7.6/100 patient years) compared to those with secondary AI (3.2/100 patient years; $P<0.0001$). Prevalence of crises was higher in individuals with APS comprising primary AI (10.9/100 patient years) and highest in patients with primary AI and type 1 diabetes (12.5/100 patient years).
Conclusions
Applying the SHI database of the TK, comprising more than 8 million individuals, we identified profound data about the risk of adrenal crises in different groups of patients with AI. For the first time our data confirm and extend the clinical observation, that patients with primary AI and additional autoimmune endocrinopathies are at highest risk for adrenal crises. Approximately one of eight patients with primary AI and type 1 diabetes suffers from an adrenal crisis per year. These data provide a basis for specific targeting of efforts aiming at the prevention of adrenal crises.

The Notch ligand Jagged1 is up-regulated in adrenocortical carcinomas and is associated with a favourable clinical outcome

Cristina Ronchi[1], Silviu Sbiera[1], Barbara Altieri[1], Sonja Steinhauer[1], Vanessa Wild[2], Michaela Bekteshi[1], Matthias Kroiss[1], Martin Fassnacht[1] & Bruno Allolio[1]
[1]Endocrine and Diabetes Unit, University Hospital Wuerzburg, Wuerzburg, Germany; [2]Institute of Pathology, University of Wuerzburg, Wuerzburg, Germany.

Background
Adrenocortical tumours consist of frequent adrenocortical adenomas (ACA) and highly malignant (ACC) with a still incompletely understood pathogenesis. Dysregulation of Notch signalling pathway is implicated in several cancers with oncogenic or tumour suppressor functions. Copy number gains and over-expression of Jagged1**,** a ligand of Notch receptor, was reported in ACC. The aim of the study was to evaluate the expression of Jagged1 and other Notch-related factors in adrenocortical tumors and to correlate it with clinical outcome.
Material and methods
mRNA expression of JAG1, NOTCH1, CTNNB1, and selected target genes of Notch signalling (HES1, HES5 and HEY2) and Wnt/β-catenin pathway (LEF1) was evaluated in 80 fresh frozen samples (28 normal adrenal glands=NAG, 24 ACA, 28 ACC) by quantitative real-time PCR. Immunohistochemistry was performed in 221 tissues on paraffin slides (16 NAG, 27 ACA, 178 ACC) for Jagged1, activated Notch1 (aNotch1) and HEY2 staining. The relationship with nuclear β-catenin expression was also investigated.
Results
mRNA expression of JAG1, NOTCH1, CTNNB1, and target genes was not significantly different between normal and neoplastic adrenal glands. At protein level, all factors evaluated were highly expressed (*H*-score 2–3) in a larger proportion of ACCs than in ACAs and NAG (Jagged1 in 27, 15 and 10% of NA, respectively, $P=0.0004$; aNotch1 in 13%, 8% and none of NAG, $P<0.0001$; HEY2 in 66, 61 and 33%, $P=0.0001$). High Jagged1 expression was associated with earlier ENSAT tumour stages ($P=0.07$) and lower number of metastases ($P=0.08$) in ACC. Accordingly, high Jagged1 levels impacted favourably on overall survival ($n=168$, 131 vs 30 months, $P=0.0023$, HR=0.45) and progression free survival (37 vs 9 months, $P=0.0023$, HR=0.51), even after adjustment for ENSAT tumour stage ($P=0.005$) and nuclear β-catenin expression ($P=0.009$).
Conclusion
Jagged1 is overexpressed in a subgroup of ACCs, being associated with a more differentiated phenotype and better clinical outcome. Notch1 signaling pathway activation might be involved in adrenocortical tumor progression, but still needs to be better investigated.

Resistin negatively regulates neuronal adiponectin signalling through the down regulation of APPL1 and adiponectin receptors

Yacir Benomar[1,2], Arieh Gertler[3] & Mohammed Taouis[1,2]
[1]Molecular Neuroendocrinology of Food Intake, UMR9197, University Paris Sud, Orsay, France; [2]Molecular Neuroendocrinology of Food Intake, Neuroscience Paris-Saclay Institute, CNRS UMR 9197, University Paris Sud, Orsay, France; [3]Faculty of Agricultural, Food and Environmental Quality Sciences, The Institute of Biochemistry, Food Science, and Nutrition, The Hebrew University of Jerusalem, Rehovot, Israel.

Obesity is linked to common metabolic diseases including insulin resistance, which constitutes a principal risk factor for type 2 diabetes. Increasing evidence indicates that changes in adipose-secreted factors in obesity, dramatically affect insulin sensitivity. Among these adipokines, resistin is described as a key factor in obesity-mediated both inflammation and insulin resistance. However, little is known about the molecular mechanisms mediating resistin effects particularly at the neuronal level. Recently, we have shown that central resistin acts by way of hypothalamic TLR4 receptors promoting overall inflammation and insulin resistance. Adiponectin is another adipokine with anti-diabetic and insulin sensitizing properties. A decrease in adiponectin level and action has been linked to insulin resistance. Here, we aim to investigate whether resistin could contribute to insulin resistance trough the impairment of adiponectin action. To test this hypothesis we examined the impact of resistin overexposure on adiponectin signaling in human neuronal cells SH-SY5Y. Interestingly, we show that resistin treatment completely abolished adiponectin-dependent Akt phosphorylation whereas ERK1/2 was not affected. Importantly, resistin treated SH-SY5Y cells showed a marked down-regulation of adiponectin receptor (AdipoR1) and APPL1, a critical mediator of both adiponectin and insulin signaling. This has been confirmed *in vivo*. Indeed, in Wistar rats, chronic ICV resistin infusion (14 days) markedly reduced hypothalamic expression of APPL1 AdipoR1 and AdipoR2. Furthermore, to assess whether resistin action on adiponectin signalling is mediated by TLR4, we generated TLR4-depleted SH-SY5Y cells. Interestingly, the knock-down of TLR4 completely abrogates the resistin-dependent down regulation of AdipoR1 and APPL1 and totally restablished adiponectin-dependent phosphorylation of AKT. Collectively, these results indicate that resistin-dependent activation of TLR4 promotes the down regulation of APPL-1 and adiponectin receptors leading to the alteration of adiponectin signalling. This could contribute, at least in part, to the impairment of the insulin-sensitizing effect of adiponectin at the neuronal level.

Odontella aurita-enriched high-fat diet prevents high-fat diet induced insulin resistance

Hamza Amine[1,2], Yacir Benomar[1,2], Nadia Meskini[3] & Mohammed Taouis[1,2]
[1]Neuroendocrinologie Moléculaire de la Prise Alimentaire, University of Paris-Sud, UMR 9197, Orsay, France; [2]Neuroendocrinologie Moléculaire de la Prise Alimentaire, Neuroscience Paris Saclay Institute, CNRS UMR 9197, Orsay, France; [3]Nutrition, Environment and Health Laboratory, University Hassan II, Casablanca, Morocco.

Omega-3 polyunsaturated fatty acids modulate the risk factors for metabolic syndrome via multiple mechanisms. However, their underlying mechanisms on insulin resistance and type 2 diabetes are still unknown. Here, we report that Odontella aurita, a microalga rich in the omega-3 polyunsaturated fatty acid eicosapentaenoic acid (EPA), prevents high saturated fat diet induced insulin resistance and inflammation in the liver of Wistar rats. High fat diet (HFD), given for 8 weeks, increased plasma insulin levels associated with the down-regulation of insulin receptor (IR) and the impairment of insulin-dependent IR phosphorylation. Furthermore, HFD increased toll-like receptor 4 (TLR4) expressions. Indeed, we have recently reported that TLR4 is implicated in resistin-induced inflammation and insulin resistance in the hypothalamus.[1] We also show that TLR-4 up-regulation is concomitant with the activation of c-Jun N-terminal kinase (JNK) and p38 mitogen-activated protein kinase (p38). Importantly, Odontella aurita enriched HFD (HFOA, 12%) normalized body weight and plasma insulin levels, and restores IR expression at both protein and mRNA levels. In addition, HFAO improves insulin responsiveness as estimated by *in vitro* phosphorylation of hepatic plasma membrane IR. Furthermore, HFOA decreased TLR4 expression and JNK/p38 phosphorylation. In conclusion, we demonstrate, for the first time to our knowledge, that omega-3 fatty acids brought by Ondontella aurita overcomes HFD-induced insulin resistance through the inhibition of TLR4/JNK/p38 MAP kinase signaling pathways.

The thyroid hormones antagonize TGFβ responses suppressing fibrosis

Elvira Alonso-Merino[1], Rosa M Martín Orozco[1], Lidia Ruiz Llorente[1], Olaia Martínez-Iglesias[1], Juan P Velasco-Martín[2], Luisa F Fanjul-Rodríguez[1], Javier Regadera[2] & Ana Aranda[1]
[1]Instituto de Investigaciones Biomédicas Alberto Sols CSIC-UAM, Madrid, Spain; [2]Departamento de Anatomía, Histología y Neurociencia, Facultad de Medicina, UAM, Madrid, Spain.

Fibrosis represents a major health concern and presently has no successful treatment. Chronic liver fibrosis leads to portal hypertension, cirrhosis, hepatocellular carcinoma and liver failure. Transforming growth factor β (TGFβ), the main profibrogenic factor, mediates its actions mainly through activation of Smad transcription factors. We have previously observed a cross-talk between the thyroid hormone receptors (TRs) and the TGFβ pathway by which the thyroid hormone-bound TRs can antagonize TGFβ-mediated responses. Here, we demonstrate the functional importance of this antagonism *in vivo* using a mouse model of hepatic fibrosis induced by CCl4, a widely used hepatotoxic agent. In normal mice, acute treatment (48 h) with CCl4 caused significant necrosis with nuclei loss of hepatocytes surrounding centrilobular veins, while this was not observed in hyperthyroid mice. Concomitantly, induction of Smad2 phosphorylation in response to CCl4 was markedly blunted in the hyperthyroid animals, showing that the thyroid hormones reduce activation of the TGFβ pathway *in vivo*. Moreover, after chronic exposure to CCl4, the hyperthyroid animals developed a less severe liver fibrosis, with less Collagen 1 deposition and significantly reduced expression of α-SMA, the main marker of myofibroblast activation. The mRNA levels of *Col1a1*, *Col1a2* and *α-Sma* in response to CCl4 were also lower in the hyperthyroid mice. Furthermore, fibrosis appeared spontaneously in livers of 18-month-old mice in which TRs have been genetically ablated, thus implicating these receptors as physiological negative regulators of the fibrotic response *in vivo* in this organ. These finding define a novel function of the thyroid hormone receptors, and suggest that development of novel TR ligands capable of disrupting TGFβ/SMAD activity could constitute a novel therapeutic approach to block the progression of fibrotic diseases.

Hospital Universitario Ramón y Cajal, Madrid, Spain.

Nuclear corepressor 1 (NCoR) associates with nuclear receptors and other transcription factors leading to transcriptional repression. Genomic studies have shown the presence of inactivating mutations of the *NCoR* gene in human tumours and we have found that NCoR depletion with siRNA in hepatocarcinoma SK-hep1 cells enhances invasion, tumour growth and metastasis in nude mice, while expression of the thyroid hormone receptor β (TRβ) increases NCoR levels, repressing tumorigenesis. We have now analysed human hepatocarcinomas, finding that NCoR expression is significantly downregulated and that there is a good correlation with TRβ in the tumours, indicating the relevance of these observations in the patients. Strikingly, up to one month after siNCoR transfection, *NCoR* mRNA was still depleted in cells and tumours. This long-term depletion cannot be explained by DNA methylation of the regulatory CpG island of the *NCoR* promoter. In contrast, in chromatin immunoprecipitation (ChIP) assays we found increased recruitment of the corepressor SMRT and histone deacetylase 3 (HDAC3), as well as increase of the repressive histone marks H3K9me3 and H3K27me3. H3K9 methylation led to recruitment of the heterochromatin protein HP1γ, local heterochromatinisation, and exclusion of the stimulatory transcription factor SP1 from the promoter. Treatment of silenced cells with TSA, a HDAC inhibitor, caused *NCoR* gene re-expression, demonstrating the important role of histone deacetylation in long-term silencing of the *NCoR* gene. In conclusion, our data define NCoR as a potent tumour suppressor and as a potential therapeutic target in hepatocarcinomas. Our results also suggest that in the absence of *NCoR* mutations, a reduction of NCoR levels at a given point in time could be propagated for several generations to the daughter cells, enhancing their tumourigenic, invasive and metastatic capacity and contributing to tumour progression.

A genome-wide shRNA screen to identify genes regulating ERα signalling and oestrogen-dependent proliferation in breast cancer cells

Justyna Kulpa[1], Xiaofeng Wang[3], David Laperrière[1,2], Karine Audette[1,2], Jean Duchaine[1,2] & Sylvie Mader[1,2]
[1]Institute for Research in Immunology and Cancer, Montreal, Quebec, Canada; [2]Universite de Montreal, Montreal, Quebec, Canada; [3]Institute de Recherche Clinique de Montreal, Montreal, Quebec, Canada.

Over 70% of breast tumours express oestrogen receptor alpha (ERa). Stimulation with oestradiol results in receptor binding to oestrogen response elements (ERE)

in target gene regulatory sequences in association with transcription cofactors, and altered gene expression, resulting in proliferation and tumour growth. Our study aimed to systematically identify genes contributing to ER signalling and oestrogen-dependent proliferation in breast cancer. A genome-wide screen for genes affecting ER signalling was undertaken using a human ER(+) luminal breast cancer cell line (T47DKBLuc) stably expressing a luciferase reporter downstream of three EREs. Stimulation with oestradiol results in a profound increase in luciferase reporter expression, which can be consistently knocked down with shER. Using the Mission shRNA lentiviral library, three shRNA clones were produced for each of >16 000 genes. Following four days of lentiviral infection and oestradiol stimulation, reporter cells were screened for luciferase activity. Primary screening identified 1033 genes (double-hits; 60% cut-off) regulating luciferase reporter expression. We also identified 62 genes (double-hits, 25% cut-off) directly affecting cellular growth. Our hit list includes both known and potentially novel regulators of ER signalling and/or expression. A subset of 614 genes was selected for confirmatory and counter-screening using oestrogen-sensitive (T47DKBLuc, MCF7-ERE-Luc) and insensitive control (T47D-ARE-Luc and MCF7-ARE-Luc; antioxidant response reporter) cells, as well as for assessment of cell proliferation. Using Ingenuity Pathway Analysis (IPA) we confirmed that our screen identified many genes known to be involved in the canonical ER-signalling pathway. In addition, we identified genes involved in other canonical pathways including G-protein coupled receptor signalling, PI3K signalling, and signalling by nuclear receptors glucocorticoid receptor (GR) and androgen receptor (AR), amongst others. This study provides a wealth of data that will give insight into important factors affecting ER biology and proliferation of ER(+) tumours, and reveals potential targets for the treatment of this subclass of breast cancer.

Obesity

OC11.1

Central resitin infusion impairs FGF21/FGFR1/β-Klotho hypothalamic expression and promotes peripheral FGF21 resistance: involvement of resistin/TLR4 signalling pathway

Yacir Benomar[1,2], Hamza Amine[1,2], Arieh Gertler[3] & Mohammed Taouis[1,2]
[1]Molecular Neuroendocrinology of Food Intake, UMR 9197, University Paris Sud, Orsay, France; [2]Molecular Neuroendocrinology of Food Intake, Neuroscience Paris-Saclay Institute, CNRS UMR 9197, University Paris Sud, Orsay, France; [3]Faculty of Agricultural, Food and Environmental Quality Sciences, The Institute of Biochemistry, Food Science, and Nutrition, The Hebrew University of Jerusalem, Rehovot, Israel.

FGF21 has recently emerged as a major regulator of metabolism and energy utilisation. FGF21 administration confers multiple metabolic benefits on insulin sensitivity, blood glucose, lipid profile and body weight in rodents and primates. FGF21 acts through a receptor complex consisting of FGF receptors (FGFR 1, 2, 3 or 4) and a co-receptor βKlotho (KLB), crucially required for FGF21 signaling. Although FGFRs are widely expressed, KLB is predominantly expressed in adipose tissue, liver, and hypothalamus making these as primary sites of FGF21 action. In obesity, circulating levels of FGF21 are elevated, and the expected beneficial effects of endogenous FGF21 are impaired suggesting an FGF21 resistance state. However, the precise pathways whereby obesity induces FGF21 resistance remain unknown. In this study, we aim to investigate whether central resistin/TLR4 pathways could contribute to FGF21 resistance. To test this hypothesis, we assessed, in C57BL6 mice and Wistar rats, the impact of ICV resistin infusion on the expression of FGF21 and its receptor components in the hypothalamus and key peripheral insulin target tissues. Here we show that ICV resistin significantly decreased hypothalamic FGF21 expression in both mice and rats. Interestingly, the expression of FGFR1, the most abundant receptor in the hypothalamus, and KLB were also markedly reduced. Similar results were obtained in resistin treated SH-SY5Y neuronal cells. In rat peripheral tissue, ICV resistin increases the expression of FGF21 in both liver and WAT, and markedly reduced WAT expression of FGFR1 and KLB. Importantly, the knockdown of TLR-4 in SH-SY5Y cells almost completely abolished resistin-dependent down regulation of FGFR1 and KLB. Collectively, these findings indicates that central resistin, by a way of TLR4, down-regulates FGF21, FGFR1 and KLB in the hypothalamus and promotes peripheral FGF21 resistance as mirrored by the overexpression of FGF21 in the liver and WAT and the down-regulation of FGFR1 in the muscle and WAT.

Serum glypican-4 levels and its association with cardiovascular risk predictor in women with polycystic ovary syndrome and healthy controls – pilot study

Andrzej Milewicz[1], Justyna Kuliczkowska-Plaksej[1], Agnieszka Lenarcik-Kabza[1], Anna Trzmiel-Bira[1], Lidia Hirnle[1], Urszula Zaleska-Dorobisz[1], Felicja Lwow[2], Lukasz Laczmanski[1], Katarzyna Kolackov[1], Natalia Sloka[1] & Diana Jedrzejuk[1]
[1]Univeristy of Medicine, Wroclaw, Poland; [2]University School of Physical Education, Wroclaw, Poland.

Glypican-4 (Gpc-4) is novel adipokine interact with insulin receptor and affects insulin sensitivity in proteoglycans. Gpc-4 serum levels show gender differences; females having higher levels than men, what can suggest mediation by sex hormones. We investigated serum Gpc-4 levels and its association with cardiovascular risk predictors in women (20–35 years old) with PCOS ($n=62$) and healthy control ($n=43$) presented different sex hormones profile. The following CVD risk predictors: BMI, waist circumference (WC), total fat (TF), androidal fat deposit (AFD), gynoidal fat deposit (GFD), AFD/GFD ratio (A/G), fasting serum glucose, insulin, HOMA, serum triglycerides, total cholesterol, HDL-cholesterol, LDL-cholesterol) and hormonal profile LH, testosterone, androstenedione (Adione), SHBG, Free Androgens Index (FAI) were estimated. Gpc-4 was determined by commercial ELISA kit. Serum Gpc-4 levels in women with PCOS was statistically significant higher than in control group (2.61 ± 1.17 vs 1.55 ± 0.47 ng/ml). Serum Gpc-4 concentration positively correlated with BMI in both groups ($P<0.001$), but with WC ($P<0.001$), WHR ($P=0.005$), TF ($P<0.001$), AFD ($P<0.001$), GFD ($P=0.008$), A/G ($P=0.002$) only in PCOS group. Serum Gpc-4 concentration were correlated positively with fasting serum insulin and HOMA in PCOS women and in control group (for both and in each group $P<0.001$). We showed that Gpc-4 concentration positively statistically significant correlated with serum Adione and FAI levels in control group and we observed only the tendency in PCOS group ($P=0.054$) also with serum LH ($P=0.071$). This original observation give new light on the role of Gpc-4 in women health, but because of some limitations further study is require.

microRNA profiling of H295R cells following stimulation of aldosterone production: a bioinformatic study

Nur Izah Ab Razak[1,2], Scott MacKenzie[1], Louise Diver[1], Martin McBride[1] & Eleanor Davies[1]
[1]Institute of Cardiovascular and Medical Sciences, University of Glasgow, Glasgow, Scotland, UK; [2]Faculty of Medicine & Health Sciences, University Putra Malaysia, Serdang, Selangor, Malaysia.

Inappropriately high secretion of aldosterone can lead to hypertension and its various cardiovascular consequences. We previously showed that microRNA (miRNA) plays a significant role in the regulation of aldosterone biosynthesis. In this study we measured miRNA levels in H295R cells, the most commonly-used human adrenocortical cell line, and investigated how these change in response to the stimulation of aldosterone biosynthesis.

H295R cells ($n=3$ per group) were stimulated with either 100 nM angiotensin II (AngII), 10 mM dibutyryl cyclic AMP (dbcAMP, to simulate ACTH effects) or 20 mM potassium chloride (KCl) for 24 h. Each treatment significantly increased aldosterone synthase (*CYP11B2*) mRNA relative to basal unstimulated cells. Microarray analysis also revealed significant and consistent changes in the quantities of specific miRNAs relative to basal levels: 20 miRNAs were differentially expressed in the AngII-treated cells, 68 in the dbcAMP-treated cells and 66 in the KCl-treated cells. Expression of 6 miRNAs was consistently altered across all three treatments, with the majority localising to one of two miRNA clusters located on either chromosome 13 or the X chromosome. Bioinformatic analysis with Ingenuity Pathway Analysis (IPA) software was used to predict mRNA targets for these six differentially-expressed miRNAs, but no direct effects on steroidogenic enzymes were identified. However, effects on various cholesterol-related genes, such as *LDLR* and *ABCA1*, were predicted. In conclusion, we have shown that consistent changes in miRNA profile result from various aldosterone-stimulating treatments *in vitro*. This includes a reduction in clustered miRNAs predicted to affect genes regulating cell cholesterol levels. This suggests a mechanism by which steroid biosynthesis could be affected and complements our results from aldosterone-producing adenoma (APA) tissue, which had consistent differences in miRNA profile relative to normal adrenal tissue. We now intend to investigate the impact of these miRNAs on cholesterol-related genes and corticosteroid biosynthesis.

Unacylated ghrelin and its analogue AZP-531 suppress ghrelin induced fat accumulation and feeding behaviours in high-fat diet fed male rats

Jan Scholte[1], Anton Scheurink[1], Thierry Abribat[2], Michel Julien[2], Axel Themmen[3], AJ van der Lely[3] & Patric Delhanty[3]
[1]University of Groningen, Groningen, The Netherlands; [2]Alizé Pharma, Lyon, France; [3]Erasmus MC, Rotterdam, The Netherlands.

The peptides acylated and unacylated ghrelin (AG and UAG) are produced predominantly in the stomach. AG is the only known circulating orexigenic hormone with obesogenic and insulin-desensitising properties. Recent evidence suggests that UAG can inhibit these activities of AG. To investigate potential inhibitory effects of UAG and AZP-531, a UAG analogue, on AG-induced appetite and obesity we used an established rat model of diet induced obesity. Animals were fed a high-fat diet, then at 3 weeks implanted with osmotic mini-pumps containing either vehicle, AG, UAG, AG+UAG, AZP-531 or AG+AZP-531 ($n=8$ per group). All peptides were infused at 4 nmol/kg per h for 4 weeks. From 1 week before the start of infusion body weight and food intake were measured daily, blood sampling and assessments of feeding behaviour were made weekly. At the end of the experiment fat mass of different tissues, and body water and lean mass were measured. Tissues were also processed for mRNA analysis. The AG treated groups showed increased weight gain relative to the non-AG treated groups, but there was no significant effect of the UAG analogues. AG significantly increased total fat, but not lean or water mass. Remarkably, UAG and AZP-531 blocked AG-induced total fat accumulation, their inhibitory effects being localised to subcutaneous and retroperitoneal depots. UAG and AZP-531 also significantly suppressed AG-driven total food intake as well as aspects of AG-driven feeding behaviour, particularly speed of food intake. These activities may occur via a central mechanism since UAG and AZP-531 prevented the suppression of hypothalamic *Mc4r* mRNA by AG. In conclusion, UAG analogues suppress AG-induced fat accumulation and feeding behaviours, and may therefore have therapeutic potential in clinical indications where hyperphagia and altered behaviour towards food are related to high ghrelin levels such as Prader-Willi syndrome.

Preliminary analysis of the PRIMAVERA Study: reduxine safety monitoring in patients with alimentary obesity

Ivan Dedov[1,2], Galina Melnichenko[1,2], Tatiana Romantsova[2] & Marina Zhuravleva[2]
[1]Endocrinology Research Center, Moscow, Russia; [2]I.M. Sechenov Moscow State Medical University, Moscow, Russia.

Background
The SCOUT trial showed that sibutramine produced weight loss with some increased cardiovascular morbidity but not mortality. But these results should not be extrapolated to a routine practice as a lot of the SCOUT participants had contraindications for sibutramine. In order to summarise data on efficacy and safety of sibutramine administration in routine clinical practice according to approved indications and to implement risks monitoring system in Russia, PRIMAVERA non-interventional study has been initiated (NCT01773733, clinicaltrial.gov).
Methods
98.774 obese patients from 142 Russian cities, treated with sibutramine 10–15 mg/day. Preliminary results were analyzed for 16 515 patients (82% – women, 18% – men). Patients were treated under control of body weight, blood pressure and pulse rate.
Results
2.5% of patients dropped out during screening phase due to contraindications to sibutamine use. 3% of patients stayed on treatment for 3 month, 65% – for 6 month and 29.5% – for 12 month. Mean weight loss was significant: 7.5 ± 2.8 kg by month 3, 14.3 ± 5.9 kg by month 6 and 18.8 ± 8.2 kg by month 12 ($P<0.01$). Mean waist circumference decreased significant: 5.85 ± 3.31 cm, 10.71 ± 6.48 cm and 15.15 ± 8.91 cm by month 3, 6 and 12 respectively ($P<0.01$). According to the Well-Being Questionnaire, body weight loss was accompanied by general increase in quality of life. Treatment with sibutramine was not associated with significant increase of blood pressure and pulse rate. Adverse events were reported for 2.8% patients. There were no reports of The Serious Adverse Events related to sibutramine use.
Conclusion
Based on preliminary analysis, sibutramine use according to approved indications is safe and effective for long-term treatment of obesity. Due to PRIMAVERA program the principles of sibutramine efficacy and safety monitoring are being implemented into routine clinical practice.

The Irish TSHoma study: a multicentre retrospective study

Agnieszka Pazderska[1], Martin Cuesta[2], Helen Wallace[3], Audrey Melvin[4], James Gibney[1], Amar Agha[2], Donal O'Halloran[4], Steven Hunter[3], Chris Thompson[2] & Mark Sherlock[1,5]
[1]Department of Endocrinology, Adelaide and Meath Hospital Incorporating the National Children's Hospital, Tallaght, Dublin 24, Ireland; [2]Department of Endocrinology, Beaumont Hospital, Dublin 9, Ireland; [3]Department of Endocrinology, Royal Victoria Hospital, Belfast, UK; [4]Department of Endocrinology, Cork University Hospital, Cork, Ireland; [5]Department of Endocrinology, Trinity College Dublin, Dublin, Ireland.

TSH-secreting pituitary adenomas (TSHomas) are rare. Previously, the reported prevalence was one case per million populations although this is probably an underestimate. A recently published study reported a prevalence of TSHomas in Sweden of 2.8/million inhabitants.
Methods/design
Observational study conducted in four tertiary referral centres in Ireland. We retrospectively collected data on the prevalence, demographics, hormonal profile, tumour characteristics, and treatment outcomes for patients with TSHomas.
Results
21 patients (eight males) were diagnosed with TSHoma between 1968 and 2014. Mean age at diagnosis was 46 years. The prevalence of TSHomas in Ireland (Republic of Ireland and Northern Ireland) is 3.3/million inhabitants. This may be an underestimate as other centres may have TSHomas that were not included. At diagnosis, the median free thyroxine was 49.9% (IQR 50.3%) above the upper reference range. Eleven patients (52%) had TSH within normal range at diagnosis. 5/21 (23.8%) patients co-secreted GH and 4/21 (19%) patients had elevated prolactin. The median adenoma size was 13.5 mm (IQR 18.7) and 12/21 patients had a macroadenoma.15/21 patients were treated with surgery (two required craniectomy) as a primary therapy, 6/21 were treated with a somatostatin receptor ligand (SRL), five as a primary therapy. Somatostatin analogues normalised thyroid function in 4/5 patients. 8/21 patients underwent radiotherapy for either persistent active disease or tumour growth. 4/21 had hormonally active disease at the last follow up; three of these were treated with transsphenoidal surgery and radiotherapy and one with SRL. 11/21 (52%) had other pituitary hormones deficiencies at the most recent follow up.
Conclusion
The prevalence of TSHoma in Ireland exceeds the previously cited estimate of one case per million. Multimodal treatment is often required to normalise thyroid function and prevent tumour growth.

We have recently reported that somatic mutations in the ubiquitin-specific protease 8 (USP8) are present in corticotropinomas of patients with Cushing's disease and that these mutations reduced the interaction with 14-3-3. Mutant USP8 exhibited higher deubiquitination activity and potentiated EGFR-induced POMC expression (Reincke *et al*., *Nat Genet* 2014). To further study the prevalence of these mutations, we have analyzed 134 ACTH-producing corticotropinomas of patients with diagnosed Cushing's disease from eight different centers by Sanger sequencing.

Results

Somatic mutations in USP8 were found in 48 cases (37%), but not in an additional cohort of 11 'silent' corticotropinomas. The center-specific prevalence ranged from 10.5 to 57% and was lower in pediatric patients (17% vs 41%; $P<0.05$). Adults having adenomas with USP8 mutations were diagnosed at earlier age (36 years vs 44 years; $P<0.05$) and had a higher BMI than those with wild type adenomas. Mutations were more frequent in females than in males (43% vs 17%; $P<0.005$) and were mainly found in adenomas of intermediate size (11.9 ± 6.3 mm). Patients with adenomas containing USP8 mutations also tended to have lower preoperative hormonal levels, although the differences were not significant, and were less prone to develop adrenal insufficiency postoperatively than those with WT tumors (49% vs 71% respectively; $P<0.05$). Mutations affected the residues Ser718 (52%) or Pro720 (48%). In addition, we identified five new alterations: one missense substitution and four in-frame deletions of several amino acids. They reduced the interaction between USP8 and 14-3-3, increased USP8 cleavage and enhanced its activity. USP8 mutants diminished EGFR ubiquitination and consequently impaired its lysosomal degradation. Furthermore, mutant USP8 proteins enhanced EGFR-induced POMC promoter activity in immortalized AtT20 corticotropinoma cells.

In conclusion, our data highlight the prevalence of USP8 mutations in Cushing's disease and link these alterations to female adult patients with younger age.

Increased secretion of GH results in gigantism in children/adolescents and in acromegaly in adults; the relative roles of the various genetic causes of acromegaly and gigantism are still unclear. To analyse the genetic causes and inherited/familial features in patients with pituitary gigantism, we studied a large international cohort. Genetic or inherited characteristics were observed in 39% of patients and included familial isolated pituitary adenomas (FIPA; $n=28$), McCune–Albright syndrome ($n=7$), Carney complex ($n=2$), and MEN1 ($n=1$). Germline mutations in the AIP gene were found in 31% of tested cases; a microduplication at Xq26.3 was detected in two kindreds and ten sporadic patients with a novel pediatric onset gigantism syndrome, termed X-linked acromegigantism (X-LAG). AIPmut positive patients were almost all males (95%), whereas X-linked acrogigantism group (X-LAG) consisted mostly of females (71%). AIPmut positive and X-LAG patients had significantly younger ages at first symptoms (13.5 and 1.5 years) and at diagnosis (16.8 and 3 years) than AIP negative patients (15 and 24 years respectively). Among non-X-LAG patients none had grown excessively before the age of 5 years. Pituitary lesions were usually macroadenomas and their size was not different in AIPmut, AIPwt, and X-LAG groups. All patients had marked hypersecretion of GH/IGF1. Prolactin co-secretion was more frequent in X-LAG than in AIPmut cases.

Conclusions

Syndromic or genetic features occurred in more than one third of patients with gigantism. Clinical presentation is affected by genetics of pituitary adenomas and AIP mutations are common. X-LAG syndrome explained most of cases with childhood gigantism.

The changing faces of corticotroph-cell adenomas: the role of proconvertase 1/3

Marco Faustini-Fustini[1], Alberto Righi[2], Sofia Asioli[3], Luca Morandi[3], Matteo Zoli[1], Diego Mazzatenta[1], Giorgio Frank[1] & Maria Pia Foschini[3]
[1]IRCCS Istituto delle Scienze Neurologiche di Bologna (ISNB), Bellaria Hospital, Bologna, Italy; [2]Department of Pathology, Rizzoli Institute, Bologna, Italy; [3]Section of Anatomic Pathology, Department of Biomedical and Neuro Motor Sciences, Bellaria Hospital, Bologna, Italy.

Introduction

The possible change in the pattern of hormonal secretion by pituitary tumours is a very intriguing issue indeed, notably in the case of corticotroph-cell adenomas.

Methods/design

We retrospectively reviewed the records of 1259 consecutive endoscopic endonasal surgical procedures for pituitary adenomas from 1998 to 2013. Of these, 132 were ACTH-secreting adenomas associated with Cushing's disease (CD) and 44 were silent corticotroph-cell adenomas (SCA). During the follow-up, seven patients (four men and three women) showed a transformation of their clinical expression from SCA to CD or, more rarely, vice versa. Of these, to date only three patients with corticotroph-cell adenomas changing their pattern of hormonal secretion during the follow-up were re-operated. Then, we examined the expression of proconvertase 1/3 (PC1/3), which plays an important role in the POMC processing within the pituitary, in tissue specimens obtained from these three patients with SCA that had developed clinical and laboratory features of CD at the time of recurrence, using both immunohistochemistry and quantitative real time-PCR.

Results

The data indicated that the immunohistochemical PC1/3 expression was negative or weak and focally positive in tissue specimens obtained in the three patients at the time of first operation (SCA), whereas we observed a strong expression in the majority of the neoplastic cells in the same three patients at the time of recurrence, when they had become CD. The PC1/3 expression, as evaluated using immunohistochemistry, showed a significant correlation with the PC1/3 levels obtained by qRT-PCR in assessing the increase of PC1/3 expression from SCA to CD. Twelve cases of SCA without changing their phenotype during the follow-up were used as controls: both the immunohistochemical PC1/3 expression and level of PC1/3 obtained by qRT-PCR were absent or weak in scattered neoplastic cells.

Conclusion

This study provides insight into the crucial role of the PC1/3 in the mechanism(s) of transformation of phenotype from SCA to CD.

X-linked acro-gigantism (X-LAG) is a rare novel genomic syndrome of pituitary gigantism that has a typical onset within the first year of life in children of normal or even low birth weight. X-LAG patients have a microduplications on chromosome Xq26.3 that includes a gene *GPR101*, which is highly upregulated in pituitary tumor tissue of affected patients. We performed a study of all 18 known X-LAG syndrome patients currently in the NICHD-University of Liège database to describe the clinical phenotype and therapy responses. All 13 sporadic cases had unique duplications; the inheritance pattern in familial cases was X-linked dominant. Typically, the abnormal growth was noted within the first year of life but could begin in the initial months of infancy. Despite significant somatic overgrowth ($\sim +4$ SDS height/weight), diagnoses of pituitary macroadenoma/hyperplasia were not made until usually >2 years after excessive growth began. A number of familiar acromegaly signs/symptoms accompanied somatic overgrowth, including acral enlargement and facial changes (including widely spaced teeth in some cases). About 25% of cases had increased appetite, and signs of insulin resistance (e.g. acanthosis nigricans) were reported. At diagnosis, patients had extremely elevated GH and IGF1 levels, which were accompanied by variably severe hyperprolactinemia. Control of growth was difficult to achieve in many cases, particularly those where primary neurosurgery did not fully resect the involved tissue. Efficacy of traditional somatostatin analogs was notably poor, whereas adjuvant pegvisomant therapy did provide control of IGF1 and slowed growth. However, due to the need for aggressive therapy to arrest excessive growth, postoperative hypopituitarism was frequent. The mechanisms behind the excessive stimulation of pituitary growth and elevated hormonal output are being studied, but both pituitary and hypothalamic aetiologies are possible, for example, due to high levels of GHRH-receptor staining in pituitary tumors in the face of normal or elevated circulating GHRH in some patients.

Low-dose ACTH testing does not predict treatment response to corticosteroids in community-acquired pneumonia

Claudine A Blum[1,2], Philipp Schuetz[3], Nicole Nigro[1], Bettina Winzeler[1], Birsen Arici[1], Julie Refardt[1], Sandrine A Urwyler[1], Matthias Briel[1,4], Beat Mueller[3] & Mirjam Christ-Crain[1]

Background
It is controversial whether the attenuated increase of circulating cortisol to ACTH stimulation predicts treatment response to corticosteroids in patients with critical illness. We investigated whether ACTH testing predicts treatment response to corticosteroids in patients with community-acquired pneumonia (CAP).
Methods
We performed a low dose (1 μg) ACTH test on admission in a prospective randomised, double-blind, placebo-controlled multicenter trial comparing prednisone 50 mg for 7 days to placebo in patients hospitalized with CAP. The results of the main study showed a benefit of corticosteroids in community-acquired pneumonia.[1] Cortisol was measured at baseline and 30 min after stimulation with 1 μg ACTH. We performed Cox regression models for time to clinical stability (TTCS) to compare baseline and stimulated cortisol levels between both treatment groups.
Results
348 patients in the prednisone group and 330 patients in the placebo group were evaluated. 176 patients in the prednisone group (50.6%) and 163 patients in the placebo group (49.4%) with a basal cortisol > median (751 nmol/l) had a significantly longer TTCS in both groups (4.4 days vs 2.1 days, $P<0.0001$ in the prednisone and 5.0 days vs 3.0 days in the placebo group, $P=0.0003$). Basal plasma cortisol levels did not predict treatment response to prednisone (P for interaction $=0.84$). Similarly, neither a delta cortisol <250 nmol/l after ACTH stimulation (P for interaction $=0.84$) nor the combination of basal cortisol and delta cortisol (P for interaction $=0.82$) predicted treatment response to corticosteroids.
Conclusion
Our data suggest that a low-dose ACTH test does not predict treatment response to corticosteroids in patients with CAP. This suggests a pharmacological effect of corticosteroids in patients with critical illness or CAP and argues against a critical illness-related corticosteroid insufficiency (CIRCI).

GP.01.02

Defining and exploring the excessive healthcare burden of adrenal insufficiency

Paul Stewart[1], Beverly M K Biller[2], Claudio Marelli[3], Candace Gunnarsson[4], Michael Ryan[4] & Gudmundur Johannsson[5]
[1]University of Leeds, Leeds, UK; [2]Massachusetts General Hospital, Boston, Massachusetts, USA; [3]Shire, Zug, Switzerland; [4]CTI Clinical Trial and Consulting, Cincinnati, Ohio, USA; [5]Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Göteborg, Sweden.

Introduction
The clinical outcome of patients with adrenal insufficiency (AI) has been shown to be less favorable than previously thought. Clinical studies have shown increased mortality, reduced cardiovascular and skeletal health and compromised quality of life, but the impact of this upon healthcare burden is unknown. This research utilised real-world evidence to compare comorbidities, healthcare utilization and expenditures in patients with AI.
Methods/design
Administrative health claims data from Truven Health MarketScan Commercial and Medicare databases (January 2006–June 2011) were used. Inclusion criteria were at least two diagnosis codes for AI and a minimum of 1 year of continuous health and pharmacy coverage following diagnosis. Patients were classified into cohorts of secondary AI (SAI) due to pituitary disorder ($n=1529$), primary AI (PAI) ($n=705$), and congenital adrenal hyperplasia (CAH) ($n=242$). Patients were matched 1:1 on age, gender, insurance type, and region to a general control population. Unadjusted average healthcare utilization and expenditures over 12 months are reported for each cohort and control. Multivariable models will be generated to estimate healthcare utilization and expenditures.
Results
All three groups showed higher relative risk of anxiety (SAI 1.87 (CI: 1.60, 2.18)); (PAI 1.89 (1.52, 2.35)); (CAH 2.14 (1.17, 3.94)); hypertension (SAI 1.25 (1.16, 1.35)); (PAI 1.15 (1.01, 1.32)); (CAH 1.60 (1.09, 2.35)); and diabetes mellitus (SAI 1.52 (1.31, 1.76)); (PAI 1.60 (1.24, 2.05)); (CAH 2.83 (1.50, 5.34)) than the general population. Depression (SAI 1.55 (1.39, 1.74)); (PAI 1.44 (1.23, 1.67)); and hyperlipidemia (SAI 1.36 (1.26, 1.47)); (PAI 1.23 (1.08, 1.41)); were higher in the SAI and PAI cohorts. Inpatient hospitalizations with infection were a frequent primary diagnosis for all three cohorts. Average total 12-month expenditures for each cohort compared to their matched controls were as follows: SAI = $29 628/control = $7044, PAI = $19 795/control = $5480, and CAH = $6145/control = $3542.
Conclusions
Patients with AI carry a significant healthcare burden with higher risk of comorbidities, hospital admissions and healthcare expenditures compared to the general population.

GP.01.03

Effect of the switch from conventional glucocorticoids to 'dual release hydrocortisone' in adult patients with primary and secondary adrenal insufficiency: a 6-month multicentre study

Rosario Pivonello[1], Chiara Simeoli[1], Andrea M Isidori[2], Alessandro Ciresi[3], Silvia Savastano[1], Renata S Auriemma[1], Chiara Graziadio[2], Carolina Di Somma[1], Carla Giordano[3], Andrea Lenzi[2] & Annamaria Colao[1]
[1]Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Federico II University, Naples, Italy; [2]Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy; [3]Section of Endocrinology and Metabolic Disease, DIBIMIS, University of Palermo, Palermo, Italy.

Adrenal insufficiency (AI) requires life-long glucocorticoid (GC) treatment, which is associated with an increased risk of metabolic syndrome (MS), probably due to cortisol overexposure for multiple drug daily doses, together with an impairment of quality of life (QoL). Moreover treatment compliance (TC) is reported to be suboptimal in AI patients. The current study aimed at investigating the impact of the switch from twice/thrice daily conventional GCs to once daily dual-release-hydrocortisone (DR-HC) treatment on metabolic profile, QoL and TC in patients with primary AI (PAI) and secondary AI (SAI). Thirty-five patients (12 with PAI (7F, 5M, 33–60 years), eight treated with cortisone acetate (37.5–75 mg/day) and four with HC (20–30 mg/day)) and 23 patients with SAI (9F, 14M, 20–77 years), 15 treated with cortisone acetate (18.75–37.5 mg/day) and eight with HC (15–20 mg/day) entered the study and were evaluated before and 6 months after the switch to DR-HC (PAI: 20–60 mg/day and SAI: 20–40 mg/day). At 6-month-follow-up, in PAI patients, body weight (BW) ($P=0.036$) significantly improved and a trend to a significant improvement was also found for waist circumference (WC) ($P=0.086$). A diagnosis of MS, performed in two patients (17%) at baseline, was not confirmed after 6 months. In SAI patients, BW ($P=0.001$), BMI ($P=0.003$), and WC ($P=0.007$) significantly improved. A clear diagnosis of MS, performed in seven patients (30%) at baseline, was confirmed only in 4 (17%) of these patients after 6 months. In a subgroup of 12 patients with AI, visceral adiposity index (VAI), an indicator of adipose function and distribution, which seems to indirectly express the cardiometabolic risk, significantly improved ($P=0.05$) while an improvement in glucose levels ($P=0.064$) and in insulin sensitivity index (ISI 120) ($P=0.052$) was reported 120 min after glucose load. In the subgroup of ten patients considered for the evaluation of QoL and TC, working ability ameliorated in six patients (60%), vitality in 5 (50%), general health perception and depression in three patients (30%) and body pain perception in 2 (20%) patients. Moreover, 9 (90%) of these ten patients improved TC, changing from low to medium adherence. In conclusion, the switch from conventional GCs to DR-HC in patients with AI improved BW, BMI, WC, prevalence of MS, glucose tolerance and insulin sensitivity, QoL and TC.

Clinical and genetic findings of an Italian series of patients with ACTH resistance syndromes

Marco Bonomi[1,2], Paolo Duminuco[2], Domenico Vladimiro Libri[2], Valeria Vezzoli[2], Alessandro Salvatoni[3], Valentino Cherubini[4], Anna Ficcadenti[5], Giorgio Radetti[6], Antonella Meloni[7] & Luca Persani[1,2]
[1]Dipartimento di Scienze Cliniche e di Comunità, Università degli Studi di Milano, Milano, Italy; [2]Divisione di Medicina ad Indirizzo Endocrino–Metabolico e Lab di Ricerche Endocrino–Metaboliche, IRCCS Istituto Auxologico Italiano, Milano, Italy; [3]Dipartimento di Pediatria, Università dell'Insubria, Ospedale Filippo del Ponte, Varese, Italy; [4]Ospedali Riuniti 'Umberto I – G.M.Lancisi – G.Salesi', SC Diabetologia Pediatrica, Ancona, Italy; [5]Clinica Pediatrica, Università Politecnica delle Marche, Ancona, Italy; [6]Ospedale Regionale di Bolzano, UO Pediatria, Bolzano, Italy; [7]UO DH II Clinica Pediatrica, Ospedale Microcitemico, Cagliari, Italy.

ACTH resistance syndromes (ARS) are rare, severe and heterogeneous diseases that include either familial glucocorticoid deficiency (FDG) or Allgrove syndrome (AS). FDG is a rare autosomal recessive disorder resulting from mutation in genes encoding either the ACTH-receptor (ACTHR) in FDG1, or its accessory protein MRAP, in FDG2. AS is characterized by adrenal insufficiency due to ACTH resistance, alacrimia, and achalasia secondary to mutations in the *AAAS* gene, which encodes a protein called ALADIN. Here we describe the clinical and genetic findings in six males with ARS (age at diagnosis: 2 days–14 years). Seizures, recurrent infection, hypoglycaemia, skin, and mucosal hyperpigmentation were common features, while achalasia and alacrimia were present in three patients, indicating AS. The genetic analyses of the three FGD patients were negative in one, but revealed a known causative heterozygous intronic variation (IVS 3ds+3insT) in MRAP in another one; and a known causative homozygous variation in ACTHR (p.Y254C), in association with two novel heterozygous non-synonimous SNPs in exons 2 and 3 of the MRAP, in the last patient. The molecular analysis of the three patients with AS showed: one known causative nonsense homozygous mutation (p.R194X) in the *ALADIN* gene in two brothers; in the last AS case, a novel homozygous intronic variant (IVS11–2) inherited from the two non-consanguineous heterozygous parents, both from Sardinia. This patient presented a congenital twisted feet and achalasia already at birth, but came to the diagnosis of AS only at the age of 14 years. The molecular characterisation of this novel variant, based on the mRNA analysis, demonstrated that it is affecting the splicing site of the exon 11 in *ALADIN* gene causing the formation of an aberrant protein with a premature stop codon. In conclusion, the frequency of FDG and AS in this short Italian series is similar, and we described a novel IVS in the Aladin gene that is causative for AS.

Prevention of adrenal crisis in stress (The PACS Study): serum cortisol during elective surgery, acute trauma and sepsis in comparison to 'stress dose' hydrocortisone administration in adrenal insufficiency

Angela Taylor[1], Niki Karavitaki[2], David Smith[3], Irina Bancos[1], Mark Foster[4], Sibylle Meier[2], Donna O'Neil[1], John Komninos[2], Dimitra Vassiliadi[1], Christopher Mowatt[1], Janet Lord[4], John Wass[2] & Wiebke Arlt[1]
[1]Centre for Endocrinology, Diabetes and Metabolism, University of Birmingham, Birmingahm, UK; [2]Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Oxford, UK; [3]School of Mathematics, University of Birmingham, Birmingham, UK; [4]NIHR Surgical Reconstruction and Microbiology Research Centre, University of Birmingham, Birmingham, UK.

Patients with adrenal insufficiency require increased hydrocortisone (HC) replacement doses during surgery, trauma and infection to avoid life-threatening adrenal crisis. However, currently administered HC doses are chosen empirically rather than on rational grounds, with huge variability in administration modes, total dose and dosing intervals. To conclusively determine serum cortisol levels observed under stress conditions, we firstly collected blood samples from healthy controls ($n=86$), soldiers under combat stress ($n=105$) and patients undergoing elective surgery with general anaesthesia ($n=22$), acute major trauma ($n=85$), and severe sepsis ($n=100$). Secondly, we undertook frequent sampling over a period of 24 h in ten patients with primary adrenal insufficiency who omitted their regular replacement and received HC 200 mg/24 h in four different administration modes: 50 mg every 6 h orally or per i.m. or i.v. bolus injection or 200 mg/24 h as continuous i.v. infusion (IV-C). All analyses were carried out by liquid chromatography/tandem mass spectrometry. Serum cortisol concentrations were highest in patients with sepsis (median 973, range 77–7717 nmol/l), followed by elective surgery with general anaesthesia (617, 269–1379), combat stress (441, 69–789), acute trauma (235, 23–1257), and healthy controls (197, 67–752 nmol/l). Initial peak concentrations after HC exceeded stress levels, but serum cortisol decreased to under the median of controls several hours before repeat administration of oral, i.v., and i.m. bolus. By contrast, HC IV-C maintained steady state cortisol levels above the median of stressed controls throughout. Linear pharmacokinetic modelling combined with mixed effects regression calculated the optimal dose and administration mode as an initial bolus of 50–100 mg HC i.v., followed by continuous i.v. infusion of 200 mg/24 h. Continuous i.v. rather than bolus administration of HC will avoid dangerous intermittent trough levels and thus represents the recommended administration mode for patients with adrenal insufficiency exposed to pathological stress due to trauma, sepsis, or surgery.

Incidence of adrenal insufficiency and its relation to mortality in patients with septic shock

Manish Gutch[1], Sukriti Kumar[2], Syed Mohd Razi[1], Abhinav Gupta[1] & Keshav Kumar Gupta[1]
[1]LLRM Medical College, Meerut, Uttar Pradesh, India; [2]SGPGI, Lucknow, India.

Background
The hypothalamic–pituitary–adrenal axis has a pivotal role in combating acute insults. Glucocorticoids play a role directly or indirectly in the maintenance of normal vascular tone and in potentiating the vasoconstrictor action of catecholamine, associated with septic shock.
Aims
To determine the incidence of adrenal insufficiency (AI) and its relation to mortality in patients with septic shock.
Settings and design
A prospective observational study done at tertiary care centre.
Methods and materials
In patients of septic shock, APACHE II score was calculated and serum cortisol was measured at the time of admission and 1 h after giving 250 μg ACTH. Hydrocortisone was added to inotropics in all patients after drawing second blood sample for serum cortisol and was continued till 7 days or less. In our study, the patients with inadequate adrenal response were divided into two groups: i) absolute AI – baseline cortisol <20 μg/dl and increment ≤ 9 μg/dl after the ACTH stimulation test and ii) relative AI – patients with baseline cortisol ≥ 20 μg/dl and increment ≤ 9 μg/dl. Statistical analysis used: data were analysed with SPSS version 17 and were presented in the values of mean, median, and percentages. The P value of <0.05 was considered significant.
Results
The incidence of AI in septic shock was ($n=100$) was 42% (in absolute 14% and relative 28%). The incidence of AI in septic shock was 42% (absolute 14% and relative 28%). The mortality rate was 48%, and it was higher in patients with AI than in patients without AI ($P=0.017$). The APACHE II score >25 carried higher mortality rate than a score of <25 ($P\leq 0.001$). Baseline serum cortisol >45 μg/dl had exceptionally high likelihood of mortality (OR 50, $P\leq 0.001$). Among those who survived, inotropic support was required for longer period in relative as compared with absolute AI and to non-AI.
Conclusions
AI is prevalent among patients with septic shock. We found that higher APACHE scores were associated with higher rates of adrenal failure and mortality in patients with septic shock. There also appears to be a bimodal distribution of mortality with adrenal status in patients with septic shock.

Mild cognitive deficits in patients on long-term, stable hydrocortisone replacement for primary adrenal insufficiency: a case–control study

Cornelie Andela[1], Jitske Tiemensma[1,2], Nienke Biermasz[1], Johannes Romijn[3] & Alberto Pereira[1]
[1]Leiden University Medical Center, Leiden, The Netherlands; [2]University of California, Merced, California, USA; [3]Academic Medical Center, Amsterdam, The Netherlands.

Background
Hydrocortisone replacement for primary adrenal insufficiency (PAI) is targeted to mimic circadian endogenous cortisol secretion. Nevertheless, patients on stable

treatment report impairments in quality of life. The brain is a major target area for cortisol considering it high density of glucocorticoid receptors and previous studies in patients treated for Cushing's disease (CD) suggest that hypothalamic-pituitary-adrenal axis dysregulation is related to cognitive impairment.
Objective
To evaluate cognitive functioning in patients with PAI and to examine the possible effect of postponing early morning hydrocortisone intake. Furthermore, we aimed to assess cognitive functioning of patients with PAI relative to patients in remission of CD.
Patients and method
Cognitive functioning was measured in 31 patients with PAI and 31 healthy matched controls using eight neuropsychological tests, evaluating memory, verbal intelligence, and executive functioning. In addition, 29 patients were included who postponed their hydrocortisone intake to after the cognitive evaluation. Cognitive functioning scores of patients in remission of CD were obtained from previous research.
Results
Compared with controls, patients with PAI performed worse on auditory and visual memory tasks (all $P \leq 0.024$) and executive functioning tasks (all $P \leq 0.012$). In contrast, patients performed better on a concentration task ($P = 0.015$) and made less errors during a focused attention task ($P = 0.041$). No differences were observed between patients with and those that postponed hydrocortisone intake, except for fewer repeats during a verbal fluency task ($P = 0.025$) in patients that postponed hydrocortisone intake. Patients with PAI performed generally similar to patients in remission of CD (except for concentration and logical memory).
Conclusions
Patients on long-term hydrocortisone replacement for PAI demonstrate mild cognitive deficits compared with controls, and perform generally similar to patients in remission of CD. Future longitudinal studies are needed to provide more insight into the development and course of the observed cognitive alterations.

Autoimmune polyendocrine syndrome in India: clinical aspects, *AIRE* mutations, and functional analysis

Eesh Bhatia[1], Ghazala Zaidi[1], Aditya Sarangi[2], Vijayalakshmi Bhatia[1], Nisha Bharani[3], Alok Sachan[4], Li Zhang[5], Liping Yu[5], Vandana Jain[6], Saroj Sahu[1], Rashmi Srivastava[7], Niharika Bharti[1], Rakesh Aggarwal[2] & Amita Aggarwal[7]
[1]Department of Endocrinology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; [2]Department of Gastroenterology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India; [3]Department of Endocrinology, Amrita Institute of Medical Sciences, Kochi, India; [4]Department of Endocrinology, Sri Venkateshwara Institute of Medical Sciences, Tirupathi, India; [5]Department of Immunology, Barbara Davis Center for Childhood Diabetes, Denver, India; [6]Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India; [7]Department of Clinical Immunology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India.

Introduction
Autoimmune polyendocrine syndrome 1 (APS1) is an uncommon, serious autosomal recessive disorder, due to *AIRE* gene mutations which result in impaired central tolerance. India has a complex genetic structure and also communities with high prevalence of consanguinity, which may result in varied clinical manifestations and genetic mutations.
Aims
To study clinical features, interferon-α antibodies (IFNA), *AIRE* mutations, and *in-silico* functional analysis of novel mutations in Indian patients with APS1.
Patients and methods
Twenty patients (17 families) with clinical features of APS1 were studied. Nine patients previously reported by us (*Clin Genet* 2009 **76** 441) were included in the analysis. Clinical features (including mortality on follow-up), IFNA, bidirectional sequencing of *AIRE* gene, and i*n-silico* functional analysis of novel AIRE mutations were studied.
Results
Patients had three ($n = 9$), two ($n = 9$), or a single ($n = 2$, family members) major manifestation of APS1, in addition to various other organ-specific autoimmune disorders. On follow-up, mortality was high ($n = 6$, 30%), occurring at early age (5–23 years). IFNA was elevated with high titres in all patients, but was within normal range in family members with heterozygous mutations/WT sequence. Ten different mutations were detected, with C322fsX372 being most frequent (six families). Novel mutations included p.V80G ($n = 3$, in three different families from an in-bred community in Kerala, South India), p.L11P, p.C302X, and p.X546L + 59aa (c.1637G > T; terminal codon). The Finn-major mutation, R257X, was present in one patient. No specific genotype–phenotype correlation was observed. Functional analysis of two novel missense mutations (V80G and L11P) in the CARD domain revealed increased instability resulting from changes in intra-helical hydrogen binding.
Conclusions
Indian patients with APS1 syndrome had high mortality. IFNA was an inexpensive and sensitive marker for APS1. Multiple different *AIRE* mutations were present, including four novel mutations. Functional analysis of novel mutations revealed disruption of intra-helical hydrogen binding and increased instability.

Steroid profiling by liquid chromatography–tandem mass spectrometry in patients with non-secreting adrenocortical adenomas and subclinical hypercortisolism

Guido Di Dalmazi[1,2], Flaminia Fanelli[1,3], Marco Mezzullo[1,3], Elena Casadio[1], Eleonora Rinaldi[1], Silvia Garelli[1], Valentina Vicennati[1], Uberto Pagotto[1] & Renato Pasquali[1]
[1]Endocrinology Unit, Department of Medical and Surgical Sciences, Alma Mater University of Bologna, Bologna, Italy; [2]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, Munich, Germany; [3]Centro di Ricerca Biomedica Applicata (CRBA), Alma Mater University of Bologna, Bologna, Italy.

Steroid profiling by liquid chromatography–tandem mass spectrometry (LC–MS/MS) offers an accurate and simultaneous detection of a panel of steroids with several advantages over traditional assays. However, only a few studies have investigated the steroid profiling in sporadic adrenocortical adenomas. Our aim was therefore to investigate steroid secretion by LC–MS/MS in patients with non-secreting adrenocortical adenomas (NSA) and subclinical hypercortisolism (SH), by analysing cortisol, 21-deoxycortisol (21-DF), 11-deoxycortisol, 17-hydroxy-progesterone (17-OHP), androstenedione, DHEA, testosterone, progesterone, 21-deoxycorticosterone (DOC), and corticosterone. Steroids were evaluated in basal condition and 60 min after stimulation with 250 μg of 1,24 ACTH. patients ($n = 94$) were analysed at baseline and compared to 190 sex- and age-matched controls. DHEA levels were progressively decreased in NSA and SH, respect to controls. Androstenedione and testosterone levels were also reduced in females. A significant positive correlation between basal DHEA and ACTH was found (correlation coefficient 0.403, $P < 0.001$), supporting the hypothesis that decreased stimulation of contralateral cortex by reduced ACTH levels is the likely cause of DHEA reduction. Considering the known anti-glucocorticoid effects of DHEA in adipocytes, we tested the potential effects of reduced DHEA on metabolic alterations. Increased BMI (correlation coefficient 2.01, $P < 0.001$) and cortisol after dexamethasone test (correlation coefficient 0.14, $P < 0.001$), and reduced DHEA (correlation coefficient −5.70, $P = 0.034$), were all factors independently associated with the increase of waist circumference. Stimulation study was performed on 56 patients and revealed that subjects with SH had higher levels of cortisol, 21-DF, DOC, corticosterone, and lower levels of DHEA and androstenedione respect to NSA. Steroid profiling with LC–MS/MS highlighted important clues into the secreting pattern of adrenocortical adenomas. Further studies are needed to address the clinical implication of the increased levels of gluco- and mineralocorticoid precursors in the pathogenesis of cardiovascular and metabolic correlates in SH.

Urinary glucocorticoid metabolites and adrenal incidentalomas?

Julie Brossaud[1,2], Dominique Ducint[1] & Jean-Benoît Corcuff[1,2]
[1]University Hospital, Bordeaux, France; [2]UMR 1286 INRA-Univ. Bordeaux, Bordeaux, France.

Objective
Urinary cortisol and metabolites represents total cortisol production and metabolism. We assayed these metabolites to compared the information that could be extracted compared to the one provided by a sole cortisol assay.

Design and patients
An inexpensive multiplex mass spectrometry assay was set up to quantify cortisol and its metabolites in 43 patients with benign secreting (AT+) or silent (AT−) adrenal tumours compared to 48 lean (Nl) or 143 obese (Ob) subjects, and to 26 patients with a Cushing's disease (CD). Their routine initial investigation included immunoreactive quantification of urinary free cortisol (UFC).
Results
Cortisol and metabolites were over-excreted in CD but not in Ob subjects. Nl and Ob were thus pooled in a control population (Ctl). Cortisol, tetrahydrocortisol (THF), and tetrahydrocortisone (THE) excretions were significantly increased in AT compared to Ctl subjects whereas immunoreactive UFC was similar. A logistic regression retaining cortisol, THF, and α- and β-cortolone as significant analytes allowed the construction of a receiver-operating characteristics (ROC) curve significantly better than the curve generated by cortisol alone (area under the curve (AUC) 0.927 vs 0.729, respectively, $P<0.0001$). More importantly, although there was no significant difference between Ctl vs AT− subjects for cortisol or metabolites a logistic regression retaining cortisol, alloTHF, and α- and β-cortolone as significant analytes generated a ROC curve performing significantly better than cortisol alone (AUC 0.910 vs 0.635, respectively, $P<0.0001$).
Conclusion
Cortisol and metabolites excretion is modified in AT, including AT−, patients even without modification of UFC. Clinical usefulness of these biomarkers has to be investigated in prospective studies following-up patients with AT.

Differential expression of the PKA subunits in adrenocortical adenomas

Isabel Weigand[1], Cristina Ronchi[1], Davide Calebiro[2], Petra Rank[3], Sonja Steinhauer[1], Felix Beuschlein[3], Bruno Allolio[1], Martin Fassnacht[1] & Silviu Sbiera[1]
[1]University Hospital Wuerzburg, Wuerzburg, Bayern, Germany; [2]Univeristy of Wuerzburg, Wuerzburg, Bayern, Germany; [3]University Hospital Munich, Munich, Bayern, Germany.

Recently, mutations in the PRKACA (catalytic subunit α of the PKA) gene have been identified as causative in 35% of adrenocortical adenomas (ACA) with overt Cushing's syndrome (Beuschlein *et al*. 2014). These mutations lead to constitutive activation of PKA signaling and subsequently to an excessive production of cortisol. Protein kinase A is a heterotetramer consisting of two catalytic and two regulatory subunits with several isoforms (Cα, β, γ, RIα, IIα, Iβ, and IIβ). The stable tetramer is inactive, only upon cAMP induced dissociation of the regulatory subunits the active catalytic subunits are released. Here, we investigated the expression of the different PKA subunits in a large set of adrenal tumors. We performed immunohistochemistry staining of all PKA regulatory subunits and Cα on FFPE tissue from normal adrenal glands ($n=8$), ACA ($n=65$, 30 cortisol-producing/CPA, 17 aldosterone-producing, and 18 inactive) and adrenocortical carcinomas (ACC: $n=29$, seven cortisol-, three androgen-, 12 mixed hormone-producing, and seven inactive). Our results indicate a significantly decreased expression of RIIβ in CPAs, but only in the *PRKACA* mutated samples. A tendency for reduced expression under *PRKACA* mutation was also observed for RIα. No change in expression was found for the other two regulatory subunits or Cα. While reduced RIIβ expression in CPAs had previously been described (Mantovani *et al*. 2008), until now, this phenomena could not be linked to *PRKACA* mutational status. The former hypothesis that the decreased level of RIIβ leads by itself to the cortisol excess seems to be wrong, because RIIβ was not significantly changed in both ACA and ACC from patients with overt Cushing's syndrome but without *PRKACA* mutation. We therefore postulate that the reduced protein expression of RIIβ in CPA described earlier is a direct or indirect consequence of the newly identified mutation and not a general feature in CPAs. If this decrease arises post-transcriptionally or at transcriptional levels still needs to be elucidated.

Mortality in patients with incidentally discovered adrenal adenomas: the experience of San Luigi Hospital

Giuseppe Reimondo[1], Marcella Coletta[1], Giulia Peraga[1], Anna Pia[1], Micaela Pellegrino[2], Chiara Massaglia[1], Barbara Zaggia[1], Paolo Cosio[1], Elena Mbachu[1], Giorgio Borretta[2] & Massimo Terzolo[1]
[1]Internal Medicine I, Department of Clinical and Biological Sciences, San Luigi Hospital, University of Turin, Orbassano, Italy; [2]Endocrinology, Santa Croce e Carle Hospital, Cuneo, Italy.

Background
Adrenal incidentalomas are found in 3–7% of radiological series and many of them are adrenal adenomas. Autonomous cortisol secretion without clinical signs of overt hypercortisolism is a common finding in these patients. Studies reported metabolic derangement and increased cardiovascular risk associated with this state of subtle cortisol excess, however scanty data are available on the natural history of this condition.
Aim
To assess the rate of mortality in patients with incidentally discovered adenomas.
Methods
We studied 110 patients (39 males and 71 females) with incidentally discovered adrenal adenomas from 1998 to 2013. Metabolic and hormonal parameters were determined. We collected the following data: blood pressure, plasma glucose, lipid profile, cortisol levels after 1 mg dexamethasone suppression test (1 mg-DST), plasma ACTH, and urinary free cortisol. Mortality data were obtained from the demographic registers.
Results
Mean age of patients was 67 years, with a mean follow-up of 94 months. Fourteen (12.7%) patients died: 4 (28.6%) for cancer, 7 (50.0%) for cardiovascular, and 3 (21.4%) for respiratory/infective causes. Twelve of them (85.6%) had 1 mg-DST >1.8 μg/dl (four had hypertension, four dyslipidaemia, and four diabetes) while 54/96 patients alive at the last follow-up (56.2%) had 1 mg-DST >1.8 μg/dl ($P=0.04$). Survival probability was significantly reduced in patients with 1 mg-DST >1.8 μg/dl, with a hazard ratio of death of 3.64 (95% CI, 1.34–9.7; $P=0.013$). Age did not differ between patients alive or dead at the last follow-up (65.1±9.8 years vs 65.1±9.8 years, NS).
Conclusion
Patients with incidental adrenal adenomas and autonomous cortisol secretion heralded by cortisol after 1 mg-DST >1.8 μg/dl may be at increased risk of mortality compared to patients with non-secreting adenomas. Excess mortality is mainly related to cardiovascular events.

GP.02.05

Comparison between PET–CT and CT in the diagnosis of recurrence of adrenocortical carcinoma

Chiara Massaglia[1], Arianna Ardito[1], Barbara Zaggia[1], Vittoria Basile[1], Ettore Pelosi[2], Vincenzo Arena[2], Daniele Penna[2] & Massimo Terzolo[1]
[1]Internal Medicine 1, San Luigi Hospital, University of Turin, Orbassano, Italy; [2]IRMET, PET–CT Diagnostic Imaging Center, Turin, Italy.

Adrenocortical carcinoma (ACC) is a rare tumour characterised by a high rate of recurrence following radical surgery. Surgery of recurrent ACC may increase survival; thus, it is mandatory a timely and accurate detection of recurrence, either to increase the chance of radical extirpation or to avoid unnecessary surgery. This study investigated the role of PET–CT in the diagnosis of recurrence of ACC during follow-up of disease-free patients and analyzed whether this tool may improve the therapeutic strategy. A retrospective evaluation of the use of PET–CT was done in ACC patients with suspected recurrence at CT imaging during their follow-up. Data of 57 patients followed at our center were retrieved. Recurrence was confirmed by pathology when lesions were removed (23 cases), or fine-needle biopsy (five cases), or detection of unequivocal tumour progression during follow-up (29 cases). CT scan of the 57 patients showed a total of 153 lesions while PET–CT showed at least one focal uptake in 40 patients (70.2%) for a total of 99 lesions. For liver lesions, PET–CT showed a significantly higher specificity and a reduced sensitivity (sensitivity, CT 80% vs PET 50%, $P=0.046$ and specificity, CT 89% vs PET 99%, $P=0.057$). With regard to local recurrence, the two tests had similar diagnostic accuracy (sensitivity: CT 87% vs PET 79%, $P=$NS and specificity: CT 94% vs PET 94%, $P=$NS). The same considerations apply to abdominal recurrences (sensitivity: CT 76% vs PET 70%, $P=$NS and specificity: CT 94% vs PET 99%, $P=$NS) and bone, in which CT and PET have equal sensitivity (86%) and specificity (98%). Conversely, in the lungs CT scan had non-significantly better diagnostic accuracy (sensitivity: CT 87% vs PET 53%, $P=$NS and specificity: CT 91% vs PET 95%, $P=$NS). In 18 patients (33%),

PET findings changed the therapeutic strategy that was planned after CT as to the possibility of a radical surgery. In conclusion, PET can be considered an useful adjunct to CT for the diagnosis of ACC recurrence, increasing diagnostic specificity for suspected liver or abdominal recurrences, and improving the identification of occult lesions or multiple tumour sites. Use of PET has important clinical implications, allowing a smarter use of surgery due to improved selection of patients who can be radically resected.

DNA methylation of *FKBP5* and its relationship with hippocampal volumes in Cushing's syndrome patients

Eugenia Resmini[1,2], Alicia Santos[1,2], Anna Aulinas[1,2], Susan Webb[1,2], Beatriz Gómez-Anson[2,3], Olivia Cox[4] & Richard Lee[4]
[1]Endocrinology/Medicine Departments, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBER-ER, Unidad 747), IIB-Sant Pau, ISCIII, Hospital Sant Pau, Barcelona, Spain; [2]Universitat Autònoma de Barcelona (UAB), Barcelona, Spain; [3]Neuroradiology Unit, Hospital Sant Pau, and IIB-Sant Pau, Barcelona, Spain; [4]Department of Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, Maryland, USA.

Introduction
FKBP5 is a protein that regulates glucocorticoid receptor sensitivity, via an ultra-short negative feedback mechanism. Variations in the *FKBP5* gene can influence the response to glucocorticoids (GC). Hypercortisolaemia plays a role on impairment of brain function and could be mediated by epigenetic variations of the *FKBP5* gene. Cushing's syndrome (CS), a disease characterized by hypercortisolaemia, is associated with memory deficits, lower hippocampal volumes and a wide range of cognitive impairments. Recently, it has been demonstrated that GC-induced methylation changes in FKBP5 observed in blood DNA can serve as a proxy to both methylation and expression changes in the brain. We aimed at evaluating DNA methylation of FKBP5 in blood and its relationship with memory and hippocampal volumes (HV) in CS patients.
Patients and methods
33 CS patients with memory impairments (nine active and 24 cured) and 33 matched healthy controls were included. Memory tests, 3Tesla MRI of the brain, and DNA extraction from total leukocytes was carried out in all subjects. DNA from CS patients and healthy controls were bisulfite treated, PCR amplified, and pyrosequenced to assess a total of 34 CpG dinucleotides in introns 1, 2, and 5 of the *FKBP5* gene.
Results
We observed lower methylation in introns 2 and 5, in both cured and active CS patients compared to controls ($P<0.001$ and $P<0.05$ respectively). We also observed a positive correlation between the total methylation values and hippocampal volumes in active patients ($r=0.86$, $P<0.01$ left HV and $r=0.80$, $P=0.01$ right HV), but not with memory tests. However, there were multiple correlations between single CpG dinucleotides and memory test variables ($P<0.01$).
Conclusion
As lower DNA methylation in FKBP5 is associated with higher GC exposure and gene expression, our results demonstrate a relationship between blood DNA methylation and GC-induced brain impairments in CS patients.

Urinary free cortisone as a potential biomarker in diagnosing patients with mild Cushing's syndrome

Laura Trementino, Carolina Concettoni, Marianna Martino, Giorgia Marcelli, Grazia Michetti, Marco Boscaro & Giorgio Arnaldi
[1]Division of Endocrinology, Polytechnic University of Marche, Ancona, Italy; [2]Endocrinology Unit, Department of Medicine DIMED, University Hospital of Padua, Padua, Italy.

Introduction
Urinary free cortisol (UFC) determination has suboptimal sensitivity (SE) and specificity (SP) especially in mild Cushing's syndrome (CS).
Aim
To determine the performance of UFC and its metabolite cortisone (UFE) measured using accurate assays such as HPLC and LC–MS/MS in diagnosing patients with CS.
Patients and methods
Sixty-seven patients with CS were compared to 49 sex- and age-matched non-CS. UFF and UFE levels were assessed by HPLC until 2009 and afterwards by LC–MS/MS. The mean value of two 24-h urine collections was used for the analysis. SE and SP were calculated at different cut-off values using ROC curve analysis.
Results
UFF and UFE values were significantly higher in patients with CS. However, the diagnostic performance of UFF by HPLC was low with 75.8% SE and 81.1% SP (cut-off value >33.9 μg/24 h). The performance of UFF by LC–MS/MS was 88.2% SE and 91.2% SP (cut-off value >47.4 μg/24 h). The performance of UFE was better than UFF by both assays. UFE by LC–MS/MS showed 97.1% SE and 91.7 SP% using a cut-off value >88.7 μg/24 h. When CS patients were stratified according to disease severity, UFE by LC–MS/MS showed a good diagnostic profile also in mild CS (UFF $<2\times$ ULN) with 92.3% SE and 91.7% SP (cut-off value >88.7 μg/24 h). Conversely, the performance of UFF in mild CS was low (84.6% SE and 75% SP; cut-off value >44.2). UFF and UFE showed an optimal diagnostic performance with 100% SE and 100% SP in moderate to severe CS (UFF $\geq 2\times$ ULN). The performance of urinary steroids was not different according to age, sex, disease aetiology, and disease status in CS.
Conclusions
UFE measured by LC–MS/MS seems to be a new and good biomarker in diagnosing CS especially in patients with mild hypercortisolism at higher risk for misdiagnosis with UFF.

ACTH-ectopic syndrome in four patients, caused by phaeochromocytoma

Eugenia Marova, Ludmila Rozhinskaya, Nikolay Kuznetsov, Anastasia Lapshina, Iya Voronkova, Svetlana Arapova, Galina Kolesnikova & Vadim Krylov
Endocrine Research Centre, Moscow, Russia.

Phaeochromocytomas are responsible for the development ACTH-ectopic syndrome in 5% cases. Less than 1% phaeochromocytoma accompanied by symptoms of ACTH-dependent hypercortisolism. We observed four cases of ACTH-secreting phaeochromocytoma during 2 years. All patients were women from 50 to 63 years. The disease duration ranged from 6 months to 5 years. The clinical picture presented the signs of hypercortisolism (matronism, hyperpigmentation of the skin, the redistribution of fatty tissue on the central type, and steroid myopathy) and hypercatecholaminaemia (arterial hypertension, tachycardia, shortness of breath, and frequent urination). Hormonal blood study found: morning ACTH 43.0–189.0 pg/ml (normal 7.0–66.0) evening 179.8–291.0 (normal 0–30.0), morning cortisol 962–4655 nmol/l (normal 123.0–626.0), evening 1256–2460 (normal 46.0–270.0), free cortisol in 24-h urine 3726.0–3828.0 nmol/day (normal 60.0–413.0); metanephrine in daily urine in three of four patients (638.0–1481.0 μg/day at the rate of 25.0–312.0) and normetanephrine (545.6–1553 μg/day at the rate of 35.0–445.0) (one patient had normal catecholamine levels). CT scans revealed tumors in the left adrenal glands sizes and density: $2.0\times1.6\times1.0$ cm (27H), $2.7\times3.0\times4.6$ cm (38H), and diameter 4.3 cm (density did not specified). In one case found two nodes: $1.8\times2.3\times2.5$ and $2.0\times2.3\times2.5$ cm (19H and 3H). Histological examination diagnosed three phaeochromocytoma combined with diffuse-nodular adrenal cortex hyperplasia and one mixed tumour (phaeochromocytoma and adenoma of the adrenal cortex). Immunohistochemical examination confirmed expression of ACTH in all cases. In all patients developed adrenal insufficiency and normalized levels of catecholamines after removal of adrenal tumors.
Conclusion
The diagnosis of ACTH-secreting phaeochromocytoma was established on the symptoms of hypercortisolism and hypercatecholaminaemia, excessive secretion of ACTH, cortisol and catecholamines in the blood and urine, the presence of neoplasms in the adrenal glands, the normalization of respective hormones after tumours removal, histological, and immuhistochemical confirmation of ACTH-secreting phaeochromocytomas.

Pregnancy in women with non-classical congenital adrenal hyperplasia: time to conceive and outcome

Ori Eyal[1,2], Anat Segev-Becker[1], Irit Ayalon[2], Anita Schachter-Davidov[1,2], Asaf Oren[1,2] & Naomi Weintrob[1,2]
[1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; [2]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel.

Background
Non-classical 21-hydroxylase deficiency (NC21OHD) is a mild form of congenital adrenal hyperplasia associated with different degrees of postnatal virilisation. Elevated serum androgen concentrations have been reported to be a risk factor for infertility, early pregnancy loss, and recurrent miscarriages in women with polycystic ovarian syndrome (PCOS).
Aims
The aim of this study was to assess time to conceive and pregnancy outcome in NC21OHD women in correlation with glucocorticoid (GC) therapy and androgen levels.
Patients and methods
We conducted a retrospective observational study in a tertiary medical centre. The outcome of 130 pregnancies among 59 women (mean age at diagnosis 20 ± 9.5 years and mean age at first pregnancy 29 ± 5years) with biochemical and genetic diagnosis of NC21OHD was reviewed. Androgen and 17OHP levels were measured before and during each trimester. The mean GC dose was 7.4 ± 3.3 mg hydrocortisone/m^2.
Results
There was no difference in time to conceive between pregnancies of women with and without treatment (7.7 ± 11 months vs 7.5 ± 25 months). There were 29 pregnancies without GC therapy and 101 with GC therapy. There was no significant difference between the rate of miscarriages between treated and untreated pregnancies (25% vs 17%, respectively, $P=0.6$). Birth weight was significantly lower in GC-treated pregnancies compared to untreated pregnancies (2.9 ± 0.4 kg vs 3.2 ± 0.5 kg, respectively, $P=0.03$). Androgen and 17OHP levels were similar in pregnancies that ended with miscarriage and those that ended with live birth.
Conclusions
Time to conceive is similar between treated and untreated pregnancies in NC21OHD women. In contrast to previous reports, there was no difference in miscarriage rates between treated and untreated pregnancies. There was significant decrease in birth weight in treated pregnancies despite the use of low doses of GC.

Androgens and erythropoiesis in females: an insight from patients with congenital adrenal hyperplasia

Nayananjani Karunasena, Richard J Ross & Eleni Daniel
Academic Unit of Diabetes, Endocrinology and Metabolism, Department of Human Metabolism, University of Sheffield, Sheffield, UK.

Background
Androgens promote erythropoiesis and have been used for the treatment of anaemia. Furthermore, polycythemia is a known side effect of androgen therapy. In congenital adrenal hyperplasia (CAH), elevated adrenal androgens cause virilisation of female patients. Glucocorticoid treatment reduces androgen levels but there is a difficult balance between excess androgens and suppressed androgens due to excess glucocorticoid treatment.
Aim of study
To investigate the relationship between androgens and erythropoiesis in females with CAH.
Methodology
A retrospective case note review of 63 patients with CAH. Androgen levels and blood counts performed on the same day were collected and analysed in 44 patients; patients with medical conditions known to affect erythropoiesis were excluded.
Results
44 patients were studied (27 females); mean age was 35.5 ± 13.2 years. In women, there was a positive correlation of testosterone, androstenedione and 17-OHP levels with haemoglobin (Hb) and haematocrit (Hct).

Table 1 Correlations of Hb and Hct with androgens and 17-OHP in women.

	17-OHP	Androstenedione	Testosterone
Hb	$r=0.42$ ($P=0.0069$)	$r=0.4129$ ($P=0.0012$)	$r=0.4442$ ($P=0.0028$)
Hct	$r=0.3564$ ($P=0.024$)	$r=0.4346$ ($P=0.0006$)	$r=0.3673$ ($P=0.0154$)

There was a difference in Hb and Hct between patients with high, normal, and low androstenedione levels (ANOVA, $P<0.01$). Hct, but not Hb was significantly different with high, normal, and low testosterone levels (ANOVA, $P<0.01$). *Post hoc* analysis showed mean Hb and Hct levels were significantly different between high and low androstenedione and testosterone subgroups ($P=0.001$).
Conclusions
There is a positive correlation between adrenal androgens and erythropoiesis in women with CAH. This effect is significant not only at high levels of androgens but also at low levels. Suboptimal control of androgens in this group of patients may increase the risk of polycythemia and anaemia. Use of Hb and Hct as markers of disease control should be investigated in larger populations of CAH women.

Radiofrequency bipolar ablation therapy for primary aldosteronism patients: investigator-initiated exploratory clinical trial

Kei Takase[1], Kazumasa Seiji[1], Ryo Morimoto[2], Yoshizugu Iwakura[2], Yoshikiyo Ono[2], Kei Omata[2], Masataka Kudo[2], Tomo Kinoshita[1], Fumitoshi Satoh[2] & Sadayoshi Ito[2]
[1]Department of Diagnostic Radiology, Tohoku University Hospital, Sendai, Japan; [2]Division of Nephrology, Endocrinology, and Vascular Medicine, Department of Medicine, Tohoku University Hospital, Sendai, Japan.

Purpose
To evaluate safety and efficacy of percutaneous radiofrequency ablation therapy for unilateral aldosterone producing adrenal adenoma in normalising aldosterone secretion.
Patients
Eight cases of aldosterone producing adrenal adenoma with following conditions: i) CT detectable adenoma without any risky organs on a puncture route. ii) Intervening adipose tissue between target adenoma and adjacent risky organs (pancreas or intestine). iii) Unilateral single functioning macroadenoma with aldosterone hypersecretion proven by adrenal venous sampling.
Methods
CT guided puncture of adrenal adenoma with one or two (according to the size of the adenoma) bipolar radiofrequency ablation needle was performed, followed by ablation with total power of 4–6 kJ. Blood pressure was monitored with an arterial catheter during the procedure. Aldosterone levels in serum and 24-h urine collection 7 days after ablation were evaluated as primary outcomes. ACTH, cortisol, serum aldosterone, renin activity, osmotic pressure, potassium level, urine osmolality, and antihypertensive medication dose at screening, 3, 7, 28, and 84 days after ablation therapy were also evaluated. Ablation effect was morphologically evaluated by enhanced CT 7 days after treatment.
Results
In all cases, aldosterone levels in serum and 24-h urine were significantly decreased; Serum potassium level was normalized without anti-aldosterone therapy. Postoperative CT showed complete ablation in six cases and subtle residual enhanced area in two cases. Doses of anti-hypertensive medication were reduced in all cases including two drug-free patients after ablation. No severe procedure-related complication was observed.
Conclusion
Bipolar radiofrequency ablation is thought to be safety and effective in treating primary aldosteronism.

Prolactinoma and primary aldosteronism: is there a causal link?

Tracy Ann Williams[1,2], Anna Dietz[1], Felix Beuschlein[1], Paolo Mulatero[2] & Martin Reincke[1]
[1]Ludwig-Maximillians-University-Munich, Munich, Germany; [2]University of Turin, Turin, Italy.

Introduction
We report the largest case series of concomitant prolactinoma and aldosterone-producing adenoma (APA), diagnosed in four patients from the German Conn Registry and in three patients at the Hypertension Unit, University of Torino. A disproportionate number (five out of seven) presented with macro-prolactinomas indicating that elevated prolactin (PRL) concentrations may play a role in APA formation. Further, increased expression of *PRLR* in the zona glomerulosa could sensitise the adrenal gland to the high circulating levels of PRL in prolactinoma patients.
Methods
PRLR gene expression data was from the GTEx Portal database2 (dbGaP accession number phs000424.vN.pN: www.gtexportal.org). Transcriptional profiles of eight APA and three normal adrenals were compared using an Affymetrix GeneChip HG-U133 Plus 2.0 gene expression platform. Effects of PRL were tested on *CYP11B2* gene expression levels and aldosterone production in NCI H295R cells.
Results
The uterus and the adrenal gland expressed the highest levels of the *PRLR* of the 45 tissues in the GTEx Portal database. Microarray analysis demonstrated a 1.55-fold upregulation of *PRLR* gene expression in APA compared to normal adrenals. In H295R cells PRL (100 nM) resulted in a 1.35 ± 0.02-fold upregulation in *CYP11B2* gene expression and a 1.26 ± 0.07-fold increase in aldosterone production.
Conclusion
High levels of PRL result in *CYP11B2* upregulation and an increase in aldosterone production *in vitro* and may play a role in APA development in cases of concomitant prolactinoma–APA.

Short-term blood pressure response to mineralocorticoid-receptor blockade in aldosteronisms: primary hyperaldosteronism vs aldosterone-associated hypertension/low-renin hypertension

Irene Crespo[1], Teresa Ruiz-Gracia[1], Ana Ortolá[1], Emilia Gomez-Hoyos[2], Martin Cuesta[3], Ana Barabash[1], María Victoria Saez-de Parayuelo[1], Marisol Sanchez-Orta[1], Alfonso Calle-Pascual[1] & Isabelle Runkle[1]
[1]Hospital Clinico San Carlos, Madrid, Spain; [2]Hospital Clinico de Valladolid, Valladolid, Spain; [3]Beaumont Hospital, Dublin, Ireland.

Introduction
Some authors consider aldosteronism to be a spectrum, ranging from aldosterone-associated (or low-renin) hypertension (AAH) to primary hyperaldosteronism (PHA) due to bilateral adrenal hyperplasia. Thus, blood pressure (BP) response to mineralocorticoid-receptor blockade (MRB) could be similar.
Methods
Retrospective analysis of 60 patients. Screening per Endocrine Society guidelines, positive screening: aldosterone (pg/ml) to direct-renin (pg/ml) (ARR) ≥ 25. 25-mg Captopril test (CAP) on doxazosine and/or long-acting verapamil, positive for PHA if aldosterone ≥ 130 pg/ml or ARR ≥ 50, 1 or 2 h post-captopril. Patients negative for PHA with basal CAP ARR ≥ 50 or low renin levels were diagnosed with AAH. MRB (50–100 mg spironolactone or 200–300 mg eplerenone) as sole BP medication. BP (mmHg). Mann–Whitney *U*, Student's *t*, and Wilcoxon, χ^2 tests. SPSS 15.
Results
Baseline characteristics HAP vs AAH: 28/60 vs 32/60 patients, 67.9% vs 75% women, mean age 55.4 (S.D.: 2.7) vs 53.9 (S.D.: 9.9). Number BP-lowering drugs: 2 (IQR: 1–2) vs 1 (IQR: 1–2). Resistant hypertension (RH): 6/28 (21.4%) vs 2/32 (6.3%). Major CV events and/or renal failure: 8/28 (28.6%) vs 5/32 (15.6%), $P=0.06$. Hypokalemia: 5/28 (17.8%) vs 0/32 (0%), $P=0.003$. Serum potassium (mmol/l) (SK): 4.0 mmol/l (S.D.: 0.6) vs 4.2 (S.D.: 0.5) (*n*: 3.5–5.5), serum creatinine (mg/dl) (SC): 1.0 (S.D.: 0.5) vs 0.89 (S.D.: 0.3), office systolic BP (SBP): 154 (S.D.: 22.6) vs 151 (S.D.: 16.6), office diastolic BP (DBP): 90 (S.D.: 14.4) vs 90 (S.D.: 12.1). Response to 2 weeks of MRB: SBP 128 (S.D.: 15.7) vs 123 (S.D.: 11.8), DBP: 77 (S.D.: 10.7) vs 75 (S.D.: 9.1). SK: 4.6 (S.D.: 0.5) vs 4.7 (S.D.: 0.5). SC: 1.14 (S.D.: 0.7) vs 1.00 (S.D.: 0.4). The descent in both SBP and DBP was significant in PHA (both $P<0.001$) as in AAH (both $P<0.001$). No significant differences were found in SBP ($P=0.569$) nor DBP ($P=0.389$) reductions following MRB in PHA vs AAH.
Conclusion
The CAP can identify both patients with PHA and AAH. Both groups present a similar, dramatic and rapid BP response to high-dose MRB, suggesting that AAH patients should be identified, and the same protocol for medical therapy used in PHA and AAH. Furthermore, our results support the hypothesis that aldosterone-induced hypertension is a continuum.

Applying a new decision threshold to an old test: does the measurement of plasma metanephrines in patients fasting and supine improve diagnostic sensitivity?

Ruth Casey, Marcia Bell, Michael Dennedy & Paula O'Shea
Galway University Hospital, Galway, Ireland.

The recently published Endocrine Society Clinical Practice guideline on phaeochomocytoma and paraganglioma (PPGL) recommends measuring plasma metanephrines (PMets) with patients in the supine position after an overnight fast and using appropriately defined reference intervals.[1] Studies have shown higher diagnostic sensitivities using the latter pretesting criteria.[2] However, this testing protocol is resource intensive and arguably impractical in routine clinical practice. In our institution blood samples for PMets are collected with patients non-fasting and seated using reference intervals established accordingly. The aim of the present study was to assess the effects on diagnostic test performance retrospectively in patients who underwent PMets screening in our institution between 2009 and 2014 using reference intervals derived in subjects fasting and supine. A total of 150 patients were included in this study. There were 79 males (53%) and 71 females (47%). The mean age was 54.3 years (S.D. 6 years). A total of 45 (30%) patients would have had a positive test result based on the supine reference interval being applied vs a total of 8 (5.3%) patients who screened positive using the decision thresholds derived in seated subjects. There were 6 (4%) patients with histologically confirmed PPGL in this cohort and no case would have been missed using the non-fasting and seated reference intervals for PMets. The most common alternative diagnosis for the 39 patients who screened positive for PMets using the new supine reference interval but who did not have a diagnosis of PPGL was essential hypertension ($n=19$, 48.7%). This study demonstrates that the existing, more pragmatic pretesting protocol for PMets collection resulted in no false-negative biochemical screening for PMets over a 5-year period and that application of a supine reference interval would have resulted in 39 false-positive results in this same time period.

Comparison of urinary metanephrine concentrations after unilateral adrenalectomy for pheochromocytoma to healthy subjects

Yoon Young Cho, Dong Ik Cha, Jae Hoon Chung, Sun Wook Kim & Jae Hyeon Kim
Samsung Medical Center, Seoul, Republic of Korea.

Background
Urinary metanephrine (MN) and normetanephrine (NMN) are used to detect recurrence of pheochromocytoma during post-operative period. Currently, reference ranges of urinary MN and NMN obtained from healthy individuals are applied to subjects with adrenalectomy. However, studies regarding the property of using reference ranges from healthy subjects in pheochromocytoma subjects with adrenalectomy are limited.
Aim
To compare urinary MN and NMN concentrations in patients after unilateral adrenalectomy to concentrations in healthy subjects.
Methods
A single-center retrospective study was conducted in pheochromocytoma patients confirmed with pathology. Eighty-two patients underwent unilateral adrenalectomy between February 2004 and June 2014 and had no evidence of recurrence during follow-up period. Urinary MN and NMN were checked before and after surgery with 3- or 6 month-intervals.
Results
Urinary MN concentration after unilateral adrenalectomy was lower than control group (70.0 μg/day vs 92.0 μg/day, $P<0.001$), whereas urinary NMN was not

different (220.9 μg/day vs 232.0 μg/day). According to post-operative period, urinary NMN determined in immediate post-operative period (whithin 1 month after surgery) was higher than the concentration in the period between 12 and 36 months (287.3 μg/day vs 204.0 μg/day, $P<0.01$). Urinary MN in male subjects was higher compared to the concentration in female subjects (81.0 μg/day vs 64.8 μg/day, $P<0.01$).

Conclusions

Urinary MN concentration in pheochromocytoma patients after unilateral adrenalectomy was lower than the concentration in control group. Different reference ranges of urinary MN are needed for post-operative pheochromocytoma patients. Urinary NMN was not different in both groups, however tendency that the concentration was higher in immediate post-operative period was observed.

Obstructive sleep apnea presenting as pseudophaeochromocytoma

Hela Marmouch[1,2], Sondes Arfa[1], Tasnim Slim[1], Fadia Boubaker[1], Manel Jmal[1,2], Hanene Sayadi[1,2] & Ines Khochtali[1,2]
[1]Department of Internal Medicine–Endocrinology, Monastir, Tunisia; [2]Faculty of Medicine, Monastir, Tunisia.

Introduction

The obstructive sleep apnea syndrome (OSAS) has a well-documented association with increase cardiovascular morbidity and mortality. The patients with OSAS have a high prevalence of hypertension (HTA).

Case report

A 52-year-old female with a history of poorly controlled resistant HTA was admitted to our hospital with severe HTA. She had a history of fatigue and intermittent episodes of palpitations. Laboratory evaluation was significant for elevated 24-h urinary catecholamine levels (CU=3.5×). This case was presenting with a clinical and biochemical picture indistinguishable from that of phaeochromocytoma. However, neither computed tomography nor MIBG scintigraphy detected any catecholamine-producing tumor in or outside the adrenal glands. Our patient was screened with full polysomnography because of heavy snoring, daytime somnolence, and obesity. It revealed severe (OSAS). After three months of continuous positive airway pressure therapy, the patient experienced resolution of his presenting symptoms, improved blood pressure control and normalisation of his CU. This case highlights sleep disordered breathing as a potentially reversible cause of pseudo phaeochromocytoma (PPH).

Discussion

The OSAS can elevate catecholamine secretion and increased sympathetic activity which may mimic the biochemical profile of PPH. Treatment of OSAS may normalise the effects of this sympathetic overdrive and resolve excessive CU secretion. In this observation, we report a case of PPH caused by OSAS; a common medical condition which is less recognised as a cause of raised catecholamines.

Dual 5α-reductase inhibition causes hepatic lipid accumulation in man

Jonathan Hazlehurst[1], Andrei Oprescu[2], Nikolaos Nikolaou[1], Annabel Grinbergs[3], Nigel Davies[4], Robert Flintham[4], Beverley Hughes[2], Angela Taylor[2], Jinglei Yu[5], Anton Wagenmakers[5] & Jeremy Tomlinson[1]
[1]OCDEM, University of Oxford, Oxford, UK; [2]CEDAM, University of Birmingham, Birmingham, UK; [3]NIHR/Wellcome Trust Research Facility, University Hospitals Birmingham, Birmingham, UK; [4]MRI Physics, University Hospitals Birmingham, Birmingham, UK; [5]School of Sport and Exercise Science, University of Birmingham, Birmingham, UK.

5α reductases 1 and 2 (SRD5A1 and SRD5A2) metabolise cortisol into inactive 5α-dihydrocortisol contributing to the regulation of cortisol availability in addition to their established role in the generation of dihydrotestosterone from testosterone. Dutasteride and finasteride are commonly prescribed to patients with benign prostatic hyperplasia but their potential metabolic effects have only recently been identified. Dutasteride inhibits both SRD5A1and SRD5A2 whilst finasteride inhibits SRD5A2 alone. Importantly, mice with deletion of SRD5A1 are more susceptible to hepatic steatosis and fibrosis. We conducted a randomised, double-blind study in 12 healthy male volunteers (age 36.3±4.4 years, BMI (kg/m^2) 26.6±1.2). Volunteers underwent hepatic magnetic resonance spectroscopy to evaluate intrahepatic lipid content and a series of detailed metabolic assessments including adipose microdialysis and a hyperinsulinaemic–euglycaemic clamp incorporating stable isotopes to measure lipogenesis and glucose handling. Subjects were then randomised to receive either finasteride (5 mg OD) or dutasteride (0.5 mg OD) for 21 days then all investigations were repeated. Dutasteride, not finasteride increased hepatic glucose output (EGP (mg/kg per min) D: 0.609±0.07, 0.924±0.14, $P=0.046$; F: 0.711±0.12, 0.539±0.08, $P=0.19$). Neither, impacted peripheral glucose disposal. Adipose tissue interstitial release of glycerol was decreased by dutasteride in the presence of insulin (AUC glycerol (μmol/l) D: 203±30.6, 104.5±22.1, $P=0.01$; F: 151.02±36.9, 160.7±21.7, $P=0.83$). Although, dutasteride increased de novo lipogenesis, this did not reach statistical significance. (D: 1.21±0.36, 6.50±2.7%, $P=0.14$; F: 1.55±0.51, 1.33±0.33%, $P=0.64$). Intrahepatic lipid increased after dutasteride, but not finasteride treatment (PDFF%: D: 0.88±0.49, 1.15±0.57, $P=0.04$; F: 3.05±2.24, 3.69±2.84, $P=0.36$). Furthermore, there was a positive correlation between change in DNL and change in hepatic steatosis in those treated with dutasteride (R^2, $P<0.01$). In conclusion, inhibiting SRD5A1 with dutasteride promotes an adverse metabolic phenotype resulting in increased intrahepatic lipid and endorses previous observations in rodent studies. Further detailed studies are needed in patients prescribed 5α-reductase inhibitor therapy.

The modulation of corticosteroid metabolism by hydrocortisone therapy in patients with hypopituitarism increases tissue glucocorticoid exposure

Mark Sherlock[1,2,3], Lucy Ann Behan[4], Mark Hannon[4], Aurora Aragon Alonso[1], Christopher Thompson[4], Robert Murray[5], Nicola Crabtree[6], Beverly Hughes[1], Wiebke Arlt[1], Amar Agha[4], Andrew Toogood[1] & Paul M Stewart[1]
[1]Centre for Endocrinology, Diabetes and Metabolism, University of Birmingham, Birmingham, UK; [2]Department of Endocrinology and Diabetes, Adelaide and Meath Hospitals, Incorporating the National Children's Hospital, Dublin, Ireland; [3]Trinity College Dublin, Dublin, Ireland; [4]Department of Endocrinology, Diabetes and Metabolism, Beaumont Hospital and RCSI Medical School, Dublin, Ireland; [5]Department of Endocrinology, Leeds Teaching Hospitals NHS Trust, St James's University Hospital, Leeds, UK; [6]Department of Nuclear Medicine, Queen Elizabeth Hospital, Birmingham, UK.

Context

Patients with hypopituitarism have increased morbidity and mortality. There is ongoing debate around the optimum glucocorticoid replacement therapy.

Objective

To assess the effect of glucocorticoid replacement in hypopituitarism on corticosteroid metabolism and its impact on body composition.

Design and patients

We assessed the urinary corticosteroid metabolite profile (using gas chromatography/mass spectrometry) and body composition (clinical parameters and full body DEXA) of 53 patients (19 females, median age 46 years) with hypopituitarism (33 ACTH deficient/20 ACTH replete) (study A). The corticosteroid metabolite profile of ten patients with ACTH deficiency was then assessed prospectively in a cross over study using three hydrocortisone dosing regimens (20/10, 10/10, and 10/5 mg) (study B) each for 6 weeks. 11β-HSD1 activity was assessed by urinary THF+5α-THF/THE.

Setting

Endocrine Centres within University Teaching Hospitals in UK and Ireland.

Main outcome measures

Urinary corticosteroid metabolite profile and body composition assessment.

Results

In study A, when patients were divided into three groups: patients not receiving HC, patients receiving HC <20 or >20 mg/day, patients in the group receiving the highest daily dose of HC had significantly higher WHR than the ACTH replete group. They also had significantly elevated THF+5α-THF/THE ($P=0.0002$) and total cortisol metabolites ($P=0.015$). In study B, patients on the highest hydrocortisone dose had significantly elevated total cortisol metabolites and all patients on hydrocortisone had elevated THF+5α-THF/THE ratios when compared to controls.

Conclusions
In ACTH deficient patients daily HC doses of >20 mg/day have increased WHR, THF+5α-THF/THE ratios and total cortisol metabolites. Glucocorticoid metabolism and induction of 11β-HSD1 may play a pivitol role in the development of the metabolically adverse hypopituitary phenotype.

DOI: 10.1530/endoabs.37.GP.04.02

GP.04.03

Using a morning cortisol to predict adrenal reserve and guide management

Conor Woods[1], Nicola Argese[3], Matthew Chapman[2], Rachel Webster[4], Andrew Toogood[2], Wiebke Arlt[2], Paul Stewart[5], Rachel Crowley[2] & Jeremy Tomlinson[1]
[1]Oxford Centre for Diabetes Endocrinology and Metabolism, University of Oxford, Oxford, UK; [2]Centre for Endocrinology, Diabetes and Metabolism, University of Birmingham, Birmingham, UK; [3]Department of Endocrinology, St Andrea Hospital, Rome, Italy; [4]Department of Biochemistry, Queen Elizabeth Hospital, University of Birmingham, Birmingham, UK; [5]Department of Endocrinology, University of Leeds, Leeds, UK.

Background
The short Synacthen test (SST) is the most widely used dynamic assessment of adrenal reserve. In some situations, the SST may be difficult to perform. Random basal cortisol levels could provide an alternative screening assessment to rationalize which patients need dynamic testing. This is highly clinically relevant, given the large numbers of patients taking prescribed glucocorticoids who are at risk of iatrogenic adrenal suppression.
Methods
3603 SST results (all performed in the morning) were analysed from electronic records in a large secondary/tertiary centre across all specialities. A 30 min cortisol value >549 nmol/l was defined as a pass. Results were divided into subgroups including age, sex, pituitary, and adrenal pathology and patients taking inhaled corticosteroids (ICS). Receiver operator characteristic curves were used to generate area under the curve (AUC), best-fit cortisol values and to predict cut-off values for specificities and sensitivities.
Results
Baseline and 30 min cortisol levels correlate positively ($r=+0.74$, $P<0.0001$). Basal cortisol levels >440 and ≥506 nmol/l gave 99 and 100% specificity respectively for passing the SST. Baseline cortisol <107 nmol/L gave a 99% sensitivity for failing. Cut-off values and AUCs were similar between groups divided by sex, age, and menopausal status. In patients currently taking ICS, 31% failed an SST (71/226). Patients taking ICS with a basal cortisol ≥359 nmol/l (36%, $n=81$) passed, and those with a cortisol <34 nmol/l (4%, $n=9$) failed an SST. In post-pituitary surgery patients ($n=329$), those with basal cortisol above 350 nmol/l (23%) passed, and those below 46 nmol/l (11%) failed the SST.
Conclusion
Baseline cortisol levels can be informative in predicting the SST response. A high clinical index of suspicion of adrenal insufficiency mandates dynamic assessment of adrenal reserve by SST. However, a basal cortisol may have a clinical utility in discrete patient cohorts, such as those on ICS, in whom, within our cohort, 40% ($n=90$) of SSTs could have been avoided.

Regulation of lipogenesis in human hepatocytes by androgens, glucocorticoids, and 5α-reductase

Nikolaos Nikolaou[1,3], Maryam Nasiri[2], Sylvia Parajes[2], Nils Krone[2], George Mastorakos[3], George Valsamakis[3], Beverly Hughes[2], Angela Taylor[2], Iwona Bujalska[2], Laura Gathercole[1] & Jeremy Tomlinson[1]
[1]University of Oxford, Oxford, UK; [2]University of Birmingham, Birmingham, UK; [3]University of Athens, Athens, Greece.

Non-alcoholic fatty liver disease (NAFLD) is rapidly becoming the commonest cause of liver cirrhosis and leading indication for liver transplant worldwide. It is tightly associated with obesity and type 2 diabetes, yet the precise mechanisms that drive its aetiology are not fully defined. Dysregulation of both glucocorticoid and androgen metabolism has been implicated in its pathogenesis. The availability of these hormones to bind and activate their receptors is mainly regulated by 5α-reductase type 2 (5αR2) that inactivates glucocorticoids and converts testosterone to dihydrotestosterone (DHT). We have therefore explored the role of androgens and glucocorticoids and their metabolism by 5αR2 upon lipid homeostasis in human hepatocytes. In human hepatoma cell lines, androgen treatment (testosterone and DHT) increased *de novo* lipogenesis (DNL) (7001.8±258.58 (ctrl) vs 8747.76±433.39 (testosterone) and 8970.03±330.17 (DHT), $P<0.05$). Furthermore, androgen receptor (AR) over expression, even in the absence of androgens, increased lipogenesis (7001.8±258.58 (ctrl) vs 14 193.2±755.17 (AR), $P<0.05$). Changes in lipid accumulation were paralleled by changes in lipogenic gene expression including fatty acid synthase (FASN) and acetyl CoA carboxylase (ACC1) (FASN: ctrl 13.90±1.99 vs AR 66.78±6.22 and ACC1: ctrl 1.06±0.26 vs AR 3.52±0.29, $P<0.05$). Similar observations were made in primary human hepatocytes from female, but not male donors. Glucocorticoids decreased DNL, an effect that was abrogated by over expression of 5αR2 and augmented by pharmacological inhibition of 5αR2 activity. In conclusion, we have demonstrated the ability of androgens and glucocorticoids to regulate lipogenesis in human hepatocytes. In addition, we have identified the potential for ligand independent activation of the androgen receptor to alter lipid flux. Finally, modulation of 5αR2 activity has the ability to regulate local steroid hormone availability that can impact upon metabolic phenotype within hepatocytes that may have implications for those patients currently taking 5αR inhibitors.

Glucocorticoid receptor and HSD11B1 gene polymorphisms influence the therapy and therapy-associated morbidities in patients with Addison's disease

Agnes Molnar[1], Annamaria Kovesdi[1], Nikolette Szucs[1], Miklos Toth[1], Peter Igaz[1], Karoly Racz[1,3] & Attila Patocs[2,4]
[1]2nd Department of Internal Medicine, Semmelweis University, Budapest, Hungary; [2]Lendület' Hereditary Endocrine Tumours Research Group, Budapest, Hungary; [3]Molecular Medicine Research Group, Hungarian Academy of Sciences, Semmelweis University, Budapest, Hungary; [4]Department of Laboratory Medicine, Semmelweis University, Budapest, Hungary.

Objective
Glucocorticoids exert their effects through the glucocorticoid receptor (GR). The local, cell-type specific glucocorticoid effect is modulated by the 11β-hydroxysteroid dehydrogenase enzymes (HSD11B) responsible for the interconversion of cortisone and cortisol. Individual sensitivity against glucocorticoids and activity of the HSD11B enzymes are at least partly determined by genetic factors.
Aim
To test whether SNPs of GR and HSD11B1 genes (N363S-rs6195, BclI-rs41423247, A3669G-rs6198 of GR; and rs12086634, rs4844880 of HSD11B1) influence the glucocorticoid replacement dosage, and clinical/laboratory parameters in patients with Addison's disease.
Patients and methods
67 patients with primary adrenal insufficiency diagnosed and treated at the 2nd Department of Medicine, Semmelweis University were studied. Clinical, laboratory data, and the dosage of the hormone replacement therapy were collected. Peripheral blood DNA was isolated, and the *GR* gene SNPs were examined using allele-specific PCR (for BclI and N363S) or TaqMan assay on real-time PCR (for A3669G, rs12086634, and rs4844880). Genotype distribution was compared to those observed in the general Hungarian population using χ^2 or Fischer' exact *t*-test. ANOVA followed by power analysis was used for association studies.
Results
The allele frequency of *N363S* polymorphism was higher in patients compared to the control group. Among *GR* gene SNPs only the *Bcl1* polymorphism associated with BMI; the number of homozygous carriers was significantly higher than that of heterozygous carriers or non-carriers ($P=0.007$, power: 100%). The disease appeared significantly earlier in patients harboring *A3669G* SNP. The *rs4844880* SNP associated with higher BMI and with higher bodyweight-adjusted glucocorticoid substitution dose, the disease developed in significantly later age in these patients. Annual decrease of bone mineral density, *t*-score and *z*-score at lumbal spine was significantly lower in carriers compared to non-carriers.
Conclusion
SNPs of *GR* and *HSD11B1* genes may be important genetic factors in the pathogenesis and therapy-related morbidities in patients with primary adrenal insufficiency.

Testosterone, androstenedione, cortisol, and cortisone levels in unstimulated, stimulated, and parotid saliva

Rahel M Büttler[1], Esra Bagci[1], Henk Brand[2], Marinus A Blankenstein[1] & Annemieke C Heijboer[1]
[1]Endocrine Laboratory, Department of Clinical Chemistry, VU University Medical Center, Amsterdam, The Netherlands; [2]Departments of Periodontology and Oral Biochemistry, Academic Centre for Dentistry Amsterdam (ACTA), Amsterdam, The Netherlands.

In recent years measurement of steroid hormones like testosterone, androstenedione, cortisol, and cortisone has become increasingly important in both patient care and research. This is mainly due to the simple and non-invasive sample collection. We investigated in twenty healthy volunteers whether there is a difference between steroid hormone concentrations in unstimulated and parotid gland saliva as well as stimulated saliva collected while chewing without aid, using cotton and synthetic Salivettes, citric acid, or chewing gum. Testosterone, androstenedione, cortisol, and cortisone were measured in all saliva samples using isotope dilution liquid chromatography–tandem mass spectrometry (ID-LC–MS/MS). Testosterone, androstenedione, and cortisol concentrations were not affected by stimulation by chewing itself, whereas cortisone levels decreased (mean decrease was 11%). Levels of all four hormones were lower in parotid gland saliva compared to unstimulated saliva (mean decrease was 27, 14, 24, and 27% respectively). Salivary levels of testosterone, androstenedione, and cortisone decreased when using synthetic Salivettes (mean decrease was 56, 38, and 25% respectively) and increased when using cotton Salivettes (mean increase was 238, 50, and 34% respectively) compared to chewing without aid, whereas cortisol levels in saliva were unaffected by both types of Salivettes. Citric acid stimulation decreased salivary cortisone levels (mean decrease was 35%). Chewing gum decreased cortisone levels (mean decrease was 25%). In conclusion, the way saliva is collected should be taken into account when analysing and interpreting salivary hormone concentrations. Parotid gland saliva has lower steroid hormone levels than total saliva. Stimulation on its own does not change the concentrations of testosterone, androstenedione, and cortisol, but decreased the levels of cortisone. This is probably due to the rate-limited conversion of cortisol to cortisone in salivary glands. Stimulation with Salivettes, should be avoided for analysis of testosterone, androstenedione, and cortisone. Stimulation with citric acid and chewing gum are not suitable for analysis of cortisone.

Differential regulation of 11β-hydroxysteroid dehydrogenase type 1 activity in patients with differing aetiologies of hypopituitarism

Lucy Ann Behan[1], Bairbre Rogers[1], K Maher[2], Norman F Taylor[3], Diarmuid Smith[1], Chris J Thompson[1], John P Monson[2] & Amar Agha[1]
[1]Department of Endocrinology, Beaumont Hospital and RCSI Medical School, Dublin, Ireland; [2]Department of Endocrinology and Chemical Pathology, St Bartholomew's Hospital, London, UK; [3]Department of Endocrinology and Chemical Pathology, King's College Hospital, London, UK.

Pituitary patients with different aetiologies of hypopituitarism exhibit differing phenotypes despite optimal replacement therapy. We hypothesised that differential regulation of the isoenzyme 11β-hydroxysteroid dehydrogenase 1 (11β-HSD1), which mediates the autocrine conversion of cortisone to cortisol in adipose tissues and liver may play a role.
We prospectively studied 11β-HSD1 activity through analysis of 24 h urine cortisol/cortisone metabolites ratio (Table 1). 36 hypopituitary patients with craniopharyngioma, treated remitted Cushing's disease and non-functioning pituitary adenomas or prolactinomas (NFPA or PRL) were studied, on and off GH replacement.
11β-HSD1 activity was higher in subjects with craniopharyngioma both on and off GH evidenced by increased tetrahydrocortisol to tetrahydrocortisone metabolite (THF + 5alloTHF/THE) ratio compared to other diagnostic groups (Table 1). There was no difference in BMI, insulin levels, serum hormone measurements, or hydrocortisone dose between groups.

Table 1

	Craniopharyngioma ($n=9$)	Treated Cushing's disease (n = 8)	NFPA or PRL ($n=19$)
THF + 5alloTHF/THE On GH	1.23 (0.8–1.4)	0.97 (0.44–1.1)	0.73 (0.61–1.04)*
THF + 5alloTHF/THE Off GH	1.3 (0.9–1.4)	0.94 (0.49–1.08)*	0.79 (0.66–1.09)†

Data are median (interquartile range), *$P<0.05$ and †$P<0.01$ are compared to craniopharyngioma.

Craniopharyngioma is associated with altered enhanced 11β-HSD1 activity compared to other diagnostic groups and this may contribute to the altered body composition seen in this condition.

Circadian variation in serum cortisol during hydrocortisone replacement is not attributable to changes in cortisol-binding globulin

Kirun Gunganah, John Monson, William Drake & Teng Teng Chung
St Bartholomew's Hospital, London, UK.

Background
Patients taking hydrocortisone replacement for primary or secondary adrenal failure require individual adjustment of their dose. Previous observations in our department suggest that total serum cortisol levels achieved following an afternoon or evening dose of 5 mg hydrocortisone are almost as high as those that result from a 10 mg dose in the early morning; and that the 'area under the cortisol curve' (AUC) generated by an evening 5 mg dose is broader than after 10 mg taken early in the morning. One potential explanation for this phenomenon might be a circadian variation in serum CBG concentration, which may, in turn, impact on the interpretation of cortisol profiles and individual dose selection for patients on hydrocortisone replacement therapy. The purpose of this study was to investigate the hypothesis that there is a circadian variation in CBG levels.
Method and results
A total of 34 male patients divided into three groups (ten patients with non-somatotroph structural pituitary disease on HC replacement, 11 patients with treated acromegaly on HC replacement, and 13 patients with treated acromegaly not on HC replacement) and ten healthy volunteers were included. Cortisol and CBG levels were measured at six time points (0800, 1100, 1300, 1500, 1700, and 1900 h). No significant circadian variation in CBG concentration was found in any of the four groups.
Conclusion
Circadian variation in serum cortisol during hydrocortisone replacement is not attributable to changes in cortisol-binding globulin. Alternatively, such changes in serum cortisol may be explained by other factors including 11β-hydroxysteroid dehydrogenase type 1 activity or circadian changes in the binding capacity of CBG.

The influence of short-term and prolonged glucocorticosteroid therapy of immunoinflammatory diseases on carbohydrate metabolism

Farida Valeeva & Guzel Nurullina
Kazan State Medical University, Kazan, Russia.

Introduction
The duration and doses of glucocorticoids (GC) are significant prognostic factors of carbohydrate metabolism disturbance (CMD).

Description of methods
165 patients with systemic lupus erythematosus (32.1% patients), systemic vasculitis (27.3% patients), and chronic glomerulonephritis (40.6% patients) were included. 98 patients received GC pulse-therapy (GCPT) (first group), which included i.v. infusion of prednisolone 10–15 mg/kg per day with 250 ml of 0.9% NaCl solution, on 3 consecutive days; course dose was 1800–3000 mg; 67 patients (second group) received oral GC therapy 15–30 mg/day. All patients passed an oral glucose tolerance test (OGTT) after the course of GCPT in the first group and after 5 days of hospital stay in the second group. An evaluation of CMD was performed.
Results
The study revealed that the incidence of CMD depends on the mode of GC therapy and does not depend on the type of immunoinflammatory disease. CMD was more prevalent in patients receiving oral GC therapy. CMD was observed in 33 (33.7%) patients, receiving GCPT and in 54 (80.6%) patients, receiving oral GC ($P=0.035$). Impaired fasting glucose (IFG) (>7.8 mmol/l 2 h after OGTT, high fasting glucose at baseline 5.5–6.1 mmol/l) was found with similar incidence in first and second groups (8 (8.2%) and 14 (20.9%), respectively, $P=0.069$). Impaired glucose tolerance (7.8–11.1 mmol/l 2 h after OGTT) and diabetes mellitus (≥ 11.1 mmol/l 2 h after OGTT) were more prevalent in the second group – in 21 (31.3%) and 19 (28.4%) patients, compared to 13 (13.3%) and 12 (12.2%) patients in the first group respectively ($P=0.038$ and $P=0.049$).
Conclusions
CMD develop more often in patients with immunoinflammatory diseases receiving long-term oral GC therapy, compared to patients on GCPT. All patients should be regularly screened for CMD and receive necessary correction.

Regulation of murine skeletal muscle mass by testosterone and 17β-oestradiol

Ryan Paul[1,2], Chris McMahon[2], Marianne Elston[1] & John Conaglen[1]
[1]Department of Medicine, Waikato Clinical School, University of Auckland, Hamilton, New Zealand; [2]AgResearch, Ruakura, New Zealand.

The predominant positive and negative regulators of skeletal muscle mass are IGF1 and myostatin respectively. The regulation of skeletal muscle mass, IGF1 and myostatin by the gonadal steroids testosterone and 17β-oestradiol (E_2) remains controversial. Male and female C57BL/6 mice underwent bilateral gonadectomy or sham surgery at 4 weeks of age, with insertion of s.c. silastic implants containing testosterone, E_2, or cholesterol (placebo) ($n=8$/treatment and sex). Blood and hindlimb muscles were collected at 13 weeks of age and muscle mass was normalised to bone length. Concentrations of IGF1 in plasma were determined by ELISA. C2C12 myoblasts were treated under differentiating conditions with testosterone (30 nM) or E_2 (10 nM) for 24 h and RNA was harvested for quantitative PCR. Myoblasts were also treated for 96 h and differentiation was assessed by immunocytochemistry. Sexual dimorphism of normalised hindlimb muscle mass was lost post-gonadectomy. In male mice, gonadectomy reduced normalised hindlimb muscle mass, reduced IGF1 mRNA expression and increased mature myostatin protein abundance ($P<0.001$). Replacement of testosterone normalised these parameters, while replacement of E_2 only normalised hindlimb muscle mass. Concentrations of IGF1 in plasma were not altered by any treatment in males. In female mice, gonadectomy $\pm E_2$ replacement did not alter normalised hindlimb muscle mass or mature myostatin protein abundance, despite reducing concentrations of IGF1 in plasma and skeletal muscle ($P<0.05$). Testosterone significantly increased normalised hindlimb muscle mass, increased concentrations of IGF1 in plasma and skeletal muscle, while reducing the abundance of mature myostatin. Testosterone significantly increased myotube hypertrophy (151%) to a greater extent than E_2 (61%); although, neither altered IGF1 mRNA expression. We conclude that the anabolic action of testosterone on skeletal muscle is partially through modulation of IGF1 and myostatin activity. However, E_2 appears to increase skeletal muscle mass independently of IGF1 or myostatin.

The differential impact of PAPS synthase isoforms on DHEAS may be explained by an isoform-specific interaction of SULT2A1 with PAPSS2, but not PAPSS1

Jon W Mueller[1], Jan Idkowiak[1], Rebecca E Hardman[1], Philip J House[1], Joanne C McNelis[1], Ian T Rose[1], Vivek Dhir[1], Edina Rosta[2] & Wiebke Arlt[1]
[1]CEDAM, University of Birmingham, Birmingham, UK; [2]Department of Chemistry, King's College London, London, UK.

Human sulfation depends on provision of the universal sulfate donor PAPS by the two PAPS synthase isoforms PAPSS1 and PAPSS2. Mutations in PAPSS2 have been identified as a monogenic cause of androgen excess presenting with premature adrenarche and polycystic ovary syndrome, due to decreased sulfation of the androgen precursor DHEA by DHEA sulfotransferase (SULT2A1) and hence increased conversion of DHEA to active androgens (*New Eng J Med* 2009 **360** (22) 2310–2318 and *J Clin Endocrinol Metab* 2015 jc20143556). Here, we examined why ubiquitously expressed PAPSS1 cannot compensate for the impact of PAPSS2 deficiency on DHEAS. First, we carried out siRNA-mediated knockdown of PAPSS1/2 in the adrenal cell line NCI-H295R1. Real-time PCR confirmed $>90\%$ knockdown and the impact at protein level was assessed by western blot and SULT2A1 activity assays. Efficient knockdown of PAPSS2 reduced DHEAS to $30\pm5\%$. Strikingly, PAPSS1 knockdown did not impact on DHEAS, providing *in vitro* evidence for non-overlapping functionality of the two PAPSS isoforms. To test whether subcellular localisation impacts on isoform-specific capacity to support DHEAS, we used HEK293 cells to co-express SULT2A1 with either WT PAPSS1/2 or exclusively nuclear or cytoplasmic PAPSS1/2 variants. WT and nuclear PAPSS1/S2 equally supported DHEAS; however, SULT2A1 activity with exclusively cytoplasmic expression of PAPSS2 was 1.6-fold higher than with cytoplasmic PAPSS1; suggesting an isoform-specific protein-protein interaction of SULT2A1 with PAPSS2, but not PAPSS1. To examine this further, we carried out docking studies using ClusPro, Z-dock and gramm-X servers employing the APS kinase protein structures 2ofx and 2ax4 for PAPSS1/2 and three different structures for human SULT2A1 (1efh, 3f3y, and 4ifb). Docking of SULT2A1 to PAPSS2 unanimously resulted in more homogeneous complexes than for SULT2A1–PAPSS1, yielding significantly higher scores by the associated docking algorithms. Such an isoform-specific interaction with SULT2A1 may be the underlying mechanism explaining why PAPSS2 deficiency results in disruption of DHEAS despite ubiquitous expression of PAPSS1. Follow-up studies to prove direct interaction of PAPSS2 and SULT2A1, employing pulldown assays and FRET analyses, are currently underway.

Determination of the topology of microsomal 17β-hydroxysteroid dehydrogenase enzymes using redox-sensitive green fluorescence protein fusions

Maria Tsachaki, Julia Birk & Alex Odermatt
University of Basel, Basel, Switzerland.

Membrane proteins of the endoplasmic reticulum (ER) are involved in a wide array of essential cellular functions. Identification of the topology of membrane proteins can provide important insight into their mechanisms of action and biological roles. This is particularly important for membrane enzymes, since their topology determines the subcellular site where a biochemical reaction takes place and the dependence on luminal or cytosolic substrates and co-factor pools. The methods currently available for the determination of topology of proteins are rather laborious and require post-lysis or post-fixation manipulation of cells. In this work, we have developed a novel and simple method for defining intracellular localisation and topology of ER membrane proteins in living cells, based on the fusion of the respective protein with redox-sensitive green fluorescent protein (roGFP). We validated the method and demonstrated that roGFP fusion proteins constitute a reliable tool for the study of ER membrane protein topology, using as control microsomal 11β-hydroxysteroid dehydrogenase (11β-HSD) proteins whose topology has been resolved, and comparing with an independent approach. We then implemented this method to determine the membrane topology of six microsomal members of the 17β-HSD family. 17β-HSD enzymes catalyse the reduction/oxidation at the position 17 of the steroid backbone of androgens and oestrogens, thus playing a key role in the control of the balance of active and inactive sex steroids. Many 17β-HSDs have been implicated in different forms of sex-specific cancer and 17β-HSD inhibitors have attracted considerable interest as therapeutic targets. Appropriate access of such inhibitors to the respective intracellular compartment needs to be considered in drug development. Our

results revealed a luminal orientation of the catalytic site for three 17β-HSD enzymes. Knowledge of the intracellular location of the catalytic site of these enzymes will enable future studies on their biological functions and roles in human diseases.

Pilot study on the effects of cross-sex hormone treatment in transsexual persons on metabolism by means of metabolomics profiling

Matthias K Auer[1], Tao Xu[2], Yasmin Roepke[1], Günter K Stalla[1], Mareike Stieg[1], Eva Van Caenegem[4], Cornelia Prehn[3], Rui Wang-Sattler[2], Jerzy Adamski[3] & Guy T'sjoen[4]
[1]Endocrinology, Diabetology and Internal Medicine, Max Planck Institute of Psychiatry, Munich, Germany; [2]Research Unit of Molecular Epidemiology, Helmholtz Zentrum München, Neuherberg, Germany; [3]Institute of Experimental Genetics, Genome Analysis Center, German Center for Diabetes Research, Neuherberg, Germany; [4]Department of Endocrinology, Ghent University Hospital, Ghent, Belgium.

Introduction
Sex steroid hormones exert a wide range of effects on metabolism. New techniques such as metabolomic profiling allow for a deeper insight into metabolic regulation. In epidemiological samples it has been demonstrated that most of these metabolites show sex-specific differences. However, if these differences are attributable to the effects of sex hormones or genetics is little understood so far.
Methods
We performed targeted metabolomics profiling in serum of fasting transmen (F2M) and transwomen (M2F) at baseline and following 12 months of cross-sex hormone treatment ($n=20$/group). Subjects investigated in this study were part of the European Network for the Investigation of Gender Incongruence (ENIGI). The targeted metabolomics approach was based on ESI–LC–MS/MS measurements by AbsoluteIDQTM p180 Kit (Biocrates Life Sciences AG).
Results
Several metabolites concentrations changed significantly between the two visits in the M2F group including DL-carnitine, octadecanyl-L-carnithine, threonine, alpha-amino adipic acid, hydroxyproline, phosphatidylcholine diacyl C34:3, ornithine, citrulline, and ornithine/arginine ratio (FDR <0.05, $P<0.05$). In the F2M group there was only a significant change in ornithine. After adjustment for age, lifestyle factors and body composition in a linear mixed effects model, these results remained significant but vanished after adjusting for sex hormone levels. This indicates a direct effect of sex hormones on metabolite levels. Opposite effects were seen, i.e. for changes in ornithine levels between the two groups. Ornithine was further strongly positively related to testosterone levels in both groups. These findings are also in line with the sex-specific dimorphism for metabolites observed in epidemiological studies.
Conclusion
In this first pilot study we could show that cross-sex hormone treatment induces several changes in serum metabolites. Our findings indicate a direct effect of sex hormones on different metabolic cycles including lipid metabolism, nitric oxide formation, and amino acid regulation.

Does the initiation of oestrogen therapy time affect final height and late metabolic outcomes in Turner syndrome?

Ruta Kriksciuniene[1,2], Birute Zilaitiene[1,2], Rima Berontiene[1,2], Ruta Nakaite[2], Jurate Drazdauskaite[2] & Rasa Verkauskiene[1,2]
[1]Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas, Lithuania.

Aim
To compare final height and late metabolic outcomes depending on oestrogen replacement initiation in Turner syndrome (TS).
Subjects
Women with TS ≥ 18 years retrospectively treated with GH and oestrogen.
Methods
Records of 117 women with TS from database of Hospital of Lithuanian University of Health Sciences were analysed. 71 did not matched the inclusion criteria; 46 patients were enrolled and divided into two groups: early oestrogen group (eE) – EI before 15 years ($n=27$, EI at a median of 13 years, range from 13 to 14 years) and delayed oestrogen group (dE) – EI ≥ 15 years ($n=19$, EI at a median of 16 years, range 16–18 years). Final height, height gain, BMI, fasting glucose, blood pressure, and bone density was compared between the groups.
Results
GH treatment was started at a median age of 11 years (range 9–12 years) in the eE and of 15 years (range 9.25–16.75 years) in the dE group ($P=0.005$). The final height was similar in both groups: median of 153 cm (range 148–156 cm) in the eE and 152 cm (range 47–155 cm) in the dE ($P=0.655$). The height before EI in the eE group was -2.26 and -2.90 SDS in dE group ($P=0.055$). Height gain was greater ($P<0.05$) in eE (median 11 cm, range 7.1–15 cm) than in dE (median 5.25 cm, range 2.5–8.1 cm) group. No significant differences in metabolic parameters have been identified between the groups (mean age 27 ± 5.6 years).
Conclusion
Puberty induction at a physiological age does not have negative effect on final height in TS patients, providing earlier start of oestrogen treatment. No relation between oestrogen initiation time and metabolic parameters during later life span had been found.

Comparison of seven LC–MS/MS methods for the simultaneous measurement of testosterone, androstenedione, and DHEA in serum

Rahel M Büttler[1], Frans Martens[1], Flaminia Fanelli[2], Brian G Keevil[3], Hai T Pham[4], Mark M Kushnir[5], Angela E Taylor[6], Tue Soeborg[7], Marinus A Blankenstein[1] & Annemieke C Heijboer[1]
[1]Endocrine Laboratory, Department of Clinical Chemistry, VU University Medical Center, Amsterdam, The Netherlands; [2]Endocrinology Unit, Department of Medical and Surgical Sciences, Center for Applied Biomedical Research, S. Orsola Malpighi Hospital, University of Bologna, Bologna, Italy; [3]Department of Clinical Biochemistry, University Hospital of South Manchester, Manchester, UK; [4]Biocrates Life Sciences AG, Innsbruck, Austria; [5]Department of Pathology, ARUP Institute for Clinical and Experimental Pathology, University of Utah, Salt Lake City, Utah, USA; [6]School of Clinical and Experimental Medicine, Centre for Endocrinology, Diabetes and Metabolism, University of Birmingham, Birmingham, UK; [7]Department of Growth and Reproduction, Faculty of Health and Medical Sciences, Rigshospitalet, Copenhagen University Hospital, University of Copenhagen, Copenhagen, Denmark.

Recently, liquid chromatography–tandem mass spectrometry (LC–MS/MS) was stated to be the method of choice to measure sex steroids.[1] Information on the mutual agreement of LC–MS/MS methods, however, is scarce. Therefore, we compared seven published LC–MS/MS methods for the simultaneous measurement of testosterone, androstenedione, and DHEA. Fifty-five random serum samples obtained from volunteers were analysed in duplicate by seven published LC–MS/MS methods.[2,3,4,5,6,7] We performed a Passing–Bablok regression analysis and calculated a Pearson's correlation coefficient to assess the agreement of the investigated methods with one of the methods in this study, arbitrarily chosen as 'reference method'. Moreover, we calculated the intra-assay coefficient of variation (CV) of each method using the duplicate results. Concentrations of testosterone, androstenedione, and DHEA were 0.2–29, 0.4–5.2, and 1.8–18 nmol/l respectively. The slopes of the regression lines calculated by Passing–Bablok regression analysis ranged from 0.92–1.05 to 1.01–1.15 for testosterone values, for the entire data set and testosterone for concentrations below 2 nmol/l respectively. For androstenedione and DHEA the slopes were 0.96–1.28 and 0.96–1.46 respectively. The correlation coefficients ranged 0.987–0.997, 0.926–0.988, 0.925–0.971, and 0.955–0.988 for all testosterone values, testosterone concentrations below 2 nmol/l, androstenedione, and DHEA respectively. The intra-assay CV were 1.2–6.2, 2.9–10, 2.7–6.9, and 4.3–16% for testosterone values higher than 2 nmol/l, testosterone concentrations below 2 nmol/l, androstenedione, and DHEA respectively. In conclusion, in general the investigated LC–MS/MS methods for simultaneous measurement of testosterone, androstenedione, and DHEA, showed a good agreement. However, there appear to be differences in standardisation between some of the assays and a high variation in some of the assays.

Prediction of affective disorders in adult men on the basis of steroid profiling

Martin Hill[1], Daniela Ripova[2], Pavel Mohr[2], Marta Velikova[1], Marie Bicikova[1], Michaela Duskova[1] & Luboslav Starka[1]
[1]Institute of Endocrinology, Prague, Czech Republic; [2]National Institute of Mental Health, Klecany, Czech Republic.

A number of evidence indicate that mood (affective) disorders are influenced by various bioactive steroids such as corticoids, sex hormones and neuroactive steroids. However, to date, there are limited data concerning the discrimination between patients suffering from the disorders and controls, or regarding the classification of individual subtypes of mood disorders on the basis of steroid profiling. Therefore 47 steroids including their conjugates and further related substances were measured in sera from male volunteers suffering from depressive disorders (D, $n=20$), anxiety disorders (AN, $n=20$), and in the group of age-comparable controls (C, $n=30$) using GC–MS and immunoassays. Based on this data, multivariate models for discrimination of D and C (sensitivity = 100% and specificity = 100%), AN and C (sensitivity = 100% and specificity = 100%), and D and AN (sensitivity = 85% and specificity = 90%) were built. When discriminating pathologies D and AN from C, the relevant predictors progesterone, allopregnanolone, and conjugated steroids negatively correlated with both AN and D groups, while LH showed the positive correlations. In addition, 5α-dihydrotestosterone and pregnanolone negatively correlated with D, while androstenedione, cortisol, 16α-hydroxy-steroids, and SHBG showed the positive correlations. Finally, pregnenolone, 20α-dihydropregnenolone, 7β-hydroxy-DHEA, and 5-androstene-3β,7α/β,17β-triols positively correlated with AN. In model discriminating the D and AN, the relevant predictors progesterone and cortisol positively correlated with AF, while LH, SHBG, sulphated Δ^5 steroids, and 16α-hydroxy-DHEA showed the negative correlations. In conclusion, various circulating steroids including the neuroactive and neuroprotective ones efficiently predicted two groups of affective diseases in adult men. The data indicated suppressed activities of CYP17A1 and SULT2A1 enzymes in adrenal zona reticularis in affective patients and even more in depressive men. In addition, the results pointed to stimulated activities of immunoprotective 16α-hydroxylating- (CYP3A7) and 7β-hydroxylating enzymes (CYP3A4) in D and AN patients respectively.

A simple and rapid method for steroid profiling by two dimensional liquid chromatography–tandem mass spectrometry: toward routine application

Flaminia Fanelli, Marco Mezzullo, Alessia Fazzini, Matthew Pedercini, Renato Pasquali & Uberto Pagotto
Endocrinology Unit, Department of Medical and Surgical Sciences, Center for Applied Biomedical Research, S. Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy.

Steroid testing has a central role in clinical decision-making and in research studies on diseases such as hypercortisolisms, female hyperandrogenism, male hypogonadism or inborn disorders of steroid synthesis. Recently, liquid chromatography–tandem mass spectrometry (LC–MS/MS) proved its superiority to routine immunoassays (IA) in accurately and sensitively measuring low level steroids. However, the replacement of automated IA with LC–MS/MS platforms is limited by the need for extraction procedures requiring operator handwork, large sample volume and long runtime. Aiming at improving LC–MS/MS practicability, we developed a 2D-LC–MS/MS method for simultaneously determining serum cortisol, testosterone, androstenedione, 17OHprogesterone (OHP), and 17OHpregnenolone (OHp) based on minimal sample preparation. One hundred µl of serum were treated by protein precipitation, diluted with H_2O and injected into the Prominence-LCMS-8050-electrospray ionisation platform (Shimadzu). Sample underwent on-line purification on perfusion column (6 ml/min, 3 min) and separation on Shim-pack XR-ODS-50×3 mm, 2 µm column (Shimadzu) in 5 min H_2O/acetonitrile gradient, before 7 min clean-up and reconditioning program. Total runtime was 15 min. Quantitative and qualitative transitions were monitored for each analyte. Isotopic dilution quantitation was performed by using d4-cortisol, d5-testosterone, d5-androstenedione, d8-OHP, and $13C_3$-estrone as internal standard for cortisol, testosterone, androstenedione, OHP, and OHp respectively. Lower limits of quantitation (pg on column) assessed in calibrators diluted in BSA (4%) were 122.1 pg/ml (1.5 pg), 9.77 pg/ml (0.12 pg), 19.5 pg/ml (0.24 pg), 39.1 pg/ml (0.49 pg), and 312.5 pg/ml (3.9 pg), and functional sensitivity assessed in charcoal-stripped serum was 122.1, 19.5, 19.5, 39.1, and 312.5 pg/ml for cortisol, testosterone, androstenedione, OHP, and OHp respectively, and was stable along 150 samples batch. Intra- and inter-assay CV ranged between 3.4–7.2% and 5.8–16.7% respectively. Androstenedione comparison with an established extractive LC–MS/MS assay revealed optimal correlation (r: 0.9933–0.9996) and slope coefficients (0.810–1.060). These preliminary data showed that our 2D-LC–MS/MS method for five steroids based on minimal sample preparation achieves performance and robustness levels that can definitively reconcile routine need for reliability and practicability.

Investigation of the effects of aldosterone on the cardiac cycle in the HL-1 mouse atrial cardiomyocyte cell line

Kostantinos Tsirlis[1], Anastasios Tsarouhas[1], Eleni Aggelidou[1], Efstratios Kosmidis[1], Aristeidis Kritis[1], Maria Albani[1] & Konstantinos Kallaras[2]
[1]Laboratory of Physiology, Aristotle University Medical School, Thessaloniki, Greece; [2]Laboratory of Experimental Physiology, Aristotle University Medical School, Thessaloniki, Greece.

Introduction
Aldosterone (Aldo) decreases the rate of repolarization in rabbit cardiomyocytes and significantly increases the duration of the monophasic action potential in patients with supraventricular arrhythmias, few minutes after its intravenous administration, implying for a non-genomic action. We have previously found a positive linear regression between left ventricular systole duration and plasma Aldo levels in NZW rabbits. To investigate the veracity of the above finding on cardiac cycle (CC) phases and elucidate the underlying mechanism we employ the HL-1 cell line of mouse atrial cardiomyocytes.
Materials and methods
Confluent beating HL-1 cells were stained with 68 µM di-8-ANEPS in 68 µM Pluronic F-127. Cell beating and the accompanied fluorescent intensity changes, were recorded with a specialized high frequency sampling (1 kHz) CMOS camera (NeuroCMOS-SM128f, Redshirt Imaging, Inc., USA) coupled to a fluorescent microscope (AxioExaminer Z1, Carl Zeiss Microimaging GmbH, Germany). 15 optical recordings, of 2 s duration, were taken 1 min apart. 50 µM Aldo in Claycomb's medium was added between the third and fourth recording (control received only the same volume of medium). CC total duration, contraction period (corresponding to cardiac systole) as well as relaxation period and duration of the 'quite' state of the cells (both corresponding to cardiac diastole) were calculated.
Results
Our results show that Aldo increases the total duration of the CC ($P<0.001$ (Z-score (standard score) and Spearman's ρ)) almost immediately after its addition to the cells lasting up to 14 min, when recordings were stopped. This increase is attributed to the 'quite' state of the cells corresponding to the diastolic phase of the CC.
Conclusion
Aldo causes a reduction of the beating frequency of the HL-1 cells. Their prompt response to Aldo denotes a non-genomic action. Taking into account of our previous finding, this action can be attributed to elongation of the first part of cardiac diastole (protodiastole).

Ghrelin and GHSR1 receptor in placentas of SGA, LGA, and AGA newborns

Martha I Gonzalez Dominguez[1], Maria Luisa Lazo de la Vega Monrroy[1], Silvio Zaina[1], Myrna Sabanero[2], Leonel Daza-Benítez[3], Juan Manuel Malacara[1] & Gloria Barbosa-Sabanero[1]
[1]Health Sciences Division, Medical Sciences Department, University of Guanajuato, Leon, Guanajuato, Mexico; [2]Natural and Exact Sciences Division, Biology Department, Guanajuato University, Guanajuato, Guanajuato, Mexico; [3]UMAE No. 48 IMSS, Leon, Guanajuato, Mexico.

Introduction
Intrauterine growth is a biological process regulated by maternal, placental, and foetal endocrine signals. Birth weight is an indicator of the health of the newborn. Alterations in foetal growth lead to perinatal health risks and favour metabolic diseases during adult life. Therefore, the study of endocrine factors determining birth weight, such as ghrelin is an important issue. Ghrelin may exist as two molecular forms, desacyl ghrelin (DAG) and acyl ghrelin (AG). Current evidence showed to DAG as an active hormone with effects on different tissues in diverse physiological and pathophysiological states. Although cord blood (CB) ghrelin levels have been correlated to birth weight, it is unknown which ghrelin's molecular variants are involved and if expression and methylation of ghrelin receptor (GHSR1) has a key role in foetal development.
Methods
We performed a cross-sectional comparative study healthy mothers and their term newborns small for gestational age (SGA), adequate for gestational age (AGA), and large for gestational age (LGA) ($n=20$/group). Total ghrelin, AG, and DAG levels were measured in CB by ELISA. Placental GHSR1 expression was evaluated by western blot and GHSR1 promoter methylation by qPCR after bisulphite modification of DNA.
Results
Cord blood DAG levels were increased in SGA compared to AGA newborns (902.1 ± 109.1 and 597.4 ± 58.2 pg/ml, respectively, $P=0.01$) while LGA and AGA showed similar values (627.2 ± 76.4 pg/ml for LGA, $P=0.80$). DAG levels negatively correlated with birth weight ($r=-0.31$, $P=0.02$) and placental weight ($r=-0.33$, $P=0.02$). No differences in AG or total ghrelin levels were found. Expression and methylation of GHSR1 in placenta was not differentially among SGA, AGA, and LGA.
Conclusions
Our results showed that expression and methylation of ghrelin receptor (GHSR1) has unrelated with birth weight. Suggesting that additional factors, such as DAG, are involved in the mechanism that determines birth weight.

GP.06.01

Habitual physical activity is associated with lower prevalence of insulin resistance in women with polycystic ovary syndrome

Fernanda Mario[1,2], Scheila Graff[1,2] & Poli Mara Spritzer[1,2]
[1]Gynecological Endocrinology Unit, Division of Endocrinology, Hospital de Clinicas de Porto Alegre, Porto Alegre, RS, Brazil; [2]Federal University of Rio Grande do Sul, Porto Alegre, RS, Brazil.

Polycystic ovary syndrome (PCOS) is a common endocrine disorder affecting 7–18% of women of reproductive age, according to different criteria. Metabolic disturbances related to PCOS include dyslipidemia, obesity, and insulin resistance (IR) and women with PCOS have higher prevalence of impaired glucose tolerance and type 2 diabetes mellitus in comparison with weight-matched women without the syndrome. Evidence indicates that regular practice of physical activity improves insulin resistance in general population. Habitual physical activity is defined as any form of body movement with energy expenditure above resting levels, including work, leisure activities, and household chores. The aim of this study was to evaluate whether habitual physical activity is associated with less insulin resistance in women with PCOS. One hundred and four participants, 61 PCOS, by the Rotterdam criteria, and 43 control women, were stratified according to physical activity status: inactive (<7500 steps/day) or active (≥ 7500 steps/day). Habitual physical activity was assessed by counting the number of daily steps, using a digital pedometer. Anthropometric, clinical, and laboratory examination were also determined. The age of participants was 23.9 ± 6.4 years old and most of them were Caucasians. While BMI was higher in PCOS than in controls, it was similar between active and inactive participants of each group. Androgen levels and HOMA-IR were higher and sex hormone-binding globulin was lower in PCOS compared to controls ($P<0.05$). Abnormal fasting insulin (≥ 20 μIU/ml) was found to be less frequent in active than in inactive PCOS (21.7 and 52.2%, $P=0.009$) as well as HOMA-IR ≥ 2.7 (34.0 and 44.7%, $P=0.005$) and lipid accumulation index (LAP) ≥ 34.5 (35.7 and 50%, $P=0.013$). Active vs inactive controls also presented similar results ($P<0.05$). In conclusion, habitual physical activity, specifically walking 7500 or more steps daily, was associated with lower frequency of insulin resistance, assessed by different clinical markers in PCOS women. These data suggest that even a slight to moderate non-structured daily physical activity might bring health benefices in PCOS before metabolic comorbidities become evident.

Early diagnostics of insulin resistance in obese pregnant women

Oksana Kononova[1], Aleksej Korotaev[2], Erik Platoshkin[1], Andrej Pristrom[3] & Volha Vasilkova[1]
[1]Gomel State Medical University, Gomel, Belarus; [2]The Republican Research Centre for Radiation Medicine and Human Ecology, Gomel, Belarus; [3]Belarusian Medical Academy of Post-Graduate Education, Minsk, Belarus.

Aim
To find early diagnostic criteria for metabolic syndrome (MS) in obese women in early pregnancy.
Materials and methods
We examined 143 pregnant women aged from 19 to 43 years (31.0 (26.0; 35.0)) and divided them into three groups: MS group ($n=55$), risk group (one to two components of MS) ($n=57$), and control group ($n=31$). Laboratory examination included blood pressure (BP) monitoring, assessment of a lipid profile, glucose metabolism, and insulin resistance (HOMA-IR).
Results
76% of pregnant women with MS and 45% of pregnant women with one to two components of MS have obesity. Hypertension was diagnosed in 54 (64%) pregnant women. We found significant differences in systolic, diastolic, and pulse pressure between pregnant women with obesity and pregnant women without obesity ($P<0.001$). There were significant differences in level of fasting glucose, insulin and HOMA-IR, triglycerides, LDL-C, and VLDL-C in pregnant women with obesity comparing with pregnant women without obesity ($P<0.001$). Gestational diabetes (GD) was identified in the MS group up to 20 weeks in 18.2% of pregnant women, after 20 weeks in 29.1% of pregnant women. There were 10.5% of women with GD up to 20 weeks and 17.5% after 20 weeks in the risk group respectively. We found no disturbances in carbohydrate metabolism in 45.5% pregnant women from MS group and 71.9% from risk group.
Conclusion
Insulin resistance and its associated disorders of carbohydrate and lipid metabolism are common in obese women during pregnancy. Early identification of risk factors in obese pregnant women is a prerequisite for the prevention of serious complications in the future as part of the mother and the foetus.

Introduction
Dyslipidaemia is a common metabolic derangement in polycystic ovary syndrome (PCOS) and may be represented with different lipid alterations. The aim of this study was to evaluate lipid profile in different PCOS phenotypes.

Methods
We evaluated 365 PCOS women (PCOS: 25.05 ± 6.24 kg/m^2; 25.48 ± 5.21 years) diagnosed using ESHRE/ASRM criteria and 125 BMI-matched healthy women (controls: 25.41 ± 5.16 kg/m^2; 30.35 ± 5.62 years). PCOS group was divided into four phenotypes: a (anovulation (ANOV), hyperandrogenism (HA), polycystic ovary morphology (PCOM)), B (ANOV, HA), C (HA, PCOM) and D (ANOV, PCOM). Phenotype D had lower BMI in comparison to all other phenotypes ($P<0.05$). Blood samples were collected in follicular phase of menstrual cycle for determination of total cholesterol (TC), LDL, HDL, triglycerides, apolipoprotein-A1 and apolipoprotein-B. Ratios TC/HDL, LDL/HDL, TG/HDL, apoliporotein-B/apolipoprotein-A1 were calculated.
Results
PCOS women in comparison to controls had higher levels of TC (5.07 ± 1.09 vs 4.89 ± 0.97 mmol/l, $P<0.001$), LDL (3.16 ± 0.97 vs 3.09 ± 0.82 mmol/l, $P=0.012$), TG (1.20 ± 0.85 vs 0.98 ± 0.54 mmol/l, $P<0.001$), apolipoprotein-B (0.88 ± 0.29 vs 0.83 ± 0.25, $P=0.021$), while there were no differences in HDL, apoliporpotein-A1 ($P>0.05$). PCOS women had higher ratios: TC/HDL (3.94 ± 1.36 vs 3.68 ± 1.03, $P=0.001$), LDL/HDL (2.46 ± 1.07 vs 2.36 ± 0.89, $P=0.019$), TG/HDL (1.02 ± 1.20 vs 0.78 ± 0.61, $P<0.001$), apoliporotein-B/apolipoprotein-A1 (0.59 ± 0.33 vs 0.52 ± 0.19, $P=0.011$). Comparisons between PCOS phenotypes revealed that phenotype D had lower levels of triglycerides and the ratio TG/HDL than other three phenotypes ($P<0.05$ for all comparisons), while there was no difference in other lipid concentrations and ratios. Phenotype A, B and C had higher TC, TG, TC/HDL, TG/HDL, and apoliporotein-B/apolipoprotein-A1 in comparison with controls, while there were no differences between phenotype D and controls.
Conclusion
In our group of women with PCOS, only phenotype D was characterised with less deteriorated lipid profile than other PCOS phenotypes.

Phenotypic characteristic of type 1 diabetic women with polycystic ovary syndrome

Agnieszka Lebkowska[1], Agnieszka Adamska[1], Monika Karczewska-Kupczewska[2,3], Agnieszka Nikolajuk[3], Elzbieta Otziomek[1], Robert Milewski[4], Slawomir Wolczynski[5], Maria Gorska[1] & Irina Kowalska[1]
[1]Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland; [2]Department of Metabolic Diseases, Medical University of Bialystok, Bialystok, Poland; [3]Department of Prophylaxis of Metabolic Diseases, Institut of Animal Reproduction and Food Research, Polish Academy of Sciences, Olsztyn, Poland; [4]Department of Statistics and Medical Informatics, Medical University of Bialystok, Bialystok, Poland; [5]Department of Reproduction and Gynecological Endocrinology, Medical University of Bialystok, Bialystok, Poland.

Introduction
The prevalence of polycystic ovary syndrome (PCOS) is increased in women with type 1 diabetes (T1DM) in comparison to the general population. It has been suggested that exogenous insulin administered to T1DM women in supraphysiological doses could act as co-gonadotropin and lead to disturbances observed in PCOS.
Aim
The aim of this study was to evaluate the phenotypic characteristic and differences between diabetic women with PCOS (T1DM + PCOS) and age-, BMI-matched women with type 1 diabetes without PCOS (T1DM-no PCOS) and non-diabetic women with PCOS (PCOS).
Study participants and methods
We studied 108 women: 39 with T1DM (18 with T1DM + PCOS and 21 with T1DM-no PCOS), 47 with PCOS and 22 healthy women. PCOS was diagnosed using the Rotterdam criteria. The anthropometric measurements, clinical parameters, estimation of plasma concentrations of sex hormones, SHBG, HbA1c and ultrasonographic evaluation of the ovaries were performed for all women. In both diabetic groups insulin sensitivity was calculated with estimated glucose disposal rate (eGDR).
Results
There were no significant differences in anthropometric measurements between all studied groups. The Ferriman–Gallwey score was higher in women with PCOS than in those with PCOS + T1DM ($P=0.074$). Hormonal profile was similar in both groups with PCOS. We observed that ovarian volume and ovarian follicle count did not differ in patients with PCOS + T1DM and PCOS. The number of ovarian follicles was higher in the PCOS + T1DM and PCOS groups versus the control ($P=0.008$, $P<0.001$) and versus the T1DM/no-PCOS group ($P<0.001$, $P<0.001$, respectively). HbA1c, daily insulin dose, eGDR were not different between PCOS + T1DM and T1DM-no PCOS. A significant negative relationship of eGDR with body fat mass and BMI was found in T1DM + PCOS ($r=-0.75$, $P<0.001$; $r=-0.75$, $P<0.001$), which was not observed in patients with T1DM-no PCOS.
Conclusion
We conclude, that phenotypic characteristic of T1DM + PCOS women is similar to PCOS. Further study are required to better understand the pathogenesis of PCOS in type 1 diabetic women.

Cytokine expression in SAT and VAT from PCOS patients and control women; possible proinflammatory effect of testosterone depending on BMI – a preliminary report

Nicolas Crisosto[1], Barbara Echiburú[1,2], Francisco Perez-Bravo[2], Cristian Flores[1,2], Cecilia Fuentes[3], Mariana Cifuentes[3], Omar Orellana[4], Fernando Maluenda[5] & Teresa Sir-Petermann[1]
[1]Laboratory of Endocrinology and Metabolism, Faculty of Medicine, West Division, University of Chile, Santiago, Chile; [2]Laboratory of Nutritional Genomics, Department of Nutrition, Faculty of Medicine, University of Chile, Santiago, Chile; [3]Basic Nutrition and Genetic Epidemiology Laboratory Institute of Nutrition and Food Technology (INTA), University of Chile, Santiago, Chile; [4]Surgery Unit, Hospital San Juan de Dios, Santiago, Chile; [5]Surgery Unit, Clinica Las Condes, Santiago, Chile.

Context
Insulin resistance is an important component of polycystic ovary syndrome (PCOS). Local cytokine production in adipose tissue increases local insulin resistance. The effect of testosterone on local adipose tissue cytokine production has not been explored thoroughly.
Aim
To evaluate cytokine expression in subcutaneous adipose tissue (SAT) and visceral adipose tissue (VAT) from PCOS and control women and evaluate the response to testosterone on the later.
Methodology
We obtained serum samples and SAT by biopsy from ten PCOS and seven control women. In six different women (three PCOS and three controls) subjected to abdominal surgery we obtained samples from omental VAT that were incubated (300 mg each well) for 72 h in basal conditions or stimulated with 10-9M or 10-6 M testosterone (T). Expression of cytokines (I-1b, CCL-2, TNF-alpha and IL-6) in tissue samples was assessed by Real Time PCR. All women studied were 18–40 years old.
Results
Basal SAT and VAT cytokine expression and serum cytokine levels showed no differences between PCOS and control patients. Regarding stimulated tissue samples, there was no significant response to T in the total group or analysing PCOS or control patients independently. Nevertheless, in VAT samples from patients with a BMI between 30 and 40, regardless of their PCOS condition, we found a significant increase in the expression of CCl-2 (ddCt 1,83 (1.75–1.96; $P=0.0036$) and IL1b (ddCt:2.84 (2.52–3.7; $P=0.0036$) when stimulated with testosterone 10–6M.
Conclusions
SAT and VAT shows no significant differences in terms of basal cytokine expression between PCOS patients and control women. Nevertheless, in the subgroup of women with a BMI between 30 and 40, testosterone seems to have a proinflammatory effect in VAT. Thus, the effects of testosterone in terms of cytokine expression might be influenced by the presence of obesity.

Does finasteride, as well as metformin, improve insulin resistance in PCOS?

Halit Diri, Fahri Bayram & Yasin Simsek
Division of Endocrinology, Erciyes University Medical School, Kayseri, Turkey.

Introduction
The effects of finasteride on insulin resistance and of metformin on hyperandrogenism in patients with polycystic ovary syndrome (PCOS) are not clear. This study therefore compared the effects of finasteride, metformin, and finasteride plus metformin treatments on hormone levels, insulin resistance, and hirsutism score in women with PCOS.
Subjects and method
Fifty-two patients with PCOS were randomly assigned to receive finasteride 5 mg/day, metformin 1700 mg/day or finasteride plus metformin for 12 months. BMI, Ferriman Gallway score (FGS), serum concentrations of estradiol, sex hormone-binding globulin, free testosterone, DHEAS, androstenedione, and HOMA-IR index and areas under the curve (AUC) for insulin and glucose were evaluated before and after 12 months of treatment.
Results
Reductions in FGS, free testosterone, DHEAS, androstenedione, HOMA-IR, AUC-insulin, and AUC-glucose were significant within each group, whereas BMI and estradiol did not. Comparisons of changes in parameters in the three groups did not clearly show the superiority of any treatment modality.
Discussion
Insulin resistance and hyperandrogenism are the two major interacting pathophysiological derangements in PCOS. Thus, treatment with finasteride alone should significantly reduce both androgen levels and parameters of insulin resistance; and our results confirmed that suggestion. In addition, metformin alone was effective, and not inferior to finasteride, in the treatment of hyperandrogenism.
Conclusion
The finasteride, metformin, and their combination therapies were effective and safe in women with PCOS, since both drug classes have beneficial effects on both hyperandrogenism and insulin resistance.

The effect of metformin and liraglutide on markers of subclinical atherosclerosis in women with polycystic ovary syndrome

Mojca Jensterle[1], Mateja Kaja Jezovnik[2], Ana Spirkoska[2], Pavel Poredos[2] & Andrej Janez[1]
[1]Department of Endocrinology, Diabetes and Metabolic Diseases, University Medical Centre Ljubljana, Ljubljana, Slovenia; [2]Department of Vascular Disease, University Medical Centre Ljubljana, Ljubljana, Slovenia.

Subclinical atherosclerosis is frequently present in women with polycystic ovary syndrome (PCOS). Metformin and liraglutide both improve metabolic control in PCOS, however they might exert different anti-atherosclerotic effects. We investigated the impact of these medications on the subclinical atherosclerotic changes of the arterial wall in PCOS patients.
Methods
72 women with PCOS (aged 28.6 ± 6.3 years, BMI 38.4 ± 5.0 kg/m^2, mean $\pm$ S.D.) were assigned to therapy with either metformin 1 g BID or liraglutide 1.2 mg QD sc. for 12 weeks. Markers of subclinical atherosclerosis including intima-media thickness (IMT), flow-mediated dilation (FMD), low-flow-mediated constriction (L-FMC), and peripheral tonometry (PAT) with pulse wave amplitude (PWA) were measured. Arterial stiffness was investigated through pulse wave velocity (PWV) and the augmentation index (AI). All measurements were obtained at baseline and at study end.
Results
25 patients on metformin and 40 patients on liraglutide completed the study. Metformin improved FMD from 7.33 ± 3.11 to $9.12 \pm 2.75\%$ ($P=0.04$). Liraglutide decreased IMT from 0.53 ± 0.06 to 0.50 ± 0.05 mm ($P=0.04$), arterial stiffness as assessed by AI from 31.4 ± 7.8 to 39.6 ± 13.1 ($P=0.03$) and also caused a border-line, non-significant improvement of PWA ($P=0.07$). Furthermore, there was a significant inverse relationship between FMD and HOMA index before and after treatment in both arms ($r=0.61$, $P<0.05$).
Conclusions
Short-term intervention with metformin and liraglutide have beneficial effect on markers of subclinical atherosclerosis in obese women with PCOS. Interestingly, the effects of metformin therapy resulted only in functional improvement, whereas liraglutide also ameliorated morphological signs of atherogenesis of the arterial wall.

Plasma brain derived neurotrophic factor is decreased in women with polycystic ovary syndrome and related to the markers of endothelial dysfunction

Irina Kowalska[1], Monika Karczewska-Kupczewska[2,3], Agnieszka Adamska[1], Agnieszka Nikolajuk[2,3], Agnieszka Lebkowska[1], Elzbieta Otziomek[1], Slawomir Wolczynski[4] & Marek Straczkowski[2,3]
[1]Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland; [2]Department of Metabolic Diseases, Medical University of Bialystok, Bialystok, Poland; [3]Department of Prophylaxis of Metabolic Diseases, Institute of Animal Reproduction and Food Research, Polish Academy of Sciences, Olsztyn, Poland; [4]Department of Reproduction and Gynecological Endocrinology, Medical University of Bialystok, Bialystok, Poland.

Introduction
Brain derived neurotrophic factor (BDNF) is a neurotrophin which plays a role in neuronal growth and differentiation. Decreased level of BDNF is supposed to play a role in the pathogenesis of the neurodegenerative diseases. Recent data indicate that BDNF could be also involved in angiogenesis. Several lines of evidence support the role of BDNF in glucose metabolism. The decreased level of BDNF are observed in obesity and type 2 diabetes mellitus. Polycystic ovary syndrome (PCOS) is a common endocrine disorder associated with insulin resistance and increased risk of cardiovascular diseases. The aim of the present study was to determine plasma BDNF concentration in patients with PCOS in comparison to healthy women.
Study participants and methods
We studied 74 women with PCOS (BMI -27.60 ± 6.73 kg/m^2) and 37 healthy, regularly menstruating women (BMI -26.69 ± 6.72 kg/m^2). PCOS was diagnosed with Rotterdam criteria. Clinical examination, an anthropometric measurements, hyperinsulinaemic, euglycaemic clamp and estimation of plasma concentrations of BDNF, sex hormone binding globulin (SHBG), adiponectin, soluble E-selectin (sE-selectin), intercellular adhesion cell molecule-1 (sICAM-1), hormonal and lipid profile were performed in all study participants.
Results
Women with PCOS had significantly higher LH ($P<0.0001$), testosterone ($P=0.011$) and FAI ($P=0.04$) in comparison to the control group. Plasma BDNF concentration was lower in PCOS group vs controls ($P=0.04$). Subgroups analysis revealed that plasma BDNF was significantly lower in the obese PCOS women vs obese controls ($P=0.03$), whereas such difference was not found between lean PCOS and control women. In PCOS group, plasma BDNF correlated significantly with SHBG ($r=0.26$, $P=0.02$), adiponectin ($r=0.29$, $P=0.012$), sICAM-1 ($r=-0.28$, $P=0.014$) and sE-selectin ($r=-0.24$, $P=0.03$), which was not observed in the control group.
Conclusion
Our data indicate that BDNF is decreased in obese PCOS women and related to the markers of endothelial dysfunction.

Preconceptional TSH and miscarriage in infertile women submitted to IVF

Guia Vannucchi[1], Danila Covelli[1], Mario Renzini[3], Claudio Brigante[3], Giovanni Coticchio[3], Maria Beatrice Dal Canto[3], Rubens Fadini[3], Davide Dazzi[4], Roberto Negro[5] & Laura Fugazzola[1,2]
[1]Endocrine Unit, Fondazione IRCCS Cà Granda, Milan, Italy; [2]Department of Transplant, University of Milan, Milan, Italy; [3]Center of Reproduction Medicine Biogenesi, Istituti Clinici Zucchi, Monza, Italy; [4]Internal Medicine, Ospedale di Fidenza, Fidenza, Italy; [5]Division of Endocrinology, 'V. Fazzi' Hospital, Lecce, Italy.

It is known that high levels of TSH are associated with higher miscarriage risk, though the precise TSH cut-offs are debated. Aim of the present study was to evaluate if pre-conceptional TSH levels associate with increased risk of early miscarriage in a large series of infertile women submitted to IVF and to determine the threshold of TSH associated with the highest prevalence of pregnancy loss. We retrospectively studied 1484 infertile women (mean ± age 36.7 ± 4.1 years, mean ± s.d. BMI 22.7 ± 4) submitted to IVF in a single center from 2004 to 2014.
Overall, 371/1484 (25%) patients had a biochemical pregnancy and 152 of them experienced a pregnancy loss. Mean TSH levels of women with a regular pregnancy were significantly lower than mean TSH levels recorded in patients with a pregnancy loss (1.8 ± 0.8 vs 2.2 ± 1.2, $P=0.01$). Interestingly, the miscarriage rate was progressively higher for increasing TSH cut-off levels ($\leq$2.5 vs $>$2.5 $P=0.08$; $\leq$3 vs $>$3 $P=0.001$; $\leq$4.5 vs $\geq$4.5 $P=0.004$). Moreover, among the 152 women with pregnancy loss, 59 (39%) were clinically pregnant and had a miscarriage in the first trimester, while in 93 patients (61%) a biochemical pregnancy without clinical evolution was documented, but no significant differences in mean TSH levels were recorded between women with different time of miscarriage.
In conclusion, in women undergoing IVF, lower TSH levels reduce the risk of early pregnancy loss. These data strongly indicate the need for TSH screening prior to IVF procedures, and suggest the treatment of women with TSH levels $>$3 mU/l.

Kisspeptin increased during reproductive ageing and is regulated by sympathetic nerve system

Daniela Fernandois, Ruth Márquez, Hernán Lara & Alfonso Paredes
Laboratory of Neurobiochemistry, Department of Biochemistry and Molecular Biology, Faculty of Chemical and Pharmaceutical Sciences, University of Chile, Santiago, Chile.

Kisspeptin is found in the ovary of different species including human and rat. We have recently described, through *in vitro* studies, that kisspeptin is under the control of sympathetic innervation of the ovary. Considering that ovarian activity of sympathetic nerves increases with ageing, it is possible that the ovarian kisspeptin also increases during this period. As a role of kisspeptin in folliculogenesis has been postulated, this increase in kisspeptin could participate in the changes in follicular dynamics that occur during the subfertility period. We conducted an *in vivo* study to determine if the ovarian sympathetic tone participates in kisspeptin expression during reproductive ageing. To achieve this, we measured kisspeptin mRNA and protein levels by qRT-PCR and western-blot at 6, 8, 10 and 12 months old rats, covering fertile (6 month), subfertile (8 and 10 months) and infertile periods (12 months). We also performed an *in vivo* blockade of β-adrenergic receptor with propranolol (5 mg/kg) and an ovarian surgery denervation to modulate sympathetic system at these ages. The non-treated rats showed an increase in kisspeptin expression at 10 and 12 months old ($P<0,05$) compared to 6 months old rats, and if we compared this kisspeptin levels with the noradrenaline content, we observed an almost perfect correlation ($r=0.994$). Ovarian kisspeptin peptide decreased both, after propranolol administration and with the surgical denervation ($P<0.01$ 8 to 12 months compared with 6 months). These results suggest that intraovarian kisspeptin is regulated by sympathetic nerve via β-adrenergic receptor, participating locally in the ovary function and that ovarian kisspeptin could participate in follicular development with noradrenaline in reproductive ageing.

The role of transvaginal ultrasonography in the evaluation of endometrial hyperplasia or cancer in pre- and perimenopausal women

Sunmie Kim[1], Kyu Ri Hwang[2], Jin Ju Kim[1], Min-Jeong Kim[1] & Seok Hyun Kim[3]
[1]Department of Obstetrics and Gynecology, Healthcare Research Institute, Healthcare System Gangnam Center, Seoul National University Hospital, Seoul, Republic of Korea; [2]Department of Obstetrics and Gynecology, Seoul Municipal Boramae Hospita, Seoul, Republic of Korea; [3]Department of Obstetrics and Gynecology, Seoul National University College of Medicine, Seoul, Republic of Korea.

Objective
The aim of our study is to determine clinical factors and sonographic findings associated with endometrial hyperplasia or cancer (EH+) in pre- and perimenopausal women.
Study design
A total of 14 340 transvaginal ultrasonography examinations of 9 888 healthy pre- and perimenopausal women were included in this retrospective study. One hundred sixty-two subjects underwent endometrial biopsy based on abnormal uterine bleeding (AUB), sonographic endometrial abnormalities (thickened endometrium, endometrial mass, or endometrial stripe abnormality), or both. The clinical factors and sonographic endometrial abnormalities were evaluated with regard to EH+.
Results
Histologically verified EH+ was found in fourteen subjects (8.6%); ten cases of endometrial hyperplasia without atypia (EH), three cases of endometrial hyperplasia with atypia (AEH), and one case of endometrial cancer. Neither clinical factors nor AUB were associated with EH+ ($P=0.32$) or AEH+ ($P=0.72$). Of sonographic findings, endometrial stripe abnormality was significantly associated with EH+ ($P=0.003$) and marginally associated with AEH+ ($P=0.05$), but a thickened endometrium was not associated with EH+ ($P=0.43$).
Conclusion
Endometrial stripe abnormality is a significant factor to predict EH+ in healthy pre- and perimenopausal women with and without AUB. However, simple measurement of endometrial thickness has a limited role in this capacity.

Expression of melanocortin receptors in human endometrium

Anastasia Lantang[1,2], Earn Gan[2], Barbara Innes[1], Simon Pearce[1] & Gendie Lash[2]
[1]Reproductive and Vascular Biology Group, Institute of Cellular Medicine, Newcastle University, Newcastle Upon Tyne, UK; [2]Institute of Genetic Medicine, Newcastle University, Newcastle Upon Tyne, UK.

Background
The melanocortin system is known to be involved in hypothalamic regulation of energy balance, which is implicated in reproductive success. However, the peripheral role for melanocortin receptor (MCR) signalling in the reproductive system has not been described. During a clinical trial of repeated high dose tetracosactide ($ACTH_{1-24}$) injection, four of nine premenopausal women with Addison's disease developed menstrual disturbances. We wondered if these adverse effects were mediated via direct melanocortin signalling in human endometrium, which has not been previously examined.
Methods
Endometrial ($n=8$) biopsies were obtained from pre-menopausal women after hysterectomy for non-endometrial pathology. Decidual (8–10 weeks gestation; $n=5$) tissues were obtained after termination of apparently normal pregnancies. The localisation of the expression of melanocortin receptors (MCR 1-5) in the human endometrium was performed using immunocytochemistry. Tissue culture was used to characterise the effects of $ACTH_{1-24}$ on decidual tissue and blood vessel integrity determined by immunostaining for vascular smooth muscle cell (VSMC) markers.

Results
Robust expression of MC5R was demonstrated in human endometrium. Moderate to strong MC2R and MC3R expressions were also shown in this tissue. Expression of MC1R and MC4R was negligible. A dose-dependent reduction in VSMC in the cultured decidual tissue's vessel wall was observed during treatment with high concentrations of $ACTH_{1–24}$. However, the difference was only significant after treatment with the highest concentration of ACTH (500 ng/ml) ($P = 0.03$).
Conclusion
Our study demonstrated for the first time MC2R, MC3R and MC5R expression in human endometrium at the protein level. These melanocortin receptors may play a role in regulating endometrial proliferation or integrity, which could mediate menstrual disturbances observed in the clinical trial. Understanding of melanocortin receptors' role in the uterus and decidual tissue could potentially inform the pathogenesis of uterine dysfunction. The effects of ACTH excess or deficiency on the endometrium via melanocortin signalling should also be explored further.

mRNA expressions of skin steroidogenic enzymes in women with idiopathic hirsutism

Serpil Taheri[1], Kursad Unluhizarci[2], Gokmen Zararsiz[3], Sulbiye Karaburgu[1], Murat Borlu[4], Tuncay Ozgun[5], Zuleyha Karaca[2], Fatih Tanriverdi[2], Munis Dundar[1] & Fahrettin Kelestimur[2]
[1]Department of Medical Genetics, Erciyes University Medical School, Kayseri, Turkey; [2]Department of Endocrinology, Erciyes University Medical School, Kayseri, Turkey; [3]Department of Biostatistics, Erciyes University Medical School, Kayseri, Turkey; [4]Department of Dermatology, Erciyes University Medical School, Kayseri, Turkey; [5]Department of Obstetrics and Gynecology, Erciyes University Medical School, Kayseri, Turkey.

Introduction
The pathogenesis of idiopathic hirsutism (IH) is not clear. On the other hand, human skin possesses all the enzymes necessary for androgen synthesis and catabolism indicating that it is an independent peripheral endocrine organ. Thus, in the present study we aimed to investigate the mRNA expression of aromatase enzyme and the other enzymes having functional roles in the steroidogenic pathway, in freshly obtained skin tissue from subumblical skin and the arm of women with IH.
Patients
We aimed to determine mRNA expressions of genes associated with local androgen synthesis and metabolism (CYP11A1, STS, CYP19A1, SRD5A1, SRD5A2, HSD3B1, AR, COMT, ESR1, ESR2, HSD3B2, CYP17A1, SULT2A1, SULT1E1, HSD17B2, IL6, TGFβ1, TNF-α) from skin biopsy and blood samples of 21 patients with IH and the data compared with 15 healthy subjects.
Results
We found that patients with IH exhibit significantly lower expression of IL-6 mRNA and higher steroid sulphatase (STS) and HSD17B2 gene mRNA expression, respectively, in the subumblical region skin biopsies. Similarly, patients with IH exhibit significantly lower IL-6 mRNA expression and higher STS and HSD17B2 gene mRNA expression, respectively, in the arm skin compared to healthy women's subumblical region. There were no significant differences in any gene expression between the arm and subumblical skin biopsies in the patient group. In addition, there were no significant differences in any gene expression in peripheral blood mononuclear cells of the patients and healthy women.
Discussion
Our results suggest that the increased mRNA expression of HSD17B2 and STS genes, decreased IL6 mRNA are not dependent on circulating levels of testosterone. In both arm and umblical skin biopsy of patients with idiopathic hirsutism, we observed an up-regulation of HSD17B2 and STS, decreased IL6, probably determining an increase in the local amount of active androgens, which could then be used as substrate for other androgen metabolic routes.

Difficulties in the evaluation of hirsutism using the modified Ferriman-Gallwey scale

Lina Ciaplinskiene, Dalia Kozloviene, Robertas Knispelis, Ruta Kriksciuniene, Rimas Zalinkevicius & Birute Zilaitiene
Lithuanian University of Health Sciences, Kaunas, Lithuania.

Inconsistences in hirsutism evaluation using The Modified Ferriman-Gallwey scale (mFG) between different evaluators and need for hirsutism diagnostics standardization has been reported in numerous publications.
The aim of the study was to determine the differences in the evaluation of female hirsutism between researchers.
Materials and methods
The study was conducted during the period March to June of 2013. The study was carried out by six physicians – one specialist in female hyperandrogenism (an expert physician), and five – with no such experience. At the beginning of the study, the expert physician trained other researchers in the evaluation of terminal hair growth using mFG scale. The study included 90 women who presented to the endocrinologist's consultation due to different reasons except hyperandrogenism and met the inclusion criteria. The subjects underwent anthropometric measurements, and were asked to perform self-evaluation of hirsutism according to the mFG scoring method. Following that, hirsutism was evaluated by the physicians-researchers using the same mFG scoring method.
Results
The study included healthy 20–34 year old (mean age 25.2 years, 95% CI 23.8–26.5) women with regular menstrual cycles. The total mean score of the subjects' self-evaluation was 7.0, 95% CI 4.6–9.3. The total mean score of the evaluation given by the researchers was 2.81, 95% CI 1.5–4.2. The odds ratio for erroneous evaluation of hirsutism on the upper lip was 1.31 (95% CI 1.02–1.69), on the lower abdomen and the thigh – 5.44 (95% CI 4.23–7.02), and on the chest – 0.02 (95% CI 0.02–0.04).
Conclusions
A discrepancy was found between the evaluations submitted by the expert physician and one of evaluators, whereas the differences between the evaluations presented by the other researchers were not significant. The women who participated in the study significantly more frequently submitted higher mFG scores when evaluating their hirsutism than the researchers did. The greatest differences between the evaluations of hirsutism were found on the upper lip, the lower abdomen, and thighs. Extensive training is needed before starting use The Modified Ferriman-Gallwey scale in order to get reliable results of hirsutism evaluation.

Incretin release in a different state of testosterone level among lean PCOS women – case control study

Sandra Mrozinska[1], Tomasz Milewicz[2], Iwona Rogatko[3], Marta Kialka[4], Magdalena Spalkowska[5], Kamila Migacz[6], Aleksandra Kowalczuk[7], Agnieszka Kawula[8] & Anna Galuszka-Bednarczyk[9]
[1]Department of Endocrinology, Collegium Medicum, Jagiellonian University, Cracow, Poland; [2]Department of Gynecological Endocrinology, Collegium Medicum, Jagiellonian University, Cracow, Poland; [3]Department of Clinical Biochemistry, Polish-American Institute of Pediatrics, Cracow, Poland; [4]Department of Gynecological Endocrinology, Collegium Medicum, Jagiellonian University, Cracow, Poland; [5]Department of Dermatology, Collegium Medicum, Jagiellonian University, Cracow, Poland; [6]Department of Gynecological Endocrinology, Collegium Medicum, Jagiellonian University, Cracow, Poland; [7]Department of Gynecological Endocrinology, Collegium Medicum, Jagiellonian University, Cracow, Poland, [8]Specialist Hospital, Rybnik, Poland; [9]Department of Gynecological Endocrinology, Collegium Medicum, Jagiellonian University, Cracow, Poland.

Introduction
Incretins are peptide hormones, responsible for 70% of the insulin release after oral glucose intake. An impaired incretins secretion was noted in several conditions involving insulin resistance, including polycystic ovary syndrome

(PCOS), known as the state with increased testosterone level. This paper considers a possible relationship between the level of free androgen index (FAI) and glucose-dependent insulinotropic peptide (GIP) among lean women affected by PCOS. To our knowledge, no previous study has evaluated the matter so far.
Case control study
50 lean women (BMI = 20.76 ± 1.83) were enrolled to the study and divided into two groups according to the FAI level. Group A consisted of 25 patients with FAI <5 and group B consisted of 25 patients with FAI >5. All subjects underwent standard meal test. Serum GIP concentration was determined both at fasting and at 60 min of the test. Calculations were computed in the Statistica Program.
Results
Mean GIP was significantly higher in group 2 before and after meal test (Mann-Whitney's U test; $P=0.006$). Likewise, group 2 exhibited higher values of medians. Spearman's test indicated significant correlation between FAI and GIP levels at $0'$ and $60'$ in total study population ($0'$: $P=0.008$; $60'$: $P=0.049$). The absence of the significant correlation was observed in each group. It might be a consequence of the limited number of patients.
Conclusion
Excess androgen activity might be a vital factor contributing to alter secretion of incretins in lean PCOS women. An increased GIP levels may induce hyperinsulinaemia and play an additive to insulin resistance role in progression to T2DM.

Introduction
Primary hypogonadism (PHG, testosterone <10.5 nmol/l and LH >9.5 U/l) without a recognisable cause affects ~2% of community-dwelling middle-aged and older men. We sought to identify the clinical significance of, and risk factors for, this apparently age-related hypogonadal state.
Methods/design
The European Male Ageing Study (EMAS) is a prospective observational cohort survey of 3.369 community-dwelling men aged 40–79 in eight European countries who underwent follow up assessment an average of 4.3 years later. Men were classified as incident i) PHG (Eugonadal (EUG) at baseline, PHG at follow-up) or persistent (p) PHG (PHG at baseline and at follow-up), and were compared to those with pEUG (EUG at baseline and at follow-up). Differences in clinical and laboratory parameters between the groups and potential risk factors for iPHG were assessed using descriptive statistics and regression models.
Results
Of the 1.996 men comprising the analytical sample, 1.946 (97.5%) had pEUG, 23 (1.15%) had iPHG, 22 (1.10%) pPHG, and 5 (0.25%) reverted to EUG. The incidence of PHG was 0.27%/year. At baseline, iPHG (compared to pEUG) men were on average 9 years older ($P<0.001$), more likely to be smokers (OR 5.9 (1.8–18.6); $P=0.003$) and tended to have more illnesses (OR 2.8 (0.9–8.5); $P=0.069$). Their baseline total and free T levels were lower, and gonadotropin levels higher than in pEUG men. Upon transition from EUG to PHG, the characteristics which worsened significantly included erectile dysfunction, walking limitation, haemoglobin, self-rated physical function and frequency of >2 illnesses. Clinical parameters in iPHG and pPHG at follow-up were in the main similar.
Conclusion
PHG is a relatively rare condition in ageing men. The major risk factors for its development include older age, smoking and chronic illness. PHG in ageing men is characterised by clinical features compatible with both androgen deficiency and deteriorating functional health.

Deregulation of Sertoli and Leydig cells function in patients with Klinefelter syndrome as evidenced by testis transcriptome analysis

Alberto Ferlin[1], Marco D'Aurora[2], Marta Di Nicola[3], Andrea Garolla[1], Luca De Toni[1], Sara Franchi[2], Giandomenico Palka[4], Carlo Foresta[1], Liborio Stuppia[2] & Valentina Gatta[1]
[1]Department of Medicine, University of Padova, Padova, Italy; [2]Department of Psychological, Humanities and Territorial Sciences, 'G.d'Annunzio' University, Chieti, Italy; [3]Department of Experimental and Clinical Sciences, 'G.d'Annunzio' University, Chieti, Italy; [4]Department of Oral Health and Biotechnological Sciences, 'G.d'Annunzio' University, Chieti, Italy.

Background
Klinefelter syndrome (KS) is the most common abnormality of sex chromosomes (47,XXY) and represents the first genetic cause of male infertility. Mechanisms leading to KS testis degeneration are still not completely defined but considered to be mainly the result of germ cells loss. In order to unravel the molecular basis of global testis dysfunction in KS patients, we performed a transcriptome analysis on testis biopsies obtained from six azoospermic non-mosaic KS patients and three control subjects.
Results
The analysis found that, compared to controls, KS patients showed the differential up- and down-expression of 656 and 247 transcripts. The large majority of the deregulated transcripts were expressed by Sertoli cells (SCs) and Leydig cells (LCs). Functional analysis of the deregulated transcripts indicated changes of genes involved in cell death, inflammatory response, lipid metabolism, steroidogenesis, blood-testis-barrier (BTB) formation and maintenance, as well as spermatogenesis failure.
Conclusions
Taken together, the present data highlight the modulation of hundreds of genes in the somatic components the testis of KS patient. The increased LCs steroidogenic function together with the impairment of inflammatory pathways and BTB structure, result in increased apoptosis. These findings might represent a critical roadmap for therapeutic intervention and prevention of KS-related testis failure.

GP.08.03

Infertile men have frequently Leydig cell dysfunction: study on hypogonadism, vitamin D and bone mass in 5177 subjects

Alberto Ferlin, Andrea Garolla, Riccardo Selice, Nicola Caretta, Damiano Pizzol & Carlo Foresta
Department of Medicine, University of Padova, Padova, Italy.

Spermatogenic disruption is normally recognized by low sperm count and FSH levels. However, Leydig cell impairment is also frequent in subjects with primary testicular damage, as evidenced for example by reduced INSL3 and 25(OH)-vitamin D levels. The latter is caused by reduced expression of CYP2R1, a major enzyme involved in 25-hydroxylation of cholecalciferol. Furthermore, testosterone (T) production by the Leydig cells might be also impaired in men with primary spermatogenic damage. To clarify these we evaluated the presence and type of hypogonadism, 25(OH)-vitamin D status and bone mass in a very large cohort of infertile males. Among subjects referred to our tertiary Universitary Centre for semen analysis during the period January 2011 to June 2014 (11 516 semen analysis) we report here the data of men who completed the andrological program, including semen culture (*n*: 10 394), history and physical examination (*n*: 7527), hormone analysis (FSH, LH, T, 25(OH)-vitamin D; *n*: 5884), and ultrasound of the testes (*n*: 5177). Men with total sperm count <10 million/ejaculate (*n*: 2583) underwent also genetic analysis (karyotype, Yq microdeletions, CFTR mutations; *n*: 2273) and DXA (*n*: 855). Azoospermia was present in 9.3% of cases, oligozoospermia (with or without reduced motility and/or normal sperm morphology) in 40.6%, asthenozoospermia in 12.2%, and normozoospermia in 34.5%. Main causes or risk factors were varicocele (28%), genetics (15%), obstruction/sub-obstruction of seminal tract (12%), cryptorchidism (6%), infections/iatrogenic causes/ejaculation disorders/prior surgery (14%) and idiopathic forms (25%). Primary hypogonadism ($T<10.4$ nmol/l, LH >8 IU/l) was found in 25.7% of cases, secondary hypogonadism ($T<10.4$ nmol/l, LH <1.5 IU/l) in 1.3%, subclinical hypogonadism ($T>10.4$ nmol/l, LH >8 IU/l) in 34.2%. Men with all forms of hypogonadism have frequently insufficient (48.5%) or deficient (25.4%) 25(OH)-vitamin D levels and higher risk of low bone mass, osteoporosis (16.8%) and osteopenia (31.5%). This study showed that hypogonadism and low vitamin D levels are very frequent in infertile males. Both conditions are implicated in the frequent low bone mass seen in these patients. Metabolic and other clinical conditions associated with low T and low vitamin D levels need therefore to be accurately evaluated in these subjects, and treatment should consider also these aspects.

Triclosan-induced breast cancer growth was antagonised by kaempferol, a phytoestrogen, via regulating cell cycle, migration and apoptosis related genes in MCF-7 breast cancer cells

Seung-Hee Kim, Kyung-A Hwang & Kyung-Chul Choi
Laboratory of Biochemistry and Immunology, College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Triclosan (TCS) is one of endocrine disrupting chemicals (EDCs) derived from toothpastes, deodorant and cleaning supplies. As a phytoestrogen, kaempferol (Kaem) is found at variety of vegetables. In this study, we examined anti-proliferative effects of Kaem in TCS-induced cell growth in MCF-7 breast cancer cells. In MTT assay, TCS (10^{-6} M) increased the cell viability of MCF-7 cells, while Kaem (50 μM) significantly reduced the cell viability compared to a control (0.1% DMSO). Kaem reversed TCS-induced MCF-7 cell growth at 50 μM. To confirm that Kaem inhibited TCS-induced cell growth, we examined the transactional levels of cell growth and apoptosis-related markers using reverse transcription (RT)-PCR. The expression levels of cyclin D, cyclin E and were increased, while that of p21 and bax mRNAs was decreased by TCS in MCF-7 cells. In addition, Kaem treatment significantly reversed TCS-induced gene expressions. In parallel with its mRNA level, the protein level of cyclin E, cyclin D, cathepsin D, p-IRS1, p-AKT, p-ERK and p-MEK1/2 were induced by TCS while it was reversed by Kaem. The expression levels of p21 and bax genes was altered by TCS and reversed by Kaem treatment. For *in vivo* assay, a xenografted mouse model was generated following injection with MCF-7 breast cancer cells. In parallel with *in vitro* results, tumour volumes following treatment with E_2 and TCS were continually increased compared to a vehicle (corn oil). It was of interest that treatment of the mice with combination of E_2 plus Kaem or TCS plus Kaem showed less tumour formation rather than that of single treated mice with E_2 or TCS. Taken together, these results indicate that Kaem may inhibit the growth MCF-7 cells via regulating the expression of cell cycle, migration and apoptosis-related genes, suggesting that TCS-induced progression of breast cancer may be suppressed by a phytoestrogen (This work was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology (MEST) of the Republic of Korea (2014R1A1A2055295)).

Involvement of oestrogen receptor-α in λ-cyhalothrin and cypermethrin-induced cancer growth in BG-1 ovarian cancer cells expressing oestrogen receptor

Cho-Won Kim & Kyung-Chul Choi
Laboratory of Biochemistry and Immunology, College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Synthetic pyrethroids (SPs) are the most common pesticides which are recently used for indoor pest control. The widespread use of SPs has resulted in the increased exposure to wild animals and humans. Recently, some SPs are suspected as endocrine disrupting chemicals (EDCs) and have been assessed for their potential oestrogenicity by adopting various analyzing assays. In this study, we examined the estrogenic effects of λ-cyhalothrin (LCT) and cypermethrin (CP), the most commonly used pesticides in Korea, in BG-1 ovarian cancer cells expressing estrogen receptors (ERs). To evaluate the estrogenic activities of two SPs, LCT and CP, we performed MTT assay and reverse-transcription polymerase chain reaction (RT-PCR) for LCT or CP treated BG-1 ovarian cancer cells. In MTT assay, LCT (10^{-6} M) and CP (10^{-5} M) significantly induced the growth of BG-1 cancer cells in a dose-dependent manner. LCT or CP-induced cell growth was reversed by addition of ICI 182 720 (10^{-8} M), an ER antagonist, suggesting that this effect appears to be mediated by an ER-dependent manner. Moreover, RT-PCR results showed that transcriptional level of ERα was significantly down-regulated by LCT and CP. Taken together, these results indicate that LCT and CP may possess estrogenic potentials to stimulate the growth of ovarian cancer cells expressing ERs via an ER-dependent manner. Based on the observations from these *in vitro* results, we will examine *in vivo* oestrogenicity of LCT and CP in a xenografted mouse model transplanted with human BG-1 ovarian cancer cells (This work was supported by Basic Science Research Program though the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology (MEST) (2013R1A1A2059092)).

Bisphenol A affects amelogenesis by modulating enamel key genes expression

Katia Jedeon[1,2], Sophia Houari[1,2], Blake Mcalpin[1,2], Sophia Loiodice[1,2], Ariane Berdal[1,2] & Sylvie Babajko[1,2]
[1]University Paris Diderot, Paris, France; [2]INSERM UMRS1138, Paris, France.

Bisphenol A (BPA) is a widespread endocrine disruptor commonly used by plastic industries. More than 95% of the world population contains BPA (ng/ml) in biological fluids raising the question of its activity and potential adverse effects. Anecdotally, molar incisor hypomineralisation (MIH), an

enamel pathology affecting 15–18% of children, is increasing concurrently with ED related pathologies. Our previous data show that BPA impacts amelogenesis and generate similar enamel defects as those described for MIH. The aim of the present study is to identify BPA target genes in order to characterize the mechanism of action of low-dose BPA in enamel hypomineralisation. First, rats were exposed daily to 5 μg/kg per day BPA from the conception to the sacrifice. RNAs from microdissected dental epithelia were submitted to microarray analysis. Among the 19 239 tested RNAs, only 41 were modulated (more than 1.5-fold) by BPA. Interestingly, among these genes, amelogenin and enamelin coding for specific enamel matrix proteins were ones of the highly up-regulated. Four other genes involved in mineralization process, SLC5A8, SLC26A4, SLC44A4 and Carbonic Anhydrase VB also appeared as BPA target genes which expression modulation may explain enamel hypomineralisation. Second, *in vitro* analysis carried out on the rat ameloblastic HAT7 cells also showed transcriptional modulations of enamel gene expression by 10^{-9} M BPA. Further studies are currently underway to decipher transcriptional modulations in relation with steroid receptors (ERα and AR) involved in BPA effects during amelogenesis. In conclusion, we report that BPA impacts enamel synthesis through modulations of enamel key gene expression. Despite the small number of BPA target genes specifically expressed in ameloblasts, ubiquitous receptors such as ERα and AR are involved in BPA effect transmission. Thus, these data help to understand how irreversible enamel defects may be used as early marker of exposure to BPA some years before the diagnosis of related heavy pathologies.

Cord blood insulin-like peptide 3 is reduced in idiopathic cryptorchidism and inversely related to free bisphenol A: a marker and/or an actor of foetal exposure to endocrine disruptors?

Patrick Fenichel[1,2], Najiba Lahlou[3], Nicolas Chevalier[1,2], Patrick Coquillard[4], Patricia Panaia-Ferrari[5], Kathy Wagner-Mahler[6], Michel Pugeat[7] & Francoise Brucker-Davis[1,2]

Introduction
Cryptorchidism, the most frequent congenital malformation in full-term male newborns, increases risk of infertility and testicular cancer. Most cases remain idiopathic but epidemiological and experimental studies have suggested the role of both genetic and environmental factors. Physiological testicular descent is regulated by two major Leydig cell hormones: Insulin-like peptide 3 (INSL3) and testosterone.
Methods and results
From a prospective case control study, 52 idiopathic non syndromic, cryptorchid newborns were compared to 118 matched controls, all born after 34 weeks pregnancy. Cord blood (cb) INSL3 (modified validated enzyme-linked immune-sorbent assay) but not cb testosterone (ultrapressure liquid chromatography-tandem mass spectrometry) was decreased in unilateral idiopathic cryptorchidism ($P=0.03$) especially in transient forms ($P=0.02$) and in the subgroup of non-palpable testis compared to the subgroup of palpable testes (supra-scrotal, inguinal or high scrotal) according to Scorer classification ($P=0.01$). cb free bisphenol A (BPA) (RIA validated by High Pressure Liquid Chromatography-tandem Mass Spectrometry) in cryptorchid boys was not significantly increased ($P=0.1$). However, in the whole study population (cryptorchid and control), cb free BPA correlated negatively with INSL3 ($P=0.01$; $R^2=0.05$) but not with testosterone.
Conclusion
INSL3, a major actor of foetal testicular descent, but not testosterone, is decreased at birth in idiopathic cryptorchidism. This hormonal decrease may have contributed earlier in foetal development, to the impaired testicular descend. The inverse correlation we found between cbINSL3 and cbBPA is strengthened by the paper reporting that INSL3 gene is negatively regulated by BPA in *ex vitro* cultivated foetal human testes. While measurements of cb BPA and cb INSL3 may not exactly reflect earlier foetal production or exposure, our results support the role of INSL3 as a marker and/or an actor of foetal exposure to endocrine disruptors such as BPA.

Evidence of stimulation of pubertal development and suppression of growth rate in boys smoking marijuana in cigarettes

Shagufta Jabeen[1], Ghazala Kaukab Raja[1], Maleeha Akram[2], Afzal Ahmad[2], Mazhar Qayyum[2] & Shakeel Raza Rizvi[2]
[1]Department of Biochemistry Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Rawalpindi, Pakistan; [2]Department of Zoology Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Rawalpindi, Pakistan.

Evidence indicates that normal pattern of progression of puberty is altered under certain conditions of stress, whereas growth rate is affected by sustained higher concentrations of cortisol, a marker of stress reactivity. Available data show that early teens commonly resort to use of drugs. The use of drugs may evoke stress responses, which may alter pubertal development and affect growth rate. Body weight (BW), height, BMI and plasma concentrations of LH, testosterone (T), GH and cortisol were determined in non-smoking ($n=220$) and marijuana addicted ($n=217$) boys. Acute effect of marijuana on salivary concentrations of cortisol was assessed by giving 0.25 g of marijuana in cigarettes to ten drug addict volunteers and determining salivary cortisol concentrations 15 min before and 1, 5, 15 and 30 min after smoking. Data were analysed using Student's *t*-test, ANOVA and Pearson correlation. Mean BW, height, BMI and plasma LH, T and cortisol concentrations increased throughout puberty, whereas plasma concentrations of GH attaining peak concentrations at mid puberty declined during late puberty/adolescence in both groups. Although circulating concentrations of LH, T and cortisol showed positive correlation throughout puberty, plasma GH concentrations were negatively correlated with LH, T and cortisol at late puberty/adolescence in both groups. The plasma concentrations of LH, T and cortisol were significantly higher in addict boys, whereas plasma GH concentrations were significantly higher in non-smoking boys during puberty. The higher levels of LH and T exhibited a positive relationship with marijuana use in addict boys. The non-smoking boys were 4 kg heavier and 4.6 inches taller than addict boys at the age of 20 years. Acute administration of marijuana induced significant increases in the salivary concentrations of cortisol. In conclusion, marijuana use may provoke stress responses resulting in stimulation of pubertal development and suppression of growth rate.

Comparison of mRNA expression pattern of retinoid and retinoid X nuclear receptor subtypes in thyroid carcinomas, breast cancer and renal carcinomas

Julius Brtko[1], Lucia Bialesova[1], Vladimir Lenko[1,3], Stefan Galbavy[2], Jan Podoba[2] & Dana Macejova[1]

Introduction
Nuclear retinoid receptors (RARs) upon a ligand binding act as all-trans retinoic acid-inducible transcription factors interacting as heterodimers with nuclear retinoid X (rexinoid) receptors (RXRs). The disruption of retinoic acid (RA) signalling pathways is believed to underlie the etiology of a number of malignancies. Retinoids – cell differentiation agents that may 'reprogram' tumours, i.e. retinoic acid derivatives or retinoic acid related compounds with reduced teratogenic and other side effects are still highly required. In this study, we have investigated expression pattern of retinoid receptor subtypes (RARα, RARβ, RARγ) and rexinoid nuclear receptor subtypes (RXRα, RXRβ, RXRγ) in

three different organ malignancies, i) thyroid different carcinoma tissues, ii) breast cancer, and iii) renal cancer tissues.
Description of methods/design
Approximately 40 samples of different types of thyroid carcinoma, more than 150 breast cancer samples, and over 100 samples of renal carcinoma have been analyzed. The expression pattern of the retinoid/rexinoid nuclear receptor subtypes has been evaluated by the RT-PCR techniques.
Results
Significantly increased expression of RARα and RARγ in overall group of papillary carcinoma patients was demonstrated. In breast cancer, the expression of respective RAR subtypes was in the following order: RARα >RARβ >RARγ. Among RXR subtypes, only RXRγ was significantly diminished in breast cancer tissue. In renal carcinomas, expression of RARα and RARβ was higher when compared to intact kidney tissue. Expression of RARγ was found to be markedly decreased in all renal tumours. All renal tumours were capable to express RXRα and RXRβ. Expression of RXRγ was significantly lower in comparison with intact renal tissue.
Conclusion
The molecular mechanisms demonstrating differences in RAR and RXR subtype mRNA expression patterns in thyroid carcinomas, breast and renal cancer may find exploitation in clinical oncology, predominantly, in the differential diagnosis of different organ neoplasms.

Proliferative vs apoptotic signals in granulosa cells: β-arrestins as switch between life and death *in vitro*

Livio Casarini[1,2] & Manuela Simoni[1,3]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Center for Genome Research, University of Modena and Reggio Emilia, Modena, Italy; [3]Azienda USL of Modena, Modena, Italy.

Background
The immortalised human granulosa cell line (hGL5) is not responding to gonadotropins, which fail to activate the cAMP/PKA/CREB pathway, progesterone production, cell rounding and apoptosis, suggesting that FSH- and LH/hCG-receptors (FSHR; LHCGR) are downregulated.
Aim
To investigate whether the mechanism of FSHR/LHCGR downregulation is associated with life/death signals in hGL5 cells.
Methods
We evaluated the FSHR/LHCGR expression in cultured hGL5 cells (0–15% serum) by real-time PCR and western blotting. The response to 50 nM FSH or 100 pM LH was evaluated by measuring cAMP and progesterone production by ELISA, as well as ERK1/2 and CREB phosphorylation by western blotting, cell viability by proliferation assay and confocal imaging, in the presence or absence of selective inhibitors/agonists (i.e. the PKA inhibitor H-89, PMA as a PKC-ERK1/2 activator, siRNA against β-arrestin1/2).
Results
Despite the positive expression of FSHR/LHCGR in the presence of serum at both mRNA and protein level (linear regression; $P<0.05$; $n=3$), FSH/LH stimulation was ineffective on cAMP/pCREB activation and progesterone production (Mann-Whitney's *U*-test; $P\geq0.05$; $n=3$), suggesting uncoupling of the receptors to the Gs-α protein. Conversely, ERK1/2 phosphorylation was FSH/LH- and dose-dependent in the presence of serum, increasing cell proliferation within 3 days, an effect similar to that obtained by PMA (Mann-Whitney's *U*-test; $P<0.05$; $n=3$). β-arrestin1/2 siRNA transfection unlocked the cAMP/PKA pathway, leading to cAMP/CREB activation and progesterone accumulation at high levels (Mann-Whitney's *U*-test; $P<0.05$; $n=3$), cell rounding, pro-caspase three cleavage and apoptosis. The pro-apoptotic effects of cAMP/PKA basal activation were augmented by FSH -but not LH- treatment and inhibited by H-89 selective PKA blockade. Accordingly, long-term (4–8 weeks) overexpression of FSHR resulted in high basal cAMP levels, cell rounding and apoptosis (Mann-Whitney's *U*-test; $P<0.05$; $n=3$), revealing the peculiar, dual role of FSHR in the activation of proliferative/apoptotic signals.
Conclusions
β-arrestins determine the FSHR-, rather than LHCGR-mediated signalling towards proliferative/apoptotic pathways, acting as selective switch between ERK or cAMP/PKA pathway activation.

Agonist-selective phosphorylation of the human sst3 somatostatin receptor determined by phosphosite-specific antibodies

Andreas Lehmann, Stefan Schulz & Thomas Günther
Institute of Pharmacology and Toxicology, University Hospital Jena, Jena, Germany.

The human somatostatin receptor 3 (hsst3) is expressed in about 50% of all neuroendocrine tumours. The sst3 receptor is unique among somatostatin receptors which can initiate apoptosis of tumour cells through activation of the tumour suppressor p53. Furthermore, treatment of the sst3 receptor with somatostatin or stable somatostatin analogues such as octreotide or pasireotide can inhibited tumour cell proliferation. However, at present little is known about the agonist-induced regulation of the human sst3 receptor. We have generated a series of phosphorylation-deficient mutants of the receptor and determined important sites for agonist-induced internalisation. Based on this information we generated phosphosite-specific antibodies for the carboxyl-terminal serine 337, threonine 341 and threonine 348, which enabled us to investigate the temporal patterns of sst3 phosphorylation and dephosphorylation. Here we demonstrate that pasireotide and octreotide were not able to promote a phosphorylation to the same extent as natural somatostatin. Similar the sst3-selective ligand L-796,778 did not promote any detectable phosphorylation or internalisation. We also show that sst3 phosphorylation occurred within minutes, whereas dephosphorylation and recycling of the sst3 receptor occurred at a considerably slower rat. We also identify G protein-coupled receptor kinases 2 and 3 (GRK2/3) and protein phosphatase 1 (PP1) as key regulators of sst3 phosphorylation and dephosphorylation.

Characterisation of insulin and β_2-adrenergic receptor heteromers: experimental and bioinformatics approach

Maja Mandić[1], Sanja Glisic[2], Christina Pedersen[3], Nevena Veljkovic[2], Jane Nøhr[3] & Milka Vrecl[1]
[1]Veterinary Faculty, Institute of Anatomy, Histology and Embryology, University of Ljubljana, Ljubljana, Slovenia; [2]Institute of Nuclear Sciences VINCA, Center for Multidisciplinary Research, University of Belgrade, Belgrade, Serbia; [3]Department of Incretin Biology, Novo Nordisk A/S, Måløv, Denmark.

Evidences for a functional link between insulin receptor (IR) and β_2-adrenergic receptor (β_2AR) exist in the mouse heart and in retina and are correlated with the cardiovascular dysfunction under insulin-resistant states[1] and a diabetic retinopathy phenotype[2]. In our recent study we showed that i) IR coexpression reduced β_2AR surface expression and accelerated its internalization, ii) provided evidence for direct interaction and higher-order β_2AR:IR oligomer formation, likely comprising heteromers of homodimers, and iii) identified prospective intracellular interaction domains engaged in heteromerisation[3]. In this study we examined the involvement of the cytoplasmic part of the IR β chain in heteromerisation and addressed the role of β_2AR:IR heteromer in signalling. Evidence suggesting that the cytoplasmic part of the IR β chain is prerequisite for the interaction with the β_2AR was provided by BRET[2] saturation and Heteromer Identification Technology (HIT) assays using a IR 1–1271 mutant lacking the IR C-terminal tail region (amino acids from 1272 to 1360). In BRET[2] saturation assays, IR 1–1271–Rluc8 mutant displayed lower $BRET_{max}$ value and slightly reduced affinity compared to the WT IR. For the complex consisting of IR 1–1271–RLuc8:β_2AR-GFP[2] the saturation was not reached; most likely reflecting only random collisions. Furthermore, in the IR 1–1271–Rluc8:β_2AR HIT assay with β-arrestin 2 no substantial agonist-induced increase in BRET[2] signal was detected that would be indicative of β-arrestin 2 recruitment to the IR 1–1271–Rluc8:β_2AR heteromer, arguing against ability of IR 1–1271 to heteromerise with the β_2AR. Additional *in silico* mutation analysis of IR predicted substitutions mostly affecting the binding to the β_2AR. β_2AR:IR heteromerization also influenced the pharmacological phenotype of the β_2AR i.e. its ability to recruit β-arrestin 2 and cAMP signalling.

Neuroprotective effects of 17β-oestradiol: a therapeutic potential drug for Alzheimer's disease

Pardeep Kumar, R K Kale & N Z Baquer
Jawaharlal Nehru University, New Delhi, India.

Objectives
Alzheimer's disease (AD) is the most common form of dementia in the elderly. AD is characterized by the presence of amyloid plaques which are formed from deposits of β-amyloid protein (Ab). These changes increase during menopausal condition in females when the level of oestradiol (E_2) is decreased. The aim of the present study was to determine the effect of neuropeptide, neurokinin B (NKB) and amyloid beta fragment Aβ (25–35) on E_2 treated aging female rat brain of 3 months (young), 12 months (adult), and 24 months (old) age groups.
Methods
The aged rats (12 and 24 months old) ($n=8$ for each group) were given s.c. injection of E_2 (0.1 μg/g body weight) daily for 1 month. After 30 days of hormone treatment, experimental animals of all the groups were sacrificed and brains were isolated for further study.
Results
The results obtained in the present work revealed that increased activities of antioxidant enzymes, membrane bound ATPases and decrease in level of calcium levels, monoamine oxidase activity and lipid peroxidation in presence of NKB and combined NKB and Aβ *in vivo* E_2 treated ageing rat brain. NKB treatment reversed the beneficial in preventing some of the age related changes in the brain. An *in vitro* incubation of E_2 treated synaptosomes with Aβ showed toxic effects on all the parameters, while NKB showed stimulating effects and the combined NKB and Aβ showed a partial effects as compared to Aβ (25–35) and NKB alone.
Conclusions
Present study elucidates an antioxidant, neuromodulatory and neuroprotective role of tachykinin peptide NKB against the β-amyloid induced toxicity in E_2 treated female rats. NKB treatment reversed the beneficial in preventing some of the age related changes in the brain.

Effects of estrogens on endothelial-derived factors implicated in the atheromatic plaque vulnerability-clarification of the molecular mechanisms

Narjes Nasiri Ansari[1], Eliana Spilioti[1], Vasiliki Kalotychou[2], Karin Dalman-Wright[3], Paraskevi Moutsatsou[1], Athanasios Papavassiliou[1] & Eva Kassi[1]
[1]Laboratory of Biochemistry, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [2]1st Department of Internal Medicine, Medical School, National and Kapodistrian University of Athens, Athens, Greece; [3]Department of Biosciences and Nutrition, Karolinska Institute, Stockholm, Sweden.

Introduction
In the presence of atherogenic plaque, estrogens may be potentially harmful. Among the key vessel wall components in the later stages of atherogenic process are endothelial cells (ECs). During the stages of plaque instability/rupture, metalloproteinases (MMP2 and MMP9), their inhibitors (TIMP2 and TIMP1), RANK, RANKL, OPG, MCP1, lysyl oxidase (LOX), PDGF, and ADAMTS4 play critical role. We aimed to investigate i) the effect of oestrogens on the expression of the above molecules in ECs and ii) which type of estrogen receptor mediates these effects.
Methods
Human aortic endothelial cells (HAECs) were cultured, in the absence or in the presence of estradiol (E_2) at various concentrations and for various incubation times without or with pre-incubation with TNFα (resembling a low grade inflammation state). The mRNA expression of all the aforementioned genes was assessed by real-time PCR. Zymography for MMP2 and MMP9 activity was also performed. The experiments were repeated in either ERα- or ERβ-transfected HAECs.
Results
HAECs did not express ERα and ERβ while they express G-protein coupled estrogen receptor 30 (GPR30). Incubation with E_2 at low concentrations induced an increase in LOX and MCP1 mRNA expression. Zymography revealed that E_2 induced a down regulation of active MMP2, dose-dependently. Incubation with E_2 following pretreatment with TNFα induced a marginal increase in MMP9 and TIMP1 expression and a ten times increase in MCP1, dose-dependently. In ERα-transfected HAECs, incubation with E_2 led to upregulation of TIMP1 and TIMP2 and in marginal increase of LOX and MCP1. E_2 increased the expression of MCP1 and LOX while decreased the expression of PDGF in ERβ-transfected HAECs.
Conclusion
E_2 induced different effects regarding atherogenic plaque instability through different ERs. The balance of expression of the various ER subtypes may play an important role in the paradoxical characterization of estrogens as both beneficial and harmful.

Androgen modulates expression of energy-related genes in brown adipocytes

Avi Lerner, Drashti Kewada, Anthony Okolo, Kate Hardy & Stephen Franks
Imperial College London, London, UK.

Polycystic ovary syndrome (PCOS) is a common endocrinopathy is associated with an adverse metabolic profile including obesity, insulin resistance, and dyslipidaemia. Hyperandrogenism is the hallmark of PCOS and androgen production is increased in the presence of increased adiposity. While a clear link between obesity and the severity of PCOS exists, the relationship between hyperandrogenism and adipose tissue is less clear. Interestingly, women with PCOS and raised androgen levels exhibit reduced postprandial thermogenesis (Robinson *et al*. *J Clin Endocrinol* 1992 **36** 537). Brown adipose tissue (BAT) is important in non-shivering and postprandial thermogenesis. In this study, we investigated the effect of androgen treatment on the differentiation and gene expression of BAT. Immortalised mouse brown preadipocytes were differentiated for 14 days in the presence and absence of dihydrotestosterone (DHT). In addition, fully differentiated adipocytes were treated with DHT or control for 24 h. Adipogenesis was observed using Oil Red O staining and quantitative PCR was used to analyse differential gene expression for a panel of genes. Our results show that DHT treatment inhibits brown fat adipogenesis in a dose-dependent manner. Hyperandrogenism also causes dysregulation of normal gene expression and several markers for BAT and thermogenesis were significantly perturbed. These included downregulation of the adipokine desnutrin/ATGL (a key gene required for BAT identity and thermogenesis) ($P<0.01$) and C/EBPα (an important early regulator of brown adipose markers and normal energy metabolism) ($P<0.01$). Furthermore, DHT treatment caused distinctive adipokine profiles similar to those found in metabolic syndrome and insulin resistance such as reduced adiponectin ($P<0.05$) and raised PAI-1 ($P<0.05$). These results suggest that androgens play a role in brown adipocyte differentiation and function and lend support for a reciprocal relationship between androgens, BAT and thermogenesis.

Study of a possible interaction between reactive oxygen species and the mTORC1 pathway in the regulation of energy balance

Magalie Haissaguerre[1,2], Samantha Clark[1,2], Antoine Tabarin[1,3] & Daniela Cota[1,2]
[1]INSERM U862, Neurocentre Magendie, Bordeaux, France; [2]University of Bordeaux, Bordeaux, France; [3]Endocrinology Department, Haut Leveque Hospital, University Hospital of Bordeaux, Pessac, France.

Obesity and its consequent metabolic disorders are severe health problems. The mechanistic target of rapamycin complex 1 (mTORC1) pathway is an important hypothalamic integrator of the actions of nutrients and hormones on food intake (FI). Nutrient availability also affects the formation of reactive oxygen species (ROS) in the hypothalamus and regulates neuronal activity. In the present study, we hypothesise that modulation of mTORC1 activity mediates ROS effects on FI. To this purpose, C57Bl6J mice or WT and KO mice deficient for the mTORC1 downstream target S6K1 were treated with an i.c.v. injection of the ROS producer H_2O_2 or the ROS scavenger honokiol, alone or in combination with the mTOR inhibitor rapamycin or the mTOR activator leptin and changes in FI and body weight were assessed. Western blots were performed to study hypothalamic mTORC1 activity. ROS levels were analysed in POMC neurons using dihydroethidium combined with immunofluorescence. I.c.v. administration of H_2O_2 induced phosphorylation of S6K1 within the hypothalamus, increased expression of c-fos, a marker of neuronal activity, in the arcuate nucleus and increased ROS signal in POMC neurons. These effects were associated with a significant decrease in food intake over 24 h. Conversely, i.c.v. administration of honokiol increased FI. The behavioural effects of H_2O_2 and honokiol were not seen in S6K1 KO mice. Pharmacological experiments using i.c.v. coadministration of H_2O_2 and rapamycin in C57Bl6J mice showed that rapamycin (at a dose not acting on FI) was able to blunt the anorexigenic effect of H_2O_2. Similarly, i.c.v. honokiol administration combined with an i.p. leptin injection decreased the anorexigenic effect of leptin, suggesting that leptin requires ROS formation to reduce FI. Our preliminary results confirm that ROS modulators require a functional mTORC1 pathway to regulate FI. Studies are ongoing to better define this relationship at the molecular and neuroanatomical level.

Roles of membrane oestrogen receptor alpha in bone sparing effects of oestrogens

Alexia Vinel[1], Coralie Fontaine[1], Eric Hay[2], Marie Valera[1], Françoise Lenfant[1], Martine Cohen-Solal[2] & Jean-François Arnal[1]
[1]INSERM U1048, Université Paul Sabatier, Toulouse, France; [2]INSERM UMR-1132, Université Paris Diderot, Sorbonne, Paris, France.

Introduction
The bone-sparing effect of oestrogen is mediated via oestrogen receptor alpha (ERα), which stimulates transcriptional action through its two activation functions (AF1 and AF2). In addition to these nuclear effects, a fraction of this receptor is targeted to the plasma membrane and triggers membrane initiated steroid signaling (MISS). Whereas, ERα AF1 plays a crucial role in trabecular bone, but not cortical bone, ERα AF2 is necessary for the oestrogen effect in both types of bone. A pharmacological approach using an oestrogen dendrimer conjugate suggested that the selective activation of membrane ERα is sufficient to elicit a sparing effect in cortical but not in trabecular bone.
Methods
The aim of this study was to define the role of ERαMISS on the beneficial actions of oestrogens on bone *in vivo*, using a mouse model in which ERα membrane localisation is abrogated due to a point mutation of the palmitoylation site of ERα (C451A-ERα).
Results
Intact (unovariectomised) C451A-ERα mice showed an accelerated loss of both trabecular and cortical bone compared to littermate WT controls. Furthermore, chronic 17β-oestradiol administration (8 μg/kg per day) elicited a strong bone protection in ovariectomised mice, whereas, these actions were significantly reduced in C451A-ERα mice.
Conclusion
We show here that in bone tissues, membrane ERα is necessary for oestrogen protection and thus that nuclear and membrane actions cooperate to the bone sparing effects of oestrogens. This contrasts with the absence of ERαMISS role for the uterotrophic action of oestrogens. Our work underlines the exquisite tissue-specific actions of ERα subfunctions, and should help to understand the mechanisms by which selective ER modulators can act *in vivo*.

Comparison of two methods in assessment of fracture risk of postmenopausal women with osteopenia

Martin Kužma[1], Eva Némethová[2], Zdenko Killinger[1] & Juraj Payer[1]
[1]5th Department of Internal Medicine, Faculty of Medicine, Comenius University and University Hospital, Bratislava, Slovakia; [2]Department of Internal Medicine, Dunajská Streda Hospital, Dunajská Streda, Slovakia.

Introduction
More than half of osteopenic patients suffer from fracture (Fx), but BMD osteopenia is usually not considered for treatment initiation. FRAX, tool that can identify patients with high Fx risk based on major risk factors, can be used as an interventional threshold. Past few years, trabecular bone score (TBS), the bone quality determinant, is a promising method identifying the high-risk patients according to degradation of trabecular bone.
Objective
Comparison of two methods, TBS and FRAX, in treatment consideration between postmenopausal women with osteopenia.
Methods
The group of osteopenic postmenopausal women were retrospectively analyzed. Using NOF cutoff values of 20% for major osteoporotic fracture and 3% for hip fracture were used to consider patients at high absolute 10 years risk of Fx. According to temporary consensus guidelines patients with BMD osteopenia+ very low (degraded) TBS (<1.1) should be treated after secondary cause was excluded. TBS Insight tool was used to assess TBS derived from L-spine DXA scans.
Results
157 postmenopausal women (mean age 65.9 years, BMI 26.7 kg/m^2, *T*-score: neck -1.2; L-spine 1.4, and TBS 1.24) were included. In total, by NOF cutoff 44 (28%) patients, who may be treated were identified. From that number 20 (12.7%) patients belonged to highly degraded TBS group. Another 32 (20.3%) patients with highly degraded TBS were identified in low risk FRAX group.
Conclusion
In the present study, the FRAX tool was able to identify additional 28% more patients in high fracture risk, which should be considered for treatment. From NOF high-risk group TBS identified 20 patients at increased risk of fracture and additional 32 patients from whole study group with degraded TBS who should be treated. According to this study, addition of TBS to FRAX brings novel info in identifying high Fx risk patients with osteopenia.

Local administration of non-diabetic MSCs to diabetic femoral fractures enhances callus remodelling and deposition of reparative bone

Luke Watson[2], Xi Zhe Chen[1], Aideen Ryan[1], Paul Loftus[2], Patrick McDonnell[1], Timothy O'Brien[1] & Cynthia Coleman[1]
[1]National University of Ireland Galway, Galway, Ireland; [2]Orbsen Therapeutics, Galway, Ireland.

Fractures in diabetic patients are slower to heal and have an increased risk for developing malunion as compared to non-diabetic individuals. Given the known deficiencies in diabetic progenitor cell number and differentiation capacity, it is reasonable to hypothesise the aetiology of diabetic fracture malunion is dysregulated progenitor function. Therefore, we investigated the therapeutic efficacy of locally administered non-diabetic human bone marrow derived mesenchymal stem cells (hMSCs) to support femoral fracture repair in a murine model of diabetes.
A dose escalation study was performed administering hMSCs directly to a femoral fracture in a murine model of diabetes. The effect of local hMSC administration on the diabetic condition was evaluated by weekly monitoring of mouse weight, blood glucose, and terminal levels of circulating HbA1c. No significant change in body weight, blood glucose, or HbA1c as a result of hMSC administration was observed throughout the 56-day study. Animals maintained their weight at 26–28 g, their blood glucose levels >13 mM and HbA1c levels of 10–15% regardless of treatment group. MicroCT analysis indicates an increase in bone volume, a statistically significant increase in bone mineral density and trabecular thickness and a statistically significant decrease in the ratio of bone surface area to bone volume in animals treated with hMSCs as compared to saline treated controls. Further, four point bending analysis demonstrated a statistically significant increase in ultimate stress and e-modulus of the reparative bone. Although, the local administration of hMSCs did not alter the organismal diabetic condition, treatment of the diabetic fracture with hMSCs resulted in enhanced mechanical integrity of de novo reparative bone.

Therefore, the local administration of non-diabetic hMSCs to diabetic fractures has the potential to enhance callus remodelling resulting in the deposition of higher quality reparative bone.

Osteoporosis and osteopenia in patients after kidney and pancreas transplantation

Jana Brunova[1], Simona Kratochvilova[1] & Josef Bruna[2]
[1]Institute for Clinical and Experimental Medicine, Prague, Czech Republic; [2]Medical Faculty Hospital Motol, Prague, Czech Republic.

Background
Organ transplantation (Tx) is the standard treatment for end-stage renal failure in diabetic patients. With an improvement in patient and graft survival, the bone loss and persistent abnormalities in bone metabolism are long-term complications to manage.
Patients and methods
We investigated the prevalence of osteoporosis and osteopenia in 256 diabetic patients (142M, 114F) after the kidney and pancreas Tx for renal failure due to diabetic nephropathy. The bone loss was diagnosed with densitometry (DEXA) using Lunar Prodigy apparatus in years 2010–2014. The characteristics of bone metabolism were regularly examined and we measured on the plain CXR the clavicle bone index, which is the ratio of cortical bone width to total bone width at the midpoint of the shaft.
Results
Osteoporosis of lumbar spine (L spine) and/or hips was diagnosed in 53/256 patients (20%), osteopenia in 135/256 (52%) and 68/256 (28%) of patients had normal bone density. Patients with osteoporosis had affected mainly proximal femurs (hips) in (50/53 (94%) cases and distal forearm in 32/53 (60%). Osteoporosis of L spine was proven in 11/53 patients (21%) and osteopenia in 28/53 (53%) cases. Patients did not differ significantly in age, creatinine, calcium and parathormone (PTH) level. There was a tendency to lower BMD with years after the kidney and pancreas Tx (see Table). The bone index showed good correlation with the bone density measured by DEXA ($P<0.01$).

Patients	*n*	Age (years)	After Tx (years)	Creatinine (μmol/l)	Ca (mmol/l)	PTH (pmol/l)
Osteoporosis	53	51.7	8.4	147.7	2.4	14.6
Osteopenia	135	52.9	7.7	145.3	2.4	16.7
Normal BMD	68	54.6	6.8	147.3	2.4	13.8

Conclusion
Diabetic patients after kidney and pancreas Tx have increased prevalence of osteopenia and osteoporosis (72%). Osteoporosis affects mainly the hips (94%) and distal forearm. Evaluation and managing of bone disease should be an integral part of pre- and after Tx medical care.

GP.10.05

Effect of 1-year cross-sex hormonal treatment on bone mineral density of the lumbar spine in transgender patients

Mariska Vlot, Maartje Klaver, Paul Lips, Renate de Jongh, Annemieke Heijboer & Martin den Heijer
VU Medical Center, Amsterdam, The Netherlands.

Background
Oestrogen can increase bone mineral density (BMD) by decreasing bone turnover, which is mainly seen in trabecular bone. Testosterone can increase bone size, but the effect on BMD is less clear. Cross-sex hormonal treatment (CSHT) in transsexuals can therefore affect the BMD. For example, in male-to-female individuals (MtFs) a lower BMD before start of CSHT has been described in comparison to healthy control men.
Objectives
To investigate the effects of CSHT on BMD during the first year of hormonal treatment in MtFs and female-to-male individuals (FtMs).
Methods
Prospective study, part of European Network for Investigation of Gender Incongruence (ENIGI). 74 adult patients who completed 1 year of CSHT were included. In 37 FtMs and 37 MtFs a dual-energy X-ray absorptiometry (DEXA) was performed to measure the BMD of the spine at start and after a year of CSHT. The FtMs received testosterone undecanoate i.m. (1000 mg/12 weeks), testosterone gel (50 mg/day), or testosterone esters i.m. (250 mg/2 weeks). The MtF group was treated with estradiol valerate (2–4 mg/day) or an estradiol patch (200 μg/week) and most MtFs received cyproteronacetate (50 mg/day) simultaneously.
Results
At baseline the BMD of the spine of the FtMs was 0.99 g/cm^2 (S.D. $\pm$0.10) and after 1 year 1.00 g/cm^2 (S.D. $\pm$0.10) reflecting a mean difference of 1% (95% CI $-$0.31 to 2.24). In the MtFs at baseline and after 1 year, the BMD of the spine was 1.00 g/cm^2, (S.D. $\pm$0.11) and 1.03 g/cm^2 (S.D. $\pm$0.11) respectively, reflecting a mean difference of 3.6% (95% CI 2.30 to 4.86).
Conclusion
In FtMs the BMD of the spine remained stable after 1 year CSHT. In the MtFs group, the BMD increased on average with 3%. Taken into account the short study period, the change in BMD suggests that BMD is an important variable in the follow up of transsexuals.

GP.10.06

The (*CAG*)*n* repeat polymorphism of the androgen receptor gene is associated with bone mineral density in menopausal women

Anastasia Markatseli[1], Leandros Lazaros[2], Harilaos Kostoulas[2], Sofia Markoula[2], Stelios Tigas[1], Ioannis Georgiou[2] & Agathocles Tsatsoulis[1]
[1]Department of Endocrinology, University of Ioannina, Ioannina, Greece; [2]Laboratory of Human Reproductive Genetics, Department of Obstetrics and Gynecology, University of Ioannina, Ioannina, Greece.

Introduction
Osteoporosis is a systemic skeletal disease with a strong genetic component. The androgen receptor (AR) is encoded by the *AR* gene and mediates the action of androgens, which play an important role in bone metabolism. Polymorphisms in the *AR* gene may be implicated in the pathogenesis of osteoporosis.
Objectives
The present study aimed to explore the influence of the (*CAG*)*n* repeat polymorphism of *AR* gene on BMD and serum levels of osteoprotegerin (OPG), receptor activator of nuclear factor-κB ligand (RANKL), and bone metabolic markers in a Greek female population.
Methods
Two hundred and seventeen peri- and postmenopausal women aged 42–63 years were enrolled. All participants underwent spinal BMD evaluation by dual-energy X-ray absorptiometry (DXA). Genotyping of the (*CAG*)*n* repeat polymorphism was performed by PCR. Levels of OPG, soluble RANKL (sRANKL), and bone metabolic markers were measured.
Results
Genotype analysis revealed alleles having 15–30 CAG repeats. The (*CAG*)*n* polymorphism was significantly associated with spinal BMD. Women having biallelic mean CAG repeat number $\geq$21 had significantly lower spinal BMD (0.797 ± 0.107 g/cm^2) than women having biallelic mean CAG repeat number $<$21 (0.841 ± 0.129 g/cm^2) ($P=0.007$). The association remained significant after adjustment for age, years since menopause (YSM) and BMI ($P=0.016$). Additionally, calcium concentration in serum was associated with the (*CAG*)*n* polymorphism. Calcium concentration in serum was higher in women with biallelic mean CAG repeat number $\geq$21 (9.88 ± 0.48 mg/dl) than in women with biallelic mean CAG repeat number $<$21 (9.73 ± 0.44 mg/dl) ($P=0.017$). No effect was observed on circulating levels of OPG and sRANKL.
Conclusions
The (*CAG*)*n* polymorphism of the *AR* gene may influence BMD at the lumbar spine in menopausal Greek women.

Role of vitamin D levels and vitamin D supplementation on bone mineral density in Klinefelter syndrome

Alberto Ferlin, Riccardo Selice, Antonella Di Mambro, Marco Ghezzi, Nicola Caretta & Carlo Foresta
Department of Medicine, University of Padova, Padova, Italy.

Introduction
Decreased bone mineral density (BMD) in Klinefelter syndrome (KS) is frequent and it has been traditionally related to low testosterone levels. However, low BMD can be observed also in patients with normal testosterone levels and testosterone replacement therapy does not necessarily increase bone mass in these patients. Nothing is known about vitamin D levels and supplementation in KS. In this study we determine vitamin D status and bone mass in KS subjects and compare the efficacy of testosterone therapy and vitamin D supplementation on BMD.
Methods
A total of 127 non-mosaic KS patients and 60 age-matched male controls were evaluated with reproductive hormones, 25-hydroxyvitamin D, PTH, and bone densitometry by DEXA. Patients with hypogonadism and/or 25-hydroxyvitamin D deficiency were treated with testosterone-gel 2% and/or calcifediol and re-evaluated after 24 months of treatment.
Results
25-hydroxyvitamin D levels were significantly lower in KS patients with respect to controls, and they had significantly lower lumbar and femoral BMD. The percentage of osteopenia/osteoporosis in subjects with 25-hydroxyvitamin D deficiency was higher with respect to subjects with normal 25-hydroxyvitamin D and was not related to the presence/absence of low testosterone levels. Subjects treated with calcifediol or testosterone + calcifediol had a significant increase in lumbar BMD after treatment. No difference was found in testosterone-treated group.
Conclusions
These data highlight that low 25-hydroxyvitamin D levels have a more critical role than low testosterone levels in inducing low BMD in KS subjects. Furthermore, vitamin D supplementation seems to be more effective than testosterone replacement therapy alone in increasing BMD.

Serum cystatin C levels were correlated with cardiometabolic features and cardiovascular diseases in patients with primary hyperparathyroidism

Chiara Verdelli[1], Federica Ermetici[2], Marcello Filopanti[3], Uberta Verga[3], Elena Passeri[4], Giorgia Dito[4], Alexis Elias Malavazos[2], C Mapelli[5], M E Raggi[5] & Sabrina Corbetta[4]
[1]Laboratory of Molecular Biology, IRCCS Policlinico San Donato, San Donato Milanese (MI), Italy; [2]Diabetology and Metabolic Diseases Unit, IRCCS Policlinico San Donato, San Donato Milanese (MI), Italy; [3]Endocrine and Diabetology Unit, IRCCS Fondazione Cà Granda Ospedale Maggiore Policlinico, Milan, Italy; [4]Endocrinology and Diabetology Unit, Department of Biomedical Sciences for Health, University of Milan, IRCCS Policlinico San Donato, San Donato Milanese (MI), Italy; [5]Clinical Pathology Laboratory, IRCCS E. Medea, Bosisio Parini (LC), Italy.

Patients with primary hyperparathyroidism (PHPT) are at risk of chronic kidney disease (CKD). PHPT patients ($n=190$, 146 females and 44 males, aged 59.7 ± 14.2 years) and non-hypertensive, non-diabetic age- and sex-matched healthy controls were evaluated for serum cystatin C and creatinine. PHPT patients and controls with established CKD were excluded. Serum cystatin C was measured by immunonephelometric assay and calculation of estimated glomerular filtration rate (eGFR) was based on serum creatinine and cystatin C (eGFRcr-cys) using the CKD–EPI equation. Serum cystatin C well correlated with serum creatinine in PHPT patients ($r=0.594$, $P=0.0001$), while mean cystatin C level was significantly higher in PHPT patients than in healthy controls (0.93 ± 0.02 mg/l vs 0.78 ± 0.01 mg/l, $P=0.001$). In particular, among PHPT patients with eGFRcr >60 ml/min per 1.73 m^2, 18.4% had cystatin C levels >1.03 mg/l (95th percentile of controls' values), consistent with a 'preclinical kidney disease'. These patients had higher HOMA-IR values and were more hypertensive. In PHPT patients, cystatin C levels positively correlated with total and ionized calcium ($r=0.151$, $P=0.024$ and $r=0.259$, $P=0.004$) and with PTH ($r=0.176$, $P=0.01$). Using the eGFRcr-cys equation, CKD (stages G3a, 3b, and 4) was diagnosed in 13.7% of PHPT patients. CKD–PHPT patients had higher total and ionized calcium, were older, more frequently males, heavier, more insulin-resistant and more frequently affected with hypertension. Any significant correlation with the occurrence of kidney stones could be detected. Regression analysis identified hypertension and HOMA-IR values as the independent variables able to predict eGFRcr-cys in PHPT patients. Considering the occurrence of cardiovascular diseases (CVD) (coronaropathy, arithmopathy, and cerebral vasculopathy), after adjustment for age and sex, CVD was positively correlated with cystatin C levels (β 0.305 ± 0.109; $P=0.006$) and negatively with eGFRcr-cys values (β -0.005 ± 0.002; $P=0.011$). In conclusion, elevated cystatin C levels were cross-sectionally associated with key CVD risk factors and with CVD diseases in PHPT patients as in the general population.

Phenotype–genotype correlation in a series of 131 patients studied for calcium-sensing receptor gene

Claire Vahe[1], Marie-Francoise Odou[1], Rachel Desailloud[2], Clara Leroy[1], Catherine Bauters[1], Arnaud Scherpereel[1], Francois Pattou[1], Bruno Carnaille[1], Jean-Louis Wemeau[1] & Marie-Christine Vantyghem[1]
[1]CHRU Lille, Lille, Nord, France; [2]CHU Amiens, Amiens, Picardie, France.

Calcium-sensing receptor gene (CASR) loss-of-function mutations lead to familial hypocalciuric hypercalcaemia (FHH), neonatal severe hyperparathyroidism, and primary hyperparathyroidism. FFH is characterized by mild hypercalcaemia, hypocalciuria, calcium clearance/creatinine clearance (CaCl/CrCl) <0.01, normal or high PTH level. Nevertheless the phenotype may vary (Thakker 2012). The aim of this work was to compare the phenotypes of patients bearing or not a pathogenic *CASR*-mutation. Patients included ($n=131$; 96 females, median (IQR) age 63 (40–77)) referred either for a calcium disorder not explained by sporadic hyperparathyroidism ($n=118$) or pulmonary hypertension ($n=13$ controls), were sequenced for *CASR* gene after written informed consent. Patients taking diuretics, diphosphonates, lithium, with kidney failure, CaSR-antibodies or gain-of-function *CASR*-mutations had been excluded. Gender, age, nephrolithiasis, bone DEXA, blood calcium, phosphate, creatinine, 25-hydroxyvitamin D and PTH levels, 24-H calciuria, and CaCl/CrCl were compared according to the level of calcaemia <100, 100–105, or >105 mg/l and the presence of a pathogenic *CASR* mutation. The *CASR*-mutated group ($n=21$) showed higher calcaemia (108 (105–116) mg/l vs 105 (98–111) mg/l) and lower PTH (50 (32–91) pg/ml vs 83 (52–107) pg/ml) than the non-mutated group ($n=110$), with no difference for other parameters, especially 25-hydroxyvitamin D (27 (21–35) ng/ml vs 23 (15–33) ng/ml, calciuria (120 (45–183) mg/24 h vs 123 (65–188) mg/24 h), and CaCl/CrCl (0.01 (0.00–0.02) vs 0.01 (0.01–0.02)). The non-mutated group included 51 normal CASR, 50 heterozygous, and nine homozygous or composite heterozygous variants. The comparison of these three sub-groups with the *CASR*-mutated group also differed for calcaemia and PTH ($P=0.01$). *CASR*-mutations and CASR-variants were identified respectively in none and 15 (53%) of the 28 patients with calcaemia <100 mg/l, 4 (14%) and 14 (50%) of the 28 patients with calcaemia between 100 and 105 mg/l, and 17 (22%) and 30 (40%) of the 75 patients with calcaemia >105 mg/l. Seven/13 (53%) patients tested without any calcium disorder bore CASR-variants.
Conclusion
50% of patients with calcaemia <105 mg/l showed a CASR-variant, whereas 40% with calcaemia >105 mg/l showed a *CASR*-mutation, with lower PTH levels, but no difference in terms of calciuria or (CaCl/CrCl) despite similar vitamin D status. Calcemia/PTH ratio could be a better marker of pathogenic *CASR*-mutation than (CaCl/CrCl) <0.01.

Hypocalcaemia development in patients operated for primary hyperparathyroidism: can it be predicted preoperatively?

Cafer Kaya[1], Abbas Ali Tam[1], Ahmet Dirikoç[1], Aylin Kılıçyazgan[2], Mehmet Kılıç[3], Şeyda Türkölmez[4], Reyhan Ersoy[5] & Bekir Çakır[5]
[1]Department of Endocrinology and Metabolism, Ataturk Training and Research Hospital, Ankara, Turkey; [2]Department of Pathology, Yildirim Beyazit University, Ankara, Turkey; [3]Department of General Surgery, Yildirim Beyazit University, Ankara, Turkey; [4]Department of Nuclear Medicine, Ataturk Training and Research Hospital, Ankara, Turkey; [5]Department of Endocrinology and Metabolism, Yildirim Beyazit University, Ankara, Turkey.

Introduction
Primary hyperparathyroidism (PHP) is a highly prevalent disease, which is treated most effectively by surgery. Postoperative hypocalcaemia, a morbidity of surgical treatment of parathyroidism, can prolong the hospital stay. The aim of this study was to identify the factors predictive of hypocalcaemia and hungry bone syndrome (HBS) in patients who undergo parathyroidectomy due to PHP.
Materials and methods
Preoperatively and on days 1 and 4, and month 6 postoperatively, the patients' laboratory data including parathyroid hormone (PTH), calcium, phosphorus, 25-hydroxyvitamin D3 (25-OHD), albumin, magnesium, alkaline phosphatase (ALP), blood urea nitrogen (BUN), and TSH, free T_3 and free T_4 levels; and neck ultrasonography (US) and bone densitometry findings were recorded.
Results
Hypocalcaemia was observed in 63 (38.4%) of 164 patients on day 1 following parathyroidectomy. On the postoperative 6th month, permanent hypocalcaemia was present in 10 (6.1%) patients. HBS was observed in 22 (13.4%) of the patients who underwent parathyroidectomy due to PHP. Among the PHP-related parathyroidectomy patients, postoperative hypocalcaemia was observed more frequently among patients with parathyroid hyperplasia and those with osteoporosis. On the other hand, PTH, ALP, and BUN values were higher among patients who developed HBS. Additionally, HBS was observed more frequently among osteoporosis and parathyroid hyperplasia patients and those who had thyroidectomy simultaneously with parathyroidectomy.
Conclusion
As a result, a more thorough preoperative follow-up is recommended for patients with risk factors for hypocalcaemia and HBS development.

The evaluation of central corneal and retinal thickness and intraocular pressure in patients with primary hyperparathyroidism

Husniye Baser[1], Fatma Neslihan Cuhaci[2], Oya Topaloglu[2], Fatma Yulek[3], Nagihan Ugurlu[3], Reyhan Ersoy[2], Nurullah Cagil[3] & Bekir Cakir[2]
[1]Department of Endocrinology and Metabolism, Ataturk Education and Research Hospital, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Faculty of Medicine, Yildirim Beyazit University, Ankara, Turkey; [3]Department of Ophthalmology, Ataturk Education and Research Hospital, Ankara, Turkey.

Introduction
Ocular changes are common in various endocrine disorders. However, there are only few studies reporting ocular changes in patients with primary hyperparathyroidism (PHPT). Here, we examined central corneal thickness (CCT) and retinal thickness (RT), intraocular pressure (IOP) and their relationships with serum intact parathyroid hormone (iPTH), calcium (Ca), and phosphorus levels in PHPT patients.
Methods
Thirty-seven patients with PHPT were included and compared with age- and sex-matched 43 controls. CCT, RT, and IOP were measured.
Results
There was no statistically significant difference in mean right and left RT between two groups ($P=0.730$ and $P=0.530$ respectively). Right CCT and IOP were significantly higher than controls ($P=0.024$ and $P=0.038$ respectively). However, no significant difference was found between groups concerning left CCT and IOP ($P=0.415$ and $P=0.070$ respectively). A negative correlation was observed between right CCT, and serum phosphorus and 24-h urine phosphorus levels ($r=-0.391$, $P=0.017$ and $r=-0.393$, $P=0.021$ respectively). Additionally, right IOP was negatively correlated with 24-h urine calcium levels ($r=-0.331$, $P=0.049$). Left CCT was negatively correlated with 24-h urine phosphorus levels ($r=-0.348$, $P=0.044$). Furthermore, negative correlation was found between left IOP and 24-h urine calcium levels ($r=-0.396$, $P=0.017$). No significant correlation was found between iPTH levels and right CCT, right RT, right IOP, left CCT, left RT, and left IOP levels ($P>0.05$ for all parameters). Also, serum Ca levels were not significantly correlated with right CCT, right RT, right IOP, left CCT, left RT, and left IOP levels ($P>0.05$ for all parameters).
Conclusion
In the literature, data about ocular diseases and PHPT are rare. In this study, we observed right CCT and IOP values of patients with PHPT were significantly higher than controls. We consider that the identification of ocular aspects of PHPT is significant, and further studies related to the condition are required.

Secondary hyperparathyroidism in HIV patients and its relation to cardiovascular risk factors

Manuel Cayón Blanco, Carolina García-Figueras Mateos, Rosa Marquez Pardo, Patricia Bancalero Herrera, Alberto Terrón Pernía & Salvador Pérez Cortés
Hospital SAS Jerez de la Frontera, Jerez de la Frontera, Andalusia, Spain.

Rationale
Low level of vitamin D can results in secondary hyperparathyroidism (SH) that has been linked to increased cardiovascular risk in general population. However, the spectrum of cardiovascular risk associated with SH in HIV-infected adults remains uncertain. Our main aim was to determine its potential association with different markers of cardiovascular risk in HIV-infected adults.
Methods
Cross-sectional study. Clinical data related to obesity, blood pressure, glucose metabolism, lipid profile, toxics use, and renal function were recorded. Hypovitaminosis D was defined by 25-hydroxy vitamin D level <30 ng/ml. SH was defined by parathyroid hormone >65 pg/ml in presence of hypovitaminosis D. Patients were divided into three groups according to status of vitamin D and the presence of SH: A) SH and hypovitaminosis D; B) hypovitaminosis D without SH, and C) vitamin D sufficient.
Results
104 HIV patients were included. Median vitamin D was 30.6 ± 13.6 ng/ml. Prevalence of hypovitaminosis D and SH were 53.8 and 13.5% respectively. Quantitatively, all parameters related to cardiovascular risk, except fasting glycaemia, were higher among patients of group A, but only levels of total cholesterol, LDL, and triglycerides reached significant difference ($P=0.002$; 0.004; and 0.01 respectively). Also, prevalence of obesity (BMI ≥30 kg/m^2) was higher in patients that developed SH (group A) when compared to groups B and C (28.6% vs 19% vs 2%, respectively; $P=0.004$). In multivariate analysis, SH was not associated with any cardiovascular risk factor.
Conclusions
Though, HIV-infected patients with SH due to hypovitaminosis D have worse cardiovascular risk profile, we can not conclude that SH is independently associated with major risk factors. Nevertheless, we think these patients require a tighter monitoring of lipid profile, blood pressure, and renal function. Further studies will be useful to clarify the role of SH in determining unfavourable cardiovascular outcomes in HIV population.

Determination of reference values for serum total 1,25-dihydroxyvitamin D_3 using an extensively validated 2D ID-UPLC–MS/MS method

Niek Dirks[1], Frans Martens[1], Dirk Vanderschueren[3], Jaak Billen[3], Mariette Ackermans[2], Erik Endert[2], Marinus Blankenstein[1] & Annemieke Heijboer[1]
[1]VU University Medical Center, Amsterdam, The Netherlands; [2]Academic Medical Center, Amsterdam, The Netherlands; [3]KU Leuven, Leuven, Belgium.

1,25-dihydroxyvitamin D_3, the hormonally active metabolite of vitamin D_3, tightly controls calcium blood levels. An increase of 1,25-dihydroxyvitamin D_3 leads to an increase in calcium concentration with calcium originating from various resources, including bone tissue. To assess a patient's vitamin D status the precursor metabolite 25-hydroxyvitamin D_3 is determined. However, measurement of 1,25-dihydroxyvitamin D is required when disorders of 1α-hydroxylation, extrarenal 1α-hydroxylation, or vitamin D receptor defects are suspected. The aim of this study was to determine reference values for 1,25-dihydroxyvitamin D_3 using a 2D ID-UPLC–MS/MS method.
The 2D ID-UPLC–MS/MS method (Xevo TQ-S tandem quadrupole mass spectrometer and an Acquity UPLC system (Waters)), able to measure picomolar concentrations of 1,25-dihydroxyvitamin D_3 in human serum, was extensively validated with regard to sensitivity, specificity, and robustness. Intra-assay variation was $<5\%$ and inter-assay variation was $<7.5\%$ over the whole dynamic range. Limit of quantitation was 3.4 pmol/l. Our method correlated well with a published 1,25-dihydroxyvitamin D_3 LC–MS/MS method (Vanderschueren *et al*. *J Clin Endocrinol Metab* 2013) ($r=0.98$) and with the average 1,25-dihydroxyvitamin D results of the vitamin D External Quality Assessment Scheme (DEQAS) determined with LC–MS/MS ($r=0.93$).
Reference values determined in 96 plasma samples of healthy volunteers (46 women and 50 men, aged 20–70 years) were 59–159 pmol/l (non-parametric 95% CI). The female part of the reference group showed a statistically significant decrease of 1,25-dihydroxyvitamin D_3 concentration with age. The presence of significantly higher average 1,25-dihydroxyvitamin D_3 levels in premenopausal women taking oral anticonceptive pills compared to postmenopausal women suggests that this effect is estrogen-related.
In conclusion, we described a 2D ID-UPLC–MS/MS method able to measure 1,25-dihydroxyvitamin D with a high sensitivity and precision. In addition, references values for 1,25-dihydroxyvitamin D were established using this method.

Relationship between serum 25-hydroxivitamin D3 and adipose tissue vitamin D receptor gene expression with obesity and type 2 diabetes

Araceli Muñoz-Garach[1], Mercedes Clemente-Postigo[2], Diego Fernandez-García[1], Fernando Cardona-Diaz[2], Manuel Macias-Gonzalez[2] & Francisco Tinahones-Madueño[1,2]
[1]University Hospital Virgen de la Victoria, Málaga, Spain; [2]Laboratorio de Investigación Biomédica, Fundación IMABIS, Málaga, Spain.

Introduction
25-hydroxyvitamin D (25(OH)D3) deficiency has been associated with diabetes and obesity. However, the mechanisms underlying these relationships are not completely understood. Vitamin D receptor (VDR) is expressed in adipose tissue; it has been reported a higher expression in obese patients than in lean subjects, suggesting a differential vitamin D dynamics in adipose tissue according to the obesity degree. In addition, 1, 25-dihydroxyvitamin D3 (1,25(OH)2D3) is able to modify VDR gene expression in mice 3T3-L1 preadipocytes.
Objective
To analyse plasma 25(OH)D3 and VDR gene expression in adipose tissue according to BMI and glycemic status. To evaluate the influence of 1,25(OH)2D3 and VDR gene expression in human adipose tissue cultures.
Materials and methods
We recruited and classified 119 subjects according to their BMI (lean, overweight, obese, and morbidly obese subjects) and to their glycemic status: normoglycemic (NG) and prediabetic/diabetic (P/D) patients. We measure plasma 25(OH)D3 and parathyroid hormone (PTH) levels as well as VDR gene expression in visceral adipose tissue. Adipose tissue from morbidly obese (ATMO) and lean (ATL) donors were cultured and treated with a range of 1,25(OH)2D3 concentrations.
Results
Plasma 25(OH)D3 were lower in P/D patients compared to NG subjects in the four BMI groups ($P<0.05$). Plasma 25(OH)D3 levels correlated negatively with HOMA-IR ($P<0.01$) and glucose ($P<0.05$). No differences were found in plasma 25(OH)D3 levels according to the BMI. There was a higher VDR gene expression levels in morbidly obese patients ($P<0.05$) compared to groups with lower BMI. 1,25(OH)2D3 increased VDR gene expression in ATMO, but not in ATL ($P<0.05$).
Conclusion
Plasma 25(OH)D3 are diminished in P/D patients compared to NG subjects independently of BMI and are closely related with glucose metabolism variables, suggesting that vitamin D deficiency is associated more with carbohydrate metabolism than with obesity. Adipose tissue VDR gene expression was significantly higher in morbidly obese patients than in the other BMI groups and its regulation by 1,25(OH)2D3 was only demostrated in morbidly obese subjects.

Tainted vitamin D responses under methyl donor deficiency of the pre-osteoblast cells are caused by a decreased VDR expression and a disruption of PGC-1a: VDR co-regulators complex

Eva Feigerlova[1,3], Essi Ewu[3], Shyuefang Battaglia[2,3], Brigitte Leininger[3], Georges Weryha[2] & Jean-Louis Gueant[2,3]
[1]Centre Hospitalier Universitaire, Poitiers, France; [2]Centre Hospitalier Universitaire, Nancy, France; [3]INSERM U954, Université de Lorraine, Nancy, France.

Folate and cobalamin are methyl donors (MD) needed for synthesis of methionine, precursor of *S*-adenosylmethionine (SAM), the substrate of methylation in epigenetic, and epigenomic pathways. The MD deficiency (MDD) leads to a decrease in SAM/SAH ratio and hyperhomocysteinemia, which has been related to osteoporosis in humans and disruption of development of epiphyseal cartilage in rat. However, the underlying molecular mechanisms remain elusive.
Method
We studied the consequences of MDD on proliferation and differentiation of MG-63 pre-osteoblasts.
Results
$1,25(OH)_2D_3$ and vehicle treated MDD cells displayed a significantly decreased nuclear expression of PGC-1α/VDR complex comparing to controls. The impaired activation of PGC-1α in deficient cells resulted from its decreased methylation related to the blunted methyl-transferase activity, and increased cellular concentration of SAH, a potent inhibitor of PRMT1. Hypomethylation of PGC-1α dramatically affected expression of differentiation markers in deficient cells with a strong increase in PPARγ and its targets (adiponectin and ERRα), and a significantly decreased expression and activity of bALP. The MDD induced a marked increase in expression of the HSP90. Although primarily cytoplasmic, HSP90 has been shown to translocate to nucleus and play a role in regulation of NR activity. In this study, strong HSP90-VDR interactions in the MDD cells make VDR less likely to bind to the PGC-1α. We suppose that the HSP90-VDR impaired formation of the VDR/NR heterodimer, with an increased expression of PPARγ targets (adiponectin and ERRα) leading to an adipogenic phenotype. Treatment with SAM rescued effects of $1,25(OH)_2D_3$ on VDR/NR normalizing expression of PPARλ, ERRα, adiponectin. Addition of AdoX, an inhibitor of methyltransferase activity, produced similar changes as MDD.
In conclusion, this is the first evidence demonstrating existence of functional interactions between PGC-1α and VDR, its key role for normal functioning of the VDR-NR transcriptional co-regulation during osteoblast differentiation, and a dramatic effect of MDD on this co-regulatory network.

Associations of visceral and hepatic fat with serum 25-hydroxyvitamin D concentrations

Renate de Jongh[1], Renée de Mutsert[2], Paul Lips[1], Frits Rosendaal[2] & Martin den Heijer[1,2]
[1]Department of Internal Medicine, VU Medical Center, Amsterdam, The Netherlands; [2]Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, The Netherlands.

Introduction
Obesity is associated with lower serum 25-hydroxyvitamin D (25(OH)D) concentrations. A major explanatory hypothesis is that vitamin D is sequestered

by adipose tissue. Another hypothesis is a decreased hepatic activation by 25-hydroxylase in obese individuals. Because adipose tissue has different characteristics and functions in different parts of the body an important question is whether serum 25(OH)D is more strongly related to visceral (VAT), hepatic, or total body fat (TBF).
Methods
In the Netherlands Epidemiology of Obesity (NEO) study, a cohort of 6671 men and women, VAT was assessed by MRI in combination with ^{1}H-MR spectroscopy of hepatic triglyceride content (HTGC) in 2076 participants. TBF was determined with bioelectrical impedance analysis and serum 25(OH)D was measured. We performed linear regression of VAT and HTGC on serum 25(OH)D, adjusted for age, sex, ethnicity, smoking, education, alcohol consumption, and TBF.
Results
After exclusion of alcohol abuse ($n=117$) and missing data ($n=24$), 1935 participants were analysed (mean and S.D. of age: 55 (6) years, BMI: 26 (4) kg/m^2, VAT: 87 (54) cm^2, HTGC: 5.6 (7.7), serum 25(OH)D: 62.7 (26.7) nmol/l, 56% women). Per S.D. of VAT serum 25(OH)D was 5.3 nmol/l (95% CI −7.5, −3.2) lower, and per S.D. HTGC 3.3 nmol/l (−3.6, −0.4) lower. Per S.D. of total body fat serum 25(OH)D was 5.7 nmol/l (−8.1, −3.2) lower. In a joint model including VAT, HTGC, and TBF, only VAT remained negatively associated with serum 25(OH)D (−4.9 nmol/l; −7.1, −2.7 per S.D.).
Conclusion
The major finding of the present study is that although all markers of total and regional adiposity were associated with lower serum 25(OH)D, joint models showed that visceral adipose tissue was most strongly related to lower serum 25(OH)D concentrations.

Physical performance in women with vitamin D deficiency

Cristina Capatina[1,2], Mara Carsote[1,2], Mihai Berteanu[3,4] & Catalina Poiana[1,2]
[1]Department of Endocrinology, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; [3]Department of Physical Medicine and Rehabilitation, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [4]Department of Physical Medicine and Rehabilitation, Elias Emergency Hospital, Bucharest, Romania.

Introduction
VD deficiency is associated with the atrophy of muscle fibres (predominantly type II). This leads to decreased muscle force and general physical performance.
Objective
To analyse the relationship between the serum concentration of 25-hydroxy vitamin D (25OHD), balance and physical performance in women with VD deficiency and the effect of VD supplementation or treatment with a VD analog.
Materials and methods
We analysed 105 women of various ages with VD deficiency defined as a serum concentration of 25OHD below 30 ng/ml. We recorded the results of the balance Tinetti scale, chair-rise test (CRT) and timed-up-and go test (TUG). We randomised the patients to receive colecalcipherol 1000 IU daily or alphacalcidol 1 μg daily, together with 500 mg calcium. The treatment was administered for 6 months.
Results
The subjects were aged between 20 and 83 years old (mean ± S.D. 51.95 ± 12.77 years). The mean baseline 25OHD concentration was 12.68 ± 5.77 ng/ml (mean ± S.D.). The Tinetti balance subscore was significantly correlated with the concentration of 25OHD ($P=0.022$). The mean results at the TUG and CRT test were 8.91 ± 2.46 and 15.34 ± 5.58 s respectively. After treatment, the mean results at TUG and CRT test became 8.5 ± 2.17 and 14.56 ± 5.56 s respectively ($P=0.000$ compared to baseline) representing a mean change of −4.9 and −7.33% respectively. The global Tinetti score and the subscores for balance and posture also improved significantly compared to baseline ($P=0.000$ for total score and balance subscore and $P=0.033$ for posture). The results were significantly better in the subgroup treated with alphacalcidol compared to the subgroup offered cholecalciferol for TUG ($P=0.012$) but not for CRT ($P=0.074$) . No difference was noted in the evolution of the Tinetti score between the treatment subgroups.
Conclusions
The major finding of the present study is that VD deficiency is significantly correlated with poor physical performance and impairment of balance and the effects are partially reversible with either VD supplementation or active VD analogs (alphacalcidol).

Comparison of umbilical cord ghrelin concentrations in full-term pregnant women with or without gestational diabetes

Murat Karakulak[1], Muzaffer Temur[2], Özgür Yilmaz[2], Ugur Saygili[3], Elif Pelin Özün Özbay[4], Mehmet Calan[5] & Hese Cosar[6]
[1]Department of Obstetrics and Gynecology, Silivri State Hospital, Istanbul, Turkey; [2]Department of Obstetrics and Gynecology, Manisa Merkezefendi Hospital, Manisa, Turkey; [3]Department of Obstetrics and Gynecology, Dokuzeylul University Medical School, Izmir, Turkey; [4]Department of Obstetrics and Gynecology, Aydin Obstetrics and Pediatrics Hospital, Aydin, Turkey; [5]Department of Endocrinology, Bozyaka Research Hospital, Izmir, Turkey; [6]Division of Neonatology, Department of Pediatrics, Manisa Merkezefendi Hospital, Manisa, Turkey.

Purpose
The purpose of this study was to analyse ghrelin concentrations in the umbilical cord of pregnant women with a diagnosis of gestational diabetes mellitus. The relationship between ghrelin concentrations and birth weights was investigated.
Methods
Sixty pregnant women with gestational diabetes mellitus and 64 healthy pregnant women with three oral glucose tolerance test results within normal limits were included in the study. Following birth but before extraction of the placenta, 10-ml blood samples were drawn from the umbilical vein in both groups. Ghrelin concentrations were measured.
Results
The mean birth weights of the babies born to mothers with GDM were higher than those in the control group ($P=0.04$). The cord blood ghrelin levels in pregnant women with GDM were significantly lower than those of the healthy women in the control group (879.6 pg/ml vs 972.2 pg/ml; $P=0.03$). The umbilical cord blood ghrelin concentrations in pregnant women with GDM undergoing insulin therapy were significantly lower than those of the control group (792.61 pg/dl vs 972.2 pg/dl; $P=0.01$). Inverse correlations were detected between umbilical cord blood ghrelin levels and birth weights of the babies both in the group with GDM patients (r: −0.785; $P=0.001$) and in the control group (r: −0.749; $P=0.001$).
Conclusions
In pregnant women with GDM, umbilical cord ghrelin concentrations are closely related to the birth weights of the babies. Ghrelin presumably may be among the factors influencing foetal development potentially with its GH stimulating effects or by means of other mechanisms.

EATM regulates the NADPH-oxidases of erythrocyte membranes and serum of patients with types 1 and 2 diabetes *ex vivo*

Yelena Aghajanova & Maria Badalyan
Yerevan State Medical University, Yerevan, Armenia.

Introduction
Embryonal antitumour modulator of Mkrtchyan (EATM) reveals a hypoglycemic effect in streptozotocin-induced diabetes in rats. The aim of the work was to determine the influence of EATM on the process of releasing of Nox of erythrocyte membranes (EM) and serum of patients with diabetes type 1 and 2.
Materials and methods
The study included 12 patients with type 1 diabetes, 12 patients with type 2 diabetes and 12 healthy volunteers. Isolation of Nox fractions of purified EM and blood serum was performed by ion-exchange chromatography. The Nox amount was determined at 530 nm. O_2^--producing activity of Nox isoforms was determined by nitrotetrazolium blue. The statistical analysis was performed by one-way ANOVA. The study was approved by the Local Ethics Committee of the YSMU.
Results
It was shown, that the Nox release in EM of type 2 and 1 diabetes is higher by 83.3 ± 7.4% and 58.4 ± 6.5%, respectively, compared with donor blood. The addition of EATM resulted in suppression of the process of the Nox release in EM in diabetes type 2 and 1 and healthy donors by 45.5 ± 6.2%, 31.6 ± 4.4% and 25.1 ± 3.7%, respectively. In the same conditions the increase of releasing of the extracellular Nox from the blood serum in diabetes type 2 and 1 is up by 109.2 ± 8.7% and 45.4 ± 5.5% respectively. Addition of EATM reduced activity of eNox by 47.9 ± 4.4%, 31.3 ± 2.9% and 29.3 ± 3.2%, respectively.
Conclusion
The suppression of the releasing Nox and eNox of EM and serum exosomes in diabetes type 1 and 2 may be apparently a novel mechanism of membrane

stabilising effect of the EATM *ex vivo*. This gives some scientific term for EATM as an agent, which helps to stabilise the EM and exosomes in diabetes type 1 and especially type 2 *in vivo*.

Can physical activity modify the impact of the genes on the incidence of type 2 diabetes mellitus?

Lukasz Szczerbinski[1], Witold Bauer[2], Joanna Goscik[3], Natalia Wawrusiewicz-Kurylonek[1], Magdalena Paczkowska[2], Magdalena Niemira[2], Anna Citko[2], Michal Ciborowski[2], Katarzyna Maliszewska[1], Edyta Adamska[2], Adam Kretowski[1,2] & Maria Gorska[1]
[1]Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland; [2]Clinical Research Centre, Medical University of Bialystok, Bialystok, Poland; [3]Centre for Experimental Medicine, Medical University of Bialystok, Bialystok, Poland.

The exact mechanism of the development of T2DM is still unclear, however, it is known that important role is played by both environmental and genetic factors. In this study we focused on describing the interactions between environmental and genetic factors and answering the question whether physical activity can modify the impact of the genes on the incidence of T2DM. We recruited 921 subjects (median age: 38 years; 49.7% man; mean BMI: 28.1) from the cohort 1000 Polish Longitudinal University Study (PLUS). PA has been assessed using International Physical Activity Questionnaire, and 37 single nucleotide polymorphisms (SNPs) associated with T2DM in GWAS have been genotyped, to explore interaction between the SNPs and the level of PA on the incidence of T2DM. Genetic risk score (GRS) as a weighted sum of risk alleles have been calculated. We also calculated the percentage of T2DM cases within each of the four strata given by high and low GRS and PA using R software. To explore GRS and PA interactions, we examined associations of PA with T2DM in each group. The incidence of T2DM was lower among physically active individuals in high GRS group (8.6% in high PA class vs. 13.8% in low PA class, $P < 0.03$) as well as in low GRS group (4.4% in high PA class vs 8.7% in low PA class, $P < 0.03$). We also found that individuals with TT variant in rs10885122 (ADRA2A) has slightly lower values of average PA compared to those with TG and GG genotypes ($P < 0.006$). In our study we proved that the genetic predisposition to T2DM can be reduced by increasing the PA, even among patients at high genetic risk. This allows to conclude that, through the use of physical activity we can reduce the incidence of T2DM, even in patients with a genetic predisposition.

Efficacy of autologous bone marrow derived mesenchymal stem cell transplantation in T2DM: a randomised placebo-controlled study

Shobhit Bhansali, Vinod Kumar, Vivekanand Jha, Neelam Marwah, N Khandelwal, Anil Bhansali & Pinaki Dutta
PGIMER, Chandigarh, India.

Introduction
There is a growing interest in cell-based therapies in T2DM as β-cell failure is progressive and inexorable. This study evaluates the efficacy of autologous bone marrow-derived mesenchymal stem cell transplantation (ABM-MSCT) in T2DM.
Methods
This prospective, randomised, single-blinded placebo-controlled study enrolled 20 patients with triple oral hypoglycaemic drug failure and requiring insulin $\geq$0.4 Units/kg per day for achieving euglycaemia (HbA1c $\leq$7.5%). They were randomly assigned to mesenchymal stem cells (MSCs) group ($n=10$) who received ABM-MSCT through targeted approach, while control arm ($n=10$) underwent sham procedure and were followed for 6 months. The efficacy of intervention was assessed by gold standard method 'hyperglycaemic clamp' to estimate C-peptide response. The primary endpoint was a reduction in insulin requirement by 50% from baseline, while maintaining HbA1c $\leq$7%.
Results
Six out of the 10 (60%) patients in the ABM-MSCT, while 1 (10%) in the control group achieved the primary endpoint ($P=0.05$). The insulin requirement decreased by 45% in the ABM-MSCT group from 45.5 (34.0–52.2) IU/day to 25 (15.0–32.5) IU/day ($P=0.0001$), while in controls it decreased by 4% from 52.0 (40.0–82.0) IU/day to 50 (22.0–58.0) IU/day ($P=0.001$) with significant reduction between both the groups at 6 months ($P=0.047$). There was a modest but significant decrease in HbA1c in cases from 6.9% (6.6–7.0%) to 6.8% (6.1–7.2%) ($P=0.001$) as well as in controls from 6.6% (6.1–6.8%) to 6.2% (6.0–6.2%) ($P=0.001$), but it was not significant between the groups ($P=0.32$). There was a significant decrease in 2nd phase C- peptide response during hyperglycaemic clamp ($P=0.004$) and HOMA-β (0.04) without any significant change in HOMA-IR ($P=0.08$).
Conclusion
The ABM-MSCT results in decrease in insulin requirement while maintaining HbA1c $\leq$7%. However, the mechanism/s related to improvement in glycaemia remains elusive.

Telomere biology and vascular ageing in patients with T2DM

Nataliia Brailova[1], Ekaterina Dudinskaya[1], Irina Strazhesko[1], Dariga Akasheva[1], Marina Pokrovskaya[1], Olga Tkacheva[1], Sergei Boytsov[1], Marina Shestakova[2] & Vladimir Vigodin[1]
[1]National Research Centre for Preventive Medicine, Moscow, Russia; [2]National Research Centre for Endocrinology, Moscow, Russia.

It is known that glucose disturbances contribute to vascular ageing. The length of telomere (TL) and telomerase activity (TA) are considered as biomarkers of cellular ageing. It is crucial to determine the role of telomere biology in different vessels changes in diabetic patients. The aim of our study was to determine the role of telomere biology in vascular ageing in patients with T2DM.
Methods
The study group included 50 patients with T2DM in mean age 58.4±7.83 years. All subjects were measured for TL and TA by quantitative polymerase chain reaction (PCR), fasting plasma glucose (FPG), glycated HbA1c; oxidative stress marked by malondialdehyde (MDA); inflammation marked by IL-6, C-reactive protein (CRP); arterial stiffness (AS) evaluated by carotid-femoral pulse wave velocity (PWV); carotid intima-media thickness (IMT), plaque presence (PP) and endothelial dysfunction evaluated by flow-mediated endothelium-dependent vasodilation (FMV) and endothelium-independent vasodilation (NDV).
Results
All patients were divided into two groups by the median of TL (9.75): «short» telomeres and «long» telomeres. Vessels changes were more pronounced in patients with «short» TL: PWV 14.11±3.22 m/s vs 11.78±3.26 m/s ($P=0.016$), IMT 1.00±0.15 mm vs 0.84±0.16 mm ($P=0.0010$), PP 2.63±0.31 vs 1.36±0.26 ($P=0.0032$), FMV 7.93±3.40 vs 10.95±3.10 ($P=0.0022$), NDV 12.63±4.25 vs 15.68±4.51 ($P=0.0186$). TA was similar in the two groups. We found increasing of oxidative stress and chronic inflammation in diabetic patients with «short» TL: MDA 3.43±1.06 mkmol/l vs 2.94±0.87 mkmol/l ($P=0.058$); CRP 9.43±2.01 mg/l vs 3.30±0.37 mg/l ($P=0.0062$). Correlation analysis showed significant association between TL and next parameters: PWV ($r=-0.50$, $P=0.0003$), IMT ($r=-0.39$, $P=0.0059$), FMV ($r=0.49$, $P=0.0003$), NDV ($r=0.41$, $P=0.0035$), FPG ($r=-0.42$, $P=0.0027$), CRP ($r=-0.40$, $P=0.0039$), TA ($r=-0.32$, $P=0.0353$).
Conclusion
In patients with T2DM and 'short' telomeres signs of vascular ageing, chronic inflammation and oxidative stress were more pronounced. Perhaps long telomeres protect vessels of patients with T2DM from accelerated vascular ageing.

Increased levels of Dickkopf-1 may indicate lower osteoblast signaling, predisposing to lower bone mineral density in children and adolescents with type 1 diabetes mellitus

Charalampos Tsentidis[1], Dimitrios Gourgiotis[2], Lydia Kossiva[1], Antonios Marmarinos[2], Artemis Doulgeraki[3] & Kyriaki Karavanaki[1]
[1]Diabetic Clinic, Second Pediatric Department University of Athens, Athens, Attica, Greece; [2]Biochemistry Laboratory, Second Pediatric Department University of Athens, Athens, Attica, Greece; [3]Department of Bone and Mineral Metabolism, Institute of Child Health, 'Aghia Sophia' Children's Hospital, Athens, Attica, Greece.

Introduction
T1DM is a risk factor for reduced bone mass, disrupting several bone metabolic pathways. Dickkopf-1 is an inhibitor of the Wnt/b-catenin bone metabolic pathway. Increased fracture risk and elevated Dickkopf-1 levels have been documented in adult patients with T2DM. No relevant data exist on childhood T1DM. Our aim was to study plasma Dickkopf-1 concentration in children and adolescents with T1DM and controls and to correlate Dickkopf-1 levels with metabolic bone markers and bone mineral density (BMD).
Methods
Forty children and adolescents with T1DM were evaluated (mean ± S.D. age: 13.04 ± 3.53 years, T1DM duration: 5.15 ± 3.33 years), along with 40 healthy matched controls (mean ± S.D. age 12.99 ± 3.3 years). Dickkopf-1, Sclerostin, osteocalcin, C-telopeptide crosslinks-CTX, electrolytes, PTH, total 25(OH) D were measured, while lumbar spine and total body BMD were evaluated.
Results
BMD was significantly lower in T1DM patients than controls. Dickkopf-1 levels demonstrated a Gaussian distribution, with higher levels in T1DM patients (13.56 ± 5.34 vs 11.35 ± 3.76 pmol/l, $P = 0.0194$). A trend for lower values was found in girls (13.36 ± 4.04 vs 11.72 ± 5.14 pmol/l, $P = 0.06$) and in pubertal children (13.61 ± 4.87 vs 11.83 ± 4.56 pmol/l, $P = 0.054$). Dickkopf-1 correlated with Sclerostin and L1-L4 BMD z-score only in controls and with Osteoprotegerin and i-Phosphorus only in patients, while in both groups a significant correlation with log(CTX) and √ALP was documented. A significant correlation of Dickkopf-1 with IGF-1 and insulin dose was also shown in patients.
Conclusion
T1DM children and adolescents had higher levels of Dickkopf-1 than controls, indicating a downregulated Wnt signalling system and possible lower osteoblast activation that could be associated with T1DM osteopathy.

GLP-1 (Active 7-36) secretory response after test meal in obese patients before and 5; 90 and 180 days after bariatric gastric bypass surgery

Dragan Micic[1], Snezana Polovina[1], Mirjana Sumarac-Dumanovic[1], Pavle Gregoric[2], Goran Cvijovic[1], Svetlana Ignjatovic[1], Marjana Dajak[1], Dusan Micic[2], Danica Stamenkovic-Pejkovic[1] & Danka Jeremic[1]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Clinical Center of Serbia, Belgrade, Serbia; [2]Emergency Center, Clinical Center of Serbia, Belgrade, Serbia.

There are different explanations concerning observed improvement of glucose control after baiatric gatric bypass surgery. The aim of our study was to investigate GLP-1 response after test meal (Fresubin drink a 200 ml; 200 kcal, 15% protein, 30% fat and 55% carbohydrate) before (day 0) and 5; 90 and 180 days after gastric bypass surgery. Glycaemia (mmol/l; glucose oxidase) and GLP-1 (Active 7-36) (pM/l; ELISA, ALPCO diagnostics) were determined in 41 obese patients (age: 37.86 ± 11.21 years; BMI: 43.45 ± 4.91 kg/m^2) in four separate days in 0, 15, 30, 45, 60, 90 and 120 min. There were significant decrease in the area under the glucose curve (X ± S.D.) (664.70 ± 186.81 vs 636.45 ± 177.35 vs 501.50 ± 90.17 vs 507.41 ± 80.08 mmol/l per min; $P < 0.05$) in respective day intervals, while there was significant increase in area under the GLP-1 curve (pmol/l per min) in days 5 (919.19 ± 653.73), day 90 (682.92 ± 489.79) and day 180 (789.41 ± 558.56) in comparison with day 0 (279.80 ± 429.97) ($P < 0.05$). There were no significant differences between basal glucose and GLP-1 levels (1.67 ± 2.64; 1.33 ± 2.12; 2.06 ± 2.75; $P > 0.05$) except for day 180 (3.52 ± 3.92 $P < 0.05$) while there was significant increase in peak GLP-1 levels in day 5 (17.12 ± 8.99), day 90 (14.44 ± 8.75) and day 180 (17.25 ± 10.52) during response after test meal in comparison with day 0 (3.82 ± 3.95) ($P < 0.05$). In conclusion, GLP-1 response after test meal is significantly increased after gastric bypass surgery early (after 5 days) and lately (after 90 and 180 days). The improvement in GLP-1 response after test meal after gastric bypass surgery may be contribute to the beneficial metabolic effects of bariatric surgery, especially concerning glucose control.

Investigating chemerin/CMKLR1 signalling as a novel link between obesity and inflammatory bowel disease

Helen J Dranse, Jillian L Rourke, Andrew W Stadnyk & Christopher J Sinal
Dalhousie University, Halifax, Nova Scotia, Canada.

Background
Chemerin is a recently identified adipocyte-secreted signalling molecule (adipokine) that regulates adipocyte differentiation, metabolism, and inflammation through activation of the cognate receptor Chemokine-Like Receptor 1 (CMKLR1). Circulating chemerin levels are increased in obese patients as well as in patients with inflammatory bowel disease (IBD) such as Crohn's disease and ulcerative colitis. Increased white adipose tissue mass (WAT) and resultant changes in the secretion of several adipokines have been shown to negatively impact the severity and treatment of IBD. Therefore, we hypothesized that chemerin/CMKLR1 signalling represents a novel link between obesity and IBD.
Objectives
To determine whether modulation of chemerin/CMKLR1 signalling impacts weight loss, clinical illness, and colonic inflammation associated with the onset of dextran sodium sulfate (DSS)-induced colitis in mice.
Results
Chemerin and CMKLR1 expression increased in the cecum and distal colon, while CMKLR1 expression decreased in WAT, of DSS-treated mice. Following DSS treatment, WT mice had significantly higher chemerin levels both in the colon and circulation. Moreover, injection of bioactive chemerin into WT mice resulted in greater weight loss and colon inflammation compared to vehicle control. Consistent with this, CMKLR1 knockout mice exhibited decreased early weight loss and a slower onset of clinical illness compared to WT controls. However, CMKLR1-null mice exhibited similar levels of colonic inflammation and clinical illness compared to WT littermates at the final endpoint.
Conclusions
Increased levels of circulating chemerin exacerbated the severity of DSS-induced colitis and CMKLR1-null mice had a delayed onset of colitis. This suggests that chemerin/CMKLR1 signalling modulates the development of IBD.

Screening for genetic and structural variation in the NPY2R gene in obese children and adolescents

Evi Aerts, Doreen Zegers[1], Laure Sorber[1], Sigri Beckers[1], An Verrijken[2], Guy Massa[3], Kim Van Hoorenbeeck[4], Stijn L Verhulst[4], Luc F Van Gaal[2] & Wim Van Hul[1]
[1]Department of Medical Genetics, University of Antwerp, Antwerp, Belgium; [2]Department of Endocrinology, Diabetology and Metabolic Diseases, Antwerp University Hospital, Antwerp, Belgium; [3]Department of Pediatrics, Jessa Hospital, Hasselt, Belgium; [4]Department of Pediatrics, Antwerp University Hospital, Antwerp, Belgium.

Objective
NPY2R is a G-protein-coupled receptor which is highly expressed in orexigenic NPY/AGRP neurons within the arcuate nucleus, a major integrator of appetite

control in the hypothalamus. Genetic evidence coming from animal and association studies, has identified NPY2R as a candidate gene for obesity. Therefore we have designed an extensive mutation and CNV-analysis investigating the prevalence of genetic and structural variation in NPY2R.
Design and methods
In the first part of this study we screened 306 obese children and adolescents and 300 healthy lean individuals for mutations in the *NPY2R* coding region with high-resolution melting curve analysis. Direct sequencing was performed for samples with melting patterns deviating from WT. In the second part of this study, Multiplex Amplicon Quantification (MAQ) analysis was performed in 308 obese children and adolescents to detect copy number variation (CNV) in *NPY2R*.
Results
Mutation analysis resulted in the identification of one rare non-synonymous heterozygous variant F87I in an obese patient. Furthermore, we identified five different synonymous variants of which three (L53L, G326G and G370G) could solely be detected among obese children and two (P105P and A278A) were only present in lean individuals. L53L was identified among three different obese patients and was not present in the control population. MAQ analysis could not identify copy number variation in the *NPY2R* region in our population.
Conclusion
By performing *in silico* analysis, we determined that the F87I variant is probably damaging to the protein structure and might have a disease causing effect. Further functional testing will be necessary to fully understand the impact on NPY2R. As we could not identify any CNV in the *NPY2R* region, structural variation in NPY2R is not likely to cause obesity.

Effects of dietary glycaemic properties on markers of inflammation, insulin resistance and body composition in postmenopausal women
Violeta Stojkovic[1,2], Christine Simpson[1], Rebecca Sullivan[1], Anna Maria Cusano[1], Karl Insogna[1] & Jessica Bihuniak[1,3]
[1]Yale University School of Medicine, New Haven, Connecticut, USA; [2]Université de Liège, Liège, Belgium; [3]University of Connecticut, Storrs, Connecticut, USA.

Whether high glycaemic index/glycaemic load (GI/GL) diets increase low-grade inflammation leading to changes in body composition and risk for chronic illness remains uncertain. We recently completed a randomised, double-blind study comparing the effects of a 45 g whey protein supplement (PRO) and an isocaloric maltodextrin supplement (CHO) on bone density and body composition in older adults. The study afforded an opportunity to evaluate the impact of a calibrated increase in GI/GL on markers of inflammation, insulin resistance and body composition. Eighty-four postmenopausal women who consumed a minimum of 20 g of either supplement (PRO, $n=38$; CHO, $n=46$) daily for 18 months were studied. GI/GL was estimated from 3-day food records at baseline and 18 months. At the end of 18 months the GL in the CHO group increased by 34%, 88.4 ± 5.2 to 118.5 ± 4.9 ($P<0.0001$ at 18 months) and did not change in the PRO group 86.49 ± 4.14 to 81.9 ± 3.6. Despite this, there were no differences in serum CRP, IL-6, or HOMA at 18 months between the two groups, nor when the individuals in the highest quartile ($n=21$) of GL at 18 months were compared to the lowest quartile ($n=20$). However, analysis of body composition showed a significant increase in truncal lean mass ($P=0.007$) and total lean mass ($P=0.038$) in the PRO group, compared to the CHO group. In contrast, the highest GL quartile had significantly higher BMI ($P=0.03$) and total fat mass ($P=0.005$) with a significant decline in the lean/fat ratio ($P=0.0008$). Our data suggest that as dietary GL increases within the moderate range, there is no detectable change in markers of inflammation or insulin resistance, despite which there is a negative effect on lean body mass.

Metabolic and gonadotropic impact of sequential obesogenic insults in the female: influence of the loss of ovarian secretion
Miguel A Sanchez-Garrido[1,3], Francisco Ruiz-Pino[1,2], Maria Manfredi-Lozano[1,2], Silvia Leon[1,2], Violeta Heras[1,2], Juan M Castellano[1,2], Maria Jesus Vazquez[1,3], Juan Roa[1,2], Antonio Romero-Ruiz[1,2], Carlos Dieguez[3,4], Leonor Pinilla[1,2] & Manuel Tena-Sempere[1,2]
[1]University of Cordoba, Cordoba, Spain; [2]Instituto Maimonides de Investigacion Biomedica de Cordoba (IMIBIC), Cordoba, Spain; [3]CIBERobn, Cordoba, Spain; [4]University of Santiago de Compostela, Santiago de Compostela, Spain.

While female fertility is known to be sensitive to conditions of low body fuel reserves, the reproductive consequences of persistent energy excess remain ill defined. Yet, the pandemic proportions of obesity, and its potential impact on the gonadotropic axis, call for a better understanding of this phenomenon. Alike, the influence of ovarian hormones on the pathophysiology of obesity and its complications merits further investigation. In this work, we aimed to elucidate the metabolic and reproductive/gonadotropic impact of various obesogenic insults in the female rat, with special attention to the influence of the loss of ovarian secretion, as model of menopause. To this end, we implemented a series of neuroendocrine studies on the metabolic and gonadotropic consequences of sequential obesogenic insults, namely, postnatal over-nutrition (SL) and high fat diet (HFD) after weaning, in gonadal-intact and ovariectomized (OVX) female rats. In young (4-mo) cyclic females, SL or HFD caused similar increases in body weight; yet, only HFD evoked additional metabolic perturbations, some of which were worsened by precedent SL. In addition, HFD caused a concomitant decrease in LH and estradiol levels, and suppressed *Kiss1* expression in the arcuate nucleus (ARC) of the hypothalamus in 4-mo females, while persistent HFD up to 10-mo induced also suppression of LH responses to kisspeptin-10. OVX caused a severe and rapid deterioration of the metabolic profile, with overweight, increased energy intake and deregulation of leptin and glucose/insulin levels; effects whose magnitude was similar, if not higher than HFD. Summation of previous obesogenic insults maximally increased body weight, basal leptin, insulin and glucose levels, and glucose intolerance. Yet, OVX obliterated the inhibitory effects of overweight/HFD on gonadotropin levels and ARC *Kiss1* expression, which were heightened due to the loss of negative feedback. In sum, our study characterizes the metabolic and gonadotropic effects of sequential exposures to obesogenic insults, and their interactions with ovarian secretions. Our data document the deleterious consequences of overweight on the female gonadotropic axis, via impairment of Kiss1 system, and substantiate the dramatic impact of OVX, as menopausal model, on the metabolic profile, especially when combined with preceding obesogenic insults.

The effects of cross-sex hormone therapy on body weight and fat percentage in transgender individuals
Maartje Klaver, Mariska Vlot, Marieke Dekker, Jos Megens & Martin den Heijer
VU Medical Center, Amsterdam, The Netherlands.

Introduction
Cross-sex hormone therapy is part of the treatment of individuals with gender dysphoria and affects several factors such as body composition and thereby cardiovascular risk. However, little is known about the specific effects on body weight and fat percentage in the first year of treatment.
Aim
The aim of this study is to examine the effects of cross-sex hormones on body weight and total fat percentage during the first year of treatment.
Methods
This prospective study (part of the ENIGI project) included 140 patients that completed one year of treatment. 70 male-to-female individuals (MtFs) received

cyproteronacetate (50 mg/day). Of them, 31 MtFs were treated with an estradiol patch (200 μg/week) and 39 MtFs received estradiol valerate (2–4 mg/day). 70 female-to-male individuals (FtMs) were treated, of which 39 FtMs got testosterone esters intramuscular (250 mg/2 weeks) and 4 FtMs received testosterone undecanoate intramuscular (1000 mg/12 weeks). 27 FtMs were treated with testosterone gel (50 mg/day). At the start and after 12 months of treatment their body weight was measured and a DEXA was obtained.
Results
At baseline the mean body weight of the MtFs was 77.5 kg (s.d. ± 16.8), which in one year increased to 79.7 kg (s.d. ± 17.0) with a mean difference of 2.2 kg (95% CI 0.7–3.8). Their mean total fat percentage increased with 4.0% (95% CI 3.0–5.0), from 25.0 to 29.0%. The mean body weight of the FtMs increased from 69.1 kg (s.d. ± 15.0) to 72.2 kg (s.d. ± 14.7) with a mean difference of 3.1 kg (95%CI 2.0-4.3). In FtMs, a 4.3% (95%CI −5.3 to −3.3) decrease in total fat percentage was seen, from 34.7 to 30.4%.
Conclusions
Despite an expected increase in fat percentage in MtFs and a decrease in FtMs, total body weight increased in both groups. Further research is needed to elucidate the mechanism of weight gain during cross-sex hormone treatment.

Effects of testosterone replacement therapy on lean body mass, total fat mass, and insulin sensitivity in aging men with type 2 diabetes - a randomised, double-blinded, placebo-controlled trial

Line Velling Magnussen[1], Dorte Glintborg[1], Pernille Hermann[1], David M Hougaard[2], Kurt Højlund[1] & Marianne S Andersen[1]
[1]Department of Endocrinology and Metabolism, Odense University Hospital, Odense, Denmark; [2]Department of Clinical Biochemistry and Immunology, Statens Serum Institute, Copenhagen, Denmark.

Lowered testosterone levels may be observed in up to 50% of ageing men with type 2 diabetes (T2D). Testosterone replacement therapy (TRT) increases lean body mass in men with lowered testosterone levels and T2D, but the effect of TRT on glucose metabolism has not been evaluated by euglycemic hyperinsulinemic clamp.
We used gold standard methods to evaluate the effect of TRT on body composition, insulin sensitivity, and oxidative metabolism in men with T2D and lowered bio-available testosterone. Our main objective was to determine whether TRT could be a novel treatment for T2D in ageing men with lowered bio-available testosterone.
Research design and methods
A randomised, double-blinded, placebo-controlled study in 39 men, aged 50–70 years with bio-available testosterone levels <7.3 nmol/l and T2D treated with Metformin. Patients were randomized to testosterone gel ($n=20$) or placebo ($n=19$) for 24 weeks. Body composition was assessed by whole body Dual-energy X-ray Absorptiometry scans including our primary outcome, lean body mass. Whole-body insulin sensitivity was assessed by rate of insulin-stimulated glucose disposal during euglycemic hyperinsulinemic clamp. Substrate oxidation was evaluated by indirect calorimetry during euglycaemic hyperinsulinaemic clamp. Coefficients (b) represent the placebo-controlled mean effect of intervention.
Results
Lean body mass ($b=1.9$ kg, $P=0.001$) increased during TRT, while total fat mass ($b=-1.3$ kg, $b=0.009$) and HDL cholesterol ($b=-0.11$ mmol/l, $P=0.009$) decreased. Insulin-stimulated glucose disposal rate was unchanged during TRT compared to placebo ($P=0.28$). Lipid and glucose oxidation during fasting and insulin stimulation were unchanged.
Conclusions
Insulin sensitivity was unchanged in men with T2D despite significant beneficial changes in lean body mass and total fat mass after 24 weeks TRT. Furthermore, HDL cholesterol levels were reduced during TRT. Our data do not suggest testosterone replacement therapy as a novel therapy for type 2 diabetes in ageing men.

GP.13.07

Three out of four adult male patients with type 2 diabetes mellitus and symptomatic moderate to severe erectile dysfunction have hypogonadism

Jubbin Jacob[1], Raman Kumar[2] & Nitin Malhotra[2]
[1]Endocrine and Diabetes Unit, Department of Medicine, Christian Medical College and Hospital, Ludhiana, Punjab, India; [2]Department of Medicine, Christian Medical College and Hospital, Ludhiana, Punjab, India.

Context
Studies suggest that 25–40% of men with type 2 diabetes mellitus (T2DM) have hypogonadism. Other studies have estimated that 40–50% of men with T2DM have erectile dysfunction (ED). Some guidelines suggest routine measurements of testosterone in all patients with T2DM.
Objectives
To estimate the prevalence of hypogonadism in adult male patients with type 2 diabetes mellitus and symptomatic erectile dysfunction.
Methods
Consecutive adult male patients (between 30 and 60 years) with ED and T2DM attending diabetic clinic in a tertiary hospital were recruited after informed consent. Patients with psychiatric illness, renal disease, liver disease, previous pelvic surgery and major neurological diseases were excluded. ED was graded using the International Index of Erectile Dysfunction (IIEF) questionnaire. Biochemical assessment of hypothalamic-pituitary-gonadal (HPG) axis was undertaken by collecting morning samples for serum luteinizing hormone, follicle stimulating hormone, prolactin and total testosterone. These were analyzed by electrochemiluminessense assays on an ELECSYS automated system. Patients were classified as either being eugonadal or having either hypogonadotropic hypogonadism (HH) or hypergonadotropic hypogonadism (HHG).
Results
patients consented for the study with a mean age of 50.3 years and mean duration of diabetes of 5.9 years. Of them 102 patients completed all the study related procedures and were included in the analysis. 54 (52.9%) of men with T2DM and ED were eugonadal, 38 (37.3%) had HH and 10 (9.8%) had HHG. All 25 patients with mild ED (IIEF scores 17–21) were eugonadal. While of 28 patients with mild to moderate ED (IIEF scores 12–16), 24 (85.7%) were eugonadal and 4 (14.3%) had HH. Of the 16 patients with moderate ED (IIEF scores 8–11) 4 (25%) were eugonadal, 9 (56.3%) had HH and 3 (18.8%) had HHG. Among the 33 patients with severe ED (IIEF score 1–7) only 1 (3%) was eugonadal, 25 (75.8%) had HH and 7 (21.2%) had HHG ($P<0.0001$).
Conclusions
Routine hormonal evaluations of the HPG axis is probably only required in patients with moderate to severe ED with type 2 diabetes. Over 75% of patients with moderate to severe ED have subnormal total testosterone levels.

Eating disorders are frequent among type 2 diabetic patients and are associated with worse metabolic and psychological outcomes: results from a cross sectional study in primary and secondary care settings

Aleksandra Speranskaya, Joana Nicolau, Luisa Ayala, Ivana Zubillaga, Pilar Sanchis, Concepcion Conchillo, Regina Fortuny & Lluis Masmiquel
Hospital Son Llatzer, Palma De Mallorca, Balearic Islands, Spain.

Objectives
Diabetes and obesity – Translational cardiovascular and obesityData regarding the prevalence of eating disorders (ED) and their influence on clinical outcomes among patients with type 2 diabetes (T2DM) are scarce. Our aim is to investigate the frequency of positive screening for ED and, specifically binge eating disorder (BED), in a T2DM sample. To analyse whether there are any differences among T2DM subjects with a positive screening for ED or BED.
Research design and methods
320 subjects with T2DM were recruited randomly. All participants were evaluated for the presence of ED by completing the 'Eating Attitudes Test-26' (EAT26). In addition the 'Questionnaire of Eating and Weight Patterns Revised' (QEWP-R) for the screening of BED was also implemented. Sociodemographic, clinical and biochemical parameters were also recorded.
Results
According to EAT26, 14% of subjects screened positive for ED. Regarding QEWP-R, 16% had a positive screening for ED, with BED having a frequency of 12.2%, being the most prevalent one. There was a positive correlation between the scores obtained with the EAT26 and the Beck Depression Inventory ($P=0.0014$). Patients with BED were younger (57.5 ± 11.1 vs 63.3 ± 10.3 years; $P=0.004$), with a lesser T2DM duration (8.5 ± 6.1 vs 12.1 ± 9.6 years; $P=0.002$).

Weight and BMI among subjects with BED were greater (89.1 ± 1.3 vs 82.4 ± 16.7 kg; $P=0.04$ and 39.4 ± 10.3 vs 30.7 ± 5.5 kg/m^2; $P=0.01$). The frequency of subjects with one admission related to T2DM or any other condition during the last year was higher (10% vs 3%; $P=0.04$ years 33% vs 21%; $P=0.01$).
Conclusions
ED among T2DM are frequent. Due to its deleterious effect on different metabolic and psychological outcomes, they should be diagnosed promptly, especially BED.

What components drive the metabolic syndrome? Results from the population-based LifeLines Cohort Study

Sandra N Slagter, Robert P van Waateringe, Marjolein Wendker, Jana V van Vliet-Ostaptchouk, Helen L Lutgers, André P van Beek, Melanie M van der Klauw & Bruce H R Wolffenbuttel
Univ Med Center Groningen, University of Groningen, Groningen, The Netherlands.

Background
The metabolic syndrome (MetS) is a combination of unfavourable health factors including visceral obesity, dyslipidaemia, hypertension and impaired fasting glucose. It is also strongly associated with increased risk of cardiovascular disease (CVD) and type 2 diabetes. We assessed which factors contribute to the prevalence of MetS in people within different weight and age categories.
Methods
64 046 western European participants aged 18–80 years from the Dutch LifeLines Cohort study were categorised into three BMI classes (BMI <25, normal weight; BMI 25–30, overweight; BMI ≥ 30 kg/m^2, obese), and six age decades. MetS was defined according to the revised NCEP ATP III criteria. Within each BMI and age class, we determined the prevalence of all five MetS components.
Results
Prevalence of elevated blood pressure increased from 22% in the youngest age group (18–30 years) to 84% in the oldest age group (70–80 years). In these cohorts, the prevalence of excess waist circumference increased from 40 to 80%. The prevalence of increased serum triglycerides and fasting blood glucose was also the highest in the oldest age group (both 30%), while HDL-cholesterol remained strikingly constant with increasing age. In normal weight and overweight individuals, elevated blood pressure was the most common contributor to the presence of MetS. In obese individuals, elevated waist circumference, blood pressure and reduced HDL-cholesterol were the largest contributors.
Conclusions
The increase in prevalence of MetS with age in western European individuals is mainly driven by elevated blood pressure, and -to a lesser extent- by waist and HDL-cholesterol. As it is known that blood pressure increases with age, using a fixed 130/85 mmHg cut-off results in a disproportionate contribution of elevated blood pressure to the prevalence of MetS.

Changes of metabolic syndrome and its components in early adolescents through a 9.9 year community-based lifestyle intervention: Tehran Lipid and Glucose Study

Parisa Amiri[1,2], Sara Jalali-Farahani[1,2], Sakine Hanifi[1,2], Leila Cheraghi[1,2], Amir Abbas Momenan[3], Firoozeh Hosseini-Esfahani[4], Parvin Mirmiran[4], Arash Ghanbarian[3] & Fereidoun Azizi[5]
[1]Research Center for Social Determinants of Endocrine Health, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Obesity Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [3]Prevention of Metabolic Disorders Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [4]Nutrition and Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [5]Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran.

Introduction
To assess the effect of community-based multidisciplinary lifestyle interventions on metabolic syndrome (MetS) and its components in an urban population of Iranian adolescents.
Methods
This longitudinal study was conducted on 1230 adolescents, aged 12–15 years, within the framework of the TLGS. They were categorised in three groups: those residing in the intervention area during study (complete intervention group; $n=195$); those residing in the intervention area at baseline and at least one follow-up (incomplete intervention group; $n=459$) and control group ($n=576$). After baseline assessments (1999–2001), all measurements were repeated every 3 years for up to 9 years. Lifestyle interventions were aimed at achieving healthy dietary patterns and increasing the level of physical activity. The MetS has been defined using Cook definition. Generalised estimating Default (GEE) models were used to analyse data.
Results
Around 6.4, 25.3 and 10.8% of participants were lost to follow-up in control, incomplete and complete intervention groups respectively. Using GEE, at the end of study in boys, overall means of FPG were significantly lower in those who were placed in both intervention groups, compared with controls ($\beta=-3.36$ and -2.28 respectively). However, in girls only the complete intervention group had significantly lower FPG mean, vs controls ($\beta=-2.32$). In both boys and girls, mean TG was significantly lower in the complete intervention group vs controls ($\beta=-14.33$ and $\beta=-8.50$ respectively). Compared with the control group, mean SBP was significantly lower in girls of the complete intervention group ($\beta=-2.56$). Compared to controls, HDL was significantly higher in girls who received incomplete $\beta=2.17$). Among girls, the complete intervention group was less likely to have MetS and central obesity than the control group (OR = 0.23 and OR = 0.32 respectively; $P<0.05$).
Conclusion
Community-based lifestyle interventions reduced the risk of MetS and central obesity in girls and improved the means of cardio-metabolic risk factors in both sexes over the study period.

GP.14.03

Clinical and biological determinants of metabolically healthy obese status

Anca Sirbu[1,2], Sorina Martin[1], Carmen Barbu[1], Suzana Florea[1], Catalin Copaescu[3] & Simona Fica[1]
[1]Carol Davila University of Medicine and Pharmacy, Endocrinology Department – Elias Hospital, Bucharest, Romania; [2]Victor Babes Institute, Bucharest, Romania; [3]Ponderas Hospital, Bucharest, Romania.

Introduction
While the unfavourable metabolic consequences of obesity have been clearly demonstrated at a population level, there is a wealth of evidence indicating the existence of individuals somehow protected from developing complications, named 'metabolically healthy obese'. The aim of our study was to identify clinical and biological parameters independently associated with 'metabolically healthy' status.
Patients and methods
440 (303 women) extremely obese patients (mean BMI = 45.33 ± 8.82 kg/m^2) were clinically (medical history, anthropometrics, blood pressure (BP)) and biologically (complete metabolic tests, adiponectin, CRP, TNF-α levels) in a research programme for bariatric surgery. Metabolically healthy obese status was alternatively defined using two criteria: i) absence of metabolic syndrome (ATPIII definition) and ii) insulin sensitivity (IS) – non-diabetic patients with HOMA <2.85 were considered IS+.
Results
Only 15.8% of patients (20.4% of women) fulfilled both criteria of metabolic health. Women were IS+ in a higher percentage than men (30.7% compared with 12.4%, $P<0.001$). IS+ patients showed a lower general (BMI) and visceral (WC, WC/HC) adiposity and more favourable parameters of lipid (HDL, triglycerides) and glucose metabolism. They also had lower BP, lower chronic inflammatory markers (TNF-α, CRP), but higher levels of adiponectin. Patients without metabolic syndrome were also younger, mostly women, had a higher insulin sensitivity, lower CRP level and increased concentration of adiponectin. In logistic regression analysis, adiponectin ($P=0.011$), VAI ($P=0.012$) and uric acid ($P=0.031$) remained significantly associated with insulin sensitivity. Area under ROC curve for the model was 0.815 (IC: 0.756–0.875; $P<0.001$).

In a similar model, independent determinant of metabolic syndrome were: adiponectin ($P=0.004$), HOMA–IR ($P=0.01$) and age ($P<0.001$). Area under ROC curve for the model was 0.799 (0.744–0.853).
Conclusion
Adiponectin is an independent determinant of metabolically healthy obese status, disregarding the criteria used for its definition.

Parental obesity in association with offspring cognitive and psychomotor development at 4 years of age: the mother child 'Rhea' cohort in Crete, Greece

Vasiliki Daraki[1,2], Vaggelis Georgiou[1], Katerina Koutra[1], Andriani Kyriklaki[1], Mariza Kampouri[1], Katerina Sarri[1], Maria Vassilaki[1], Stathis Papavasiliou[2], Manolis Kogevinas[1] & Leda Chatzi[1]
[1]Department of Social Medicine, Faculty of Medicine, University of Crete, Heraklion, Greece; [2]Department of Endocrinology Diabetes and Metabolic Diseases, University Hospital of Crete, Heraklion, Greece.

Introduction
Animal studies suggest that maternal obesity may impact foetal brain structure and function and increase long-term susceptibility to neurodevelopmental and neuropsychiatric disorders. Few human studies have examined these associations with conflicting results. It is unclear if reported associations are due to genetic background or intrauterine mechanisms.
Objective
To investigate the association of maternal and paternal obesity status with offspring cognitive and psychomotor development at 4 years of age using data from a longitudinal, prospective pregnancy cohort, 'Rhea' study in Crete, Greece.
Design and methods
The present study includes 652 mother-child pairs, after excluding twin pregnancies and women with pre-gestational diabetes. Pre-pregnancy maternal BMI and paternal BMI were calculated at the first prenatal visit (mean: 12 weeks, S.D.: 1.5) neurodevelopment at 4 years was assessed by means of the McCarthy Scales of Children's Abilities (MSCA). Emotional and behavioural development at 4 years was assessed by means of Strengths and Difficulties Questionnaire (SDQ) and Attention Deficit Hyperactivity Disorder (ADHD) Test. Multivariable linear regression models were used to estimate the effect of pre-pregnancy BMI and paternal BMI on child neurodevelopment at 4 years of age after adjusting for multiple confounders.
Results
Maternal obesity pre-pregnancy was associated with reduced general cognitive (score reduction: −2.51; 95% CI: −4.78, −0.24), quantitative (score reduction: −2.50 95% CI: −4.89, −0.11) and memory development scores (score reduction: −2.66 95% CI: −5.07, 0.26) at 4 years of age. These associations were more pronounced in girls compared to boys. No association was found between pre-pregnancy BMI and child emotional and behavioural development or ADHD symptoms at 4 years of age. Paternal BMI was not associated with offspring cognitive and behavioural development at 4 years of age.
Conclusion
Maternal pre-pregnancy BMI was associated with reduced cognitive development at preschool age. This association appeared more likely to be due to intrauterine mechanisms than shared family and social characteristics.

The effect of Roux-en-Y gastric bypass, sleeve gastrectomy and adjustable gastric banding on renal function and remission of metabolic disease: a five-year longitudinal study

Karl Neff[1], Gregory Baud[2], Violeta Raverdy[2], Carel le Roux[1] & Francois Pattou[2]
[1]Diabetic Complication Research Centre, UCD Conway Institute, School of Medicine and Medical Science, University College Dublin, Dublin, Ireland; [2]Department of General and Endocrine Surgery, Lille University Hospital, Lille, France.

Introduction
There are few data on renal function following bariatric surgery. We evaluated the effect of Roux-en-Y gastric bypass (RYGB), adjustable gastric banding (AGB) and sleeve gastrectomy (SG) on renal function over a 5-year post-operative period. We also evaluate the effect of these procedures on remission of diabetes and hypertension.
Methods
Analysis of a prospectively collected database at Lille University Hospital. Patients were assessed pre-operatively and then at 1 and 5 years post-operatively.
Results
Subject undergoing RYGB ($n=190$), AGB ($n=271$) and SG ($n=16$) were included. Estimated glomerular filtration rate (eGFR) increased following RYGB ($95+/-2$ to $101+/-1$, $P=0.01$) and AGB: $88+/-1$ to $93+/-2$, $P=0.02$). In those with eGFR <60 ml/min per 1.73 m^2 at baseline, eGFR improved over 5 years ($52+/-2$ to $68+/-7$ ml/min per 1.73 m^2, $P=0.01$). RYGB induced remission of diabetes and pre-diabetes to a greater extent than AGB (43% vs 15%; $P<0.001$). Remission of hypertension was also greater in the RYGB group at year 1 (32% vs 16%, $P=0.008$) and year 5 (23% vs 11%, $P=0.02$).
Conclusions
Bariatric surgery maintains eGFR over time. This may be due to the effect on blood pressure and glycaemia.

Higher HOMA levels and failed decrease in body fat can be considered unfavourable predictors of restoring euglycaemia in diabetic cirrhotic patients undergoing liver transplantation

Valeria Grancini[1,2], Elena Lunati[1,2], Veronica Resi[1], Anna Spada[1,2] & Emanuela Orsi[1]
[1]Endocrinology and Diabetology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy.

Introduction
Diabetes mellitus (DM) is a very common complication of cirrhosis (prevalence: 20–60%), primary due to increased hepatic insulin-resistance (IR). After liver transplantation (LT), DM recovers in 67% of cases, while 33% of patients remain diabetic because of a concomitant decreased beta cell function. The roles played by pre-transplant factors determining changes in glucose tolerance after LT are imperfectly known.
Aim of the study
To highlight any factors that predict increased risk of persistence of post-transplant glucose homeostasis alterations in diabetic cirrhotic patients undergoing LT.
Materials and methods
42 patients with liver cirrhosis, 31M/11F, age 53 ± 9.9 years, underwent a metabolic and anthropometric evaluation, they underwent a bioelectrical impedance analysis (BIA) and an oral glucose tolerance test (OGTT) was performed to diagnose diabetes, before and 6 months after LT. Depending on OGTT results, patients were classified as Non Diabetic (ND) patients, who remain euglycaemic before and after LT, Diabetic (D) patients, who didn't recover from diabetes after LT, or Regressors (R), who were diabetic and returned to euglycaemia after LT. No euglycaemic cirrhotic patients became diabetic after LT, so this group was not considered. IR was assessed with HOMA index, body fat was quantified with BIA (being BMI and waist circumference unreliable in cirrhotic patients because of the presence of ascites).
Results
Depending on this classification, our population was composed by 22 ND, 13 D and seven R patients. HOMA levels before LT were higher in D patients if compared to ND and R (7.7 ± 1.7 vs 3.1 ± 0.6 and 3.7 ± 1.8 respectively, $P<0.05$).

Moreover, R showed a significant decrease in body fat, if compared to D patients ($-13.3 \pm 9\%$ vs $1.5 \pm 0.2\%$, $P<0.05$).
Conclusions
In diabetic cirrhotic patients undergoing LT, higher HOMA levels and failed decrease in body fat after LT can be considered unfavourable predictors of recovering from diabetes after transplantation.

Degree of control of type 2 diabetes in Spain according to individualised glycaemic targets
Inka Miñambres[1], José Javier Mediavilla[2], Diego González-Segura[3] & Antonio Pérez[1]
[1]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; [2]Centro de Salud Burgos Rural, Burgos, Spain; [3]Almirall, Barcelona, Spain.

Our objective was to estimate the distribution of Spanish diabetic patients attending to individualized glycaemic targets recommended by the ADA/EASD consensus with and without considering hypoglycaemia risk. We conducted a cross-sectional study in a Spanish primary care setting between 2011 and 2012. A total of 5382 type 2 diabetic subjects under antihyperglycaemic treatment for at least 3 months prior to inclusion completed a study visit in which clinical data including age, diabetes duration, complications and treatment, and presence of a hypoglycaemia during the last year were collected. A capillary HbA1c was measured by the A1CNow+ system. Patients were classified into different targets of HbA1c according to i) the ADA/EASD consensus without taking into account hypoglycaemia risk (presence of hypoglycaemia that required medical assistance during the past year and/or treatment with at least two insulin doses). ii) The ADA/EASD consensus taking into account hypoglycaemia risk. Mean HbA1c was 7.2 (1.2) % and 48.6% of our patients had an HbA1c $<7\%$. According to the ADA/EASD strategy without taking into account hypoglycaemia risk, 15.9, 17.1 and 67% of the patients applied to glycaemic targets of <6.5, <7 and $<8\%$ and 67.4% of the patients were considered to have an adequate glycaemic control. On the other hand, according to the ADA/EASD strategy taking into account hypoglycaemia risk 14.9, 15.5 and 69.6% of the patients applied to glycaemic targets of <6.5, <7 and $<8\%$ and 68.5% were considered to have an adequate glycaemic control. The degree of concordance between both strategies in terms of classifying patients at a certain HbA1c target was 97.4% (κ coefficient $=0.9413$).
In conclusion, individualisation of glycaemic targets increases the proportion of patients considered adequately controlled. The inclusion of information regarding hypoglycaemia risk in the ADA/EASD strategy does not affect patient classification.

Factors associated with islet yield and insulin independence after total pancreatectomy and islet cell autotransplantation in patients with chronic pancreatitis utilising off-site islet isolation: Cleveland Clinic experience
Philip C Johnston[1], Yu Lin[1], Matthew Walsh[1], Tyler Stevens[1], Rita Bottino[2], Massimo Trucco[2], James Bena[1] & Betul Hatipoglu[1]
[1]Department of Endocrinology, Diabetes and Metabolism, Cleveland Clinic, Cleveland, Ohio, USA; [2]Division of Immunogenetics, Department of Paediatrics, University of Pittsburgh, Pittsburg, Pennsylvania, USA.

Context
Total pancreatectomy (TP) with islet cell autotransplantation (IAT) can reduce or prevent diabetes by preserving β-cell function, and is normally performed with on-site isolation laboratory facilities.
Objective
We examined factors associated with islet yield and metabolic outcomes in patients with chronic pancreatitis undergoing TP-IAT. We report our experience of TP-IAT with an off-site islet isolation laboratory.
Patients and methods
Data (August 2008–February 2014) were obtained from a TP-IAT database which included information from medical records, clinic visits, questionnaires and follow-up telephone calls. Each patient was assessed with pre- and post-operative 5-h mixed meal tolerance tests for metabolic measurements and with serial HbA1c determinations.
Results
Thirty-six patients with a mean age of 38 years (range 16–72 years) underwent TP-IAT for different aetiologies. At a median follow-up time of 28 months (range 3–66), 12 patients were insulin independent and 24 patients were on at least one insulin injection a day. Post-operatively, C-peptide levels ≥ 0.3 ng/ml were present in 23/33 (70%) of the patients, with a median fasting C-peptide value of 0.8 ng/ml (range <0.2–1.5 ng/ml). Those who were insulin independent were more likely to be female ($P=0.012$), have normal morphology on pre-operative pancreatic imaging ($P=0.011$), and have significantly higher median islet yield (6845 IEQ/kg, $n=12$ vs 3333 IEQ/kg, $n=24$; $P<0.001$).
Conclusions
Islet cell autotransplantation after total pancreatectomy performed in our facility with an off-site islet isolation laboratory shows islet yield and rates of insulin independence that are comparable to other large centres with on-site laboratories.

Topical application of CD362$^+$ human mesenchymal stem cells (cyndacel-M) seeded in Excellagen scaffold augments wound healing and increases angiogenesis in a diabetic rabbit ulcer model
Swapnil Patil[1], Xizhe Chen[1], Luke Watson[2], Paul Loftus[2], Lisa O' Flynn[2], Lois Chandler[3], Gabor Rubanyi[3], Stephen Elliman[2] & Timothy O'Brien[1,4]
[1]Regenerative Medicine Institute (REMEDI) and Biosciences Research Building, National University of Ireland (NUIG), Galway, Ireland; [2]Orbsen Therapeutics, National University of Ireland, Orbsen Building, Galway, Ireland; [3]Cardium Therapeutics, San Diego, California, USA; [4]Department of Medicine, Galway University Hospital (GUH), Galway, Ireland.

Non-healing foot ulcers are a major complication in diabetic patients. Mesenchymal stem cells (MSCs) are known to promote angiogenesis with improved wound healing. Orbsen Therapeutics has identified a novel antibody (CD362$^+$) which can be used to prospectively FACS-isolate CD362$^+$CD45$^-$ MSC from human bone marrow with enhanced MSC/MNC purity ratios of up to 1/4. Excellagen matrix was used to seed the cells as biomaterials are well reported to enhance viability and therapeutic efficacy of cells. In this study, 1 million of CD362$^+$, CD362$^-$ and plastic adherent human MSCs were seeded in an Excellagen matrix and applied to cutaneous wounds in an alloxan-induced diabetic rabbit ear ulcer for a 1 week period. Statistical analysis between groups revealed that the wounds treated with an Excellagen-CD362$^+$ cell treatment demonstrated increased percentage wound closure with more prominent neovasculature. The wound sections were immunohistochemically stained by using CD31 and GSL-B4 lectins to study neovasculature. In stereological analysis, significantly increased surface density, length density and reduced radial diffusion distance was observed in the Excellagen-CD362$^+$ cell treated wound groups in comparison to untreated wounds. A subsequent study compared the beneficial effects of a combination treatment (IV delivery of cells at 2×10^6 cells/kg plus topical treatment) to topical treatment alone. A slight increase was observed in percentage wound healing in combination versus topical treated animals but this difference was not significant. There was no lowering of blood glucose levels in the combination treated animal groups over the seven day study period. Hence, with improved wound healing potential and augmenting angiogenesis, topical treatment with these specifically selected CD362$^+$ MSCs seeded in an Excellagen matrix may lead to a new therapeutic product to treat non-healing diabetic foot ulcers.

Sex hormone-binding globulin protects against non-alcoholic fatty liver disease

Cristina Saez Lopez[1], Anna Barbosa-Desongles[1], Cristina Hernandez[1], Roger A Dyer[2], Sheila M Innis[2], Simo Rafael[1] & David M Selva[1]
[1]Diabetes and Metabolism Research Unit, Vall Hebron Institut de Recerca (VHIR), Universitat Autònoma de Barcelona and CIBERDEM (ISCIII), Barcelona, Spain; [2]Child and Family Research Institute, Department of Paediatrics, Faculty of Medicine, University of British Columbia, Vancouver, Canada.

Low plasma sex hormone-binding globulin (SHBG) levels are present in patients suffering chronic metabolic diseases, including non-alcoholic fatty liver disease (NAFLD). However, whether altered SHBG production plays a role in development and progression of this disease is unclear. To investigate SHBG involvement in NAFLD, we studied the effects of overexpressing SHBG in two mouse models, a genetically-induced model, by developing a double transgenic mouse by crossing the human *SHBG* transgenic mouse with the C57BL/ksJ-db/db mouse and a diet-induced model by feeding human *SHBG* transgenic mice and their WT littermates with high fructose diet (HFrD) during 8 weeks. In addition, HepG2 cells were also used to explore the molecular mechanisms involved on the SHBG role in NAFLD. Moreover, human liver biopsies were used to corroborate the *in vivo* and *in vitro* findings. The SHBG overexpression in C57BL/ksJ-db/db mice significantly reduced liver weight and liver fat accumulation by reducing lipogenesis via acetyl-CoA carboxylase (ACC), fatty acid synthase (FAS) and ATP citrate lyase (ACLY) downregulation. Next we showed that human SHBG transgenic mice were protected against NAFLD induced by HFrD feeding that was evident in their WT littermate mice. The SHBG overexpression in this diet-induced NAFLD mouse model also reduced hepatic lipogenesis via ACC, FAS and ACLY downregulation. Furthermore, we showed a SHBG cell-autonomous effect on hepatocyte lipogenesis since SHBG overexpression reduced total triglyceride content by downregulating ACC mRNA and protein levels in HepG2 cells. Finally, the SHBG expression was inversely correlated with total triglycerides and ACC mRNA levels in human liver biopsies. Overall, we conclude that SHBG is a protective against NAFLD by inhibiting lipogenesis. Therefore, SHBG could be a new therapeutic target whereby increased expression may reduce NAFLD.

Cardiomyopathy in the male obese diabetic db/db mice is alleviated by oxytocin treatment

Jolanta Gutkowska, Eric Plante, Ahmed Menouar, Jean-Louis Chiasson & Marek Jankowski
Department of Medicine, University of Montreal, CRCHUM, Montreal, Quebec, Canada.

Oxytocin (OT) is involved in the regulation of energy metabolism and in the activation of cardio-protective mechanisms. We evaluated whether chronic treatment with OT could prevent the metabolic and cardiac abnormalities associated with diabetes and obesity using the db/db mice model. Four-week-old male db/db mice and their lean non-diabetic littermates (db/+) serving as controls were treated with OT (125 ng/kg per h) or saline vehicle for a period of 12 weeks. Compared to db/+ mice, the saline-treated db/db mice developed obesity, hyperglycaemia and hyperinsulinaemia. These mice also exhibited a deficient cardiac OT/natriuretic peptide system and developed systolic and diastolic dysfunction resulting from cardiomyocytes hypertrophy, fibrosis and apoptosis. These abnormalities were associated with increased ROS production, inflammation and suppressed AMP-kinase signalling pathway. The male db/db mice displayed reduced serum levels of adiponectin and adipsin and elevated levels of resistin. OT treatment increased circulating plasma OT levels, significantly reduced serum resistin, body fat accumulation (19%: $P<0.001$), fasting blood glucose levels by (23%; $P<0.001$), and improved glucose tolerance and insulin sensitivity. OT also normalized cardiac OT receptors, ANP and BNP expressions and prevented systolic and diastolic dysfunction as well as cardiomyocytes hypertrophy, fibrosis and apoptosis. Furthermore, OT reduced cardiac oxidative stress and inflammation, and normalized the AMP-activated protein kinase signalling pathway. The complete normalization of cardiac structure and function by OT treatment in db/db mice contrasted with only partial improvement of hyperglycaemia and hyperinsulinaemia. These results indicate that chronic treatment with OT partially improves glucose and fat metabolism, reverses abnormal cardiac structural remodelling, preventing cardiac dysfunction in db/db mice, therefore OT plays a cardio-protective role in the diabetes.

Novel human resistin antagonist (monomeric C6A mutant) reduced body weight gain and restored insulin responsiveness in mice fed high fat diet

Yacir Benomar[1,2], Gili Solomon[3], Hamza Amine[1,2], Ahlem Othmane[1,2], Arieh Gertler[3] & Mohammed Taouis[1,2]
[1]Molecular Neuroendocrinology of Food Intake,UMR 9197, University Paris Sud, ORSAY, France; [2]Molecular Neuroendocrinology of Food Intake, Neuroscience Paris-Saclay Institute, CNRS UMR 9197, University Paris Sud, ORSAY, France; [3]Faculty of Agricultural, Food and Environmental Quality Sciences, The Institute of Biochemistry, Food Science, and Nutrition, The Hebrew University of Jerusalem, Rehovot, Israel.

Resistin promotes both inflammation and insulin resistance associated with energy homeostasis impairment. Resistin is secreted by adipose tissue and macrophages, but its mechanism of action remained unknown because its receptor was not characterised. Recently, we have shown that central resistin acts by way of hypothalamic TLR4 receptors promoting overall inflammation and insulin resistance. Here, we aim to block resistin action in HFD mice that are prone to obesity and inflammation, and attempt to reverse these metabolic disorders. For this purpose, we have developed recombinant human resistin mutant (C6A) that does not form the dimeric molecule of resistin and acts as resistin antagonist (RA). The quality and purity of RA has been verified by SDS–PAGE and SEC analysis. Firstly, we tested the efficacy of RA in human neuronal cells SH-SY5Y and in mouse hypothalamic cell line. We showed that resistin (100 ng/ml) induced the phosphorylation of Akt, while RA had no such activity in both cell lines. Importantly, RA (10 mg/ml) treatment totally abolished resistin-dependent Akt phosphorylation. Once, the efficacy of RA demonstrated, we attempted to reverse the HFD-dependent insulin resistance by RA treatment *in vivo*. For this purpose, we have fed male C57BL/6 mice with HFD for 6 weeks and then mice received for 14 days daily injection of RA (0.3 mg/day per mice). We clearly show that RA leads to a significant decrease in body weight of HFD mice mainly due to loss of visceral fat. Importantly, RA treatment significantly improved both glucose tolerance and insulin responsiveness of HFD mice. Interestingly, hypothalamic IL6 expression, and reactive gliosis in the arcuate nucleus were markedly reduced in RA-treated HFD mice. Collectively, these findings indicates that the blockade of resistin action reduced body weight gain, visceral fat content and hypothalamic inflammation and restored insulin responsiveness of mice fed high fat diet.

Stable analogues of the dual agonist dogfish glucagon show better therapeutic potential than exendin-4 in diet induced obese diabetic mice

Finbarr P M O'Harte, Ming T Ng, J Michael Conlon & Peter R Flatt
University of Ulster, Coleraine, N. Ireland, UK.

Recent acute *in vivo* studies have shown that structural modifications of dogfish glucagon improves peptide stability and these analogues can act as dual agonists at both glucagon and GLP-1 receptors. Here, we compared the effects of chronic (51 days) twice daily administration of [D-Ala^2]dogfish glucagon (Pep-N) and [D-Ala^2]dogfish glucagon-exendin-4(31–39) construct (Pep-C), exendin-4(1–39) or saline treated controls on metabolic status in groups ($4\times n=8$) of male (Swiss TO) diet induced (4 months pre-conditioned on 45% high fat diet) diabetic mice. Non-fasting blood glucose was significantly reduced in all treatment groups vs saline controls after one week and remained lower throughout the remaining study period ($P<0.05$ to $P<0.001$). Peptide therapies had no significant effect on cumulative food intake but the increase in body weight gain was lower ($P<0.05$) following Pep-N and Pep-C administration vs saline treated controls. Plasma insulin concentrations progressively increased ($P<0.05$ to $P<0.01$) in all three peptide treated groups vs high fat fed saline treated controls. After day 51, Pep-N and Pep-C showed an improved overall glycaemic response (0-120 min, area under curve AUC) to i.p. glucose (18 mmol/kg body weight) ($P<0.001$), along with exendin-4 ($P<0.05$) compared to saline treated controls. Also a significant

rise in plasma insulin concentration was noted over 120 min within all peptide treatment groups with Pep-C being the most effective insulinotropic peptide ($P<0.001$). Following chronic treatment, an insulin sensitivity test (25 U/kg body weight) showed that exendin-4 ($P<0.05$) and Pep-C ($P<0.001$) had enhanced insulin sensitivity vs saline treated controls. Terminal DEXA scan densitometry analysis revealed that percentage body fat mass was significantly decreased ($P<0.001$) in Pep-N and Pep-C treated mice but not following exendin-4 treatment. Pep-C effectively lowered plasma triglyceride concentrations ($P<0.01$). Pep-N and Pep-C caused a reduction in the terminal circulating plasma glucagon concentrations ($P<0.01$) compared to saline treated controls. Finally, pancreatic insulin content was unchanged in all of the peptide treated groups compared to saline treated control mice. In conclusion, chronic twice daily treatment with the novel dual agonist Pep-C demonstrated improved glycaemic control and lipid profiles compared with exendin-4 therapy in diet induced obese diabetic mice.

GP.15.06

Activation of GPR120 by lipid agonists modulates glucagon secretion in pancreatic islets and improves glucose tolerance in mice

Noella Gormley, Peter Flatt & Aine McKillop
Ulster University, Coleraine, UK.

GPR120 is a rhodopsin-like GPCR that has a high affinity for long-chain saturated fatty acids 14–18 carbons and unsaturated fatty acids 16–22 carbons. The beneficial effects of GPR120 on β-cell function and glucose homeostasis have recently been reported however its role in glucagon secretion is unknown. GPR120 and glucagon expression were examined by double immunohistochemical studies using a glucagon secreting cell line (α-TC1.9) and pancreatic tissue from normal and high-fat fed (HFF) NIH-Swiss mice. Mechanistic and molecular studies with GPR120 agonists were used to examine alterations in intracellular Ca^{2+} and GPR120 mRNA expression in α-TC1.9 cells. Cytotoxicity was assessed by LDH release. Acute *in-vivo* effects of lipid GPR120 agonists on plasma glucose and islet hormone levels were assessed in NIH-Swiss mice. Immunocytochemistry demonstrated GPR120 co-localisation with glucagon in mouse pancreatic islets; results were confirmed in α-TC1.9 cells. Histological studies revealed that insulin was reduced ($P<0.001$) whilst glucagon ($P<0.01$) and GPR120 ($P<0.05$) expression was increased in HFF model of diabetes compared to lean controls. In mechanistic studies, endogenous GPR120 agonist DHA increased intracellular Ca^{2+} by 4.2-fold ($P<0.001$) whilst synthetic agonist GW-9508 induced a threefold increase ($P<0.05$) in α-TC1.9 cells at 5.6 mM glucose. At 16.7 mM glucose, DHA and GW-9508 augmented intracellular Ca^{2+} 5.0-fold ($P<0.01$) and 2.6-fold ($P<0.05$), respectively. No cytotoxicity was observed. PCR studies revealed that DHA increased GPR120 mRNA expression in TC1.9 cells at 5.6 mM glucose. Administration of GPR120 agonists (0.1 μmol/kg per body weight) in glucose tolerance studies was tested in NIH-Swiss mice. DHA and ALA improved glucose tolerance ($P<0.001$), augmented insulin secretion ($P<0.01$) whilst DHA reduced glucagon secretion ($P<0.001$) by 94% after 30 min. GW-9508 augmented insulin secretion ($P<0.01$) by 48% after 15 min and glucagon secretion ($P<0.001$) by 67% after 30 min. GPR120 is expressed on pancreatic alpha cells, and agonists at this receptor modulate glucagon secretion, with therapeutic potential for type-2 diabetes.

Nephroprotective properties of metformin and vildagliptin: experimental facts in type 2 diabetes

Valentina Bayrasheva[1], Elena Grineva[1,2], Alina Babenko[1,2], Yurii Dmitriev[1], Ivan Shatalov[3], Svetlana Chefu[2,1] & Alexandra Ivanova[4,5]
[1]Federal North-West Medical Research Centre, Saint-Petersburg, Russia; [2]Pavlov First St Petersburg State Medical University, Saint-Petersburg, Russia; [3]St Petersburg national research University of Information, Technologies, Mechanics and Optics, Saint-Petersburg, Russia; [4]Saint Petersburg State University, Saint-Petersburg, Russia; [5]The Komarov Botanical Institute of the Russian Academy of Sciences, Saint-Petersburg, Russia.

Background
Recent studies have demonstrated antioxidant and anti-inflammatory properties of metformin and vildagliptin, that could result in some positive effects on kidney function in diabetes. Indeed, in our previous study vildagliptin attenuated routine renal dysfunction markers in insulinopenic diabetic rats, however metformin didn't improve it. In our current study we evaluated not only glomerular dysfunction marker (albuminuria), but also novel markers of proximal tubular injury (KIM-1, NGAL) in rats with non-genetic type 2 diabetic nephropathy treated with metformin and vildagliptin.
Methods
In 3 weeks after unilateral nephrectomy adult male Wistar rats were randomly divided into diabetic group (fed high-fat diet for 5 weeks and then successively received nicotinamide (230 mg/kg) and streptozotocin (65 mg/kg) intraperitoneally) and non-diabetic group (ND) fed with normal diet and received citrate buffer without streptozotocin. Ten weeks later, diabetic animals were divided to receive either metformin (M group) 300 mg/kg per day, either vildagliptin (V group) 8 mg/kg per day, or placebo (P group) for another 10 weeks, $n=9$ each.
Results
HbA1c in diabetic groups was considerably higher compare to ND ($4.6\pm0.12\%$). At the end of the experiment vildagliptin treatment was able to considerably improve creatinine clearance (2.9 ± 0.13 ml/min per kg), and reduce urinary albumin excretion ratio (21.9 ± 1.4 mg/24 h). Even though metformin didn't attenuate routine kidney dysfunction markers such as creatinine, creatinine clearance and albuminuria (61 ± 2.9 μmol/l; 2.6 ± 0.18 ml/min per kg; 25.9 ± 4.6 mg/24 h, respectively) compared to P group (65 ± 3.6; 2.3 ± 0.21; 38.8 ± 2.5, $P\geq0.05$ each),urinary levels of KIM-1 (589 ± 93.3 ng/ml) and NGAL (1544.9 ± 100.6 pg/ml) in metformin-treated animals were significantly lower than that in diabetic rats without treatment (1097 ± 91.1; 1918.6 ± 118.1, respectively), $P<0,05$ each. Moreover, renoprotection in studying groups confirmed by morphological examination.
Conclusion
Thus, whereas vildagliptin treatment could attenuate routine markers of kidney injury, metformin has shown tubuloprotective properties without any effects on glomerular dysfunction in type 2 diabetic rats.

Suppression of plasma free fatty acid concentrations similarly reduces myocardial lipid content and left ventricular systolic function in type 2 diabetic patients and healthy controls

Peter Wolf[1], Yvonne Winhofer[1], Sabina Smajis[1], Anja Catic[1], Jürgen Harreiter[1], Lana Kosi-Trebotic[1], Siegfried Trattnig[2], Sabina Baumgartner-Parzer[1], Anton Luger[1], Martin Krssak[1,2] & Michael Krebs[1]
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria; [2]Department of Radiology, MR Centre of Excellence, High Field MR, Medical University of Vienna, Vienna, Austria.

Background
Metabolic inflexibility in T2DM might result in reliance on free fatty acids (FFA) as substrates to maintain myocardial energy metabolism compared to lean and healthy controls. Thus, we investigated the effects of an acute suppression of circulating FFA on myocardial lipid content and left ventricular function in extreme phenotypes.
Methods
T2DM patients (age: 56 ± 11a; BMI: 28 ± 3.5 kg/m^2; HbA1c: $7.29\pm0.88\%$) and nine healthy young controls (age: 24 ± 3a; BMI: 24 ± 3.5 kg/m^2) were investigated on two study days in random order. At baseline and at 180 min placebo or Acipimox was administered to inhibit adipose tissue lipolysis. Myocardial lipid content (MYCL) and systolic LV-function was measured by 1H-magnetic-resonance-spectroscopy and tomography at timepoints I (0–60 min), II (180–240 min) and III (420–480 min).
Results
In T2DM and controls Acipimox similarly reduced MYCL significantly (T2DM: -0.39 ± 0.07 vs CON: $-0.39\pm0.41\%$ compared to baseline), accompanied by a distinct decrease in parameters of LV systolic function without any difference between both groups (EF -13 ± 8 vs $-9\pm7\%$ compared to baseline; cardiac index: -16 ± 15 vs $-11\pm13\%$ compared with baseline; T2DM vs CON). Baseline MYCL and EF were higher in T2DM compared to controls (MYCL $0.48\pm0.12\%$ vs $0.18\pm0.01\%$; $P<0.001$; EF: $77\pm1.7\%$ vs $61\pm1.2\%$; $P<0.001$; T2DM vs CON). At baseline a strong correlation of MYCL and EF ($r=0.537$; $P<0.001$) was observed.

Discussion
Pharmacological inhibition of adipose tissue lipolysis reduces MYCL to a similar extent in T2DM and healthy controls. Thus, cardiac lipid stores might be essential for maintaining systolic heart function. These results are of clinical interest, since lipolysis-inhibiting drugs are frequently used in routine care in T2DM (insulin, nicotinic-acids).

The effect of omega-3 polyunsaturated fatty acids on the arterial stiffness parameters in patients with diabetes mellitus type 2 and cardiovascular autonomic neuropathy

Victoria Serhiyenko, Volodymyr Segin & Alexandr Serhiyenko
Lviv National Medical University, Lviv, Ukraine.

Introduction
The aim of study was to analyse the effect of long-chain polyunsaturated higher ω-3 fatty acids (PUFAs) on the arterial stiffness parameters in patients with type 2 diabetes (T2DM) and cardiovascular autonomic neuropathy (CAN).
Description of methods
The study involved 39 patients with moderate CAN (55.2±3.8 years, HbA1c 7.1±0.5%. The aorta (AIxao), brachial augmentation index (AIxbr), pulse wave velocity (PWV) were assessed by TensioMedTM Arteriograph 24 (Hungary). Patients with CAN were allocated to two groups: control ($n=18$) received standart therapy and treatment ($n=21$) received in addition one capsule/day of the ω-3 PUFAs (Δ90%). The duration of the study was 3 months. Statistics: ANOVA.
Results
The arterial stiffness parameters in patients with moderate CAN exceed the physiological values, in particular AIxao +26.2% ($P<0.01$), AIxbr +66.2% ($P<0.001$), PWV +24.7% ($P<0.001$) compared to patients with T2DM without CAN. Prescription of ω-3 PUFA was accompanied by more decrease of AIxao, PWV during the 24 h, decrease of AIxao, PWV during the day and decrease of AIxao, AIxbr, PWV during the night. Simultaneously no significant influence on the AIxbr during the active period of day was not found (table).

Table

	Patients with T2DM and CAN ($n=39$)				
Parameters	Groups	Day/night	Baseline	After treatment	% change from baseline
AIxao, %	Control	Day	30.4±1.97	28.4±1.68	−4.3±4.76
		Night	33.2±1.98	30.1±1.27	−6.6±4.15
	Treatment	Day	32.0±1.32	26 4±1.12[b]	−16.2±3.12
		Night	36.6±1.65	31.7±1.23[a]	−11.2±4.2
AIxbr, %	Control	Day	−10.6±3.37	−12.0±3.11	−19.3±12.14
		Night	−4.2±2.8	−5.9±2.48	−10.0±17.23
	Treatment	Day	−9.8±2.76	−14.3±2.84	−42.8±9.0
		Night	−1.6±2.79	−10.4±3.23[a]	−98.0±18.1
PWV, m/s	Control	Day	10.2±0.4	9.6±0.4	−6.0±2.21
		Night	10.9±0.4	10.3±0.36	−4.93±1.41
	Treatment	Day	11.0±0.35	9.7±0.39[a]	−11.6±2.09
		Night	11.3±0.48	9.0±0.44[b]	−18.9±3.9

Note: The results are given as absolute values and as % change from baseline, (Δ%, Mean±SEM); [a]$P<0.05$, [b]$P<0.01$ – compared to baseline.

Conclusion
Therefore, the administration of ω-3 PUFA for 3 month promotes reduction of artery stiffness parameters in patients with T2DM and CAN.

GP.16.03

The dipeptidyl peptidase-IV inhibitor (gemigliptin) inhibits the expression of vascular adhesion molecules and inflammatory cytokines in HUVECs via Akt- and AMPK-dependent mechanisms

Ho Cheol Hong, Hwan-Jin Hwang, Hyun Jung Lee, Min Jung Lee, Ji A Seo, Sin Gon Kim, Nan Hee Kim, Kyung Mook Choi, Dong Seop Choi, Sei Hyun Baik & Hye Jin Yoo
Division of Endocrinology and Metabolism, Department of Internal Medicine, Korea University, Seoul, n/a, Republic of Korea.

Recently, dipeptidyl peptidase-IV (DPP-IV) inhibitor, a major anti-hyperglycaemic agent, has received substantial attention as a possible therapeutic target for inflammatory diseases such as atherosclerosis. However, the direct molecular mechanisms through which DPP-IV inhibitor mediates anti-inflammatory effects in vascular endothelial cells have not been clarified. The effects of the DPP-IV inhibitor, gemigliptin, were analysed in human umbilical vein endothelial cells (HUVECs) and THP-1 cells. Using western blotting, we demonstrated that gemigliptin efficiently increased the level of AMP-activated protein kinase (AMPK) and Akt phosphorylation in a dose-dependent manner. The levels of lipopolysaccharide (LPS)-mediated phosphorylated nuclear factor-κB (NF-κB) and c-Jun N-terminal kinase (JNK) were significantly decreased after gemigliptin treatment. Furthermore, gemigliptin reduced LPS-induced expression of adhesion molecules and inflammatory cytokines such as vascular cell adhesion molecule-1 (VCAM-1), E-selectin, tumour necrosis factor-α (TNF-α), monocyte chemoattractant protein-1 (MCP-1), interleukin-1β (IL1β), and IL6 in HUVECs. In macrophage-like THP-1 cells, gemigliptin effectively inhibited LPS- and LDL-induced foam cell formation. However, these anti-inflammatory and anti-atherosclerotic effects of gemigliptin in HUVECs and THP-1 cells were significantly reduced after treatment with an AMPK or an Akt inhibitor. Our results suggest that gemigliptin efficiently inhibited LPS-induced pro-inflammatory effects in vascular endothelial cells by attenuating NF-κB and JNK signalling via Akt/AMPK-dependent mechanisms. Therefore, the DPP-IV inhibitor, gemigliptin, may directly protect the vascular endothelium against inflammatory diseases such as atherosclerosis.

Nocturnal blood pressure cut off points related to the development of microvascular complications and arterial hypertension in patients with type 1 diabetes

María Belén Ojeda-Schuldt[1], Isabel Mateo-Gavira[1], Francisco Javier Vilchez-López[1], Ana Montero-Galván[2], José Ortejo-Rojo[1] & Manuel Aguilar-Diosdado[1]
[1]Department of Endocrinology, University Hospital Puerta del Mar, Cádiz, Spain; [2]Nursing Unit, Department of Endocrinology. University Hospital Puerta del Mar, Cádiz, Spain.

Introduction
In preliminary results of our group, we detected an association between the mean nocturnal blood pressure and development microvascular complications. The objective was to evaluate possible nocturnal blood pressure cut off points in relation to the development or progression of retinopathy, microalbuminuria and arterial hypertension in type 1 diabetic patients.
Methods
We designed a prospective observational study of 85 patients, clinically normotensive and without microalbuminuria, monitored over 7 years. We performed a 24 h-ambulatory blood pressure monitoring (ABPM) at the beginning and after 7 years. We evaluated the development/progression of retinopathy and development of microalbuminuria and established hypertension over the follow up period. We analyzed different ranges of nocturnal systolic blood pressure (SBP) and diastolic blood pressure (DBP) as independent variables for the development of such complications
Results:
Of the 85 patients included in the analysis, 55.3% (n:47) were women with an average age of 27.9±6.1 years and a length of disease of 12.3±6.5 years. 69 patients completed 7-year study. After the follow up period, 31.8% presented development/progression of retinopathy, 10.14% developed microalbuminuria and 7.24% of the normotensive patients progressed to established hypertension. Initial nocturnal DBP greater than 65 mmHg showed as a risk factor for the progression of retinopathy and the development of hypertension after 7 years. In spite of the association between the nocturnal SBP and development of microalbuminuria, we did not detect a cut off point from which a significant risk appeared.
Conclusions
In clinically normotensive and normoalbuminuric patients with type 1 diabetes, a nocturnal DBP greater or equal to 65 mmHg is related to the development/progression of retinopathy and the development of established hypertension.

Evaluation of cardiovascular risk factors in long-term survivors of brain tumours who received cranial irradiation

Nikolaos Kyriakakis[1], Satish S. Kumar[1], Julie Lynch[1], Ramzi Ajjan[2], Adam Glaser[3], Georgina Gerrard[4], Carmel Loughrey[4] & Robert D. Murray[1]
[1]Leeds Centre for Diabetes and Endocrinology, St James's University Hospital, Leeds Teaching Hospitals NHS Trust, Leeds, UK; [2]Division of Cardiovascular and Diabetes Research, Leeds Institute of Cardiovascular and Metabolic Medicine (LICAMM), University of Leeds, Leeds, UK; [3]Paediatric Haematology and Oncology, Leeds Teaching Hospitals NHS Trust, Leeds, UK; [4]Clinical Oncology, St James's University Hospital, Leeds Teaching Hospitals NHS Trust, Leeds, UK.

Introduction
There is strong evidence that adult survivors of childhood cancer have excess premature vascular morbidity and mortality, the pathophysiological mechanism of which remains unresolved.
Methods
We undertook a cross sectional study to assess cardiovascular risk in long-term survivors of brain tumours following cranial irradiation compared with healthy matched controls. The following cardiovascular markers were measured: full lipid profile, fasting glucose and parameters of body composition. Basal anterior pituitary hormone profile and dynamic pituitary tests (ITT or GST) were also undertaken in the patient group.
Results
36 patients (mean age 30.9 ± 13.9 years) and 36 controls (mean age 31.5 ± 13.4 years) were assessed. Evidence of hypopituitarism was present in 91.2% of patients (severe GHD 64.7%, partial GHD 26.5%, LH/FSH deficiency 17.6%, severe ACTH deficiency 8.8%). No significant difference was found in the TSH ($P = 0.2$) and free T_4 ($P = 0.4$) values between patients and controls. Total and LDL-cholesterol were significantly higher in patients compared with controls (5.3 ± 1.1 mmol/l vs 4.6 ± 1.0 mmol/l, $P = 0.007$ and 3.1 ± 0.8 mmol/l vs 2.7 ± 0.9 mmol/l, $P = 0.011$ respectively). Body composition analysis showed patients had significantly elevated waist circumference (93.9 ± 15.6 cm vs 80.3 ± 10.9 cm, $P < 0.001$), waist-hip ratio (0.88 ± 0.08 vs 0.82 ± 0.08, $P < 0.001$), fat mass (FM) and FM% (24.0 ± 12.2 kg vs 15.7 ± 6.6 kg, $P = 0.003$ and 29.6 ± 9.7% vs 22.1 ± 8.3%, $P < 0.001$), truncal FM and truncal FM% (13.0 ± 6.7 kg vs 8.2 ± 3.7 kg, $P = 0.004$ and 29.4 ± 10.0% vs 21.0 ± 8.1%, $P < 0.001$) and summative (suprailiac, infrascapular, biceps, triceps) skinfold thickness (75.7 ± 32.3 mm vs 42.5 ± 16.4 mm, $P < 0.001$) when compared with controls. No differences were found in the HDL, triglycerides, glucose, BMI and lean body mass between the two comparison groups.
Conclusion
Our results show that cancer survivors following cranial irradiation demonstrate an adverse lipid and body composition profile, which may contribute to the increased cardiovascular risk of these patients. The high prevalence of hypopituitarism in the patient group may explain at least partially the alterations observed in the cardiovascular risk markers.

Cardiovascular complications in type 1 diabetic patients

Ines Barka, Ines Slim, Nesrine Cheikhrouhou, Koussay Ach, Yosra Hasni, Amel Maaroufi, Maha Kacem, Molka Chaieb & Larbi Chaieb
Department of Endocrinology, Sousse, Tunisia.

Background
Although the issue of cardiovascular complications in type 2 diabetic patients is widely discussed and recommendations for such screening are known, it is less common to do so for type 1 diabetes mellitus (T1DM). Unfortunately, the mortality rate due to vascular complications is higher among type 1 diabetic patients than in the general population.
Patients and methods
Seventy-six patients with T1DM history over 20 years were included in our study. We analysed the occurrence of cardiovascular complications and their risk factors: BMI, HbA1c, lipid profile, hypertension, smoking, alcohol consumption and family history of cardiovascular diseases and diabetes
Results
A total of 76 patients were enrolled: 43 men and 33 women, the mean age and the mean diabetes duration was 39.9 years ±9.5 (24–61 years) and 28.18 ± 5.9 years respectively. The HbA1c was 10.26 ± 1.76%. Smoking was present in 23.7% of our patients;hypertension was associated in 25.3 ± 4,3% and dyslipidaemia in 11.3 ± 3.18% The frequency of chronic diabetic complications was as follows: diabetic retinopathy = 75%,peripheral polyneuropathy = 55.3% and nephropathy = 28.9%. 9/76 patients had cardiovascular complications: among this group eight patients were smoker, seven had a family history of diabetes mellitus and six without nephropathy. Proven stroke was diagnosed in six patients with over 20 years of T1DM history, coronary disease and peripheral arteriopathy were present in three and two patients respectively.
Conclusion
Beyond 20 years of diabetes history, cardiovascular complications dominate the prognosis.

Lipocalin-2 regulates cardiomyocyte autophagy to control apoptosis and insulin sensitivity: importance in heart failure

Hyekyoung Sung, Yee Kwan Chan & Gary Sweeney
York University, Toronto, Canada.

Lipocalin 2 has become an important biomarker for kidney disease and it is important to now understand it's role in cardiomyopathy and understand it's direct effects on the heart. Autophagy is now established as a critical determinant of cardiac function and here we investigated regulation of cardiac autophagy by lipocalin-2 and the functional consequences. After treating H9c2 cells with lipocalin-2 we used transmission electron microscopy, Western blotting and immunofluorescence for LC3-II, tandem fluorescent LC3 overexpression and MagicRed assay for lysosomal cathepsin activity to show that lipocalin-2 reduced autophagic flux. Lipocalin-2 also reduced oxidative stress in response to hypoxia. This correlated with reduced insulin sensitivity which was reversed when rapamycin was used to stimulate autophagy. We also observed that lipocalin-2 induced cardiomyocyte apoptosis. Mechanistically, we have shown that lipocalin-2 increased intracellular iron levels to mediate pro-apoptotic effects. We translated these studies to animal models by performing coronary artery ligation surgery to induce ischemia in wildtype and lipocalin-2 knockout mice. Our preliminary data indictaes that ischemia-induced caspase-3 and -12 activity was exaggerated in lipocalin-2 knockout versus wildtype. In summary, lipocalin-2 regulates cardiomyocyte autophagy, oxidative stress, apoptosis and insulin sensitivity and the exact physiological significance of these cardiac remodeling effects must now be determined.

Vascular and cardiac function in young adults with classical congenital adrenal hyperplasia

Joanna Wierzbicka-Chmiel[1], Artur Chmiel[2], Dariusz Kajdaniuk[1,3] & Bogdan Marek[1,3]
[1]Department of Endocrinology and Diabetology, Rybnik, Silesia, Poland; [2]Department of Cardiology, Rybnik, Silesia, Poland; [3]Division of Pathophysiology, Department of Pathophysiology and Endocrinology, Silesian Medical University, Zabrze, Poland.

Background
The patients with classical congenital adrenal hyperplasia (CAH) have increased cardiovascular risk due to the lifelong glucocorticoid therapy and the disease per se.
Objective
To evaluate vascular and cardiac function in adults with CAH during optimal corticosteroid and fludrocortisone replacement therapy.
Patients and methods
Cross-sectional study of 19 adults with CAH (age 23.7 years ±3.8; males 63%) compared to 21 healthy voluntaries (age 23.2 years ±2.6; males 60%) matching to the age and BMI. All of the participants had assessed the flow mediated

dilatation of the brachial artery (FMD), the intima-media thickness of the common carotid artery (CIMT), the intima-media thickness of the common femoral artery (FIMT), the left ventricular ejection fraction (LVEF%), left ventricular mass index (LVMI) and longitudinal left ventricular function using two-dimensional speckle-tracking echocardiography (LSTE). Classical cardiovascular risk factors and hormones status were also measured.
Results
The patients with CAH compared with controls have decreased FMD (mean FMD% 9.4, 95% CI: 7.2–11.6 vs mean 19.8, 95% CI: 17.7–21.9; $P<0.01$) and the difference was still significant after correction for potential confounders such as: brachial artery diameter, age, sex, the dose of corticosteroid and fludrocortisone (mean FMD% after correction 9.2, 95% CI: 4.2–14.3 vs 20.0, 95% CI: 15.2–24.9; $P=0.02$). The CIMT and FIMT was higher in the CAH group baseline (for CIMT mean 0.47 mm, 95% CI: 0.46–0.49 vs mean 0.40 mm, 95% CI: 0.38–0.42; $P<0,001$, for FIMT mean 0.47 mm, 95% CI: 0.45–0.48 vs mean 0.41 mm 95% CI: 0.38–0.42; $P<0.001$) but not after correction for potential confounders such as: age, sex, the dose of corticosteroid and fludrocortisone, total cholesterol level, smoking status (for CIMT $P=0.44$, for FIMT $P=0.12$). The CAH subjects compared with controls have normal and similar LVEF%, LVMI. The mean absolute value of LSTE differs in the CAH patients compared with controls (20.9%, 95% CI: 20.2–21.6 vs 21.9%, 95% CI: 21.2–22.5; $P=0.03$).
Conclusions
Young adults with CAH have impaired endothelial function but the increased of IMT may be related to hormones supplementation. In addition patients with CAH have impaired left ventricular function in two-dimensional speckle-tracking echocardiography.

Retinoic acid increases glucocorticoid receptor phosphorylation via cyclin-dependent kinase 5

Hélène Roumes[1], Julie Brossaud[1,2], Aloïs Lemelletier[1], Marie-Pierre Moisan[1], Véronique Pallet[1], Anabelle Redonnet[1] & Jean-Benoît Corcuff[1,2]
[1]UMR1286 INRA Univ Bordeaux, Bordeaux, France; [2]University hospital, Bordeaux, France.

Background
According to the literature, glucocorticoid receptor (GR) function is modulated by phosphorylation. Retinoic acid (RA) can activate some cytoplasmic kinases able to phosphorylate GR.
Aim
As RA and glucocorticoids interact in neuronal cells, we investigated whether RA could modulate GR phosphorylation in such cells.
Methods
HT-22 hippocampal cells were cultured 4d with or without dexamethasone (Dex, 10-6 M) or RA (10-6 M). Western blots were either performed on total cell extracts or cytosolic and nuclear fractions.
Results
Indeed, a 4 d treatment by RA decreased the nuclear expression of GR phosphorylated on Serine 220 (pSer220GR). Conversely, RA increased Dex-dependent nuclear pSer220GR expression in HT22 cells. This treatment by RA had no effect on cyclin-dependent kinase 5 (CDK5) expression but increased the expression of p35 a major CDK5 cofactor. In the nucleus, roscovitine, a CDK5 inhibitor, suppressed the RA-dependent increase of the Dex-induced pSer220GR expression. Furthermore, roscovitine altered RA-dependent decrease of GR-induced transcriptional activity when using either a reporter gene with GR response elements or GR sensitive genes such as BDNF or tissue transglutaminase.
Conclusion
This study demonstrates that RA modulates GC signalling by increasing Ser220GR phosphorylation through at least a modulation of CDK5/p35 activity with an increase of cytoplasmic p35/p25 ratio. This study supports the idea that GR phosphorylation depends on the cellular environment aside from the presence of GR ligands.

Glp-1 regulates the reproductive function and synchronizes the onset of the puberty in female rats

Veronica Outeiriño Iglesias[1,2], Marina Romaní Perez[3], Juan Fandiño Gómez[1,2], Lucas Carmelo González Matías[1,2], Federico Mallo Ferrer[1,2] & Eva María Vigo Gago[1,2]
[1]Faculty of Biology. University of Vigo, Vigo (Pontevedra), Spain; [2]Group of Endocrinology and Neurophysiology, Biomedical Research Center (Cinbio), University of Vigo, Vigo (Pontevedra), Spain; [3]Nutrineuro, Universitè of Bordeaux, Inra, Bordeaux (Aquitaine), France.

GLP-1 is a gut hormones with insulinotropic effects. GLP-1 is expressed at the hypothalamus having regulatory functions in food intake and neuroendocrine corticoadrenal axis (HPA). Energy balance and HPA have deep influence in the gonadal function of mammals. Exendin-4 (Ex4) is a potent agonist for the GLP-1 receptor.
Objectives
To evaluate the effects of native GLP-1 (7–36)-NH2(GLP-1) and Ex4 in the function of the reproductive system in adulthood and onset of puberty in female rats.
Methods
Adult female rats were *i*cv injected with a single dose of GLP-1/Ex4 or vehicle (Veh) in the morning of proestrous. Blood samples were taken by jugular venipuncture at different stages of the subsequent estrous cycle. Ovaries were isolated for histological studies. Another group of females was housed with males for mating that confirmed by sperm-positive vaginal plug. The dams were sacrificed by decapitation after delivery, and number of undelivered but implanted fetuses and neonates born were counted and weighed. Prepubertal rats were treatment with GLP-1/Ex4/Veh and monitoring of body weight, intake, vaginal opening (VO) and hormone levels was done.
Results
GLP-1 administration in the morning of proestrus doubled the amplitude of preovulatory LH surge and modified the estradiol and progesterone levels along the estrous cycle. That promoted a marked increase in number of Graafian follicles and corpora lutea, and consequently in litter size. Conversely, Ex4 produced a partial blockade of preovulatory LH surge, yet not affecting the number of mature follicles or corpora lutea. Administration of low doses of GLP-1 to pre-pubertal rats synchronized vaginal opening and increased LH levels. By contrast, chronic exposure to Exendin-4 produced a significant reduction in LH and complete blockade of puberty onset.
Conclusions
GLP-1 increases the preovulatory surge of gonadotropins and ovulation rate in adulthood and synchronise the onset of puberty. These effects were not reproduced by Ex4.

Background
The mechanisms underlying the association between severe hypoglycaemia and increased cardiovascular mortality among patients with diabetes mellitus are not

fully understood. Our aim was to evaluate changes in GH/IGF1 axis during insulin-induced hypoglycaemia, as a possible link.
Methods
Twenty-five healthy subjects, 12 obese participants (OP; 6/ 6; 34.4 ± 1.7 kg/m^2), and 13 healthy lean participants (LP; 6/ 7; 21.7 ± 0.6 kg/m^2) were studied using insulin tolerance test and changes in GH, total IGF1, IGF binding proteins (IGFBPs) and IGF1 bioactivity, measured by the cell-based KIRA method, were investigated. Moreover, the effect of insulin on mRNA expression of parts of the GH/IGF1 system was further studied in mouse primary hepatocytes.
Results
Under hypoglycaemic conditions, insulin significantly increased IGFBP2 and decreased IGF1 bioactivity in both groups ($P < 0.01$). This was followed by a surge in GH ($P < 0.01$). As expected, insulin decreased IGFBP1 levels, whereas no changes in total IGF1 and IGFBP3 levels were observed. *In vitro*, insulin stimulation of primary hepatocytes lead to a decrease of IGFBP1 and IGFBP3 and increase of IGFBP2 mRNA expression.
Conclusion
The insulin-induced hypoglycaemia is associated with a decrease in IGF1 bioactivity through up-regulation of IGFBP2. Our results point to a possible and previously poorly explored mechanism explaining the strong association between hypoglycaemia and increased cardiovascular mortality among diabetic patients.

Copeptin reflects thermal strain during exercise in a hot environment
Mike Stacey[1,2], David Woods[2,3], Stephen Brett[1,4], Simon Delves[5], Sophie Britland Britland[5], Joanna Fallowfield[5] & Adrian Allsopp[5]
[1]Imperial College, London, UK, [2]Royal Centre for Defence Medicine, Birmingham, UK; [3]Carnegie Faculty Leeds Beckett University, Leeds, UK; [4]Hammersmith Hospital, London, UK, [5]Institute of Naval Medicine, Alverstoke, Hants, UK.

Background
Exertional heat illness (EHI) is an incapacitating and sometimes fatal phenomenon. It is associated with elevated core temperature (Tc), cardiovascular instability and the systemic inflammatory response syndrome. EHI-preventive guidelines recommend maintaining Tc ≤38 °C, an important thermoregulatory threshold above which vasomotor compensation plateaus and pronounced excursions in key pituitary and adrenal hormones occur. Copeptin, the C-terminal part of the vasopressin (AVP) precursor peptide, can be assayed as a surrogate for AVP. Copeptin shows prognostic potential in a range of inflammatory and cardiovascular conditions but its relationship with Tc has not been characterised.
Objective
To investigate the serum copeptin response to Tc changes during exercise in a hot environment.
Methods
15 subjects from a British Army infantry battalion were studied on their sixth day in Kenya during a 4.5 h simulated combat assault exercise. Tc was recorded by telemetry from ingested pills every 60 s during the exercise. Serum copeptin was assayed pre- and post-exercise.
Results
Tc increased in 15/15 subjects. Average Tc (TcAv) was 37.36 ± 0.21 °C. Change in plasma copeptin concentration (Δcopeptin) was positive in 13/15 subjects. Mean Δcopeptin was 6.67 ± 5.83 pmol/l ($P = 0.0006$). In eight subjects with maximum Tc (TcMax) >38 °C, mean Δcopeptin was more than 400% greater than for the seven subjects with TcMax <38 °C (10.40 ± 4.34 pmol/l vs 2.40 ± 4.2 pmol/l; $P = 0.0059$). There was a strong positive correlation between TcAv and Δcopeptin ($r = 0.75$, $P < 0.01$).
Conclusions
Copeptin stratified military subjects relative to the critical thermal threshold of 38 °C. Copeptin may be a plausible biomarker of thermal strain and EHI risk in both military and civilian populations.

GP.17.05

Hypernatremia and copeptin levels in the elderly hospitalised patient
Gabriel Munter[1,2], Michal Liber[1,2] & Moshe Sonnenblick[1,2]
[1]Shaare Zedek Medical Center, Jerusalem, Israel; [2]Hadassah Medical School-Hebrew University, Jerusalem, Israel.

Introduction/objective
Elderly patients have a higher prevalence of hypernatremia. Previous studies suggested that impaired ADH secretion contributes to development of hypernatremia in the elderly. Copeptin is the C terminal part of the ADH precursor and is more stable in plasma than ADH. The aim of this study was to detect demographic and clinical characteristics of the elderly hypernatremic patient hospitalized in the internal medicine ward, and to increase the understanding of the role of ADH secretion in the pathogenesis of hypernatremia.
Design
Case–control study.
Setting
Internal Medicine ward in a University affiliated hospital.
Participants
/33 hypernatremic patients (admission sodium >150 meq/l, age >70) compared to 34 normonatremic patients.
Measurements
Demographic, functional and clinical data (APACHE II score) were collected at admission. Serum copeptin levels were obtained 48 hours from admission. Mortality and change in the functional status were followed up to 30 days after discharge.
Results
Patients with hypernatremia presented with significantly lower baseline functional and cognitive states and higher APACHE II score (21.3 ± 8.6 vs 15.4 ± 6.7, $P < 0.01$). Dementia was present in 97% of the hypernatremic patients compared to 46% of the control group ($P < 0.001$). Mortality within 30 days of discharge was higher in the hypernatremic group (58% vs 32%, $P < 0.05$). Higher Copeptin levels were found in the hypernatremic group compared to the normonatremic group (100.2 ± 60.6 pmol/l v. 66.5 ± 57.2 pmol/l, $P < 0.05$). High levels of Copeptin were associated with higher in hospital ($P < 0.05$) and 30 days mortality ($P < 0.01$). Sodium levels were found to correlate with Copeptin levels; yet, an even stronger correlation was demonstrated between Copeptin levels and Apache II score ($r = 0.52$, $P < 0.001$).
Conclusions
Hypernatremia in the elderly at admission is associated with a high rate of mortality. Copeptin is appropriately secreted by the elderly patient with dementia and seems to be a good single disease severity marker.

Predictors of response to fluid restriction in hyponatremic patients due to the syndrome of inappropriate antidiuresis
Sophia Lengsfeld[1,3], Bettina Winzeler[1,4], Nicole Nigro[1,4], Isabelle Suter-Widmer[1,4], Philipp Schütz[2,4], Birsen Arici[1,4], Martina Bally[2,4], Claudine Blum[2,4], Andreas Bock[4,5], Andreas Huber[2,6], Beat Müller[2,4] & Mirjam Christ-Crain[1,4]
[1]Division of Endocrinology, Diabetes and Metabolism, Department of Internal Medicine, University Hospital Basel, Basel, Switzerland; [2]Medical University Clinic, Division of Endocrinology, Diabetology and Metabolism, Kantonsspital Aarau, Aarau, Switzerland; [3]Division of Emergency Medicine, Department of Internal Medicine, University Hospital Basel, Basel, Switzerland; [4]Department of Clinical Research, University Hospital Basel, Basel, Switzerland; [5]Division of Nephrology, Dialysis and Transplantation, Department of Internal Medicine, Kantonsspital Aarau, Aarau, Switzerland; [6]Institute of Laboratory Medicine, Kantonsspital Aarau, Aarau, Switzerland.

Introduction
Fluid restriction (FR) is often the recommended first-line treatment for hyponatremia due to the syndrome of inappropriate antidiuresis (SIAD). However, FR not always leads to successful correction of hyponatremia, making predictive markers of treatment response desirable. The aim of this study was to

evaluate routinely measured laboratory parameters, copeptin and pro-atrial natriuretic peptide (pro-ANP) as possible predictors of treatment success to FR.
Methods and design
We analysed 106 patients with SIAD out of 298 prospectively observed patients with profound hyponatremia (serum sodium <125 mmol/l). 82/106 patients with SIAD were initially treated with FR and included in this study. FR was defined as a total daily intake of <1000 ml. According to the change from baseline to follow-up serum sodium (within 24 h), we classified patients into FR responders (increase of >3 mmol/l) or FR non-responders (≤ 3 mmol/l). We performed regression models to look for correlations between different urine and serum parameters and treatment response.
Results
Of the 82 patients (mean age 67.6 years, 64.6% females) 48 (58.5%) responded to the initial trial of FR. Both baseline levels of urinary sodium and u-osmolality showed a significant correlation with treatment response (P for interaction $=0.004$ and $P=0.041$ respectively), whereat high levels indicate a FR failure. Initial serum sodium did not predict response to FR ($P=0.26$). Similarly, levels of copeptin – a surrogate marker of arginine vasopressin (AVP) – did not reveal a significant correlation with treatment success ($P=0.68$). Finally, we found a predictive value of pro-ANP; the higher pro-ANP levels the greater the likelihood of a positive response (P for interaction $=0.004$).
Conclusion
Easy measured urinary parameters and pro-ANP correlate with therapeutic success of fluid restriction and may enhance the management of patients with hyponatremia due to SIAD.

Heterogenous patterns of recovery from adipsic diabetes insipidus in adult patients

Martin Cuesta Hernandez, Rosemary Dineen, Saket Gupta, Ridhwaan Salehmohamed & Christopher Thompson
Academic Department of Endocrinology, Beaumont Hospital, Dublin, Ireland.

Introduction
The natural history of adipsic diabetes insipidus (ADI) is not completely understood. Isolated case reports suggest occasional recovery of adipsia. We present the follow up of a cohort of 12 patients with ADI.
Setting
National pituitary unit with interest in diabetes insipidus.
Methods
ADI was identified by demonstrating absent thirst and AVP responses to hypertonic saline infusion. Results 12 patients with ADI were identified (fivecraniopharyngioma, four ACOM aneurysm repair, one congenital, one neurosarcoidosis, and one prolactinoma). Three patients died. Six patients had permanent adipsic diabetes insipidus. Three patients had recovery of thirst, with a heterogenous pattern of recovery.
Case 1: A 41-year-old female with an intrasellar craniopharyngioma developed postoperative ADI with persistent hypernatremia (147–172 mmol/l). Two years postoperatively, she complained of thirst, and hypertonic saline infusion showed normal thirst but absent AVP responses, confirming recovery of thirst with persistent DI.
Case 2: A 29-year-old Caucasian had craniotomy and radiotherapy for craniopharyngioma which had previously presented with chronic headache and bitemporal hemianopia and developed ADI postoperatively. Eight years post-op, she presented with thirst, seizures and pNa of 112 mmol/l. Hypertonic saline infusion showed persistent DI but thirst responses typical of compulsive water drinking; she has had recurrent hyponatraemia since then.
Case 3: A 51-year-old gentleman developed ADI after clipping of an ACOM aneurysm and was treated with desmopressin and sliding fluid scale. 10 years post surgery; he sensed the return of thirst; repeated hypertonic saline infusion showed recovery of both thirst and AVP secretion. He is asymptomatic off desmopressin.
Conclusion
We report that three out of 12 patients with ADI recovered thirst after longstanding adipsia. The pattern of recovery was heterogenous and included complete recovery of ADI, recovery of adipsia only and conversion of adipsia to polydipsia. Both the mortality of 25% and the recovery rate of 25% should be considered during long-term surveillance.

A study of hyponatraemia in acute medical admissions

Heidy Hendra[1], Fiona Graham[1], Christine Catley[1], Tatjana Boitsova[1], Tamer Rezk[1], Suki Sankaralingam[2] & Sumith Abeygunasekara[1]
[1]Renal Unit, Chelmsford, Essex, UK; [2]Clinical Chemistry, Chelmford, Essex, UK.

Introduction
Hyponatraemia is the commonest electrolyte disorder in clinical practice and is closely associated with increased morbidity, mortality and length of hospital stay. It can be classified into mild (124–134 mmol/l), moderate (115–124 mmol/l), and severe (<115 mmol/l). The aim of the study was to determine the prevalence, aetiology, and management of hyponatraemia in general hospital.
Methods
A total of 4139 acute medical admissions were studied. Hyponatraemia was found in 536 patients with 441 being mild, 86 moderate and nine severe; 130 cases were analysed further in details.
Results
Out of 130 cases; 86 were of mild (66%), 42 moderate (32%), and one severe hyponatraemia (0.8%). The mean age was 75.1 years (17–99) and there is equal male to female ratio. The cause of hyponatraemia was only identified in 68% with diuretics accounting for 41 (46%), Syndrome of Inappropriate ADH Secretion (SIADH) for 36 (40%) and fluid overload for 12 (9%) of cases. The treatment of hyponatraemia included intravenous fluid resuscitation in 52, cessation of diuretics in 43 and fluid restriction in 48 of cases. One subject with severe hyponatraemia received demeclocycline, none of the subjects received hypertonic saline or Vasopressin receptor antagonist. While the average length of stay for all medical admissions was 4 days, the average length of stay is 17.1 days (2–70) in those with hyponatraemia.
Conclusion
Hyponatraemia, which presents in 12.9% of our admissions, is associated with significantly prolonged hospital length of stay. The use of diuretics and SIADH were the main cause of hyponatraemia in our cohort. Our study highlighted the challenge in the diagnosis as evidenced by 32% of patients in whom diagnosis was not reached. A trust guideline has been developed as a response to this issue.

The dopastatin BIM-23A760 distinctly influences key functional endpoints in different types of pituitary adenomas and normal pituitaries: role of somatostatin and dopamine receptor profile

[1]Department of Cell Biology, Physiology and Immunology, Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Hospital Universitario Reina Sofia, CIBER Fisiopatolo, University of Cordoba, Córdoba, Spain; [2]Research Unit, Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Hospital Universitario Reina Sofia, University of Cordoba, Córdoba, Spain; [3]Service of Endocrinology and Nutrition, Hospital Universitario Reina Sofia, Instituto Maimónides de Investigación Biomédica de Córdoba, Córdoba, Spain; [4]Service of Neurosurgery, Hospital Universitario Reina Sofia, Córdoba, Spain; [5]Metabolism and Nutrition Unit, Instituto de Biomedicina de Sevilla (IBIS), Hospital Universitario Virgen del Rocío, Sevilla, Spain; [6]Department of Morphological Sciences, University of Cordoba, Córdoba, Spain; [7]Endocrinology and Nutrition Unit, Complejo Hospitalario de Jaén, Jaén, Spain; [8]Service of Endocrinology and Nutrition, Hospital Clínico Universitario Virgen de la Victoria, Málaga, Spain; [9]Department of Pathology, Hospital Universitario Virgen del Rocío, Sevilla, Spain; [10]Department of Endocrinology and Nutrition, Carlos Haya Hospital, Málaga, Spain; [11]Department of Endocrinology, Centre for Biomedical Research on Rare Diseases (Centro de Investigación Biomédica en Red de Enfermedades Raras Unit 747), Hospital Sant Pau, Autonomous University of Barcelona, Barcelona, Spain; [12]Research and Development Division, Department of Medicine, Jesse Brown Veterans Affairs Medical Center, University of Illinois at Chicago, Chicago, Illinois, USA; [13]IPSEN Bioscience, Cambridge, Massachusetts, USA.

Chimeric somatostatin (SST)/dopamine (DA) compounds, termed dopastatins, such as BIM-23A760, an agonist for SST (sst2 and ss5) and DA (D2) receptors, are emerging as promising new approaches to treat pituitary adenomas. However, their actions and mechanisms on the different types of pituitary tumours are still incompletely understood. Thus, the aim of this study was to analyse a set of key functional parameters (signaling pathways, hormonal expression and secretion, cell viability, and apoptosis), in response to BIM-23A760 in a series of 74 human pituitary tumors: 22 somatotropinomas, five mixed GH/PRL-secreting adenomas, 11 corticotropinomas, 26 NFPAs, six prolactinomas, one FSH-secreting gonadotropinoma and three TSH-omas; and in five normal human pituitaries and pituitary samples derived from three female olive baboons (*Papio anubis*). Although, BIM-23A760 has recently been withdrawn from clinical development after finding that a dopaminergic metabolite accumulates and interferes with the activity of the parent compound *in vivo*, it is still considered a good prototype molecule for dopastatins, and the results generated herein might be indeed useful in understanding and predicting the response to this type of compounds, which may be used for clinical purposes in the future. Our results demonstrate that BIM-23A760 differentially impacted all functional parameters analysed, with most responses being clearly inhibitory for cell signalling, hormone secretion and cell survival. Yet, interestingly, certain pituitary adenomas displayed distinct, even opposite responses to BIM-23A760 (i.e. paradoxical stimulatory responses), which were associated with the relative expression levels of SST- and DA-receptors. In particular, alterations on the expression of sst5 and its truncated variant, sst5TMD4, might represent potential molecular signatures contributing to the differential, inhibitory/stimulatory response to BIM-23A760 in GH- and ACTH-secreting adenomas. Altogether, our results reinforce the notion that chimeric dopastatins (e.g. BIM-23A760) can affect multiple, clinically relevant parameters on most types of pituitary adenomas and may represent new therapeutic tools to treat pituitary tumours, wherein the relative SST/DA receptor expression profile might provide useful molecular markers to predict the ultimate response of these tumours to BIM-23A760.

Chronic stress decreases circulating endocannabinoid 2-arachidonoylglycerol in healthy human subjects

Buqing Yi[1], Igor Nichiporuk[2], Matthias Feuerecker[1], Gustav Schelling[1] & Alexander Choukèr[1]
[1]Hospital of the University of Munich (LMU), Munich, Germany; [2]Institute for Biomedical Problems, Moscow, Russia.

Increasing evidence indicates chronic stress plays an important role in a variety of health problems such as the development of autoimmune disease, and the results from mice studies suggest that the central endocannabinoid (eCB) system regulates endocrine and neuronal responses to stress. However, it is unclear how the eCB system responds to chronic stress in healthy humans. A 520-day isolation-and-confinement study simulating an interplanetary spaceflight mission to Mars provided an extraordinary chance to study the effects of chronic stress imposed by prolonged isolation. Six healthy males participated in this mission and stayed in the simulated spacecraft for 520 days. The current study aimed to investigate the effects of chronic stress on circulating concentrations of eCBs in these healthy subjects. Blood samples for eCBs measurements were obtained before and at regular intervals during the isolation period. Salivary samples were taken for cortisol assay. 24 h urine samples were collected for catecholamines measurements. Blood concentrations of the eCBs, N-arachidonylethanolamine (anandamide, AEA) and 2-arachidonoylglycerol (2-AG), were determined. Compared with the baseline level, stress hormone cortisol levels and urine norepinephrine secretions were significantly increased during the isolation period, indicating a stressed condition. Interestingly, stress decreased blood concentrations of 2-AG, but not AEA. Furthermore, 2-AG concentrations were negatively correlated with salivary cortisol levels. These results indicate that chronic stress decreases circulating 2-AG in healthy human subjects, suggesting dysregulation of 2-AG signalling is specifically implicated in humans under chronic stress.

Neuroactive steroids as predictive markers for Alzheimer's disease

Marketa Vankova[1], Daniela Vejrazkova[1], Petra Lukasova[1], Olga Bradnova[1], Gabriela Vacinova[1], Katerina Dvorakova[1], Martin Hill[1], Josef Vcelak[1], Robert Rusina[2], Iva Holmerova[3] & Bela Bendlova[1]
[1]Institute of Endocrinology, Prague, Czech Republic; [2]Thomayer Hospital, Prague, Czech Republic; [3]Faculty of Humanities, Charles University, Prague, Czech Republic.

Background and aims
Neuroactive steroids and their metabolites play an important regulatory role in the nervous system affecting the neuronal plasticity, stress response, learning, and memory. The aim of the study was to compare the steroid metabolome in AD patients and controls.
Materials and methods
The study comprised of 48 AD patients (30 women and 18 men; age 73.8±9.54 years) and 33 matched controls (22 women and 11 men; age 68.2±5.94 years). All subjects underwent neuropsychological examination and magnetic resonance imaging of the brain. Biochemical characterisation included examination of fasting glucose and lipid metabolism and the determination of extended spectrum of steroid hormones by GC–MS method (38 steroids and their sulfates). Statistical analyzes were performed using Statgraphics Centurion XVI 16.0.07 Software.
Results
AD patients had significantly higher insulin secretion (fasting insulin, HOMAF) and lower C peptide/insulin ratio compared to controls which indicates the decreased hepatic insulin extraction. AD patients had higher C21 steroids (5β-pregnane-3α, 20α-diol conjugate, women in addition pregnenolone, 16α-hydroxy-pregnenolone, 16a-hydroxy-progesterone, men in addition 16α-hydroxy-DHEA, and pregnanolone) and lower C19 steroids (5α-androstan-3β, 17β-diol conjugate, women in addition conjugates of androsterone, epiandrosterone, epietiocholanolon, and 5β-androstane-3β, 17β-diol) compared to controls. Neither in AD nor in controls a direct relationship of steroids with fasting glucose, insulin and HOMAR was found.
Conclusion
C21 steroid levels were consistently higher in AD, suggesting an increased activity of the zona fasciculata of adrenal gland. Conversely, levels of stable 5α/β reduced catabolites of C19 steroids, particularly their sulfates, are consistently reduced in AD (unlike insignificantly different unreduced androgenic precursors showing a diurnal variation). This indicates a decrease in the activity of the adrenal zona reticularis in AD. AD patients have higher levels of insulin in the periphery, however, the direct relationship between glucose tolerance and steroid metabolome was not confirmed.

Regulation of sexually dimorphic growth of murine skeletal muscle by Stat5a and Stat5b

Ryan Paul[1,2], Marianne Elston[1], John Conaglen[1] & Chris McMahon[2]
[1]Department of Medicine, Waikato Clinical School, University of Auckland, Hamilton, New Zealand; [2]AgResearch, Ruakura, New Zealand.

GH regulates IGF1 predominantly through the intracellular signallers Stat5a and Stat5b. Inactivating mutations of Stat5b in humans result in severe growth retardation and low circulating IGF1 concentrations in males and females. In mice, however, there is only a loss of sexually dimorphic growth in males when Stat5b is deleted. No study has observed Stat5b$^{-/-}$ mice beyond 12 weeks or investigated any subsequent changes in skeletal muscle mass or IGF1 expression. Blood and hindlimb muscles of male and female Stat5b$^{-/-}$ mice and WT littermates were collected at 6, 12, and 24 weeks of age ($n=16$/time and sex). Plasma IGF1 and IGF1 protein concentrations were determined by ELISA and muscle mass was normalised to bone length. C2C12 myoblast cell lines were treated with viral Stat5b siRNA and/or Stat5a siRNA or a scrambled vector (control), then differentiated and treated with GH (100 ng/ml) for 24 h. RNA was harvested for quantitative PCR. The treated cell lines were also treated for 96 h with GH (100 ng/ml) and differentiation was assessed by immunocytochemistry. Sexual dimorphism was reduced, but persisted in Stat5b$^{-/-}$ mice. Nasoanal length, tibia length and normalised hindlimb muscle mass were decreased to a greater extent in male (23%) than in female (14%) Stat5b$^{-/-}$ mice at all ages ($P<0.001$). Concentrations of IGF1 in plasma and skeletal muscle were significantly reduced in male Stat5b$^{-/-}$ mice at all ages and in female Stat5b$^{-/-}$ mice at 6 weeks. Stat5a knockdown inhibited myotube differentiation (36%) to a lesser extent than Stat5b or dual Stat5a/5b knockdown (80%) ($P<0.001$). Either Stat5a or Stat5b knockdown prevented the GH-induced myotube hypertrophy, but only Stat5a knockdown blocked the upregulation of IGF1 mRNA by GH. We conclude that both Stat5a and Stat5b have independent roles in GH signaling in murine skeletal muscle.

A small hypothalamic volume correlates with impaired cognitive outcome in childhood onset craniopharyngioma on long-term follow up

Sigridur Fjalldal[1], Cecilia Follin[1], Sanaz Gabery[2], Åsa Petersén[2], Lars Rylander[3], Bertil Ekman[4], Aki Johansson[5], Kai Österberg[3], Magdalena Jansson[5], Andrea Rovira[5] & Eva-Marie Erfurth[1]
[1]Department of Endocrinology, Skåne University Hospital, Lund, Sweden; [2]Translational Neuroendocrine Research Unit, Department of Experimental Medical Science, Lund University, Lund, Sweden; [3]Division of Occupational and Environmental Medicine, Lund University, Lund, Sweden; [4]Department of Medical and Health Sciences, Linköping University, Linköping, Sweden; [5]Institution of Psychology, Lund University, Lund, Sweden.

Background
Hypothalamic damage caused by craniopharyngioma (CP) is related to memory deficits, disturbed attention, and impaired processing speed. This is the first study that aims to establish a structure to function relationship by assessing cognitive function in adult patients with childhood-onset (CO) CP along with volumetric analysis of the hypothalamus.
Method
Forty-one (24 women) surgically treated CO-CP patients (median age at diagnosis; 11 years) from the South Medical Region of Sweden were included in the study. Eighteen patients had received cranial radiotherapy. Twenty-eight patients had panhypopituitarism, 35 were treated with ADH and 32 with GH. Time since first operation was 23 years (range 4–49) and median age at investigation was 35 years. Hypothalamic damage was found in 23 patients. All subjects were examined with a battery of cognitive tests and 35 patients underwent magnetic resonance imaging (MRI). A novel delineation procedure based on T1-weighted MRI and landmarks used in histologically processed postmortem hypothalamic tissue was used to estimate hypothalamic volume. Comparisons were made with 32 healthy matched controls.
Results
CP patients with hypothalamic damage ($n=23$) had lower cognitive performance pertaining to vocabulary ($P=0.02$) short term memory ($P=0.04$ and $P=0.01$), spatial ability ($P=0.02$), and executive functions ($P=0.01$ and $P=0.02$). A significantly positive correlation was found between the tests of vocabulary ($r=0.352$, $P=0.04$) and short term memory ($r=0.354$, $P=0.04$), ($r=0.357$, $P=0.04$) and hypothalamic volume.
Conclusion
Adults with hypothalamic damage due to CO-CP have impaired memory, spatial ability and executive function. Patients with smaller hypothalamic volume have worse cognitive outcome. To be able to preserve hypothalamic function we need tailored surgical and radiation strategies. Long-term follow up should include training programs pertaining to impaired cognitive function.

Presence and functional actions of In1-ghrelin splicing variant reveals a potentially relevant pathophysiological role in human pituitary adenomas

[1]Department of Cell Biology, Physiology and Immunology, Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Hospital Universitario Reina Sofia, University of Cordoba, CIBER Fisiopatolo, Córdoba, Spain; [2]IPSEN Bioscience, Cambridge, Massachusetts, USA; [3]Department of Pathology, Puerta del Mar University Hospital, Cádiz, Spain; [4]Service of Neurosurgery, Hospital Universitario Reina Sofia, Córdoba, Spain; [5]Department of Pathology, Hospital Universitario Virgen del Rocío, Sevilla, Spain; [6]Metabolism and Nutrition Unit, Instituto de Biomedicina de Sevilla (IBIS), Hospital Universitario Virgen del Rocío, Sevilla, Spain; [7]Service of Endocrinology and Nutrition, Instituto Maimónides de Investigación Biomédica de Córdoba, Hospital Universitario Reina Sofia, Córdoba, Spain; [8]Department of Endocrinology and Nutrition, Carlos Haya Hospital, Málaga, Spain; [9]Department of Physiology, University of Santiago de Compostela, CIBER Fisiopatología de la Obesidad y Nutrición, Santiago de Compostela, Spain.

Pituitary adenomas comprise a heterogeneous group of tumours causing serious comorbidities, which would benefit from identification of novel, common molecular/cellular biomarkers and therapeutic targets. The ghrelin system comprises a complex molecular family with multiple functions, and some of its components have been linked to development of various endocrine-related cancers. In this work we aim at better delineating the patho-physiological significance of the ghrelin regulatory system in pituitary tumours, by pursuing two specific objectives: i) to analyse the presence in pituitary tumours of key components of the ghrelin system: native-ghrelin, the recently discovered splicing variant In1-ghrelin, ghrelin receptors GHS-R1a (full-length) and GHS-R1b (truncated variant), and MBOAT4 (GOAT), the enzyme responsible for ghrelin acylation and ii) to compare the direct effects of native-ghrelin and In1-ghrelin variant administration on selected functional parameters in cell cultures derived from the main types of pituitary adenomas. To this end, we studied a large series of 180 pituitary samples: 76 somatotropinomas, 57 non-functioning pituitary adenomas, 29 corticotropinomas, seven prolactinomas, and 11 normal pituitary samples. The results obtained revealed that expression pattern of ghrelin system components undergoes a striking alteration in pituitary adenomas, as compared with normal pituitary, particularly In1-ghrelin, which was consistently over-expressed in all human pituitary adenoma subtypes. Interestingly, similar to that observed for native-ghrelin, In1-ghrelin was functionally active in cultured pituitary adenoma cells, as it increased GH and ACTH secretion, Ca^{2+} and ERK1/2 signalling, and cell viability, being the effects of In1-ghrelin variants generally greater than those evoked by native-ghrelin. Finally, overexpression of In1-ghrelin (by transfection using an specific expression plasmid) increased cell viability, while the use of a specific siRNA for this ghrelin variant reduced cell viability. Altogether, our results indicate that ghrelin system components are present and markedly altered in human pituitary tumours, where In1-ghrelin variant, particularly, could play a relevant functional role in the regulation of adenoma pathology, this paving the way for using In1-ghrelin variant as a new tool to explore novel diagnostic/prognostic biomarkers and/or therapeutic targets in these human tumours.

Comparison of high-throughput platforms in evaluation of whole genome miRNA expression profiles in pituitary tissues

Henriett Butz[1], Otto Darvasi[2], Peter M Szabo[1], Istvan Liko[2], Lorinc Pongor[2], Sandor Czirjak[3], Karoly Racz[1,4] & Attila Patocs[2]
[1]Molecular Medicine Research Group, Hungarian Academy of Sciences, Semmelweis University, Budapest, Hungary; [2]'Lendület' Hereditary Endocrine Tumors Research Group, Hungarian Academy of Sciences, Semmelweis University, Budapest, Hungary; [3]National Institute of Neurosurgery, Budapest, Hungary; [4]2nd Department of Medicine, Faculty of Medicine, Semmelweis University, Budapest, Hungary.

Introduction
There are three principal high-throughput methods that have been widely used to determine whole genome miRNAs expression profiles: i) microarrays, ii) qPCR based arrays, and iii) next generation sequencing (NGS). Our aim was to compare the results obtained from these platforms in normal and adenomatous pituitary samples and to validate the results by an independent sample set using qPCR.
Material and methods
Using four normal pituitary (NP) and eight non-functioning pituitary adenoma (NFPA) samples we determined miRNA expression profile by GeneChip microRNA Galaxy Array v1, SOLiD NGS and qPCR based TaqMan Low Density Array Card (TLDA). For biological confirmation expression of 22 miRNAs by individual TaqMan assays on additional 24 NFPAs and ten NPs was used as validation cohort.
Results
Totally 848 miRNAs of which only 162 were detected by all three approaches. Significant but not strong correlations between microarray and NGS (R^2: 0.471 and 0.220; $P<0.01$), microarray and TLDA (R^2: 0.462 and 0.339; $P<0.01$), and NGS and TLDA (R^2: 0.353 and 0.290; $P<0.01$) were detected in NFPAs and NPs respectively. Various bioinformatics, including commercially available software CLCbio, free, web based (Bowtie) and one our own algorithms were used in order to test whether the different evaluation of NGS data would affect the correlations. Correlations between different bioinformatical approaches were strong (R^2: 0.96–0.99) suggesting that these algorithms are useful and give similar results. Biological validation showed that 81% of TLDA results, and 72% of both microarray and NGS results could be validated regarding the direction of expression changes.
Conclusion
miRNA expression profiles measured by different platforms showed poor correlation and they were hardly comparable. Consequently, selection of screening method can influence experimental results obtained by analyses using high-throughput data (e.g. pathway analysis). However, individual miRNA expression from microarrays and NGS results were replicable in an acceptable percentage by qPCR.

The hypothyroidism alters circadian clock expression in anterior pituitary gland

Paula Bargi-Souza, Rodrigo A Peliciari-Garcia, Rafael Maso Prévide & Maria Tereza Nunes
Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil.

The anterior pituitary gland occupies a central position in the hypothalamus–pituitary glands axes and secretes hormones involved in reproduction, growth, and metabolism. The plasma concentrations of pituitary hormones present fluctuations during the 24 h and are markedly altered during the hypothyroidism. The presence of an intra-pituitary circadian oscillator might be related to these oscillations; however, the molecular mechanism and the consequences of the hypothyroidism are still unknown. The purpose of the present study was to investigate the expression of *Bmal1, Per2*, *Dbp*, *Nr1d1*, *Rora*, and *Dio2* in pituitary during the adult hypothyroidism. For this, euthyroid and thyroidectomized (Tx) male Wistar rats were euthanized during 24 h, every 6 h. The pituitaries were excised and the mRNA expression was evaluated by RT-qPCR. *Gapdh* and *Rpl19* were used as internal control. One and two-way ANOVA, as well as, cosinor analysis were used to evaluate the time-of-day-dependent differential expression for each gene/group and their interactions. The expression of *Bmal1*, *Per2*, *Dbp*, *Nr1d1*, *Rora*, and *Dio2* presented a circadian pattern in anterior pituitary of euthyroid rats and the peak of *Per2*, *Dpb*, *Rora*, and *Dio2* expression occurred at ZT 12, while for Bmal1 was ZT 0/24. In the hypothyroid animals, the circadian pattern of *Bmal1*, *Rora*, and *Dio2* was lost and the acrophase of *Per2*, *Dbp*, and *Nr1d1* was advanced about 2.5 h, 3 h, and 45 min respectively. Tx also reduced Mesor values of *Dbp* and *Nr1d1*. Our studies reveal that the expression of core clock and clock-controlled genes in anterior pituitary gland are changed during the hypothyroidism and might contribute directly or indirectly to the altered hormonal pattern of secretion observed in this pathological condition. Further studies are in progress to assess this issue.

Role of miR-375 in oncogenesis of pituitary adenomas

Laura Sanchez-Tejada[5], Ruth Sanchez-Ortiga[1], Pedro Riesgo[8], Javier Abarca[6], Carmen Fajardo[3], Irene Monjas[7], Rosa Cámara[4], Cristina Lamas[2] & Antonio Picó[1]
[1]Endocrinology Department, Hospital General Universitario Alicante, Alicante, Spain; [2]Endocrinology Department, Hospital General Universitario Albacete, Albacete, Spain; [3]Endocrinology Department, Hospital La Ribera, Alzira, Spain; [4]Endocrinology Department, Hospital Universitario La Fe, Valencia, Spain; [5]Research Unit, Hospital General Universitario Alicante, Alicante, Spain; [6]Neurosurgery Department, Hospital General Universitario Alicante, Alicante, Spain; [7]Otorhinolaryngology Department, Hospital General Universitario Alicante, Alicante, Spain; [8]Neurosurgery Department, Hospital La Ribera, Alzira, Spain.

Purpose
MicroRNAs (miRNAs) are a fundamental component of gene regulation mechanisms. Presently, altered miRNA patterns of expression have been documented in different human cancers, and they may explain the distinct behavior of pituitary adenomas (PA) and the differences between subtypes. miR-375 can target among other genes to IGF1 receptor (IGF1R) and participes in reprogramming cancer cell metabolism. The aim of this study was to assess the miR-375 role on pathogenesis of different PA subtypes.
Methods
In this cross-sectional descriptive study, we evaluated miR-375 by qRT-PCR analysis on 60 human PA samples: 29 gonadotrophs (GT), 15 somatotrophs (ST), eight functioning corticotroph (CT), and eight silent corticotroph adenomas (SCA). Nine healthy pituitary from autopsies were used as calibrator reference. Aggressiveness was graded according to invasiveness (Hardy's grade IV) and Ki-67 gene expression (>2.59 fold change (FC)).
Results
In our whole sample miR-375 was associated with sex (men: 3.00 (1.63–4.36) FC values vs women: 1.35 (0.47–1.92) FC values, $P=0.002$) and was positively correlated with age ($r=0.466$, $P=0.000$). miR-375 expression patterns differed depending on PA subtype ($P=0.000$) and non functioning PA (GT and SCA) revealed overexpression compared with functioning PA (CT and ST) (81.3 (26/37) vs 39.3 (11/23)), entailed a risk of 6.7 (2.1–21.5) times higher ($P=0.001$). Its expression was also correlated with tumor maximum diameter ($r=0.303$, $P=0.022$) and associated with their extension (intrasellar: 1.05 (0.47–1.47); extrasellar: 2.50 (1.47–4.39); and invasive: 2.50 (1.07–3.88); $P=0.008$). In addition, 66.7% tumors with high or medium aggressiveness grades overexpressed miR-375 vs 28.6% with low grade, which entailed a risk 5.0 (1.6–16.0) times higher ($P=0.005$).
Conclusion
Our results revealed a different role for miR-375 in the pathogenesis of PA depending on subtype. This miRNA may be a marker of aggressiveness, but further studies are needed for endorse this utility.

GP.18.09

Molecular classification of pituitary adenomas

Antonio Picó[1], Laura Sanchez-Tejada[5], Ruth Sanchez-Ortiga[1], Rosa Cámara[4], Cristina Lamas[2], Javier Abarca[6], Irene Monjas[7], Pedro Riesgo[8] & Carmen Fajardo[3]
[1]Endocrinology Department, Hospital General Universitario Alicante, Alicante, Spain; [2]Endocrinology Department, Hospital General Universitario Albacete, Albacete, Spain; [3]Endocrinology Department, Hospital La Ribera, Alzira, Spain; [4]Endocrinology Department, Hospital Universitario La Fe, Valencia, Spain; [5]Research Unit, Hospital General Universitario Alicante, Alicante, Spain; [6]Neurosurgery Department, Hospital General Universitario Alicante, Alicante, Spain; [7]Otorhinolaryngology Department, Hospital General Universitario Alicante, Alicante, Spain; [8]Neurosurgery Department, Hospital La Ribera, Alzira, Spain.

Purpose
The 2004 edition of the WHO text 'Histological typing of endocrine tumors' classified pituitary adenomas (PA) on the basis of their histological and immunohistochemical characteristics. Recent advances on the knowledge of the molecular patterns of these tumours may allow establishing a molecular classification with higher accuracy and specificity than previous one.
Methods
Within the pale of the multicenter Spanish Molecular Registry of Pituitary Adenomas (REMAH), a multicentre clinical-basic project, we had obtained the molecular phenotype of 172 PA. Expression levels of 26 genes were measured by qRT-PCR, including all pituitary hormones, receptors for somatostatin, dopamine, and others: GH-releasing hormone receptor, gonadotropin-releasing hormone receptor, type 1 corticotropin-releasing hormone receptor, arginine vasopressin receptor 1b and type 1 ghrelin receptor, and three housekeeping genes for normalization. Nine healthy pituitary from autopsies were used as calibrator reference.
Results
Based on the established clinical diagnosis (functioning PA (FPA: somatotroph, corticotroph, tirotroph, and lactotroph adenomas) and non-functioning PA (NFPA)) and immunohistochemical data, we have defined ranges of expression for all hormones and receptors with 25th and 75th percentiles for each subtype. NFPA and FPA presenting expression of several hormonal genes were subclassified depending on the dominant expression, establishing as 'gold standard' the p25 expression in the complete sample. On the basis of our study we have been able to define the following molecular classification: somatotroph (pure, mixed, and plurihormonal), functioning corticotroph, tirotroph, lactotroph, gonadotroph (FSHoma, LHoma, and mixed), null cell, and silent corticotroph adenomas with higher accuracy than the immunohistochemical previous classification.
Conclusion
Advances in the molecular knowledge of the pathogenesis of PA may allow a more specific classification of PA, especially in the case of NFPA, helping physicians to better manage these patients.

Coagulation parameters and platelet function analysis in patients with acromegaly

Hamiyet Yilmaz Yasar[1], Mustafa Demirpence[1], Ayfer Colak[1], Banu Ozturk Ceyhan[2], Yusuf Temel[1], Nese Simsek[1], Ismail Karademirci[1] & Umit Bozkurt[1]
[1]Tepecik Research and Training Hospital, Izmir, Turkey; [2]Aydin Medline Hospital, Izmir, Turkey.

Objective
Acromegaly is associated with increased cardiovascular morbidity and mortality. But the data about the evaluation of coagulation and fibrinolysis in acromegalic patients is very limited and to our knowledge, platelet function analysis has never been investigated. So we aimed to investigate the levels of protein C, protein S, fibrinogen, antithrombin 3, and platelet function analysis in patients with acromegaly.
Methods
Thirty-nine patients with active acromegaly and 35 healthy subjects were included in the study. Plasma glucose and lipid profile, fibrinojen levels, GH, and IGF1 levels and protein C, protein S, and antithrombin III activities were measured in all study subjects. Also, platelet function analysis was evaluated with collagen/ADP- and collagen–epinephrine-closure times.
Results
Demographic characteristics of the patient and the control were similar. As expected, fasting blood glucose levels and serum GH and IGF1 levels were significantly higher in the patient group compared with the control group (pglc: 0.002, pGH: 0.006, and pIGF1: 0.001 respectively). But lipid parameters were similar between the two groups. While serum fibrinogen and antithrombin III levels were found to be significantly higher in acromegaly group (pfibrinojen: 0.005 and pantithrombin III: 0.001), protein S and protein C activity values were signicantly lower in the patient group (protein S: 0.001 and protein C: 0.001). Also, significantly enhanced platelet function (measured by collagen/ADP- and collagen/epineprine-closure times) was demonstrated in acromegaly (pcol-ADP: 0.002 and pcolepineprine: 0.002). There was a negative correlation between serum GH levels and protein S (r: −0.25, P: 0.04) and protein C (r: −0.26, P: 0.04) values. Likewise, there was a negative correlation between IGF1 levels and protein C values (r: −0.39, P: 0.002), protein S values (r: −0,39, P: 0.001), collagen/ADP-closure times (r: −0.28, P: 0.02), and collagen/epineprine-closure times (r: −0.26, P: 0.04). Also we observed a positive correlation between IGF1 levels and fibrinogen levels (r: 0.31, P: 0.01).
Conclusion
Acromegaly was found to be associated with increased tendency to coagulation and enhanced platelet activity. However, with the treatment of IGF1 hypersecretion, these changes in haemostatic parameters could be possibly controlled.

Assessment of bone quality, measured by trabecular bone score, in acromegaly

Elena Malchiodi[1,2], Elisa Sala[1,2], Elisa Verrua[1], Elisa Cairoli[1,2], Giulia Carosi[1,2], Emanuele Ferrante[2], Marcello Filopanti[2], Fabio Massimo Ulivieri[3], Cristina Eller-Vainicher[2], Iacopo Chiodini[1,2], Giovanna Mantovani[1,2] & Anna Spada[1,2]
[1]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [2]Endocrinology and Diabetology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]Nuclear Medicine Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.

Introduction
Acromegaly is characterised by chronic exposure to high GH and IGF1 levels that leads to increased bone turnover. Regardless of BMD value, acromegalic patients seem to have an increased vertebral fracture risk probably due to a reduction of bone quality. Trabecular bone score (TBS) is a new index used for assessing bone microarchitecture. In this study TBS was used for the first time to analyze bone quality in acromegaly.
Methods
16 new acromegalic patients (12F, age 56.3±13.8, BMI 28.1±6.3) and 16 controls matched for age, gender, menopausal state, and BMI were enrolled. Patients with MEN1, ectopic GHRH secretion, and history of secondary osteoporosis were excluded. All participants underwent lumbar radiograph and dualenergy X-ray absorptiometry scan on lumbar spine (LS) and femur (total:FT and neck:FN). TBS was assessed in the region of LS-BMD.
Results
56% of patients had a macroadenoma, 18% had hypopituitarism (all hypoadrenalism), and nobody had cosecretion. BMDs were not different between the two groups (acromegalic patients vs controls: LS T-score −0.5±1.3 vs −0.7±1.0, P=0.7 and LS Z-score 0.5±1.3 vs 0.5±1.5, P=0.7; FN T-score −0.6±0.9 vs −0.7±1.2, P=0.8 and FN Z-score 0.3±0.7 vs 0.2±0.8, P=0.4; FT T-score 0.02±1.01 vs −0.5±0.99, P=0.2 and FT Z-score 0.64±0.84 vs 0.4±0.8, P=0.4) while acromegalic patients had lower TBS than controls (TBS Z-score −2.27±2.05 vs −1.00±0.9, P=0.04 and TBS value 1.195±0.14 vs 0.8±0.6, P=0.01). Two patients and one control had vertebral fractures (P=1.0). In acromegalic patients, at bivariate analysis TBS was associated with age at diagnosis (r^2: −0.25, P=0.04), GH serum levels (r^2: 0.36, P=0.01), FN T-score (r^2: 0.35, P=0.02), and Z-score (r^2: 0.81, P=0.01). Vertebral fractures were

associated with age at diagnosis (r^2: 0.36, $P=0.02$). LS-BMD and FT-BMD were related to alteration of glucose metabolism (r^2: 0.25, $P=0.04$ and r^2: 0.49, $P=0.002$ respectively).
Conclusions
Acromegalic patients had impaired bone quality despite normal bone density. Further larger studies are needed to define TBS role in fracture risk in acromegaly.

Perceived quality of life in acromegaly: results from a tertiary UK centre

Nikolaos Kyriakakis[1], Julie Lynch[1], Stephen G Gilbey[1], Susan M Webb[2] & Robert D Murray[1]
[1]Leeds Teaching Hospitals NHS Trust, Leeds Centre for Diabetes and Endocrinology, St James's University Hospital, Leeds, UK; [2]Biomedical Research Institute Sant Pau (IIB Sant Pau), Hospital de Sant Pau, Universitat Autònoma de Barcelona, Barcelona, Spain.

Introduction
Patients with acromegaly are frequently left with long-term adverse sequelae. When compared with individuals with other pituitary adenomas, patients with acromegaly demonstrate greater impairment in their quality of life (QoL).
Methods
The disease-specific questionnaire, AcroQoL, and the generic psychological general well-being schedule (PGWBS) were used to evaluate QoL in an acromegaly patient cohort. Longitudinal data were also collected to determine change in QoL over a 5-year period.
Results
Baseline responses were collected from 58 patients (age 55.1 ± 13.0 years). For the entire cohort, mean GH and IGF1 values at baseline were 1.53 ± 2.07 μg/l and 102.1 ± 51% of the upper limit of normal (ULN) respectively. Mean duration of GH control (GH <2 μg/l) was 5.4 ± 4.8 years, whereas for IGF1 this was 4.4 ± 4.3 years. Follow-up responses were obtained from 23 patients (age 55.6 ± 10.0 years). For this subgroup, mean GH and IGF1 at follow-up were 0.76 ± 0.75 μg/l and 110.4 ± 54.3% of ULN respectively (vs 1.6 ± 2.4 μg/l and 110.5 ± 64.7% of ULN at baseline). The mean total score for AcroQoL at baseline was 67.8 ± 18.4 (48.0%). The domain of appearance was the most under-marked, while the highest scores were noted in the personal relationships domain. For the subgroup of 23 patients, no significant difference was found in the baseline and follow-up AcroQoL scores (64.2 vs 65.7, $P=0.58$). PGWBS scores were significantly lower in the patient group compared with reference population, both at baseline (median score 71.5 (IQR 52.0–86.5) vs 89.5 (IQR 81.0–95.75), $P<0.001$) and follow-up (median score 61.0 (IQR 46.0–83.0) vs 89.5 (IQR 81.0–95.75), $P<0.001$). Baseline and follow-up PGWBS scores were not statistically different for the subgroup of 23 patients. Positive well-being, general health and vitality were the mostly under-marked domains.
Conclusion
Our results demonstrate impairment of QoL in acromegaly, which fails to improve despite long-term disease control. A more holistic approach, potentially in a multi-disciplinary setting involving clinical psychologists, should be implemented.

GP.19.04

Molecular and pathological determinants of somatostatin analogue resistance: somatotropinomas in AIP mutated and X-LAG syndrome patients

Misu Lee[1], Adrian Daly[2], Liliya Rostomyan[1], Natalia Pellegata[2] & Albert Beckers[1]
[1]Institute of Pathology, Helmholtz Zentrum München, Munich, Germany; [2]Department of Endocrinology, CHU de Liège, University of Liège, Liège, Belgium.

Poor hormonal and tumour responses to somatostatin analogues (SSA) in acromegaly can occur although the aetiology is often unclear. Two genetic syndromes are associated with relative SSA resistance: acromegaly due to AIP mutations (AIPmut) and the newly described X-linked acrogigantism (X-LAG) syndrome due to chromosome Xq26.3 microduplications. We studied whether SSA resistance in these conditions was related to somatostatin receptor (SSTR) levels in tumour tissues. We studied six XLAG and seven AIPmut patients, none of which had hormonal control on chronic SSA therapy, and ten mutation-negative patients (controls). Immunostains were evaluated semi-quantitatively and an immunoreactive score (IRS) was recorded for each section. Staining was assessed as negative for IRS 0–1, weakly positive for IRS 2–3, moderately positive for IRS 4–8, and strongly positive for IRS >8. In AIPmut cases, one was negative for SSTR2, two for SSTR5 and three for SSTR1. SSTR3 was the most highly expressed receptor in both acromegaly controls (average IRS 9.8) and in AIPmut (average IRS 9.5) somatotropinomas. SSTR1 and SSTR5 were present at higher levels in the controls vs AIPmut cases. The difference between AIPmut and controls was statistically significant for SSTR1 ($P=0.039$) but not for SSTR5 ($P=0.239$). Interestingly, the expression level of SSTR2 was significantly higher in the control somatotropinomas (average IRS 7.9) compared with the AIPmut (average IRS 2.3) adenomas ($P=0.0026$). Furthermore, in the AIPmut somatotropinomas, six out of seven samples had SSTR2 IRS scores <3, while in controls only three out of 13 had SSTR2 IRS <3. In XLAG syndrome cases, SSTR2 and SSTR3 were expressed in all samples analyzed, while one was negative for SSTR1, and another was negative for SSTR5. We observed that the expression of SSTR2 was variable but moderate to high in all cases (IRSs 4–10), despite the poor to absent SSA responses. SSTR3 was also highly expressed (average IRS 8.8) in the analyzed XLAG tumours, while the levels of SSTR1 and SSTR5 were lower than that of SSTR2 in these cases. Despite both having poor responses to SSA, variable expression of SSTR2 occurs in AIPmut and XLAG syndrome somatotropinomas. SSTR3 appears to be highly expressed in somatotropinomas, irrespective of the genetic background.

Clinical and biochemical outcomes during pregnancy in patients with acromegaly

Triona O'Shea[1], Saket Guptha[1], Audrey Melvin[2], Karen McGurran[1], Ruth Casey[2], Donal O'Halloran[2], James Gibney[3], Christopher Thompson[1] & Mark Sherlock[3]
[1]Beaumont Hospital, Dublin 9, Ireland; [2]Cork University Hospital, Cork, Ireland; [3]Tallaght Hospital, Dublin, Ireland.

Acromegaly is a rare condition resulting from excess secretion of GH and IGF1. Acromegaly is frequently associated with subfertility. As such there is little data on the course of the disease during pregnancy, and of the effects of the disease and its treatments on the foetus.
Objective
We describe known pregnancies in women with acromegaly within the Republic of Ireland over a 15-year period.
Methods
We collected clinical, biochemical, and outcome data during and following pregnancy.
Results
We have identified 11 pregnancies in eight women. All women had a pituitary macroadenoma. In eight cases there was concurrent prolactin hypersecretion. Ten out of 11 patients were medically treated prior to conception. Dopamine agonists were most commonly used (8/11) followed by somatostatin analogues (4/11). One patient was treated with both dopamine agonists and somatostatin analogues. In 7/11 cases dopamine agonist therapy was continued throughout the pregnancy. Median IGF1 at conception was 240% above the upper limit of the age related reference range (IQR 230–380%). At the time of conception 2/11 cases had IGF1 levels within the age related reference range. During the third trimester IGF1 was within the reference range in 6/10 cases, and in all cases IGF1 levels fell during pregnancy. One patient was treated for hypertension throughout two pregnancies. No patient developed diabetes mellitus or any neurological complications during pregnancy. All babies were delivered via elective Caesarean section at term. Four babies were breastfed post delivery. Mean birth weight was 2.8 kg, with no cases of macro- or microsomia.
Conclusions
Our data suggests that pregnancy in acromegalic women is not associated with excess morbidity to mother or baby. There is a high rate of Caesarean section. Our data correlates with previous studies showing a beneficial effect of pregnancy on biochemical control of acromegaly.

GP.19.06

Criteria for disease control in acromegaly under SSA treatment: mean GH profile or GH random?

Nunzia Prencipe, Chiara Bona, Joannis Karamouzis, Alessandro Maria Berton, Stellina Valentina Di Giacomo, Federica Guaraldi, Ezio Ghigo & Silvia Grottoli
Endocrinology, Diabetology and Metabolism, AOU Città della Salute e della Scienza of Turin, University of Turin, Turin, Italy.

Acromegaly is due to increased GH secretion usually sustained by a GH-secreting pituitary adenoma. Somatostatin analogues (SSA) can control GH hypersecretion in 60% of patients and tumor volume in 30%. The disease control is, in turn, associated with lower mortality and therefore to verify the optimal control of the disease activity is of critical importance to adapt the dose and the choice of alternative treatment. The criteria for optimized disease control had been assumed as mean GH <2.5 ng/ml and normal for age IGF1 levels. In 2010 a consensus proposed as new criteria GH random (GHR) <1 ng/ml and normal for age IGF1 levels. We compared the reliability of mean GH profile (GHP) <2.5 and GHR <1 ng/dl as good marker of disease activity in acromegaly; we also evaluated the association between GH levels (mean and random) and IGF1/IGFBP3 levels. To this goal in an observational and retrospective study, we enrolled 34 responsive to SSA treatment acromegalic patients (25F, 33–86 years). The clinical response had been defined by normal IGF1 levels and no clinical activity. In all subjects the dose of SSA had been stable in last 2–5 years. In all subjects in phase 1 (before 2010) mean GHP, IGF1, and IGFBP3 and in phase 2 (after 2010) GHR, IGF1, and IGFBP3 had been evaluated. In all subjects in both phases of the study IGF1 (phase 1: 186.8 ± 10.0 and phase 2: 175.0 ± 37.3) and IGFBP3 (phase 1: 2.7 ± 0.1 and phase 2: 2.5 ± 0.1) levels were normal for age. GHR (2.2 ± 0.48 ng/ml) levels are higher ($P=0.1$) than GHP (1.17 ± 0.57 ng/ml). Concordance between GHP <2.5 ng/ml and normal IGF1 was demonstrated in 85.3% of patients while between GHR <1 ng/ml and normal IGF1 just in 29.4% ($P<0.01$). Our study shows that in acromegalic patients responsive to SSA, GHP <2.5 ng/ml better than GHR <1 correlate with normal IGF1 levels, thus indicating that evaluation by GHP would more reliably reflect an appropriate disease control.

Patient experience of living with acromegaly in the UK

Antonia Brooke[1,4], Jacqui Lyttle[3], Lynne Goss[1,4], Louis Pobereskin[2] & South West Peninsula Endocrinology Network[4]
[1]Royal Devon and Exeter NHS Foundation Trust, Exeter, UK; [2]Plymouth Hospitals NHS Trust, Plymouth, UK; [3]JSL Consulting and Associates Ltd, Devon, UK; [4]South West Peninsula Endocrinology Network, Devon and Cornwall, UK.

61 patients (104 invited participants), within 10 years of active treatment for acromegaly, from five hospitals in the South West Peninsula (UK) (one neurosurgical centre) were interviewed to explore the experience of living with acromegaly, access to information, support and their ability to make decisions about their care. Semi-structured interviews by an independent consultant (60–120 min each) included 34 males and 27 females; 25–85 years old; 52 (85%) patients had surgery. 56 (92%) experienced a significant delay from symptoms to diagnosis, but prompt effective secondary care treatment. Communication and coordination of care between teams was criticised. Patients felt a lack of psychological and emotional support. Those in contact with a 'specialist' consultant or an endocrine nurse specialist felt most supported. 52 (85%) felt they had access to a consultant who understood the condition. Those without contact with an endocrine nurse specialist felt their care might have been compromised as a result. Patients felt unprepared for the life-long effect of their condition. 36 (59%) were on additional medical treatment and had issues with the ordering, dispensing or administering of the drug. 46 (75%) would be willing to travel anywhere in the UK to receive treatment (25% to next available hospital) if not available locally. Although, many felt involved in decision-making, few had been offered choice (but would value their consultant's advice). Whilst 53 (87%) patients felt they understood about their condition now, many felt this took a long time with extensive personal research. 67% had been offered written information, 69% had looked on websites, 61% were aware of patient groups but only 20% had joined or sourced information from 1 and 15% attended a meeting (despite a desire to help others with acromegaly). This is the largest acromegaly qualitative patient experience study undertaken in the UK, reflecting the issues of living with acromegaly.

GP.19.08

Effects of long-term combined treatment with somatostatin analogues and pegvisomant on cardiac structure and performance in acromegaly

Renata S Auriemma, Ludovica F S Grasso, Mariano Galdiero, Claudia Pivonello, Ciro Salzano, Mariarosaria Negri, Cristina de Angelis, Annamaria Colao & Rosario Pivonello
Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, University 'Federico II', Naples, Italy.

Somatostatin analogues (SA) are known to revert acromegalic cardiomyopathy mainly in young patients with short disease duration, whereas pegvisomant (PEG) reportedly improves cardiac structure and performance in patients resistant to SA. To date, no data are available on the effects of long-term SA+PEG on cardiovascular complications. The current study aimed at investigating the effects of long-term SA+PEG on cardiac structure and performance in acromegaly. Thirty-six acromegalic patients (14M, 22F, aged 52.3 ± 10.2 years) entered the study. Weight, BMI, systolic (SBP) and diastolic (DBP) blood pressure, IGF1, fasting glucose (FG), fasting insulin (FI), HOMA-IR, HbA1c and lipids were evaluated at diagnosis (T0), after long-term (median 36 months, range 6–156 months) SA (T1), and after 12 (T12) and 60 (T60) months of SA+PEG, with last follow up (LFU) being performed after a median time of 78 months (range 60–144 months). At each time point all patients underwent echocardiography. SA induced a slight but not significant decrease in IGF1 ($P=0.077$), whereas FI ($P=0.004$), HOMA-IR ($P=0.013$), ejection fraction (EF, $P=0.013$), early (E) to late (A) ventricular filling velocities (E/A, $P=0.001$) and isovolumetric relaxation time (IVRT, $P=0.000$) significantly improved. At T12 weight ($P=0.004$), BMI ($P=0.005$), IGF1 ($P=0.000$), FI ($P=0.001$), HOMA-IR ($P=0.000$), left ventricular mass index (LVMi, $P=0.000$) and E/A ($P=0.006$) significantly improved compared to T0, with HOMA-IR further improving ($P=0.000$) compared to T1. At T60, IGF1 ($P=0.000$), FI ($P=0.001$), HOMA-IR ($P=0.000$), E/A ($P=0.05$) and IVRT ($P=0.014$) significantly ameliorated compared to T0. At LFU IGF1 normalized in 83.3%; IGF1 ($P=0.000$), FG ($P=0.043$), FI ($P=0.000$), HOMA-IR ($P=0.000$), HDL ($P=0.031$), EF ($P=0.035$), LVMi ($P=0.000$), E/A ($P=0.02$) and IVRT ($P=0.001$) significantly improved compared to T0. PEG dose significantly correlated with LVMi at T12 ($r=0.575$, $P=0.000$) and T60 ($r=0.403$, $P=0.037$). In conclusion, long-term PEG addition to SA improves cardiac structure and performance, particularly diastolic dysfunction, in acromegalic patients resistant to SA.

Management of pasireotide-induced hyperglycaemia with proactive monitoring and early intervention: key learnings from the phase III, 24-week PAOLA study

Monica R Gadelha[1], Thierry Brue[2], Maria Fleseriu[3], Ilan Shimon[4], Karina Hermosillo Reséndiz[5], Albert Kandra[6], Alberto M Pedroncelli[6] & AnnaMaria Colao[7]
[1]Division of Endocrinology, Medical School and Hospital Universitário Clementino Fraga Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [2]Hôpital de la Timone, Aix-Marseille University, Centre National de la Recherche Scientifique, and Assistance Publique-Hôpitaux de Marseille, Marseille, France; [3]Northwest Pituitary Center, Oregon Health & Science University, Portland, Oregon, USA; [4]Rabin Medical Center, and Sackler School of Medicine, Tel-Aviv University, Petah-Tiqva, Israel; [5]Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, USA; [6]Novartis Pharma AG, Basel, Switzerland; [7]Dipartimento di Medicina Clinica e Chirurgia, Università Federico II di Napoli, Naples, Italy.

Introduction
In PAOLA study, pasireotide showed superior efficacy over continued treatment with octreotide/lanreotide in patients with inadequately-controlled acromegaly; 64% of patients receiving pasireotide long-acting release (LAR) reported hyperglycaemia-related adverse events. Pasireotide has been shown to inhibit insulin secretion. The aim of this exploratory analysis was to investigate the effect of timing of antidiabetic medication (ADM) intervention on the fasting plasma glucose (FPG) outcome during pasireotide LAR treatment.
Methods
Patients randomised to pasireotide LAR, who received ≥ 1 dose of pasireotide and had a valid post-baseline safety assessment (safety population for pasireotide; $n=125$), were included and categorised by baseline diabetic status: non-diabetic; pre-diabetic (FPG 100–<126 mg/dl or HbA1c 5.7–$<6.5\%$ or 2 h post-OGTT glucose 140–<200 mg/dl); diabetic (current/prior ADM use or FPG ≥ 126 mg/dl or HbA1c $\geq 6.5\%$ or 2 h post-OGTT glucose ≥ 200 mg/dl).

Results
Hyperglycaemia (first occurrence of FPG $\geq$126 mg/dl or HbA1c $\geq$6.5% in non-diabetic/pre-diabetic; or first occurrence of FPG or HbA1c increase $\geq$20% from baseline in diabetic) was experienced by 5/19 non-diabetic, 9/24 pre-diabetic and 68/82 diabetic patients. Due to fewer non-diabetic/pre-diabetic patients, the analysis is focused on 68 diabetic patients. ADM was initiated/adjusted in 36/68 diabetic patients after 0–<15 ($n=7$), 15–<30 ($n=8$) or $\geq$30 ($n=21$) days; mean FPG change $\pm$S.D. at week 20 (maximum follow-up) was –110.0$\pm$96.3 mg/dl (from 255.9$\pm$89.8 mg/dl during occurrence of hyperglycaemia), –7.3$\pm$91.1 (from 186.9$\pm$92.2) and 2.1$\pm$78.9 (from 178.7$\pm$38.0), respectively. Mean FPG change was –10.7$\pm$91.5 mg/dl (from 152.4$\pm$44.0) in patients who did not receive ADM ($n=32$). Significant ($P<0.01$) factors predicting hyperglycaemia were BMI $\geq$25 kg/m^2 (OR=2.3), per unit increase in HbA1c (OR=4.3) and diabetes at baseline (OR=4.8); and history of dyslipidaemia (OR=3.6).
Conclusions
Pasireotide-induced hyperglycaemia can be managed with proactive monitoring and early intervention (e.g., within 2 week if FPG >250 mg/dl). These data suggest that in patients receiving pasireotide, early intervention can improve hyperglycaemia control.

[1]The Christie NHS Foundation Trust, Manchester, UK; [2]University of Sheffield, Sheffield, UK; [3]University Hospital Birmingham, Birmingham, UK; [4]King's College Hospital, London, UK; [5]Cardiff University, Cardiff, UK; [6]St Bartholomew's Hospital, London, UK; [7]University Paris-Sud, Paris, France; [8]Hopital de la Conception, Marseille, France; [9]Hospital de Sant Pau, Barcelona, Spain; [10]Hospital Universitario La Ribera, Valencia, Spain; [11]Hospital Universitario Puerta de Hierro, Madrid, Spain; [12]St. Vincent Hospital, Sydney, Australia; [13]Royal Adelaide Hospital, Adelaide, Australia; [14]Antisense Therapeutics, Melbourne, Australia; [15]Ludwig-Maximilians University, Munich, Germany.

ATL1103 is a second generation antisense oligomer directed at the GH receptor. It is a 20mer with a phosphorothioate backbone and 2′-*O*-methoxyethyl modifications of the five nucleotides at either end intended to increase its plasma half-life and affinity for the target RNA to allow post-hybridization RNaseH degradation. We report a phase 2 randomised, open-label, parallel group study of subcutaneously administered ATL1103 in patients with active acromegaly. Appropriate ethical approval was obtained in each centre and the study is registered as EudraCT 01200314730. Patients gave written informed consent. The protocol entailed appropriate washout from ongoing medical therapy after which IGF1 had to be at least >1.3 times age-related ULN. Patients were randomised to receive either ATL1103 200 mg once or twice weekly for 13 weeks. After completion of drug administration, patients were monitored for a further 8 weeks. The primary objectives were to evaluate the safety and pharmacokinetics. 34 patients were recruited in 13 centres and 26 (mean age 50.4 years; 11 male) were randomised, and all completed treatment. ATL1103 was well tolerated with mild to moderate injection site reactions being the most common drug-related AE. Four SAEs were reported (three in a single patient) but none were felt to be study drug related. Two patients withdrew at completion of dosing. There was a significant fall in serum IGF1 of 26% by week 14 with 200 mg twice weekly (577$\pm$198 vs 411$\pm$174 ng/ml (mean$\pm$S.D.), $P<0.0001$) although the nadir had not been reached. Once weekly dosing did not result in a significant fall in IGF1. The fall in IGF1 with twice weekly dosing was associated with a mean reduction ring size circumference of 1.150 mm ($P=0.014$) and an increase in GH ($P=0.001$). This study provides proof-of-concept that ATL1103 is able to significantly lower IGF1 in patients with acromegaly.

Reduced mortality due to malignant neoplasms in patients receiving long-term GH replacement therapy – a Swedish study based on more than 4000 patient-years

Daniel S Olsson[1], Anna G Nilsson[1], Penelope Trimpou[1], Bengt-Åke Bengtsson[1], Eva Andersson[2] & Gudmundur Johannsson[1]
[1]Department of Endocrinology at Sahlgrenska University Hospital, Göteborg, Sweden; [2]Department of Occupational and Environmental Medicine at Sahlgrenska University Hospital, Göteborg, Sweden.

Patients with hypopituitarism and untreated growth hormone (GH) deficiency have excess mortality. GH replacement therapy (GHRT) has many beneficial effects, but its impact on mortality has not been proven and there are still safety concerns regarding the potential cancer risk. We have therefore studied the mortality in non-functioning pituitary adenoma (NFPA) patients with and without GHRT. Only patients with NFPA were studied in order to eliminate the influence of the aetiology of hypopituitarism.
NFPA patients within the Sahlgrenska University Hospital's catchment-area (1.5 million inhabitants) were identified through the Swedish National Patient Registry. The records of all identified patients were reviewed. All patients were cross-referenced with the Swedish National Death Registry. The study period was 1987–2011. Standardised mortality ratios (SMRs) with 95% CIs (reference: Swedish population) were calculated.
We identified 435 patients with NFPA, out of which 433 had complete records and were included in the study. GHRT had been used for at least one year by 187 patients and 246 patients had not been treated with GHRT. Mean ($\pm$S.D.) age at diagnosis was lower ($P<0.001$) in the GHRT-group (54.3$\pm$11.7) than in the non-GHRT-group (64.0$\pm$15.4). Mean duration of GHRT was 10.9 (6.1) years and mean follow-up time in the non-GHRT-group was 6.9 (5.4) years. The total number of deaths in the study was 83. The overall SMR was 0.49 (0.27–0.80, $P=0.003$) for the GHRT-group and 0.98 (0.76–1.24; $P=0.94$) for the non-GHRT-group. The SMR was significantly lower in the GHRT-group compared to the non-GHRT-group ($P=0.02$). SMR for malignant neoplasms was significantly reduced in the GHRT-group (0.19; 0.02–0.68; $P=0.003$), and was not significantly changed in the non-GHRT-group (0.74; 0.37–1.31; $P=0.37$).
This is the first study to report a reduced mortality in NFPA patients receiving long-term GHRT. Furthermore, mortality due to malignant neoplasms was decreased in the GHRT-group and not in the non-GHRT-group.

Association of serum IGF1 concentration with cardiovascular function in adults with GH deficiency with different GH treatment regimes: a randomised clinical trial

Christa C van Bunderen[1], Rick I Meijer[2], Paul Lips[1], Mark H Kramer[3], Erik H Serné[2] & Madeleine L Drent[1]
[1]Department of Internal Medicine, section Endocrinology, Neuroscience Campus Amsterdam, VU University Medical Center, Amsterdam, The Netherlands; [2]Department of Internal Medicine, Institute for Cardiovascular Research (ICaR-VU), VU University Medical Center, Amsterdam, The Netherlands; [3]Department of Internal Medicine, VU University Medical Center, Amsterdam, The Netherlands.

Objective
Epidemiological evidence for a link between serum IGF1 concentration and cardiovascular disease in the general population and in patients with GH deficiency or hypersecretion has been demonstrated. However, the underlying mechanisms remain unresolved. We investigated associations between IGF1 levels within the reference range and different measures of cardiovascular function and risk factors in substituted GH deficient adults within a randomized clinical trial.
Methods
Thirty-two subjects receiving GH therapy for at least a year with a stable IGF1 concentration of -1 to 1 SDS were included and randomised to receive either a decrease of their regular dose (IGF1 target level: -2 to -1 SDS) or an increase of their dose (IGF1 target level: 1 to 2 SDS) for a period of 6 months. Measurements of micro- and macrovascular function, lipid profile, inflammation, and insulin resistance (HOMA-IR) were performed.

Results
Thirty subjects (65.6% male, mean age 46.6 (9.9 s.d.) years) could be analysed. A relationship with vasomotion of skin microvasculatory blood flow measured by skin laser Doppler flowmetry seemed evident. Decreasing GH dose led to a decrease in energy contribution from the local endothelial activity (Δ -0.27 (0.42 s.d.), $P=0.03$), which was significantly different from increasing GH dose ($P=0.03$). There was a trend for a difference between de- and increasing GH dose in the augmentation index during pulse wave analysis in favour of a high-normal IGF1 level ($P=0.06$). Decreasing the GH dose led to an increase in hs-CRP (Δ 1.49 mg/l (3.84 s.d.), $P=0.03$), which was significantly different from increasing GH dose ($P=0.04$). Increasing the GH dose led to an increase in HOMA-IR (Δ 0.38 (0.52 s.d.), $P=0.01$), which was significantly different from decreasing GH dose ($P=0.01$).
Conclusions
IGF1 level within the reference range in GH treated adults is related to microvascular endothelial activity, inflammation, and metabolic insulin resistance.

Timing is everything? Postpartum pituitary dysfunction – variability of clinical and radiological presentation

Amit Tirosh[1,2], Hiba Masri Iraqi[1,2], Dania Hirsch[1,2], Eyal Robenshtok[1,2], Uri Yoel[3], Yoel Toledano[2,4], Orit Twito[2,5], Gloria Tsvetov[1,2] & Ilan Shimon[1,2]
[1]Endocrine Institute, Rabin Medical Center, Petah Tiqva, Israel; [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [3]Endocrine Institute, Soroka Medical Center and Ben Gurion University of the Negev, Beer Sheva, Israel; [4]Endocrinology clinic, Division of maternal Fetal Medicine, Helen Schneider Hospital for Women, Rabin Medical Center, Petah Tiqva, Israel; [5]Endocrine Institute, Meir Medical Center, Kfar Saba, Israel.

Introduction
Two aetiologies are responsible for postpartum hypopituitarism; Sheehan's syndrome which develops following traumatic labour, and lymphocytic hypophysitis. Since management of lymphocytic hypophysitis does not require surgery in most cases, pathology is usually absent, and the clinical presentation, in combination with laboratory and imaging characteristics establish the diagnosis. We aimed to describe the various patterns of presentation, including assisting analyses, among women with probable lymphocytic hypophysitis.
Methods
A retrospective study of women with pituitary dysfunction presented immediately or several months following delivery. Clinical characteristics data, pituitary hormone levels, and imaging findings were collected.
Results
Eight women were included; mean age at delivery was 34.8 ± 7.4 years.
Most patients (6/8) presented with breastfeeding difficulty, and 5/8 reported headache. Among the patients with headache, 2/5 presented during pregnancy, and the others – 2, 4 and 9 months following delivery. Hypopituitarism symptoms appeared immediately after delivery in half of the patients, between 7–12 months in 3/8; in one patient severe headache was the sole complaint. All patients had central hypocortisolism, hypogonadotrophic hypogonadism, and growth hormone deficiency, and 7/8 had central hypothyroidism. Prolactin levels were low in 2/8. None of the patients had diabetes insipidus. Five patients passed MRI within 3 months of symptom onset, four of them (80%) complained about headaches. These patients had either normal pituitary structure (2/5), pseudo-adenoma (1/5) or diffusely enlarged and hyperintense gland, suggestive for hypophysitis (2/5). Three patients have been diagnosed more than a year following presentation, all had reduced pituitary volume on MRI, and two of them had panhypopituitarism.
Conclusion
Over 300 cases of autoimmune hypophysitis were reported in the literature. Thus, a high index of suspicion is required to identify women in the postpartum period with breastfeeding difficulty, with or without headaches, and to study their pituitary function.

Irradiation-induced hypopituitarism in adult brain tumour survivors: single-centre longitudinal data

Nikolaos Kyriakakis[1], Julie Lynch[1], Susan C Short[2], Paul Hatfield[2], Carmel Loughrey[2], Georgina Gerrard[2], Steve M Orme[1] & Robert D Murray[1]
[1]Endocrinology, Leeds Centre for Diabetes and Endocrinology, St James's University Hospital, Leeds, UK; [2]Oncology, Leeds Cancer Centre, St James's University Hospital, Leeds, UK.

Introduction
Radiation-induced hypopituitarism is a well-recognized complication of cranial radiotherapy (cXRT) for childhood brain tumours when the hypothalamo–pituitary axis is within the irradiation field. Few data are available for survivors of adult brain tumours who have received cranial irradiation.
Methods
We retrospectively reviewed medical records of patients referred to Endocrinology following cXRT for primary non-pituitary brain tumours during adulthood. Longitudinal data regarding pituitary-related treatment outcomes were collected. The ITT and/or GST were used to assess GH and HPA axes integrity. Basal values for the additional anterior pituitary hormones were used to determine gonadotropin, TSH and prolactin status.
Results
107 patients (mean age 40.0 ± 13.1 years) with mean duration of post-cXRT follow-up of 9.1 ± 5.7 years were studied. 32.7, 19.6, 20.6 and 27.1% of patients had tumours located in the anterior, middle, posterior cranial fossa and central (perisellar) regions respectively. 94.4% received fractionated photon radiotherapy (mean dose 51.7 ± 6.5Gy, mean number of fractions 28.6 ± 3.5), while the remaining patients received proton beam or stereotactic radiotherapy. Evidence of pituitary dysfunction was present in 88.8% of patients. The GH axis was affected in 86.9% of patients (severe GHD 64.5%, partial GHD 22.4%), followed by LH/FSH (34.6%), ACTH (23.4%), and TSH (11.2%) axes. Clinically significant ACTH deficiency necessitating glucocorticoid replacement was present in only 10.3% of cases. Hyperprolactinaemia was noted in 15.0% of patients. Single pituitary axis dysfunction was found in 41.1% of patients, while multiple axes were affected in 47.7% of cases. Longitudinal data analysis showed accumulation of pituitary hormone deficits the longer the duration of follow-up.
Conclusions
Pituitary dysfunction in survivors of adult brain tumours following cXRT is very common. The majority of deficits develop within 5 years post-cXRT, however late onset or progression of severity of a previously developed hormone deficiency was also observed. Long-term follow-up of these patients in specialist endocrine centres is strongly recommended.

GP.20.05

Long-term follow-up of 520 patients with non-functioning pituitary adenomas from two large tertiary referral centres: a UK-Republic of Ireland collaborative study

Michael O'Reilly[1], Saket Gupta[2], C A Thompson[2], Harriet Pearce[1], Gabriella Bugg[1], Andrew Toogood[1], Neil Gittoes[1], Christopher Thompson[2] & John Ayuk[1]
[1]University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK; [2]Beaumont Hospital, Dublin, Ireland.

Abstract
Non-functioning pituitary adenomas (NFPAs) are the most common pituitary tumours, often presenting with chiasmal compression or hypopituitarism. Surgical resection, accompanied by radiotherapy (RTX) in selected cases, is the treatment of choice for compressive tumours. Long-term health consequences of NFPAs and their treatment are unclear. In this retrospective study, we aimed to assess long-term pituitary function, recurrence and mortality in a large NFPA cohort across two tertiary centres. Case-note review of all patients treated for NFPA in Queen Elizabeth Hospital Birmingham and Beaumont Hospital Dublin between 1997 and 2012 was performed; data on patients treated before 1997 was included where available. Clinical presentation, imaging characteristics, long-term pituitary function and co-morbidities were recorded in each case. Data on mortality was recorded via Clinical Portal in Birmingham and from GP contact in Dublin.
519 patients were included in the analysis (Birmingham $n=271$; Beaumont $n=248$; 59.2% male, mean age at presentation 55.2 ± 14.1 years). Mean duration of follow-up was 8.5 ± 6.3 years (0.5–43). 90.8% of patients underwent surgery (81.1% transsphenoidal). 184 patients (35.4%) underwent pituitary radiotherapy, either postoperatively (43.5%) or at recurrence

(56.5%). Tumour regrowth was recorded in 35.6% of cases; mean time to regrowth was 47.6±51.6 months, (range 1–276). The incidence of panhypopituitarism was higher in irradiated patients (49.4% vs 38.1%, $P<0.001$). The incidence of second intracranial tumours was 3.2% and 0.6% in irradiated and non-irradiated patients respectively, $P<0.001$. 75 patients (14.5%) died during follow-up. Mean age at death in RTX and RTX-naïve patients was 69.8±12.7 vs 77.7±9.8 years, respectively, $P=0.006$.

This large collaborative study between Britain and Ireland highlights important health consequences in patients treated for NFPA. Tumour recurrence may occur many years after initial treatment, necessitating lifelong follow-up. Pituitary irradiation may have consequences on the risk of secondary intracranial tumours and on mortality. Further analysis is required to understand the associations observed here.

Somatic complaints, pain and health related quality of life in patients treated for secondary adrenal insufficiency – results from a randomised controlled trial

Jorien Werumeus Buning[1], Pauline Brummelman[1], Janneke Koerts[2], Robin P F Dullaart[1], Gerrit van den Berg[1], Melanie M van der Klauw[1], Oliver Tucha[2], Bruce H R Wolffenbuttel[1] & André P van Beek[1]
[1]University Medical Center Groningen, Groningen, The Netherlands; [2]University of Groningen, Groningen, The Netherlands.

Introduction

There is growing evidence that quality of life (QoL) in patients with adrenal insufficiency (AI) is impaired. Undertreatment with glucocorticoids is associated with symptoms such as fatigue and gastrointestinal complaints whereas overtreatment is associated with impaired QoL. However, evidence for this is derived from observational studies which are prone to bias. Therefore, the aim of the present study was to compare two different physiological doses of hydrocortisone (HC) on somatic complaints, pain and QoL in an RCT.

Methods

Forty-seven patients (29 males, 18 females; mean (S.D.) age, 51(14) years) with secondary AI participated. In this RCT with cross-over design, patients received first a lower dose of HC (0.2–0.3 mg/kg body weight/day in three divided doses) for 10 weeks followed by a higher dose of HC (0.4–0.6 mg/kg body weight/day in three divided doses) for 10 weeks, or vice versa. Health related quality of life was assessed with questionnaires after each treatment period and daily with a mood and symptom checklist.

Results

After 10 weeks on the higher dose of HC patients reported significantly fewer depressive symptoms ($P=0.016$) (Hospital Anxiety and Depression Scale), less general and mental fatigue ($P=0.004$ and $P=0.003$, respectively), less reduced motivation ($P=0.021$) (Multidimensional Fatigue Inventory-20) compared to the lower dose. Furthermore, after treatment with the higher dose patients reported better physical functioning ($P=0.041$), general health ($P=0.013$) and more vitality ($P=0.025$) (RAND-36). In addition, while on the higher dose fewer somatic symptoms ($P=0.022$) (Patient Health Questionnaire-15) and less pain ($P < 0.001$) were experienced.

Conclusion

While on the higher dose of HC, patients reported a better quality of life with regard to general health, mental health, depressive symptoms, common somatic complaints, pain and fatigue compared to the lower dose of HC.

Outcome and prognosis of typical and atypical pituitary adenomas in a monocentric experience

Sabrina Chiloiro[1], Francesco Doglietto[2], Donato Iacovazzo[1], Antonella Giampietro[1], Francesco Di Nardo[3], Chiara de Waure[3], Libero Lauriola[4], Annunziato Mangiola[5], Carmelo Anile[5], Giulio Maira[5], Laura De Marinis[1] & Antonio Bianchi[1]
[1]Section of Endocrinology, Department of Internal Medicine, Catholic University, School of Medicine, Rome, Italy; [2]Neurosurgery, University of Brescia, Brescia, Italy; [3]Institute of Hygiene, Catholic University, School of Medicine, Rome, Italy; [4]Institute of Anatomic Pathology, Catholic University, School of Medicine, Rome, Italy; [5]Institute of Neurosurgery, Catholic University, School of Medicine, Rome, Italy.

Background and objective

Atypical pituitary adenomas (APA), in 2004, were defined according to WHO classification, as those with Ki-67>3%, excessive p53 expression and increased mitotic activity and invasive behaviour. The real usefulness of this classification is still controversial, so we reviewed compared clinical and prognostic features in our typical and atypical pituitary adenomas.

Patients and methods

We retrospectively reviewed 343 consecutive pituitary adenomas (PAs). APAs occurred in 18.7% of cases. All patients were operated on in the Department of Neurosurgery at our institution and followed up at the Hypothalamic-Pituitary Disease Unit of the same institution. None patient had an adjuvant treatment pre-neurosurgery. Median follow-up time in our series was 75 months (range: 7–345 months).

Results

More frequently APAs were diagnosed in younger patient. However we found a similar prevalence of APAs in male and female patients. A higher risk of being affect for an APA was identified in cases characterised by an ACTH- and PRL-immunohistochemical positivity. According to WHO classification, cavernous sinus invasion was associated with higher risk of being affected of an APA and consequently a higher risk of a partial PA neurosurgery resection. In our series we separately analysed recurrence and disease free survival time (DFST) in patients undergone radical neurosurgery (219 cases). In this group of radically resected PAs, we find a similar risk of recurrence-disease and a superimposable DFST between typical and atypical pituitary adenomas. Moreover, in this series we found that Ki-67 expression>1.5% was associated to a higher risk of recurrence and to a worse DFST, even after correction for age at diagnosis, gender, immunohystochemical classification, tumor size, invasiveness and Knosp classification ($P=0.01$; HR: 2.572; 95% CI: 1.251–5.285). PAs with Ki-67>1.5% showed a worse DFST as compared to PAs with Ki-67<1.5% (HR: 2.166; 95% CI: 1.154–4.064).

Conclusion

In this series, atypical and typical PAs didn't differ for recurrence and DFST. PAs with Ki-67≥1.5% showed a higher recurrence risk and a worse DFST as compared to PAs with Ki-67<1.5%. We suggest that a Ki-67≥1.5% may be useful as prognostic marker.

'Pseudo-resistance' in macroprolactinomas treated with dopamine agonists; recognising delayed radiological response and a role for ^{11}C-methionine PET-CT in guiding management

Andrew S Powlson[1], Olympia Koulouri[1], Andrea Steuwe[2], Daniel Gillett[2], Sarah Heard[2], Andrew Hoole[3], Miriam Scott[1], Benjamin G Challis[1], Nagui Antoun[4], Heok K Cheow[4], Richard J Mannion[5] & Mark Gurnell[1]
[1]Metabolic Research Laboratories, Institute of Metabolic Science, University of Cambridge, Cambridge, UK; [2]Department of Nuclear Medicine, Addenbrooke's Hospital, Cambridge, UK; [3]Department of Medical Physics, Addenbrooke's Hospital, Cambridge, UK; [4]Department of Radiology, Addenbrooke's Hospital, Cambridge, UK; [5]Department of Neurosurgery, Addenbrooke's Hospital, Cambridge, UK.

Background

Endocrine Society guidelines classify macroprolactinomas as 'resistant' if there is failure to normalise prolactin, or to achieve radiological tumour shrinkage of >50%, on standard doses of dopamine agonist. In this context, escalation of treatment to maximal tolerable doses and/or referral for surgery is advised. However, we have recently observed several 'discordant responders', where tumour shrinkage lags significantly (>6 months) behind the biochemical response, but is ultimately achieved without treatment escalation.

Methods

i) A Pubmed search for 'medical treatment of prolactinomas' was performed & papers reporting discordance between biochemical and radiological responses identified and ii) We searched our pituitary database for patients treated locally over a 10-year period. A case where ^{11}C-methionine PET-CT was used to guide management is described.

Results

From an initial return of 845 papers, 21 provided sufficient information, describing 340 patients, 92 of whom exhibited a discordant response. Of 89 macroprolactinomas in our local database, we identified 14 patients in whom prolactin normalised, but tumour shrinkage was <50% at >6 months after commencing treatment. One of these, a 36-year-old man (initial prolactin 14,123mU/l) achieved biochemical normalisation within eight weeks; however, despite continued prolactin suppression (28mU/l; 500mcg twice-weekly) at 12 months his tumour showed no reduction in size. Reassuringly, ^{11}C-methionine PET-CT coregistered with MRI demonstrated a complete absence of tracer uptake in the 'residual adenoma'. With this evidence, contrary to Endocrine Society

Guidelines, cabergoline was reduced to 250mcg twice-weekly. 24-months later serum prolactin remained well-controlled (76 mU/l), and substantial (>50%) tumour shrinkage was evident on MRI.
Conclusions
These cases demonstrate that a delayed radiological response may be seen without further dose escalation, once biochemical normalisation has been achieved in prolactinomas; current guidelines may therefore inappropriately categorise such tumours as 'dopamine agonist resistant'. Our literature and local database review suggests this may be an under-recognised phenomenon. Furthermore, the case described here highlights the utility of functional imaging in aiding management in such patients.

Thyrotropinoma: diagnosis and management of a rare but increasingly recognised pituitary tumour – novel insights from a large prospective UK study

Olympia Koulouri[1,2], Carla Moran[2], Andrew Powlson[1,2], Nagui Antoun[2], Neil Donnelly[2], Richard Mannion[2], John Pickrd[1,2], David Halsall[1,2], Krish Chatterjee[1,2] & Mark Gurnell[1,2]
[1]University of Cambridge, Cambridge, UK; [2]Addenbrooke's hospital, Cambridge, UK.

Background
Thyrotropinomas (TSHomas) are traditionally considered a rare, albeit important cause of thyrotoxicosis. Although early case series reported a predominance of invasive macroadenomas, emerging evidence suggests microadenomas are being increasingly diagnosed, and the clinical/biochemical phenotype appears to be more variable than previously suspected. We therefore performed detailed phenotyping of patients referred to our centre with a diagnosis of TSHoma over a 4-year period.
Methods
35 patients with hyperthyroxinaemia and non-suppressed TSH were studied prospectively. Laboratory assay artefact, confounding intercurrent illness/drug therapy and *THRB* mutations were excluded in all cases. Further investigations included: hyperthyroid symptom score, measurement of resting energy expenditure, sleeping heart rate, bone mineral density, sex hormone-binding globulin (SHBG), alpha-subunit (ASU):TSH molar ratio, TRH test, OGTT, octreotide (100 mcg) suppression test (OST), volumetric MRI (vMRI) and ^{11}C-methionine PET-CT. Patients then proceeded to a formal trial of depot somatostatin analogue (SSA) therapy.
Results
Clinical/metabolic features varied markedly, ranging from euthyroid to overtly hyperthyroid, and were not clearly correlated with the degree of hyperthyroxinaemia. Similarly, SHBG and ASU:TSH did not reliably identify many cases (both raised in <50%), especially microadenomas. In contrast, a blunted TSH response to TRH (<4.5-fold rise), combined with normalization of thyroid function during a 3 month trial of SSA therapy, was observed in 90% of cases. Interestingly, TSH and FT3 responses in the OST did not predict efficacy of depot SSA. 50% of patients had microadenomas, with several not reliably visualised using conventional MRI. In these patients, vMRI combined with PET/CT identified the site of the microadenoma. All 35 patients received SSA as a bridge to surgery or as long-term treatment where pituitary surgery was deemed inappropriate.
Conclusions
Modern diagnostic algorithms for TSHomas should place greater emphasis on the TRH test and response to depot SSA therapy. vMRI and functional imaging may aid visualisation/confirm the site of a suspected microadenoma and thereby guide surgical resection.

Pituitary - Diagnosis of Cushing's disease

GP.21.01

A reappraisal of second line tests in the differential diagnosis of ACTH-dependent Cushing's syndrome: the role of three dynamic tests

Mattia Barbot[1], Laura Trementino[2], Filippo Ceccato[1], Marialuisa Zilio[1], Nora Albiger[1], Marco Boscaro[1], Giorgio Arnaldi[2] & Carla Scaroni[1]
[1]Endocrinology Unit, Department of Medicine DIMED, University Hospital, Padova, Italy; [2]Endocrinology Unit, Università Politectnica delle Marche, Ancona, Italy.

Introduction
The diagnosis of Cushing's syndrome (CS) might be challenging especially in ACTH-dependent CS when it comes to detect the origin of ACTH secretion.
Materials and methods
We retrospectively recorded data about 170 patients with ACTH-dependent CS (149 CD, 21 EAS) referring to two Endocrinology Units. We focused especially on the performance of 3 dynamic tests: the dexamethasone 8 mg overnight challenging (HDDST), the CRH and the desmopressin (DDAVP) test.
Results
Patients with EAS were slightly older and had higher 0800 h. ACTH levels, 0800 h. and after 1 mg dexamethasone cortisol levels, and UFC than patients with CD ($P<0.01$). On the contrary CD patients had a greater ACTH and cortisol response after CRH injection ($P<0.0001$) and also a more pronounced decreased of cortisol after HDDST ($P<0.0001$). A threshold for ACTH increase after CRH stimulation of 72% was able to identify CD with a sensitivity (SE) of 93% (95% CI: 68–83%) and a specificity (SP) of 82% (95% CI: 83–100%). Regarding HDDST, a cortisol reduction >53% suggested a pituitary origin with SE of 88% (95% CI: 81–93%) and SP of 90% (95% CI: 68–99%); the latter could be increased to 100% by moving the cut-off to 75% of decrease. The AUC of CRH test and HDDST was 0.93 (95% CI: 0.89–0.97) in both cases (P=ns). There were no EAS with both positive responses to these 2 tests. ACTH and cortisol increases after DDAVP test were also higher in CD than in EAS ($P<0.01$), but they added very little to the power of the other dynamic tests.
Conclusions
Patients with CD showed an increased response to both HDSST and CRH; the cut-offs found had good SE and SP in discriminating patients with CD from those with EAS. Lack of response of both tests was highly suggesting of EAS. On the contrary when both tests gave positive responses it indicated CD. We also confirmed the limited role of DDAVP test in this diagnostic phase. In conclusion, dynamic tests may play an important tool in the differential diagnosis of ACTH-dependent CS.

GP.21.02

Bilateral inferior petrosal sinus sampling reliably differentiates pituitary from ectopic Cushing's, but frequently fails to predict pituitary tumour location, especially when lateralizing to the right

Olympia Koulouri[1,2], Nishita Nigam[1], Andrew Powlson[1,2], Neil Donnelly[2], Richard Mannion[2], John Pickard[1,2], Brendan Koo[2], David Halsall[1,2] & Mark Gurnell[1,2]
[1]University of Cambridge, Cambridge, UK; [2]Addenbrooke's hospital, Cambridge, UK.

Background
BIPSS remains the gold standard for differentiating pituitary and ectopic sources in ACTH-dependent Cushing's syndrome. A pituitary:peripheral ACTH ratio >2 in the basal state, and/or >3 following CRH stimulation, is considered indicative of pituitary Cushing's, with a range of sensitivities and specificities cited in the literature. In addition, in Cushing's disease a peak interpetrosal gradient of >1.4 has been reported to predict the site of the adenoma in approximately 2/3 of cases. We examined the performance of BIPSS against these criteria in a cohort of patients who had undergone the procedure in our centre over the last decade.
Methods
39 patients with biochemically proven ACTH-dependent Cushing's, who had undergone BIPSS and had either subsequent histological confirmation of the ACTH source, or significant improvement/cure of their Cushing's following transsphenoidal surgery, were included in the study.
Results
Based on basal ACTH levels (pre-CRH stimulation), 89% of patients were deemed to have pituitary Cushing's and 11% an ectopic source. Post-CRH stimulation 94% of patients reached the cut-off for pituitary Cushing's. This gave a sensitivity of 97% and a specificity of 100% for pre-CRH stimulation and 100% sensitivity and 67% specificity for post-CRH stimulation. Two thirds (65%) of BIPSS procedures exhibited lateralisation to the right side, but this was subsequently shown at surgery to be correct in only half of the patients. In contrast, left lateralisation had a much higher positive predictive value (80%). When combined, lateralisation (either right or left) was accurate in only 60% of cases.
Conclusions
Predominance of right sided lateralisation on BIPSS may signify a 'dominant' right sinus in many patients undergoing this procedure. We suggest therefore that whole gland exploration is particularly important in 'right sided' BIPSS cases, and additional pituitary imaging (e.g. volumetric MRI, functional imaging) may be helpful in informing the surgical approach.

Altered neural processing during emotional faces in remitted Cushing's disease

Cornelie Andela[1,3], Janna Marie Hoogendam[1,3], Steven Van der Werff[1,3], Nienke Pannekoek[1,3], Henk Van Steenbergen[2,3], Onno Meijer[1,3], Mark Van Buchem[1,3], Serge Rombouts[1,3], Roos Van der Mast[1], Nienke Biermasz[1,3], Nic Van der Wee[1,3] & Alberto Pereira[1,3]

[1]Leiden University Medical Center, Leiden, The Netherlands; [2]Institute of Psychology Leiden University, Leiden, The Netherlands; [3]Leiden Institute of Brain and Cognition, Leiden, The Netherlands.

Background

Patients with long-term remission of Cushing's disease (CD) demonstrate residual psychological complaints. At present, it is not known how previous exposure to hypercortisolism affects psychological functioning in the long-term. In foregoing Magnetic Resonance Imaging (MRI) studies, abnormalities of brain structure and resting-state connectivity were demonstrated in patients with long-term remission of CD. However, no data are available on functional alterations in the brain during the performance of emotional or cognitive tasks in these patients.

Objective

To investigate brain activation during emotion processing in patients with long-term remission of CD.

Design

A cross-sectional functional MRI study.

Methods

Processing of emotional faces versus a non-emotional control condition was examined in 21 patients with long-term remission of CD and 21 matched healthy controls. Functional MRI analyses focused on activation and connectivity of two a priori determined regions of interest: the amygdala and the medial prefrontal cortex (mPFC). In addition, we assessed psychological and cognitive functioning, and clinical disease severity.

Results

Patients with long-term remission of CD showed hypoactivation in the mPFC during processing of emotional faces in patients relative to controls. In addition, functional coupling between the mPFC and posterior cingulate cortex (PCC) was decreased. No differences were found in the activation of the amygdala.

Conclusion

The present study is the first to show alterations in brain function and functional coupling in patients with long-term remission of CD relative to matched healthy controls. These alterations in brain function may, together with abnormalities in brain structure, explain the persisting psychological morbidity these patients after long-term remission.

Exaggerated and additive ACTH responses following the combined ghrelin + CRH test in patients with Cushing's disease

Dragana Miljic[1,2], Snezana Polovina[3], Mirjana Doknic[1,2], Sandra Pekic[1,2], Marko Stojanovic[1], Milan Petakov[1,2], Vera Popovic[1,2] & Dragan Micic[1,2]

[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia; [2]Medical Faculty, Belgrade University, Belgrade, Serbia; [3]Obesity Outpatient Clinic, Clinical Center of Serbia, Belgrade, Serbia.

Ghrelin is able to stimulate HPA axis in both humans and animals. Exaggerated ACTH and cortisol responses to ghrelin have been shown in patients with CD. Here we studied the role of ghrelin alone or in combination with CRH in the diagnosis of CD. In 21 CD patient (18 female, age 49.8 ± 10.2 years, BMI 29.8 ± 0.8 kg/m^2, ten macroadenomas 11 microadenomas) we performed: i) ghrelin test (100 μg iv bolus) ii) CRH test (100 μg iv bolus) and iii) ghrelin + CRH, in random order, one week apart. We also included 8 (seven female, age 40.6 ± 5.3 years, BMI 29.9 ± 1.2 kg/m^2) control subjects (C) in the study. Peak ACTH, cortisol, PRL and GH responses to ghrelin and/or CRH were evaluated (mean ± S.E.). At baseline, ACTH (CD: 71.2 ± 15.6 ng/l; C: 18.9 ± 4.1 ng/l; $P < 0.01$) and cortisol levels (CD: 643.1 ± 41.7 nmol/l; C: 316.4 ± 23.7 nmol/l $P < 0.01$) were significantly higher in CD vs C. After ghrelin administration peak ACTH (CD: 192.3 ± 40.4 ng/l vs C: 71 ± 30.9 ng/l, $P < 0.01$) and cortisol responses (CD: 979.8 ± 46.5 nmol/l vs C: 529.3 ± 74.8 $P < 0.01$) were significantly higher in CD compared with C but similar with ACTH (CD: 179 ± 26.5 ng/l vs C: 59.8 ± 12.3 ng/l, $P < 0.01$) and cortisol responses (CD: 1088.7 ± 51.4 nmol/l vs C: 677.3 ± 71.3 nmol/l, $P < 0.01$) to CRH in both patients with CD and controls. Following the co-administration of ghrelin + CRH an additive ACTH response was observed in both groups (CD: 384.1 ± 74.2 ng/l; C: 176.3 ± 48.5 ng/l) but at a different level. ACTH and cortisol responses, during all three tests, were similar in CD patients with micro- and those with macroadenomas. After stimulation with ghrelin the peak PRL responses (CD: 1046.6 ± 179.7 mU/l; C: 998.4 ± 222.4 mIU/l; $P > 0.05$) were similar in CD compared to C, while GH responses (CD: 21.2 ± 3.7 mIU/l; C: 54.6 ± 9.1 mU/l; $P < 0.05$) were significantly lower in CD. Our results show that ACTH and cortisol secretion remain regulated and responsive to trophic stimuli in patients with CD, which are characterised by exaggerated ACTH and cortisol responses to ghrelin and CRH. Additive ACTH responses to the combined ghrelin + CRH administration, suggest that their ACTH releasing activities may be mediated independently in both patients and controls.

Mental fatigue and executive dysfunction in patients with Cushing's syndrome in remission

Eleni Papakokkinou[1], Peter Berglund[2], Birgitta Johansson[2] & Oskar Ragnarsson[1]

[1]Section for endocrinology, Department of Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Sahlgrenska University Hospital, Gothenburg, Sweden; [2]Department of Clinical Neuroscience and Rehabilitation, Institute of Neuroscience and Physiology, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden.

Background

Patients with Cushing's syndrome (CS) in remission often suffer from impaired quality of life and cognitive dysfunction. Mental fatigue is characterized by mental exhaustion which appears especially during sensory stimulation or following mentally strenuous tasks. Other typical features are long recovery time for restoration of mental energy, irritability, impaired memory and concentration and sensitivity to stress, light and noise. The primary aim of this study was to investigate the occurrence of mental fatigue by using the recently developed mental fatigue scale (MFS) in patients with CS in remission. The secondary aim was to examine whether the more demanding parts C and D of the trail making test (TMT) are more sensitive, compared to the conventional parts A and B, to evaluate speed proceeding, visual search, motor performance and executive functioning.

Methods

This was a cross-sectional study including 51 patients with CS in remission and 51 controls, matched by age, gender and education. All subjects completed the self-administrated MFS and performed all four parts of the TMT.

Results

The mean (± S.D.) age of patients and controls was 52.5 ± 14.6 years and 53.6 ± 13.9 years ($P = 0.7$), respectively. The median time in remission was 12 (4–18) years. The patients had higher scores on all components of the MFS, indicating worse outcome, except for sensitivity to noise. The mean total score on the MFS was 13.5 ± 7.4 in the patients compared to 7.8 ± 4.9 ($P < 0.001$) in controls. After adjustment for fatigue, depression and anxiety the patients performed worse on part D of the TMT ($P < 0.05$) but not on parts A, B and C.

Conclusions

Mental fatigue is common in patients with CS in remission. The most demanding part of the TMT, part D, is more useful to capture cognitive deficits in patients with CS in remission compared to the conventional parts A and B.

Prolactine and urinary free cortisol measurement improve inferior petrosal sinus sampling results in ACTH dependent Cushing's Syndrome

Carmen Fajardo Montañana[1,2], Lucia Camarena Navarro[1], Ma Dolores Ferrer Puchol[2], Carmen Valldecabres Ortiz[2], Jose Gomez Vela[2] & Pedro Riesgo Suarez[2]
[1]Hospital Universitario de La Ribera, Alzira, Spain; [2]Facultad de Medicina. Universidad Católica San Vicente Martir (UCV), Valencia, Spain.

Introduction
Inferior petrosal sinus sampling (IPSS) is considered to be the gold standard for confirming the source of ACTH secretion in patients with Cushing's syndrome (CS). Prolactin measurement during IPSS can improve diagnostic accuracy and reduces false negative responses.
Patients and methods
56 patients with ACTH-dependent CS were included (45 F/11 M, mean age 43.6 ± 10.8 years and 90.1% Cushing's disease) diagnosed since 2000. IPSS was performed in 27 cases (15 with PRL measurement, two excluded due to incomplete data). Depending on IPSS results were classified as typical IPSS response if basal ACTH ratio Central/peripheral (C/P) was >2 and/or after CRH >3, considering others as atypical. Response to surgical treatment and utility of PRL determination were analyzed.
Results
Cortisol response to high DXM suppression test was $>50\%$ in 62.9%, and $>90\%$ in 37% in Cushing's disease. Preoperative pituitary MRI did not identify adenoma in 12.5%. MRI adenoma lateralization was concordant with surgical adenoma lateralization in 92.7%. IPPS was typical in 46.3% (6/13) and there were significant differences typical vs atypical (basal ACTH C/P ratio, ACTH C/P ratio after CRH, peak time, urinary free cortisol (UFC) and PRL correction). Basal PRL ratio C/P was <1.8 in all atypical IPPS and 50% of typical IPPS. Venograms were reviewed and ACTH C/P peak corrected with PRL was >0.8 in Cushing's disease, being most of them >1.2 (5/7). Only two patients have an intermediate value (a cyclic Cushing's disease 1.09 and a microadenoma 1.05). Four patients with atypical IPPS corrected with PRL were referred to surgery and they meet remission criteria up today. After transsphenoidal surgery 90.9% of patients met remission criteria (100% of microadenomas and in those without previous MRI image).
Conclusion
PRL measurement in atypical IPSS allows reclassification, whereas in typical cases can be useful to validate the peak ACTH C/P. PRL elevation after CRH and its use in the correction of the ACTH C/P ratio does not interfere with the interpretation of ACTH C/P peak. It is essential to evaluate UFC to complete the assessment

Pituitary - Therapy of Cushing's disease

GP.22.01

Phase III, multicentre, double-blind, randomised withdrawal study of osilodrostat (LCI699) in patients with Cushing's disease: a study design

Akira Shimatsu[1], Nicholas Sauter[2], Roxzana Kelly[2], Peter Unge[3], Xin Zhi[2] & Maria Fleseriu[4]
[1]Clinical Research Institute, National Hospital Organization Kyoto Medical Center, Kyoto, Japan; [2]Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, USA; [3]Novartis Pharma AG, Basel, Switzerland; [4]Northwest Pituitary Center, Oregon Health & Science University, Portland, Oregon, USA.

Introduction
Osilodrostat is a potent, oral inhibitor of 11β-hydroxylase, the enzyme that catalyses final step of cortisol biosynthesis. In a phase II study, 15/19 patients treated with osilodrostat met the primary endpoint (normal urinary free cortisol (UFC) at 22 weeks); osilodrostat was generally well tolerated. This phase III study aims to confirm the efficacy and long-term safety of osilodrostat.
Patients and methods
Adults (18–75 years) with persistent or recurrent CD post-surgery and/or post-irradiation or with *de novo* CD not considered surgical candidates.
Design
Phase III, multicentre, double-blind, randomised withdrawal study of osilodrostat. Period 1 (week 1–12): Osilodrostat will be initiated at 2mg bid and dose adjusted (range: 1–30 mg bid) based on UFC and patient's safety. Period 2 (week 13–24): Stable dose. Period 3 (wk 26–34): 8-week, double-blind, placebo-controlled randomised withdrawal phase. Patients with mean UFC (mUFC) $\leq$ULN at week 24 and with no dose increase above dose level established at week 12, will be randomised (1:1) at week 26 to continue the same dose of osilodrostat or to receive matching placebo. Patients who are non-responders (UFC $>1.5\times$ULN) will discontinue from randomised withdrawal and resume open-label osilodrostat. Non-randomised patients will continue to receive open-label osilodrostat. Period 4 (week 34–48): Single-arm, open-label osilodrostat treatment for all patients. Endpoints: Primary: proportion of randomised patients in each treatment group with mUFC $\leq$ULN at week 34. Key secondary: proportion of patients with mUFC $\leq$ULN at week 24 with no dose increase above the level established at week 12.
Conclusion
This study design, with a short (8-week) double-blind, placebo-controlled randomised withdrawal period, following a 24-week run-in period of open-label osilodrostat treatment allows assessment of efficacy (versus placebo) and long-term safety of osilodrostat in a larger CD population. This design is well suited to patients with rare and serious diseases such as CD as long-term placebo-controlled studies would be difficult to conduct.

GP.22.02

Surgical outcome and factors associated with Cushing's disease recurrence in 101 consecutive patients operated on by a single pituitary neurosurgeon: the Cleveland Clinic experience

Philip C Johnston[1], Amir H Hamrahian[1], Jim Bena[2], Bob Weil[3] & Laurence Kennedy[1]
[1]Department of Endocrinology, Diabetes and Metabolism, Cleveland Clinic, OH, USA, Cleveland, Ohio, USA; [2]Department of Biostatistics, Quantitative Health Sciences, Cleveland Clinic, OH, USA, Cleveland, Ohio, USA; [3]Department of Neurosurgery, Geisinger Health System, Danville, PA, USA, Pennsylvania, USA.

Background
Transsphenoidal tumour resection (TSS) is the first-line treatment for Cushing's disease (CD). With an experienced neurosurgeon, immediate remission rates $>80\%$ are expected for patients with microadenomas (<10 mm).
Aim
To report initial and long-term remission rates in a specialist centre, and to ascertain factors associated with disease recurrence after TSS.
Methods
Patients with CD ($n=101$, 28M, 73F) having TSS by one neurosurgeon (RJW) at Cleveland Clinic between 2004 and 2013, with a minimum one-year follow-up. Glucocorticoids were withheld during and immediately after surgery; ACTH and cortisol were closely monitored postoperatively with a standard protocol to determine initial remission. After discontinuing hydrocortisone for surgically-induced adrenal insufficiency, long-term recurrence was defined by 24 h UFC $>$ULN, and/or late night salivary cortisol $>$ULN, and/or 8 AM serum cortisol >1.8 mcg/dl after 1 mg overnight dexamethasone.
Results
Median (range) for age and follow up were 46 (15–87) and 4.33 (1–9.8) years, respectively. 74 patients had microadenoma, 27 macroadenoma. Initial remission rates were: microadenoma 89% (66/74), macroadenoma 63% (17/27). Initial non-remission occurred in 18 patients, ten macro- and eight microadenoma. Six of the 83 patients with initial remission have had recurrence of hypercortisolism requiring either repeat TSS or adjunctive therapy. At last follow-up, continuing remission rates are: microadenoma 90%, macroadenoma 74%; 14 (seven macro, seven micro) have persistent hypercortisolism. Macroadenoma ($P=0.003$) and tumour invasion beyond the pituitary ($P<0.001$) were associated with failure of initial remission and greater likelihood of late recurrence. Absence of tumour on pre-operative imaging was not associated with failure of initial remission.
Conclusions
Surgery by a dedicated neurosurgeon in a specialised pituitary centre gives excellent initial and long-term results for CD. Presence of adenoma extension beyond the pituitary and immediate post-operative ACTH and cortisol levels are highly predictive of long-term outcome.

Introduction
Cushing's disease (CD) is a rare disorder caused by an ACTH-secreting pituitary adenoma. Transsphenoidal surgery (TSS) is the recommended first-line treatment. However, an equivocal or even normal preoperative MRI can preclude the surgical management and the outcome of these patients.
Objectives
Evaluate the relationship between preoperative MRI and TSS efficacy in patients with CD.
Methods
Retrospective cohort study of patients with CD followed in our centre between 1977 and 2013 ($n=84$). Patients who lost follow-up or with insufficient data on their personal records were excluded ($n=51$). Statistical analysis: SPSS (21).
Results
Thirty three patients, 29 (87.9%) women, with a median of 33 years (24–70) were included. All patients underwent TSS as first treatment option and were followed postoperatively during a median period of 8 years (1–28). Patients were divided in: Group A ($n=19$), cured patients; and Group B ($n=14$), patients with persistent ($n=3$) or recurrent ($n=11$) CD within a median of 12 months. No significant demographic and clinical differences were recorded between the two groups. Group B patients presented a greater frequency of non-diagnostic preoperative images (28.6 vs 10.5%). And, in patients with a precisely visualized pituitary lesion ($n=27$), those of Group A presented significant lower tumour diameters (8.4 vs 13.9 mm, $P<0.01$), a greater number of pituitary micro-adenoma (68.4 vs 35.7%, $P<0.05$), and none invasive macroadenoma (0% vs 21.4%) compared to Group B patients. All patients with non-diagnostic preoperative MRI ($n=6$) performed inferior petrosal sinus sampling (IPSS), with identification of lateralization of ACTH secretion in all patients (2/2) of Group A and one patient (1/4) of Group B. A pituitary adenoma (confirmed by pathological examination) was found in 84.2% patients of Group A but only in 50% of Group B.
Conclusions
Precise preoperative localisation of a corticotroph adenoma, particularly a microadenoma, in preoperative MRI was associated with a greater efficacy of TSS and a higher probability of cure. Performance of IPSS can be useful in patients with non-diagnostic preoperative MRI.

Long-term (5 years) treatment of Cushing's disease with pasireotide

Stephan Petersenn[1], Luiz R Salgado[2], Jochen Schopohl[3], Lesly Portocarrero-Ortiz[4], Giorgio Arnaldi[5], André Lacroix[6], Shoba Ravichandran[7], Albert Kandra[8], Teresa Bagulho[7] & Beverly MK Biller[9]
[1]ENDOC Center for Endocrine Tumors, Hamburg, Germany; [2]Division of General Internal Medicine, Hospital das Clínicas, University of São Paulo Medical School, São Paulo, Brazil; [3]Medizinische Klinik IV, University of Munich, Munich, Germany; [4]Department of Neuroendocrinology, National Institute of Neurology and Neurosurgery, Mexico City, Mexico; [5]Division of Endocrinology, Polytechnic University of Marche Region, Ancona, Italy; [6]Division of Endocrinology, Centre hospitalier de l'Université de Montréal, Montreal, Quebec, Canada; [7]Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, USA; [8]Novartis Pharma AG, Basel, Switzerland; [9]Neuroendocrine Clinical Center, Massachusetts General Hospital, Boston, Massachusetts, USA.

Background
In a large 12-month Phase III study, pasireotide led to rapid and sustained decreases in UFC and provided clinical benefit in patients with Cushing's disease. Here, we report data following an open-label, open-ended extension.
Methods
162 patients with persistent/recurrent or *de novo* Cushing's disease were randomized in the core study. 58 patients with mean UFC ≤ ULN or clinical benefit at month 12 entered the extension. Dose titration was permitted at the investigators' discretion (300–1200 μg s.c. bid). Efficacy data are presented for those patients who attended the visit at month 60; safety data are presented up to study end for all randomized patients.
Results
16 and seven patients were ongoing at months 60 and 72, respectively; maximum exposure was 76.6 months. For patients who reached month 60, percentage change in median UFC (range) from core baseline was −82.6% (−96.5% to 324.0%; $n=16$) and −81.8% (−94.9% to 3.4%; $n=15$) at months 12 and 60, respectively; of these patients, 10/16 and 11/16 had UFC ≤ ULN at months 12 and 60, respectively. Percentage change in median ACTH (range) was −34.7% (−72.0% to 66.7%; $n=16$) at month 12 and −8.3% (−68.0% to 100.0%; $n=16$) at month 60. Improvements in clinical signs, including systolic and diastolic blood pressure, weight, BMI, and total cholesterol level, were observed by month 6 and were sustained up to month 60. The most common AEs reported from core baseline until study end were diarrhoea (58.6%), nausea (53.7%), hyperglycaemia (41.4%), and cholelithiasis (32.7%); diabetes mellitus was reported in 22.2% of patients.
Conclusions
Initial reductions in UFC and improvements in clinical signs were maintained over 5 years of pasireotide treatment. No new safety signals were reported during long-term treatment. Results from this study suggest that pasireotide may be effective in the long-term treatment of Cushing's disease.

Effects of osilodrostat (LCI699) on cytochrome P450 enzymes in healthy volunteers indicates a low drug–drug interaction potential

Lillian Ting[1], Anadya Prakash Tripathi[2], Christelle Darstein[3], Tracy White[1] & Nicholas Sauter[1]
[1]Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, USA; [2]Novartis Healthcare Pvt Ltd, Hyderabad, Telangana, India; [3]Novartis Pharma AG, Basel, Switzerland.

Introduction
In vitro assessments of osilodrostat (LCI699), a potent oral inhibitor of 11β-hydroxylase suggested potential drug–drug interactions (DDIs) with cytochrome P450 (CYP) enzyme metabolism. This clinical study evaluated the effect of osilodrostat on the pharmacokinetics (PK) of CYP1A2, CYP2C19, CYP2D6, and CYP3A4 probe substrates, caffeine, omeprazole, dextromethorphan, and midazolam, respectively.
Methods
A single-centre, open-label, Phase I, DDI study in healthy adult volunteers ($N=20$; male/female = 10/10). Day 1: A single dose of probe substrates (cocktail approach; caffeine (100 mg), omeprazole (20 mg), dextromethorphan (30 mg), and midazolam (2 mg)) was administered; PK assessments were done over 48 h. Day 2–7: 6-day washout period. Day 8: a single dose of osilodrostat 50 mg was administered followed by a single dose of probe substrates 0.5 h later. PK assessments were conducted over 48 h.
Results
AUC_{last} geometric mean ratio (GMR) and 90% CI of probe substrate exposure with osilodrostat administration were 2.33 (2.10–2.59), 1.91 (1.74–2.11), 1.48 (1.34–1.63), and 1.50 (1.41–1.60); AUC_{∞} GMR (90% CI) were 2.54 (2.34–2.75), 1.86 (1.61–2.15), 1.54 (1.40–1.69), and 1.50 (1.41–1.59) for caffeine, omeprazole, dextromethorphan and midazolam, respectively. C_{max} GMR (90% CI) for the change in substrate exposure was 1.07 (0.988–1.15), 1.61 (1.40–1.84), 1.35 (1.21–1.50), and 1.47 (1.32–1.62) for caffeine, omeprazole, dextromethorphan and midazolam, respectively. CYP1A2 and CYP2C19 are moderately inhibited and CYP2D6 and CYP3A4 are weakly inhibited by osilodrostat; exposures of probe substrates increased by ∼2.5-, ∼2.0-, ∼1.5-, and ∼1.5-fold, respectively.
Conclusions
It is reassuring that CYP3A4 (most clinically important CYP enzyme) was only weakly inhibited by osilodrostat 50 mg single dose, which covers the daily exposure of the maximum dose of 30 mg currently used in clinical trials. In a Phase II study, osilodrostat ≤10 mg twice-daily normalised urinary free cortisol levels in most patients with Cushing's disease; hence osilodrostat is unlikely to have a clinically relevant impact on the exposures of other medications cleared by CYP3A4.

Universitat de Barcelona, Barcelona, Spain; [7]Department Endocrinology, Hospital Clinic, Universitat de Barcelona, Barcelona, Spain; [8]Endocrinology/ Medicine Department, Hospital Sant Pau, IIB Sant Pau, Barcelona, Spain.

Context
Cushing's syndrome (CS) is a rare endocrine disease, due to cortisol hypersecretion. CS patients have several comorbidities, often still present after biochemical cure. There are no specific nursing healthcare programs to address this disease and achieve improved health related quality of life (HRQoL). Thus, an educational nursing intervention in these patients, through the development and promotion of specific educational tools, appears to be justified.
Objective
To assess the effectiveness of an educational nursing programme in CS patients to improve HRQoL, clinical parameters, level of pain and physical activity, patterns of rest and use of health resources.
Patient and methods
A prospective, randomized study was conducted in two reference hospitals for CS. Sixty-one patients (mean age 47 ± 12.7 years, 83.6% females) were enrolled and divided into two groups: an 'intervention' group where educational sessions were performed over nine months and a 'control' group, without these sessions. Specific questionnaires were used at the beginning and end of the study.
Results
After the educational sessions, the intervention group had a better score in Cushing QoL ($P<0.001$), improved level of pain ($P<0.05$), physical activity ($P<0.01$) and healthy lifestyle ($P<0.0001$) compared to the control group. A correlation between the Cushing QoL questionnaire score and improvement in pain ($P<0.05$), physical activity ($P<0.01$) and sleep ($P<0.01$) was observed.
Conclusions
This educational nursing program improved HRQoL, physical activity, healthy lifestyle and promoted adherence to therapy and better sleep patterns in CS patients, reducing health resources consumption. The brief nature of the programme makes it a good candidate to be used in patients with CS.

Neurosurgery outcome in patients with Cushing's disease with and without visualised pituitary adenoma on MRI, who underwent inferior petrosal sinus sampling

Zhanna Belaya, Patimat Khandaeva, Ludimila Rozhinskaya, Aleksandr Vorontsov, Ivan Sitkin, Andrey Grigoriev, Oksana Ivashenko, Larisa Dzeranova & Galina Melnichenko
Endocrinology Research Centre, Moscow, Russia.

Objective
To estimate the outcome of neurosurgery in patients with Cushing's disease (CD) with and without pituitary adenoma visualisation on MRI.
Material and methods
Patients with confirmed CD (11.2008–11.2014) by both inferior petrosal sinus sampling (IPSS) and histological evaluation after neurosurgery were enrolled into the study. Subjects were referred for IPSS because of non-visualised pituitary adenoma or contradictory results of non-invasive tests. Remission of Cushing's disease was confirmed in the event of development of adrenal insufficiency or normalisation of serum cortisol and 24 h urinary free cortisol (24hUFC) levels along with clinical remission at least during 3–6 months after neurosurgery. MRI was performed using Siemens Magnetom Harmony 1.0 T.
Results
A cohort of 113 (88 female) consecutive patients with CD confirmed by IPSS was enrolled, median of age (Q25–Q75) – 36 (27–50) years old; 24hUFC – 1903 (922–4219) nmol/24h; ACTH – 89.5 (60–135) pg/ml. In 51 cases pituitary adenoma was not visualised on MRI with gadolinium, 33 subjects were referred for IPSS because of adenoma ≤ 6 mm, 29 patients underwent IPSS due to negative for CD non-invasive tests. After the first neurosurgery remission was not achieved in 15 (29.4%) patients out of 51 without visualised adenoma on MRI; and in 9 (17.3%) cases out of 62 patients with visualised pituitary adenoma $P=0.066$ OR- 2.45 (0.97–6.21).
Conclusion
Remission rate after neurosurgery does not statistically significant differ between patients with CD with non-visualised pituitary adenoma on MRI and other patients with CD initially referred for IPSS.

Evaluation of strain elastography for differentiation of thyroid nodules: results of a prospective multicentre study

Mireen Friedrich-Rust[1], Christian Vorlaender[2], Christoph F Dietrich[3], Wolfgang Kratzer[4], Wolfgang Blank[5], Andreas Schuler[6], Nathalie Broja[1] & Joerg Bojunga[1]
[1]Department of Internal Medicine 1, University Hospital Frankfurt, Frankfurt, Germany; [2]Department of General Surgery, Buergerhospital Frankfurt, Frankfurt, Germany; [3]Department of Internal Medicine 2, Caritas-Krankenhaus Bad Mergentheim, Bad Mergentheim, Germany; [4]Department of Internal Medicine I, University Hospital Ulm, Ulm, Germany; [5]Department of Internal Medicine 1, Klinikum am Steinberg, Reulingen, Germany; [6]Department of Internal Medicine, Helfenstein Klinik, Geislingen, Germany.

Introduction
Work-up of thyroid nodules remains challenging. At present, many patients with thyroid nodules are referred to surgery for diagnostic rather than therapeutic purposes. Therefore, the value of non-invasive diagnostic methods to optimize the selection of patients for surgery is needed. Strain elastography (SE) enables the determination of tissue elasticity and has shown promising results for the differentiation of thyroid nodules.
Methods
The aim of the present study was to evaluate the value of SE in a prospective multicentre study. A sample size calculation was performed when planning the study and the study was registered at clinical-trials.com. The study was approved by the local ethical committees of all participating centres, and written informed consent was obtained from all patients. All patients received an ultrasound (US) of the thyroid gland including colour doppler US and TIRADS classification. In addition all nodules were evaluated by strain elastography (Hitachi Medical System) using qualitative image interpretation of colour distribution (elastography score (ES) 1–4), strain value and strain ratio. Cytology and/or histology was used as reference method for all benign and histology only for all malignant nodules.
Results
Overall, 604 patients with 659 thyroid nodules (570 benign, 89 malignant) from six centres across Germany were included in the final analysis. Sensitivity, specificity, NPV, PPV, +LR were 22%, 74%, 86%, 11%, 0.8 for colour Doppler vascularization pattern 3–4; 79%, 40%, 92%, 17%, 1.3 for TIRADS; 69%, 74%, 92%, 36%, 2.66 for SE-ES; 58%, 81%, 92%, 32%, 3.0 for SE-strain value (cut-off 0.165); 60%, 78%, 92%, 31%, 2.7 for SE- strain ratio (cut-off 0.376), respectively. The diagnostic accuracies were 70% for TIRADS, 75% for SE-ES, 72% for SE-strain value, and 71% for strain ratio, respectively. No significant difference was found between these diagnostic accuracies.
Conclusions
Strain elastography as an additional ultrasound tool improves the diagnostic value of ultrasound for the exclusion of malignant thyroid nodules. Qualitative and semiquantitative elastography scores are comparably good.

Accuracy of sentinel lymph node biopsy in papillary thyroid carcinoma in decision for selective lateral neck dissection

Ivan Markovic[1,2], Marko Buta[1], Merima Oruci[1], Igor Djurisic[1], Nada Santrac[1], Gordana Pupic[1], Andjela Babic[1], Marija Markovic[1] & Radan Dzodic[1,2]
[1]Institute of Oncology and Radiology of Serbia, Belgrade, Serbia; [2]Medical Faculty University of Belgrade, Belgrade, Serbia.

Introduction
The incidence of occult lymph node metastases (LNM) in papillary thyroid carcinoma (PTC) reaches 80%, still their surgical management in clinically node negative (cN0) patients remains controversial and ranges from 'wait and see' principle to prophylactic dissections of both central and lateral neck compartments. This encouraged some authors to apply the concept of sentinel lymph node biopsy (SLNb) in PTC. Our aim to investigate if SLNb using methylene blue dye is accurate in detection of LNM in lateral neck compartment and may help in decision for selective modified lateral neck dissection in cN0 patients with PTC.
Study design
Study included 153 cN0 patients with PTC. All underwent total thyroidectomy with prophylactic central neck dissection and SLNb of lateral lymph nodes using methylene blue dye with selective modified lateral neck dissection in metastatic SLNs.
Results
Over 80% of patients had pT1 tumours, including 57% of microcarcinoma. Neck LNM were histologically verified in 40.9% of cases. Central neck compartment LNM were predictive for lateral LNM in 80.5% of cases. Predictive factors for LNM were: male gender, patients younger than 45 years, tumours greater than 1 cm, capsular and vascular tumour invasion. Our method enabled detection of metastases in 21% of SLN in lateral neck compartment, which were over 50% predictive of metastasis to other lateral lymph nodes. SLN identification rate (IR) was 91.81%. Sensitivity, specificity, positive and negative predictive value were 85.7, 96.7, 88.3 and 95.9% respectively. The overall accuracy of the method was 94.3%, with 91.2% probability of repeating the results in the second specimen (ROC AUC, 95% CI; 84.2–98.3%).
Conclusion
The proposed method of SLN biopsy is feasible, safe and accurate in detection of additional LNM in the lateral neck compartment and may help in decision for selective modified lateral neck dissection in cN0 patients with PTC.

GP.23.03

Incremental value of serial preablative thyroglobulin measurements in identifying distant metastatic differentiated thyroid cancer

Teng Zhao[1,2], Jun Liang[2], Yansong Lin[1], Xiaoyi Li[1], Tianjun Li[2] & Ke Yang[1]
[1]Peking Union Medical College Hospital, Beijing, China; [2]The Affiliated Hospital of Qingdao University, Qingdao, China.

Introduction
Thyroglobulin plays a vital role in the follow-up of patients with differentiated thyroid carcinoma (DTC) after thyroidectomy combined with radioiodine (RAI) ablation. As to preablative stimulated thyroglobulin (ps-Tg), though several studies have manifested its potential in identifying distant metastatic DTC (DM-DTC), it remains unclear whether a single ps-Tg is sufficient for predicting DM-DTC. This retrospective study was aimed to evaluate the utility of serial ps-Tg measurements in identifying DM-DTC.
Methods
A series of ps-Tg, thyroid-stimulating hormone (TSH) and anti-Tg antibody (TgAb) was measured in 317 consecutive DTC patients before RAI administration, among which data collected at the first time were marked as Tg1, TSH1 and TgAb1, respectively, while as Tg2, TSH2 and TgAb2 at the last time. Patients were divided into two groups as M1 ($n=72$) and M0 ($n=245$) according to the presence of DM or not. Parameters derived from the change in ps-Tg including ΔTg (Tg2-Tg1), $\Delta Tg'$ (Tg2/TSH2-Tg1/TSH1) and ΔTg/ΔTSH (ΔTg/(TSH2-TSH1)) were calculated and further combined with an actual or corrected value of ps-Tg (Tg1, Tg2, Tg1/TSH1 or Tg2/TSH2). All the independent and combined parameters were tested for diagnostic performance in identifying DM-DTC.
Results
Higher Tg1, Tg2, Tg1/TSH1, Tg2/TSH2 and wider amplitudes of ΔTg, $\Delta Tg'$, ΔTg/ΔTSH were observed in M1 (all $P<0.01$). Tg2 and Tg2/TSH2, with corresponding areas under ROC curves (AUC) of both 0.947, were more accurate than Tg1 and Tg1/TSH1. ΔTg/ΔTSH manifested the highest accuracy (88.64%) and specificity (90.20%) among the three parameters of preablative changes, with a diagnostic range of $-0.40\sim0.41$ ng/μIU. Moreover, the diagnostic performance was further improved with a larger AUC (0.951) by combing ΔTg/ΔTSH with Tg2/TSH2.
Conclusions
Serial ps-Tg measurements hold incremental value in identifying DM-DTC. ΔTg/ΔTSH in conjunction with Tg2/TSH2 is a favorable indicator for DM-DTC as well as a feasible approach to assist in preablative assessment and decision-making.

Impact of antithrombotic and/or anticoagulant treatment in cytological results of thyroid fine-needle biopsy

Carlos Arana Molina, Alberto Torres Cuadro, Natividad González Rivera, Clara García García, Virginia Hernando Jiménez, Luna Florencio Ojeda & Tomás Martín Hernández
Endocrinology and Nutrition Clinical Administration Unit, Virgen Macarena-Virgen del Rocío University Hospitals, Seville, Spain.

Introduction
Fine-needle aspiration biopsy (FNAB) of the thyroid gland is an accurate diagnostic test used routinely in the initial evaluation of nodular thyroid disease. A sizeable subset of patients are found to be taking antithrombotic and/or anticoagulant (AT/AC) medications. This creates a dilemma for the endocrinologist, who must weigh the risk of withholding these medications (and the associated potential benefit of diagnosis) against the perceived increased risk of iatrogenic bleeding.
Material and methods
We examined records of patients who underwent ultrasound-guided fine needle aspiration biopsy (US-FNAB) of thyroid nodules from the whole period 2012–2014, in order to determine whether there was a significantly increased incidence of bleeding complications in patients on AT/AC medications (test group) compared to patients not receiving AT/AC therapy (control group). All the studies were performed by the same experienced operator and cytopathologist team. The χ^2 test was used to assess statistically significant differences between test group and control group.
Results
A total of 83 patients (9.09%) were taking AT/AC medications without preprocedural interruption. Five US-FNAB-related hematomas (0.5%) occurred. Three hematomas developed in patients on AT/AC treatment, and two hematomas developed in patients who did not take AT/AC medications ($P=0.0014$). Twenty-four patients in the test group (40.6%) were labelled as 'nondiagnostic' cytology, vs 84 patients in the control group (10.1%) ($P<0.0001$).
Conclusion
Our results revealed an increased incidence in 'non diagnostic' or 'unsatisfactory' cytology in patients on AT/AC treatment, finding not described in previous studies until now. This could be related to a higher rate of cytological artifacts associated with lower blood coagulability. Our results also showed an increased bleeding risk in patients on AT/AC treatment. Despite this fact, most of studies argue that US-FNAB may be performed safely on a patient taking standard doses of aspirin or anticoagulants.

GP.23.05

Comparison of cytopathology vs thyroglobulin measurement in fine-needle aspiration biopsy in patients with differentiated thyroid cancer

Ahmet Kaya, Mustafa Kulaksizoglu & Feridun Karakurt
Necmettin Erbakan University, Meram Medical Faculty Internal Medicine, Konya, Turkey.

Aim
Differentiated thyroid cancer (DTC) is the most commonly seen endocrinological tumour. During the follow up of DTC, serum thyroglobulin (TG) levels, neck ultrasound, fine needle aspiration biopsy (FNAB) of the suspicious lymph nodes are important tools. TG washout of the suspicious lymph node as well as the FNAB can detect metastasis and recurrences earlier. In this study we aimed to show the diagnostic role of TG washout of suspicious lymph node FNAB which is not routinely done.
Methods
Totally 80 DTC patients that had suspicious lymph nodes during the follow up after thyroidectomy and radioactive ablation were retrospectively evaluated. All of patients' FNAB and TG washouts were done. Patients that underwent an operation thereafter were also evaluated according to the pathology.
Results
Totally 80 papillary thyroid cancer (PTC) patients, 91 lymph nodes were evaluated. 22 patients were operated, the rest of the patients that needed operation did not accepted operation. In 16 patients; FNAB was malign and TG washout were positive and all these two predicted the operation pathology which was malign. In three patients FNAB was suspicious, TG washouts were negative but operation pathology was benign, Tg washout predicted the true benign pathology in these three patients. In three patients FNAB was benign but TG washouts were positive and operation pathology was malign and TG washout predicted the pathology. TG washout predicted benign disease in three and malign disease in three patients which FNAB showed the contrary
Conclusion
Our study showed that TG washout can be used with adjunct to FNAB during the follow up of DTC patients that had already operated and received radioactive ablation especially in patients with suspicious lymph nodes on follow up neck ultrasounds. TG washout can aid in diagnosing recurrences and metastasis earlier and can increase the survey of the disease.

GP.23.06

FDG-avidity of thyroid cancer does not predict clinical aggressiveness in PET incidentaloma

Jee Hee Yoon, Hee Kyung Kim & Ho-Cheol Kang
Department of Internal Medicine, Chonnam National University Medical School, Gwangju, Republic of Korea.

Objective
18F-FDG-avid differentiated thyroid cancers (DTC) have been known to behave more aggressively, especially in metastatic sites (flip-flop phenomenon). However, the clinical behaviour of DTC detected incidentally by FDG–PET (PET incidentaloma) has been sparsely reported. We wanted to know whether flip–flop phenomenon is applicable in PET incidentalomas.
Methods
165 DTC patients who underwent thyroid surgery and had pre-operative FDG–PET examination at Chonnam National University Hwasun Hospital between January 2006 and August 2013 were included in the study. We compare the clinical characteristics between screening PET–CT group (thyroid incidentaloma) and staging PET–CT group.
Results
129 DTC patients were FDG-avid and 36 patients non-FDG-avid. FDG avid PTC is more aggressive than FDG non-avid PTC on the clinico-pathologic findings. After removal of high-risk group (staging PET–CT group), thyroid PET–CT incidentaloma patients ($n=107$) were compared according to FDG avidity. Among thyroid PET–CT incidentaloma patients, FDG avid PTC group ($n=75$) revealed larger tumour size (0.97 ± 0.52 vs 0.61 ± 0.35, $P=0.001$), but extrathyroidal invasion (ETI), cervical lymph node metastasis, and distant metastasis is not different between FDG avid PTC group and FDG non-avid PTC group. A cumulative risk of cervical lymph node metastasis according to primary tumour size of FDG avid PTC group is not different from those of FDG non-avid PTC group ($P=0.394$).
Conclusions
DTC detected with FDG-avidity do not seem to behave aggressively, based on initial operative findings. FDG-avidity of DTC does not add to conventional risk factor assessment for initial therapeutic decision.

Immunohistochemical tool for the diagnosis of benign and malignant follicular tumours

Esmeralda Castelblanco[1,2], Montserrat Martinez[3], Ma Dolores Santos[3], Verónica Mancikova[5], Mercedes Robledo[5], Xavier Matias-Guiu[3,4], Javier Maravall[3] & Didac Mauricio[1,2]
[1]Servicio de Endocrinología y Nutrición, Hospital Germans Trias i Pujol, Badalona, Catalunya, Spain; [2]Instituto de Investigación en Salud Germans Trias i Pujol, Badalona, Catalunya, Spain; [3]Instituto de Investigación Biomédica de Lleida, Universidad de Lleida, Lleida, Catalunya, Spain; [4]Servicio de Patología y Genética Molecular, Hospital Universitario Arnau de Vilanova, Lleida, Catalunya, Spain; [5]Centro Nacional de Investigaciones Oncológicas, Madrid, Catalunya, Spain.

Introduction
Follicular tumours of the thyroid gland include benign follicular adenomas, follicular carcinomas and the follicular variant of papillary carcinoma. Although, molecular markers are a promising area of research to differentiate thyroid neoplasms, there is ample room for improvement in the research and clinical applications in this field. Furthermore, the final diagnosis requires thyroid lobectomy. The present study examined whether a differential protein expression could provide an accurate tool to improve diagnosis in these tumours.
Design
The expression of 19 proteins was evaluated in 125 surgically removed thyroid tumours including 81 follicular adenomas (FA) and 44 malignant tumours (nine follicular carcinomas (FTC) and 35 follicular variant of papillary carcinomas (FVPTC)). Classification trees and scoring systems were constructed based on protein expression to generate models that could allow a differential diagnosis between benign and malignant tumours. Forty hyperplastic nodules (HN) were used to test the goodness of fitness of the generated models.
Results
The classification tree that better discriminated between benign and malignant nodules was APLP2 ($n=0$), RRM2 ($n>5$), PRC1c ($n\geq40$), APLP2c ($n\leq105$), and SIAH1 ($n\leq5$), with a sensitivity of 100% and a specificity of 98.8%. In HN, the sensitivity was 94.8%. The punctuation system model $4\times$(APLP2 ($n=0$))$+$ $2\times$(RRM2 ($n>5$))$+1\times$(PRC1c ($n\geq40$)) reached a sensitivity of 100% and a specificity of 71.3%.
Conclusion
Our findings support the potential of these models to improve not only the diagnosis of follicular thyroid tumours but also, the management and wellness of patients by reducing the number of exploratory surgeries. We are currently validating these results in an independent series.

Clinical characteristics in sporadic and familial medullary thyroid carcinomas: worse outcome in sporadic cases even when disease stage at diagnosis is similar

Katerina Saltiki, Loukia Spanou, Sofia Kouki, Gianna Rentziou, Vasiliki Vasileiou, Eleni Anastasiou & Maria Alevizaki
Endocrine Unit, Department of Medical Therapeutics, Alexandra Hospital, Athens University School of Medicine, Athens, Greece.

Objectives
Medullary thyroid carcinoma (MTC) has varying clinical course with familial cases (fMTC) diagnosed earlier than sporadic ones (sMTC). We examined the presentation of these entities in our centre.
Methods
223 MTC patients (familial: 42.6%, males: 36.8%) were followed for 0.9–30 years (mean 6.23 ± 5.9, median 4.0 years). 44 (19.7%) fMTC patients were operated after genetic screening.
Results
Median age at diagnosis was for fMTC: 32.4 ± 16.3 years (range 4–73) and for sMTC: 52.4 ± 13.6 years (range 16–81, $P<0.001$). This difference remained when cases diagnosed after genetic screening were excluded ($P=0.001$). fMTC was more frequent in women than men (48.2% vs 32.9%, $P=0.018$). Capsular invasion, lymph node invasion, distant metastasis at diagnosis was similar. The size of sMTCs was more frequently ≥1.5 cm ($P=0.012$). Stage at diagnosis was more favorable in fMTCs (stages I and II: 60.4% vs 51.2%, stage III: 8.8% vs 23.2%, and stage IV: 42.1% vs 57.9%, $P=0.021$). Preoperative and postoperative calcitonin levels were significantly lower in fMTCs. fMTC had more frequently remission (62.9% vs 49.2%) and less frequently progressive disease (9% vs 36.3%, $P<0.001$).

After excluding patients diagnosed through genetic screening, no difference in stage at diagnosis was observed. Tumour size and postoperative calcitonin levels did not differ. Outcome was more favorable in fMTC compared to sporadic (remission: 56.3% vs 48.8%, stable: 29.2% vs 14.6%, and disease progression: 14.6% vs 36.6%, $P=0.008$). The 10-year probability of lack of progression of disease differed significantly between familial and sporadic MTCs (85.4% vs 63.4%, Kaplan–Meier analysis, $\chi^2=19.01$, $P<0.001$).
Conclusions
After excluding those diagnosed through genetic screening, although stage at diagnosis is currently similar and does not differ between familial and sporadic cases, disease outcome remains worse in sporadic MTCs. Women may have increased awareness for genetic screening in familial cases.

Low/undetectable pre-ablation thyroglobulin in well-differentiated thyroid cancer patients with positive post-ablative ^{131}I whole body scans: causes and consequences

Daniela Guelho[1], Fernando Albán[2], Miguel Melo[1], Cristina Ribeiro[1], Isabel Paiva[1], Carolina Moreno[1], Nuno Vicente[1], Luis Cardoso[1], Diana Martins[1], Diana Oliveira[1], Margarida Balsa[3], Gracinda Costa[2] & Francisco Carrilho[1]
[1]Endocrinology, Diabetes and Metabolism Department, Coimbra Hospital and University Centre, Coimbra, Portugal; [2]Nuclear Medicine Department, Coimbra Hospital and University Centre, Coimbra, Portugal; [3]Endocrinology, Diabetes and Nutrition Department, Baixo Vouga Hospital Centre, Aveiro, Portugal.

Introduction
In patients with well-differentiated thyroid cancer (DTC) low/undetectable thyroglobulin (Tg) at time of remnant ablation usually reflects a complete previous surgery. However, in a small percentage (6.3–16%) it can represent false negative values.
Objectives
Evaluate the frequency of patients with low/undectable Tg at time of remnant ablation with locoregional or distant lesions at post-ablative ^{131}I whole body scan (WBS) and the influence of Tg levels in long-term outcome.
Methods
Retrospective analysis of all patients with DTC submitted to ablative ^{131}I treatment in our centre. Included: patients with a stimulated Tg <5 ng/ml (measured at time of remnant ablation) and locoregional or distant uptake at post-ablative ^{131}I WBS, performed 6–7 days after. Excluded: patients with TSH <30 mUI/ml after thyroid hormone withdrawal or with a follow-up <6 months. Statistical analysis: SPSS (21).
Results
Of 967 patients, 211 (21.8%) were included (178♀; 33♂). Ninety-two (43.6%) presented anti-Tg antibodies. Only patients with negative anti-Tg antibodies ($n=119$) were considered at subsequent analysis. In those, Tg was lower if lymphocytic infiltrate ($P<0.05$) or abundant solid areas ($P<0.05$) present at histopathological evaluation. Post-ablative ^{131}I WBS showed thyroid bed (73.3%), laterocervical (5.9% unilateral and 16.8% bilateral), supraclavicular (0.8%), mediastinal (1.6%), and pulmonar (1.6%) uptake. During a follow-up of 8 ± 4.8 years, 17 (14.3%) patients showed persistence/recurrence of the disease: eight local and nine distant. The probability of persistence/recurrence was significantly higher if lymph node metastasis (OR=11.8; $P<0.01$) or extrathyroid uptake at post-ablative ^{131}I WBS (OR=20.8; $P<0.01$). Disease-free survival was inversely correlated with Tg ($\rho=-0.59$; $P<0.01$), being significantly higher in patients presenting undectable Tg ($P<0.05$).
Conclusion
A fifth of DTC patients presented low/undectable Tg at time of remnant ablation with uptake (locoregional or distant) at post-ablative ^{131}I WBS. In about half was justified by anti-Tg antibodies. In the others, may be related to the presence of microscopic lesions or specific histopathological features. In these patients, low/undectable Tg did not exclude risk of persistence/recurrence, but it seems related with disease-free survival. This study also highlights the importance of post-ablative ^{131}I WBS in the evaluation of these patients.

Prox1 transcription factor is differentially expressed in thyroid cancer and contributes to the regulation of invasion and migration of thyroid cancer cells

Magdalena Rudzinska[1], Damian Gawel[1], Kamila Karpinska[1], Miroslaw Kiedrowski[2], Tomasz Stepien[3], Magdalena Marchlewska[3], Wanda Krasuska[1], Joanna Ledwon[1], Maria Macios[1], Dariusz Lange[4] & Barbara Czarnocka[1]
[1]Department of Biochemistry and Molecular Biology, The Center of Postgraduate Medical Education, Warsaw, Poland; [2]Department of Oncology and Hepatology, Clinical Hospital Ministry of Interior, Warsaw, Poland; [3]Department of General and Endocrinological Surgery, Copernicus Memorial Hospital, Warsaw, Poland; [4]Department of Tumor Pathology, Institute of Oncology Gliwice Branch, Maria Sklodowska-Curie Memorial Cancer Center, Gliwice, Poland.

Introduction
The differentiated thyroid cancer (DTC) is the most frequent endocrine malignancy with the incidence increasing worldwide. Although, DTCs are considered to be mostly indolent lesions, the proportion of patients develop metastases. Therefore, identification of molecular factors that are involved in thyroid tumour progression might help to better understand the mechanism of thyroid cancer metastasis. In the present study we examine the role of the transcription factor prospero homeobox 1 (Prox1) in DTC biology. Prox1 is the nuclear transcription factor expressed specifically in LEC cells and as recently shown, also in several human cancers.
Methods
We performed studies using follicular and papillary thyroid cancer derived cell lines. The Prox1 protein and transcript expression levels and its localization were determined using molecular biology methods: Q-RT-PCR, gene silencing, western blot, and immunocytochemistry. To determine the Prox1 role in regulating the hallmarks of malignant cell phenotype we analysed migration, invasion, anchorage-independent growth, proliferation, cell cycle, apoptosis, and adhesion upon *Prox1* gene silencing.
Results
We observed significant difference in the Prox1 expression between FTC and PTC derived cancer cell lines. Prox1 transcript and protein levels were overexpressed in follicular cancer cell lines FTC133 and CGTH when compared with PTC cell lines. Moreover, the protein was localized in the nucleus or both the nucleus and cytoplasm respectively. RNA-i knockdown of Prox1 suppressed cellular migration, invasion and anchorage independent growth of FTC-133 cells, whereas proliferation, cell cycle and adhesion were unchanged. Moreover, Prox1 down regulation modified of FTC133 cells shape by actin cytoskeleton reorganization.
Conclusion
Our data suggest an important role for transcription factor Prox1 in i) the regulation of hallmarks of the malignant cell phenotype as migration and invasive capacity and ii) in the actin cytoskeleton remodelling in thyroid cancer cells. Further on-going studies will clarify the role of Prox1 in thyroid cancer cells dissemination.

GP.24.02

In papillary thyroid cancer *TERT* promoter mutations have a worst impact on outcome than *BRAF* mutations

Marina Muzza[2], Carla Colombo[2], Maria Carla Proverbio[1], Stefania Rossi[3], Delfina Tosi[3], Michela Perrino[2], Simone De Leo[2], Valentina Cirello[1], Gaetano Bulfamante[3], Leonardo Vicentini[4] & Laura Fugazzola[1]
[1]Endocrine Unit, Department of Pathophysiology and Transplantation, Fondazione IRCCS Ca' Granda, University of Milan, Milan, Italy; [2]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [3]Division of Pathology, Department of Health Sciences, San Paolo Hospital, University of Milan, Milan, Italy; [4]Endocrine Surgery Unit, Fondazione IRCCS Ca'Granda, Milan, Italy.

TERT promoter mutations (chr5: 1 295 228C>T e chr5: 1 295 250C>T) were recently described in thyroid tumors, with a prevalence ranging 8–25% in papillary thyroid cancer (PTC). We and others reported that these mutations strongly associate with a poor outcome in differentiated thyroid cancers. Aim of

the present study was to further investigate the prognostic role of both *TERT* promoter ($TERT^{MUT}$) and $BRAF^{V600E}$ mutations in a larger series of 216 PTCS with a long follow-up (median: 77 months). We also evaluated the possible additive effect on the outcome of the coexistence of the two genetic alterations. Genetic data were obtained by direct sequencing and were correlated with full clinical data. The prevalence of $TERT^{MUT}$ and of $BRAF^{V600E}$ was 12 and 35% respectively. Ten cases (5%) harbored both $TERT^{MUT}$ and $BRAF^{V600E}$. Cases with a $TERT^{MUT}$ alone, but not those with $BRAF^{V600E}$ alone, were significantly associated with older age at diagnosis and poorer outcome ($P=0.04$ for both). No differences in the outcome were noted between cases with the $TERT^{MUT}$ alone or with the coexistence of $TERT^{MUT}$ and $BRAF^{V600E}$. In conclusion, *TERT* mutations were found to have a 12% prevalence in PTCs and were confirmed to be a major indicator of poor prognosis. On the other hand, $BRAF^{V600E}$ was not associated with the outcome, consistent with data previously obtained in our series. Moreover, the outcome was not different among tumors with isolated $TERT^{MUT}$ and those with coexistent mutations ($TERT^{MUT}/BRAF^{V600E}$), indicating that $BRAF^{V600E}$ does not confer an additional effect in the disease persistence.

Evaluation of genetic background of sporadic medullary thyroid carcinomas

Vlasta Sykorova[1], Sarka Dvorakova[1], Josef Vcelak[1], Eliska Vaclavikova[1], Daniela Kodetova[2], Petr Lastuvka[3], Jan Betka[3], Petr Vlcek[4], Pavla Sykorova[4] & Bela Bendlova[1]
[1]Department of Molecular Endocrinology, Institute of Endocrinology, Prague, Czech Republic; [2]Department of Pathology and Molecular Medicine, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic; [3]Department of Otorhinolaryngology and Head and Neck Surgery, 1st Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic; [4]Department of Nuclear Medicine and Endocrinology, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic.

Objectives
Although, almost all patients with inherited medullary thyroid carcinomas (MTC) harboured *RET* proto-oncogene mutation, in patients with sporadic MTC, mutations in *RET* are detected only in half of cases. Thus still unknown genetic causes are responsible for half of sporadic MTC and it is necessary to search for another mutations.
Methods
DNAs from fresh frozen thyroid tissues of 27 sporadic MTC were extracted. The next-generation sequencing (NGS) approach was used to target 175 exonic regions of 26 genes involved in tumors. The samples were prepared using a TruSight Tumor panel (Illumina) and sequenced with a MiSeq sequencer (Illumina). Analysis of variants was performed by MiSeq Reporter Software and evaluated by Illumina VariantStudio Software. *RET* and *HRAS* genes were analysed separately using direct sequencing by CEQ 8000 (Beckman Coulter), because these two genes were not included in the panel.
Results
RET mutations were detected in 12 samples – mutation in exon 16 (Met918Thr) in eight patients and mutations in exon 10 and 11 (Cys618Ser, Cys620Ser, Cys630Ser, and 628–632del) in four patients. In four MTC tissues mutations in *HRAS* genes (codons 13 and 61) were detected. NGS revealed mutations in *KRAS* gene in codons 12 and 61 in three MTC patients. Futher, we identified missense mutation Thr273Asn in gene for hepatocyte growth factor receptor (MET) in the patient with mutation Gln61Arg in *HRAS* gene. Except this patient all mutations were presented exclusively.
Conclusions
In our cohort of sporadic MTC tissues, mutations were detected in 19 patients (70.3%) – *RET* mutations in 44.4% and RAS mutations in 25.9%. Except of known mutations in *RET* and *RAS* genes, the unknown variant in conserved sequence of *MET* gene was revealed which was identified as deleterious and possibly damaging in software SIFT and PolyPhen-2 respectively.

Lymph node involvement using one-step nucleic acid amplification according to *BRAF* gene mutation status in patients with papillary thyroid carcinoma submitted to lymph node dissection

Carles Zafon, Oscar Gonzalez, Jordi Temprana, Gabriel Obiols, Amparo Garcia-Burillo, Xavier Serres, José María Balibrea, Joan Castell, Jordi Mesa & Carmela Iglesias
Hospital Universitari Vall d'Hebron, Barcelona, Spain.

Introduction
The relationship between the *BRAF* gene mutation in papillary thyroid cancer (PTC) and the presence of lymph node metastasis (LNM) is a subject of controversy.
Objective
To analyse the influence of BRAF mutation status in the characteristics of lymph nodes in patients with PTC submitted to lymph node dissection (LND).
Material and methods
Lymph nodes obtained from 20 patients (12 females, mean age 50 ± 15 years old), corresponding to 21 LND were evaluated. LNM were detected using the molecular technique one-step nucleic acid amplification (OSNA), that measures the number of copies of mRNA of cytokeratin 19 (CK19) as a marker. According to the presence/absence of *BRAF* gene mutation cases additional clinical, histological, and node related variables were studied.
Results
A total of 277 lymph nodes from 21 LND were evaluated. BRAF was positive in 13 patients. There were no significant differences in clinical and histological variables according to BRAF mutation. There were no differences in the total number of nodes dissected per patient. There were 67 nodes from BRAF-negative patients and 210 nodes from BRAF-positive patients. There were no significant differences in lymph node weight or size between BRAF-negative and BRAF-positive cases. LNM were detected in 88 nodes, 14 out of 67 (20.9%) in the BRAF-negative group and 74 out of 210 (35.2%) in the BRAF-positive patients ($P=0.03$). Finally, no significant differences were found in the total copy number of mRNA of CK19 between both groups.
Conclusion
The probability of LNM is higher among those lymph nodes with BRAF mutated tumours than in BRAF not mutated cases. However, there were no differences in morphological characteristics of dissected lymph nodes.

Telomerase reverse transcriptase promoter mutation analysis on thyroid core needle biopsy

Marcella Callea[1], Anna Crescenzi[1], Pierpaolo Trimboli[2], Davide Cicciarella Modica[2], Chiara Taffon[1], Leo Guidobaldi[2], Silvia Taccogna[3], Alberto Rainer[1], Marcella Trombetta[1], Enrico Papini[3] & Giovanni Zelano[4]
[1]Campus Bio-Medico University Hospital, Rome, Italy; [2]Israelitico Hospital, Rome, Italy; [3]Regina Apostolorum Hospital, Rome, Italy; [4]Sacro Cuore Catholic University Hospital, Rome, Italy.

Introduction
Among molecular markers proposed to improve diagnosis of thyroid nodules, mutations in telomerase reverse transcriptase (TERT) promoter have been correlated to malignant tumors with highest recurrence and decreased patient's survival. This suggests an important role of TERT mutational analysis in the clinical diagnosis and management of thyroid cancer patients. In this study, we investigate the potential use of core needle biopsy (CNB) for the preoperative assessment of TERT mutational status and we correlate TERT status with BRAF mutation, definitive histology and post-operative TNM staging of the neoplasia.
Methods
The series included 50 thyroid nodules, retrospectively selected among 187 patients who underwent CNB due to an inconclusive fine-needle aspirate (FNA) report, during last 2 years at two different institutions in Rome. Selected cases consisted of 30 papillary thyroid carcinomas (PTC), one follicular carcinoma (FTC), nine follicular adenomas, and ten nodular hyperplasias. Core samples were processed for morphological and molecular analysis. TERT mutational analysis was performed by Sanger sequencing and *BRAF* gene was analysed by pyrosequencing.
Results
C228T TERT promoter mutation was found in 3/30 (10%) of PTC with prevalence of 17.6% among locally advanced PTCs. The only case of FTC, adenomas and hyperplastic nodules did not show the mutation. Mutated cases showed locally invasive PTC with multiple lymph-node metastases and, in one patient, with lung metastasis. All TERT mutated cases showed concomitant V600 BRAF mutation.

Conclusions
The present study demonstrates the feasibility of TERT promoter mutational analysis on thyroid CNB. This methodology consents to identify tumors with a worse outcome at the preoperative time on specimens evaluated for quality and representativeness. This information might be used to individualise treatment decisions, surgical options and follow-up design.

Gene expression profiling in differentiated thyroid carcinoma

Sorina Schipor[1], Ana-Maria Niculescu[3], Dana Manda[1], Andra Caragheorgheopol[1], Sabina Oros[1], Susana Vladoiu[1], Oana Popa[1], Diana Paun[1,2] & Corin Badiu[1,2]
[1]National Institute of Endocrinology C. I. Parhon, Bucharest, Romania; [2]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; [3]Agilrom Scientific SRL, Bucharest, Romania.

Thyroid carcinoma is the most common endocrine malignancy and represents ~1% of all types of human cancer.
Objective
As the molecular pathogenesis of thyroid cancer still remains to be clarified, the goal of our study was to find new molecular markers that could improve the diagnostics, follow-up protocols, treatment outcome, prognosis and the quality of life of differentiated thyroid cancer patients.
Subjects and methods
Matched tumour and normal thyroid tissue samples were obtained from patients that have surgical cure for differentiated thyroid carcinoma after they gave their informed consent. RNA was extracted using the RNeasy Mini Kit from Qiagen and the quality was checked with the Infinite® 200 NanoQuant (Tecan) and with the 2100 Bioanalyzer (Agilent). 24 samples with RIN >7 were chosen for microarray gene expression analysis (six with classical papillary thyroid carcinoma and six with papillary thyroid carcinoma folicullar variant). Microarray analysis was performed following Agilent One-Color Microarray-Based Gene Expression protocol, ver 6.6, using SurePrint G3 Human Gene Expression arrays 8x60K v2.
Results
Using GeneSpring ver 12, we identified 25 genes and two long intergenic non-protein coding RNA (lincRNA 1140 and BROAD Institute lincRNA (XLOC_005062)/lincRNA (TCONS_00010536) down regulated in the tumour tissue compared with the normal one, P value <0.05 and fold change ≥ 2. When accounting for the two thyroid cancer types studied, we identified three genes up-regulated (COL13A1, EDA2R, and KLHDC8A) and eight down regulated (SLITRK5, CCL21, TFPI, TBX1, LOC389033, ADH1C, MMRN1, and F10) in both subtypes. The level of gene expression disregulation is much higher in the case of classical papillary thyroid carcinoma.
Conclusion
Gene expression is altered in papillary thyroid carcinoma. Our study identified three hyper-expressed genes and eight genes with low expression in tumoural tissue compared to normal one. Further studies are undergoing for gene expression data validation by qPCR.

Combination of serum miRNA-190 and -95 is a powerful non-invasive tool in the differential diagnosis of thyroid nodules: preliminary data of a prospective series

Tania Pilli[1], Silvia Cantara[1], Giulia Busonero[1], Sandro Cardinale[1], Gabriele Cevenini[3], Guido Sebastiani[2], Francesco Dotta[1] & Furio Pacini[1]
[1]Department of Medicine, Surgery and Neuroscience, Siena, Italy; [2]Fondazione Umberto Di Mario ONLUS, Toscana Life Sciences, Siena, Italy; [3]Department of Medical Biotechnologies, University of Siena, Siena, Italy.

Background
MicroRNAs (miRNAs) are small non-protein encoding RNAs which negatively regulate gene expression. Tissue miRNA profiles may be useful to distinguish benign from malignant lesions. Recently, we have identified in the serum of a retrospective series of patients, with benign nodular goiter ($n=80$) and papillary thyroid cancer (PTC: $n=79$), two miRNAs (-190 and -95) that in combination (providing the risk of malignancy defined as pmiRNA) allow the differential diagnosis of thyroid nodules with great accuracy. This study was aimed to confirm the diagnostic accuracy of miRNA-190 and -95 in a prospective series of patients.
Methods
Blood samples were collected from 126 consecutive patients undergoing fine-needle aspiration cytology at our Institute. miRNAs were extracted from serum using the miRNeasy Serum/Plasma Kit (Qiagen), and reverse-transcribed using Megaplex Human microRNA RT primers pools v2.1 (Life Technologies). cDNA was then pre-amplified. Relative expression quantification was evaluated by the comparative cycle threshold (CT) method ($2^{-\Delta\Delta CT}$) (Rotor-gene Q, Qiagen). Endogenous miRNA-16 and miRNA-451 were selected as reference to normalize miRNA expression values.
Results
Based on cytology (following BTA guideline): the lesions were benign (Thy2) in 85/121 (70.2%) cases, suspicious for malignancy or malignant (Thy4/5) in 14/121 (11.6%), indeterminate (Thy3) in 16/121 (13.2%), and non diagnostic (Thy1) in 6/121 (5%). A subgroup of 48 patients underwent surgery and the lesions at histology were benign in 30/48 (62.5%) cases and malignant in 18/48 (37.5%). PmiRNA showed a high sensitivity (84%), specificity (93.5%), and diagnostic accuracy (90%) in PTC diagnosis. Moreover, by applying pmiRNA, we could have avoided two out of three unnecessary surgeries in patients with Thy3 cytology.
Conclusions
These preliminary data confirm that pmiRNA may be useful as a non-invasive diagnostic tool for the differential diagnosis of thyroid nodules, particularly in case of indeterminate lesions where pmiRNA role is promising but further studies are warranted.

Identification of a LIN28B/miR-30a axis controlling thyroid cell invasion and proliferation

León Wert-Lamas & Pilar Santisteban
IIB Alberto Sols UAM–CSIC, Madrid, Spain.

The oncofoetal miRNA-binding protein LIN28B plays an important role in differentiation and cancer progression. Lin28B induces epithelial-mesenchymal transition, and it is considered as a bad prognostic marker in several tumours. The aim of this work was to study the effect and regulation of LIN28B on the thyroid cancer progression process. In a first approximation a miRNA targets computational predictions were performed with miRanda algorithm and we found that among others the miR-30a binds to the 3′ UTR of LIN28B. As previous results, obtained by next-generation sequencing expression analysis, performed in our laboratory showed that miR-30a is one of the most significantly miR subexpressed in thyroid cancer, we decided to focus on its role over LIN28B. miR-30a expression vector was transfected in 8505c and Cal62 cells; LIN28B in NThy-ori thyroid cells; and reporter construct containing LIN28B 3′ UTR in HeLa cells. The levels of mRNA and protein were determined by RT-qPCR and western blot. Invasion and proliferation assays were performed in Transwell® and TC20 cell counter, respectively, Lin28B protein expression was determined in 16 thyroid cancer cell lines and was correlated with RAS and BRAF mutations in ATC derived cells. Overexpression of miR-30a resulted in LIN28B, HMGA2, H-RAS, PI3Kβ, BCL2, and CDK6 mRNA and protein silencing, and in an increase in p27(Kip) protein levels in the nucleus. Inversely, LIN28B over-expressing cells showed a decrease in miR-30a levels and an increased expression of HMGA2 and H-RAS oncogenes. Furthermore, we observed that the LIN28B inhibition by miR-30a is specifically elicited through a direct binding to its 3′ UTR. The general outcome was a significant decrease in invasion and proliferation in miR-30a overexpressing cells and, conversely, an increase in these parameters in LIN28B overexpressing cells. These data suggest the existence of a LIN28B/30a axis, with a double negative feedback regulation, whose tumoural shift, leading to overexpression of LIN28B and silencing of miR-30a, widely contributes to thyroid cancer progression.

Long-term results of US-guided high-intensity focused ultrasound treatment of benign thyroid nodules

Roussanka Kovatcheva[1], Jordan Vlahov[1], Julian Stoinov[2] & Katja Zaletel[3]
[1]Department of Thyroid and Metabolic Bone Disorders, University Hospital of Endocrinology, Sofia Medical University, Sofia, Bulgaria; [2]Department of Endocrine Surgery, University Hospital of Endocrinology, Sofia Medical University, Sofia, Bulgaria; [3]Department of Nuclear Medicine, Ljubljana University Medical Centre, Ljubljana, Slovenia.

Introduction
Thyroid nodules can be detected by ultrasound (US) in 20–30% of unselected populations. Various non-surgical techniques such as laser and radiofrequency ablation have been developed to reduce thyroid nodule size. High-intensity focused ultrasound (HIFU) ablation is a new, non-invasive method that has been shown recently. The aim of our study was to assess the long-term efficacy and safety of US-guided HIFU treatment of benign solid thyroid nodules.
Methods
In our prospective study, 14 patients, mean age 47.6 ± 11.2 years, were treated with US-guided HIFU system (EchoPulse, Theraclion) in one session and under conscious sedation. Thyroid nodule volume and volume reduction were established at baseline, 1, 3, 6, and 12 months after treatment. Adverse events were evaluated and pain related to treatment was rated on 0–100 mm visual analogue scale (VAS). Written informed consent was acquired from all patients.
Results
The mean energy applied per nodule volume was 3.7 ± 1.5 kJ/ml. The mean nodule volume decreased from 4.97 ± 2.54 to 3.56 ± 2.01 ml at 1 month, 2.84 ± 1.95 ml at 3 months, 2.55 ± 2.23 ml at 6 months, and reaching 2.35 ± 2.34 ml at 12 months follow-up. The mean nodule reduction was 29.5 ± 15.9% at 1 month ($P < 0.001$), 46.2 ± 18.5% ($P < 0.001$) at 3 months, and 52.8 ± 23.3% ($P < 0.001$) at 6 months follow-up. By the 12th month, the mean volume reduction was 55.7 ± 27.2% with a maximum of 95.4%. Transient subcutaneous oedema and mild skin redness were observed in two patients. VAS score was 26.1 ± 19.5 mm.
Conclusion
One session HIFU ablation is effective non-invasive treatment for benign thyroid nodules at long-term follow-up, without serious adverse events. Our results indicate that US-guided HIFU might become an alternative to surgery and other minimally invasive treatment techniques.
Disclosure
The device for US-guided HIFU treatment and financial support for the supplies were provided by Theraclion (Paris, France).

Thyroid hormones influence the expression of TNF-related apoptosis-inducing ligand

Stella Bernardi[1,2], Fleur Bossi[1], Fabiola Giudici[1], Paola Secchiero[2], Giorgio Zauli[3] & Bruno Fabris[1]
[1]Department of Medical, Surgical, Health Sciences, University of Trieste, Trieste, Italy; [2]Department of Morphology, Surgery, and Experimental Medicine, LTTA Center, University of Ferrara, Ferrara, Italy; [3]Institute for Maternal and Child Health, IRCCS 'Burlo Garofolo', Trieste, Italy.

Background
There is growing evidence supporting TNF-related apoptosis-inducing ligand (TRAIL) involvement in weight and body composition regulation, which are classically influenced by thyroid hormones. This study aimed at investigating the relationship between thyroid hormones and TRAIL.
Methods
Circulating TRAIL was measured in 40 controls, 40 hyperthyroid, and 25 hypothyroid patients before and after their respective treatments. In the same patients *TRAIL* gene expression was quantified in peripheral blood mononuclear cells. The effect of T_3 and T_4 on TRAIL secretion was evaluated *in vitro*.
Results
TRAIL gene and protein expression significantly increased in hyperthyroid and decreased in hypothyroid patients (vs controls $P < 0.05$). TRAIL gene and protein expression normalized once euthyroidism was restored ($P < 0.05$). There was a significant correlation between TRAIL and both T_3 and T_4 ($P < 0.05$). Moreover, the changes in body weight and BMI that we found once euthyroidism was restored were significantly correlated to the changes in TRAIL ($P < 0.05$). The *in vitro* study showed that T_3 stimulated TRAIL release in a dose-dependent manner.
Conclusion
These findings are consistent with the view that TRAIL might be involved in body weight regulation. In addition, this work sheds light on the possibility that TRAIL might be one of the molecules mediating thyroid hormone peripheral effects.

Malignancy rate in thyroid nodules with AUS/FLUS cytology in a Cancer Center (Bethesda System for Reporting Thyroid Cytopathology 2009)

Joana Menezes Nunes[1,2], Raquel Martins[2,3], Jacinta Santos[3], Teresa Martins[3], Ana Paula Moniz[4], Olga Ilhéu[4], Paulo Figueiredo[4] & Fernando Rodrigues[3]
[1]Endocrinology, Diabetes and Metabolism Department, Centro Hospitalar S. João, Porto, Portugal; [2]Faculty of Medicine, Oporto University, Porto, Portugal; [3]Endocrinology Department, Instituto Português de Oncologia Francisco Gentil, Coimbra, Portugal; [4]Pathology Department, Instituto Português de Oncologia Francisco Gentil, Coimbra, Portugal.

Introduction
The Bethesda System for Reporting Thyroid Cytopathology is the standard for interpreting fine-needle aspiration (FNA) and created a new diagnostic category (III): 'atypia of undetermined significance/follicular lesion of undetermined significance' (AUS/FLUS). The risk of malignancy for this category has been ascribed of 5–15% but the real malignancy rate remains unclear and plays a key role to define appropriate management.
Objective
To determine malignancy rate in AUS/FLUS cytologies.
Methods
A total of 126 consecutive patients with AUS/FLUS cytology were retrospectively identified. Results of follow-up, repeat biopsy or surgical pathology were evaluated. Data are presented as frequencies. For comparison we performed Student's *t*-test (statistically significance < 0.05).
Results
Among 126 patients, 19.0% (24/126) underwent immediate surgery and 50.0% (63/126) repeated FNA. Of patients immediately submitted to surgery, just one was found to have a papillary microcarcinoma inserted into the index lesion, the remaining suspicious nodules being benign. We found five incidental papillary carcinomas (4 < 1 cm). Repeat FNA cytology was unsatisfactory/non-diagnostic in 22.2% (14/63), benign in 17.5% (11/63), AUS/FLUS in 49.2% (31/63), suspicious for malignancy in 9.5% (6/63), and malignant in 1.6% (1/63). Of nodules with two consecutive AUS/FLUS cytologies that were resected (21/31), 23.8% (5/21) were malignant and in one case the lesion couldn't be determined as benign/malignant. We found no statistical significance regarding nodule size and probability of malignancy of the suspicious nodule (31.7 mm vs 23.0 mm, $P = 0.145$). Overall, 57 patients underwent surgery to remove the index lesion, yielding a malignancy rate of 19.3% (11/57), as one case couldn't be classified by histology. Incidental cancers were found in 21.0% (12/57).
Conclusions
Repeating biopsy allows a significant proportion of AUS/FLUS patients to avoid surgery. In our series, nodules with two AUS/FLUS cytologies harbour a malignancy rate of 23.8%. Incidental papillary carcinomas cancers are frequent (21.0%), in accordance with its high prevalence in general population.

GP.25.04

Evaluation of benign thyroid nodules in a 10-year follow-up

João Silva, Catarina Ivo, Mafalda Marcelino, Hélder Simões, Luís Lopes, Dolores Passos & João Jácome de Castro
Armed Forces University Hospital, Lisbon, Portugal.

Introduction
American Thyroid Association recommends that benign thyroid nodules should be revaluated 6–18 months after initial FNA and in case of stability the follow-up should be 3–5 years. However there isn't any consensus about the periodicity of the follow-up.
Aim
To evaluate the nodules in terms of function, size and malignancy in a 10-year follow-up.

Methods
Retrospective study of 347 patients (543 benign thyroid nodules) followed in consultation. Inclusion criteria: follow-up $\geq$10 years; normal thyroid function; Initial benign FNAC. Evaluation at 5 and 10 years of the following parameters: size, growth (>20% diameter and at least 2 mm in two dimensions), cytology, thyroid function, and therapeutic approach. The variables were analysed by methods of descriptive statistics: frequency tables and contingency for categorical variables and mean, S.D., minimum, and maximum for continuous variables.
Results
We included for analysis 441 nodules of 282 patients, 71% females, mean 56.3$\pm$13.1 years old. The average of nodules size were 18.9$\pm$12.1 mm in the first evaluation. In 5 years 29.45% had increased (mean 9.91$\pm$8.46 mm) and decreased 19.1% (average 8.81$\pm$4.85 mm). In 10 years 31.5% had increased (average 11.53$\pm$7.31 mm) and 15.7% decreased (6.84$\pm$4.83 mm). None of the evaluated nodules turned hyperfunctioning. 17.1% of the evaluated nodules were submitted to surgery, 72% of which for its size (>40 mm or compressive complaints) and the rest by cytological abnormalities. 28% of the nodules revealed to be malignant (4.79% of total).
Conclusions
In this study it was found that about 1/3 of nodules increased in size and 4.79% revealed to be malignant, even with a previous benign cytology. Our results favour a monitoring and a FNAC repetition of the nodules during follow-up, an usual practice in our department.

Sox9 is expressed in thyroid follicular cells and regulates the expression of thyroid differentiation genes

Arístides López-Márquez, Carlos Carrasco-López & Pilar Santisteban
Instituto de Investigaciones Biomédicas 'Alberto Sols' CSIC–UAM, Madrid, Spain.

The transcription factor Sox9 is a member of the HMG-box-DNA binding family essential for chondrocyte differentiation, sexual determination, and the maintenance of the stem/progenitor cells in several tissues. Furthermore, Sox9 is involved in the development of endoderm-derived-organs. Owing to the endodermic origin of the thyroid, we proposed to study the expression of Sox9 in thyroid follicular cells and its regulation by TSH and TGFβ, two main factors involved in thyroid function. In addition the role of thyroid transcription factors Nkx2-1, FoxE1, and Pax8 was studied. Sox9 mRNA, protein levels and promoter activity were determined by RT-qPCR, western blot, and transient transfection assays after TSH and TGFβ treatment. Forskolin and H89 were used to study the cAMP/PKA pathway. Co-transfections in Hela cells were performed to elucidate the role of the different transcription factors in the regulation of Sox9 as well as its role over other thyroid specific genes. We showed that Sox9 is expressed in thyroid cells and TSH induced the mRNA, protein levels and promoter activity, while TGFβ inhibited the TSH induction. The TSH effect takes place through cAMP/PKA pathway as forskolin mimics its effects and the PKA inhibitor H89 inhibited it. The *in silico* analysis of Sox9 promoter reveals the presence of CRE, Smad and thyroid transcription factors binding sites. The results obtained have demonstrated that Sox9 promoter is activated by Pax8 and CREB and inhibited by FoxE1. Interestingly, Sox9 activates FoxE1 promoter while inhibited Nkx2-1 and Pax8 ones. These results demonstrate the involvement of Sox9 in the physiology of the thyroid, something hitherto unknown. In addition our results open a new field to study the role of Sox9 in the development and differentiation of the thyroid gland.

Clinical outcome of thyroid nodules characterised as atypia of undetermined significance or follicular lesion of undetermined significance (The Bethesda System for Reporting Thyroid Cytopathology) after fine-needle aspiration

Fernando García[1], Mariana Tomé[2], Guillermo Martínez de Pinillos[1], Eyveé Arturo Cuéllar[1], Mariola Méndez[1], Juan Manuel García de Quirós[1], Ignacio Fernández Peña[1], Ignacio Fernández López[1], Juana Hidalgo[1], Margarita Rivas[1], Santiago Durán[1] & María Victoria Cózar[1]
[1]Hospital de Valme, Seville, Spain; [2]Hospital Punta Europa, Cádiz, Spain.

Introduction
'Atypia of undetermined significance (AUS) or follicular lesion of undetermined significance' category is established by The Bethesda System for Reporting Thyroid Cytopathology because of the necessity to report those thyroid fine-needle aspiration (FNA) results that are not easily classified into the benign, suspicious or malignant categories. In most cases, a repeated FNA results in a more definitive interpretation. Estimated risk of malignancy for an AUS nodule is 5–15%.
Description of methods
A restrospective study was conducted in which those patients with a result of AUS after thyroid FNA between 2010 and 2013 were included. The following variables were considered: proportion of repeated FNA and average time of delay; consistency between repeated and initial FNA; therapeutical management and malignancy incidence rate.
Results
We studied 59 patients (94.9% females, mean age 48.3$\pm$14.3 years). FNA was repeated in 76.3% of patients with an average delay of 195.5$\pm$125.4 days between both FNA. We achieved the following interpretations: benign 55.6%; persistent AUS 17.8%; follicular neoplasm or suspicious of folicular neoplasm 17.8%; and suspicious for malignancy 8.9%. Thyroidectomy was performed in 55.2% of all patients (40.6% without repeating FNA and 59.4% after repeating FNA). In all cases lobectomy was the selected procedure. The incidence of malignancy was 10.2% of the total sample (18.2% of patients who underwent surgery).
Conclusion
Repeating FNA in patients with a result of 'atypia of undetermined significance/folicular lesion of undetermined significance' may contribute to clarify the diagnosis in a large number of cases, helping in the selection of patients who should undergo surgery or alternatively should be observed clinically. The incidence of malignancy detected in our series is consistent with the incidence expected by The Bethesda System.

Malignancy risk stratification of thyroid nodules by TIRADS; correlation with cytological results

Antonio J Martínez, Virginia Hernando, Clara García, Alberto Torres & Tomás Martín
Virgen Macarena Hospital, Seville, Spain.

Introduction
Knowing that only in 5–15% of FNABs the pathological analysis shows malignancy, enhance diagnostic accuracy is needed. The use of the TIRADS score and a revised version proposed by the British Thyroid Association (BTA) intend to determine if a FNAB should be performed or not in the evaluation of nodular goitre.
Objective
To determine whether an adequate correlation is present between the risk category assigned to the nodules studied under TIRADS/BTA system and cytological results.
Material and methods
To assess the potential of the TIRADS/BTA systems and the degree of concordance with the results derived from FNAB, we designed a retrospective, observational study including 230 patients who underwent thyroid ultrasonography and FNAB. Nodules were classified following the BTA score as benign (U2), probably benign (U3), and suspicious/probably malignant (U4+5). FNAB samples were informed according to the Bethesda classification. Statistical analysis was assessed using the SPSS Statistical Suite (ver 21.0).
Results
Total sample n=230 (valid pairs, n=204); 71.3% females, mean age 59.2$\pm$5.6 years. U2 nodules were 76%; in one case (0.7%) the pathological analysis was consistent with malignancy/suspicious for malignancy while the rest of them (99.3%) were informed as benign. U3 nodules comprised 18 nodules, from which 55% had a benign pathological diagnosis, 16.66% probably benign, and 27.77% malignant or suspicious for malignancy. The high-risk group (U4+5) included n=31 (15.1%) nodules: FNAB results showed a malignant/suspicious for malignancy diagnosis in 80.6%, in 12.9% benign, and in 6.4% probably benign. TIRADS score sensitivity was 75% (95% CI: 57.79–87.85%); specificity was 97.62% (95% CI: 94.01–99.33%), with a positive predictive value of 87.1% and a negative predictive value of 94.8%. Cohen's κ coefficient was 0.69 (P<0.001).
Conclusions
The TIRADS/BTA risk scores have proven to be a useful tool to assess thyroid nodules and the need for FNAB, enhancing diagnostic accuracy and resource allocation.

Quality of life in primary hypothyroidism after long-term levothyroxine replacement

Marina Djurovic[1], Alberto Pereira[2], Olga Vasovic[3], Zvezdana Jemuovic[1], Dragan Pavlovic[4], Milan Petakov[1], Biljana Salak[5] & Svetozar Damjanovic[1]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Clinical Centre of Serbia, University of Belgrade, Belgrade, Serbia; [2]Department of Endocrinology and Metabolic Diseases, Leiden University Medical Center, Leiden, The Netherlands; [3]Institute for Gerontology and Palliative Care, Belgrade, Serbia; [4]Faculty of Philosophy, University of Belgrade, Belgrade, Serbia; [5]Institute of Neurology, Clinical Centre of Serbia, University of Belgrade, Belgrade, Serbia.

Introduction
There is an increasing awareness for intrinsic imperfections of endocrine replacement therapy affecting general well-being in the long-term. For thyroid hormone, many factors affect the variable responses to hormone replacement, like common genetic variations in deiodinase and thyroid hormone transport proteins, and the inability to provide adequate individual combined T_4 and T_3 therapy. Despite levothyroxine (L-T_4) replacement in primary hypothyroidism and restoration of biochemical euthyroidism, many patients have persistent complaints that have anecdotally been associated to high levels of antibodies against TPO (anti-TPO).
Aim of the study
i) To assess quality of life (QoL) in patients with Hashimoto's thyroiditis (HT) on adequate L-T_4 replacement and ii) to explore potential associations with serum TSH and anti-TPO.
Design
Cross-sectional, case–control study.
Patients and controls
One hundred and twenty patients on long-term L-T_4 replacement for HT (mean age 54.0 ± 14.0 years, range 21–75 years) and 60 euthyroid control subjects (aged 53.1 ± 12.4), matched for age, gender, and educational level.
Methods
Evaluation of FT_4, TSH, and anti-TPO concentrations, and of QoL as measured with the Short Form-36 Health Survey (SF-36) for mental health and vitality in both patients and controls. Patients and controls were subdivided into two age groups: 20–49 years (GR1) and 50–75 years (GR2), with a mean duration of L-T_4 replacement of 3.95 and 9.27 years respectively.
Results
FT_4 and FT_3 levels were not different between patients and controls, but TSH was slightly higher in Hashimoto patients (GR1 3.64 ± 2.74 vs 1.93 ± 1.10, $P<0.05$ and GR2 3.93 ± 2.84 vs 1.91 ± 0.90, $P<0.05$). SF-36 scores in the patients were significantly lower for both age groups compared with controls (patients vs controls): dimension A–physical health; GR1: 70.18 ± 15.74 vs 76.54 ± 13.71, $P<0.05$; GR2: 55.84 ± 20.2 vs 75.1 ± 121.0, $P<0.01$; SF-36 score GR1: 69.8 ± 16.4 vs 76.4 ± 14.1, $P<0.05$; GR2: 57.6 ± 21.1 vs 73.7 ± 14.2, $P<0.05$. In addition, in both groups anti-TPO levels, but not TSH, were associated with SF-36 scores subscale2 $r=-0.208$, $P=0.029$; subcale3 (body pain) $r=-0.268$, $P=0.005$; subcale4 (general health) $r=-0.198$, $P=0.038$; dimension A $r=-0.224$, $P=0.019$; and SF-36 score $r=-0.191$, $P=0.046$.
Conclusion
Patients on long-term L-T_4 replacement for HT have impaired QoL that is associated with higher anti-TPO levels.

High serum IgG4 concentrations in patients with Hashimoto's thyroiditis

Anna Poplawska-Kita, Maria Kosciuszko-Zdrodowska, Katarzyna Siewko, Beata Telejko, Justyna Hryniewicka, Robert Milewski, Małgorzata Szelachowska & Maria Gorska
Medical University of Bialystok, Bialystok, Poland.

Purpose
Recent reports strongly suggest that at least some cases of Hashimoto's thyroiditis (HT) may be closely associated with IgG4-related disease. In the present study we aimed to find out, whether the measurement of serum IgG4 allows for an identification of distinct types of HT, with different clinical, sonographic and serologic characteristics.
Methods
The group studied consisted of 53 patients with HT and 28 healthy individuals. All the participants underwent thyroid ultrasonography and body composition analysis. Serum concentrations of IgG4, TSH, anti-peroxidase antibodies (TPOAb), anti-TSH receptor antibodies, TNFα, TGF-β1, Fas ligand, TRAIL, and chemokines: CXCL9, CXCL11, and CXCL10 were also measured by commercial ELISA or RIA.
Results
The group with IgG4 level >135 IU/ml accounted for 32.5% of the patients. The percentage of male patients was 7.5% in the subgroup with normal IgG4 and 18.2% in the subgroup with high IgG4 concentration. The signs of fibrosis were present in 27.0% of the high-IgG4 patients and in 9.1% of the normal-IgG4 group. The patients with elevated IgG4 required higher doses of L-thyroxine, had significantly lower level of TPOAb ($P=0.02$) than the non-IgG4-HT individuals, and higher TNFα level in comparison with the controls ($P=0.01$); whereas the concentrations of other cytokines/chemokines and apoptotic markers did not differ between the groups studied.
Conclusions
Our results suggest that the measurement of serum IgG4 allows for an early identification of patients more rapidly progressing and destructive form of HT, who require higher doses of L-thyroxine. A relatively low TPOAb level and the absence of co-existing autoimmune diseases may suggest a distinct pathomechanism of this type of thyroiditis.
Disclosure
The study was supported by grant number 123-50-723L from the Medical University of Bialystok, Poland.

GP.26.03

Adverse metabolic correlations relate to free T_3 levels in subclinical hypothyroidism; common FOXE1 polymorphisms associate with blood pressure

Anna de Lloyd[1], Ilaria Muller[1], Alan Dodd[2], Ameen Bakhsh[1], Hilary Durrant[2], Lei Zhang[1], Carol Evans[2], Aled Rees[1] & Marian Ludgate[1]
[1]Thyroid Research Group, IMEM, Cardiff University, Cardiff, UK; [2]Department of Medical Biochemistry and Immunology, University Hospital of Wales, Wales, UK.

Introduction
The effects of mild subclinical hypothyroidism (SH; TSH <10 mU/l) on metabolic outcomes are unclear. This may relate to differences in aetiology, including thyroid autoimmunity or genetic factors such as TSH-receptor mutations (TSHR-M) and FOXE1 polyalanine tract length (FOXE1–PTL) polymorphisms, which are associated with altered thyroid function. We hypothesised that the metabolic manifestations of SH may depend upon its aetiology.
Aims
i) To establish whether free T_4, free T_3, or TSH associate with metabolic parameters and blood pressure (BP) in SH. ii) To investigate whether SH aetiology has a differential effect on metabolic parameters and BP.
Methods
A total of 208 adults with primary untreated SH (TSH ≥ 5 mU/l) were recruited and underwent a medical/lifestyle history, resting BP and BMI measurement, genetic evaluation (for TSHR-M and FOXE1–PTL status), thyroid function, anti-TPO antibody measurement, and metabolic assessments (HOMA-IR, full lipid profile). Associations were examined using stepwise multivariate regression analyses.
Results
TSH showed a small positive association with free T_3 (R $+0.6$, $P=0.01$) and a negative association with free T_4 (R -1.1, $P<0.001$) but no association with metabolic factors or BP. Free T_3 showed a positive association with BP (systolic R $+10$, $P<0.001$ and diastolic R $+3$, $P=0.02$) and HOMA-IR (R $+1.3$, $P=0.009$). No significant metabolic associations were found for TSHR-M or TPO antibody positivity. The 14/14 FOXE1–PTL (60% of cohort) was positively associated with free T_3 compared to other genotypes (R $+0.2$, $P=0.007$) and negatively associated with BP (systolic R -6, $P=0.006$ and diastolic R -4, $P=0.01$).
Conclusions
Free T_3 correlated positively with BP and HOMA-IR in this cohort, irrespective of SH aetiology. An unexpected association between FOXE1–PTL polymorphisms and BP was revealed.

Nkx2.5 gene mutations are not associated with congenital heart defects in children with thyroid dysgenesis

Helton Estrela Ramos[1,2], Taise Lima de Oliveira Cerqueira[2], Yane Rocha Ramos[1], Paula Leite[3], Jailciele Santos[1], Daniel San Martin[1], Anabel Goes Costa[3], Vladimir Fernandes[4], Giorgia Strappa[1], Mariana Souza de Jesus[1], Tatiana Amorim[5] & Ana Marice Ladeia[3]
[1]Universidade Federal da Bahia, Salvador, Bahia, Brazil; [2]Centro de Pesquisa Gonçalo Moniz – FIOCRUZ, Salvador, Bahia, Brazil; [3]Escola Bahiana de Medicina e Saúde Pública, Salvador, Bahia, Brazil; [4]Diagnoson – Grupo Fleury, Salvador, Bahia, Brazil; [5]Associação de Pais e Amigos dos Excepcionais – APAE, Salvador, Bahia, Brazil.

Context
Several specific transcriptional factors, in view of their important role in thyroid organogenesis and thyroid specific gene expression, would be strong candidate genes for the etiology of TD. The homeobox transcription factor *NKX2.5* was thought to be only required for the organogenesis of the heart tube. However, *NKX2.5*$^{-/-}$ embryos also exhibited a smaller outgrowing thyroid bud. Indeed, several loss of function mutations in *NKX2.5* have been described in patients with congenital heart disease (CHD), and an Italian study has identified three mutations in patients with TD.
Objectives
To search for genetic alteration in *NKX2.5* gene in patients presenting both TD/CHD and isolated TD.
Methods
Among 1051 neonates screened between 2001 and 2013, 851 children were identified with CH. Individual phenotypes were analyzed in 86 children with TD using thyroid function tests (TT_4 and TSH), scintigraphy and ultrasound as diagnostic tools. Seven patients had CHD and TD. DNA was extracted from whole blood and *NKX2.5* gene coding region was amplified by PCR and sequenced.
Results
CHD were found in 8.1% of patients with TD investigated. The mutation screening revealed two known polymorphisms in 48 patients with isolated TD or TD associated with CHD. None of them are predicted to result in codon change in conserved domain (p.Glu21; p.Gln181).
Conclusion
NKX2.5 mutations were not found in patients having TD or TD associated with CHD. *NKX2.5* gene might not be a strong candidate gene for mutation screening in population based studies. It would be of interest to attempt to identify additional NKX2.5 downstream target genes and upstream signaling pathways for a more complete knowledge of the function of this homeobox protein during thyroid migration and morphogenesis.

Oral liquid thyroxine assumed at breakfast: preliminary results of the TICO study

Ilenia Pirola, Annamaria Formenti, Linda Daffini, Alessandra Cristiano, Elena Gandossi, Floriana Pini & Carlo Cappelli
Endocrine and Metabolic Unit, Department of Medical and Surgical Sciences, University of Brescia, Brescia, Italy.

Many conditions may interfere with intestinal absorption of levothyroxine (L-T_4). In addition, it has been demonstrated a failure in the normalisation of TSH values in patients consuming L-T_4 tablets with coffee or with water followed by coffee taken shortly afterwards. Recent studies showed that oral liquid L-T_4 could remove the problem of L-T_4 malabsorption by coffee and food observed with traditional tablets formulations. To evaluate the efficacy of oral liquid T_4 assumed at breakfast, we conducted the TICO study: a double-blind, placebo-controlled trial, designed to enrolled 80–100 hypothyroid patients, aged from 18 to 75 years who have to start replacement therapy. All the patients were given two identical and indistinguishable vials (labelled A and B), one containing in a single dose of the oral solution and the other a placebo; one had to be assumed half an hour before breakfast and the other one during their usual breakfast. After 40 days of treatment, all the patients were submitted to TSH, fT_4, and fT_3 evaluation to ensure euthyroidism values had been reached. All the patients then had to switch the order in which the vial contents were ingested. After 40 days, TSH, fT_4, and fT_3 values were re-tested. At this time 72 patients (54/18 females/males, mean age 48.8±5.7 years old) completed the study. The mean dose of L-T_4 was 64.71±30.17 μg/day. At the end of the study no differences to TSH serum (2.84±1.91 mIU/l vs 2.62±1.76 mIU/l, $P=0.470$), fT_4 (10.57±1.32 pg/ml vs 10.44±1.24 pg/ml, $P=0.546$), and fT_3 (2.75±0.36 pg/ml vs 2.85±0.28 pg/ml, $P=0.193$) were observed among the patients whether assuming vials A or vials B at breakfast. In conclusion, we have clearly demonstrated that liquid L-T_4 can be taken at breakfast, facilitating compliance to L-T_4 replacement therapy. Finally, the oral solution L-T_4 could be suitable for patients who cannot swallow the solid formulations.

Analysis of hypothyroidism in patients admitted to internal medicine wards in Spain 2005–2012

Rona Penso[1], Alejandra Duran[1], Teresa Ruiz Gracia[1], Irene Crespo[1], Ana Ortola[1], Paz De Miguel[1], Manuel Mendez[1], Karla Nuñez[1], Judith Lopez[2] & Javier Marco[1]
[1]Hospital Clinico San Carlos, Madrid, Spain; [2]Hospital Universitario de Canarias, San Cristobal de la Laguna, Spain.

Introduction
Hypothyroidism (hT) is a very common disease that can affect inpatients prognosis. We analysed the clinical profile of patients with hT admitted to Internal Medicine using a large clinical-administrative database.
Methods
A descriptive analysis based on the minimum-data-set database of the Spanish National health System of patients who were discharged from the services of Internal Medicine with the diagnoses of hT during 2005–2012 was performed.
Results
A total of 3 984 533 patients admitted to Internal Medicine were included, identifying 141 616 cases of hT (3.6%). From the population 75.8% were women, average age in hT patients was 74.34 (S.D.: 14.30). Overall mortality in hT group was 7.6% vs 10% in nonhT (nhT). The 14.3% of the patients hT were readmitted, whereas in the whole population the 13.3% did it. The average hospital stay was 9.73 (S.D.: 10.04) days. The comorbidities associated to hT were as follows: connective tissue disease (2.2% in hT vs 1.1% in nonhT), diabetes mellitus (32.5% vs 27.5% respectively), hypertension (42.1% vs 36.9% respectively), hypercholesterolemia (23.4% vs 16.2% respectively), obesity (12.8% vs 7.5% respectively), anemia (21.9% vs 16.1% respectively), and chronic renal impairment (15.9% vs 11.5% respectively). In the multivariable analysis hT was associated to a lower mortality rate OR 0.71 (95% CI 0.70–0.73; $P<0.05$). In the adjusted analysis by age (95% CI 1.052–1.053; $P<0.05$) and by comorbidities Charlson index OR 1.246 (95% CI 1.245–1.248; $P<0.05$).
Conclusion
Hypothyroidism was associated with cardiovascular risk factors as well as other comorbidities (obesity, anemia, kidney failure, and connective tissue pathologies). Some authors suggest that the increase in TSH levels could have a protective effect during admission. However, surprisingly in the hT group there was lower mortality rate. Further studies are needed to confirm this results and determinate other involved factors.

Cardiovascular risk factors in autoimmune thyroiditis and subclinical hypothyroidism

Celestino Neves[1], César Esteves[1], João Sérgio Neves[1], Oksana Sokhatska[2], Miguel Pereira[1], Carmo Palmares[2], Camila Dias[3], Davide Carvalho[1], Luís Delgado[2] & José Luís Medina[1]
[1]Endocrinology Service, Faculty of Medicine, São João Hospital, University of Porto, Porto, Portugal; [2]Immunology Department, Faculty of Medicine, São João Hospital, University of Porto, Porto, Portugal; [3]Department of Biostatistics and Medical Informatics, Faculty of Medicine, São João Hospital, University of Porto, Porto, Portugal.

Introduction
Subclinical hypothyroidism appears to be related with an increased risk of cardiovascular disease. It was our objective to evaluate the relationship between autoimmune thyroiditis, subclinical hypothyroidism, and cardiovascular risk factors.
Methods
We evaluated thyroid function tests, autoimmunity, total cholesterol, LDL-cholesterol, HDL-cholesterol, triglycerides, ApoA1, ApoB, Lp(a), homocysteine, high sensibility CPR, folic acid, vitamin B12, HOMA-IR, HOMA-β, QUICKI,

HISI, WBISI, and IGI in 186 subjects with autoimmune thyroiditis and in euthyroid state and in 69 subjects with autoimmune thyroiditis and subclinical hypothyroidism. Statistical analysis was performed with Mann–Whitney *U* test, logistic regression, and Spearman correlations. In our study group, 94% of patients were females. The median age was higher in the euthyroid group (49 years vs 42 years; $P=0.03$). The results were adjusted for age and BMI and are expressed by median ± percentiles 25 and 75. Statistical significance was considered for a bilateral value of $P<0.05$.

Results

Patients with higher levels of total cholesterol (OR = 1.008; $P=0.03$), CPR (OR = 1.684; $P=0.04$), or anti-thyroglobulin antibodies (OR = 1.002; $P=0.02$) have an increased likelihood of having subclinical hypothyroidism. In the total group of patients, we observed positive correlations between TSH and CPR ($r=0.132$; $P=0.043$), between TSH and HOMA-IR ($r=0.158$; $P=0.029$), between free T_3 and HDL-cholesterol ($r=0.16$; $P<0.01$), and between free T_4 and IGI ($r=0.22$; $P<0.01$). TSH levels correlated negatively with QUICKI ($r=-0.16$; $P=0.02$), HISI ($r=-0.16$; $P=0.03$) and WBISI ($r=-0.16$; $P=0.02$) and free T_4 levels with WBISI ($r=-0.18$; $P=0.01$). In the group with subclinical hypothyroidism, we found negative correlations between free T_3 and homocysteine ($r=-0.36$; $P=0.01$) and between free T_4 levels and anti-TPO antibodies ($r=-0.28$; $P=0.02$).

Conclusion

The interrelations between thyroid function, lipid profile, CPR, and insulin resistance demonstrate an increase of cardiovascular risk in subclinical hypothyroidism due to autoimmune thyroiditis.

GP.26.08

Prevalence and clinical associations of calcium-sensing receptor and NALP5 autoantibodies in patients with autoimmune polyendocrine syndrome type 1

Mahmoud Habibullah[1], Nicolas Kluger[2], Annamari Ranki[2], Harpreet Sandhu[1], Kai Krohn[3], Anthony Weetman[1] & Helen Kemp[1]
[1]University of Sheffield, Sheffield, UK; [2]University of Helsinki, Helsinki, Finland; [3]Helsinki University Central Hospital, Helsinki, Finland.

Rationale and hypothesis

Autoimmune polyendocrine syndrome type 1 (APS1) is a rare autosomal recessive disease which is characterised by chronic mucocutaneous candidiasis and multiple autoimmune endocrinopathies and results from mutations in the autoimmune regulator (*AIRE*) gene. Approximately 80% of APS1 patients present with hypoparathyroidism which is suggested to result from aberrant immune responses against the parathyroid gland. As patients typically display organ-specific autoantibodies which correlate with a particular clinical manifestation, there has been much research to identify a parathyroid-specific autoantibody target. Previous studies have identified the parathyroid-expressed calcium-sensing receptor (CaSR) and NALP5 as autoantigens in APS1. However, it is unclear if autoantibodies against CaSR or NALP5 are a specific or sensitive marker for APS1-associated hypoparathyroidism.

Methodology

A case–control study including 44 APS1 patients and 38 healthy control subjects. Methods included ELISA; radioligand binding assays; immunoprecipitation assays; DNA sequencing; and statistical analysis.

Findings

CaSR and NALP5 autoantibodies were detected in 16/44 (36%) and 13/44 (30%) of APS1 patients, respectively, but not in healthy control subjects. No statistically significant association was found between the presence of CaSR or NALP5 autoantibodies and hypoparathyroidism ($P>0.05$). The detection of CaSR and NALP5 autoantibodies had specificities of 83 and 50%, and sensitivities of 39 and 26%, respectively, for the diagnosis of hypoparathyroidism. There were no significant associations between the presence of CaSR or NALP5 autoantibodies and either sex, age, or age at disease presentation (P values were >0.05). However, a significant association between a shorter APS1 duration (<10 years) and positivity for CaSR autoantibodies was noted ($P=0.019$). This was not the case for NALP5 autoantibodies.

Conclusions

Since CaSR and NALP5 autoantibodies are not specific or sensitive markers for hypoparathyroidism in APS1, further investigations are required to identify a useful diagnostic marker for this clinical manifestation in APS1.

No effect of Thr92Ala DIO2 polymorphisms on thyroid parameters, health-related quality of life, and cognitive functioning

Bruce H R Wolffenbuttel, Hannah C M van Loon, Martin F Elderson, Jana V van Vliet-Ostaptchouk, Hanneke J C M Wouters, Anneke Muller Kobold, Thera P Links, Sandra N Slagter & Melanie M van der Klauw
University of Groningen, Univ Med Ctr Groningen, Groningen, The Netherlands.

Introduction

The Thr92Ala polymorphism of deiodinase 2 (DIO2) is associated with increased expression in the brain of genes associated with oxidative stress, and may predict favourable response to combination thyroxine (L-T_4) plus triiodothyronine (T_3) therapy. We examined whether the Thr92Ala polymorphism (rs225014) was associated with differences in thyroid hormone parameters, health-related quality of life (HR-QOL) and cognitive functioning in a large population-based study.

Methods

In 4223 participants from the LifeLines Cohort Study (141 using L-T_4) TSH, free thyroxine (FT_4), and free T_3 (FT_3) levels were measured. HR-QOL was assessed with the Short Form-36 questionnaire. The Ruff figural fluency test (RFFT) was used as a sensitive cognitive test. Linear regression with an additive model was used to analyse association between the Thr92Ala genotypes and phenotypes of interest.

Results

Mean (± S.D.) age was 56 ± 10 years and BMI 27.3 ± 4.4 kg/m^2 in the L-T_4 users vs 51 ± 11 years and 26.4 ± 4.1 kg/m^2 in non-L-T_4 users; 3847 subjects had normal TSH (0.4–4.5 mU/l), and 90% of L-T_4 users were females. The rarer CC genotype (Thr92Ala-D2) of the rs225014 polymorphism in DIO2 was present in 10.2% of the total study population. In non-L-T_4 users, the Thr92Ala-D2 polymorphism was not associated with differences in TSH, FT_4, FT_3, and the FT_3/FT_4-ratio, and there were no differences in any of the eight HR-QOL domains or the RFFT score. L-T_4 users had higher FT_4, lower FT_3 and lower FT_3/FT_4-ratio, lower scores on the HR-QOL domains physical functioning, general health and vitality (all $P<0.001$) and lower RFFT scores ($P=0.004$). Also, their thyroid hormone parameters, HR-QOL and cognitive functioning were not influenced by the Thr92Ala genotype.

Conclusion

The Thr92Ala polymorphism of DIO2 was not associated with thyroid parameters, HR-QOL and cognitive functioning in the general population and subjects with hypothyroidism.

HLA-DR in Hashimoto's thyroiditis

Agata Jabrocka-Hybel[1,2], Anna Skalniak[1,2], Jakub Piętkowski[1,2], Renata Turek-Jabrocka[1,2], Palina Vyhouskaya[1], Adrian Tsang[3], Katarzyna Lizis-Kolus[4], Grzegorz Sokołowski[2], Dorota Pach[1,2] & Alicja Hubalewska-Dydejczyk[1,2]
[1]Jagiellonian University Medical College, Krakow, Poland; [2]University Hospital in Krakow, Krakow, Poland; [3]University of Ottawa, Ottawa, Ontario, Canada; [4]Swietokrzyskie Oncology Centre, Kielce, Poland.

Background

The human leukocyte antigen (HLA) cluster is a genetic region that has been associated with multiple autoimmune disorders, also with autoimmune thyroid diseases. Plenty attempts to establish the significance of class II HLA-DR in Hashimoto's thyroiditis (HT) development were undertaken in the past; however, reports are rather divergent. This might be caused by different criteria used to diagnose HT. There is however an alternative hypothesis, according to which a specific amino acid signature in the binding cleft, found among different types, might be more important in triggering susceptibility to HT than the type itself.

Aim

The presented study tests the hypothesis of whether and how HLA-DR can alter HT risk.

Materials and methods

Five hundred unrelated Hashimoto cases and healthy controls were studied. Including criteria for HT were in accordance with current recommendations (positive auto-antibodies, hypothyroidism, characteristic ultrasound). We sequenced the binding cleft-encoding exon of *HLA-DRB1* in all participants. For differences of allele frequencies between groups the χ^2 test was implemented.

Stepwise logistic regression analysis was performed for testing the importance of amino acid signatures of the binding cleft.
Results and conclusions
We show results for HLA-DR of a big project on the genetics of HT. We found that, indeed, the amino acid signature of the binding cleft, encompassing positions 26, 30, 70, 71, and 74, might be important for the development of the disease, but our results let us also conclude that this model would explain only about 5% of the susceptibility to HT. The results for HLA-DR may also differ when additional genetic and environmental factors are considered simultaneously. It therefore seems reasonable to include this genetic region into analyses encompassing multiple genes as well as non-genetic factors. This will be the next step of our ongoing project.

The effect of TSH suppression therapy on the cortical bone geometry in the patients with differentiated thyroid cancer

Jae Hoon Moon[1], Hoon Sung Choi[3], Chan Hyun Jung[2], Kyung Young Kim[2], Young Joo Park[2], Do Joon Park[2] & Kyong Yeun Kim[1]
[1]Seoul National University Bounding Hospital, Seongnam, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea; [3]Kangwon National University Hospital, Kangwon-do, Republic of Korea.

Background
TSH suppression therapy has been associated with hip and vertebral fracture. However, the relationship between TSH suppression and bone mineral density (BMD) remains controversial. The aim of this study was to evaluate the effect of TSH suppression therapy on cortical bone geometry in differentiated thyroid cancer (DTC) patients.
Methods
This study included 122 subjects (19 men, 27 premenopausal women, and 75 postmenopausal women) who have been on TSH-suppressive doses of levothyroxine after thyroidectomy due to DTC during at least 3 years. Patients were matched with 366 healthy controls. Dual-energy X-ray absorptiometry at the hip and lumbar spine was performed and geometry of hip was analysed.
Results
The mean TSH level was 0.23 ± 0.44 μIU/ml and the proportion of calcium/vitamin D supplement was 51.6% in 122 subjects. TSH suppression therapy did not impair the BMD of patients compared with controls. In addition, cortical bone geometry including cortical width of femur neck (5.5 ± 1.9 vs 5.4 ± 1.1, $P=0.903$ in men, 5.9 ± 1.1 vs 5.0 ± 0.6, $P=0.079$ in premenopausal women, and 5.0 ± 0.9 vs 5.1 ± 0.7, $P=0.563$ in postmenopausal women) and buckling ratio (4.0 ± 2.1 vs 4.0 ± 1.4 in male, 3.0 ± 0.8 vs 3.4 ± 0.3 in premenopausal women, and 3.6 ± 0.7 vs 3.5 ± 0.6 in postmenopausal women) showed no significant difference in patients compared to healthy controls.
Conclusions
There was little evidence of adverse effect of TSH suppression on cortical bone geometry in DTC patients.

MIVAT vs traditional thyroidectomy: a 5-year follow up in 284 cases

Elisa Bertocchi, Paolo Del Rio, Lorenzo Viani, Elena Bonati & Mario Sianesi
General Surgery and Organ Transplantation, University Hospital of Parma, Parma, Italy.

Introduction
Minimally invasive video-assisted thyroidectomy (MIVAT) was introduced for the treatment of selected patients. Our experience from 2005 indicates that outcome of surgery in differentiated thyroid cancer (DTC) is comparable in patients treated with MIVAT vs conventional thyroidectomy; minimally invasive technique is characterized by a better postoperative discomfort.
Material and methods
In this prospective study from July 2005 to December 2009, 284 patients with cytological negative node underwent either MIVAT ($n=102$) or conventional thyroidectomy ($n=182$). The following criteria for MIVAT were applied: thyroid volume, nodule size, and pathological criteria. We have collected age, nodule mean size, operative time, serum calcium level pre and post surgery. In follow-up these data were recorded: cumulative dose of radio-active iodine (RAI) and serum thyroglobulin (Tg) at 5 years.
Results
The clinical parameters of the MIVAT and conventional thyroidectomy groups were comparable except for age (mean 44.8 ± 9.9 years vs 52.3 ± 14.1 years, $P=0.03$) and operative time (mean 63 ± 23.5 min vs 54 ± 15.4 min, $P=0.02$); the mean tumour size was similar between groups (1.3 ± 0.6 cm vs 1.6 ± 0.8 cm, $P=0.15$). Surgical morbidity was similar in both groups. Median follow-up was 5 years. RAI dose (mean 73 ± 36 mCu vs 97 ± 45 mCu, $P=0.33$) and serum Tg at 5 years (mean 0.4 ± 0.1 years vs 0.4 ± 0.2 years, $P=0.3$) were not significantly different between the minimally invasive and the conventional thyroidectomy groups.
Conclusion
MIVAT can be safely utilised in patients with DTC providing early oncological outcome comparable to conventional thyroidectomy. Patients treated with minimally invasive surgery showed an improvement of postoperative pain and cosmetic result.

Clinical and biochemical factors affecting prognosis of disease persistence in micro papillary thyroid carcinomas

Katerina Saltiki, Michael Apostolakis, Sophia Kouki, Loukia Spanou, Anastasia Athanasiadou, Evangelia Zapanti & Maria Alevizaki
Endocrine Unit, Department of Medical Therapeutics, Alexandra Hospital, Athens, Greece.

Introduction
In recent years, micro papillary thyroid carcinomas (mPTCs; ≤ 1.0 cm) are increasingly diagnosed. Although clinical course is usually favourable, disease persistence may occur and multiple treatments needed. We examined factors that could be predictors of clinical behaviour and disease persistence.
Patients and methods
478 mPTC patients (78.9% females) followed-up for 0.6–10 years were classified according to tumour size in group 1: 0.1–0.2 ($n=85$), group 2: 0.3–0.4 ($n=81$), group 3: 0.5–0.6 ($n=96$), group 4: 0.7–0.8 ($n=79$), and group 5: 0.9–1.0 cm ($n=137$).
Results
Median age at diagnosis, sex and histological type did not differ between subgroups. Capsular and lymph node invasion as well as soft tissue involvement was more frequent with increasing tumor size ($P<0.001$). Multifocality and distant metastasis at diagnosis was similar. Patients with mPTCs ≥ 0.7 cm (groups 4 and 5) underwent more frequently lymph node dissection ($P=0.009$) as well as ablation with ^{131}I ($P<0.001$). In those who underwent thyroid ablation, disease remission during the 12-month Tg-stimulation (Tg ≤ 1.0 ng/ml) was less frequent in group 5 (group 1: 85.7%, group 2: 88.2%, group 3: 92.7%, group 4: 85.4%, and group 5: 69.1%, $P=0.007$). However, after multiple treatments (>1 surgeries and/or repeated ^{131}I administration) the disease outcome did not differ significantly. The 10-year probability of lack of progression of disease did not differ between groups (100% vs 97% vs 100%, vs 100%, vs 95.5%, respectively, $P=0.3$). In Cox proportional hazard analysis when age at diagnosis, tumour size, lymph node, capsular and tissue invasion were taken into account the only predictor for disease progression was lymph node invasion (HR 0.039, 95% CI 0.004–0.379, $P=0.005$). Similar results were found when only those who underwent ablation with ^{131}I were examined. 10.3% of patients with lymph node invasion showed disease progression; all belonged to group 5 ($P=0.038$, Pearson χ^2).
Conclusions
Although, patients with tumours ≥ 0.9 cm have more frequently disease persistence, the final outcome is similar in all mPTC groups. Lymph node invasion may be the only factor predicting disease progression in mPTCs.

TIM16 inhibition enhances sensitivity to paclitaxel and decreases calcitonin secretion by reducing mitochondrial membrane potential in a human medullary thyroid carcinoma cell line

Teresa Gagliano[1], Eleonora Riva[1], Federico Tagliati[1], Daniele Matteotti[1], Valentina Brugnoli[1], Silvia Sambugaro[1], Marta Bondanelli[1], Erica Gentilin[1], Simona Falletta[1], Katiuscia Benfini[1], Carmelina Di Pasquale[1], Remo Guerrini[2], Severo Salvadori[2], Ettore degli Uberti[1] & Maria Chiara Zatelli[1]
[1]Section of Endocrinology and Internal Medicine, Department of Medical Science, University of Ferrara, Ferrara, Italy; [2]Department of Chemical and Pharmaceutical, University of Ferrara, Ferrara, Italy.

TIM16, a protein of the translocase complex TIM23 of the mitochondrial inner membrane, is encoded by the Magmas a gene. Magmas silencing has been associated with a greater sensitivity to apoptotic stimuli in pituitary adenoma cell lines. We recently demonstrated that in a human medullary thyroid carcinoma cell line (TT) compound 5, a TIM16 inhibitor, was not cytotoxic but enhanced the proapoptotic effects of staurosporine. The aim of our study is to verify whether mithocondrial function is involved in compound 5 effects. To evaluate cell viability we performed ATPlite assay, while caspase 3/7 assay was used to determine apoptotic activation. ELISA test was used for calcitonin detection in cell culture medium, while TMRM assay was employed to evaluate mitochondrial membrane potential (MMP). Our data show that paclitaxel 10 nM was reduced cell viability by 40%, while compound 5 alone had no effects. However, compound 5 was able to significantly increase the effects of paclitaxel by nearly 14%. In addition, paclitaxel increased caspase 3/7 activity by 130%, which was further increased by co-incubation with compound 5. In addition, we found that compound 5 was able to reduce basal and pentagastrin induced calcitonin secretion. Furthermore, compound 5 and paclitaxel decreased MMP (by -15 and -20% vs CT respectively), and their combination was even more potent (-50% vs CT). In conclusion, compound 5 could represent a tool to increase the effects of chemotherapeutic agents and to control hypercalcitoninemia in medullary thyroid carcinoma.

Effect of a very low dose of rituximab on active moderate–severe Graves' orbitopathy: an interim report

Guia Vannucchi[1], Irene Campi[1], Danila Covelli[1], Nicola Currò[2], Davide Dazzi[3], Sabrina Avignone[4], Clara Sina[4], Claudio Guastella[5], Lorenzo Pignataro[5] & Mario Salvi[1]
[1]Endocrine Unit, Fondazione IRCCS Cà Granda, Milan, Italy; [2]Ophthalmology, Fondazione IRCCS Cà Granda, Milan, Italy; [3]Neuroradiology, Fondazione IRCCS Cà Granda, Milan, Italy; [4]Otolaryngology, Fondazione IRCCS Cà Granda, Milan, Italy; [5]Internal Medicine, Ospedale di Fidenza, Fidenza, Italy.

Previous studies have shown that Rituximab (RTX) is effective as a disease modifying drug at doses of 500 mg or 1000×2 mg in active Graves' orbitopathy (GO). We have conducted a pilot study (EUDRACT 2012-001980-53) in which patients with active moderate-severe GO were treated with a single infusion of low dose RTX (100 mg). Ten patients were enrolled of whom seven completed the study at 52 weeks. Five patients did not respond to a previous treatment with i.v. methylprednisolone, whereas five had newly diagnosed GO. Disease activity was assessed with the clinical activity score (CAS) and severity with NOSPECS score. The primary endpoint was the decrease of the CAS of 2 points or CAS ≤3.

Results

Of the seven patients who completed the study, six had inactive disease at 12 weeks (ANOVA, $P=0.01$); one was submitted to surgical orbital decompression because of signs of optic neuropathy (ON). Another patient, although who had disease inactivation at 12 weeks, underwent surgical orbital decompression at 22 weeks because of suspected subclinical ON. At 24 weeks four patients were inactive (ANOVA, $P=0.001$); one had a transient disease reactivation with stabilization at 40 weeks. The treatment was well tolerated with only minor infusion-related reactions.

Conclusion

Very low dose of RTX seems effective in disease inactivation but may not modify the natural course of disease as has been observed with higher therapeutic doses.

hCG levels are essential for the correct interpretation of gestational TSH levels: the clinical risk assessment of premature delivery

Tim Korevaar, Marco Medici, Layal Chaker, Henning Tiemeier, Theo Visser & Robin Peeters
Erasmus University Medical Center, Rotterdam, The Netherlands.

Context

High maternal TSH and/or low FT_4 during pregnancy is associated with an increased risk of premature delivery. hCG is the main determinant of thyroid function changes during pregnancy but has a versatile pattern with high inter and intra-individual variability. We hypothesised that the correct interpretation of thyroid function tests and its use in the risk assessment of premature delivery during pregnancy depend on hCG levels.

Design, setting, and participants

TSH, FT_4, hCG, and TPO-antibody levels were available in 5956 women. In logistic regression models for premature delivery we tested for interaction between TSH or FT_4 and hCG and when significant analyses were stratified. All analyses were adjusted for maternal age, smoking, education level, ethnicity, parity, BMI, height, and foetal gender.

Results

The association between TSH levels and premature delivery was different according to hCG levels (P interaction $=0.02$). The risk of premature delivery in women with high TSH levels $\geq$85th, $\geq$90th, or $\geq$95th percentile but low hCG levels was decreased by 47, 61, and 18% respectively. The risk of premature delivery in women with high TSH levels $\geq$85th, $\geq$90th, or $\geq$95th percentile but high hCG levels was increased two-, 3.1-, and 6.1-fold respectively (P low vs high <0.001). The association between FT_4 levels and premature delivery was not different according to hCG levels (P interaction $=0.23$). However, women with very low FT_4 levels ($\leq$3rd percentile) had different risks for premature delivery according to hCG (low to high OR 1.99–3.11; $P=0.02$). All results remained similar after exclusion of TPOAb positive women, women with preeclampsia or amongst women with spontaneous premature delivery only.

Conclusion

The addition of hCG may improve the risk assessment of premature delivery according to TSH. High TSH levels despite high hCG levels reflect the inability of thyroid function to increase according to hCG stimulation. This inability to increase is a novel risk factor for premature delivery. Future studies are needed to replicate these results and incorporate these findings into clinical decision models.

Plasmapheresis in thyroid storm caused by exogenous thyroid hormone intake: a case series

Tiago Nunes da Silva[1], Bernardo Dias Pereira[1], Henrique Vara Luiz[1], Ricardo Macau[2], Ana Catarina Matos[1], Isabel Manita[1], Pedro Bravo[2], Maria Carlos Cordeiro[1], Luisa Raimundo[1] & Jorge Portugal[1]
[1]Hospital Garcia de Orta–Endocrinologia e Diabetes, Almada, Portugal; [2]Hospital Garcia de Orta–Nefrologia, Almada, Portugal.

Thyroid storm (TS) is one extreme of a continuum beginning with thyrotoxicosis. It's rarely caused by exogenous thyroid hormone intake (ETHI). Aggressive medical therapy is the cornerstone of treatment; nevertheless, it might not be sufficient. Plasmapheresis is an extracorporeal technique that can rapidly lower thyroid hormone levels. The aim of this study was to assess the efficacy of plasmapheresis in TS secondary to ETHI. We evaluated retrospectively all TS cases (Burch–Wartofsky score >45) caused by ETHI, treated with plasmapheresis between 1991 and 2014 in a tertiary hospital. Patient clinical data, normal thyroglobulin and negative anti-thyroglobulin antibodies ruled out endogenous causes. Statistical analysis was performed with Wilcoxon's test (SPSS v.21).

Five cases were recorded. The median age was 45 years and four patients were female. The Burch–Wartofsky score ranged from 50 to 85. All patients presented with delirium, the median heart rate was 134 b.p.m. and four patients required an intensive care unit because of hemodynamic instability. Standard medical therapy for TS was initiated on admission. Plasmapheresis sessions ranged from 3 to 4 and were started between days 2 and 5 after admission. Before the first plasmapheresis, median TT_4 was 70 μg/dl (4.5–12.5), FT_4 17.2 ng/dl (0.8–1.5), TT_3 1800 ng/dl (80–200), and FT_3 46 pg/ml (1.5–5). The first session induced a significant decrease in median TT_4 and FT_4 levels of 40 and 46% respectively ($P=0.043$). After the last session, a significant large decrease in all thyroid hormone levels was observed: TT_4 – 75%, FT_4 – 72%, TT_3 – 92%, and FT_3 – 85%. ($Z=-2.023$, $P=0.043$, $r=0.64$). Euthyroidism was achieved after a median of 12 days.

Our study showed that plasmapheresis induced a significant and rapid decrease in hormone levels, allowing all the patients to recover. It should be considered as a second line therapy for refractory TS induced by ETHI and should be started relatively soon in the treatment algorithm.

There is a detectable immune activity in the orbits of all patients diagnosed with Graves' disease regardless of later development of Graves' orbitopathy

Eszter Berta[1,2], Bernadett Újhelyi[4], Lajos Szabados[3], László Galuska[3], Annamária Erdei[1], Annamária Gazdag[1], Sándor Halmi[1,2], Endre Nagy[1] & Miklós Bodor[1,2]
[1]Division of Endocrinology, Department of Medicine, University of Debrecen, Debrecen, Hungary; [2]Department of Clinical Pharmacology, University of Debrecen, Debrecen, Hungary; [3]Department of Nuclear Medicine, University of Debrecen, Debrecen, Hungary; [4]Department of Ophthalmology, University of Debrecen, Debrecen, Hungary.

Graves' orbitopathy (GO) is a common complication of Graves' disease (GD) which is often responding poorly to therapy. GO may develop before or together with, or during the course of GD. In an individual patient, the development of GO cannot be predicted. We assumed that orbital autoimmune activity is predictable using orbital 99mTc-labelled diethylenetriamine pentaacetic acid (99mTc-DTPA) SPECT. We aimed to determine whether any orbital autoimmune activity can be identified in patients who do not develop GO during their follow-up. Fifty-four orbits of 27 patients newly diagnosed with GD were entered into the study. Patients with present GO were excluded. None of the patients had received antithyroid drugs or ophthalmic measures before entering the study. An initial 99mTc-DTPA SPECT was performed and DTPA uptake as sign of disease activity calculated in each case. SPECT was repeated during follow-up if clinical signs of GO occurred, and a final SPECT was performed at the end of the follow-up period, after 1 year. Twenty orbits of control patients who underwent DTPA SPECT of the hands for Raynaud's phenomenon served as controls. During the 2-year follow-up, six out of the 27 patients (22%) were diagnosed with newly developed GO. The mean initial DTPA uptake of the orbits of GD patients with or without later developing GO was significantly higher than results obtained from the control group (10.45 ± 1.72, 9.18 ± 1.18, and 7.7 ± 2.44 MBq/cm^3, respectively, $P < 0.05$). Initial DTPA uptake values of the six patients who later developed GO were not different from the rest of the GD group. All GD patients have mild orbital activity signs by the DTPA technique in the early stage of GD, irrespective of development or lack of GO during the course of GD. This uniform ongoing subclinical inflammation may be a reversible early stage of GO.

Introduction
Available literature on series of patients affected by ectopic Cushing's syndrome (ECS) deriving from neuroendocrine tumours (NETs) is relatively scarce. This is the first Italian multicentre study regarding clinicopathologic features, modalities of treatment, and survival of patients with NETs and ECS.

Patients and methods
Retrospective analysis of data from patients with ECS from NETs collected in 14 centres between 1986 and 2014, obtained by a specific questionnaire.
Results
96 patients, 58.3% females, mean (S.D.) age at diagnosis 50.4 ± 15 years. Clinical presentation included hypertension (87%), diabetes mellitus (67%), proximal myopathy (67.7%), weight loss (28.1%), skin fragility (53%), hypercoagulopathy (28%), osteoporosis (47%), and psychiatric disease (32.3%). Regarding prevalence of NETs, 42.7% were bronchial carcinoids, 3.1% small-cell lung carcinoma (SCLC), 13.5% pancreatic (p), 8.3% thymic, 4.2% phaeochromocytoma, 5.2% others, and 23% occult. Tumour diameter of p-NETs was larger than that of bronchial carcinoids (47.3 ± 34 mm vs 28 ± 21.4 mm, P 0.035). Distant metastases were more prevalent in p-NETs, SCLC and thymic than in bronchial carcinoids and occult (77.7, 66.7, 50% vs 24.4, 13.6% respectively). Among 45 NETs with available Ki67, 46.7% were G1, 37.8% G2 and 15.6% G3. Immunostaining for ACTH was positive in 85.4%. Surgery was performed in 54,1%, steroidogenesis inhibitors in 77.1%, somatostatin analogues in 53.1%, cabergoline in 9.4%, mifepristone in 1%, everolimus in 6.2%, sunitinib in 1%, chemotherapy in 23%, PRRT in 10.4%, mono/bilateral adrenalectomy in 29%, and interventional treatments of liver metastases in 5.2%. Mean survival was 78 months (range 1–276), 24% died due to NET.
Conclusions
Bronchial carcinoids are the main NET associated with ECS, whereas 23% of cases are still occult. p-NETs are larger than bronchial carcinoids and more aggressive. Hystopathology, grading and distant metastases are the main prognostic factors. A multimodal treatment, including surgery of NET whenever possible, and adrenalectomy to definitively solve hypercortisolism thus reducing the risk of complications, can prolong survival.

Localisation of insulinoma: comparison of glucagon-like peptide 1 receptor SPECT/CT, PET/CT, and MRI: preliminary results of a prospective clinical study

Kwadwo Antwi[1], Melpomeni Fani[1], Tobias Heye[1], Guillaume Nicolas[1], Elmar Merkle[1], Jean Claude Reubi[2], Beat Gloor[3], Stefan Fischli[4], Damian Wild[1] & Emanuel Christ[5]
[1]Clinic of Radiology and Nuclear Medicine, University of Basel Hospital, Basel, Switzerland; [2]Division of Experimental Pathology, Department of Pathology, University of Bern, Bern, Switzerland; [3]Department of Visceral Surgery, University Hospital of Bern, Inselspital, Bern, Switzerland; [4]Division of Endocrinology, Diabetology and Clinical Nutrition, Hospital of Luzern, Luzern, Switzerland; [5]Division of Endocrinology, Diabetology and Clinical Nutrition, University Hospital of Bern, Inselspital, Bern, Switzerland.

Purpose
We aim at prospectively comparing the detection rate of glucagon-like peptide 1 receptor (GLP1R) PET/CT vs GLP1R SPECT/CT vs standardised contrast enhanced 3T MRI in patients with endogenous hyperinsulinaemic hypoglycaemia.
Methods
14 patients with neuroglycopenic symptoms due to endogenous hyperinsulinaemic hypoglycaemia were already enrolled (mean age 56 years, ten females and four males). A standardized contrast enhanced 3T MRI was performed. Afterwards the patients received a SPECT/CT at 4 and 72 h after injection of ^{111}In-DOTA-exendin-4 and a PET/CT 2.5 h after injection of ^{68}Ga-DOTA-exendin-4, in a randomized order. Standard of comparison was the histological diagnosis after surgery.
Results
In 11 patients histological diagnosis confirmed benign insulinoma, one patient had adult nesidioblastosis. In one patient none of the imaging modalities were able to find any lesion. Another patient refused surgery despite a positive PET/CT scan. In 8/12 patients previously performed conventional imaging (CT/MRI) was not able to localise the insulinoma. Standardized 3T MRI was able to predict the correct localisation of the insulinoma in 8/12 patients. PET/CT correctly identified the insulinoma or nesidioblastosis in 12/12 patients whereas SPECT/CT correctly identified the insulinoma in 10/12 patients. PET/CT was the only modality which identified the region of islet cell hyperplasia (adult nesidioblastosis) within the pancreas.
Conclusion
GLP1R PET/CT defines a novel, non-invasive, highly sensitive tool in localizing insulinomas. Standardised contrast enhanced MRI improves the diagnostic accuracy compared to locally performed conventional imaging. Further studies will have to confirm whether PET/CT is able to localise adult nesidioblastosis.

Could ^{99m}Tc labelled glucagon-like peptide 1 analogue scintigraphy be an answer for patients with persistent hypoglycaemia?

Alicja Hubalewska-Dydejczyk[1], Anna Sowa-Staszczak[1], Agnieszka Stefanska[1], Dorota Pach[1], Monika Buziak-Bereza[1], Małgorzata Trofimiuk-Müldner[1], Aleksandra Gilis-Januszewska[1], Agata Jabrocka-Hybel[1], Monika Tomaszuk[1], Romana Tomaszewska[2], Maciej Malecki[3], Tomasz Bednarczuk[4], Grzegorz Kaminski[5], Aldona Kowalska[6], Renata Mikolajczak[7] & Barbara Janota[7]
[1]Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; [2]Department of Pathology, Jagiellonian University Medical College, Krakow, Poland; [3]Department of Metabolic Diseases, Jagiellonian University Medical College, Krakow, Poland; [4]Department of Endocrinology, Medical University of Warsaw, Warsaw, Poland; [5]Department of Endocrinology and Radioisotopic Therapy, Military Institute of Medicine, Warsaw, Poland; [6]Department of Endocrinology and Nuclear Medicine, Holycross Cancer Center, Kielce, Poland; [7]Radioisotope Center POLATOM, National Centre for Nuclear Research, Otwock, Poland.

Surgery is the only effective therapy for insulinoma patients, therefore there is a necessity to develop diagnostic strategies in cases of unknown tumour location, possibly through the use of new biomarkers. ^{99m}Tc labelled glucagon-like peptide 1 analogue (^{99m}Tc-GLP1) scintigraphy has been developed in our centre as an imaging technique of insulinoma. Labelled GLP1 analogue might also be applied in diagnosis of various forms of nesidioblastosis allowing to determine the range of surgery in its focal and diffuse types, if suitable.
Material and methods
Study included: 40 patients with suspected insulinoma in whom CT/MR/EUS/SRS failed to visualise tumour thus excluding surgical intervention, 3patients with malignant insulinoma and three with nesidioblastosis (to assess its type form). (Lys^{40}(Ahx-HYNIC-^{99m}Tc/EDDA)NH_2)exendin-4-SPECT/CT with volumetric analysis was performed.
Results
21/40 cases were true positive with focal tracer uptake in pancreas including histopathologically confirmed bifocal insulinoma. In all operated patients symptoms resolved postsurgically. One false negative result appeared to be malignant insulinoma, in one no tumour was found (false positive result). Nine cases were true negative with no ^{99m}Tc-GLP1 uptake (reactive hypoglycemia or Munchausen syndrome); eight patients were lost from follow up. Sensitivity, specificity, PPV of ^{99m}Tc-GLP1-SPECT/CT were 95, 90, and 95% respectively. Scintigraphy revealed diffuse tracer uptake in two, and a focal lesion in one nesidioblastosis patients (histopathology: coexistent nesidioblastosis and insulinoma). ^{99m}Tc-GLP1–SPECT/CT confirmed different biology of primary tumour (PT) and metastases in malignant insulinoma (phenomenon well known in NENs): both PT and metastases were negative in one patient, PT positive and metastases negative in 1, PT negative and metastases positive in last case.
Conclusions
In our study ^{99m}Tc-GLP1–SPECT/CT proved to be helpful in management of persistent hypoglycaemia patients. ^{99m}Tc-GLP1–SPECT/CT could also be considered in the former stages of diagnostic schemes to optimise the procedures with a more effective strategy to allow sparing operation as well as to improve the quality of life of these patients.

Receptor tyrosine kinase expression and their role in the response to target therapy in bronchopulmonary NET

Tersa Gagliano, Katiusci Benfini, Erica Gentilin, Simona Falletta, Marta Bondanelli, Carmelina Di Pasquale, Eleonora Riva, Ettore degli Ubertu & Maria Chiara Zatelli
Section of Endocrinology and Internal Medicine, Department of Medical Science, University of Ferrara, Ferrara, Italy.

Surgery is not feasible for infiltrating and metastatic bronchopulmonary NET (BP-NET). In those cases, medical therapy is tried with controversial results. Thus, it is important to identify new therapeutic targets to provide adequate medical treatment for patients with BP-NET. Sunitinib, is a multi-targeted receptor tyrosine kinase inhibitor (TKI), mainly described to inhibit VEGFR.
The aim of our study is to verify whether insulin receptor (IR), IGF1R, and EGFR could be involved in Sunitinib mechanism of action in BP-NET cells.
For this purpose human BP-NET cell lines and human BP-NET primary cultures were treated with Sunitinib and/or EGF, IGF1, or VEGF. Cell viability and caspase 3/7 activation were measured after 48 h of treatment. Receptor expression was detected by Western blot in both cell lines and primary cultures. Phosphorylation of IGF1R and EGFR was analysed by Alphascreen sure fire assay.
Our results show that Sunitinib is capable of inhibiting cell viability of BP-NET cell lines and primary cultures, and activates caspase 3/7. Both events are counteracted by EGF and IGF1, but not by VEGF. Moreover, both cell lines and tissues invariably express IR, IGF1, and EGFR, while VEGFRs are expressed only in some samples. Treatment with Sunitinib decreased the phosphorylation of both EGFR and IGFR1, in both cell lines and primary cultures.
In conclusion, these data indicate that the expression of EGFR and IGF1R are important for Sunitinib action in BP-NET. The effects of Sunitinib on BP-NET cell viability could be due to a double inhibition of EGFR and IGF1R, while the role of IR needs to be further investigated.

Filamin-A is involved in stabilisation, signal transduction, and angiogenesis regulation mediated by somatostatin receptor 2 in pancreatic neuroendocrine tumors

Eleonora Vitali[1], Valeria Cambiaghi[1], Federica Loiarro[1], Alessandro Zerbi[2], Piergiuseppe Colombo[3], Anna Spada[4], Giovanna Mantovani[4], Erika Peverelli[4], Carlo Carnaghi[5] & Andrea Lania[1,6]
[1]Laboratory of Cellular and Molecular Endocrinology, IRCCS Clinical and Research Institute Humanitas, Rozzano, Milan, Italy; [2]Pancreas Surgery Unit, IRCCS Humanitas Clinical Institute, Rozzano, Milan, Italy; [3]Department of Pathology, IRCCS Humanitas Clinical Institute, Rozzano, Milan, Italy; [4]Endocrine Unit, Department of Clinical Sciences and Community Health, Fondazione IRCCS Ospedale Maggiore Policlinico, University of Milan, Milan, Italy; [5]Medical Oncology and Hematology Unit, Cancer Center, Humanitas Clinical and Research Center, Rozzano, Milan, Italy; [6]Biometra Department, Neurosurgery Department, IRCCS Humanitas Clinical Institute, University of Milan, Rozzano, Milan, Italy.

Somatostatin receptor type 2 (SST2) is the main pharmacological target of long-acting somatostatin analogues (SSA) widely used in patients with pancreatic neuroendocrine tumours (P-NETs). A subset of patients is resistant to SSA, although the molecular mechanisms responsible for resistance are poorly understood. Several studies identified cytoskeleton protein interactions as determinant in receptor anchoring, expression and signalling. Since SST2 was recently demonstrated to associate to filamin A (FLNA), we investigated the role of this cytoskeleton protein in SST2 expression, signalling and angiogenesis in human P-NETs and in QGP1 cell lines. We found no correlation between FLNA and SST2 expression in P-NETs, confirming this, FLNA knockdown did not induce changes in SST2 levels in QGP1 cells. Conversely, a significant reduction in SST2 expression was observed in FLNA silenced cells after selective long term SST2 activation with BIM23120 ($-49\pm17\%$, $P<0.05$ vs basal). To evaluate the role of FLNA on SST2 signalling, we analysed cyclin D1 expression, ERK1/2 phosphorylation, and cAMP accumulation. Interestingly, the reduction in cyclin D1 levels ($-44\pm22\%$, $P<0.05$ vs basal) and ERK1/2 phosphorylation ($-59\pm18\%$, $P<0.05$ vs basal) induced by SST2 agonist (BIM23120) was abolished in FLNA-silenced QGP1 cells. Similarly, BIM23120 inhibited forskolin-stimulated cAMP accumulation in cells transfected with negative control and this effect was abrogated in FLNA silenced cells. In addition, BIM23120 incubation induced a decrease in both VEGF expression ($-31\pm7\%$ in negative control transfected cells, $P<0.001$ vs untreated cells) and VEGF release into control cell supernatants ($-39\pm24\%$, $P<0.05$ vs untreated cells) and these effects being completely abolished by FLNA silencing. In conclusion, these results demonstrate that FLNA is required for SST2 stabilisation, signalling and angiogenesis in tumoural pancreatic neuroendocrine cells, thus suggesting a possible role of this cytoskeleton protein in determining the different responsiveness to SSA observed in P-NET patients.

Patient-reported time to diagnosis of neuroendocrine tumors (NETs) in Europe: results from the first global NET patient survey: a collaboration between the International Neuroendocrine Cancer Alliance (INCA) and Novartis

Marianne Pavel[1], Teodora Kolarova[2], Grace Goldstein[3], John Leyden[4] & Maia Sissons[5]
[1]Charité Universitätsmedizin Berlin, Berlin, Germany; [2]APOZ and Friends, Sofia, Bulgaria; [3]The Carcinoid Cancer Foundation, Inc., White Plains, New York, New York, USA; [4]The Unicorn Foundation, Mosman, New South Wales, Australia; [5]NET Patient Foundation, Hockley Heath, UK.

Background
Neuroendocrine tumor (NET) symptoms are often similar to common conditions or may not arise until metastasis occurs, delaying diagnosis and impacting survival. We present data on time to diagnosis from the European (EU) NET patient perspective.
Methods
In 2014, 1928 NET patients from >12 countries (Europe ($n=763$): Belgium, Bulgaria, France, Germany, Norway, UK, and other EU countries (not specified); Americas; Asia; Oceania) participated in a survey on the NET patient experience, including diagnosis, conducted by Hall and Partners on behalf of International Neuroendocrine Cancer Alliance (INCA)/Novartis and funded by Novartis. All comparisons were significant at $P<0.05$.
Results
60% of respondents reported being diagnosed <5 years ago; median time from symptom onset to diagnosis was 24 months (for overall population and patients diagnosed <5 years vs ≥5 years ago). Notably, 24% reported a ≥5-year lag for diagnosis. 63% had metastases at diagnosis (higher in patients diagnosed <5 years (67%) vs ≥5 years (57%) ago). Patients saw a mean of seven health care providers (HCPs) with a mean of 11 HCP visits prior to NET diagnosis. While 67% visited a NET specialty center (mean 4.7 times/year), only 25% were diagnosed there. For 43% of patients, NET was not the initial diagnosis, and 26% were diagnosed with NETs during testing for another condition. The most common early diagnoses were digestive disorders. Most patients (74%) did not suspect their symptoms were cancer related. Patients diagnosed <5 years ago felt more informed (able to get answers (65%)/had sufficient information (58%)) than those diagnosed ≥5 years ago (56%/48% respectively). The majority (65%) felt there was much room for improvement in NET diagnosis: 52% wanted clearer information about long-term impact; 42% wanted better direction regarding NET-related information.
Conclusion
This large global NET patient survey demonstrated delays in NET diagnosis in EU patients, consistent with global findings in the literature, and identified areas for improvement.
Disclosure
The Global NET Patient Survey was conducted as a collaboration between the INCA and Novartis Pharmaceuticals. Funding for this survey was provided by Novartis.

Complete remission of hepatic metastasis after total gastrectomy for a gastric carcinoid tumor type 1: a case report

Alberto Stefano Tresoldi[1], Cristina Bonifacio[2], Giovanna Pepe[3], Carlo Carnaghi[4] & Andrea Gerardo Antonio Lania[1,5]
[1]Department of Endocrinology, Humanitas Clinical and Research Center, Rozzano (MI), Italy; [2]Department of Radiology, Humanitas Clinical and Research Center, Rozzano (MI), Italy; [3]Department of Nuclear Medicine, Humanitas Clinical and Research Center, Rozzano (MI), Italy; [4]Department of Oncology, Humanitas Clinical and Research Center, Rozzano (MI), Italy; [5]Department of Biotechnologies and Translational Medicine, Milano (MI), Italy.

Gastric carcinoids secondary to autoimmune atrophic gastritis (GC type 1) are usually well differentiated neoplasia, with an indolent course and an excellent overall prognosis. However, a subset of these tumors (<5%) may develop advanced disease, with lymph node and/or hepatic metastasis. The pathogenesis of these carcinoids is related to chronic trophic stimuli to enterochromaffin-like (ECL) cells due to chronic hypergastrinemia. Treatments directed to remove the source of hypergastrinemia (such as antrectomy and SSAs) have been used with good results in localized tumors. These approaches had been used in localized disease, while its effectiveness had never been demonstrated in metastatic cases. In this report, we describe the case of a woman with type 1 gastric carcinoid with liver metastasis documented by abdominal CT and ^{68}Ga-PET DOTATOC. The patient underwent total gastrectomy with lymph node dissection; during surgery an hepatic US was performed, showing seven subcentimeter metastases. Histological examination revealed a neuroendocrine neoplasm G2 (WHO 2010) of 30 mm, Ki67 20%, 15 mitoses/10 HPF; chronic gastritis and micronodular hyperplasia of endocrine cells was associated. During the early months of follow up a gradual reduction in size of liver metastases, until the complete disappearance of them was observed. This is to our knowledge the first case ever described in literature of complete remission of liver metastatic type 1 GC after removal of the source of excessive gastrin, showing a possible preservation of responsiveness of metastases to gastrinemic stimuli. This could lead to a possible change in therapeutic approach in these neoplasm.

GP.28.08

General characteristics and evaluation of β-cell function and insulin sensitivity in a large monocentric series of insulinomas

Raluca Maria Furnica, Laure Istasse, Jean-Francois Gigot, Pierre Deprez, Martin Buysschaert & Dominique Maiter
Cliniques Universitaires Saint Luc, Brussels, Belgium.

Background
Insulinomas are the most common functional neuroendocrine tumours of the pancreas. Hypoglycaemic manifestations are highly variable and largely independent on tumour size and severity of insulin hypersecretion.
Objectives
In this study we investigated the clinical, biological and tumoural characteristics of a large series of patients with insulinoma and we evaluated the sensitivity of peripheral tissues to insulin before and after surgery.
Patients and methods
This is a retrospective analysis of 40 patients followed between 1982 and 2012 in our academic hospital. Insulin sensitivity and β-cell function could be evaluated by HOMA test in a subset of these patients.
Results
The mean age at onset of symptoms was 48.8±20.1 years and the mean age at diagnosis was 50.7±19.9 years. A sex ratio of 0.6 (15 men for 25 women) was found. Adrenergic symptoms were observed in 75% of patients and neuroglucopenic symptoms in 90%. In addition, 33% of patients suffered from epileptic disorders and 20% from psychiatric manifestations. Weight gain was observed in 40% of the patients. The most effective imaging techniques to localize the tumour were endoscopic ultrasound (90% sensitivity) and intraoperative ultrasound (94% sensitivity). Insulin sensitivity (measured outside hypoglycaemic episodes) was greatly reduced in patients with insulinoma (38.9± 22.3%), while β-cell function was increased (359.0±171.5%), but to a variable extent (range 110.6–678.6%). After complete resection of the tumour and disappearance of hypoglycaemia, insulin sensitivity normalizes from 36.9±19.0 to 80.6±18.4% ($P<0.001$) in 12 cured patients with available pre- and post-operative HOMA tests.
Conclusion
The general characteristics of our series are consistent with the general features reported for insulinomas in the literature. We also show that in response to chronic hyperinsulinaemia, patients with insulinoma develop protective mechanisms responsible for a marked insulin resistance, which is fully reversible after complete resection of the tumour.

Association of angiopoietin/TIE2 plasma level and VEGF system with progression in gastroenteropancreatic neuroendocrine tumors

Miguel Sampedro-Nuñez[1,4], Ana Ramos-Leví[1,4], Alicia Vicuña[1], Sandra Campos[1], Ana Serrano[1,4], Ana Rodríguez-Muñoz[1,4], Rebeca Martínez-Hernández[1,4], Elena Martín-Pérez[2,4], Magdalena Adrados[3,4] & Mónica Marazuela[1,4]
[1]Department of Endocrinology and Nutrition, Hospital Universitario de la Princesa, Madrid, Spain; [2]Department of General and Gastrointestinal Surgery, Hospital Universitario de la Princesa, Madrid, Spain; [3]Department of Pathology, Hospital Universitario de la Princesa, Madrid, Spain; [4]Universidad Autónoma de Madrid, Instituto de Investigación Sanitaria Princesa, Madrid, Spain.

Introduction
Angiopoietins (ANG) -1 and 2, their receptor TIE2, and the vascular endothelial growth factor (VEGF) are involved in the process of angiogenesis. However, their

role in the pathogenesis and development of gastroenteropancreatic neuroendocrine tumours (GEP-NETs) is not completely understood. In a previous study of 42 patients with GEP-NET, we observed an elevation of these serum markers, especially in those with metastatic disease. The objective of this study was to analyse the relationship between plasma levels of the ANG/TIE2-VEGF system in patients with GEP NETs who exhibited progression after 3 years of follow-up.
Methods and materials
26 Patients with GEP-NETs were studied. Primary location of tumours was pancreas ($n=13$) and intestine ($n=13$). Plasma levels of ANG-1, ANG-2, TIE2 and VEGF were determined by ELISA. We evaluated response to medical and/or surgical treatment using clinical and radiological criteria and patients were assigned to three categories (complete remission, stable disease or progressive response), accordingly. Statistical nonparametric analysis tests was performed.
Results
At diagnosis, 13 patients had positive regional lymph nodes and 13 distant metastases. Thirteen patients achieved complete response, six had stabilization and seven were classified as disease progression. Plasma TIE-2 levels at initial evaluation were higher in patients who had progressive disease (31 803.17 $\pm$ 5495.55 pg/ml) vs those who had complete response (18 930.00 $\pm$ 3914.20 pg/ml) or remained stable (25 236.67 $\pm$ 1072.40 pg/ml) ($P=0.012$). No differences were found in these angiogenic markers when comparing primary tumour location (pancreas or intestine), the presence or absence of metastases, or response to somatostatin analogue therapy.
Conclusion
TIE2 plasma values are higher in patients with GEP-NETs with progressive disease. This suggests a possible involvement of ANG/TIE2 system in the pathogenesis of GEP-NETs and a possible relevance as diagnostic and/or therapeutic target.

Mitotane inhibits sterol-o-acyltransferase leading to lipid-mediated endoplasmic reticulum stress and apoptosis of adrenocortical carcinoma cells

Silviu Sbiera[1,2], Martin Fassnacht[1,3], Ellen Leich[4], Gerhard Liebisch[5], Andreas Schirbel[6], Laura Wiemer[1], Silke Matysik[5], Jens T Vanselow[7], Felix Gardill[1], Annemarie Gehl[1], Sabine Kendl[1], Melanie Beyer[1], Margarita Bala[1], Cristina L Ronchi[1], Timo Deutschbein[1], Andreas Schlosser[7], Gerd Schmitz[6], Andreas Rosenwald[2,4], Bruno Allolio[1] & Matthias Kroiss[2]
[1]Endocrinology and Diabetes Unit, University Hospital Würzburg, Würzburg, Germany; [2]Comprehensive Cancer Center Mainfranken, Würzburg, Germany; [3]Clinical Chemistry and Laboratory Medicine, University Hospital Würzburg, Würzburg, Germany; [4]Institute of Pathology, University of Würzburg, Würzburg, Germany; [5]Institute of Clinical Chemistry and Laboratory Medicine, University Hospital Regensburg, Regensburg, Germany; [6]Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, Germany; [7]Rudolf Virchow Center for Experimental Biomedicine, Würzburg, Germany.

Context
Mitotane is the only drug approved for treatment of adrenocortical carcinoma (ACC) and in clinical use for more than 50 years. Mitotane counteracts both tumour growth and tumoral steroid hormone production but treatment is associated with severe side effects. The molecular mechanism of mitotane is still unknown, which hampers progress in treatment of ACC.
Objective
To identify the mechanism of action and molecular target of mitotane.
Methods
We combined expression genomics, proteomics and lipidomics in an *in vitro* study using the NCI-H295 ACC reference cell line and four non-steroidogenic cell lines.
Results
Pathway analysis of gene expression data demonstrated activation of endoplasmic reticulum (ER) stress and altered lipid metabolism. Strongly increased expression of ER-stress marker C/EBP-homologous protein (CHOP, 26.7 $\pm$ 0.1-fold, $P<0.001$) and activated XBP1-mRNA splicing (23.2 $\pm$ 3.2-fold, $P<0.001$) was in sharp contrast to weak ER-stress activation in non-steroidogenic cell lines (HepG2: 2.6/1.4-fold, HEK293: 2.5/3.7, HeLa: 3.5/6.4, IMR-32: 1.5/2.1). ER-stress experimentally triggered by thapsigargin mimicked mitotane effects on steroidogenesis and apoptosis. Mass spectrometry revealed specific mitotane-induced lipid alterations with elevated free cholesterol (2.53-fold, $P<0.05$), oxysterols like 7-dehydrocholesterol (5.4-fold, $P<0.001$) and fatty acids, e.g. C20:4 (arachidonic acid; 3.2-fold, $P<0.01$) in NCI-H295 cells but not in other cell lines. Inhibition of Acyl-CoA-Cholesterol-Acyl-transferase (SOAT1) by mitotane (IC50 = 22 μM) was identified as the mechanism underlying these events.
Conclusions
Mitotane confers adrenal specific cytotoxicity and down-regulation of steroidogenesis by lipid-induced ER-stress through inhibition of SOAT-activity. This finding opens new avenues for improved ACC treatment. Cancer specific lipid metabolism may be a treatment target in other types of cancer.

Recently, we demonstrated for adrenocortical carcinoma (ACC) promising antitumoural effects for LEDP-M (etoposide, liposomal doxorubicin, liposomal cisplatin, mitotane) a novel liposomal variant of the classical EDP-M protocol (etoposide, doxorubicin, cisplatin, mitotane). However, clinical translation of novel therapeutic regimens remains challenging due to high tumor heterogeneity. Thus, to obtain preclinical results with more clinically predictive power we investigated for the first time LEDP-M in three different xenograft models for ACC *in vivo*. Moreover, we included liposomal etoposide resulting in a novel treatment scheme called L(l)EDP-M. After one therapeutic cycle NCI-H295R, SW-13 and SJ-ACC3 tumours were excised and immunohistochemically (cells/high power fields (HPF)) analysed regarding total number of tumor cells (Ki67 positive and negative/HPF) and apoptosis (TUNEL positive cells/HPF). In previous experiments on NCI-H295R xenografts we detected a significant reduction in overall tumor cell count for LEDP-M which was in the current study not reached by L(l)EDP-M. In contrast, regarding apoptosis L(l)EDP-M ($P<0.01$) led to a further improvement of therapeutic efficacy as compared with LEDP-M ($P<0.05$ vs controls). In SW-13 xenografts, the number of tumor cells decreased in all treatment schemes with highest therapeutic efficacy of the liposomal variants (EDP-M: 20.5 $\pm$ 1.6 $P<0.01$; LEDP-M: 17.2 $\pm$ 1.3 $P<0.001$; L(l)EDP-M: 14.7 $\pm$ 0.9 $P<0.001$) vs. controls (28.9 $\pm$ 2.2). In addition, most distinctive necrosis was detectable for L(l)EDP-M followed by LEDP-M, EDP-M and controls. In SJ-ACC3 xenografts a decrease in tumor cell number was found only following EDP-M treatment (30.3 $\pm$ 1.2 vs controls 35.9 $\pm$ 1.3, $P<0.05$). In summary, these data indicate that liposomal regimens could represent promising treatment options for clinical translation for adult, but not for pediatric ACC. However, our results also show that tumor heterogeneity should be taken into account in preclinical studies.

Immunoexpressions of CYP11B2 and HSD3B2 in genetically characterised aldosterone producing adenomas

Christian Gebhard[1], Yara Rhayem[1], Anna Dietz[1], Anna Riester[1], Constanze Hantel[1], Marion Schuster[1], Tim M Strom[2,3], Celso Gomez-Sanchez[4,5], Martin Reincke[1] & Felix Beuschlein[1]
[1]Medizinische Klinik und Poliklinik IV, Ludwig-Maximilians-University, Munich, Germany; [2]Institute of Human Genetics, Helmholtz Zentrum Munich, Munich, Germany; [3]Institute of Human Genetics, Technische Universität München, Munich, Germany; [4]Division of Endocrinology, G.V. (Sonny) Montgomery VA Medical Center, Jackson, Mississippi, USA; [5]Department of Medicine-Endocrinology, University of Mississippi Medical Center, Jackson, Mississippi, USA.

Primary aldosteronism caused by aldosterone-producing adenoma (APA) or bilateral adrenal hyperplasia is the most prevalent cause of secondary hypertension. Somatic mutations of *KCNJ5*, *ATP1A1*, *CACNA1D* and *ATP2B3* have been shown to be involved in the formation of APA. We studied the immunoexpressions of CYP11B2 and HSD3B2, the rate-limiting enzyme for aldosterone production and the prevalent isoform of β-HSD found in APA respectively, and correlated these findings with the mutation status, histopathology of APA and to the biochemical and clinical outcome of adrenalectomy. In our study, APA tissues obtained by adrenalectomy were divided into five subgroups (*KCNJ5*, *ATP1A1, CACNA1D, ATP2B3* or WT) after characterization of the respective mutational status by direct or exome sequencing. Paraffin-embedded tumors were evaluated for size and cell composition. Immunolocalization and semi-quantitative immunoexpressions of CYP11B2 and HSD3B2 were analysed. Scoring staining intensity was determined along with clinical findings. Our results show that a majority of APAs consists of both *zona fasciculata*-like and *zona glomerulosa* (*ZG*)-like cells. *CACNA1D* mutated-APA were significantly smaller than *KCNJ5* mutated-APA ($P<0.05$). All mutated APAs presented CYP11B2 positive clusters or variably stained scattered cells while WT APAs were weakly or negatively stained for CYP11B2 with only clusters in adjacent ZG. H-Score for CYP11B2 was significantly different between WT and *KCNJ5* mutated APAs ($P<0.05$). Immunoreactivity of HSD3B2 was strongly present in all analyzed tissues independently of the tumoural cell type and no significant difference was noted between the subgroups' HSD3B2 H-scores. Biochemically, serum potassium levels of all patients were normalized after adrenalectomy. High aldosterone to renin ratio at diagnosis and shorter duration of hypertension preceding surgery were associated with better clinical outcome. Our findings suggest that *KCNJ5* and not *ATP1A1, CACNA1D or ATP2B3* mutated APAs have significantly different CYP11B2 immunoreactivity, compared with WT-APA while immunoreacivities of HSD3B2 or CYP11B2 are not correlated with outcome.

Synergistic action of 9-cis retinoic acid and mitotane in a H295R adrenocortical cancer xenograft model

Zoltan Nagy[1], Kornelia Baghy[1], Peter M Szabo[2], Ilona Kovalszky[1], Pal Perge[1], Attila Patocs[3], Karoly Racz[1] & Peter Igaz[1]
[1]Semmelweis University, Budapest, Hungary; [2]National Cancer Institute, Bethesda, Maryland, USA; [3]'Lendulet-2013' Hereditary Endocrine Tumours Research Group, Budapest, Hungary.

Background
Current drug treatment options for adrenocortical carcinoma (ACC) are rather limited and intensive efforts are going on to find novel effective agents. In our previous functional genomics study, retinoid signalling via the retinoid X receptor (RXR) was identified as a major pathogenic pathway in ACC and we have demonstrated the *in vitro* activity of 9-cis retinoic acid (9-cisRA) acting via the RXR on NCI-H295R cells and also found that 9-cisRA has antitumoural effects in a small pilot xenograft study.
Aim
To investigate the antitumoural effect of 9-cisRA and its combination with mitotane in a large-scale xenograft study.
Methods
43 male SCID mice xenografted with NCI-H295R cells were treated in four groups (i) control – corn oil vehicle, ii) 5 mg/kg 9-cisRA, iii) 200 mg/kg mitotane, iv) 5 mg/kg 9-cisRA + 200 mg/kg mitotane) for 28 days. Tumor size follow-up, histological and immunohistochemical (Ki-67) analysis, tissue gene expression microarray (4×44 K Agilent Whole Genome Microarray) have been performed. Quantitative real-time-PCR (TaqMan) was used for the validation of the microarray results and to detect circulating microRNAs.
Results
Both 9-cisRA and mitotane reduced tumor growth relative to control, but only the combination of the two agents resulted in significant tumour size reduction. The Ki-67 index was significantly reduced in both 9-cisRA and 9-cisRA + mitotane groups. Gene expression analysis revealed 483 genes with significant differences in expression, but only without Benjamini-Hochberg correction. Seven genes have been selected for validation by qRT-PCR, but only one (APOA4) was found significantly increased in the combined group compared with the control. The expression of circulating hsa-mir-483-5p was found significantly reduced in combined treatment relative to control.
Conclusions
Our results show that 9-cisRA might be a helpful additive in the treatment of ACC in combination with mitotane, but its mechanism of action awaits further investigations.

EGFR as potential new molecular target in the medical treatment of adrenocortical cancer

Teresa Gagliano[1], Francesco Balboni[1], Carmelina Di Pasquale[1], Erica Gentilin[1], Katiusci Benfini[1], Simona Falletta[1], Marta Bondanelli[1], Paola Franceschetti[1], Carlo Feo[2], Ettore degli Uberti[1] & Maria Chiara Zatelli[1]
[1]Section of Endocrinology and Internal Medicine, Department of Medical Sciences, University of Ferrara, Ferrara, Italy; [2]Department of Morphology, Surgery and Experimental Medicine, University of Ferrara, Ferrara, Italy.

Adrenocortical cancer (ACC) is a rare and aggressive malignancy. Currently the main therapeutic option is surgery, but due to difficult and delayed diagnosis and to the onset of metastases, medical therapy is often tried. ACC treatment is mainly represented by Mitotane alone or in association with chemotherapy, with variable results. Understanding the molecular mechanisms that regulate ACC proliferation could be useful to identify new therapeutic options. Sunitinib, a multitarget tyrosine-kinase inhibitor, showed controversial results in phase II trials for advanced refractory ACC. It has been previously demonstrated that epidermal growth factor (EGF) increases HSD3B2 expression in ACC cells. The aim of our study is to verify whether EGF pathway could represent a target for Sunitinib in human ACC cells. For this purpose we used two human adrenocortical carcinoma cell lines (SW13 and NCI-H295 cells) and human adrenal tumor primary cultures. We found that EGF increased proliferation and reduced apoptosis not only in SW13 but also in adrenal tumour primary culture, while it did not affect NCI-H295 cells. Sunitinib reduced cell viability in both cell lines, being counteracted by EGF in SW13 cells and in the majority of primary cultures analysed. We investigated in both cell lines the expression of EGFR family members, which are more expressed in SW13 cells as compared to NCI-H295 cells. Moreover, we investigated the intracellular signal transduction pathway of EGF in ACC cells. Our results show that in SW13 cells Sunitinib inhibited EGFR phosphorylation on tyrosine 1068, and counteracted EGF-induced phosphorylation of ERK1/2. In SW13 Sunitinib increased the expression of SAPK/JNK leading to caspase 3/7 activation. In NCI-H295 Sunitinib did not reduce EGFR phosphorylation, but inhibits PI3K/mTOR/AKT pathway. To verify the involvement of EGFR in regulating ACC cell viability we tested Erlotinib, a selective EGFR inhibitor, in the two cell lines. We found that Erlotinib was capable of dose dependently reducing cell viability and activating caspase 3/7 in SW13 cell line, having no effects on NCI-H295 cells. Therefore, EGF may be important in regulating EGFR expressing ACC cell proliferation. In conclusion, our data suggest that EGF pathway could represent a new molecular target in drug design for treatment of ACC that display enhanced EGFR expression.

The incidence of consecutive manifestations of VHL disease

Carlijn Frantzen[1], Roeliene C Kruizinga[1], Wim J Sluiter[1], Elisabeth G E de Vries[2], Bernard A Zonnenberg[3], Cornelis J Lips[3], Annemiek M E Walenkamp[2], Anouk N A van der Horst-Schrivers[1] & Thera P Links[1]
[1]Department of Endocrinology, University Medical Center Groningen, University of Groningen, Groningen, The Netherlands; [2]Department of Medical Oncology, University Medical Center Groningen, University of Groningen, Groningen, The Netherlands; [3]Department of Internal Medicine, University Medical Center Utrecht, Utrecht, The Netherlands.

Background
Von Hippel Lindau (VHL) disease is a rare tumour syndrome with a high penetrance. VHL mutation carriers develop numerous disease related manifestations in multiple organs during life, but precise difference in growth velocity and incidence of lesions in different organs is still unknown. We aimed to gain insight in the incidence of consecutive new disease manifestations in the organs of patients with VHL.
Patients and methods
Clinical data including age at diagnosis of each new VHL-related manifestation of 75 VHL mutation carriers, with standardised follow-up, in two Dutch VHL-expert centres were retrospectively evaluated. Only consecutive lesions in the retina, the CNS, the kidneys and the pancreas were analysed. New organ lesions were defined as a new organ manifestations detected on imaging or in case of retinal lesions detected by fundoscopy. The Kaplan Meier method was used to construct the cumulative proportions of first and all consecutive manifestations in each organ against age. The cumulative average number of manifestations in all organs during life was calculated by summating these cumulative proportions. Poisson model parameters served to calculate average time to the detection of VHL manifestations in each organ.
Results
Consecutive VHL-related kidney and retina manifestations during life occur according to Poisson distribution model. The second VHL pancreas manifestation occurred later and the consecutive CNS hemangioblastomas were detected earlier than predicted by the Poisson model. The average total systemic number of manifestations rises in a linear way to seven VHL-related manifestations at age 60 years.
Conclusion
The incidence of new VHL-related manifestations after the first organ involvement is highly constant during life in VHL-carriers. Therefore, the accelerations and arrests in appearance of new manifestations observed in individual subjects are caused by the randomness of events and not by variation in disease activity.

Penetrance and optimal surveillance for SDHB mutation carriers

Karin Eijkelenkamp[1], Thamara E Osinga[1], Mirjam M de Jong[2], Wim J Sluiter[1], Robin P F Dullaart[1], Thera P Links[1], Michiel N Kerstens[1] & Anouk N A van der Horst-Schrivers[1]
[1]Department of Endocrinology and Metabolic Diseases, University Medical Center Groningen, Groningen, The Netherlands; [2]Department of Clinical Genetics, University Medical Center Groningen, Groningen, The Netherlands.

Context
Germline mutations of the gene encoding succinate dehydrogenase subunit B (*SDHB*) predispose to head and neck paraganglioma (HNPGL), sympathetic PGL, phaeochromocytoma and renal cell carcinoma for which regular surveillance is required. *SDHB*-associated tumors harbor germline and somatic mutations, consistent with Knudson's two-hit hypothesis stating that the combination of an inactivating germline mutation as a first hit and somatic loss of function of the wild type allele as a second hit is essential for tumor development. The aim of this study was to assess the penetrance and optimal surveillance for different manifestations of *SDHB* mutation carriers.
Patients and methods
This study included all *SDHB* mutation carriers (18 index cases from 20 non-consanguineous families) who were prospectively followed at the department of Endocrinology at the University Medical Center of Groningen. Kaplan Meier curves were used to assess the penetrance. Poisson distribution model was used to calculate the hit rate and average time to detect the first and subsequent manifestation, to assess the optimal age to start surveillance and intervals.
Results
Eighty-three *SDHB* mutation carriers (33 men and 50 women) were included. Twenty-three mutation carriers (28%) had a manifestation, of whom 18 carriers (22%) were index patients. First manifestations included HNPGL ($n=15$), sympathetic PGL ($n=9$) and phaeochromocytoma ($n=1$), with an overall penetrance 35% at the age of 60 years. The optimal age to start surveillance for HNPGL was age 24 years, with a subsequent interval of 4 years.
Conclusion
This study emphasises a relatively low penetrance of disease in *SDHB* mutation carriers. By using a Poisson distribution model a more accurate estimation of the age to initiate surveillance and subsequent intervals is provided for HNPGL, suggesting that guideline recommendation regarding the screening of these mutation carriers might need to be revised.

Context
Successful used of temozolomide (TMZ) treatment has been described in 40–50% of aggressive pituitary tumour (PT) or rare pituitary carcinoma. These results are based on 50 case-reports and small series, data on long-term follow-up being rare.
Objectives
To describe initial results and long-term follow-up of a large French cohort of patients presenting PT treated with temozolomide.
Design
Members of the French Society of Endocrinology were surveyed regarding the clinical characteristics of PT treated with TMZ. Hormone and tumour responses to treatment were evaluated after three to six cycles and at the last follow-up.
Patients
32 patients (M=20) from 16 centers, 19 aggressive PT, 13 carcinomas including 16 ACTH, 12 PRL, and four GH-secreting tumours were followed 21.7 ± 18 months after the treatment.
Results
Age at diagnosis was 42.8 ± 19 years. All patients underwent radiotherapy, 28/32 pituitary surgeries (1–5). TMZ, 150–200 mg/m^2 5days a month, was initiated (with radiotherapy in five cases) 8.2 ± 7.5 years after diagnosis for 8.4 cycles (3–24). Tolerance was good (thrombopenia, $n=3$ and pancytopenia, $n=2$). Overall, early response was noted in 18/32 (56.3%) with similar rate between ACTH (56%) and PRL (58%), lower for GH (50%) and higher rate in adenomas (63%) than carcinomas (46%). End of treatment response was maintained in only 13/18 patients after 10.2 ± 5.6 cycles. No initial resistant cases responded to TMZ after 6.6 ± 4.4 cycles. Among the 18 responders, four were in remission (three ACTH) after 30 ± 13 months, regrowth was noted in ten patients 18 ± 18 months after TMZ administration. Second try of TMZ failed in all cases ($n=7$). 8/14 resistant cases deceased compare to 2/18 initially sensitive cases. In case of TMZ failure, carboplatin-VP16, cisplatin$\pm$adriblastine, everolimus have been tested without significant effect.
Conclusion
Initial PT response to TMZ is frequent but long-term control or remission is rare. This survey underlined lack of homogeneous therapeutic protocol and the need for guideline.

Clinicopathological significance of fractional allelic loss in prognosis of follicular cell-derived thyroid tumours

Monika Migdalska-Sęk[1], Karolina H Czarnecka[1], Michał Kusiński[2], Dorota Pastuszak-Lewandoska[1], Ewa Nawrot[1], Justyna Kiszałkiewicz[1], Daria Domańska[1], Krzysztof Kuzdak[2] & Ewa Brzeziańska-Lasota[1]
[1]Department of Molecular Bases of Medicine, I Chair of Internal Medicine, Medical University of Lodz, Lodz, Poland; [2]Department of Endocrine, General and Vascular Surgery, Chair of Endocrinology, Medical University of Lodz, Lodz, Poland.

The genetic instability, i.e. loss of heterozygosity (LOH) and microsatellite instability (MSI) are frequent molecular events in thyroid tumour aetiopathogenesis. They were found in several chromosomal critical areas, including 3p12–p21.2, 3p24.2–p25.3, 7q21.1–q31.2, 10q22–24, and 15q11–q13, with loci of oncogenes and tumour suppressor genes.
Aim of the study
Evaluation of usefulness of LOH/MSI as diagnostic/prognostic biomarker in follicular cell-derived thyroid tumours.
Materials
Thyroid tumour and macroscopically unchanged tissues (control) obtained from 93 patients with: follicular adenoma (FA; $n=11$), papillary thyroid carcinoma (PTC; $n=31$), follicular thyroid carcinoma (FTC; $n=8$), and nodular goitres (NG; $n=43$).
Methods
Ten microsatellite markers linked with regions 1p31.2, 3p21.3, 3p24.2, 9p21.3, 11p15.5, and 16q22.1 were amplified in PCRs and then allelotyped. Fractional allelic loss (FAL) values defined as LOH/MSI coincidence in various chromosomal regions were assessed.
Results
LOH/MSI frequency was the highest in 3p21.3–3p24.2 (15%) and 11p15.5 (14.29%), followed by 1p31.2, 9p21.3 (12%), and 16q22.1 (10.23%). Statistical analysis of LOH/MSI frequency in FTC revealed significantly increased LOH/MSI in 1p31.2 ($P=0.028$). Significantly increased LOH/MSI in 3p21.3 was found for pT1 tumours, AJCC stage I and tumours with diameter <10 mm; in 1p31.2: for pT2–T4, stages II–IV, and tumours with diameter 10–30 mm; in 11p15.5: for pT2–T4, stages II–IV, and tumours with diameter >30 mm ($P<0.05$). Mean FAL values were significantly higher in men ($P=0.002$), and in younger patients (<40 years, $P=0.016$). FAL was significantly higher in: FA and FTC compared with NG and PTC ($P=0.033$); pT2–T4 vs pT1 ($P=0.021$). Increased FAL value significantly correlated with increased tumour diameter ($P=0.044$).
Conclusions
Our findings confirmed LOH/MSI occurrence in 3p21.3 at early stage of tumorigenesis while in 1p31.2 and 11p15.5, not recognised as critical areas, seems to be characteristic for advanced stage of thyroid tumours. FAL defined as LOH/MSI coincidence in various chromosomal regions may be useful biomarker in prediction of tumour progression. The increased FAL values in FA/FTC can be regarded as promising distinguishing biomarker from PTC and NG.

GP.30.03

The role of androgen receptor in glucose transporters expression in prostate cancer cells

Pedro González-Menéndez, David Hevia, Juan C Mayo & Rosa M Sainz
Departamento de Morfología y Biología Celular, Instituto Universitario de Oncología del Principado de Asturias (IUOPA), Universidad de Oviedo, Oviedo (Asturias), Spain.

Cancer cells show different metabolic requirements than normal cells, being the high rate of glucose uptake one of the most important aspects. An increase in glucose uptake has been associated mainly with GLUT1 overexpression but may also involve other transporters including GLUT4, whose presence in prostate cancer cells was recently discovered in our laboratory. Moreover, androgens stimulate anabolic synthesis and increase glucose uptake. Despite this, the regulation of GLUT transporters by androgens has been scarcely studied. Thus, the aim of this work was to study the relation between GLUT1/4 and the androgen receptor (AR) signalling pathway in prostate cancer cells. GLUT1/4 and AR protein levels were analysed by immunoblot. Glucose uptake and glucose concentration in culture media were measured using 2-deoxyglucose and a glucometer respectively. The analysis of cell cycle was performed by flow cytometry. Finally, cell viability and proliferation were estimated by MTT reduction and Hoechst staining. Results show that GLUT1/4 expression is dependent of glucose concentration in culture media. GLUT1 was overexpressed when glucose concentration was reduced in the androgen-sensitive LNCaP and PC-3AR cells, being the number of cells in G1 phase lower. Glucose consumption was also higher in PC-3AR cells than in androgen-insensitive PC-3 cells. On the other hand, the effect of insulin (that stimulates GLUT4 transport) or indinavir (that inhibits GLUT4) were higher in androgen-insensitive cells. Moreover, AR signalling was involved in GLUT expression. Nuclear translocation of AR was increased at low glucose concentration correlating with the increment of GLUT1 levels. In addition, DHT stimulated glucose uptake and GLUT1 levels while bicalutamide (an androgen inhibitor) prevented this increment in androgen-sensitive LNCaP cells. In conclusion, AR pathway favours GLUT1 expression and functioning, while might be related to its carcinogenic properties in the prostate while GLUT4 transporter is more involved in glucose uptake in androgen-insensitive prostate cancer cells.

Re-introduction of type 1 iodothyronine deiodinase in renal cancer cells affects their migration and expression of adhesion-related genes

Piotr Poplawski[1], Joanna Boguslawska[1], Hanna Kedzierska[1], Beata Rybicka[1], Zbigniew Tanski[2], Theo J Visser[3], Alicja Nauman[1,4] & Agnieszka Piekielko-Witkowska[1]
[1]Department of Biochemistry and Molecular Biology, The Centre of Postgraduate Medical Education, Warsaw, Poland; [2]Regional Hospital Ostroleka, Ostroleka, Poland; [3]Department of Internal Medicine, Erasmus University Medical Center, Rotterdam, The Netherlands; [4]Laboratory of Human Cancer Genetics, Centre of New Technologies, CENT, University of Warsaw, Warsaw, Poland.

Introduction
Type 1 iodothyronine deiodinase (DIO1) is one of the three enzymes regulating bioavailability of thyroid hormones. In contrast to DIO2 and DIO3, the specific cellular role of DIO1 remains controversial. Our previous studies showed that DIO1 expression in clear cell renal cell carcinoma (ccRCC) is decreased, followed by lowered intracellular T_3 concentration. In this study we explored how re-introduction of *DIO1* in ccRCC cells affects their migration and proliferation.
Material
75 matched pairs of ccRCC tumours and control samples, approved by the local Bioethical Committee. Two *ccRCC* cell lines *KIJ-265T* and *KIJ-308T*.
Methods
ccRCC cell lines (KIJ-265T-pcDNA3-DIO1 and KIJ-308T-pcDNA3-DIO1) with stable re-expression of DIO1 and control cell lines (KIJ-265T-pcDNA3 and KIJ-308T-pcDNA3) stably transfected with empty pcDNA3 vector were generated. The expression of genes involved in adhesion and ECM was analysed with RT^2 Profiler PCR Array (SABiosciences), followed by SYBRGreen/qPCR validation. Scratch test and Cell Proliferation ELISA, BrdU were used for analysis of migration and proliferation respectively.
Results/conclusions
Expression of collagen COL1A1 and integrin ITGB2 was elevated in ccRCC tumours compared with control samples. Re-expression of DIO1 in KIJ-265T (grade IV) and KIJ-308T (grade II) cell lines resulted in decreased expression of COL1A1 (74 and 68% respectively) and ITGB2 (58 and 34% respectively). Scratch test revealed that migration of KIJ265 was stimulated by DIO1 expression while in KIJ308T DIO1 had no effect. Proliferation of both cells was reduced by DIO1 expression. We show, for the first time, that DIO1 has opposite roles in ccRCC tumourigenesis: it reduces proliferation with concomitant stimulation of migration in higher tumour grade cells. This effect is probably mediated by DIO1-induced changes in expression of genes involved in cellular adhesion. The specific mechanisms of DIO1 action in ccRCC require further investigation.

FSH receptor (FSHR) expression has been shown in gonadal tumours, as well as in endothelial tumour vessel cells of various cancers. FSHR, due to its transmembrane localization could be a good candidate for receptor-mediated targeted cancer therapy. In recent years, a number of membrane disrupting lytic peptides have been used for receptor-based cancer therapy. In the present study, we characterised the specificity and cytotoxicity of a lytic peptide Phor21 conjugated to three different amino-acid (AA) sequence fragments of the FSHβ-chain (AA33–53, AA81–95, and AA33–53 + 81–95) with several other enhancing modifications of the peptides, to ablate FSHR-positive cells *in vitro*. As there exists no cancer cell lines expressing functional endogenous FSHR, Phor21-FSHβ conjugates were tested in a human FSHR cDNA-stably transfected HEK293 cell line (FSHR-positive cell) and HEK293 (FSHR-negative cells). Conjugate-mediated cytotoxicity was assessed by measurement of lactate dehydrogenase (LDH), a stable cytosolic enzyme that is released upon membrane disruption by lytic peptide. Conjugate of Phor21 linked to FSHβ–AA33–53, in which cysteine (Cys53) was replaced by serine (Ser) and stabilized with N-terminal amino group (Phor21-FSHβ33–53Cys/Ser-CONH) displayed the highest specific cytotoxicity to FSHR-positive cells vs. any other tested compound. Phor21-FSHβ33–53Cys/Ser-CONH conjugate showed in a dose dependent manner (0.5, 1, 2.5, and 5 μM) two- to ten fold higher ability to destroy the FSHR-positive cells than Phor21 alone. Pre-incubation or co-treatment competitive studies in FSHR-positive cells with recombinant human FSH 100 IU/L significantly decreased the cytotoxicity of Phor21-FSHβ33–53C/S-CONH conjugate at two lowest concentrations (0.25 and 0.5 μM). Conjugating FSHβ fragment sequences to Phor21 slightly enhanced their cytotoxic effects in comparison to Phor21 backbone in FSHR-negative cells. Our results prove the principle that Phor21-FSHβ33–53Cys/Ser-CONH may provide a novel specific therapeutic lead into targeted destruction of FSHR expressing cancer cells *in vitro* and as well as for further *in vivo* studies.

Though there is no evidence of a constitutive nuclear accumulation of β-catenin, the Wnt/β-catenin pathway might be deregulated in parathyroid tumours. We investigated unphosphorylated active β-catenin distribution by western blot in 16 typical parathyroid adenomas (PAds): β-catenin accumulation in the nuclear protein fractions varied from the levels detected in Caco-2 cells with constitutively active Wnt signalling (three PAds) to the levels measured in HEK293 cells with intact Wnt signalling (six PAds) and positively correlated with *AXIN2* mRNA levels ($r = 0.546$, $P = 0.03$). The Wnt/β-catenin pathway is intimately connected to the embryonic pluripotent core circuitry. Therefore, we treated PAds-derived cells ($n = 3$) with 10–20 mM lithium chloride for 72 h: we detected nuclear accumulation of β-catenin and concomitant increases in mRNA levels of *NANOG*, decreases of *SOX2*, no changes of *POU5F1/OCT4*. In PAds nuclear β-catenin levels positively correlated with the *NANOG* mRNA levels and negatively with the *SOX2* mRNA levels. Immunohistochemistry of tumour sections (11 PAds and eight carcinomas (PCas)) identified cells expressing at nuclear level the stem cell genes: NANOG-expressing cells were more abundant in parathyroid carcinomas (40.0 ± 5.8%; range 30–70%) than in PAds (11.4 ± 4.5%; range 1–40%; $P = 0.01$), while OCT4 was similarly detected in 5–20% of cells in both PAds and PCas and 42% of PAds showed SOX2-expressing cells. SOX2-expressing cells were more abundant in PAds than in PCas (15.8 ± 5.9% vs 7.0 ± 3.6%; $P = 0.05$). Patients harbouring the PAds with detectable *SOX2* transcripts ($n = 22$) had a more severe hyperparathyroidism at diagnosis: serum PTH and calcium levels were higher than that in patients with *SOX2*-undetectable PAds ($n = 14$; PTH: 324.2 ± 248.0 pg/ml vs 150.2 ± 56.0 pg/ml; $P = 0.014$; calcium: 11.9 ± 1.2 mg/dl vs 11.2 ± 0.7 mg/dl, $P = 0.06$). Immunofluorescence detected few cells coexpressing SOX2 and NANOG or OCT4, while parathyroid tumour cells expressing PTH were negative for all the stem cell genes. In conclusion, we firstly showed that i) a subset of parathyroid tumour cells express the pluripotent stem cell genes and ii) β-catenin might be involved in the regulation of the stem-like phenotype acquisition by a subset of parathyroid tumour cells.

Steroid metabolome analysis reveals that prostate cancer has potent 5α-reductase, 3α- and 17β-hydroxysteroid dehydrogenase activities, but lacks 17-hydroxylase/17,20-lyase

Johannes Hofland[1,2], Angela E Taylor[1], Orli Turgeman[1], Donna M O'Neil[1], Paul A Foster[1] & Wiebke Arlt[1]
[1]Centre for Endocrinology, Diabetes and Metabolism, University of Birmingham, Birmingham, UK; [2]Erasmus MC, Rotterdam, The Netherlands.

Introduction
Prostate cancer (PC) is dependent on androgen receptor (AR) activation by its canonical ligands testosterone and 5α-dihydrotestosterone (DHT). Intratumoural androgens persisting after castration give rise to castration-resistant PC (CRPC). These intraprostatic androgen levels are hypothesized to result from either adrenal androgen conversion or intratumoural *de novo* DHT synthesis through the classic or alternative pathways. Quantifying the steroid fluxes responsible for CRPC development can help optimize current endocrine treatment strategies.
Methods
Five PC cell lines were incubated with 1 μM of 16 steroid intermediates of the classic and alternative androgen synthesis pathways. A PC steroid metabolome was constructed through measurement of steroid metabolite concentrations with liquid chromatography/tandem mass spectrometry (LC–MS/MS). Steroidogenic enzyme expression was estimated by quantitative PCR.
Results
Steroid metabolites could be detected for up to three enzymatic steps downstream of the employed steroid substrate. 17-hydroxylase/17,20-lyase activity was undetectable in all PC cell lines with eight different substrates tested, thereby excluding conversion above 0.03% of the substrate. In contrast, 3α-, 3β- and 17β-hydroxysteroid dehydrogenase and 5α-reductase activities were present in all cell lines to varying degrees. Steroid flux analysis confirmed conversion of adrenal androgen precursors and androgen metabolites into DHT. Furthermore, C21 steroids progesterone and 17hydroxy-progesterone were metabolised into intermediates of the alternative pathway without reaching androsterone. The highest steroidogenic activity was observed in C4-2B cells, a castration-resistant, bone-metastasizing clone of LNCaP. Expression profiles of steroidogenic enzymes matched the observed enzymatic activities.
Conclusion
For the first time, a quantitative steroid metabolome of PC cells has been generated through LC–MS/MS, providing strong evidence against intratumoural *de novo* steroid synthesis. Adrenal androgens can effectively be converted into DHT, whereas precursor C21 steroids divert towards the alternative pathway. The presence of these hormones in PC might suggest a role for activity or further metabolism of alternative pathway steroids in PC evolution.

Evaluation of cases by short synacthen test (dose: 250 μg i.v.) suspected as secondary adrenal insufficiency of prolonged steroid abuse

S M Ashrafuzzaman, Jubaidul Islam & Zafar A Latif
BIRDEM, DHAKA, Bangladesh.

Introduction
Adrenal insufficiency is a common problem in our country due to steroid abuse in various forms. In many occasions the patients even do not know about its side effects and consequences of non-prescribed usage. Many of them presents with sudden withdrawal and adrenal crisis. Many of them admits in Gastroenterology unit due to vomiting, some of them in Medical unit with unexplained fever, weakness, anaemia, etc. Many of them having subtle features of Iatrogenic Cushing's. In this case series, patients of history of chronic steroid use but, are not taking steroid at least since last 4 weeks are evaluated due to their minimal symptoms.
Methods
All patients having history of supraphysiological dose of steroid use more than 3 months in any form but not taking for at least 1 month. Clinically stable, not at crisis. All 34 subjects were evaluated by short synacthen test 250 μg i.v. Three samples S.cortisol were test 0 h, and after Inj. synacthen 250 μg i.v. 30 and 60 min. S.ACTH was tested with 0 min cortisol.
Result
At 0 h S.cortisol value ranges from 53 to 313 nmol/l. At 30 min after Inj. synacthen 250 μg i.v. S.cortisol ranges from 76 to 622 nmol/l and at 60 min 87–587 nmol/l. In the group who has 0900 h S.cortisol <140 nmol/l ($n=15$) they have at 30 min S.cortisol 53–411 nmol/l and at 60 min 76–527 nmol/l. S.ACTH at 0900 h was within normal limit.
Conclusion
In cases of suspected secondary adrenal insufficiency due to steroid abuse (basal S.cortisol <240 nmol/l) synacthen test with 250 μg Tetracosactren (Synacthen) i.v. mostly shows partial adrenal insufficiency. In most cases immediate replacements were depended on clinical presentation not on lab values. So for representative lab values (whom to treat or not to treat with steroid) dose of synnacthen for the 'TEST' can be reconsidered at lower dose between 1 and 250 μg. As 1 μg is not available, preparation by self-dilution method, is not standardised in lab always. Pharmaceutical companies should be requested for standard strength of ACTH may be 10–100 μg/ml for dispensing. Further RCT with 1 μg to 10 μg can be considered to find the standard dose of the 'Low Dose Test'.

Management of urgent surgical intervention due to coexistence of phaeochromocytoma and hydrocephalus in a patient presenting with Von Hippel Lindau syndrome

Gulsah Yalin[1], Mehmet Barbur[2], Gulcin Yegen[3], Seher Tanrikulu[1], Ayse Kubat Uzum[1], Ferihan Aral[1] & Refik Tanakol[1]
[1]Division of Endocrinology, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey; [2]Division of Radiology, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey; [3]Division of Pathology, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey.

A 41-year-old woman was admitted with headache and hypertension. She described worsening of headaches in the last 2 months. On physical examination blood pressure was 150/90 mmHg, and grade 1 hypertensive retinopathy was present. Her sister died at the age of 24 due to pancreas neuroendocrine tumour and her mother was followed up with multiple pancreatic cysts. Abdomen MRI revealed a 6 cm phaeochromocytoma lesion on the right surrenal and multiple cysts in the pancreas, kidneys and ovaries. Urinary catecholamin levels were elevated by sixfold. Other laboratory results were normal. Doxazosin 4 mg (b.i.d.) and amlodipin 5 mg were initiated. Patient's family history, presence of multiple visceral cysts and phaeochromocytoma led us to consider Von Hippel Lyndau sydrome. Cranium MRI which was performed due to severe headaches revealed a 5 cm serebellar hemanjioblastoma and hydrocephalus of the third ventricle. Urgent surgical intervention was indicated due to presence of hydrocephalus and risk of herniation. Coexistence of phaeochromocytoma, risk of hypertensive crisis and deterioration of herniation with anaesthesia induction made it mandatory to perform the two surgeries sequentially in the same surgical session. As the patient had been receiving α blockers for a sufficient time of preoperative period, laparoscopic right surrenalectomy was performed, followed by hemangioblastoma excision in the same session. Pathological evaluation revealed, right surrenal phaeochromocytoma with a Ki score of 3% and grade 1 serebellar hemanjioblastoma. Two months after the surgery patient was normotensive without any antihypertensive treatment and symptoms of headache were omitted. Screening of the family members revealed multiple pancreas, renal and epididymal cysts, serebellar hemangioblastoma and phaeochromocytoma in her brother compatible with Von Hippel Lindau syndrome and treatment was initiated. Evaluation of the other family members were normal and a surveillance programme was scheduled.
Conclusion
Hemangioblastoma of central nervous system which may complicate the surgery of phaeochromocytoma must be considered in patients who present with phaeochromocytoma and multisystemic manifestations implicating presence of a genetic syndrome.

A case of polyglandular autoimmune syndrome type 1 with hypercalcaemia and hypotension

Nilufer Ozdemir Kutbay[1], Banu Sarer Yurekli[1], Miray Yaman[2], Mehmet Erdogan[1], Sevki Cetinkalp[1], Fusun Saygili[1], Sukran Darcan[3] & Gokhan Ozgen[1]
[1]Endocrinology and Metabolism Department, Faculty of Medicine, EGE University, Izmir, Turkey; [2]Internal Medicine Department, Faculty of Medicine, EGE University, Izmir, Turkey; [3]Pediatric Endocrinology and Metabolism Department, Faculty of Medicine, EGE University, Izmir, Turkey.

Autoimmune polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED) is also known as autoimmune polyendocrine syndrome type 1 (APS-1). We present a case of autoimmune polyendocrine syndrome type 1 with hypercalcaemia of adrenal insufficiency during the calcium treatment because of hypoparathyroidism.
Case
A 20-year-old female patient was diagnosed with APS-1 in 2004. She applied to ER with the complaints of nausea and vomiting. Her laboratory findings proved hypercalcaemia, hyponatremia and hypotension. She'd had an upper respiratory infection a week prior to her application to our hospital. In her ECG, t-waves were found to be commonly inverted. Her echocardiography revealed increased pericardial brightness. Thus, indomethacin 2×1 was started as pericardite was suspected. BP of 90/40 mmHg and dry skin were found in the physical examination. Horizontal ridges and trophic deformities on both finger nails and toes were observed (Picture 1). The laboratory findings were as follows: BUN: 58 mg/dl, creatinine: 0.82 mg/dl, Na: 127 mEq/l, K: 4.6 mEq/l, Ca: 12.6 mg/dl, FSH: 4.42 mIU/ml, LH: 5.63 mIU/ml, ACTH: 124 pg/ml, cortizol: 0.40 μg/dl, DHEAS: 4.6 μg/dl, free T_3: 1.94 pg/ml, free T_4: 1.07 ng/dl, TSH: 3.26 μIU/ml, anti TPO: 14.7, PTH: 0.01 pg/ml. Hypercalcemia was associated to adrenal insufficiency. I.v. hydration and steroid of stress dose was started because of hypercalcemia and hypotension. We applied maintenance doses of hydrocortisone (30 mg/day) and fludrocortisone ($0.1\text{ mg}\times1/2$ a day) to the improved patient. Calcitriol and calcium were restarted to the patient as her Ca level was 6.5 mg/dl in the follow-up period. The patient had a leukoplakic lesion characterized with candida plaque on the right buccal mucosa. Thus, sodium bicarbonate and mycostatin suspensions were added to the treatment.
Discussion
The most important components of OPS type 1 are hypoparathyroidism, Addison's disease and candidiasis with other disease associations of hypothyroidism, hypogonadism and infertility, alopecia (baldness), malabsorption, chronic active (autoimmune) hepatitis. It is a genetic disorder inherited in autosomal recessive tendency due to a defect in the auto immune regulator (AIRE) gene located on chromosome 21.q223. In our case, hypercalcaemia was thought to develop as a result of calcitriol and calcium treatment and addition of adrenal insufficiency. One should always remember that calcitriol and calcium treatment simultaneously with adrenal crisis triggered by stress assist the development of hypercalcaemia in the cases with APECED.

The value of high effective liquid chromatography in the diagnosis of primary aldosteronism

Dina Rebrova, Natalya Vorokhobina, Ludmila Velikanova & Zulfiya Shafigullina
North-Western State Medical University n.a. I.I. Mechnikov, St. Petersburg, Russia.

Objectives
Primary aldosteronism (PA) is considered to be the most common cause of secondary hypertension. Therefore, a relevance of early diagnosis of PA is obvious.
Methods
We evaluated 98 patients with hypertension in age 47.8 ± 1.4 years. We measured serum potassium by indirect porentiometry, serum aldosterone and plasma rennin activity (PRA) by RIA, serum corticosterone (B), 18-hydroxycorticosterone (18-OH-B), 11-deoxycorticosterone (DOC), 11-dehydrocorticosterone (A), 11-deoxycortisol (S) and urine 18-hydroxycorticosterone (U18-OH-B) by high effective liquid chromatography (HELC). All patients underwent saline infusin test and computed tomography with contrast. Adrenal vein sampling (AVS) was performed in all patients with confirmed PA.
Results
PA was diagnosed in 46 patients, 27 of them had unilateral form – aldosterone-producing adenoma (APA), 19 – idiopathic hyperplasia (IHA). 52 patients were found essential hypertensives (EH), 27 of them were low-renin EH. PA patients had higher levels of some corticosteroids than EH: B (6.5 ± 0.8 vs 3.0 ± 0.6 ng/ml respectively, $P < 0.001$), DOC (7.8 ± 1.4 vs 2.0 ± 1.8 ng/ml respectively, $P < 0.01$), 18-OH-B (2.1 ± 0.5 vs 4.8 ± 0.5 ng/ml respectively, $P < 0.001$), S (4.4 ± 1.2 vs 1.0 ± 0.3 ng/ml respectively, $P < 0.01$), A (6.4 ± 0.8 vs 2.5 ± 0.3 ng/ml respectively, $P < 0.001$).
Conclusion
The determination of the precursors of aldosterone in blood and urine samples by HELC is a safe method for the patients who have contraindications to recommended confirmatory tests. It can be used in patients with uncontrolled hypertension and high risk of cardiovascular complications. Our data showed that increased levels of serum B, S, DOC, A and 18-OH-B, U18-OH-B are laboratory signs of PA which can be determined during screening.

Influence of glucocorticoids on markers of inflammation in community-acquired pneumonia

Claudine A Blum[1,2], Nicole Nigro[1], Philipp Schuetz[3], Bettina Winzeler[1], Birsen Arici[1], Julie Refardt[1], Sandrine A Urwyler[1], Matthias Briel[1,4], Beat Mueller[3] & Mirjam Christ-Crain[1]
[1]Endocrinology, Diabetology and Metabolism, Department of Internal Medicine and Department of Clinical Research, University Hospital Basel, Basel, Switzerland; [2]Service d'Accueil des Urgences, CHU Pitié-Salpêtrière et AP-HP, Paris, France; [3]Medical University Clinic, Departments of Internal and Emergency Medicine and Department of Endocrinology, Diabetology and Clinical Nutrition, Kantonsspital Aarau, Aarau, Switzerland; [4]Department of Clinical Epidemiology and Biostatistics, McMaster University, Hamilton, Ontario, Canada.

Background
Glucocorticoids are frequently prescribed in inflammatory diseases. We investigated the influence of prednisone on classical and novel inflammatory markers in community-acquired pneumonia (CAP).
Methods
We evaluated levels of C-reactive protein (CRP), procalcitonin, leukocyte and neutrophil count in a prospective randomized, double-blind, placebo-controlled multicenter trial which compared prednisone 50 mg for 7 days to placebo in patients hospitalized with CAP. We performed Mann–Whitney *U* tests to compare biomarker levels between groups on day 1 before the first administration of prednisone and thereafter on days 3, 5, 7 and discharge.
Results
335 patients in the prednisone group and 350 patients in the placebo group were evaluated. At baseline, all investigated markers levels did not differ between prednisone and placebo group. At days 3, 5, and 7, CRP levels were significantly lower in the prednisone group than in the placebo group ($P < 0.0001$ for each time point). At hospital discharge, CRP levels were similar ($P = 0.53$). For procalcitonin, this attenuating effect of steroids on circulating levels was not visible ($P > 0.05$ for all points). Leukocyte and neutrophil count were higher in the prednisone group during administration of glucocorticoids ($P < 0.0001$ for all time points including discharge).
Discussion
Administration of glucocorticoids in patients with CAP lowers CRP levels and increases leukocyte and neutrophil count, but has no influence on procalcitonin levels. Therefore, procalcitonin may be a more adequate inflammatory marker to measure treatment response in patients with an infectious disease receiving glucocorticoids.

Clinical and pathological characteristics of hypertensive and normotensive adrenal phaeochromocytomas

Bi Yan, Zhu Dalong & Lu Yao
Drum Tower Hospital Affiliated to Nanjing University Medical School, Nanjing, China.

Context
Distinct differences of clinical manifestations exist in hypertensive pheochromocytomas (HPs) and normotensive phaeochromocytomas (NPs), however the comparative analysis is lacking.
Objective
The objective of the study was to assess the clinical symptoms, haemodynamics, metabolism, radiological and histological features of patients with HPs and NPs.
Research design and methods
This retrospective study included 104 patients who underwent a unilateral adrenalectomy with a diagnosis of phaeochromocytoma at the Drum Tower Hospital Affiliated to Nanjing University Medical School from January 2004 to December 2014. All available clinical, biochemical, and radiological records were reviewed in phaeochromocytomas patients who were then categorized into HPs ($n = 69$) and NPs ($n = 35$) groups. Tumour samples were examined to determine the adrenal gland scale score and were available for measurement of gene transcriptions. Clinical and biochemical examinations of consecutive 95 subjects with primary hypertention (PH) were recorded for comparative study.
Results
Patients with NPs showed lower proportion of clinical triad, inapparent metabolic disorders and lower urinary catecholamine levels than HPs, but higher than PH. Tumour weight positively correlated with 24 h urinary norepinephrine level in patients with HPs ($P = 0.028$), and tumour diameter negatively correlated with phenylethanolamine-*N*-methyltransferase (PNMT) immunohistochemistry ($P = 0.011$) in NPs but not in HPs. The adrenal gland scale score of NPs group was similar to that of HPs group. The positive percentage of E-type of catecholamine in HPs group was higher than that in the NPs, while the positive percentage of NE-type or no function of catecholamine in HPs group was lower than that of the NPs. The transcript levels of PNMT, secretogranin II (SGII) and neuropetide Y (NPY) from tissue samples were significantly lower in NPs than in HPs, while vesicular monoamine trasporter 1 (VMAT1) had no difference between HPs and NPs.
Conclusions
HPs and NPs have distinct differences in clinical, biochemical and pathological phenotypes, which are closely related with the catecholamine pathway productions involved in tumour occurrence and development.

New onset sarcoidosis after remission of Cushing's syndrome

Zeynep Canturk[1], Alev Selek[1], Serap Bariş[2], Berrin Cetinarslan[1], Ilhan Tarkun[1] & Zeynep Akyay[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Kocaeli University, Kocaeli, Turkey; [2]Department of Chest Diseases, Faculty of Medicine, Kocaeli University, Kocaei, Turkey.

Introduction
Glucocorticoids, even endogenous or exogenous, suppress the inflammatory response therefore they are the most preferred treatment options in inflammatory diseases. Persistent hypercortisolism induces lymphopenia and lymphoid tissue atrophy. Excessive endogenous hypercortisolism might mask the active inflammatory disease. Rebound immune modulation may occur after Cushing's syndrome (CS) remission, leading to the new onset of autoimmune diseases.
Case
Here, we report a 27-year-old female patient newly diagnosed as sarcoidosis after remission of CS. Adrenal CS was treated successfully with right adrenalectomy. The patient was free of sarcoidosis during the course of CS with normal thorax imaging and without any symptoms of sarcoidosis. After complete remission of

CS she started to complain of cough and was diagnosed sarcoidosis with clinical, radiological and bronchoscopic evidence.
Conclusion
Endogenous Cushing's syndrome is caused either by excess ACTH secretion or by autonomous cortisol release from the adrenal cortex. Glucocorticoids are the main endogenous mechanism to suppress the inflammatory response genes. Exposure to persistent hypercortisolism induces lymphopenia and lymphoid tissue atrophy resulting in immunosupression. After treatment of CS rebound immunity occurs especially in patients with overt disease. In rare cases, the treatment of CS may result in unmasking or aggravation of diseases responsive to glucocorticoid medication such as thyroid, rheumatologic and allergic diseases. Excessive hypercortisolism might suppress the active inflammatory stage of sarcoidosis. However, the disease became apparent after the reduction of cortisol levels following the treatment of CS.

Extra-adrenal myelolipomas in association with cortisol hypersecretion

Betul Cavusoglu[2], Evrim Cakir[1], Suleyman Ahbab[2], Esra Ataoglu[2] & Mustafa Yenigun[2]
[1]Haseki Training and Research Hospital, Endocrinology and Metabolic Diseases, Istanbul, Turkey; [2]Haseki Training and Research Hospital, Internal Medicine, Istanbul, Turkey.

Extraadrenal perirenal myelolipom has been reported since 1980. In recent years, it has been reported at an increasing rate in different sites of the body ranging from the nasal cavity, mediastinum to presacral, paravesical region. However, it was the first reported case that perirenal multiple myelolipomas, each myelolipomas was about 5 cm in diameter, in associated with cortisol hypersecretion. A patient was an emigrant. She was followed in her country and was prescribed ketokonazol. She did not take her medicine and she was brought to emergency service when her situation deteriorated. She was exposed to hypercortisolemia for a long time and had severe muscle weakness, fatigue, amenorrhea and weight loss at admitted-time. Physical examination revealed cushingoid appearance with trunk obesity, sebaceous moon face, hirsutism, muscle wasting, high blood pressure, acanthosis nigricans and abdominal striae. Laboratory tests were as following; glucose: 170 mg/dl (70–100), urea:42.3 mg/dl (17–43), creatinin: 0.82 mg/dl (0.51–0.95), sedimentation: 35 mm/h (0–30), HbA1c: 8.8%, FSH: 1.59 mIU/ml (4.54–22.51) LH: 0.31 mIU/ml (12–12.86 mIU/ml), estradiol: 16 pg/ml (49–291), progesterone: 1.75 ng/ml (5.16–18.56), total testesterone: 0.48 pg/ml (0.1–0.75), cortisol: 30.40 μg/dl (6.7–22.6), ACTH: <1 pg/ml (7.2–63.3). Eosinopenia, lymphocytopenia and neutrophilia was obtained in whole blood cell evaluation. Cortisol level was 27.60 μg/dl after 1 mg dexamethasone suppression test, result revealed failure of suppression. Pituitary MR was normal. A contrast enhanced abdominal MR showed multipl lobulated bilateral perirenal masses and a cystic mass at the caput of the pancreas without solid component. Majority of perirenal masses was located in the right perirenal area with 5×4 cm in diameter. The MR followed by a F-18 fluorodeoxyglucose tomography (FDG PET/CT). The increased FDG uptake in the right pararenal area. Myelolipoma was diagnosed in microfiber biopsy of the perirenal mass. In her hospitalisation period femur fracture occurred. After operation for femur fracture she could not be extubed because of the respiratory muscle weakness. Adrenal myelolipomas with Cushing syndrome have been reported previously. However, extra-adrenal perirenal myelolipomas presented with Cushing syndrome is the first case of the literature.

Salivary cortisol after overnight dexamethasone suppression test in different patient groups

Meral Mert[1], Refik Tanakol[2], Hande Karpuzoglu[3], Semra Dogru Abbasoglu[3], Ozlem Soyluk[2], Sema Yarman[2] & Faruk Alagol[2]
[1]Bakirkoy Dr. Sadi Konuk Education and Research Hospital, Endocrinology and Metabolism, Istanbul, Turkey; [2]Division of Endocrinology and Metabolism, Department of Internal Medicine, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey; [3]Department of Biochemistry, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey.

Introduction
The aim of this study was to evaluate the worth of the salivary cortisol after overnight 1 mg dexamethasone suppression test (DST) in different patients.
Materials and methods
The patient groups of the study consisted of 18 Cushing's syndrome patients, 12 patients with non-functional adrenal incidentaloma, 37 patients with obesity, 16 patients with hirsutism and 26 healthy control patients. Salivary cortisol (SC) and plasma cortisol after 1 mg-overnight DST were measured. SC was measured with luminescense immunoassay kit.
Results
Salivary cortisol levels after overnight DST was found significantly different between all groups ($P<0.05$) except between patients with hirsutism and obesity and between patients with adrenal incidentaloma and healthy control group ($P=0.357$). In this context, plasma cortisol levels after overnight DST were not significantly different between patients with hirsutism and control group and between patients with obesity and control patients both, while it was significantly different between all the other groups.
When all the patient groups are evaluated in a whole group there was a significant positive correlation between plasma and salivary cortisol ($r=0.542$, $P=0.0001$). In the subgroup analyses, there was no correlation between salivary and plasma cortisol in patients with hirsutism and Cushing's syndrome. In the groups with adrenal incidentaloma and healthy control, highly significant correlation between salivary and plasma cortisol was found ($r=0.750$ – $P=0.02$, $r=0.679$ – $P=0.008$ respectively).
Conclusion
Salivary cortisol after overnight DST may be one of the new non-invasive diagnostic tools for the differential diagnosis of Cushing's syndrome and pseudo-Cushing syndrome. However, laboratory test results and clinical findings should be evaluated together in clinical practice.

Overview of phaeochromocytomas at Vilnius University Hospital Santariskiu clinics (VUHSC): 5 year results

Milda Girdziute[1] & Zydrune Visockiene[1,2]
[1]Vilnius University, Vilnius, Lithuania; [2]Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania.

The aim of our study was to estimate the prevalence and describe diagnosis, treatment and follow up strategy of phaeochromocytomas at VUHSC.
Results
There were 702 patients diagnosed with adrenal masses from 2010 to 2014. Only half of patients were screened for phaeochromocytoma which included 24 (the incidence is 3.4%). Phaeochromocytoma was diagnosed in 5 (20.8%) males and 19 (79.2%) females, average age 55 ± 11.5 years. After surgery 2 (8.3%) were confirmed as paragangliomas. Although there were 21 (87.5%) symptomatic patient – most commonly with hypertension – 16 (66.7%), episodic tachycardia – 13 (54.2%), episodic elevations of blood pressure – 12 (50.0%) and sweating – 4 (16.7%), phaeochromocytoma was found incidentally in 15 (62.5%) cases. The average tumour size of 48.0 ± 23.4 mm and density of 33.7 ± 11.6 HV was estimated by computed tomography performed for all patients. Most tumours were found in the left adrenal – 15 (62.5%), bilaterally – in 1 (4.2%) patient. In 45.8% of cases scintigraphy with iodine-123-metaiodobenzylguanidine was performed and uptake confirmed in all suspected tumours. Hormonal activity was confirmed in 20 (83.3%) cases by elevation of plasma metanephrine and/or normetanephrine or urine/plasma adrenaline and/or noradrenaline. Isolated elevations of either adrenaline or metanephrine was detected in 4 (16.7%), noradrenaline or normetanephrine – in 3 (12.5%) cases. Adrenalectomy was performed in 21 (87.5%) patient with suspicion of malignant tumour in 9 (42.9%) of cases after histological examination. Two of them received chemotherapy, but were diagnosed with the recurrence of disease, others are under follow up with no disease relapse. Genetic syndromes were diagnosed in 2 (8.3%) subjects: Von Hippel Lindau syndrome and type 1 neurofibromatosis.
Conclusions
The incidence of phaeochromocytoma in our hospital is 3.4% and meets the rates estimated by others. High prevalence of asymptomatic patients and suspicion of malignant tumours after histology urge for careful assessment of all adrenal masses for phaeochromocytoma.

Aldosterone- and cortisol-co-secreting adrenal adenoma in an adolescent girl: a case report

Serap Baydur Sahin[1], Ahmet Hamdi Aktan[2], Osman Zikrullah Sahin[3], Ahmet Fikret Yucel[4] & Ekrem Algun[1]
[1]Department of Endocrinology and Metabolism Disease, Recep Tayyip Erdogan University Medical School, Rize, Turkey; [2]Department of Internal Medicine, Recep Tayyip Erdogan University Medical School, Rize, Turkey; [3]Department of Nephrology, Recep Tayyip Erdogan University, Rize, Turkey; [4]Department of General Surgery, Recep Tayyip Erdogan University, Rize, Turkey.

Introduction
Primary aldosteronism (PA) is the most common reason for secondary hypertension. Among adrenal disorders, rarely aldosterone- and cortisol-co-secreting adenomas (A/CPA) can lead to PA. 35 patients with A/CPA were reported to date and their mean age was 52 (range 34–80) years. We report an A/CPA in an adolescent girl presenting with hypertension combined with hypokalemia and signs of hypercortisolism.
Case report
A 18-year-old girl admitted to endocrinology outpatient clinic with the complaint of hypertension. Physical examination revealed central obesity (BMI:31 kg/m^2), moon face, hirsutism, buffalo hump and abdominal striae. Her blood pressure was 170/110 mmHg. Laboratory examination revealed serum potassium level of 2.4 mEq/l. The mean aldosterone to renin ratio was 308 (aldosterone: 98.77 ng/dl, plasma renin activity (PRA): 0.32 ng/ml per h). Intravenous saline infusion test was performed as the confirmatory test. Her post-infusion aldosterone level was 80.69 ng/dl. While the midnight serum cortisol level was 7.6 μg/dl, her serum cortisol levels failed to suppress during a 1 mg dexamethasone suppression test (DST) (5 μg/dl) and 2 mg DST (9.8 μg/dl). Serum ACTH and DHEA-S levels were 13.1 pg/ml and 11.12 μg/dl (*n*: 65–368) respectively. Computed tomography of adrenal glands revealed a 24×14 mm hypodense solid lesion in the right adrenal gland. She underwent laparoscopic right adrenalectomy with perioperative steroid replacement. At the postoperative day 4 at 0800 h, serum cortisol level was 0.6 μg/dl and she was put on substitution therapy with oral glucocorticoids. The aldosterone level and PRA were 2.12 ng/dl and 5.59 ng/ml per h 2 days after the operation, respectively. At the follow-up, her blood pressure and serum potassium level returned to normal.
Conclusion
Patients with A/CPA may present with overt or subclinical hypercortisolism. Therefore, pre-operative screening of cortisol co-secretion in patients with aldosterone-producing adenomas is important to prevent adrenal crises at the perioperative period.

Comparison of a RIA assay and a CLIA assay for aldosterone determination

Nassima Belaidi, Julie Brossaud, Agnès Georges & Jean-Benoît Corcuff
University Hospital, Bordeaux, France.

Objective
To extend knowledge about the clinical performances of a new chemiluminescent immunoassay (CLIA) for aldosterone set up in available analysers.
Design and patient
We compared the results of a RIA assay to those of a CLIA assay in 198 serum and 80 urine samples from patients in endocrine and hypertension departments. Furthermore, for serum samples the concordance of results for postural tests was analysed.
Results
RIA and CLIA aldosterone serum concentration was linearly correlated with a slope of 0.988 and an intercept of 70.4 pmol/l. The variations of aldosterone serum concentration obtained with the two assays during postural tests were very consistent. There was no significant difference of aldosterone concentrations after thawing with the CLIA. RIA and CLIA aldosterone urine concentrations were linearly correlated with a slope of 0.787 and an intercept of −2.64 nmol/l. Omitting the preservative boric acid from urine samples did not modify aldosterone concentration at least up to 48 h after collection.
Conclusion
The RIA and CLIAs were well correlated for the most useful serum samples. It is well suited to circumvent isotopic assays with the throughput of available analysers.

Does IGF-1 have a role in ethiopathogenesis of adrenal incidentaloma?

Çiğdem Tura Bahadir & Hulusi Atmaca
Ondokuz Mayis School of Medicine, Samsun, Turkey.

Objectıve
Due to increased usage of imaging modalities today, incidence of adrenal incidentaloma (AI) has increased. Insulin resistance is considered as the etiopathogenic mechanism. Since both insulin and IGF-1 are capable of interacting with same receptors, we aimed to investigate whether IGF-1 has a role in development of adrenal incidentaloma.
Materıals and method
50 female patients with nonfunctional adrenal incidentaloma and 55 acromegaly patients (20 male, 35 female) that admitted to endocrinology outpatient ward between 01/08/2012 and 01/01/2014 and have had undergone abdominal CT or MRI scan were included in this study in addition to a control group of 38 female patients who was performed abdominal CT scan due to urolithiasis. Those patients in adrenal, acromegaly and control groups were analysed regarding age, BMI, waist circumference and serum IGF-1 levels.
Results
Regarding age, no significant difference was present between three groups. BMI and waist circumference (WC) in the control group was lower than those in the acromegaly and adrenal groups ($P<0.001$). Although BMI and WC values were higher in adrenal group, IGF-1 values were significantly higher when compared to the control group ($P<0.001$). Prevelance of adrenal incidentaloma was found to be significantly higher in the acromegaly patients than the control group (25% vs 3%). The results were similar when male patients in acromegaly group are excluded and analysis was conducted only among female subjects. Adrenal incidentaloma prevelance in female acromegaly patients was 34% whereas in the control group it was 3%.
Discussion
In this study, our findings of elevated serum IGF-1 levels in nonfunctional AI patients and higher prevelance of adrenal incidentaloma in acromegaly patients when compared to control group let us think that IGF-1 has a role in the etiopathogenesis of adrenal incidentaloma.

Effects of megestrol acetate on adrenal function and survival in cancer patients

Guzin Fidan Yaylali[1], Gamze Gokoz Dogu[2], Atike Gokcen Demiray[2], Ahmet Ergin[3], Arzu Yaren[2] & Fulya Akin[1]
[1]Department of Endocrinology and Metabolic Diseases, Faculty of Medicine, Pamukkale University, Denizli, Turkey; [2]Department of Oncology, Faculty of Medicine, Pamukkale University, Denizli, Turkey; [3]Department of Public Health, Faculty of Medicine, Pamukkale University, Denizli, Turkey.

Introduction
Megestrol acetate (MA) has been used in various cancers as a palliative agent to treat cancer cachexia. It has glucocorticoid activity and can induce significant secondary adrenal suppression. We designed this study to determine the extent of adrenal insufficiency in cancer patients receiving MA and find out whether ther was any predictive factor for this.
Methods
Thirty-one patients (11 females and 20 males, aged 48–83 years) who were receiving MA took part in this study. They were evaluated for HPA axis; before the initiation and 1 month later. Serum concentrations of TSH, ACTH, free T_4, cortisol were measured in samples obtained at 0700 h, at baseline and 1st month. Standart ACTH (250 mg) stimulation test was performed if cortisol levels were below 18 μg/dl at any time.
Results
1 month after drug initiation, 32% of patients were accepted as adrenal insufficient. There wasn't any correlation between the basal cortisol, ACTH levels, any biochemical parameter and overall survival. There was negative correlation between 1 month cortisol levels and survival time ($P=0.04$) If cortisol levels were lower at month of theraphy survival time was longer. Cox regression analysis showed that patients having lower cortisol levels at first month had 98% lower risk of death compared to patients having higher cortisol levels ($P=0.02$: OR 0.12 (0.02–0.75)).

Conclusion
It is important to be aware of the effects of MA on adrenal functions and evaluate adrenal functions especially during episodes of infection or after withdrawal of MA therapy since this may require prompt corticosteroid treatment.

DOI: 10.1530/endoabs.37.EP14

The effect of retinoic acid on human adrenal corticosteroid secretion *in vitro*

Antonella Sesta[1], Laura Tapella[2], Maria Francesca Cassarino[1], Luigi Castelli[3], Francesco Cavagnini[1] & Francesca Pecori Giraldi[1,2]
[1]Neuroendocrinology Research Laboratory, Istituto Auxologico Italiano, Milan, Italy; [2]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [3]Clinica San Carlo, Paderno Dugnano, Italy.

Retinoic acid, a derivative of vitamin A, has recently yielded promising results in the treatment of Cushing's disease (Pecori Giraldi *et al*. JCEM 2012). Its main site of action appears to be the tumoural corticotrope as retinoic acid inhibits *POMC* transcription and corticotrope proliferation (Paez-Pereda *et al*. JCI 2001). Studies on tumoural adrenal cell lines have revealed an additional inhibitory effect on cell proliferation and stimulated corticosteroid secretion (Paez-Pereda *et al*. JCI 2001). *Aim* of the current study was to evaluate whether retinoic acid modulates corticosteroid secretion by normal human adrenals *in vitro*.
Methods
Primary cultures from nine normal human adrenals were incubated with 10 nM, 100 nM and 1 μM retinoic acid with and without 10 nM ACTH for 24 h. Cortisol levels in medium were measured by Coat-A-Count RIA (Siemens Healthcare Diagnostics, Erlangen, Germany); *CYP11A*, *STAR* and *MC2R* gene expression were analyzed by real-time PCR (7900 HT Sequence Detection System, Applied Biosystems, Foster City, USA) normalized to *RPLP0*.
Results
A clear-cut increase in cortisol secretion during retinoic acid incubation was observed in five adrenal specimens (10 nM: 183.9±55.9%, 100 nM: 210.1±82.6% and 1 μM: 141.3±11.7% baseline). Gene expression analysis revealed a marked decrease in *MC2R* expression (10 nM: 0.65±0.13, 100 nM: 0.63±0.09 and 1 μM: 0.55±0.08 over baseline) and an increase in *STAR* in wells treated with retinoic acid (10 nM: 1.53±0.26, 100 nM: 1.62±0.17 and1 μM: 1.63±0.16 over baseline). *CYP11A* was on average unchanged by retinoic acid. Incubation with ACTH led to a marked increase in cortisol secretion and in *CYP11A1*, *STAR* and *MC2R* expression. Retinoic acid and ACTH co-incubation resulted in a sligthly greater cortisol release (10 nM: 125.4±16.6%, 100 nM: 141.1±29.5% and 1 μM: 139.6±31.3% ACTH) and *MC2R* inhibition (10 nM: 0.76±0.13, 100 nM: 0.56±0.07 and 1 μM: 0.64±0.09 over ACTH) than ACTH alone.
Conclusions
Retinoic acid exerts a stimulatory effect on adrenal corticosteroid secretion *in vitro*, activates *STAR* expression and blunts *MC2R* transcription. This paves the way for novel avenues of research in patients with Cushing's syndrome.

Adrenal malignant melanoma masquerading as a phaeochromocytoma

Maria Barmpari[1], Christos Savvidis[1], Anastasia Dede[1], Haridimos Markogiannakis[2], Dimitrios Giannopoulos[3], Christina Dikoglou[3] & Sofia Malaktari-Skarantavou[1]
[1]Department of Endocrinology and Metabolism, Hippokration Hospital, Athens, Greece; [2]Department of Endocrine Surgery, First Department of Propaedeutic Surgery, Athens Medical School, Hippokration Hospital, University of Athens, Athens, Greece; [3]Department of Pathology, Hippokration Hospital, Athens, Greece.

Introduction
Adrenal masses usually represent benign and nonfunctional adrenal adenomas however, primary or metastatic malignancy should also be considered. Discovery of an adrenal mass needs further evaluation in order to exclude malignancy and hormonal secretion. Primary adrenal melanoma is an extremely rare entity, while metastases of cutaneous melanoma to the adrenals occur much more often. We present a rare case of a possibly primary adrenal malignant melanoma with imaging and biochemical features of a phaeochromocytoma.
Case report
A 61-year-old male farmer was referred for evaluation of a mass in the right supraclavicular region and a left adrenal lesion. The patient had a history of a multifocal papillary and medullary thyroid carcinoma 3 years before presentation. Genetic analysis for RET mutations was negative. Laboratory tests revealed increased 24-h urinary dopamine and also increased serum calcitonin and neuron specific enolase. The adrenal lesion measured 88.5 mm on MRI, displayed inhomogeneous enhancement of the contrast agent and low diffusion rate. Both lesions appeared positive in In 111-Pentetreotide scintigraphy, while meta-iodo-benzyl-guanidine (MIBG) scintigraphy was negative. Pathologic examination of the resected right supraclavicular mass and left adrenal was consistent with malignant melanoma. Rough evaluation for a primary melanoma site was negative.
Conclusion
This is the case of a possibly primary adrenal malignant melanoma with imaging and biochemical features of a pheochromocytoma. Melanocytes and chromaffin cells share a common embryological origin and in melanoma tissue there is expression of tyrosine hydroxylase leading to production of DOPA and melanins. Although this case is very rare, and there are rigid diagnostic criteria for the diagnosis of primary adrenal melanoma, the differential diagnosis of a dopamine secreting adrenal mass should include primary or metastatic malignant melanoma in order to determine the best diagnostic approach to the patient and select the most appropriate surgical management.

Cushing's disease: experience in a third level hospital from Zaragoza (Spain)

Francisco Losfablos Callau[1], Paloma de Castro Hernández[2], Pablo Trincado Aznar[2], Marta Monreal Villanueva[2] & Javier Acha Pérez[2]
[1]Calatayud Hospital, Zaragoza (Aragón), Spain; [2]Miguel Servet Hospital, Zaragoza (Aragón), Spain.

Objective
Cushing's disease (CD) is caused by pituitary corticotrophin (ACTH)-secreting tumours. Our aim is to show our experience in a third level hospital attending a 500 000 based population area from 1990 to now.
Methods
We review retrospectively the medical reports of all patients diagnosed as CD from 1990 by a data collection protocol. We reject the reports without enough or inadequate information. We present results by using descriptive statistics.
Results
29 patients were diagnosed as CD in the period study (estimate average incidence of 2.41 cases/million people per year). Nine medical reports contain insufficient or misleading information including two from dead patients. The remaining 20 patients were included in our analysis. Mean age at diagnosis was 39 years (range 17–75 years) with a bimodal distribution. Mean BMI was 28.45 kg/m^2. Mean follow up time was 11 years (range 2–24). 90% were women. Reference most common reason was hyperandrogenism (acne and hirsutism, 55%). Most common symptom were also hirsutism, 65%. Mean plasma basal cortisol value was 27.9 μg/dl (range 18–51 μg/dl). Mean basal cortisol value after 1 mg of DXM was 14.6 μg/dl (3.38–34.9 μg/dl). Mean basal cortisol value after 4 mg of DXM was 14.53 μg/dl (3.08–23.46 μg/dl). Mean basal cortisol value after 8 mg of DXM was 7.96 μg/dl (0.34–24.45 μg/dl). Mean 24-h urinary free cortisol value was 840.7 μg/24-h (97–5530 μg/24-h). Mean cortisol value at midnight was 13.63 μg/dl (9.26–18.03 μg/dl). Mean ACTH value was 71.96 pg/dl (20–231 pg/dl). 35% of tumours were not visible at MRI, 55% were microadenomas and 10% macroadenomas. 95% of patients were treated surgically. The ratio of curation after the first surgery was 65%. One patient (5%) was treated only pharmacologically (ketoconazole) and remain controlled after 9 years of follow up. 30% of patients required a second treatment. Mean time to this second treatment was 5.32 years (range 0.3–12 years). 30% of patients required a second surgery with a curation rate of 50%. 15% of patients have required radiotherapy and 5% bilateral adrenalectomy. 15% of patients remain with hypopituitarism and 35% with hydrocortisone supplementation.
Conclusions
Our patients reproduce well referenced data from other series. Hiperandrogenism was the main cause of consultation.

Subclinical Cushing's syndrome and clinical implications in bilateral compared to unilateral adrenal incidentalomas: a meta-analysis

Stavroula A Paschou[1], Eleni Kandaraki[1], Fotini Dimitropoulou[1], Dimitrios G Goulis[2] & Andromachi Vryonidou[1]
[1]Department of Endocrinology and Diabetes, Hellenic Red Cross Hospital, Athens, Greece; [2]Unit of Reproductive Endocrinology, First Department of Obstetrics and Gynecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece.

Introduction
The aim of this study was to systematically review the literature for studies that have investigated possible differences in prevalence of subclinical Cushing's syndrome (SCS) and related clinical implications between patients with unilateral (UAI) and bilateral adrenal incidentalomas (BAI) and to meta-analyze the best evidence available.
Methods
Electronic databases PubMed, MEDLINE and EMBASE were systematically searched. Main study outcome was the prevalence of SCS in patients with UAI and BAI. Secondary outcomes were the prevalence of obesity, diabetes, glucose intolerance, hypertension, dyslipidaemia and osteoporosis in patients with UAI and BAI. Random effects odds ratios (OR) or standardized mean differences (SMD) and 95% CI were calculated. Meta-analysis was conducted using Review Manager (RevMan 5.3).
Results
Six studies were included in the meta-analysis involving in total 1239 patients, 968 with UAI and 271 with BAI. Patients with UAI had lower prevalence of SCS compared with those with BAI (OR (95% CI) 0.51 (0.32; 0.81), $I^2=55\%$). The mass diameter of UAI did not differ from BAI (the size of the largest lesion) (SMD (95% CI) −0.40 (−0.97; 0.17), $I^2=91\%$). The prevalence of obesity (SMD (95% CI) 0.06 (−0.10; 0.22), $I^2=0\%$), diabetes (OR (95% CI) 0.78 (0.51; 1.21), $I^2=0\%$), hypertension (OR (95% CI) 1 (0.47; 2.12), $I^2=74\%$) and dyslipidaemia (OR (95% CI) 0.93 (0.49; 1.78), $I^2=49\%$) did not differ between UAI and BAI.
Conclusions
Patients with BAI present a higher prevalence of SCS compared to patients with UAI, without any differences in related clinical implications.

Association of psoriasis with Cushing's syndrome

Cigdem Tura Bahadir, Feyzi Gokosmanoglu, Elif Kilic Kan, Gulcin Cengiz Ecemis, Aysegul Atmaca, Hulusi Atmaca & Ramis Colak
Ondokuz Mayis University, Samsun, Turkey.

Introduction
Psoriasis is a chronic, inflammatory and T-cell mediated autoimmune disease of skin. Its prevalence is 2–3%. It may improve due to immunesupressive effects of hypercortisolaemia during the active phase of Cushing's syndrome (CS) and may exacerbate after treatment. The aim of this study was to investigate association of psoriasis with CS.
Methods
We prospectively followed 62 patients who had been diagnosed with CS between 2010 and 2014 in our clinic. Of the patients, 60% was Cushing disease (CD) (29 female, eight male) and 40% was ACTH-independent CS (20 female, five male). The patients were evaluated for psoriasis.
Results
The prevalence of psoriasis was 5% among our patients with CS. Psoriasis was diagnosed in three patients; two had pituitary adenoma and one had adrenal adenoma. Two were diagnosed before treatment of CD, and the other was diagnosed after 2 years following remission of ACTH-independent CS. The pathological evaluation of two patients with CD was reported as densely granulated corticotrophic adenoma and the pathological evaluation of the patient with ACTH-independent CS was reported as adrenocortical adenoma with nuclear pleomorphism and possible malignant behaviour. In the light of these findings, potential hypersecretory tumours should be considered.
Discussion
Endogenous hypercortisolism supresses inflammatory response and induces a state of immunesuppression. Once cortisol levels come back to normal following remission of CS, rebound response of immunity may result in exacerbation of autoimmune diseases like psoriasis. Prevalence of psoriasis is elevated in CS. If the patient is known to have a history of stress-responders psoriasis prior to surgery, we should evaluate the patient more carefully and frequently for exacerbation of psoriasis after remission of CS. Autoimmune diseases may exacerbate or may be newly diagnosed because of rebound immunity in remission of CS.

DOI: 10.1530/endoabs.37.EP19

EP20

Should Cushing syndrome be only evaluated by endocrinologists and neurosurgeons?

Cigdem Tura Bahadir, Feyzi Gokosmanoglu, Elif Kilic Kan, Gulcin Cengiz Ecemis, Aysegul Atmaca, Hulusi Atmaca & Ramis Colak
Ondokuz Mayis University, Samsun, Turkey.

Objective
Physical features such as central obesity, purple stria, thin skin, moon face and buffalo hump may be observed in Cushing's syndrome (CS). Psychiatric and psychological disturbances may also be present in addition to the physical problems. The most common mental disturbance is major depression. Mania and anxiety disorders may also be seen. It may be detected both in active period or in remission of CS on account of persistent effect of previous period of hypercortisolism, hypopituitarism and glucocorticoid deficiency. In this study, we aimed to analyse the frequency of psychopathologic disorders in CS.
Methods
We prospectively followed 62 patients that had been diagnosed with CS between 2010 and 2014 in our clinic. Of the patients, 60% were Cushing's disease (CD) (29 female, eight male) and 40% were ACTH-independent CS (20 female, five male). The patients who had been under medication for psychopathology were included in the study.
Results
The prevalence of psychopathology was 19% in CS (12 patients). In ACTH-independent CS and CD it was 12 and 24%, respectively. Eleven (92%) patients were female. Nine (75%) patients had active diseases. Two patients, one with CD and one with ACTH-independent CS, had history of suicide attempts 1.5 and 2 years after surgery, respectively. Both suicide attempts happened after surgery. The patients who attempted suicide had glucocorticoid deficiency and hypopituitarism, respectively.
Discussion
In CS patients, psychiatric and psychological disorders may be seen before or after treatment. Despite treatment for CS, they still may have severe psychopathologic disorders to the degree of suicide attempts due to hormonal insufficiencies in the postoperative period that may result from medication or surgical complications. For this reason, patients should be evaluated not only by endocrinology and neurosurgery clinics, but also psychiatry clinics both before and after the surgery.

DOI: 10.1530/endoabs.37.EP20

Necessity of thrombophylaxis in Cushing's syndrome

Cigdem Tura Bahadir, Feyzi Gokosmanoglu, Elif Kilic Kan, Gulcin Cengiz Ecemis, Aysegul Atmaca, Hulusi Atmaca & Ramis Colak
Ondokuz Mayis University, Samsun, Turkey.

Introduction
Cushing's syndrome (CS) is accompanied by a ten times increased risk of venous thromboembolism and arterial thrombosis. In this study we aimed to analyze frequency of thromboembolism in CS.
Methods
We prospectively followed 62 patients who had been diagnosed with CS between 2010 and 2014 in our clinic. Of the patients, 60% had Cushing's disease (CD) (29 females and eight males) and 40% had ACTH-independent CS (20 females and five males). Frequencies of arterial and venous thromboembolic events were recorded.
Results
The prevalence of thromboembolic events was 5% in our patient population. Thromboembolism was diagnosed in three patients (two CD and one ectopic CS); one with venous thromboembolism, two with arterial thrombosis (Table 1). Two of them were diagnosed in the postoperative period, but one of them was suspected to have the event before the surgery. Remaining one of the three patients was diagnosed with recurrent pulmonary thromboembolism both before and after surgery for CS.

Table 1 Location and time of thromboembolism in our patient population.

					Time of diagnosis	
	Age/ sex	Aetiology of CS	Vessel	Thromboembolic event	Preoperative period	Postoperative period
1	45-F	Pituitary adenoma	Venous	DVT of lower extremity	-	After 4 months
2	40-M	Pituitary adenoma	Arterial	Subacute thrombosis of external iliac artery	-	After 1 week
3	42-M	Ectopic	Arterial	Fatal PTE	Before 9 months	After 2 weeks

DVT, deep venous thrombosis; PTE, pulmonary thromboembolism.

Discussion
Thromboembolism may occur before and after surgery in CS. It generally occurs in the first year, especially in the first 3 months following surgery. It may be venous or arterial in origin. Thus, thromboprophylaxis should be administered to patients with active CS before and after the surgery for 6 months.

Short Synacthen testing: are we referring appropriately and over diagnosing adrenal insufficiency?

Abu Saeed, Sara Guthrie, Oliver Pickles & Parijat De
City Hospital, Birmingham, UK.

Background
A previous short Synacthen test (SST) audit in our hospital (2012) showed 70% of initial SST tests were normal with 9% inappropriate requests. A new pro forma was devised whereby one of four criteria (specific symptoms, medications, previous diagnosis, and physical findings) had to be satisfied to be able to undergo a SST. Additionally, we noticed that a number of patients were probably being over-diagnosed wth adrenal insufficiency (AI) based on a single 30 min cortisol estimation following SST.
Aims
To evaluate if this new pro forma helped reduce inappropriate referrals for SST and whether the added value of 60 min cortisol (rather than only 30 min) helped minimise overdiagnosis of AI.
Method
The results of this new proforma and a full SST incorporating both 30 and 60 min cortisol following SST were collected and analysed between Sept and Nov 2014.
Results
All 27 requests (100%) for SST were appropriate. 63% (17/27) of patients had an abnormal result at 30 min and 44% (12/27) at 60 min. 12 patients (44%) had both abnormal 30 and 60 min cortisol results (five on steroids, five asymptomatic, four with pituitary pathology, three hyponatremia, and one each with hypotension, T1DM and and new pigmentation). 18% (5/27) had an abnormal result at 30 min but a normal result at 60 min. 4/6 patients referred with hypotension/hyponatremia had abnormal SST result. 7/7 patients who satisfied only the 'symptoms' criteria had a normal SST result whereas 0/5 patients who satisfied the 'symptoms' criteria and at least one other criteria had a normal result.
Conclusion
The new pro forma has made the referral system more effective. Nearly a fifth of over diagnosis of AI can be prevented by routinely measuring serum cortisol at 60 min. By selecting symptomatic patients who satisfied at least one other criteria will also further help minimise unnecessary SSTs.

Primary hyperaldosteronism: predictors of response to therapy in Singapore

Minyang Chow[1,2], Grace Lum[2] & Rinkoo Dalan[1]
[1]Tan Tock Seng Hospital, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore.

Background
Primary hyperaldosteronism is a common cause of secondary hypertension, accounting for up to 5% of cases locally. It is treated medically with spironolactone and/or amiloride, or surgically with adrenalectomy. This study determines the prognostic factors for response to treatment, resulting in reduction of blood pressure to normotensive levels.
Methods
We retrospectively reviewed records of 57 patients who were diagnosed with primary hyperaldosteronism by a saline suppression test, and subsequently underwent treatment. The patients were divided into two groups – hypertensive and normotensive (WHO $<140/90$), based on their blood pressure readings at 1 year since starting treatment. We collected baseline characteristics of both groups, including patient demographics – age, gender, race, BMI, as well as medical comorbidities, use of anti-hypertensive medications, and results of screening and diagnostic tests, and compared them via multivariate analysis.
Results
At 1 year post treatment, 28 (49.1%) patients were normotensive, and 29 (50.9%) were hypertensive. We found that the hypertensive group had more person-years of diabetes (mean $=2.52$ vs 0.41, $P<0.05$), and also had a higher baseline aldosterone level (mean $=749.15$ vs 532.61, $P<0.05$), than the normotensive group. Other factors, including the patient age, gender, race, BMI, baseline blood pressure, years of hypertension, number and type of antihypertensive medications, baseline creatinine, potassium, sodium, renin, saline suppression test results, treatment type, presence of adenoma on CT scan, did not differ significantly between the two groups.
Discussion and conclusion
In patients diagnosed with primary hyperaldosteronism, predictors for achieving normotension with treatment include not having or having fewer years of diabetes, and having a lower baseline aldosterone level. This knowledge is helpful for physicians to prognosticate response to treatment in newly diagnosed patients.

Reduced salivary cortisone, but similar cortisol day curves in Addison's disease in patients on hydrocortisone replacement

Ian Ross[1], Miguel Lacerda[1], Tahir Pillay[1,2], Dirk Blom[1], Gudmundur Johannsson[3], Joel Dave[1], Naomi Levitt[1], David Haarburger[4] & Jan-Stefan van der Walt[5]
[1]University of Cape Town, Cape Town, South Africa; [2]NHLS, Tshwane, South Africa; [3]University of Gothenburg, Gothenburg, Sweden; [4]Ampath Laboratories, Pomona, South Africa; [5]Astellas Pharma, Leiden, The Netherlands.

Background
Salivary cortisol, as measured using electro-chemiluminescence has been used to monitor patients with Addison's disease (AD) on hydrocortisone replacement. Salivary cortisone has been suggested as an alternative to salivary cortisol, as it may accurately reflect plasma free cortisol. We wished to examine the pharmacokinetics of these analytes in patients and controls.
Methods
We measured salivary cortisol and salivary cortisone by liquid chromatography–tandem mass spectrometry using a day curve with 16 time points in patients with AD on hydrocortisone and in healthy controls with endogenous cortisol secretion.
Results
There were 25 patients and 26 healthy controls. The median (interquartile range) area under the curve (AUC) for cortisol was not different for patients, 55.63 (32.91–151.07), compared with controls 37.49 (27.41–52.00) nmol/min per l; $P=0.098$, whereas the peak cortisol (Cmax) was higher 32.61 (5.75–146.19) nmol/l vs 8.96 (6.96–12.23) nmol/l; $P=0.013$ and time to peak (Tmax) 1.5 (0.5–2.0), compared with controls 0.0 (0.0–0.5) h; $P<0.001$. The AUC for cortisone was reduced for patients, 23.65 (6.10–54.76), compared with controls, 227.73 (200.10–280.52) nmol/min per l; $P\leq0.001$, Cmax for cortisone was lower 11.11 (2.91–35.85) nmol/l vs 33.12 (25.97–39.95) nmol/l; $P=0.002$ and longer Tmax 2.5 (2.0–9.5), compared with 0.25 (0.00–0.50) h, respectively; $P<0.001$.
Conclusions
Although there was no difference in cortisol exposure, there was less cortisone exposure in patients than controls, possibly due to the pharmacological effect of hydrocortisone on the 11-β-hydroxysteroid dehydrogenase enzymes. Lack of cortisone exposure and less metabolism of cortisol in patients with AD may predispose to metabolic consequences.

Problems in ACTH–ectopic syndrome diagnostics in clinical practice

Natalya Volkova, Ilya Davidenko & Maria Porksheyan
Rostov State Medical University, Rostov-on-Don, Russia.

Introduction
Cushing's syndrome describes symptoms associated with prolonged exposure to inappropriately high levels of cortisol. It may be increased as a result of high ACTH production in the pituitary gland or from tumours outside pituitary–adrenal system.
Case report
Patient 34 years old was hospitalised with complaints of muscle weakness, shooting-pain in thoracic, lumbar spine, decreased height, amenorrhea, arterial hypertension and change in appearance at September 2009. The first symptom of disease was elevated blood pressure at 2007. Patient marked appearance of red striae at July 2009. Next month, compression fracture of five to nine thoracic vertebras was founded based on MRI. At the same time, increased level of ACTH was revealed, but his fact was disregarded. Thus, it was passed 2 years from first complaints to supposition of Cushing's syndrome. In the hospital, as a result based on positive suppression test with dexamethasone 1 mg and positive test with desmopressin, ACTH–ectopic syndrome was diagnosed. In the same time, tumour of central mediastinum was revealed. Patient was operated, but histology found out, that this tumour consisted of adipose tissue. Patient was repeatedly hospitalized with same complaints at October 2010. New attempts of revealing ACTH-productive tumour was become unsuccessful again. Thus, left-side laparoscopic adrenalectomy was performed 6th October 2010. Right-side laparoscopic adrenalectomy was done in 2 weeks. Hormonal replacement therapy (prednisolone 30 mg/daily) was prescribed after surgery. But, acute adrenal insufficiency was developed in 3 weeks, and patient died. Clinical diagnosis was confirmed on autopsy. But, ACTH-productive tumour wasn't revealed.
Conclusion
This clinical case demonstrates problems in ACTH–ectopic syndrome diagnostics. it was passed 2 years since first complaints until supposition of Cushing's syndrome, despite of typical clinical signs in this patient. Also, there is no common guideline of ACTH–ectopic syndrome. Lingering search of tumour delayed decision making about two-sided laparoscopic adrenalectomy.

Primary adrenal lymphoma: case report

Rosa Márquez-Pardo, Maria-Gloria Baena-Nieto, Manuel Cayón-Blanco, Lourdes García-García-Doncel, Rosario López-Velasco & Isabel Torres-Barea
Jerez Hospital, Jerez, Cadiz, Spain.

Introduction
Malignancy is an uncommon cause of adrenal incidentaloma in patients without a known diagnosis of cancer. The actual frequency of primary adrenal carcinoma in patients with adrenal incidentaloma is ∼2–5%; another 0.7–2.5% have nonadrenal metastases to the adrenal gland. The presence of a nonadrenal primary tumour is exceptional and has been scarcely reported in medical literature.
Case report
We present a case of 71-year-old male who presented with fatigue, anorexia, weigh loss, and hypotension. Initial laboratory evaluation didn't reveal any anormal result. Computed tomography (CT) scans of the abdomen and pelvis demonstrated large bilateral adrenal masses (the right adrenal gland measured $15\times8.6\times7$ cm and the left adrenal gland measured $11.6\times6.5\times6$ cm). The masses were nonfunctional according to hormone test results (cortisol of 270 mmol/l, ACTH level of 92.18 pmol/l, 24 h urinary level of normetanephrine 425 μg/day, and metanephrine 148 μg/day). The laboratory test showed adrenal insufficiency (plasma cortisol of 267.62 nmol/l; cortisol failed to increase during the ACTH stimulation test (267.62–226.23 nmol/l) and ACTH was elevated (79.03 pmol/l). A CT-guided core needle biopsy of the left adrenal mass was performed and revealed diffuse large B-cell lymphoma. Bone marrow biopsy was negative for lymphomatous involvement. An F-18 fluorodeoxyglucose (FDG) positron emission tomography (PET) scan showed intense FDG accumulation in both adrenal glands (SUV 24.6), there was no abnormal FDG uptake in the rest of the body.
Conclusions
Primary adrenal lymphoma is a very rare extranodal lymphoma, generally occurring among patients of advanced age (mean: 68 years) and dominantly in males. The most frequently histological type is diffuse large B-cell B lymphoma and is usually bilateral. Prognosis is poor. Treatment consist in chemotherapy regimens (the most common regimen is CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone)) and in some cases treatment with surgery and radiotherapy is necessary.

Cushing's syndrome and diabetes

Said Azzoug, Leyla Rabehi, Sara Hannachi, Houda Medjdoubi & Farida Chentli
Endocrinology and Metabolic Diseases Department, Bab El Oued Hospital, Algiers, Algeria.

Introduction
Cortisol has numerous actions on glucose metabolism and insulin action which explain the frequency of glucose abnormalities in Cushing's syndrome (CS). The aim of our work was to assess the prevalence and characteristics of diabetes in CS.
Material and methods
This is a retrospective study concerning 51 CS (44F/7M) in whom we looked for the presence of diabetes either by fasting glycaemia or 75 g oral glucose tolerance test. Thereafter, we looked for the characteristics of diabetes in CS. CS was secondary to Cushing's disease in 82% and to adrenal adenoma in 18%.
Results
55% of patients have diabetes. Among diabetic patients, 39% have high blood pressure and 42% have a family background of diabetes. 40% of diabetics were treated with oral treatment, 25% with insulin and 35% were on life style therapy. Mean age was 31.92 ± 10.26 years; it was 31.62 ± 10.54 years in patients with diabetes vs 32.45 ± 10.04 years in patients without diabetes. Mean BMI was 31.47 ± 7.33 kg/m^2; it was 31.30 ± 7.77 kg/m^2 in patients with diabetes vs 31.89 ± 6.47 kg/m^2 in patients without diabetes. Diabetic retinopathy was present in 10% and diabetic neuropathy in 5%. After treatment of CS diabetes resolved in 40% and persisted in 60%.

Conclusion
Diabetes mellitus is frequent in cortisol excess states, the high frequency of diabetes in our study may be explained by preexistent undiagnosed diabetes as diabetes persisted in 60% after resolution of CS.

EP28

Cushing's syndrome and dyslipidaemia

Said Azzoug, Leyla Rabehi, Sara Hannachi, Houda Medjdoubi & Farida Chentli
Endocrinology and Metabolic Diseases Department, Bab El Oued Hospital, Algiers, Algeria.

Introduction
Cortisol activates lipolysis in adipose tissue resulting in the release of free fatty acids into the circulation, it also activates cholesterol and triglycerides synthesis. The consequence is an increase in total circulating cholesterol and triglycerides with their inherent risks on the cardiovascular system. The aim of our work was to assess the prevalence and characteristics of dyslipidaemia in Cushing's syndrome (CS).
Material and methods
This is a retrospective study concerning 51 CS (44F/7M) in whom we looked for the presence of hypertriglyceridemia (triglycerides level ≥ 1.50 g/l) and/or hypercholesterolemia (total cholesterol level ≥ 2 g/l). Thereafter we looked for the characteristics of dyslipidaemia in CS. Their mean age was 32.34 ± 10.42 years. CS was secondary to Cushing's disease in 82% and to adrenal adenoma in 18%.
Results
53.12% of patients have hypertriglyceridemia. Triglycerides level was between 1.50 and 1.99 g/l in 41.17% and ≥ 2 g/l in 48.83%. 88.23% of hypertriglyceridemic patients have diabetes and hypertension. 51.61% of patients have hypercholesterolemia. 68.75% of hypercholesterolemic patients have hypertriglyceridemia, 87.5% have diabetes, and 87.5% have hypertension.
Conclusion
Dyslipidaemia is frequent in CS. Hypertriglyceridemia and hypercholesterolemia are frequently associated with hypertension and/or diabetes, which may explain the increased risk of cardiovascular disease in cortisol excess states.

Cushing's syndrome and hypertension

Said Azzoug, Leyla Rabehi, Sara Hannachi, Houda Medjdoubi & Farida Chentli
Endocrinology and Metabolic Diseases Department, Bab El Oued Hospital, Algiers, Algeria.

Introduction
Patients with Cushing's syndrome (CS) are prone to hypertension as cortisol stimulates renal reabsorption of sodium and enhances vascular sensitivity to catecholamine and angiotensin II. This explains the frequency of hypertension in patients with CS. The aim of our work was to assess the prevalence and characteristics of hypertension in CS.
Material and methods
This is a retrospective study concerning 51 CS (44F/7M) in whom we looked for the presence of high blood pressure (HBP). Thereafter, we looked for the characteristics of HBP in CS. CS was secondary to Cushing's disease in 82% and to adrenal adenoma in 18%.
Results
HBP was present in 67%. Among hypertensive patients, 33% have diabetes mellitus and 33% have a background of familial hypertension. Mean age was 32.03 ± 9.87 years and mean BMI was 30.77 ± 6.58 kg/m^2. HBP was treated with one anti-hypertensive drug in 41% and two or more anti-hypertensive drugs in 33%. In 26% patients were treated with life style therapy only. 12% have hypertensive retinopathy, 5% have nephropathy, and 9% have cardiovascular disease. After treatment of CS hypertension persisted in 45% and resolved in 55%.
Conclusion
Hypertension is frequent in CS, it's association with diabetes, dyslipidaemia and a pro-coagulant state also frequent in CS explain the high frequency of cardiovascular events in hypercortisolism states.

Asymmetric dimethylarginine level and markers of atherosclerosis in Cushing's syndrome

Cemile Ozsurekci[1], Mujde Akturk[1], Cigdem Ozkan[1], Ozlem Gulbahar[2], Alev Altinova[1], Muhittin Yalcin[1], Emre Arslan[1] & Fusun Toruner[1]
[1]Department of Endocrinology, Faculty of Medicine, Gazi University, Ankara, Turkey; [2]Department of Biochemistry, Faculty of Medicine, Gazi University, Ankara, Turkey.

Objective
Cushing's syndrome (CS) is related to diabetes mellitus, dyslipidaemia, hypertension, and obesity, which lead to cardiovascular disease (CVD). CVD is the major cause of mortality and morbidity in CS. The aim of our study was to investigate CVD risk markers, such as asymmetric dimethylarginine (ADMA), lipoprotein-associated phospholipase A2 (Lp-PLA2), highly sensitive C-reactive protein (hsCRP), homocysteine, lipid levels, ankle-brachial index (ABI), and carotid intima–media thickness (CIMT) in CS.
Methods
Our study included 27 patients with active CS and age, sex, BMI, and co-morbid diseases matched 27 control patients.
Results
Plasma ADMA levels were significantly lower in CS compared to the control group ($P = 0.013$). Total cholesterol, LDL cholesterol, HDL cholesterol, apo A1, and apo B levels were higher in patients with CS than the control group ($P < 0.05$). We did not find any statistically significant difference in hsCRP, Lp-PLA2, and homocysteine levels, CIMT and ABI measurements between CS and control groups ($P > 0.05$).
Conclusion
Our results suggest that CVD in CS may occur primarily due to comorbid diseases with CS. We found that ADMA levels were lower in CS than co-morbid diseases matched control group, which should be further investigated.
Disclosure
This project was supported by IMSED (Internal Medicine Postgraduate Education Association).

A case of aldosterone-secreting giant adrenal carcinoma: a case report

Mehtap Evran, Gamze Akkus, Murat Sert & Tamer Tetiker
Cukurova University, Adana, Turkey.

Introduction
Primary aldosteronism is presented with signs of hypertension and hypokalaemia classically, however, primary adrenal carcinoma is very rare condition. We aimed to present a patient with a metastatic adrenal carcinoma after the primary diagnosis of hyperaldosteronism.
Case report
A 46 years old male patient was referred to our hospital with weakness, dry mouth and weight loss. He had lost weight as 31 pounds during last 3 months. Physical examination revealed diffuse crackles in lungs. The others system examination was found normal without any organomegaly or lymphadenopathy. Arterial tension was measured 170/100 mmHg, serum sodium 140 mEq/dl, potassium 1.9 mEq/dl at admission. Differential diagnosis was planned on uncontrolled hypertension and persistent hypokalaemia with elevated aldosterone levels and low renin levels as 753 ng/dl (3–28 ng/dl) and 0.57 ng/ml per h (0.65–5 ng/ml per h) respectively. After potassium replacement therapy, potassium was 3.1 mEq/dl. Doxazosin 8 mg/day with spironolactone 100 mg/day was started. Supression was established with 1 mg dexamethasone in cortisol level. In thorax–abdominal CT was showed bilateral diffuse nodules (biggest was nearly $\sim$2.5 cm) in lungs were consisted with metastatic cancer. A giant mass with 12 cm diameter in suprarenal region, which involves liver partially, consisted with adrenal gland tumour was determined. The miliary tuberculosis ruled out by bronchoscopy. Metastatic multiple hyper-metabolic lesions in lungs and hyper-metabolic mass in surrenal region were detected in positron emission tomography. Fine needle aspiration biopsy was performed from right surrenal

mass with CT scan. Pathology revealed adrenocortical carcinoma. Chemotherapy (mitotane) was the chosen treatment because of the distant metastases. Patient died during the chemotherapy.
Conclusions
Primary adrenal carcinoma is very rare with annual incidence of one per one million populations. Less than 1% of all secrete aldosterone. Also clinicians should be aware that primary hyperaldosteronism could occur in the context of adrenocortical carcinoma.

DOI: 10.1530/endoabs.37.EP31

EP32

The incidence and characteristics of adrenal insufficiency among patients with suspicious symptoms in general hospital in Korea

Namkeong Kim, MiKyung Kim, Nanhee Cho, YeYeon Lee & Hyesoon Kim
Keimyung Medical School, Daegu, Republic of Korea.

Objective
Adrenal insufficiency is the clinical manifestation of deficient production or action of glucocorticoids, with or without mineralocorticoids deficiency and adrenal androgens. The mortality of untreated adrenal insufficiency reaches up to 80% in 2 years. Moreover, the symptom is non-specific like malaise, dizziness. Therefore, history taking, prompt diagnosis and management are more important. The diagnostic investigation, although well established, can be challenging, especially in patients with secondary or tertiary adrenal insufficiency. However, information about the prevalence and characteristics of adrenal insufficiency in Korea is lack. Therefore, we reviewed the characteristic of patients of adrenal insufficiency.
Methods
We reviewed medical records of patients who visited Keimying University Dongsan Medical Center for 4 months and conducted a test such as rapid ACTH stimulation test and insulin tolerance test.
Results
In 267 participants enrolled, most common reason (38.9%) to conduct a test was that patients complained suspicious symptoms related with adrenal insufficiency and the second reason (29.6%) was for diagnosis the cause of hyponatremia. Among them, 37.4% patients was diagnosed as adrenal insufficiency. 70% was female and mean age was 65.23 years old. Basal cortisol level was 3.93 ± 3.81 and it was significantly lower than normal patients ($P = 0.000$). Common symptoms are anorexia, nausea, dehydration, and arthralgia. 67% patients had history of steroid medication and 53% of patients took steroid within 3 months.
Conclusion
A lot of patients who diagnosed adrenal insufficiency are related with steroid medication. History taking about long-term use of steroid is necessary for early detection. Basal cortisol level could not be diagnosis but provide an useful clue for diagnosis of adrenal insufficiency. In addition, when we use steroid, we are more cautious about development adrenal insufficiency. We need further study to evaluate the prevalence and characteristics in a large population.

EP33

A case of Addison's disease: high clinical suspicion should guide diagnosis and caution should be used when reviewing initial laboratory investigations

Mark Sutton-Smith, Maria Ravelo, David Lipscomb & Naik Haya
East Sussex Healthcare NHS Trust, The Bending and Sheppard Centre for Diabetes and Endocrinology, Kings Drive, Eastbourne, East Sussex BN21 2UD, UK.

A 69-year-old lady with a history of autoimmune diabetes mellitus and primary autoimmune hypothyroidism presented to the Specialist Diabetes Clinic with a significant inexplicable variation in her capillary blood glucose. She had been undergoing investigations with the gastroenterologists for nausea, vomiting, and weight loss. Despite extensive investigations including: oesophageal–gastro-duodenoscopy, CT–thorax, abdomen, pelvis scanning, and gastric emptying studies no cause for her symptoms had been found. Her drug therapy included ranitidine, omeprazole, metformin, levothyroxine, folic acid, simvastatin, lantus, and novorapid. Given her clinical presentation and autoimmune diagnoses, metformin was stopped and she was investigated for adrenal insufficiency. Her basal serum cortisol was 410 nmol/l (normal range >400 nmol/l). Her short Synacthen test results were 421 nmol/l at 30 min and 433 nmol/l at 60 min. Basal ACTH 1100 ng/l (normal range 5–46), plasma renin 28 nmol/l per h (normal range 0.5–3.1), and plasma aldosterone 110 pmol/l (normal range 100–800). Anti-adrenal antibody titre was positive at 1:10 dilution.
Discussion
Baseline serum cortisol level was perceived to be adequate; however response to ACTH was stunted. The ACTH, aldosterone, and renin levels together with positive anti-adrenal antibody titre are consistent with a diagnosis of primary autoimmune adrenal insufficiency (Addison's disease). She was immediately started on hydrocortisone replacement with explanation about steroid sick day rules, mineralocorticoid was added and she was reviewed in clinic 3 weeks later. Her glycaemic profile improved, hypoglycaemic episodes were abolished and gastroenterological symptoms completely resolved. This case highlights the importance of retaining a high degree of clinical of suspicion in diagnosing adrenal insufficiency despite a 'normal' basal cortisol and how ACTH, aldosterone, renin, and anti-adrenal antibody testing may aid diagnosis in such cases.

Selective adrenal venous sampling is not always useful in primary aldosteronism

Miguel Paja[1], Borja Peña[2], Laura A Calles[1] & Cristina Moreno[1]
[1]Endocrinology Department, Hospital Universitario de Basurto, Bilbao, Basque Country, Spain; [2]Radiology Department, Hospital Universitario de Basurto, Bilbao, Basque Country, Spain.

Adrenal venous sampling (AVS) is regarded as the gold-standard for the study of lateralisation of primary aldosteronism (PA) after its biochemical diagnosis. After catheterisation of both adrenal veins, confirmed by ratio of cortisol concentration in each adrenal vein and peripheral vein (selectivity index (SI)), lateralization is accepted if aldosterone/cortisol (A/C) ratio between both adrenal veins is over 3–4 (lateralization index (LI)), particularly if non-dominant vein has A/C level lower than peripheral vein. We present two cases of PA with selective AVS, but puzzling results about lateralisation: case 1 – woman (52 years), severe hypertension for the last 2 years, with elevated ratio aldosterone/plasmatic renin activity (RAR) and urinary aldosterone of 16.4 μg/24 h with hypernatriuria (340 mEq/24 h). First sample showed right SI of 44.3 and left SI of 12.2, and suggested bilateral production (LI: 1.12), with both adrenal A/C levels higher than peripheral vein. Second sample, 5 min later, showed right SI of 18.9 and left SI of 10.3, but indicated right lateralisation (LI: 3.2), coincident with adrenal tumour in CT, with A/C ratio in left vein lower than peripheral A/C ratio. Case 2 – woman (52 years), severe hypertension, only one selective sample in AVS (right SI: 10.83 and left SI: 15.32), A/C ratio in both veins lower than peripheral vein (18.2 and 8.5 vs 71.9). Normal CT scan. These two cases illustrate potential inaccuracies of AVS. These probably are due to superselective canalisation of adrenal veins, not draining venous effluent of the tumour producing aldosterone excess. In both cases, right SI were very high. These high ratios have been proposed as suggestive of very selective sampling, collecting blood of suppressed adrenal tissue, but not from the adenoma. Other possibility in the second case is anomalous drainage of pathologic tissue, by accessories veins not canulated in AVS, or an undetected extraadrenal source of aldosterone.

The safety of steroid replacement and patient's knowledge

Ali Ahmed[1], Enis Mumdzic[2], Paul Wolfsan[3], Suha Atabani[4] & Mohammed Malik[4]
[1]Hull and East Yorkshire NHS Hospitals, Hull, UK; [2]Sheffield Teaching Hospitals, Sheffiled, UK; [3]Watford General Hospital, London, UK; [4]Christie Hospital, Manchester, UK.

Background
In steroid dependent patients the knowledge of steroid dose change during illness and stress is of paramount importance.
Objectives
i) To assess patient's knowledge of steroid management during acute illness and stressful condition. ii) To evaluate whether there is a relation between patient knowledge and admission with documented adrenal crisis. iii) To improve medical access to information about patients on steroid at Emergency Department.
Methods
i) Self-completed patient's questionnaire of 53 patients testing knowledge of on-going steroid treatment; self-held safety alert methods, dose adjustment during acute illness or surgery. ii) Review of patients' Clinical notes for documentation of advice given by the medical team. Also notes were reviewed for any documented hospital admissions in proven or suspected adrenal crisis over the study period.
Results
While vast majority of participants opted for continuing steroids during illness, only less than half answered they would double the dose. In case of recurrent vomiting; only 40% suggested the need for steroid injection. Half of participants were aware of the need for extra steroid during surgical procedure. Fifth of the total 53 participants did not carry a steroid card, and half did not wear any bracelet or have an emergency steroid injection.
Conclusion
This audit showed considerable gap in patients' knowledge and education. More effort is needed, probably using new methods. We introduced an electronic alert message for patients on steroid at the hospital emergency computer systems. We also suggested adopting a smart phone application advising patients about all aspects of steroid use.

Pituitary macroadenoma with adrenocortical hypersecretion as the initial presentation of compensated adrenocortical failure

Serafino Lio & Monica Albin
Endocrine Unit, Ospedale Civile Oderzo-ASL n.9, Oderzo-TV, Italy.

Long-standing primary failure of pituitary-dependent endocrine glands may induce pituitary hyperplasia and adenoma both related to duration and severity of peripheral gland insufficiency, although the formation of an adenoma is rare. We report the case of an elderly man with pituitary macroadenoma but compensated adrenocortical failure. A 70-year-old man referred our centre in 2013 for headache and horizontal diplopia. MRI revealed pituitary macroadenoma (1.9$\times$ 1.1$\times$2.2 cm) with suprasellar extension, invasion of cavernous sinus, very close to the optic chiasm, localised T1 weighted-hyperintensity area suggestive of bleeding. Hormonal evaluation showed central hypothyroidism, hypogonadotropic hypogonadism, normal PRL, and GH/IGF1 serum levels, ACTH hypersecretion (fourfold above normal upper limit) with cortisol basal serum level at 6.1 μg/dl and peak level after corticotropin stimulation test (1 μg i.v.) at 21.2 μg/dl; renin and aldosterone serum levels were in the normal range; antibodies to adrenal cortex were negative, while those 21OH-Ab and very-long chain fatty acid unfortunately could not sampled; ANA-AMA-ADNA-ASMA-APCA, antiphosholipid Ab and TgAb-TPOAb were negative. Adrenal glands appeared normal at CT scan. Medical history was negative for tubercolosis. Weigt loss, hypotension, dehydratation, hyperpygmentation, fever, abdominal pain, as well as hyponatremia, hypo- or hyperkaliemia, hypo- or hypercalcaemia were not present; type 2 diabetes mellitus was diagnosed. Transphenoidal endoscopic excision was performed; the specimen was identified as adenoma at microscopical examination and immunocytochemical analysis showed diffuse immunoreactivity for ACTH, absent immunoreactivity for FSH, PRL, TSH, and GH; Ki67 $<$3% with p53 not expressed. In conclusion, this case shows that the formation of a pituitary adenoma is also possible in the forms yet compensated adrenal insufficiency; likely duration of adrenal failure, rather than the severity, may led a major role in the formation of the pituitary adenoma.

Pregnancy-induced Cushing's syndrome

Corina Andreescu, Leo Hofland, Hans Hofland, Leendert Looijenga, Wouter de Herder & Richard Feelders
Erasmus Medical Center, Rotterdam, The Netherlands.

Cushing's syndrome (CS) during pregnancy is a rare metabolic condition with only a few cases reported in the literature. Misdiagnosis of CS is common because of the overlapping features of fatigue, weight gain, striae, and emotional changes that occur during normal pregnancy. The clinical presentation together with laboratory and imaging findings help to make a diagnosis. However, changes in maternal hormones and their binding proteins complicate assessment of the normal level of glucocorticoid hormones during gestation. CS during pregnancy is attributable most frequently to an adrenal adenoma and to a lesser degree to ACTH hypersecretion from a pituitary adenoma. Furthermore aberrant expression of various hormone receptors in the adrenal glands have been suggested to be involved in the pathogenesis of this condition, in particular the LH receptor. We investigated and treated three pregnant women with ACTH-independent CS and an adrenal tumor. After uncomplicated delivery patient 1 underwent *in vivo* testing for aberrant hormone receptor expression in the adenoma. Cortisol responses were found after administration of LHRH, human chorionic gonadotropin (hCG), TRH, glucagon, vasopressin, and a standard mixed meal. All patients were treated with laparoscopic adrenalectomy, after which signs and symptoms of hypercortisolism partially resolved. Adrenal tumour tissue of patients 1 and 2 showed positive immunohistochemical staining of LH receptors. Considering the cortisol responses to LHRH and hCG, and the development of CS during pregnancy in these patients, it is likely that ACTH-independent hypercortisolism was induced by the pregnancy-associated rise in hCG levels that activated aberrantly expressed LH receptors in the adrenal adenoma. Remarkably adrenal adenomas may simultaneously express multiple aberrant receptors and individual ligands may play a role in the regulation of cortisol production responsible for pregnancy-induced CS.

Cardiovascular system abnormalities in patients with Cushing's syndrome

Tatiana Lebedeva, Victoria Pronina, Svetlana Fedorova, Alexander Dreval & Irina Komerdus
Moscow Regional Research Clinical Institute n.a.M.F. Vladimirsky, Moscow, Russia.

Background
Patients with Cushing's syndrome (CS) have a lot of complications due to chronic exposure of cortisol.
Aim
To reveal specific changes of cardiovascular system in patients with CS.
Material and methods
i) Six patients with CS (five females, one male, 47.1$\pm$1.5 years old), duration of CS 3.4$\pm$1.2 years, ii) 19 healthy patients (48.1$\pm$3.0 years old), and iii) ten patients with ischemic heart disease (IHD) (48.2$\pm$3.1 years old). Echocardiography; Holter monitoring (HM) and 24-h ambulatory blood pressure monitoring (ABPM) in bifunctional mode with program assessment of hemodynamic parameters and arterial stiffness (total peripheral vascular resistance (TPVR), index of arterial stiffness, heart rate variability, and circadian index) were assessed.
Results
Arterial hypertension was in all patients with CS. Mean daily BP 176$\pm$8/100$\pm$ 6 mmHg. Systolic pressure–time index 67.7$\pm$8.7%, diastolic pressure–time index 89.3$\pm$10.5%. 24-h rhythms of BP were disturbed in 67%, with prevalence of non-dippers and night-pickers in CS-patients. Strong correlations were found between cortisol levels (0800 and 2300 h) and systolic (SBP) and diastolic (DBP) day and night pressure (for 0800 h cortisol: SBP r=0.75, DBP r=0.8 (P=0.05); and 2300 h cortisol: SPB r=0.9, P=0.01; DPB r=0.95, P=0.05). Index of arterial stiffness was higher in patients with CS in comparison with patients with IHD. TPVR was increased in all patients with CS. Echocardiography: left atrial expansion in 67% of patients (4.2$\pm$1.1 cm), left ventricular hyperthrophy (in 50%), diastolic dysfunction (in 67%). Holter: mean heart rate (day 91.6$\pm$3.2 and

night 73.5±3.8) were higher in patients with CS than in other groups. 83.3% CS-patients had cardiac rhythm abnormalities that show predominance of activity of sympathetic nervous system.
Conclusion
All tests reveal significant changes in cardiovascular system in patients with CS with great predominance of activity of sympathetic nervous system. Index of arterial stiffness in patients with CS were higher than in patients with IHD, leads to higher risk of serious cardiovascular events in CS.

Clinical management of adrenal insufficiency shows significant heterogeneity: data from the EU-AIR study

Robert D Murray[1], Bertil Ekman[2], Beverly A Jones[3], Claudio Marelli[4], Marcus Quinkler[5] & Pierre Zelissen[6]
[1]Leeds Teaching Hospitals NHS Trust, Leeds, UK; [2]Linköping University, Linköping, Sweden; [3]Shire PLC, Chesterbrook, Pennsylvania, USA; [4]Shire International GmbH, Zug, Switzerland; [5]Endokrinologie in Charlottenburg, Berlin, Germany; [6]University Medical Center Utrecht, Utrecht, The Netherlands.

Introduction
No consensus guidelines currently exist as to the optimal glucocorticoid regimen in adrenal insufficiency (AI). In clinical practice physicians utilise a number of different glucocorticoids, usually administered in several doses throughout the day.
Methods
The EU-AIR registry is a European multinational, multicentre, prospective, observational study sponsored by Shire inclusive of all patients with AI irrespective of aetiology. We analysed the baseline data of patients with primary (PAI) and secondary AI (SAI), excluding patients with CAH, to gain insight into AI current clinical management.
Results
As of 5th November 2014, 946 patients with AI (54.6±16.4 years, 510 (53.9%) F, BMI 28.0±5.5 kg/m^2, 310 (32.8%) PAI) were enrolled in to the study. Overall 91.8% of patients were receiving hydrocortisone (HC) as preferred glucocorticoid replacement, 6.8% prednisolone, 1.6% cortisone acetate, and 0.1% dexamethasone. For patients receiving HC, daily doses ranged from 5 to >45 mg. Most patients received 20–<25 mg (44.9%), with 24.3 and 16.0% receiving 15–<20 and 25–<30 mg respectively. 15.0% of patients were receiving HC doses ≥30 mg. Patients with PAI and SAI were receiving average HC doses of 23.3 and 19.3 mg respectively. HC was taken OD, BID, TID, and QID in 6.7, 52.1, 43.9, and 1.8% respectively. Patients with PAI were more likely to be receiving HC TID compared with those with SAI (56.9% vs 37.6%), who received their HC most frequently as a BID dosage (42.0% vs 56.9%). For patients receiving prednisolone daily doses ranged from <2 to >7.5 mg, with the majority (65.6%) receiving 5–<6 mg/day. A daily dose ≥6 mg was taken by 21.8%. Prednisolone was taken OD, BID, and TID in 73.4, 29.7, and 1.6% respectively.
Conclusions
We have demonstrated significant heterogeneity in the current management of AI in type of glucocorticoid, dosage, and frequency of administration. This likely reflects individualisation of regimes in the absence of robust data supportive of the optimal regimen for long-term outcomes.

Postural orthostatic tachycardia syndrome unmasked by successful treatment of primary aldosteronism

Abbi Lulsegged, Nataliya Zuyeva & Nick Gall
Kings College Hospital NHS Foundation Trust, London, UK.

A 50-year-old woman was referred with a history of chronic, symptomatic hypokalaemia. She also had hypertension. There was no history of diarrhoea, increased bowel motions, vomiting, or laxatives/diuretic use. She was not diabetic and she did not have menopausal symptoms. Her mother had seven strokes and myocardial infarction. On examination weight is 69.9 kg, height 1.65 m, BP 163/99, pulse 70, heart sounds normal, and examination of the abdomen was unremarkable. ECG was normal. Despite taking potassium supplements, repeat blood tests showed sodium 148 mmol/l, potassium 3.3 mmol/l, magnesium 0.87, creatinine 56, and eGFR >90. Spot urine potassium 25 mmol/l. Primary aldosteronism was suspected. Her renin was undetectable (<1.1 ng/l) and serum aldosterone 772 pmol/l. Saline suppression test showed non-suppressible aldosterone levels. Glucocorticoid-remediable aldosteronism was excluded. MRI failed to show a adrenal lesion. Adrenal vein sampling however confirmed a unilateral, right sided adrenal source for the aldosterone excess and she underwent successful right adrenalectomy. Histology was supportive of the diagnosis. Shortly after the operation she started to experience significant postural dizziness. It was initially thought that this was due to relative suppression of aldosterone secretion by the contralateral gland and so fludrocortisone was started. A short Synacthen test excluded adrenal deficiency. She required increasing doses of fludrocortisone but despite this remained symptomatic. Additionally she experienced headaches, fatigue, cold intolerance, and breathlessness. Therefore a neurocardiogenic process was suspected and she was referred to cardiology. Tilt table test showed her heart rate gradually rose to 138 b.p.m. This was thought to be consistent with a POTs type response. Thus our patient had confirmed primary aldosteronism due to a adrenal adenoma, removal of which helped to unmask POTS. We hypothesise that the excess mineralocorticoid activity from the adenoma hyper secreting aldosterone helped to mask the neurocardiogenic process.

Effect of stress-dosed hydrocortisone on physical capacity in patients with Addison's disease

Katerina Simunkova[1], Nevena Jovanovic[2], Marianne Oksnes[2], Kristian Lovas[1] & Eystein Sverre Husebye[1]
[1]Department of Clinical Science, University of Bergen, Bergen, Norway; [2]Department of Medicine, Haukeland University Hospital, Bergen, Norway.

The current conventional glucocorticoid (GC) replacement therapy in primary adrenal insufficiency (Addison's disease) and congenital adrenal hyperplasia (CAH) renders the cortisol levels unphysiological, resulting in very high levels alternating with almost undetectable levels of cortisol over the day. This reduces not merely the patient's quality of life but increases the patient's morbidity and mortality. The HPA axis is characterised by a dynamic circadian variation of cortisol with highest circulating levels in the early morning and a nadir late in the evening. The current therapeutical approach does not restore the circadian rhythm of cortisol. Recently replacement by continuous subcutaneous hydrocortisone infusion (CSHI) has been shown to mimic the circadian cortisol rhythm (Oksnes *et al*. 2014). CSHI treatment requires proper patient education and close monitoring during the first week of treatment until the correct dosage of hydrocortisone is defined. The starting dose is calculated according to body surface area and divided into four dosing intervals per day, corresponding with the circadian rhythm of cortisol. During the first day, the patient may report clinical signs of under-treatment; thus it is essential that the patient is thoroughly informed, and has the possibility to contact the physician directly if needed. The cortisol dosage should be double-checked in one week with serum cortisol, ACTH, cortisol saliva profile, and (possibly) 24 h urine collection, allowing for dose adjustment. In case of any illness the patient has to switch to the conventional tablet treatment and increase the dose of hydrocortisone according to the recommendation.

Phenotypic characteristics of bilateral adrenal masses: about 34 cases

Nora Soumeya Fedala[1], Ali El Mahdi Haddam[2], Leyla Ahmed Ali[1], Mounia Benoumechiara[1], Farida Chentli[1] & Djamila Meskine[2]
[1]Bab El Oued Hospital, Algiers, Algeria; [2]Bologhine Hospital, Algiers, Algeria.

Introduction
Bilateral adrenal tumours are rare and account for 10–15% of adrenal lesions. They can be infectious, inflammatory, tumour, hémmoragiques, and genetic. The clinical and imaging used to guide diagnosis.
Aim
Assess clinical, etiologic, and therapeutic characteristics of bilateral adrenal masses.
Population and methodology
This is a retrospective study of the records of patients with bilateral adrenal masses collected over 26 years. All patients have benefited from a biological exploration (specific and non-specific) and oriented radiological investigation.
Results
34 patients were identified. The mean age at diagnosis was 45 ± 0.4 years. Sex ratio was 24 men/ten women. Diagnostic circumstances were: a chance discovery 11.8%, exploration of congenital adrenal hyperplasia (*n*: 44.11%), the staging of thyroid cancer: 17.64%, the exploration of a failure adrenal: 2.94%, 23.51% adrenergic signs. The etiological exploration revealed a bilateral phaeochromocytoma 10 (29.4%), adrenal metastases 8 (23.52%), nodular adrenal hyperplasia 15 (44.1%), and adrenal tuberculosis 1 (2.94%). The surgery was reported in 41.17% (all cases of phaeochromocytoma, nodular adrenal hyperplasia *n*: 3, suspicious adrenal masses of primitive non-Hodgkin lymphoma *n*: 1). The intervention was recused in other cases of adrenal metastases. Monitoring was instituted in other cases.
Discussion and conclusion
Bilateral adrenal masses are quite particular entity because of their rarity, their aetiologies and treatment. They must be characterised to be treated effectively. The improvement of radiological techniques and therapeutic modalities have enhanced their management.

EP43

Impact of congenital adrenal hyperplasia and glucocorticoid treatment on the final size and gonadal function

Nora Soumeya Fedala[1], Ali El Mahdi Haddam[2], Leyla Ahmed Ali[1], Mounia Benoumechiara[1], Farida Chentli[2] & Djamila Meskine[1]
[1]Bab El Oued Hospital, Algiers, Algeria; [2]Bologhine Hospital, Algiers, Algeria.

Introduction
Congenital adrenal hyperplasia (CAH) are genetic diseases with a deficit of one of the enzymes of steroidogenesis (21 hydroxylase OH, 90%). The consequences of the adrenal hyperandrogenism that results are observed when the treatment is not undertaken precociously.
Aim
To study the impact of CAH and or treatment by glucocorticoids on the final size and gonadal function in girls.
Materials and methods
25 patients with CAH by 21-hydroxylase deficiency ($n=25$) or 11β-hydroxylase ($n=3$) with completed puberty were studied to assess the impact of affection and or glucocorticoid treatment on final height, pubertal development, and gonadal function in girls. Impact of congenital adrenal hyperplasia and glucocorticoid treatment on the final size and gonadal function.
Results
The mean age at diagnosis and initiation of treatment was 5 ± 2.4 years old (3–9). The mean final height was 150 ± 1.2 cm for girls ($n=18$) and 158 ± 2 cm for boys ($n=7$). 20% of patients have early puberty. In the remaining cases, delayed puberty was observed with a mean age of 14 ± 0.1 and 17 ± 1.2 years for onset of puberty and ménarchie in girls; 15 ± 1.4 years for boys. All girls had polycystic ovarian disease. 70% of patients had a persistent hyperandrogenism. 50% of patients were tightly controlled, 25% underdosed, and 25% overdosed.
Discussion and conclusion
Delayed diagnosis and poor compliance in our patients have resulted in a significant impact on growth in stature, pubertal development, and gonadal function. The introduction of routine neonatal screening for CAH in our country and more éfficace care of pathology will improve the functional prognosis of patients.

Adrenal inclusions in congenital adrenal hyperplasia: clinical and progressive characteristics

Ali El Mahdi Haddam[1], Nora Soumeya Fedala[2], Leyla Ahmed Ali[2], Mounia Benoumechiara[2], Djamila Meskine[1] & Farida Chentli[2]
[1]Bologhine Hospital, Algiers, Algeria; [2]Bab El Oued Hospital, Algiers, Algeria.

Introduction
Intra-testicular adrenal inclusions (ISIT) are benign tumors made of ectopic adrenal cortex tissue hyper stimulated by ACTH in excess. All pathologies causing a rise ACTH levels may be associated with adrenal inclusions. They are found mainly in patients with congenital adrenal hyperplasia (CAH) of untreated or poorly treated.
Objective
Search the frequency of ISIT in CAH and clarify clinical and progressive characteristics.
Materials and methods
Forty patients with CAH responsible adrenal insufficiency (35 in 21 and one in five hydroxylase) underwent testicular echo-Doppler in search of ISIT. The volume of each testicle, the presence of ISIT, their size, echogenicity, and vascularity at diagnosis and during follow up.
Results
Adrenal inclusions were found in ten patients (25%). They were asymptomatic and bilateral in all case. Doppler ultrasound was suggestive in all patients (hilar localisation, mitigating but not calcified appearance, vascular architecture preserved). Partial regression after glucocorticoid treatment was noted in 95% of cases. In two cases the adrenal inclusion continued to grow requiring orchidéctomie. Histological study was in favour of a Leydig cell tumours.
Discussion and conclusion
ISIT are common in CAH (between 27 and 94%). Related to chronic stimulation by ACTH, they often reflect an insufficient suppressive treatment with glucocorticoid. The Doppler allows the characterisation. They must be systematically sought and monitored. They usually regress or stabilise with replacement glucocorticoid treatment. Sometimes they can grow, while raising the problem of the histological nature and risk of subfertility related to the mass effect of the ISIT and toxic effects of adrenal steroids and hypogonadotropic hypogonadism.

X-linked adrenal hypoplasia congenita with a novel *DAX1* missense mutation

Fen-Yu Tseng[1], Yu-Ting Tseng[1], Shyang-Ron Shih[1] & Pei-Lung Chen[1,2]
[1]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; [2]Department of Medical Genetics, National Taiwan University Hospital, Taipei, Taiwan.

Introduction
X-linked adrenal hypoplasia congenita (AHC) is a rare developmental disorder of the adrenal cortex. Adrenal insufficiency typically begins in infancy or in childhood. A few individuals present adrenal insufficiency in adulthood.
Case report
A 21-year-old man visited our endocrine out-patient clinic due to underdeveloped secondary sexual characteristics, which was found at physical examination for military service. Physical examination revealed small bilateral testes, sparse pubic, axillary hair, and a large arm span-to-height ratio. Besides, pigmentation in mouth, on palmar creases and joints were noted. Endocrine function evaluation showed high ACTH (>1250 pg/ml), low cortisol (5.37 μg/dl), low testosterone (0.541 ng/ml) with low FSH (4.79 mIU/ml), and low LH (2.77 mIU/ml). Peak LH level was 16.4 mIU/ml after LHRH stimulation, but response of FSH, LH, and testosterone to clomiphene was impaired. Thyroid function, HbA1c and serum electrolyte, plasma renin activity, and aldosterone levels were normal. Abdominal computed tomography scan revealed bilateral small adrenal glands. Brain MRI revealed no lesion at pituitary gland or hypothalamus. Adrenal hypoplasia congenital was suspected due to combined primary adrenal insufficiency and hypogonadotropic hypogonadism. Genetic study revealed a missense mutation (c.849G$>$C) in the *DAX-1* gene (dosage-sensitive sex reversal adrenal hypoplasia congenita, critical region on the X chromosome gene-1), which was transmitted from his mother.
Conclusion
DAX-1 gene deletions or mutations have been reported to be responsible for AHC. We report a case of AHC with adult-onset adrenal insufficiency, hypogonadotropic hypogonadism, and a novel missense mutation in the *DAX-1* gene.

DOI: 10.1530/endoabs.37.EP45

Adrenal insufficiency during prednisolone treatment: need for cortisol replacement strategies in patients on long-term low-dose glucocorticoid treatment?

Stina Willemoes Borresen[1], Bo Baslund[3], Marianne Klose[1], Åse Krogh Rasmussen[1], Lennart Friis-Hansen[2], Linda Hilsted[2], Henning Locht[4], Annette Hansen[5], Merete Lund Hetland[6] & Ulla Feldt-Rasmussen[1]
[1]Department of Endocrinology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; [2]Department of Clinical Biochemistry, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; [3]Department of Rheumatology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; [4]Department of Rheumatology, Copenhagen University Hospital, Frederiksberg Hospital, Copenhagen, Denmark; [5]Department of Rheumatology, Copenhagen University Hospital, Gentofte Hospital, Copenhagen, Denmark; [6]Department of Rheumatology, Copenhagen University Hospital, Glostrup Hospital, Copenhagen, Denmark.

Background
Patients on long-term glucocorticoid treatment are at risk of adrenal insufficiency during glucocorticoid treatment. The side effect can occur during glucocorticoid treatment if there is a mismatch between glucocorticoid requirements and production/intake. High-dose glucocorticoid treatment is often sufficient to overcome most stressful situations. A low-dose of 5 mg prednisolone/day is however, equivalent to 20 mg hydrocortisone, a dose often used as basal glucocorticoid replacement in adrenal insufficiency. Contrary to patients in replacement therapy for adrenal insufficiency, patients treated with long-term low-dose glucocorticoids for various reasons are often not instructed in self-administration of supplemental doses in stressful situations.
Objective
We aimed to assess the prevalence of adrenal insufficiency in patients treated with 5 mg prednisolone/day.
Subjects and measures
As part of a larger study, 37 patients with rheumatoid arthritis (26 women, aged 36–85 years) treated with 5 mg prednisolone/day for at least 6 months (mean 108, range 6–336 months) had a 250 μg Synacthen test performed, after mean prednisolone pause of 47 h (range 36–96 h). P-cortisol was measured before and 30 min after Synacthen injection. Cut-off for normal adrenal function was 30 min P-cortisol >500 nmol/l as this is validated for our local cortisol assay. As a cut-off of 550 nmol/l is often used these data are also shown.
Results
Of the 37 patients 11 (30%) had an insufficient adrenal response to the Synacthen test. Using cut-off of 550 nmol/l 16/37 (43%) had adrenal insufficiency.
Conclusion
We found adrenal insufficiency in approximately one third of patients treated with 5 mg prednisolone/day. Since prednisolone treatment is often sustained for years in these patients, adrenal suppression is likely equally prolonged. Our findings raise the question whether a Synacthen test should be routinely performed in patients on long-term low-dose glucocorticoid treatment and insufficient patients handled with the same cortisol replacement strategies as other patients with verified adrenal insufficiency.

A challenging case of paraneoplastic Cushing's syndrome

Adina Mazilu[1], Mona Gheorghiu[2], Madalina Musat[2], Aurelian-Emil Ranetti[1,2], Victor-Catalin Mazilu[1], Narcis Tanase[1], Razvan Petrescu[1], Adrian Ciuche[1], Augustin Tudose[1], Florina Vasilescu[1] & Carmen Ardeleanu[3]
[1]Central Military Emergency Hospital, Bucharest, Romania; [2]National Institute of Endocrinology 'C.I.Parhon', Bucharest, Romania; [3]Monza Hospital, Bucharest, Romania.

Introduction
Paraneoplastic Cushing' syndrome (CS) represents 5–10% of all CS and has a severe prognosis due to severe metabolic imbalance, denutrition, associated infections, and progression of tumoural underlying pathology.
A 67 years old woman presented with mental confusion, progressive weight loss, severe oedema and kypokalaemia, without typical features of Cushing or hyperpigmentation. Investigations revealed paraneoplastic Cushing's with ACTH 82.5 pg/ml, cortisol levels more than 63 μg/dl, probably produced by pulmonary tumour. Patient associated also empty sella syndrome with TSH and gonadotrophic insufficiency, left breast tumour, *Helicobacter pylori* gastritis, polinodular goitre, denutrition, and hepatic dysfunction. 99m-Tc tektrotyd scintigraphy was negative for pulmonary tumor, showing uptake in both adrenals and ileum. Patient needed 1200 mg/day ketoconazole and 200 mg/day of mifepristone in order to obtain normal cortisol levels and metabolic parameters. Owing to pulmonary sepsis and hepatic dysfunction we choose left adrenalectomy as first intervention, allowing reduction of ketoconazole to 600 mg/day and secondary left pulmonary lobe resection. Even if ketoconazole was stopped 1 day prior to adrenalectomy, patient developed adrenal insufficiency, needing noradrenaline support for 1 day and hydrocortisone replacement for 2 days. Histology exam showed benign bronchial carcinoid with ACTH staining and benign hyperplasia of left adrenal. Patient recovered almost completely. Mild hypokaliaemia and hypomagnesemia, even with oral supplementation, sartan therapy and normal levels of cortisol and ACTH persisted after surgery, probably due to severe deficit of intracellular compartment.
Conclusion
This case was difficult due to metabolic challenges, multiple associated pathology, lack of $SSTR_2$ and $SSTR_5$ receptors with negative scan, mild elevation of cromogranine A levels despite a typical bronchial carcinoid. Patient's sister was operated for adrenal adenoma confirmed on histology exam, her daughter had papillary thyroid cancer, but no MEN association was proven in this family.

DOI: 10.1530/endoabs.37.EP47

EP48

The treatment with 'dual release' hydrocortisone (DR-HC) in congenital adrenal hyperplasia: short-term (6 months) and long-term (12 months) follow-up after the switch from conventional glucocorticoids to DR-HC

Chiara Simeoli, Maria Cristina De Martino, Davide Iacuaniello, Teresa Mannarino, Alessia Cozzolino, Monica De Leo, Claudia Pivonello, Mariarosaria Negri, Cristina De Angelis, Annamaria Colao & Rosario Pivonello
Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Università 'Federico II' di Napoli, Naples, Italy.

In patients with congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency, life-long glucocorticoid (GC) treatment is often required to replace cortisol deficiency and to avoid the ACTH-dependent androgen levels increase. However, in these patients, the multiple daily doses required with conventional GCs can cause cortisol overexposure, leading to an increased risk of metabolic syndrome (MS), an impaired quality of life (QoL), and poor treatment compliance (TC). The current study aimed at investigating the impact of the switch from twice or thrice daily conventional GCs to once daily 'dual release' hydrocortisone (DR-HC) on metabolic and hormonal profile, QoL, depression status (DS), and TC in a cohort of patients with CAH. Twenty-three CAH patients (16F, 7M, 20–38 years), treated with HC (10–40 mg/day) or prednisone (6.25–12.5 mg/day) for at least 12 months, switched to DR-HC (10–40 mg/day) entered the study and were evaluated before and after 6–12 months of DR-HC. Metabolic and hormonal parameters were measured using routine assays and the MS was evaluated according with IDF criteria. QoL, DS, and TC were assessed using AddiQoL Questionnaire, Beck Depression Inventory II, and Morisky 8-items medication Adherence Questionnaire respectively. The change in metabolic and hormonal parameters in the same cohort of patients along the year between baseline and 12 months before the switch, while patients stably performed conventional GCs, was used as control. At 6-month follow-up, fasting plasma glucose ($P=0.003$) was significantly reduced, whereas at 12-month follow-up HDL ($P=0.000$) and LDL-cholesterol levels ($P=0.024$) were significantly improved as compared with baseline. A clear diagnosis of MS was performed in one patient at baseline, but this patient displayed no criteria for this diagnosis after 6 and 12 months. No significant change in morning plasma ACTH, UFC, and serum aldosterone, 17-OH progesterone, testosterone, DHEA-S, and androstenedione levels were observed and no clinical worsening of symptoms and signs related to hyperandrogenism were reported. Excluding from the analysis the four patients treated with prednisone at baseline, a significant increase in morning serum cortisol levels was registered after 6 months ($P=0.016$) but it was not confirmed after 12 months. Despite the unchanged fludrocortisone doses, both in the entire cohort ($P=0.002$) and in the subgroup of patients with salt wasting form ($P=0.005$) a significant decrease in renin levels was reported at 6-month follow-up, but it was not confirmed at 12-month follow-up. As control, no significant difference was observed in metabolic and hormonal parameters in the same cohort of patients between baseline and 12 months before the switch. Additionally, DS improved both after 6 months ($P=0.04$) and 12 months ($P=0.07$) whereas TC significantly, progressively, improved after 6 months ($P=0.009$) and after 12 months ($P=0.000$). In conclusion, the switch from conventional GCs to

DR-HC significantly improves MS, DS, and TC, maintaining an optimal hormone control in patients with CAH due to 21-hydroxylase deficiency.

The effect of oxidative stress to cardiovascular risk profile among non-functional adrenal incidentaloma patients

Hanife Bolat[1], Kamile Gul[2], Gulizar Sokmen[3], Murat Sahin[2], Ergul Kurutas[4], Ayten Oguz[2], Abdullah Sokmen[3], Dilek Tuzun[2], Safiye Seyma Taner[4] & Omer Faruk Akgul[1]
[1]Department of Internal Medicine, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [2]Department of Endocrinology and Metabolism, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [3]Department of Cardiology, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [4]Department of Biochemistry, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey.

Aim
In this study our aim was to investigate the effects of non-functional adrenal incidentalomas to cardio-metabolic risk factors and endothelial function.
Materials and methods
Our study involved 30 patients with non-functional adrenal incidentaloma (patient group), and two control groups without adrenal incidentaloma (control group 1 involved 26 patients have DM and/or HT and control group 2 involved 24 healthy control). Metabolic parameters (fasting blood glucose and lipid profile), hsCRP, oxidative stress parameters such as malondialdehyde (MDA), nitric oxide (NO), nitrotyrosine (3-NTx), and antioxidants parameters such as catalase (CAT), superoxide dismutase (SOD), glutathione peroxidase (GPx), and melatonin were evaluated in all participants.
Results
When we compared the patient and control groups; hsCRP, oxidative stress parameters (MDA, NO, and 3-NTx) were significantly higher in patient group ($P<0.001$) but antioxidant parameters such as melatonin, GPx, and SOD were significantly lower in patient group ($P<0.001$). Cortisol levels after 1 mg dexamethasone suppression test were significantly higher in patient group ($P<0,01$). There was a significant positive correlation between cortisol levels after 1 mg dexamethasone suppression test and hsCRP, MDA, NO, and 3-NTx levels ($P<0.05$) and there was a significant negative correlation between cortisol levels after 1 mg dexamethasone suppression test and melatonin, GPx, and SOD levels ($P<0.001$).
Conclusion
Adrenal incidentalomas are usually thought to be benign and asymptomatic lesions. But recent studies reported that autonomic cortisol secretion was higher than expected in incidentalomas and they have increased cardiovascular risk. But it is not clear whether adrenal incidentalomas increase the atherosclerosis and cardio-metabolic risk or this adrenal tumours mostly seen in patients that have cardio-metabolic risks. According to the data obtained from this study; we suggest that the oxidative stress increases markedly in the patients with non-functional adrenal incidentalomas, so this process leads the atherosclerosis eventually. Moreover we showed that non-functional adrenal incidentaloma patients have higher cortisol levels when compared both with healthy controls and patients that have cardiovascular risk factors. Therefore we suggest to consider the factors that mentioned above when evaluating the non-functional adrenal incidentaloma patients.

Malignant phaeochromocytoma: about seven observations

Mounia Benoumechiara[1], Nora Soumeya Fedala[2], Ali El Mahdi Haddam[2], Leyla Ahmed Ali[1], Farida Chentli[1] & Djamila Meskine[2]
[1]Bab El Oued Hospital, Algiers, Algeria; [2]Bologhine Hospital, Algiers, Algeria.

Introduction
Malignant phaeochromocytomas are rare tumours, developed at the medulla and paraganglia. Their diagnosis is established by the presence of metastases of organs devoid of chromaffin tissue or by the appearance of neoplastic recurrence. They are characterized by a morbidity and mortality due to the effects of uncontrolled and important hypersecretion cathécolaminergique and resistance to conventional cancer treatments.
Aim
Report the observations of seven cases observed in 26 years.
Materials and methods
Seven patients with malignant phaeochromocytomas were treated in our department. Three were males and four females and their ages ranged between 17 and 45 years old. The circumstances discoveries were adrenergic signs and severe hypertension in all cases. Hormonal balance showed very high levels of metanephrine: 20 ± 1.4 (16–22) and CT + MRI showed a large and characteristic adrenal mass: 12.6 ± 1.2 cm (14–9.6). Malignancy was confirmed by the presence of metastasis at diagnosis in five cases and in the developments in the rest of the cases. Evolution was marked a year and a half after on average (after surgery and chemotherapy) by a normalisation of blood pressure, methoxylated derivatives in five patients. Two deaths occurred after the first course of chemotherapy.
Discussion and conclusion
Surgery of malignant phaeochromocytoma, even at metastatic stage increases survival. Chemo radiotherapy and MIBG are part of the therapeutic arsenal. The management of these patients requires a multidisciplinary follow up (surgeon, oncologist, endocrinologist, histopathologist, and geneticist).

Comparison of 17-OH progesterone response to various dose of tetracosactide

Mikuláš Kosák[1], Michaela Duškova[2], Katerina Šimunková[1,2], Václav Hána[1], Michal Kršek[1], Hana Jandíková[2], Hana Pospíšilová[2], Monika Šrámková[2], Marta Velíková[2] & Luboslav Stárka[2]
[1]3rd Department of Medicine, General University Hospital and First Faculty of Medicine, Charles University, Prague, Czech Republic; [2]Institute of Endocrinology, Prague, Czech Republic.

ACTH test is widely accepted as diagnostic tool in suspicion on peripheral as well as on central hypocorticism. The optimal dose of tetracosactide for determination of hypocorticism is still matter of debate. The 250 μg as a standard dose of tetracosactide has been approved for diagnosis of congenital adrenal hyperplasia (CAH) many years ago. Moreover, current limited availability of tetracosactide and its increased financial cost on the market raised the question whether the lower dose of tetracosactide for diagnosis of CAH may be sufficient stimulation.
Aims
To compare response of 17-OH progesterone (17-OHP) to various doses of tetracosactide in healthy volunteers.
Methods
In ten healthy volunteers (four males, median 42 years) with normal adrenal function (based on clinical and biochemical evaluation) the ACTH tests with i.v. administration of 250 μg (HDST), 10 μg (MDST), and 1 μg (LDST) tetracosactide were performed.
Results
Similar response in 17-OHP levels in all three variants of the test was observed. Median 17-OHP levels 30 min after the tetracosactide administration were 6.62, 6.62, and 5.68 nmol/l for HDST, MDST, and LDST respectively. 60 min after the administration the median levels were 6.93, 5.91, and 4.70 nmol/l.
Conclusion
Our data support the hypothesis of ACTH test reliability for the diagnosis of CAH in all variants with lower doses of ACTH compared to standard dose. Further confirmation of our observation in patients with known non-classical form of CAH would be appropriate.

Functional oncocytic adrenocortical tumour: a case report

Murat Sahin[1], Dilek Tuzun[1], Ayten Oguz[1], Mehmet Fatih Yuzbasioglu[2], Hamide Sayar[3], Hakan Demir[4] & Kamile Gul[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [2]Department of General Surgery, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [3]Department of Pathology, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [4]Department of Internal Medicine, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey.

Introduction
Adrenocortical oncocytomas are rare seen tumours. Most of these tumours are benign and non-functioning. We present here a case of oncocytic adrenocortical tumour, detected incidentally, presented with Cushing's syndrome.
Case
A 41-year-old male patient, while investigating for abdominal pain, bilateral adrenal masses were detected in abdominal ultrasonography and was admitted to Endocrinology Clinic. He had no history of hypertension. Physical examination revealed, a pulse rate of 80 beats/min and a blood pressure of 180/90 mmHg. Patient had typical cushingoid appearance including a plethoric moon face, truncal and centripetal obesity and abdominal cutaneous striae. In his laboratory investigations; glucose level was 97 mg/dl, ALT 80 U/l (30–65), cortisol 18.47 μg/dl (5–23), DHEAS >1000 μg/dl (35–560), and ACTH <5 pg/ml (9–52). In the 24-h urine metanephrine level, normetanefrin and plasma aldosteron concentration, plasma renin concentration were normal. Other biochemical blood test results were within normal ranges. The plasma cortisol level was 24 μg/dl after 1 mg overnight, 22 μg/dl after 2 days 2 mg dexamethasone suppression test, and midnight cortisol was 14 μg/dl. According to these findings Cushing's syndrome was considered. Surrenal magnetic resonance imaging (MRI) that showed bilateral adrenal adenomas that were 35×32 mm in size in the right and 78×64 mm in the left adrenal gland, isointense in T1A and T2 and included cystic regions. Left adrenalectomy was performed to the patient. The postoperative histopathological diagnosis was borderline oncocytic adrenocortical tumour with myelolipoma foci and Ki-67 proliferation index was under 1%. The patient is still under follow-up at our clinic with the replacement therapy of steroid.
Conclusion
The incidence of adrenal incidentaloma is increasing according to technological development and frequency of radiological imaging. Adrenocortical oncocytomas are rare seen tumours. Most of these tumours are benign and non-functioning. Some of that tumours are malign and while the others are borderline. Oncocytic neoplasms microscopically consist of so called oncocytes, large cells with rich eosinophilic granulations due to the high concentration of mitochondria. We present a case with oncocytic adrenocortical tumour presented with Cushing's syndrome because it is seen rare.

Beneficial effects of replacement therapy with modified-release hydrocortisone in patients with adrenal insufficiency

Valentina Morelli[1], Erika Messina[2], Marco Mendola[3], Elisa Cairoli[1], Bruno Ambrosi[3], Salvatore Cannavò[2], Iacopo Chiodini[1] & Anna Spada[1]
[1]Unit of Endocrinology and Mebabolic Diseases, Fondazione IRCCS Cà Granda-Ospedale Maggiore Policlinico, University of Milan, Milan, Italy; [2]Unit of Endocrinology, Azienda Ospedaliera Universitaria Policlinico Gaetano Martino, University of Messina, Messina, Italy; [3]Endocrinology and Diabetology Unit, IRCCS Policlinico San Donato, San Donato Milanese, University of Milan, Milan, Italy.

Introduction
The classical replacement therapy for hypoadrenalism may expose patients to non-physiologic glucocorticoids levels with negative metabolic consequences. Up to now, one study demonstrated that, as compared to the classical treatment, a modified-release hydrocortisone (MRH), improves weight, blood pressure, glycaemic control and QoL in a 3-month follow-up period. Few data are available on the long-term persistence of these benefits.
Design/methods
Ten patients with Addison's disease and seven with central hypocortisolism (mean±s.d., age 50.8±10.7 years, BMI 27.9±7.0 kg/m^2, 9M/8F) were enrolled in three Italian Endocrine Units. 12 patients were treated with cortisone acetate (30.2±10.9 mg/day), five patients with hydrocortisone (25±5 mg/day), with an inadequate control of the disease. 80% of patients reported fatigue. In all patients, after baseline evaluations, the classical therapy was replaced with MRH (20.3±1.2 mg/day). At 1, 3, 6, and 12 months after the therapy modification (mean follow-up: 8.8±4.2 months) we evaluated parameters of adrenal function, BMI, blood pressure, HbA1c levels, and symptoms of over- or under-treatment.
Results
MRH caused higher morning cortisol levels than the classical therapy (after 12 months: 20.7±6.5 μg/dl vs 13.2±3.5 μg/dl, $P=0.012$), but comparable UFC values (after 12 months: 29.1±14 μg/24 h vs 24.1±9.5 μg/24 h, $P=0.299$), confirmed at each evaluation. In Addisonian patients MRH did not influence ACTH levels over time (after 12 months: 175.8±215 pg/ml vs 150.6±157 pg/ml, $P=0.781$). Paired sample *T*-test showed that metabolic parameters did not change after 1, 3, and 6 months. The ten patients that completed the 12 months follow-up, showed a reduction of BMI (29.2±5.8 vs 28.3±5.2, $P=0.027$) and systolic (126±18 mmHg vs 115±18 mmHg, $P=0.03$) blood pressure, while HbA1c decreased in the two diabetic patients (8.1±0.7% vs 5.9±1.1%). 60% of patients showed an improvement of fatigue after 6 months ($P=0.023$) that persisted at 12 months.
Conclusion
In patients with hypoadrenalism, a 12 months treatment with MRH seems to improve some metabolic parameter and to reduce weakness.

A phase 1, randomised, open-label, four-period crossover, single-dose study to evaluate the pharmacokinetics of hydrocortisone modified release tablets

Gudmundur Johannsson[1], Hans Lennernäs[2], Claudio Marelli[3], Kevin Rockich[4] & Stanko Skrtic[1]
[1]Department of Endocrinology, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gotheburg, Sweden; [2]Department of Pharmacy, Uppsala University, Uppsala, Sweden; [3]Shire, Zug, Switzerland; [4]Shire PLC, Chesterbrook, Pennsylvania, USA.

Novel biopharmaceutical techniques have allowed the development of a hydrocortisone modified release (MR) tablet (once-daily administration for replacement therapy in adrenal insufficiency) mimicking more closely the physiological serum cortisol profile. Robust bioavailability is needed to secure this new treatment safety.
Aims
To compare single-dose pharmacokinetics (PK) of MR tablets manufactured at two different sites by assessing intra-subject variability (dose range: 5–20 mg).
Methods
Thirty-two healthy men and women (20–55 years; BMI: 18–30 kg/m^2) were enrolled into a randomized, open-label, four-period crossover, single-dose PK study with collection of baseline 24 h endogenous cortisol secretion. During four periods 5, 15, 20 (new manufacturing site R), and 20 mg (reference site G) were administered orally at 0800 h after overnight fast. Endogenous cortisol secretion during PK sampling was suppressed using dexamethasone. PK parameters were determined using non-compartmental analysis. Plasma cortisol was measured using LC–MS/MS.
Results
Within-individual comparison between the endogenous profile and the 20 mg tablet showed hydrocortisone treatment provided higher than endogenous concentrations 0–4 h post-dose and similar concentrations 5–15 h post-dose. Mean hydrocortisone *C*max (s.d.) was 82.0 (18.2), 148.8 (29.3), 177.1 (25.5), and 178.0 (28.1) ng/ml and mean AUC∞ was 523.8 (128.0), 1024.5 (158.1), 1178.2 (222.2), and 1191.4 (190.9) h×ng/ml for 5, 15, 20 mg R treatments, and 20 mg G treatment respectively. Bioequivalence, defined as the 90% CI being within the 80 125% limits, was demonstrated. Within-subject variability was below 15% for all examined PK parameters for the 20 mg R and G MR tablet oral administration. Exposure PK parameters were found to be less than dose proportional, i.e. AUC∞ with a 0.78 slope (95% CI: 0.70–0.85) in the 5–20 mg dose range.
Conclusions
Once daily MR hydrocortisone demonstrates a physiological cortisol exposure during the day. Within-individual day-to-day PK variability is very low underpinning product safety for replacement therapy. Hydrocortisone PK is less than dose proportional, an important PK property of oral hydrocortisone that should be considered in the intercurrent illness management of adrenal insufficiency.

Rare case of ectopic ACTH secreting tumour causing cyclical Cushing's syndrome

Jayashekara Acharya, Sriranganath Akavarapu, Ali Abbara, Valsalakumari Parvathy & J F Todd
Hammersmith Hospital, London, UK.

We are reporting a rare case of ectopic ACTH secreting tumour causing cyclical Cushing's syndrome. A 63-year-old lady presented in March 2013 with tiredness and bilateral leg swelling and weakness associated with easy bruising. She was admitted to local hospital in April 2013 with worsening proximal myopathy and

peripheral oedema. Her midnight cortisol was elevated at 1710 nmol/l. ACTH 610 mU/l, prolactin 476 mU/l, GH 0.21 IU/l, TSH 0.73 mU/l, free T_4 of 11.0 pmol/l, LH 0.5 IU/l, and FSH 1.5 IU/l. A cortisol day curve on metyrapone 500 mg tds showed elevated cortisol of 507, 989, and 273 nmol/l at 0900, 1200, and 1800 h. MRI pituitary showed normal appearance of the pituitary gland. Abdominal CT scan revealed bilateral adrenal hyperplasia. Despite metyrapone 250 mg tds her cortisol levels remained elevated (200–400 nmol/l). Metyrapone was stopped a week before (30th May) bilateral inferior petrosal sinus sampling. Results were suggestive of central ACTH-dependent Cushing's syndrome. However her cortisol levels normalised post IPSS, without reintroduction of metyrapone (between 125 and 250 nmol/l). Her midnight cortisol was low at 41 nmol/l and ACTH of 43 mU/l. She was discharged home as her symptoms resolved and biochemistry normalised post discharge insulin stress test in August showed suboptimal cortisol response of 409 nmol/l. She was started on hydrocortisone replacement. Her symptoms relapsed in September 2013 with midnight cortisol of 1400 nmol/l with ACTH of 431 nmol/l consistent with relapsed Cushing's syndrome. She failed to suppress on a low dose dexamethasone test and she was restarted on metyraone to improve her symptoms. She underwent Gallium DOTATATE scan, which showed right lower lobe Gallium avid lesion. Repeat IPSS done in September did not show any central gradient confirming an ectopic source. She underwent surgical excision of lung lesion in December 2013. Histology was consistent with neuro endocrine tumour (Ki67 $<3\%$). Her symptoms improved after surgery and her cortisol levels fell. She was started on hydrocortisone after she failed on short Synacthen test.

Conclusion

Cyclical Cushing's syndrome is a rare cause of hypercortisolism. Corticotroph adenoma is the most common cause. Cyclical Cushing's syndrome due to ectopic ACTH is extremely difficult to diagnose due to fluctuating clinical picture and biochemistry. In suspected cases specific biochemical and imaging investigation for neuroendocrine tumour is required.

Review of clinical presentation of primary hyperaldosteronism and identify unique features in our cohort

Daphne Lee, Shaikh A K K Abdul Shakoor, Uei Pua, Daniel Wong & Lawrence Quek
Tan Tock Seng Hospital, Singapore, Singapore.

Aim

Review of clinical presentation of primary hyperaldosteronism (PHA) and identify unique features in our cohort.

Method

Patients with PHA were identified from patients who underwent adrenal vein sampling (AVS) at our centre until October 2014.

Results

45 PHA patients (32 males, mean age of 50 years, 33 older than 45 years) were identified after confirmation with high aldosterone:renin ratio >15 and/or positive saline suppression test. All had hypertension and 41/45 (91.1%) presented with hypokalaemia. CT adrenal findings were; 31/45 (68.9%) unilateral nodule (one had two nodules unilaterally), 5/45 (11.1%) bilateral nodules, 7/45 no nodules, 1/45 bilateral bulky adrenals, and 1/45 left adrenal limb thickening. The mean tumour size on CT was 1.41 (0.7–2.3) cm. All underwent AVS (four had repeat investigation). Based on biochemical criteria, 61% (30/49) of cases were successfully cannulated bilaterally. Final diagnosis of PHA was established after evaluating both CT and AVS findings (ratio of higher over lower aldosterone/cortisol of >4 for aldosterone producing adenoma (APA) and <3 for bilateral adrenal hyperplasia (BAH)) by the primary clinician: 18 had APA, 16 had BAH, and 11 were inconclusive. 17/45 (37.8%) patients underwent surgery (all confirmed as APA on histology). After surgery, hypokalemia normalised in all, 15/17 (88.2%) BP improved and 3/17 (17.6%) were cured of hypertension. Among 27 patients treated medically, 25/27 (92.6%) had normalisation of potassium, 25/27 (92.6%) BP improved and 2/27 (7.4%) were cured of hypertension. One patient declined treatment.

Discussion

The prevalence of BAH is higher in our cohort compared to reported series but this could be due to selection of cases through AVS procedure as some cases of APA may have been missed because they did not undergo AVS. The prevalence of inconclusive diagnosis after AVS was higher, which could be related to the expertise in our centre.

DOI: 10.1530/endoabs.37.EP56

EP57

To identify usefulness of adrenal vein sampling in clinical management of primary hyperaldosteronism

Daphne Lee, Shaikh A K K Abdul Shakoor, Uei Pua, Daniel Wong & Lawrence Quek
Tan Tock Seng Hospital, Singapore, Singapore.

Aim

To identify usefulness of adrenal vein sampling (AVS) in clinical management of primary hyperaldosteronism (PHA).

Method

Biochemical and radiological review (by two independent radiologists) of 48 AVS in 45 patients with PHA who underwent CT adrenals/AVS.

Results

CT adrenal findings were: 31/45 (68.9%) unilateral nodule (one had two nodules unilaterally), 5/45 (11.1%) bilateral nodules, 7/45 no nodules, 1/45 bilateral bulky adrenals, and 1/45 left adrenal limb thickening. Selectivity index (adrenal vein cortisol/infra adrenal IVC cortisol) >5 and lateralisation index (ratio of higher over lower aldosterone/cortisol ratio) >4 for aldosterone producing adenoma (APA) and <3 for bilateral adrenal hyperplasia (BAH) were used for AVS. Based on radiological review, 29% (14/48) of cases were cannulated bilaterally. Between radiologists, there was discordance in opinion regarding successful cannulation; 48% (23/48) right side vs 8.3% (4/48) left side. There was better agreement between radiological review and biochemical criteria on the left side (37/48 vs 18/48). Based on biochemical criteria, 59% (29/48) of cases were cannulated bilaterally; 14/29 APA, 12/29 BAH, and 3/29 inconclusive. Clinical conclusion in the remaining 19 unsuccessful cases were; 4/19 APA on secondary criteria (non-suppression of aldosterone on contralateral side) and 3/19 BAH and 12/19 inconclusive. AVS finding in patients with unilateral nodule on CT; 13/31 (42%) APA on same side as CT (four using secondary criteria), 10/31 (32.2%) BAH, and 8/31 inconclusive. On the contrary, AVS lateralised to one side in four patients with bilateral nodules and one with normal CT. Nodules >1.5 cm predicted lateralisation to the same side in AVS, with a positive predictive value of 70% compared to nodules ≤ 1.5 cm on CT.

Conclusion

AVS provided additional information over CT in the management of PHA; AVS helped to save 11 patients from unnecessary surgery and directed five patients who would otherwise have been treated medically, for curative surgery.

Diagnosis of Cushing's syndrome using scalp hair cortisol

Vincent L Wester[1], Jan W Koper[1], Erica L T van den Akker[2], Yolanda B de Rijke[3], Laura Manenschijn[1], Richard A Feelders[1] & Elisabeth F C van Rossum[1]
[1]Department of Internal Medicine, Erasmus MC, University Medical Center Rotterdam, Rotterdam, The Netherlands; [2]Department of Pediatrics, Erasmus MC, University Medical Center Rotterdam, Rotterdam, The Netherlands; [3]Department of Clinical Chemistry, Erasmus MC, University Medical Center Rotterdam, Rotterdam, The Netherlands.

Background

Endogenous Cushing's syndrome (CS) is caused by overproduction of cortisol. Current first-line screening tests for CS can produce false positive results due to medication use and stress, rely heavily on patient adherence to sampling instructions, and only measure short-term cortisol exposure which limits sensitivity. In general multiple tests are required to establish a diagnosis. Hair cortisol concentrations (HCC) offer a minimally invasive way to measure long-term cortisol exposure over months of time, and are a promising additional screening tool for CS. In addition, HCC can be used to create retrospective timelines of cortisol exposure.

Methods

We collected scalp hair from patients suspected of CS in a single academic medical center, and in healthy controls. HCC were measured using ELISA. Receiver operator curve (ROC) analysis was used to determine the optimal cut-off for CS.

Results

HCC levels were available in 35 patients with CS, 20 patients in whom the diagnosis CS could be rejected during diagnostic work-up (non-CS patients), and 174 healthy controls. CS patients had higher HCC than non-CS patients and healthy controls (157.6 vs 9.7 and 8.4 pg/mg, respectively, $P<0.001$). At a cut-off of 31.1 pg/mg, HCC could differentiate between CS patients and healthy controls with a sensitivity of 94% and a specificity of 90%. With non-CS patients as a reference, sensitivity and specificity remained similar (94 and 90%

respectively). As expected, HCC was higher in ectopic ACTH secretion than in pituitary or adrenal CS (661.1 vs 105.9 and 123.0 pg/mg, respectively, $P < 0.05$). Retrospective timelines of HCC corresponded well with clinical course in CS.
Conclusion
Analysis of cortisol in a single scalp hair sample offers diagnostic accuracy for CS similar to current first line tests and a collection procedure which is highly convenient for clinical practice, and therefore seems a valuable tool in the diagnosis of CS.

Role for ^{131}I-6β-iodomethyl-norcholesterol scintigraphy in subclinical Cushing's syndrome with bilateral adrenal lesions

Daniela Guelho[1], Rui Ferreira[2], Isabel Paiva[1], Ana Paula Moreira[2], Carolina Moreno[1], Luis Cardoso[1], Nuno Vicente[1], Diana Martins[1], Diana Oliveira[1], Margarida Balsa[3], Gracinda Costa[2] & Francisco Carrilho[1]
[1]Endocrinology, Diabetes and Metabolism Department, Coimbra Hospital and University Centre, Coimbra, Portugal; [2]Nuclear Medicine Department, Coimbra Hospital and University Centre, Coimbra, Portugal; [3]Endocrinology, Diabetes and Nutrition Department, Baixo Vouga Hospital Centre, Aveiro, Portugal.

Introduction
Subclinical Cushing's syndrome (SCS) is the most frequent endocrine dysfunction found in adrenal incidentalomas. Although adrenalectomy constitutes a therapeutic option for selected cases, the presence of bilateral tumours can difficult the surgical decision.
Objective
Evaluate the utility of ^{131}I-6β-iodomethyl-19-norcholesterol scintigraphy in SCS with bilateral adrenal tumours.
Methods
Retrospective analysis of all patients with SCS and bilateral adrenal lesions submitted to ^{131}I-6β-iodomethyl-19-norcholesterol scintigraphy in our Nuclear Medicine Department. Following suppression with dexamethasone, planar thoracoabdominal scintigraphy, and single photon emission computed tomography (SPECT/CT) images were obtained at 3rd, 5th, and 7th days after i.v. administration of 1 mCi of ^{131}I-6β-iodomethyl-19-norcholesterol.
Results
Five scintigraphy were performed in four women, aged 57.5 years (46–67 years), with SCS and bilateral incidentalomas identified by abdominal CT: at right with a median diameter of 19 mm (17–35 mm) and at left with 18 mm (7–28 mm). All patients presented osteoporosis; two had dyslipidaemia and two had arterial hypertension. Two patients showed radiopharmaceutical uptake at right adrenal with non-visualisation of contralateral gland: both were proposed to adrenalectomy. Histopathological study confirmed the adrenal cortical adenoma. After surgery, a significant improvement of their comorbidities was observed with reduction of anti-hypertensive drugs. Other patient exhibited symmetrical uptake and was maintained on medical treatment. In the fourth patient, both the first scintigraphy and adrenal vein sampling were inconclusive. However, after a second scintigraphy that suggested a hyperfunctioning right adenoma, she was submitted adrenalectomy that confirmed the lesion.
Conclusions
This work suggests a high resolution of the adrenal ^{131}I-6β-iodomethyl-19-norcholesterol scintigraphy, providing a more precise picture of functional structural lesions that crosses the information obtained by CT and hormonal assays. In these patients enabled a more targeted surgical approach, preserving the other adrenal and improving their comorbidities.

EP60

Diagnostic pitfalls of Cushing's syndrome without specific clinical signs among patients with obesity

Nalalia Volkova, Maria Porksheyan & Lilia Ganenko
Rostov State Medical University, Rostov-on-Don, Russia.

Introduction
Prevalence of CS without specific signs is thought to be high, which might be an indication for its general screening. However, conclusive data about its diagnostics is absent.
Design
189 overweight patients were studied. Nobody had clinical evidence of hypercortisolism. Diagnostic of CS was 1-mg overnight dexamethasone suppression test (1-mg DST; cut off 50 nmol/l) as a screening; midnight plasma cortisol (MPC) (<207 nmol/l) and 24-h urinary free cortisol (UFC) (<180 μg/24 h) as a confirmatory tests; morning plasma ACTH (5–46 pg/ml), 8-mg DST and imaging studies as topical diagnostics.
Results
Among 189 patients 166 were excluded to have CS according to results of DST 1 mg (<50 nmol/l). 23 had impaired result of 1-mg DST. Among these 23 patients there were diagnosed four cases of corticotropinomas, two corticosteromas. Other 17 patients were excluded to have CS by long-term follow-up and, therefore, they had falsely positive results of confirmatory tests. The diagnostic characteristic of MPC and UFC with established cut off were calculated: MPC – Sen 83.33% (95% CI 35.88–99.58), Sp 63.64% (95% CI 30.79–89.07), LR+ 2.29, LR− 0.26, DOR 8.75 (95% CI 0.73–103.82), UFC – 83.33% (95% CI 35.88–99.58), Sp 18.18% (95% CI 2.28–51.78), LR+ 1.02, LR− 0.92, DOR 1.11 (95% CI 0.07–15.53). In order to adjust diagnostic efficiency without a certain threshold value, the logit regression equation was calculated. The percent of concordance for UFC made 53%, MPC – 81.8%. Also there were performed comparison results of patients with and without CS: results of MPC (significant difference) and UFC (insignificant difference).
Conclusions
High prevalence of CS without specific signs was confirmed on our study (about 3%). Among tests used to screen and confirm CS without specific signs, UFC has the worst diagnostic characteristics and, therefore, should not be used. MPC has better characteristics, however, the question of threshold value has to be discussed.

The utility of current guidelines in the assessment of adrenal incidentalomas

Emily Austin, Lisa Shepherd, Asad Rahim & Andrew Bates
Heart of England Foundation Trust, Birmingham, UK.

Adrenal incidentaloma's are a common clinical dilemma with increasing utilisation of cross-sectional imaging modalities. The aims of management include i) exclusion of possible malignancy and ii) identification of hormonally active lesions. Our unit has adopted AACE guidelines, including a screen for adrenal androgen hypersecretion. This audit aimed to review the utility of such an approach. We identified case notes of 100 consecutive adrenal incidentaloma's referred to endocrinology prior to November 2014. All were subject to radiological scrutiny by a dedicated radiologist, whilst endocrine investigations, including two 24 h urinary metanephrines, 1 mg overnight dexamethasone suppression test, renin:aldosterone ratio and DHEAS were arranged, together with electrolytes and blood pressure. Radiologically, 84% were considered to be benign adrenal adenomas on the basis of either CT density (<10 HU), CT contrast washout at 10 min (>60%) or in and out of phase MRI. 3% were myolipomas and 4% phaeochromocytomas. 8% were indeterminate and referred for further investigation or surgery. From a functional perspective, we identified four phaeochromocytomas, all of whom had imaging studies inconsistent with a benign adenoma and raised urinary metanephrines. Five had a 0900 h cortisol of >100 following 1 mg dexamethasone, none of whom had symptoms/signs consistent with cortisol excess and two of whom have already had cortisol excess excluded by further investigation. The remainder have further investigations pending. Two males had elevated DHEAS levels and both had abnormal imaging, one of which proved to be a phaeochromocytoma. There were no abnormal renin:aldosterone ratios. 89% of the cohort was hormonally inactive. On the basis of this audit, we are concerned that adrenal incidentalomas are currently over-investigated. In patients with no symptoms/signs of an underlying endocrinopathy, normal blood pressure, normokalaemia and imaging consistent with a benign adenoma, universal endocrine investigation is largely unrewarding.

Prospective evaluation of cardiovascular risk in subclinical Cushing's syndrome

Serkan Yener[1], Yasin Cekdemir[2], Mustafa Baris[2], Mustafa Demirpence[3], Tevfik Demir[1] & Mustafa Secil[2]
[1]DEUTF, Division of Endocrinology, Izmir, Turkey; [2]DEUTF, Department of Radiology, Izmir, Turkey; [3]Tepecik EAH, Division of Endocrinology, Izmir, Turkey.

Introduction
Natural history of adrenal incidentalomas has not been totally understood. Current data from subjects with adrenal incidentalomas demonstrated an increased rate of metabolic disturbances and cardiovascular risk. It has been shown that subjects with subclinical cortisol excess were more susceptible to diabetes, hypertension, and obesity. However, there is no data regarding prospective cardiovascular risk evaluation in subjects with subclinical Cushing's syndrome.
Methods
Patients referred to Dokuz Eylul University between January 2013 and January 2014 were included. Patients with subclinical Cushing's syndrome ($n=20$), patients with non functioning adrenal adenomas ($n=30$) and subjects without adrenal adenomas ($n=25$) were enrolled. Interventions included physical examination, anthropometric measures, imaging with CT (MRI if CT was contraindicated), 1 mg DST, ACTH, UFC, urinary catecholamine levels, PAC/PRA (if indicated), hcCRP, lipid profile, HOMA index, and fibrinogen levels. Additionally all subjects underwent carotid intima media thickness (IMT) measurement and evaluation of flow mediated dilatation (FMD) of the brachial artery All laboratory tests were repeated in both groups after 12 months follow up.
Results
Baseline anthropometric parameters were comparable. Briefly, patients with subclinical Cushing's syndrome did not exhibit any deteriorations in IMT of the carotid arteries or FMD of brachial artery after 12 months follow up.
Discussion
Although subclinical Cushing's syndrome is associated with several cardio-metabolic disturbances, endothelial function does not seem to be altered in 12 months follow up. Therefore, the decision of adrenalectomy vs follow up should be conservative and short-term follow up seems feasible.

Salivary cortisol values among nurses at Pathology and Emergency Department

Blertina Dyrmishi[1], Taulant Olldashi[1], Emirvina Kolici[2], Zamira Ylli[2] & Agron Ylli[2]
[1]Hygeia Hospital, Tirana, Albania; [2]Neo Style Clinic, Tirana, Albania.

Aim
To see the difference between salivary cortisol values and correlation with the work stress.
Methods
The salivary and serum cortisol values were analysed in two groups of nurses, six nurses in the Emergency Department and six nurses in the Pathology Department at our hospital, three females and three males for each group. The samples were taken before beginning the work and after finishing the work. The cases respected all the rules for salivary testing of cortisol and the average age of the participants was the same for both groups, 28.5 years old.
Results
Median serum cortisol values in the Emergency Department in the morning were 188.8 nmol/l (normal range 55–230) and median salivary cortisol values 3.1 μg/dl (normal range 1–11.3) and at the end of work (1600 h) the values were: serum cortisol values 130.2 nmol/l (normal range 28–140) and salivary cortisol values 1.87 μg/dl (normal range 0.2–2.7). In the Pathology Department: in the morning (0800 h) average serum cortisol values were 125 nmol/l and salivary cortisol values 2.1 μg/dl and at the end of the work (1600 h): serum cortisol values were 94.0 nmol/l and salivary cortisol values 1.22 μg/dl.
Conclusions
Since the stress of work is higher in the Emergency Department, even the results of the salivary cortisol values were higher in the nurses of the Emergency Department compared to the nurse of Pathology Department and there existed a correlation between salivary and serum values, but the study needed a bigger group of nurses to have more trustful conclusions.

Serum brain-derived neurotrophic factor in Cushing's syndrome patients

Alicia Santos[1], Eugenia Resmini[1], Ma José Barahona[2], Iris Crespo[1], Elena Valassi, Ma Antonia Martinez[3], Ana Marin[4] & Susan M Webb[1]
[1]Endocrinology/Medicine Departments, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBER-ER, Unidad 747), Hospital Sant Pau, IIB-Sant Pau, ISCIII and Universitat Autònoma de Barcelona, Barcelona, Spain; [2]Endocrinology Department, Hospital Universitari Mútua de Terrassa, Terrassa, Spain; [3]Escola Universitària d'Infermeria, Hospital de Sant Pau, Universitat Autònoma de Barcelona (UAB), Barcelona, Spain; [4]Internal Medicine Department, Hospital Sant Pau, Barcelona, Spain.

Introduction
Brain-derived neurotrophic factor (BDNF) is a protein that has been linked to several cardiovascular risk factors and bone status. Stress and corticosteroid exposure can affect BDNF levels, although this has never been studied in Cushing's syndrome (CS). The aims of this study were to establish if BDNF levels were reduced in CS and to check possible associations to cardiovascular risk factors and bone status.
Methods
52 patients (18 active CS and 34 in remission) and 52 controls matched for sex and age were studied. Blood tests (including biochemistry, cortisol, and BDNF), anthropometry, complete clinical examination and a whole body DEXA were performed. Statistical analysis was performed using ANOVA with Bonferroni correction and Pearson correlations.
Results
BDNF was reduced in both active and in remission CS patients, compared to controls ($P<0.001$ and $P<0.05$). Both patient groups had higher waist ($P<0.01$ and $P<0.05$) and diastolic blood pressure ($P<0.001$ both), while CS in remission also showed higher systolic blood pressure ($P<0.01$) and triglycerides ($P<0.01$) than controls. Correlations including the whole sample showed that BDNF positively correlated with bone mineral content ($r=0.285$, $P<0.01$), meaning that reduced BDNF indicated less bone mineral content. BDNF also negatively correlated to diastolic blood pressure ($r=-0.210$, $P<0.05$).
Conclusion
BDNF is reduced in CS patients, even after cure. It may contribute to persistent comorbidities seen in CS patients, such as osteoporosis and hypertension.

Urinary metanephrine levels can be spurious in the diagnosis of patients with phaeochromocytoma: preliminary results from a single centre

Oya Topaloglu[1], Husniye Baser[2], Cevdet Aydin[1], Ahmet Dirikoc[1], Reyhan Ersoy[1], Ozcan Erel[3] & Bekir Cakir[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Yildirim Beyazit University, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Atatürk Education and Research Hospital, Ankara, Turkey; [3]Department of Biochemistry, Faculty of Medicine, Yildirim Beyazit University, Ankara, Turkey.

Introduction
Phaeochromocytomas (PHEO) are diagnosed with classic findings and symptoms but biochemical confirmation must be made. Either urinary or plasma chatecholamines and metanephrines can be used for biochemical evaluation. Normal values rule out the diagnosis, whereas fourfold increase above the upper limit of normal confirm the diagnosis. But value of borderline or less than fourfold elevations in the diagnosis is not clear. We aimed to determine the urinary fractionated metanephrine and catecholamine levels in patients with PHEO.
Material and methods
Thirteen patients with final diagnosis of PHEO (PHEO group) and ten patients (non-PHEO group) who underwent to adrenalectomy and finally diagnosed as benign neoplasm (six adenomas, three cysts, and one hyperplasia) were evaluated retrospectively. Urinary metanephrines were evaluated by HPLC.

Results
In PHEO group urinary metanephrines were as follows: 3 (25%) had borderline elevations, 9 (75%) had normal values, however 1 (10%) had borderline elevation, 1 (10%) had sixfold elevations, and 8 (80%) had normal values in non-PHEO group. The difference was evaluated as statistically insignificant ($P=0.19$). Normetanephrine values were as follows: borderline elevation in 5 (41.7%), twofold elevation in 1 (8.3%), sixfold elevation in 1 (8.3%), and normal values in 5 (41.7%) patients in PHEO group; borderline elevations in 2 (20%), twofold elevation in 1 (10%), normal values in 7 (70%) patients in non-PHEO group. This was also statistically insignificant ($P=0.39$). There were also no significant differences in urinary adrenaline and noradrenaline levels between groups.
Conclusion
Patients with borderline-elevated urinary metanephrine levels can also have PHEO. In patients with adrenal incidentalomas who are candidate for surgery and have borderline elevated metanephrines should be evaluated carefully. In this group of patients, we advocate either routine preoperative preparation as patients possessing PHEO or further diagnostic tests in order to prevent the serious complications.

Clinical significance of contralateral adrenal suppression during adrenal vein sampling in primary aldosteronism

Silvia Monticone[1], Fumitoshi Satoh[2], Andrea Viola[1], Eveline Fischer[3], Oliver Vonend[4], Giampaolo Bernini[5], Marcus Quinkler[6], Gilberta Giacchetti[7], Ryo Morimoto[2], Holger Willemberg[4], Mauro Maccario[1], Franco Veglio[1], Sadayoshi Ito[2], Martin Reincke[3] & Paolo Mulatero[1]
[1]University of Torino, Torino, Italy; [2]Tohoku University, Sendai, Japan; [3]Ludwig Maximilian University, Munich, Germany; [4]University of Düsseldorf, Düsseldorf, Germany; [5]University of Pisa, Pisa, Italy; [6]Charité University Medicine Berlin, Berlin, Germany; [7]Università Politecnica delle Marche, Ancona, Italy.

Objective
Adrenal vein sampling (AVS) is recognised by Endocrine Society guidelines as the only reliable mean to distinguish between aldosterone producing adenomas and bilateral adrenal hyperplasia, the two most common subtypes of primary aldosteronism (PA). However, AVS protocols are not standardised and vary between centres. The objective of the present study was to assess whether the presence or absence of contralateral adrenal (CL) suppression has an impact on the postoperative clinical and biochemical parameters in patients who underwent unilateral adrenalectomy for PA.
Design and methods
The study was retrospectively carried out in eight referral hypertension centres in Italy, Germany, and Japan. Screening and subtype differentiation were performed according to the Japan Endocrine Society and the Endocrine Society guidelines and a total of 234 AVS procedures were included in the study. CL suppression was defined as $\text{aldosterone/cortisol}_{\text{nondominantadrenalvein}}/\text{aldosterone/cortisol}_{\text{peripheralvein}} < 1$.
Results
Overall, 82% of patients displayed CL suppression at AVS, with no statistically significant differences among centres. This percentage was significantly higher in ACTH-stimulated compared with basal procedures (90% vs 77%). The CL ratio was inversely correlated with the aldosterone level at diagnosis and, among AVS parameters, with the lateralisation index ($P<0.02$ and $P<0.01$ respectively). To investigate whether the presence of CL suppression was correlated with response to adrenalectomy, we analysed the CL suppression status with regard to the patient's clinical and biochemical postoperative parameters. No differences were observed between the two groups for the main clinical and biochemical parameters (systolic and diastolic blood pressures, aldosterone, PRA, PRC, K^+, number of drugs, reduction of blood pressure levels, and the number of classes of drugs assumed), but patients with CL suppression underwent a significantly larger reduction in aldosterone levels after adrenalectomy.
Conclusions
For patients with lateralisation indices of >4, CL suppression should not be required to refer patients to adrenalectomy because it is not associated with a larger blood pressure reduction and might exclude patients from curative surgery.

Glucocorticoid receptor polymorphisms not affect the therapy efficiency in adult, Hungarian patients with 21-hydroxylase deficiency

Koncz Klára[1,2], Farkas Abigél[1], Doleaschall Marton[3], Szücs Nikolett[1], Tóth Miklós[1], Igaz Péter[1], Rácz Károly[1] & Patócs Attila[1,2]
[1]2nd Department of Medicine, Semmelweis University, Budapest, Hungary; [2]'Lendület' Hereditary Endocrine Tumors Research Group, Hungarian Academy of Sciences, Semmelweis University, Budapest, Hungary; [3]Molecular Medicine Research Group, Hungarian Academy of Sciences, Semmelweis University, Budapest, Hungary.

Background
Congenital adrenal hyperplasia (CAH) is an autosomal recessive inherited disorder caused by 21-hydroxylase deficiency in 95% of all cases. Two main clinical subtypes: the classical (manifested after birth, or in early newborn period) and the late onset (LO) phenotype (manifested commonly during puberty). The lifelong glucocorticoid (GC) supplementation is essential in therapy of these patients. Response to GC therapy is individual and partly genetically determined.
Objective
Our aim was to study the effect of three well-known polymorphisms (SNPs; BclI, N363S, A3669G) of the GR on therapy, clinical, and laboratory parameters in gene in adult Hungarian patients with 21-hydroxylase deficiency.
Patients and methods
The diagnosis of 21-hydroxylase deficiency was based on clinical, laboratory, and molecular genetic tests including the identification of the most common *CYP21A2* gene mutations and determination of the allelic copy number (CN) of the *CYP21A2* gene. In 93 patients (54 classical and 39 late-onset, age: 28.8 ± 13.7 years) with 21-hyídroxylase deficiency the BclI and N363S polymorphisms were measured using allele-specific PCR, the A3669G polymorphism and the CN variations were detected by real-time qPCR. Allele frequencies of GR polymorphisms were compared to a Hungarian, control population ($n=160$). Association between GR SNPs and clinical, hormone laboratory, and GC supplementation dosage was studied.
Results
Allelic frequency of the GR polymorphisms did not differ from those observed in control population and did not associate with clinical, laboratory parameters or dosage of the GC supplementation. The CN of the *CYP21A2* in both groups of patients a significantly negatively correlated with GC therapy ($P=0.03$).
Conclusion
The GR polymorphisms associated sensitivity against glucocorticoids is not a major factor in determination of the dose of glucocorticoid supplementation. The *CYP21A2* CN measurement is a rapid, cheap and sensitive method for prediction the GC need in patients with 21-hydroxylase deficiency.

The antidiabetic drug metformin affects H295R cells proliferation

Roberta Armignacco, Giada Poli, Giulia Cantini, Letizia Canu, Michaela Luconi & Massimo Mannelli
Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy.

Adrenocortical carcinoma (ACC) is a rare, heterogeneous malignancy with a poor prognosis, particularly when metastatic at diagnosis. To date, radical surgery, possibly associated to mitotane adjuvant therapy, is the only available treatment. However, the mean 5-year survival rate drops under 10% in metastatic ACC and chemo-resistance often develops. Thus, more specific and effective drugs for ACC treatment are urgently required. The antidiabetic drug metformin, used in type 2 diabetes treatment, has been associated with decreased cancer incidence and mortality in several human cancers, suggesting us the possibility to test its potential efficacy on ACC too. Our study wants to evaluate the potential anti-cancer effects of metformin *in vitro* on H295R adrenocortical tumour cell line. Treating cells with increasing doses of metformin (0.5–250 mM) affects cell viability and proliferation in a dose- and time-dependent manner, as we observed by MTS and cell count assay (IC_{50} after 7days: 23.8 ± 0.9 and 10.1 ± 0.3 mM respectively). This inhibitory effect was also confirmed by [^{3}H]thymidine incorporation assay. Moreover, combining metformin and mitotane leads to a synergistic effect which reduces cell viability more than metformin alone (IC_{50} after 7days: 16.7 ± 1.1 mM). To further investigate the molecular mechanisms by which metformin inhibits cell growth, we performed western blot analysis after 6 and 24 h treatment with different doses of metformin (20, 50, and 100 mM), and

we analysed some of the signalling pathways related to cell proliferation and survival. We observed a dose-dependent decrease of ERK1/2 phosphorylation and an increase of AMPK activation, associated with a decreased mTOR phosphorylation. In conclusion, our data suggest that metformin interferes *in vitro* with H295R proliferation, showing a synergistic effect when combined with mitotane. Further studies have to be performed *in vivo* by using animal models to prove the potential anti-cancer effect of metformin in adrenocortical carcinoma.

Prevalence and natural history of adrenal incidentalomas: a prospective cohort study

Panagiotis Anagnostis, Athanasios Siolos, Chrisanthi Zouli, Fotini Adamidou, Zoe Efstathiadou, Athanasios Panagiotou, Gesthimani Mintziori & Marina Kita
Department of Endocrinology, Hippokration Hospital of Thessaloniki, Thessaloniki, Greece.

Introduction
Adrenal incidentalomas (AIs) are frequently detected due to the increasing use of abdominal imaging for diagnostic purposes. However, few prospective studies exist with respect to their natural history, regarding their size and clinical course. The aim of this study was to report the prevalence and natural history of AIs.
Methods/design
Interim analysis of a prospective cohort study. The following tests were performed: serum cortisol nocturnal rhythm, 24 h-urinary free cortisol, low-dose dexamethasone suppression test, aldosterone to plasma-renin-activity ratio and 24 h-urinary total metanephrines and catecholamines. In cases of positive results, confirmatory tests were performed. Radiological assessment was repeated at 6–12 months and yearly thereafter.
Results
Sixty-four patients (19 (30%) males, mean age 59.7 ± 12.1 years) were included. Follow-up data were available for 57 AIs (median time: 36 months, range 4–84). Median size was 2.5 mm (range 0.5–6.5) (unilateral adenoma in 50 (78%)). The final diagnosis was: 56 non-functioning adenomas (87.5%), 5 (7.8%) subclinical Cushing's syndrome (SCS), 1 (1.6%) phaeochromocytoma, 1 (1.6%) aldosteronoma, and two adrenocortical carcinomas (3.2%), of which one had also SCS. Mass enlargement (9 mm) was observed in one patient (2.8%), while a decrease (7–27 mm) in 3 (8.5%). No hormonal evolution was noticed. Regarding glucose metabolism, 12, 16.7, and 20% of the patients presented deterioration in glucose metabolism at the first, second, and third year of follow-up respectively. The respective percentages for dyslipidaemia were 26, 43, and 44% and for hypertension or blood pressure worsening were 38, 44, and 48%. After excluding those with SCS, these percentages did not alter significantly. New cardiovascular events or fractures were recorded in 7.8% of the patients.
Conclusions
The vast majority of AIs involved benign, non-secretory masses. Mass enlargement was rare. More than one-third of patients developed hypertension or their lipid profile worsened, while one fifth showed deterioration in glucose metabolism, irrespectively of the presence of SCS.

Prevalence of hypercortisolism in type 2 diabetes patients: a meta-analysis

Charlotte Steffensen[1], Alberto Pereira[2], Olaf M Dekkers[2,3] & Jens Otto Jørgensen[1]
[1]Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark; [2]Department of Endocrinology/Epidemiology, Leiden, The Netherlands; [3]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark.

Background
Type 2 diabetes (T2D) and hypercortisolism associated with Cushing's syndrome (CS) share clinical characteristics such as hypertension, dyslipidaemia, hyperglycaemia, and obesity. Several studies have recorded a relatively high prevalence of hypercortisolism in T2D, which may have therapeutic implications. The aim of this systematic review and meta-analysis was to assess the prevalence of hypercortisolism in T2D patients.
Methods
Original articles assessing the prevalence of endogenous CS in T2D were eligible. A search was performed in SCOPUS, MEDLINE, and EMBASE. Data were pooled in a random effects logistic model.
Results
Fourteen articles were included, with a total of 2827 T2D patients. The reported prevalence of hypercortisolism in T2D ranged between 0 and 12.1%. The pooled prevalence of hypercortisolism in T2D was 3.6% (95% CI 3.0–4.4). The prevalence did not differ between studies of unselected patients and patients selected on the basis of complications such as obesity or poor glycaemic control ($P = 0.41$). Imaging in patients with hypercortisolism ($n = 102$) revealed adrenal tumour(s) and pituitary tumours in 14 and 52% respectively.
Conclusion
Hypercortisolism is a reproducible and relatively frequent finding in T2D. This observation merits continued interest.

Fludrocortisone therapy in patients with primary adrenal insufficiency: relationships with different hydrocortisone doses

Bertil Ekman[1], Marcus Quinkler[2], Beverly A Jones[3], Claudio Marelli[4], Robert Murray[5], Pierre Zelissen[6] & Jeanette Wahlberg[1]
[1]Department of Medical and Health Sciences, Linköping University, Linköping, Sweden; [2]Endokrinologie in Charlottenburg, Berlin, Germany; [3]Shire PLC, Chesterbrook, Pennsylvania, USA; [4]Shire International GmbH, Zug, Switzerland; [5]Leeds Teaching Hospitals NHS Trust, Leeds, UK; [6]University Medical Center Utrecht, Utrecht, The Netherlands.

Introduction
During recent years many authors have advocated lower hydrocortisone doses in patients with primary adrenal insufficiency (PAI) mainly due to worries for non-physiological effects like increased cardiovascular risk and bone resorption, but very little attention has been drawn to fludrocortisone dosing. Our main hypothesis was that that the higher hydrocortisone dose, the lower the fludrocortisone dose and *vice versa*.
Design
The European Adrenal Insufficiency Registry (EU-AIR) sponsored by Shire with 20 centers in Germany, The Netherlands, Sweden and the UK started enrolling patients with AI in August 2012. At enrolment, comprehensive demographic and baseline data, etiology of PAI, details of glucocorticoid replacement therapy and safety data (intercurrent illnesses, adrenal crisis) are collected electronically. This report compares baseline data of PAI (including classic adrenal hyperplasia (CAH)) treated with hydrocortisone/cortisone acetate or the new modified release hydrocortisone tablet (Plenadren) given in lower doses ≤ 20 mg or doses > 20 mg with regards to the dose of fludrocortisone.
Results
As of 5th November 2014, 345 patients with PAI, 50.1 ± 15.7 years., 221 (64.1%) F, BMI < 25 44.1%, 25–< 30 30.4% and ≥ 30 18% (missing BMI data 7.5%), were registered in EU-AIR. The distribution of hydrocortisone-equivalent doses were: $n = 179$ received ≤ 20mg, while $n = 166$ received > 20 mg (of those $n = 27$ received > 30 mg). The median fludrocortisone dose for all patients was 100 μg (range 0–300). No clear differences were found between gender, but a tendency to higher doses of fludrocortisone in males, if treated with hydrocortisone < 20 mg, was found. On the other hand, increasing doses with fludrocortisone were slightly associated with higher BMI and with hydrocortisone doses > 30 mg.
Conclusions
Our data shows that the fludrocortisone dose differs widely between patients. We could not demonstrate a general effect that higher hydrocortisone doses compensating the mineralocorticoid effect with correspondingly lower doses of fludrocortisone in PAI.

Prevalence of Cushing's syndrome at overweight and obese patients

Mehtap Navdar Basaran[1], Berçem Ayçiçek Doğan[1], Eda Demir Önal[1], Ersen Karakılıç[1], Dilek Berker[1] & Serdar Güler[1,2]
[1]Numune Education and Training Hospital Endocrinology Department, Ankara, Turkey; [2]Hitit University Medical Faculty Endocrinology Department, Çorum, Turkey.

Background
In the presence of specific symptoms and signs, Cushing's syndrome (CS) may be easily recognised. On the other hand, in overweight and obese patients without typical features of CS, diagnosis may be omitted. Our aim was to evaluate the prevalence of CS among overweight and obese patients.
Methods
We enrolled 264 overweight and obese patients who has not overt CS clinical features between January 2012 and December 2014 at Ankara Numune Education and Training Hospital. All patients were screened via overnight 1 mg dexamethasone suppression test (DST). Patients who had positive screening test has undergone other diagnostic tests.
Results
In eleven patients cortisol levels has not been supressed under 1.8 μg/dl after overnight 1 mg DST. Overnight 2 mg DST cortisol levels were supressed under 1.8 μg/dl in these four patients. The remaining seven patients (five women, two men) CS were confirmed with a standard 2-day, 2-mg DST, and high late-night salivary cortisol levels (2.6%). While six of them were ACTH-dependent CS, only one were adrenal CS. Mean BMI of CS patients was 38.3 kg/m^2, the remainings mean BMI was 38.8 kg/m^2. There was four predibaetes and two diabetes mellitus patients in CS group. Four of CS patients were hypertensive.
Conclusion
We found prevalence of CS 2.6% in overweight and obese patients whether or not accompanying overt DM or HT. Overnight 2 mg DST results yielded more specific results than 1 mg DST. Based on these results we consider screening CS with 2 mg DST in this population may be reasonable.

The clinical course of patients with adrenal incidentaloma: is it time to reconsider the current recommendations?

Darko Kastelan[1,2], Ivana Kraljevic[2], Tina Dusek[1,2], Nikola Knezevic[2], Mirsala Solak[2], Bojana Gardijan[2], Marko Kralik[2], Tamara Poljicanin[3], Tanja Skoric Polovina[2] & Zaljko Kastelan[1,2]
[1]Zagreb University School of Medicine, Zagreb, Croatia; [2]University Hospital Center Zagreb, Zagreb, Croatia; [3]Croatian National Institute of Public Health, Zagreb, Croatia.

Context
The current guidelines for the management of adrenal incidentaloma advise hormonal and radiological follow-up of the patients for 2–5 years after the initial diagnosis. However, a vast majority of adrenal incidentaloma are non-functional, benign cortical adenomas that require no treatment, so the routine application of the current strategies often results in a number of unnecessary biochemical and radiological investigations.
Objective
The aim of this study was to analyse the clinical course of patients with adrenal incidentaloma and to provide a critical review of the current management strategy of the disease. Design and setting: This was a retrospective study performed in the Croatian Referral Center for adrenal gland disorders. Patients: The study included 319 consecutive patients with adrenal incidentaloma 174 of which were followed for at least 24 months.
Results
A vast majority of patients were diagnosed with benign adrenal masses whereas in about 5% of them adrenal tumour corresponded to adrenal carcinoma or metastasis. Tumour density was found to be superior to tumour size in distinguishing benign adrenal masses from malignant tumors and pheochromocytomas. During the follow-up no patient demonstrated a clinically significant increase in tumour size. In addition, no changes, either in metanephrines and normetanephrines or in the activity of renin-aldosterone axis, were observed during the follow-up. Six patients developed SCS.
Conclusion
The study indicates that the risk of an adrenal mass initially diagnosed as benign and non-functional to become malignant or hormonally active is rather low. Therefore, the clinical management of those patients should be tailored on an individual basis in order to avoid unnecessary procedures.

An audit of the investigation and follow up of adrenal incidentalomas

Fred McElwaine, Peter Ellis, David McCance, Patrick Bell, Steven Hunter, Hamish Courtney & Karen Mullan
Royal Victoria Hospital, Belfast, UK.

An adrenal incidentaloma is defined as an adrenal mass >1 cm diameter, discovered serendipitously on radiological imaging done for another reason. They are important because a percentage will turn out to be malignant or secrete excess hormones. The aim of the current study was to ascertain if these lesions were being investigated and followed appropriately compared to American Association of Clinical Endocrinologists guidelines. All imaging reports for the calendar year 2010 were searched for the terms 'adrenal' and 'adenoma' and then checked manually. Imaging done for staging of cancer or for investigation of possible adrenal disease was excluded. 95 patients were identified. Clinical information was obtained form the Northern Ireland Electronic Care Record and clinical notes. Incidentalomas were commoner in older patients, 49 of the patients were over 70 years of age. 64 patients had no follow up imaging performed, including two patients with lesions greater than 4 cm in diameter. Three patients were under the care of endocrinology or endocrine surgery. 19 patients were referred to endocrinology. 25 patients were screened for hypercortisolaemia, 25 were screened for phaeochromocytoma, 70 patients underwent no screening for hormonal excess. 35 patients had a history of hypertension but only nine were screened for primary hyperaldosteronism. All patients referred to endocrinology or endocrine surgery were investigated according to guidelines. Only three patients not referred to endocrinology underwent appropriate investigations with screening for hypercortisolaemia or phaeochromocytoma. In summary, the majority of adrenal incidentalomas are not followed up appropriately. To address this radiology will, in future, advise endocrine referral for patients with incidentally detected adrenal lesions >1 cm in diameter.

Pasireotide (SOM230) is a multireceptor ligand somatostatin analogue with high binding affinity to somatostatin receptor subtype 5, which is predominantly expressed in ACTH-secreting pituitary adenomas. It is indicated for the treatment of adult patients with Cushing's disease (CD) for whom pituitary surgery is not an option or has not been curative. Our study evaluated the effects of pasireotide, administered for 12 months at a dose of 600–900 μg/daily, in five CD patients with persistent/recurrent disease after pituitary surgery. 24-h urinary free cortisol (UFC) levels, weight, BMI, waist circumference, blood pressure and glucose and lipid metabolism parameters were evaluated in all patients. After 6 months of therapy 4/5 patients (80%) had normal UFC levels, confirmed at 12 months. UFC normalization was associated with a slight improvement in anthropometric values and amelioration of lipid profile. In the remaining 20% of patients (1/5), normalization of UFC levels after 1 month of therapy was followed by escape from response. No patient experienced adrenal insufficiency. Hyperglycaemia due to pasireotide therapy occurred in two patients with normal glucose metabolism prior to treatment. These findings suggest that Pasireotide is an

effective treatment for most of the patients with persistent/recurrent CD after surgery.

Ectopic thyroid tissue in the adrenal gland: report of a case

Emre Bozkirli[1], Okan Bakiner[1], Sedat Belli[2], Emrah Kocer[3], Serife Ulusan[4] & Mehmet Reyhan[5]
[1]Endocrinology Department, Faculty of Medicine, Baskent University, Adana, Turkey; [2]General Surgery Department, Faculty of Medicine, Baskent University, Adana, Turkey; [3]Pathology Department, Faculty of Medicine, Baskent University, Adana, Turkey; [4]Radiology Department, Faculty of Medicine, Baskent University, Adana, Turkey; [5]Nuclear Medicine Department, Faculty of Medicine, Baskent University, Adana, Turkey.

Background
Ectopic thyroid tissue (ETT) can be explained as the localisation of thyroid parenchyma outside the orthotopic position of the thyroid gland. It can be more easily found in the tongue, neck, mediastinum, great vessels, heart and anywhere along Wölfler area, but presentation in the adrenal glands is absolutely very rare.
Case
A 39-year-old woman was referred to our Endocrinology outpatient clinic with an incidental adrenal mass which was seen in abdomen CT performed because of a nonspecific abdominal pain. Her abdomen CT revealed a 13×18 mm non-adenoma solid mass in the right adrenal gland which showed 43 Hounsfield units (HU) in precontrast series, 71 HU in portal phase and 67 HU in late phase. Endocrinologic evaluation showed that it was a non-functional tumour. Her PET CT scan revealed a hypermetabolic nodular lesion in the right adrenal gland and physiological FDG uptake in bilateral adnexal regions. The patient underwent surgery and histological examination showed thyroid tissue in the adrenal gland seen as large islets. No sign of atypia was observed. Immunohistochemical studies were negative for CK-19, HBME-1 and GAL-3. Patient's thyroglobulin level was within normal ranges as 23.80 ng/ml (1.60–55). She had a subtotal thyroidectomy history and her current neck USG revealed several benign appearing thyroid nodules with the largest as 12×9 mm in diameter. A thyroid fine needle aspiration biopsy was performed and found as benign.
Conclusion
To date, intraadrenal ETT has been reported in ten cases in the literature. Only one of them was solid like our case, and the remaining were cystic lesions. Clinicians and pathologists must be careful during distinguishing it from metastatic thyroid cancer. For our case we planned a complementary thyroidectomy to exclude a metastatic thyroid cancer. However her PET CT scan results, thyroglobulin level, benign appearance of thyroid nodules, benign biopsy result and absence of any other solid organ metastasis may propose an existence of ETT in the adrenal gland.

Prevalence of neoplasms in patients with primary aldosteronism

Katharina Lang[1,2], Katrin Weber[1], Marcus Quinkler[3], Anna Dietz[4], Henri Wallaschofski[5], Anke Hannemann[5], Oliver Vonend[6], Holger Willenberg[7], Martin Reincke[4], Bruno Allolio[1] & Stefanie Hahner[1]
[1]Department of Internal Medicine I, Endocrinology and Diabetology and Comprehensive Heart Failure Center, Wuerzburg, Germany; [2]Centre for Endocrinology, Diabetes and Metabolism, University of Birmingham, Birmingham, UK; [3]Clinical Endocrinology, Charité Campus Mitte, Charité University Medicine, Berlin, Germany; [4]Medizinische Klinik und Poliklinik IV, University Hospital Munich, Munich, Germany; [5]Institute of Clinical Chemistry and Laboratory Medicine, University Medicine Greifswald, Greifswald, Germany; [6]Department of Nephrology, Medical Faculty, Heinrich- Heine Universitaet Duesseldorf, Duesseldorf, Germany; [7]Division for Specific Endorinology, Medical Faculty, University Duesseldorf, Germany, Duesseldorf, Germany.

Context
Primary aldosteronism (PA) is the most common cause of secondary hypertension. Aldosterone excess can cause oxidative stress and respectively DNA damage *in vitro* and *in vivo* and increased levels of oxidative stress have been demonstrated in PA patients. Single case reports describe a coincidence of PA with renal cell carcinoma (RCC) and other tumours. However, so far no data on the prevalence of benign and malignant neoplasms in patients with PA exists.
Patients and methods
In the multicentre MEPHISTO study the prevalence of benign and malignant tumours was investigated in 338 patients with confirmed PA both retro- and prospectively. The SHIP cohort served as a matched control group for subjects with primary hypertension.
Results
Of the 338 patients, 120 (35.5%) had been diagnosed with a tumour at any time, 31 had more than one tumour diagnosis. Malignancy at any life stage was reported in 9.5% of PA patients and in 6.0% of hypertensive controls ($P=0.08$). Interestingly, PA patients with malignancies in history had significantly higher baseline aldosterone levels at initial diagnosis of PA ($P=0.009$) and a positive correlation between aldosterone levels and prevalence of malignancies was observed ($P=0.02$). In total, 159 neoplasms were identified in the PA patients, which were benign in 62% and malignant in 24% of cases. RCC was diagnosed in five patients (13% of all malignancies) and 80% of RCC patients had been diagnosed with renal cysts prior to tumour diagnosis. The relation between tumour formation and aldosterone levels was most abundant in PA patients with RCC.
Conclusion
In this cohort of PA patients a trend towards an increased lifetime prevalence for malignancies was observed which was particularly obvious for RCC and correlated significantly with baseline aldosterone levels.

Outcomes of short synacthen test in a university teaching hospital: are baseline and time 30 min sufficient?

Mohamed Ahmed[1], Gunness A[1], Rakovac-Tisdall A[2], Cullen E[1], Barnwell N[1], Neary C[1], Boran G[2], Gibney J[1] & Sherlock M[1]
[1]Department of Endocrinology, The Adelaide and Meath Hospital incorporating the National Children's Hospital, Tallaght, Dublin, Ireland; [2]Department of Chemical Pathology, The Adelaide and Meath Hospital incorporating the National Children's Hospital, Tallaght, Dublin, Ireland.

Introduction
Short synacthen test (SST) has become the standard method of assessing the hypothalamic–pituitary–adrenal (HPA) axis. However, there are still variances in practice with regards to performing and interpreting this test in particular the need for measuring cortisol level at both time 30 and 60 min.
Methods
A retrospective review of 500 consecutive SST performed at a University teaching Hospital in Dublin between 2005 and 2012. Serum cortisol was measured at time 0, 30, and 60 min following synacthen. A cortisol level of >500 nmol/l was considered adequate to out rule adrenal insufficiency.
Results
Out of 500 patients, 297 (59.4%) were females, and the average age was 57.4±19.3 years. 215 (43%) of subjects had at least one random cortisol level checked in the preceding 6 months prior to the synacthen test date, and the mean random cortisol for those who passed the test was 367.6±195.7 nmol/l compared to 133.5±81.8 in those who failed it, $P<0.01$. 225 (45%) of patients had at least one low serum sodium (<135 nmol/l) during the 6 months prior to test. Hyponatraemia was more prevalent in those who failed the test compared to those with adequate cortisol response (58% vs 43%, $P<0.05$).
438 (87.6%) patients passed their SST at both time 30 and 60 min and 53 (10.6%) failed it. In nine cases only (1.8%), the peak value of >500 nmol/l was achieved at time 60 but not at time 30 min.
Conclusion
Our data shows that patients with low random cortisol and hyponatraemia in the 6 months prior to the SST are likely to fail it. Measuring the baseline and time 30 min cortisol will lead to the correct diagnosis in over 98% of cases. Checking cortisol level at time 60 is of little added value in the majority of cases.

Functional muscle capacity and daily physical activity deficits in patients with endogenous Cushing's syndrome

A Assimakopoulou[1], Z Louvaris[2], M Balomenaki[1], N Chynkiamis[2], M Tzanela[1], I Vogiatzis[2] & S Tsagarakis[1]
[1]Department of Endocrinology, Diabetes and Metabolism 'Evangelismos Hospital', Athens, Greece; [2]Department of Physical Education and Sports Science, National and Kapodistrian University, Athens, Greece.

Cushing's syndrome (CS) is a disease entity that through hypercortisolism affects all body's tissues leading to increased morbidity, decreased quality of life and mortality. Muscles are among the tissues primarily affected. However, data on the impact of endogenous hypercortisolism on functional muscle capacity and daily physical activity levels are scarce. We studied 23 subjects with endogenous CS (mean age: 40.73 ± 2.17 years) and 22 healthy aged and sex matched controls. Assessment of the degree of hypercortisolism was based on cortisol day-curve, midnight cortisol and 24 h urine cortisol levels (UFC). Body composition was measured by bioelectrical impedance method (BIA). Functional capacity was assessed by the 6-min walking distance test (6MWT) and by quadriceps muscle strength and endurance during maximal isometric voluntary contraction test (QMVC). Respiratory muscles strength was assessed during maximal inspiratory pressure (MIP) and maximal expiratory pressure (MEP) manoeuvres. Daily physical activity in terms of number of steps (steps/day) and body movement acceleration (VMU/min) was recorded by a triaxial accelerometer (Actigraph GT3X) during 7 consecutive days. The fat mass was greater in CS patients compared to controls ($P=0.005$). No differences were found between the two groups in the parameters of MIP ($P=0.79$) and MEP ($P=0.66$). Muscle force and endurance were significantly compromised in patients with CS ($P=0.04$). Six minute walking distance covered was lower in CS group ($P<0.001$). In addition, 6MWT was well correlated with time lapsed since diagnosis ($P=0.02$). Daily physical activity levels were lower in CS group compared to controls (steps/day, $P=0.0001$, and VMU/min, $P=0.0001$). Finally, there was a strong negative correlation between daily physical activity in terms of body movement acceleration (VMU/min) and biochemical indices of hypercortisolism. In conclusion, endogenous hypercortisolism has a profound negative influence on various parameters related to functional capacity and daily physical activity and these measurements may be a useful tool.

Metabolic abnormalities in patients with nonfunctional adrenal incidentaloma: random or causal?

Alina Daniela Belceanu[1], Ioana Armasu[1], Oana Cirdei[1], Felicia Crumpei[2], Cristina Preda[1], Letitia Leustean[1], Didona Ungureanu[3], Voichita Mogos[1] & Carmen Vulpoi[1]
[1]Endocrinology Department, University of Medicine and Pharmacy Gr. T. Popa, Iasi, Romania; [2]Radiology Department, University of Medicine and Pharmacy Gr. T. Popa, Iasi, Romania; [3]Laboratory Department, University of Medicine and Pharmacy Gr. T. Popa, Iasi, Romania.

Introduction
With a prevalence of 0.5–2% in computed tomography series, incidentally diagnosed nonfunctional adrenal tumours (NAI) become more and more common in clinical practice. It is not clear if the higher frequency of NAI in patients with metabolic syndrome is causal or random.
Patients and methods
We retrospectively analysed patients diagnosed with adrenal tumors on computed tomography in 1 year interval (January–December 2014). Including criteria was an incidentally discovery. Excluding criteria were known malignancies and signs or symptoms of hormone excess which could determine the imagistic investigation, as well as subclinical disease, with adrenal axis modifications.
Results
Study group consisted in 48 patients (40 females, eight males), aged between 31 and 80 years (mean age 59 ± 10.7). Mean BMI was 29.6 ± 5.9 kg/m^2: 12 patients with normal weight, three overweight and 33 obese. Arterial hypertension was diagnosed in 43 patients (89.58%), diabetes or impaired glucose tolerance in 25 patients (52%) and hypercholesterolemia in 45 patients (93.75%). A significant positive correlation between BMI, glucose ($r=0.69$, $P<0.05$), total cholesterol ($r=0.74$) and systolic blood pressure ($r=0.98$) values was recorded. Cortisol remained within normal limits, but a slight positive correlation with cholesterol ($r=0.38$), systolic blood pressure ($r=0.2$), glucose ($r=0.25$) and BMI ($r=0.35$) was observed.
Conclusions
It is still a matter of debate whether NAI increases the risk of metabolic syndrome, having some degree of autonomous adrenal function, with subtle modifications before measurable changes of adrenal axis. Although the retrospective nature of our data did not allow us to draw any conclusions about the cause of increased prevalence of metabolic abnormalities, we suggest that some degree of adrenal autonomy – not recognised by current methods – is responsible for increased hormonal secretion and increased metabolic risk.

Acute adrenal insufficiency as a first sign of metastatic pulmonary carcinoma

Adina Manolachie[1], Constantin Volovat[2], Cristina Grigorescu[3], Gina Eosefina Botnariu[4], Bogdan Gafton[5], Ioana Armasu[1], Letitia Leustean[1] & Carmen Vulpoi[1]
[1]Department of Endocrinology, University of Medicine and Pharmacy 'GR. T. Popa', Iasi, Romania; [2]Departament of Medical Oncology, Iasi, Romania; [3]Department of Thoracic Surgery, University of Medicine and Pharmacy 'GR. T. Popa', Iasi, Romania; [4]Department of Diabetes, Nutritional and Metabolic Diseases, University of Medicine and Pharmacy 'GR. T. Popa', Iasi, Romania; [5]Regional Institute of Oncology, Iasi, Romania.

Introduction
Adrenal glands are common sites for secondary lesions derived from malignant tumours (lymphoma, melanoma, renal, breast, colon, and bronchopulmonary cancer). Patients with adrenal secondary lesions are typically asymptomatic but 1% may present with adrenal insufficiency as a first manifestation. We report the cases of two males with lung adenocarcinoma, first presented with acute adrenal insufficiency.
Cases presentation
Case 1: LC, 65 years old, was hospitalised for acute asthenia, anorexia, severe digestive disorder, weight loss, and hypotension, associated with hypokalaemia. Adrenal insufficiency was confirmed by increased ACTH (344 pg/ml) and low-normal cortisol (6.38 μg/dl). Steroid substitution was started with amelioration of the general status. Abdominal imagery (ultrasonography and CT) revealed enlarged adrenals and a probable secondary hepatic lesion. Liver biopsy suggested a pulmonary adenocarcinoma metastasis, for which chemotherapy was started, with favorable evolution.
Case 2: BV, 57 years old, heavy smoker and drinker, decompensated, after an intervention for Dupuytren retraction, with a primary adrenal insufficiency confirmed by the biological data. Steroid substitution was started with a good initial evolution but after 3 months he stopped the treatment and was hospitalized with adrenal crisis (cortisol <1 μg/dl). Intensive treatment was efficient but the persistence of anorexia, asthenia, and inflammatory syndrome suggested a severe underlying cause. Pulmonary radiography showed a right apical lung nodule confirmed by thoraco-abdominal CT, which also revealed bilateral adrenal invasion. Pulmonary biopsy confirmed poorly differentiated adenocarcinoma and chemotherapy schema was proposed.
Conclusions
The frequency of adrenal metastasis of primary lung cancer increases with disease progression, from 10 to 40%. However, clinical manifestations of adrenal insufficiency are significantly less frequent, probably because a destruction of more than 90% of adrenal cortex is needed for clinical symptoms. Adrenal crisis was, in our two cases, the first symptom of advanced pulmonary cancer, leading to its diagnostic and therapeutic solutions.

Marked hypercholesterolaemia caused by mitotane adjuvant chemotherapy for adrenocortical carcinoma

Banu Sarer Yurekli, Nilufer Ozdemir Kutbay, Ilker Altun & Gokhan Ozgen
Endocrinology Department, Ege University Faculty of Medicine, Izmir, Turkey.

Aim
Mitotane (o,p′-DDD) has been used to treat adrenocortical carcinoma (ACC) for several decades. Mitotane is often given in adjuvant setting after surgical resection of ACC and treatment usually lasts 2–3 years to reduce ACC recurrence. The use of mitotane is associated with multiple adverse effects. We herein report a case of marked hypercholesterolemia in a man receiving mitotane as adjuvant chemotherapy for ACC.
Case
A 64-year-old man was admitted to our Endocrinology Department with the laboratory findings of adrenal insufficiency. Mitotane was started as adjuvant chemotherapy for ACC by the Oncology department. With the usage of 4 g mitotane for 25 days, laboratory results were as follows: ACTH: 298 pg/ml, cortisol: 5.7 µg/dl, DHEAS: 7.3 µg/dl. Hydrocortisone was started as 30 mg/day. As Potassium levels were normal with the hydrocortisone treatment, fludrocoritsone was not added to the treatment. Interestingly, the patient developed marked hyper-LDL cholesterolaemia at a level of 236 mg/dl following introduction of mitotane. Before the mitotane treatment, LDL level of the patient was 139 mg/dl. After mitotane treatment, total cholesterol was 370 mg/dl, triglyceride was 160 mg/dl, HDL was 94 mg/dl. TSH level of the patient was 1.7 µIU/ml. There was no findings of hypogonadism. There was no medical history of primary familial and secondary hyperlipidaemia. Low dose atorvastatin was started for hyperlipidaemia.
Discussion
In the literature, 21 Cushing's syndrome patients treated with mitotane exhibited increased cholesterol level (primarily LDL cholesterol) with an average of 68% increase. Mitotane may increase cholesterol by inhibiting the formation of the oxysterol. It may decrease cholesterol catabolism by inhibiting the production of cholesterol oxidase. Mitotane may be able to stimulate the activity of HMG-CoAreductase strongly enough to significantly increase LDL-cholesterol synthesis.
Conclusion
We recommend careful monitoring of serum cholesterol level following the introduction of mitotane chemotherapy.

Fasting during Ramadan in patients with adrenal insufficiency

Melika Chihaoui, Wafa Grira, Fatma Chaker, Meriem Yazidi & Hedia Slimane
University Hospital La Rabta, Tunis, Tunisia.

Long fasting in patients with adrenal insufficiency could cause hypotension, dehydration or hypoglycaemia. No studies evaluated these risks and there is no recommendations about fasting for these patients. The aim of our study was to evaluate the potential risks of fasting during the month of Ramadan in patients with adrenal insufficiency.
Subjects and methods
It is a cross sectional study that concerned 125 subjects (97 women and 28 men, mean age = 47.8 years) followed up and treated for adrenal insufficiency (primary in 34 cases and secondary in 91 cases). These patients were questioned about fasting during the last month of Ramadan; changes in the modalities of the treatment, eventual complications, number of fasted days, and were evaluated about their disease knowledge. The mean duration of daily fast during Ramadan 2014 in Tunis was about 14 h.
Results
Fasting was allowed by the physician in 11 cases (8.8%). 59 patients tried to fast: 36 patients (28.8%) could complete the fast of the whole month and 23 patients (18.4%) stopped fasting for fatigue in 20 cases, hypoglycaemia in four cases, dehydration (thirst, hypotension) in 12 cases. Four patients were hospitalized for acute adrenal insufficiency. Compared to patients who could fast the whole month, patients who stopped fasting had a more advanced age (49.3 years vs 47.1 years), more frequently a primary adrenal insufficiency (27% vs 17%) and a longer duration of the disease (10.6 years vs 8.7 years).
Conclusion
Fasting during Ramadan can be complicated especially in aged patients, a longstanding disease and a primary origin. More studies are needed and a consensus should be established for safe fasting in patients with adrenal insufficiency.

DOI: 10.1530/endoabs.37.EP83

EP84

Awareness of adrenal crisis prevention in long-term steroid users

Muhammad Ridhwaan Salehmohamed[1,2], Mark Griffin[2], Tom Branigan[2], Martin Cuesta[1,2] & Chris Thompson[1,2]
[1]Academic Department of Endocrinology and Diabetes Metabolism, Beaumont Hospital, Dublin, Ireland; [2]Royal College of Surgeons in Ireland, RCSI, Dublin, Ireland.

Background
Patients taking corticosteroids for immune suppression are vulnerable to adrenal crisis during intercurrent illness or if steroids are stopped abruptly. Although patients on glucocorticoids for adrenal failure are routinely provided with sick day rules, we wished to ascertain whether patients on immunosuppressive steroids are appropriately counselled.
Aim
This study sets out to compare patient awareness of steroid sick day rules in endocrine and non-endocrine patients.
Methods
A 9 point questionnaire to determine knowledge of steroid sick day rules was designed. 92 patients were consecutively recruited from non-endocrine clinics – respiratory ($n=22$), rheumatology ($n=24$), gastroenterology ($n=20$) and nephrology ($n=26$). 46 patients were consecutively recruited from the pituitary clinic. All patients completed the questionnaire.
Results
Endocrine patients exhibited better steroid awareness; they were more likely to double their steroid dose when ill (76.1% vs 6.5%), to obtain parenteral steroid during vomiting (82.6% vs 27.1%), and during surgery (87.0% vs 30.4%), and were aware of the need to carry a medicalert bracelet or a steroid-aware card (82.6% vs 20.7%), $P<0.001$ for all. However the endocrine patients were at par with the non-endocrine ones in terms of knowing the need to inform their doctor of being on steroid (91.3% vs 88.0%).
Conclusion
Endocrine patients exhibited a significantly greater knowledge of precautions for steroid use. The data does highlight the lack of patient awareness of the sick day rules in patients on immunosuppressive therapy for non-endocrine conditions. Endocrinologist could assist colleagues in other specialities in awareness of steroid sick day rules.

Subclinical Cushing's syndrome: report of 17 cases

Faten Haj Kacem, Nesrine Cheikhrouhou, Nadia Charfi, Najwa Lassoued, Fatma Mnif, Mouna Mnif, Nabila Rkik & Mohamed Abid
Department of Endocrinology, Hedi Chaker Hospital, Sfax, Tunisia.

Introduction
Subclinical Cushing's syndrome refers to autonomous cortisol secretion in patients who do not have the typical signs and symptoms of hypercortisolism. This study was undertaken to describe clinical, biological and radiological features of this disease and to evaluate the clinical outcome after surgical and medical treatment.
Methods
Retrospective study conducted over a period of 12 years and including 17 patients hospitalised in our department of endocrinology for subclinical Cushing's syndrome.
Results
The average age of our patients was 58.94 years (38–77) with a sex ratio (M/F) of 1.12. The average waist circumference was 99.05 cm (range: 80–134). Obesity was found for 46% of patients, overweight for 54% of patients. The response of dexamethasone suppression test (2 mg) was altered for all patients. Urinary free cortisol was dosed for four patients (23.5%), normal in three cases (75%) and high in one case (25%). The mean level of ACTH was 20.21 ng/l (10–39.7). The adrenal CT showed an unilateral adenoma for 82%, bilateral adrenal hyperplasia for 12% and two right adrenal adenoma for 6% of cases. The repercussions of subclinical Cushing's syndrome were HTA for 47.05%, dyslipidaemia for 23.5%,

diabetes for 23.52%, impaired glucose tolerance for 29.41%, metabolic syndrome for 41.17%, obesity for 46% and hypokalaemia for 11.7% of cases. 58.8% of patients were operated, 50% of them presented adrenal insufficiency, all patients presented an improvement of anthropometric parameters and regression dyslipidaemia. 33% presented an improvement in hypertension and 28.57% presented a regression of diabetes. Conservative management was decided for 23.52% of patients, their evolution, with a mean follow of 4.75 years (3–7), showed an aggravation of diabetes for 50% and aggravation of dyslipidaemia for 50% of cases. No one presented an evolution to a Cushing. 17.64% were lost of follow up.

Conclusion

Adrenal surgery appears to be beneficial in case of pre-Cushing' syndrome for both metabolic and cardiovascular complications.

Challenges in a the management of adrenal Cushing's syndrome associated with bilateral adrenal tumours and uterine leiomyoma

Catalina Poiana[1,2], Mara Carsote[1,2], Adriana Gruia[3], Dan Peretianu[4], Ermina Gheorghiu[2], Rodica Petris[3], Sorin Paun[1,5], Anda Dumitrascu[2] & Dan Hortopan[2]

[1]C. Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]C.I.Parhon National Institute of Endocrinology, Bucharest, Romania; [3]Medlife Medical Centre, Bucharest, Romania; [4]SCM Povernei Medical Centre, Bucharest, Romania; [5]Floreasca Emergency Hospital, Bucharest, Romania.

Introduction

The Cushing's syndrome associated bilateral adrenal tumours comprise a wide area of diagnosis; the therapeutic approach is challenging since unilateral intervention might involve persistent hypercotisolemia, and bilateral adrenalectomy induces chronic adrenal insufficiency. The adrenal vein catheterism is not available in many countries.

Case report

50-year old non-smoker female has the following medical history: 2 years ago she presented to endocrinology because of weight gain with android features. On admission, diabetes mellitus and high cholesterol were found. The plasma ACTH was low (of 3 pg/ml), and the 2 mg of 2 days dexametasone suppression test showed no suppression of plasma morning cortisol. The computed tomography showed a right adrenal tumour of maximum 3 cm diameter and a smaller left adrenal tumour. Laparoscopic right adrenalectomy was performed. After surgery, no sign of adrenal insufficiency was found, so no glucocorticoid substitution was necessary. The blood levels remained normal. Six months after surgery, the morning plasma cortisol after 2 mg or 2 days dexametasone was 1.13 μg/dl. After six more months, the patient accused asthenia, and presented hemorrhagic diathesis as skin bruising, and three episodes of menopausal metrorrhagia. Also, the Cushing syndrome was suspected, the adrenal axes remained normal (morning cortisol of 11.9 μg/dl, ACTH of 7 pg/ml) but the left adrenal tumour increased at 4 cm maximum diameter; the pelvic ultrasound revealed an uterine leiomyoma of 2.82 cm. Endometrial haemostasis was performed by biopsy. 18 months after surgery the patient felt well, and the dexamethasone suppression test was still normal. Close follow-up is necessary.

Conclusion

Unilateral adrenalectomy in the bilateral adrenal tumours underling Cushing's syndrome may involve the syndrome remission but life follow-up is necessary because the risk of syndrome relapsing (in case of bilateral macronodular hyperplasia); the lack of adrenal insufficiency after first intervention is the marker of bilateral involvement.

Spectrum of presentation and aetiology of adrenal haemorrhage: a case series

John Joseph McCabe[1], Colm Mac Eochagain[1], Donal O'Connor[2], James Gibney[1,3], Kevin Conlon[2] & Mark Sherlock[1,3]

[1]Department of Endocrinology, Adelaide and Meath Hospital incorporating the National Children's Hospital, Tallaght, Dublin, Ireland; [2]Department of Upper Gastrointestinal and Hepatobiliary Surgery, Adelaide and Meath Hospital incorporating the National Children's Hospital, Tallaght, Dublin, Ireland; [3]Department of Endocrinology, Trinity College, Dublin, Ireland.

Introduction

Adrenal haemorrhage is rare. There is a broad spectrum of clinical presentation and aetiology of the condition making it challenging to diagnose. Endocrine dysfunction frequently complicates cases of adrenal haemorrhage. Failure to recognise the condition or its complications can lead to devastating consequences for the patient.

Methods

All patients referred to our centre with adrenal haemorrhage between 2004 and 2014 were included in this retrospective study. The clinical notes, laboratory & radiological investigations of each case were recorded.

Results

Ten patients with adrenal haemorrhage were identified. Seven patients presented with acute abdominal pain. Adrenal haemorrhage was an incidental histological finding in two patients and an incidental radiological finding in one patient. Three of ten patients were diagnosed with hypoadrenalism. Six of ten patients underwent elective adrenalectomy following haemodynamic stabilisation with no associated operative mortality.

Conclusion

The aetiology of adrenal haemorrhage is variable and identifying the underlying diagnosis can be challenging. The appropriate management of the condition requires an awareness of the potential endocrinological consequences of adrenal dysfunction including glucocorticoid deficiency and catecholamine hypersecretion. In our centre elective adrenalectomy following endocrine investigations and haemodynamic stabilisation rather than emergency adrenalectomy is preferred. In this series there was no operative mortality associated with this approach, which is recognised as being elevated in patients operated on acutely for adrenal haemorrhage.

A single-centre 10-years experience with pasireotide in Cushing's disease: patients characteristics and outcome

Laura Trementino[1,2], Grazia Michetti[1,2], Alessia Angeletti[1,2], Giorgia Marcelli[1,2], Carolina Concettoni[1,2], Marina Cardinaletti[1,2], Barbara Polenta[1,2], Marco Boscaro[1,2] & Giorgio Arnaldi[1,2]

[1]Division of Endocrinology, Polytechnic University of Marche, Ancona, Italy; [2]Endocrinology Unit, Department of Medicine DIMED, University-Hospital of Padua, Padua, Italy.

Introduction

Pasireotide is the first pituitary-directed drug approved for Cushing's disease (CD). We report our 10-years experience with pasireotide in CD reviewing and analysing data about all the patients treated with pasireotide at our referral centre both in randomised trials and in clinical practice.

Patients and methods

Twenty active CD patients were treated. Fourteen patients were treated with pasireotide in randomised trials and six patients were treated with pasireotide s.c. (Signifor; Novartis AG) in clinical practice. The mean treatment duration was 20.5 months (median 9 months; range, 3–72 months). The mean daily s.c. dose was 1333 μg (range, 1200–1800 μg) at the beginning of treatment as well as 1366 μg at last follow-up (range, 600–2400 μg).

Results

Urinary free cortisol (UFC) levels mean percentage change ($\pm$S.D.) at last follow-up was –40.4% ($\pm$35.1; range, 2–92%; median reduction 33.3%) with a normalisation rate of 50% (10/20). UFC normalisation occurred by months 1–3 in the majority of patients (8/10; 80%). Ten patients achieved sustained normalised late night salivary cortisol (LNSC) levels during treatment. LNSC normalisation was associated with UFC normalization (7/10 patients). Serum cortisol and plasma ACTH significantly decreased from baseline to last follow-up. Body weight decrease and blood pressure improvement during treatment were independent from UFC response. Glucose profile worsening was observed in all the patients except one. The frequency of diabetes increased from 40% (8/20) at baseline to 85% (17/20) at last follow-up requiring to start medical treatment only in a half of patients (8/17).

Conclusions

Pasireotide treatment was associated with sustained biochemical and clinical benefit in about 50% of CD patients. Glucose profile alterations are a frequent complication of pasireotide treatment however this adverse event seems to be easy to manage with diet and lifestyle intervention in almost half of patients.

Low DHEAS: a sensitive and specific screening test for the detection of subclinical hypercortisolism in adrenal incidentalomas

Michael Conall Dennedy[1,4], Anand K Anamalai[1], Olivia Prankerd Smith[1], Andrew S Powlson[1], Johann Graggaber[1], Ashley Shaw[2], David J Halsall[3] & Mark Gurnell[1]
[1]Metabolic Research Laboratories, Institute of Metabolic Science, Addenbrooke's Hospital, University of Cambridge and National Institute for Health Research Cambridge Biomedical Research Centre, Cambridge, UK; [2]Departments of Radiology, Addenbrooke's Hospital, University of Cambridge and National Institute for Health Research Cambridge Biomedical Research Centre, Cambridge, UK; [3]Departments of Clinical Biochemistry, Addenbrooke's Hospital, University of Cambridge and National Institute for Health Research Cambridge Biomedical Research Centre, Cambridge, UK; [4]Discipline of Pharmacology & Therapeutics (MCD), National University of Ireland, Galway, Galway, Ireland.

Subclinical hypercortisolism (SH) occurs in 5–30% of incidentally-detected adrenal adenomas (AIs). Common screening tests for ACTH-independent hypercortisolism have significant false positive rates, mandating further investigations that are both time and resource intensive. We investigated whether a low basal DHEAS level is a sensitive and specific screening test for the detection/exclusion of SH in patients with newly-diagnosed AI. We recruited 185 consecutive patients with AI referred to our clinic between 2006 and 2013 were screened for clinical and biochemical evidence of adrenal medullary and cortical (1 mg dexamethasone suppression test, 24 h urinary free cortisol (UFC), serum DHEAS, plasma renin and aldosterone) hyperfunction. All positive dexamethasone suppression (>1.8 μg/dl (50 nmol/l)) and UFC ($>$ upper limit of reference range) results were further investigated, and we diagnosed SH when at least two of the following criteria were met: raised UFC, raised midnight serum cortisol, 48 h dexamethasone suppression test cortisol >1.8 μg/dl (50 nmol/l). Plasma ACTH was <10 pg/ml (2.2 pmol/l) in all patients with SH. At presentation, 29 patients (16%) were diagnosed with SH. We calculated an age-and gender-specific DHEAS ratio (derived by dividing measured DHEAS by the lower limit of the respective reference range) for all patients in the cohort and found that a ratio ≤ 1.12 was a sensitive (100%) and specific (91.9%) screening test for the diagnosis of SH. In comparison, a cortisol level after a 1 mg dexamethasone suppression test of 1.9 μg/dl (53 nmol/l) was a sensitive (100%) screening test for SH, but had lower specificity (82.9%). 24 h UFC lacked sensitivity (69%) and specificity (68%). A single basal measurement of DHEAS offers comparable sensitivity and greater specificity to the existing gold-standard 1 mg dexamethasone suppression test for the detection of SH in patients with AIs.

Ultrasound importance in adrenal incidentalomas diagnostication and management

Yllka Themeli[1,2], Myftar Barbullushi[2,3], Aqif Gjokutaj[2,3], Gjergji Dilo[4] & Lindita Hoxha[4]
[1]'IKEDA' Hospital, Tirana, Albania; [2]DC 'Med.al', Tirana, Albania; [3]UHC 'Mother Teresa', Tirana, Albania; [4]DC 'Dermolife', Tirana, Albania.

Background
Adrenal incidentalomas are detected in about 0.1% of general health screening with ultrasound, in 0.4–1.9% among patients evaluated for nonendocrinologic complaints, in ~4.4% among patients who have a previous cancer diagnosis. Majority are benign, but careful evaluation is warranted to rule out carcinoma and functional adenomas.
Aim
The purpose of presenting these cases is to highlight the importance of ultrasound examination in diagnostication and management of adrenal incidentalomas.
Materials and methods
We have prescribed six patients presenting in our clinic during a 3-year period, which resulted with adrenal incidentaloma in abdominal ultrasound. They underwent specific blood tests, depending on the clinical situation.
Results
Case 1 was a 41-year old male, presenting with hyperglycemia found to have Conns' syndrome with aldosterone producing adenoma on routine ultrasound. Case 2 was a 21-year old boy, who had phaeochromocytoma misdiagnosed as anxiety disorders. Case 3 was a 49-year old female, presenting amenorrhoea which was mistaken as menopause, and minimal hirsutism which was mistaken as postmenopausal hirsutism. She resulted with adrenal androgen secreting adrenocortical carcinoma. Case 4 was a 59-year old hypertensive male, presenting with fever had phaeochromocytoma with catecholamine excess, producing fever. Case 5 was isolated adrenal tuberculosis, who presented with chronic diarrhea. Case 6 was a 43-year old female, presenting with drug-resistant hypertension and diabetes, found to have Cushing's syndrome.
Conclusion
Adrenal incidentalomas are common, most are non-secreting adenomas. When a hormonal disorder is suspected clinically, specific blood tests for Cushing, Conn and/or pheaochromocytoma, are indicated.

RNALDO: the effects of blocker withdrawal on renin and angiotensin

Tomas Griffin[1,3], Gerard A Browne[1], Paula M O'Shea[2] & Michael Conall Dennedy[1,3]
[1]Discipline of Pharmacology & Therapeutics, NUI Galway, Galway, Ireland; [2]Department of Clinical Biochemistry, Galway University Hospital, Galway, Ireland; [3]Department of Endocrinology, Galway, Ireland.

Primary hyperaldosteronism (PHA) prevails in up to 20% of individuals with essential hypertension, but often presents a diagnostic challenge due to difficulty in interpreting the aldosterone renin ratio (ARR) largely due to anti-hypertensive medication interference. Interpretation of the ARR in the context of beta blockers presents a particular challenge and may produce false positive results due to renin suppression. We investigated the effects of beta blocker withdrawal on ARR in a cohort taking long term beta blocker therapy for blood pressure (BP) control. Hypertensive individuals with suboptimally controlled BP on a combination of beta blockers, thiazide diuretics and ACEi/ARB were recruited and followed over 8 weeks. Beta blockers were withdrawn at the first visit. Serial measurements of BP were performed and patients had blood drawn serially for measurement of plasma renin activity (PRA), renin mass, aldosterone and electrolytes. BP was optimised at each visit by maximising non-renin-suppressing antihypertensive agents. Main outcome measures were ARR, renin and aldosterone concentrations following beta-blocker withdrawal. 50 individuals were enrolled under informed consent and ethical approval. Interpretation of ARR on beta-blockade gave a false positive diagnosis of PHA in 22%. Beta blocker withdrawal produced a rapid (>50%) recovery of PRA ($F=28.6$; $P<0.0001$) and renin mass ($F=18.4$; $P=0.0007$) which reached significance within 2 weeks of withdrawal and return of the ARR to normal range in all individuals ($F=29.3$; $P=0.0003$). Aldosterone remained unchanged throughout the duration of the study ($F=2.5$; $P=0.1$). BP remained unchanged throughout the duration of the study ($F=1.0$; $P=0.4$). Both renin mass ($r^2=0.67$; $P<0.05$) and PRA ($r^2=0.69$; $P<0.05$) were inversely correlated with beta blocker dose. While clean screens using the ARR are seldom possible, our results demonstrate a high false positive rate for PHA in those taking beta blockers. Beta blocker withdrawal was well tolerated, BP control easily optimised and the ARR more accurate within 2 weeks of withdrawal. We provide convincing data to support beta blocker withdrawal, 2 weeks in advance of screening for PHA.

Long-term outcome from unilateral adrenalectomy in patients with primary aldosteronism

Mark J Hannon, Candy Sze, Robert Carpenter, Laila Parvanta, Matthew Matson, Anju Sahdeve, Maralyn R Druce, Mona Waterhouse, Scott A Akker & William M Drake
St Bartholomew's Hospital, London, UK.

Primary aldosteronism (PA) is an important cause of hypertension which confers significant cardiometabolic risk. In approximately half of cases, the cause is a surgically resectable unilateral aldosterone-producing adrenal adenoma, making PA the most common potentially curable form of hypertension. Despite this, long-term data on surgical outcomes that could be used to guide discussions with patients are sparse. Here, we report on clinical outcomes several years post-adrenalectomy in those patients from our prospectively studied cohort who underwent surgery.
Of 120 consecutive patients investigated for PA, 51 underwent laparoscopic-assisted adrenalectomy. Blood pressure, number of antihypertensive medications, and serum potassium were recorded before adrenalectomy, and at the time of most recent follow-up. Recumbent renin and aldosterone were measured ≥ 3 months after surgery, to determine if PA had been biochemically cured. This was performed in the absence of interfering antihypertensive medication, and with oral potassium supplementation given as necessary.

The cohort consisted of 31 males and 20 females, median age 54 (range 30–83). Median duration of follow up was 48 months (range 3–154). Median pre-operative blood pressure (on medication) was 160/95 (range 120/80–250/150). Overall, blood pressure significantly improved post-operatively, to a median of 130/80 (range 110/70–160/93, $P<0.0001$). Median serum potassium level increased from 3.2 mmol/l pre-operatively (range 2.3–4.7) to 4.4 mmol/l post-operatively (range 3.3–5.3, $P<0.0001$). Median number of antihypertensive medications used improved from median 3 pre-operatively to median 1 post-operatively ($P<0.0001$). 3/51 patients (5.9%) did not achieve any improvement in blood pressure post-operatively; however, histological examination of these patients' removed adrenal glands confirmed the presence of fully excised, typical Conn's adenomas in each case.

Laparoscopic-assisted unilateral adrenalectomy provides excellent long term improvements in blood pressure control, polypharmacy, and hypokalaemia. These data may help inform discussions with patients about possible surgical outcomes.

Phaeochromocytoma-the Mater hospital experience over the past two decades

Bernadette Monaghan, Sinead Egan, Gerry McEntee & Maria Byrne
Mater Misericordiae University Hospital, Dublin, Ireland.

Phaeochromocytoma is a rare neuroendocrine tumour. Incidence has been quoted at two to eight cases per million people. This study reviews all cases of surgically resected phaeochromocytoma in a large tertiary referral centre since 1996 with particular focus on preoperative care. 22 patients were diagnosed with Phaeochromocytoma with average age at diagnosis of 47 years. 13.6% ($n=3$) of patients had malignant phaeochromocytoma. Two patients had confirmed neurofibromatosis Type 1. The remaining cases were deemed sporadic and are awaiting genetic analysis. In terms of pre-operative optimisation, medical treatment involves alpha blockade initially +/− beta blockade if tachycardic. It took 9.7 ± 8.2 days on average to obtain adequate alpha blockade. The mean dose of phenoxybenzamine used was 88.1 ± 74.1 mg. The mean preoperative blood pressure on the day of surgery was $122/71\pm19/12$ mm/Hg. The average postoperative blood pressure which was measured in recovery was $109/63\pm15/10$ mm/Hg. The mean heartrate pre-operatively was 74 ± 16 bpm corresponding with a postoperative value of 75 ± 14 bpm. Of the 22 patients that underwent surgical resection, 81.8% of patients ($n=18$) required ITU/HDU care post-op with an average length of stay of 3.1 ± 1.6 days. 50% ($n=11$) required inotropic support post-op for an average of 1.9 ± 1.1 days. In terms of immediate post-op complications, hypotension was the most common. One patient (known catecholamine induced cardiomyopathy) developed a cardiac arrest during anaesthesic induction. There was one case of post op hypertension requiring nitrate infusion. Mortality related to surgery was nil. One patient has died secondary to complications of metastatic phaeochromocytoma, the other patient died of an unrelated condition. In the 22 cases described, each presented a unique set of management challenges. This report showed that once diagnosed, intensive medical stabilisation is required to prevent adverse surgical outcomes.

Combined effects of sirolimus and mitotane in the inhibition of growth in human adrenocortical carcinoma cells

Maria Cristina De Martino[1,2], Peter M van Koetsveld[1], Richard A Feeldes[1], Steven W J Lamberts[1], Wouter W de Herder[1], Annamaria Colao[2], Rosario Pivonello[2] & Leo J Hofland[1]
[1]Division of Endocrinology, Department of Internal Medicine, Erasmus MC, Rotterdam, The Netherlands; [2]Dipartimento di Medicina Clinica e Chirurgia Endocrinologia e Metabolismo Università degli Studi di Napoli Federico II, Naples, Italy.

Adrenocortical cancer (ACC) is a rare cancer with poor prognosis and scant treatment options. Mitotane alone, or in combination with cytotoxic chemotherapy, represents the referral current treatment for patients with unresectable ACC. Recent studies have shown that mTOR inhibitors suppress growth of ACC cells. This study aimed at evaluating the effects of mitotane in combination with mTOR inhibitors. In H295 and SW13 cells we tested the effects of a 6 day treatment with increasing doses of mitotane in the presence or absence of selected doses of sirolimus on cell proliferation as measured by the total DNA content. The tested doses of mitotane ranged between 10^{-7}–10^{-5} M in both H295 and SW13 cells, sirolimus was tested at concentrations of 5×10^{-9} and 10^{-6} M in H295 and 5×10^{-11} and 10^{-10} M in SW13. In H295, mitotane significantly inhibited cell proliferation at all concentrations tested, with an IC50 of 4.5×10^{-6} M and a maximal inhibition of 87% as compared with vehicle-treated controls ($P<0.001$). In SW13, mitotane significantly inhibited cell proliferation at concentrations higher than 2.5×10^{-6} M, with an IC50 of 1.6×10^{-5} M and a maximal inhibition of 81% as compared with vehicle-treated controls ($P<0.001$). In both H295 and SW13 sirolimus significantly inhibited cell proliferation at both concentrations tested and when combined with mitotane, it showed statistically significant additive effects. This additivity was observed only with low mitotane doses (between 10^{-7} and 5×10^{-6} M). Using mitotane doses higher than 5×10^{-6} M the cell proliferation inhibition was already nearly maximal and no significant additive effects could be observed. The current study demonstrates that sirolimus has additive antiproliferative effects when combined with low mitotane doses. These doses correspond to concentrations lower than the therapeutic range of mitotane. If this effect can also be achieved *in vivo* our data suggest that the addition of sirolimus to mitotane might be useful in ACC patients when the therapeutic range of mitotane range is not reached.

Linear growth and endocrine function in patients with ataxia telangiectasia; a cohort of 13 patients in Qatar

Mohammad Ehlayel[1,2] & Ashraf Soliman[1,2]
[1]Hamad Medical Centre, Doha, Qatar; [2]Weill Cornell Medical College, Doha, Qatar.

Introduction

Ataxia telangiectasia (AT) is a rare, genetic, primary immune deficiency disease characterised by immunodeficiency and neurological manifestations, with increased tendency to infection, malignancy, and autoimmune diseases. Both growth delay and endocrine abnormalities are occasionally reported in these patients.

Aim

To study linear growth in relation to endocrine and immune functions in a cohort of children with AT.

Patients and methods

We studied growth parameters (height (Ht), weight, BMI and measured the HtSDS) of 13 patients (age 7.7 ± 3.5 years) with AT in relation to their mid-parental HtSDS. We measured their biochemical (serum calcium (Ca), phosphorus (PO_4), alkaline phosphatase (ALP), alanine transferase (ALT), ferritin, creatinine and albumin), endocrine (free thyroxine (FT_4), TSH, IGF1, 8 AM cortisol) and immune functions (IgG, IgM and IgA antibodies). Growth data were correlated to hormonal and immune data.

Results

Presented in table.

	HtSDS	BMI (kg/m^2)	MPH-tSDS	IGF1 (μg/l)	FT_4 (pg/ml)	TSH (mIU/l)	Anti TPO (U/ml)	Albumin (g/l)	ALT (U/l)	Ferrtin (μg/l)
Mean	−1.4	15.1	−1.3	149.0	15.2	7.3	88.7	39.2	42.2	324.0
SDS	1.2	2.4	1.1	110	3.8	13.6	131	7.2	24.2	606.3
No=	13.0	13.0	13.0	8.0	13.0	13.0	13.0	13.0	13.0	9.0
Abnormal	22%	31%	38%	31%	38%	15%	31%	15%	15%	38%

All patients had normal renal function. Thirty-one percent of patients with AT had short stature (HtSDS <-2). However, their MPHtSDS denoted that their short stature is familial as 4/13 had MPHtSDS <-2. They had low BMI and two of them had low serum albumin and IGF1 denoting malnutrition. Low IGF1 (IGF1 SDS <-1.5) can be explained in part by under- nutrition or disturbed GH secretion. Elevated serum ALT and ferritin in some patients suggest immune-related inflammation in the liver. Thirty percent of patients had high TSH, two of them had low FT_4 diagnosing clinical (15%) and sub-clinical (15%) hypothyroidism. Anti-peroxidase antibodies were high in 2/13 denoting immune-related thyroid aggression. 8/13 had vitamin D deficiency (<20 ng/ml) however, their serum Ca and PO_4 levels were normal. One adolescent girl (14.5 years) had hyper-gonadotropic hypogonadism (low estradiol and high FSH) All patients had normal AM cortisol. None of the growth parameters were correlated with the immunoglobulin (IgG, IgM or IgA) levels.

Summary
Patients with AT had high prevalence of growth delay and endocrine dysfunction in the form of low IGF1 clinical and subclinical hypothyroidism and hypogonadism. Early diagnosis and management of these endocrinopathies is important or improving the prognosis of the disease.

Unusual presentation of the apparent mineralocorticoid excess, triggered by mild Cushing's disease in an adult

Andrej Zavratnik[1], Matej Zavrsnik[1], Urska Ksela[1], Evgenija Homsak[1], Antonela Sabati Rajic[2], Damien Gruson[3] & Marija Pfeifer[2]
[1]Univeersity Clinic Centre Maribor, Maribor, Slovenia; [2]University Medical Centre Ljubljana, Ljubljana, Slovenia; [3]Cliniques Universitaires St-Luc and Université Catholique de Louvain, Brussels, Belgium.

Introduction
The syndrome of apparent mineralocorticoid excess (AME), a genetic disorder, resembles findings similar to those in primary aldosteronism, but aldosterone levels are low. AME is due to deficiency in the 11-beta-hydroxysteroid-dehydrogenase-enzyme-type-2 isoform (11-beta-HSD2), which normally converts cortisol to cortisone to prevent its mineralocorticoid activity at the aldosterone-sensitive sites. The deficiency in 11-beta-HSD2 leads to marked elevation in net mineralocorticoid activity caused by unconverted cortisol.
Case report
50-years old woman was hospitalised after collapse. She had had arterial hypertension for 10 years (bisoprolol 5 mg/day, perindopril/indapamide 8/2.5 mg/day). At the presentation she was hypotensive 96/64 mmHg, mildly Cushingoid, BMI 28 kg/m^2. Initial laboratory results: s-K 2.44 mmol/l, spot u-K 56 mmol/l, blood pH 7 440. Patient's medical records revealed, that hypokalaemia had developed after 2001 and had been worsening gradually. After correction of hypokalaemia primary aldosteronism was excluded (PRA 0.015 nmol/l, aldosterone 0.22 nmol/l, after saline infusion aldosterone suppressed to 0.08 nmol/l). Cushing's disease was confirmed (s-ACTH: 5.31 pmol/l, cortisol after standard 2-day 2-mg dexamethasone test: 213 nmol/l, late evening cortisol: 157 nmol/l, pituitary MRI: 3×4 mm microadenoma, IPSS: a central-to-peripheral plasma ACTH-gradient of 17.5, and left to right ACTH-ratio of 2.37 before CRH administration). Since mild Cushing's disease couldn't explain severe hypokalaemia additional underlying cause was suspected. After exclusion of licorice ingestion and adrenocortical tumour, the AME was confirmed by undetectable free-cortison levels in urine measured by liquid-chromatography–tandem mass-spectrometry in two consecutive 24-h urine samples (free cortisol 60.44 and 61.27 nmol/l, free cortison two-times undetectable). Spironolactone was introduced. With the dose of 150 mg/day the patient is normokalaemic, and the hypertension is well controlled by additional bisoprolol 5 mg/day and perindopril 4 mg/day.
Conclusion
11-beta-HSD2 deficiency is a rare cause of hypertension and hypokalaemia. Presented case report is of special interest showing that mild Cushing's disease has unmasked the underlying enzyme deficiency. Genetic testing is in progress. Transsphenoidal microadenomectomy is planned.

DOI: 10.1530/endoabs.37.EP97

Evaluation of β-oestradiol induced DNA damage in the leukocytes of young, elderly and Alzheimer's disease patients in the comet assay

Lada Zivkovic[1], Biljana Spremo-Potparevic[1], Ninoslav Djelic[2] & Vladan Bajic[3]
[1]Department of Physiology, Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia; [2]Department of Biology, Faculty of Veterinary Medicine, University of Belgrade, Belgrade, Serbia; [3]Department of Radiobiology and Molecular Genetics, Institute for Nuclear Sciences 'Vinca', University of Belgrade, Belgrade, Serbia.

Oestrogen has very complex effects on the CNS. It protects neurons from noxious effects of β amyloid *in vitro*, ameliorates the cerebral metabolism and increases the level of acetylcholine in the basal forebrain and hippocampus. Its beneficial impact in Alzheimer disease may be attributed in part to its antioxidant activity. On the other hand, it has been demonstrated that oestrogens may exhibit genotoxic effects, especially at elevated tissue concentrations. Therefore, the aim of the present investigation was to determine wether oestradiol induces DNA damage in whole blood leukocytes from healthy young females and males, healthy elderly females and males and females and males with Alzheimer disease. All experiments were performed using the alkaline version of the Comet assay (single cell gel electrophoresis). Cell viability was determined by Trypan blue exclusion assay. A significant increase of DNA migration in the Comet assay was observed in leukocytes of all treated groups (young and elderly females, young and elderly males, females and males with Alzheimer disease) at all concentrations of oestradiol (50, 100 and 250 μM) used in this investigation. In all experiments the cell viability was over 80%. Therefore, it can be concluded that leukocytes are sensitive to oestradiol in the Comet assay regardless of gender, age and health condition of examined subjects.

Serum alanine aminotransferase and γ-glutamyltranspeptidase activities: new markers for polycystic ovary syndrome

Halime Kiliç[1], Fatma Aydin[2], Burak Uz[3], Feridun Karakurt[4], Mustafa Koroglu[5] & Ayse Kargili Carlioglu[6]
[1]Nenehatun Hospital of Gynecology and Obstetrics, Erzurum, Turkey; [2]Department of Gynecology and Obstetrics, Şifa Hospital, Erzurum, Turkey; [3]Department of Hematology, Fırat University Medical School, Elazig, Turkey; [4]Department of Endocrinology, Selçuk University Medical School, Konya, Turkey; [5]Department of Hematology, Karaelmas University Medical School, Zonguldak, Turkey; [6]Department of Endocrinology, Erzurum Regional Training and Research Hospital, Erzurum, Turkey.

Objective
Polycystic ovary syndrome (PCOS) is associated with insulin resistance, central obesity and dyslipidaemia. Furthermore, abnormal aminotransferase activity is common in women with polycystic ovary syndrome. The aim of this study is to assess the γ-glutamyltranspeptidase (GGT) and alanine aminotransferase (ALT) levels in women with PCOS in whom non-alcoholic fatty liver disease was excluded by history, serum testing and abdominal ultrasonography.
Study design
Present work is included 135 consecutive outpatient between January and July 2006. Ninety patients for the diagnosis of PCOS and 45 age-matched healthy subjects in the control group. Women with PCOS were separated into two groups. Group A were treated with 0.035 mg of Ethinyl Oestradiol and 2 mg of cyproterone acetate for 6 months. Group B did not take any drug. Serum levels of ALT, as-partat aminotransferase (AST), GGT, alkaline phosphatase (ALP), lipid and glucose metabolism parameters were measured on the 6th month of treatment.
Results
The plasma levels of both ALT and GGT were significantly higher in the subjects with PCOS (total) compared to the controls. Serum GGT levels were significantly higher in the group A and B than in controls, whereas no difference was found between group A and B. On the other hand group B had significantly higher ALT levels than in controls. However, no differences in ALT levels were found between group A and controls.

Conclusions
The ALT and/or GGT levels are important in the pathogenesis of PCOS and that hepatic enzymes may be useful additional measures in identifying women at high risk of metabolic syndrome.

Achievement of therapy targets in children and adolescents with type 1 diabetes mellitus at the 'Diabetes School'

Akmaral Tashmanova[1,2]
[1]Center for the Scientific and Clinical Study of Endocrinology, Tashkent, Uzbekistan; [2]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan.

Aim
To assess efficacy of training and achievement of therapy targets in children and adolescents with type 1 diabetes mellitus in 'Diabetes Schools'.
Materials and methods
The 5-day training course was conducted in 'Type 1 Diabetes School' at the Center for the Scientific and Clinical Study of Endocrinology, Uzbekistan Public Health Ministry (Tashkent). The training was conducted by means of a structured program containing all appropriate sections. Before and after training course all participants were tested with a questionnaire containing 30 key questions for self-control. On the basis of the findings children and adolescents with type 1 diabetes mellitus were divided into groups. 54 of 80 children and 38 of 57 adolescents were preliminary trained, 26 children and 19 adolescents got no training. DS5 Glycomat (USA) was used to measure HbA1c by means of high pH anion-exchange liquid chromatography. Certified by the National Glycohaemoglobin Standardization Program this method became the reference one. It helps demonstrate the predicting role of HbA1c level as a criterion for assessment of chronic glycaemia and achievement of therapy targets in children and adolescents with type 1 diabetes mellitus.
Results and discussion
Frequency of target HbA1c level ($\leq$7.5%) achievement in the trained patients was 68%. Among children who got no preliminary training target HbA1c level was found in 12%. Among trained adolescents 58% achieved compensation. The target HbA1c level was found in 11% of adolescents who got no training.
Conclusions
Frequency of target HbA1c level ($\leq$7.5%) achievement was found in 68% of children with type 1 diabetes mellitus having received preliminary training at 'Diabetes School' to be significantly higher ($P<0.001$) than the one in the group of patients who got no preliminary training (12%). Among adolescents target HbA1c level achievement was observed in 58% of the trained patients to be significantly higher ($P<0.001$) as compared with those who got no preliminary training (11%). Better compensation and higher frequency of target HbA1c level achievement in children as compared with those among adolescents confirms the role of family in the type 1 diabetes mellitus control.

Interrelation between level of knowledge and type 1 diabetes mellitus compensation degree in children and adolescents

Akmaral Tashmanova[1,2]
[1]Center for the Scientific and Clinical Study of Endocrinology, Tashkent, Uzbekistan; [2]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan.

Aim
To assess level of knowledge and compensation degree in children and adolescents with type 1 diabetes mellitus in "Type 1 Diabetes School".
Materials and methods
The 5-day training course was conducted in 'Type 1 Diabetes School' at the Center for the Scientific and Clinical Study of Endocrinology. The training was conducted by means of a structured program containing all appropriate sections. In total 137 children and adolescents with type 1 diabetes mellitus were included into the study. Among them 92 patients got training; 45 children and adolescents hospitalized at the Center for the Scientific and Clinical Study of Endocrinology got no training in the 'Type 1 Diabetes School'. DS5 Glycomat (USA) was used to measure HbA1c by means of high pH anion-exchange liquid chromatography.
Results and discussion
Study on efficacy of the training in the 'Diabetes School' by means of the questionnaire demonstrated that before training children with mean diabetes duration of 4.7 ± 1.8 years could give right answers to five or six questions only. Low-motivated children from low-motivated families with low level of knowledge who got no training were hospitalized at the intensive care unit more frequently both before and after training at 'Type 1 Diabetes School'. At follow-up they could give six or 11 right answers. Among trained adolescents with type 1 diabetes mellitus initially number of right answers was six, in 5 years they could give right answers to 19. Among the untrained adolescents level of knowledge was low both initially and after a 5-year follow-up. HbA1c level in the trained children after 5 years was found reduced by 2.4 ± 0.24% as compared with the initial one; it was reduced by 0.8 ± 0.3% in the untrained children. In trained adolescents with type 1 diabetes mellitus after 5 years HbA1c level reduced by 3.0 ± 0.36%; in those untrained the value was 2.3 ± 0.32%, but the adolescents did not achieved target HbA1c level.
Conclusions
Within a 5-year follow-up mean HbA1c level in the trained and untrained children was 7.8 and 10/8%, respectively. Among adolescents the values were 8.1 and 10.1%, respectively. Better compensation and higher frequency of target HbA1c level achievement in children as compared with those among adolescents confirms the role of family in the type 1 diabetes mellitus control.

Influence of ecologically adverse factors on physical and sexual development of children living in the Aral Sea area

Nilufar Ibragimova & Feruza Hojaeva
Republican Specialized Research and Practical Medical Centre of Endocrinology, Tashkent, Uzbekistan.

Drying of the Aral Sea resulted in serious problems including pollution of air, water (mineralization of clear water) and soil which in its turn caused rise in various somatic diseases in population and produced a negative effect on health of children and adolescents.
Purpose
To study the influence of ecologically adverse factors on physical and sexual development of children of the Aral Sea area.
Materials and methods
To estimate physical and sexual development of adolescents of the Aral Sea area an epidemiological survey was carried out in 2008 using a method of random sampling considering age and sex. The study group comprised 1120 children (600 girls and 620 boys) aged 12 to 16. The study included anthropometry (coefficient of standard deviations SDS), BMI, estimation of sexual development (according to Tanner), USI of the small pelvis organs.
Results
Of 1220 children examined, stunting was found in 143 (11.7%) and weight deficiency in 67%. It should be noted that 85% of children were registered at the dispensary for anemia. The ratio of occurrence of stunting between boys and girls made 2:1. Of 620 boys examined stunting was found in 14.3%, sexual development retardation in 20% of boys, hypogonadism in 3%, obesity in 1.7%, micropenis in 2.5%, unilateral cryptorchism in 1.2%, other boys had normal for age puberty development. Of 600 girls examined stunting was revealed in 7.3%, abnormal puberty in 2.8%, retardation of sexual development in 12.8%, late menarche in 12.1% and primary amenorrhea in 4.3% of girls. Thus, the results obtained suggest on direct influence of adverse ecological factors (pollution of air, water, soil) of the Aral Sea area on health of children being confirmed with frequency of stunting (11.7%) in children and sexual development disorders revealed.

Leptin and kisspeptin evaluation in childhood obesity

Francesco Leo[1], Antonio Mancini[1], Chantal Di Segni[1], Sebastiano Raimondo[1], Angelina Barini[2], Diego Currò[3] & Aurora Natalia Rossodivita[4]
[1]Department of Medical Sciences, Division of Endocrinology, Catholic University of Sacred Heart, Rome, Italy; [2]Institute of Biochemestry and Clinical Biochemestry, University of Sacred Heart, Rome, Italy; [3]Institute of Farmacology, University of Sacred Heart, Rome, Italy; [4]Department of Gynecology and Pediatrics, University of Sacred Heart, Rome, Italy.

Kisspeptin is a neuropeptide secreted in anteroventral-periventricular and arcuate hypothalamic nuclei involved pubertal onset and in other functions of adult life. Kisspeptin levels are sex dependent, so they are higher in prepubertal girls and in adult women compared to age-matched male. This sex-related pattern has been reported in adult obesity, but few data are reported in childhood obesity. In order to evaluate correlations between metabolic status and kisspeptin, we studied Kisspeptin levels in a population of 27 prepubertal children (13 males) aged 5–12 years, classified as overweight (n = 3) or obese (n = 24) according to Cole's criteria. Eight normal weight children, aged 6–12 years, were enrolled as controls. Several metabolic parameters were evaluated: glucose and insulin levels after oral glucose load, total- LDL- and HDL-cholesterol, triglycerides, uric acid, total proteins, C Reactive Protein. Leptin was evaluated using ELISA method (DRG Instruments GmbH, Germany). In order to evaluate kisspeptin levels, morning blood samples were collected; after acidification, peptides were extracted in a C-18 SEP-Column (Phenomenex, Inc., USA). The eluted samples were evaporated and stored at −80 °C until assayed. Kisspeptin (pg/ml) was measured using the RIA kit KISS1 (61-121)-Amide-Metastin (1-54)-NH2 (Phoenix Pharmaceuticals, Burlingame, USA). We did not find significant differences between obese and normal weight children (mean ± S.E.M: 20.1 ± 1.96 and 20.7 ± 0.68 pg/ml, respectively) and between males and females obese children (19.05 ± 3.39 and 20.9 ± 2.49 pg/ml). Kisspeptin levels did not correlate with SDS BMI, HOMA index and Insulin peak levels after glucose load. As expected, Leptin levels were higher in obese children than in controls (20.41 ± 2.84 and 4.21 ± 2 ng/ml, respectively), while showed a significant correlation with Kisspeptin levels in normal children ($R^2 = 0.12$; P value = 0.46), but not in obese ($R^2 = 0.03$; P value = 0.6). These preliminary data suggest that Kisspeptin could play a role in metabolic status and could be regarded as metabolic modulator and not only a regulator of pituitary gonadal axis.

Kisspeptin hormone levels in girls and adolescent girls

Olga Gumeniuk, Yuriy Chernenkov, Natalia Zakharova & Inna Ivanenko
Saratov State Medical University, Saratov, Russia.

Kisspeptin (formerly known as metastin) is a neuropeptide, has an important role in initiating secretion of gonadotropin-releasing hormone at puberty. Kisspeptin hormone levels disorders cause hypogonadism or premature sexual development and sterility.

Aims

The study was undertaken to research the kisspeptin level in healthy girls and adolescent girls and in girls and adolescents with gynaecological and endocrine disorders.

Patients and methods

Serum kisspeptin levels were determined in 100 children and adolescents (aged 0.7–18 years). The healthy children was 12, children with precocious puberty (central precocious puberty CPP and premature isolated thelarche PIT) – 11, healthy adolescents – 30, girls with amenorrhea – 23, patients with polycystic ovary syndrome (PCOS) – nine and pregnant adolescent girls – 15. The concentration of kisspeptin was measured using Kisspeptin-10 and competitive enzyme immunoassay. Results were analyzed using two-way ANOVA. Data are expressed as median, P value of <0.05 was considered statistically significant.

Results

The investigation shows that healthy and pregnant adolescent girls had kisspeptin median levels 0.03 ng/ml. Among the girls with amenorrhea and PCOS kisspeptin levels were lower 0.01 ng/ml ($P = 0.014$). Serum kisspeptin levels were significantly higher in children with CPP and PIT and adolescent girls with PCOS than in control group (0.08 and 0.3 vs 0.03 ng/ml, $P = 0.012$ and $P < 0.01$).

Conclusion

Kisspeptin levels were various in healthy children, adolescents and girls with amenorrhe, PCOS, children with central precocious puberty and PIT. In this study, we demonstrated that serum kisspeptin levels were not different in healthy adolescents and pregnant adolescent girls. In this study, we demonstrated that serum kisspeptin levels were significantly lower in girls with amenorrhea and PCOS and higher in children with CPP and PT. The serum kisspeptin levels may be used as a marker of reproductive disorders and PCOS in girls.

Clinical and endocrine features Hashimoto thyroiditis in children and adolescents

Slavica Markovic[1], Zoran Igrutinovic[2], Biljana Vuletic[2], Rasa Medovic[2] & Lidija Stankovic[2]
[1]Pediatric Clinic Clinical Centre Kragujevac, Kragujevac, Serbia; [2]Faculty of Medical Sciences Univerity of Kragujevac, Kragujevac, Serbia.

Introduction

Hashimoto's thyroiditis (HT) is the most common autoimmune thyroid disease and the most common cause of euthyroid goitre and acquired hypothyroidism in childhood.

Objective

To describe the clinical manifestations, course and outcome of HT in children and adolescents.

Method

The study included 43 patients with HT, aged 3–16 years, mean age 12.5 years, 36-girls, seven boys; 15 (35%) prepubertal, 28 (65%) pubertal, monitored on average of 4.9 years.

Results

Goitre is the most common symptom of HT, recorded in 19 (44.3%), and during follow-up in 31 (72%) of the children. In 17 (89.5%) were diffuse goitre, and in 15 (34.4%) children was isolated symptom. Goitre was recorded in 14 (73.7%) girls and 5 (21.3%) boys. Other clinical symptoms HT are: anaemia in seven patients (16.2%), fatigue in 5 (11.8%), increased appetite in 4 (9.7%), obtaining in TM 3 (7.0%), growth retardation in 2 children (4.7%) and irregular menstrual cycle in 5 (23.8%) out of 21 pubertal girls. Hypothyroidism is initially recorded in 7 (16.3%), and during follow-up the euthyroid state in 25 patients (58.1%). A positive family history of autoimmune thyroid disease had 18 (41.9%) children, of which 13 (72.2%) demonstrated hypothyroidism. In 12 (27.8%) children were identified: DMT1 in six children, vitiligo in two, M.Coeliacus in three, and M.Gravis in one child.

Conclusion

HT is five times more common among girls. The most common clinical symptom HT is a diffuse goitre, and hypothyroidism is recorded in 42%. The frequency of positive family history of autoimmune thyroid disease is high in children with HT, which increases the risk of developing hypothyroidism. As almost one-third of children with HT manifested and other autoimmune diseases, clinical follow-up involves the search for them.

Neonatal screening for hypothyroidism in Romania

Ioana Ardeleanu[1,2], Michaela Nanu[1], Florentina Moldovanu[1] & Andrei Nanu[2]
[1]Mother and Child Health Care Institute 'Alfred Rusescu', Bucharest, Romania; [2]University of Medicine and Pharmacy 'Carol Davila', Bucharest, Romania.

Introduction

Neonatal screening is an effective method for early detection of congenital hypothyroidism, a disorder that requires the prompt initiation of the treatment, in order to prevent the subsequent neuropsychiatric impairments. Neonatal screening for hypothyroidism in Romania was initiated as a pilot project in 1979, has been expanded since 2002, and is currently conducted through the National Health Program funded by the Ministry of Health.

Objective

To assess the current state of hypothyroidism screening and management in Romania and determine the incidence of hypothyroidism at birth in 2013.

Material and methods

We analysed data reported to the Implementation Unit of Health Programs in 2013 by the four regional centres (Bucharest, Cluj, Iasi and Timisoara) and the parameters registered in the Hypothyroidism National Registry (in Bucharest and Iasi). Confirmed cases were treated and monitored by the endocrinology network. All the newborns were investigated by the 'dry spot' method; blood samples were collected from the heels. TSH levels were assessed by immunofluorimetric

method in three regional centres and by Elisa technique in the fourth. The diagnosis was locally confirmed by TSH, T_4 and free-T_4 levels in patients serum.
Results
In 2013, 92.76% of newborns were screened for hypothyroidism. 96 patients (0.07%) were found positive, when a neo-TSH cut-off value of 15 mU/l was used; in 41 newborns (0.03%) congenital hypothyroidism was confirmed. The family refused the diagnosis investigations in three patients (0.002%). The hypothyroidism incidence in this study is 1/3409 infants.
Conclusion
The incidence of congenital hypothyroidism in Romania is within the limits reported in literature. We attempt to increase the number of the newborns tested for hypothyroidism by raising awareness about screening benefit among the families. Taking into account the false positive cases, we estimate that ongoing studies will enable the increase of the neo-TSH cut-off value at 17 mU/l.

Paediatric hypothyroidism: effect of thyroxin replacement therapy on growth hormone secretion and linear growth velocity

Sadia Saqib[1], Amjad Rashid Kiani[1], Urooj Anwar[1], Maleeha Akram[1], Gulbin Shahid[2], Osama Ishtiaq[3], Afzaal Ahmad[1], Mazhar Qayyum[1] & Shakeel Raza Rizvi[1]
[1]Department of Zoology Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Rawalpindi, Pakistan; [2]The Children's Hospital Pakistan Institute of Medical Sciences (PIMS), Islamabad, Pakistan; [3]Shifa International Hospital, Islamabad, Pakistan.

Thyroid gland secretes thyroid hormones, which play a critical role in growth, differentiation, reproduction and metabolism, whereas hypothyroidism in children is associated with short stature and normalisation of thyroid function with thyroxin replacement therapy increases linear growth velocity (LGV). In stimulating LGV, thyroxin may have its direct effects on bone cells or it may affect LGV through its effect on growth hormone (GH) secretion. The present study attempted to examine the effect of thyroxin replacement therapy on LGV in hypothyroid short children, its effect on GH secretion and the stage of puberty at which thyroxin replacement therapy could be more effective in influencing LGV. Blood samples were obtained and plasma T_3, T_4, TSH, GH and IGF-I were determined using specific assay systems. Data were analysed using Student's *t*-test and ANOVA. Twenty hypothyroid children (ten boys and ten girls) diagnosed on the basis of lower plasma levels of T_4 and T_3 and higher plasma concentrations of TSH, were given varying doses of thyroxin (16.6–150 μg/day for 12–36 months) administered orally at different ages (8–16 years) and stages (early, mid and late) of pubertal development. Following replacement therapy, children grew at a greater rate at higher doses of thyroxin. In addition, thyroxin replacement at early puberty in girls and at mid puberty in boys caused higher increases in LGV. The concentrations of GH and IGF-I increased significantly after treatment of hypothyroid patients with thyroxin. In conclusion, the present study demonstrates that hypothyroid children grow at a greater rate at higher doses of thyroxin and that thyroxin replacement therapy at early puberty in girls and mid puberty in boys causes higher increases in LGV. In addition, the current investigation indicates that increases in LGV following thyroxin replacement therapy are secondary to GH and subsequent IGF-I secretion.

Evolution of the signs of true precocious puberty under suppressive treatment by LH RH analogues in girls

Ali El Mahdi Haddam[1], Nora Soumeya Fedala[2], Leyla Ahmed Ali[2], Djamila Meskine[1] & Farida Chentli[2]
[1]Bologhine Hospital, Algiers, Algeria; [2]Bab El Oued Hospital, Algiers, Algeria.

Introduction
Impact of suppressive therapy with LH RH analogues is more stop the premature pubertal development, reduce the acceleration of bone maturation that compromises the final size and avoid psychological disturbances caused by hormonal imbalance.
Aim
To study the effects of treatment on pubertal development, bone maturation and evolution of the size during and at the end of treatment and final height in 20 patients with central precocious puberty treated by triptorelin.
Subjects and methods
15 children (chronological age at diagnosis: 8 ± 1.8 years) at the end of treatment (11 ± 0.1 years) and the final size (15.9 ± 2.5 years) were treated for a central precocious puberty. The selection criteria for this study were treatment of central precocious puberty by Decapeptyl during 2 years or more. We assessed pubertal status, size and bone maturation at the beginning and the final size after stop taking treatment.
Results
At the beginning of treatment, pubertal development was S3 (S2–S4, size $+2.1 \pm 0.8$ DS/TC) and AO/10.5 ± 0.8 years. Under treatment, breast development decreased and bone maturation decelerated. The mean final height was 158.2 ± 6.6 cm; -1.5 ± 0.1 DS/TC.
Discussion and conclusion
Treatment of central precocious puberty by GnRH agonists stabilizes or regressed pubertal development and decreases bone maturation rate. However when indicated late, the prognosis size is not satisfactory.

DHEA and its metabolites – daily profile

Monika Šrámková[1,2], Michaela Dušková[1], Luboslav Stárka[1], Beáta Racz[1] & Martin Hill[1]
[1]Institute of Endocrinology, Prague, Czech Republic; [2]First Faculty of Medicine, Charles University in Prague, Prague, Czech Republic.

Introduction
DHEA is a well-known neurosteroid. Its plasmatic level is reduced with ageing in most individuals. A non-negligible portion of DHEA is hydroxylated at C7 and C16 to 7α-, 7β- and 16α- and 16β-hydroxyderivatives. A part of the antiglucocorticoid function of DHEA has been described to its 7-oxygenated metabolites, namely to 7α-hydroxy-DHEA. Due its anti-glucocoticoid action it is also considered a factor in fat deposition processes. Thus, we were interested in examining daily profiles of DHEA and its metabolites, as well as possible associations with daily variation of hormones associated with food intake.
Description of methods
8 women of reproductive age with normal BMI were given five standardised meals, and their hormonal milieu was determined during the course of the day. Plasma from 12 withdrawals was analysed for DHEA and its 7- and 16-hydroxylated metabolites. The Ethical Committee of the Institute of Endocrinology approved the study.
Results
Free DHEA showed a small but significant decrease after lunch and dinner, whereas conjugated DHEA decreased only after dinner. Androstenediol decreased after lunch, but other changes were not significantly influenced by meals. 7α-hydroxy-DHEA and 3β,7α,17β-hydroxyandrostentriol followed the profile of DHEA, but 7β-isomer, 7-oxo-derivative and 3β,7β,17β-hydroxy-androstentriol did not. DHEA and all its derivatives showed an increase at 2200–2300 h, which, however, was significant only for free and conjugated DHEA, 7β-hydroxy-DHEA and 16α-hydroxy-DHEA.
Conclusion
The daily profile of DHEA levels shows a decrease throughout the day from the highest values in the morning value, with additional significant decreases after main meals. Only some hydroxylated metabolites and conjugated derivatives show a similar profile.

Aetiologies of thick stalks pituitaries: about 24 observations

Ali El Mahdi Haddam[1], Nora Soumeya Fedala[2], Leyla Ahmed Ali[2], Djamila Meskine[1] & Farida Chentli[2]
[1]Bologhine Hospital, Algiers, Algeria; [2]Bab El Oued Hospital, Algiers, Algeria.

Introduction
The inflammatoirs background processes, and infiltrating tumour of the pituitary stalk are rare. They are a heterogeneous group of lesions responsible of partial or global hypopituitarism.

Aim
Search for thickening of the pituitary stalk aetiologies and specify the clinical aspects.
Population methodology
This is a retrospective study of 24 patients with thickening of the pituitary stalk. All patients benefited from a clinical, biological and radiological exploration.
Results
A female predominance (17 women) with four paediatric cases are observed. The average age is 30 years (7–48). RMI was performed for hypopituitarism dissociated (*n*: 19); diabetes insipidus (*n*: 4) and early puberty (*n*: 1). The attainment of the stem is associated with a hyperprolactinaemia in 15 cases (62, 4%). Thyrotropin insufficiency in 16 cases (66.6%), gonadotropin insufficiency in ten cases (41.6%), corticotropin insufficiency in five cases (20, 8%), somatotropin insufficiency in four cases (16.6%) and central diabetes insipidus in four cases (16, 6%). The aetiological investigation led to the diagnosis of sellar metastasis in three cases (12, 5%), neurosarcoidosis in 15 cases (62.4%), autoimmune hypophysis in two cases (8, 3%) and germinoma in one child (4, 16%). Finally the aetiological investigation was negative in the remaining three cases (12.5%, two children).
Discussion and conclusion
The causes of thickening of the pituitary stalk are varied. They must be some thoroughly researched and monitored in idiopathic forms. La frequency of pituitary involvement encouraged to make regular hormonal evaluations.

The beast behind the dwarf

Cosmina Rimbu[1], Lisandra Damian[1,2], Letitia Leustean[1,2], Ingrith Miron[2,3], Alexandru Florescu[2], Carmen Vulpoi[1,2] & Maria Christina Ungureanu[1,2]
[1]Endocrinology Clinic, 'St. Spiridon' Emergency Clinical Hospital, Iasi, Romania; [2]'Grigore T. Popa' University of Medicine and Pharmacy, Iasi, Romania; [3]Forth Pediatric Clinic, 'St. Maria' Hospital, Iasi, Romania.

Abnormalities of growth are one of the most common reasons for the paediatric–endocrinology consults. It's an obvious manifestation with countless possible causes behind, and sometimes we can have unexpected diagnosis.
Case presentation
we investigated the case of a 4 years old girl, born at term, naturally, SGA: birth weight = 1950 g, who presented in the Endocrinology Department for short stature. Clinical evaluation: 89.5 cm (−4 DS), 11 kg (−2.5 DS), discreet ocular asymmetry. Blood test: anaemia, decreased IGF-1, normal adrenal and thyroid function, normal karyotype, normal thoracic X-ray and abdominal ultrasound. Moreover, the first day of admission we noted polyuria and polydipsia not reported by mother: ingestion 3750 ml/24 h excretion 3950 ml/24 h. Afterwards, biochemical tests confirmed the suspicion of diabetes insipidus. Ophthalmologic exam – important papillary oedema. MRI revealed an expansive mass with contrast enhancement located in posterior fossa. An angio MRI and a biopsy were performed and established the final diagnosis: histiocytosis. Even if in our patient's case, the short stature and diabetes insipidus, were considered initially easy to manage and benign, the histiocytosis was found to be an unexpected and unpleasant diagnosis which involves more aggressive treatment and complications.

EP112

Final size of turner patients: about 40 patients

Hafsa Siyoucef[1], Ali El Mahdi Haddam[1], Nora Soumeya Fedala[2], Djamila Meskine[1] & Farida Chentli[2]
[1]Bologhine Hospital, Algiers, Algeria; [2]Bab El Oued Hospital, Algiers, Algeria.

Introduction
The growth failure constant in turner syndrome is responsible for a spontaneous reduction in adult height with an average of 143 cm. Treatment with growth hormone has enhanced the stature prognosis.
Aim
Studying the final size of turner patients who have completed their growth.
Population, methodology
40 patients became adult patients were assessed on linear growth. The following factors were studied: The age and size at diagnosis, the introduction of treatment with GHr and the final size.
Results
The mean age at diagnosis was 8.9 ± 0.4 years, 45% over 10 years. The size at diagnosis was −4 DS/M and −3DS/TC. The age at initiation of treatment was 10 ± 0.1 years with a mean treatment duration of 5 ± 0.1 years. Ten patients were not able to be processed. Final height was −3, 5 DS/M and −2.5 S.D./TC with an average of 144 ± 0.2 cm for patients treated and −4DS/M and −4 DS/TC for the others.
Discussion and conclusion
Unfavourable results in our patients are explained by delayed diagnosis. Treatment may not be éfficace if the GHr treatment is not given precociously patient inflammatoirs background processes, and infiltrating tumour of the pituitary stalk are rare. They are a heterogeneous group of lesions responsible of partial hypopituitarism or global objective. Search for of thickening of the pituitary stalk aetiologies and specify the clinical aspects.

Sarcopenia, more that dehydration, may be associate to underweight Portuguese centenarians

Alda Pereira da Silva[1,2], Andreia Matos[2,8], Ana Valente[5], Angela Gil[2,8], Isanete Alonso[6], Ricardo Ribeiro[2,7], Gorjão Clara[3,4] & Manuel Bicho[2,8]
[1]Alameda Primary Care Health Center, Lisbon, Portugal; [2]Faculty of Medicine, Genetics Laboratory and Environmental Health Institute – ISAMB, University of Lisbon, Lisbon, Portugal; [3]Universitary Geriatric Unit of Faculty of Medicine of Lisbon, University of Lisbon, Lisbon, Portugal; [4]Academic Medical Center of Lisbon – North of Lisbon Hospital Center, Lisbon, Portugal; [5]Department of Nutritional Science, Faculty of Medicine, Oeiras and Environmental Health Institute – ISAMB, Atlantica University, University of Lisbon, Lisbon, Portugal; [6]Nutrition division St Louis Hospital, Lisbon, Portugal; [7]Molecular Oncology Group, Portuguese Institute of Oncology, Porto Centre OPorto, Porto, Portugal; [8]Institute of Rocha Cabral, Lisbon, Portugal.

Introduction
Fat-free mass has a functional significance in aging. The objective of this study was to evaluate the prevalence of underweight in a Portuguese population of centenarians and their relationship with dehydration or sarcopenia.
Methods/design
Anthropometric data were obtained using standard procedures from 252 centenarians (100.26 ± 1.99 years), 77.8% women (W). Body composition was assessed by tetrapolar bioimpedance. It was considered dehydration: total body water (TBW) (%) < 45 (W) and < 50 male (M), and excess of fat mass (FM) (%): > 35 (W) and > 25 (M). The fat mass index (FMIndex): FM (kg)/height (m^2) and muscle mass index (MMIndex): MM (kg)/height (m^2) were calculated. Statistical methods: *T*-student, ANOVA, χ^2, linear correlation.
Results
In the sample, 61.4% had normal weight (BMI = 21.42 ± 1.86), but 25.3% were underweight (BMI = 16.84 ± 1.51), and of these, 28.8% were women. Instead, overweight (BMI = 27.52 ± 2.40) checked in 13.3% subjects, was predominant in men (10.6 vs 22.6%). Dehydration was observed in 12.9% of subjects and was tendentiously higher in women (15.4 vs 5.0%, $P = 0.087$). Excess of FM was found in 6.0% of subjects with no gender differences ($P = 0.225$). In the overweight subgroup there were differences in TBW ($P = 0.003$) and FM ($P = 0.022$) between genders, which was not observed in the underweight subgroup. The FMIndex in underweight or overweight subgroups did not vary significantly with gender. Muscle mass and MMIndex were different between genders, with the lowest values observed in underweight W compared to M (31.7 ± 3.96 vs 36.3 ± 2.84; $P = 0.01$) or to the other subgroups. There was a direct linear correlation between BMI and MM ($\beta(M) = 0.749$; $\beta(W) = 0.683$) and inverse with TBW ($\beta(M) = -0.428$; $\beta(W) = -0.397$), men and women, $P < 0.001$.
Conclusion
The underweight was more represented in the Portuguese centenarians. More than body water and FM, sarcopenia may be responsible for this low weight particularly in the women.

Salt and puberty: self-regulated salt intake and the effect of salt on puberty

Dori Pitynski, Francis Flynn & Donal Skinner
University of Wyoming, Laramie, WY, USA.

The onset of puberty is changing in western countries. Puberty is the activation of the reproductive system, and is initiated by a complex series of events that are not fully understood. BMI has been linked to the advancement of puberty, but is unlikely to be the whole story as girls with a normal BMI are also advancing through puberty earlier. It is well known that western diets are high in calories, but the high salt content in these diets has been overlooked as a potential contributing factor. Salt consumption in the US and Europe far exceeds the recommended daily values. We hypothesize that salt intake may affect the timing of puberty. Our study on Sprague Dawley rats fed a high salt (8%) diet from weaning (Day 21) have a significant delay in the onset of puberty compared to a control, 0.3% salt, diet. Corticosterone levels were not different between control and high salt-fed rats, suggesting that the pubertal delay was not mediated by stress. FGF-21, which has been implicated in puberty onset, also did not differ between high salt and control rats. Salt intake was then varied to determine if lower salt intake may be stimulatory to puberty. Rats were fed no salt (0.01%), control (0.3%), 2%, or 4% salt. Rats fed no salt showed significantly delayed puberty. Our data showed a trend for 2% salt to cause a slight advancement in puberty, whereas 4% salt was not significantly different from control. To establish optimal salt-intake, rats were given the option of drinking saline (0.5% salt) or pure water while being fed no salt, 0.3%, or 2% salt in their chow. Rats fed no salt consumed 3.6 ± 0.8 mg/g rat per day salt compared to total food intake. Control rats consumed 2.9 ± 0.9 mg/g rat per day salt, and 2% salt fed rats consumed 5.1 ± 0.5 mg/g rat per day total salt. This data suggests that our 2 and 4% high salt diets are within the physiological ranges of salt consumption in rats. Our data shows that high salt can delay puberty at the highest levels, but may advance puberty at lower levels. Current salt loading in western populations has the potential to effect reproductive health, and warrants further attention.

Exploring the psychosocial impact of congenital adrenal hyperplasia on children and their parents

Amy Simpson & Amy Hunter
Genetic Alliance UK, London, UK.

Congenital adrenal hyperplasia (CAH) is a genetic condition associated with a deficiency in cortisol and an overproduction of androgens, requiring life-long, daily medication. Little is known about the psychosocial impact of living with and treating CAH, particularly for the parents of young patients. The study was conducted by Genetic Alliance UK as part of the European Commission funded Treatment of Adrenal Insufficiency in Neonates (TAIN) Project, which aims to develop a new formulation of hydrocortisone for neonates and infants. Taking a qualitative approach, 17 semi-structured interviews were conducted in the UK with parents of children affected by CAH. Interviews were conducted face-to-face or via the telephone, and lasted approximately 1 h. They were audio-recorded, transcribed verbatim and analysed thematically with the support of Computer Assisted Qualitative Data Analysis Software, NVivo 8. As primary caregivers, parents experienced disruption to both their daily routine and sleep patterns as a result of their child's intensive medication regime. Parents reported a 'latent anxiety' associated with getting the right dose of medication at the right time, and often found separation from their child and delegating responsibility for treatment difficult. Parents expressed concerns about the potential impact of CAH on their child in the future and in particular, their child's ability to effectively self manage their condition. Challenges associated with the rarity of the condition also emerged during interviews including: a lack of awareness of CAH amongst the medical profession; delays in getting an accurate diagnosis; disparities in care across the UK; and difficulties finding the appropriate support. In conclusion, the study offers a rare insight in to the daily experiences of families affected by CAH and has important implications for the care and treatment of the condition in the future.

Biochemical and molecular modelling analyses explain the functional loss of *HSD17B3* mutant G133R in three Tunisian patients

Roger Engeli[1], Bochra Ben Rhouma[2], Christoph R Sager[1], Faiza Fakhfakh[2], Leila Keskes[2], Angelo Vedani[1], Neila Belguith[2,3] & Alex Odermatt[1]
[1]University of Basel, Basel, Switzerland; [2]University of Sfax, Sfax, Tunisia; [3]Hedi Chaker Hospital, Sfax, Tunisia.

17β-Hydroxysteroid dehydrogenase type 3 (encoded by *HSD17B3*) catalyses the conversion of Δ4-androstene-3.17-dione to testosterone and has a key role in male sexual development. Mutations in the *HSD17B3* gene can result in reduced enzyme activity and decreased testosterone synthesis, leading to a rare autosomal recessive aetiology of 46, XY Disorders of Sex Development (46, XY DSD) named 17β-HSD3 deficiency. Here, we characterised three Tunisian patients from non-consanguineous families with a 46, XY karyotype and impaired virilisation of the external genitalia. The hormonal analysis and family history pointed to 17β-HSD3 deficiency. Genetic analysis revealed novel compound heterozygous mutations, i.e. a missense mutation (G133R) and a premature stop codon (C206X) in the *HSD17B3* gene. Using site-directed mutagenesis, an expression plasmid for 17β-HSD3 G133R was constructed. Additionally, expression plasmids for substitutions of glycine 133 to alanine (G133A), to phenylalanine (G133F), and to glutamine (G133Q) were created. WT and mutant enzymes were expressed in HEK-293 cells, followed by assessment of the conversion of radiolabeled Δ4-androstene-3.17-dione to testosterone. Mutants G133R, G133Q and G133F were almost completely inactive, whereas G133A retained more than 80% of WT activity. A homology model of 17β-HSD3 predicted that the loss of activity is due to a disruption of the cofactor-binding site. While an alanine at position 133 was still tolerated, more bulky side-chains led to steric hindrance thus preventing cofactor binding. The glycine at position 133 is highly conserved among the short-chain dehydrogenases. The functional analysis and homology modelling revealed an important role of this residue in the structural arrangement of the cofactor binding pocket. The results provide an improved mechanistic understanding of the 17β-HSD3 structure-function relationship and explained the 17β-HSD3 deficiency observed in the patients.

Search for DHEASism and DHEASoma

Tomas Kurakovas[1], Ilona Banisauskaite[1], Birute Zilaitiene[1], Rytas Ostrauskas[1], Vaidotas Urbanavicius[2], Valentinas Matulevicius[1] & Irina Bilodid[3]
[1]Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Faculty of Medicine, Vilnius University, Vilnius, Lithuania; [3]University of Medicine, Minsk, Belarus.

Recently we described clinical case of 38-year-old fertile woman with sudden onset of a multiple clinical symptoms: weight gain, secondary amenorrhea, hirsutism and seizures. Adrenal tumour co-secreted high amounts of DHEA sulfate, testosterone (T) and aldosterone (A) (Matulevicius *et al*. 2014). The symptoms of the disease disappeared after laparoscopic removal of adrenal tumour, which proved to be an adrenocortical oncocytoma. A hypersecretion of A remained after resection of adrenal tumour, suggesting subclinical hyperandrosteronism. In attempt to find more such cases, we analysed results of DHEAS determinations in two university hospitals of Lithuania (Vilnius and Kaunas) during 1 year – 2014. We checked 1215 DHEAS results of 18–50-year-old woman to investigate our hypothesis. Increased DHEAS was considered when patient's DHEAS concentration was higher than maximal value of DHEAS indicated in the assay kit (11.76%) and was found in 143 cases. Mild increase was in 87.4%, moderate increase – in 9.8% and high increased – in 2.8%. These results confirm that mild increase of DHEAS is frequent (DHEASism). High increase of DHEAS is very rare – found only in four patients (DHEASoma). From these DHEASoma is confirmed in one patient and three are under investigation. Analysing the publications of the last 10-years about increased DHEAS concentration we found that increased DHEAS concentration is frequent in 18–50-year-old woman. These findings are linked to the polycystic ovary syndrome. In this syndrome DHEAS is increased in 20–30%. Elevated DHEAS was found in 9/11 adrenal cancers. Apart of our case, we found two more DHEASoma benign tumor cases in literature. Rarity of DHEASoma suggests that multicentral and multidisciplinary efforts are necessary for discovering and defining the disease.

Psychological problems in children with diabetes mellitus type 1

Anzhalika Solntsava, Olga Zagrebaeva, Nadeya Peskavaya, Viktoryia Kozel & Hanna Mikhno
Belarusian State Medical University, Minsk, Belarus.

Objectives
The prevalence of diabetes mellitus type 1 (DM 1) had increased nowadays in children in Belarus. Psychological problems are one of side-effects of the disease.
Aim
To determine the presence of psychological problems in children with DM 1.
Methods
We examined 45 children (boys – 23, girls – 22) age 14.4 ± 0.8 years, with DM 1 in University hospital (Minsk) in 2014–2015 years. All children underwent psychological examination: depression self-rating scale (DSRS), child behaviour checklist (CBCL), quality of life questionnaire (QL). We examined: HbA1c, fasting glucose levels, day insulin (IU/kg), the experience of DM 1, stages on Tanner. Results were conducted using SPSS.18.
Results
The experience of DM 1 was 4.9 ± 3.6 years, HbA1c levels – 9.7 ± 1.7%, fasting glucose levels – 8.9 ± 1.5 mmol/l, insulin – 1.67 ± 0.3 IU/kg. ANOVA DSRS showed that sleep deprivation was dependent on the experience of DM 1 ($P=0.036$) and glucose level ($P=0.045$). Low concentration ($P=0.003$), mood ($P=0.001$), higher irritability ($P=0.017$), low emotional ($P=0.01$), low confidence ($P=0.044$) levels, pessimism ($P=0.027$) levels were dependent on the stage of Tanner. At the same time low mood was dependent on the glucose ($P=0.05$) and insulin (IU/kg) ($P=0.018$) levels; higher irritability – with the experience of DM 1 ($P=0$–04); low confidence with insulin (IU/kg) ($P=0.045$); weight increasing – with insulin (IU/kg) ($P=0.036$). CBCL and QL showed that disorganization ($P=0.02$), the loss of time due to DM 1 ($P=0.003$) and time, conducted on glucose monitoring ($P=0.005$) were correlated with the experience of DM 1. The higher experience of DM 1 the more children are afraid of teacher's attitude ($P=0.009$).
Conclusions
We found, that some psychological problems in children with DM 1 (sleep deprivation, low mood, low confidence) were dependent on the compensation of DM 1 and were increased due to puberty and the experience of DM 1.

Influence of food on daily profiles of steroids
Michaela Duskova, Beáta Rácz, Monika Šrámková, Martin Hill & Luboslav Stárka
Institute of Endocrinology, Prague, Czech Republic.

Introduction
Whereas the daily profiles of the main steroid hormones are well known, minor differences in the course of their levels related to defined and standardised food intake were studied rarely.
Methods
Eight women (mean age 29.48 ± 2.99 years, mean BMI 21.3 ± 1.3 kg/m^2) in follicular phase of menstrual cycle were examined. The levels of C-peptide, glucose, LH, FSH, SHBG, cortisol, testosterone, dihydrotestosterone, progesterone, pregnenolone, oestrone and oestradiol were studied during a daily regimen (16 h) that included standardized food intake. The study protocol has been approved by Local Ethical Committee. A written informed consent was obtained from all participants.
Results
LH and FSH showed a monotonous decrease during the day with an implicated insignificant decrease after main meals. The course of androgen levels did not show much relation to food intake with the exception of dihydrotestosterone increase 2 h after lunch. SHBG evidently showed a small decrease after meals. C21 steroids showed a significant decrease 1 h after wakening up and then a monotonous decrease during the day. Cortisolemia continuously decreased during the day and an additional significant decrease of cortisol related to food intake was observed only 2 h after lunch. Estrogens did not show any striking trend of course during the day; oestradiol significantly decreased after lunch and dinner.
Conclusion
In our study the known nycthemeral rhythm of LH, FSH, cortisol, testosterone, progesterone and pregnenolone after food intake was confirmed but also significant changes after meals were observed in the levels of cortisol, estradiol and SHBG for the first time. The effect was seen only after the main meals (lunch and dinner). The effect of breakfast and snacks (small effect or long period from the meal and blood withdrawal) was probably hidden in the huge changes of the nycthemeral rhythm.

Six-month interim safety and efficacy of different dose levels of transCon hGH administered once weekly versus standard daily human growth hormone replacement therapy in pre-pubertal children with growth hormone deficiency (GHD)
Pierre Chatelain[1], Oleg Malievsky[2], Klaudziya Radziuk[3], Heba Hassan Elsedfy[4], Evgenia Mikhailova[5] & Michael Beckert[6]
[1]University Claude Bernard, Lyon, France; [2]Bashkir State Medical University, Ufa, Russia; [3]2nd Children City Clinic, Minsk, Belarus; [4]Ain Shams University Hospital, Cairo, Egypt; [5]Samara State Medical University, Samara, Russia; [6]Ascendis Pharma A/S, on behalf of the TransCon hGH study group, Denmark.

Background
TransCon hGH is a long-acting prodrug of recombinant human GH (hGH) that releases into the blood compartment fully active unmodified hGH. TransCon hGH was shown in two Phase 1 studies and a Phase 2 study in AGHD to be safe and well tolerated and inducing an IGF-I pharmacodynamic response within the normal range throughout the dosing period. This interim analysis consists of 25 patients completing all 6 months of treatment.
Objectives
The objective of this study is to investigate i) safety and tolerability, ii) pharmacokinetics and pharmacodynamics, and iii) efficacy of TransCon hGH in children with GHD.
Design and methods
Pre-pubertal, treatment naïve GHD children received s.c. injections of one of three once-weekly TransCon hGH doses (0.14, 0.21 or 0.30 mg hGH/kg per week) or daily hGH (Genotropin; 0.03 mg hGH/kg per day = 0.21 mg/kg per week) over a 6-month treatment period.
Results
Mean annualised height velocities ranged from 11.9 cm for the 0.14 mg/kg per week dose to 14.5 cm for the 0.30 mg/kg per week dose, which were comparable to 11.5 cm for the active comparator, Genotropin at a 0.21 mg/kg per week dose. No SAEs occurred and injection site reactions were generally mild and transient and occurred in only a few patients. Maximum hGH blood concentrations are comparable between equivalent weekly doses of TransCon hGH and daily hGH; and a dose–proportional increase in IGF-I levels into the normal range was observed for the three TransCon hGH dose levels.
Conclusions
To date, TransCon hGH has demonstrated efficacy and safety comparable to that observed with daily hGH. Injection site reactions have been mild and similar to what is expected with daily hGH injections, with no nodule formation or lipoatrophy noted. This TransCon hGH Phase 2 study conducted in a paediatric population confirms the excellent safety and efficacy profile observed in previous clinical trials.

Analysis of androgen profile in teenage girls and young women with acne of various severity
Elzbieta Sowinska-Przepiera[1], Elzbieta Andrysiak-Mamos[1], Aleksandra Walkowiak[1], Mirela Niedzielska[1], Grazyna Jarzabek-Bielecka[2], Witold Kedzia[2] & Anhelli Syrenicz[1]
[1]Department of Endocrinology, Metabolic Diseases and Internal Diseases, Pomeranian Medical University, Szczecin, Poland; [2]Department of Gynaecology, Poznan University of Medical Sciences, Poznan, Poland.

Introduction
Acne is the most commonly diagnosed skin condition in teenage girls and young women. Acne results from androgen excess or hypersensitivity of the skin to normal androgen levels. Therefore, determination of androgen concentrations in patients with acne may facilitate early implementation of appropriate treatment. The aim of the study was to retrospectively analyse the profiles of androgen concentration in female patients with acne of various severity.
Material and methods
The study included 270 girls and young women (16–25 years of age) with acne. The participants were classified based on the severity of acne assessed according to the Leeds grading system: group I – mild acne ($n=80$), group II – moderate acne ($n=90$), group III – severe acne ($n=20$), and group C – controls ($n=80$). Concentrations of androgens: DHEAS, androstenedione, testosterone, and sex hormone binding globulin (SHBG) were determined in all the study participants, and the level of bioavailable testosterone (BAT) was calculated.

Results
Patients from the investigational groups I, II, and III presented with significantly higher concentrations of androgens: DHEAS ($P<0.000$), testosterone ($P<0.000$), androstenedione ($P=0.007$), and BAT ($P<0.000$) than the controls. Moreover, we found significant inverse correlations between the concentrations of testosterone and androstenedione ($r=-0.420$, $P<0.000$), SHBG and DHEAS ($r=-0.391$, $P<0.000$), SHBG and androstenedione ($r=-0.272$, $P<0.009$) in group II and III participants.
Conclusions
Determination of the hormonal profile of girls with acne is vital for the management of this condition and prevention of its recurrence. Juvenile acne is a clinical marker of hyperandrogenism and can be considered a transient manifestation of puberty in teenage girls.

The NCEP ATP III criteria may overestimate the diagnosis of metabolic syndrome in obese and overweight adolescents

Hasan Sav[1], Umut Mousa[1], Osman Koseoglulari[1] & Ruveyde Bundak[2]
[1]Department of Endocrinology and Metabolism, B Nalbantoglu Hospital, Nicosia, Cyprus; [2]Department of Pediatric Endocrinology, Istanbul Univeristy, Istanbul, Turkey.

Introduction
The diagnosis of the metabolic syndrome is less definite in children and adolescents compared to adults. The International Diabetes Federation (IDF) and National Cholesterol Education Program Adult Treatment III guidelines (NCEP ATP III) have proposed two different criteria for its diagnosis in these age groups. In this study we planned to compare these two criterias in detecting the metabolic syndrome in obese and overweight adolescents in a study group in Northern Cyprus.
Subjects and methods
A total of 274 obese and 46 overweight adolescents were included from the northern region of Cyprus. The mean age was 13.72 ± 1.15 years (11.2–17). 156 (48.8%) were girls and 164 were boys (51.2%). We measured the subjects' blood pressure, fasting blood glucose levels, HDL-C levels, triglycerides, body weight to the nearest 0.1 kg, body height to the nearest 0.1 cm. We calculated the BMI by dividing the weight in kilograms to the height in centimetres squared.
Results
Metabolic syndrome was detected in 18.2 and 47.8% in obese adolescents and 17.4 and 30.4% in overweight adolescents according to the IDF and NCEP ATP III criteria respectively.
Conclusion
The prevalence of metabolic syndrome was much higher when using the NCEP-III criteria compared to the IDF criteria both in obese and in overweight adolescents leading to a debate in determining which criteria to be used.

Is there a link between lipid profile and thyroid function modification during somatropinum treatment for GH deficiency in children?

Lavinia Stejereanu[1], Luminita Cima[1], Alice Albu[1,2], Carmen Barbu[1,2] & Simona Fica[1,2]
[1]Elias Emergency Hospital, Bucharest, Romania; [2]UMF Carol Davila, Bucharest, Romania.

Background
Previous studies suggested that treatment with somatropinum in children with GH deficiency (GHD) may alter lipid profile and pituitary–thyroid axis function. However, results are divergent and data regarding a possible association between changes of thyroid function and of circulating lipids are scarce. The aim of this study was to report the changes of the lipid profile in children with GHD treated with somatropinum and the relationship between thyroid function and circulating lipids modifications.
Patients and methods
We performed a retrospective study in which we included children diagnosed with GHD ($n=101$, 68 males and 33 females with a mean age of 8.6 years) treated with somatropinum during January 2008–January 2012. We recorded from the medical files the following data: weight, height, total-, HDL-, LDL-cholesterol, triglycerides, TSH, and free T_4 at inclusion (start of the treatment) and every 6 months during the first year of treatment with somatropinum.
Results
Patients with GHD had increased serum triglycerides levels at 6 months after initiation of treatment (from a mean of 60.41 mg/dl at inclusion to 79.93 mg/dl, $P=0.025$), increased HDL (from a mean 55.35 mg/dl at inclusion to 60.50 mg/dl, $P=0.05$) and decreased LDL after 1 year (from a mean of 99.35 to 88.35 mg/dl, $P=0.05$) Although, TSH and free T_4 decreased at 6 and 12 months in comparison with baseline, this modification was not statistically significant. However, the changes in triglycerides and LDL levels were significantly correlated with the TSH levels modification from baseline ($r=0.549$, $P=0.015$ for triglycerides and $r=0.731$, $P=0.011$ for LDL).
Conclusion
Our study showed that lipid profile significantly changes during treatment with somatropinum for GHD in children and this alteration could be partially due to a slight modification of thyroid function. However, further prospective studies are necessary to clarify this aspect.

Haploinsufficiency of the *SHOX* gene associated with mosaicism 45,X/46,XY with chromosome Y ring as causes of delayed growth and puberty

Diana Martins[1], Carla Baptista[1], Margarida Bastos[1], Ana Garabal[2], Joaquim Sá[1], Carolina Moreno[1], Daniela Guelho[1], Nuno Vicente[1], Luís Cardoso[1], Margarida Balsa[3], Diana Oliveira[1] & Francisco Carrilho[1]
[1]Endocrinology, Diabetes and Metabolism Department, Coimbra Hospital and University Centre, Coimbra, Portugal; [2]Genetics Department, Pediatric Hospital Carmona da Mota of Coimbra Hospital and University Centre, Coimbra, Portugal; [3]Endocrinology, Diabetes and Nutrition Department, Baixo Vouga Hospital Centre, Aveiro, Puerto Rico, Portugal.

Introduction
The height growth is regulated by multiple factors, including specific genetic mutations that ensure correct differentiation and proliferation of chondrocytes. We present a case of double association of haploinsufficiency of the *SHOX* gene with a mosaic 45,X/46,X,r(*Y*) karyotype responsible for growth and pubertal delay.
Case
Male patient, observed in endocrinology consultation at age of 12, with constitutional delay of growth (below the 5th percentile) and pubertal delay. Hormonal analytical study excluded GH deficit and showed reduction of total testosterone (0.2 ng/ml) and free testosterone (0.2 pg/ml) and proof of GnRH with abnormal response. Coeliac disease was excluded. Radiographic study presented delay of skeletal maturation and echographic study established the presence of well positioned testes with normal morphology. Magnetic resonance of the pituitary was also normal. Karyotype's study was performed and revealed the presence of a mosaic 45,X/46,XY. About 63% of the cells didn't had the *SRY* gene.
He made two cycles of 4 months with testosterone enanthate (dose of 62.5 mg/month) with regular progression of pubertal development, however the patient kept growth delay in the follow up. Now, at the age of 18, it was performed karyotype study with extended banding that confirmed an aneuploid line for the Y chromosome (45,X) without *SRY* gene, and a line with a ring Y chromosome (46,X,r (Y)) without the *SHOX* gene and the presence of *SRY*.
Conclusions
The case described highlights the importance of accurate diagnosis of sex chromosome abnormalities and mutations of the *SHOX* gene to establish a diagnostic strategy and appropriate therapy in patients with constitutional delay of growth and puberty. We also recommend for the need of regular monitoring, because the potentially associated complications.

Endocrine and metabolic profiles in adults with Prader–Willi syndrome

Delia Bogdanet, Agnieszka Pazderska, Mark Sherlock & James Gibney
The Adelaide and Meath Hospital, Dublin Incorporating the National Children's Hospital, Dublin, Ireland.

Introduction
Prader–Willi syndrome (PWS) is a genetic syndrome usually diagnosed in childhood. Its reported prevalence ranges from one in 8000 to one in 45 000 with geographical variation. Clinical manifestations include obesity, hyperphagia, short stature, incomplete sexual development, and cognitive disabilities. The majority of published data regarding PWS comes from paediatric populations.
Materials and methods
This is a retrospective observational study of adult patients with PWS performed in an Irish tertiary referral centre. We collected anthropometric measurements, hormonal data, results of genetic testing, and clinical data regarding co-morbid conditions, psychological, and social circumstances.
Results
Twenty-two adult patients (15 women) with a diagnosis of PWS were identified. The median age was 24.5 years. Median height and BMI was 154.3 cm and 41.7 kg/m^2 respectively. Eighteen of patients were assessed for GH deficiency (GHD), 15 using the insulin tolerance test. Sixteen (88.2% of the patients tested) had severe GHD. Fifteen received GH therapy. Height velocity was 4 cm in the first 6 months and 9 cm in the first year of therapy. Fifty percent of patients had evidence of obstructive sleep apnoea; 90.9% had spinal scoliosis; 81.8% had hypogonadism; and 50% of those who had a DXA scan had osteoporosis ($n=5$). Fifty percent of patients had abnormal blood pressure, 22% had lipid abnormalities and 13% had an abnormal HbA1c. 21/22 had learning disabilities, and 50% had associated psychiatric diagnoses. There was no difference in BMI, height, lipids, fasting glucose between GH treated and untreated patients. However the number of patients was small so this could be underpowered to detect a true difference.
Conclusion
Adult patients with PWS have multiple endocrine abnormalities and require careful follow up and management. Early diagnosis and management of endocrine manifestations will potentially improve health and developmental outcomes in adulthood.

Diagnostic value of amino-terminal peptide of type I procollagen when retesting GH deficiency in the transition period

Mariana Costache-Outas[1,2], Camelia Procopiuc[2], Andra Caragheorgheopol[2], Raluca Costache[3] & Simona Fica[1,4]
[1]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania; [2]National Institute of Endocrinology 'C.I.Parhon', Bucharest, Romania; [3]Clinical Hospital Dr. Ioan Cantacuzino, Bucharest, Romania; [4]Elias Emergency University Hospital, Bucharest, Romania.

N-terminal peptide of type I procollagen (P1NP) is a marker of GH (hGH) anabolic action on bone formation. We evaluated the diagnostic value of P1NP in GH deficiency (GHD) in the transition period using receiver operating characteristic (ROC) plot analysis. We compared the diagnostic value of P1NP with IGF1. 16 male patients (chronological age, 16.6–21.5) with GH replacement therapy during childhood (ten IGHD and six MPHD) were evaluated at minimum 3 months after completion of treatment (1.86 ± 1.46 years from rhGH withdrawal). A control group (CG) of nine healthy males (chronological age, 15.2–17.5) was selected. GH secretion was evaluated in IGHD group using insulin tolerance test and were divided as persistent IGHD (three patients) or reversible IGHD (seven patients) according to a GH cut-off below or above 5.6 ng/ml. There were no significant difference between IGF1 and P1NP in the control group and reversible IGHD group. The SDS for IGF1 and P1NP was calculated from the 16 participants with normal GH status (controls and reversible IGHD). The ROC plot showed that the best IGF1 SDS cut-off line was -0.76 (sensitivity (S), 87.5%; specificity (Sp), 88.9%, AUC$=0.944$). For P1NP SDS, the best cut-off line was -0.81 (sensitivity (S), 81.3%; specificity (Sp), 66.7%, AUC$=0.743$).
Conclusion
IGF1 is a better GH biomarker for diagnostic of persistent growth deficiency in the transition period with better specificity and sensibility comparing to P1NP.

Precocious puberty in the obese child as a diagnostic challenge

Pawel Matusik, Zofia Prokopowicz & Ewa Malecka-Tendera
Department of Paediatrics, Paediatric Endocrinology and Diabetes, School of Medicine in Katowice, Medical University of Silesia, Katowice, Poland.

The aim of this study was to evaluate whether the coexistence of obesity in children with precocious puberty symptoms influences significantly the diagnostic process.
Material and methods
We retrospectively analysed a group of 200 children's records (F/M 164/36) hospitalised because of precocious puberty suspicion. The analysis evaluated the nutritional status based on BMI percentile level, compatibility between the bone age and the chronological age; and the final clinical diagnosis.
Results
In the analysed group excessive body weight was found in 66 (33%) children – overweight in 34 (17%) and obesity in 32 (16%) patients respectively. It is noticeable that children with excessive body weight are significantly more likely to have mild variants of precocious puberty (71% vs 66.4%) despite the fact that the accelerated bone age in this group was more frequently observed (47% vs 24.6%). In the group with mild variant of PP and accelerated bone age ($n=41$ (28.9%)) up to 75.6% of children were overweight or obese. In the group of CPP accelerated BA was observed only in 23 (52.3%) children. Frequently recognized variant of PP in obese children was premature pubarche ($n=20$ (62.5%)).
Conclusions
Obesity and overweight significantly modifies puberty, and by accelerating the bone age can hinder the initial diagnosis of PP. The bone age acceleration seems to be poor indicator of central precocious puberty, especially in obese children. The population of overweight and obese children is dominated by a mild variant of precocious puberty – premature pubarche.

Is thyroid function related to masked hypertension?

Ihsan Ates[1], Mustafa Altay[1], Mustafa Kaplan[1], Nihal Ozkayar[2], Erdem Alagüney[1] & Adem Ozkayar[3,4]
[1]Department of Internal Medicine, Ankara Numune Education and Research Hospital, Ankara, Turkey; [2]Department of Nephrology, Ankara Numune Education and Research Hospital, Ankara, Turkey; [3]Department of Family Medicine, Ankara Numune Education and Research Hospital, Ankara, Turkey; [4]Department of Family Medicine, Faculty of Medicine, Hitit University, Çorum, Turkey.

Background
Thyroid hormones affect almost all the tissues of the body and their cardiovascular effects are very significant. The relationship between masked hypertension (MHT) and thyroid hormones is not known. Therefore, we sought to investigate any relationship between patients with MHT, newly diagnosed by home blood pressure monitoring, and thyroid hormones.
Methods
Patients older than 18 years of age without a previous diagnosis of hypertension and presenting to the Outpatient Department with hypertensive symptoms were enrolled. Patients were categorized into three groups as MHT, primary hypertension (PHT) and normotensive, according to blood pressures taken at home and office. The levels of TSH, free triiodothyronine (fT_3), and free thyroxine (fT_4) were measured by electro-chemiluminescence immunoassay in the three groups.
Results
Of the 712 participants enrolled in the study, 206 had PHT, 73 had MHT, and 433 were normotensive. The average log(TSH) level was higher while average fT_4 level was lower in the PHT group as compared to the MHT and normotensive groups. Log(TSH) and fT_4 levels were similar in the MHT and normotensive groups. Stepwise multiple regression analysis showed average systolic and diastolic blood pressures to be related to log(TSH), fT_4, and presence of hypothyroidism in the PHT group. No such relationship was found in the MHT and normotensive groups.
Conclusion
In conclusion, no relationship was found with thyroid hormones in patients with MHT in contrast to patients with PHT. Randomised controlled studies with a larger population size and longer follow-up duration are needed to understand the relationship between blood pressure values and thyroid hormones in patients with MHT.

Effect of metformin on sex steroid levels in postmenopausal type 2 diabetic patients

Ugur Ünlütürk[1], Filiz Bakar[2], Yuksel Ürün[1], Serpil Nebioglu[2] & Ali Riza Uysal[1]
[1]Faculty of Medicine, Ankara University, Ankara, Turkey; [2]Faculty of Pharmacy, Ankara University, Ankara, Turkey.

Introduction
Metformin treatment was associated with decreased risk of various cancers including breast cancer. Exposure to sex steroid is related with increased risk of breast cancer. In this study, we aimed to evaluate the effect of metformin treatment on serum levels of sex steroids and sex hormone binding globulin (SHBG) in postmenopausal women with type 2 diabetes mellitus.
Methods
Postmenopausal patients with newly diagnosed type 2 diabetes were recruited to the study. Before starting life-style modifications and metformin treatment anthropometric measurements were done and fasting blood samples were collected in order to evaluate insulin, glucose, HbA1c, serum levels of sex hormones, and SHBG. All of the basal tests were repeated for each subject at the end of 12 weeks.
Results
At the end of 12 weeks, 36 patients completed the study and were included into analyses. Five of 36 patients did not use metformin due to gastrointestinal side effects or noncompliance with therapy. Remaining patients used at least 500 mg to maximum 2000 mg/day of metformin treatment. Mean body-weight and body fat mass, fasting insulin, HbA1c levels significantly decreased in patients who used metformin. Patients receiving metformin treatment also showed significant decrease in testosterone (−28%), oestradiol (−9%), and oestrone levels (−11.5%), and significant increase in DHEAS (8.9%) and SHBG (4.5%) levels. A borderline significant decrease was seen in androstenedione levels as well. Fasting plasma glucose and oestrone sulphate levels did not change significantly. When compared to the patients who did not use metformin therapy, changes in oestradiol levels were significant, and changes in estrone and testosterone levels marginally significant in patients receiving metformin.
Conclusion
Metformin treatment may have favourable effect on breast cancer risk through decreasing androgen and oestrogen levels in postmenopausal type 2 diabetic patients.

Serum prolactin levels in transgender persons before and during cross-sex hormonal treatment

Nienke Nota, Maartje Klaver, Martin den Heijer, Marieke Dekker & Annemieke Heijboer
VU University Medical Center, Amsterdam, The Netherlands.

Introduction
Gender dysphoria refers to the incongruence between the subject's experienced sex on the one hand and the assigned sex on the other hand. Several studies assume a relationship between oestrogen substitution therapy and serum prolactin levels.
Aim
The aim of this study is to get more insight into the effect and time-course of changes in serum prolactin levels during cross-sex hormone therapy.
Methods
This prospective study included 82 transgender persons who completed 1 year of treatment, 45 male-to-female individuals (MtF's) (mean age ± s.d. 34 ± 13 years) and 37 female-to-male individuals (FtM's) (mean age ± s.d. 27 ± 10 years). MtF's were treated with cyproteronacetate (50 mg/day) and estradiol valerate (2–4 mg/day) or an estradiol patch (200 μg/week). FtM's were treated with testosterone esters i.m. (250 mg/2 weeks), testosterone undecanoate i.m. (1000 mg/12 weeks), or testosterone gel (50 mg/day). We determined serum prolactin levels at baseline and after 3 and 12 months. Serum prolactin was measured by immunometric assay (Centaur, Siemens).
Results
In MtF's mean serum prolactin levels increased from 0.16 to 0.41 U/l (160% (132–188%)) between 0 and 3 months and from 0.41 to 0.47 U/l (15% (0.2–29%)) between 3 and 12 months (mean level in biological women 0.28 U/l). In FtM's mean serum prolactin levels decreased from 0.27 to 0.23 U/l (−16% (−28 to −4%)) between 0 and 3 months and from 0.23 to 0.21 U/l (−9% (−30 to 13%)) between 3 and 12 months (mean level in biological men 0.16 U/l).
Conclusions
In MtF's an increase in mean serum prolactin levels was seen whereby those levels exceeded mean serum prolactin levels of biological women. In FtMs a decrease in mean serum prolactin levels was seen whereby those levels did not reach the values of biological men. In both groups the biggest change was observed during the first 3 months of treatment.

25-Hydroxyvitamin D status in elderly patients with Hashimoto's thyroiditis

Fulden Sarac[1], Sumru Savas[1], Pelin Tütüncüoglu[2] & Fehmi Akcicek[1]
[1]Department of Geriatrics Medicine, Izmir, Turkey; [2]Department of Endocrinology, Katip Celebi University, Atatürk Training and Research Hospital, Izmir, Turkey.

Introduction
Low serum levels of 25-hydroxyvitamin D (25(OH)D3) lower than has been reported to be prevalent in several autoimmune diseases. The aims of the study were i) to evaluate the 25(OH)D3 levels in patients with Hashimato's thyroiditis (HT) and ii) to investigate the relationships between 25(OH)D3, TSH, free T_4, free T_3, and anti-thyroid peroxidase (anti-TPO) levels in elderly patients with HT.
Subjects and method
Study population included 80 (mean age 58.1 ± 9.3 years; 60 females and 20 males) patients with HT. Data such as 25(OH)D3, TSH, fT_4, fT_3, and anti-TPO tests were retrospectively searched. Vitamin D insufficiency was defined as 25(OH)D3 concentrations lower than 30 ng/ml.
Results
In elderly with HT, mean levels of 25(OH)D3 were found to be 39.7 ± 6.5 ng/ml. However, mean levels of 25(OH)D3 were 52.0 ± 12.3 ng/ml in patients with HT (age <60 years) ($P=0.05$). In patients with HT (age <60 years) means level of 25(OH)D3 concentrations were inversely correlated with the anti-TPO levels ($r=-0.700$, $P=0.04$). And also, in elderly group, mean levels of 25(OH)D3 concentrations were positively correlated with the fT_4 levels ($r=-0.700$, $P=0.04$).
Conclusion
25(OH)D3 deficiency was significantly higher in elderly. And also, mean levels of 25(OH)D3 were positively correlated with fT_4 in elderly with HT, but inversely correlated with anti-TPO levels in patients with HT (age <60 years).

How much insulin resistance in polycystic ovary syndrome: comparison of HOMA and insulin resistance (Belfiore) index models

Krzysztof Lewandowski, Katarzyna Lukasiak, Katarzyna Marczuk, Aleksandra Dukowicz, Magdalena Cedro, Malgorzata Bienkiewicz, Elzbieta Skowronska-Jozwiak & Andrzej Lewinski
Department of Endocrinology and Metabolic Diseases, The Medical University of Lodz, Lodz, Poland.

Background
Polycystic ovary syndrome (PCOS), the commonest endocrinopathy of women in the reproductive age is often accompanied by insulin resistance (IR). The aim of the study was to assess the prevalence of IR in women diagnosed with PCOS, where IR was assessed by methods most commonly used in clinical practice, i.e. homeostatic model assessment (HOMA) and insulin resistance index (IRI), also known as the Belfiore index.
Patients and methods
The study involved 137 women diagnosed with PCOS according to the Rotterdam (2003) criteria, age (mean ± s.d.) 25 ± 7 years, BMI 27.61 ± 7.43 kg/m^2. IR was assessed according to the HOMA method (glucose (mmol/l)) × (insulin (μU/ml))/22.5 and IRI methods, where IRI, can be obtained through the formula: $2/((1/(INSp \times GLYp))+1)$, where where INSp, GLYp = insulinemic and glycemic, areas during 75 g OGTT. IR was diagnosed for IRI >1.25.
Results
There was a strongly significant ($P<0.0001$), but still relatively moderate correlation between IRI and HOMA methods ($r=0.5$ and $r=0.57$ for a linear and non-linear model respectively). IR was much more prevalent according to IRI (49.6%) than according to HOMA (22.6 and 15.8% for 3.46 and 3.8 cut-off points,

respectively, $P<0.01$). The majority of patients with high HOMA also had high IRI (e.g. 86% for HOMA >3.8), but the majority of patients with raised IRI, would not be diagnosed as insulin resistant according to HOMA (61.7 and 73.5%, for $HOMA_{3.46}$ and $HOMA_{3.80}$ respectively). IRI concentrations were higher among patients with concomitantly raised HOMA (1.55 ± 0.18 vs 1.44 ± 0.14, $P=0.014$ and 1.60 ± 0.18 vs 1.44 ± 0.13, $P=0.0008$ for $HOMA_{3.46}$ and $HOMA_{3.80}$ respectively).

Conclusions

IRI, based on glucose and insulin measurements during OGTT demonstrates more cases of insulin resistance than HOMA model in women with PCOS. Therefore, detection of insulin resistance among women with PCOS is highly method-dependent with more severe cases being detected with HOMA than with IRI.

Surrogate markers of insulin resistance obtained from oral glucose tolerance test in different phenotypes of polycystic ovary syndrome

Ivana Bozic Antic[1], Jelica Bjekic-Macut[2], Danijela Vojnovic Milutinovic[3], Dusan Ilic[1], Bojana Popovic[1], Tamara Bogavac[1], Biljana Kastratovic-Kotlica[4], Tatjana Isailovic[1], Valentina Elezovic[1], Sanja Ognjanovic[1], Svetozar Damjanovic[1] & Djuro Macut[1]

[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [2]CHC Bezanijska kosa, Belgrade, Serbia; [3]IBISS, University of Belgrade, Belgrade, Serbia; [4]Clinic of Gynecology and Obstetrics, Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction

Insulin resistance (IR) is a well recognised feature in women with polycystic ovary syndrome (PCOS). The aim of this study was to analyse IR indices obtained from oral glucose tolerance test (OGTT), in different PCOS phenotypes.

Methods

We evaluated 240 PCOS women (PCOS: 24.86 ± 5.97 kg/m^2; 25.25 ± 4.98 years) diagnosed using ESHRE/ASRM criteria and 70 BMI-matched healthy women (controls: 26.14 ± 4.86 kg/m^2; 30.76 ± 5.82 years). PCOS group was divided into four phenotypes: A (anovulation (ANOV), hyperandrogenism (HA), and polycystic ovary morphology (PCOM)), B (ANOV and HA), C (HA and PCOM), and D (ANOV and PCOM). Phenotype D had lower BMI in comparison to all other phenotypes ($P<0.05$). Standard OGTT with 75 g glucose was performed in all subjects. IR was estimated by the homeostasis model assessment of IR (HOMA-IR), insulin sensitivity index (ISI), hepatic IR index (HIRI), and insulinogenic index (IGI). Areas under insulin (AUCi) and glucose (AUCg) and their ratio, termed the insulin secretion-sensitivity index-2 (ISSI-2) were calculated.

Results

The whole PCOS group in comparison with controls had higher levels of basal glucose (4.89 ± 0.45 mmol/l vs 4.57 ± 0.50 mmol/l, $P=0.003$) and insulin (17.16 ± 10.36 mU/l vs 11.95 ± 6.53 mU/l, $P<0.001$), HOMA-IR (3.64 ± 2.38 vs 2.66 ± 1.48, $P<0.001$), HIRI (3.98 ± 2.65 vs $2.20\pm0.85\times10^6$, $P=0.027$), IGI (22.13 ± 15.86 vs 10.31 ± 4.13, $P=0.027$), AUCg (711.63 ± 153.87 vs 670.68 ± 86.48, $P=0.012$), AUCi (7847.97 ± 4660.48 vs 4647.80 ± 1665.78, $P=0.029$), and ISSI-2 (10.83 ± 5.49 vs 6.51 ± 2.14, $P=0.019$) while ISI (4.50 ± 2.14 vs 6.04 ± 2.71, $P=0.032$) was lower. Phenotype B had higher levels of basal insulin and HOMA-IR then phenotypes A, C, and D while AUCi, HIRI, ISSI-2 were higher and ISI was lower then in phenotypes C and D. There were no differences in basal glucose, AUCg and IGI between phenotypes.

Conclusion

In our group of women with PCOS, classical hyperandrogenemic phenotype B was characterised with the most exaggerated indices of IR.

A case of dyskeratosis congenita associated with hypothyroidism and hypogonadism

Nilufer Ozdemir Kutbay[1], Zehra Erdemir[2], Banu Sarer Yurekli[1], Emin Karaca[3], Mehmet Erdogan[1], Sevki Cetinkalp[1], Gulsen Kandiloglu[4], Gokhan Ozgen[1], Ferda Ozkinay[3] & Fusun Saygili[1]

[1]Endocrinolgy and Metabolism Department, Faculty of Medicine, Ege University, Izmir, Turkey; [2]Internal Medicine Department, Faculty of Medicine, Ege University, Izmir, Turkey; [3]Genetics Department, Faculty of Medicine, Ege University, Izmir, Turkey; [4]Pathology Department, Faculty of Medicine, Ege University, Izmir, Turkey.

Introduction

Dyskeratosis congenita is a rare multisystemic disease characterised with atrophy on skin, pigmentation, nail dystrophy, leukoplakia in mucous membrane, bone marrow failure, and tendency to malignancy. We present a rare case of dyskeratosis congenita associated with hypothyroidism and hypogonadism.

Case

A 30-year-old male patient was referred to Endocrinology Department with the findings of micropenis and atrophic testicles. His parents had cousin marriage. Physical examination results: BP: 130/80 mmHg, height: 172 cm, weight: 83 kg, and BMI: 28 kg/m^2. There were hypopigmented skin lesions in the whole body. The skin was dry and the nails were dystrophic. His axillary and pubic hair was normal but facial hair was scarce. He had alopecia in 1/3 of outer eyebrow (Omnibus sign) and saddle nose. Micropenis and testicles were found to be atrophic. The laboratory findings: WBC: 3140/mm^3, neutrophil: 1740/mm^3, Hb: 12.5 g/dl, plt: 187 000/mm^3, free testosterone: 1.4 pg/ml, total testosterone: 0.70 ng/ml, FSH: 77.28 mIU/l, LH: 15.38 mIU/l, E_2: <20 pg/ml, prolactin: 6.77 ng/ml, DHEAS: 222.1 µg/dl, free T_3: 3.35 pg/ml, free T_4: 0.98 ng/dl, TSH: 10.88 mIU/l, anti-TG: 203 IU/ml, ACTH: 24.1 pg/ml, and cortisol: 13.34 µg/dl. Hypergonadotropic hypogonadism was suspected as testosterone was low and FSH and LH were high. Hyperkeratosis keratoderma was found in skin biopsy. In the biopsy of lymph node from right cervical, we found disseminated histiocytic proliferation that changes the normal appearance of lymph node and granulomas that are characterised with rare giant cell formation and that don't include necrosis.

Conclusion

Dyskeratosis congenita is a rare disease showing X-linked recessive inheritance along with autosomal dominant and recessive forms. Although the pathogenesis of the disease is still unknown, *DKC1* gene localised to Xq28 is thought to be responsible for the X-linked dyskeratosis congenita. Our patient is still genetically studied. In this syndrome, the association of hypothyroidism and hypogonadism should be kept in mind.

NMDA receptor mediated limbic encephalitis in a woman with mature cystic ovarian teratoma: a case report

Melinda Vanya[1], Zoltan Kovacs[2,4], Nikos Gorgoraptis[3], Afram Salek-Haddadi[3], Laszlo Kovacs[4] & Gyorgy Bartfai[1]

[1]Department of Obstetrics and Gynaecology, Faculty of Medicine, Albert Szent-Györgyi Health Centre, University of Szeged, Szeged, Hungary; [2]Department of Psychiatry, Faculty of General Medicine, Albert Szent-Györgyi Health Centre, University of Szeged, Szeged, Hungary; [3]Department of Neurology, Centre for Neurosciences, The Royal London Hospital, London, UK; [4]Department of Rheumatology, Faculty of General Medicine, Albert Szent-Györgyi Health Centre, University of Szeged, Szeged, Hungary.

Objective

Our aim was to present a case of paraneoplastic NMDA-R antibody-mediated limbic encephalitis in a woman with OT thereby providing information facilitating diagnosis of OT in women, who present with symptoms of paraneoplastic limbic encephalitis (LE) for obstetricians and gynaecologists with appropriate.

Case

We report the case of a 25-year-old women, who developed NMDA-R-antibody mediated autoimmune encephalitis and who displayed confusion, disorientation, a behavioural disturbance with agitation and features of paranoia and at least one reported generalised tonic clonic seizure associated with orofacial dyskinesia. Magnetic resonance imaging revealed 3.3 cm functional ovarian cyst measuring which was removed surgically and demonstrated histologically to be a mature cystic OT. The serum was positive for antibodies to NMDA receptors. Following i.v. immunoglobulin treatment, oophorectomy and a 5-day course of plasma exchange, followed by corticosteroid and azathioprine immunosuppressive therapy, the patient displayed a significant clinical improvement.

Conclusion

Cystic teratomas are common benign ovarian lesions in women of reproductive age. Although the association of OTs and NMDA-R antibody-mediated encephalitis has been described in the neurologic literature, this relationship needs to be considered from on interdisciplinary aspect by the healthcare providers.

DOI: 10.1530/endoabs.37.EP135

The impact of bleeding patterns and hormonal contraceptives on migraine headache: a retrospective cross-sectional study

Melinda Vanya[1], Ivan Devosa[3], Fanni Bokros[2], Marta Szucs[1], Delia Szok[2] & Gyorgy Bartfai[1]
[1]Department of Obstetrics and Gynaecology, Albert Szent-Gyorgyi Clinical Centre, University of Szeged, Szeged, Hungary; [2]Department of Neurology, Faculty of Medicine, Szent-Gyorgyi Albert Health Centre, University of Szeged, Szeged, Hungary; [3]Faculty of Medicine, Institute of Behavioural Medicine, Szent-Gyorgyi Albert Health Centre, University of Szeged, Szeged, Hungary.

Introduction
Clinical studies revealed an increased incidence of migraine attacks in conditions with falling levels of plasma oestrogen in the perimenstrual phase of the menstrual cycle and during the hormone-free interval in women taking combined oral contraceptives.
Objective
The purpose of the study was to assess the connection between menstrual cycle, bleeding patterns of women with migraine and the clinical characteristics of the migraine attacks.
Methods
The questionnaire-based survey ($n=186$) was undertaken in the South-Eastern Hungary with the collaboration of the Department of Neurology and the Department of Obstetrics and Gynaecology. We invited all women with M0 and MA in the Outpatient Headache Unit of the Department of Neurology, Szeged, Hungary to participate in the questionnaire-based study. We collected a data in two time periods: between 2006–2009 and 2013–2014. We collected the answers via three ways: personal face-to-face interviews, online and postal way. The main outcome measures were to describe the menstrual pattern of women with migraine, the relationships between menstrual cycle and clinical characteristics of the migraine attacks.
Results
Our study group consisted of 108 (52%) women with M0 and 78 (48%) women with MA. The average age of the patients at the diagnosis of migraine was 18.79 ± 6.97 years. The Pearson's correlation test revealed a relationship between duration of menstrual cycle and the intensity of headache pain ($P=0.012$). However, there was no significant relation between the intensity of headache pain and other study parameters (e.g. duration of use of COC, length of bleeding, menstrual cramps, amount of bleeding, and BMI).
Conclusions
According to our best knowledge this is the first study in Hungary to describe contraceptive habits of migraineurs and the connection between the duration of menstrual cycle and intensity of the migraine head pain.

Constitutive and inducible regulation of PEPCK isoform genes in human cells

Venu Seenappa[1], Manjunath B Joshi[1], Bidyadhar Das[2] & Satyamoorthy Kappaettu[1]
[1]School of Life Sciences, Manipal, Udupi, Karnataka, India; [2]Northeast Hill University, Shillong, Meghalaya, India.

Introduction
Phosphoenolpyruvate carboxykinase (PEPCK) is the key rate determining enzymes of gluconeogenesis pathway. PEPCK exists in cytosolic (PEPCK-C) and mitochondrial (PEPCK-M) isoforms. PEPCK isoforms maintain glucose/lipid homeostasis and is being explored as a therapeutic target for treating metabolic diseases. We tested the influence of a naturally occurring compound Genistein (a soy derived isoflavone) to constitutively regulate PEPCK isoforms to address its potential use as a therapeutic molecule.
Methods
HepG2 and fibroblasts were tested for the effects of genistein by western blot; RNA stability was examined by RT-PCR using actinomycin treated cells; transcriptional regulation was performed by reporter assays and CpG DNA methylation was analysed by bisulfite sequencing.
Results
Expression and activity of PEPCK isoforms in fibroblasts was lower than in HepG2 hepatoma cells. In HepG2 cells, genistein induced degradation of PEPCK-C transcript and proteins but increased PEPCK-M expression. In fibroblasts, genistein increased PEPCK-C expression through promoter demethylation but PEPCK-M was unaffected. Reporter gene and RT-PCR assays suggested genistein mediated RNA degradation of PEPCK-C in HepG2 cells is due to the existence of AU-rich elements (AREs) in 3′-UTR of the gene.
Conclusion
We show an evidence for the regulation of PEPCK-C gene by promoter DNA methylation in human fibroblasts, which might be responsible for maintaining baseline PEPCK activity in non-gluconeogenic tissues. We show selective effect of soy isoflavone genistein on PEPCK isoform genes in hepatic and extra hepatic cell types by increasing the expression of PEPCK-M as a compensatory mechanism and there by maintaining glucose homeostasis in cells as a pro-survival effect.

Study on the correlation between serum androgens and sexual function in post-menopausal women

Soheila Nazarpour[1], Masome Simbar[1], Fahimeh Ramezani Tehrani[2], Maryam Tohidi[3] & Hamid Alavi Majd[4]
[1]Midwifery and Reproductive Health Department, Faculty of Nursing and Midwifery, Shahid Beheshti University of Medical Sciences and Health Services, Tehran, Iran; [2]Research Institute for Endocrine Sciences, Reproductive Endocrinology Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [3]Research Institute for Endocrine Sciences, Prevention of Metabolic Disorders Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [4]Biostatistics Department, Faculty of Paramedicine, Shahid Beheshti University of Medical Sciences and Health Services, Tehran, Iran.

Introduction
Sexual dysfunction could be under the influence of menopause and the changes it causes in hormone levels. The purpose of this study is to examine the correlation between serum levels of androgens and sexual function in post-menopausal women.
Methods
This is a community-based, descriptive-analytical study involving 405 post-menopausal women, aged 40–65 years, who had reached menopause up to 3 years prior to the study. A multi-stage, randomized sampling was conducted in the cities of Chalous and Nowshahr. The data was collected using the female sexual function index (FSFI) questionnaire, a researcher-made questionnaire, and blood sampling to study the serum levels of androgens (testosterone and DHEAS), sex hormone-binding globulin (SHBG), and oestradiol in the laboratory. The acquired data was analysed statistically using SPSS.
Results
61% of the subjects were suffering from female sexual dysfunction (FSD). Total testosterone levels had a negative correlation with scores in the domain of desire ($r=-0.108$, $P=0.029$), DHEAS levels were positively correlated with scores in the domain of pain ($r=0.113$, $P=0.022$), and the free estradiol index (FEI) was positively correlated with scores in the domain of pain ($r=0.115$, $P=0.020$). Satisfaction with marital relationship had a significant positive correlation with total testosterone levels ($r=0.131$, $P=0.008$) and the free androgen index (FAI) ($r=0.100$, $P=0.044$). In examining the correlation between FSFI scores and hormone levels, multiple regression analysis showed that serum levels of total testosterone and free androgen index were predicting factors in, respectively, the domain of lubrication ($P=0.042$) and satisfaction ($P=0.021$).
Conclusion
Androgenic hormones can affect certain aspects of sexual function in post-menopausal women. This subject area, however, requires further investigation.

Increased circulating urocortin-3 levels is associated with polycystic ovary syndrome

Muzaffer Temur[1], Özgür Yilmaz[1], Saliha Aksun[2], Pelin Özün Özbay[3], Mehmet Calan[4], Tuncay Küme[5], Murat Karakulak[6] & Hüseyin Anil Korkmaz[7]
[1]Department of Obstetrics and Gynecology, Manisa Merkezefendi State Hospital, Manisa, Turkey; [2]Department of Medical Biochemistry, Izmir Katipcelebi University Medical School, Izmir, Turkey; [3]Department of Obstetrics and Gynecology, Aydin Obstetrics and Pediatrics Hospital, Aydin, Turkey; [4]Department of Endocrinology, Izmir Bozyaka Education and Research Hospital, Izmir, Turkey; [5]Department of Medical Biochemistry, Dokuz Eylul University Medical School, Izmir, Turkey; [6]Department of Obstetrics and Gynecology, Silivri State Hospital, Istanbul, Turkey; [7]Division of Pediatric Endocrinology, Dr Behçet Uz Children Research and Training Hospital, Izmir, Turkey.

Purpose
This study aims to compare serum urocortin-3 levels in women with PCOS and healthy women, and establish what role urocortin-3 levels play in PCOS.
Methods
Fifty-two patients with PCOS and 55 healthy women were included in the study, matched for age and BMI. Fasting blood glucose (FBG), insulin, hs-CRP, urocortin-3, and free testosterone levels of the all participants were measured. HOMA-IR was used to calculate the insulin resistance.
Results
Circulating urocortin-3 levels were significantly increased in women with PCOS than in control subjects (54.49 ± 5.77 pmol/l vs 51.28 ± 5.86 pmol/l, $P=0.005$). Urocortin-3 levels positively correlated with hs-CRP in PCOS group ($r=0.391$, $P=0.004$). There was no any correlation between urocortin-3 and other parameters. Multivariable binary logistic regression analysis showed that elevated urocortin-3 levels were associated with PCOS. Receiver operating characteristic curve analysis showed that urocortin-3 levels were useful as a diagnostic marker for PCOS. The optimal cut-off value of urocortin-3 for detecting PCOS was ≥ 51.46 pmol/l, at which the sensitivity was 75% and specificity was 68%.
Conclusions
Circulating concentration of urocortin-3 are significantly increased in women with PCOS. Furthermore, increased urocortin-3 levels were associated with PCOS after adjustment for potential confounders. This link in between urocortin-3 and PCOS may be due to an underlying chronic inflammation in subjects with PCOS.

Implication of non polar phytocomponents of aloe vera gel in management of polycystic ovarian syndrome

Laxmipriya Nampoothiri, Radha Maharjan & Arpi Dey
M S University of Baroda, Vadodara, India.

Background
Aloe vera gel has been proven to have hypoglycaemic, hypolipidemic, and steroid enzyme regulating properties. These are of clinical significance in reproductive pathology namely polycystic ovary syndrome (PCOS). Preliminary, '*in-vitro*' studies suggested that non-polar component is responsible for the steroid enzyme modulating effect. This study investigates the role of non polar phytocomponent's of aloe vera gel, which could be responsible in management of this pathology.
Aim
The aim of this study was to evaluate the effects of non-polar phyto-components on the PCOS pathology using rodent model.
Design and methods
Rodent model was developed using letrozole (0.5 g/kg body weight daily orally for 21 days) and validated for PCOS pathology. Later, the non-polar component, extracted using petroleum ether (containing phytosterols validated by HPTLC) was administered to PCOS rats daily ($\sim$25 μg/kg body weight) for 2 months, with respective controls (Aloe and vehicle). After the course of treatment, ovarian expression profile (mRNA and protein) of major steroidogenic genes namely StAR, 3 beta-hydroxysteroid dehydrogenase (3β-HSD), aromatase, LHR, and FSH-R were monitored in addition to biochemical parameters. Parallely, phytochemical elucidation of non-polar fraction was evaluated.
Results
Expression of StAR, 3β-HSD, and LHR was found to be decreased ($P<0.01$), both at transcript as well as protein level in non-polar fraction treated PCOS group as compared with untreated PCOS control while other genes studied did not show any significant change. Phytochemically, aloe vera non-polar fraction exhibited the presence of β-sitosterol in major quantity, along with minor amounts of stigmasterol, lupeol, and its derivatives.
Conclusion
Non-polar fraction of aloe vera gel has a potential to manage PCOS phenotype, by modifying steroidogenic targets. This study may serve as platform for designing drugs by exploring these novel targets.

Is idiopathic hirsutism associated with an increase in metabolic disturbances?

Samira Behboudi-Gandevani[1], Fahimeh Ramezani Tehrani[1], Masoomeh Simbar[3] & Fereidoon Azizi[2]
[1]Research Institute for Endocrine Sciences, Reproductive Endocrinology Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Endocrine Research Center, Shaheed Beheshti University of Medical Sciences, Tehran, Iran; [3]Department of Reproductive Health, Shahid Beheshti University of Medical Sciences, Tehran, Iran.

Introduction
Idiopathic hirsutism (IH) is one of the most frequent complaints affecting 13% of reproductive aged women. The relationship between IH and metabolic abnormalities are not fully understood. The aim of this study was to evaluate the relationship between IH and metabolic abnormalities.
Methods
A total number of 100 idiopathic hirsute women (range 15–45 years) recruitment from a population based cohort study of Tehran Lipid and Glucose Study. Control age-matched women were selected from the same population. Biochemical characteristics of the participants including waist and hip circumferences and ratio, blood pressure, glucose, androgens and lipid profiles, and insulin resistance by HOMA-IR were compared. Differences between the two groups in univariate analysis were detected by independent Student's *t*-test for continuous variables with normal distribution or by the Mann–Whitney *U* test for those without normal distribution. Analysis of covariance (ANCOVA) was used for comparison of groups with adjustment for the BMI.
Results
The IH subjects had higher BMI and waist to hip circumferences ratio compared with healthy controls, 25.4 (3.2) and 0.83 (0.04) in IH vs 23.9 (4.2) and 0.81 (0.05) in controls ($P=0.02$ and $P=0.04$) respectively. The mean fasting insulin, HOMA-IR, and TG in IH women were statistically higher than in controls but there were not any statistical differences between them and other biochemical, anthropometric, lipid, and blood pressure profiles after adjustment for age and BMI.
Conclusions
Our data suggest that IH did not associate with metabolic disturbances. It seems that no more additional intervention and evaluation are needed in IH subject later in life.

Prevalence and pattern of menstrual disorders and related factors among Iranian women in reproductive ages: a population based study

Marzieh Rostami Dovom[1], Fahimeh Ramezani Tehrani[1], Maryam Farahmand[1], Somayeh Hashemi[1] & Freydoun Azizi[2]
[1]Research Institute for Endocrine Sciences, Reproductive Endocrinology Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Research Institute for Endocrine Sciences, Endocrine Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran.

Introduction
Menstrual disturbances can be considered as a sign of reproductive system disorders in women in reproductive ages. These disturbances can be indicators of serious underlying problems. The aim of this study was to determine the prevalence and pattern of menstrual related manifestation among Iranian women.
Methods
This was a population-based study conducted among women ($n=941$) aged 18–45 years. The participants who met the eligibility criteria were selected from four provinces using quota stratified cluster sampling, and invited for further comprehensive interview.
Results
The most common menstrual disorders in Iranian women were dysmenorrhea (67/5%) and premenstrual syndrome (54/9%) respectively. Prevalence of other non-anatomical abnormal uterine bleeding was 19.9%. Some demographic factors such as younger age, married at older ages, as well as celibacy was correlated with the incidence of dysmenorrheal ($P<0.5$). The results have shown that more than 83% of women younger than 25 years old suffer from dysmenorrheal. Younger women (<25 years) are 2.3 times as likely to have dysmenorrheal than women 25 years and older (OR=2.3, 95% CI: 1.5–3.7, $P<0.0001$). Also, never married women are 2.1 times as likely to have dysmenorrhea than married women (OR=2.1, 95% CI: 1.2–3.6, $P<0.0001$). Higher BMI and higher levels of education had a significant relationship with oligomenorrhea and premenstrual syndrome respectively ($P<0.5$). The result of this study has shown that younger menarche age was significantly associated with the occurrence of menorrhagia.
Conclusion
Almost one out of every four Iranian women in reproductive age suffers from at least one menstrual disorder. Encouraging women to change lifestyles in reproductive ages, counselling and giving adequate information on menstrual disorders can play a main role in reducing the adverse effects of these disorders.

Testosterone level in men correlates with BMI and cardiorespiratory fitness but is not related to age

Laura DeFina[2], Nina Radford[3], David Leonard[2], Erica Howard[2], Rick Wilson[3], Tyler Cooper[2], Michael Clark[3] & Ugis Gruntmanis[1]
[1]University of Texas Southwestern, Dallas, Texas, USA; [2]The Cooper Institute, Dallas, Texas, USA; [3]Cooper Clinic, Dallas, Texas, USA.

Background
Presently it is unknown how much of testosterone decline associated with aging is actually due to ageing *per se*, and how much is related to weight gain, decreased activity, and other age-related factors. Understanding the modifiable factors associated with low testosterone, such as obesity or cardiorespiratory fitness (fitness) is critical.
Methods
The observational, cross-sectional study included 1653 men, ≥50 and <80 years of age, seen between January 2012 and December 2012 for a preventive medical examination and underwent BMI, total testosterone, and objective fitness measurements as defined by the total duration of time on a maximum Balke treadmill test. Treadmill time was then used to estimate metabolic equivalents (METs). All participants underwent morning (0700–0900 h) total testosterone measurement using the standard chemiluminescence method. Testosterone thresholds were categorized into low (<250 ng/dl), low normal (250–<400 ng/dl), and normal (≥400 ng/dl). We used traditional sample statistics to summarise characteristics of the sample within decades of age and ordered categories of BMI.
Results
While levels of mean testosterone levels in all age groups were in the normal range were statistically different between groups, (50–59 years, testosterone mean=479.0 ng/dl (S.D.=175.4); 60–69 years, testosterone mean=457.2 ng/dl (S.D.=204.1); and 70–79 years, testosterone mean=464.6 ng/dl (S.D.=176.7); trend P value=0.05), although, the trend was statistically different, mean testosterone levels in all groups were in the normal range. The prevalence of low testosterone did not significantly differ between 50–59, 60–69, and 70–79 age groups (<250 ng/dl=7.6–9.3% to 8.7%; trend test $P=0.17$) but did change with increasing BMI, (<250 ng/dl=3.4–6.8% to 17.8%; trend test $P<0.001$). Finally, fitness was positively correlated with total testosterone levels ($P<0.001$) and this correlation persisted after adjustment for age and BMI.
Conclusion
In this group of generally healthy men, there was no decrease in the mean total testosterone level with increasing age, yet we found statistically and clinically negative correlation between testosterone and BMI and positive correlation between testosterone and fitness.

Analysing by decade, testosterone undecanoate depot injectable does not increase prostate volume: study during up to 7 years on hypogonadic patients

Matei Pisoschi[1], Mara Carsote[2], Catalina Poiana[2], Dana Cristina Staicu[3] & Dan Peretianu[3]
[1]Hospital 'Th. Burghele', Bucharest, Romania; [2]Institute of Endocrinology, Bucharest, Romania; [3]Societatea Civila Medicala 'Povernei', Bucharest, Romania.

Aim
Re-analysing the effect of injectable testosterone undecanoate depot (TUD) in hypogonadic patients.
Materials and method
(A) Patients: at onset 210 men with hypogonadism (median age: 61.5 years). (B) Distribution: by decade; $n=4$, 12, 21, 54, 59, 43, 16, and 1. (C) TUD (NebidoR-Bayer-Schering) 1000 mg was injected one per 3 months i.m. (D) Prostate volume (PV) appreciated by per-abdominal ultrasound: 3.5 MHz probe, elliptical volume (cm^3), Aloka 550. (E) Time of analysis: before starting testosterone (T0), after ½ month (T1), 3 months (T2), 6 months (T3), 1 year (T4), 2 years (T5), 3 years (T6), 4 years (T7), 5 years (T8, $n=28$), 6 years (T9, $n=12$), and 7 years (T10, $n=6$). (F) Maximum increment from T0 was noted Δ M %. Average increment was noted A %. (G) Statistical analysis: Student' t-test.
Results
i) All average prostatic volume for decade in figure. Maximum increment (Δ M %) per decade (45.95; 20; 40.35; 42.5; 45.45; 64.41; and 39.56), including the moment (Δ M % at) and average increment (Δ A %) (Table). (II) PV at T0 increases with age, from minimum 15.38 (19–29 years) to maximum 47.41 (80–89 years), $P=0.0007$. (III) Considering all observations (some at 5/6/7 years), TUD did not increase PV significantly (in fact the average of increment in all patients was negative=−12.54%). Δ M % per decade: 20. (IV) Inside a specific decade no significant increase in PV was registered: all $P>0.05$; exception: 80–89 decade, $P=0.002$, at 3–5 years. (V) In some patients, especially from 50 to 79 years, TUD could decrease slightly prostatic volume.
Conclusions
Considering the risk for prostate (in elderly), testosterone undecanoate 1000 mg depot injectable is a safe treatment, even after 3–7 years of administration. Precautions should be accorded to men over 80 years old, after the 3rd year administration.

DOI: 10.1530/endoabs.37.EP145

EP146

Testosterone undecanoate 1000 mg at 3 months did not increased prostatic specific antigen level: January 2015

Matei Pisoschi[1], Mara Carsote[2], Catalina Poiana[2], Dana Cristina Staicu[3] & Dan Peretianu[3]
[1]Hospital 'Th Burghele', Bucharest, Romania; [2]Institute of Endocrinology, Bucharest, Romania; [3]Societatea Civila Medicala 'Povernei', Bucharest, Romania.

Aim
To find if testosterone undecanoate (TUD) 1000 mg injection (NebidoR; Bayer-Schering) at 3 months has a negative effect on prostate.
Materials and method
i) PSA (ng/ml) registred before (T0) and after TUD at T1 (2 weeks) to T10 (7 years) (see Pisoschi, this Congress); ii) statistical analysis: *t*-test, simple correlation, and multiple regression.
Results
(A) Patients at onset: 143 men, 18–96 years, average: 60.38; median: 60. (B) Prostatic volume before TUD (cmc): average: 34.81; in evolution (see Pisoschi, this Congress). (C) Average PSA (no patients): before TUD = 1.59 (143); at 1 year = 1.69 (99); 2 years = 1.4 (73); 3 years = 1.85 (48); 4 years = 2 (38); 5 years = 1.86 (26); 6 years = 1.51 (10); and 7 years = 2.86 (6). (D) Statistical difference of average: nonsignificant for all the times from 2 weeks to 7 years. (E) Correlation between age and PSA was: i) significant before and after treatment till 2 years but nonsignificant for 3–7 years (PSA did not change as age after treatment). (F) Correlation between PSA and prostatic volume was significant, both before and after treatment (depending on group size); r before TUD = 0.56, at 1 year = 0.51, 2 years = 0.55, 3 years = 0.42, 4 years = 0.11, 5 years = 0.57, 6 years = −0.06, and 7 years = 0.52. (G) Multiple regression test ($r^2 = 0.53$–0.99, $F = 36.36$–4906) shows that PSA level post testosterone does not depend on testosterone but on age, prostatic volume (before and after treatment), and PSA initial level (before testosterone administration); $p \ll 0.001$.
Conclusions
i) Testosterone undecanoate 1000 mg injectable i.m. at 3 months did not increase PSA level after 7 years administrations. ii) PSA level post testosterone was in fact dependent only on age, prostatic volume before treatment and PSA level before treatment.

Role of elevated serum adiponectin in delayed puberty of thalassemic patients

Mohamed Mekawy, Merhan Nasr, Soha Youssef, Mahira Almogy & Nevine Gamal
Ain Shams University, Cairo, Egypt.

Background
Adipose tissue dysfunction can play a role in the neuroendocrine and haematopoietic dysfunctions affecting thalassaemic patients.
Aim of the work
In this work, we aimed to study the serum levels of adiponectin, an adipocytokine, in Egyptian β-thalassemia patients in relation to their endocrinal complications.
Subjects and methods
The study included 60β-thalassaemia patients; (major, intermedia, and minor) and 30 healthy age- and sex-matched controls. The diagnosis of thalassemia was based on clinical, haematological, and genetic studies. Anthropometric measurements, clinical neuroendocrinal assessment, iron profile (serum ferritin, serum iron, and total iron binding capacity) and measurment of serum levels of adiponectin using ELISA were performed for all subjects. Our β-thalassemia major and intermedia patients had significantly lower BMI, shorter height, lower weight, delayed growth and puberty while thalassemia minor patients showed no significant delay in puberty compared with healthy controls.
Results
A significantly higher level of adiponectin was found in thalassemic patients (median = 3.5 ng/ml) compared to controls (median = 0.4 ng/ml) with the level becoming progressively higher with degree of clinical severity (median = 0.6 ng/ml in minor, 2.5 ng/ml in intermedia, and 4.3 ng/ml in major). The level of adiponectin was negatively correlated to height, weight, and BMI in both thalassemia intermedia and major while it was negatively correlated to puberty only in thalassemia major patients. A clinically significant level of adiponectin was obtained at >0.8 ng/ml for delayed puberty and iron overload (high serum iron and serum ferritin).
Conclusion
We found that high adiponectin levels correlated to iron overload and delayed growth in both β-thalassemia major and intermedia patients as well as to delayed puberty in thalassemia major.

Prevalence of autoimmune thyroid markers in euthyroid women with polycystic ovary syndrome

Ahmed Bahaa El-Din, Alyaa El-Sherbeny & Emad Abd El-Hadi
Ain Shams University Hospital, Cairo, Egypt.

Introduction
Polycystic ovary syndrome (PCOS) is the most common endocrinopathy in women in reproductive age. A condition that causes irregular menstrual periods because monthly ovulation is interrupted and levels of androgens are elevated. It occurs in about 5–10% of women and is considered to be the most common cause of anovulatory infertility in reproductive age.
Objectives
To compare the prevalence, levels of thyroid auto-antibodies in a group of Egyptian women with PCOS and a control group in reproductive age to determine whether women with PCOS have a greater risk of thyroid autoimmune diseases, thyroid dysfunction or not.
Patients and methods
This study was conducted on 45 euthyroid women with PCOS and 18 healthy women as a control in the Outpatient Clinics of Endocrinology, Ain Shams University Hospital. PCOS was defined by the revised 2003 Rotterdam criteria. Thyroid function was evaluated by measurement of TSH and FT_4 levels, anti-thyroid peroxidase, and anti-thyroglobulin antibodies (anti-TPO and anti-TG respectively) as markers for thyroid autoimmunity. All parameters were measured using electrochemiluminescence immunoassay.
Results
Women with PCOS had a significantly higher levels of anti-TPO in comparison to controls (27 ± 10 and 21 ± 10 IU/ml, respectively; $P < 0.05$) with no significant difference in anti-TG, TSH, or FT_4 between the two groups. Patients with PCOS had a non-significant higher prevalence of positive anti-TG and/or anti-TPO in comparison to controls (40 and 22.2%, respectively; $P > 0.05$), anti-TPO alone (28.9 and 16.7, respectively; $P > 0.05$), and anti-TG alone (22.2 and 11.1%, respectively; $P > 0.05$).
Conclusions
Women with PCOS had a significantly higher levels of anti-TPO than controls that may put them at a higher risk for thyroid autoimmune disease.

Stereoselective effects of statins on xenobiotic-metabolising pathways

Martina Korhonova & Zdenek Dvorak
Department of Cell Biology and Genetics, Faculty of Science, Palacky University, Slechtitelu 11, 783 71 Olomouc, Czech Republic.

Several of currently used drugs are chiral compounds. Majority of them are clinically administered as a racemic (equimolar) mixture of enantiomers. Individual enantiomers of one drug can qualitatively and quantitatively differ in their biological activities (pharmacology, toxicology, pharmacokinetics, etc.). Therefore, enantiopure drugs have been developed and introduced to the therapy. Statins are drugs used to lower cholesterol levels by inhibiting the enzyme HMG-CoA reductase. Atorvastatin, rosuvastatin, and fluvastatin are the most often prescribed statins. They have two chiral centres, thus they form four enantiomers (3R5R, 3R5S, 3S5R, and 3S5S). They are marketed as a racemic mixture of these enantiomers; however their enantiopure forms have been introduced to clinic recently (3R5R-atorvastatin, 3R5S-rosuvastatin, and 3R5S-fluvastatin). In this study, we investigated enantiospecific interactions of all four enantiopure forms of atorvastin, rosuvastatin, and fluvastatin with main transcriptional regulators of drug-metabolizing enzymes – aryl hydrocarbon receptor (AhR), glucocorticoid

receptor (GR), and pregnane X receptor (PXR). Agonist and antagonist activities of tested compounds towards AhR, PXR, and GR were determined using human reporter cell lines. Moreover, we have tested enantiospecific effects of statins on the expression of drug-metabolising enzymes CYPs on mRNA and protein level in primary human hepatocytes.

Serum N-terminal pro-B-type brain natriuretic peptide levels detection and cardiac interventricular septum tissue Doppler echocardiographic evaluation of women with polycystic ovary syndrome

Mehmet Emin Ayhan[1], Senay Arikan Durmaz[2], Ayse Carlioglu[2] & Selami Demirelli[2]

[1]Erzurum Regional Training and Research Hospital, Erzurum, Turkey; [2]Dörtyol Government Hospital, Hatay, Turkey.

Introduction

The aim of this study, left ventricular systolic and diastolic function by echocardiography and tissue Doppler echocardiographic evaluation and relationship serum N-terminal pro-B-type brain natriuretic peptide (NT-proBNP) levels of women with polycystic ovary syndrome (PCOS).

Materials and method

Thirty-two women with PCOS (age: 23.4–4.6 years; BMI: 23.8–4.8 kg/m^2), similar age and BMI have features 30 healthy womens controls involved in the study. Anthropometric features, NT-proBNP levels, HOMA-IR index, renal and hepatic function parameters, serum lipid and cholesterol levels, hormonal tests were measured. Interventricular septum was evaluated by tissue Doppler echocardiography. Statistical Package for the Social Sciences (SPSS) 17 programme was used in the statistical analysis of data. Student's *t*-test, Pearson's correlation test, and multiple regression analyse test results of all the parameters stuided in the PCOS and control group. İmportance level of values whose P value <0.05 is taken as statiscally significantly.

Results

PCOS group had NT-proBNP ($P=0.04$), total testosterone ($P=0.005$), cholesterol ($P=0.02$), and triglycerides ($P=0.006$) levels higher than control group. Echocardiographic assessment of the interventricular septum thicknes and width of the aortic root measurements levels in the PCOS group higher than the control group. Also, left ventricular mitral valve E-wave velocity ($P=0.039$) in the PCOS group were significantly less than the control group and left ventricular deseleration time ($P=0.035$) longer than control group. PCOS group with multiple regression analysis when the high NT-proBNP levels was positively correlated with age ($r=0.364$, $P=0.002$), interventricular septum thicknes (İVST) ($r=0.299$, $P=0.02$), and width of aortic root ($r=0.272$, $P=0.025$).

Conclusions

Our study results have shown that, NT-proBNP levels have able to a biochemical cardiac early marker of diagnosis subclinical diastolic dysfunction in younger women with PCOS. Early time examined by conventional echocardiography and tissue Doppler echocardiography possibly to helpful determinate early diastolic dysfunction of women with PCOS.

The effects of endocrine disruptors on the *in vitro* hormone regulation of rat pituitary

Zsuzsanna Valkusz[1], Marianna Radács[2], Regina Pálföldi[2], Zoltan Molnar[2], Krisztián Sepp[1], Anna László[2], Tamás Alapi[3] & Marta Galfi[2]

[1]First Department of Medicine, Szeged, Hungary; [2]Department of Environmental Biology and Education of Gyula Juhasz, Faculty of Education, Szeged, Hungary; [3]Department of Inorganic and Analytical Chemistry, Faculty of Science and Informatics, Szeged, Hungary.

Endocrine disruptor compounds (EDCs) may cause disorders and alter the normal hormone synthesis and/or release.

Aim was to investigate the effects of EDCs on normal hypophysis regulation; particularly the arginine–vasopressine (AVP) activated ACTH release from adenohypophysis cells and the monoamine activated AVP release from neurohypophysis cells.

Primary monolayer cell cultures prepared from Wistar rat hypophyses. Separated adenohypophysis (AdH) and neurohypophysis (NH) tissues were dissociated by enzymatic and mechanic methods. The 14-day-old cultures were standardized for ACTH in AdH for AVP in NH cultures and for cell-viability. ACTH and AVP contents of the endocrine cells were checked and the hormone release function was challenged with an aspecific osmotic stimulus (30 mM K^+). Untreated cultures used as control. Cultures treated – (I) 1 h 0.1 μg/ml EDCs (ClB, MU, DU, and PU)/$n=8$; (II) 10^{-6} M monoamines (epinephrine: A; serotonine: 5HT) alone/$n=8$; and (III) the stimulant agents (AVP, monoamines) in combinations with EDCs/$n=8$. ACTH and AVP and protein content was measured from supernatant media.

Results

Basal ACTH (1470 pg ACTH/mg protein) and AVP (47.25 pg AVP/mg protein) from AdH and NH respectively did not change significantly after the EDCs (I) treatment. The AVP induced ACTH release (11 750 pg ACTH/mg protein) and the monoamines induced AVP (5HT: 194.18 pg AVP/mg protein and A: 199.26 pg AVP/mg protein) (II) became strongly increased.

In the (III) experimental protocols, combined treatments where were used (AdH/ACTH: AVP+ClB: 14 620 pg ACTH/mg protein; AVP+PU: 13 114 pg ACTH/mg protein; AVP+MU: 14 997 pg ACTH/mg protein; AVP+DU: 15 174 pg ACTH/mg protein; NH/AVP: A+CLB: 216.16 ng AVP/mg protein; 5HT+CLB: 203.28 pg AVP/mg protein; A+PU: 173.29 pg AVP/mg protein; 5HT+PU: 163.42 pg AVP/mg protein; A+MU: 184.66 pg AVP/mg protein; 5HT+MU: 181.39 pg AVP/mg protein; A+DU: 211.28 pg AVP/mg protein; and 5HT+DU: 216.88 pg AVP/mg protein).

Data demonstrate that EDCs can moderate pituitary cell regulation *in vitro*. AVP and monoamine regulated hormone release from hypophyseal cells was influenced variably depending from the EDCs applied.

EP152

Endocrine disruptive effect of plastic byproduct bisphenol A on GH activity

Fahad Zadjali, Mohammed Al Masroori & Mohammed Habais

Sultan Qaboos University, Muscat, Oman.

Bisphenol A (BPA) is a byproduct of polycarbonate plastic widely present in food containers. BPA is historically a known endocrine disruptor and due to its oestrogen agonist activity, BPA consumption is associated with hypothyroidism and reproductive disorder. Recent studies have shown that oestrogen antagonised GH actions. Since BPA has oestrogen agonist activity, the effect of BPA exposure on GH activity has not yet been investigated.

Aim

To study the *in vivo* effect of acute/chronic consumption of BPA on long body growth and *in vitro* effect of BPA on cellular GH signalling.

Method

CD-1 mice treated with BPA (1.75 mM orally) for 3 months starting from weaning (day 20). Body weight, tail length, and tibia length were monitored weekly. Liver tissue were collected 15 min after injection of GH or PBS.

Results

Mice given BPA in drinking water showed significant reduction in body weight from days 30 to 60 compared to control littermate. However, as result of catch-up growth, the BPA-treated mice weight became similar to control after day 60. Similar changes were observed in tibia length in which mice treated with BPA had significantly shorter tibia on days 30–50 and started to rise. Chronic treatment of BPA increased expression of SOCS2, which is a known cellular inhibitor of GH signalling.

Conclusion

In humans, there is a dramatic decrease in longitudinal bone growth, which begins during intrauterine life and is interrupted briefly at puberty. Here we found for first time that exposure to BPA, a plastic byproduct, interrupt linear growth with downregulation of GH signalling and mice exposed to BPA exhibit supranormal linear growth phenomenon known as catch-up growth. Further investigation is need to study the effect of BPA on the metabolic action of GH specially those related to body fat content and impact on increasing world epidemic of obesity.

A possible link between LH and macrophage migration inhibitory factor levels in polycystic ovary syndrome

Mehmet Calan[1], Tuncay Kume[2], OzgUr Yilmaz[3], Tugba Arkan[1], Gokcen Unal Kocabas[4], Ozge Dokuzlar[5], Kemal Aygun[5], Mehmet Asi Oktan[5], Nilay Danıs[5] & Muzaffer Temur[3]
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Dokuz Eylul University Medical School, Izmir, Turkey; [2]Department of Medical Biochemistry, Dokuz Eylul University Medical School, Izmir, Turkey; [3]Department of Obstetrics and Gynecology, Manisa Merkezefendi Hospital, Manisa, Turkey; [4]Division of Endocrinology and Metabolism, Department of Internal Medicine, Izmir Bozyaka Training and Research Hospital, Izmir, Turkey; [5]Department of Internal Medicine, Dokuz Eylul University Medical School, Izmir, Turkey.

Purpose
Macrophage migration inhibitory factor (MIF) is a multi-functional cytokine which plays a role in metabolic and inflammatory processes. Increasing evidence suggests that there is a link between MIF and ovulation. We aimed to evaluate plasma MIF levels in women with polycystic ovary syndrome (PCOS) and to determine whether MIF levels differ between the follicular phase and mid-cycle of the menstrual cycle in eumenorrheic women.
Methods
Ninety women with PCOS and 80 age- and BMI-matched healthy eumenorrheic women were consecutively recruited into this prospective observational study. For all subjects, plasma MIF levels in early follicular phase were measured by ELISA; for the 40 healthy controls, MIF levels were also measured during mid-cycle of the same menstrual cycle.
Results
Plasma MIF levels were significantly higher in women with PCOS than in eumenorrheic women (14.16 ± 1.59 ng/ml vs 10.39 ± 0.70 ng/ml; $P<0.001$). MIF levels were significantly higher at mid-cycle than in the follicular phase in eumenorrheic women (11.15 ± 0.61 ng/ml vs 10.56 ± 0.82 ng/ml; $P<0.001$). MIF was positively correlated with BMI, hs-CRP, and HOMA-IR in both groups. MIF was positively correlated with LH and free-testosterone only in the PCOS group. Binary logistic regression analyses revealed that the odds ratio (OR) for PCOS independently increases linearly with elevated MIF (OR = 1.385, 95% CI = 1.087–1.764, $P=0.017$).
Conclusion
MIF may play a crucial role in the reproductive system in women, including the development of PCOS and normal ovulation.

Analysis of gonadal steroid secretion in the serum of women during ovarian stimulation

Marie Claude Menet[1,2], Guillaume Damiens[1], Erwan Méténier[1], Nacéra Sraouia[1], Marie Clémence Leguy[1], Vanessa Gayet[1] & Jean Guibourdenche[1,2]
[1]AH-HP, Paris, France; [2]Université Paris Descartes, Paris, France.

Introduction
Biochemical follow up of the ovarian function after ovarian stimulation is restricted to the measurement of serum oestradiol and progesterone. We aim to investigate the entire ovarian steroidognesis after ovarian stimulation.
Materials and methods
50 women (26 IVF and 24 ICSI) who underwent AMP induction (based on rFSH stimulation after GnRH agonist or antagonist) for the same cause of infertility were retrospectively involved and compared to 11 IUI (control). Oestrogens (oestrone, oestradiol, and oestriol), androgens (Δ4-androstenedione and testosterone), and progestatives (progesterone and 17 hydroxyprogesterone) were measured using immunoassay (RIA and CobasR Roche) each 48 h (days 5–13 in AMP and days 8–14 in control). Steroid profiles were characterized using mass spectrometry. Results are expressed as median values and a $P<0.05$ was considered significant.
Results
Steroids basal secretion was within the normal range (IVF, ICSI, and IUI respectively): oestradiol (223, 317.5, and 314 pmol/l), testosterone (1124.5, 903.5, and 1606.5 pmol/l), Δ4-androstenedione (3902, 3100, and 5618 pmol/l), 17 hydroxyprogesterone (1186, 1350, and 2397.5 pmol/l), and progesterone (1150, 1150, and 2950 pmol/l). We observed a significant increase in oestradiol (4638, 7864.5, and 1282 pmol/l) and Δ4-androstenedione (5932, 11 850, and 7477 pmol/l) (IVF, ICSI, and IUI respectively). The 48 h increase was significantly different between control and AMP for estradiol (1.5-fold for IIU, 1.8-fold for IVF, and 1.9-fold for ICSI) and Δ4-androstenedione (1.02-fold for IIU and 1.31-fold for ICSI). Testosterone, hydroxyprogesterone, and progesterone increase significantly only in the induced group, i.e. 1702.5 and 1470 pmol/l; 12 344 and 8650 pmol/l; and 2450 and 4150 pmol/l for IVF and ICSI respectively. There was no difference in the 48 h increase of those steroids between ICSI and FIV except for Δ4-androstenedione which increased (1.15-fold for FIV and 1.31-fold for ICSI).
Conclusion
rFSH treatment in AMP is likely to induce a biochemical ovarian hyperplasia. However, we have highlighted individual variations, which we are exploring by mass spectrometry.

Lower peripheral fat persists in HIV-infected subjects despite viral suppression in the era of highly-active antiretroviral therapy

Louie Mar Gangcuangco[1,2], Jennifer Wong[2], Dominic Chow[2] & Cecilia Shikuma[2]
[1]Bridgeport Hospital–Yale New Haven Health, Bridgeport, Connecticut, USA; [2]University of Hawaii, Honolulu, Hawaii, USA.

Background
We compared body composition parameters in older HIV-positive individuals on stable antiretroviral therapy to age-matched HIV-seronegative individuals to assess whether differences in body composition parameters persist in the era of potent antiretroviral therapy.
Methods
Inclusion criteria to the ageing HIV cohort required subjects to be >40 years old and be on stable antiretroviral therapy for >6 months. Only subjects with undetectable plasma HIV RNA (<50 copies/ml) were included to eliminate the effects of uncontrolled HIV disease. Weight and height were measured in triplicate and averaged. Body composition (total fat, trunk fat, peripheral fat, lean tissue, and bone mineral content) was measured by dual-energy X-ray absorptiometry (DXA) using Lunar Prodigy scanner (GE Medical Systems, Inc., Milwaukee, WI, USA). Statistical analyses utilised were Wilcoxon's rank-sum test, χ^2 test, and multivariate linear regression.
Results
Body composition parameters from 133 HIV-positive individuals were compared to 74 HIV-seronegative controls. HIV-positive individuals were younger than HIV-seronegatives (medians: 51 years vs 54 years, $P=0.04$), and comprised of more males (88% vs 80%, $P<0.001$). Among HIV-positive individuals, the median CD4 count was 510 cells/μl. HIV-positive individuals had similar BMI (25.9 kg/m^2 vs 26.8 kg/m^2, $P=0.25$), but lower total fat (medians: 20.168 g vs 24.817 g, $P=0.005$) which was accounted for by differences in peripheral fat (6.811 g vs 9.634 g, $P<0.001$) with similar truncal fat levels. In a multivariate linear regression model, HIV status was a significant risk factor for lower peripheral fat content, adjusting for age, gender, ethnicity (Caucasian or non-Caucasian), BMI and past use of zidovudine or stavudine ($\beta = -0.08$, $P=0.02$).
Conclusion
Infection with HIV is still characterized by differences in body composition despite use of potent antiretroviral therapy. Specifically, HIV is associated with lower peripheral fat content independent of past use of antiretroviral therapy known to cause peripheral fat loss.

An audit of prevalence and management of erectile dysfunction and LUTS in a diabetes clinic?

Anna Haley & Parijat De
Department of Diabetes and Endocrinology, City Hospital, Birmingham, UK.

Introduction
UK NICE guidelines recommend that men with diabetes mellitus (DM) should be reviewed annually regarding symptoms of erectile dysfunction (ED) in view of

possible phosphodiesterase-5 (PDE-5) inhibitor treatment. Previous studies have shown that 70% of men with ED have concomitant lower urinary tract symptoms (LUTS). It has been suggested that there may be some common patho-physiology accounting for the improvement in LUTS seen in men with ED and LUTS treated with PDE-5 inhibitors.

Aims

Our primary aim was to assess the prevalence and management of erectile dysfunction and concomitant LUTS in a diabetic cohort. Male patients attending a diabetic clinic in SWBH, Birmingham were consented to answer questions regarding their erectile function (IIEF) and urinary storage and voiding problems (IPSS).

Results

60 men (mean age 64 years) answered the questions (July–Oct 14). 53% reported moderate ($n=27$) or severe ($n=5$) LUTS. The most commonly reported symptoms were urgency, frequency, and weak stream. Nine men said they had no partner or no opportunity for sexual activity. Of those that did have a partner ($n=51$), 78% ($n=40$) reported symptoms of erectile dysfunction (IIEF score <25). Prevalence of moderate/severe LUTS in patients wishing to be sexually active but suffering from ED was 58% ($n=23$) vs 27% ($n=3$) in those with normal erections. Only six patients were already taking PDE-inhibitors.

Discussion

This survey has shown that of men with diabetes managed in a hospital clinic and who have partners ($n=51$), 70% ($n=36$) have symptoms of erectile dysfunction and aren't on any medication for this. Of these men, 61% ($n=23$) have concomitant LUTS. Overall a high proportion of men seen in a hospital diabetes clinic (presumably more complicated diabetic patients) had erectile dysfunction and urinary symptoms. These patients would potentially benefit from consideration for PDE-5 inhibitor treatment in the secondary care setting.

Maternal obesity in pregnant rats is associated to increased levels of oestradiol during early postnatal life and altered ovarian follicular development in the offspring

Aldo Reyes[1], Luisa Ramírez[1], Valery Ambrosetti[1], Marcelo Guerra[1], Daniela Álvarez[1], Sofía Olguín[1], Daniela Fernandois[2], Ramón Sotomayor-Zárate[3] & Gonzalo Cruz[1]
[1]Laboratorio de Alteraciones Reproductivas y Metabólicas, CNPC, Facultad de Ciencias, Instituto de Fisiología, Universidad de Valparaíso, Valparaíso/Valparaíso, Chile; [2]Programa de Doctorado en Farmacología, Facultad de Ciencias Químicas y Farmacéuticas, Universidad de Chile, Santiago/Santiago, Chile; [3]Laboratorio de Neuroquímica y Neurofarmacología, CNPC, Facultad de Ciencias, Instituto de Fisiología, Universidad de Valparaíso, Valparaíso/Valparaíso, Chile.

Obesity during gestation has been related to predisposition to endocrine and metabolic diseases in the offspring. Regarding reproductive effects, an increase in BMI in pregnant mothers is associated with precocious puberty in their offspring. This has been replicated in animal models of high fat diet (HFD) administration to mothers. Also, gestational obesity has been associated to higher susceptibility to developing breast cancer in the offspring. As both precocious puberty and breast cancer are strongly related to higher oestrogens levels, we studied if offspring of rats exposed to a HFD had increased levels of endogenous oestradiol from neonatal until adult age. In addition, we evaluated ovarian follicular development in adult rats because early exposure to oestrogens alters ovarian follicular development. Twenty-four Sprague–Dawley rats were fed with HFD (60% kcal fat, Research Diet) and control diet (12% kcal fat, Champion) 1 month previous to pregnancy, during pregnancy and during nursing. Offspring rats were killed at postnatal day (PND) 1, PND7, PND14, PND30, and PND60. We found that offspring of obese mothers had an increase in body weight from PND1 until PND60, and they had an early vaginal opening indicating precocious puberty. At PND60 the offspring of obese mothers showed less antral follicles and appearance of follicular cyst in the ovary. Female offspring of obese mothers had an increase in serum levels of oestradiol at PND1, PND7, PND14, PND30, and PND60. We also found a decrease in the expression of hepatic cyp3a in offspring of obese mothers in concordance with clear signs of hepatic steatosis. We conclude that maternal obesity alters hepatic metabolism of oestradiol in the offspring leading to increased levels of endogenous oestradiol. In addition, the increase in oestradiol levels during early postnatal development may be responsible of altered reproductive function in the offspring of obese mothers.

Glucagon-like peptide-1 stimulates insulin secretion and then somatostatin secretion in rat islets

Seungjoon Oh[1,2], So Young Park[2], Kwang Sik Suh[2] & Sung-Woon Kim[1,2]
[1]Endocrinology, School of Medicine, Kyung Hee University, Seoul, Republic of Korea; [2]Endocrinology, Medical Hospital, Kyung Hee University, Seoul, Republic of Korea.

Glucagon-like peptide-1 (GLP-1) is known to stimulate insulin and somatostatin secretion in pancreatic islet cells. The exogenous somatostatin inhibits insulin secretion, but GLP-1 increases insulin secretion in spite of stimulating somatostatin secretion from δ-cell. So, we investigated whether there exists a time difference of insulin and somatostatin secretion inside the islets after GLP-1 stimulation or insulin secretion depends on secreted GLP-1 or somatostatin concentration inside the islets. We isolated pancreatic islets from five 8-week-old Sprague–Dawley rats by collagenase digestion. The islets were incubated in RPMI-1640 medium before experiments. *In vitro*, insulin and somatostatin measured at 5, 10, and 30 min depending on glucose (2.7, 5.5, and 16.7 mM as hypo-, normo-, and hyperglycaemic condition respectively) and GLP-1 concentrations (0, 0.1, and 10 ng/ml) from culture media using ELISA kit. Each well contained 30 islets/well. Insulin secretion showed continuously increased by time and GLP-1 concentration at any glucose concentration. Somatostatin secretion was increased significantly 10 min later after GLP-1 administration at hypo- and normoglycaemia. However, in hyperglycaemia, insulin secretion showed the same pattern compared with the other glycaemic conditions, but somatostatin was maximally stimulated until 10 min and decreased after that without GLP-1 administration. Adding the GLP-1, somatostatin was increased continuously until 30 min. This suggested hyperglycaemic condition itself might need more insulin secretion in the β-cell than somatostatin secretion in δ-cell. Therefore, we observed time lag of intraislet somatostatin secretion was existed with GLP-1 stimulation. We observed GLP-1 induced insulin secretion is noted earlier in β-cell than somatostatin secretion in δ-cell of rat islets. Hyperglycaemic condition might primarily secrete insulin even though and inhibit somatostatin secretion inside the islets.

Treatment with antifungal agents, fenhexamid and cyprodinil, resulted in an increase of cell cycle- and metastasis-related genes in an oestrogen receptor-dependent pathway in cellular and xenografted mouse models with BG-1 ovarian cancer cells

Ryeo-Eun Go & Kyung-Chul Choi
Laboratory of Biochemistry and Immunology, College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Fenhexamid and cyprodinil are antifungal agents used in agricultural applications and present at measurable amounts in fruits and vegetables. In this study, the effects of fenhexamid and cyprodinil on cancer cell viability and metastasis were examined and the expression levels of proteins such as cyclins D1 and E, and cathepsins B and D were analysed in BG-1 ovarian cancer cells with oestrogen receptors (ERs). BG-1 cells were cultured with 0.1% DMSO (control), 17β-oestradiol (E_2; 1×10^{-9} M), fenhexamid or cyprodinil (10^{-5}–10^{-8} M). As results, in MTT assay, E_2 as a positive control markedly increased BG-1 cell viability about five times and these antifungal agents increased BG-1 cell viability about 1.5–2 times compared to control. When the respective treatment was co-treated with ICI 182 780, an ER antagonist, BG-1 cell viability was reversed to the level of control. In wound-healing scratch assay, the scratched area was reduced by BG-1 cells treated with E_2 or these antifungal agents compared with control. However, when BG-1 cells were treated with ICI 182 780, the scratched area was maintained to the level of control. Protein levels of cyclins D1 and E, cathepsins B and D were induced by E_2 and these antifungal agents, but when co-treated with ICI 182 780, the increased protein levels were reversed. In xenografted mouse models transplanted with BG-1 cells, E_2 significantly increased the tumour mass formation about six times and cyprodinil also induced tumor formation about two times compared to vehicle (0.1% DMSO) during 80 days. However, fenhexamid did not increase the tumour mass formation. These results imply that the fenhexamid and cyprodinil may have disruptive effects on ER expressing cancer by alteration of cell cycle- and metastasis-related genes via ER dependent pathway. EP160

Ovarian cancer growth was induced by 2,3,7,8-tetrachlorodibenzo-*ρ*-dioxin through the regulation of *CYP1A1* gene in an oestrogen receptor-dependent pathway in BG-1 ovarian cancer cells

Ryeo-Eun Go & Kyung-Chul Choi
Laboratory of Biochemistry and Immunology, College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Environmental factors such as high meat consumption, caffeine, cigarette smoking, and endocrine disrupting chemical (EDCs) may enhance the risk of ovarian cancer. Cytochrome P450 (CYP) 1A1 may play a major role in metabolic activation of procarcinogens to carcinogens. 2,3,7,8-Tetrachlorodibenzo-*ρ*-dioxin (TCDD) is a commonplace pollutant and a promoter of carcinogenesis as the most potent substance. In this study, we examined the effects of TCDD in the presence of 17β-estradiol (E_2) on the expressions of CYP1A1, CYP1B1, and aryl hydrocarbon receptor (AhR) by RT-PCR and western blot analysis. In addition, the cell viability by TCDD and E_2 was examined in BG-1 human ovarian cancer cells by MTT assay. To evaluate the cell viability, BG-1 cells were cultured with control (0.1% DMSO), E_2 (1×10^{-9} M), or TCDD (10^{-6}–10^{-8} M). E_2 markedly increased BG-1 cell viability about five times and TCDD also induced BG-1 cell viability the most at 1×10^{-8} M compared to control. When co-treated with ICI 182 780, an ER antagonist, BG-1 cell viability was reversed to the level of control. Although, mRNA expression of CYP1B1 or AhR was not altered by E_2 or TCDD, the transcriptional level of CYP1A1 appeared to be increased by E_2 or TCDD in a time-dependent manner. Furthermore the translational level of AhR and CYP1A1 appeared to be increased by E_2 or TCDD in a time-dependent manner. In xenografted mouse models transplanted with BG-1 cells, E_2 treatment significantly increased the tumour mass formation about six times and TCDD induced tumour formation about four times compared to vehicle (0.1% DMSO) during 80 days. In addition, expression levels of proliferation cell nuclear antigen, AhR and CYP1A1 are increased in E_2 or TCDD-treated tumour section compared to the control. Taken together, TCDD may induce ovarian cancer cell growth via *CYP1A1* gene expression and have a disruptive effect in ER expressing cells or tissues. Hormonal disorders in adult women with acne

Liudmyla Naumova
Bogomolets National Medical University, Kyiv, Ukraine.

Introduction
Up to 30% of women of reproductive age suffer from acne. In most cases, acne leads to different reproductive disorders.
The purpose of the study
To determine the frequency of hormonal disorders in women with acne and acne-similar changes of the skin.
Methods and materials of research
The study involved 30 female patients of 18–55 years old. Examined were their stature, the spread of acne and its predominant localization, and the presence of hirsutism syndrome. Among morphometric parameters measured were the circumference of waist and hips with calculation of the waist:hip ratio. BMI was determined as well. All patients were tested for venous blood glucose and HbA1c. Hormonal examination included the determination of following parameters: free testosterone, prolactin, TSH, 17-oxyprogesterone, DHEAS, oestrogen, progesterone, steroid-binding globulin, and anti-Müllerian hormone. Sonography of thyroid gland and pelvic organs was also performed.
Results of the survey
Study women were found to have ovarian hyperandrogenism, among different pathological conditions related to acne and acne-similar rash with the following percentage: atypical (late) forms of congenital adrenal dysfunction (27%); polycystic ovarian syndrome (20%); type 2 diabetes mellitus (17%); hypothyroidism (12%); hyperprolactinaemia (12%); early menopause (10%); and adrenal hyperandrogenism (1%). These parameters were only normal in 1% of examined subjects.
Conclusions
The background of acne and acne-similar rash changes in women of reproductive age are numerous hormonal and metabolic changes in the female organism. Not all cases of acne are accompanied with hyperandrogenism. Local treatment of acne in women should be preceded by intensive hormonal and instrumental examination of woman's reproductive system, and determination of carbohydrate metabolism and thyroid status.

Modulation of the circadian clock by glucocorticoid receptor in H295R cell line

Zsolt Nagy[1,2], Henriett Butz[3], Istvan Liko[2], Karoly Racz[1,3] & Attila Patocs[2,4]
[1]2nd Department of Medicine, Faculty of Medicine, Semmelweis University, Budapest, Hungary; [2]'Lendulet' Hereditary Endocrine Tumors Research Group, Hungarian Academy of Sciences, Semmelweis University, Budapest, Hungary; [3]Molecular Medicine Research Group, Hungarian Academy of Sciences, Semmelweis University, Budapest, Hungary; [4]Department of Laboratory Medicine Institute, Faculty of Medicine, Semmelweis University, Budapest, Hungary.

Background
Peripheral clocks are set by different nervous, hormonal and metabolic stimuli and regulate the circadian expression of several genes. It has been demonstrated that circadian oscillation of gene expression can be detected in various cell lines *in vitro*.
Aim
To explore whether a peripheral clock could be induced in human adrenocortical cell line H295R and what are the effects of glucocorticoids on this clock system.
Methods
H295R human adrenocortical cell line was studied. For serum shock experiments cells were serum starved for 24 h and incubated with 30% Nu serum for 2 h then returned to normal medium with either vehicle or 100 nmol dexamethasone (Dex). For Dex experiments cells were serum starved for 24 h, maintained in serum free medium and treated with vehicle or 100 nmol Dex with or without 1 μmol RU486. Cells were harvested at the indicated time points. All experiments were carried out in triplicate. RT-PCR was carried out using predesigned TaqMan gene expression assays. PER1, PER2, CRY1, ARNTL, NR1D1, NR3C1, StAR, POMC, CRH, and actin expressions were measured by qRT-PCR on 7500 Fast Real-Time PCR System.
Results
After synchronisation of cells the rhythmic oscillation of clock genes *PER1, PER2, NR1D1*, and *ARNTL* was observed. Glucocorticoid treatment induced a rapid respond of PER1 in a glucocorticoid receptor (GR)-dependent manner. Continuous glucocorticoid stimulation caused elevation of PER1 and altered its rhythm. Glucocorticoid treatment induced the expression of PER2 and delayed its phase, increased expression of CRY1 and, after 6 h, it suppressed expression of NR1D1. Administration of a GR antagonist, RU486 disrupted the circadian oscillation of clock genes and prevented the acute changes in PER1, PER2 and CRY1 levels. These alterations occurred independently from ACTH or CRH.
Conclusions
Our data demonstrated that a peripheral clock system is present in human adrenocortical cell line and periodic oscillation of clock genes are influenced by glucocorticoids.

An information theoretic approach to GnRH signalling

Kathryn Garner[1], Rebecca Perrett[1], Margaritis Voliotis[2], Thanh Pham[3], Krasimira Tsaneva-Atanasova[4] & Craig McArdle[1]
[1]Laboratories for Integrative Neuroscience and Endocrinology, School of Clinical Sciences, University of Bristol, Bristol, UK; [2]School of Mathematics, University of Bristol, Bristol, UK; [3]Texas A&M University, College Station, Texas, USA; [4]Department of Mathematics, College of Engineering, Mathematics and Physical Sciences, University of Exeter, Exeter, UK.

One way in which cells receive information about their environment is through hormones binding to appropriate receptors on their cell surface. Single cell measurements of signalling proteins typically reveal high cell–cell variability raising questions about how reliably individual cells sense their environment in order to make decisions. Information theoretic approaches can be used to explore such sensing, treating cell signalling pathways as 'noisy' communication channels. Mutual information (MI) can be calculated between system inputs and outputs as a statistical measure of the reliability of sensing. GnRH acts via $G_{q/11}$-coupled seven-transmembrane receptors to stimulate ERK and nuclear factor of activated T-cells (NFAT), but information transfer has not previously been quantified for these (or other) hormone receptors. Here, we do so using automated fluorescence microscopy to quantify dual-phosphorylated (pp)ERK and the nuclear fraction (NF) of NFAT1c–EFP as activation readouts. In gonadotroph-derived LβT2 cells, GnRH increased ppERK and NFAT-NF levels with maximal effects at 5–60 min. MI between GnRH and ppERK or between GnRH and NFAT-NF followed similar time courses but did not exceed 0.8 bits, implying that information transfer through these pathways is insufficient for an individual cell to unambiguously distinguish even two states of the environment. We also used imaging reporters for transcription activation (Egr1-driven or NFAT-RE-driven asRED) and again MI between GnRH and these outputs was always <0.8 bits. As a possible explanation for such unreliable sensing we consider GnRH receptor (R) number, using recombinant adenovirus to express GnRHR at sub-physiological to super-physiological levels ($<20\,000$–$>170\,000$ sites/cell) in HeLa cells. This revealed that information transfer is indeed dependent on GnRHR number but MI values were <0.8, even at the highest GnRHR levels. Accordingly, this novel approach to quantification of information transfer suggests that individual pathways and cells are very inefficient sensors of GnRH concentration.

Prevalence of vitamin D deficiency in Slovak women with polycystic ovary syndrome and its relation to metabolic and reproductive abnormalities

Jana Figurová[1], Ingrid Dravecká[1], Martin Javorský[2], Jana Petríková[1] & Ivica Lazúrová[1]
[1]1st Department of Internal Medicine, Medical Faculty, P.J.Šafarik University, Košice, Slovakia; [2]4th Department of Internal Medicine, Medical Faculty, P.J.Šafarik University, Košice, Slovakia.

Objective
Polycystic ovary syndrome (PCOS) is the most common endocrine disorder characterised by menstrual dysfunction, infertility, presence of polycystic ovaries and biochemical and clinical hyperandrogenism affecting up to 4–18% women of reproductive age. Vitamin D is thought to influence the development of PCOS through gene transcription and hormonal modulation of insulin metabolism and fertility regulation. The aim of this prospective case–control study was to investigate prevalence of vitamin D deficiency and its relation to clinical, anthropometrical, and biochemical findings in PCOS and controls.
Methods
25(OH)D, anthropometric, endocrine, and metabolic parameters were evaluated in 99 women with PCOS according to Rotterdam criteria and in 66 controls, recruited prospectively.
Results
There was no significant difference in 25(OH)D levels between PCOS women and controls (24.79 ± 10.77 ng/ml vs 25.07 ± 10.14 ng/ml, $P=0.868$) and also in the prevalence of 25(OH)D deficiency in both groups (80% vs 70%; $P=0.138$). PCOS women with metabolic syndrome (MS) had lower serum 25(OH)D compared to those without MS (20.6 ± 8.3 ng/ml vs 25.9 ± 11.3 ng/ml, $P=0.049$). PCOS women with vitamin D deficiency had borderline higher serum triacylglycerides (1.44 ± 0.93 vs 1.03 ± 0.46, $P=0.051$) and tended to have higher HOMA-IR (median (quartiles): 2.24 (1.38–3.51) vs 1.85 (1.04–3.68), $P=0.467$) compared to PCOS with sufficient vitamin D levels. 25(OH)D correlated positively with HDL-cholesterol in all subjects ($r=0.159$, $P=0.043$; P adjusted for age, BMI, $P\_adj=0.03$) and negatively with LH/FSH ratio ($r=-0.211$, $P=0.037$) in PCOS.
Conclusions
Insulin resistance and other metabolic abnormalities in PCOS women seem to be related to PCOS rather than to vitamin D deficiency.

Identification of p53 regulation site on the p27 promoter

Sung-Po Hsu[1,2], Po-Han Lin[2] & Wen-Sen Lee[1,2]
[1]Department of Physiology, School of Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan; [2]College of Medicine, Graduate Institute of Medical Sciences, Taipei Medical University, Taipei, Taiwan.

Angiogenesis is a crucial physiological phenomenon in female reproductive cycle. Our previous studies have shown that progesterone could inhibit proliferation of human umbilical vein endothelial cells (HUVEC) through a p53-dependent mechanism, by which the levels of p21 and p27 protein were increased, subsequently inhibiting the CDK2 kinase activity, and finally impaired the transition of the cell from the G1 phase to the S phase. While previous studies had clearly demonstrated that p53 protein directly activates p21 expression though binding onto the p21 promoter, the p53-regulated p27 gene expression has not been reported. Accordingly, the aim of this research was to investigate the precise binding domains of p53 protein on the p27 promoter. Luciferase assay showed that the potential p53 binding region spans on sites 258–310 upstream the start codon of the p27 gene. Within this range, there are three potential binding fragments with 70% similarity of p53 consensus binding domain and between each fragment is separated by <13 bp. Deletion or TCCT sequence replacement at the internal site of anyone of these fragments resulted in an irresponsiveness to progesterone treatment, suggesting that all these three fragments are essential for p53 protein to regulate the p27 promoter activity. Moreover, immunoprecipitation and chromatin-immunoprecipitation analysis demonstrated that both the formation of p53-progesterone receptor complex in the nucleus and the binding of progesterone receptor onto the p53 binding fragment of the p27 promoter were increased by progesterone treatment, suggesting that progesterone receptor might be also involved in the p53-regulated the p27 promoter activity. To our knowledge, this is the first demonstration that progesterone up-regulated p27 expression in HUVEC through a p53-dependent pathway.

The influence of late onset hypogonadism on the formation of proinflammatory cytokines imbalance in patients with obesity and type 2 diabetes

Irina Khripun, Zalina Gusova, Elizaveta Dzantieva, Valentina Puzireva, Asiat Sultanmuradova & Sergey Vorobiev
Rostov State Medical University, Rostov-on-Don, Russia.

Currently actively studied the role of certain inflammatory and proinflammatory cytokines in the pathogenesis of insulin resistance, type 2 diabetes, obesity, atherosclerosis. However, the influence of testosterone deficiency on the balance of proinflammatory cytokines is unexplored. The aim of the work was to evaluate the influence of testosterone deficiency on metabolic parameters and levels of proinflammatory cytokines in patients with obesity and type 2 diabetes.

Materials and methods

We examined the 85 male patients, aged 40–65 years with obesity and type 2 diabetes, which were divided into two groups, matched for age. The first group included 44 patients with testosterone levels above 12.1 nM/l, the second – 41 men with content of hormone <12.1 nM/l.

Results and discussion

Analysis of the data shows a statistically more significant BMI in the group of hypogonadal patients (BMI 42.03 ± 1.44 kg/m^2), compared with eugonadal males (BMI 34.36 ± 1.22 kg/m^2). Also in the second group there were a statistically significant increases in the levels of serum total cholesterol (6.64 ± 0.13 vs 5.79 ± 0.16 mM/l) and triglycerides (2.31 ± 0.31 vs 1.72 ± 0.17 mM/l). In estimating the concentration of TNF-a in the serum was found that its level in patients with deficiency of testosterone (6.32 ± 0.49 pg/ml) was significantly higher ($P \leq 0.05$) that those without hypogonadism (4.38 ± 0.37 pg/ml). The results of the study of IL-6 showed a statistically significant increase in its content in the serum of patients with hypogonadism (5.39 ± 0.89 pg/ml) compared with patients with normal levels of testosterone (3.78 ± 0.36 pg/ml).

Conclusion

Reduced serum testosterone level is a factor contributing to manifestations of metabolic disorders and cytokine imbalance in patients with obesity and type 2 diabetes. Androgen deficiency may be regarded as an additional risk factor for cardiovascular disease and diabetes.

Palmitic acid enhances TLR4 expression and promotes resistin/TLR4 signalling

Hamza Amine[1,2], Yacir Benomar[1,2], Arieh Gertler[3] & Mohammed Taouis[1,2]
[1]Neuroendocrinologie Moléculaire de la Prise Alimentaire, University of Paris-Sud, UMR 9197, Orsay, France; [2]Neuroendocrinologie Moléculaire de la Prise Alimentaire, Neuroscience Paris Saclay Institute, CNRS UMR 9197, Orsay, France; [3]Faculty of Agricultural, Food and Environmental Quality Sciences, The Institute of Biochemistry, Food Science, and Nutrition, The Hebrew University of Jerusalem, Rehovot, Israel.

Toll-like receptor 4 (TLR4) has a critical role in innate immunity, and the activation of inflammatory pathways plays an important role in the induction of insulin resistance. Indeed, we have recently demonstrated that TLR4 is implicated in resistin-induced inflammation and insulin resistance in the hypothalamus.[1] We have also shown that TLR4 is up-regulated in the hypothalamus of mice fed a high-fat diet. Here, we aim to decipher the molecular mechanisms implicated in the regulation of TLR4 expression. For this purpose, human neuroblastoma cells (SHSY-5Y) were exposed during 4 h to either palmitic acid (a saturated fatty acid) or the omega-3 polyunsaturated fatty acid docosahexaenoic acid (DHA). Cells were then treated with resistin. Firstly we analysed the effect of resistin, palmitic acid and DHA on inflammation markers. We show that only resistin was able to activate NF-κB and to increase the phosphorylation of Akt and p38 MAPK. However, palmitic acid pretreatment increases the expression of inflammatory cytokines (IL-6 and TNF-α), similar to resistin. Interestingly, DHA pretreatment suppresses palmitic acid and resistin induced up-regulation of IL-6 and TNF-α. Secondly, we studied the possible synergistic interaction between resistin and palmitic acid on TLR-4 expression. We show that palmitic acid pretreatment increases TLR4 expression, at both protein and mRNA levels, while DHA pretreatment had no effect. Importantly, palmitic acid pretreatment potentiates resistin effects. In conclusion, we show for the first time, to our knowledge, that palmitic acid induces TLR4 expression and this leads to the amplification of resistin effects promoting then insulin resistance at the neuronal level.

Heterogeneity of human chorionic gonadotropin (hCG) in commercial preparations of hCG and human menopausal gonadotropin

Laura Riccetti[1], Elisa Pignatti[1,2] & Manuela Simoni[1,3]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Center for Genomic Research, University of Modena and Reggio Emilia, Modena, Italy; [3]Azienda USL of Modena, Modena, Italy.

Introduction

Human chorionic gonadotropin (hCG) is a glycoprotein hormone composed by two subunits, an alpha subunit common to all gonadotropins and a specific beta subunit. hCG is produced by trophoblast cells as differently glycosylated isoforms with a wide range of molecular weight, from 30 to 50 KDa ('regular' hCG is 37 KDa). hCG is used in the treatment of infertility. The aim of this study is to analyse and compare the composition of different commercial hCG.

Design

Three hCG preparations from pregnancy urine (50 mIU Gonasi-IBSA, 50 mIU Pregnyl-Organon, 70 mIU Sigma C0434), one recombinant (5 ng r-hCG, Ovidrel-Serono) and an urinary hMG (75–300 mIU Meropur-Ferring) were compared by 12% SDS–PAGE and western blotting using a polyclonal antibody against hCG beta subunit (Dako A0231). Different conditions were used in processing all the preparations such as denaturing and reducing samples or preserving their 'native' conformation. The western blotting patterns were confirmed by ConA Affinity Chromatography.

Results

Despite no particular differences were observed under denaturing-reducing conditions, we found qualitatively and quantitatively peculiar patterns under 'native' conditions. In the urinary hCG preparations up to three isoforms were found with different molecular weights (32, 37 and 45 KDa; $n=4$). In contrast, in r-hCG four variants were found (one doublet at 31–32 KDa and a doublet more expressed at 44–45 KDa; $n=4$). All preparations, including hMG, seem to contain hyperglycosylated hCG (hCG-H) of about 45 KDa which was characterized against hCG-H purified from human choriocarcinoma cell line (JEG-3) culture medium as control. ConA Affinity Chromatography confirmed that all the isoforms detected were glycosylation variants of hCG.

Conclusions

The commercial hCG and hMG preparations consist of several isoforms which differ in molecular weight and grade of glycosylation. Surprisingly, r-hCG has a wider range of glycosylated variants than urinary hCG. The peculiar signal pattern observed by western blotting demonstrates the heterogeneity of hCG in commercial preparations.

Differential cell cycle control protein profiles characterise bronchial carcinoids sensitive to mTOR inhibitors

Katiuscia Benfini, Teresa Gagliano, Erica Gentilin, Eleonora Riva, Simona Falletta, Carmelina Di Pasquale, Marta Bondanelli, Maria Rosaria Ambrosio, Ettore Ciro degli Uberti & Maria Chiara Zatelli
Section of Endocrinology and internal medicine, Department of Medical Sciences, University of Ferrara, Ferrara, Italy.

Background

Bronchial carcinoids (BC) are rare neoplasm, still orphan of medical therapy, which arise from neuroendocrine cells. It has been previously demonstrated that the atypical BC human cell line NCI-H720 is sensitive to everolimus (E), an m-TOR inhibitor, in terms of cell viability reduction, with a G0 cell-cycle arrest and a Cyclin D1 protein reduction. On the contrary, the typical human BC cell line NCI-H727 is not sensitive to E, despite the Cyclin D1 reduction. The mechanisms underlying this phenomenon have not been fully clarified, yet.

Aim
Our aim is to further investigate cell cycle mechanisms that underlie resistance to mTOR inhibitors in BC cells, in order to identify new therapeutic approaches.
Materials and methods
Human BC cell line cultures (NCI-H720 and NCI-H727 cells) were investigated by Western blot, cell viability and caspase activation assays before and after a challenge with E.
Results
Protein profiling of the main complexes regulating G0/G1 ≫ S progression (CDK2/Cyclin E and CDK4/Cyclin D1) and CDK-inhibitors (p27 and phospho p27_SER10) was performed. At basal levels the two BC cell lines showed a different protein profile with the positive regulators of the cell cycle (Cyclin D/CDK4 and Cylin E/CDK2) more expressed in NCI-H727 cells (resistant to E) as compared to NCI-H720 cells (sensitive to E), suggesting that in the Resistant BC cell line p27kip1, despite being over-expressed, has an impaired function. We also found that E reduced Cyclin D/CDK4 protein complex as well and Cyclin E expression, but induced CDK2 expression, possibly explaining the escape of NCI-H727 from the antiproliferative effects of E. On the other hand, no modification of cell cycle control protein profile has been observed in NCI-H720 after treatment with E, indicating that the latter exerts its antiproliferative effects on this cell line by a cyclin-independent mechanism.
Conclusion
Our data indicate that resistance to mTOR inhibitors may be linked to a deranged cell cycle control protein profile. Therefore the characterization of these proteins may represent a putative marker of resistance to E, possibly contributing to a better patients selection for a therapeutic approach with mTOR inhibitors.

DOI: 10.1530/endoabs.37.EP169

EP170

Influence of mTOR and ERK 1/2 pathways on the IGF1 negative feedback in GH secreting pituitary adenoma cell line

Carmelina Di Pasquale[1], Mariaenrica Bellio[1], Erica Gentilin[1,2], Teresa Gagliano[1], Simona Falletta[1], Katiuscia Benfini[1], Maria Rosaria Ambrosio[1], Ettore degli Uberti[1,2] & Maria Chiara Zatelli[1,2]
[1]Section of Endocrinology and Internal Medicine, Department of Medical Science, University of Ferrara, Italy, Ferrara, Italy; [2]LTTA, laboratorio per le tecnologie delle terapie avanzate, Ferrara, Italy.

Background
Gigantism and acromegaly are the main consequences of GH excess, mainly due to a pituitary adenoma. Surgery is the first therapeutic option, but also medical therapy is employed, being mostly represented by somatostatin analogues (SSA), that reduce both tumour mass and GH hypersecretion. However about 10% of patients is resistant to SSA.
PI3K/Akt/mTOR pathway, activated by growth-factors such as IGF1, is important in regulating many cellular processes.
Aim
To understand whether PI3K/Akt/mTOR and ERK 1/2 pathway can influence IGF1 feed-back in GH secreting pituitary adenoma cell lines, we employed three inhibitors: everolimus (mTOR inhibitor), NVP-BEZ235 (mTOR and PI3K inhibitor) and SCH772984 (ERK 1/2 inhibitor), evaluating their effects in presence or in absence of IGF1.
Materials and methods
Cell viability and GH secretion assays have been performed in the GH3 cell line (rat GH-secreting pituitary adenoma cell line).
Results
IGF1 induced cell viability by 30%. Everolimus significantly reduced viability up to 30%, and this effect was not counteracted by IGF1. NVP-BEZ235 reduced cell viability and IGF1 counteracted this effect, suggesting that this compound could act, at least in part, on IGF1 activated pathways. GH secretion was reduced by IGF1 (40%); Everolimus and NVP-BEZ235 did not significantly affect GH secretion and these compounds did not enhance the negative feed-back of IGF1 on GH secretion. SCH772984 did not influence viability but reduced GH secretion up to 20% without enhancing IGF1 negative feed-back. Moreover, Everolimus and NVP-BEZ235 did not influence SCH772984 effects.
Conclusions
These data indicate that IGF1 is important in regulating proliferation and GH secretion in GH3 cells. mTOR blockade reduce viability without affecting GH secretion. ERK 1/2 affects secretion but not IGF1 negative feed-back. In conclusion, our data suggest that mTOR and ERK 1/2 pathways are not involved in IGF1 feed-back on GH secretion.

Role of TGFβ1 in pancreatic neuroendocrine tumour

Simona Falletta[1], Teresa Gagliano[1], Erica Gentilin[1], Carmelina Di Pasquale[1], Katiuscia Benfini[1], Vanessa Polenta[2], Massimo Falconi[2], Maria Rosaria Ambrosio[2], Stefano Partelli[2], Ettore degli Uberti[1] & Maria Chiara Zatelli[1]
[1]Section of Endocrinology and Internal Medicine, Department of Medical Science, University of Ferrara, Italy, Ferrara, Italy; [2]Pancreatic Surgery Unit, San Raffaele Hospital, Vita-Salute San Raffaele University, Via Olgettina 60, 20132 Milan, Italy.

Introduction
Neuroendocrine tumours (NETs) are heterogeneous neoplasms arising from neuroendocrine cells spread in the respiratory and gastro-entero-pancreatic epithelium. The role of transforming growth factor beta-1 (TGFβ1) in NET biology is largely unknown. TGFβ1 signalling pathway is tumour suppressive in most non-transformed epithelial cell lines. In contrast, many human carcinomas are refractory to the growth–inhibitory effects of TGFβ1.
Aim
To understand the possible role of TGFβ1 on cell viability and apoptosis in pNET and to evaluate whether this protein may affect the response to therapeutic molecules currently used in the management of pNETs.
Methods
20 pNETs primary cultures were treated with TGFβ1 and/or everolimus, a mTOR inhibitor. Cell viability and caspase activity were evaluated.
Results
TGFβ1 reduced cell viability and promoted apoptosis (∼50%) in four pNETs. In the same group, TGFβ1 enhanced (+15%) the growth arrest induced by everolimus alone (50%). On the contrary in 16 pNETs we observed a 30% increase in cell viability and a similar decrease in caspase activation.
Conclusions
In conclusion, TGFβ1 reduces cell viability in a pNET sub-group and may cooperate with everolimus. Further studies are necessary to understand TGFβ1 related functional context in pNETs.

Reduction of growth and lesser utilisation of energy reserves in heroin addicted boys during pubertal development

Muhammad Saqlain[1], Ghazala Kaukab Raja[1], Maleeha Akram[2], Samar Minallah[2], Afzaal Ahmad[2], Mazhar Qayyum[2] & Shakeel Raza Rizvi[2]
[1]Department of Biochemistry Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Rawalpindi, Pakistan; [2]Department of Zoology Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Rawalpindi, Pakistan.

The secretion of leptin, an indicator of energy reserves, declines as energy stores are consumed in growth and development at puberty. The pubertal growth and development are often altered under different kinds of stresses. Usually, stress stimulates the release of cortisol, which is a labelled marker of stress. Early teens are inclined to drug abuse that may put their bodies under stress and may induce excessive secretion of cortisol. Since, sustained high levels of cortisol may affect growth rate at puberty, the present investigation examined body weight (BW), height, BMI and plasma concentrations of leptin and cortisol in non-smoking ($n=220$) and heroin addicted ($n=211$) boys and observed relationship between heroin addiction and circulating concentrations of leptin and cortisol during different stages of pubertal development. Data were analysed using Student's *t* test, ANOVA and Pearson correlation. The mean BW, height, BMI and plasma concentrations of cortisol progressively increased throughout puberty and adolescence in both non-smoking and heroin addicted boys. The concentrations of cortisol were significantly higher during all stages of pubertal development in heroin addicted boys compared to non-smoking boys. The concentrations of leptin gradually declined through puberty in both groups but still remained markedly higher in heroin addicted boys. In non-smoking boys, cortisol and leptin concentrations were negatively correlated with each other at puberty. A position relationship was observed between heroin addiction and concentrations of cortisol and leptin at different stages of pubertal development. At the age of 20 years, non-smoking boys were ∼10 kg heavier in weight and ∼5 cm taller in size than heroin addicted boys. In conclusion, this study demonstrates reduction in growth and partial utilization of energy reserves in heroin addicted boys compared to non-smoking boys, who appeared to utilize all their energy reserves in attaining full growth at puberty.

Persistent Mullerian duct syndrome: a case report

Raquel Almeida, António Canha, Jorge Santos, Anabela Rocha & Jorge Dores
Centro Hospitalar do Porto, Porto, Portugal.

Persistent Mullerian duct syndrome (PMDS) is a rare disorder of sex development characterized by the persistence of Mullerian duct derivatives in a genotypic (46,XY) and phenotypic normally virilised male. PMDS is transmitted in an autosomal recessive manner, caused by mutations in the anti-Mullerian hormone gene or in the gene encoding the AMH receptor. The authors report a case of a male patient aged 62 years, with bipolar disorder, referred to the endocrinologist by incidental discovery of uterus and fallopian tubes during emergency laparotomy for acute peritonitis associated with Crohn's disease diagnosed later. In the anamnesis: childbirth at home in a village, appropriate pubertal development, no history of gynecomastia; no erectile dysfunction or changes in libido; had no children although there was that intention. At the physical exam: male phenotype with normal penis but missing testicles in the scrotum; not eunuchoid proportions; no gynecomastia; hairy distribution with male pattern and male voice. MRI showed 'uterus in middle location with normal anatomical pattern, inserted in the region of the seminal vesicles; prostate and seminal vesicles with normal characteristics; gonads in ovarian topography with uncharacteristic signal behavior for ovarian tissue, suggesting ovotestes'. Hormonal study revealed hypergonadotrophic hypogonadism and no other abnormalities; Normal karyotype 46,XY. Normal bone densitometry. Histology of the right gonad (the patient refused removal of both gonads) showed atrophic testicular tissue with scattered microcalcifications, without signs of malignancy. The authors decided to present this case not only because of its rarity, but also to draw attention to the late diagnosis that was performed despite the presence of cryptorchidism. Early diagnosis and treatment of PMDS can reduce the risk of degeneration and testicular malignancy associated with prolonged cryptorchidism. Surgical replacement of the gonads in the scrotum does not ensure fertility if there is an abnormal connection between the testicles and the excretory ducts.

47,XYY syndrome and hypogonadotropic hypogonadism: is this coincidence or a diverse spectrum of the syndrome?

Fatma Dilek Dellal[1], Cevdet Aydin[2], Nagihan Bestepe[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Department of Endocrinology and Metabolism, Ataturk Education and Research Hospital, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, School of Medicine, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey.

Introduction
47,XYY syndrome is characterized by an extra copy of the Y chromosome in each cells of a male. It occurs in about 1/1000 of newborn boys and most males with this syndrome have normal sexual development and fertility. They tend to have tall stature and mild motor and language developmental problems. Testosterone levels are normal. Increased rate of criminal activity in XYY males was related to a lack of judgement and lower socioeconomic status due to a lower mean IQ score.
Case report
A 21 year-old-man applied to our clinic with complaints of small testis and penis and, lack of beard and ejaculation. He had normal libido and erection. There was no family history of infertility. He had not commited any crime. In physical examination, he had eunuchoid habitus, his height was 178 cm, weight was 66.6 kg, and BMI was 21 kg/m^2. His testes were palpable in the scrotum. Axillary and pubic hair development were consistent with Tanner stage 4. Penis length was 6.5 cm. His neurocognitive development were normal. Hormonal tests revealed hypogonadotropic hypogonadism. Other hypophyseal hormones were normal. Bone age was 14 years and epiphyseal plates were open. In testicular ultrasonography, volumes were 8 ml on the right and 7.5 ml on the left. Hypophyseal MRI showed partially empty sella. In chromosomal analysis, 47,XYY karyotype was detected. After administration of human chorionic gonadotropin treatment, androgen levels increased and ejaculation started although in small amounts (<0.5 ml).
Conclusion
Men with 47,XYY syndrome have a diverse spectrum of clinical presentation and because of the heterogeneous phenotype and lack of specific symptoms, its diagnosis may be difficult. As presented in our case, hypogonadotropic hypogonadism might be a presenting feature in patients with 47,XYY genotype.

EP175

Endocrine disorders in women with Turner syndrome

Agnieszka Zwolak[1,2], Anna Dabrowska[1] & Jerzy Tarach[1]
[1]Chair and Department of Endocrinology, Medical University of Lublin, Poland, Lublin, Poland; [2]Chair of Internal Medicine and Department of Internal Medicine in Nursing, Medical University of Lublin, Poland, Lublin, Poland.

Introduction
Turner syndrome (TS) is the most common chromosomal abnormality in women. It occurs in 1/2500 to 1/3000 live-born females and results from a total or partial absence of the X chromosome. The clinical manifestations are diverse and TS is accompanied by multiple medical problems.
Methods
We analysed retrospectively six cases of women with TS aged 20–66 years, treated at Endocrinology Department between 2003 and 2014, to describe endocrine disorders in such patients. In the studied subjects, the diagnosis of TS was made in childhood (one patient), in adolescence (three cases) or in adulthood (two women), based on clinical symptoms and genetic tests.
Results
Short stature was diagnosed in all patients, three of them received recombinant human GH. The average height was 152.5 ± 6.53 cm. None of women were obese (BMI: 24.12 ± 2.88 kg/m^2). We stated primary amenorrhea in five patients, in one case premature ovarian insufficiency was observed. Clitoromegaly was found in one patient, in another case leukoplakia vulvae was diagnosed. Sex hormone replacement therapy was used by four women, two the oldest non-treated patients suffered from osteoporosis. Hypothyroidism due to Hashimoto's thyroiditis developed in five cases and they used levothyroxine. Diabetes mellitus (type 1 and type 2) appeared in two women. Patient with type 1 diabetes had many diabetic complications such as: coronary heart disease, cerebrovascular disease, peripheral vascular disease, sensory neuropathy, diabetic amyotrophy, glaucoma, cataract. One women was operated because of non-functioning pituitary adenoma. Moreover other non-endocrine diseases were observed, including: coeliac disease (two cases), hypertension (three patients), mitral incompetence and tricuspid regurgitation (one woman), impaired hearing (two subjects), ectopic or horseshoe kidney (two cases). The intellectual performance was within the normal range in four women, two patients were mentally retarded.
Conclusion
Most of subjects with TS have hormonal disorders. Therefore, endocrine care is needed to optimise patients' treatment.

***In vitro* effects of aspartic acid, coenzyme Q10 and zinc on sperm function**

Filippo Giacone, Rosita Condorelli, Sandro La Vignera & Aldo Eugenio Calogero
Department of Clinical and Experimental Medicine, Catania, Sicily, Italy.

Introduction
D-aspartic acid (D-AA) is involved in the regulation of spermatogenesis by influencing hormonal biosynthesis and secretion, resulting in an increased sperm concentration and progressive motility. Coenzyme Q10 (CoQ10) correlates positively with sperm concentration and motility at high concentrations, and it plays an antioxidant role, improving sperm motility and fertilization rate in ICSI cycles. Finally, low concentrations of zinc (Zn) have been found in azoospermic patients, while higher concentrations improve sperm motility, concentration and viability. On these premises, the aim of this study was to evaluate the *in vitro* effects of these three compounds on spermatozoa.
Methods
We enrolled ten patients with oligo-astheno-teratozoospermia (OAT) and five normozoospermic subjects (age range: 20–45 years), without infection/inflammation of the male accessory glands, varicocele or other andrological diseases. Spermatozoa were incubated for 3 h with BWW (group A), BWW + ethanol + PBS (group A1) (control groups) or D-AA (500 mg/ml), CoQ10 (40 mg/ml) and Zn (10 g/ml) (group B). After incubation, the following parameters were assessed: sperm progressive motility, non conventional sperm parameters (mitochondrial membrane potential, degree of viability and/or apoptosis, sperm DNA fragmentation, lipid peroxidation). Subsequently, sperm selection was performed by swim-up technique in all groups.
Results
In OAT, progressive motility and the number of motile spermatozoa recovered by swim-up increased in group B compared to groups A and A1 ($P<0.05$). This was associated with an improvement of lipid peroxidation in group B vs A or A1

($P<0.05$). The other sperm parameters did not change. No significant change was observed in normozoospermic subjects.
Conclusions
These results showed that D-AA + CoQ10 + Zn act with antioxidant mechanism, ensuring a higher rate of motile spermatozoa recovered after swim-up, probably related to the improvement of progressive motility. These results suggest the use of this combination in both *in vivo*- and *in vitro*-assisted reproductive techniques.

The effect of androgen replacement therapy on platelet aggregation in male patients with isolated hypogonadotropic hypogonadism

Ayten Oguz[1], Dilek Tuzun[1], Murat Sahin[1], Numan Guvenc[2], Elif Inanc[3], Irem Gokalp[3] & Kamile Gul[1]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [2]Department of Family Medicine, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey; [3]Department of Internal Medicine, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey.

Aim
To evaluate the effect of androgen replacement therapy on lipid profile and platelet aggregation in in male patients with isolated hypogonadotropic hypogonadism (IHH).
Material and methods
36 male patient, mean age 32.2 (18–54)with IHH, admitted to the outpatient clinic of Endocrinology and Metabolism were included to the study. Patients in the study were divided into two groups as Testosterone ($n=18$) and human chorionic gonadotropin (HCG) therapy ($n=18$) groups. Total testosterone, fasting plasma glucose (FPG), alanine aminotransferase (ALT), lipid profile, mean platelet volume (MPV), platelet distribution width (PDW) and platelet count were evaluated before and after 6 months of the treatment in all patients.
Results
There was no statistically significant difference according to FPG, triglyceride levels, MPV and platelet counts when all patients ($n=36$) were evaluated due to pre-treatment and post-treatment ($P>0.05$). However, ALT and LDL levels were detected statistically significantly lower after treatment ($P>0.05$), HDL, PDW and testosterone levels were significantly higher after treatment ($P<0.05$). There was no significant difference due to testosterone, FPG, ALT, lipid profile, MPV, PDW and platelet levels compared according to treatment (HCG ($n=18$), and testosterone replacement ($n=18$)) ($P>0.05$). While there was negative correlation with testosterone and ALT levels ($r=-0.25$, $P=0.03$), positive correlation was detected between testosterone and PDW ($r=0.31$, $P=0.007$).
Conclusion
Platelets are involved in homeostatic process and have an important role in atherosclerosis and arterial thrombosis. MPV and PDW are two markers of platelet activation, and have recently been recognised as risk predictors of cardiovascular diseases. Our study revealed that androgen replacement therapy may have beneficial effects on lipid profile and ALT and negative effects on platelet aggregation. Therefore, we think that this situation should be taken into consideration when androgen replacement therapy is planned.

Visceral adiposity index – new anthropometric marker in women with polycystic ovary syndrome: preliminary reports

Anna Bronczyk-Puzon[1], Pawel Jagielski[2], Karolina Kulik-Kupka[1], Justyna Nowak[1], Aneta Koszowska[1] & Barbara Zubelewicz-Szkodzinska[1]
[1]Department of Nutrition-Associated Disease Prevention, Faculty of Public Health, Medical University of Silesia, Katowice, Poland; [2]Faculcy of Clinical Biochemistry, Institute of Genetic Diagnostics and Nutrigenomics, Collegium Medicum of Jagiellonian University, Krakow, Poland.

Introduction
Early detection of carbohydrate and fat metabolism disorders in women with polycystic ovary syndrome allows the early prevention of cardiovascular diseases and type II diabetes.
Aim
The purpose of this study was to assess the selected metabolic indicators and anthropometric measurements in two groups of women: metabolically healthy polycystic ovary syndrome (MH-PCOS) and metabolically unhealthy PCOS (MU-PCOS).
Materials and methods
Cross sectional study was conducted in a group of 44 women hospitalized in the endocrinology department who met the Rotterdam criteria of PCOS syndrome. Tested women were divided into a MH-PCOS (VAI <1.675) group and a MU-PCOS (VAI >1.675) group. Body composition was analyzed via bioelectrical impedance analysis (BIO). During the statistical analysis it was assumed that $\alpha=0.05$.
Results
Examined women, was at age 18–38 years (26.52 ± 5.73). The average age of the MH-PCOS group was 26 (22.5–31) and 25.27 ± 5.57 ($P>0.05$) in the MU-PCOS group. The study showed statistically significant differences between the MU-PCOS group and the MH-PCOS group in term of values: body mass (87.04 ± 19.12 vs 61.3 (54.9–70.25); BMI indicator (32.61 ± 6.44 vs 22.85 (20.7–25.25); $P=0.001$), waist circumference (100.5 ± 16.03 vs 79.52 ± 11.9; $P<0.01$), serum triglyceride concentration (1.6 (1.37–2.03) vs 0.81 ± 0.26; $p=0.001$), HOMA IR (2.72 ± 1.21 vs 1.66 (1–2.5); $P=0.0387$). Statistically, the average value of HDL cholesterol was significantly lower in the MU-PCOS group than in the MH-PCOS group (1.16 ± 0.09 vs 1.83 ± 0.39) ($P<0.01$). In the study, a statistically significant positive correlation was noticed between the Visceral Adiposity Index (VAI) value and the body mass ($r=0.69$), the insulin level ($r=0.46$) and the HOMA IR indicator ($r=0.33$) ($P<0.05$ for all).
Conclusion
Visceral Adiposity Index may be an easy and effective tool to assess metabolically unhealthy women with PCOS in the daily diet and medical practice.

Evaluation of most common symptoms and findings in Turkish adolescent girls with polycystic ovary syndrome

Mina Gulfem Kaya[1], Cevdet Aydin[2], Sefika Burcak Polat[1], Duriye Deniz Demirseren[3], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Department of Endocrinology and Metabolism, Atatürk Education and Research Hospital, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Yildirim Beyazit University Faculty of Medicine, Ankara, Turkey; [3]Department of Dermatology, Atatürk Education and Research Hospital, Ankara, Turkey.

Objective
Polycystic ovary syndrome (PCOS) is a complex endocrinopathy affecting 5–10% of women in reproductive period. Our goal is to determine which symptoms and findings are the most common in Turkish adolescents with PCOS.
Material and method
Ninety three adolescents (15–19 years old) who admitted to our outpatient clinic with at least one of the complaints (acne, obesity, menstrual irregularities and hirsutism) were enrolled in the study. All patients were evaluated due to both Rotterdam and NIH criteria.
Results
Due to Rotterdam and NIH criteria 40 (43.01%) and 32 (34.40%) of patients were diagnosed as PCOS respectively. Due to Rotterdam menstrual irregularities were 90%, hirsutism was 45%, obesity was 25% and acne was 32.5% in patients diagnosed as PCOS. Due to NIH these ratios were 96.9, 50, 25 and 31.3% respectively. Patients were divided into 12 subgroups due to combinations of complaints. Due to Rotterdam, PCOS diagnosis were 100% for menstrual irregularities and hirsutism together, 75% for menstrual irregularities and acne together, 66.7% for menstrual irregularities and obesity together, 66.7% for only hirsutism, 50% for hirsutism and acne together, 40% for only menstrual irregularities, 3.7% for only acne and 0% for only obesity. Due to NIH, PCOS diagnosis were 100% for menstrual irregularities and hirsutism together, 66.7% for menstrual irregularities and acne together, 44.4% for menstrual irregularities and obesity together, 33.3% for only hirsutism, 26.7% for only menstrual irregularities, 0% for only acne or only obesity. Eight patients were diagnosed as PCOS only due to Rotterdam.
Conclusion
The most common complaints in Turkish adolescents with PCOS were menstrual irregularities, hirsutism, acne and obesity in our study. According to guidelines PCOS in adolescents is based on clinical and/or laboratory hyperandrogenism together with persistent oligomenorrhoea. Polycystic ovarian morphology can be a part of reproductive changes in adolescents.

Post load insulin vs fasting levels in prediction of type 2 diabetes in women with PCOS

Mirjana Sumarac-Dumanovic[1,2], Dragan Micic[1,2], Danica Stamenkovic-Pejkovic[1,2], Ana Gligic[2], Danka Jeremic[2], Jelena Milin-Lazovic[1] & Goran Cvijovic[1,2]
[1]School of Medicine, University of Belgrade, Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Belgrade, Serbia.

Introduction
Women with polycystic ovary syndrome (PCOS) are at increased risk of developing insulin resistance (IR) and T2DM. In this study, we attempted to detect IR parameters that could be the best predictor T2DM in PCOS comparing to controls.
Description of methods/design
In 130 women with PCOS (BMI = 29.7 ± 0.66 kg/m^2; age: 25.6 ± 0.59 years) and 41 controls (age and BMI matched) (BMI = 28.5 ± 1.35 kg/m^2; age: 26.5 ± 0.89 years) OGTT and IVGTT (minimal model analyses) were performed. All women has normal fasting glucose, but 16 PCOS women had post load glucose level (120 min) over 7.8 mmol/l.
Results
After excluding PCOS women with IGT, there was no difference between fasting glucose, but glucose at 2 h (OGTT) were still higher in PCOS ($P < 0.05$). Fasting insulin was significantly higher in PCOS (PCOS vs control) (17.02 ± 1.07 vs 12.54 ± 1.72) as well as insulin at 120 min of OGTT (86.85 ± 7.18 vs 56.31 ± 10.57). There was no statistically significant difference between areas under insulin curve between two groups (10417.12 ± 733.14 vs 8098.36 ± 1098.2). Minimal model confirmed no difference in IV glucose tolerance (kg) between PCOS and controls and in acute insulin response (AIR). Si parameter of insulin sensitivity was significantly lower in PCOS (2.46 ± 0.18 vs 3.59 ± 0.39). Disposition index (DI) were significantly higher in controls (166.57 ± 13.9 vs 220.89 ± 33.47). Additional analyses of two PCOS subgroups with normal (NGT) and impaired glucose tolerance (IGT) showed: significant lower Si in IGT subgroup, not different AIR, lower DI. The best correlation with Si (from minimal model) showed OGIS (0.490, $P < 0.01$) (glucose 0.90 i 120 min and insulin at 0 and 90 min), weaker correlation showed HOMA index (0.271; $P < 0.01$) and fasting insulin (−0.247, $P < 0.01$).
Conclusion
These insulin sensitivity indexes could be potentially used to identify subgroups of insulin resistant PCOS women with increased risk of T2DM. Our result suggests that indexes included basal and post load glucose and insulin constitute a more sensitive tool for screening metabolic abnormalities in PCOS.

Ameliorated effects of allium sativum against bisphenol A-induced reproductive toxicity in male rats

Mokhtar Ibrahim Yousef[1], Al-Sayeda A Newairy[2], Afrah F Salama[3] & Shaimaa E M Saber[3]
[1]Department of Environmental Studies, Institute of Graduate Studies and Research, Alexandria University, 163 Horreya Avenue, Chatby 21526, PO Box 832, Alexandria, Egypt; [2]Department of Biochemistry, Faculty of Science, Alexandria University, Alexandria, Egypt; [3]Chemistry Department, Biochemistry Section, Faculty of Science, Tanta University, Tanta, Egypt.

There is growing evidence that bisphenol A (BPA) may adversely affect humans. BPA is an endocrine disruptor that has been shown to be harmful in laboratory animal studies. A comprehensive literature search found 91 studies linking BPA to human health; 53 published within the last year. This body of literature is showing associations between BPA exposure and adverse perinatal, childhood, and adult health outcomes, including reproductive and developmental effects, metabolic disease, and other health effects. These studies encompass both prenatal and postnatal exposures, and include several study designs and population types. But until recently, there were relatively few studies examining the effect of BPA on sperm quality and the protective effects of antioxidants against its reproductive toxicity. Thus, present examination tries to assess powerful antioxidant garlic against BPA. Rats were assigned to one of four groups: 0 mg BPA and 0 g garlic/kg BW (control); 2 g garlic/kg BW; 40 mg BPA/kg BW; BPA plus garlic. Rats were orally administered their respective doses daily for 70 days. BPA caused deterioration in semen characteristics and histological changes in testes. Body weight, plasma acid phosphatase, LH and FSH were increased, while total proteins, testosterone and sex organ weights (testes, epididymis, prostates and seminal vesicles) were significantly decreased. BPA increased thiobarbituric acid-reactive substances (TBARS) and decreased the activities of the antioxidant enzymes. Testicular 17-ketosteroid reductase, acid phosphatase and protein content were decreased, while 17β-hydroxysteroid dehydrogenase was increased. Garlic alone reduced TBARS, induced the activities of the antioxidant enzymes and improved semen characteristics. Administration of garlic with BPA intoxicated rats reduced the testicular toxic condition, morphological and biochemical changes were brought back to normal. In termination, antioxidant potential of garlic, ameliorates the changes that are induced by BPA.

Is serum estradiol really increased in patients with Klinefeler syndrome? Results from a meta-analysis study

Daniele Santi, Sara Scaltriti & Vincenzo Rochira
Unit of Endocrinology, Department of Biomedical, Metabolic, and Neural Sciences, University of Modena and Reggio Emilia, Azienda USL of Modena, Modena, Italy.

Background and aim
KS has been classically described as characterized by hyperestrogenism and elevated serum E_2 together with increased gonadotropins and low-to-normal serum testosterone (T). In literature, data on increased serum E_2 are not solid. The aim of this study is to meta-analyse data from studies evaluating serum E_2 in both KS and healthy subjects (HS) in order to verify if E_2 is increased in KS.
Methods
An extensive MEDLINE was performed using 'PubMed' with the following key words: 'KS' and 'E_2' or 'T' or 'sex steroids' from 1946 to January 2015 (current contents-ISI was used for searching oldest studies). All studies (case–control, case–series, case–reports) reporting E_2 measurement were considered. Controlled–studies were used for meta-analysis, the others only for reviews. Only serum E_2 at baseline (no ongoing treatments) was included. Meta-analysis was conducted according to the PRISMA statement using RevMan.
Results
Out of 956 articles, 26 case–control studies, 15 case–series and 21 case–reports had data on serum E_2. A total of 878 KS and 1000 HS were included in the meta-analysis. Serum E_2 was significantly higher in HS than in KS, with a mean difference of 7.93 pg/ml (CI: 2.24, 13.61; $P = 0.006$), with a $\chi^2 = 688.32$ (I-square = 97%). Serum T was significantly lower in KS than in HS, with a mean difference of −2.79 ng/ml (CI: −3,46, −2,11; $P < 0.001$), with a $\chi^2 = 198,29$ (I-square = 89%). Data from case–series and case–reports confirmed that E_2 is not above the normal range in KS.
Conclusions
Serum E_2 is not increased in KS and is significantly lower than in HS in this meta-analysis. The limits of this study are the heterogeneity of methods for steroids measurement and the lack of studies having the comparison of serum E_2 between KS and HS as primary endpoint. The traditional belief that KS is associated to elevated E_2 should be reconsidered together with some pathophysiological and clinical issues.

Relationship between diabetes mellitus type 1 and male reproductive function

Sandro La Vignera
Department of Clinical and Experimental Medicine, Catania, Italy.

Diabetes mellitus type 1 (DM1), an autoimmune disease, affects an increasing number of young men in reproductive age. It has been estimated that its

prevalence increases at a rate of ~3% per annum. Diabetes may affect male reproductive function by acting on the hypothalamic-pituitary-testicular axis, causing sexual dysfunction and disrupting male accessory gland function. According a recent study shows that men with DM1 have a smaller number of live births than controls. Despite such evidence, little is known about sperm parameters (mainly limited to conventional sperm parameters) and other aspects of the male reproductive function in these patients. Therefore, this study was undertaken to evaluate both conventional and non-conventional sperm parameters, serum gonadal hormones and didymo-epididymal ultrasound features in patients with DM1. To accomplish this, 30 patients with DM1 (aged 18–35 years) and 20 age-matched fertile healthy men were enrolled in this prospective study. Patients with diabetic neuropathy, other endocrine disorders or conditions known to alter sperm parameters were excluded from the study. Conventional sperm parameters were evaluated according to the WHO 2010 criteria. As far non-conventional sperm parameters, mitochondrial function (mitochondrial membrane potential, MMP), apoptosis and chromatin/DNA integrity were evaluated by flow cytometry following specific staining. Serum total testosterone, 17β-oestradiol, LH, FSH and prolactin were measured in all patients and controls. Finally, testicular and epididymal morphometry was evaluated by ultrasound scan before and after ejaculation. Patients with DM1 had a significantly lower percentage of spermatozoa with progressive motility than controls. This abnormality was significantly lower in DM1 patients with long (>10 years) than short (<5 years) disease duration. In addition, the percentage of spermatozoa with high MMP was significantly lower in DM1 patients than in controls. This non-conventional parameter was significantly worse in patients with long or intermediate (5–10 years) vs short DM1 duration. Disease duration correlated inversely with the percentage of spermatozoa with high MMP. Patients with DM1 had a significantly higher cephalic and caudal epididymal diameters after ejaculation compared to controls, suggesting a lack of the physiological epididymal post-ejaculatory shrinkage. This aspect of the epididymal physiology was significantly more compromised in patients with long vs short disease duration. All the other parameters did not show any statistically significant difference. Finally, HbA1c did not correlate with any of the parameters evaluated. In conclusion, patients with DM1 had lower sperm progressive motility, impaired mitochondrial function (which precedes the onset of motility disturbance) and epididymal post-ejaculatory dysfunction which cannot be ascribed to endocrinopathy and/or neuropathy. These findings may explain why patients with DM1 experience fertility disturbance.

Serum dihydrotestosterone equivalent levels in women: a new index of hyperandrogenemia

Yeon-Ah Sung[1], Do Kyeong Song[1], Sei Hyun Baik[2] & Dong Sun Kim[3]
[1]Ewha Womans University, Seoul, Republic of Korea; [2]Korea University, Seoul, Republic of Korea; [3]Hanyang University, Seoul, Republic of Korea.

The measurement of androgens is critical for the diagnosis of polycystic ovary syndrome (PCOS) but it has been difficult based on poor specificity and sensitivity of assays in the female range. The direct total androgen activity can be measured with dihydrotestosterone equivalent concentration (DEQ) using chemically activated luciferase gene expression (CALUX) bioassays. The aim of the study is to determine whether DEQ levels can be the index for hyperandrogenemia to be required for diagnosis of PCOS. The study involved 100 women with PCOS and 100 healthy women with regular menstrual cycles. The initial evaluation including case history, anthropometrical data, excess facial and body hair and two-dimensional vaginal ultrasound was assessed. All hormonal investigations (T, total testosterone; A, androstenedione; fTc, calculated free testosterone from T and SHBG; DEQ levels by CALUX bioassay) were performed. A correlation of T ($r=0.3912$, $P<0.001$), A ($r=0.41$, $P<0.001$) and fTc ($r=0.45$, $P<0.001$) with DEQ levels. DEQ levels were significantly higher in women with PCOS compared to controls ($P<0.05$). Increased levels (95percentile of serum levels in control women) of T, fTc, A and DEQ were noted in 73, 71, 69 and 82% in women with PCOS, respectively. A total of 98% of the subjects with the highest quartile of DEQ levels had PCOS. The optimal DEQ cutoff value for predicting PCOS was 151.9 pg/l (96.0% sensitivity, 87.0% specificity) and the area under the ROC curve was 0.97 (95% confidence interval, 0.94–0.99). The DEQ levels were correlated with ovarian volume ($r=0.51$, $P<0.001$) and ovarian follicle number ($r=0.58$, $P<0.001$), total cholesterol ($r=0.21$, $P=0.004$), LDL cholesterol ($r=0.16$, $P=0.022$), fasting plasma insulin ($r=0.31$, $P=0.002$), post-load 2-h plasma insulin ($r=0.21$, $P=0.034$). DEQ levels may be a good indicator of hyperandrogenemia in women. We also confirm that measurement of DEQ levels in serum can be useful in making a diagnosis of PCOS.

Eating habits of women without hormonal contraception depends on menstrual cycle - preliminary report

Anna Spalik-Bytomska[1], Justyna Nowak[2], Aneta Koszowska[2], Anna Bronczyk-Puzon[2], Karolina Kulik-Kupka[2], Agata Kulpok[3] & Barbara Zubelewicz-Szkodzinska[2,3]
[1]Faculty of Public Health, Medical University of Silesia, Katowice, Poland; [2]Department of Nutrition-Associated Disease Prevention, Faculty of Public Health, Medical University of Silesia, Katowice, Poland; [3]Department of Endocrinology, Country Hospital Piekary Slaskie, Piekary Slaskie, Poland.

Introduction
Hormonal changes during menstrual cycle among women without hormonal contraception could probably influence the food intake. Sex hormones modulate body energy expenditure by affecting hypothalamus neurohormones.
Aim
The aim of the study was to assess the way of nutrition among menstruating women without hormonal contraception, depend of menstrual cycle.
Materials and methods
77 menstruating women in age 19–26 entered the study. The way of nutrition (caloric intake, protein, fat, carbohydrates content) was assessed in each phases of menstrual cycle (menstrual phase, ovulatory phase, luteal phase). The 24 h feeding interview was used. The collected data were statistically analysed, $\alpha=0.05$.
Results
The mean of age was 22.79 ± 1.94 years. The mean of caloric intake in menstrual phase was 1825.65 ± 471.97 kcal, ovulatory phase 1842.28 ± 391.74 kcal, luteal phase 2225.82 ± 551.30 kcal. The mean fat intake in menstrual phase was 66.44 ± 27.06 g, ovulatory phase 70.32 ± 25.40 g; luteal phase 88.44 ± 40.38 g. The mean carbohydrates intake in in menstrual phase 247.89 ± 72.62 g, ovulatory phase 244.73 ± 57.54 g, luteal phase 290.18 ± 68.16 g. The statistical significance difference was observed between energy intake in particular cycle phases ($P<0.0001$). Moreover the statistical significance differences were also observed between fat intake ($P<0.0001$) and carbohydrate intake ($P<0.0001$).
Conclusion
The way of nutrition among women without hormonal contraception depend on phases of menstrual cycle. In the luteal phase intake of carbohydrates including sugars was the highest. This observation could be helpful for maintaining a proper weight by better controlling of food intake.

Relationship between polycystic ovary syndrome and platelet distribution width

Özgür Yilmaz[1], Muzaffer Temur[1], Mehmet Calan[2], Elif Pelin Özün Özbay[3], Murat Karakulak[4] & Tuncay Kume[5]
[1]Department of Obstetrics and Gynecology, Manisa Merkezefendi Hospital, Manisa, Turkey; [2]Department of Endocrinology, Izmir Bozyaka Research Hospital, Izmir, Turkey; [3]Department of Obstetrics and Gynecology, Aydin Obstetrics and Pediatrics Hospital, Aydin, Turkey; [4]Department of Obstetrics and Gynecology, Silivri State Hospital, Istanbul, Turkey; [5]Department of Medical Biochemistry, Dokuz Eylul University Medical School, Izmir, Turkey.

Purpose
Polycystic ovary syndrome (PCOS) is the most common endocrine disorder in women of reproductive period, and it has been considered as a risk factor in cardiovascular disease due to increased prevalence of hypertension, dyslipidaemia, obesity, and insulin resistance. Platelets have a pivotal role in the

development of atherothrombosis. Platelet distribution width (PDW) is a marker of platelet size that reflects the heterogeneity of the platelets. This arithmetical index routinely analyses as part of a whole blood count without additional costs. In this study we purposed whether PCOS associated with PDW.
Materials and methods
Cross-sectional study of 119 healthy women with regular menses and 133 women with PCOS age- and BMI-matched. Waist and hip circumferences, body fat percentage, CBC, plasma fasting glucose, insulin, high sensitive C-reactive protein (hs-CRP), lipids, and total testosterone levels were measured. In multivariate linear regression model, PCOS was defined as a dependent variable and PDW and other platelet indices such as mean platelet volume and platelet large cell ratio were determined as independent variables.
Results
PDW levels were significantly higher in the PCOS group compared with the control group ($13.648 \pm 0.424\%$ vs $13.447 \pm 0.489\%$; $P=0.003$) PDW levels were not correlated with hs-CRP, HOMA-IR, and BMI ($P>0.005$). According to linear regression model, only PDW was associated with PCOS ($R^2=0.05$, $\beta=0.177$, $P=0.022$).
Conclusions
PDW levels were significantly higher in women with PCOS; however this index was correlated with neither HOMA-IR nor hs-CRP which is recognized as a cardiovascular risk factor in PCOS. PDW was associated with PCOS; however higher PDW levels cannot be considered as a cardiovascular risk factor in PCOS.

Clinical significance of ADAMTS1, ADAMTS5, ADAMTS9 aggrecanases and IL17, IL23, IL33 cytokines in polycystic ovary syndrome

Melia Karakose[1], Kadir Demircan[2], Esra Tutal[1], Taner Demirci[1], Muyesser Sayki Arslan[1], Mustafa Sahin[3], Huseyin Tugrul Celik[4], Fatmanur Kazanci[4], Erman Cakal[1] & Tuncay Delibasi[1,5]
[1]Department of Endocrinology and Metabolism, Diskapi Teaching and Research Hospital, Ankara, Turkey; [2]Department of Medical Biology, Turgut Ozal University School of Medicine, Ankara, Turkey; [3]Department of Endocrinology and Metabolism, Ankara University School of Medicine, Ankara, Turkey; [4]Department of Biochemistry, Turgut Ozal University School of Medicine, Ankara, Turkey; [5]Department of Internal Medicine, Hacettepe University School of Medicine, Kastamonu, Turkey.

Introduction
Polycystic ovary syndrome (PCOS) is one of the most common endocrine disorders among women of reproductive age. A disintegrin and metalloproteinase with thrombospondin-like motifs (ADAMTS) are involved in inflammation and fertility. The aim of this investigation was to evaluate to serum levels of ADAMTS1, ADAMTS5, ADAMTS9, IL17, IL23, IL33 and to find out the relationship between these inflammatory cytokines and ADAMTSs in PCOS patients.
Methods
Eighty patients with PCOS and 78 healthy female volunteers were recruited in the present study. Serum ADAMTS and IL levels were determined by a human ELISA in all subjects.
Results
The ADAMTS1 level was significantly lower and IL17A, IL23 levels were significantly higher in the PCOS patients compared to the controls ($P<0.05$). We could not find significant difference between the groups in terms of ADAMTS5, ADAMTS9, and IL33 levels. ADAMTS1 and ADAMTS9 had negative correlations with age, BMI, and waist/hip ratio. IL17A had positive correlation with total cholesterol and LDL.
Conclusion
The understanding of the molecular organization and function of ADAMTS in patients diagnosed with PCOS, which has an unknown pathogenesis, gains an importance and emerging hot topic. Based on the results of the present study, ADAMTSs and ILs might have key roles in PCOS pathogenesis. Further efforts are needed to establish causality for ADAMTS–IL axis.

Effects of thiouracil compounds on chemically induced rat mammary gland carcinogenesis

Dana Macejová[1], Slavomíra Ondková[1], Ján Líška[1,2] & Július Brtko[1]
[1]Institute of Experimental Endocrinology SAS, Bratislava, Slovakia; [2]Medical Faculty, Institute of Histology and Embryology, Comenius University, Bratislava, Slovakia.

Introduction
Thyroidal status can play important role in progression mammary gland tumour growth. We have already shown that hypothyroidism induced by application of 6-*n*-propylthiouracil (PTU) – inhibitor of type I iodothyronine 5′-deiodinase (5′-DI) – prolonged tumour latency and reduced number, volume and burden of 1-methyl-1-nitrosourea (MNU) induced rat mammary gland tumours in Sprague–Dawley female rats.[1]
Design
4-Hydroxy-2-mercapto-6-methylpyrimidine (MTU) is a derivative of PTU, thus the effects of PTU or MTU on tumour progression as well as expression of selected nuclear receptors in MNU-induced mammary gland tumours and rat livers were investigated in this experiment. Female Sprague–Dawley rats were given 50 mg/kg MNU i.p. on 62nd, 109th, and 150th day of age. From 56th day of age, the PTU group of MNU treated rats was receiving PTU (1 mg/kg) intragastrically 3× per week and MTU group of MNU animals 0.1% w/v of MTU in drinking water until the end of experiment.
Results
Administration of PTU to MNU treated animals markedly reduced number of tumours when compared to MNU group of animals. Furthermore, we did not find any tumour in the MTU group of animals. However we have detected significantly reduced body weight when compared to PTU, untreated MNU animals and healthy control animals. Administration of MTU resulted in reduced expression of RARα, RXRα and increased expression of RARγ in rat liver (vs MNU and C). Using EMSA method, we have found significantly reduced amount of nuclear receptor-hormone responsive elements (RARE, TRE, and VDRE) complex in tumours of PTU treated animals (vs MNU animals). Since MTU did not affect 5′-DI in the liver, the mechanism of MTU action needs further investigation.

The role of tailored treatment on conception and pregnancy at patients with insulin resistance

Katalin Nas, Helga Breyer & László Tűű
Mens Mentis EC, Budapest, Hungary.

Patients with insulin resistance are often confronted with conception difficulties. Our database of 1178 conceivable female patients with metabolic disorder shows that more than 40% of them suffer from menstrual cycle disorders. More than 25% out of 480 pregnant women with hyperinsulinaemia had at least one assisted reproduction procedure in their lives. 42% of patients with insulin resistance experienced missed abortion, out of them 26% one time, 12% two times. Our aim was to provide a complex and tailored treatment to women with insulin mediated metabolic disorder who desired pregnancy. The tailored treatment consisted of diet, physical exercises based on BMI and body constitution, medical treatment (if needed) and coaching. Setting BMI goals between 20 and 24, the outstanding role of dietary treatment is remarkable: patients attending (not necessarily following!) dietary counselling became pregnant up to 90%, while patients not attending these consultations were successful up to 68%. Owing to this complex and tailored method more than 71% out of 224 women became pregnant. Pregnancy rates were different according to ages: 75% up to 35 years of age, getting less to 43% above 40 years of age. During pregnancy the complex tailored treatment continued. GDM occurred in 39%of the cases. Mothers with former PCOS developed GDM up to 36%. The average birth weight of the babies was 3321 g. The complex tailored treatment requires a close follow-up and interactive cooperation.

Eating pattern does not depend on the menstrual cycle phase in a group of women taking hormonal contraceptives: preliminary reports

Anna Spalik-Bytomska[1], Justyna Nowak[2], Anna Bronczyk-Puzon[2], Aneta Koszowska[2], Karolina Kulik-Kupka[2], Anna Dittfeld[3] & Barbara Zubelewicz-Szkodzinska[2]
[1]Faculty of Public Health, Medical University of Silesia, Katowice, Poland; [2]Department of Nutrition-Associated Disease Prevention, Faculty of Public Health, Medical University of Silesia, Katowice, Poland; [3]Doctoral Study in the School of Medicine with the Division of Dentistry in Zabrze, Medical University of Silesia, Katowice, Poland.

Introduction
Sex hormones, such as estrogens or progesterone may have, both directly and indirectly, an influence on the appetite changes in. In addition, exogenous sex hormones are commonly used as one method of contraception.
Aim
The purpose of this study was to assess whether the eating style in a group of menstruating women, taking oral hormonal contraceptives, is different in the individual menstrual cycle phases.
Material and methods
28 menstruating women taking oral hormonal cantraceptives in age 19–25 were included to the study. The way of nutrition (caloric intake, protein, fat, and carbohydrates content) was assessed in each phases of menstrual cycle (menstrual phase, ovulatory phase, and luteal phase). The 24 h feeding interview was used. The collected data were statistically analyzed, $\alpha = 0{,}05$.
Results
The average age of surveyed women was 22.04 ± 1.86 years. The average daily energy consumption was in the: menstrual phase 1841.76 ± 562.67 kcal; ovulatory phase 1799.53 ± 501.36 kcal; and luteal phase 2052.58 ± 473.74 kcal. The average fat content was in the: menstrual phase 70.67 ± 31.46 g; ovulatory phase 65.88 ± 28.10 g; and luteal phase 79.89 ± 27.75 g. The average carbohydrates content was in the: menstrual phase 244.59 ± 79.88 g; ovulatory phase 247.96 ± 83.94 g; and luteal phase 273.73 ± 70.77 g. The average saccharose content was in the: menstrual phase 38.73 ± 21.66 g; ovulatory phase 42.41 ± 28.69 g; and luteal phase 64.28 ± 39.11 g. The saccharose content was statistically significantly different between the menstrual phase and the luteal phase ($P = 0.0077$) and the ovulatory phase and the luteal phase ($P = 0.0255$). The average daily energy consumption was not statistically significantly different in the individual cycle phases ($P = 0.0572$). Furthermore, there was not statistically significant differences between fat content ($P = 0.1178$) and carbohydrates content ($P = 0.1797$) between the individual menstrual cycle phases.
Conclusion
Oral hormonal contraceptives does not influence eating pattern of the examined women.

The PCOS demographic in a dedicated University Hospital Clinic

Maeve Durkan[1,2] & Bernard Kennedy[1,2]
[1]Galway University Hospital, Galway, Ireland; [2]NUI Galway School of Medicine, Galway, Ireland.

This retrospective review of all adult women referred to a dedicated University Clinic for presumed polycystic ovarian syndrome (PCOS) aims to determine i) the true PCOS prevalence and ii) to evaluate baseline demographics by diagnostic criteria and their relationship to metabolic and cardiovascular risk parameters. All charts were reviewed. The diagnosis of PCOS rests on excluding another endocrinopathy, and fulfilling any two of the three criterias as per the Rotterdam statement, i.e. oligomenorrhoea, hyperandrogenism, and/or polycystic ovaries. We reviewed coexistent hypertension, dyslipidaemia, dysglycaemia, metabolic syndrome (MetS), and NAFLD in the proven PCOS cohort. The cohort was also divided into three groups based on their inclusion criteria: group 1 (oligomenorrhoea and hyperandrogenism), group 2 (oligomenorrhea and polycystic ovaries), and group 3 (hyperandrogenism and polycystic ovaries) and these factors assessed per category. 250 women were referred with a presumed diagnosis of PCOS. 134 (54%) had confirmed PCOS. The other 116 (46%) included ectopic Cushing's, prolactinoma, nonclassical CAH, PIH, POF, hypothalamic, and obesity driven oligomenorrhoea. The PCOS cohort had a mean systolic BP 124.78 (s.d. 15.8) and a mean diastolic BP 75.46 (s.d. 9.4). Mean age was 27.74 years (s.d. 6.7 years). Mean BMI was 31 (s.d. 8.34). 30.4% of the PCOS group were normal weight or underweight (BMI <24.9). 71.6% had a BMI >24.9 (21.6% overweight and 48% obese). Metabolic datasets were incomplete but 2.5% had pre-diagnosed DM2 and one patient was diagnosed at presentation. 9/54 patients evaluated had ↑ ALT/GGT. 120 patients met group 1 criteria, six met group 2 criteria, and four met group 3 criteria and 14 patients only met all three. 124/134 PCOS women had hyperandrogenism either biochemically alone (8), phenotypically alone (4) but most (113) having both. Hypertension was more prevalent in group 1 (20/120) vs group 2 (0/6) vs group 3 (0/4). The BMI range was higher in group 1 ($31.42 + 8.28$) and group 3 ($33.89 + 14.77$) vs group 2 ($25.52 + 5.59$) raising a question of a relationship to hyperandrogenism. Equally group 1 were more likely to have ↑ Tg levels (18/120 vs 1/6 vs 0/4), ↓ HDL (30/120 vs 1/6 vs 1/6) and MetS (10/120 vs 1/6 vs 0/6). 38 women having a BMI <25 had no hypertension or MetS. Of 60 women with a BMI >35, 13 had hypertension and 11 had MetS. This is the first review of an Irish cohort. It is striking that 30% of proven PCOS patients have a normal BMI undermining the assumption of obesity as a prerequisite phenotype. 90% were diagnosed with oligomenorrhoea and hyperandrogenism alone. In keeping with the international literature, this cohort has greatest metabolic risk mandating focused risk assessment and intervention. Our data is weakened by sporadic metabolic testing but nonetheless supports new guidelines recommending this. Finally, our results reiterate the principle of PCOS as a diagnosis of exclusion with almost 50% having a different underlying diagnosis.

Hypercoagulable overall haemostatic potential is not intrinsically associated with PCOS but worsens with increasing BMI

Matej Rakusa[1], Mojca Jensterle[2], Andrej Janez[2] & Mojca Bozic Mijovski[3]
[1]Division of Internal Medicine, Department of Endocrinology and Diabetology, University Medical Centre Maribor, Maribor, Slovenia; [2]Division of Internal Medicine, Department of Endocrinology, Diabetes and Metabolic Diseases, University Medical Centre Ljubljana, Ljubljana, Slovenia; [3]Laboratory for Haemostasis and Atherothrombosis, University Medical Centre Ljubljana, Ljubljana, Slovenia.

Introduction
Growing evidences imply a role of coagulation system in the development of thromboembolic events and progression of atherosclerosis in PCOS. The aim of the study was to identify potential relationship of overall haemostatic potential (OHP) with a syndrome *per se*, BMI and androgens. OHP has not yet been assessed in PCOS.
Methods
In 89 women with PCOS aged 30.9 ± 8.1 years (50 obese, 13 overweight, and 27 normal weight) and 21 healthy age matched controls (11 obese and ten normal weight) OHP with overall coagulation potential (OCP) and overall fibrinolytic potential (OFP) was determined spectrophotometrically by repeated fibrin formation and degradation registration in two parallel plasma samples. OFP was calculated as $((OCP - OHP)/OCP) \times 100$ (%).
Results
OHP increased with BMI in PCOS (15.5 ± 3.8 in obese, 12.5 ± 5.1 in overweight, and 9.6 ± 2.3 Abs-sum in normal weight) and in controls (17.3 ± 4.6 in obese and 9.1 ± 1.0 in normal weight). There was significant difference between obese and normal weight PCOS ($P < 0.001$) and between obese and normal weight controls ($P < 0.001$). OCP also increased with BMI in PCOS (28.5 ± 5.2 in obese vs 25.7 ± 5.2 in overweight vs 22.6 ± 3.9 Abs-sum in normal weight; $P < 0.001$ for obese vs normal weight) and in controls (29.0 ± 7.1 in obese vs 22.3 ± 3.4 Abs-sum in normal weight, $P < 0.001$). OFP decreased with BMI in PCOS (46 ± 6 in obese, 52 ± 6 in overweight, and 57 ± 6% in normal weight; $P < 0.001$) and in controls (40 ± 10 in obese and 59 ± 3% in normal; $P < 0.001$). OHP in healthy obese and PCOS obese did not differ significantly, while OHP for healthy obese was increased and OFP reduced in comparison to overweight and normal weight PCOS ($P < 0.001$). Androgens did not affect OHP, OCP, and OFP.
Conclusion
PCOS was not associated with increased OHP when compared with BMI- and age-matched controls. However, increase in OHP was positively associated with BMI in PCOS and healthy women.

PZ-TR: a novel human luciferase reporter cell line for assessment of thyroid receptor transcriptional activity

Peter Illes & Zdenek Dvorak
Department of Cell Biology and Genetics, Faculty of Science, Palacky University Olomouc, Slechtitelu 11, 783 71 Olomouc, Czech Republic.

Regulation of gene expression mediated by thyroid hormones (THs) plays an essential role in variety of physiological processes. It is known that large group of natural and synthetic compounds, generally termed endocrine disruptors, can interfere with endocrine system and thus disrupt homeostasis of hormonal regulation processes in human organism. In order to screen for substances with potential disrupting effects on TH pathway, we developed and characterized human luciferase reporter gene cell line for assessment of thyroid receptor (TR) transcriptional activity – PZ-TR. PZ-TR cell line was derived from human hepatocellular carcinoma cells HepG2, which were stably transfected with reporter plasmid containing two copies of tandem thyroid response elements (TREs) upstream of reporter gene for luciferase. Dose–response analyses showed that triiodothyronine (T_3), natural ligand of TR, induced luciferase activity in PZ-TR cells in dose-dependent manner and sensitivity of luciferase assays allowed detection of T_3 in nanomolar range of concentrations. Maximum fold induction of luciferase activity ranged from 2.5× to almost 3× after 24 h of exposure to T_3. We did not observe unspecific induction of luciferase activity by other steroid hormones and VDR ligands, only exception was partial increase of luciferase activity after treatment of PZ-TR cells with retinoic acids. Cryopreservation of PZ-TR cells did not influence their functionality, similarly responsivity to T_3 and cell morphology maintained unaffected even after long-term cultivation. Novel PZ-TR cell line was used for evaluation of effects of organic tin compounds on transcriptional activity of TR. We found that both, tributyltin derivatives and triphenyltin derivatives induced luciferase activity in PZ-TR cells. These findings indicate that organic tin compounds have potential to interfere with TR-mediated regulation of gene expression and thus influence physiological activity of THs.

Evaluation of an automatic referral system for inpatients with hyponatraemia: prompt referral leads to active intervention

Jayamalathy Mannar Mannan, Mamta Joshi, Roy Vincent, Roy Sherwood, Bahram Jafar-Mohammadi, Jackie Gilbert, Benjamin Whitelaw & Simon Aylwin
King's College Hospital, London, UK.

Inpatients with hyponatraemia have a high mortality and longer length of stay. We instituted a system of automatic referral to the endocrinology team where any inpatient with a serum (Na^+) ≤125 mmol/l was referred automatically from their biochemical results.

Aims

We evaluated the diagnosis, management, and outcome of the patients referred with hyponatraemia over 6 months.

Methods

Data were prospectively captured electronically. We recorded demographics, discharge diagnoses, serum (Na^+) level, osmolalities, urinary electrolytes, thyroid function test (TFT), and cortisol status. Patients were categorised according to their initial volume status and final endocrine diagnosis. Interventions were: fluid restriction, N/Saline, hypertonic (1.8%) saline +/− furosemide or tolvaptan. Outcomes were recorded as time to sodium correction, length of stay and discharge status.

Results

61 patients were referred of whom 56 were actively managed by the endocrine team. 'True' hyponatraemia was identified in 54/56 patients. They were classified as: hypovolaemic (22.2%), hypervolaemic (25.9%), and euvolaemic (51.9%). Cortisol status was recorded or established in 81.5% and TFTs in 88.9%. Of the euvolaemic patients (28/54), 25 had SIADH-including two patients newly diagnosed with cancer; 2/28 had gluco-corticoid deficiency; one low solute intake. In patients with hypervolaemia, 42.9% were treated with fluid restriction alone and 42.9% received diuretic and hypertonic saline. 66.7% of hypovolaemic hyponatremia patients corrected with 0.9% saline alone. Amongst 25 SIADH patients, nine responded to restriction +/− drug withdrawal alone, ten were corrected with hypertonic (1.8%) saline. Glucocorticoid replacement corrected hyponatraemia in two patients. Tolvaptan was needed in four cases. Correction of sodium ((Na^+) ≥130 mmol/l) was achieved in 64.8% after a mean of 5 days.

Conclusion

Automatic referral to a specialist team from the laboratory was appropriate in >90% and led to a prompt diagnostic evaluation and active intervention.

Klinefelter syndrome: a small sample retrospective analysis

Ana Margarida Balsa[1], Margarida Bastos[2], Carolina Moreno[2], Daniela Guelho[2], Luís Cardoso[2], Nuno Vicente[2], Diana Martins[2], Diana Oliveira[2], Márcia Alves[1], Joana Guimarães[1] & Francisco Carrilho[2]
[1]Serviço de Endocrinologia, Diabetes e Nutrição do Centro Hospitalar do Baixo Vouga, Aveiro, Portugal; [2]Serviço de Endocrinologia, Diabetes e Metabolismo do Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal.

Introduction

Klinefelter syndrome (KS) is characterized by the presence of supernumerary X-chromosome and thus a 47,XXY karyotype. This syndrome remains under-diagnosed, with only about 25% of patients being identified, and only 10% during childhood.

Methods

Retrospective analysis of 11 KS patients followed-up in the Endocrinology Department of Coimbra's Hospital and Universitary Center. The registered data included education and occupation, time and motif of diagnosis, co-morbidities and treatment. Patients were divided in two groups: A – diagnosis at pediatric age, $n=8$ and B – diagnosis during adulthood, $n=3$.

Results

The mean age of diagnosis was 34.45 ± 14.2 years (A – 10.5 ± 3.1 years and B – 42.7 ± 14.2). Group A patients were diagnosed during workup of learning disabilities; on the last evaluation five had gynecomastia (62.5%) and two osteopenia (25%), none had carbohydrate metabolism disorder; they started testosterone replacement at the age of puberty; their final height was 170.3 ± 9.8 cm; four group A patients completed highschool and one couldn't read or write. One group B patient was diagnosed on account of infertility, and two on the workup of hypogonadotropic hypogonadism; on the last evaluation two had gynecomastia (66.7%), two osteopenia (66.7%), one osteoporosis (33.3%), two had psychiatric and behavioural disorders with cognitive impairment (66.7%), and two had diabetes mellitus with difficult metabolic control and proliferative retinopathy; their final height was 177.3 ± 3.8 cm. One group B patient completed highschool and had an occupation; the other two didn't finish junior high school and were unemployed.

Conclusion

Cognitive impairment was found in 90.9% of patients and was the most frequent comorbidity, with educational and professional impact. Ginecomastia and osteopenia were frequent as well. Timely diagnosis can result in a better care with proper follow-up and regular screening of possible comorbidities.

Endocrinopathies associated with lithium therapy in an Irish tertiary referral centre

Rosemary Dineen[1], Delia Bogdanet[1], C J Thompson[1], D Thompson[1], Gerard Boran[1], James Gibney[1], Veronica Keane[1] & Mark Sherlock[2]
[1]Department of Endocrinology, Adelaide and Meath Hospital Incorporating the National Childrens Hospital, Tallaght, Dublin, Ireland; [2]Department of Pyschiatry, Adelaide and Meath Hospital Incorporating the National Childrens Hospital, Tallaght, Dublin, Ireland.

Lithium is used in psychiatric practice as maintenance therapy in bipolar disorder. It has a narrow therapeutic index with serious toxic potential. Lithium is associated with multiple endocrine and metabolic disturbances but data regarding the rates of these in individual patients is lacking. In a tertiary referral centre, all patients on lithium therapy from 2000 to 2014 were identified. The aim of this study was to assess the impact of lithium therapy on the development of endocrinopathies.
Results
Five-hundred and eighty patients were identified across the 14-year period. The median number of serum lithium measurements per person was 5 (IQR 11) with a median duration of therapy of 4.2 years (IQR 10). Toxic lithium levels were observed in 27.8% ($n=161$) of patients during follow up. Impaired renal function was more common in patients with toxic lithium levels compared to those with normal lithium levels (52.8% vs 47.2%, $P<0001$). Hypernatraemia (sodium >145 mmol/l) was observed in 16.4% of the study population ($n=95$), and it correlated with impaired renal function ($r=+0.5$, $P<0001$). 25.3% ($n=24$) of patients who had hypernatraemia also developed hyponatraemia during the follow up period. 12/29 patients assessed with hypernatremia had biochemical evidence of nephrogenic diabetes insipidus with a median plasma osmolality 295 mOsm/kg (IQR 17.75) and urine osmolality of 206.5 mOsm/kg (IQR 235).Impaired renal function was observed in 39% ($n=226$) of the study population. 30.7% ($n=178$) of patients had a TSH level >4.2 mU/l. Serum calcium was measured in 503 patients with hypercalcaemia observed in 6.4%. 4/16patients (25%) assessed for hypercalcaemia had elevated PTH level but all also had impaired renal function.
Conclusion
Chronic lithium maintenance therapy and impaired renal function were risk factors for toxicity. This study highlights the multiple electrolyte and hormone disturbances observed in patients on lithium. Clinicians should be aware of this in order to monitor, detect and institute early and appropriate management of endocrinopathies.

The connection between serum prolactin, TSH, and insulin resistance in polycystic ovary syndrome patients

Alice Albu[1,2], Serban Radian[1], Suzana Florea[2] & Simona Fica[1,2]
[1]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; [2]Elias Hospital, Bucharest, Romania.

Introduction
Both TSH and prolactin serum levels within normal range were previously reported to be associated with metabolic parameters.
Aim
To analyse the connections between serum levels of prolactin, TSH, and insulin resistance in polycystic ovary syndrome patients.
Material and methods
322 PCOS patients (mean age 24.3 ± 5.16 years and mean BMI 28 ± 7.57 kg/m^2) with normal serum prolactin and without thyroid dysfunction evaluated between January 2007 and January 2014 were included in the study. Anthropometric, metabolic, and hormonal parameters were measured in all the patients. HOMA-IR was calculated as an index of insulin resistance.
Results
HOMA-IR was negatively correlated with serum prolactin ($P=0.001$) and positively with serum TSH ($P=0.03$) and with adiposity indices (BMI $P<0.0001$, waist $P<0.0001$, and waist:hip ratio $P<0.0001$). In multivariate linear regression both prolactin ($\beta=-0.203$, $P=0.015$) and TSH ($\beta=0.165$, $P<0.05$) were independently associated with HOMA-IR. Several models of multivariate linear regression were built with HOMA-IR as dependent variable and all the parameters associated with HOMA-IR in bivariate analysis as independent variables. In each model one of the adiposity indices (BMI, waist, or waist:hip ratios) were included in order to avoid collinearity. In these models the only independent predictor for HOMA-IR was adiposity.
Conclusion
Although, both TSH and prolactin serum levels were related to insulin resistance, this connection seems to be due to the interplay between adiposity and all these parameters in PCOS patients.

The serum AMH/total follicle count ratio is equal in women with and without PCOS

Sverre Christian Christiansen[1,2], Tina Bjørsvik Eilertsen[3,4], Eszter Vanky[4,5] & Sven Magnus Carlsen[1,2]
[1]Unit for Applied Clinical Research, Institute for Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway; [2]Department of Endocrinology, St Olavs Hospital, Trondheim University Hospital, Trondheim, Norway; [3]Department of Obstetrics and Gynaecology, Hospital of Namsos, Nord-Trøndelag Hospital Trust, Namsos, Norway; [4]Department of Laboratory Medicine, Children's and Women's Health, Norwegian University of Science and Technology, Trondheim, Norway; [5]Department of Obstetrics and Gynecology, St Olav's Hospital, Trondheim University Hospital, Trondheim, Norway.

Background
Anti-Müllerian hormone (AMH) has a positive linear relationship to antral follicle count (AFC) in healthy women. However, studies of intra-follicular AMH-levels indicate a non-linear relation to AFC. It is speculated whether high AMH in polycystic ovary syndrome (PCOS) women is due to overactive follicles rather than directly reflect AFC.
Study design
We used data from a previous case–control study, including 262 women with prior term (controls) and preterm births (cases) in 1999–2006. Fasting blood tests, clinical and vaginal ultrasound examination were performed. The participants were categorised to have PCOS, polycystic ovary morphology (PCOM) or to be normal controls.
Methods
PCOS was defined according to the Rotterdam criteria, PCOM was defined as having ≥12 pre-antral follicles measuring 2–9 mm in diameter, and/or increased ovarian volume (>10 ml) in at least one ovary. We analyzed AMH/AFC ratio, adjusted for age, BMI, androstenedione, free testosterone index, and insulin.
Main results
AMH had a similar linear relationship to AFC in women with PCOS, PCOM, and normal controls. Other variables included in the multivariate analysis did not change this association. The AMH/AFC ratio was similar in the three groups.
Limitations
The results apply for women who have given birth. We did not have the possibility to correct for a distribution towards either small follicles (>2 mm) or larger follicles (<9 mm).
Implications of the findings
AMH seems to be a reliable predictor of AFC independent of PCOS diagnosis or ovarian morphology. AMH can be used as a substitute indicator of AFC in most women of fertile age.

Endocrine emergencies as problem in Emergency Department 6 years observation including over 200 000 admissions

Krzysztof Marczewski[1,2], Michal Slomian[1,2], Dorota Boniek-Poprawa[1,2] & Marek Maciejewski[1,2]
[1]Pope John Paul II Regional Hospital, Zamosc, Poland; [2]Zamosc University of Management and Administration, Zamosc, Poland.

Introduction
Emergencies in endocrinology often require a doctor's high-speed operation, which is closely related to the ability to fast obtain a diagnosis. To remain a champion requires exercise. Therefore, we decided to check how often the doctors in the Emergency Department (ED) meet such patients.
The aim of our study was to investigate the frequency of endocrine emergencies in Department of Emergency in Tertiary Care Hospital with Department of Endocrinology.
Results
In 6 years from 16th Jul 2006–15th Jul 2012 to our ED was sent or came 200 954 patients (100 727 women). From this patients 40% was sent for treatment to other departments of the hospital and 60% were treated only in the ED. Among these 120 506 patients, endocrine emergency as the main diagnosis was established in 1100 (0.9%) patients. Among patients with endocrine emergencies, the vast majority were diabetes ($793=0.66\%$) and thyroid diseases ($128=0.11\%$). For the remaining 179 (0.15%) patients, ED doctors established 28 different diagnoses, including seven diagnoses identified in only one patient. This means that the ED

doctors treated this patient approximately every 12 days as one of the 55 patients with other diseases. Among patients referred for treatment to other departments of the hospital with indications of endocrine emergencies only diabetes occurred relatively frequently.
Comments
We cannot exclude that part of the endocrine diseases was undiagnosed or not given as the main diagnosis. The majority of our endocrine patients are admitted elective mainly from the specialised outpatient clinics or family physicians.
Conclusion
Endocrine emergencies except diabetes and thyroid diseases are rare or very rare diseases and their diagnosis is a challenge for ED physicians. Very important, therefore, seems to be good cooperation between ED and Endocrinology Department.

ThyrART: association of embryo quality and reproductive outcome after IVF with thyroid autoimmunity

Gesthimani Mintziori[1], Efstratios M Kolibianakis[1], Aristidis Slavakis[2], Basil C Tarlatzis[1] & Dimitrios G Goulis[1]
[1]Units of Reproductive Endocrinology and Human Reproduction, First Department of Obstetrics and Gynecology, Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Hormone Assay Laboratory, Department of Biochemistry, Hippokration Hospital, Thessaloniki, Greece.

Introduction
The role of thyroxine (T_4) during embryo development is recognised as crucial. The research question of this study was if embryo quality and reproductive outcomes after IVF are affected by maternal thyroid function and/or thyroid autoimmunity (TAI).
Methods/design
We conducted a prospective study (ThyrART), assessing embryo quality and reproductive outcome of women undergoing ovarian stimulation with a flexible GnRH-antagonist protocol for IVF (classic or ICSI), whose thyroid function (TSH, fT_3, and fT_4) and TAI (anti-TPO and anti-Tg) were closely observed. Embryo quality scores were calculated and reproductive outcomes were recorded.
Results
Best embryo score at day 2 was positively correlated with the overall change of fT_4 concentrations ($r=0.64$, $P=0.048$). Biochemical pregnancy and live birth rates were negatively correlated with overall change of TSH concentrations ($r=-0.741$, $P=0.004$ and $r=-0.534$, $P=0.06$ respectively).
Conclusion
The facts that changes in maternal TSH concentrations are associated with pregnancy outcomes and that changes in thyroid hormones are associated with embryo parameters need further confirmation. Interventional studies in women undergoing ovarian stimulation for IVF are needed to demonstrate a possible positive influence of levo-thyroxine supplementation, in selected cases, on their reproductive outcomes.

Association of rs1800790 in fibrinogen beta polypeptide chain gene (FGB) with endometrium in Iranian women

Zohreh Omidi[1] & Ahmad Ebrahimi[2]
[1]Department of Medical Genetics, Tehran Medical Sciences Branch, Islamic Azad University, Tehran, Iran; [2]Cellular and Molecular Research Center, Obesity Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran.

Background
Endometriosis is a common disease in women and considered as one of the most important reasons infertility, and it means abnormal growth of the endometrial tissue outside of the uterine. The exact prevalence of endometriosis disease is unknown. estimated that the endometriosis exists in 10% of women in productivity. Possibly, several genes interacting with each other as well as environment to result endometriosis. Given that one of the cellular pathways involved in endometriosis coagulation is since beta fibrinogen level rise increases the fibrin and it is an increasing cause of venous thrombosis? association of this gene and gene polymorphism FGB-455 (rs-1800790) was examined in Iranian women.
Materials and methods
After isolation of genomic DNA from the blood lymphocytes, assessing of this polymorphism was conducted by using TETRA ARMs–PCR method in 100 endometriosis patients and 100 control individuals.
Results
FGB gene polymorphism genotype frequencies were compared in the patients and control individuals. Abundance of AA, AG, and GG genotypes of the gene polymorphism FGB were 28, 48, and 24% in patients respectively, and 66, 31, and 3% in control group respectively. Results showed that there is meaningful relation between patients and control group ($P=4.619\times10^{-11}$).
Conclusion
Our findings showed that there was significant relationship between *FGB* gene polymorphism and increased risk of endometriosis in women studied. Therefore can be a determining predictive molecular biomarker identification faster and better treatment of endometriosis should be used.

EP202

A haplotype of the *EPCR* gene is associated is a candidate risk factor for uterine myomas in Iranian women

Zeinab Fathkhani[1] & Ahmad Ebrahimi[2]
[1]Department of Medical Genetics, Tehran Medical Sciences Branch, Islamic Azad University, Tehran, Iran; [2]Cellular and Molecular Research Center, Obesity Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran.

Introduction
Uterine myomas are the most frequent benign uterine tumours of smooth muscle cells of myometrium. Myoma is the most common uterine tumours occurring in 20–30% of women during their reproductive years. Despite this common complication of benign tumours, in most cases there are barrier of natural fertility and pregnancy continuing. Therefore, to understanding better the genetic characteristics of myoma help us in the treatment and preventive measures in these cases. The protein product of the *EPCR* gene activates a part of the protein C anti-coagulation pathway. The purpose of this study is to examine EPCR 4600A>G (A3 haplotype) and its relationship with uterine myoma in affected Iranian women with myoma.
Methods
In this case–control study, 100 women with myoma and 100 healthy women were studied as controls and genotype distribution of polymorphism in *EPCR* gene was investigated through tetra-ARMS-PCR method and the test results were analysed using χ^2 test.
Results
EPCR gene polymorphism (rs867186) genotype frequencies were compared in the patients and control groups; the frequency of AA, AG, and GG genotypes were 19, 78, and 3% in the patients group and 37, 43, and 20% in the control groups respectively. Results showed that there was no significant difference between patients and control group ($P=0.9$).
Conclusion
The results of present study revealed that there is a possible association between the presence of C allele in *EPCR* gene polymorphism (rs867186) and risk of uterine myoma in Iranian population and suggests this variation as a predictor marker for estimating the risk of uterine myoma.

Sexual function in women with polycystic ovary syndrome

Justina Sematonyte[1], Vilija Danylaite[2], Lina Ciaplinskiene[2], Dalia Kozloviene[2], Audrone Sebokaite[2], Malvina Pagareckaite[1] & Birute Zilaitiene[2]
[1]Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Objective
Polycystic ovary syndrome (PCOS), is a common endocrine disorder in women of reproductive age, which influences metabolic, psychological and sexual aspects of their life. We aimed to evaluate the sexual function of women with PCOS in comparison with age-matched controls.
Methods
In this prospective cross-sectional study, 40 women with PCOS (mean age 27.02 ± 4.54 years) were compared with a control group of 40 healthy volunteers (mean age 25.28 ± 4.37 years). All women used barrier contraception methods at the enrolment into the study. The degree of hirsutism was assessed using the modified Ferriman–Gallwey scale. Subjects' sexual function was evaluated using the female sexual function index (FSFI). Women were considered to be at risk for sexual dysfunction in the case of FSFI score $\leq$26.55. Testosterone and SHBG concentrations were measured by RIA Kits (DIA Source, Belgium).
Results
Mean FSFI score in women with PCOS was 24.89 ± 10.61, in the control group 24.71 ± 7.16 ($P=0.498$). There were no differences in the FSFI domains scores between groups as well. 65% ($n=26$) of women in PCOS and 65% ($n=26$) in the control group were at risk for sexual dysfunction ($P=0.946$). Non-obese PCOS women reported higher FSFI scores than obese women with PCOS ($P=0.041$). FSFI scores in PCOS patients with amenorrhea ($\leq$3 menstrual cycles/year) were lower if compared with patients with oligomenorrhea (4–8 cycles/year), $P=0.045$. Neither testosterone concentration nor hirsutism score were related to the sexual function of the study subjects.
Conclusions
The sexual function in women with PCOS did not differ from their age-matched healthy counterparts. A high percentage of young Lithuanian women are at risk for sexual dysfunction independently of their androgen status. Clinical features of PCOS might determine sexual function in PCOS patients.

Salivary cortisol response to psychological stress in late adolescent and young women: impact of menstrual irregularity, hirsutism, and hyperandrogenaemia

Marco Mezzullo, Alessandra Gambineri, Flaminia Fanelli, Andrea Repaci, Olga Prontera, Guido Di Dalmazi, Uberto Pagotto & Renato Pasquali
Endocrinology Unit, Department of Medical and Surgical Science, Center for Applied Biomedical Research, S.Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy.

Hyperandrogenic disorders cause psychological implication in young girls, limiting the quality of life. Salivary cortisol (SalF) testing was proved to be useful in the evaluations of acute stress responses. Aim of this study was to investigate SalF responses to a stressor event in late adolescent females. We selected 165 drug-free females aged 16–19 years from a cross-sectional epidemiological study. Saliva was collected in the morning before and after a stressor event consisting in a physical examination by a trained physician for anthropometric data collection and hirsutism scoring and in a structured interview about familiar and menstrual history. Blood was collected for biochemical and hormonal evaluation. SalF and serum total testosterone (TT) were assessed by liquid chromatography–mass spectrometry. Subjects were subdivided in: menstrual irregularities group (MI, $\leq$10 bleeding/year; $n=27$), isolated hirsutism group (IH, modified Ferriman–Gallwey score $\geq$8; $n=37$), isolated hyperandrogenaemia group (IHA, TT> age/menstrual phase-specific cut-off; $n=11$), and normal controls (NC; $n=90$). Glucose, insulin, and lipid profile were normal and non different among groups. Compared to NC (21.2 ± 0.3 kg/m^2), IH (22.4 ± 0.52 kg/m^2, $P=0.0169$) and IHA (23.5 ± 0.77 kg/m^2, $P=0.004$) displayed higher BMI; IHA also displayed higher waist circumference (75.4 ± 0.71 cm vs 81.0 ± 2.3 cm, respectively, $P=0.015$). Compared to NC, IH had lower SHBG (48.11 ± 1.75 nmol/l vs 42.7 ± 2.96 nmol/l, respectively, $P=0.039$). Basal SalF was not different among groups ($P=0.977$); a significant SalF increase after the stressor event was observed only in ICH (1.21 ± 0.15 ng/ml vs 1.67 ± 0.23 ng/ml, $P=0.029$). SalF relative increase (dSalF%) was significantly different among groups ($P=0.015$); in particular, dSalF% was significantly higher in ICH compared to NC (56.1 ± 18.2% vs 3.4 ± 5.1%, respectively, $P=0.010$), and this data was confirmed after adjustment for BMI, SHBG, and waist circumferences ($P=0.0051$). We conclude that hirsutism, major feature of clinical hyperandrogenism but not mestrual irregularities nor hyperandrogenaemia, plays a major role in the responsiveness to stress as measured by SalF in young girls.

Leptin and insulin resistance: impact on gonadal function in Algerian obese women

Djida Remini[1], Aziza Smili[1], Djamila Meskine[2], El Hadj Ahmed Koceir[3] & Yacine Soltani[1]
[1]Laboratory of Biology and Physiology of Organisms, Endocrinology Team, Faculty of Biological Sciences, USTHB, Algiers, Algeria; [2]Department of Endocrinology, IBN ZIRI Hospital, Bologhine, Algiers, Algeria; [3]Laboratory of Biology and Physiology of Organisms, Bioenergetic and Intermediate Metabolism Team, Faculty of biological Sciences, USTHB, Algiers, Algeria.

Introduction
Excess of abdominal fat may disturb metabolic parameters that affect insulin level and may lead to menstrual disorders, consecutively to disturbance in sex steroids production. The aim is to link the metabolic hormones in abdominal obesity, with reproductive axis hormones in women at age.
Patients and methods
85 no menopausal women aged between 17 and 52 were recruited: 62 with abdominal obesity (BMI >30 kg/m^2 and waist circumference >80) and 23 normal weight for controls (BMI <25). Lipidemia, fasting plasma glucose, insulin, leptin, adiponectin, LH, FSH, oestradiol (in follicular phase), progesterone (in luteal phase), 17OHP, SDHEA, total and free testosterone using free androgen index (FAI), and sex hormone binding globulin (SHBG) were analysed. Insulin resistance and sensitivity were estimated by HOMA-IR and QUIKI indexes.
Results
Obese women show ovulation disorders (52%) type spaniomenorrhea sometimes up to amenorrhea, hirsutism (50.79%), acne (25.4%) associated to high leptin (60.91%, $P<0.001$), cholesterol (17.32%, $P=0.00017$), triglycerides (38.98%, $P=0.00014$), LDL-c (18.80%, $P=0.0014$), decreased HDL-c (17.02%, $P=0.0085$), and insulin resistance (HOMA: 10.11 vs 4.39) due to decreased insulin sensitivity (QUIKI: 0.68 vs 0.83). The high levels of FSH (32.89%, $P=0.0495$), oestradiol (11.18%, $P=0.46$), LH (16.93%, $P=0.349$), total and free testosterone (15%, $P=0.23$), and FAI (20.42%), were associated to significant rise of leptin (68.69%, $P=0.001$), slight decrease of adiponectin reduced both progesterone (64.22%, $P=0.0003$), 17OHP (24.34%, $P=0.18$), and DHEAS (8%, $P=0.587$) as well as circulating SHBG (11.83%, $P=0.38$).
Conclusion
Insulin resistance and dyslipidaemia in obese women may contribute to increase aromatase activity and decrease liver SHBG production which led to increase total and free plasma testosterone, whereas the rise of plasma gonadotropins should be consecutive to the stimulating effect of leptin on LHRH neurons. According to clinical thresholds, our results may suggest the occurrence of hyperandrogenism in obese women, but not associated with polycystic ovary syndrome.

PCOS and thyroid disorder

Samia Ould Kablia, Aicha Lechghem & Assya Cheikh
Central Hospital of the Army, Algiers, Algeria.

Background
PCOS and thyroid disorder are two of the most frequent endocrine disorder in the general population. Although, the aetiopathogenesis of thyroiditis and PCOS is completely different this two entities have many features in common (cystic ovaries in hypothyroidism and thyroid disorder in PCOS).

Objective
Our objective was to assess the increased incidence of thyroid disorder in females with PCOS.
Methods and materials
We conduct a prospective study from 2005 to 2012, 150 PCOS and 80 controls were enrolled. All patients were screened for TSH, TPO antibodies, and a clinical exam of the neck.
Results
PCOS and controls were matched for age and BMI. The mean BMI was 27.2 kg/m^2 and the mean age 24.5 years. The thyroid disorders were more frequent in PCOS (8.66%) than in controls (1.25%). two goitres, nine thyroiditis, and two infraclinical hypothyroidism (TSH >4.5 UI/ml) were found in PCOS women. The TPO antibodies were positive in 6% of them and the mean level = 250 UI/ml.
Discussion
In our study thyroid disorders are more frequent in PCOS women than in controls, however the prevalence (8.66%) is quite similar to the general population. Increased BMI, insulin resistance, hyperostrogenemia, proinflammatory markers are thought to be the link between this two disorders.
Conclusion
There is enough literature report to argue that prevalence thyroid disorders is increased in PCOS women. The link between this two disorders is not elucidated.

Biochemical and hormonal parameters in patients presenting with hirsutism

Yildiz Okuturlar[1], Samet Sayilan[1], Meral Mert[2], Ozlem Soyluk[2], Ezgi Erdogan[1], Ozlem Harmankaya[1] & Abdulbaki Kumbasar[1]
[1]Department of Internal Medicine, Bakirkoy Dr. Sadi Konuk Education and Research Hospital, Istanbul, Turkey; [2]Department of Endocrinology and Metabolism, Bakirkoy Dr. Sadi Konuk Education and Research Hospital, Istanbul, Turkey.

Introduction
It was aimed to evaluate the biochemical and hormonal parameters in female patients with and without polycystic ovary and presenting with symptoms of hirsutism.
Materials and methods
In this study, 217 female patients presenting with symptoms of hirsutism were enrolled. Seventy-two female patients having polycystic ovaries by ultrasonography were named as group 1 and 145 female patients with normal ovaries were named as group 2. FSH, LH, plasma total and free testosterone, DHEA-S, 17-hydroxyprogesterone (17-OH Prog), glucose, homeostasis model assessment (HOMA-IR), HbA1c, total cholesterol, triglyceride, LDL cholesterol (LDL-C), and HDL cholesterol (HDL-C) were recorded.
Results
While there was statistically significant difference between total testosterone (0.62 ± 0.26, 0.56 ± 0.24) and LH/FSH ratio (1.54 ± 1.21, 1.18 ± 0.92) in groups 1 and 2 ($P = 0.09$ in both), there were no differences among the values of free testosterone, LH, FSH, 17-OH Prog, and DHEA-S. There were no significant differences in lipid profile, glucose, insulin, HOMA-IR, HbA1c, and plasma uric acid levels. While there were positive correlations between HbA1c and total testosterone, free testosterone and HOMA-IR, HbA1c and insulin in group 1, there were negative correlations between LDL-C and total testosterone, HDL-C and free testosterone in group 2. There was a positive correlation between HOMA-IR and insulin in LH/FSH ratio only in group 2.
Conclusion
Hirsutism cases should be closely monitored in terms of metabolic parameters and cardiovascular risk factors. While evaluating hormone profile in these patients, it may be appropriate to conduct research in terms of glucose metabolism disorders and dyslipidaemia.

An endocrine disrupting chemical, bisphenol A: could it be associated with sex differentiation in brain regarding to transsexuality?

Banu Sarer Yurekli, Nilufer Ozdemir Kutbay & Fusun Saygili
Endocrinology Department, Faculty of Medicine, Ege University, Izmir, Turkey.

Transsexuality is characterised by a belief of having been born in a wrong body. Sexual differentiation of genitals take place in the first 2 months of pregnancy. Sexual differentiation of brain takes place in the second half of pregnancy. It is found that there is structural sex differences in the central nucleus of the bed nucleus of the stria terminalis (BSTc). Structural differences were found to be reversed in transsexual people. In humans main mechanism appears to involve a direct effect of testosterone on the developing brain. Direct effect of testosterone on developing brain in boys and lack of this effect in girls are crucial factors in the development of male and female gender identity. The origin of transsexuality is based on the fact that the differentiation of sexual organs takes place before the sexual differentiation of the brain. It was found a reversal in BSTc. In men this area is twice the size of that in women. In male-to-female transsexuals they found female BSTc. They had shown that sex reversal of the differences in the BSTc were independent of changing hormone levels in adulthood. The size of BSTc and the number of neurons match the gender that transsexuals feel they belong to, not the sex of their sexual organs. An endocrine disrupting chemical (EDC), bisphenol A (BPA), acts as oestrogen mimic compund. BPA may affect sexual differentiation of brain and cause reversal of differentiation in male to female transsexual as female brain. Brain expresses the oestrogen receptors and other hormone receptors making it a potential target for EDC. Transsexuality presume a combination of a genetic background and an early effect on interaction of sex hormones with developing brain during critical foetal period. We hypothesize that exposure to BPA may be a cause for transsexualism.

The commonly used plasticisers (bisphenols and phthalates) as endocrine disrupting chemicals in healthy women and women with polycystic ovary syndrome

Aleksandra Rutkowska[1], Aleksandra Konieczna[1], Kamila Wilczewska[2], Agnieszka Ciechanowicz[2], Radoslaw Czernych[4], Agnieszka Kowalewska-Wlas[5], Lukasz Laczmanski[3], Justyna Kuliczkowska[3], Agnieszka Lenarcik[3], Anna Trzmiel-Bira[3], Anna Brona[3], Monika Kuligowska-Jakubowska[1], Agata Kot-Wasik[2], Andrzej Wasik[2], Andrzej Milewicz[3], Jacek Namiesnik[2], Lidia Wolska[4] & Dominik Rachon[1]
[1]Department of Clinical and Experimental Endocrinology, Medical University of Gdansk, Gdansk, Poland; [2]Department of Analytical Chemistry, Gdansk University of Technology, Gdansk, Poland; [3]Department and Clinic of Endocrinology, Diabetology and Isotope Therapy, Medical University of Wroclaw, Wroclaw, Poland; [4]Department of Environmental Toxicology, Medical University of Gdansk, Gdansk, Poland; [5]Independent Specialist of Gynaecology, Gdansk, Poland.

Plasticisers such as bisphenol A (BPA), bisphenol S (BPS), and phthalates (PAE) are commonly used in daily life in electronic equipment, cans, plastic food containers, and bottles. These substances can interact with oestrogen receptors as well as androgen receptors and therefore they are called endocrine disrupting chemicals (EDC). The aim of this study was to evaluate serum concentrations of BPA, BPS, and selected PAE in healthy women and women with polycystic ovary syndrome (PCOS). In total 191 women were studied. Eighty-six patients were diagnosed with PCOS according to the ESHRE/ASRME criteria. The healthy group consisted of 105 women without any endocrinopathies and not taking any hormonal contraceptives. Serum levels of prolactin, LH, FSH, 17OH-progesterone, total testosterone, DHEAS, insulin, and sex hormone binding globulin were measured. BPA and BPS concentration were analysed in all women's sera using high pressure liquid chromatography method combined with mass spectrometry. Phthalates concentration were identified in biological samples using gas chromatography. Serum concentration of plasticisers were detected in 35% of samples for BPS and 90% of samples for BPA and PAEs respectively. The results of the analysis have pointed also to the higher levels of BPA in the sera of women with PCOS in comparison with healthy controls. There has been a strong positive correlation between serum concentrations of BPA and BPS with free androgen index and negative correlation with serum oestradiol level. Summarising, the results for plasticisers' concentrations and their impact on the hormonal profile confirm their endocrine disrupting potential.

Serum gonadotropins secretion is not reduced with advancing age in HIV-infected females: results of a case–control study in menopausal women

Chiara Diazzi[1,2], Giulia Brigante[1,2], Giovanni Guaraldi[3], Manuela Simoni[1,2] & Vincenzo Rochira[1,2]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Azienda USL of Modena, Modena, Italy; [3]Metabolic Clinic, Infectious and Tropical Diseases Unit, Department of Medical and Surgical Sciences for Children and Adults, University of Modena and Reggio Emilia, Modena, Italy.

Introduction
HIV infection treated with highly active antiretroviral therapy (HAART) seems to be associated with hypogonadism in men. Less is known in HIV-infected women gonadal status. The aim of this study is to investigate gonadal function, in menopausal HIV-infected women compared sex- and age-matched healthy subjects (HS).
Methods
We retrospectively compared 188 HIV-infected women with 192 HS selected reviewing record charts and laboratory database respectively. We considered only women older than 50 years and we grouped them according to their age (50–54; 55–59; and >60 years). Basal serum LH, FSH, estradiol, and testosterone were measured. The FSH cut-off of 40 UI/l for establishing menopausal status.
Results
The percentage of subjects with FSH levels >40 UI/l was higher in HIV-infected women (67.5%) than in healthy controls (59.4%). This difference was found also in the younger subgroup (38% vs 27%). FSH serum levels in HIV-infected women (54.08±31.47 mUI/ml) did not differ ($P=0.27$) from HS (50.87±31 mUI/ml). Accordingly, no significant differences were found in LH, estradiol, and testosterone levels.
Conclusions
Menopause seems to occur at a younger age than HS in HIV-infected women. Moreover, differently from what was documented in HIV-infected male counterpart, HIV-infected women seem to not develop hypogonadotropic hypogonadism, but have a tendency to higher serum FSH at a younger age (<54 years) suggesting premature hypergonadotropic hypogonadism. With this in view menopause may be considered an element of the process of premature aging associated with HIV infection and its comorbidities.

Association between Apa-I polymorphism in the vitamin D receptor gene and metabolic syndrome in polycystic ovary syndrome

Betânia R Santos[1,2] & Poli Mara Spritzer[1,2]
[1]Gynecological Endocrinology Unit, Division of Endocrinology, Hospital de Clinicas de Porto Alegre, Porto Alegre/RS, Brazil; [2]Federal University of Rio Grande do sul, Porto Alegre/RS, Brazil.

Women with polycystic ovary syndrome (PCOS) have higher prevalence of metabolic disturbances such as changes in lipid profile, diabetes, hypertension and metabolic syndrome. Variants on vitamin D receptor (VDR) gene have also been related to metabolic comorbidities in general population. Therefore, the aim of the present study was to investigate whether Apa-I polymorphism (rs7974232) in the VDR gene is associated with metabolic syndrome and endocrine profile in PCOS. In this cross-sectional study 190 PCOS (Rotterdam criteria) and 100 non-hirsute and ovulatory control women were enrolled. Endocrine and clinical measurements were assessed and genotypic analyses were evaluated by real time PCR. PCOS women were younger (22.9±6.7 vs 25.2±7.7 years; $P=0.013$) and had significantly higher BMI (29.7±6.4 vs 27.0±6.1 kg/m^2; $P=0.001$), total testosterone (0.90±0.40 vs 0.54±0.17 ng/ml; $P<0.001$) and fasting insulin (16.87 (9.81–26.97) vs 11.09 (7.34–15.44); $P<001$). Metabolic syndrome was present in 26.5% of PCOS and in 4.8% of controls. The genotypic distribution for Apa-I SNP in PCOS (AA: 32.1%%, AC: 46.3%, CC: 21.6%) and controls (AA: 36.0%%, AC: 48.0%, CC: 16.0%) was similar. PCOS participants with the CC genotype (CC vs CA+AA) of Apa-I had higher risk for metabolic syndrome (OR: 2.133; 95% CI 1.020–4.464, $P=0.042$). While the analyses among control participants showed that metabolic syndrome is more frequent in CC that CA+AA genotype (13.3% vs 2.9%), no significance was found, (OR: 5.154; 95% CI 0.665–39.954, $P=0.145$), maybe because of the low prevalence of metabolic syndrome in this group. The CC genotype was also associated with higher systolic blood pressure ($P=0.009$), total cholesterol ($P=0.040$) and LDL ($P=0.038$) in both PCOS and control groups (ANOVA two-way). In conclusion, the present results suggest that variant Apa-I in VDR gene may be associated with metabolic syndrome in women with PCOS.

XbaI and PvuII oestrogen receptor alpha gene polymorphism and Y chromosome deletions in infertile vs fertile men

Suzana Vladoiu[1], Dana Dinu[1], Gabriela Anton[2], Anca Botezatu[2], Dana Manda[1], Sabina Oros[1], Olga Ianas[1], Diana Paun[1], Corin Badiu[1] & Roxana Rosca[1]
[1]C.I.Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Stefan S. Nicolau Institute of Virology, Bucharest, Romania.

Only a few genes involved in spermatogenesis have clinical importance: Y chromosome micro deletions in the region called azoospermia factor (AZF) and oestrogen receptor alpha gene polymorphisms (ESR1).
Objective
The study aim to evaluate ESR1 and Y chromosome deletion in infertile men.
Subjects and methods
43 infertile men, and 34 fertile men aged 20–50 years 50, were enrolled after signing the informed consent. Screening for microdeletions in the azoospermia factor (AZF) region of Y chromosome was performed by multiplex PCR and oestrogen receptor alpha (ESR1) gene polymorphisms XbaI and PvuII was performed by RFLP.
Results
In infertile patients ESR XbaI polymorphism 15 cases were wild type homozygote (XX), 23 heterozygote (Xx) and four mutant homozygote (xx). The frequency of x allele was 0.37, and 0.63 for X allele, $\chi^2=1.299$. In normal patients ESR XbaI polymorphism 14 cases were homozygote for normal allele (XX), 17 were heterozygote (Xx) and three were mutant homozygote (xx). The frequency of x allele in population was 0.34, for X allele the frequency was 0.66, $\chi^2=0.464$. In infertile patients ESR PvuII polymorphism 12 cases were homozygote (PP), 22 were heterozygote (Pp) and eight were mutant homozygote (pp). The frequency of p allele was 0.45, and 0.55 for P allele, $\chi^2=0.137$. In normal patients ESR PvuII polymorphism ten cases were homozygote for normal allele PP), 18 were heterozygote (Pp) and six were mutant homozygote (pp). The frequency of p allele was 0.44, for P allele the frequency was 0.56, $\chi^2=0.184$. 6.97% of all patients presented microdeletions in AZFc region and 2.32% in AZFb region, 6.97% in AZFb and AZFc regions.
Conclusion
For the two ESR1 studied polymorphism the investigated group is in HW equilibrum. No significant differences were found between the mutant allele's frequency between the infertile patients and the control group.

The impact of adiposity on serum anti-Mullerian hormone in normal and overweight women with decreased ovarian reserve

Dragos Albu, Raluca Tulin & Alice Albu
University of Medicine and Pharmacy Carol Davila, Bucharest, Romania.

Background
Few previous studies suggested a negative impact of obesity on anti-Mullerian hormone (AMH) serum levels in patients with decreased ovarian reserve, but the data regarding the relationship between AMH and adiposity in the same category of patients without severe excess of body weight are scarce.
Aim
The aim of the study was to evaluate the relationship between AMH serum levels and BMI in normal weight and overweight patients with reduced ovarian reserve.
Material and methods
Patients were 196 infertile women with reduced ovarian reserve defined as AMH $\leq$ 1 ng/ml evaluated in a Department of Assisted Reproduction between January 2007 and January 2014. Inclusion criterion was BMI $\leq$ 30 kg/m^2. Weight, height, age were recorded and AMH was measured in all the patients.
Results
Mean age of the study group was 36.9 $\pm$ 4 years and mean BMI 21.8 $\pm$ 2.8 kg/m^2 (170 normal weight patients and 26 overweight patients). Serum AMH was negatively correlated with age ($r = -0.154$, $P < 0.05$) and BMI ($r = -0.147$, $P < 0.05$) when the entire group was analyzed, but the correlation was lost when only normal weight women were included in analysis. In a multivariate linear regression model both age ($P < 0.0001$) and BMI ($P = 0.017$) were independently associated with serum AMH.
Conclusion
We found that in women with decreased ovarian reserve there is a negative impact of only slightly increased adiposity on serum AMH and this effect is independent of age.

Clinical characteristics of different phenotypes of polycystic ovary syndrome

Tamara Bogavac[1], Djuro Macut[1], Ivana Bozic Antic[1], Jelica Bjekic-Macut[2], Danijela Vojnovic Milutinovic[3], Bojana Popovic[1], Biljana Kastratovic-kotlica[4], Dusan Ilic[1], Tatjana Isailovic[1], Valentina Elezovic[1], Sanja Ognjanovic[1] & Svetozar Damjanovic[1]
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Belgrade, Serbia; [2]CHC Bezanijska kosa, Belgrade, Serbia; [3]IBISS, University of Belgrade, Belgrade, Serbia; [4]Clinic of Gynecology and Obstetrics, Belgrade, Serbia.

Introduction
Although phenotype D is well recognised in clinical studies about PCOS, there is still a debate if this phenotype should be evaluated as part of PCOS spectrum. The aim of this study was to evaluate usual anthropometric characteristics in PCOS phenotypes.
Methodology
We evaluated 365 PCOS women (PCOS: 25.05 $\pm$ 6.24 kg/m^2; 25.48 $\pm$ 5.21 years) diagnosed using ESHRE/ASRM criteria and 125 BMI-matched healthy women (Controls: 25.41 $\pm$ 5.16 kg/m^2; 30.35 $\pm$ 5.62 years). PCOS group was divided into four phenotypes: a (anovulation (ANOV), hyperandrogenism (HA), polycystic ovary morphology (PCOM)), B (ANOV, HA), C (HA, PCOM) and D (ANOV, PCOM) and analyzed for menarche age, number of menstrual cycles/year, mean diameter of the ovaries measured by the ultrasound, and degree of hirsutism assessed by Ferriman–Gallway score.
Results
Phenotype C had the same mean number of menstrual cycles per year as Controls (11.39 $\pm$ 1.18 vs 11.74 $\pm$ 0.96, $P > 0.05$) and significantly more than all other phenotypes (A: 5.62 $\pm$ 3.49, B: 7.24 $\pm$ 4.27, D: 6.82 $\pm$ 3.39, $P < 0.05$). Menarche started significantly ($P < 0.05$) later in phenotype A and D (12.94 $\pm$ 1.69 and 13.09 $\pm$ 1.12 years, respectively) in comparison to phenotypes B, C and Controls (12.51 $\pm$ 1.26, 12.59 $\pm$ 1.40 and 12.52 $\pm$ 1.36 years, respectively). Ovaries were significantly smaller ($P < 0.05$) in phenotype B and Controls (28.79 $\pm$ 7.09 and 27.93 $\pm$ 5.73 mm, respectively, $P > 0.05$) than phenotypes A (33.13 $\pm$ 5.29 mm), C (31.94 $\pm$ 4.76 mm) and D (32.76 $\pm$ 3.89 mm). Degree of hirsutism was the same in phenotype D and Controls (3.24 $\pm$ 2.50 and 3.73 $\pm$ 2.23, $P > 0.05$) and was significantly ($P < 0.001$) lower than in all other phenotypes (A: 9.99 $\pm$ 6.13, B: 10.33 $\pm$ 4.73 and C: 11.64 $\pm$ 5.66, $P > 0.05$).
Conclusion
Our results showed that assessed clinical characteristics (menstrual frequency and degree of hirsutism) are in relation to the mainly hyperandrogenic phenotypes while it was not a case for the ovarian characteristics.

Effects of oral contraceptives on the periodontium

Ioana Virtej[1,2], Theodoros Ikonomou[3], Anca Virtej[4], Petrache Vartej[5] & Catalina Poiana[2]
[1]Endocrine Private Practice, Trikala, Greece; [2]Department of Endocrinology, University of Medicine, Bucharest, Romania; [3]Orthodontic Private Pratice, Trikala, Greece; [4]Department of Biomedicine, University of Bergen, Bergen, Norway; [5]Department of Obstetrics and Gynecology, University of Medicine, Bucharest, Romania.

Gingivitis is the most frequent periodontal manifestation during oral contraceptives therapy, mainly due to the altered oral bacterial flora under the influence of oestrogen and progesterone. The aim of this study was to investigate the influence of low-dose oral contraceptives on periodontal health in young females.
Methods
42 women aged 18–38 years without systemic disease, non-smokers, were divided in two study groups: 22 women treated with low-dose oral contraceptives (OC) for 12 months and a control group of 20 women not using OC. Periodontal assessment included gingival index, probing depth, and attachment level at six sites per tooth. The OC users were examined before, at 6 and 12 months of therapy. The gingival index was appreciated as normal (Score 0), minimal (Score 1), moderate (Score 2) or severe (Score 3) depending on gingival colour, vascularisation, oedema, bleeding, ulceration.
Results
Pretreatment 72% had normal gingival aspect (Score 0) and 28% had a Score 1. The percentage of patients with moderate gingivitis (Score 2) was 42% at 6 months and 75% at 12 months. A severe gingival index (Score 3) was noted only at 12 months in 18% of cases. OC users at 12 months had higher gingival index scores, deeper mean probing depths (3.7 mm vs 2.4 mm; $P = 0.01$) and more severe attachment loss (2.4 mm vs 1.5 mm; $P = 0.015$) compared to non-users.
Conclusions
Current users of oral contraceptives had poorer periodontal health compared to non-users. Oral contraceptives may increase the risk of severe gingivitis after 12 months of use. Periodontal disease is not a contraindication for oral contraceptives, but the maintenance of a good oral hygiene should be encouraged, especially the reduction of dental plaque.

Relationship between androgen levels and markers of endothelial dysfunction in men with type 2 diabetes

Irina Khripun, Igor Belousov, Sergey Vorobiev, Elizaveta Dzantieva, Zalina Gusova, Valentina Puzireva, Asiat Sultanmuradova & Maria Haritonova
Rostov State Medical University, Rostov-on-Don, Russia.

It is well known that type 2 diabetes causes the endothelial dysfunction. However, insufficient attention is paid to the role of androgen deficiency in the formation of the early signs of endothelial dysfunction. The aim of the work was to evaluate the relationship between testosterone deficiency and markers of endothelial dysfunction in men with type 2 diabetes.
Materials and methods
Were examined 88 men aged 40–65 years with type 2 diabetes. All patients were divided into two groups matched for age. The first group included 47 patients with normotestosteronemy, the second – 41 men with testosterone concentration below 12 nM/l. Statistical analysis was performed using analysis of the median (Me [UQ; LQ] and comparison of two independent groups (U - Mann Whitney).
Results and discussion
We didn't found statistically significant difference between the two groups in a concentration of E-selectin, P-selectin and VCAM-1. In the second group was found a significant increase of resistin ($P = 0.01$): 5.81 (5.05; 8.7) ng/ml at the interval of values (2.98–18.52) vs 4.82 (3.63; 6.34) ng/ml (0.97–13.27) and ICAM-1 ($P = 0.04$): 512.45 (350.1; 644.4) ng/ml vs 361.15 (256,8; 478.5) ng/ml. In addition, was observed an increase in CRP levels in patients with late onset

hypogonadism compared to eugonadal men (12.65 (10.9, 14.00) vs 6.62 (2.59; 8.61) mg/l) ($P=0.0001$).
Summary
Hypotestosteronemy in patients with type 2 diabetes increases the concentrations of markers of endothelial dysfunction and CRP level which leads to raise of cardiovascular risk in these patients. Research of resistin and ICAM-1 concentrations in patients with type 2 diabetes and androgen deficiency reveals endothelial dysfunction at the early stage.

Subclinical hypothyroidism in patients with polycystic ovary syndrome
Hamiyet Yılmaz Yasar[1], Omercan Topaloglu[1], Mustafa Demirpence[1] & Banu Ozturk Ceyhan[2]
[1]Tepecik Research and Training Hospital, Izmir, Turkey; [2]Medline Hospital, Aydin, Turkey.

Objective
Polycystic ovary syndrome (PCOS) is a common endocrine metabolic disorder that affects 5–10% of women of reproductive age. In various studies, it was found to be associated with subclinical hypothyroidism. Serum TSH levels were also reported to be increased in obese individuals. In order to define the impact of obesity on the subclinical hypothyroidism observed in patients with PCOS, we aimed to investigate subclinical hypothyroidism both in lean and overweight or obese PCOS patients.
Methods
The study included 95 lean and 122 overweight or obese women with a diagnosis of PCOS defined in accordance with the Rotterdam criteria. The control group consisted of age and BMI matched healthy individuals and grouped as lean (n: 66) and or obese (n: 65) controls. Women with chronic disease such as overt hypo- or hyperthyroidism, kidney or liver failure, hyperprolactinaemia, late-onset adrenal hyperplasia, and diabetes were excluded from the study. Anthropometric data (BMI and waist circumference) was recorded and hirsutism in accordance with Ferriman–Gallway index was evaluated. Plasma glucose and lipid profile, TSH, free T_3, free T_4, anti-thyroperoxidase antibody, anti-thyroglobulin antibody and insulin levels were measured in all study subjects. FSH, LH, total testosterone, oestradiol and DHEA-S levels were measured in patients with PCOS.
Results
There were no significant differences between all groups with respect to glucose, free T_3, free T_4, anti-thyroperoxidase antibody and anti-thyroglobulin antibody levels. Insulin and TSH levels were significantly increased in both overweight or obese women with PCOS and overweight or obese control with respect to lean groups (pinsulin: 0.001, pTSH: 0.029). But no correlation was observed between TSH levels and other studied parameters.
Conclusion
TSH elevations observed in patients with PCOS may be associated with obesity rather than the effect of PCOS.

Subclinical hypothyroidism in young women with polycystic ovary syndrome
Yllka Themeli[1,2], Kozeta Mustafaraj[2,3], Gjergji Dilo[4] & Lindita Hoxha[4]
[1]'IKEDA' Hospital, Tirana, Albania; [2]DC'Med.al', Tirana, Albania; [3]DC'La vita', Tirana, Albania; [4]DC'Dermolife', Tirana, Albania.

Background
Separately, polycystic ovary syndrome (PCOS) and subclinical hypothyroidism (SCH) exert adverse effects on metabolic parameters. This study evaluated whether SCH in women with PCOS affects clinical, hormonal, and metabolic parameters.
Aim
To analyse the relationship between selected clinical and metabolic parameters in young women with PCOS and normal thyroid function or SCH.
Materials and methods
In this cross-sectional cohort study were enrolled 80 women diagnosed with PCOS. Their clinical, hormonal, and metabolic parameters were evaluated. SCH was defined as TSH levels of 4.5–10 mIU/l.
Results
The mean age of the 80 women was 26 ± 4.6 years. Mean BMI was 34.1 ± 6.4 kg/m^2. Thyroid function was normal in 64 women, and 16 had SCH. Prolactin and serum LDL cholesterol levels were significantly higher in the women with SCH (18.2 ± 6.2 ng/ml and 131.3 ± 17.4 mg/dl, respectively) compared with those with normal thyroid function (13.2 ± 9.7 ng/ml and 107.2 ± 29.4 mg/dl, respectively). No changes in other lipid profile parameters, insulin resistance or phenotypic manifestations were observed.
Conclusions
In young women with PCOS, SCH is associated with higher LDL cholesterol and prolactin levels. These two altered parameters should be considered as the SCH predictors in women diagnosed with PCOS.

The relationships of bisphenol A levels with leptin and adiponectin in premenopausal women
Sevgi Polat[1], Banu Sarer Yurekli[2], Gokcen Unal Kocabas[1], Raika Durusoy[3], Murat Aksit[4], Giray Bozkaya[4], Arif Yuksel[1] & Fusun Saygili[1]
[1]Endocrinology Department, Bozyaka Education and Research Hospital, Izmir, Turkey; [2]Endocrinology Department, Faculty of Medicine, Ege University, Izmir, Turkey; [3]Public Health Department, Faculty of Medicine, Ege University, Izmir, Turkey; [4]Biochemistry Department, Bozyaka Education and Research Hospital, Izmir, Turkey.

Aim
Bisphenol A (BPA) is the most common endocrine disruptor among environmental estrogens. BPA is an ingredient that is commonly used in polycarbonate plastics. In this study, our main concern is to measure the levels of BPA in premenopausal obese women and to examine the relationship of BPA with adiponectin and leptin.
Materials and methods
47 obese women and 39 non-obese healthy women were enrolled in this study. All participants were premenopausal. In this cross-sectional study, all participant's BPA, adiponectin and leptin levels were measured. BPA levels in serum were measured by ELISA method. Obese and control group mean values were compared by t-test. BPA's relationship with other parameters were analysed by Spearman rank correlation. The average values were presented with the standard deviation.
Results
The average age of obese premenopausal women were 34.4 and 33.4 in the control group ($P=0.56$). BMI mean value of the obese participants was 34.1 ± 4.0 kg/m^2 and the control group's mean BMI value was 22.8 ± 1.6 kg/m^2 ($P<0.001$). BPA levels in obese women were significantly higher than the control group (1.19 ± 8.12 ng/ml, in obese and 9.5 ± 1.13 ng/ml in the control group, $P=0.001$). All groups in the analysis; there were a significant positive correlation between leptin and BPA levels ($r=0.317$, $P=0.003$), and a negative correlation between BPA levels and adiponectin ($r=-0.269$, $P=0.012$).
Conclusion
There are many recent studies showing the relationship between BPA and obesity. The effects of BPA that impair the regulation of body weight and lead to obesity may be related to the disruptive effects on adipocyte differentiation, fat deposition, insulin resistance and impact on the secretion of adiponectin.

Characteristics of body composition in different phenotypes of women with polycystic ovary syndrome
Dusan Ilic[1], Djuro Macut[1], Ivana Bozic Antic[1], Jelica Bjekic Macut[2], Danijela Vojnovic Milutinovic[3], Bojana Popovic[1], Tamara Bogavac[1], Biljana Kastratovic Kotlica[4], Tatjana Isailovic[1], Valentina Elezovic[1] & Sanja Ognjanovic[1]
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases and Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [2]CHC Bezanijska kosa, Belgrade, Serbia; [3]IBISS, Belgrade, Serbia; [4]Clinic of Gynecology and Obstetrics, and Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Obesity is closely associated with PCOS and worsens its metabolic and reproductive characteristics. The aim of this study was to evaluate body

composition in different PCOS phenotypes. We evaluated 365 PCOS women (PCOS: 25.05±6.24 kg/m^2; 25.48±5.21 years) diagnosed using ESHRE/ASRM criteria and 125 BMI-matched healthy women (Controls: 25.41±5.16 kg/m^2; 30.35±5.62 years). PCOS were analyzed through four phenotypes: a (anovulation (ANOV), hyperandrogenism (HA), polycystic ovary morphology (PCOM)), B (ANOV, HA), C (HA, PCOM) and D (ANOV, PCOM). In all subjects body composition was evaluated using bioelectrical impedance (Tanita). We analyzed basal metabolic rate (BMR), whole body fat mass (WBFM), whole body fat free mass (WBFFM), total body water (TBW), abdominal fat mass (AFM), abdominal fat free mass (AFFM), legs fat mass (LFM). Ratio upper body (arms+abdomen)/legs fat mass was calculated.
BMI of phenotypes were: A: 25.11±6.36, B: 27.03±6.96, C: 25.63±5.84, D: 21.41±3.93 kg/m^2. PCOS in comparison to controls had higher WBFM (24.42±13.50 vs 18.19±11.75 kg, $P<0.001$), AFM (12.17±7.68 vs 8.84±6.59 kg, $P=0.002$), LFM (4.50±2.03 vs 3.84±2.04 kg, $P=0.006$) and ratio upper body/legs fat mass (2.80±0.82 vs 2.39±0.75, $P=0.007$). There were no differences in BMR, WBFFM, TBW, AFFM between whole PCOS group and Controls. Phenotype D had lower BMI, WBFM, AFM and higher LFM than all other phenotypes ($P<0.005$). Phenotypes B and C had higher BMR, TBW and AFFM than phenotypes A and D and higher ratio upper body (arms+abdomen)/LFM than phenotype D ($P<0.005$). Phenotype B had higher WBFM and LFM than phenotype A ($P<0.005$). Our results demonstrated that body composition could relate to the androgenic status. Accordingly, phenotype B expressed the most altered body composition structure.

Copy number variations in the X chromosome of Klinefelter syndrome

Alberto Ferlin[1], Maria Santa Rocca[1], Vanna Pecile[2], Riccardo Selice[1], Nicola Caretta[1] & Carlo Foresta[1]
[1]Department of Medicine, University of Padova, Padova, Italy; [2]Institute for Maternal and Child Health, IRCCS 'Burlo Garofalo', Trieste, Italy.

Introduction
Klinefelter syndrome (KS) is characterised by the presence of at least one extra X chromosome and represents the most common chromosomal aberration in men. Apart from infertility, the clinical spectrum of KS is variable and often not directly related to hypogonadism, whose expression is also not unpredictable. Several genetic mechanisms may explain the clinical features and variability of the phenotype in KS. In particular, gene-dosage effects and the parental origin of the supernumerary X chromosome in conjunction with (possibly skewed) X-chromosome inactivation may play significant roles. Here we investigated, for the first time, the genetic property of the X chromosomes by analysis of Copy Number Variations (CNV).
Materials and methods
We studied 93 non-mosaic (47,XXY) KS and 85 controls (46,XY men and 46,XX women) by SNP array using thel HumanOmniexpress Bead Chip 700K (Illumina), which includes more than 700 000 SNP markers. Data generated on the Illumina Infinium platform have been analysed by the GenomeStudio software v2011.1 (cnvpartition 3.1.6) and PennCNV.
Results
In KS the total number of CNV was 6.5/patient, significantly higher than 46,XY males (3.9 CNVs/patient) and 46,XX females (1.5 CNVs/patient). These CNV included duplications/patient and 12 deletions/patient, both significantly higher with respect to normal males and females. Also the total length of duplications and deletions, and the length of duplications and deletions per patient were significantly different from controls. After exclusion of CNV mapping to the PAR1 (69 CNVs) and PAR2 (six CNVs), regions of X–Y homology (401 CNVs), centromere (72 CNVs), and CNVs not containing genes (seven CNVs), we identified 94 CNVs in KS, ten in 46,XY men and 37 in 46,XX women. The number of deletion/patient and the length of deletion/patient were higher in KS with respect to controls. Furthermore, we identified 12 CNVs in genic regions that were patient-specific.
Conclusion
This is the first study showed the spectrum of CNVs in the X chromosomes in KS and might be important in better understanding the biology of the X chromosome in this syndrome and the role of CNVs in the genotype-phenotype relation.

Circulating levels of FSH in men are genetically determined: study of the combined effect of polymorphisms in FSHR and FSHB genes

Alberto Ferlin, Cinzia Vinanzi, Elena Speltra, Manuel Pengo, Maria Santa Rocca & Carlo Foresta
Department of Medicine, University of Padova, Padova, Italy.

Introduction
Polymorphisms in the gene for FSH receptor (FSHR) and FSH β subunit (FSHB) might modulate FSH levels and represent genetic markers for a pharmacogenetic approach to male infertility treatment. rs6166 (c.2039 A>G, Asn680Ser) and rs1394205 (c.−29 G>A) in FSHR have been better analysed in women, whereas rs10835638 (−211 G>T) in FSHB seems to have a determinant role especially in men. However, studies considering the combined effect of these three polymorphisms have not been conducted.
Materials and methods
We studied 572 consecutive infertile males (including 93 with azoospermia-cryptozoospermia, 231 with oligozoospermia and 248 with normozoospermia) by means of semen analysis, FSH, LH, and T levels, testicular volume, and rs6166, rs1394205 and rs10835638 genotyping by RFLP and direct sequencing.
Results
The *FSHB* promoter polymorphism 211 G>T is significantly associated with FSH levels (9.6±7.6, 7.2±5.8 and 2.6±1.9 IU/l respectively in men GG homozygotes, GT heterozygotes and TT homozygotes, $P<0.001$). The polymorphisms −29 G>A and Asn680Ser in *FSHR* taken alone were not associated with different FSH concentrations. Combined analysis of the three polymorphisms showed again that the major determinant of FSH levels is the −211 G>T polymorphisms, only slightly modulated by the −29G>A polymorphism, so that men with the genotype −211 GG/−29 GG had the highest levels of FSH and men with the genotype −211 TT/−29 AA the lowest. Polymorphism Asn680Ser in *FSHR* had no effect neither alone nor in combined analysed. The three polymorphisms had no effect on LH and T levels, and in accordance in these data the total number of sperm and testicular volume are modulated by the genotype. TT homozygotes for the −211 SNP are invariably azoo-oligozoospermic with low testicular volume and FSH levels <8 UI/l.
Conclusions
This is the first study analysing the combined contribution of the most common polymorphisms in *FSHR* and *FSHB* genes in influencing male reproductive system and showed that −211 G>T in *FSHB* has a determinant role, in determining FSH levels, sperm count and testicular volume. This polymorphism alters the transcriptional activity of the gene, and therefore it determines a sort of isolated FSH deficiency with azoo-oligozoospermia and represents the ideal pharmacogenetic marker of FSH treatment.

Development of an ELISA for the measurement of free 25OH vitamin D

Nicolas Heureux[1], Michel Anciaux[1], Martin Poncelet[1], Fabienne Mathieu[1], Leon Swinkels[2], Tonnie Huijs[2], Saskia Boerrigter[2], Ernst Lindhout[2], Gregg Mayer[2] & Mike Martens[2]
[1]DIAsource Immunoassays, Louvain-la-Neuve, Belgium; [2]Future Diagnostics BV, Wijchen, The Netherlands.

The objective of this project was to develop and characterise a simple immunoassay for the quantification of free 25-hydroxyvitamin D (25OH Vit D). Recent studies suggest that the concentration and genotype of vitamin D binding protein (DBP) are important factors that determine the bioavailability of 25OH Vit D in blood. It has been suggested that measurement of free, non-protein bound 25OH Vit D in serum, may provide more relevant diagnostic information than total 25OH Vit D, for instance in chronic kidney disease, bladder cancer and pancreatic cancer, or in haemodialysis patients. A two-step enzyme-linked immunosorbent assay (ELISA) was developed for the quantification of free 25OH Vit D assay, using a highly specific anti-25OH Vit D monoclonal antibody. The assay was calibrated against a symmetric dialysis method. The calibrator range was 0–35 pg/ml. The LoB was 1.1 pg/ml; the LoD was 1.7 pg/ml. Total assay precision was 5.7% at 6.3 pg/ml, 3.8% at 15.9 pg/ml and 4.8% at 24.8 pg/ml. The assay was recently compared with calculated free 25OH Vit D in clinical populations (J Schwartz J. Clin. Endocrinol. Metab. 2014). An assay was developed that reproducibly determines the level of free 25OH Vit D in serum. The assay

can be used as a valuable tool in studies to establish the clinical relevance of free 25OH Vit D.

Brown tumour in a patient with ectopic mediastinal parathyroid adenoma: a case report

Faiza Qari
King Abdulaziz, Jeddah, Saudi Arabia.

A 55-year-old Saudi woman with a complaint of anterior maxilla mass of 1 month duration. Initial examination revealed a painful mass in the anterior maxilla. Surgery was not undertaken because routine laboratory investigations revealed hypercalcemia.
Initial laboratory tests performed on admission showed the following: alkaline phosphates 143 IU/l, corrected serum calcium 3.2 mmol/l, PTH 120 pmol/l A provisional diagnosis was made for hypercalcemia due to hyperparathyroidism. Technetium thallium (99mTc-201Th) subtraction scintigraphy (Sestamibi scanning), which demonstrated a single, ectopic anterior mediastinal parathyroid adenoma. Treatment was initiated by hydration and intravenous bisphosphonate. Initially the patient underwent extirpation of the mass and curettage of the bone. Histological sections showed multiple giant cells consistent with Brown tumour of primary hyperparathyroidism. She underwent mediastinal parathyroidectomy by median sternotomy. The post-operative course was uneventful and the patient was discharged on the 6th post-operative day without complications. postoperative laboratory tests were normal.
Conclusions
Due to recent improvements in analytical techniques, the diagnosis of hyperparathyroidism usually occurs when the disease is in an asymptomatic phase, and the incidence of patients with advanced bone lesions is rare. The treatment of choice for bone lesions is parathyroidectomy.

Influence of vitamin D binding protein and C3-epimer on accuracy of 25OH vitamin D ELISA assays

Nicolas Heureux, Michel Hars & Fabienne Mathieu
DIAsource Immunoassays, Louvain-la-Neuve, Belgium.

The measurement of 25OH vitamin D has tremendously evolved since the first competitive protein-binding assay. Amongst the different techniques that are now routinely employed, ELISA still represents a common tool to quantify the level of 25OH Vitamin D in individuals. Several 25OH Vitamin D ELISA assays have been developed and commercialized in the last 3 years. They all differ by the antibody used and by the technology that is applied to release 25OH Vitamin D from its binding proteins. While chemiluminescence based assays (CLIA) have been extensively evaluated and compared in the literature, virtually no studies have been conducted on the 25OH Vitamin D ELISA assays. Six commercially available 25OH Vitamin D ELISA have been compared towards increasing concentration of Vitamin D binding protein (DBP) and C3-epi-25OH Vitamin D3 (C3-epimer). The concentration of DBP in human blood is not constant and can be influenced by a number of factors including obesity, pregnancy, the use of oral contraceptives, hormone replacement therapy, liver disease, renal disease, proteinuria and intensive care. On the other hand, C3-epimer is present in the circulation of the majority of adults and children, with levels up to 93 ng/ml reported. The DIAsource Immunoassays ELISA was the only assay not being negatively biased by the addition of increasing amounts of DBP. Mean bias of -6 to -21% were observed with the other assays. Two assays were clearly impacted by the addition of C3-epimer, with mean positive bias of 28 and 30%. The performance of a 25OH Vitamin D immunoassay is mainly influenced by the choice of the antibody and by the efficiency of the method that is used to release 25OH Vitamin D from its binding proteins. Half of the assays involved in this study were significantly impacted by the addition of endogenous interferents. This confirms that 25OH Vitamin D remains a difficult assay.

Pitfalls in the interpretation of bone turnover markers in liver transplantation

Charlotte Krol[1], Desi Meiland[1], Olaf Dekkers[1], Eveline van der Veer[2], Herman Kroon[1], Ton Rabelink[1], Bart van Hoek[1] & Neveen Hamdy[1]
[1]Leiden University Medical Centre, Leiden, The Netherlands; [2]Groningen University Medical Centre, Groningen, The Netherlands.

Introduction
Osteoporosis and fractures are common in liver disease and fracture incidence increases after orthotopic liver transplantation (OLT). The value of bone turnover markers (BMTs) in the prediction of bone loss and fracture risk pre- and post-OLT is not known.
Study design
The BMTs P1NP, osteocalcin, BALP and CTX were measured initially or in Biobank stored sera at screening and at 3, 6 and 12 months post-OLT in consecutive OLT recipients between 2008 and 2011. A prerequisite was the availability of BMD data and of spinal radiographs at screening and 6 and 12 months post-OLT.
Results
51 patients (80% male, median age 59 years) were included. Most common liver pathology was alcoholic (41%) and viral liver disease (26%). At screening, osteoporosis and osteopenia were prevalent in respectively 16 and 33% at the lumbar spine (LS) and 4 and 44% at the femoral neck (FN), and vertebral fractures were prevalent in 67%. Post-OLT, LS BMD remained stable but FN BMD decreased and 43% of patients developed new fractures. At screening, P1NP and CTX levels were high and osteocalcin levels low, but only CTX levels were predictive for bone loss and fracture risk. An increase in BALP at 6 month post-OLT was predictive for fracture risk a year post-OLT.
Conclusion
Despite the many pitfalls in the interpretation of particularly collagen-derived BTMs in liver disease, high CTX levels pre- OLT and an increase in BALP post-OLT were respectively predictive for bone loss and fracture risk during the first post-OLT year.

The evaluation of oxidative status via the measurements of total oxidant status, total anti-oxidant status, ischaemia-modified albumin and oxidised-low density lipoprotein in patients with vitamin D deficiency

Husniye Baser[1], Ummugulsum Can[2], Salih Baser[3], Bahauddin Taha Hidayetoglu[3], Uysaler Aslan[3], Ilker Buyuktorun[3] & Fatma Humeyra Yerlikaya[4]
[1]Department of Endocrinology and Metabolism, Konya Education and Research Hospital, Konya, Turkey; [2]Department of Biochemistry, Konya Education and Research Hospital, Konya, Turkey; [3]Department of Internal Medicine, Konya Education and Research Hospital, Konya, Turkey; [4]Department of Biochemistry, Necmettin Erbakan University Faculty of Medicine, Konya, Turkey.

Introduction
Oxidative damage may be responsible for pathogenesis and complications of many diseases. Vitamin D deficiency has been suggested as a potential mediator of various extra-skeletal pathologies. However, there are limited data on anti-oxidant properties of vitamin D.
Methods
Forty-one subjects with vitamin D deficiency and 30 healthy controls were enrolled in the study. The levels of total anti-oxidant status (TAS), total oxidant status (TOS), ischaemia-modified albumin (IMA), oxidized-low density lipoprotein (ox-LDL), high-sensitivity C-reactive protein (hs-CRP) and fibrinogen were measured in the patient and control groups. These measurements were repeated in 17 patients after the replacement of vitamin D.
Results
Serum IMA and TOS levels were significantly higher ($P<0.001$ and $P=0.035$, respectively), while TAS levels were significantly lower in patients, compared with controls ($P<0.001$). Additionally, fibrinogen was significantly higher in patients than controls ($P=0.003$), while ox-LDL and hs-CRP levels were similar between two groups. After the replacement of vitamin D, TAS level was significantly increased ($P=0.037$), and TOS and fibrinogen levels were significantly decreased ($P=0.043$ and $P=0.010$, respectively). Vitamin D levels were negatively correlated with IMA and fibrinogen levels ($r=-0.500$, $P<0.001$ and $r=-0.391$, $P=0.002$, respectively), although positively

correlated with TAS levels ($r=0.430$, $P<0.001$). No correlation was found between vitamin D levels, and TOS, ox-LDL and hs-CRP levels.
Conclusions
In this study, while serum IMA, TOS and fibrinogen levels were increased, TAS levels were seen to be decreased in patients with vitamin D deficiency. These results suggest that oxidative/anti-oxidative balance shifts in favours of oxidative status in vitamin D deficiency.

Vitamin D status among the doctors in a tertiary referral centre in Kerala

Mavila Veetil Vimal, P Abdul Majeed & M C Naseerali
Malabar Institute of Medical Sciences, Calicut, Kerala, India.

Vitamin D deficiency is very common in India. Doctors are vulnerable to Vitamin D deficiency since they are almost always indoors. The purpose of this study was to assess the Vitamin D status among doctors in a tertiary referral centre in Kerala, a southern state of India.
Methods
Levels of Vitamin D, calcium, phosphorus, alkaline phosphatase, and parathyroid hormone were assessed among 82 doctors and 50 healthy control subjects using ChemiLuminescence immunoassay.
Results
Vitamin D deficiency (<20 ng/ml) was seen among 93.9% of the study group compared to 40% of the control group. Severe Vitamin D deficiency was seen among 54.9% of the study group and only 3.3% of control group. There was no significant correlation between the levels of vitamin D and other biochemical parameters – calcium, phosphorus,and alkaline phosphatase but there was significant negative correlation with Parathyroid hormone levels.
Conclusion
Vitamin D deficiency is highly prevalent among doctors in Southern part of India.

The relationship between vitamin D and non-alcoholic fatty liver disease in type 2 diabetic Egyptian patients

Randa Fayez Abd-el-Salam[1], Moustafa Mamdouh Sayed[2], Sahar Al-Wakeel[1], Inas Kostandi Malaty[1] & Laila Rashed[1]
[1]Faculty of Medicine – Cairo University, Cairo, Egypt;
[2]Al-Nakheel Hospital, Cairo, Egypt.

Background
Diabetes mellitus, hypovitaminosis D, and non-alcoholic fatty liver disease (NAFLD) are common medical conditions that share some risk factors, one of which is obesity. Both NAFLD and vitamin D deficiency have been linked to the development of metabolic syndrome and type 2 diabetes. The aim of this study is to evaluate the level of serum 25-hydroxy vitamin D [25(OH)D] in type 2 obese diabetic Egyptian patients with variable degrees of hepatic steatosis.
Methods
Sixty type 2 obese diabetic patients were recruited. BMI, HbA1c, aspartate aminotransferase (AST), alanine aminotransferase (ALT), γ glutamyl transpeptidase (GGT), lipid profile, and 25(OH)D were measured. NAFLD was assessed semi-quantitatively by ultrasound on a scale of 0–3.
Results
There was a significant negative correlation between 25(OH)D and age, $P=0.027$; HbA1c, $P=0.000$; triglycerides (TG), $P=0.022$ and degree of steatosis, $P=0.047$. 25(OH)D showed a significant positive correlation with HDL, $P=0.046$. ANOVA showed a significant association between the degree of steatosis and BMI, $P=0.000$. Using multivariate analysis HbA1c was the only significant predictor for vitamin D level when tested with BMI and duration of diabetes, $P=0.000$. Patients were divided into two subgroups according to 25(OH) D level; group 1 had normal levels, group 2 were deficient in 25(OH)D. There was a significant difference between both groups as regards age, $P=0.035$; HbA1c, $P=0.000$; TG, $P=0.004$; and HDL, $P=0.028$, with vitamin D deficient patients showing higher age, higher HbA1c, higher TG and lower HDL levels. The two groups did not differ significantly as regards the grading of hepatic steatosis.
Conclusion
Poor glycaemic control is associated with lower levels of 25(OH)D independent of BMI. Higher degrees of steatosis correlated with hypovitaminosis D.

Study of vitamin D levels in adult males in Dakahlia Governorate

Raef Botros, Rania Sayed, Merhan Nasr & Mohamed Yassin
Ain Shams University, Cairo, Egypt.

Background
Vitamin D is a growing endemic problem. Wide proportions of healthy adults are deficient in vitamin D. It is very important for skeletal and non-skeletal health. It is now well established that many people have vitamin D levels that are less than currently recommended for optimal health
Aim of this work
To assess vitamin-D sufficiency/deficiency in a sample of healthy Egyptian adult males in Dakahlia Governorate in Northern Egypt and correlate it to social status, Sun exposure and Vitamin D intake in food.
Subjects and methods
This cross-sectional study was conducted on 90 healthy Males selected randomly from the relatives of patients in Outpatient Clinics and Internal Medicine Departement of El-Gamalia General Hospital. Medical History, Dietary Questionnaire and Sun exposure Questionnaire were taken from all participants who were clinically examined as well. Laboratory investigations including hemoglobin, serum creatinine, ionized calcium were measured in all subjects and 25-(OH) vitamin D was measured in 57 subjects.
Results
Forty four out of 57 subjects (77%) had deficient vitamin D levels (<20 ng/ml), eight (14%) had insufficient levels (21–30 ng/ml) and five (9%) had sufficient levels (>30 ng/ml). 55.6% of our subjects had moderate intake of vitamin D rich foods while 18.9% had high intake and 25.6% had low intake. Fifty three subjects had indoor occupations while 37 subjects had outdoor occupation. Sun exposure was found to be positively and significantly correlated with vitamin D levels, ($R=0.37$, P value 0.005). Vitamin D was positively and significantly correlated to sun exposure in case of moderate intake of vitamin D rich foods only, (R 0.419, P value 0.021) and for indoor activities, (R 0.451, P value 0.005). Multiple regression analysis showed that intake of vitamin D rich foods was an independent predictor for vitamin D level.
Conclusion
Our results show a high rate of hypo-vitaminosis D in adult Egyptian Males in Dakahlia Governorate.

Is there a relationship between neutrophil/lymphocyte ratio and vitamin D levels in individuals over 65 years of age?

Merve Yilmaz[1], Arzu Gedik[2], Tevfik Demir[3], Ayten Eraydin[4], Dilek Cimrin[5], Abdurrahman Cömlekci[3] & Sevinc Eraslan[3]
[1]Endocrinology Department, Samsun Gazi State Hospital, Samsun, Turkey; [2]Endocrinology Department, Agri State Hospital, Agri, Turkey; [3]Endocrinology Department, Dokuz Eylül University Medical Faculty, Izmir, Turkey; [4]Endocrinology Department, Gaziantep University Medical Faculty, Gaziantep, Turkey; [5]Biochemistry Department, Dokuz Eylul University Medical Faculty, Izmir, Turkey.

Introduction
Vitamin D deficiency may be an important predisposing factor for infections as well as autoimmune diseases in old individuals. Neutrophil/lymphocyte ratio (NLR), is a meaningful indicator of inflammation throughout the body. In this study we aimed to show, whether or not a relationship exists between vitamin D levels and NLR in patients older than 65 years.
Materials and method
Data of 82 patients over 65 years of age was retrospectively examined. Those without chronic renal or liver failure, active infection or disease affecting hemogram values and bone metabolism were included to study. Complete blood count and vitamin D levels of patients were recorded. NLR was calculated.

The correlation analysis was done on patients, in order to understand whether the relationship between vitamin D levels and NLR exists.
Results
The mean level of vitamin D was 21.20±10.99 and NLR was 2.09±0.97. Patients were divided into four groups according to the level of vitamin D. There was not statistically significant difference between the groups in terms of NLR ($P=0.433$). When the patients were divided into two groups according to the adequate (>30 ng/ml) and inadequate (≤30 ng/ml) levels of vitamin D, there was not significant difference between the groups in terms of NLR ($P=0.169$). Significant correlation was not detected between the mean vitamin D levels and NLR in patients. There was not significant correlation between vitamin D levels and NLR, even when divided into three groups according to their age.
Conclusions
An important relationship between vitamin D levels and immune system function has been reported. Increase in NLR, which is an indicator of acute phase response, is associated with poor prognosis in various diseases. In our study, there was not significant relationship between vitamin D levels and NLR. However, there is not any study done on this topic in the literature. Further studies with higher number of patients may be beneficial.

Relationship among plasminogen activator inhibitor-1, bone mineral density, metabolic and bone turnover markers in postmenopausal women with type 2 diabetes mellitus

Silvija Canecki-Varzic[1,2], Ines Bilic-Curcic[1,2] & Ivana Prpic-Krizevac[1,2]
[1]Clinical Hospital Center Osijek, Osijek, Croatia; [2]Faculty of Medicine, University of Josip Juraj Strossmayer, Osijek, Croatia.

Background
Women with type 2 diabetes mellitus (T2DM) have a higher risk of fractures despite increased bone mineral density (BMD). In experimental studies a potential role of plasminogen activator inhibitor-1 (PAI-1) in bone remodelling is suggested but studies in humans are lacking. This is a first study in humans investigating whether circulated levels of PAI-1 in postmenopausal women with T2DM are related to BMD and adiposity.
Methods
Anthropometric variables, PAI-1 and insulin levels, serum lipids and bone turnover markers were measured in 117 postmenopausal women with T2DM. A total of 117 female patients were divided according to lumbar spine BMD measurements via dual-energy X-ray absorptiometry in three groups: 47 with osteopenia, 21 with osteoporosis and 49 with normal BMD.
Results
Diabetic patients with normal BMD had significantly higher BMI, greater waist circumference and lower bone turnover markers than diabetics with osteopenia and osteoporosis ($P<0.01$). PAI-1 was lower in diabetics with osteoporosis and osteopenia compared with diabetics with normal BMD ($P<0.05$). In the multiple regression models the strongest determinants of PAI-1 among metabolic parameters were triglyceride and insulin levels and the duration of T2DM, among therapy beta blockers, and among bone markers pyrilinks ($P<0.05$). Final regression analysis model revealed insulin ($P=0.003$), triglycerides levels ($P=0.0002$) and pyrilinks ($P=0.0002$) to be the strongest predictors of PAI-1 levels in all patients.
Conclusion
Our findings suggest that the PAI-1 has a protective effect on bone loss by suppression of bone turnover in obese diabetic patients, and the effect is primarily mediated through the influence of metabolic factors, hyperinsulinaemia, hypertriglyceridaemia and obesity. However, the fact that pyrilinks is also independently correlated to PAI-1 implies its direct involvement in bone metabolism influencing bone mass and strength.

Different influences of physiological and medicamentous hyperprolactinaemia on calcium metabolism in rats – experimental study

Danijela Radojkovic[1,2], Milica Pesic[1,2], Sasa Radenkovic[1,2], Slobodan Antic[1,2], Marija Vukelic Nikolic[1] & Tatjana Jevtovic Stoimenov[1]
[1]Medical Faculty, University Nis, Nis, Serbia; [2]Clinic of Endocrinology, Diabetes and Metabolic Disorders, Clinical Center Nis, Nis, Serbia.

Introduction
The aim of this study was to compare prolactin receptor gene (*Prlr*) expression in the duodenum, vertebra and kidney, during physiological and medicamentous hyperprolactinaemia.
Methods
Wistar female rats 18 weeks old were divided into: Group P: nine rats, 3 week pregnant; Group M: ten rats that were intramuscular administrated Sulpirid (10 mg/kg) twice daily for 3 weeks; and age matched nulliparous rats as a control group: ten rats, 18 weeks old (C). Laboratory analysis included: prolactin, serum ionized calcium, phosphorus, urinary calcium and phosphorous excretion, and serum procollagen type 1 N-terminal propeptide (P1NP). Relative quantification of *Prlr* gene expression in duodenum, vertebra and kidney was determined by quantitative real time polymerase chain reaction.
Results
PRL concentrations were significantly higher in group P and M, compared to C ($P<0.001$). In the pregnancy ionized calcium was significantly decreased compared to C and M ($P<0.001$); serum phosphorus was significantly increased compared to C ($P<0.05$); urinary calcium was increased compared to C ($P<0.01$) and lower compared to M (with no significance); urinary phosphorous was significantly increased compared to C and M ($P<0.001$) and P1NP was significantly increased compared to C and M ($P<0.001$). In the physiological hyperprolactinaemia expression of *Prlr* gene was significantly higher in the duodenum ($P<0.001$) and significantly lower in the vertebra ($P<0.01$). While down-regulation of *Prlr* gene was verified in the kidney, in both groups.
Conclusions
In medicamentous hyperprolactinaemia, down-regulation of *Prlr* gene expression in duodenum could be underlying reason for diminished intestinal calcium absorption. Increased calcium uresis could be partly due to down-regulated *Prlr* gene expression in the kidney. In order to maintain calcium homeostasis, since intestinal absorption is compromised and loosing via kidney elevated, prolactin will rapidly take calcium from skeletal system, thank to increased *Prlr* gene expression in the vertebra, leading to more harmful effect on bone metabolism compering to physiological hyperprolactinaemia.

EP234

The effects of maternal iron status on infant fibroblast growth factor-23 and mineral metabolism

Vickie S Braithwaite[1], Ann Prentice[1,2], Momodou K Darboe[2], Andrew M Prentice[2,3] & Sophie E Moore[1,2]
[1]MRC Human Nutrition Research, Cambridge, UK; [2]MRC Keneba, MRC Unit, Banjul, Gambia; [3]MRC International Nutrition Group, London, UK.

Fibroblast growth factor-23 (FGF23), a phosphate-regulating hormone is elevated in hypophosphataemic syndromes and is a predictor of mortality in patients with kidney disease. Recent findings demonstrate iron deficiency as a potential mediator of FGF23 expression and murine studies have shown *in utero* effects of maternal iron deficiency on FGF23 and phosphate (P) metabolism and bone formation (Clinkenbeard, *JBMR*, 2013).
The aim of the current study was to investigate the impact of maternal iron status on infant mineral metabolites in humans over the first two years of life. Infants born to mothers with normal (NI $n=25$) and low (LI $n=25$) iron status during pregnancy, from a mother-infant trial ISRCTN49285450 from rural Gambia, West Africa, had blood and plasma samples analysed at 12, 24, 52, 78 and 104 weeks of life for circulating haemoglobin (Hb), C-terminal (C-FGF23; Immutopics, USA) and intact-FGF23 (I-FGF23; Kainos, Japan), P, total alkaline phosphatase (TALP) and cystatin C (Cys C) (Kone Analyser 20i, Finland). Circulating I-FGF23, P, TALP and Hb decreased and estimated glomerular filtration rate (eGFR; 74.835/(cys C (mg/l)$^{1.333}$) increased over time (mean (S.D.) I-FGF23: 49.1 (13.1) to 34.3 (10.9) pg/ml, P: 1.86 (0.13) to 1.69 (0.17) mmol/l, TALP: 406 (133) to 318 (135) U/l, Hb: 10.7 (1.6) to 9.4 (1.6) g/dl and eGFR: 59.9 (11.2) to 94.5 (23.4) ml/min all $P\leq0.0001$)). C-FGF23 did not change significantly over time (402 (218) to 487 (502) RU/ml, $P=0.15$). C-FGF23 and TALP were significantly higher in LI compared with NI from 52 weeks for C-FGF23 (52 weeks: 732 (702) vs 334 (225), 78 weeks: 702 (827) vs 417 (754) and 104 weeks: 628 (628) vs 347 (283) RU/ml) and from 24 weeks for TALP (24 weeks: 373 (153) vs 306 (77), 78 weeks: 310 (106) vs 258 (66), 104 weeks: 340 (162) vs 289 (93) U/l). Adjusted for timepoint Hb was the strongest negative predictor of C-FGF23 concentration (Beta coefficient (S.E.) −104.1 (27.28) RU/ml, $P\leq0.0002$; group difference $P=0.03$) and P the strongest positive predictor of I-FGF23 (31.4 (3.9) pg/ml, $P\leq0.0001$, group difference $P=0.8$) and I-FGF23 did not predict C-FGF23 (−2.68 (3.56) RU/ml, $P=0.45$, group difference $P=0.03$). In conclusion, this study suggests that poor maternal iron

status leads to an increased infant C-FGF23 and TALP concentration in humans. Further studies are required to investigate the role of maternal iron status in the regulation of offspring FGF23 status and mineral metabolism.

Vitamin D and seasonal variation among Greek female patients with osteoporosis

Georgios Papadakis, Ioannis Keramidas, Kassiani Kakava, Theodora Pappa, Vassiliki Villiotou, Paraskevi Manitarou, Styliani Kalaitzidou, Eleni Triantafillou, Victoria Kaltzidou & Anastasios Pappas
Metaxa Cancer Hospital, Piraeus, Athens, Greece

Background
25 hydroxy vitamin D (25(OH)D) vitamin levels are positively associated with bone mineral density and season, time of day and sun exposure duration influence its synthesis. Variations in daylight throughout the year and zenith angle, depending on the latitude of residence, influence u.v. solar radiation which is closely related to serum 25(OH)D levels. The aim of this study was to investigate the degree of seasonal variation of 25(OH)D serum levels in a population-based cohort of postmenopausal women with osteoporosis.
Methods
Serum levels of 25(OH)D were assessed in 596 Greek patients (mean age 65.3 years old; S.D. = 9.4) in different months between August 2012 and December 2014. Each patient contributed one blood sample during the observation period and all women received vitamin D supplements as a multivitamin tablet or as a Calcium carbonate with vitamin D chewable tablet. Total hip bone mineral density was measured by dual-energy X-ray absorptiometry and all women had a *T* score of -2.5 or less.
Results
The minimum 25(OH)D serum level was observed in March (13.4 ± 9.5 ng/ml) and the maximum levels in August, September and October (29.1 ± 16.1; 28.9 ± 12 and 28.4 ± 8.9 ng/ml respectively). The prevalence of vitamin deficiency (<20 ng/ml), insufficiency (20–<30 ng/ml) and sufficiency (≥ 30 ng/ml) in March was 76.5, 15.7 and 7.8% respectively. On the contrary, the highest prevalence of vitamin D sufficiency was observed in August, September and October (38.1, 45.3 and 46.5% respectively).
Conclusion
Seasonal variations should be considered when measuring and correcting vitamin D serum levels. Although Greece is a country with sunshine, the majority of postmenopausal women with osteoporosis do not reach sufficient 25(OH)D levels, regardless of type and dose of vitamin D supplementation and degree of sun exposure.

Is vitamin D receptor gene polymorphism TaqI effect the occurrence and subtype of Hashimoto's thyroiditis?

Fulya Akin[1], Bedia Guleryuz[2], Sebehat Turgut[3], Senay Topsakal[1], Guzin Fidan Yaylali[1], Melek Tunc Ata[3] & Mukaddes Mergen Dalyanoglu[3]
[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Pamukkale University, Denizli, Turkey; [2]Department of Internal Medicine, Faculty of Medicine, Pamukkale University, Denizli, Turkey; [3]Department of Physiology, Faculty of Medicine, Pamukkale University, Denizli, Turkey.

Background
Hashimoto's thyroiditis (HT) is a common autoimmune disease of thyroiditis. There is a relation with Vitamin D levels, vitamin D receptor (VDR) and HT reported. More than 30 gene polymorphisms are found in VDR gene. The most common four types of polymorphisms studied in autoimmune disease are FokI (exon 2), BsmI (intron 8), ApaI (intron 8) and TaqI (exon 9). The aim of this study is to investigate the association between VDR TaqI gene polymorphism and HT subtypes.
Methods
We performed a case-control study that included 139 cases with HT (50 euthyroid, 50 subclinical hypothyroid, 39 overt hypothyroid patients) and 50 healthy control. Subjects were collected from Endocrinology Clinic. VDR gene polymorphisms TaqI were typed by RFLP.
Results
At the TaqI genotype distribution, 34% TT genotype, 38% Tt genotype and 28% tt genotype were identified in the control group. TT genotype in 46.9%, Tt genotype in 32.7% and tt genotype in 20.4% were identified in the euthyroid group. TT genotype in 55.1%, Tt genotype in 38.8% and tt genotype in 6.1% were detected in subclinical hypothyroid group. In evident hypothyroid group TT genotype in 31.6%, Tt genotype in 55.3% and tt genotype in 13.2% identified. In euthyroid group and subclinical hypothyroidism group TT genotype, in the evident hypothyroidism groups and the control group Tt genotype was detected at the highest rate.
Conclusion
Statistically significant differences was observed when all HT group compared with the control group according to TaqI genotype distribution. There is relationship between VDR TaqI gene polymorphism and HT. This study showed that VDR TaqI gene polymorphism may be predisposed to the HT occurrence.

[1]Department of Endocrinology and Metabolism, Faculty of Medicine, Pamukkale University, Denizli, Turkey; [2]Department of Internal Medicine, Faculty of Medicine, Pamukkale University, Denizli, Turkey; [3]Department of Physiology, Faculty of Medicine, Pamukkale University, Denizli, Turkey.

Background
Hashimoto's thyroiditis is the most common autoimmune endocrine disorders and often leads to hypothyroidism. There is a relation with Vitamin D levels, vitamin D receptor (VDR) and HT reported. More than 30 gene polymorphisms are found in VDR gene. The most common four types of polymorphisms studied in autoimmune disease are FokI (exon 2), BsmI (intron 8), ApaI (intron 8) and TaqI (exon 9). The aim of this study is to investigate the association between VDR FokI gene polymorphism and Hashimoto's thyroiditis subtypes.
Methods
We performed a case-control study that included 139 cases with HT (50 euthyroid, 50 subclinical hypothyroid, 39 overt hypothyroid patients) and 50 healthy control. Subjects were collected from Endocrinology Clinic. VDR gene polymorphisms FokI were typed by RFLP.
Results
At the FokI genotype distribution analysis, 49% of FF genotype, 36.7% of Ff genotype and 14.3% of ff genotype were detected in euthyroid Hashimoto's thyroiditis group. The FF genotype in 46.9%, Ff genotype in 38.8% and ff genotype in 14.3% of group were detected in subclinical hypothyroidism group. In evident hypothyroidism, the FF genotype was observed in 36.8%, Ff genotype in 52.6% and ff genotype in 10.5% of the patient. In the control group, FF genotype in 58%, Ff genotype in 32% and FF genotype in 10% of the group were determined. At the FokI genotype distribution in euthyroid, subclinical hypothyroid and control groups the FF genotype was observed in the highest rate while Ff genotype was detected at the highest rate in evident hypothyroidism group. There were no statistically significant differences were observed in all Hashimoto's thyroiditis group compared with the control group. No statistically significant difference was seen between euthyroid, subclinical hypothyroid, evident hypothyroid groups and the control group.
Conclusion
This study showed that VDR FokI gene polymorphism not affected the occurrence of the HT.

Effect of supplementation with vitamin D and calcium to excessive suppression of bone metabolism during antiresorptive therapy

Tijana Icin[1], Branka Kovacev-Zavisic[1], Jovanka Novakovic-Paro[1], Ivana Bajkin[1], Bojan Vukovic[2], Ivanka Percic[2], Nemanja Kovacev[3] & Milica Medic-Stojanoska[1]
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Medical Faculty, Clinical Center of Vojvodina, University of Novi Sad, Novi Sad, Serbia; [2]Medical Faculty, Emergency Center, Clinical Center of Vojvodina, University of Novi Sad, Novi Sad, Serbia; [3]Clinic of Orthopaedic Surgery and Traumatology, Clinical Center of Vojvodina, Novi Sad, Serbia.

Introduction
Long-term therapy with bisphosphonates is considered a risk factor for the development of atypical fractures of the femur. One of the mechanisms of these fractures is excessive suppression of bone metabolism. The supplementation dose of vitamin D and calcium could have an impact on the degree of suppression of bone turnover.
The aim
To determine whether the presence or dose of supplementation with vitamin D and calcium during antiresorptive therapy have an impact on the achieved degree of suppression of bone metabolism.
Methods and materials
This was a prospective longitudinal study that included 200 postmenopausal women with antiresorptive treatment of osteoporosis. We analysed osteocalcin, CTx and ionic calcium, before treatment and 3 months after starting the therapy, and dose of supplementation with vitamin D and calcium. Based on the values of osteocalcin and CTx after 3 months of therapy, patients were divided into four groups: Group1-accelerated bone metabolism, Group2-awaited response to therapy, Group3-excessive suppression of bone resorption, Group4-excessive suppression of bone remodelling.
Results
Calcium supplementation was carried out in 77.5% of patients, usually in a dose of 500 mg/day and vitamin D in 92.5% usually at a dose of 400 IU. The dose of calcium is satisfied recommended dose in 14% of cases, a dose of vitamin D in 42.5% of cases. Calcium supplementation was not associated with the degree of suppression of bone metabolism ($P=0.557$, $\chi=0.155$). Supplementation with vitamin D was not associated with the degree of suppression of bone metabolism ($P=0.652$, $\chi=0.241$). The values of ionic calcium before and during treatment were in the reference range.
Conclusion
Most patients with antiresorptive therapy for osteoporosis takes supplementation with vitamin D and calcium. The supplementation dose in many cases was less than the recommended dose. The degree of suppression of bone metabolism during antiresorptive therapy did not depend on the supplementation dose of calcium nor vitamin D.

Familial hypercalcaemic hypocalciuria in a woman with Graves' disease: a case report of mistaken identity

Roxana Novac
Emergency Hospital, Moinesti, Romania.

We present the case of a 58 years old woman with a long history of Graves' disease and mild hypercalcaemia (total calcium registered a maximum of 11.1 mg/dl) that was first interpreted as a consequence of hyperthyroidia. After 10 year of being treated with anti-thyroid drugs the patient finally decides to undergo surgery. Immediately after surgery this particular patient does not develop hypoparathyroidism, her calcium level remaining a little high. Six weeks after surgery under appropriate thyroid supplementation the calcium levels still remains a little high (10.8 mg/dl). The labs also show normal phosphate, with normal alkaline phosphatase, normal PTH, normal renal function. Other causes of hypercalcaemia were also excluded. We raised the suspicion of a FHH although the patient did not have any familial history. We found hypercalciuria (3 mg/24 h) and a low calcium/creatinine clearance (0.002) witch sustain our supposition. After that we started searching the same disease in the family but unfortunately we were only able to find it in her only son, her parents being already dead and she does not any other siblings. What also intrigued us in this patient is the bone density witch is not normally affected in FHH but here we found a poor mineral density (especially on radius of Ts $=-3.4$) which we interpreted as being due to the long evolution of hyperthyroidism. In conclusion we describe the case of FHH in a woman with Graves' disease in which hypercalcaemia was initially attributed to hyperthyroidism.

EP240

Recalcitrant hypocalcaemia in a patient with post-thyroidectomy hypoparathyroidism and roux-en-y gastric bypass

Gonzalo Allo Miguel, Elena García Fernández, Soledad Librizzi, Guillermo Martínez Díaz-Guerra & Federico Hawkins Carranza
Endocrinology Service, 12 de Octubre University Hospital, Madrid, Spain.

Introduction
Roux-en-Y gastric bypass (RYGB) places patients at an increased risk of hypocalcemia due to the reduction in calcium absorption (because the procedure bypasses the duodenum and jejunum) and vitamin D deficiency. Subsequent thyroid surgery increases the risk of severe hypocalcemia due to potential post-operative hypoparathyroidism. Only a few cases have been published before of this kind of treatment-challenging hypocalcaemia.
Case report
We report the case of a 31-year-old woman with a previous RYGB, who suffered severe and symptomatic chronic hypocalcaemia after total thyroidectomy. Six months after the surgery, corrected calcium level had severely decreased (5.2 mg/dl) and the patient related generalised muscle cramps, labile mood and increased anxiety. She required aggressive therapy with oral calcium and calcitriol (highest dose: 12 g of calcium carbonate and 8 µg of calcitriol per day) and frequent calcium infusions, but there was no improvement in serum calcium level. Due to the lack of response to standard therapy, teriparatide treatment was started (first with s.c. injections and thereafter with a multipulse s.c. infusor) but the results were disappointing. As there was no response to different medical treatments, reversal of RYGB was performed with no complications and a subsequent sustained increase in serum calcium level.
Conclusions
This case shows that patients with postoperative hypoparathyroidism and RYGB have increased risk of severe recalcitrant symptomatic hypocalcaemia. In our case teriparatide was ineffective but, as this is the first patient reported, more results are needed to evaluate properly the effect of teriparatide in this kind of hypocalcaemia. The reversal of RYGB may be an optimal treatment, if medical management has failed, because the surgery recovers an adequate absorption of calcium and vitamin D from previously bypassed duodenum and proximal jejunum.

Hypovitaminosis D in pregnancy: can the Mediterranean paradox be explained? A systematic review

Spyridon Karras[1], Stavroula A Paschou[1], Eleni Kandaraki[1], Panagiotis Anagnostis[1], Cédric Annweiler[2,3], Basil C Tarlatzis[1], Bruce W Hollis[4], William B Grant[5] & Dimitrios G Goulis[1]
[1]Unit of Reproductive Endocrinology, First Department of Obstetrics and Gynecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Department of Geriatric Medicine, University Hospital, Angers, France; [3]Department of Medical Biophysics, Robarts Research Institute, Schulich School of Medicine and Dentistry, University of Western Ontario, Ontario, Canada; [4]Medical University of South Carolina Children's Hospital, Charleston, South Carolina, USA; [5]Sunlight, Nutrition, and Health Research Center, San Francisco, California, USA.

Introduction
Despite high levels of sunshine, maternal hypovitaminosis D during pregnancy is prevalent in the Mediterranean region, consisting a paradox. The aim of the study was to systematically review trials that investigated vitamin D concentrations during pregnancy in this region, in order to determine predictors of hypovitaminosis D and explain the paradox.
Methods
After applying inclusion/exclusion criteria, 15 studies were entered into the systematic review, involving 2649 pregnant women and 1820 neonates. The main outcome was maternal vitamin D concentration. Possible predictors of the outcome included study, maternal and neonatal characteristics (age, BMI, race, socioeconomic status, skin type, gestational age, sun exposure, calcium and vitamin D intake and supplementation, smoking status, parity, season of delivery, pregnancy complications).
Results
Studies differed widely in vitamin D deficiency criteria, methods of measurement and outcomes. However, prevalence of maternal and neonatal hypovitaminosis D was up to 90%. Predictors of maternal hypovitaminosis D were dark skin phototype, race and sartorial habits. Only a few pregnant women met the recommended dietary daily intake of calcium and vitamin D. Vitamin D supplementation was not a common practice.

Conclusions
Hypovitaminosis D during pregnancy is prevalent in the Mediterranean region. Racial, social and cultural habits, as well as the absence of preventive strategies seem to negate the benefits of sun exposure.

Association between BMI and femoral neck bone mineral density in post-menopausal women: analysis of NHANES cross sectional data 2008–2012

Sangeeta Chandramahanti, Henry Driscoll, Adenrele Olajide, Omolola Olajide, Ralph Webb & Prasanna Santhanam
Joan C Edwards School of Medicine, Marshall University, Huntington, West Virginia, USA.

Introduction
Obesity was thought to be protective against osteoporosis, but studies have shown conflicting results. We analysed the cross-sectional data from the National Health and Nutrition Examination Survey Data (NHANES) survey (2008–2012) to observe the association between BMI (BMI and/or waist circumference) and bone mineral density (BMD) at the femoral neck.
Research methods and design
We categorised the study population (women aged 50 years and above) into three groups based on their BMI- lean (BMI <18.5 kg/m^2), normal (BMI between 18.6–24.9 kg/m^2), and overweight/obese (BMI >25 kg/m^2). We reviewed and tabulated data on the demographics (age, race and other covariates), waist circumference (cm), mean systolic BP (mm/Hg), HOMA insulin resistance, and total cholesterol (mg/dl). We analysed the data on femoral neck BMD (gm/cm^2), total femur BMD, femoral neck bone mineral content (BMC in gm) and total femur BMC. We used the one-way ANOVA to test the difference between the groups. We also performed a correlation (non-parametric spearman's ρ) between BMI and femoral neck BMD and waist circumference and femoral neck BMD.
Results
There were 1071 persons in the cohort. There was no significant difference in BMD or BMC between the groups at the femoral neck ($P=0.39$, $P=0.79$ respectively) or total femur ($P=0.75$, $P=0.86$ respectively). Systolic blood pressure was higher in obese/overweight women ($P<0.01$). There was no correlation between femoral neck BMD and BMI (spearman's $\rho -0.07$, $P=0.25$) or femoral neck BMD and waist circumference (spearman $\rho -0.09$, $P=0.14$).
Conclusions
Our results shows that BMI and waist circumference are not associated with differences in femoral neck BMD in post-menopausal women.

The response to teriparatide of a patient with β-thalassemia and multiple endocrine complications

Luminita-Nicoleta Cima[1,3], Alice Albu[2,3], Ioana Lambrescu[1,3], Carmen Gabriela Barbu[2,3] & Simona Fica[2,3]
[1]Babes Institute, Sectorial Operational Programme Human Resources Development (SOPHRD), financed by the European Social Fund and the Romanian Government under the contract number POSDRU 141531, Bucharest, Romania; [2]Elias Hospital, Bucharest, Romania; [3]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
Osteopenia/osteoporosis in young adults with β-thalassemia major (BTM) is a prominent cause of morbidity despite adequate transfusion and iron chelation therapy. The reported frequency of osteoporosis, even in well treated TM patients varies from 13.6% to 50%, with an additional 45% affected by osteopenia.
Case report
We present the case of a 36-years-old male patient with BTM treated for 1 year with teriparatide for osteoporosis. Our patient was diagnosed with BTM at 6 months of age and he was treated with chronic blood transfusions since that moment associated intermittently with chelation therapy due to limited availability and lack of compliance of the patient. From his medical history we mention splenectomy at the age of 3, iron overload-related liver disease, chronic hepatitis C, cardiomegaly (hemosiderosis), femural dyaphysis fracture (1992), hypogonadotropic hypogonadism, secondary diabetes mellitus (2008), and hyperparathyroidism (2009). For his endocrine complications he received substitutive treatment with testosterone undecanoate, calcium, vitamin D and insulin. In January 2009 he was diagnosed with severe osteoporosis with multiple vertebral fractures, he had vertebroplasty performed at T11 and T12; alendronate treatment was initiated until November 2013 when a new vertebral fracture occurred at L5. In this context, the alendronate treatment was considered suboptimal/ineffective; therefore, therapy with rPTH was initiated. After 1 year of therapy with teriparatide his DXA measured lumbar spine BMD significantly improved (9.8% increment) without any signs of a new fracture.
Conclusions
The osteoporosis in BTM has a complex mechanism; both increased bone resorption and decreased formation being involved. Probably the extent of contribution of the two mechanisms varies in each patient. Although the bisphosphonates are the most used treatment for osteoporosis in BTM, our case report suggests that, at least in some patients, decreased bone formation is the predominant mechanism and teriparatidum could be the most appropriate therapy.

Quick PTH improves the cure rate of minimally invasive surgery in patients with primary hyperparathyroidism and preoperative localized parathyroid adenoma

Cristian Velicescu, Alina Gatu, Radu Danila, Alexandru Grigorovici & Voichita Mogos
University of Medicine and Pharmacy 'Gr.T.Popa', Iasi, Romania.

Introduction
Intraoperative quick PTH (iqPTH) monitoring is important in the treatment of primary hyperparathyroidism (pHPTH), allowing, together with preoperative localisation, the switch from routine bilateral neck exploration to limited gland excision.
Aims
We checked the advantage of iqPTH for improving the cure rate of patients operated for pHPTH by using minimally invasive surgery (MIS).
Materials and methods
Retrospective study comparing two groups of patients with pHPTH caused by isolated sporadic parathyroid adenomas localised before surgery with sesta-MIBI scintigraphy and ultrasound. All patients were operated by MIS. Adenoma excision was histologically confirmed. The 40 patients from the first group (control, C) were operated without measuring iqPTH, whereas iqPTH and serum calcium were assessed in the second group (iqPTH) of 13 patients 5 min after the excision of the adenoma and before wound suture. When iqPTH dropped $<50\%$ the pre-excision value, MIS was converted to open neck surgery.
Results
Six out of the 40 patients from the C group (15%) had persistent hypercalcemia and elevated PTH at 24 h, 3 and 6 months after surgery, needing reintervention. Eleven out of the 13 patients from the iqPTH group had an important drop of iqPTH after adenoma excision, whereas two of them (15.4%) persisted having high iqPTH levels. Conversion to open neck surgery allowed localising a preoperatory undetected supplementary parathyroid adenoma in both cases. Excision of the second adenoma allowed PTH normalization and cure in only one surgical intervention, thereby increasing success rate to 100% in the iqPTH group ($P<0.05$).
Conclusion
The addition of an iqPTH assay to MIS provides a quick and reliable intraoperative confirmation of accurate adenoma removal. iqPTH is able to distinguish between single and multiple gland disease. Persistence of high iqPTH indicates conversion to bilateral neck exploration, thereby increasing cure rate in the same intervention.

A rare cause of increased bone mineral density in adulthood: autosomal dominant osteopetrosis

Yuksel Altuntas, Feyza Yener Ozturk, Idris Kuzu, M Masum Canat, Savas Karatas & Sezin Dogan Cakir
Sisli Hamidiye Etfal Training and Research Hospital Department of Endocrinology and Metabolism, Istanbul, Turkey.

Introduction and aim
Osteopetrosis is a rare genetic disorder of reduced osteoclastic bone resorption. Defective bone remodelling induces skeletal sclerosis and abnormally dense but brittle bones. We present here a case of autosomal dominant osteopetrosis type II as a cause of high bone mineral density (BMD).
Case report
A 52-years-old woman with a complaint of bone pain and headache referred to our clinic for evaluation of high BMD. Her medical history and physical examination were unremarkable. Increased BMD in DXA scanning affecting both spine and hip was classified as generalised and acquired causes were evaluated initially. Serum fluoride concentration, renal and liver function tests, IGF-1 level, hepatitis C serology were all normal excluding fluorosis, renal osteodystrophy, acromegaly, hepatitis C associated osteosclerosis. There was no splenomegaly or hematologic abnormality for miyelofibrosis. Serum tryptase level was normal excluding mastocytosis. She denied any usage of oestrogen implants. Excluding the acquired causes, the specific features suggesting monogenic disorders such as osteopetrosis or sclerosing bone dysplasias were investigated. Rugger-jersey spine due to vertebral end plate thickening, bone within bone in pelvis and transverse sclerotic bands within distal femur, the classic signs of osteopetrosis, were recognized at plain radiographs. She denied any history of fracture and also, whole body radiographic survey showed no pathological fractures. Her serum acid phophatase was high. She was diagnosed as adult type osteopetrosis type II. Complication screening revealed only mild decrease in high-pitched voice in audiology.
Conclusion
Autosomal dominant osteopetrosis exhibits a heterogeneous trait with milder symptoms, often diagnosed at later adolescence or adulthood. Two distinct types (type I and II) have been described on the basis of radiographic, biochemical and clinical features. Type II disease appears to increase the risk of fracture. The disease requires no treatment although the complications may require intervention.

Hypocalcaemia due to 22q11.2 deletion syndrome diagnosed in adulthood

Maria Cabrer Vidal, Guillermo Serra Soler, Marzena Wos, María Soledad Gogorza Pérez, Iñaki Argüelles Jiménez, Santiago Tofé Povedano, Elena Mena Ribas, Honorato García Fernández & Vicente Pereg Macazaga
Hospital Universitari Son Espases, Palma de Mallorca, Spain.

Introduction
Hypocalcaemia is present in half of the patients with 22q11.2 deletion syndrome (DiGeorge-velocardiofacial syndrome). Most of these cases are diagnosed during childhood.
Case report
A 56-year-old man was evaluated for symptomatic hypocalcaemia after undergoing a left nephrectomy because of renal tumour. He had paraesthesia around his mouth and hands and Trousseau's sign. His past medical history included high blood pressure, type 2 diabetes, dyslipidaemia and chronic obstructive pulmonary disease. He mentioned a hypocalcaemia episode 10 years ago, frequent bronchitis at childhood and learning difficulties. Blood tests showed hypocalcaemia of 6.2 mg/dl (NV: 8.4–10.2) hypoalbuminaemia of 29.7g/l, (35–50 g/l), corrected calcium of 7.08 mg/dl, hyperphosphataemia of 4.8 mg/dl (2.3–4.7) and normal magnesium. Parathyroid hormone (PTH) was 11 pg/ml (15–88), 25-hydroxy vitamin D 16 pg/ml (>30) and 1.25-dihydroxy vitamin D 20.1 pg/ml (26.1–95). Thyroid function was normal. The electrocardiogram showed no prolonged QT interval. Endovenous and oral calcium and calcitriol were initiated, with normalization of calcium levels. Based on hypocalcaemia secondary to primary hypoparathyroidism anti-parathyroid antibodies and anti-calcium sensor receptor were requested. Due to childhood medical history and dysmorphic phenotype (hooded eyelid, bulbous nasal tip) a genetic test of 22q11.2 deletion was made. Anti-parathyroid antibodies were negative, anti-calcium sensor receptor antibodies finally were not made and the genetic test confirmed the diagnosis, so more tests were made in the outpatient clinic. Treatment at discharge was oral calcium and calcitriol. Echocardiography was normal. Densitometry revealed no bone mass loss. Immunologic studies showed a mild disturbance of cellular immunity. He received genetic advice of affected offspring.
Conclusions
It is important to classify hypocalcaemia diagnosed at any age, and especially hypocalcaemia due to genetic syndromes, as in our case, due to the 50% risk of an affected offspring.

Clinical and biochemical response to denosumab in a young adult patient with craniofacial fibrous dysplasia

Elisa Cairoli[1], Cristina Eller-Vainicher[1], Diego Sergio Rossi[2], Giada Anna Beltramini[2], Antonio Russillo[2], Giovanna Mantovani[1], Anna Spada[1] & Iacopo Chiodini[1]
[1]Unit of Endocrinology and Metabolic Diseases, Fondazione IRCCS Ca' Granda – Ospedale Maggiore Policlinico, Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [2]Department of Maxillofacial Surgery and Odontostomatology, Fondazione IRCCS Ca' Granda – Ospedale Maggiore Policlinico, University of Milan, Milan, Italy.

We report on the clinical and biochemical outcomes in a 20-year-old male suffering from active craniofacial monostotic fibrous dysplasia (MFD) treated with the RANK-L inhibitor, Denosumab, following unsatisfactory responses to prior long-term bisphosphonates therapy. The patient had been treated over 9 years with pamidronate (cumulative dose of 81 mg), but experienced only mild reductions in pain scores. Following initiation of Denosumab 60 mg subcutaneously, bone pain and bone turnover markers (osteocalcin, total and bone alkaline phosphatase and β-crosslaps) were monitored over a period of 14 months. Following the first administration, the patient demonstrated a promptly and pronounced clinical and biochemical response: within few hours the patient reported pain disappearance and after 4 weeks bone turnover markers fell to levels within the normal range. Three months after initiation of Denosumab the patient reported an acute pain reactivation that required a second administration. As previously, after few hours the pain disappeared. Later Denosumab was administered according to pain reappearance and the injections were always followed by complete pain relief. However, a gradual shortening of the pain-free interval between administrations was observed, ranging from 90 days after the first one to 75 days after the fifth one. Treatment with Denosumab was always well tolerated. The monitoring of bone turnover showed that all markers stayed in the lower half of the normal range, even at the moment of pain reappearance, suggesting that the effect of Denosumab on pain depends on mechanisms other than bone resorption suppression.
In conclusion, Denosumab appears to be effective in reducing bone turnover and bone pain in adult patients with active MFD and could represent a good alternative to bisphosphonates, allowing to avoid elevate cumulative doses of these agents. Further studies are required to clarify the efficacy, safety and mechanisms of long-term therapeutic RANK-L inhibition in MFD.

Hypophosphataemic rickets: two unrelated Mexican female cases and review of the literature

Nory Omayra Davalos[1,2], Ruth Minerva Martínez[3], Jose de Jesus Magallanes-Ordoñez[4], Celia Andrea Ramírez-Aréchiga[5], Enrique Cervantes-Pérez[6], J F Michel Monrroy[7] & J Fonseca Cárdenas[7]
[1]Instituto de Genética Humana Dr. Enrique Corona, Doctorado de Genética Humana, CUCS, Universidad de Guadalajara, Guadalajara, Mexico; [2]Servicio de Genética, HRVGF ISSSTE, Zapopan, Mexico; [3]Endocrinología, HRVGF ISSSTE, Zapopan, Mexico; [4]Cirugia Plastica y Reconstructiva, HRVGF ISSSTE, Zapopan, Mexico; [5]CORENTE, Instituto Especializado en la CorInteligencia S.C, Zapopan, Mexico; [6]Departamento de Bienestar y Desarrollo Sustentable Centro Universitario del Norte U de G, Colotlán, Mexico; [7]Ortopedia y traumatología, HRVGF ISSSTE, Zapopan, Mexico.

Introduction
Hypophosphataemic rickets (HR) is a rare genetic disorder characterized by poor growth, short desproporcionate stature and lower limb anomalies.

Clinical manifestations usually appear before 1 year of age, this entity is characterised by osseus hypomineralisation, secondary to the increased expression of phosphatonins, especially FGF23, which acts in the sodium and phosphate co-transporters of the proximal convoluted tubule, inducing phosphaturia. HR exhibits AD, AR or X-linked inheritance patterns.
Objective
We present two unrelated HR case reports, with clinical radiological and laboratory studies of Hypophospataemic Rickets with osseous complications and adverse medical events.
Case reports
Case 1: 7.6-year-old girl, physical examination showed height 113 cm, weight 24 kg, arm spam 116 cm, OFC 48 cm, with disproportional short stature, *genu varo*, gait difficulties, asymmetric thorax; actually presenting normocalcaemic, normophosphataemia, phosphaturia, calcitriol deficiency and secondary hyperparathyroidism.
Case 2
15-year-old girl at physical examination showed height 141 cm, weight 76 kg, with surgical antecedents, the first one in order to correct bilateral tibia deformity at age 3, and genu varum correction surgery at age 5; actually presents recidivant *genu varo*, normocalcaemic, hypophosphataemia, and phosphaturia.
Discussion
Hypophosphataemic rickets should be suspected in any child with disproportionate short stature, developmental delay and short, malformed legs. Only one-third are due to nutritional deficit, clinical cases presented meet clinical criteria and radiological rickets. In case 1 presents normocalcaemic, normophosphataemia indicating good control in the treatment. The case 2 has normocalcaemia, hypophosphatemia and vitamin D insufficiency, renal presenting microlithiasis and secondary hyperparathyroidism, which suggests a more aggressive disease character.
Conclusions
Due to functional complications in HR, early diagnosis and treatment is necessary, based in growth curves as well as serum values of phosphorus, calcitriol, alkaline phosphatase, and others, in order to offer an optimal medical care and prevent secondary osseous deformities.

Analytical evaluation of a new fully automated immunoassay for the quantification of 1,25-dihydroxyvitamin D

Nathalie Miller & Damien Gruson
Cliniques Universitaires St Luc, Brussels, Belgium.

Background
Quantification of 1,25-dihydroxyvitamin D ($1,25(OH)_2D$) remains challenging because of low circulating concentrations and potent cross-reactivities with steroid-like structures. The most frequent assays for $1,25(OH)_2D$ testing are still based on RIA format with preliminary extraction. The analytical performances and the turnaround time of analysis (TAT) for these assays are limited. Several novel assays for $1,25(OH)_2D$ testing are emerging. The aim of our study was therefore to evaluate the analytical performances of a recently developed automated immunoassay for the measurement of $1,25(OH)_2D$.
Methods
We evaluated the performances of the LIAISON XL $1,25(OH)_2D$ assay (DiaSorin), a fully automated immunoassay that uses a recombinant fusion protein for capturing $1,25(OH)_2D$. The limit of detection and the within- and between-run imprecision were determined. Method comparison was performed with our routine RIA method and with a reference Liquid chromatography-tandem mass spectrometry (LC-MS/MS) method.
Results
The limit of detection was <5 pg/ml. The within-run coefficients of variation (CV) were 2.6 and 4.4% for $1,25(OH)_2D$ concentrations of 6.7 and 19.7 pg/ml and the between run CVs were 9.3 and 13.1% for concentrations of 25.4 and 101.1 pg/ml. The automated $1,25(OH)_2D$ assay was significantly correlated to RIA ($r=0.74$; $P<0.0001$) and LC-MS/MS ($r=0.9975$; $P<0.0001$). The comparison of the automated assay and RIA revealed through Passing-Bablok regression analysis a slope of 0.86 and an intercept of 14.12. The mean bias observed on the Bland-Altman plot was -2.8 pg/ml. The comparison of automated assay and LC-MS/MS revealed through Passing-Bablok regression analysis a slope of 1.07 and an intercept of -1.87. The mean bias observed on the Bland-Altman plot was -8.2 pg/ml.
Conclusion
The LIAISON XL $1,25(OH)_2D$ automated assay demonstrated superior analytical performances in comparison to RIA assay and a clear improvement of TAT. Furthermore, we demonstrated a strong agreement between this $1,25(OH)_2D$ automated assay and a reference LC-MS/MS method.

EP250

High offset point for normocalcaemic secondary hyperparathyroidism due to vitamin D deficiency

Taimur Gulfam, Naveen Aggarwal, Murali Ganguri & Richard Quinton
Department of Endocrinology, Royal Victoria Infirmary, Newcastle Upon Tyne, UK.

Introduction
Vitamin D deficiency occurs more frequently in patients with primary hyperparathyroidism compared to general population, and is usually associated with an aggravated form of the disease. Current guidelines recommend measurement of vitamin D level in all patients with primary hyperparathyroidism, and their repletion if the levels are <50 nmol/l.
Case report
We present a 56 years old Caucasian lady who underwent right parathyroidectomy & thyroid lobectomy for right parathyroid carcinoma in 1998. Her initial serum parathyroid level was 48.2 pmol/l (1.1–6.4). Postoperatively, her parathyroid level improved to 7.5 pmol/l but never came back to normal. She was followed up in endocrine clinic for persistent normocalcaemic hyperparathyroidism with no evidence of recurrent parathyroid cancer. In January 2010 her parathyroid level was 7.8 pmol/l with concomitant vitamin D level being 80 nmol/l (>50 nmol/l). She was started on ergocalciferol 400 IU twice daily. After 6 months, her parathyroid levels were 4.3 pmol/l which suggested secondary hyperparathyroidism due to relative vitamin D deficiency. In March 2012, despite being on vitamin D supplementation, her parathyroid levels were elevated at 6.6 pmol/l with vitamin D level being 86 nmol/l. She was advised to continue with same dose of vitamin D supplement. In March 2014, her parathyroid level increased further to 8.6 nmol/l with her being vitamin D replete at 107 nmol/l. This time it was decided to increase the dose of vitamin D to 2000 IU/day. After 6 months of treatment with increased dose of vitamin D, her parathyroid level normalized to 4.6 pmol/l with vitamin D levels of 152 nmol/l. She was normocalcaemic during all this time.
Discussion
In this patient, her parathyroid levels normalised after achieving a vitamin D level, which was higher then usually recommended level. In selected patients, we may need to aim for a higher vitamin D level before seeing an improvement in parathyroid levels.

Low bone mass in Sheehan's syndrome: prevalence and management

Melika Chihaoui, Dhouha Ben Salah, Meriem Yazidi, Fatma Chaker, Bochra Ftouhi & Hedia Slimane
University Hospital la rabta, Tunis, Tunisia.

Introduction
Hypopituitarism is a known cause of bone mineral loss. Our study aimed to evaluate the frequency of osteopenia and osteoporosis in patients with Sheehan's syndrome and to evaluate its management.
Subjects and methods
It is a retrospective longitudinal study concerning 60 cases of Sheehan's syndrome that have had a bone mineral density measurement. The parameters of osteodensitometry, the received treatment and the follow up data were collected. The baseline parameters of osteodensitometry were compared to those of 60 age-, height- and weight- matched healthy control women.
Results
The mean age at osteodensitometry measurement was 49.4 ± 9.9 years (range 25–76 years). Osteopenia was present in 25 patients (41.7%) and osteoporosis in 23 (38.3%). Bone mineral density was significantly lower than in the control group ($P<0.001$). The odds-ratio of osteopenia-osteoporosis was 6.3. Low bone mineral mass concerned more frequently lumbar spine ($P<0.05$). Bone fracture was reported by three patients (5%). Only six of the osteoporotic patients were treated with bisphosphonates. Osteodensitometry was controlled in 15 cases after a mean duration of 6 years and showed an improvement in four cases.

Conclusion
Low bone mineral mass was very frequent in patients with Sheehan's syndrome. Treatment was insufficient.

Comparison of the pre-operative and post-operative haemogram parameters of the patients with primary hyperparathyroidism

Ulku Aybuke Tunc[1,2], Tevfik Demir[1,2], Merve Yilmaz[1,2] & Arzu Gedik[1,2]
[1]TEMD, Turkey; [2]The Endocrine Society, USA.

Anaemia prevalence is reported between 5 and 31.8% in patients with PHPT. Anaemia in PHPT shows correlations with serum calcium, PTH, alkaline phosphatase levels, severity of the bone disease and PHPT duration. In this study we compared pre-operative and post-operative haemogram parameters of patients with PHPT who received a parathyroidectomy at our department. We determined the prevelance of pre-operative anaemia, thrombocytopenia, neutropenia and observed if any of this parameters were recovered after the surgery. We excluded patients with systemic diseases which may interfere with cytopenias. Likewise, we determined pre-operative and post-operative variations of some parameters such as RDW, MPV, neutrophile/lymphocyte rates, that are often disregarded in haemogram reports but related to chronical inflammation. Out of 157 patients with PHPT, 127 (80.9%) were women and 30 (19.1%) were men. There was no significant difference in terms of prevalence of cytopenia before and after the surgery for PHPT. Correlation analysis did not reveal any significant differences between studied parameters except that there was a moderate-weak relation between PTH level and neutrophile/lymphocyte rate. Mean RDW was high in patients with PHPT before the surgery, however it did not improve after the operation significantly. There are no studies in the literature evaluating RDW, MPV values and neutrophile/lymphocyte rates that are related to primary hyperparathyroidism (or secondary, tertiary hyperparathyroidism). Our study has the feature of being the first study in this field, more significant data is expected to be obtained as the number of included patients increase.

TSH and free-T_3 correlate negatively and independently with bone mineral density in adults with subclinical hypothyroidism

Anna de Lloyd[1], Ilaria Muller[1], Alan Dodd[2], Hilary Durrant[2], Rebecca Pettit[3], Sarah Darlington[3], Lei Zhang[1], Carol Evans[2], Aled Rees[1] & Marian Ludgate[1]
[1]Thyroid Research Group, IMEM, Cardiff University, Cardiff, Wales, UK; [2]Department of Medical Biochemistry and Immunology, University Hospital of Wales, Cardiff, Wales, UK; [3]Department of Medical Physics, University Hospital of Wales, Cardiff, Wales, UK.

The role of the thyrotropin receptor (TSHR) in bone is unclear. TSHR-deficient mice have low bone mineral density (BMD) and focal osteosclerosis despite normal thyroid hormones (suggesting TSHR function, in bone, is important). Subclinical hypothyroidism (SH) has various aetiologies including thyroid autoimmunity (TA) and inactivating TSHR mutations (TSHR-M). In TSHR-deficiency & TSH-M elevated TSH compensates for reduced TSHR function, whereas in TA it compensates for reduced thyroid synthetic responsiveness (inflammation mediated). We hypothesised differential bone effects in SH relating to these causes.
Aims
i) To establish whether free-T_4, free-T_3 or TSH are associated with BMD and bone turnover (BT) in SH. ii) To explore whether SH aetiology influences BMD and BT.
Methods
208 adults with primary untreated SH (TSH$\geqq$5 mU/l) and free of known bone disease were recruited. A medical/lifestyle history, anthropometric data and blood samples were collected (free-T_3, free-T_4, TSH, anti-TPO antibodies, BT markers (CTX, P1NP)). Mutational screening of the entire TSHR coding region was undertaken by dHPLC and confirmed by direct sequencing. A DXA bone scan (lumbar spine (LS) and hip) generated *Z*-scores (relative to age/sex-matched normals (BMD-Z)) which were evaluated alongside thyroid parameters in stepwise multivariate regression analyses.
Results
50% of the cohort were TPO+ and 6% had TSHR-Ms. After adjustment for potential confounders, TSH associated negatively with BMD-Z at the LS ($R=-1.7$, $P<0.001$) whereas free-T_3 associated negatively with BMD-Z at both sites (hip: $R=-0.35$, $P=0.005$; LS: $R=-0.5$, $P=0.002$) and free-T_4 showed no independent associations. Stratification by SH aetiology showed no influence of TSHR-M on BMD-Z (despite lower free-T_3 relative to TSH ($R=-0.34$, $P=0.01$) but TPO+ associated negatively with BMD-Z at the LS ($R=-0.65$, $P<0.001$). Male gender associated negatively with BMD-Z at all sites ($R=-0.8$, $P=0.001$). BT markers did not associate with thyroid function or BMD.
Conclusions
In adults with SH, BMD is associated negatively with free-T_3, TSH, male gender and TPO antibody positivity.

Vitamin D deficiency in patients with autoimmune thyroiditis

Ivan Pankiv
Bukovinian Medical Univetsity, Chernivtsi, Ukraine.

There is increasing interest in the role of vitamin D deficiency in a number of chronic health problems including autoimmune diseases. The aetiology and pathogenesis of most autoimmune disorders remain obscure and a number of factors have been implicated in their pathogenesis, one of the most recent agents found to be associated with autoimmunity is vitamin 25(OH)D. The aim of the study was to assess total vitamin 25(OH)D status in patients with autoimmune thyroiditis with subclinical and overt hypothyroidism.
Methods and materials
70 patients (54 females and 16 males) and 20 apparently healthy individuals with matched age and sex were underwent a detailed clinical examination, thyroid function tests (TSH, fT_4, fT_3, thyroid peroxidase antibodies) and serum total vitamin 25(OH)D.
Results
The patient group with autoimmune thyroiditis was classified according to the level of TSH into subclinical and overt hypothyroid groups. Levels of serum TSH were significantly increased in subclinical (6.80 ± 1.84 μIU/ml) and hypothyroid (10.24 ± 2.09 μIU/ml) groups as compared to control group (2.16 ± 0.39 μIU/ml) ($P<0.05$). The thyroid peroxidase antibodies level was 312.83 ± 7.19 IU/ml in subclinical hypothyroid group and was 529.31 ± 9.62 IU/ml in the hypothyroid group. The levels of serum total 25(OH)D were significantly decreased in subclinical (18.8 ± 1.2 nmol/l) and overt hypothyroid groups (21.9 ± 1.1 nmol/l) as compared to control group (27.1 ± 1.2 nmol/l), ($P<0.05$). A highly significant negative correlation was found between serum TSH, thyroid peroxidase antibodies and total 25(OH)D levels ($P<0.001$). Also highly significant positive correlation was found between the levels of serum total 25(OH)D and serum fT_4 ($P<0.001$). There was significant positive correlation between TSH and thyroid peroxidase antibodies levels ($P<0.05$).

PTH 1–34 replacement therapy in post-surgical hypoparathyroidism: preliminary results from the 6-month follow up study

Antonella Franchi, Valentina Congedo, Doris Tina, Gianmarco Raggiunti, Giuseppe Fiore & Bruno Raggiunti
Endocrinology and Metabolic Desease Unit, Atri Hospital, Atri, Abruzzo, Italy.

Hypoparathyroidism is characterised by parathyroid hormone (PTH) levels inadequate to maintain plasma calcium concentration within the normal range. Even if the conventional treatment with calcium supplements and active vitamin D analogues is usually able to maintain normocalcemia, episodic low plasma calcium, neuromuscular complaints, renal disease and gastric discomfort are not infrequent. 29 patients with post-surgical hypoparathyroidism were started on PTH 1–34 therapy, because of persistent low plasma calcium, related to low calcium intake due to calcium intolerance and decreased quality of life (QoL). The still ongoing protocol includes periodic visits with biochemical exams,

quantitative ultrasound of calcaneus (QUS) and a questionnaire to assess QoL. We present the preliminary data on the 14 patients (12 females, mean age: 60.7 ± 9.29 years old), who have completed the 6-month follow up, reaching the 1-year visit in six cases. At the baseline, the mean plasma calcium was 7.68 ± 0.68 mg/dl (normal range: 8.6–10.2) and the mean 24-h urinary calcium was 218.71 ± 161.4 mg/dl (normal range: 100–300). PTH 1–34 was added at an initial dose of 0.5–0.7 μg/kg (~20–80 μg/die), twice a day. The PTH 1–34 and vitamin D analogues were titrated based on clinical and biochemical results, while the calcium supplements were progressively stopped in all patients. At the 6-month follow up, the mean plasma calcium was 8.84 ± 0.93 mg/dl (+15%) and the mean 24-h urinary calcium was 267.36 ± 98.3 mg/dl (+22%). The QoL had improved in all patients. The muscular pain, referred in three patients, was the most common complaint, causing a temporary discontinuation of PTH 1–34 only in one case. No serious adverse events were reported. These preliminary results have confirmed the efficacy and safety of PTH 1–34 in post-surgical hypoparathyroidism. The ongoing follow up will define the long-term effects of PTH 1–34-RT.

Vitamin D is essential for the musculoskeletal health, its effect being independent of age, menopause or PTH level: our study aims to find the threshold of 25OH-D, suggestive for osteoporosis

Dana Stoian[1], Mihaela Craciunescu[2], Marius Craina[1] & Bogdan Timar[3]
[1]Department of Obstetrics Gynecology, Victor Babes University of Medicine, Timisoara, Romania; [2]Department of Microbiology, Victor Babes University of Medicine, Timisoara, Romania; [3]Department of Medical Informatics, Victor Babes University, Timisoara, Romania.

We evaluated 341 postmenopausal women, aged 29–84 years (mean age 58.18 ± 9.01) and referred to the Center for Osteoporosis starting December 2013. Secondary causes of osteoporosis/bone loss and patients under antiosteoporotic medication or under vitamin D substitution were excluded from the study. All patients performed DXA measurement (Dexxum T, Osteosys, Inc., South Korea) (same expert). FRAX and 25 HO vitamin D levels were determined. We defined vitamin D deficiency as levels below 10 ng/ml and insufficiency as levels below 30 ng/ml. The mean 25 HO vitamin D value in the investigated group was 23.69 ± 11.40 ng/ml (4.1–71.3 ng/ml). Vitamin D insufficiency was present in 65.39% and deficiency in 9.38% of the cases. The level of deficiency/insufficiency increased with age, but was described even in young woman (below 40). When we analyzed the DXA results, the hip and spine density turned out to be lower in the presence of vitamin D insufficiency. Using the ROC curve and Youden index, we observed that a 25 HO vitamin D level lower than 21.80 ng/ml is highly predictive for lumbar and femoral neck demineralisation.

Conclusion

Evaluation of vitamin D status is important in the assessment of bone health in postmenopausal women, decreased levels of vitamin D being associated with increased prevalence of bone demineralisation.

Diabetes mellitus type 1

Alexander Shishkin & Victoria Manulenko
Saint Petersburg State University, Saint Petersburg, Russia.

Materials and methods

A survey was 95 people (45 people with diabetes mellitus type 1, 50 people with diabetes mellitus type 2). The age of examined patients 39.12 ± 3.8. The disease duration ranged from 6 to 20 years. Level of biochemical indicators – normal limits. Condition of mineral density of a bone tissue it was estimated by method of a dual-energy X-ray absorptiometry (DEXA). The analysis of DEXA researches showed that change of mineral density of a bone tissue at patients with diabetes of 1 type meets – 26 (57.7%), osteoporosis at 18 people (40%), osteopenia at eight people (17.7%); norm – at 19 patients (42.3%). DEXA analysis of studies in patients with type 2 diabetes showed that 21 (42.6%) patients occurs change in bone mineral density (in 8 (16%) patients – osteoporosis, 13 (26%) – diabetic osteopenia); the norm in 29 (58%). Our analysis showed that for patients with diabetes mellitus type 1 the most characteristic changes of DEXA parameters in three standard areas of study. While for patients with diabetes mellitus type 2 is characterized by changes in mineral density of bone tissue in two standard zones of the study. As well as that of patients with diabetes mellitus types 1 and 2 changes in mineral density of bone tissue previously only detected in the lumbar spine. In patients with diabetes mellitus types 1 and 2 was positive correlation between the duration of diabetes, diabetes compensation, the presence of diabetes complications and bone mineral density ($P < 0.05$).

Primary hyperparathyroidism with negative pre-operative imaging: a review of current and emerging localisation modalities

Zhi Guang Ng & Cherng Jye Seow
Tan Tock Seng Hospital, Singapore, Singapore.

Introduction

Primary hyperparathyroidism (PHPT) is usually caused by a single hyperfunctioning parathyroid adenoma. Preoperative localization studies allow for minimally invasive surgical removal. We present a case of PHPT caused by a solitary adenoma that could not be localised pre-operatively and review existing and emerging localisation modalities.

Case report

A 65-year-old Chinese lady admitted for neck of femur fracture was found to have hypercalcaemia of 2.82 mmol/l (RI: 2.15–2.58 mmol/l) and PTH level of 16.2 pmol/l (RI: 0.8–6.8 pmol/l). History was unremarkable for renal impairment, drug related causes or malignancy. Her calcium/creatinine clearance ratio of 2.12% was suggestive of PHPT. Ultrasonography did not localize any hypoechoeic ovoid structures but showed multiple thyroid nodules. Fine needle aspiration cytology (FNAC) of the thyroid nodules was negative for malignancy. Dual tracer parathyroid scintigraphy did not reveal any sestamibi-avid or enlarged parathyroid lesion. A total thyroidectomy and exploratory parathyroidectomy subsequently revealed a right parathyroid adenoma embedded within the thyroid tissue.

Discussion

PHPT is accounted for by a solitary adenoma in 85–90% of all cases. Preoperative localization techniques allows for minimally invasive surgery which reduces morbidity. Non-invasive modalities include ultrasonography, parathyroid scintigraphy, sestamibi-single photon emission computed tomography (SPECT), 4-dimensional CT, positron emission tomography and MRI, with scintigraphy being the most sensitive (scintigraphy 54–96%, 4D-CT 88%, SPECT 79%, ultrasonography 76%, MRI 43–71%). The sensitivity of scintigraphy is decreased in four-gland hyperplasia, double adenomas or concomitant thyroid disease. The results of scintigraphy can be enhanced by combination with SPECT or using dual tracer subtraction scans. Invasive techniques such as venous PTH sampling and selective arteriography are reserved for patients with recurrent or persistent hyperparathyroidism.

Conclusion

The pre-operative localisation of a solitary adenoma in PHPT remains a challenge despite new, emerging techniques.

Rapid and profound decrease in resorbtion markers preceded early and profound increase in BMD after successful surgery in osteitis fibrosa cystica

Daniel Grigorie[1,2], Andra Caragheorgheopol[1], Maria Iacob[1] & Alina Sucaliuc[1]
[1]National Institute of Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine, Bucharest, Romania.

Introduction

Successful parathyroid surgery in patients with OFC leads to early and marked improvements in BMD but data on very early changes in bone markers are missing.

Case report

A 20-year-old girl was hospitalised because of severe bone pains and multiple pathological fractures (left humerus and left proximal femur) after minimal trauma. She had lost weight, was amenorrhoeic for the last 12 months and was bleeding from brown tumours in her mouth. She was unable to walk and was

complaining for general fatigue, anorexia, polyuria and polydipsia. Skeletal X-rays revealed multiple osteolytic lesions throughout the entire skeleton, brown tumours in the mandible and OFC change of the left shoulder. Serum calcium and PTH were of 14.7 mg/dl and 1243 pg/ml, respectively; alkaline phosphatase activity was 1372 U/l. After hydration with i.v. sodium chloride, the patient was given i.v. pamidronate (60 mg) and serum Ca fell to 12.4 after 2 days. The patient underwent parathyroid surgery and a right superior parathyroid adenoma (2.2 g) was removed. She was treated with oral calcium carbonate (2.4 g daily) and cholecalciferol 2000 U/daily. A marked reduction in BMD at LS (0.594 g/cm), FN (0.530 g/cm) and total body (0.680 g/cm) was seen by DXA, with *T*-scores in the markedly osteoporotic range (-4.9 and -3.9 S.D., respectively). After 9 months there were increases of 23.7, 39.6 and 31.2%, respectively; after 2 years of 44.1% (LS) and 64% (FN). In three other similar cases (OFC on X-ray) serum CTX decreased after 1 month by three to six times, while OC increased in one patient by 1.2 times and decreased in the other two by 90 and 53%, respectively. After 1 year CTX and OC were normal in the two patients with available data.

Conclusion

The cases show an unexpected rapid and profound decrease in resorbtion just 1 month after surgery while formation decreased at a much slower pace, changes that preceded the marked increase in BMD, especially at the cortical sites.

Primary hyperparathyroidism in pregnancy: a case series

Naile Gokkaya[1], Adem Gungor[1], Arzu Bilen[2] & Habib Bilen[1]
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Faculty of Medicine, University of Ataturk, Erzurum, Turkey; [2]Department of Internal Medicine, Faculty of Medicine, University of Ataturk, Erzurum, Turkey.

Introduction

Primary hyperparathyroidism (PHP) in pregnancy is very rare condition and the true incidence of PHP in pregnancy is not well known. PHP is associated with significant maternal and foetal morbidity and mortality. PHP is diagnosed based upon levels of blood calcium and parathyroid hormone (PTH) in normal renal function status. However diagnosis of PTH can be difficult, the physiological changes of pregnancy in calcium homeostasis such as maternal blood volume expansion, hypoalbuminaemia and increased glomerular filtration rate contribute to the difficulty of PHP diagnosis during pregnancy.

Cases

We present four case reports about patients, having PHP in pregnancy. Three of patients, not to be controlled biochemically, denied the parathyroidectomy operation although they are informed about the details of their disease. They are followed up with medical therapy. The first one had no maternal or foetal complications, the second one acquired nephrolithiasis crisis in the last trimester and the third one gave a birth prematurely born baby who succumbed to tetany. The fourth patient who underwent parathyroidectomy operation in the second trimester had no maternal or foetal complications.

Conclusion

PHP in pregnancy is a preventable cause of foetal and maternal morbidity and mortality. Suspecting PHP during the pregnancy period and an early diagnosis can provide maternal and foetal well-being. During pregnancy, surgery should be avoided in the first and third trimester and conservative management should be preferred instead. Current evidence supports parathyroidectomy as the main treatment in the second trimester of pregnancy.

EP261

Comparative effectiveness of biphosphonates and parathyroidectomy in osteoporosis related to primary hyperparathyroidism

Jersy Jair Cardenas Salas, Beatriz Barquiel Alcala, Cristina Alvarez-Escola, Beatriz Lecumberri Santamaria, Beatriz Pelegrina Cortes, Luis Felipe Pallardo Sanchez & Antonio Torrijos Eslava
Hospital Universitario La Paz, Madrid, Madrid, Spain.

Introduction

The use of Bisphosphonates could be a treatment option of osteoporosis secondary to primary hyperparathyroidism (OPHP) in patients not eligible or that refuse/reject surgery.

Methods/design

We analysed data of 46 patients diagnosed of OPHP. Fourteen underwent surgery and 32 were treated with bisphosphonates at standard dose. Densitometric parameters and of calcium-phosphorus metabolism were analyzed before and after 1 and 2 years of treatment. The analysis was performed with SPSS-20.0.

Results

There were not differences in age, BMI, menopause age, years since menopause, alcohol consumption, diagnosis of previous low-trauma fracture, calcium intake, creatinine clearance, serum PTH, urinary calcium, serum alkaline phosphatase, urinary D-pyridinoline, vitamin D; neither in the mineral density (MD) of lumbar spine, femoral neck or total hip at baseline between groups. Smoking was more frequent and serum calcium lower in the bisphosphonate group (BG) ($P<0.05$). Serum calcium and PTH decreased after 1 and 2 years of treatment within surgery group (SG) ($P<0.01$) but remained stable in the BG. Urinary calcium decreased in the SG, urine D-pyridinoline decreased in the BG and Serum alkaline phosphatase decreased in both groups after 1 and 2 years. There were no differences between groups. The lumbar spine MD increased after 1 year (0.754 ± 0.121 vs 0.785 ± 0.132; $P<0.01$) and 2 years (0.754 ± 0.121 vs 0.791 ± 0.107; $P<0.01$) in the BG, and only after 2 years (0.749 ± 0.144 vs 0.794 ± 0.189; $P<0.05$) in the SG. Femoral neck MD increased after 1 year (0.622 ± 0.091 vs 0.640 ± 0.093; $P<0.01$) but remained stable after 2 years in the BG. It also remained stable in the SG and in total hip MD in both groups. No differences were found between groups in MD in any location.

Conclusions

Bisphosphonates treatment could be as effective as parathyroidectomy in the treatment of OPHP.

Investigating the bone metabolic parameters and serum 25-hydroxyvitamin D levels in male patients with asymptomatic hyperuricemia

Orsolya Ács[1], Emőke Csupor[2], Viktóra Ferencz[3], Szilvia Mészáros[3], Edit Tóth[4], Gábor Farkas[5] & Csaba Horváth[3]
[1]Semmelweis University School of PhD Studies, Budapest, Hungary; [2]The Health Service of Budavári Local Authorities, Budapest, Hungary; [3]1st Department of Medicine, Semmelweis University, Budapest, Hungary; [4]Department of Rheumatology, County Hospital Flór Ferenc, Kistarcsa, Hungary; [5]Centrum-Lab KFT, Budapest, Hungary.

Introduction

Over the past few years the clinical relevance of serum uric acid level has changed. The elevated serum uric acid level not only impairs the joints and the kidney function but it is also linked with an increased risk of cardivascular diseases. The aim of our study was to examine how bones are affected (change of bone mineral density (BMD), bone metabolism parameters, serum 25-hydroxy-vitamin D levels and frequency of fractures) by elevated serum uric acid level.

Materials and methods

We investigated a total of 136 patients divided into two groups according to serum uric acid level: 68 male patients with (age: 54.9 ± 1.6 years) and 68 male patients without (age: 55.2 ± 1.9 years) hyperuricemia. In all cases hyperuricemia (se level >428 μmol/l) was asymptomatic. BMD was measured by dual-energy X-ray absorptiometry (DEXA), for bone markers such as: parathyroid hormone (PTH), β-CrossLaps, 25-(OH) vitamin D3 and osteocalcin (OC) electrochemi-luminescence immunoassay was used and routine labor parameters were measured. Medical history including prevalence of bone fractures was also recorded. Statistical analysis was performed by ANOVA, with *post-hoc* Bonferroni correction (Satistica software 9.0).

Results

In patients with asymptomatic hyperuricemia lumbar spine (L2-4) BMD (*T*-score: -2.53 ± 0.20 vs -1.91 ± 0.20, $P<0.05$) and left femoral neck BMD (*T*-sc: -2.45 ± 0.16 vs -1.98 ± 0.15, $P<0.05$) were lower than in patients without hyperuricemia. Serum 25-(OH) vitamin D3 levels were also lower in the hyperuricemic group (48.4 ± 15.1 nmol/l vs 55.86 ± 16.7 nmol/l, $P<0.05$). Bone fracture had occurred in 17 of 68 hyperuricemic patients, while in the non-hyperuricemic group only seven fractures were recorded.

Conclusion

The in-time recognition and treatment of elevated serum uric acid level could positively influence the bone metabolism and be part of fracture prevention.

Clinical outcome of patients with parathyroid gland carcinoma – single centre experience

Maja Baretic[1], Margareta Dobrenic[2], Drago Prgomet[3] & Ivana Pavlic-Renar[1]
[1]Internal Clinic, Department of Endocrinology, University Hospital Centre Zagreb, Zagreb, Croatia; [2]Clinical Department of Nuclear Medicine and Radiation Protection, University Hospital Centre Zagreb, Zagreb, Croatia; [3]Department of Ear, Nose and Throat, Head and Neck Surgery, University Hospital Centre Zagreb, Zagreb, Croatia.

Aim
To determine clinical predictors of parathyroid gland carcinoma recurrence.
Methods
We evaluated outcome of eight patients with primary hyperparathyroidism due to parathyroid carcinoma who were followed at University Hospital Centre Zagreb in period from 2004 to 2014. The median follow-up was 6 (range 2–14.5) years. Six patients (three male, three female; median age 57.5 (42–71) years) experienced long-term remission after the surgery whereas two patients had unfavourable course of the disease. In patients with remission hypercalcaemia was known in median for 4 (1–16) years before the surgery. At the time of diagnosis median PTH was 48 (24–147) pmol/l (normal value 0.2–6.7 pmol/l). All of them had renal impairment, hypertension and osteoporosis with two of them previous fractures. Following surgery hypocalcaemia rapidly developed requiring intravenous calcium replacement and prolonged hospital stay. Two female patients (age at diagnosis 31 and 32 years) had poor disease outcome. Their initial diagnosis was established on the basis of acute complication of hypercalcaemia; one of them was pregnant and her newborn had severe neonatal hypocalcaemia whereas another patient had episode of acute pancreatitis. Formerly they had no recognized comorbidities related to hypercalcaemia with the exception of osteoporosis without fractures. Their PTH values were 72 and 36 pmol/l and serum calcium concentrations 4.03 and 3.8 mmol/l respectively. Following surgery there were no clinical manifestations of hypocalcaemia and no need for intravenous calcium supplementation. Within 1 year hypercalcaemia reoccurred and metastatic disease was confirmed. In both patients multiple endocrine neoplasia was excluded and chromogranin was repeatedly negative.
Conclusion
Younger age, lack of chronic consequences of hypercalcaemia and hyperparathyroidism, no signs of sever symptomatic hypocalcaemia following surgery and no need for postoperative calcium supplementation could be clinical predictors of parathyroid gland carcinoma recurrence.

Measuring BMD at forearm aids in diagnosing osteoporosis and identifies more patients for surgery in asymptomatic primary hyperparathyroidism

Laura Gianotti, Elena Castellano, Francesco Tassone, Micaela Pellegrino, Michela Ghio, Anna Racca & Giorgio Borretta
Division Endocrinology, Diabetology and Metabolism, Department Internal Medicine, S. Croce & Carle Hospital, Cuneo, Italy.

Introduction
Reduction in bone mineral density (BMD) is a common feature in primary hyperparathyroidism (PHPT), involving mostly cortical site. In the management of asymptomatic PHPT (aPHPT), guidelines indicate measuring BMD at lumbar spine, hip and forearm and surgery is recommended for patients with a *T*-score of −2.5 or less at one of these sites. However, BMD at forearm is not always performed.
Aim
Our aim was to evaluate the impact of measuring forearm BMD in the clinical and therapeutical management of aPHPT.
Subjects and methods
We retrospectively reviewed a prospective database of 116 patients with aPHPT at our institution between 1998 and 2013. The study cohort was identified by examining those patients who at the time of diagnosis had a dual X-ray absorptiometry (DXA) scan at all three sites. In all patients we measured PTH, total serum and ionized calcium, urinary calcium excretion, vitamin D and creatinine levels.
Results
Out of 116 patients with aPHPT we identified 13 (group A, 11.2%) who had a *T* score lower than −2.5 at forearm only, of which 6 (5.2%) possessed the criteria for surgery identified on the basis of forearm BMD only. Group B were the remaining 103 patients. Group A was older than group B (71±7.6 vs 62.7±11.8 years, $P<0.016$) while no significant difference was found in the biochemical measurements or in the BMD values at either of the other sites.
Conclusions
In our series of aPHPT, in 11.2% of patients, DXA on three sites revealed osteoporosis at forearm, but not at other sites. Among these patients, half were identified for surgery based on BMD at forearm. Except for age, these patients did not show any clinical, biochemical or BMD difference from the remaining patients. Preoperative forearm DXA increases the number of patients who meet the criteria for surgery based on BMD alone.

EP265

Severe refractory hypocalcaemia associated with osteoblastic metastatic breast carcinoma

Vikram Lal, Simon Ashwell, Alison Humphreys & Sath Nag
James Cook University Hospital, Middlesbrough, UK.

Introduction
Hypercalcaemia is well associated with metastatic malignancy. Hypocalcaemia is an uncommon complication of osteoblastic metastases and occurs most commonly with breast and prostate carcinoma.
Case
A 46-year-old woman with metastatic breast carcinoma and osteoblastic skeletal metastases treated with denosumab presented with severe symptomatic hypocalcaemia. Serum calcium was persistently low with a nadir value of 1.45 mmol/l (2.2–2.6) and predated the use of denosumab. 25OH-cholecalciferol level was low (24.1 nmol/l). Serum PTH was inappropriately normal at 4.3 (1.3–7.3) for the prevailing level of hypocalcaemia suggesting hypoparathyroidism. Renal function and magnesium were normal.
Management
Treatment with intravenous calcium gluconate was instituted during symptomatic episodes. Vitamin D deficiency was managed with high dose choleclaciferol (20 000 IU, three times a week for 12 weeks) and oral calcium equivalent to 6 g of elemental calcium was commenced. Symptomatic hypocalcaemia persisted despite progressively increasing doses of elemental calcium (final dose 9 g). In view of persistent hypocalcaemia, treatment with Bendroflumethiazide 2.5 mg/day and Alfacalcidol 1 μg/day was instituted. The dose of Alfacalcidol was incrementally increased to 8 μg/day. Normocalcaemia was achieved in 16 weeks.
Discussion
Hypocalcaemia is an uncommon complication of malignancy and is caused by osteoblastic bone metastases. The putative mechanism is increased uptake of calcium by osteoblastic lesions. Hypocalcaemia in our patient was exacerbated by denosumab therapy and vitamin D deficiency. However, hypoparathyroidism in the context of severe hypocalcaemia was suggestive of impaired parathyroid reserve presumed secondary to microscopic malignant infiltration of the parathyroid glands.
Conclusion
Malignancy-related hypocalcaemia occurs almost exclusively with osteoblastic bone metastases and is generally associated with secondary hyperparathyroidism. Our case highlights the fact that microscopic malignant infiltration of the parathyroid glands can occur with advanced malignancy and result in severe refractory hypocalcaemia. Supraphysiological doses of elemental calcium and vitamin D are generally required to induce and maintain normocalcaemia.

EP266

Osteoporotic fracture risk in menopausal women with obesity

Snjezana Popovic-Pejicic[1] & Vera Aksentic[2]
[1]Medical Faculty, Clinical Center Banja Luka, University Hospital, University of Banja Luka, Banja Luka, Republic of Srpska, Bosnia and Herzegovina; [2]Institute for Physical Theraphy and Rehabilitation, Banja Luka, Republic of Srpska, Bosnia and Herzegovina.

Introduction
Osteoporosis is a metabolic disease that is characterised by low mineral bone density (BMD) and increased risk of fractures. Weight loss reduced BMD and increased risk of hip fractures, while it reduces in a weight gain. Osteoporosis

fracture risk and BMI correlate more frequently denied in recent studies. The aim of this study was to examine relationship between BMI and BMD in a group of postmenopausal women.
Design
The study involved 100 postmenopusal women, aged 46 to 70 years (59.08 ± 6.07). BMD was determined by DXA method (dual energy X-ray absorptiometry) by Lunar Prodigy Advance Unit. BMD was measured at lumbal spine and both hips. BMI values were correlated with total *T* score values of the lumbal spine and both hips, as well as total *T* score values of spine and hip.
Results have shown that BMI was normal in 18% subjects, 1st grade obesity was found in 52%, 2nd grade obesity in 23%, 3rd grade obesity in 7% of subjects. Median BMI value was found in 28.27 ± 4.12. Median lumbal spine *T* score was −2.19 S.D. ± 1.25 , and hip *T* score −1.11 S.D ± 0.95. A statistically significant positive correlation was found between BMI and BMD of hip ($r=0.01$), whereas between BMI and BMD of lumbal spine there was no. There was, statistically significant correlation ($r=0.01$) between BMD values of lumbal spine and hip.
Conclusion
In postmenopausal women BMI is more important predictor of hip BMD, as compared to spine BMD. BMD of hip is increased with increase of BMI in postmenopausal women, what indicates that incidence of fracture of the hip decrease in women with obesity. A lack of correlation between BMI and BMD of spine might be due to predominant effect of lack of oestrogen and faster bone metabolism in spinal region.

Evaluation of the effect of bisphosphonate therapy of postmenopausal osteoporosis using Dolga index

Jovanka Novakovic-Paro[1], Tijana Icin[1], Dragana Tomic-Naglic[1], Milena Mitrovic[1], Radoslav Pejin[1], Milan Dolga[3], Ivana Bajkin[1], Bojan Vukovic[2], Damir Benc[1], Djordje Popovic[1], Andrijana Milankov[1], Milica Medić-Stojanoska[1] & Branka Kovačev-Zavisic[1]
[1]Medical Faculty, Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Vojvodina, University of Novi Sad, Novi Sad, Serbia; [2]Medical Faculty, Emergency Center, Clinical Centre of Vojvodina, University of Novi Sad, Novi Sad, Serbia; [3]Smart Line Agency, Novi Sad, Serbia.

Introduction
Bisphosphonates are commonly used in the treatment of osteoporosis. The aim was to determine the effect of bisphosphonate therapy for osteoporosis on bone mineral density (BMD) depending on the Dolga index.
Materials and methods
The study included 36 postmenopausal women with osteoporosis. BMD was measured by DXA of the spine and hip before treatment and 2 years after starting bisphosphonate therapy. Parameters of bone turnover: osteocalcin and beta crosslaps were measured before treatment. On the basis of these values was calculated Dolga index. The Dolga index expresses excessive suppression of bone resorption and excessive suppression of the entire remodelling if the value obtained above 0.
Results
Average age of the respondents was 62.94 ± 8.49 years, with a mean BMI 25.60 ± 3.68 kg/m^2. After 2 years of therapy, a statistically significant difference in the parameters of bone remodelling and BMD (OC: 37.05 ± 14.36 vs 17.95 ± 5.62 ng/ml, $P<0.05$; beta crosslaps: 658.37 ± 264.57 vs 173.0 ± 96.92 pg/ml, $P<0.05$; L1–4 BMD: 0.813 ± 0.010 vs 0.862 ± 0.132 g/cm^2, total hip: 0.793 ± 0.08 vs 0.826 ± 0 07 g/cm^2; hip neck: 0.764 ± 0.08 vs 0.07 ± 0.788 g/cm^2. Using Dolga index, statistically significant improvement in spine and hip BMD were obtained in the group that did not have excessive suppression of bone resorption and bone remodelling. (L1–4: 0.803 ± 0.007 vs 0.842 ± 0.009 g/cm^2, $P<0.05$; total hip: 0.792 ± 0.007 vs 0.825 ± 0.008 g/m^2, $P<0.05$; hip neck: 0.780 ± 0.005 vs 0.802 ± 0.006 g/cm^2, $P<0.05$).
Conclusions
The use of bisphosphonate therapy leads to improvements in BMD with primary effect on bone resorption affecting the overall bone remodelling. The test results demonstrate the usefulness of the application of Dolga index in choosing patients with postmenopausal osteoporosis for the application of bisphosphonate therapy in order to achieve the best therapeutic effect. Continued research is ongoing on a larger sample in order to confirm the results, make new conclusions and recommendations for the treatment of postmenopausal osteoporosis bisphosphonate therapy.

Patients with new onset diabetes after liver transplantation have higher sclerostin levels that tend to decrease after an oral glucose tolerance test

Guillermo Martínez Díaz-Guerra[1], Gonzalo Allo Miguel[1], Mercedes Aramendi Ramos[2], Soledad Librizzi[1], Sonsoles Guadalix Iglesias[1], Elena García Fernández[1] & Federico Hawkins Carranza[1]
[1]Endocrinology Service, 12 de Octubre University Hospital, Madrid, Spain; [2]Laboratory Service, 12 de Octubre University Hospital, Madrid, Spain.

Introduction
Decreased bone formation has been proposed as a mechanism involved in the higher risk of fractures in diabetic patients. Some clinical studies have found that sclerostin (SCL, a negative regulator of bone formation) is increased in diabetic patients. However, there is no information about the relationship between SCL and new onset diabetes after transplantation (NODAT). The aim of our study is to evaluate serum SCL levels in a cohort of patients with liver transplantation (LT).
Patients and methods
85 LT patients without previous diabetes mellitus were enrolled. A 75 g oral glucose tolerance test was performed (OGTT) and diagnostic ADA criteria were followed. Serum SCL was measured in fasting, 60- and 120-min samples during OGTT. MANOVA test were used to evaluate the evolution of sclerostin levels (from baseline to 120-min).
Results
48 patients (64%) showed normal glucose tolerance (NGT), 31 (36.4%) impaired glucose tolerance (IGT) and six NODAT (7.05%). Results of SCL for OTTG were (ng/ml; baseline, 60′, 120′): i) NGT: 0.70 ± 0.27/0.65 ± 0.22/0.69 ± 0.23 ng/ml; ii) IGT: 0.83 ± 0.31/0.71 ± 0.20/0.75 ± 0.20 ng/ml; iii) NODAT: 1.75 ± 1.20/1.55 ± 1.24/1.46 ± 1.1 ng/ml. SCL levels were significantly higher in NODAT patients at baseline ($P<0.001$); 60′ ($P<0.001$) and 120′ ($P=0.001$). During OGTT, sclerostin showed a significant decrease ($P=0.01$), which was more pronounced in the NODAT group, with a percent of change of: −0.32 ± 0.64.
Conclusions
Our results show that after LT basal SCL levels are higher in patients with NODAT than in patients with prediabetes or NGT. Also, we have found that during an OGTT sclerostin significantly decrease, particularly in NODAT patients. Based on our results, we suggest further studies to investigate a plausible link between higher levels of sclerostin in NODAT patients and their increased fracture risk.

X-linked hypoparathyroidism: an Indian kindred!

Ravindra Shukla, Asish Basu & Animesh Maity
Medical College Kolkata, Kolkata, West Bengal, India.

Introduction
X-linked hypoparathyroidism is an extremely rare disease, so far described in only two multigenerational kindreds. In US, who later on the genetic testing were found to be interrelated. W describe X-linked congenital hypoparathyroidism in a family from India.
Case report
Case 1 presented with hypocalcaemic non-febrile generalised tonic clonic seizures at 16 months of age. Seizures controlled after hypocalcaemia correction. He was put on T. calcitriol 0.5 mg B.D, 1.5 g calcium/day. Case 2 presented with hypocalcaemic neonatal generalised tonic clonic seizure. He was put on calcitriol 0.5 mg/day, 1 g of calcium. Both had delayed milestones and growth, developed

Table 1

Case	S.calcium at diagnosis (mg/dl)	S.phosphorus at diagnosis (mmol/l)	Vit. D at diagnosis	iPTH at diagnosis	S.calcium at present (mEq/l)	S.phosphorus at present (mEq/l)	iPTH at present	Average 24 hr urinary calcium in last 6 years
19-year male	1.05	10.61	16	<1	8.4	6.1	5.2	340
14-year male	2.3	9.4	12	<1	9	5.3	3.9	290
19-year old sister	9.6	4						
22-year old sister	9.4	4.3						
Father	9.8	3.9						
Mother	8.6	4.8						

B/L cataract and B/L basal ganglia calcification, required addition of phenobabitone at 10–12 year of age. Parents and two sisters are asymptomatic. History of death of a male child at age of 2 years on maternal sides (Table 1).
Conclusion
This is first report of X-linked hypoparathyroidism outside the Missouri kindred. The two brothers exibit strikingly similar phenotype. In addition we also describe abnormalities of dentition and cataract in presence of seemingly adequate calcitriol and calcium replacement. Genetic analysis of such family could throw insight into as yet known aspects of parathyroid gland development and disease.

A case of a mitochondrial myopathy with multiple endocrinopathy

Mina Gulfem Kaya[1], Sefika Burcak Polat[1], Sebnem Eker Guvenc[2], Sahin Doganay[3], Reyhan Ersoy[3] & Bekir Cakir[3]
[1]Department of Endocrinology and Metabolism, Atatürk Education and Research Hospital, Ankara, Turkey; [2]Department of Family Medicine, Atatürk Education and Research Hospital, Ankara, Turkey; [3]Department of Endocrinology and Metabolism, Faculty of Medicine, Yildirim Beyazit University, Ankara, Turkey.

Introduction
Mitochondrial diseases usually occur by mutations of mitochondrial or nuclear DNA. Mitochondrial cytopathy is a disease affecting many systems including endocrine system. We present a case diagnosed as mitochondrial myopathy previously accompanying multiple endocrinological pathologies.
Case
Fifty-two years old female patient admitted in another center with a complaint of drooping of upper eyelids 25 years ago. Acetylcholine receptor antibodies were negative and her EMG was compatible with progressive external ophthalmoplegia. She was diagnosed as mitochondrial myopathy by left biceps muscle biopsy. Coenzym Q 10 and L-carnitine treatments were started. She admitted to our center with numbness and spasm in her hands. Serum calcium was 6.1 mg/dl, phoshorus was 6.9 mg/dl, magnesium was 1.5 mg/dl and parathyroid hormone level was 8.9 pg/ml. There were common symmetric calcifications at basal ganglions, bilateral cerebellar hemispheres, thalamus and periventricular white matter in cranial CT. EEG was normal. Creatine kinase was 507 U/l, LDH was 435 U/l and plasma lactate level was 2.4 mmol/l. Calcium carbonate and calcitriol were administered to the patient with diagnosis of hypoparathyroidism. Thyroid autoantibodies were positive. Thyroid hormone levels were normal. Thyroid ultrasound was compatible with chronic thyroiditis. In eye examination bilateral ptosis and cataract were detected. Retina examination was normal. Her audiometry was normal. She was diagnosed as type 2 DM.
Conclusion
Mitochondrial myopathies can be together with various endocrinological problems. Our patient had adult onset pure mitochondrial cytopathy and primary hypoparathyroidism, chronic autoimmune thyroiditis and type 2 DM were accompying endocrinological pathologies. Associations with hypoparathyroidism, autoimmune thyroiditis, DM and GH deficiency have been reported in patients with Kearns Sayre syndrome in the literature. Also mitochondrial myopathy, encephalopathy, lactic acidosis, stroke (MELAS) and adrenal insufficiency's association was reported. Because of probability of affecting multisystem, cases with mitochondrial myopathies should be evaluated for various endocrinological pathologies.

Vitamin D receptor genotypes and their association with the 5-year changes in bone mineral density in Spanish postmenopausal women

Jose M Moran, Maria Pedrera-Canal, Jesus M Lavado-Garcia, Raul Roncero-Martin, Purificacion Rey-Sanchez, Julian F Calderon-Garcia & Juan D Pedrera-Zamorano
Metabolic Bone Diseases Research Group, University of Extremadura, Caceres, Spain.

Our aims were to follow the longitudinal changes after 5-year in femoral neck (FN), femoral trochanter (FT), L2, L3, L4 and L2–L4 bone mineral density (BMD) in Spanish postmenopausal women and to study whether the polymorphism BsmI in the vitamin D receptor (VDR) may influence these results. We conducted a 5-year prospective study of BMD and its change in 174 women, aged 43–78 years. BMD was measured by densitometry. The women were members of the Caceres Reference Database for the Diagnosis of Osteoporosis (CAFOR), a population-based longitudinal study of BMD. Changes were analysed by Wilcoxon test. We also examined the effect of adjustments for dietary and anthropometric factors on these associations. After the 5-year period significant changes were observed in L3, L4, L2–L4, FN and FT ($P<0.001$ in all cases). No significant changes were observed in L2 ($P=0.598$). Before adjustments, in women homozygous for the b allele (genotype (bb) $n=25$) no significant changes were observed ($P>0.05$ in all cases). Women heterozygous (genotype (Bb) $n=73$) had less FT BMD ($P<0.001$), L4 ($P<0.001$) and L2–L4 ($P=0.010$) over time; no changes were observed over the 5-year period in Bb women in FN, L2 and L3 BMD. In women homozygous for the B allele ($n=76$) significant loss in BMD was observed in FN ($P=0.010$) and FT ($P<0.001$) BMD as well as in L4 ($P<0.001$) and L2–L4 ($P=0.012$) BMD after the 5-year period. No changes were observed in L2 and L3 BMD ($P>0.05$ in both cases). Upon adjustment for dietary and anthropometric factors no further statistically significant associations to BsmI polymorphism were found.
Our results reveal that to correctly address the association between bone loss and VDR polymorphism BsmI in small samples, it is necessary to consider the variations in dietary and anthropometric factors.

Cinacalcet remains effective in primary hyperparathyroidism after 4 years of treatment

Inés Luque-Fernández, Florentino Del Vall, Alessandra Luque, Almudena Vicente, Julia Sastre & Amparo Marco
Hospital Virgen de la Salud, Toledo, Spain.

Introduction
Cinacalcet is an oral calcimimetic indicated in treatment of primary hyperparathyroidism in patients who are unable to undergo parathyroidectomy: do not accept surgery, there is failure of previous surgery or serious comorbidity that makes surgery impossible.
Methods
Descriptive study that includes nine patients with primary hyperparathyroidism who have completed at least 48 months of treatment with cinacalcet (seven patients refusal to parathyroidectomy and two surgery not possible due to comorbidities). We recorded clinical and biochemical data at baseline and after 3, 6, 12, 24 and 48 months of treatment.
Results
Median time of treatment was 49 months. After 12 months serum calcium was significantly decreased as compared to baseline (10.12 vs 11.59 mg/dl $P=0.008$) and phosphorus levels were significantly increased (2.84 vs 2.45 mg/dl $P=0.021$). No significant differences were observed in PTH levels (155.45 vs 136.9 pg/ml $P=0.6$). No further variation was observed after 24 and 48 months compared to 12 months follow up except for an increase in PTH to baseline levels. As compared to baseline, after 4 years of therapy, serum calcium remained significantly decreased (10.13 vs 11.59 mg/dl $P=0.008$) and serum phosphorus significantly increased (2.93 vs 2.45 mg/dl $P=0.02$). Normocalcemia (S-Ca <10.2 mg/dl) was achieved in 55.7% of patients. Usually the medication was well-tolerated and no serious adverse events were observed.
Conclusion
Hypercalcemia is rapidly improved by Cinacalcet and remains stable after 48 months follow-up. Cinacalcet is an effective and safe alternative in non-surgical treatment of primary hyperparathyroidism.

DOI: 10.1530/endoabs.37.EP272

Bone mineral density evolution after parathyroidectomy in patients with primary hyperparathyroidism

Alicia Vicuña, Ana Ramos-Leví, Miguel Sampedro-Nuñez, Sandra Campos, Magaly Zelada & Mónica Marazuela
Department of Endocrinology and Nutrition, Hospital Universitario de la Princesa, Madrid, Spain.

Introduction
Primary hyperparathyroidism results in increased bone resorption. The presence of osteoporosis is at present an established surgery criteria.

Objective
The aim of this study was to evaluate the changes in bone mineral density (BMD) after surgery in patients with primary hyperparathyroidism.
Material and methods
Retrospective study of 58 patients with primary hyperparathyroidism treated by parathyroidectomy from 2004 to 2012. We analysed the percent change in BMD of spine, hip and radio densitometry 12 and 36 months after surgery.
Results
Among the 58 patients enrolled, we obtained densitometry data of 26 patients after 12 months and 37 after 36 months. The average age of the patients was 61 ± 12 years and 70.7% were women. We observed an increased BMD at lumbar spine and hip 1 year after surgery (+2.3% ± 5.1, $P=0.027$; +5.7% ± 6.3, $P=0.000$, respectively). Improvement at 36 months was also observed in both locations (+4.9% ± 7.4, $P=0.001$; +8.5% ± 6.0, $P=0.000$). In radio, there were no changes in BMD in any of the follow-up times, although a slight increase at 36 months (+0.96% ± 4.2, $P=0.576$) was observed. Sixteen of the 58 patients (27.6%) also were treated with bisphosphonates. There were no differences in changes of BMD between these patients and those who did not received bisphosphonates.
Conclusion
Hip and spine BMD improved 1 and 2 years after surgery in patient's whit primary hyperparathyroidism. It would be interesting to evaluate the response to longer term.

Effect of the inhibition of a cholesterol membrane transporter on vitamin D absorption: a double-blind randomised placebo-controlled study

Mariana Costa Silva[1], Gustavo A M Faulhauber[1,2], Érica N Leite[2], Kamila R Goulart[2], Jorge M A Ramirez[2], Fernanda M Cocolichio[2] & Tania W Furlanetto[1,2]
[1]Postgraduation Program in Medicine: Medical Sciences, Federal University of Rio Grande do Sul, Porto Alegre, RS, Brazil; [2]Internal Medicine Division, Hospital de Clinicas de Porto Alegre, Porto Alegre, RS, Brazil.

Introduction
Oral supplements are important to prevent and treat vitamin D deficiency. Membrane transporters could be involved in its absorption. As vitamin D is structurally similar to cholesterol, it is possible that they share absorption mechanisms. Ezetimibe decreases cholesterol absorption, through inhibition of NPC1L1 transporter. It has been shown *in vitro* and in rodents that ezetimibe decreases vitamin D absorption, so the aim of this study was to evaluate the effect of ezetimibe on 25-hydroxyvitamin D [25(OH)D] levels in response to a single oral dose of vitamin D, in young persons.
Methods
This randomised, double-blind, placebo-controlled trial (ClinicalTrials.gov NCT02234544) was developed in a South Brazilian University Hospital. Fifty-one medical students were randomised to ezetimibe 10 mg/day or placebo for 5 days. On the 5th and 19th days, blood samples for 25(OH)D, PTH, calcium, and albumin were collected after overnight fast. On the 5th day, all participants received a single oral 50 000 IU cholecalciferol dose during a 15 g fat meal. 25(OH)D was measured by the immunoassay Diasorin Liaison. Measurements were compared in a general linear model adjusted for multiple comparisons by the Bonferroni test.
Results
At baseline, 25(OH)D was <30 and <20 ng/ml, respectively, in all and 82.3% of the participants. Fourteen days after a single 50 000 IU oral dose of cholecalciferol, the mean (S.D.) change in 25(OH)D was of 8.75 (3.74) ng/ml in the ezetimibe group, vs 10.02 (3.84) ng/ml in the placebo group, after adjustment to baseline 25(OH)D levels and BMI ($P=0.26$). Mean 25(OH)D, PTH, calcium and albumin remained similar in both groups.
Conclusions
Ezetimibe had no effect on the mean change in serum 25(OH)D after a single oral dose of cholecalciferol.

Acquired FGF23 resistance: the primacy of parathyroid hormone over fibroblast growth factor 23 in renal phosphorus handling

Malachi McKenna[1,2], Sinead Kinsella[1], Michelle Morrin[1], Melissa Sloman[3], Ahad Abdalla[1], Myra O'Keane[1], Barbara Murray[1], John Holian[1,2], Alan Watson[1,2] & Mark Kilbane[1]
[1]St Vincent's University Hospital, Dublin, Ireland; [2]University College Dublin, Dublin, Ireland; [3]Royal Devon and Exeter NHS Foundation Trust, Exeter, UK.

Introduction
Fibroblast growth factor 23 (FGF23) excess is the cause of chronic hypophosphatemia in rare conditions such as X-linked hypophosphataemic rickets (XLHR) and tumour-induced osteomalacia (TIO), but animal studies indicate that the effect of FGF23 on serum phosphorus is dependent on the presence of parathyroid hormone (PTH). In this case series of rare disorders with abnormalities in renal phosphorus handling, we sought to explore the relative roles of PTH and FGF23 on renal handling of phosphorus.
Methods
We studied 16 patients with congenital hypophosphatemia (of whom two were hypoparathyroid post total parathyroidectomy), two patients with TIO, one patient with hypophosphataemic bone disease due to congenital renal tubular acidosis, and three patients with hypoparathyroidism (HP). We performed genetic mutation analysis, and we measured FGF23, PTH, renal phosphorus threshold (TmP/GFR), ionised calcium, 25-hydroxyvitamin D (25OHD), and a panel of bone turnover markers (BTMs). We also studied 30 patients with chronic kidney disease (CKD) who had estimated glomerular filtration (eGFR) stages 3–5.
Results
Patients with congenital hypophosphatemia and TIO had low TmP/GFR and varying degrees of FGF23 excess. The patient with hypophosphatemia and renal tubular acidosis had the lowest FGF23 and the three patients with HP had low PTH, elevated FGF23, but high TmP/GFR. The two patients with congenital hypophosphatemia and hypoparathyroidism had normal TmP/GFR despite having marked elevation in both C-terminal and intact FGF23. Both patients had CKD, but FGF23 was still about tenfold higher than expected for level of eGFR.
Conclusions
While FGF23 is a determinant of TmP/GFR in congenital and acquired disorders of dysregulated FGF23 production, the full effect of FGF23 on TmP/GFR is dependent on PTH secretion. FGF23 resistance is extant when PTH is absent.

Lower levels of vitamin D as a predictor of reduced muscle strength in moderately obese postmenopausal women

Miljanka Vuksanovic[1], Branka Arsenovic[1], Milica Marjanovic Petkovic[2], Andjela Gavrilovic[3] & Teodora Beljic Zivkovic[1,4]
[1]Division of Endocrinology, Diabetes and Metabolism, Section of Osteoporosis and Bone Densitometry, Zvezdara University Hospital, Belgrade, Serbia; [2]Division of Endocrinology, Diabetes and Metabolism, Zvezdara University Hospital, Belgrade, Serbia; [3]Division of Neurology, Zvezdara University Hospital, Belgrade, Serbia; [4]Belgrade University School of Medicine, Belgrade, Serbia.

Introduction
Low concentration of serum 25-hydroxyvitamin D (25-OHvitD) have been associated with low bone loss and risk of falls in postmenopausal women. Moderate obesity is not a risk factor for osteoporosis.
Aim
The aim of this study was to investigate how vitamin D concentration correlates with muscle strength and bone density in moderately obese postmenopausal women.
Methods
We include 33 postmenopausal women, between 50 and 60 years of age, coming for the first measure of dual-energy X-ray absorptiometry (DXA). The assessed parameters were: BMI, waist circumference (WC), 25-OHvitD, bone mineral density (BMD) measured by DXA and muscle strength. Muscle strength was measured as hand grip strength (HGS) with JAMAR Hand Dynamometer. Three measures on the right or left hand were averaged to get the absolute HGS and compared to the normative data for this aged group (47.3–57.3 pounds). *T*-test for

continuous variables and Spearman test for correlations between variables were used.
Results
The postmenopausal women were 56.4±2.8 years old, menopausal duration 6.5±2.7 years, with BMI 28.01±3.4 kg/m^2 and WC 89.0±8.1 cm. The mean level of 25-OHvitD was 32.5±13.9 nmol/l. A significant negative correlation was observed between 25-OHvitD levels and both WC ($\rho_{wc}=-0.65$; $P<0.001$) and BMI ($\rho_{bmi}=-0.49$; $P<0.003$). The average HGS of these moderately obese participants was 28.3±4.2 pounds. It was significantly lower than the normative grip strength for referent range group ($t=-21.65$; $P<0.001$). A significant positive correlation was observed between 25-OHvitD levels and HGS ($\rho_{hgs}=0.45$; $P<0.009$). Average BMD on lumbar spine was 0.862 and 0.668 g/cm^2 on total hip. There was a very weak correlation between serum 25-OHvitD and BMD at lumbar spine ($\rho=0.167$; $P=0.35$) and hip ($\rho=0.228$; $P=0.20$).
Conclusion
Decreased levels of 25-OHvitD in moderately obese postmenopausal women are associated with low muscular strength. Decreased muscular strength may increase the risk of falls and fracture in moderately obese postmenopausal women.

Evaluation of calcium and vitamin D disorders: case report of two patients

Andreja Maric
County Hospital Cakovec, Cakovec, Croatia.

Introduction
Differential diagnosis of hypocalcaemia is extensive, and careful diagnostic algorithm should be performed to adequately treat hypocalcaemic disorders.
Case report
Two female patients with hypocalcaemia are presented. The first one was 49 years old, admitted to hospital due to weakness, hampered mobility and bone pain (hips, thorax). Six years ago she was hospitalized due to chronic renal failure, osteoporosis, fractures of hip neck and both pubic bones, but did not take any medication. Current diagnostic procedures revealed several rib fractures (X-ray), and laboratory tests showed: iron deficiency, urea and creatinine increased, high alkaline phosphatase (297 U/l), low total serum (1.8 mmol/l) and ionizing calcium (0.56 mmol/l), low urinary calcium, low serum phosphate, low vitamin D (34 nmol/l) and vitamin B12 values, and high PTH (44.3 pmol/l) and bone markers. Densitometry (DXA) showed characteristics for severe osteoporosis. The diagnosis of osteomalacia was made, and therapy with calcitriol (2× 0.25 μg/day), calcium ($CaCO_3$ 3×1 g), vitamin B12 and folate was introduced, with significant clinical improvement. Other patient was 39 years old, admitted due to chronic bone pain and suspected bone metastases on scintigraphy. Medical history revealed cerebral palsy, epilepsy and chronic gastritis. Diagnostic evaluation did not confirmed malignant disease, but hypocalcemia (1.97 mmol/l) and hypophosphatemia (0.46 mmol/l) were found. TSH (7.72 mIU/l) and PTH (21.3 pmol/l) were increased, with low vitamin D (9.3 nmol/l) and high alkaline phosphatase (360 U/l). DXA showed low bone mineral density. Final discharge diagnosis were osteomalacia, hypothyroidism and megaloblastic anemia. Calcium ($CaCO_3$ 1 g) and vitamin D replacement therapy (4000–6000 drops/day) were started, with clinical and laboratory tests improvement.
Conclusion
Calcium, PTH and vitamin D disorders require detailed medical history, diagnostic evaluation and differential diagnosis. Adequate therapy, monitoring and follow up guarantee well treated and satisfied patient.

25-OH vitamin D: a predictor of clinical outcomes in primary hyperparathyroidism

Mustafa Sahin, Gozde Sengul Aycicek, Demet Corapcioglu, Rıfat Emral, Sevim Gullu, Murat Faik Erdogan, Vedia Tonyukuk Gedik, Nilgun Başkal & Ali Rıza Uysal
Ankara University, Ankara, Turkey.

Objectives
We aimed to find if there is any relationship between vitamin D levels and clinical, laboratory parameters and osteoporosis, in primary hyperparathyroidism (PHPT).
Material and methods
128 patients with PHPT and 30 patients as a control group were analysed. Patients with PHPT were grouped due to vitamin D levels and levels low than 20 μg/ml accepted as deficiency.
Results
Patients with 25-OH vitamin D <20 μg/l were younger ($P=0.043$). Also they were more obese; BMI ≥30 ($P=0.18$) and more hypertensive ($P=0.032$). Metabolic syndrome (MS) incidence was higher in the patients with 25-OH vitamin D levels <20 μg/l ($P=0.44$). Incidence of thyroid nodules and thyroid nodule volume were similar between two groups. Also, fasting plasma glucose (FBG), HDL, LDL, triglyceride (TG), creatinine (Cr), glomerular filtration rate (GFR), TSH, T_4, PTH, Ca, 24 h urinary Ca and neuthrophil/lymphocyte ratio were similar. There was no significant difference in the incidence of nephrolithiasis, osteoporosis and parathyroid adenoma size between the groups. MS incidence was higher (32.8%) in PHPT ($P=0.042$). 25-OH vitamin D was found to be associated with age, BMI, thyroid volume and triglyceride in regression analyses.
Conclusion
25-OH vitamin D levels may be an indicator of hypertension (HT) and MS in PHPT. It also may be used as a treatment target in the severe disease.

The diagnostic value of parathyroid hormone washout in primary hyperparathyroidism patients with negative or unequivocal 99mTc-MIBI results

Cevdet Aydin[1], Sefika Burcak Polat[1], Fatma Dilek Dellal[1], Cafer Kaya[1], Seyda Turkolmez[2], Mehmet Kilic[3], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Endocrinology and Metabolism Department, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey; [2]Nuclear Medicine Department, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey; [3]General Surgery Department, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey.

Introduction
Primary hyperparathyroidism (pHPT) is a common endocrine disease mainly caused by single or multiple hyperfunctioning parathyroid lesions. In 2–7% of cases, surgery is not curative at first operation and reoperation is required. Ultrasonography and sestamibi scan are the most widely used methods for identification of the culprit parathyroid gland with the disadvantage of high false positives caused by other cervical pathologies. Herein we aimed to search the diagnostic value of measurement of parathyroid hormone (PTH) concentration in the needle washout of suspicious lesions suggestive for parathyroid adenoma with negative or unequivocal MIBI results.
Methods
Our endocrine database was searched retrospectively for the patients with PHPT who underwent PTH washout. There were 100 lesions of 70 patients. Among them, 21 lesions in 16 patients were operated and data of these lesions were analysed. All patients had at least one suspicious parathyroid lesion detected by ultrasonography and all patients were evaluated by 99mTc-MIBI.
Result
The mean age of the patients was 53.3±10.6 years with the majority of them being female (87.5%). The mean preoperative serum calcium level was 11.04± 0.33 mg/dl. The median serum PTH level was 140 pg/ml (ranging from 55 to 371) and the median serum PTH washout level was 3316 pg/ml ranging from 13 to 5000. Preoperatively 99mTc-MIBI scan was negative or unequivocal in 15 of 21 operated lesions while it was positive in six. For the lesions that the MIBI failed to localise, the sensitivity of PTH washout was 91% and the specificity was 66%.
Conclusion
PTH washouts can contribute significantly in establishing the parathyroid nature of cervical lesions that has conflicting preoperative sestamibi results and also might help the surgeon to perform a more successful operation.

Proximal femur strength, cortical thickness and bone structure in Klinefelter syndrome

Enrico Schileo[2], Alberto Ferlin[1], Ilaria Palmadori[2], Fulvia Taddei[2], Alessandro Coran[1], Sigurdur Sigurdsson[3], Vilmundur Gudnason[3], Tamara Harris[4] & Carlo Foresta[1]
[1]Department of Medicine, University of Padova, Padova, Italy; [2]Istituto Ortopedico Rizzoli, Bologna, Italy; [3]Icelandic Heart Association, Kópavogur, Iceland; [4]National Institute on Aging, Bethesda, Maryland, USA.

Introduction
Klinefelter syndrome patients (KS) frequently show low bone mass, which could have multiple aetiologies. The structural basis of low bone mass and its consequences on bone strength are almost not known, but analogies in bone microstructure and strength between KS and ageing women have proposed by studying distal tibia by HRpQCT. The aim of this study was to compare proximal femur strength and bone structure of KS with elderly women and men.
Patients and methods
Proximal femur QCT analysis was performed on 18 KS (mean age 44 ± 8 years) and compared with 89 elderly women (76 ± 6 years) and 39 elderly men (79 ± 5 years). QCT-based estimates of proximal femur strength were obtained with a personalized Finite Element procedure previously validated *in-vitro* and *in-vivo* under loading conditions corresponding to ten fall directions to span accidental conditions. Bone structure analysis included trabecular and cortical volumetric bone mineral density (Tb.vBMD, Ct.vBMD), and cortical thickness (Ct.Th.), mapped to 18 sectors covering the whole femoral neck. Femoral neck length and cross-sectional area were calculated.
Results
KS and women had similar bone strength (KS: 2981 ± 514 N, W: 2822 ± 627 N, Mann–Whitney $P = 0.14$), both significantly lower ($P < 0.001$) than elderly men (4176 ± 985 N). Bone cortex was significantly thinner in KS patients with respect to women ($P < 0.05$ in 13 out of 18 sectors). Ct.vBMD was equivalent in KS and women, whereas Tb.vBMD was instead higher in KS ($P = 0.003$). Femoral neck was significantly larger in KS patients (CSA 25% higher, $P < 0.001$).
Conclusion
We showed for the first time that, at proximal femur, KS and elderly women are similar in terms of bone strength. This similarity emerged however from different structural traits: KS had thinner femoral neck cortex, partially compensated by a denser trabecular compartment and larger bone dimensions (i.e. higher moments of area and bone mass).

Introduction
^{18}F-fluorocholine is a PET tracer used in the diagnostic work-up of patients with prostate cancer but was incidentally found to detect other tumours such as meningiomas, pituitary and parathyroid adenomas. ^{18}F-fluorocholine PET/MRI is currently under investigation as an imaging tool for detecting hyperfunctioning parathyroid glands in primary or secondary hyperparathyroidism, especially in patients qualifying and willing to undergo parathyroid surgery where standard diagnostic localization procedures such as neck ultrasound and scintigraphy failed to localize an adenoma.
Case report
A male patient was diagnosed with X-linked hypophosphataemic rickets at the age of 5 years with severe dwarfism and leg deformities. Treated with phosphate supplements and calcitriol (and several orthopaedic correction surgeries), he reached reasonable growth and height, with at least partial correction of mineralization deficit and without obvious kidney damage. As expected, tubular phosphate reabsorption (TmP/GFR) remained low (< 0.4 mmol/l) and FGF23 remained high. At the age of 23 years, he developed hypercalcaemia which persisted after treatment (including calcitriol) was stopped, i.e. a laboratory constellation of primary hyperparathyroidism. However, both neck ultrasound and dual-isotope ^{99m}Tc-tetrofosmin and ^{123}I sodium iodide SPECT failed to localize an adenoma. Since the patient and his physicians preferred surgery (rather than cinacalcet) when feasible with maintaining normal parathyroid function, the patient consented to off-label imaging with ^{18}F-fluorocholine PET/MRI, revealing intense focal tracer accumulation at the right lower position. Minimally invasive videoassisted selective parathyroidectomy was performed, resulting in an intraoperative drop of PTH from 258 to 73 ng/ml and subsequent normalization of serum calcium. Calcium and PTH remain normal for more than a year of follow-up, up to this writing.
Conclusion
Our finding suggests that ^{18}F-fluorocholine PET/MR can be a helpful and sensitive tool to localize the dominant source of PTH in difficult selected cases where minimally invasive selective parathyroidectomy is considered the treatment of choice.

A prospective study on juvenile primary hyperprathyroidism population

Federica Saponaro, Federica Cacciatore, Edda Vignali, Antonella Picone, Chiara Banti, Antonella Meola, Simona Borsari, Elena Pardi, Claudio Marcocci & Filomena Cetani
Endocrinology U.O., University of Pisa, Pisa, Italy.

Primary hyperparathyroidism (PHPT) is a common disorder in adults but is uncommon in young people and features of juvenile PHPT (J-PHPT) are debated in literature. The aim of the study was to evaluate the characteristics of PHPT in juvenile sporadic (S) and familial (F) patients. It's a monocentric prospective study at a referral centre in 154 patients with ≤ 40 years. Patients were evaluated at diagnosis and at the last follow-up visit (median follow-up 2 years), comparing clinical presentation, biochemical, densitometric, histological parameters, percentage of cure after parathyroidectomy (PTx) between S and F. One hundred-twelve patients had SJ-PHPT, 31 patients had multiple endocrine neoplasia type 1 (MEN1) syndrome and 11 familiar isolated hyperparathyroidism (FIHP). Symptomatic nephrolithiasis was observed in 44% of SJ-PHPT and in 48.4% of FJ-PHPT and aspecific neuropsychic symptoms in 95% of all patients. Ninety SJ-PHPT and 27 FJ-PHPT underwent PTx. The histology showed in SJ-PHPT and FJ-PHPT respectively: a single adenoma in 86 and seven patients, hyperplasia in two and 19 patients, carcinoma in one SJ-PHPT and exploration without excision of parathyroid tissue was observed in one S-JPHPT and one F-JPHPT. Ionized serum calcium and PTH significantly decreased after PTx in both group. The persistence/recurrence rate of disease was 15% in sporadic cases and 52% in familial cases. There were not statistically significant ($P < 0.001$) differences in biochemical and densitometric markers between sporadic and familial group. In both groups males showed a more statistically significant ($P < 0.001$) severe PHPT for both biochemical and densitometric markers. When the overall patients were stratified for age ≤ 25 and > 25 years, younger patients appeared to have a significantly ($P < 0.001$) more severe disease.
In conclusion, J-PHPT is generally sintomatic and more severe in males; it has a higher rate of persistence/recurrence disease, even in sporadic patients; S and F patients show similar features.

Outcome of subtotal parathyroidectomy in patients with renal hyperparathyroidism

Kiera Welman, Peter Veitch & Neal Banga
Royal Free London NHS Foundation Trust, London, UK.

Introduction
Hyperparathyroidism is common in patients with end-stage renal failure (ESRF): up to 20% require treatment for hyperparathyroidism within 10 years of commencing haemodialysis. Despite the significant cost of long-term medical treatment with calcimimetics and poor patient compliance, only a minority of patients are referred for surgery, usually due to their significant co-morbidity.
Methods
Outcome data of patients with secondary or tertiary hyperparathyroidism undergoing subtotal parathyroidectomy in our department from 2012 to 2014 were reviewed. All patients underwent bilateral neck exploration with nerve monitoring. Serum parathyroid hormone (PTH) and calcium levels were measured postoperatively.

Results
25 patients (median age 52 years) underwent subtotal parathyroidectomy. 18/25 patients (72%) had ESRF and secondary hyperparathyroidism whilst 7/25 patients (28%) had post-transplant tertiary hyperparathyroidism. The majority of patients had evidence of osteopaenia or osteoporosis on bone densitometry and 17/25 patients (68%) had some degree of hypercalcaemia at referral. At least four parathyroid glands were identified intra-operatively in 19/25 patients (76%) and a subtotal procedure was performed, leaving ~50 mg of parathyroid tissue in-situ. In 6/25 patients, three or fewer parathyroid glands were identified, and in these patients all the identified glands were excised. 24/25 patients (96%) had serum PTH levels <14 pmol/l at most recent follow up (range 3–24 months). Normocalcaemia was achieved in 16/17 (94%) of the patients who were hypercalcaemic pre-operatively. Post-operative complications included severe transient hypocalcaemia requiring i.v. calcium infusion in two patients, and one patient required emergency reoperation for bleeding. One patient experienced temporary unilateral recurrent laryngeal nerve palsy which recovered fully within 3 months post-surgery.
Conclusion
Subtotal parathyroidectomy can deliver biochemical success in >90% of patients with renal hyperparathyroidism. It offers a safe and cost-effective alternative to medical treatment, particularly in patients with poor compliance, and without the risk of future adynamic bone disease associated with total parathyroidectomy.

Asymptomatic pulmonary cement embolism after vertebroplasty: a case report

Zoe A Efstathiadou, Eleni Karathanassi, Maria Poulasouchidou & Marina D Kita
Department of Endocrinology, 'Hippokration' General Hospital of Thessaloniki, Thessaloniki, Greece.

Introduction
Vertebroplasty is a commonly performed technique in the management of vertebral compression fractures. However, it is associated with some serious adverse effects. Most complications are related to the leakage of bone cement (polymethylmethacrylate) into the spinal canal or the perivertebral venous system.
Case report
A 74-year-old lady was subjected to percutaneous verterbroplasty for osteoporotic compression fractures on T11, T12, L1 and O4. The procedure was uneventful. One year later, on routine chest radiograph, a high density material was found in branches of pulmonary artery. The same material was also found in the perivertebral venous system and had identical density with the bone cement present in the treated vertrebrae. Findings were confirmed by chest computed tomography. No specific medical treatment was given.
Conclusion
Biologic cement leakage is a frequent adverse event of vertebroplasty, with pulmonary cement embolism occurring in about one-quarter of the patients and remaining in most cases asymptomatic. However, close monitoring and early recognition of this clinical situation might be critical for some patients.

Low extracellular sodium promotes adipogenic commitment of human mesenchymal stromal cells: a novel mechanism for chronic hyponatremia-induced bone loss

Cristiana Deledda[1], Benedetta Fibbi[1], Corinna Giuliani[1], Susanna Benvenuti[1], Paola Luciani[1], Benedetta Mazzanti[2], Riccardo Saccardi[2] & Alessandro Peri[1]
[1]Department of Experimental and Clinical Biomedical Sciences 'Mario Serio', University of Florence, Firenze, Italy; [2]Department of Hematology, Careggi Hospital, Firenze, Italy.

Hyponatraemia represents an independent risk factor for osteoporosis and fractures, affecting both bone density and quality. A direct stimulation of osteoclastogenesis and bone resorption in the presence of reduced extracellular sodium concentrations ([Na+]) has been shown, but, to date, the effects of reduced [Na+] on osteoblasts have not been elucidated. This study investigated the effects of a chronic reduction of extracellular [Na+], independently of osmotic stress, on human mesenchymal stromal cells (hMSC) from bone marrow, the common progenitor for osteoblasts and adipocytes. As regards hMSC homeostasis, we found a significant inhibition of adhesion and viability, but no alteration of their surface antigen profile and immuno-modulatory properties. Low extracellular [Na+] were able to modulate the osteoblastic production of factors (MCP-1 and CXCL-12) that stimulate osteoclast recruitment and bone resorption. Next, we tested whether chronic hyponatremia was able to alter the cellular commitment of hMSC. We found that hMSC maintained their ability to commit toward the osteogenic and the adipogenic phenotypes, as demonstrated by the unaltered gene expression of specific differentiation markers. However, the dose-dependent increase in the number of adipocytes as a function of reduced [Na+], observed by Oil-Red-O staining, suggested a preferential commitment toward the adipogenic phenotype at the expense of osteogenesis. This observation was further supported by the amplified inhibitory effect on the expression of osteoblastic markers exerted by adipocyte-conditioned media in low [Na+] conditions. Finally, the analysis of cytoskeleton by immunofluorescent microscopy showed that low [Na+] was associated with disruption of tubulin organization in hMSC-derived osteoblasts, thus suggesting a negative effect on bone quality. These findings add new evidence that hyponatremia should be carefully taken into account by clinicians because of its negative effects on bone, in addition to the known neurological effects, and indicate for the first time that impaired osteogenesis may be involved.

Thalassemia-induced osteoporosis and bisphosphonate treatment: a systematic review and meta-analysis

Athanasios Tsartsalis[1], George Lambrou[2], Christos Savvidis[3], George Chrousos[2] & Antonis Kattamis[2]
[1]Department of Endocrinology and Diabetes, Naval Hospital, Athens, Greece; [2]1st Department of Pediatrics, University of Athens, Athens, Greece; [3]Department of Endocrinology and Metabolism, Hippocration General Hospital, Athens, Greece.

Introduction
Osteopenia and osteoporosis develop with aging in thalassemia patients despite clinical treatment therapy has improved. Bisphosphonates, which are potent inhibitors of osteoclastic bone resorption, have been recently used to correct the bone abnormality in thalassemia with encouraging results. Bisphosphonates are a class of drugs that prevent the loss of bone mass, used to treat osteoporosis and similar diseases. They are the most commonly prescribed drugs used to treat osteoporosis. Bisphosphonates act by inhibiting osteoclastic recruitment and maturation, preventing the development of monocyte precursors into osteoclasts, inducing osteoclast apoptosis and interrupting their attachment to the bone.
Scope
The scope of the present work was to meta-analyse available data concerning the role of bisphosphonates in thalassemia-induced osteoporosis.
Methods
A search was carried out to find relevant studies and reviews published up to date. The database used was Pubmed. The MeSH terms used were: bisphosphonate, thalassemia and/or anaemia, osteoporosis, which yielded 33 results. From those 22 has been selected for further processing as more relevant to the topic of study.
Results
Based on the meta-analysis of selected studies it appeared that bisphosphonates could prove an effective treatment for osteoporosis. In particular, zoledronic acid was effective in the treatment of osteoporosis, while clodronate did not appear to be equally effective. In total, bone mineral density as well as markers of bone remodelling (CTX, bALP, OPG, etc.) were higher in the bisphosphonate-treatment groups as compared to the placebo group.
Conclusions
Cross-examination of several studies suggests that bisphosphonates are to be considered as a therapeutic option for the treatment of thalassemia-induced osteoporosis.

Bones in pseudohypoparathyroidism type 1a

Slavica Savic[1], Tanja Nisic[1], Tijana Lalic[1], Biljana Nedeljkovic-Beleslin[1,2], Mirjana Stojkovic[1], Marija Barac[1], Milos Stojanovic[1], Jasmina Ciric[1,2] & Milos Zarkovic[1,2]
[1]Clinic of Endocrinology, Diabetes and Metabolic diseses, Clinical Centre of Serbia, Belgrade, Serbia; [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Pseudohypoparathyroidism type 1a (PHP1a) is disorder characterised by resistance to the biological actions of circulating parathyroid hormone (PTH) along with typical features of Albright's hereditary osteodystrophy (AHO). Tissue-specific imprinting of GNAS gene results in complete resistance to PTH in renal proximale tubule, but skeletal responsiveness to PTH appears intact, since Gαs is biallelically expressed in human bones. The objective of this study was to determine BMD, and its relation to PTH levels in a group of young adult patients with PHP1a (age range 19–32 years). BMD measurements (Hologic QDR 4500) at the lumbar spine (LS), total hip (TH) and femoral neck (FN) were obtained in five patients with PHP1a (diagnosis was based on presence of AHO features combined with multihormone resistance). All patients were diagnosed with this condition earlier, and treatment was begun between ages 4 and 21 years. Caracteristics of study patients: intact PTH levels ranged from 120.9 to 436 pg/ml (reflecting inadequate dosing of calcium and calcitriol); all patients were taking levothyroxine and TSH levels were mildly elevated (range 5.98–12.10 mIU/l); three subjects were GH deficient, and none recieved GH therapy. The mean BMD Z-score for the LS was −1.4 (range −2.6 to −0.6), which is not significantly different from normal. Three subjects had Z-scores out of ±1, range expected for the normative population, and one of them met the criteria for low BMD. The mean BMD Z-score for the TH was −1.1 (range −1.6 to −0.8), and for the FN was −0.8 (range −1.9 to 0.2), both not significantly different from normal controls. Our results show that subjects with PHP1a, despite significant secondary hyperparathyroidism, had normal bone mass, with exept of one subject (20%) who had low LS BMD. These results are somewhat conflicting with previous study wich demonstrated that bone mass is either normal or increased in PHP1a.

Clinical risk factors for osteoporosis in type 1 diabetes

Monica Goia-Socol[1,2], Ileana Duncea[1,2], Mihai-Andrei Goia-Socol[1,3], Georgeta Hazi[2], Daniel-Corneliu Leucuta[4], Marius Pauliuc[1,2], Ioana Ilie[1,2] & Carmen Emanuela Georgescu[1,2]
[1]Department of Endocrinology, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania; [2]Endocrinology Clinic, Cluj County Emergency Hospital, Cluj-Napoca, Romania; [3]Diabetes Center, Cluj County Emergency Hospital, Cluj-Napoca, Romania; [4]Department of Medical Informatics and Biostatistics, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania.

Introduction
Type 1 diabetes secondary osteoporosis is an underdiagnosed condition and there are few studies that addressed the topic of clinical risk factors in this context, although, for a better diagnosis and management, it is of great importance to find such predictors.
Aim
To evaluate bone mineral density and parameters of bone metabolism in patients with type 1 diabetes in comparison with a group of healthy subjects and to determine possible risk factors for osteoporosis in the context of type 1 diabetes.
Patients and methods
102 patients with type 1 diabetes and 59 healthy controls (pre-menopausal women and men, aged between 20 and 55 years), matched by age, sex, and BMI were included in the study. All subjects with secondary causes of osteoporosis except type 1 diabetes and diabetic patients with stage 3 nephropathy or more (GFR <60 ml/min per 1.73 m^2) were excluded. Their lifestyle, personal and parental history were evaluated with a questionnaire, anthropometric measurements were made and DXA osteodensitometry was performed. Serum osteocalcin, intact PTH, 25(OH) vitamin D, total calcium, phosphorus and magnesium were determined.
Results
The risk for low BMD (at least a *Z* score equal or lower than −2.0 S.D. at any site) was 1.2 higher in type 1 diabetes (95% CI 0.43–3.33), however BMD was not significantly different between patients and controls ($P=0.88$ for lumbar spine and 0.56 for femoral neck).Type 1 diabetic patients had a median age of 28 and a median disease duration of 11.5 years. Median HbA1c was 8.1%. BMD for a disease duration over 10 years was significantly lower than that for 0.5-5 years ($P=0.008$, ANOVA). Diabetic nephropathy (stages 1 and 2) increased the risk for low BMD and was associated with a significant rise of PTH. Age was negatively associated with lumbar spine BMD and positively with PTH. BMI was positively associated with BMD at all sites.
Conclusions
The most important predictors for osteoporosis in our study were type 1 diabetes duration (over 10 years) and the presence of diabetic nephropathy. Age towards the upper limit of inclusion (i.e. 55 years old) or low BMI values (low/low normal) may complete an indication for performing DXA in type 1 diabetic patients. Long-term lifestyle measures that we found to be protective for osteoporosis were: avoiding coffee and alcohol consumption, regular exercise and an optimal metabolic control of diabetes.

Glucocorticoid induced osteoporosis; can we do more to prevent it?

Plaisanu Cristina[1], Iorgoveanu Vasilia[2] & Trifanescu Raluca[3]
[1]Carol Davila Medicine University, Bucharest, Romania; [2]Saint Mary Clinical Hospital, Bucharest, Romania; [3]'I.C Parhon' Endocrinology Institute, Bucharest, Romania.

Introduction
Osteoporosis is a well-known and extremely debated side effect of glucocorticoid therapy being able to generate vertebral fractures even at low doses. Our study highlights the need for better prevention through improved doctor-patient communication and correct implementation of available screening tools.
Methods
Since August–December 2014 we distributed to 85 rheumatic patients a self-compiled questionnaire. We recorded patient data and their awareness on current recommendations, osteoporosis screening/treatment information. Hospital's electronic database provided DXA and radiographic results.
Results
Study included 72/85 women, median age 57.5 years, 38/85 rheumatoid arthritis, 20/85 systemic lupus erythematous, and 27/85 other diseases, median disease duration 72 months. 55/85 (64.70%) received <7.5 mg/day, whilst 30/85 (35.29%) received >7.5 mg/day for >3 months. 40/85 (47.05%) have undergone a DXA and 24/40 (60%) have osteoporosis and bisphosphonate treatment. Only 51/85 (60%) is aware of this therapy risk. FRAX 10 years probability of osteoporotic fractures was >20% in 9/24 (37.5%) patients. Only 31/85 (36.47%) were aware that smoking cessation is recommended, 62/85 (72.94%) knew excessive alcohol intake must be avoided and 20/85 (23.52%) were aware of the need for weight-bearing activities. Only 50/85 (58.82%) have a radiographic imaging of the spine and 10/50 (20%) have vertebral fractures on radiography. 70/85 (82.35%) have received vitamin D supplements.
Conclusion
Study revealed a lack of proper screening for glucocorticoid osteoporosis and a high percentage of patients not aware of existing recommendations regarding lifestyle modifications needed for prevention. Clinicians should make more efforts for patient to properly understand this risk, to know the ways to diminish it and, last but not least, the utility of early diagnostic and treatment.

Barakat syndrome: an uncommon cause of hypocalcaemia

Teresa Rego, Fernando Fonseca & Ana Agapito
Endocrinology Department, Curry Cabral Hospital, Lisbon, Portugal.

Introduction
Barakat syndrome is a very rare disease and an uncommon aetiology of hypocalcaemia. Also known as HDR syndrome it is an autosomal dominant disorder characterised by hypoparathyroidism, sensorineural deafness and renal disease.
Clinical case
A 59-year-old Caucasian woman was admitted to our Endocrinology ward in May 2014 due to hypocalcaemia despite being medicated with oral calcium. At 35 years old a diagnosis of hypoparathyroidism was established in another hospital when she presented generalized seizures and cardiac failure. Intracranial basal ganglia calcification where revealed at that time and a diagnosis of hypocalcaemic miocardiopathy was established. At the present admission in our hospital, further history revealed progressive hearing loss for the last 20 years. Laboratory work up: Ca^{2+} 7.7 mg/dl (8.6–10.2 mg/dl), Pi 3.1 mg/dl (2.5–4.5), Mg^{2+} 1.9 mg/dl (1.6–2.3), PTH 1.3 pg/ml (12–88), and creatinine 1.10 mg/dl. Abdominal CT scan showed right kidney hypoplasia. DNA sequence analysis revealed on exon 5 of *GATA3* gene a heterozygotic mutation c.1043T > C (p.Leu348Pro) that confirmed the diagnosis of Barakat syndrome. We observed one of the two adult sons and the adult daughter of this patient. Hypocalcaemia due to hypoparathyroidism and neurosensorial bilateral deafness were documented in both. Genetic study of this offspring is in course.
Comments
Barakat syndrome may present a variable phenotype. Renal manifestations are the most heterogeneous and usually determine disease prognosis. This patient has the classical triad. The severity of hypocalcaemia since young age and subsequent irreversible cardiac involvement were determinant for prognosis. Timely diagnosis and appropriate hypocalcaemia treatment are paramount. Genetic screening of relatives takes particular relevance in this context.

The diagnostic value of parathyroid hormone washout after fine-needle aspiration in patients with primary hyperparathyroidism

Fotini Adamidou[1], Panagiotis Anagnostis[1], Vasileios Champidis[1], Simoni Katergari[1], Georgios Zacharioudakis[2] & Marina Kita[1]
[1]Department of Endocrinology, Hippokration Hospital of Thessaloniki, Thessaloniki, Greece; [2]Fifth Department of Surgery, Hippokration Hospital of Thessaloniki, Aristotle University of Thessaloniki, Thessaloniki, Greece.

Introduction
Commonly used pre-operative methods (ultrasonography and sestamibi scan) to localize the culprit parathyroid gland(s) in patients with primary hyperparathyroidism (PHPT), frequently yield false positive or false negative results. Parathyroid hormone (PTH) washout after fine-needle aspiration (FNA) may allow for a targeted surgical approach. The aim of this study was to test the diagnostic value of preoperative PTH washout after FNA in PHPT patients.
Methods/design
Retrospective study conducted in a tertiary centre. Ultrasound-guided FNA was performed if a structure compatible with a parathyroid adenoma was found on cervical ultrasound. A PTH washout cut-off value was considered diagnostic if it was higher than the concomitant serum PTH value.
Results
Twenty-nine patients (2 (6.8%) males, mean age 58.6 ± 9.1 years) were included. Mean pre-operative serum PTH levels were 194.2 ± 176.8 pg/ml (normal: 10–53), while serum calcium and 25-hydroxy-vitamin D levels were 11.5 ± 1.4 mg/dl (normal: 8.8–10.6) and 24.1 ± 20.5 ng/ml (deficiency: < 20 ng/ml) respectively. Post-operative serum PTH and calcium levels were 45.9 ± 26.3 pg/ml and 9.04 ± 0.7 mg/dl respectively. A single adenoma was identified in 26 (89.7%) patients and a double adenoma in 1 (3.4%). Two (6.9%) patients were harbouring an ectopic parathyroid adenoma (upper mediastinal and intrathyroid). Twenty-four patients (82.7%) had elevated PTH washout concentrations (mean values: 2009.5 ± 1417.6 pg/ml). True positive and false negative results were 24 and 4 respectively. The sensitivity, specificity and positive predictive value (PPV) were 85.71, 100, and 100% respectively. Interestingly, in ten out of 12 patients with a negative sestamibi scan, the PTH washout yielded a truly positive result.
Conclusions
Elevated PTH washout concentrations after ultrasound-guided FNA is an highly accurate diagnostic tool in identifying parathyroid adenomas and guiding parathyroid surgery.

Relationship between vitamin D supply and healing in patients with hip fracture

Erzsebet Toldy, Antal Salamon, Balazs Hepp, Akos Matrai, Csaba Biro, Katalin Agota, Emoke Fata & Zoltan Locsei
Markusovszky Hospital, Szombathely, Hungary.

Background
Vitamin D (VD) deficiency is important risk factor of fractures. Yet, the relation of serum 25-hydroxyvitamin D (25OHD) levels and recovery of fractures is poorly studied. Our aim was to investigate the VD supply in hip fractures also with regard to lifestyle and other clinical (malignancy, kidney and liver disease, osteoporosis) conditions.
Method
25OHD (protein binding assay, Cobas, Roche) and parathyroid hormone (PTHi) (electrochemiluminescence immunoassay, Cobas, Roche) levels of 202 patients (67 men and 135 women) with hip fracture (age 75 ± 12 years) and 102 age-matched persons with active lifestyle, as controls were investigated.
Results
VD deficiency and secondary hyperparathyroidism occurred significantly more frequently in patients with hip fracture than in the control group (73% vs 36% and 33% vs 12% respectively). Patients with better condition after surgery showed significantly higher 25OHD (median with interquartilis ranges: 44 (28–72) vs 15 (9–43) nmol/l; $P < 0.001$) and lower PTHi (51 (35–64) vs 63 (48–88) pg/ml, $P < 0.05$) levels than patients with bad condition. 31 patients who died after surgery (median survival time: 19 (5–52) days) had lower 25OHD levels than those who survived (23 (9–43) vs 33 (17–57) nmol/l) without significant difference in PTHi levels. These results were independent of chronic disorders.
Conclusion
The correlation between 25OHD levels and better postoperative condition confirm the importance of VD substitution in prevention, as well as in healing, and in increased survival rate.

An oral high dose of cholecalciferol restores vitamin D status in deficient postmenopausal HIV-1 infected women independently of protease inhibitors therapy

Jessica Pepe, Ivano Mezzaroma, Alessandra Fantauzzi, Mario Falciano, Alessandra Salotti, Mario Di Traglia, Daniele Diacinti, Sara Belcastro, Sara Piemonte, Cristiana Cipriani & Salvatore Minisola
Sapienza University, Rome, Italy.

Introduction
The best repletion and maintenance dosing regimens with cholecalciferol in vitamin D deficient HIV-1 patients remain unknown. Protease inhibitors (PIs) have been shown to inhibit vitamin D 1α- and 25α-hydroxylation in hepatocyte and monocyte cultures. We therefore evaluated the effect of a single high dose of cholecalciferol in vitamin D deficient HIV-1 postmenopausal women undergoing treatment with highly Active Anti-Retroviral Therapy (cART), with and without PIs.
Methods
Forty HIV-1 postmenopausal women treated with cART, with hypovitaminosis D (< 20 ng/ml), were enrolled. We measured serum changes of 25-hydroxyvitamin D (25(OH)D), 1,25-dihydroxyvitamin D ($1,25(OH)_2D$), parathyroid hormone (PTH), serum calcium and urinary calcium excretion following a loading dose of 600 000 IU of cholecalciferol after 3, 30, 60, 90, and 120 days.
Results
The sample was divided according to the presence PIs (group A, $n = 20$) or absence (group B, $n = 20$). There were no significant differences between the two groups at baseline (mean 25(OH)D group A 13.93 ± 3.85 vs group B 12.94 ± 3.86 ng/ml, P = NS). The cART scheme was not modified during the study period. We did not find any significant changes in the two groups, as regards: the mean CD4 values, the HIV RNA values, and the body mass index. A significant increase in mean 25(OH)D and $1,25(OH)_2D$ levels at day 3 and throughout the entire observation period was found in both groups ($P < 0.001$). PTH levels concomitantly decreased in both groups ($P < 0.001$). Mean albumin-adjusted serum calcium increases with respect to baseline were significant only at days 3 and 30 for both groups ($P < 0.01$). There were no significant differences between the groups at any time, by two-way RM ANOVA.

Conclusions
An oral dose of 600 000 IU of cholecalciferol in HIV-1 postmenopausal women rapidly increases 25(OH)D and $1,25(OH)_2D$ levels reducing PTH levels, regardless of the presence of PIs in the cART scheme.

[1]Institute for Scientific Research Bento Rocha Cabral, Lisbon, Portugal; [2]ISAMB, FMUL, Lisbon, Portugal; [3]CIPER, FMH-UL, Lisbon, Portugal; [4]Clinic of Endocrinology, Diabetes and Metabolism, Lda, Lisbon, Portugal; [5]Department of Endocrinology, Diabetes and Metabolism, HSMaria-CHLN, Lisbon, Portugal.

Aims
To study the association of protein tyrosine phosphatase (LMW–PTP/ACP1) polymorphism with bone mineral density and metabolic parameters of bone remodelling.
Methods
BMD (g/cm^2) was measured by DEXA in 760 subjects: 448 normal BMD (359F/89M; 49.7 ± 12.9 years; $30.2 \pm 5.4\ kg/m^2$) and 312 osteoporosis (265F/47M; 63.9 ± 10.4 years; $27.16 \pm 4.4\ kg/m^2$). Metabolic bone remodelling parameters were analyzed: LDL, HDL, total cholesterol, triglycerides, HOMA, alkaline phosphatase (AP), and osteocalcin. ACP1 activity was measured by spectrophotometry. ACP1 polymorphism was evaluated by PCR.
Results
Association was found between the genetic polymorphism of ACP1 and its enzymatic activity with higher values for genotypes AC + BC, intermediate values for BB and lower values for AA + AB. Osteoporosis: i) increased LDL, total cholesterol, AP, osteocalcin and ACP1, and decreased HOMA; ii) association between genotypes BB + BC + AC and increased total cholesterol, LDL, and ACP1; and iii) positive correlation between AP and LDL, total cholesterol, and osteocalcin. Normal BMD: i) association between genotypes BB + BC + AC (intermediate and higher ACP1 activity) and increased ACP1 and decreased AP and ii) positive correlation between AP and osteocalcin and HOMA. Only correlations of AP with LDL and total cholesterol remained significant when analyzed separately AA + AB individuals.
Conclusion
In osteoporosis, ACP1 polymorphism appears to modulate some metabolic parameters associated with a decrease in BMD, including total cholesterol, LDL, and ACP1 activity.

Pancreatitis in familial hypocalciuric hypercalcaemia

Iulia Potorac[1], Olivier Malaise[2], Adrian Daly[1] & Albert Beckers[1]
[1]Department of Endocrinology, CHU de Liège, University of Liège, Liège, Belgium; [2]Department of Rheumatology, CHU de Liège, University of Liège, Liège, Belgium.

Familial hypocalciuric hypercalcaemia (FHH) is a characteristically asymptomatic condition that is caused principally by calcium sensing receptor gene (CASR) mutations and less frequently by GNA11 or AP2S1 mutations. We report a case of recurrent symptomatic pancreatitis in an FHH patient. The 17-year-old patient was hospitalized with abdominal pain and raised pancreatic enzymes due to acute pancreatitis. The only predisposing factor on investigation was a very elevated serum calcium level (3.3 mmol/l; NR: 2.15–2.60). This was associated with concomitantly moderately elevated PTH (33 ng/l; NR: 4–26), normal 25-OH vitamin D (44 ng/ml; NR: 30–80), elevated $1,25(OH)_2$ vitamin D (133 pg/ml; NR: 23–109), and undetectable urinary calcium. Family history revealed that the patient's grandmother was also known to suffer from hypocalciuric hypercalcaemia, and that hypercalcaemia had been found in the patient's mother, uncle, brother and sister. CASR sequencing revealed the patient (and family members) to be heterozygotic for a R185Q mutation, previously suggested to be a dominant negative mutation and leads to higher calcium levels than other known CASR mutations. Cinacalcet treatment lowered serum calcium to 2.95 mmol/l and the patient has not presented new pancreatitis episodes.

Giant parathyroid adenoma with severe hypercalcaemia: case report

Cristina Spiroiu, Aurelian Emil Ranetti & Claudiu Nistor
Central University Military Hospital 'Dr Carol Davila', Bucharest, Romania.

Introduction
Parathyroid adenomas are the main cause of primary hyperparathyroidism. They are usually small – weighing <1 g – and not easy to find – requiring meticulous imaging studies for localisation. Giant adenomas are uncommon; large tumours and high levels of PTH raise the suspicion of parathyroid malignancy.
Case presentation
A 68-year-old female presented in our clinic with polydipsia, poliuria, nausea, weight loss, and extreme muscular weakness – she wasn't able to walk – and depressive mood. Clinical exam revaled dehydration and right cervical mass. Calcium was 21 mg/dl and PTH was 2238 pg/ml. The patient was also vitamin D deficient – 25OH vitamin D 14 μg/l. Radiographic study showed fracture of the first lumbar vertebra, CT scan showed multiple osteolytic areas of the skull. Osteodensitometry demonstrated osteoporosis (lumbar spine T score -2.9 S.D. and distal radius T score -6.7 S.D.). Ultrasonography revealed a hypoechoic inhomogeneous mass, 38/30/45 mm, laterally and caudally to the right thyroid lobe. Parathyroid scintigraphy (99Tc-MIBI) demonstrated a large area of high uptake in that region. The patient received intravenous fluids, loop diuretic, i.v. bisphosphonate (zoledronate) and calcitonin to reduce the level of calcium, then she was successfully operated. Calcemia dropped after surgery and it was managed with i.v. calcium and alpha calcidol. Mild hypocalcemia persisted for more than 6 months thereafter and so did the high levels of PTH, that raised to 506.5 pg/ml, then returned to normal – the hungry bones syndrome. The pathologic diagnosis was benign parathyroid tumour – parathyroid adenoma.
Conclusions
This is a rare case of giant parathyroid adenoma. The peculiarities of the case are the size of the tumour, the very high level of calcium and PTH – suggesting a malignant tumour, and the persistence of high levels of PTH and hypocalcemia months after surgery.

Primary hypoparathyroidism is common in adult patients with β-thalassemia and protect patients from osteoporosis

Anna Ansaloni[1], Francesca Ferrara[3], Chiara Diazzi[1,2], Antonello Pietrangelo[3], Manuela Simoni[1,2] & Vincenzo Rochira[1,2]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Azienda USL of Modena, Modena, Italy; [3]Unit of Internal Medicine, Research Center 'Mario Coppo', University Hospital Policlinico, Modena, Italy.

Introduction
β-thalassemia (bT) is associated to several endocrine abnormalities mainly due to iron overload. With the increase in bT-patients life expectancy, due to progresses in iron chelation therapy, more patients enter into adulthood than in the past and the prevalence of endocrine diseases is being reconsidered. The aim of the study is to investigate the prevalence of primary hypoparathyroidism (pHPT) in adult bT-patients and to characterize the relative clinical phenotype with particular regard to bone health.
Methods
We enrolled 26 adult patients with major or intermedia bT (12M and 14F; mean age ± S.D. of 38.1 ± 7.5 years). Serum PTH, 25-hydroxyvitamin D (25OHD), calcium, phosphorous, albumin, bone turnover markers, and bone mineral density (BMD) by dual-energy X-ray absorptiometry (Hologic) at lumbar and femoral site were measured.

Results
pHPT (PTH <15 pg/ml) was found in seven of the 26 patients (27%). Of them, four patients (57%) had hypocalcemia and two were on chronic calcium therapy. Lumbar BMD was significantly higher in patients with pHPT (0.884 ± 0.189 g/cm^2) than in patients without pHPT (0.731 ± 0.124 g/cm^2) ($P=0.023$). No significant difference was found in femoral BMD, even though a trend for higher BMD was present in pHPT (0.704 ± 0.117 vs 0.670 ± 0.143 g/cm^2 in pHPT and no-pHPT respectively) ($P=0.578$). The prevalence of osteoporosis was higher in patients without pHPT (68%) than in patients with pHPT (29%). Two patients had a history of bone osteoporotic fractures and both of them did not present pHPT. Bone turnover markers were no different in the two groups.
Conclusions
The prevalence of pHPT in adult bT-patients is higher if compared to that observed in pediatric bT-patients, the latter ranging from 8 to 11%. Moreover we found an higher prevalence of pHPT compared to that reported in literature on adult bT patients. As expected, pHPT seems to exert a protective role on the development of osteoporosis in these patients.

Renal calcification in hypoparathyroid patients treated with calcium and vitamin D: can biochemistry help?

Sivatharshya Pathmanathan[1], Scott Tolhurst[2], Emma Illingworth[1], Claire Higham[1], Peter Trainer[1] & Phillip Monaghan[2]
[1]Department of Endocrinology, The Christie NHS Foundation Trust, Manchester, UK; [2]The Christie Pathology Partnership, The Christie NHS Foundation Trust, Manchester, UK.

Introduction
Hypoparathyroidism is most commonly observed following neck surgery and is characterized biochemically by deficient parathyroid hormone (PTH) and hypocalcaemia alongside hyperphosphataemia and reduced 1,25-dihydroxyvitamin D. Standard treatment with oral calcium and vitamin D aims to maintain serum calcium within the low-normal range whilst avoiding hypercalciuria due to over replacement. However, concerns remain over the presence of hypercalciuria and the associated risk of renal calcification.
Aim
To assess whether serum and urine biochemical parameters are associated with the presence of renal calcification in hypoparathyroid patients on Alfacalcidol therapy.
Method
A 12-month audit of the laboratory database was undertaken of paired requests for 24-h urine calcium (24 h-Ca), spot calcium:creatinine ratio (Ca:Creat), serum calcium, phosphate, urea, and creatinine. A review of case notes was performed to confirm aetiology of hypoparathyroidism, Alfacalcidol dose and results of renal ultrasound scan (USS).
Results
A total of 34 patients were identified as having hypoparathyroidism and receiving Alfacalcidol therapy. 24 h-Ca and Ca:Creat were not-normally distributed, however significant associations were found between 24 h-Ca and Ca:Creat when log-transformed (linear regression β-coefficient $=0.64$; 95% CI 0.36–0.92; $P<0.001$, $\beta=0.63$). 17 patients had documented hypercalciuria evidenced by elevated 24 h-Ca (five patients), Ca:Creat (eight patients), or both (four patients). 13 patients had undergone renal USS; four had evidence of renal calcification. Interestingly, these four patients each had an elevated Ca:Creat, in contrast with only one patient having elevated 24 h-Ca.No patient had hypercalcaemia. However, 20 patients had low, or low-normal serum adjusted calcium (Ca <2.2 mmol/l); nine of these patients having documented hypercalciuria evidenced by an elevated 24 h-Ca (78% of patients) or Ca:Creat (89% of patients).
Conclusion
Ca:Creat appears a sensible and convenient marker for the follow-up of patients on long term Alfacalcidol therapy to determine associated risk of renal calcification.

Parathyroid tissue in ectopic thyroid tissue

João Silva, Catarina Ivo, Mafalda Marcelino, Dolores Passos, Hélder Simões, Luís Lopes & João Jácome de Castro
Armed Forces University Hospital, Lisbon, Portugal.

Introduction
Postmortem studies have shown that a fifth parathyroid gland may be present in about 5% of patients with hyperparathyroidism. 1% of parathyroid glands are located in thyroid tissue. There's a prevalence of 7–10% of thyroid ectopic tissue.
Case report
A 53-year-old male, submitted to bilateral nephrectomy due to a Grawitz tumour at the age of 25. Under haemodialysis since then (with a rejected renal transplant in the past), he was recently referred to our department with a tertiary hyperparathyroidism diagnosis. Treated intra-hemodialysis with alfacalcidol 0.25 µg and cinacalcet. Analytically had a PTH 1604 pg/ml, calcium 9.5 mg/dl, phosphorus 5.6 mg/dl, and creatinine 11.4 mg/dl. Cervical ultrasound did not identify parathyroid gland and thyroid scintigraphy suggested parathyroid adenoma in the bottom right. PET-scan showed bone lesions suggestive of brown tumours. The patient was submitted to surgery and has removed four parathyroid glands (9–20 mm) with an histology of 'nodular hyperplasia of the parathyroid'. Was also removed a fifth nodule located in the lower left region with 9 mm, described as 'focus of parathyroid in parenchyma thyroid (intra-thyroid parathyroid?)'. Three months after surgery he's treated with 1 g of calcium carbonate $(3+3+3)$ and 0.25 µg calcitriol $(1+0+1)$, with PTH 139 pg/ml, calcium 8.2 mg/dl, and phosphorus 2.6 mg/dl.
Conclusions
In this patient despite scintigraphy suspicion of a functioning parathyroid adenoma, since it is a tertiary hyperparathyroidism, we chose surgical exploration with resection of all parathyroid glands. It was found a fifth focus of parathyroid tissue within an ectopic thyroid tissue. This case presents the association of three relatively rare situations: supernumerary parathyroid gland, in thyroid tissue in an ectopic location.

Anti-diabetic treatment as an additional factor in a FRAX based evaluation of osteoporotic fracture risk

Maria P Yavropoulou, Athanasios Mousiolis, Vasiliki Kolokouri, Pelagia Kolimpianaki, Athina Dimitriou, Petros Papalexis, Michael Daniilidis & Kalliopi Kotsa
Department of Endocrinology and Diabetes, AHEPA University Hospital, Thessaloniki, Greece.

Background
The present study is designed to assess the incidence of osteoporotic fractures and the associated risk factors and particularly those used to predict the 10-year fracture risk in FRAX score based on data gathered in general practitioner's records of rural Greece.
Patients and methods
We conducted a retrospective analysis of all patients with osteoporosis presented between October 2013 and December 2014. Data from medical records including gender, age, previous history of low energy fractures (spine, and distal radius), past medical history, and medication use with specific reference to treatment with bisphosphonates and glucocorticoids were obtained. Patients with metabolic bone disease other than osteoporosis were excluded from the final analysis.
Results
One hundred and sixty seven patients (127 women and 40 men) aged between 44 and 90 years old were included in the final analysis. Twenty-seven percent of the study population ($n=45$) had sustained a low energy fracture and only 43% of them had received anti-osteoporosis treatment. Regarding concomitant medications only anti-diabetic treatment was significantly associated with the presence of osteoporotic fracture ($F=4.260$, $P=0.042$), and had a considerable effect on the 10-year risk of major osteoporotic and hip fractures in drug-naïve patients.
Conclusion
Anti-diabetic treatment should be taken into consideration when evaluating fracture risk in osteoporotic patients.

EP301

A giant parathyroid cyst manifesting with a neck mass and hypercalcaemic crisis

Fotini Adamidou, Christina Manani, Vassilis Champidis, Panagiotis Anagnostis, Apostolos Kambaroudis & Marina Kita
Hippokration General Hospital, 49 Konstantinoupoleos Street, Thessaloniki 54642, Greece.

Introduction
Functional parathyroid cysts represent an uncommon cause of primary hyperparathyroidism (PHPT) and an even rarer cause of a cervical mass.
Case report
A 57-year-old woman was referred to our department following emergency treatment of hypercalcaemic crisis (serum calcium 16.4 mg/dl) with i.v. hydration and zoledronic acid. She was found to have multiple vertebral fractures by plain radiographs one month previously. Despite being diagnosed and treated with cinacalcet for PHPT for a year prior to these events and a neck mass was noted, it was considered a cystic thyroid nodule. At presentation she had generalized weakness and left-sided neck discomfort with pressure symptoms. Her corrected serum calcium was 13.1 mg/dl, phosphate 0.9 mg/dl, PTH 330 pg/ml, alkaline phosphatase 260 (ULN 220 U/l), and kidney function was normal. Past history was notable for partial thyroidectomy in the 1970s. On examination, a firm, fixed cervical mass was palpable from the sternal notch to the jaw angle. On ultrasound, the mass was cystic with various septa and measured $9\times4\times4$ cm. Needle aspiration of the cyst evacuated 45 ml of hemorrhagic fluid, with PTH washout levels measuring 570 pg/ml. Within the next 2 weeks, a hematoma formed that resolved uneventfully, but the cyst recurred almost to its original dimensions, again causing local pressure. At surgery, the cyst measured $6.4\times4\times4$ cm and histology was consistent with hemorrhagic cystic necrosis of parathyroid adenoma surrounded by an intact thick (0.2–0.5 cm) fibrous capsule without evidence of local invasion. Postoperatively, serum calcium and phosphate were 8.6 and 3.8 mg/dl respectively. The patient remains normocalcemic on calcium and vitamin D supplementation 9 months after surgery.
Conclusion
This case highlights that a large functional parathyroid cyst can elude diagnosis because of its rarity; however, early identification is crucial for proper patient management.

Observational study of PTH secretion dynamics in patients with secondary hyperparathyroidism

Natalia Karlovich
Belarusian State Medical University, Minsk, Belarus.

The aim was to analyse dynamics of PTH secretion in dialysis patients during different period of observation and to determine factors of secondary hyperparathyroidism progression. We examined 92 patients, 52f, 40m; age 47.2 ± 11.4 years; dialysis duration 4.9 ± 3.9 years; mean observational period 8.9 ± 4.3 months (6–24). Serum PTH, 25(OH)D3, osteocalcin (OC), C-terminal telopeptide of type I collagen (β-CTx), alkaline phosphotase (ALP), calcium (Ca), and phosphorus (P) were measured initially and at the end of observation. All patients were recommended to follow low-phosphate diet and 74.4% received calcium carbonate. PTH level was 559.6 ± 552.5 initially and 603.9 ± 581.6 pg/ml at the end of observation, $P=0.251$. Frequency of high, normal uremic and low PTH levels was 55.4% vs 57.6%, 20.7% vs 21.7% and 23.9% vs 20.7% respectively ($P>0.05$). P decreased from 2.34 ± 0.67 to 2.14 ± 0.60 mmol/l, $P=0.0003$. In patients with initial hypercalcaemia PTH increased from 525.3 ± 518.4 to 616.2 ± 606.2 pg/ml, $P=0.03$. PTH level at the end of observation correlate with age ($r=-0.25$), OC ($r=0.58$), β-CTx ($r=0.76$), and ALP ($r=0.40$). Strong correlation was found with the initial PTH ($r=0.84$). At the end of observation PTH decreased in 40 patients (43.5%), mean decrease 204.6 ± 250.1 pg/ml; increased in 52 patients (56.5%), mean increase 235.6 ± 274.5 pg/ml. Subgroups with decreased and increased PTH didn't show differences of demographic data, levels of Ca, P, and bone turnover markers. Comparison of initial and repeated PTH level in subgroups with duration of observation 6, 9, 12, and >12 months didn't reveal significant changes. We can assume that in dialysis patients with stable parameters of Ca, P, and bone turnover markers in the absence of therapeutic intervention of secondary hyperparathyroidism PTH level remains unchanged during period of observation up to 12 months and even more. In such patients reasonable interval of PTH measurement should be 6–12 months. Initial level of PTH is the most important predictor of parathyroid function dynamics. Young age, high Ca, P, and bone turnover markers levels are another factors influencing secondary hyperparathyroidism progression.

Fragility fractures as the initial manifestation of indolent systemic mastocytosis

Evangeline Vassilatou[1], Nickolas Gavoyiannakis[3], Alexia Chatzipetrou[3], Christoforos Koulias[3], Michael Makris[3], Eustathios Garoflos[1], Dimitrios Hadjidakis[1,2], Dimitrios Rigopoulos[4] & George Dimitriadis[2]
[1]Endocrine Unit, 2nd Department of Internal Medicine–Propaedeutic, 'Attikon' University Hospital, Athens, Greece; [2]2nd Department of Internal Medicine–Propaedeutic, 'Attikon' University Hospital, Athens, Greece; [3]Mastocytosis Outpatient Clinic, Allergy Unit 'D. Kalogeromitros', 2nd Department of Dermatology and Venereology, 'Attikon' University Hospital, Athens, Greece; [4]2nd Department of Dermatology and Venereology, 'Attikon' University Hospital, Athens, Greece.

Introduction
Systemic mastocytosis (SM) is a rare disorder characterised by clonal proliferation of abnormal mast cells in several tissues, most often skin and bone marrow. Indolent systemic mastocytosis (ISM) is the commonest disease variant in adults, characterised by very low rate of mast cell proliferation. SM has been recognised as a cause of secondary osteoporosis.
Objective
To evaluate bone mineral density and fragility fractures in ISM patients.
Methods
Fourteen patients (nine women and seven premenopausal), aged 27–63 years (43.4 ± 11.8) diagnosed according to World Health Organization criteria were studied retrospectively. Clinical and biochemical data and bone mineral density (BMD) measurements by dual X-ray absorptiometry at the lumbar spine, the total proximal femur and the lower one-third radius were analysed. *T*-score was used to define osteopenia (<-1 to >-2.5 S.D.) or osteoporosis (-2.5 S.D. or lower) in postmenopausal women or men older than 50 years, and *z*-score <-2.0 for low BMD in younger men and premenopausal women, according to the International Society for Clinical Bone Densitometry. No patient reported other diseases or use of treatments known to affect bone or mineral metabolism, at initial assessment.
Results
Two patients (14.3%) had osteoporosis, two patients (14.3%) had osteopenia and seven patients (50%) had low BMD. BMD was generally lower at the spine than at the hip. Three patients (21.4%) reported fragility fractures: a 43-year-old premenopausal woman and a 38-year-old man had vertebral fractures, while a 31-year-old premenopausal woman had non-vertebral fractures. None of the patients with fragility fractures had cutaneous mastocytosis and only one of them reported a mild episode of anaphylaxis.
Conclusion
Bone involvement is frequent in ISM patients and may be the initial manifestation. Osteoporotic fractures of unknown aetiology should lead to the suspicion of SM particularly in individuals younger than 50 years.

Evaluation of clinical and biochemical features of patients with atypical parathyroid adenoma: a retrospective study

Sefika Burcak Polat[1], Mehmet Kilic[2], Cevdet Aydin[1], Didem Ozdemir[1], Nuran Sungu[3], Reyhan Ersoy[1] & Bekir Cakir[1]
[1]Endocrinology and Metabolism Department, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey; [2]General Surgery Department, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey; [3]Pathology Department, Ataturk Education and Research Hospital, Yildirim Beyazit University, Ankara, Turkey.

Introduction
Primary hyperparatyhyroidism (PHPT) is usually caused by single or multiple adenomas and cancer is rare accounting for $<1\%$ of all presentations. The presence of certain cytological and architectural features such as adherence to adjacent organs, a solid growth pattern, broad bands of fibrosis, cytological atypia, and an irregular growth contour do not indicate malignancy but are recognised as atypical features encountered more commonly in malignant than benign tumours. Tumours that demonstrate these atypical features and do not fulfill criteria for carcinoma can be classified as atypical adenomas. Herein we aimed to evaluate the clinical and biochemical features of the patients histopathologically diagnosed with an atypical parathyroid adenoma.

Method
Our endocrine database was searched retrospectively for the patients with operated PHPT and diagnosed with atypical adenoma. Demographic, clinical, and biochemical data of the patients were recorded. A control group was formed from the patients who were also operated with the diagnosis of PHPT and classical parathyroid adenoma was detected histopathologically.
Results
There were 16 patients in the atypical adenoma group and thirty patients in the control group. Age and gender distribution of the patients were similar in between groups with female predominance. Serum Ca and P levels were also similar where as preoperative serum PTH, ALP, and urinary Ca excretion were significantly higher in patients with atypical adenoma ($P<0.001$, $P<0.001$, and $P=0.021$ respectively). Adenoma size was significantly higher in the atypical adenoma group compared to controls ($P=0.006$) and cystic degeneration and isoechoic appearance on USG were more prevalent among the atypical adenomas ($P=0.016$).
Conclusion
Preoperatively high PTH, ALP, and urinary Ca levels may be predictive for atypical adenoma or carcinoma within a patient being evaluated for PHPT. The surgeon might prefer enbloc parathyroidectomy instead of minimal invasive surgery in such cases with more strict postoperative follow up.

Investigation of the relationship between type 2 diabetes and osteoporosis

Nada Boughanmi, Sonia Rekik, Hela Sahli, Elhem Cheour & Mohamed Elleuch
La Rabta Hospital, Tunis, Tunisia.

Introduction
Diabetes is often associated with complications and comorbidities. Osteoporosis (OP) is increasingly recognised as a significant comorbidity of type 2 diabetes mellitus (T2DM). The aim of this study was to determine the prevalence of OP in postmenopausal women with T2DM and to assess the association between T2DM and bone mineral density (BMD).
Methods
This cross-sectional study was carried out in 50 postmenopausal women with type T2DM and 50 age-matched non-diabetic women. Medical and lifestyle characteristics were recorded. BMD was measured in lumbar spine and femoral neck by dual-energy X-ray absorptiometry.
Results
Prevalence of OP in subjects with T2DM was 48%, whereas 30% of the non-diabetic subjects had OP ($P=0.002$). Patients with lumbar and/or hip osteoporosis were older ($P=0.004$), had a lower BMI ($P<0.001$) and had a longer duration of disease ($P<0.001$). BMD at the hip was positively correlated with BMI ($P<0.001$). Age ($P=0.004$), duration of diabetes ($P<0.001$), mean HbA1c levels ($P=0.01$), the presence of retinopathy ($P=0.04$) were negatively associated with BMD at the hip and lumbar spine. No correlation was found between BMD and presence of microalbuminuria, neuropathy, peripheral artery disease, cerebrovascular event, and coronary artery disease.
Conclusion
We found a high prevalence of osteoporosis in postmenopausal women with T2DM. The insufficiency of insulin and the decreased insulin sensitivity are important causes for OP in the patients with T2DM.

Intraoperative parathyroid hormone monitoring during parathyroidectomy: description of our clinical experience

Mariana Tomé[1], Guillermo Martinez De Pinillos[2], Mariola Méndez[2], Eyvée Arturo Cuéllar[2], Fernando García[2], Ignacio Fernández López[2], Ignacio Fernández Peña[2], Juan Manuel García De Quirós[2], Juana Hidalgo[2], Margarita Rivas[2], Santiago Durán[2] & Maria Victoria Cózar[2]
[1]Hospital Punta De Europa, Algeciras, Spain; [2]Valme University Hospital, Sevilla, Spain.

Introduction
Primary hyperparathyroidism is caused by a single adenoma in 85% of cases. This is why bilateral neck exploration seems to be a very aggressive procedure in a large number of cases. Intraoperative parathyroid hormone (IOPTH) monitoring could be a useful tool in primary hyperparathyroidism surgery allowing a less invasive surgical approach. The aim of our study is to evaluate the possible impact of the measurement of IOPTH during surgery.
Methods
Retrospective study in which we included all patients who underwent parathyroidectomy with IOPTH monitoring between 2008 and 2013. We considered the following variables: preoperative localization techniques; neck exploration (uni or bilateral); prediction of curative parathyroid resection by using MIAMI criteria (>50% drop from highest baseline IOPTH level at 10 min after excision) and cure (normal calcaemia 6 months after surgery). Subsequently, we compared this sample with a group of patients who underwent parathyroidectomy between 2000 and 2002 without IOPTH monitoring.
Results
We studied 115 patients (80.9% females; mean age 57.4 ± 14.1 years). In most cases Technetium-99m-sestamibi scintigraphy was the preferred localization technique (97.4% of patients) with positive result in 76.8% of scintigraphies. 76.5% of patients underwent unilateral neck exploration (100% of them were cured). Following MIAMI criteria we were able to predict curative resection in 97.2% of these patients. 93.9% of the total sample were cured after surgery. We compared this results with a series of 35 patients without IOPTH monitoring (74.3% females, 58.51 ± 9.1 years). We did not find significant differences in cure (93.9% vs 91.4%, $P=0.61$). However, in the second group 100% of patients underwent bilateral neck exploration (23.5% in IOPTH group, $P=0.0005$).
Conclusion
By monitoring IOPTH in focused parathyroidectomy it is possible to perform a less invasive surgical approach without reduction in cure rate.

Hypercalcaemia in patient with primary hyperparathyroidism and acromegaly

Gordana Pemovska[1], Cvetanka Volkanovska Ilijevska[2] & Brankica Krstevska[1]
[1]Medical Faculty, University Clinic of Endocrinology, Diabetes and Metabolic Diseases, Skopje, Macedonia; [2]General City Hospital 8-mi Septemvri, Skopje, Macedonia.

Introduction
Hypercalcaemia in acromegaly can be a result of several pathophysiological mechanisms. Multiple endocrine neoplasia type 1 (MEN1) syndrome, mitogenic effect of hyperactivated GH–parathyroid gland axis, i.e. primary hyperparathyroidism and hypercalcaemia mediated by elevated 1,25-dihydroxyvitamin D should be considered.
Case report
We describe a case of acromegaly associated with primary hyperparathyroidism. A 52-year-old female was diagnosed with acromegaly due to GH secreting pituitary microadenoma. Evaluation at diagnosis showed normal levels of hormones other than GH and IGF1, and presence of hypertension and multinodular goiter (volume 80 mm^3). Because the patient denied surgery, treatment with cabergoline was administrated and a biochemical control was accomplished.
Within 1 year of the diagnosis laboratory data showed hypercalcaemia (serum calcium 1.51 mmol/l (1.10–1.40)) in the setting of elevated parathormone (PTH) levels (158 pg/ml (15–65)) and low levels of vitamin D (5.6 nmol/l (>25)). Bone densitometry detected osteoporosis limited to the right radius (*T* score value −4.0 S.D.). Analysis of 24-h urine showed normal calcium and phosphate excretion. This findings were consistent with diagnosis of primary hyperparathyroidism. Imaging and radioisotope studies identified enlarged thyroid gland, predominantly the left lobe with consequent tracheal compression, and higher radioisotope uptake in the lower pole of the left thyroid lobe. Surgical excision of left lower parathyroid gland and subtotal thyroidectomy was done. Histopathological examination confirmed hyperplasia of parathyroid and thyroid gland. After surgery, serum calcium normalised, PTH levels significantly reduced to 73.2 pg/ml. Vitamin D remained low (17.8 nmol/l) and TSH levels elevated to 27 mU/l (0.4–4) for which vitamin D and levothyroxine substitution was started.

Conclusion
The approach to hypercalcaemia in the course of acromegaly implies evaluation for several potential pathophysiological mechanisms, which in turn dictates the treatment strategy – parathyroidectomy vs biochemical control of acromegaly.

The value of intraoperative sonographic evaluation of neck in primary hyperparathyroidsm: case report of preoperative double adenoma upgraded to triple intraoperatively

Fatih Kuzu[1], Dilek Arpaci[1], Guldeniz Karadeniz Cakmak[2], Rabia Uslu Erdemir[3], Mehmet Cabuk[3], Sevil Ilikhan Uygun[4] & Taner Bayraktaroglu[1]
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Faculty of Medicine, Bulent Ecevit University, Zonguldak, Turkey; [2]Department of General Surgery, Faculty of Medicine, Bulent Ecevit University, Zonguldak, Turkey; [3]Deparment of Nuclear Medicine, Faculty of Medicine, Bulent Ecevit University, Zonguldak, Turkey; [4]Department of Internal Medicine, Faculty of Medicine, Bulent Ecevit University, Zonguldak, Turkey.

Background
Primary hyperparathyroidism (PHPT), caused by increased parathyroid hormone (PTH) secretion, leads to generalised disorder of bone metabolism characterised with hypercalcaemia and hypophosphatemia. Causes of PHPT include solitary parathyroid adenoma (80%), primary parathyroid hyperplasia (10–15%), and parathyroid carcinoma (1–2%). Other rare cause is double parathyroid adenomas (DPA) with frequency <1–2%, which can be sporadic or familial. DPA should be considered for persistent or recurrent PHTP cases.
Case report
A 45-year-old female patient with type 2 diabetes was admitted with weakness, fatigue, and generalized bone pain. She had a history nephrolithaisis five times in the last 2 years. In laboratory examination, serum calcium level was 12.3 mg/dl (8.8–10.6), phosphorus level was 2.9 mg/dl (2.4–5.1), albumin level was 4.1 g/dl (3.5–5.3), PTH level was 237 pg/ml (12–88), alkaline phosphatase was 99 IU/l (60–105 IU/l), 25-OH vitamin D level was 6.4 ng/ml (20–30 ng/ml), 24-h urine calcium was 483 mg/day, creatinine clearance was 75 ml/min, and prolactin level was 26 ng/ml (5–26 ng/ml). I.v. saline and furosemide treatment was administered. Bone densitometry measurement was showed osteoporosis. Neck ultrasound imaging revealed no abnormality in the thyroid gland with bilateral smooth, ovoid, hypoechoic lesion considered parathyroid adenomas at inferior contiguity of thyroid gland in size of $15\times11\times8$ mm on the right and $18\times12\times7$ mm on the left side. Tc99m-MIBI scan detected parathyroid adenoma in the lower part of the left thyroid lobe consistent with radioactivity uptake, while in the lower part of the right thyroid was suspicious. PTH level from fine needle aspiration material of parathyroid washout was measured 2097 pg/ml from the right side and 1989 pg/ml from left side. Hence, bilateral minimally invasive parathyroidectomy was intended to be performed, but the surgeon saw a third adenoma at retrosternal location by using intraoperative ultrasonography (US), all were removed and pathology report was consistent with parathyroid adenoma.
Conclusion
Intraoperative parathyroid evaluation by US plays an important role preventing patient from unnecessary surgery.

Parathyroid hormone therapy for postoperative resistant hypocalcaemia

Safak Akin, Miyase Bayraktar & Alper Gurlek
Deparment of Endocrinology and Metabolism, Faculty of Medicine, Hacettepe University, Ankara, Turkey.

Introduction
No consensus guideline on the treatment of hypoparathyroidism. Hypoparathyroidism is a disease characterized by hypocalcaemia and insufficient PTH. Conventional therapy includes calcium and active vitamin D supplementation, often in large doses.
Case report
A 31-year-old woman presented with hypercalcemia. Serum calcium and phosphorus levels were 10.5 and 2.56 mg/dl respectively. The serum PTH level was increased (1619 pg/ml). The serum 25-OH vitamin D level was decreased (3.5 ng/ml). Her past medical history revealed osteoporosis (femur T score -4.0). Parathyroid USG showed left and right parathyroid adenomas. Double adenoma excision from left and right inferior sites and total thyroidectomy was performed. On pathological examination of thyroid was benign thyroid nodules. Double parathyroid adenomas was identified. Postoperative serum calcium level was 5.5 mg/dl. She recieved daily calcium gluconate infusions. Discharge with calcitriol and $CaCO_3$ with latest calcium level was 6 mg/dl. During follow-up, she was taken to internal medicine ward with symtomatic hypocalcaemia. Serum calcium, phosphorus, PTH, and 25-OH vitamin D levels were 5.2 mg/dl, 3.2 mg/dl, <3 pg/ml, and 5 ng/ml respectively. The doses were progressively increased up to 12 μg/day calcitriol. Under this tretatment serum calcium level was 6.9 mg/dl. Phosphorus level was 3.8 mg/dl. Follow-up, 20 μg teriparatide b.i.d. was added to the treatment. She has used teriparatide for a period of 10 months. At the end of teriparatide treatment, calcitriol reduced to 4.5 μg/day and calcimax D3 reduced 3×1 tb. Final control visit her calcium level was 8.5 mg/dl and phosphorus level was 4.1 mg/dl while taking calcitirol dose of 3.5 μg/day and calcimax D3 dose of 2×2 tb.
Conclusion
In our postoperative hypocalcaemic case, calcitriol dose reduced and calcium level increased after the teriparatide treatment. Teriparatide may be useful in postoperative resistant hypocalcaemia.

Vitamin D deficiency and bone health in patients with learning disability

Abbi Lulsegged[1], Nataliya Zuyeva[1] & Rob Winterhalder[2]
[1]Kings College Hospital NHS Foundation Trust, Farnborough, Kent, UK; [2]Oxleas NHS Foundation Trust, Farnborough, Kent, UK.

There is limited data on vitamin D status in patients with learning disabilities. As a group they possess multiple risk factors for vitamin D deficiency including limited access to sunlight, problems with mobility and anticonvulsant use. We reviewed the data for 105 patients with learning disabilities grouped according to the severity of learning disability (profound, severe, moderate, and mild). Data was available on vitamin D and calcium levels, dose of vitamin D3 needed to correct the vitamin D deficiency with the aim of correcting above a minimum target level of 80 nmol/l or 32 μg/l. There was a very weak negative correlation between baseline 25-vitamin D levels and the degree of learning disability ($r=-0.14$). There was no significant difference between the four groups before treatment, however there was a clear trend of higher vitamin D levels with a significantly higher post treatment vitamin D level in the profound learning disability group compared to those mild deficiency. The average dose of vitamin D3 needed to increase the vitamin D level above 80 nmol/l was 1945 units daily. Our data shows that in a group of patients with significant risk factors of vitamin D deficiency, the average dose of vitamin D needed to correct deficiency was on average a modest dose given the need for anticonvulsants. Indeed the response to treatment was greatest in the group who had the most profound disability.

Primary hyperparathyroidism presented as humeral brown tumor and multiple bone fractures

Lia Ferreira, Pedro Gomes, Pedro Cardoso, Vitor Valente, Ana Amado, Maria Teresa Pereira, Susana Garrido, Raquel Almeida, Cláudia Freitas, Cláudia Amaral, Isabel Palma & Fátima Borges
Centro Hospitalar do Porto, Porto, Portugal.

Primary hyperparathyroidism (PHPT) is frequently diagnosed as an incidental finding of hypercalcemia. Overt bone disease (osteitis fibrosa cystica or brown tumor), with history of pathologic fractures is a rare presentation.
A 48-year-old woman was admitted in with pain in the right thigh after a trivial fall. She also complained of generalized weakness and lethargy over the last 2 years. Her medical history mention multiple bone fractures in the last 6 years, namely left patella, both wrists and 4 years before surgery to lytic lesion of the right humerus, assumed as aneurysmal bone cyst. Her last follow-up CT, revealed recurrence of lytic lesion and she was propose to shoulder arthroplasty.
Plain X-rays and CTs revealed pathologic fracture of the right femur, multiple osteolytic lesions (right humerus, right femur, both shoulder blades and iliac bones), subperiosteal erosions in the distal phalanges and old fractures in the ribs. Bone scan showed increased uptakes over the right humerus, right femur and tibias. Femur fracture was managed with osteosynthesis and humeral biopsy documented multiple giant cells consistent with brown tumor of PHPT.
Analysis revealed severe PHPT (serum calcium 3.49 mmol/l, phosphorus 0.53 mmol/l, and PTH 1435 pg/ml). Ultrasound showed an $5.8\times3.9\times2.4$ cm mixed texture lesion in the left superior parathyroid and sestamibi scanning confirmed a left parathyroid adenoma, with a necrotic centre and bone uptakes coincident with previous bone scan.
Considering patient's age and high level of PTH, chest–abdomen CT were performed to excluded metastatic disease. Hereditary cancer syndromes were also excluded. Treatment was initiated with hydration and zolendronic acid and parathyroidectomy was perform. Histopathology confirmed the diagnosis of parathyroid adenoma. Hungry bone syndrome developed following surgery and was necessary treatment with calcium carbonate and alfacalcidol.
Conclusion
Pathological fractures in young adults should always be investigated. A high index of suspicion is necessary to diagnose this unusual presentation of PHPT.

EP312

Comparative diagnostic value of ultrasound, ultrasound-guided fine needle aspiration and sestamibi scintigraphy for the correct preoperative localisation of parathyroid adenomas

Stefan Bilz[1], Nathalie Rogowski-Lehmann[1], Ina Krull[1], Michael Brändle[1], Rene Oettli[3], Walter Kolb[2] & Thomas Clerici[2]
[1]Division of Endocrinology, Department of Internal Medicine, Kantonsspital, St Gallen, Switzerland; [2]Department of Surgery, Kantonsspital, St Gallen, Switzerland; [3]Division of Radiology and Nuclear Medicine, Kantonsspital, St Gallen, Switzerland.

Background
This study prospectively assessed the sensitivity and positive predictive value (PPV) of ultrasound (US), ultrasound-guided fine needle aspiration with PTH measurement in the needle washout (US-FNA) and sestamibi scintigraphy (SS) for the localisation of parathyroid adenomas in patients with primary hyperparathyroidism (pHPT) and features of uniglandular disease.
Methods
51 consecutive patients with pHPT referred for first time surgery with an open minimally invasive approach (OMIP) were included. US and US-FNA and double isotope scanning with 99mTc pertechnetate and 99mTc sestamibi were performed in all patients. A localisation procedure was considered correct if surgical removal of a parathyroid gland at this.
Results
The sensitivities for correctly identifying the localisation of a hyperfunctioning adenoma were 65% (SS), 91% (US) and 68% (US-FNA).The respective PPVs were 94% (SS), 89% (US) and 96% (US-FNA). US and SS were consistent in 64%. The majority of the inconsistent studies were attributable to false-negative SS (22%). In US negative cases or if the lesion identified by ultrasound is very small (<0.25 ml), the addition of scintigraphy allowed the correct preoperative location of an adenoma in 39%. 47% of small US lesions (<0.25 ml) were correctly classified by US-FNA. 96% of the patients were cured following first surgery and and unilateral approach was succesful in 84%.Hemorrhagic and/or fibrotic changes following US-FNA were detectable intraoperatively in 28% and complicated surgery in three cases.
Conclusion
Preoperative localisation with US, SS and US-FNA allows a minimal/unilateral surgical approach in 84% of the patients. Ultrasound is significantly more sensitive and accurate than SS and US-FNA, which have a high PPV. The performance of all localisation procedures decreases in parallel to adenoma size, with ultrasound still remaining most sensitive. US-FNA, although highly specific, is complicated by a relatively high rate of haemorrhagic and/or fibrotic changes in the biopsied adenoma and should be used cautiously.

The effects of single high dose vs daily low dose oral cholecalciferol treatment on vitamin D levels and muscle strenght in posmenapousal women

Mahmut Apaydin[1], Asli Gencay Can[3], Seyfullah Kan[1], Selvihan Beysel[1], Taner Demirci[1], Mustafa Caliskan[1], Muhammed Kizilgul[1], Ozgur Ozcelik[1], Muyesser Sayki Arslan[1], Mustafa Ozbek[1], Erman Cakal[1] & Tuncay Delibasi[1,2]
[1]Department of Endocrinology and Metabolism, Diskapi Yildirim Beyazit Teaching and Research Hospital, Ankara, Turkey; [2]Department of Internal Medicine, School of Medicine (Kastamonu), Hacettepe University, Ankara, Turkey; [3]Department of Physical Medicine and Rehabilitation, Diskapi Yildirim Beyazit Teaching and Research Hospital, Ankara, Turkey.

Introduction
Vitamin D deficiency is a common health problem. Vitamin D supplements are used to improve vitamin D status. However, there are few data about what doses to give and how often to give. The aim of this study is to determine the effects of single high dose or daily low dose oral cholecalciferol (vitamin D_3) on vitamin D levels and muscle strenght.
Methods and design
60 healthy postmenouposal women who had serum vitamin D levels were <20 ng/ml were enrolled in the study in the winter and spring of 2013–2014. First group ($n=32$) was given daily oral doses of 800 IU vitamin D_3, second group ($n=28$) was given single oral dose of 300 000 IU vitamin D_3. Serum vitamin D levels and muscle strengths were measured at the beginnig, 4th and 12th weeks. Muscle strength tests were performed at 60°s with Biodex system 3 isokinetic dynamometer.
Results
The mean vitamin D levels of first and second group at the beginnig were 10.2 ± 4.4 ng/ml; 9.7 ± 4.4 ng/ml ($P=0.637$), respectively. Significant increase in vitamin D levels was measured in both two groups at 4 and 12 weeks after vitamin D_3 treatment. At 4th week the increase in single dose of vitamin D_3 group (16.9 ± 5.8 ng/ml) (35.9 ± 9.6 ng/ml) was significantly higher than the daily low dose oral vitamin D_3 group (35.9 ± 9.6) (16.9 ± 5.8 ng/ml) ($P=0.01$). At 12th week the increase in single dose of vitamin D3 group (19.8 ± 7.2 ng/ml) (23.4 ± 4.7 ng/ml) was significantly higher than the daily low dose oral vitamin D_3 group (23.4 ± 4.7) (19.8 ± 7.2 ng/ml) ($P=0.049$). Quadriceps muscle strength score increased significantly in daily group at 4th week ($P=0.038$). Hamstring muscle strength score increase significantly in daily group at 12th week ($P=0.037$).
Conclusion
Although daily administration routes are effective in muscle strength, single administration is more effective in increasing vitamin D levels.

Idiopathic hypercalcaemia in pregnancy not due to PTHrP: suggestion for another pathomechanism by genetic defect of 24-hydroxylase

Csaba Horvath[1], Szilvia Meszaros[1], Orsolya Acs[2], Eva Hosszu[2], Julia Nemeth[3], Emoke Csupor[4], Miklos Szathmari[1], Nandor Acs[5] & Eugene V McCloskey[6]
[1]1st Department of Internal Medicine, Semmelweis University, Budapest, Hungary; [2]2nd Department of Pediatrics, Semmelweis University, Budapest, Hungary; [3]Synlab Hungary, Budaors, Hungary; [4]Budavar Endocrine Center, Budapest, Hungary; [5]2nd Department of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary; [6]Centre for Metabolic Bone Diseases, Sheffield University, Sheffield, UK.

A 32-year-old women initially presented with recurrent kidney stones and was found to have nephrocalcinosis. She was found to normocalcaemic but hypercalciuric, with a plasma ionized calcium at upper-limit of normal and a PTH in lower normal range. One year later, during the first trimester of a pregnancy, she presented with severe hypercalcaemia, hypercalciuria and suppression of PTH. Extensive investigations for causes of hypercalcaemia excluded hyperparathyroidism, other endocrine diseases, hematologic or other malignancies, granuomatous diseases, renal tubular acidosis and milk-alkali syndrome. Plasma PTHrP was suppressed. She had not taken any form of vitamin D, however, her serum level of 25OHD3 was normal throughout the pregnancy (even in wintertime) and the serum level of 1,25(OH)2D was elevated. Continuous high oral and parenteral fluid intake resulted in a moderate decrease of hypercalcaemia and no change in hypercalciuria. At 35 weeks a healthy boy was born with a transient hypercalcaemia that normalized spontaneously within a few days. The maternal hypercalcaemia decreased but remained above reference range with continuing suppression of PTH. Disturbed vitamin D metabolism, especially a reduction in 24-hydroxylation by genetic mutations has been observed in familial cases of nephrocalcinosis and in infants with idiopathic hypercalcaemia after usual doses of vitamin D supplementation. We hypothesise that our patient had an insufficient 24-hydroxylation in the kidney and it has been intensified during pregnancy by the placenta as a well-known site of vitamin D activation for local immune purposes. If this is the case, then our patient could be the first one in whom the defective 24-hydroxylation produces hypercalcaemia without provocative effect of external vitamin D stimulation. To prove this hypothesis, the genetic analysis of mutations in CYP24A1 gene will be performed.

The peripheral serotonin, the serum osteocalcin and CrossLaps: the assay in menopausal women

Mara Carsote[1,2], Cristina Capatina[1,2], Andra Caragheorgheopol[2], Dan Peretianu[3], Dana Manda[2], Rene Baloescu[2], Ana Maria Stefanescu[2], Diana Paun[1,2] & Catalina Poiana[1,2]
[1]C.Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]C.I.Parhon National Institute of Endocrinology, Bucharest, Romania; [3]SCM Povernei Medical Centre, Bucharest, Romania.

Introduction
17th European Congress of Endocrinology 2015. The skeleton health is reflected by the turnover markers as serum CrossLaps (CL = bone resorption), and serum osteocalcin (OC = bone formation), and by the calcium metabolism parameters (as ionic blood calcium, and, probably, by the 24-h urinary calcium = 24-h ca). The peripheral serotonin might have intra-normal levels in patients with osteoporosis but yet represents a part of the complex equation related to the bone homeostasis.
Aim
we analysed the bone parameters, including serotonin in relationship to the bone loss as reflected by central DXA.
Material and method
This is a transversal study in menopausal women, starting from 2009 up to the present. No patient with active neoplasia or with tumours history (including primary hyperparathyroidism) was included. The patients with osteoporosis or anti-resorptive therapy for osteoporosis were also excluded. The lumbar DXA (Prodigy) provided the bone mineral density (BMD), and the WHO criteria allowed the including the patients into the osteopenia or the normal group. The blood assay were ionic calcium, OC, CL (ELISA kit), serotonin (ELISA), parathormon (PTH), 25-hydroxy vitamin D or 25OHD, (chemiluminescence), the urinary assay was 24-h ca. Statistical significance (SS) was considered at $P < 0.05$.
Results
55 women had osteopenia ($N1 = 22$), and normal DXA ($N2 = 33$). The ionic calcium was not SS different between the two groups (4.02 vs 3.92 mg/dl, $P = 0.23$), neither PTH (42.6 vs 44.6 pg/ml, $P = 0.5$), serotonin (155.36 vs 166.9 ng/ml, normal < 440 ng/ml, $P = 0.55$), 24-ur ca (0.14 vs 0.18 ng/ml, $P = 0.19$), 25OHD (14.64 vs 13.52 ng/ml, $P = 0.5$). BC, and OC are SS higher in osteopenia group vs normal: 0.49 vs 0.38 ng/ml ($P = 0.05$), respective 25.68 vs 17.73 ng/ml ($P < 0.005$).
Conclusion
Based on our observations, the bone turnover markers are higher in women with osteopenia vs normal, while the serotonin, or the calcium (regardless urinary or serum) and PTH are similar. Overall, a high prevalence of low 25-hydroxy vitamin D levels is found in menopause.

Vitamin D deficiency in acutely ill patients

Ifigenia Kostoglou-Athanassiou[1], Eleni Pantazi[2], Iordanis Mavropoulos[2], Ourania Skioti[2], Georgios Katsoulis[2], Dimitrios Kousouris[3] & Socrates Kontogiannis[3]
[1]Department of Endocrinology, Red Cross Hospital, Athens, Greece; [2]2nd Department of Endocrinology, Alexandra Hospital, Athens, Greece; [3]Acute Care Unit, Department of Internal Medicine, Alexandra Hospital, Athens, Greece.

Introduction
Vitamin D deficiency has been reported to be widely found within the population. Vitamin D deficiency was also found to be prevalent in patients with autoimmune inflammatory diseases such as rheumatoid arthritis and systemic lupus erythematosus. Vitamin D deficiency was reported in almost all patients with acute myocardial infarction in a US multicenter study. Low concentrations of 25-hydroxyvitamin D (25(OH)D) are reported to be an independent risk factor for cardiovascular events, in particular for strokes and sudden cardiac deaths.
Aim
The aim was to study and report vitamin D levels in acutely ill patients being cared for in an acute care unit.
Methods
In 20 patients being cared for in an acute care unit and in 20 controls matched for age and sex $25(OH)D_3$ levels were measured. In the patient population CRP and procalcitonin were also measured. $25(OH)D_3$ was measured by RIA, normal values being 47.7–114 nmol/l.
Results
In the patients being cared for in the acute care unit $25(OH)D_3$ levels were 30.33 ± 3.63 nmol/l (mean $\pm$ S.E.M.), whereas in the controls 60.37 ± 4.41 nmol/l ($P < 0.001$, Student's t-test). In the patients being cared for in the acute care unit vitamin D deficiency or insufficiency was found 18 of the 20 patients.
Conclusions
Low vitamin D levels were found in patients hospitalised in an acute care unit. These findings are in agreement with findings of other investigators having reported low levels of vitamin D in patients with acute myocardial infarction. It has been proposed that low vitamin D levels may be a risk factor for cardiovascular events and in patients with acute myocardial infarction may predict adverse outcomes. It has also been proposed that vitamin D levels may decrease during the acute phase response, however, more studies are needed to confirm or refute this hypothesis.

DOI: 10.1530/endoabs.37.EP316

EP317

The clinical profile of primary hyperparathyroidism: a single centre experience

Eleni Pantazi[1], Ifigenia Kostoglou-Athanassiou[2], Iordanis Mavropoulos[1], Ourania Skioti[1], Georgios Katsoulis[1] & Eleni Xanthakou[3]
[1]2nd Department of Endocrinology, Alexandra Hospital, Athens, Greece; [2]Department of Endocrinology, Red Cross Hospital, Athens, Greece; [3]Endocrinologist, Sparti, Greece.

Introduction
Primary hyperparathyroidism is currently a frequent disorder. In the past primary hyperparathyroidism was diagnosed late in the course of the disease. With the introduction of routine calcium measurements, as well as the awareness of the disease amongst clinicians, the disorder is frequently recognized in asymptomatic patients. Thus, the clinical profile of primary hyperparathyroidism is changing.
Aim
The aim was to describe the clinical profile of primary hyperparathyroidism in a single hospital center in Athens, Greece.
Methods
The clinical presentation and clinical characteristics of patients with primary hyperparathyroidism being followed up in a single center in Athens are described. All patients had a complete biochemical profile. In all patients calcium, PTH and

$25(OH)D_3$ were measured. In all patients thyroid and parathyroid ultrasonography was performed, as well as, parathyroid scintigraphy for the localisation of parathyroid tumors.
Results
In a single centre in Athens 35 patients with primary hyperparathyroidism are being cared for. Within this group of 35 patients, nine had mild primary hyperparathyroidism. Within this group of patients 12 were on treatment with cinacalcet for the management of the disease, whereas eight were on treatment with alendronate.
Conclusions
Primary hyperparathyroidism is a frequent disorder nowadays. As shown in the results of this study from a single center in Athens mild hyperparathyroidism is prevalent. Cinacalcet seems to be an option for patients not willing or not able to withstand surgery. Alendronate is another option for the pharmaceutical management of primary hyperparathyroidism, a drug treatment which aims to improve osteoporosis as well as calcium levels in patients with primary hyperparathyroidism.

DOI: 10.1530/endoabs.37.EP317

EP318

Raised calcium & PTH, not always a primary hyperparathyroidism

Fareeda Tabassum, Stephanie Baldeweg & Tom Kurzawinski
University College Hospital, London, UK.

Case
A 50-years-old gentleman underwent cardiac surgery which was complicated by postoperative arrythmias and ischemic stroke. He was found to have raised calcium of 2.9 (2.2–2.6 mmol/l) subsequent to which PTH was tested and found to be raised at 34.2 (1.6–6.9 pmol/l) which increased to 41.2 pmol/l in few days. He was referred for work up and management of primary hyperparathyroidism. An USS of the neck showed 1.5 cm nodule posterior to left thyroid lobe and Sestimibi scan also showed increased tracer uptake on the left side, findings consistent with parathyroid adenoma. During the course of investigations, calcium increased to 3.4 mmol/l and he required hospital admission for acute management of hypercalcaemia. In view of cardiac history and severe hypercalcaemia, he underwent left parathyroidectomy for parathyroid adenoma but histology of the excised gland showed features consistent with Parathyroid Adenocarcinoma. He was investigated to look for metastases. The CT scan of chest and SPECT CT did not show local or distant Metastases. A repeat surgery was undertaken for left hemithyroidectomy which showed no local spread of carcinoma. The calcium and PTH normalized after the surgery until 6 months when PTH increased again up to 11.4 pmol/l but it was found to be associated with hypocalcaemia and low Vitamin D and improved with Vitamin D replacement. He has been having regular follow up and being monitored with calcium and PTH. DEXA bone scan shows improving bone density. There has been no recurrence for 6 years after the surgery.
Discussion
Parathyroid carcinoma is a rare malignancy with incidence of $<1\%$ among all hyperparathyroidism cases. There are no distinguishing features or investigations to differentiate adenoma from carcinoma. It is mostly diagnosed on histological examination of the excised parathyroid gland. Raised PTH with hypercalcaemia is usually suggestive of primary hyperparathyroidism but severe hypercalcaemia with markedly raised PTH should raise suspicion of Parathyroid Carcinoma.

Diabetes (pathiophysiology & epitemiology)

EP319

Insulin receptor substrate 1 and 2 genes polymorphisms are associated with metabolic syndrome but not cardiovascular risk factors in patients with metabolic syndrome

Fulden Sarac[1], Sefa Sarac[2], Sumru Savas[1] & Fehmi Akcicek[1]
[1]Department of Geriatrics Medicine, Izmir, Turkey; [2]Department of Cardiology, Izmir, Turkey.

Objective
The aim of our study was to investigate the relationships between insulin receptor substrat-1 (IRS-1) and insulin receptor substrat-2 (IRS-2) gene polymorphisms and cardiovascular factors such as blood pressures, BMI, LDL- cholesterol, triglyceride, HOMA-IR, homocysteine, hsCRP and fibrinogen levels in patients with metabolic syndrome (MetS).
Subjects and methods
The study population included 100 patients with MetS and 30 patients without MetS as control group. All entire coding exons of IRS-1 and IRS- 2 gene were amplified by PCR. Insulin resistance (IR) was estimated using the homeostasis model assessment (HOMA).
Results
In patients with MetS, 34 (34%) patients had G972R gene polymorphism and 66 (66%) had no nucleotide substitution at IRS-1 gene ($P<0.0001$). And, in IRS-2 gene, 44 (44%) had no nucletide substitution, 18 (18%) had G1057D heterozygous, 11 (11.0%) had G1057D homozygous, 2 (2%) had P1031P heterozygous/P1033PG1057 heterozygous, 17 (17.0%) had P1033P hererozygous, 3 (3.0%) had P1033P homozygous and 5 (5%) had P1033P heterozygous/G 1067D heterozygous polymorphisms in MetS ($P=0.0001$). However, all of control had no nucleotide substitution in IRS-1 and IRS-2 genes. There were no statistically differences between patients who had gene polymorphism and not polymorphism in IRS-1 and IRS-2 for systolic and diastolic blood pressures, BMI, LDL- cholesterol, triglyceride, HOMA-IR, homocysteine, hsCRP and fibrinogen.
Conclusion
Insulin receptor substrat 1 and 2 genes polymorphisms were associated with metabolic syndrome but not cardiovascular risk factors such as blood pressure, BMI, cholesterol, triglyceride, HOMA-IR, homocysteine, hsCRP and fibrinogen levels.

Changing of expression of NOD-like receptors in GALT of rats at an experimental diabetes mellitus and pentoxifylline administration

Alex Kamyshny & Anna Degen
Zaporozhye State Medical University, Zaporozhye, Ukraine.

Introduction
Changing of expression of pattern-recognition receptors (PRR) of innate immune response by the gut-associated lymphoid tissue (GALT) can play a critical role in an induction and progression of T1DM.
Aim
To study the peculiarities of NOD2 receptors in gut-associated lymphoid tissues (GALT) of rats with experimental STZ-induced diabetes mellitus and pentoxifylline (PTX) administration.
Methods
Researches were made on Wistar rats. For an induction of diabetes streptozotocin was used in doses 50 mg/kg. Structure of population of NOD2+ cells has been studied by the analysis of serial histological sections using the method of indirect immunofluorescense with monoclonal antibodies to NOD2 of rat.
Results
It has been established that diabetes development was accompanied with 37–45% ($P<0.05$) increase in quantity of NOD2 cells on the 14th day, but by the 4th week of disease their number returned to the benchmarks. Induction of diabetes leads to increased in concentrations of NOD2 on 7–28% in macrophages and dendritic cells and a decrease on 8–12% in lymphocytes. PTX administration of diabetic animal reduces the quantity of NOD2+ cells on 29% ($P<0.05$) in mucous membrane of villus 42% in subepithelial zone of ILF by the 14th day of experimental diabetes mellitus. But by the 4th week of disease their number returned to the benchmarks in mucous membrane of villus and in subepithelial zone of ILF it increase on 29%. The concentration of NOD2 also decreased in 2nd week of diabetes on 8–15% in NOD2+-macrophages and NOD2+-dendritic cells.
Conclusions
The expression augmentation with NOD2 in ileum immunopositive cells can influence the differentiation of subsets of immunopositive cells and their proinflammatory cytokines production, thus acting as one of triggers of diabetes development and progression.

Vitamin B12 levels and relationship between B12 and fasting insulin levels elderly patients with metabolic syndrome

Fulden Sarac[1], Sumru Savas[1], Sefa Sarac[2] & Fehmi Akcicek[1]
[1]Department of Geriatrics Medicine, Ege University Medical Faculty, Izmir, Turkey; [2]Department of Cardiology, Katip Celebi University, Atatürk Training and Research Hospital, Izmir, Turkey.

Introduction
Biochemical and clinical vitamin B12 deficiency has been demonstrated to be highly prevalent among patients with diabetes mellitus. The aims of the study were 1. to compare the vitamin B12 (VB12) levels, and 2. to investigate the relationship between VB12, fasting insulin and HOMA-IR levels in elderly patients with metabolic syndrome (MetS).
Subjects and method
Study population included 121 (mean age 64.3±14.1 years) (80 female, 41 male) elderly patients. Patients were evaluated for MetS by Adult Treatment Panel III (ATPIII). Data such as VB12, insulin and other tests were retrospectively searched. Vitamin B12 deficiency was defined as B12 concentrations <197 pg/ml.
Results
Metabolic syndrome was diagnosed in 39 elderly patients (%32.2). The prevalence of low VB12 was 45.8% in elderly with MS. Serum VB12 levels were significantly lower among patients aged ≥70 years ($P<0.05$). In elderly patients with MetS, mean levels of VB12, fasting insulin and HOMA were found to be 370.1±58.6 pg/ml, 13.4±1.1 μU/l, 3.0±0.1, respectively. However, mean levels of VB12, fasting insulin and HOMA were found to be 383.9±66.0 pg/ml, 8.4±2.7 μU/l, 2.71±0.9, in the other elderly patients, ($P=0.90$), ($P=0.70$), ($P=0.003$), respectively. Mean levels of VB12 were negatively correlated with fasting insulin levels ($r=-0.800$, $P=0.01$) in elderly with MetS.
Conclusion
Mean levels of VB12 were not different in elderly patients with or without MetS, but negatively correlated with fasting insulin in elderly with MetS.

Does hepatitis C virus (HCV) infection has a role in the pathogenesis of diabetes mellitus in patients with β thalassemia

Vincenzo De Sanctis[2], Ashraf Soliman[1], Giancarlo Candini[3] & Heba Elsedfy[4]
[1]Hamad Medical Centre, Doha, Qatar; [2]Quisisana Hospital, Ferrara, Italy; [3]St Anna Hospital, Ferrara, Italy; [4]Ain Shams University, Cairo, Egypt.

Introduction
In patients with β thalassemia major (TM) The interplay between liver siderosis and hepatitis C virus (HCV) infection may facilitates the progression to insulin resistance (IR) and diabetes mellitus (DM).
Objectives
Many TM patients are infected with either HCV. Therefore, we aimed to explore if there is any association between DM and HCV-RNA positivity with different genotypes.
Patients and methods
148 TM patients (age range: 15–53 years; 72 males and 76 females), 78 were HCV-RNA positive. Fifteen patients (10.1%) had type 1 DM. The HCV genotype was done using specific primers in all thalassemic patients with DM as well as in 46 non diabetic TM patients. Serum HCV-RNA was detected using a sensitive polymerase chain reaction assay. We assessed also the frequency of DM in TM patients with HCV+ and HCV-RNA−, and HCV+ and HCV-RNA+.
Results
The commonest genotype in TM patients with and without DM was 1b (Table 1). HCV genotype did not differ statistically between diabetic and non-diabetic thalassemic patients (χ^2 test). In addition the frequency of DM did not differ among TM patients with HCV+ and HCV-RNA−, and HCV+ and HCV-RNA+. No significant correlation was observed between biochemical parameters (albumin, total protein, liver enzymes or INR) serum ferritin, IGF-I on the one hand and HCV-RNA status on the other hand.

Table 1.

HCV genotype	TM patients with diabetes	TM patients without diabetes
1b	9 (60%)	27(58.6%)
1b/2	0	1 (2.1%)
2	4 (26.6%)	14 (30.4%)
2a,2c	1 (6.6%)	1 (2.1%)
3a	1 (6.6%)	3 (6.5%)

Summary
Our study did not show statistically significant association between DM and HCV-RNA positivity. larger studies are required for acquiring better knowledge about the pathogenic mechanisms that link HCV infection with abnormal glycemic abnormalities.

The relationship between higher left ventricular mass index and plasma total homocysteine levels in patients with type 2 diabetes mellitus

Harun Kundi[1], İhsan Ates[2], Nihal Ozkayar[3] & F Vasfi Ulusoy[1]
[1]Department of Cardiology, Ankara Numune Education and Research Hospital, Ankara, Turkey; [2]Department of Internal Medicine, Ankara Numune Education and Research Hospital, Ankara, Turkey; [3]Department of Nephrology, Ankara Numune Education and Research Hospital, Ankara, Turkey.

Purpose
The aim of the present study was left ventricular mass index (LVMI) in type 2 diabetes mellitus (T2DM) patients may be related increased circulating homocysteine (Hcy) levels.
Methods
The study group comprised 130 patients, and all patients were newly diagnosed with diabetes and were not taking any medication. Measures of left ventricular mass (LVM) were assessed using Devereux formula and left ventricular mass index (LVMI) was calculated as LVM divided by body surface area. Hcy levels were measured using high-performance liquid chromatography.
Results
Forty five patients (34.6%) of all patients with higher LVMI. In univariate logistic regression analyses age, creatinine and Hcy count all significantly associated with higher LVMI. When these three variables were included in a multivariate regression modeling Hcy levels were found to be significantly associated with the higher LVMI.
Conclusions
Hyperhomocysteinemia (Hhcy) can be a predictor of in T2DM patients.

Description of practices related to insulin injection therapy and sharp disposal among patients attending the diabetic clinic, Colombo North Teaching Hospital, Sri Lanka

Kushani Atukorala[1,2], Deepama Sumanasekera[3], Kumudu Wickramasinghe[3] & Sumudu Wickramasinghe[4]
[1]Deptartment of Physiology, Faculty of Medicine, University of SriJayawardenapura, Gangodawila, Sri Lanka, [2]Deptartment of Family Medicine, University of Kelaniya, Kelaniya, Sri Lanka, [3]National Eye Hospital, Colombo, Sri Lanka, [4]MOH Office, Boralesgamuwa, Boralasgamuwa, Sri Lanka.

Introduction
Diabetic patients on insulin therapy are compelled to use sharps such as insulin needles and lancets on a regular basis. As a result thousands of used sharps and bloodstained materials are generated daily by them. While there is a huge concern over sharps disposal practices in healthcare settings, the sharps disposal practices of diabetic patients living at home has been poorly documented.

Methodology
Randomly selected sample of 158 diabetic patients were obtained from the diabetic clinic, Colombo North Teaching Hospital. Data collected using an interviewer administered questionnaire and clinic records.
Results
Sample population was aged between 21 and 90. Mean age 60. Majority had used insulin for more than 1 year 131/158 (83%). Very few 5/158 (3%) used the insulin pen while majority used syringes to inject insulin. Only 10 (6%) regularly checked blood sugar using needles/lancets. Majority 132/158 (84%) injected insulin more than twice per day and $\geq$50% used the same needle more than six times, for more than 3 days. Majority 150/153 (98%) of the syringe users recapped the needle. A significant number 73/158 (46%) also involved others when injecting and disposing needles. Used needles/pens were disposed in to a common household garbage bin, sharps container, toilet pit, garbage dump and indiscriminately by 66 (42%), 9 (6%), 8 (5%), 14 (8%), 11 (7%), respectively. Some 15/158 (9.5%) have collected sharps since beginning without disposing. Many respondents had received no information on how to dispose of their sharps. Those who recalled receiving information were more likely to dispose of their sharps safely.
Conclusions
Insulin-dependent diabetic patients are not educated on safe sharps disposal methods, leading to unsafe disposal of needles. Appropriate education on the correct disposal of sharps should be an integral part of their diabetic counselling.

EP326

Vaccination status and factors affecting vaccination among diabetics

Kevser Onbasi[1], Bengur Taskiran[2], Lezan Keskin[3], Turkan Pasali Kilit[1] & Serdar Ucgun[1]
[1]Dumlupinar University, Kutahya, Turkey; [2]Yunus Emre State Hospital, Eskisehir, Turkey; [3]Malatya State Hospital, Malatya, Turkey.

Vaccines are the most effective tools for preventing some infections. World Health Organization (WHO) and Ministry of Health (MoH) in Turkey recommends vaccination for people with diabetes. Our aim was to determine the prevalence of vaccination rates among diabetes in three different cities (Kütahya, Eskisehir and Malatya) in Turkey. 475 patients (307 female, 168 male) attending outpatient clinics for endocrinology were asked to fill in a questionnaire. The vaccination rates were very low. The rate being vaccinated was 27% for influenza. The vaccination rate for pneumococcus, tetanus and hepatitis B were 8%, 20, 6% and 16, 2, respectively. The vaccination rates among type 1 diabetics were higher than type 2 diabetics. Survey results indicated that leading factor negatively influencing vaccine uptake for influenza was that 25.9% of diabetics did not know that they are in risk for influenza and 5.3% do not believe that there may be a threat of influenza pandemic or epidemic.6.1% did not want vaccination because of side effects. The reason for the lowest vaccination rate for pneumococcal vaccine may be dependent on the factor that this vaccine is not provided by health care providers, but the other vaccines are free for risk groups in Turkey. Also the pneumococcus vaccine is not well known among diabetics, because 60.6% of diabetics in our study population did not hear about the vaccine. 46.3% of diabetics reported that they did not know that there is a need of booster for tetanus immunization. Increased awareness of physicians may help improve vaccination rates against influenza, pneumococcal disease, tetanus and hepatitis B. Education programs for physicians and also diabetic patients may improve the vaccination rates in patients with diabetes.

Prevalence of orthorexia in diabetic patients

Cuneyd Anil, Gozde Aritici, Hacer Ari & Neslihan Bascil Tutuncu
Baskent University Faculty of Medicine, Ankara, Turkey.

Introduction
Orthorexia (nervosa) is an eating disorder, characterised by an obsession with avoiding foods perceived to be unhealthy. Though it has not been recognised as a pathological entity in Diagnostic and Statistical Manual of Mental Disorders – IV yet, interest in the condition has increased recently. This study aimed to determine the prevalence and risk factors of orthorexia in a group of diabetic patients.
Methods and design
134 (63 female) diabetic patients who admitted to the outpatient clinic of our department were enrolled. Demographic information, educational status, diabetic history, care, and treatment, height, and weight of all cases were recorded. Ortho-15 Questionnaire was applied to all participants. Each patient can score minimum 15, maximum 60 points from this test. Those scoring 40 points and less are accepted to be orthorectic.
Results
The mean age of the group was 59.9 ± 11.7 years. The Ortho-15 test revealed that the minimum score was 25, and the maximum 46 points. No relation was determined between educational status, BMI and presence of orthorexia. 15.5% of males and 11.1% of females were found to be orthorectic ($P > 0.05$). The mean duration of diabetes of the whole group was 10.1 ± 8.8 years and there was no relation between duration of diabetes and presence of orthorexia.
Conclusion
This study revealed that orthorexia was not frequent in this group of patients. Performing the test on larger groups making comparisons, may introduce different results.

EP328

Metabolic control in patients with 1 diabetes mellitus associated with depression

Yana Navmenova[1], Tatiana Mokhort[2], Elena Mahlina[3] & Maria Rusalenko[3]
[1]Gomel State Medical University, Gomel, Belarus; [2]Belarusian State Medical University, Minsk, Belarus; [3]The Republican Research Centre for Radiation Medicine and Human Ecology, Gomel, Belarus.

Objective
The assessment of glycemic control and concentration of lipids in the blood in patients with type 1 diabetes mellitus (DM-1), depending on the presence of depression (DP).
Methods
There were examined 163 patients with DM-1. To assess severity of DP there was used Hospital Anxiety and Depression Scale (HADS). There were determined the level of fasting blood glucose (BG), BG level in 2 hours after a meal, the average daily BG level for 3 days and HbA_{1C} level. Also there were determined the total amount of cholesterol (TC), triglycerides (TG), HDL cholesterol (HDL-C). The amount of LDL cholesterol (LDL-C) and the amount of very LDL cholesterol (VLDL-C) were determined by calculation.
Results
Increased level of HbA_{1C} was found in patients with DP, the mean daily glucose compared with patients without DP (9.70% vs 8.40%, $P < 0.001$; 9.02 mmol/l vs 8.10 mmol/l, $P = 0.03$ respectively). There has been established a positive correlative relationship between the level of DP according to the HADS scale and HbA_{1C} level ($r = 0.20$; $P < 0.05$), as well as between the level of DP according to the HADS scale and the level of the mean daily BG ($r = 0.22$; $P < 0.05$). Development of DP at DM-1 is associated with the level of HbA_{1C} 7.5% or more (OR = 0.89; $P = 0.03$; 95% CI 0.30–1.48). The results of evaluation of biochemical parameters characterizing lipid metabolism according to the presence of DP indicate, that the level of TC in patients with DP was higher than in patients without DP (5.10 mmol/l vs 4.80 mmol/l; $P = 0.04$). There has also been determined that the level of LDL-C was 3.10 mmol/l in patients with DP vs 2.65 mmol/l in patients without DP and exceeded by 14.5% the value of comparison group ($P = 0.05$).
Conclusions
The risk of development of DP in DM-1 is associated with decompensation of carbohydrate metabolism and dyslipidaemia.

DOI: 10.1530/endoabs.37.EP328

EP329

Trends in diabetic ketoacidosis presentations at a major rural referral centre in Australia

Tamara Young
Orange Health Service, Orange, NSW, Australia.

Aim
To study trends in presentation and management of diabetic ketoacidosis (DKA) at a rural referral centre, to ultimately assist with development of a formal management protocol.

Methods
A retrospective audit of medical records for all presentations of DKA over a two year period was conducted to source age of patient, distance from Orange Health Service, new onset vs known type 1 diabetes mellitus, initial pH, time to normalisation of ketones, any episodes of hypokalaemia or clinically significant hypotension during their management, episodes of hyperchloraemia, and overall length of stay. Statistical analysis was carried out to determine the mean and S.D., where data was normally distributed, and the median when data was not normally distributed. Furthermore, Spearman's correlations were conducted to examine the relationship between distance and age, length of stay and initial pH.
Results
23 cases met the inclusion criteria for analysis. The mean age of patients was 25 years. (S.D. 8.1 years). The mean length of stay was 4.57 days (S.D. of 3.34 days). Complications were recorded in half of patients with complete data sets. The mean initial pH was 7.134 with a S.D. of 0.144. There was a statistically significant positive association between age and length of stay ($rs=0.44$, $n=23$, $P<0.05$) and a statistically significant negative association between length of stay and initial pH ($rs=-0.51$, $n=23$, $P<0.05$). Distance was not correlated with length of stay nor initial pH.
Conclusions
A significant proportion of patients have a severe presentation, and many patients are transferred from outlying facilities. These factors need to be considered when planning service delivery and have been considered when developing a formal protocol appropriate for a major rural referral centre.

DOI: 10.1530/endoabs.37.EP329

EP330

Clinical characteristics in patients with type 2 diabetes mellitus: a cohort study

Sandra Herranz Antolín, Visitación Álvarez de Frutos, Ascensión Sutil Folgado, Dolores Mateo Pascual & Eduardo Platero Rodrigo
Hospital Universitario de Guadalajara, Guadalajara, Spain.

Objective
To assess metabolic control, cardiovascular risk factors and treatments in type 2 diabetes mellitus (T2DM) patients.
Methods
Observational and cross-sectional study of 238 T2DM patients who visited endocrinology clinics for the first time or those who did not undergo periodic revisions during the previous year of the study. All reported patients were outpatients, over 18 years of age and they signed informed consent statistical analysis was done by SPSS 20.0.
Results
61.8% males; main age. 64.2 ± 12.7 years. Diabetes duration (years): <1 8.8%; 1–5 20.2%; 5–10 25.2%; >10 45.8%. Cardiovascular risk factors: hypertension 80.7%, dyslipidaemia 80.3%, smoking 18.9% and obesity 61.4% (BMI 33.4 ± 8.2 kg/m^2).

Table 1.

	Mean ± S.D.	Targets (ADA 2013)	% patients who achieved targets
HbA1c (%)	8.1 ± 1.9	≤7	37.3
LDL-c (mg/dl)	109.6 ± 43.0	≤100	44.8
HDL-c (mg/dl)	42.3 ± 10.9	≥50	21.7
Triglycerides (mg/dl)	169.2 ± 116.0	≤150	53.4
Systolic BP (mmHg)	140.1 ± 21.6	≤130	36.3
Dystolic BP (mmHg)	77.4 ± 12.7	≤80	64.5

No patients achieved all the targets.

30.3 and 24.7% of the patients have not HbA1c and lipids tests respectively during the 6 previous months. Hypoglycaemic agents: patients with and without treatment: 91.6 and 8.4% respectively. Oral therapy 58.6%; oral theraphy + insulin 21.2%; insulin 12.2%. Antihypertensive drugs 74.8%; lipid lowering drugs 64.3%; antiplatelet agents 41.1%.

Conclusion
The prevalence of risk factors was very high in our study. However, no patients achieved all ADA targets, in spite of the wide use of antihypertensive, lipid lowering and hypoglycaemic drugs.

DOI: 10.1530/endoabs.37.EP330

The influence of actual and retroactive T2DM regulation on duration of hospital stay and clinical outcome of patients suffered from NSTEMI/STEMI

Zoran Gluvic[1], Pejka Kovacevic[2], Vladimir Samardzic[1], Jelena Tica Jevtic[1], Marina Vujovic[1], Vesna Popovic-Radinovic[1], Milena Lackovic[1], Bojan Mitrovic[1], Ratko Tomasevic[1], Anastasija Panic[3] & Esma R Isenovic[3,4]
[1]Zemun Clinical Hospital, Zemun, Belgrade, Serbia; [2]Bezanijska Kosa Hospital, Zemun, Belgrade, Serbia; [3]Laboratory for Molecular Genetics and Radiobiology, Institute for nuclear sciences 'Vinca', Belgrade, Serbia; [4]Albany College of Pharmacy and Health Sciences, The Pharmaceutical Research Institute at Albany, New York, New York, USA.

Introduction
A link between diabetes and coronary heart disease is well-known. The aim of this study is to examine the influence of actual and retroactive diabetes regulation parameters (admission glycaemia and HbA1C value) on duration of hospital stay and clinical outcome of T2DM patients suffered from NSTEMI/STEMI.
Material and methods
Cross sectional study involved 103 examinees with past history of T2DM actually hospitalised in CCU due to acute myocardial infarction (NSTEMI or STEMI). Beside some demographic, epidemiological, laboratory and clinical parameters, the impact of admission glycaemia (mmol/l) and HbA1C values (%) on duration of hospital stay and clinical outcome were observed. Obtained data were analysed by SPSS for Windows 18.0 statistical package. Level of statistical significance was 0.05.
Results
Out of 103 examinees, 66 (64.1%) suffer from STEMI. Mean age of study population is 67 ± 9 years, 59 (57%) are males. Mean T2DM duration is 7 (1–30) months and it influences on duration of hospital stay ($\rho=0.232$, $P<0.05$), but not on clinical outcome ($\rho=0.174$, $P>0.05$). Mean duration of hospital stay is 8 and 8.5 days in STEMI and NSTEMI patients respectively, with no difference between groups (log rank $\chi^2=0.476$, $P>0.05$). HbA1C values influence on duration of hospital stay ($\rho=0.213$, $P<0.05$), opposite to admission glycaemia ($\rho=0.148$, $P>0.05$). Out of four patients (3.9%), who passed away, three suffered from STEMI. Neither admission glycaemia ($\rho=0.165$, $P>0.05$) nor HbA1C values ($\rho=0.047$, $P>0.05$) do not have effect on clinical outcome.
Discussion and conclusion
In present study, admission glycaemia do not influence either on duration of hospital stay or clinical outcome. Diabetes duration and HbA1C values extend mean duration of hospital stay, but do not influence on clinical outcome.

Serum apelin, salusin-α and salusin-β levels in type 2 diabetes mellitus and hypertension

Kader Ugur[1], Süleyman Aydin[2], Selçuk Yusuf Sener[1], Kadriye Yildirim[3] & Yusuf Özkan[1]
[1]Department of Endocrinology, Firat University Faculty of Medicine, Elazig, Turkey; [2]Department of Biochemistry, Firat University Faculty of Medicine, Elazig, Turkey; [3]Department of Internal Medicine, Firat University Faculty of Medicine, Elazig, Turkey.

Introduction
Diabetes mellitus (DM) is a metabolic illness caused by insulin resistance or lack of it. Hypertension (HT) has been seen frequently in diabetic patients, and causes morbidity and mortality with its complications. Salusins are vasodilator and hypotensive peptids which function most in cardiovascular system. Apelin is an insulin-sensitive, vasoconstructive, positive inotropic-effective peptide. In this study, determining the levels of serum salusin-α, salusin-β and apelin in diabetic and hypertensive patients as well as examining the relationship between diabetes mellitus and hypertension are aimed.

Methods
For this study, 36 patients with only diabetes, 41 patients with diabetes + hypertension, 32 patients with only hypertension, and 30 healthy controlled group are examined. In addition to regular blood tests, the levels of salusin-α, salusin-β, and apelin are also examined.
Results
The level of salusin-α was high in controlled group compared with HT and DM + HT groups (respectively, $P<0.05$, $P<0.01$). Although this level was high in DM group, it was not statistically significant. Compared with the control group salusin-β level was high in all groups, but it was not statistically significant ($P=0.205$). Compared with the control group, apelin level was low in DM group ($P<0.05$) but high in HT group, but not statistically significant. In DM + HT group, apelin level was similar as the control group.
Conclusion
As a result, salusin-α and salusin-β levels were observed to have increased in HT and DM + HT groups. The reason why these peptides increase is to decrease the arterial pressure. This may be a reply fort the cardioprotectivity. The reason why apelin level was low only in DM group may be due to fact that insulin level was low in diabetic group and apelin was an important mediator of glucose.

Variability of anthropometric, echocardiographic and biochemical indices with comorbidity pathology – essential hypertension and type 2 diabetes

A S Shalimova[1], A N Belovol[2], M N Kochueva[1], V L Lutsyk[3] & A V Linskaya[3]
[1]Kharkiv Medical Academy of Postgraduate Education, Kharkiv, Ukraine; [2]Kharkiv National Medical University, Kharkiv, Ukraine; [3]Institute of Neurology, Psychiatry and Narcology of NAMS of Ukraine, Kharkiv, Ukraine.

The mechanisms of development and progression of essential hypertension (EH) and concomitant type 2 diabetes (DM2) still remain not completely studied, so the comprehensive evaluation of the contribution of various indicators to the formation of this comorbidity have scientific interest.
The aim of the study was comprehensive assessment of the variability of anthropometric, echocardiographic and biochemical parameters in patients with EH and concomitant DM2. We examined 243 patients aged 45–60 years. The main group consisted of 153 patients with EH stage II, grade 2 and DM2 moderate, subcompensated; comparison group – 70 patients with EH stage II, grade 2 without DM2. The control group consisted of 20 healthy individuals.
Integrated data processing was carried out with the help of factor analysis using principal component. In the analysis there were 73 variables, based on the relationships among which there were four factors that together explain 52.61% of the total variability of the empirical data. In this case the first and the most powerful factor explained 33.07% of the total variability of indices. The highest load of Factor 1 were at indicators diene conjugates, malondialdehyde, tumor necrosis factor-α, interleukin-6, blood glucose, insulin, HbA1c, HOMA, leptin, intima-media thickness of the common carotid artery, while at the negative pole of this factor were superoxide dismutase, catalase, endothelium-dependent vasodilatation, adiponectin, HDL).
Averaged factor estimates for Factor 1 were: 0.517 ± 0.025 – in the main group, -0.986 ± 0.039 – in the comparison group and -2.476 ± 0.037 – in the control group with highly significant differences between the factor scores in all groups ($P<0.001$).
Conclusion
We discovered four main factors, the general action of which explained 52.61% of variability indices in comorbid pathology – EH and DM2. Factor assessment of the most powerful Factor 1 with high significance made the studied groups of patients differ from each other.

Salt addition and the risk of type 2 diabetes mellitus: a case–control study

Lina Radzeviciene[1], Rytas Ostrauskas[1] & Evelina Praneviciene[2]
[1]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Faculty of Medicine, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction
Type 2 diabetes appears to involve interaction between susceptible genetic backgrounds and environmental factors. It is important to identify modifiable risk factors that may help reduce the risk of type 2 diabetes. Data on salt intake and the risk of type 2 diabetes are limited. The aim of the study was to assess the relationship between adding salt to prepared meal and the risk of type 2 diabetes mellitus.
Methods
A case–control study included 234 cases with a newly confirmed diagnosis of type 2 diabetes mellitus during the one whole year and 468 controls which were free of the disease. Cases and controls (ratio 1:2) were matched by gender and age (±5 years). A specifically designed questionnaire was used to collect information on possible risk factors of type 2 diabetes. Anthropometrical measurements were made according to World Health Organization recommendations. The odds ratios (OR), and 95% CI for type 2 diabetes were calculated by a conditional logistic regression.
Results
The cases had higher BMI and significantly lower education level, compared to the controls. Variables such as family history of diabetes, education, BMI, waist circumference, morning exercise, eating speed, cigarette smoking, arterial hypertension, plasma triglycerides, occupational and marital statuses were retained in the models as confounders because their inclusion changed the value of the OR by more than 5% in any exposure category. After adjusting for possible confounders about two-fold increased risk of type 2 diabetes mellitus was determined in those subjects whose adding salt to prepared meal when it is not enough or almost every time without tasting (1.82; 95% CI 1.19–2.78; $P=0.006$) vs subjects whose never adding salt to prepared meal.
Conclusion
Our data support a possible relationship between adding salt to prepared meal and the increased risk of type 2 diabetes mellitus.

Relationship between adiponectin and anthropometric parameters, insulin resistance and transaminase levels in patients with nonalcoholic fatty liver disease and type 2 diabetes

Larysa Zhuravlyova & Anna Zhuravlyova
Kharkiv National Medical University, Kharkiv, Ukraine.

The basis of the pathogenesis of nonalcoholic fatty liver disease (NAFLD) is insulin resistance (IR) which appears on the background of abdominal obesity (AO) which, in turn, is a key factor in the emergence of an imbalance between adipocytokines entailing a disturbance of lipid and carbohydrate metabolism, which ultimately leads to the damage of the liver cells, the development of inflammation, fibrosis and apoptosis. The goal – to study features of changes in the level of adiponectin (AN), depending on the function of the liver and IR index in patients with NAFLD and type 2 diabetes mellitus (T2DM) and AO.
Methods
25 patients with NAFLD and T2DM (HbA1c $<7.5\%$) and control group ($n=10$) underwent clinical examination including assessment of BMI, waist circumference (WC), liver function (transaminases – ALT, AST) and index HOMA-IR.
Results
The changes in BMI were observed in 94.5% of patients, including obesity 1st degree – in 54.6%, 2nd degree – in 31.4 and 4.6% – obesity 3rd degree. AN level was reduced compared to control (8.7 ± 2.4 ng/ml vs 15.4 ± 2.1 ng/ml, $P<0.05$) and correlated with the degree of obesity – 6.5 ± 2.1 ng/ml in patients with grade 3 obesity ($P<0.05$). There was a negative relationship between the level of AN and BMI ($r=-0.36$; $P<0.01$), WC ($r=-0.34$; $P<0.05$). The level of AN significantly decreased with increasing levels of ALT ($r=-0.44$, $P<0.001$) and AST ($r=-0.46$; $P<0.001$). An inverse relationship between the level of AN and the index HOMA-IR was determined ($r=-0.46$; $P<0.001$).
Conclusions
Hypoadiponektinaemia in patients with NAFLD and T2DM is associated with AO, the deterioration of the liver function and progression of IR that contributes to the further development of metabolic abnormalities in the liver.

DOI: 10.1530/endoabs.37.EP335

Diabetic gallbladder, dyspepsia and metabolic effects

Larysa Zhuravlyova, Tetyana Moiseyenko & Maryna Filonenko
Kharkiv National Medical University, Kharkiv, Ukraine.

The purpose of the study was to determine the functional state of the gallbladder (GB) in patients with type 2 diabetes mellitus (T2DM) in combination with metabolic syndrome (MS).

Methods

40 patients with T2DM and obesity of I–II degree were examined as well as 20 healthy volunteers. Ultrasonography, dynamic echocholecystography and duodenal intubation were performed. The motor function of GB was assessed by emptying coefficient (Kempt $=(V_c)/V_0 \times 100\%$) and the index of contractility ($IC = V_{max}/V_{min}$). Lipid and carbohydrate metabolism was assessed.

Results

The following signs of GB hypotension were revealed: increase of GB initial volume to 80.2 ± 1.1 cm^3 (in the control group – 25.9 ± 1.9 cm^3) ($P < 0.05$); increase of GB hypokinesia – reduced Kempt of GB on 30th minute of investigation (0.6 ± 0.1 vs 49.2 ± 2.5 ($P < 0.05$)), on 45th minute (7.8 ± 0.3 vs 61.2 ± 2.7 ($P < 0.05$)) and on 60th minute (17.2 ± 0.4 vs 67.4 ± 2.4 ($P < 0.05$)). The reduction of GB propulsive function was confirmed by the increase of GB final volume to 66.3 ± 0.9 cm^3 vs 8.1 ± 0.8 cm^3, increase of the GB latent period duration to 28.2 ± 0.2 min vs 12.6 ± 0.5 min and reduced IC to 1.21 ± 0.1 vs 3.1 ± 0.3 ($P < 0.05$). Hypotonic-hypokinetic type of GB dyskinesia was confirmed by a reduction of GB wall thickness (2–3 mm) and a frequent presence of GB twist phenomenon. Typical clinical manifestations included dyspeptic signs, asthenic syndrome and silent course of the disease. The presence of dyskinesia in patients with T2DM and MS was accompanied by significant fluctuations of blood glucose levels during the day (the phenomenon of glycaemic swings), indicating the unsatisfactory state of carbohydrate control. Also, these patients showed signs of dyslipidaemia, which included increased content of TC, TG and LDL in comparison to control data.

Conclusions

Patients with T2DM and MS show signs of GB dyskinesia with dilatation and reduced GB contractile function that are associated with disorders of carbohydrate and lipid balance.

Tumour necrosis factor-α and insulin resistance in patients with nonalcoholic fatty liver disease in combination with type 2 diabetes mellitus

Larysa Zhuravlyova & Olena Ogneva
Kharkiv National Medical University, Kharkiv, Ukraine.

Tumour necrosis factor-α (TNF-α) impairs liver function and contributes to the pathogenesis of nonalcoholic fatty liver disease (NAFLD) in patients with type 2 diabetes mellitus (DM-2) with different trophological status.

Purpose

To assess the relationship between the level of TNF-α and indices of carbohydrate metabolism in patients with NAFLD and its combination with DM-2 with different trophological status.

Methods

90 patients with isolated NAFLD and in combination with DM-2 with normal weight and obesity (BMI ≥ 30 kg/m^2) were divided into three groups: 1 group ($n = 20$) – comprized the patients with NAFLD, 2 group ($n = 20$) – patients with combination of NAFLD and DM-2 with normal body weight and 3 group ($n = 50$) – patients with comorbid disorder and obesity. The controls ($n = 20$) were apparently healthy individuals. The levels of insulin (IRI) and TNF-α were determined by ELISA method.

Results

TNF-α was significantly ($P < 0.001$) increased in all groups as compare to the control (24.2 ± 1.06 pkg/ml), the level was the highest in group 3 (96.6 ± 0.72 pkg/ml) and was significantly different from that in groups 1 and 2 (66.2 ± 1.07 pkg/ml and 86.4 ± 1.21 pkg/ml, respectively). In groups 1 and 2 the correlation was established between TNF-α and IRI ($r = 0.33$, $P < 0.05$ and $r = 0.37$; $P < 0.05$, respectively). In group 3 the significant correlation was established between the level of TNF-α and fasting blood glucose ($r = 0.46$; $P < 0.05$), IRI ($r = 0.78$; $P < 0.05$) and HOMA-IR ($r = 0.64$; $P < 0.05$).

Conclusion

The correlation between TNF-α and indices of carbohydrate metabolism is connected with the ability of TNF-α to enhance the carbohydrate metabolism, insulin resistance, and support the role of TNF-α in pathogenesis of NAFLD, namely, in damage of hepatic gluconeogenesis, especially in patients with associated DM-2 and obesity. In addition, isolated NAFLD can independently cause the metabolic consequences.

Pancreatogenic diabetes

Seif eldin Yahia, Budd Mendis, Tom Crabtree & Nandini Seevaratnam
Nottingham University Hospital, Nottinghamshire, UK.

Aims

Diabetes mellitus secondary to pancreatic disease and pancreatic surgery (pancreatogenic; type 3c) is a discrete entity to common types of diabetes and there are no well established guidelines for its management. At Nottingham University Hospitals, we have set up a multidisciplinary pancreatogenic diabetes clinic since 2008. The aim of this study is to look at the outcome of the clinic since it's been established.

Methods

Case notes and hospital database of all 51 patients (32 male, 19 female) attending the clinic between 2008 and April 2014 were reviewed retrospectively. Their mean duration of diabetes was $5 + 0.76$ years.

Results

Mean HbA1c on first attendance was 70.4 (s.d. 21.6) and at 1 year it was 68.1 (s.d. 21.2). Mean weight at 1 year showed an increase from $75.2 + 3.1$ kg to $83 + 4.1$ kg. BMI increased from 26.0 to 29.8 kg/m^2. During the first year in the clinic, 15 patients had their medications reviewed and changed and there were only four patients admitted; three had problem with glycaemic control with DKA and one had multiple admissions due to hypoglycaemia.

Conclusions

There was improvement in HbA1c of the patients at 1 year. Mean BMI showed that patients were initially overweight and their BMIs have increased at 1 year. Attendance rates at the clinic are generally good; 80% of appointments have been attended. This showed that there is positive outcome of the pancreatogenic diabetes clinic. Therefore, patients with pancreatogenic diabetes should be managed in such clinic rather than usual diabetes clinics.

Vitamin D level in impaired fasting glucose and impaired glucose tolerance (prediabetic) patients

Mehmet Gültekin[1], Zeliha Hekimsoy[2], Derya Öz[2], Ogün Hatiboglu[2], Pinar Alarslan[2], Bilgin Özmen[2], Ece Onur[3] & Ceyhun Gözükara[3]
[1]Department of Internal Medicine, Celal Bayar University Medical Faculty, Manisa, Turkey; [2]Division of Endocrinology and Metabolism, Department of Internal Medicine, Celal Bayar University Medical Faculty, Manisa, Turkey; [3]Department of Clinical Biochemistry, Celal Bayar University Medical Faculty, Manisa, Turkey.

Introduction

Impaired fasting glucose (IFG) is defined as being present in those whose fasting blood glucose level is consistently elevated above normal, but is not high enough to be considered as having diabetes mellitus. Impaired glucose tolerance (IGT) is defined as being present in those whose second hour plasma glucose level is higher than normal, but is not high enough to be considered as having diabetes mellitus. Low serum 25-hydroxyvitamin D levels are associated with glucose intolerance, diabetes mellitus, and metabolic syndrome. To date, the literature is conflicting regarding the relationship between vitamin D levels and prediabetes. Our aims in this study were to evaluate serum 25-hydroxyvitamin D levels and their association with prediabetic metabolic patterns.

Material and methods

Participants were 220 patients from our endocrine clinic: 85 with isolated IFG, 50 with isolated IGT, 85 with both IFG and IGT, and 80 normoglycaemic healthy subjects with similar age, gender, and BMI. A detailed history and physical examination of the patients were performed. 25-hydroxyvitamin D, calcium, phosphorus, albumin and PTH levels were measured. 25-hydroxyvitamin D levels were categorised as adequate if >30 ng/ml, insufficient if 20–30 ng/ml, and deficient if <20 ng/ml.

Results
We found significantly lower 25-hydroxyvitamin D levels in the IGT (11.7 ± 6.5 ng/ml) ($P < 0.007$) and IFG + IGT patients (13.2 ± 7.2 ng/ml) compared to controls (16.6 ± 9.8 ng/ml) ($P < 0.047$). Lower 25-hydroxy vitamin D levels were associated with a higher risk of IGT (OR 2.57, 95% CI 1.01–6.53, $P = 0.043$). 25-hydroxyvitamin D levels were similar in the control group and IFG group. Significant differences in 25-hydroxyvitamin D levels between the IFG group, IGT group and IFG + IGT group were not found.
Conclusion
Vitamin D insufficiency and deficiency are associated with IFG, IGT, and combined IFG and IGT. However, the only statistically significant association was that between 25-hydroxyvitamin D levels and IGT.

Effects of H. pylori eradication on metabolism and body weight in obese and non-obese patients

M Mar Roca-Rodríguez[1], Isabel Cornejo-Pareja[1], Leticia Coín-Aragüez[2], Juan Alcaide[2], Carlos Clu-Fernández[1], Laura Viñuela-González[3], Elena Durán-Martín[3], Laura Mora-Navas[3], Isabel Mancha-Doblas[1] & Francisco J Tinahones[1,2]
[1]Department of Endocrinology and Nutrition, Virgen de la Victoria and Regional Hospitals, Malaga, Spain; [2]Investigation Unit (IBIMA), Virgen de la Victoria Hospital, Malaga, Spain; [3]Department of Microbiology, Virgen de la Victoria Hospital, Malaga, Spain.

Introduction
Many studies showed that H. pylori infection could be an independent predictor for insulin resistance and could regulate metabolism and body weight.
Aim
To evaluate changes in metabolism induced by an oral glucose tolerance test (OGTT) before and after antibiotic eradication treatment in patients colonized by H. pylori.
Materials and method
Prospective case-controlled study with a sample of patients colonized by H. pylori. In an intra-subject analysis, clinical data and levels of ghrelin and GLP1 were analysed at baseline and post-OGTT before and after antibiotic eradication treatment.
Results
We studied 32 patients (75% women and 21.9% obese). Average age was 49 ± 11.5 and 46.9% had personal history of gastrointestinal disease. We found a significant decrease of HbA1c and 120 post OGTT glucose after treatment; and significant correlations between ghrelin with waist circumference and BMI (negative), and with glucose, insulin, HbA1c and LDL-Chol (positive). We also found significant positive correlations between GLP-1 and insulin, and between the difference in HbA1c and levels of GLP-1 post-treatment at all times after OGTT. No significant differences were found in obese patients before and after treatment, whereas non obese patients showed significant decrease in levels of 120 post OGTT glucose and HbA1c. Comparing non obese and obese patients, we found significant differences pre-treatment in fasting insulin and C-peptide; and post-treatment in diastolic blood pressure and C-reactive protein. 78.1% of patients completed correctly the treatment and 81.3% achieved the eradication of H. pylori.
Conclusions
Significant improvement in carbohydrate metabolism was observed after H. pylori eradication. No significant differences in body composition, blood pressure figures and levels of ghrelin and GLP-1 were found after treatment, but nearly significant decline in ghrelina. Significant correlations between plasma glucose and insulin with ghrelin and GLP-1 were found. More than 85% of patients achieve H. pylori eradication.

Discrepancies between the glycosylated haemoglobin based criteria and glucose based criteria for diagnosis of diabetes and pre-diabetes

Sujan Sharma & Siddha Bahadur Rana Magar
Kathmandu University School of Medical Sciences, Dhulikhel, Nepal.

Objectives
The number of people with diabetes is increasing globally; hence necessitate identifying diabetes earlier and more efficiently. Recently, American Diabetes Association (ADA) recommended the use of glycated haemoglobin (HbA1c) as an alternative to glucose based criteria for diagnosing type 2 diabetes and pre-diabetes. Hence, we aimed to evaluate the discrepancies between HbA1c- and glucose-based criteria for diagnosis of diabetes and pre-diabetes in Nepalese population.
Methods
A total of 2502 subjects aged 30 years or older, who attended university hospital and subjected for measurement of HbA1c, fasting plasma glucose (FPG) and 2-hour plasma glucose (PPG) level were recruited in the study. Newly diagnosed diabetes and pre-diabetes were defined by ADA-glucose based and ADA- HbA1c criteria. Statistical analyses were performed using SPSS software to evaluate discripancies.
Results
The percentages of newly diagnosed individuals with diabetes were 12.87% (322/2502) using the FPG criterion alone, 12.07% (302/2502) using the PPG criterion alone, 14.55% (364/2502) using the HbA1c criterion alone and 10.51% (263/2502) using FFG, PPG & HbA1c criteria in combination. Significant discordance occurred for 3.28% (82/2502) with HbA1c- and glucose-based criteria and for 1.68% (42/2502) with HbA1c- and FPG-criteria. Among the study subjects, 2.86% of individuals with a FBG and 2.12% of individuals with HbA1c were found to be pre-diabetes.
Conclusions
Significant discordance exists between the HbA1c- and glucose-based diagnostic criteria for diagnosis of diabetes and pre-diabetes in Nepalese population. Hence, we concluded that using glucose based criteria merely may result in an underestimation of diabetes and pre-diabetes.

Familial partial lipodystrophy linked to a novel peroxisome proliferator activator receptor-γ mutation, H449L

Tevfik Demir[1], Hüseyin Onay[2], David B Savage[3], Ayse Kubat Kuruuzum[4], Senay Savas Erdeve[5], Canan Altay[6], Samim Ozen[2], Leyla Demir[7], Umit Cavdar[1] & Baris Akinci[1]
[1]Division of Endocrinology, Dokuz Eylul University, Izmir, Turkey; [2]Department of Medical Genetics, Ege University, Izmir, Turkey; [3]Metabolic Research Laboratories, Wellcome Trust-Medical Research Council Institute of Metabolic Science, University of Cambridge, Cambridge, London, UK; [4]Division of Endocrinology, Istanbul University, Istanbul, Turkey; [5]Division of Pediatric Endocrinology, Dr Sami Ulus Women and Children's Hospital, Ankara, Turkey; [6]Department of Radiology, Dokuz Eylul University, Izmir, Turkey; [7]Department of Biochemistry, Ataturk Training Hospital, Izmir, Turkey.

Introduction
Familial partial lipodystrophy (FPL) is a rare genetic disorder characterised by a selective lack of subcutaneous fat that is associated with insulin resistance and diabetes. FPL has been reported to be caused by mutations in the peroxisome proliferator activator receptor-γ (PPARG) gene, which encodes a key transcription factor that regulates adipocyte differentiation and insulin sensitivity.
Material and methods
The objective of this study was i) to describe the phenotype associated with a novel heterozygous missense PPARG mutation, H449L, discovered in a Turkish family; and ii) to compare the fat distribution and metabolic characteristics of subjects with the PPARG H449L mutation ($n = 4$) to that of a cluster of FPL patients with various LMNA mutations ($n = 5$; R482W, R582H, L306V and T528M).
Results
Compared to patients with LMNA mutations, fat loss was generally less prominent in subjects with PPARG H449L mutation. Partial fat loss was limited to the extremities whilst truncal fat mass was preserved. The PPARG H449L mutation was associated with insulin resistance, hypertriglyceridemia and non-alcoholic fatty liver disease in all affected subjects but the severity was variable. Three of four mutation carriers were overtly diabetic or had impaired glucose tolerance. Pioglitazone therapy in these three individuals resulted in a modest improvement in their metabolic control, and regular menstrual cycles in both females.
Conclusion
We suggest that relatively modest fat loss in patients with PPARG mutations may render the recognition of the syndrome more difficult in routine clinical practice.

The PPARG H449L mutation is associated with insulin resistance and metabolic complications; however the severity is variable among the affected subjects, suggesting that additional factors such as variations in other predisposing genes, gender, age and lifestyle factors might affect the clinical features in patients with PPARG mutations.

Irisin plasma level is connected with the android adipose tissue deposit

Katarzyna Pukajlo, Katarzyna Kolackov, Lukasz Laczmanski, Justyna Kuliczkowska-Plaksej, Marek Bolanowski, Andrzej Milewicz & Jacek Daroszewski
Department of Endocrinology, Diabetes and Isotope Therapy, Wroclaw Medical University, Wroclaw, Poland.

Irisin (Ir), a recently identified adipomyokine, cleaved and secreted to the circulation from the FNDC5 protein in response to physical activity and some environmental conditions has been postulated to induces the differentiation of a subset of white adipocytes into brown fat and mediates the beneficial effects of exercise on metabolic homeostasis. Polycystic ovary syndrome (PCOS) – one of the most frequent endocrinopathies affecting women of child-bearing age is associated with reproductive problems and also metabolic alterations leading to obesity and obesity-related diseases. It is commonly accepted that obesity-associated disorders are related to the type of fat distribution. Individuals with excess of visceral (android) fat but with normal BMI, called MONW (metabolically obese but normal weight), are burdened with obesity-related disease. The aim of our study was to evaluate the relationship between Ir plasma concentrations in PCOS patients and healthy control group in the context of adipose tissue deposits. Our study group consisted of 179 patients with PCOS and a population of 122 healthy control group (both groups aged 25–35 years). We isolated a MONW patients using DEXA criteria of depA (android fat deposit, $>30.2\%$ and BMI <25) for the Polish population. In the MONW patients we observed a negative correlation with Ir concentration. We found a statistically significant positive association between Ir concentration and type of adipose tissue deposit – (depA) in the whole study group ($P=0.006$) and in the control group ($P=0.00$), while in the PCOS a negative correlation between depA and Ir group ($P=0.00$) was shown. Our data revealed for the first time that Ir concentration is connected with type of body fat distribution. In this respect PCOS differs from healthy subjects. Moreover we confirmed that an increased Ir secretion in obesity could result from an adaptive response or Ir-resistance.

The GH treatment results in the increase of irisin concentration in plasma

Beata Wikiera[2], Katarzyna Pukajlo[1], Lukasz Laczmanski[1], Natalia Sloka[1], Aleksander Basiak[2], Marek Bolanowski[1], Anna Noczynska[2] & Jacek Daroszewski[1]
[1]Department of Endocrinology, Diabetes and Isotope Therapy, Wroclaw Medical University, Wroclaw, Poland; [2]Department and Clinic of Endocrinology and Diabetology for Children and Adolescents, Wroclaw Medical University, Wroclaw, Poland.

Brown adipose tissue metabolism is of remarkable pathophysiological interest, because it could be a target for future therapies for obesity and metabolic syndrome. Irisin (Ir), recently identified novel adipomyokine is essential in a white-to-brown fatty tissue transdifferentiation, and mediates some of the positive influences on metabolic disorders through increase of energy expenditure. The exact regulation of Ir secretion and action is unknown but significant positive associations of circulating Ir with GHs and IGF1 were found. We studied Ir response in a group of patients treated with supraphysiological doses of GH (rGH). The study group consisted of 36 Turner syndrome (TS) patients aged 3.2–16.07 years (mean 8.2 years) diagnosed by karyotyping. The rGH was applied in a dose 0.05 mg/kg per day Prior to and following the treatment (mean 1.47 ± 0.89 years) anthropometrical data were recorded as well as biochemical parameters were measured: Ir, OGTT, insulin,IGF1, and IGFBP3. The increase of IGF1 concentration at the end of observation was significant (from 119.4 ± 62.46 to 413.37 ± 204.38 ng/ml, mean $\pm$ S.D., $P=0.000$). The significant rise of Ir level was recorded on rGH treatment (2.1 ± 1.03 vs 2.47 ± 0.79 μg/ml, mean $\pm$ S.D., $P=0.035$). The rGH treatment influenced insulin resistance revealed by increased HOMA values (median 0.64 ± 0.45 before and 0.92 ± 0.97 after, $P=0.02$). The correlation between Ir and IGF1 levels was not significant neither before nor on the treatment ($P=0.22$ and $P=0.95$ respectively). The correlation between Ir and insulin ($r=0.44$, $P=0.01$) and Ir and HOMA ($r=0.46$, $P=0.007$) was significant. Result of the study showed an increase in Ir level following GH application. It seems to be not IGF1 mediated. Ir may mediate some metabolic effects of GH treatment. We are unable to conclude whether Ir rise is connected with direct GH stimulation, their influence of body composition, or with altered insulin sensitivity.

Acquired partial lipodystrophy is associated with increased risk for metabolic complications

Baris Akinci[1], Fatos Koseoglu[2], Huseyin Onay[3], Sevgi Yavuz[4], Canan Altay[5], Ilgin Yildirim Simsir[10], Secil Ozisik[1], Leyla Demir[6], Meltem Korkut[7], Nusret Yilmaz[8], Samim Ozen[3], Gulcin Akinci[9], Tahir Atik[3], Mehmet Calan[1], Mustafa Secil[5], Abdurrahman Comlekci[1] & Tevfik Demir[1]
[1]Division of Endocrinology, Dokuz Eylul University, Izmir, Turkey; [2]Department of Internal Medicine, Tepecik Training Hospital, Izmir, Turkey; [3]Department of Medical Genetics, Ege University, Izmir, Turkey; [4]Kanuni Sultan Suleyman Training Hospital, Izmir, Turkey; [5]Department of Radiology, Dokuz Eylul University, Izmir, Turkey; [6]Department of Biochemistry, Ataturk Training Hospital, Izmir, Turkey; [7]Division of Pediatric Gastroenterology, Yeditepe University, Istanbul, Turkey; [8]Division of Endocrinology, Akdeniz University, Antalya, Turkey; [9]Division of Pediatric Neurology, Dr. Behcet Uz Childrens' Hospital, Izmir, Turkey; [10]Division of Endocrinology, Ege University, Izmir, Turkey.

Objective
Acquired partial lipodystrophy (APL) is a rare disorder characterized by progressive selective fat loss. In previous studies, metabolic complications were reported to be relatively rare in APL, while they were quite common in other types of lipodystrophy syndromes. However, so far, there has been no systematic study on metabolic complications in APL.
Methods
We have systematically evaluated 21 APL patients in the Turkish Lipodystrophy Study Group (TuLip) registry who were enrolled in a prospective follow-up protocol. Patients with congenital generalized lipodystrophy (CGL), type 1 diabetes, type 2 diabetes and healthy controls were included for comparison. Subjects were investigated for metabolic abnormalities. Fat distribution was assessed by whole body MRI. Hepatic steatosis was evaluated by ultrasound, MRI and MR spectroscopy. Patients with diabetes underwent a mix meal stimulated C-peptide/insulin test to investigate pancreatic β cell functions. Leptin and adiponectin levels were measured.
Results
Fifteen individuals (71.4%) had at least one metabolic abnormality. Six patients (28.6%) had diabetes, 12 (57.1%) hypertrigylceridemia, 10 (47.6%) low HDL, and 11 (52.4%) hepatic steatosis. Steatohepatitis was further confirmed in two patients with liver biopsy. Anti GAD was negative in all APL patients with diabetes. Their leptin and adiponectin levels were decreased compared to patients with type 2 diabetes and controls. However, consistently very low leptin levels as detected in patients with CGL, was not the case. The mix meal test suggested that APL patients with diabetes had a significant amount of pancreatic β cells functioning, and their diabetes was apparently associated with insulin resistance.
Conclusions
Our results reveal that most patients with APL develop metabolic abnormalities associated with insulin resistance. Further research is needed to clarify if they would benefit from metreleptin treatment.

Association between +276 G > T polymorphism of the adiponectin gene (*ADIPOQ*) and insulin resistance in Ukrainian patients with type 2 diabetes mellitus (T2DM)

Yuri Karachentsev, Nonna Kravchun, Maryanna Gorshunska, Lubov Atramentova, Nataliia Krasova, Tatyana Tyzhnenko, Zhanna Leshchenko, Alexander Gladkih, Artyom Pochernyaev, Yuliia Opaleiko, Olga Plohotnichenko & Victoria Poltorak
SI 'V. Danilevsky Institute of Endocrine Pathology Problems of NAMS of Ukraine', Kharkiv, Ukraine.

Variants of *ADIPOQ* have been inconsistently associated with adiponectin level in diverse populations. We explored association of single nucleotide polymorphism (*SNP*) in the *ADIPOQ* (*+276 G>T*, rs1501299) with circulating total adiponectin and insulin resistance (IR) in Ukrainian T2DM cohort.
Materials and methods
544 T2DM patients (M/F: 241/303, age 56.3±0.4 years, diabetes duration 7.8±1.0 years, BMI 31.7±0.2 kg/m^2, HbA1c 7.6±0.2%) and 215 healthy controls (C) were genotyped. The *SNP +276G>T* in the *ADIPOQ* was detected using PCR-RELP. Plasma total adiponectin, IR and lipid profile were determined. Statistical analysis was performed with ANOVA and χ^2 test.
Results
Comparing with C significant ($P<0.001$) increase in triglyceridaemia (2.89±0.12 vs 1.23±0.26 mM), plasma FFA levels (1.35±0.03 vs 0.34±0.07 mM), plasma insulin levels (132.47±6.11 vs 85.21±8.01 pM) and HOMA-IR (8.35±0.40 vs 1.77±0.41) as well as hypoadiponectinaemia (4.99±0.16 vs 11.80±1.45 mg/l) were observed in T2DM patients. Major allele in the studied groups was *G* (frequency in C: 0.691, and in diabetics: 0.601). In T2DM the *T* allele frequency was 0.399 and different significantly from C (0.307). In comparison with C, T2DM had more *TT* (16.9% vs 9.3%, $P<0.05$), but less *GG* (37.1% vs 47.4%, $P<0.05$) homozygotes. It was determined lower severity of dyslipidemia, i.e. total cholesterol ($P<0.01$), triglycerides ($P<0.02$) and β-lipoprotein cholesterol ($P<0.05$) against the background of less hypoadiponectinaemia (on 15.4%) in *GG* homozygotes ($P<0.1$) compared to *TT*-carriers. Higher HOMA-IR was revealed in *TT* compared to other genotypes with maximal difference in patients with obesity (HOMA-IR indexes in carriers of *TT*, *GT* and *GG* genotypes were 10.96±1.52, 8.40±0.65 and 8.96±0.74, respectively, $P<0.02$ for *TT* vs *GT* and *GG*).
Conclusions
The study demonstrates for the first time that *ADIPOQ* variants are associated with IR phenotype in Ukrainian T2DM patients. We suggest the predominant impact of metabolic disturbances and hyperinsulinaemia on diabetic hypoadiponectinaemia genesis.

Vitamin D level in diabetic retinopathy

Rümeysa Selvinaz Erol[1], Muhammet Kazim Erol[2], Sayid Shafi Zuhur[3], Feyza Yener Ozturk[3], Esra Çil Şen[3], Aysegul Mavi[3], Masum Canat[3], Dilek Güven Çakmak[3] & Yüksel Altuntaş[3]
[1]Ordu Government Hospital, Ordu, Turkey; [2]Antalya Educational and Training Hospital, Antalya, Turkey; [3]Şişli Educational and Training Hospital, Istanbul, Turkey.

Purpose
To determine the relationship between grade of diabetic retinopathy and serum vitamin D levels in diabetic patients.
Materials and methods
A total of 173 diabetic patients consisting of patients without retinopathy ($n=67$), patients with non proliferative diabetic retinopathy (NPDRP group $n=47$), patients with proliferative diabetic retinopathy (PDRP group $n=59$) was included in the study. Age and sex matched 55 healthy subjects was taken as a control group. Patients with type 1 DM, those taking vitamin D, multivitamin including vitamin D, drug affecting vitamin D metabolism like rifampin, phenytoine was excluded from the study. Patients with chronic renal failure was also excluded. Dilated fundoscopic examination of all subject was done and serum creatinine, HbA1c, 25 hydroxy vitamin D (25 (OH) D) level of all subject were measured between May 2012 and September 2012.
Result
There was no statistical difference in age, sex, systolic tension, diastolic tension and BMI between groups. Serum creatinine level was also not statistically different between groups ($P=0.11$). The mean 25 (OH)D levels of PDRP group, NPDRP group, diabetic patients without retinopathy and control group was 11.9±6.4, 18.8±10.2, 16.6±7.5 and 20.1±9.2 ng/ml respectively. There was statistically significant difference between PDRP group and other groups in univariate analysis ($P<0.001$). When comparing 173 diabetic patients, regardless of retinopathy, with control group, 25 (OH) D levels was significantly lower in diabetic patients than control group ($P=0.004$).
Conclusion
Diabetic patients especially, patients with proliferative diabetic retinopathy had lower serum vitamin D level than healthy subjects. Additionally randomised, controlled, prospective studies are necessary to determine whether vitamin D treatment will stop or slow the progression of diabetic retinopathy in diabetic patients.

Abnormalities in glucose metabolism are present in HCV/HIV co-infected patients with severe liver fibrosis even in the absence of diabetes

Manuel Cayón Blanco, Carolina García-Figueras Mateos, Gloria Baena Nieto, Patricia Bancalero Herrera, Salvador Pérez Cortés & Alberto Terrón Pernía
Hospital SAS Jerez de la Frontera, Jerez de la Frontera, Andalusia, Spain.

Rationale
Type 2 diabetes mellitus (T2DM) is a well known independent prognosis factor associated with cirrhosis. Nevertheless, few studies are focused on the association between glucose metabolism and liver fibrosis in HCV/HIV patients and their conclusions are contradictory. The aim of our study was to investigate the relationship between glucose homeostasis and liver fibrosis in these patients.
Methods
In a cross-sectional study, we compared prevalence of glucose disorders and data related to its homeostasis according to degree of liver fibrosis. Liver stiffness was measured using transient elastography. Severe liver fibrosis was defined as liver stiffness ≥14 kPa. Insulin resistance was defined as a level of homeostasis model for assessment (HOMA-IR) ≥2.
Results
65 HCV/HIV co-infected patients were included. Prevalence of prediabetes and T2DM was higher (40 and 24%, respectively) among patients with severe fibrosis as compared to 37 and 3.7% among those with less severe degree of fibrosis ($P=0.005$). Among parameters related to glucose metabolism, levels of fasting glucose, HbA1c and HOMA-IR were significantly higher in patients with severe fibrosis ($P=0.006$, $P=0.048$ and $P=0.001$ respectively). Also, there was a positive correlation between HOMA-IR and liver fibrosis ($r^2=0.5$; $P<0.001$). When patients with T2DM were excluded, levels of fasting plasma insulin, HOMA-IR and the prevalence of insulin-resistance, were significantly higher among those with severe fibrosis ($P=0.004$, $P=0.003$ and $P=0.049$, respectively) and the positive correlation between HOMA-IR and liver fibrosis remained significantly present ($r^2=0.45$; $P<0.001$).
Conclusions
Our data support that hyperinsulinism and insulin-resistance are frequently observed in HCV/HIV co-infected patients with severe liver fibrosis even in absence of overt T2DM. Detection of a high degree of liver fibrosis in HCV/HIV co-infected patients is another reason to optimize glycaemic control in this population.

Gamma glutamyl transferase and C-reactive protein in type 2 Saudi diabetic patients in relation to management modality and components of metabolic syndrome

Suhad Bahijri[1], Maimoona Ahmed[1], Khalid Al-Shali[1], Samia Bokhari[1,3], Amani Alhozali[1], Anwar Borai[1,2], Amani Gusti[1,3], Ghada Ajab Noor[1], Jawahir Al Ahmadi[1], Ahmed Alghamdi[1], Mohammed Asiri[1], Osamah Bashawieh[1], Abeer Aljahdali[1] & Jaakko Tuomilehto[1,4]
[1]Saudi Diabetes Research Group, Faculty of Medicine, King Fahd Medical Research Center, King Abdulaziz University, Jeddah, Saudi Arabia; [2]King Abdullah International Medical Research Center, King Saud bin Abdulaziz University for Health, Jeddah, Saudi Arabia; [3]King Fahad Armed Forces Hospital, Jeddah, Saudi Arabia; [4]Department of Public Health, Hjelt Institute, University of Helsinki, Helsinki, Finland.

Background
Different management modalities are used to control hyperglycaemia associated with type 2 diabetes (T2DM). Research has indicated an association of single or combined insulin therapy with increased cardiovascular events. Metabolic syndrome (MS), as well as increased levels of C-reactive protein (CRP), and gamma glutamyl transferase (GGT) are also associated with increased CVD risk.
Aim
To study the relationship between management modality, glycaemic control, components of metabolic syndrome and serum levels of GGT and CRP.
Methods
T2DM subjects were recruited from outpatients clinics at two hospitals in Jeddah. Pregnant subjects, and those having any other severe chronic illness or diabetes complications were excluded. Anthropometric measurements, and blood pressure were taken. Treatment plan was recorded. Fasting blood samples were obtained to measure glucose, HbA1c, lipids profile, CRP and GGT.
Results
A total of 153 subjects were recruited (46.4% males, 53.6% females). MS was present in 131 (85.6%) patients. In spite of significantly lower mean HbA1c in hypoglycaemic drugs users compared to means in those using single or combined insulin therapy ($P<0.001$), and significantly lower mean diastolic blood pressure (DBP) in insulin users ($P=0.025$), no significant difference was found in means of GGT or CRP. Significantly higher mean GGT was found in uncontrolled compared to controlled, and hypertensive compared to normotensive patients ($P<0.05$ in both cases).GGT correlated positively with triglycerides ($r=0.227$, $P=0.028$), and negatively with HDL-C ($r=-0.188$, $P=0.049$). CRP correlated positively with waist circumference ($r=0.204$, $P=0.045$), and mean value being higher in abdominally obese group compared to non-obese ($P=0.048$).
Conclusions
Serum GGT and CRP levels do not appear to be affected by management regimen in T2DM Saudi patients. Some components of MS, hypertension and poor glycaemic control are associated with higher levels of either CRP or GGT, hence increased cardiovascular risk.

EP350

The prevalence of metabolic syndrome in patients with diagnosed type 2 diabetes

Aldi Shehu[2], Erion Thengjilli[1], Albana Doko[1] & Florian Toti[1]
[1]University Hospital Center 'Mother Theresa', Tirana, Albania; [2]Laboratory 'Intermedica', Tirana, Albania.

Background and aims
The identification of metabolic syndrome (MS) is important for the appropriate management of associated cardiovascular risk factors. There are different criteria for the diagnosis of the metabolic syndrome proposed by the WHO and the National Cholesterol Education Program 2001 – NCEP/ATP III. The aim of our study was to determine the prevalence of the MS as the NCEP/ATP III criteria in a selected population of type 2 diabetes.
Patients and methods
We randomly selected 500 patients with T2 diabetes in Tirana district. 321/500 (64.2%) responded, 158 (49.2%) males. All the patients had completed anthropometric measures and lipid profile after an 8-h fast. The patients having two more criteria except diabetes, were defined as having MS.
Results
The prevalence of the MS was 64.5%, males 56.8% and females 75.7%. The prevalence increased with age, from 16% before 40 years of age to 78% at 70 years. Diabetes duration was not different in patients with or without MS (M: 6.7 ± 3.4 vs 6.9 ± 3.7; F: 7.2 ± 3.8 vs 6.8 ± 3.6 years). The number of components of the MS was related to the age (ANOVA $P<0.05$) but not to diabetes duration. Central obesity was present to males 36% females 85.4%, HTA 49.6 and 60.2%, low HDL 52 and 90%, high triglycerides 70.9 and 66.7% respectively. HbA1c was higher in persons with MS (9.6 ± 2.2 vs $8.7\pm1.4\%$, $P<0.01$).
Conclusion
The results show that MS is two-fold more prevalent in type 2 diabetes, compared with the general Albanian population (64.5 vs 32%). The levels of cardiovascular risk factors are increased in type 2 diabetics and urged immediate efforts directed at controlling the components of MS (mainly obesity, physical inactivity and lipid control).

Insulin-induced lipohypertrophy diagnostics in diabetic patients: subcutaneous fat ultrasonography

Natalya Volkova, Ilya Davidenko, Julya Rudakova & Anna Sesukina
Rostov State Medical University, Rostov-on-Don, Russia.

Introduction
Lipohypertrophy (LH) is a chronic complication of diabetes mellitus that caused by frequent s.c. injections of insulin. Nowadays, LH were modified due to good quality modern insulin and expansion their concentration. As a result, some difficulties of diagnosis were appeared.
Design
The aim of this study has been to compare the frequency of insulin induced LH in diabetic patients revealed by ultrasonography of subcutaneous fat with those founded by palpatory method. This study was done on 215 diabetic patients (142 females and 73 males, mean age was 46 years) who had been under the treatment with insulin a mean 10 years. Observation and palpation techniques, as well as ultrasonography of subcutaneous fat were used in assessing LH in these diabetics. Evaluation of subcutaneous fat was made in typical injection sites: paraumbilical and buttocks regions, lateral surfaces of hips and shoulders. All patients injected insulin in physiological regimen.
Results
On the basis of palpation LH were revealed in 66 patients (30.7%), while pathologic areas of subcutaneous fat didn't discover in 149 subjects (69.3%). Further ultrasonography of injection sites was performed to all patients. LH were revealed in 186 patients (86.5%), including those 66 subjects with palpatory changes. Pathologic areas of subcutaneous fat the most often were occurred in paraumbilical regions – 131 patients (61%). Also LH were found simultaneously in two sites: paraumbilical regions and lateral surface of hips – 32 subjects (15%); paraumbilical regions and lateral surface of shoulders – 24 patients (11%).
Conclusions
LH were modified due to good quality modern insulin and expansion their concentration. As a result, pathologic areas of subcutaneous fat were revealed in 30.7% patients by palpation, while LH were found in 86.5% subjects by ultrasonography. Ultrasonography of subcutaneous fat could be used to diagnose LH in diabetic patients in clinical daily practice.

Unvisible lipohypertrophy and diabetes compensation: is there link?

Natalya Volkova, Ilya Davidenko & Julya Rudakova
Rostov State Medical University, Rostov-on-Don, Russia.

Introduction
Lipohypertrophy (LH) is a chronic complication of diabetes mellitus that could develop in any age, any injection site, and be any size. At present time, new method, as ultrasonography of subcutaneous fat, of LH diagnostics were appeared.
Design
The aim of this study has been to estimate efficiency of insulinotherapy in diabetic patients after LH was diagnosed by ultrasonography. This study was done on 50 diabetic patients (31 females and 19 males) who had been under the treatment with insulin a mean 10 years. Ultrasonography of subcutaneous fat was used in assessing LH in typical injection sites. All patients injected insulin in physiological regimen. HbA1c level, fasting and postprandial glucose, episodes of hypoglycaemia, body mass and BMI were evaluated at the moment of LH and after 6 month in all patient. Results were considered to be statistically significant $P<0.05$.
Results
BMI reduced from 26.34 ± 6.07 kg/m^2 to 25.25 ± 4.06 kg/m^2 ($P<0.05$). Body mass decreased from 72.44 ± 15.75 kg to 70.08 ± 15.02 kg ($P<0.05$). Also good glycaemic control was demonstrated by measuring glucose and HbA1c level. Thus fasting glucose reduced from 9.03 ± 3.98 mmol/l to 7.11 ± 2.95 mmol/l ($P<0.05$). Postprandial glucose decreased from 10.27 ± 3.72 mmol/l to 9.34 ± 2.61 mmol/l ($P<0.05$). HbA1c level reduced from $9.27\pm2.32\%$ to $7.43\pm1.52\%$ ($P<0.05$). Frequency of hypoglycaemia reduced from 1.97 ± 2.23 to 1.10 ± 0.91 in month ($P<0.05$).

Conclusions
There were significant improvement of all estimated parameters which characterised the diabetes compensation after changing injected sites because of detected by ultrasonography LH. Since ultrasonography of subcutaneous fat is more sensitive than classic LH diagnostics, it might be used in general clinical practice instead of common detection of LH. Thus, early LH diagnostics can provide to good glycaemic control.

Glycoregulation during pregnancy

Violeta Mladenovic[1], Aleksandar Djukic[1], Svetlana Djukic[1] & Djuro Macut[2]
[1]CC Kragujevac, Kragujevac, Serbia; [2]CC Serbia, Belgrade, Serbia.

Background
Pregnancy presents a state of insulin resistance that can predipose diabetes development in some women, and is associated with increased risk for neonate and for mother. Gestational diabetes is a period of glucose intolerance that manifests at the beginning of the third trimester.
Aim
The aim of this study is to analyse glycoregulation in healthy pregnant women.
Materials and methods
This study included 77 healthy pregnant women in third trimester registered in centre for endocrinology CC Kragujevac that were tested, according to positive 3 h OGTT with 100 g glucose (ADA Criteria), with specifying glycaemia and insulinaemia in 0, 60, 120, and 180 min, and HbA1c. According to OGTT results we divided patients in two groups: normal glucose tolerance (NGT) and gestational diabetes mellitus (GDM).
Results
Patients were average 30.8 ± 4.7 (19–41) years old. It was shown that there was impact the number of risk factors on degree of glucose tolerance disorder ($P = 0.034$), while most of patients had no risk factor (48%). The average glycaemia during OGTT in NTG vs GDM in 0 min was 3.92 ± 0.43 vs 4.39 ± 0.46 in 120 min, 6.34 ± 0.99 mmol/l vs 7.14 ± 1.4 mmol/l. From 77 patients, 18 was with GDM (23.3%). As pregnancy progress, disorder of glucose tolerance increased (in second and third trimesters), while 4 weeks after delivery all were with NGT. The average insulinaemia during pregnancy was the greater during third trimester in 0 and 60 min in GDM group, in NTG vs GDM in 0 min was 30.81 ± 14.81 vs 33.33 ± 16.29, while in 120 min was 198.1 ± 144.25 μIU/ml vs 200.77 ± 120.82 μIU/ml. The average HbA1c during pregnancy was: NTG vs GDM 5.06 ± 0.29% vs 5.1 ± 0.27%.
Conclusion
This research brought for the first time established values of glycaemia during OGTT in healthy women in our population during third trimester, and showed increased prevalence of GDM.

Smoking habits and the risk of type 2 diabetes mellitus in women

Lina Radzeviciene[1], Rytas Ostrauskas[1] & Evelina Praneviciene[2]
[1]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Faculty of Medicine, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction
Type 2 diabetes appears to involve interaction between susceptible genetic backgrounds and environmental factors. It's important to identify modifiable risk factors for type 2 diabetes, which may help reduce the risk of the disease. The aim of the study was to assess the relationship between smoking and the risk of type 2 diabetes in women.
Methods
In case–control study included 168 cases with a newly confirmed diagnosis of type 2 diabetes during the one whole year and 336 controls which were free of the disease. A specifically designed questionnaire was used to collect information on possible risk factors of type 2 diabetes. Smoking was assessed according to: smoking habits, duration of smoking, number of cigarettes smoked per day, pack years, and smoking cessation. The odds ratios (OR), 95% CIs for type 2 diabetes were calculated by a conditional logistic regression.
Results
The cases had higher BMI and significantly lower education level, compared to the controls. Variables such as family history of diabetes, education, BMI, waist circumference, morning exercise, eating speed, cigarette smoking, occupational and marital statuses were retained in the models as confounders because their inclusion changed the value of the OR by more than 5% in any exposure category. After adjustment for possible confounders increased risk of type 2 diabetes was determined for those, whose smoked ten and more cigarettes per day (OR = 2.83; 95% CI 1.04–7.71 vs non-smokers). It has also been defined an association between the disease and duration of smoking (OR = 4.55; 95% CI 1.11–18.61 for 40 years or more smokers vs non-smokers) and those, whose smoking cessation is 19 years and less had higher risk for diabetes (OR = 6.40; 95% CI 1.50–27.34 vs non-smokers).
Conclusion
Our data support a possible relationship between smoking and the increased risk of type 2 diabetes in women.

DOI: 10.1530/endoabs.37.EP354

EP355

Optimal glycaemic control and a low rate of micro and macrovascular complications in patients with HNF1A–MODY treated in a dedicated tertiary referral centre

Siobhán Bacon, Ma Peyh Kyithar, Ailbhe McCarthy, Marie Burke & Maria Byrne
Mater Misericordiae University Hospital, Eccles St, Dublin 7, Ireland.

Objective
HNF1A gene mutations are the most common cause of monogenic diabetes. Patients with HNF1A–MODY display sensitivity to sulphonylurea therapy, however the long term efficacy has yet to be established. There is also limited literature as to the prevalence of complications in this unique cohort. The aim of the study was to determine the natural progression of HNF1A–MODY diabetes in a dedicated MODY clinic.
Design
$n = 60$ HNF1A–MODY mutation carriers and a cohort of $n = 60$ BMI, age, ethnicity, and diabetes duration matched T1DM participated in the study. All subjects were phenotyped. Additional samples were drawn for the cardiovascular biomarkers sCD36/hsCRP. A 12 lead ECG was completed. Peripheral neuropathy and peripheral vascular disease was assessed clinically/ABI. Retinal screening was performed on an annual basis. Detailed clinical follow up of the HNF1A–MODY cohort occurred on a bi-annual basis for 84 months.
Results
Following a genetic diagnosis of MODY the majority of cohort remained insulin independent at 84 months follow up (75%). The HbA1c in the sulphonylurea treated group improved significantly over the study period (55 mmol/mol (45–64) vs 46 mmol/mol (39–58), $P = 0.009$). The group that remained on sulphonylurea therapy alone lost an average of 5.6 kg weight during the study follow up. The rate of retinopathy was significantly lower than that noted in the T1DM group (18.3% vs 50%, $P = 0.0001$). There was also a lower rate of microalbuminuria, neuropathy, and cardiovascular disease in the HNF1A–MODY group than that noted in the T1DM group.
Conclusions
This study demonstrates that the majority of HNF1A–MODY mutation carriers can be maintained successfully on sulphonylurea therapy in the long term. We note a significantly lower rate of micro- and macrovascular complications than that reported in the literature. The use of appropriate therapy at early stages of the disorder and attendance at a dedicated MODY clinic may decrease the rate of complications.
Disclosure
This study was supported by a grant from the Health Research Board of Ireland awarded to S Bacon. Grant number HPF-2013-459.

DOI: 10.1530/endoabs.37.EP355

Plasma omentin-1 level does not change in the first trimester in women with gestational diabetes mellitus

Seda Sancak[1], Hasan Aydın[2], Mehmet Sargın[3], Asuman Orçun[4], Ali Özdemir[5], Ayhan Çelik[6] & Gülgün Aslan[7]
[1]Division of Endocrinology and Metabolism, Fatih Sultan Mehmet Training and Educational Hospital, Istanbul, Turkey; [2]Division of Endocrinology and Metabolism, Yeditepe University Hospital, Istanbul, Turkey; [3]Diabetes Department, Kartal Lutfi Kirdar Training and Educational Hospital, Istanbul, Turkey; [4]Division of Biochemistry, Kartal Lutfi Kirdar Training and Educational Hospital, Istanbul, Turkey; [5]Department of Internal Medicine, Fatih Sultan Mehmet Training and Educational Hospital, Istanbul, Turkey; [6]Division of Obstetrics and Gynecology, Fatih Sultan Mehmet Training and Educational Hospital, Istanbul, Turkey; [7]Department of Internal Medicine, Kartal Lutfi Kirdar Training and Educational Hospital, Istanbul, Turkey.

Objective
Gestational diabetes mellitus (GDM) is strongly associated with maternal obesity. Omentin-1 is secreted from the adipose tissue and enhances insulin action. Circulating levels are inversely correlated with body weight, decreased in type 2 diabetes. Pre-existing maternal obesity has been shown to be associated with lower omentin-1 expression in placenta, adipose tissue and maternal plasma. In our previous study, we had shown that plasma omentin-1 level is decreased in women with GDM and increased after delivery. The aim of this study was to assess the maternal plasma omentin-1 level in the first trimester and its predictive value on development of GDM.
Materials and methods
Pregnant women in their first trimester ($n=220$) were included into the study. Those that developed GDM ($n=66$) was compared with non-diabetic pregnant women ($n=154$). WHO criteria was used for the diagnosis of GDM and screening was done at gestational weeks 24–28. Plasma omentin level was measured with ELISA. Fasting blood glucose and insulin were also measured and HOMA-IR was calculated.
Results
Patients with GDM was overweight compared to controls at the beginning of pregnancy (BMI: 28.2 ± 4.4 vs 25.2 ± 3.0). HOMA-IR was higher in GDM group (2.07 ± 1.4 vs 1.40 ± 0.6). Omentin level was not different between groups (2.22 ± 0.8 ng/l vs 2.05 ± 0.9 ng/l). After delivery plasma omentin level increased with a mean level of 166.6 ± 74.1 ng/l. There was no correlation between plasma omentin-1 level and glucose levels during oral glucose tolerance test. Omentin-1 level did not also correlate with BMI, HOMA-IR, and age.
Conclusion
Plasma omentin-1 level during early periods of pregnancy is did not differ between healthy and GDM-developed women. Since decreased levels were observed in GDM patients in previous studies, our findings could indicate that omentin-1 levels decrease as the pregnancy ages or change is only observed when GDM develops.

The role of *TCF7L2* polymorphism in the development of type 2 diabetes in subjects with metabolic syndrome

Konstantinos Katsoulis[1], Stavroula Paschou[1], Elissavet Hatzi[2], Stelios Tigas[1], Ioannis Georgiou[2] & Agathocles Tsatsoulis[1]
[1]Department of Endocrinology, University of Ioannina, Ioannina, Greece; [2]Laboratory of Human Reproductive Genetics, University of Ioannina, Ioannina, Greece.

Introduction
Transcription factor 7 like-2 (*TCF7L2*) gene variants (rs12255372 and rs7903146) have been consistently shown to raise genetic risk for type 2 diabetes (T2D). The aim of this study was to investigate the possible role of these variants in the development of dysglycemia (T2D or impaired fasting glucose (IFG)) in patients with metabolic syndrome (MS).
Patients and methods
The study population consisted of 228 patients with MS who were divided in two groups. The first group consisted of 148 patients with MS and dysglycaemia (39M/109F, 59.8 ± 14.6 years) and the second group of 80 patients with MS without dysglycaemia (16M/64F, 56.1 ± 15.8 years). The diagnosis of MS was based on the criteria proposed by the American Heart Association/National Heart, Lung, and Blood Institute (AHA/NHLBI) Scientific Statement. The BMI and the waist circumference were recorded and blood samples were obtained after overnight fasting for biochemical tests. The rs12255372 and rs7903146 *TCF7L2* polymorphisms were genotyped in peripheral blood leucocytes.
Results
Genotype analysis revealed that the frequency of the T allele of the *TCF7L2* rs12255372 variant was 38.2% in the study population, while the frequency of the T allele of rs7903146 variant was 35.3%. The T allele of rs12255372 was more frequently present in patients with MS and dysglycaemia (48.3%) compared to patients with MS without dysglycaemia (19.4%) (OR: 3.89, 95% CI: 2.47–6.12, $P<0.0001$). Also, the T allele of the rs7903146 variant was more frequently found in patients with MS and dysglycemia (44.6%) compared to patients with MS without dysglycaemia (18.1%) (OR: 3.64, 95% CI: 2.29–5.78, $P<0.0001$).
Conclusion
The presence of variants rs12255372 and rs7903146 of the *TCF7L2* gene is associated with dysglycaemia (IFG and/or T2D) in patients with MS.

Serum irisin level increases throughout the gestational period and it does not play role in development of gestational diabetes mellitus

Seda Seda[1], Hasan Aydın[2], Mehmet Sargın[3], Asuman Orçun[4], Ali Özdemir[5], Ayhan Çelik[6] & Gülgün Aslan[7]
[1]Division of Endocrinology and Metabolism, Fatih Sultan Mehmet Training and Educational Hospital, Istanbul, Turkey; [2]Division of Endocrinology and Metabolism, Yeditepe University Hospital, Istanbul, Turkey; [3]Diabetes Department, Kartal Lutfi Kirdar Training and Educational Hospital, Istanbul, Turkey; [4]Division of Biochemistry, Kartal Lutfi Kirdar Training and Educational Hospital, Istanbul, Turkey; [5]Department of Internal Medicine, Fatih Sultan Mehmet Training and Educational Hospital, Istanbul, Turkey; [6]Division of Obstetrics and Gynecology, Fatih Sultan Mehmet Training and Educational Hospital, Istanbul, Turkey; [7]Department of Internal Medicine, Kartal Lutfi Kirdar Training and Educational Hospital, Istanbul, Turkey.

Objective
Irisin is a novel adipomyokine that regulates the differentiation and phenotype of adipose tissue. It induces an increase in total body energy expenditure, improves insulin sensitivity, and glucose tolerance. It showed that the levels of irisin are low in obese, diabetic and impaired glucose tolerance patients. However, the information of the levels of circulating irisin in gestational diabetes mellitus (GDM) is controversial. In this study, we investigated i) the levels of irisin over the first and third trimester of gestation and ii) the change of irisin between first and third trimesters in GDM subjects.
Material and methods
Serum irisin was measured by an ELISA in a longitudinal prospective cohort study in 220 women. There are 154 healthy pregnant and 66 GDM women.
Results
The levels of irisin were low in the first trimester, but higher in the third trimester (0.76 ± 0.54 vs 1.32 ± 0.76, $P<0.0001$). There was a significant negative correlation between age (P: 0.002, r: −0.207), BMI (P: 0.03, r: −0.188) and weight in the first trimester (P: 0.03, r: −0.185) and HbA1c in the first trimester (P: 0.0001, r: −0.374). There was not any correlation between any parameters and the levels of irisin in the third trimester. The levels of irisin in the first trimester are low but high in the third trimester in the patients with GDM (0.62 ± 0.35 vs 1.26 ± 0.86, $P<0.0001$). But the levels were not different between women with GDM and healthy controls.
Conclusions
The levels of irisin are low in the first trimester but high in the later stage in third trimester. There is no effect of irisin on the development of GDM. The physiological significance of these findings needs to be assessed in future experiments.

Gestational diabetes mellitus may associate with atherosclerosis due to high mean platelet volume which is a determined of platelet function

Senay Arikan Durmaz[1], Ayse Carlioglu[2], Bilge Eris[1], Faruk Yildiz[2] & Halime Kiliç[3]
[1]Department of Endocrinology and Metabolism, Kirikkale University, Kirikkale, Turkey; [2]Department of Endocrinology and Metabolism, Erzurum Region Education and Research Hospital, Erzurum, Turkey; [3]Department of Gynecology and Obstetrics, Nenehatun Doğumevi Hospital, Erzurum, Turkey.

Aim
Mean platelet volume (MPV), which is a determinant of platelet function, is an independent risk factor for atherosclerosis. The aim of this study is to evaluate MPV values in gestational diabetes mellitus (GDM).
Material and methods
Forty-nine women with gestational diabetes mellitus (mean age 28.2 ± 4.7 years) and 40 healthy pregnant women (mean 26.2 ± 4.6 years age) who came to our Out-Patient Clinic of Endocrinology were included in the study. GDM group and the control group were matched for age. All the study subjects were evaluated by platelet parameters. All complete blood count analysis was performed with an automatic hematologic analyser.
Result
The MPV levels in GDM were significantly higher than those control group (7.9 ± 0.6 and 7.6 ± 0.54 fl, respectively; $P = 0.0001$). In addition, there was found a positive correlation between MPV and fasting glucose (FG) levels ($r = 0.52$; $P = 0.03$). The multiple regression analysis of MPV was performed. High MPV value in GDM was independent from age, BMI, and FG levels ($\beta = 0.238$, $P = 0.046$). No statistically significant differences were found for the other parameters such as haemoglobin, platelet count, lymphocyte count, neutrophil count, white blood cell count, platelet distribution width, and plateletcrit.
Conclusion
Our findings suggest that GDM are susceptible to increased MPV values, which contribute to increased risk of atherosclerosis. Future prospective studies that MPV was compared with other risk factors of atherosclerosis are required to determine their clinically importance in GDM.

Role of nitrosative and oxidative stress on the development of gestational diabetes mellitus and their effect in GDM placenta

Cristina López-Tinoco, Francisco Visiedo, Celeste Rosendo, María Belén Ojeda, Isabel Mateos, Carmen Segundo & Manuel Aguilar-Diosdado
Hospital Puerta del Mar, Cádiz, Spain.

Background and aims
The relationship between gestational diabetes mellitus (GDM) and oxidative stress is not well known and the effect of both oxidative and nitrosative stress in GDM placenta and the impact that could have on perinatal morbidity and risk of future complications is still pending to be elucidated. The aim of the study was to evaluate the relationships between maternal and placental tissue levels of markers of nitrosative and oxidative stress and antioxidants in women with GDM, which potentially may have considerable clinical implications in the pathogenesis and/or the evolution of GDM.
Material and methods
Pregnant women ($n = 78$; 53 with GDM, 25 controls), between the 24th and 29th weeks of gestation were enrolled. Both groups were analysed for demographic data, perinatal and obstetrics results and the levels of the markers oxidative stress and antioxidants status were measured (measured in serum or plasma using a commercial kit (Cayman Chemical, Ann Arbor, MI, USA)). Seven placenta GDMs and seven normal placentas were studied. Placental tissue levels of markers of oxidative stress and antioxidant were measured by Western Blotting techniques and Biotin-switch technique has been performed to identify *S*-nitrosylated protein in placental tissue.
Results
In the univariate analysis control versus patient results were: pre-gestational BMI 23.31 ± 4.2 kg/m^2 vs 27.13 ± 4.6 kg/m^2 ($P = 0.001$); weeks at delivery 39.2 ± 3.05 vs 38.9 ± 1.8 ($P = 0.09$); caesarean delivery 12.5% vs 43% ($P = 0.004$); macrosomia 4% vs 9.4% ($P = 0.6$); lipoperoxides (LPO) 2.06 ± 1.00 mol/mg vs 3.14 ± 1.55 mol/mg ($P = 0.001$); catalase 3.23 ± 1.41 nmol/min per ml vs 2.52 ± 1.3 nmol/min per ml ($P = 0.03$); superoxide dismutase (SOD) 0.11 ± 0.04 U/ml vs 0.08 ± 0.01 U/ml ($P = 0.0003$); glutathione peroxidase (GPX) 0.03 ± 0.006 nmol/min per ml vs 0.025 ± 0.006 nmol/min per ml ($P = 0.01$); glutathione reductase (GSH) 0.004 ± 0.002 nmol/min per ml vs 0.004 ± 0.004 nmol/min per ml ($P = 0.9$); and glutathione transferase (GST) 0.0025 ± 0.0012 nmol/min per ml vs 0.0027 ± 0.00017 nmol/min per ml ($P = 0.7$). Multivariate analysis that was performed using non-conditional logistic regression showed catalase might have a protective effect and LPO seems to be a risk factor for GDM development. In GDM placenta, protein expression of catalase ($n = 0.05$), SOD ($n = 0.03$), and GPx ($n = 0.04$) were significantly increased. In addition, an increased *S*-nitrosylation of catalase ($n = 0.02$), SOD, and GPx has been determinate in GDM placenta comparing with control.
Conclusions
i) An increase in oxidative stress and a decrease in antioxidative defence can be observed in plasma of women with GDM. However, in placental tissue, elevated expression of antioxidant enzymes and an increment of their *S*-nitrosylation have been found which could be related with regulation of these activity. ii) Results suggest that resistance to oxidative insults generated in placenta by a chronic mild oxidative/nitrosative environment could alleviate the effect of systemic elevation of ROS and RNS. The effect of both oxidative and nitrosative stress in GDM placenta and the impact that could have on perinatal morbidity should be studied more extensively.

Dynamic thiol/disulfide homeostasis in patients with newly diagnosed type 2 diabetes mellitus

Nergiz Bayrakci[1], Ihsan Ates[2], Nihal Ozkayar[1], Fatma Meric Yilmaz[3,4], Canan Topcuoglu[3], Salim Neselioglu[4], Ozcan Erel[4] & Mustafa Altay[1]
[1]Department of Nephrology, Ankara Numune Education and Research Hospital, Ankara, Turkey; [2]Department of Internal Medicine, Ankara Numune Education and Research Hospital, Ankara, Turkey; [3]Department of Biochemistry, Ankara Numune Education and Research Hospital, Ankara, Turkey; [4]Department of Biochemistry, Faculty of Medicine, Yildirim Beyazit University, Ankara, Turkey.

Background
Thiol/disulfide homeostasis plays an important role in antioxidative defense mechanism, detoxification, signal transport, management of enzyme activity and trascription factors, and apoptosis. When thiol/disulphide homeostasis breaks down, these important cellular functions get deranged. Pathologies secondary to oxidative stress are seen in organeles in which this homeostasis is deranged. The aim of the study was to investigate dynamic thiol/disulfide homeostasis in newly diagnosed type 2 diabetes mellitus.
Materials and methods
Blood thiol/disulfide homeostasis status, that consists of native thiol–disulphide exchanges, was investigated in 60 patients (22 males and 38 females) diagnosed with type 2 diabetes mellitus and 60 healthy control subjects (25 males and 35 females). Serum native thiol and total thiol concentrations were measured as a paired test. The half of the difference between total thiol and native thiol concentrations gave the disulphide bond amount.
Results
In comparison to the control group, patients with diabetes mellitus had lower levels of serum thiol and total thiol (340.7 ± 46.1 μmol/l vs 313.7 ± 57.4 μmol/l; $P = 0.005$ and 366.7 ± 46.7 μmol/l vs 343.7 ± 59.0 μmol/l; $P = 0.020$ respectively) while higher average disulfide level (12.9 ± 3.2 μmol/l vs 15.0 ± 4.6 μmol/l; $P = 0.008$). In patients with diabetes mellitus, average disulfide/thiol ratio (%) (3.9 ± 1.2 vs 5.0 ± 1.6; $P = 0.001$) and disulfide/total thiol ratio (%) (3.6 ± 1.0 vs 4.5 ± 1.6; $P = 0.001$) was higher while average thiol/total thiol ratio (%) was lower (92.8 ± 2.1 vs 91.0 ± 3.4; $P = 0.001$) than the control group. HbA1c level and age correlated positively with serum disulfide/thiol ratio and disulfide/total thiol ratio ($r = 0.239$, $P = 0.009$ and $r = 0.228$, $P = 0.012$ respectively) while thiol/total thiol ratio was correlated negatively ($r = -0.228$, $P = 0.012$).
Conclusion
A tendency towards disulfide formation in thiol/disulfide homeostasis was found in patients with diabetes mellitus and there was a positive correlation between HbA1c and disulfide/thiol ratio.

DOI: 10.1530/endoabs.37.EP361

EP362

The growth patterns in children born to mothers with gestational diabetes mellitus

Joanna Rutkowska, Elzbieta Bandurska-Stankiewicz, Dorota Wiatr-Bykowska, Katarzyna Myszka-Podgórska, Ewa Kuglarz & Wojciech Matuszewski
Endocrinology, Diabetology and Internal Medicine Clinic, University of Varmia and Masuria, Olsztyn, Poland.

Introduction
The aim of the study was to assess if gestational diabetes mellitus (GDM) influence the pregnancy outcomes and the growth patterns in children.
Design
Our prospective study cohort consisted of 261 children born to mothers with GDM and 153 control children born to non-diabetic mothers. In both groups children's weight, length were assessed. Children were matched for large for gestational age (LGA) (birth weight >90th percentile for gestational age), appropriate for gestational age (AGA) (birth weight between the 10th and 90th percentiles), and small for gestational age (SGA) (birth weight <10th percentile) status. Children anthropometric measurements were made at 12, 18, 24, and 30 months. BMI was calculated. The overweight was diagnosed at BMI between 90 and 96 percentiles, obesity between 97 and 100 percentiles. The WHO child growth standards were implemented. The bioethics committee agreement was obtained.
Results
Among 261 GDM children, 80.5% were AGA, 10% SGA, 9.6% LGA; in control group 19% LGA. Birth weight of the child in GDM pregnancies was 3.30 ± 0.53 kg comparing to the control children 3.42 ± 0.54 kg, $P=0.01$. No changes in weight and BMI were found between groups in the 12th month of life. The weight >90 percentile at this period was observed in 34.6% children, BMI between 90 and 96 percentiles in 17.33% and between 97 and 100 percentiles in 17.33%. At the age of 18 months the weight of childrem born to GDM mothers was >90 percentle in 54.8% comparing to the control group in 29%, $P=0.04$; No changes were found in BMI. At the age of 24 and 30 months we found no differences in BMI in both groups.
Conclusions
We found that children who were LGA at birth were less often born to GDM mothers after implementation of dietary regiment comparing to general population. GDM did not influence the growth pattern in first 36 months of live.

Insulin resistance is associated with larger thyroid volume in adults with type 1 diabetes

Anita Rogowicz-Frontczak, Stanislaw Pilacinski, Anna Chwialkowska, Bogna Wierusz-Wysocka & Dorota Zozulinska-Ziolkiewicz
Department of Internal Medicine and Diabetology, University of Medical Science, Poznan, Poland.

Background
Larger thyroid volume and nodular thyroid disease were found to be associated with insulin resistance (IR) in patients with type 2 diabetes (T2DM). Similar analyses is lacking in T1DM.
Aims
To check the association between thyroid volume and IR using estimated glucose disposal rate (eGDR) in patients T1DM.
Materials and methods
We included 99 consecutive patients with T1DM aged 29 (mean, S.D.=6) with diabetes duration 13 (6) years. Exclusion criteria were: history of thyroid disease, current treatment of L-thyroxine or anti-thyroid drugs. Anti-thyroid peroxidase (ATPO), anti-thyroglobulin (ATg) antibodies, and anti-TSH receptor antibodies (TRAb) were determined. Assays for TSH and free thyroid hormones (trijodothyronine, fT_3, and thyroxine (fT_4)) were also performed. Thyroid was measured using ultrasonography. IR was assessed using eGDR, calculated according to the formula $(24.4 - 12.97 \times \text{WHR} - 3.39 \times \text{HT} - 0.60 \times \text{HbA1c})$, where WHR -waist-to-hip ratio and HT – history of hypertension (yes=1 and no=0).
Results
The prevalence of thyroid autoimmunity (positivity for ATPO, ATg, or TRAb) in the study group was 31%. Subclinical hypothyroidism was diagnosed in 7%, and overt hypothyroidism in 2% of patients. Mean (S.D.) thyroid volume was 15.6 (6.2) ml in patients with eGDR ≤ 7.5 (patients with IR) and 11.7 (4.7) ml in patients with eGDR above 7.5 ($P=0.002$). Thyroid volume correlated inversely with eGDR ($r=-0.35$, $P<0.001$). In multivariate linear regression model association between thyroid volume and eGDR was independent from sex, duration of diabetes, BMI, TSH, and presence of thyroid autoimmunity (β: -0.22, $P=0.025$).
Conclusion
Lower insulin sensitivity is associated with larger thyroid volume in patients with T1DM independently from BMI and signs of autoimmune thyroid disease.

EP364

Rate of impaired glucose regulation in outpatient care

Lina Zabuliene[1,2], Birute Pauliukiene[2] & Jurgita Urboniene[3]
[1]Clinics of Rheumatology, Traumatology – Orthopaedics and Reconstructive Surgery, Faculty of Medicine, Vilnius University, Vilnius, Lithuania; [2]Antakalnio Outpatient Clinic, Vilnius, Lithuania; [3]Infectious Diseases and Tuberculosis Hospital, Vilnius University Hospital 'Santariskiu klinikos', Vilnius, Lithuania.

The objective was to assess rate of impaired glucose regulation and progression to diabetes in adults using routinely collected health-care data.
Material and methods
We conducted an audit on results of 75-g standardized oral glucose tolerance tests (OGTT) performed at Vilnius Antakalnio Outpatient Clinic from 3rd Jan 2011 to 15th Dec 2014 and analysed data of adult patients. We excluded from analysis results of 358 patients who didn't perform 2-h plasma glucose concentration (2 h PG) test. 5575 patients' data were included into analysis. We applied 2006 World Health Organization criteria for diabetes, impaired glucose tolerance (IGT) and impaired fasting glucose (IFG).
Results
Mean patients' age was 53.64 ± 15.59 years. 36.4% of the patients were men and 63.6% were women. Mean fasting plasma glucose (FPG) concentration was 5.87 ± 0.65 mmol/l, mean 2 h PG was 6.20 ± 2.25 mmol/l. FPG in women was lower than in men (5.79 ± 0.67 mmol/l vs 6.03 ± 0.60 mmol/l, $P<0.001$), but 2 h PG was higher in women than in men (6.25 ± 2.14 mmol/l vs 6.09 ± 2.44 mmol/l, $P=0.011$). Mean 2 h PG increased with age. OGTT detected diabetes in 286 (5.1%) patients. 778 (14.0%) patients met criteria for IGT and 1518 (27.2%) for IFG. Normal glucose tolerance was found in 2993 patients. The rate of impaired glucose regulation increased with age achieving peak in groups of 50–59 and 60–69 years old patients (27.3 and 23.4% respectively). 787 patients came back for repeated OGTT. Repeated OGTT revealed 48 new cases of diabetes. Before developing diabetes 58.3% patients had IGT, 22.9% had IFG, and 18.8% had normal glucose tolerance. Mean time from the first OGTT to diabetes development was 18.15 ± 9.36 months. Female gender (OR=2.42, $P=0.028$) and IGT (OR=6.08, $P<0.001$) predicted diabetes.
Conclusion
This analysis revealed that the rate of undiagnosed diabetes is 5.1%; nearly half of outpatients with risk factors for diabetes have impaired glucose regulation. Women with IGT have higher risk for diabetes development.

EP365

The prevalence of diabetes and associated risk factors among adult population in a Turkish population (Trabzon city)

İrfan Nuhoğlu, Cihangir Erem, Halil Önder Ersöz, Mustafa Koçak & Nadim Civan
KTÜ TIP FAK, Trabzon, Turkey.

Objective
The objectives of this study were to determine the prevalence of diagnosed and undiagnosed diabetes mellitus (DM), prediabetes and to evaluate the associated risk factors in the sample of adult Turkish population.
Methods
A total of 4000 eligible study subjects aged 20 years or older, chosen by multistage sampling on a field were selected. Of those 3721 subjects (2139 women and 1582 men) participated in the study. The study was performed between January 2010 and September 2012 in central Trabzon and its ten town.
Results
The prevalences of prediabetes and DM were found to be as 6.4 and 10.4% (newdiagnosed 3.6%) respectively. There was no a significant difference between men and women for the prevalence of diabetes. Diabetic prevalence was found to

increase significantly by aging in both genders ($P<0.0005$). The prevalence reached its peak level in age group of ≥ 70 years (29.2%). In multivariate logistic regression analysis, advanced age (OR: 21.6 in the 60–69 age group and OR: 26.7 in the group 70 years and over), marriage (OR: 2.05), housewives (OR: 1.34), high monthly income (OR: 2.52 in the group of income ≥ 2250 TL), positive family history of diabetes (OR: 2.84), overweight (OR: 1.61), obesity (OR: 2.25), hypertension (OR: 1.42), and dyslipidaemia (OR: 1.38) were independent risk factors for the development of diabetes.

Conclusion

DM is an important health problem in the adult population of Trabzon city. It seems that the prevalence of diabetes is increasing in our region as well as our country and the world. New diagnosed diabetic patients who are unaware of their status are at high risk. To control DM and associated risk factors, effective public health education and taking urgent steps including serious education and teaching, providing a well-balanced diet and increasing physical activity are needed.

EP366

Diabetes mellitus in patients with rheumatoid arthritis

Ifigenia Kostoglou-Athanassiou[1], Aikaterini Tzanavari[2], Theodota Banti[2], Charoula Katsavouni[2], Natalia Kalaycheva[2] & Panagiotis Athanassiou[2]
[1]Department of Endocrinology, Red Cross Hospital, Athens, Greece;
[2]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece.

Introduction

In rheumatoid arthritis (RA) glucose metabolism may be affected either by the autoimmune inflammatory disease itself, or by the treatment used to manage the disease. Metabolic syndrome seems to be prevalent in RA patients.

Aim

The aim was to study the prevalence of diabetes mellitus type 2 and metabolic factors related to the development of atherosclerosis within a cohort of RA patients cared for within a single Rheumatology Department.

Methods

Within a cohort of 204 RA patients, aged 29–88 (mean $\pm$ S.E.M.) 62.87 $\pm$ 08.86 years the incidence of diabetes mellitus and metabolic factors related to the development of atherosclerosis was studied. In the cohort of RA patients ESR was 37.12 $\pm$ 1.57 mm/h, CRP 1.56 $\pm$ 0.15 mg/dl, and the disease activity index DAS28 was 3.80 $\pm$ 0.13, 49% being positive for rheumatoid factor and 23% having positive anti-CCP antibodies.

Results

Within the cohort of 204 RA patients 45 (22.06%) were found to suffer from diabetes mellitus type 2, five being on therapy with a combination of insulin and oral antidiabetic agents, ten on oral antidiabetic agents, and the rest on diet only. Within the cohort of RA patients morning glucose concentration was 110 $\pm$ 2.6 mg/dl (mean $\pm$ S.E.M.), cholesterol concentration 200.3 $\pm$ 2.98 mg/dl, HDL cholesterol 55.64 $\pm$ 1.18 mg/dl, LDL cholesterol 123.19 $\pm$ 2.41 mg/dl, and triglyceride 125.4 $\pm$ 3.7 mg/dl. Within the cohort of RA patients 33 had hyperlipidemia requiring therapy with lipid lowering agents, mainly statins and in two cases a combination of statin and fenofibrate.

Conclusions

Diabetes mellitus type 2 seems to be prevalent amongst patients with RA, hyperlipidemia being also prevalent. The disease itself, which is related to an autoimmune inflammatory process and the medications required for its management may affect blood glucose metabolism adversely.

EP367

Correlation between fasting plasma glucose levels and HbA1c for diagnosis of prediabetes and diabetes: the 2011 Korea National Health and Nutrition Examination Survey

Sung-Hee Ihm, Jun Goo Kang, Chul Sik Kim, Seong Jin Lee, Yoon Jung Kim, Ju Ri Park, Sung Hoon Yu, Ohk Hyun Ryu, Eun Gyung Hong, Doo-Man Kim, Jae Myung Yoo, Moon Gi Choi, Ho Young Son & Hyung Joon Yoo
Hallym University Sacred Heart Hospital, Anyang, Republic of Korea.

Aim

HbA1c is recommended as a diagnostic criterion for diabetes in clinical practice guidelines for type 2 diabetes in 2011 (10). Although there have been several reports that compared HbA1c-based diagnosis for diabetes with glucose-based diagnosis in Koreans, it is thought that larger epidemiological studies are required to confirm the association of HbA1c and FPG for diagnosis of diabetes for the Korean population. We conducted this study to examine the relationship between FPG and HbA1c levels measured for diagnosis of diabetes and assess the differences in FPG and HbA1c values according to the HbA1c-based and FPG-based diagnosis of diabetes recommended from the ADA in the recent Korea National Health and Nutrition Examination Survey (KNHANES).

Methods

KNHANES, conducted periodically by the Korea Centers for Disease Control and Prevention and initiated in 1998, designed to provide comprehensive information of Korean on health status, health behavior, and nutritional status. Data from second (2011) years KNHANES V (fifth) which samplings include HbA1c over 10 years old men and women and fasting blood glucose were used in this cross-sectional analysis. From an initial total of 8518 men and women, 6066 persons (2677 men and 3389 women), with HbA1c and fasting glucose data and without diabetic medications, were evaluated. From 6066 persons, 1585 were excluded for several reasons. Baseline characteristics are presented as means for continuous variables, and proportions for categorical variables. The association of fasting blood glucose and HbA1c was examined using linear regression models.

Results

We found the results of linear regression analysis in the study population and in the subjects with diabetes by FBS criteria only. FPG 100 mg/dl, predicted HbA1c 5.75% in the study population and 5.76 in the subjects with diabetes by FBS criteria only respectively. FPG 126 mg/dl also predicted HbA1c 6.4 and 6.44%. However, in the subjects with diabetes by HbA1c criteria only, FPG 100 mg/dl, predicted HbA1c 6.49%, FPG 126 and 130 mg/dl, and predicted HbA1c 7.14 and 7.24% respectively.

Conclusions

This study is the first epidemiological report showing that an association between HbA1c and FPG levels for the diagnosis of prediabetes and diabetes is consistent with ADA recommendations in over 19 years old Korean population without diabetic medications. This conclusion requires further study to compare the characteristics of individuals with newly diagnosed diabetes by each only HbA1c- and only FPG-based diagnostic criteria and large-scale longitudinal study to assess the relation of HbA1c to incident diabetic retinopathy.

Blood lead is associated with impaired fasting glucose in middle-aged population: the 2008–2011 Korean National Health and Nutrition Examination Survey

Sang Yong Kim & Jin Hwa Kim
Chosun University Hospital, Gwang-Ju, Republic of Korea.

Objective

Environmental exposure to heavy metals has affected human health. Several studies have suggested that lead increase oxidative stress and induce mitochondrial dysfunction. The objective was to determine whether there was an association between blood lead level and impaired fasting glucose (IFG) in middle-aged population.

Research design and methods

This study was based on the data from the Korean National Health and Nutrition Examination Survey (KNHANES), conducted by the Korean Ministry of Health and Welfare in 2008–2011. Of 37 753 participants, data for 2366 adults ≥ 40 years of age without diabetes were included in the analysis. Subjects were subdivided according to quartile of blood lead level. Multivariate logistic regression analyses were used to identify whether there was an independent association between blood lead level and IFG by adjusting for confounding factors.

Results

Blood concentration of lead was significantly higher in IFG group, compared with normal glucose tolerance (NGT) group (IFG, 2.723 $\pm$ 0.565 μg/dl and NGT, 2.522 $\pm$ 0.384, $P=0.002$). The prevalence of IFG increased significantly by increasing quartile of blood lead level (Q1, 20.6%; Q2, 21.6%; Q3, 26.7%; and Q4, 31.1%; $P=0.001$). After fully adjusting for confounding factors, including lifestyle behaviors, sociodemographic factors, family history of diabetes, and known diabetes risk factors, the fourth quartile of blood lead level (>3.091 μg/dl) was significantly associated with IFG (odds ratio 1.491 (95% CI 1.004–2.214)).

Conclusions

Blood lead level was independently associated with IFG in middle-aged population. We propose that the lead may contribute to increasing glucose level and risk of prediabetes.

EP369

The state of superoxidedismutase activity as marker of oxidative stress in patients with impaired glycaemic states

Volha Shyshko[1], Tatjana Mokhort[1], Natalia Tsapaeva[1], Inna Buko[2] & Elena Konstantinova[3]
[1]Belarussian State Medical University, Minsk, Belarus; [2]Belarussian Republic Center of Cardiology, Minsk, Belarus; [3]A.V.Luikov Heat and Mass Transfer Institute of the National Academy of Science, Minsk, Belarus.

One of the key enzymes of antioxidant system is superoxide dismutase (SOD) that catalyses dismutation of superoxide anionic radical ($O_2^{\cdot -}$)l to molecular oxygen (O_2) and hydrogen (H_2O_2). It was revealed that activity of SOD is decreased in patients with decompensated type 2 diabetes (T2D) but there is insufficient data about enzyme activity in compensated states and prediabetes.

Purpose

To analyse the state of SOD activity in patients with compensated T2D and prediabetes.

Materials and methods

195 patients were divided into five groups: group 1 – 23 patients with impaired fasting glucose (IFG), group 2 – 23 patients with impaired glucose tolerance (IGT), group 3 – 41 patients with T2D, group 4 – 48 patients with T2D and concomitant coronary heart disease (CHD), and group 5 – 41 almost healthy person (control). All patients were before 60 years old and patients with T2D had compensated glycaemic state. Activity of SOD was measured by reduction of nitrotetrazolium by superoxide radical.

Results

The lowest activity was registered in group 4 (71.71 (48.14; 80.37) CU/ml) and in group 3 (76.49 (35.43; 85.22) CU/ml) compared to control group (104.96 (66.86; 142.82) CU/ml) ($P4–5 < 0.001$ and $P3–5 < 0.005$). Activity of SOD was significantly higher in patients with IGT (92.95 (60.21; 144.02)) compared to other groups ($P2–3 < 0.005$ and $P2–4 < 0.001$) and almost was not different compared to almost healthy person ($P > 0.1$). We didn't reveal any significance in activity of SOD on patients with IFG and other groups.

Conclusion

T2D is associated with decreased activity of SOD which is more significant when associated with CHD. Prediabetes is not associated with changes in the activity of SOD.

EP370

Comparison between aldosterone and renin measurement by chemiluminescent immunoassay and RIA for the diagnosis of primary aldosteronism

Jacopo Burrello[1], Fabrizio Buffolo[1], Silvia Monticone[1], Tracy Ann Williams[1], Andrea Viola[1], Giulio Mengozzi[2], Franco Veglio[1] & Paolo Mulatero[1]
[1]University of Torino, Torino, Italy; [2]Città della Salute e della Scienza, Torino, Italy.

Objective

Primary aldosteronism (PA) is the most frequent cause of secondary hypertension. According to the Endocrine Society Guidelines, up to 50% of hypertensive patients should be screened for PA, using the aldosterone to renin (or plasma renin activity (PRA)) ratio (AARR and ARR respectively). The automated Diasorin LIAISON chemiluminescent immunoassay for renin and aldosterone measurement became available and in many laboratories is currently used instead of the classical radioimmunometric PRA and aldosterone assay. Aim of the study was to prospectively compare the diagnostic accuracy of AARR and ARR as screening test for PA and the two aldosterone assays also during confirmatory test in patients with a positive screening test.

Design and methods

100 patients were screened for PA and 44 patients underwent confirmatory test (i.v. saline load or captopril challenge test). We considered as cut off for the AARR 2.7 (ng/dl/mU/l) and for the ARR 30 (ng/dl/ng/ml/h). All patients positive to one of the two screening test underwent confirmatory test; patients with positive confirmatory test underwent subtype diagnosis by CT scanning and adrenal vein sampling.

Results

73 patients were diagnosed as essential hypertensives, 22 had bilateral adrenal hyperplasia, and five had an aldosterone producing adenomas (APA). The AARR displayed a sensitivity of 78% and a specificity of 100%, whereas the ARR had a sensitivity of 96% and a specificity of 90%. Of the 6/27 PA patients missed by AARR, none resulted to be affected by APA. All PA patients were correctly diagnosed by chemiluminescence at confirmatory test. In the overall sample of 181 measurements available both the correlation for the PRA with renin and for aldosterone in chemiluminescence and RIA were highly significant ($\rho = 0.66$, $P < 0.0001$ and $\rho = 0.80$, $P < 0.0001$ respectively). On ROC curves, the AUC for AARR was 0.905 (95% CI 0.821–0.988) and for ARR 0.947 (95% CI 0.903–0.991) were not significantly different.

Conclusions

The automated aldosterone and renin chemiluminescent assay is a reliable alternative to the well-established radioimmunometric method, especially for the detection of APA.

Listening to the patient's story: a qualitative approach to pre-gestational diabetic pregnancy

Catherine O'Hare[1] & Richard Greene[1,2]
[1]University College Cork, Cork, Ireland; [2]Cork University Maternity Hospital, Cork, Ireland.

Pre-gestational diabetics frequently rise to the challenge of pregnancy with remarkable improvements in diabetic control. Optimising pregnancy outcomes necessitates rigorous diabetes self-care, which is critically dependent on women's capacity and the support they receive. The aim of this study was to identify self-reported drivers and inhibitors of self-care in pre-gestational diabetic pregnancies. The study was carried out at a tertiary referral maternity unit. Convenience sampling was used. Ten women were recruited: age range 20–40 years, median age 33 years; nine type 1 diabetics; one type 2 diabetic; duration of diabetes ranged from 1 to 33 years, median was 16.5 years; 6 were unplanned pregnancies; six primigravida; two received diagnosis of foetal complications. Baseline Hba1c ranged from 42 to 85 mmol/l, median was 73 mmol/l. Follow-up measures ranged from 35 to 53 mmol/l, median was 48 mmol/l. Qualitative methods were employed to extract novel insights. We interviewed ten pregnant diabetics using six open-ended questions. Audio recordings were transcribed and 'computer assisted qualitative data analysis software' (CAQDAS) assisted coding and analysis of transcripts. Content analysis of transcripts revealed numerous themes. In addition, changes in self-care during pregnancy were measured using a validated questionnaire, 'Summary of Diabetes Self-Care Activities' (SDSCA). Nine women reported being highly motivated, driven predominantly by concern for baby's wellbeing. Numerous challenges were identified: difficulty maintaining a strict diet, hypoglycaemia, turbulent blood glucose and emotional challenges. Women perceived the glycaemic targets as demanding. In contrast numerous supports were perceived to facilitate self-care, particularly the diabetic care team. Other supports were family and the working environment. Regular daily routine was viewed as crucial. The 'SDSCA' questionnaire surprisingly did not detect significant changes, yet considerable changes in self-care were reported at interview. In conclusion, pre-gestational diabetic women are highly self-motivated as shown by this qualitative research. 'SDSCA' was not sensitive in this setting.

Biorhythms of contrinsular hormones in pregnant with type 1 diabetes receiving insulin with pump therapy and multiple injections

Tatsiana Mokhort[1], Tatsiana Skryplionak[2], Olga Pancratova[2] & Vladislav Rimashevskiy[3]
[1]Belarusian State Medical University, Minsk, Belarus; [2]«Mother and Child» National Research Center, Minsk, Belarus; [3]Belarusian Medical Academy of Post-graduated Education, Minsk, Belarus.

Pregnancy affects on the course type 1 diabetes (T1D), which is a result of changes in the production of hormones and their biorhythms.

Aim

To examine circadian biorhythms of contrinsular hormones (BCh) contribution in the morning postprandial glycaemia depending on the type insulin therapy.

Materials and methods

The study involved of 91 pregnant with T1D in 31–34 weeks on a background the maximum insulin resistance. Evaluation of circadian BCh (cortisol, progesterone, and placental lactogen) held on the results of the ELISA (DRG, Germany) serum samples, picks up in 0300, 0700, 1200, 1700, and 2200 h.

Results
The estimation of cortisol levels dynamics in acrophase marked invariable, which accounted at 0700 h, and minifase at 0300 h regardless of the type of insulin therapy. The acrophase of placental lactogen accounted at 1700 h, at the same time minifase at 2200 h and does not depend on the type of insulin therapy. The opposite results we get after estimation of progesterone levels. Progesteron acrophase accounted at 1700 h on the pump therapy and at 2200 h on multiple injections of insulin. Minifase of progesterone in both cases accounted at 0700 h.
Conclusion
Expressed of insulin resistance in the first half of the day determine the need for the use of high carb ratios for breakfast in order to achieve target levels of postprandial glycaemia is caused by cortisol acrophase and not placental lactogen and progesterone, which are laminated to the maximum mezor these hormones in third trimester. The use of pump insulin therapy accompanied by a shift of progesterone acrophase.

Higher glucose levels and prevalence of prediabetes in patients with autoimmune thyroiditis

Georgios Boutzios, Krystallenia Alexandraki, Stavros Liatis, Eleni Lampropoulou, Georgios Nikolopoulos, Aikaterini Bouki, Eleni Papaoiconomou, Kokkona Paradeisi, Nikolaos Tentolouris & Gregory Kaltsas
Section of Endocrinology, Department of Pathophysiology, National and Kapodestrian University of Athens Medical School, Athens, Greece.

Introduction
Thyroid autoimmunity and diabetes mellitus type 2 (DM2) are the commonest endocrine disorders in the general population. The aim of the study was to investigate whether there is an association between thyroid autoimmunity and β-cell secretion in patients with impaired fasting glucose (IFG) and/or impaired glucose tolerance (IGT).
Methods/design
501 patients (381 females) 46.5±14.2 years with IFG and/or IGT and autoimmune thyroiditis (AIT, TgAb, and/or TPOAb positive) were included in the study. Characteristics recorded were age, gender, waist circumference (cm), and BMI (kg/m^2). Fasting glucose (mg/dl) and insulin levels (μIU/ml), glucose 120 min post-oral glucose tolerance test (OGTT), HbA1c (%), HOMA and QUICKI insulin-resistance (IR) indices, and IR status as HOMA >2.16 and OUICKI <0.34 were also assessed. In 291 patients who had an oral glucose tolerance test (OGTT) with glucose and insulin measurement in five different time points), first, second phase insulin sensitivity index (ISI) and ISI were also assessed. Patients with hypothyroidism and DM2 were excluded from the study.
Results
Patients (n=266) who had AIT compared to non-AIT patients (n=) were older (48.6±13.5 vs 44.1±14.66 (P=0.001)), had larger waist (95.4±15.6 vs 91.4±15.5 (P=0.007)), higher glucose levels (99.9±12 vs 95.5±12.5 (P<0.001)), and higher prediabetes rates (64.2%) (χ^2=27.2, P<0.001) but similar rates of IR (51.8%). Prediabetic (P=64) patients with AIT had first phase ISI: 1293.8±774.6, second phase ISI: 432.3±231.8, and ISI: 0.06±0.05 comparable albeit higher to non-AIT (first phase ISI: 934.3±670.5 second phase ISI: 324.8±207.9, and ISI: 0.07±0.05) but similar ISI (P=0.06, P=0.06, and P=0.6 respectively).
Conclusion
Patients with AIT and impaired β-cell secretion had higher HbA1c levels with similar rate of insulin resistance and higher prevalence of prediabetes compared to non-AIT. Thyroid autoimmunity could be eventually a possible factor modifying β-cell secretion. Nevertheless further studies are needed to confirm these findings.

Effectiveness of Aβ classification of diabetes prone to ketosis in real clinical practice

Natalia Volkova, Maria Porksheyan & Julia Rudakova
Rostov State Medical University, Rostov on Don, Russia.

Introduction
Prevalence of so-called diabetes prone to ketosis (DPK), has been increasing. The necessity of lifelong insulinotherapy is determined by Aβ classification of DPK.
Design
Seven patients with atypical course of T2DM were studied. All patients had gradual development of hyperglycemia, obesity 1–2 stages, and acetonuria. Noone had acute weight loss. Stage 3 had positive GAD-AB, stage 4 – negative. Initially all patients were treated by insulin during 2–3 weeks. Thereafter, C-peptide was determined and type of diabetes, prone to ketosis, was established. If C-peptide was more than 1.2 ng/ml, oral hypoglycemic drugs were prescribed. Patients were followed up during 1 year with studying BMI, C-peptide, HbA1c, and acetonuria.
Results
Three patients had diagnosis of A+β+DPK and took oral medicine. However, during 1-year follow up, all these patients had HbA1c greater 7.5%, unmotivated weight loss and periodical acetonuria. After 6-month of follow up C-peptide was <1.2 ng/ml at all patients, which was an indication to lifelong insulinotherapy. Four patients were diagnosed with DPK A−β+ and took oral medicine. During 1-year follow up, 2 patients had HbA1c <7.5% and no cases of acetonuria. With stable weight, the level of C-peptide was still >1.2 ng/ml at the end of follow up. Thus, the prescribed treatment with oral hypoglycemic agents were continued. Two patients had HbA1c >7.5%, frequent cases of acetonuria and significant weight loss. C-peptide were declining progressively during 1-year follow up. That's why the diagnosis was changed to DPK A−β−, and lifelong insulinotherapy were prescribed.
Conclusions
Current Aβ classification of DPK is thought to allow to determine necessity of year-long insulinotherapy, which were not proved in our pilot study. The more clinical experience is needed to make strict follow up and treatment recommendations for patients with atypical diabetes.

Evaluation of quality indicators in hospital discharge reports in diabetic patients from an Internal Medicine Service: are we doing a good clinical practice?

José M Varela-Aguilar[1,2], Rafael Terán-Redondo[1], Maria Luz Calero-Bernal[1], Ana Calzada-Valle[1], Rosa García-Contreras[1], Estefanía Pereira-Díaz[1], Fidel Moreno-Verdejo[1], Francisco Ruiz-Ruiz[1] & Enrique Calderón-Sandubete[1,2]
[1]Internal Medicine Service. Virgen del Rocio Hospital, Seville, Spain; [2]CIBER de Epidemiología y Salud Pública, Seville, Spain.

Spanish Scientific Societies involved in diabetic patient care produced a consensus document with recommendations and quality indicators for hospital discharge reports (HDR).
Objective
To analyse adequacy of HDR in diabetic patients from an Internal Medicine Service according to these recommendations (*Med Clin* (Bar) 2012 **138** 666.e1–666.e10).
Methods
Study based on a programme continuity of care among Primary Care and Internal Medicine Service. We analyse 150 consecutive HDR in diabetic patients from an internal medicine service of a tertiary hospital. HDR were identified by hospital database and five cases were excluded by death. Clinical information was revised according to nine items recommended in document consensus.
Results
Average age 73.5 years, men 47% and women 53%.T2D 96%, 2% T1D, and steroid diabetes 2%. Diabetes *de novo* was present in five cases (3.4%). Time evolution diabetes was recorded in 27% of HDR and HbA1c only in 17.8%. Renal function (MDRD-4): Normal FGR 26.8%, 18.5% CKD stage 2, stage 3 33.5%, stage 4 15.7%, and stage 5 5.5%; however, FGR only was recorded in 9% HDR. Antidiabetic treatment preadmission was not collected in 36.3%. Where it was present were: monotherapy oral antidiabetic agents (OAA) 26.7%, 8.9% combination OAA, OAA more insulin 9.5%, alone insulin 18.6%. At discharge changes were made in the treatment at 35% but only 23.2% consisted justification at HDR. Changes were: first insulinisation 19.8%, OAA substitution 7.5%, and replacing insulin type 7.7%. The 45% of HDR collected recommendations on diet and exercise, glycaemic control targets in 7.5%, other control cardiovascular risk factors 9.5%, periodicity 13% glycaemic control and medical supervision (within review and assistance level) 11%.
Conclusions
Quality of HDR diabetic patients is low compared with the established recommendations. An improvement program should be introduced to optimise and tailor treatment in diabetic patients at hospital discharge.

Gonadal hormone regulates the expression MATE1 and OCT2 in type 2 diabetes mice

Ligen Ai, Dandan Zhang, Wolin Hou, Junxi Lu, Junling Tang, Huijuan Lu, Taishan Zheng & Fang Liu
Department of Endocrinology and Metabolism, Shanghai Clinical Medical Center of Diabetes, Shanghai Key Clinical Center of Metabolic Diseases, Shanghai Jiao-Tong University Affiliated Sixth People's Hospital, Shanghai, China.

Background and aims
Multi-drug and toxin extrusion 1 (MATE1) and organic cation transporters 2 (OCT2) are important proteins of metformin transport and excretion in liver and kidney. Our previous study showed that there were gender difference of metformin's hypoglycaemic effect and it was independently linked with the oestrogen and testosterone levels in type 2 diabetes patients. This study was designed to observe the impact of oestrogen and androgen on the renal expression of MATE1 and OCT2 in female and male *db/db* diabetic mice.
Materials and methods
Eight week-old *db/db* and their normal control mice were divided into hormone intervention group ($n=20$) which were injected testosterone 10 mg/kg per day ($n=10$) or oestradiol 1 mg/kg per day ($n=10$) for 7 consecutive days, and control group ($n=10$) received the same volume of olive oil for 7 days. Both the intervention group included male subgroup ($n=10$) and female subgroup ($n=10$), respectively, and also had normal control group ($n=5$). The blood were collected to detect plasma testosterone or oestradiol levels at day 7, the RNA and protein were extracted from kidney tissue to detect the expression of MATE1 protein and *OCT2* mRNA and protein with western blot and real-time PCR.
Results
i) After treatment with exogenous hormones, plasma levels of oestrogen (6.2 ± 1.3 vs 5.0 ± 0.94) and androgen (92 ± 23 vs 64 ± 9) increased markedly in both male and female mice ($P<0.01$). ii) Renal *OCT2* mRNA levels in testosterone-treated male (TM) and female (TF) mice were significantly higher than control female mice (CF, 2.6 ± 3.78, $P<0.05$). On the contrary, treatment with oestrogen in both of males (EM) and females (EF) had no significant impact on *OCT2* mRNA expression (both $P>0.05$). Simultaneously, the *MATE1* mRNA levels in testosterone-treated male group increased significantly compared to control male mice(CM, $P<0.05$) and oestrogen-treated male mice ($P<0.05$). No obvious changes of *MATE1* mRNA levels were found in both EM and EF ($P>0.05$). iii) The expression of OCT2 protein in TF was significantly higher than that of CF ($P<0.05$). However, the expression of both the MATE1 and OCT2 protein levels in TM group were higher markedly compared to CM ($P<0.05$). In oestrogen-treated males, the MATE1 expression elevated significantly ($P<0.05$), but the OCT2 expression had no apparent change ($P>0.05$).
Conclusions
Oestrogen and androgen up-regulate MATE1 expression of kidney in male diabetic mice, but have little effect on that of female mice; androgen increases OCT2 expression both in male and female mice, but oestrogen has little effect on their OCT2 expression.

The clinical effectiveness of screening for gestational diabetes mellitus in primary vs secondary care: results of a randomised controlled trial

Angela O'Dea[1], Marie Tierney[1], Liam Glynn[1], Andrii Danyliv[1], Louise Carmody[2], Brian McGuire[1], John Newell[1], Eoin Noctor[1] & Fidelma Dunne[1]
[1]National University of Ireland, Galway, Ireland; [2]HSE, Galway, Ireland.

Aims
The aim of this paper is to report on the outcomes of a clinical trial investigating the clinical effectiveness of universal screening for gestational diabetes mellitus (GDM) in primary care vs secondary care.
Design and methods
A parallel group randomised controlled trial of universal screening for GDM in primary vs secondary care. The primary outcome – uptake of screening in primary vs secondary care is reported elsewhere. In this article we report on the secondary outcomes of the trial: i) GDM prevalence, ii) timing of screening, iii) time to access antenatal diabetes care, and iv) maternal and neonatal outcomes.
Results
The prevalence of GDM was similar in primary care and secondary care screening groups, and groups were comparable in terms of the timeliness of screening, with both groups receiving screening at a mean of ~26 weeks. However there was a considerable delay (in both groups) in the time to access hospital treatment for women with GDM. For patients screened in the hospital the delay is 19 days, for those screened at the GP the delay is 24 days. Further research is needed to understand the reasons for this delay. In addition the GP group had a higher proportion of large for gestational age infants than the hospital group. It is possible that the delay in access to care is implicated in the increased infant size in this group; further research on a larger sample will be needed to answer this question. There were no differences between groups in maternal outcomes.
Conclusions
The evidence presented in this paper, shows that the hospital is still the best option for GDM screening, in terms of access to screening and in terms of time to access hospital care for those with GDM. Implications for long term GDM care are discussed.

Risks of having gestational diabetes in the future for mothers and their offspring

Sabin Goktas Aydin[4], Ayse Kubat Uzum[1], Banu Kucukemre Aydin[2], Seyda Ozel Yildiz[3], Selda Gedik[1], Cemile Idiz[1], Bülent Canbaz[1], Firdevs Bas[2], Ruveyde Bundak[2] & Nevin Dinccag[1]
[1]Endocrinology and Metabolism Division, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey; [2]Paediatric Endocrinology and Metabolism Division, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey; [3]Biostatistics Department, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey; [4]Department of Internal Medicine, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey.

Introduction
Gestational diabetes (GDM) has an important short and long-term health consequences for both the mother and her offspring. The aim of this study was to evaluate current metabolic status of women with GDM history and their offspring approximately at 10th year after delivery.
Methods
24 mothers who had GDM 10 years before (mean age 41.08 ± 4.13 years and BMI 30.3 ± 5.9) and their children (11 females, 13 males; mean age of 11.0 ± 1.9 years) were enrolled into the study. To evaluate current metabolic status of mothers, 75 g OGTT was performed and according to ADA criteria they were classified into two groups as normal glucose tolerance (group 1: NGT) and glucose intolerance (group 2: IGT and/or DM). Outcomes of foetal determinants were recorded and current clinical status and laboratory features of offspring were checked and evaluated if there would be any associations with mothers' metabolic status.
Results
41.6% of mothers had any degree of glucose intolerance at 10th year after delivery. As we concluded foetal determinants in groups, measurements of birth weight (g), length (cm) were found as 3625.6 ± 680 vs 3197.6 ± 608; 147.6 ± 11.5 vs 146.7 ± 13.0 respectively. As we considered daily status of children, their BMI and waist circumferences were observed as 18.4 ± 3.1 kg/m^2 vs 20.6 ± 5.7 kg/m^2 and 67.7 ± 12.2 cm vs 71.9 ± 10.1 cm respectively ($P>0.05$). Although the difference was not significant, waist circumference and central obesity of offspring in group 2 was found higher. Also results of fasting glucose and insulin levels of children in group 2 were higher than the others; but difference was not statistically significant. Five of them had lipid profile changes.
Conclusion
Frequency of glucose intolerance may be increased in the follow-up years; offspring of mothers having prediabetes may have great risk for obesity and insulin resistance in the future; especially at pubertal period. Those adolescents should be identified and efforts should be done to prevent development of metabolic syndrome and lifestyle should be planned to preserve beta cell function of the pancreas before puberty.

Maintenance of risk reduction during 3-year follow up in prevention of type 2 diabetes by lifestyle intervention in primary health care setting: Diabetes in Europe Prevention using Lifestyle, physical Activity and Nutritional intervention (DE-PLAN) project

Aleksandra Gilis-Januszewska[1], Beata Piwonska-Solska[1], Zbigniew Szybinski[1], Katarzyna Kissimova-Skarbek[2], Roman Topor-Madry[2], Grzegorz Glab[5], Jaana Lindstrom[3], Marku Peltonen[3], Peter Schwarz[4], Dorota Pach[1], Jaakko Tuomilehto[3] & Alicja Hubalewska-Dydejczyk[1]
[1]Chair and Department of Endocrinology, Jagiellonian University, Krakow, Poland; [2]Institute of Public Health, Jagiellonian University, Krakow, Poland; [3]Diabetes Prevention Unit, National Institute for Health and Welfare, Helsinki, Finland; [4]Department of Medicine III, Carl Gustav Carus of the Technical University Dresden, Dresden, Germany; [5]Department of Rehabilitation, Faculty of Physiotherapy, University School of Physical Education, Krakow, Poland.

Introduction
Extended up to 20 years follow-up of several randomised control trials showed 34–43% diabetes risk reduction. Real life implementation studies performed worldwide in different settings and populations proved that also non-intensive, low budget lifestyle interventions can be effective. However little is known about long-term results of the translational studies.
Objective
To study the risk factors changes of the DEPLAN non-intensive lifestyle intervention in primary health care setting during 3-year follow up.
Research design and methods
Study participants ($n=114$) with baseline diabetes type 2 risk FINDRISC >14, no diabetes, received ten group lifestyle counselling sessions, six motivation phones, and two letters and physical activity. Measurements performed at 12 months after the initiation of the intervention were repeated after 36 months.
Results
Statistical significant risk reduction at 1 year was maintained at 3 years in weight (82.9 vs 81.6 kg), BMI (31.2 vs 30.1 kg/m^2), serum total cholesterol (5.5 vs 5.4 mmol/l), TG (1.85 vs 1.6 mmol/l ($P<0.09$)), and FINDRISC (18.4 vs 16.2 ($P<0.05$)). After 3 years 6% of participants converted to diabetes, while 56% of baseline IFG and IGT reversed to NGT. Physical activity increase, increased consumption of vegetable and fruit and decreased of saturated fat and change of saturated fat to unsaturated observed at one year were also maintained during follow up ($P<0.05$).
Conclusions
Diabetes type 2 prevention through non intensive, real life lifestyle intervention with modest weight reduction is feasible in a primary health care setting and can be maintained during long time observation.

Discrepancies between the HbA1c criteria and glucose-based criteria for diagnosis of diabetes and pre-diabetes

Raj Kumar Shrestha[1], Prabin Gyawali[2], Eans Tara Tuladhar[1], Vijay Kumar Sharma[1], Sweta Shrestha[1] & Bharat Jha[1]
[1]Department of Biochemistry, Institute of Medicine, Tribhuvan University Teaching Hospital, Kathmandu, Nepal; [2]Department of Clinical Biochemistry, Dhulikhel Hospital, Kathmandu University Hospital, Dhulikhel, Nepal.

The number of the people with type 2 diabetes is increasing globally, therefore there is an increasing need to identify diabetes earlier and more efficiently. Nearly 80% of people with diabetes live in low and middle income countries (LMICs). Traditionally, we have relied on glucose-based criteria (fasting, postprandial, and random) to make the diagnosis of diabetes; however, HbA1c has recently been endorsed as a diagnostic test, as superior alternative to glucose-based criteria. It is still controversy about implementation of HbA1c criteria in LMICs especially due to several cons one of them being high cost. Previous studies have suggested that some degree of discrepancies exist between the HbA1c and glucose based criteria and may vary by race, ethnicity, sex, and age in various populations. Hence, we aimed to access the discrepancies between the new HbA1c-based criteria over glucose-based criteria for diagnosis of diabetes and pre-diabetes among clinically diagnosed Nepalese population. A total of 1277 clinically suspected type 2 diabetes and prediabetes, who attended Tribhuvan University Teaching Hospital (TUTH), Kathmandu, Nepal between January 2012 and April 2014 were recruited in the study. Initial screening was carried out using the FINDRISC questionnaire. The American Diabetes Association (ADA)-glucose based and ADA-HbA1c criterions were used to diagnose diabetes and pre-diabetes. The discrepancies between two criteria to diagnose pre-diabetes and diabetes were evaluated. Significant discordance exists between the HbA1c- and glucose-based criteria for diagnosis of diabetes in Nepalese population. Furthermore, the substantial numbers of subjects with pre-diabetes were missed by HbA1c criterion.

The correlation of serum ferritin and diabetes, glucose control or insulin resistance, related or not?

Jiang Li, Cheng Xiao & Yongtong Cao
China-Japan Friendship Hospital, Beijing, China.

Background
We have previously investigated the association between serum ferritin levels and risks of metabolic syndrome (MetS) using the same database from 2009 wave of the China Health and Nutrition Survey (2009 CHNS). We confirmed that MetS components are associated with increased serum ferritin levels in both men and women group, included abdominal obesity, hypertriglyceridemia, low HDL cholesterol, high blood pressure, and abnormal glucose level. Although, the prevalence of anaemia was not associated with having diabetes, the anaemic participants have abnormal iron metabolism. This will influence the serum ferritin level. So in this study, we aimed to further investigate the association between serum ferritin concentrations with diabetes, glucose control and IR adjusted for other confounders in non-anaemic Chinese population, especially adjusted other MetS components in multivariable logistic regression analyses.
Methods
Fasting blood samples and anthropometric data collected on 7362 adults aged 18 and older in 2009 wave of the China Health and Nutrition Survey (2009 CHNS). Data were collected by trained physicians. The fasting serum glucose and blood routine examination were measured at local hospitals. Other biochemical markers were analyzed by an automatic clinical chemistry analyser at the Department of Laboratory Medicine of CJFH.
Results
For both men and women, higher concentrations of serum ferritin were associated with higher values for markers of insulin resistance. But after adjusted for age, and some of MetS components, the difference became weak.
Conclusion
We observed a weak association between serum ferritin levels and the prevalence of diabetes and IR in non-anaemic population. Additional studies are needed to elucidate the mechanisms of serum ferritin and risks of diabetes. This may help to reduce diabetes or pro-diabetes.

DOI: 10.1530/endoabs.37.EP381

Impact of *ACE* gene polymorphism on preeclampsia development and insulin resistance aggravation in pregnant women with type 1 diabetes mellitus

Andriy Hrybanov[1,3], Zoya Rossokha[2] & Tatiana Avramenko[1]
[1]State Institution 'Institute of Pediatrics, Obstetrics and Gynecology by The Academy of Medical Sciences of Ukraine', Kiev, Ukraine; [2]State Institution 'Reference-centre for molecular diagnostics by The Ministry of Public Health of Ukraine', Kiev, Ukraine; [3]Maternity Hospital #2, Nikolayev, Ukraine.

Type 1 diabetes mellitus (T1DM) and preeclampsia (PE) in pregnant women share common pathophysiological pattern (hypovolemia, increased vascular resistance, and kidney damage) and both are genetically determined. Genetic impact on PE development and aggravation of insulin resistance in T1DM pregnant women has been underinvestigated. Thus, the aim of this case-control study was to evaluate the influence of *ACE* gene *I/D* polymorphism on risk of PE and insulin resistance development.
Materials and methods
Inclusion criteria were as following: for group I – T1DM with superimposed PE (30 patients) and for group II – DM without PE (30 patients). Standard examination was undertaken during pregnancy and postpartum, as well as detection of *ACE* gene polymorphism with allele-specific PCR. The obtained results were analysed using STATISTICA 10.0 Software.
Results
Patients of group II had significantly higher prevalence ($\chi^2=10.35$; $P<0.01$) of *II* genotype compared to group I (56.7 and 16.7% respectively) supporting the

protective effect of *II* genotype on PE development in the investigated population (OR = 0.15; 95% CI 0.05–0.51). Fasting lucose levels (*per se* and in relation to different genotypes) didn't differ between both groups before PE appearance, as well as prior to delivery. But in group I we detected elevated glucose levels depending on genotypes: 8.72 ± 1.26 mmol/l – in patients with *DD* genotype, 8.72 ± 1.26 mmol/l – in patients with *ID* genotype, 5.93 ± 0.52 mmol/l – in women *II* genotype. In group I differences in glucose levels reported in patients with *II* genotype compared to patients with *DD* and *ID* genotypes were found to be statistically significant ($P < 0.05$). Other parameters supporting deeper insulin resistance aggravation have been identified prior to delivery only among patients of group I with *DD* and *ID* genotypes.

Conclusion

ACE gene polymorphism determines the risk of PE in pregnant women with T1DM and modulates unfavourable course of the disease, particularly, aggravation of insulin resistance in patients with *DD* and *ID* genotypes.

Mechanisms of development of carbohydrate metabolism disturbances in acromegalic patients depending on treatment

Alexander V Dreval[1], Irina V Trigolosova[1], Anna V Vinogradova[1] & Bruce H R Wolffenbuttel[2]
[1]Moscow Regional Clinical Research State Institute named after M.F. Vladimirsky, Moscow, Russia; [2]Department of Endocrinology, University of Groningen, University Medical Center Groningen, Groningen, The Netherlands.

Background

In acromegaly, carbohydrate metabolism disorders (CMD) are frequently observed. The effect of therapy of acromegaly on pathogenesis of CMD is not clear.

Aim

To assess the effect of somatostatin analogues (SSA) on pathogenesis of carbohydrate metabolism disturbance in acromegaly.

Patients and methods

103 acromegaly patients were examined (31 men, 72 women; age 54 (46–61) years; 60 had newly diagnosed acromegaly (NA), 23 receiving SSA, 20 after transsphenoidal surgery (TSS). We analyzed fasting plasma insulin and glucose levels (FPI and FPG), HbA1c, the Matsuda, and HOMA-IR indices, area under insulin curve in the first 30 min (AUCins.30) and from 30 to 120 min of oral glucose tolerance test (AUCins.30–120). In 23 NA patients we assessed these parameters after 3 and 6 months of SSA therapy (12 patients) and TSS (11 patients).

Results

The prevalence of CMD in NA, SSA, and TSS groups was 52, 87, and 35% respectively. Levels of HOMA-IR index and FPI did not differ between SSA and TSS groups, but were considerably lower compared to the NA group (HOMA-IR 1.7 (IQR 0.7–3.1) vs 3.3 (2.0–7.4), $P = 0.008$; FPI 46.0 (IQR 17.1–88.00) vs 90.0 (55.3–179.5) mU/l, $P = 0.002$). Early insulin secretion estimated by AUCins.30 was severely reduced in the SSA group compared to the NA and TSS groups ($P < 0.01$). Among 12 prospective SSA-treated patients, the reduction of IGF1 after 6 months coincided with a decrease of FPI and HOMA-IR (both $P < 0.05$), and an increase of the Matsuda index ($P = 0.068$). SSA-treatment resulted in a considerable reduction of early insulin secretion (AUCins.30) during an OGTT compared to the TSS group, while the reduction of AUCins.30–120 was similar between these groups.

Conclusions

Despite reduction of IGF1 levels and insulin resistance during SSA therapy and after TSS, the decrease of early insulin secretion on SSA therapy leads to the development of CMD.

TRAIL downregulates endothelin 1 and upregulates superoxide dismutase 1 in human aortic endothelial cells under pro-atherorgenic conditions

Hannah Forde[1,2], Colin Davenport[1], Diarmuid Smith[1] & Phil Cummins[2]
[1]Beaumont Hospital, Beaumont, Dublin 9, Ireland; [2]Dublin City University, Glasnevin, Dublin 9, Ireland.

Introduction

Increased oxidative stress is associated with endothelial dysfunction in atherosclerosis and cardiovascular diseases (CVD). Evidence suggests that tumour necrosis factor-related apoptosis-inducing ligand (TRAIL), a member of the tumour necrosis factor (TNF) superfamily, may also be involved in the pathogenesis of CVD. Observational studies have demonstrated that serum levels of TRAIL are inversely correlated with severity of coronary artery disease. This concurs with other recent *in vivo* findings suggesting that TRAIL may exhibit vasoprotective effects towards the endothelium, although the mechanism of TRAIL-mediated vasoprotection remains poorly understood. The aim of this study therefore was to characterise the effect of TRAIL on inflammatory gene expression from vascular endothelial cells *in vitro* under oscillatory flow, an essential component of atherosclerotic plaque formation.

Methods

Primary-derived human aortic endothelial cells (HAECs) were exposed to pathological oscillatory shear stress (± 10 dyns/cm^3) using the IBIDI$_R$ μslide perfusion unit in the presence and absence of recombinant human TRAIL (100 ng/ml, 24 h). RNA was isolated from the cells using a modified Mirvana method. Gene expression was assessed by a PCR array using qPCR.

Results

TRAIL downregulated expression of endothelin 1 (*EDN1*) gene, which encodes the proinflammatory cytokine EDN1. EDN1 is also associated with reactive oxygen species formation. TRAIL upregulated expression of superoxide dismutase 1 (*SOD*) gene, which encodes the potent antioxidant enzyme SOD1.

Conclusion

TRAIL exerts an anti-inflammatory effect on the endotheium under pro-atherogenic conditions, at least in part through reduction of oxidative stress.

Surgical trauma and insulin resistance

Snezana Polovina[1], Dusan Micic[2], Zlatibor Loncar[2], Mirjana Sumarac-Dumanovic[1], Predrag Savic[2], Goran Cvijovic[1], Vladimir Resanovic[2], Svetlana Zoric[1], Danica Stamenkovic-Pejkovic[1], Vladimir Djukic[2] & Dragan Micic[1]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Clinical Center of Serbia, Belgrade, Serbia; [2]Emergency Center, Clinical Center of Serbia, Belgrade, Serbia.

Introduction

Different surgical procedures are followed by alteration in insulin sensitivity. The aim of our investigation was to analysed the influence of major (open cholecystectomy) and minor surgical stress (laparoscopic cholecystectomy) on insulin resistance.

Methods

Insulin resistance was calculated by HOMA-IR before surgery and at 1st, 3rd, and 7th day after the elective operations. All participants were divided in two groups: group A with open cholecystectomy $n = 20$; 38.8 ± 4.3 years of age; mean BMI 26.9 ± 1.6 kg/m^2 and group B with laparoscopic cholecystectomy; $n = 20$; 39.8 ± 4.5 years of age; mean BMI 26.8 ± 1.9 kg/m^2.

Results

There were no difference in HOMA-IR between groups A and B before surgery (mean 2.5 ± 0.33 vs 1.99 ± 0.70; $P > 0.05$) as well as the 1st day after surgery (2.55 ± 0.62 vs 1.85 ± 0.58; $P > 0.05$). HOMA-IR was higher in group B 3rd day after operation than in group A (7.56 ± 2.34 vs 2.8016 ± 0.78; $P < 0.05$). There were no difference between two groups 7 days after surgery (0.65 ± 0.45 vs 0.74 ± 0.40; $P > 0.05$).

Conclusion

Open and laparoscopic cholecystectomy are followed by transient insulin resistance which become normal a week after the operation. Laparoscopic cholecystectomy less deteriorate insulin sensitivity in response to stress than open approach.

EP386

A case of maternally-inherited diabetes with deafness

Maja Bakula[1], Maja Cavlovic Naglic[1], Miro Bakula[2] & Lea Smircic Duvnjak[1]
[1]Clinical Hospital Merkur, University Clinic Vuk Vrhovac, Zagreb, Croatia; [2]Clinical Hospital Sveti Duh, Zagreb, Croatia.

Introduction
Maternally-inherited diabetes with deafness (MIDD) is a rare form of monogenetic diabetes caused by a point mutation in mitochondrial DNA at a position 3243A > G. The syndrome is characterised by diabetes and sensoneural hearing impairment. Additional clinical features include short stature, cardiomyopathy, myopathy, renal disease, macular dystrophy, and gastrointestinal disease. The majority of patients usually require insulin therapy within 2 years and metformin is probably best avoided because of interference with mitochondrial function. The genetic change is passed down from an affected mother to all her children. However, the clinical phenotype associated with the mutation may be very heterogeneous.
Case report
We present a case of a lean 35-year-old female patient who was diagnosed with diabetes at the age of 29 years, suffering from hearing loss and migraine. She tested negative for anti-islet humoral markers (ICA, anti-GAD, and anti-IA2) and her insulin secretory reserve was partially maintained. Four years after the diagnosis, insulin was introduced to therapy. Bilateral neurosensory hearing loss was diagnosed at the age of 29 and required the use of hearing aid. There is a family history of diabetes affecting her mother, maternal uncle, and grandmother. The clinical suspicion of MIDD was confirmed by the detection of mitochondrial DNA mutation m.3243A > G in patient's urinary epithelial cell DNA sample.
Conclusion
It is assumed that MIDD affects up to 1% of all patients with diabetes but often goes unrecognised and is misdiagnosed as either type 1 or type 2 diabetes. Although, it is not possible to predict the likely clinical course associated with this mutation due to variation in phenotype, it is important to suspect and confirm the diagnosis by the genetic testing in order to treat the patient optimally, to screen the patient for other clinical features of the syndrome and to look for the affected family members.

Association of neutrophil to lymphocyte ratio with different glucose metabolism status

Betül Ekiz Bilir[1], Neslihan Soysal Atile[1], Bülent Bilir[2], Birol Topçu[3], Sonat Pınar Kara[2], Derya Baykiz[4] & Murat Aydin[5]
[1]Tekirdag State Hospital, Tekirdag, Turkey; [2]Internal Medicine Department, Namik Kemal University, Tekirdag, Turkey; [3]Biostatistics Department, Namik Kemal University, Tekirdag, Turkey; [4]Cardiology Department, Tekirdag State Hospital, Tekirdag, Turkey; [5]Biochemistry Department, Namik Kemal University, Tekirdag, Turkey.

Introduction
Several studies have shown that prediabetic patients had increased concentrations of inflammatory markers and this association is independent of underlying obesity. Netrophil to lymphocyte ratio (NLR) is considered as a new inflammatory marker and has been studied extensively in a variety of clinical conditions especially in solid tumours and cardiovascular diseases. Studies evaluating the subclinical inflammation in prediabetes revealed positive association of some inflammatory markers with hyperglycaemia. The aim of this study is to evaluate the association of NLR with different glucose metabolism status groups.
Methods/design
The study included 259 patients (213 females, 46 males; mean age 47.4 ± 11.5 and 48.8 ± 15.7 respectively) who admitted to an Out-Patient Endocrinology Clinic of a State Hospital in Turkey. The asymptomatic adults were classified in three groups as normal glucose metabolism, impaired fasting glucose, and impaired glucose tolerance according to 75 g-oral glucose tolerance test. The patients who had diabetes, any thyroid dysfunction, malignancy, pregnancy, any acute or chronic infectious or inflammatory disease, or patients who were on oral anti-diabetic drugs were excluded from the study. BMIs of patients, serum fasting glucose and insulin levels, lipid parameters and complete blood counts with differentials were registered.
Results
There were statistically significant differences between groups in terms of fasting glucose and HOMA-IR levels as expected ($P = 0.000$ and $P = 0.047$ respectively). Otherwise there are no differences in terms of BMI, insulin, lipids, and NLR.

Groups	Age	BMI	Glucose	Insulin	HOMA-IR	TG	HDL	LDL	NLR
Normal ($n = 53$)	42.2 ± 13.9	34.7 ± 7.1	93.9 ± 7.3	11.6 ± 6.9	2.7 ± 1.6	152 ± 97	48 ± 14	136 ± 31	1.86 ± 0.67
IFG ($n = 120$)	48.7 ± 11.1	34.6 ± 7	106.8 ± 7	12.9 ± 6.5	3.4 ± 1.7	160 ± 90	44 ± 13	138 ± 39	1.8 ± 0.61
IGT ($n = 86$)	49.5 ± 12.3	35.9 ± 8	107.6 ± 8.1	13.7 ± 7.3	3.7 ± 2.1	178 ± 106	45 ± 12	133 ± 36	1.85 ± 0.76

Conclusion
Glucose metabolism status was not associated with NLR in our small study cohort. Studies based on a wider population might give a different result in this manner.

DOI: 10.1530/endoabs.37.EP387

EP388

Contribution of glucose variability to HbA1c levels in patients with type 1 diabetes

Luis Cardoso[1], Carla Batista[1], Dírcea Rodrigues[1,2], Carolina Moreno[1,2], Daniela Guelho[1], Nuno Vicente[1], Margarida Balsa[3], Diana Martins[1], Diana Oliveira[1] & Francisco Carrilho[1]
[1]Department of Endocrinology, Diabetes and Metabolism, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [2]Faculty of Medicine, University of Coimbra, Coimbra, Portugal; [3]Department of Endocrinology, Centro Hospitalar do Baixo Vouga, Aveiro, Portugal.

Background
Optimal management of type 1 diabetes requires full understanding of the relationships between the triad: HbA1c, fasting plasma glucose, and glucose variability (GV). As GV may contribute to HbA1c we assessed the influence of GV in HbA1c levels.
Research design and methods
We retrospectively analysed 9393 h of continuous glucose monitorings (CGMs) from 61 patients with type 1 diabetes. Periods of 24 h with missing values were excluded. We calculated various measures of GV and used a regression model to determine the impact of each GV measure to HbA1c level. GV was calculated using EasyGV Software and CGMs were recorded using iPro2 (Medtronic, Northridge, CA, USA).
Results
A total of 9393 h of CGM were analysed. Mean duration of diabetes was 17.7 ± 9.6 years and HbA1c was 7.9 ± 1.1%. S.D., continuous overlapping net glycaemic action (CONGA), mean absolute glucose (MAG), and mean of daily differences (MODD), were positively correlated with HbA1c (correlation coefficient of 0.26, 0.37, 0.26, and 0.33, respectively, all $P < 0.05$), and all measures of GV were significantly higher for higher values of HbA1c (<7, 7–8, 8–9, and >9%, all $P < 0.05$). Intraday GV measures contributed to 4–16% of HbA1c (S.D.: 10.2%, CONGA: 15.7%, mean amplitude of glycemic excursions (MAGE–CGM) 3.9%, and MAG 8.1%, $P < 0.05$). Interday variability, measured by MODD, accounted for 13.1% of HbA1c. Furthermore, MODD was positively correlated with measures of quality of glycemic control, like glycemic risk assessment in diabetes equation (GRADE) score, J-index, high blood glucose index (HBGI), *M*-value, and average daily risk ratio (ADDR) (correlation coefficient of 0.41, 0.54, 0.57, 0.54, and 0.80, respectively, all $P < 0.05$).
Conclusion
GV contributes significantly to HbA1c levels. This effect is more pronounced at higher HbA1c levels. Interday variability was the most important contributor to HbA1c. GV impairs significantly the quality of glycemic control of type 1 diabetic patients.

Increasing NAD^+ availability in skeletal muscle to augment energy metabolism

Rachel Fletcher, Craig Doig, Agnieszka Zielinska, Aliesha Griffin, Andrew Philp & Gareth Lavery
University of Birmingham, Birmingham, UK.

NAD^+, an essential coenzyme in energy production, has recently risen to prominence as a signalling molecule central in mediating cellular metabolism and mitochondrial function. NAD^+ dependent protein deacetylase sirtuin (SIRT) proteins regulate key metabolic transcription factors, including FOXOs and PGC-1α in muscle, in response to cellular energy demands and metabolic stress. Declining NAD^+, metabolic and mitochondrial function are hallmark features of many patho-physiological processes such as ageing and type 2 diabetes. Thus, boosting NAD^+ availability may have beneficial and therapeutic potential. NAD^+ consumption (e.g. SIRTS) requires its re-synthesis through precursor salvage to maintain appropriate levels. Here we further define a skeletal muscle specific pathway to NAD^+ and energy metabolism. Through mRNA and protein expression analysis of NAD^+ biosynthesis genes we show that skeletal muscle relies on a limited set of salvage enzymes for NAD^+ biosynthesis and replenishment. The most highly expressed and skeletal muscle specific of which is nicotinamide riboside kinase 2 (Nmrk2), which salvages the NAD^+ precursor molecule nicotinamide riboside (NR) to produce NAD^+. Nmrk2 demonstrates muscle fibre type specificity, being fivefold enriched in type II fibres compared to type I. Nmrk2 expression is induced during mouse myotube differentiation and embryonic muscle development in zebrafish. Primary derived mouse muscle cells supplemented with 0.5 mM NR for 24 h showed a significant 30% increase ($P<0.001$) in NAD^+ levels with unchanged NADH, suggesting a shift in the redox ratio in favour of the oxidised form. Moreover, oxygen consumption rate was increased by 20% in NR treated myotubes when assessed using a Seahorse extracellular flux analyser, indicating that the NR is enhancing mitochondrial respiration as a result of boosting cellular NAD^+ availability. Our data provides evidence that Nmrk2 is important for skeletal muscle NAD^+ bioavailability and highlights the therapeutic potential for NR supplementation to target mitochondrial function in skeletal muscle.

Prepregnancy care: an opportunity not to be missed

Aoife Egan, Andriy Danyliv, Louise Carmody, Breda Kirwan & Fidelma Dunne
National University of Ireland Galway, Galway, Ireland.

Introduction

Our aim was to evaluate the effectiveness of a regional prepregnancy care (PPC) programme for women with both types 1 and 2 diabetes.

Methods

This prospective cohort study included women with pregestational diabetes attending five antenatal centres in the West of Ireland between January 2006 and December 2013. Comparisons were made between those that did and did not attend the PPC programme. Primary outcomes included composite adverse neonatal outcome (shoulder dystocia, congenital malformation, stillbirth, or neonatal death), macrosomia, caesarean delivery, admission to neonatal care unit, per trimester HbA1c, and prepregnancy folic acid use.

Results

In total 452 women were included, 275 (60.8%) with type 1 diabetes and 177 (39.2%) with type 2 diabetes. PPC was attended by 148 (32.7%) women. Those who attended PPC were older (33.8 versus 31.8 years, $P<0.01$) and a higher proportion used prepregnancy folic acid (96.6% vs 54.9%, $P<0.01$). Mean first trimester HbA1c was lower among those who attended PPC (6.9% vs 7.8%, $P<0.01$), as was the mean second trimester HbA1c (6.6% vs 6.2%, $P<0.01$). There was no significant difference in third trimester HbA1c between groups. Rates of adverse neonatal outcomes were higher in those that did not attend PPC (9.5% vs 4.1%, $P=0.04$). A lower proportion of infants born to women who attended PPC required neonatal unit admission (37.2% vs 48.7%, $P=0.02$). There was no difference in rates of caesarean delivery or macrosomia between groups. Binary logistic regression analysis identified that attendance at PPC independently reduced the odds of a serious adverse neonatal outcome (aOR 0.27, CI 0.09–0.83, $P=0.02$).

Conclusion

These findings suggest that provision of a regional PPC programme confers both an individual and economic benefit and should be available to all women with pregestational diabetes.

EP391

Lipoprotein associated phospholipase A2 was not associated with diabetic rethinopathy

Zehra Candan[1], Fatma Dilek Dellal[2], Esranur Ademoglu Dilekci[3], Ziynet Alphan Uc[4], Handan Bekdemir[5], Gonul Koc[6], Cavit Culha[6], Yalcin Aral[6], Guner Uney[6] & Zuleyha Yalniz Akkaya[6]
[1]Ankara Medical Park Hospital, Ankara, Turkey; [2]Ankara Ataturk Training and Research Hospital, Ankara, Turkey; [3]Bitlis State Hospital, Bitlis, Turkey; [4]Usak State Hospital, Usak, Turkey; [5]Izmir Sifa University Hospital, Izmir, Turkey; [6]Ankara Research and Training Hospital, Ankara, Turkey.

Aim

Diabetic rethinopathy is an important microvascular complication in diabetic patients. The association between hyperlipidemia and diabetic rethinopathy remains elusive. Lipoprotein associated phospholipase A2 (Lp-PLA2) is Ca independent serine kinase that hydrolyses oxidized LDL and forms lysilphoshotidylcholine and free fatty acid. The aim of the study was to determine serum levels of Lp-PLA2, traditional lipids, apolipoproteins in patients with diabetic rethinopathy and to evaluate correlation of these parameters with disease severity.

Methods

A total of 67 diabetic patients were divided into three groups (nonproliferative diabetic rethinopathy, proliferative rethinopathy, and no rethinopathy) based on fundoscopic examination and matched to 15 healthy and nondiabetic people. Blood samples for lipids, apolipoproteins, Lp-PLA2 were drawn.

Results

No significant difference was observed in terms of total cholesterol, TG, LDL-C levels between groups. However HDL-C levels were similar in proliferative diabetic rethinopathy, nonproliferative rethinopathy patients and diabetic controls (42.5 ± 6.4, 46.8 ± 12.3) and were lower than healthy controls (61.1 ± 14.5, $P<0.005$). No statistically significant difference was shown with respect to apolipoprotein A1, apolipoprotein B, apo B:apo A1 ratio in all comparisions. Serum levels of Lp-PLA2 was similar in all groups.

Conclusions

Serum levels of lipids, apolipoproteins and Lp-PLA2 were not associated with diabetic rethinopathy. Although, Lp-PLA2 were found to be associated with macrovascular complications of diabetes in most studies, the role of this molecule in microvascular complications wasn't known. The larger sample sized studies may clarify the relationship between Lp-PLA2 and rethinopathy.

Concentrations of the vitamin D metabolite 1,25(OH)2D and its relationship to inflammatory and metabolic parameters in diabetes type 2

Silvija Canecki-Varzic[1,2], Ivana Prpic-Krizevac[1,2] & Ines Bilic-Curcic[1,2]
[1]Clinical Hospital Center Osijek, Osijek, Croatia; [2]Faculty of Medicine, Josip Juraj Strossmayer University, Osijek, Croatia.

Background

While 25-hydroxy-vitamin D (25(OH)D) has been thoroughly investigated, the role of active vitamin D metabolite $1,25(OH)_2D$ in a metabolic syndrome still remains unclear. The aim of our study was to determine the association between 25(OH)D and $1,25(OH)_2D$ levels and several metabolic parameters and inflammatory markers in postmenopausal women with diabetes type 2 (T2DM).

Methods

Anthropometric variables, serum 25(OH)D, $1,25(OH)_2D$, C-reactive protein (CRP), fibrinogen, PAI-1, fasting glucose, fasting insulin, and HbA1c were measured in 125 postmenopausal women with T2DM. Insulin resistance was estimated by homeostasis model assessment (HOMA-IR) and β-cell function by HOMA-B. A total of 125 diabetic patients were divided by BMI in normal weight group ($n=22$, BMI 22.7 ± 1.5 kg/m^2) and adipose group ($n=93$, BMI 32.2 ± 5.8 kg/m^2). Control group consisted of healthy obese postmenopausal women ($n=46$, BMI 34.9 ± 6 kg/m^2).

Results

Serum 25(OH)D concentrations were highest in the lean diabetics compared with obese diabetics and control subjects ($P<0.0007$) and were significantly associated with fasting glucose, insulin, HOMA-B, BMI, and PAI-1. In diabetic patients 25(OH)D levels were positively associated with HDLC ($P<0.01$) and negatively with triglycerides ($P<0.04$) and PAI-1 ($P<0.001$). Serum $1,25(OH)_2D$ concentrations were significantly higher in control obese subjects (77.4 ± 17.0 nmol/l) compared with adipose diabetics ($P<0.001$), with no difference in relation to lean diabetics. Fasting glucose and HbA1c negatively correlated ($P<0.01$), whereas cholesterol and LDLC positively correlated

($P<0.01$) with 1,25(OH)$_2$D. Furthermore, 25(OH)D correlated with PAI-1 in all subjects while 1,25(OH)$_2$D correlated with fibrinogen but only in obese control subjects.
Conclusions
In T2DM women low serum 25(OH)D and 1,25(OH)$_2$D levels were associated with atherogenic dyslipidemia, glucose parameters, and low grade inflammation. The active hormonal form of vitamin D, 1,25(OH)$_2$D correlated with cholesterol, LDLC, and fibrinogen, while 25(OH)D correlated with triglycerides, HDLC, and PAI-1, suggesting that there may be an independent mechanism of action for 1,25(OH)$_2$D in relation to metabolic dysregulation.

10 years of improving outcomes for women with pre-gestational diabetes

Lisa Owens[1,2], Louise Carmody[1,2], Aoife Egan[1,2] & Fidelma Dunne[1,2]
[1]Galway Diabetes Research Centre, Galway, Ireland; [2]Atlantic Diabetes in Pregnancy Programme, Galway, Ireland.

Pregnancy for women with type 1 or type 2 diabetes is a high-risk time. The Atlantic diabetes in pregnancy (DIP) programme aims to provide coordinated, optimal evidence-based clinical care for women with diabetes over five hospital centres in the West of Ireland. After previously auditing pregnancy outcomes in 2008 and again in 2011 we now look at our 10-year outcomes. Changes in clinical care delivery that have occurred over that time include; the provision of dedicated combined antenatal/diabetes clinics, pre-pregnancy care clinics delivered by specialist diabetes and obstetric staff, use of a diabetes electronic management system, use of locally developed clinical care guidelines and professional and patient education materials. We examined outcomes in 440 pregnancies, divided into groups in groups of pre- and post-audit cycles, after which further change was implemented (2005–2008, 2009–2011, and 2012–2014). We saw a trend towards reduction in a lot of major outcomes. This is despite an increase in maternal age, maternal weight/BMI and a significant increase in numbers of women obese at the start of pregnancy. There has been an overall significant reduction in gestational weight gain. There has not however been a reduction amongst overweight women, just obese and normal weight women. We also saw an increase in attendance at pre-pregnancy care and a reduction in mean HbA1c values. There has been a significant reduction in congenital malformations and a non-significant reduction in large for gestational age babies, birth weight, smoking, neonatal hypoglycaemia, jaundice and admissions to the neonatal intensive care unit.
Conclusion
Changing the process of clinical care delivery can improve outcomes in women with pregestational diabetes. We now need to target women prior to pregnancy in order to optimise BMI.

Unawareness hypoglycaemia in patients with type 1 diabetes mellitus: prevalence and predictive clinical characteristics

Mariola Méndez Muros, Eyveé Arturo Cuéllar Llocl la, Fernando García Pérez, Guillermo Martínez de Pinillos Gordillo, Mariana Tomé Fernández-Ladreda, Juan Manuel Garcíade Quirós Muñoz, José Ignacio Fernández Peña, José Ignacio Fernández López, Margarita Rivas Fernández, Juana Magdalena Hidalgo Amat, Santiago Durán García & María Victoria Cózar León
Valme University Hospital, Seville, Spain.

Background
The prevalence of unawareness hypoglycaemia in patients with type 1 diabetes mellitus (T1DM) is uncertain. This study aims to determine its prevalence and predictive clinical characteristics with greater precision.
Methods
Prospective study. 128 patients were recruited between September 2013 and January 2014. Awareness of hypoglycaemia was assessed using the 'Clarke' questionnaire and was classified into two groups, depending on the presence (group 1) or absence (group 2) of symptoms perception.
Results
The 'Clarke' questionnaire was completed by 128 patients with T1DM: 53.8% females; mean age 36.2 ± 12.8 years; duration of diabetes 15.65 ± 9.18 years; HbA1c 7.45 ± 1.35%; 87.5% used intensive insulin therapy with multiple insulin doses. 80 patients (62.5%) were included in group 1 and 48 (37.5%) in group 2. The frequency of at least one episode of severe hypoglycaemia during the previous year was 20.3% in group 1 and 37.5% in group 2. 43% of patients in group 1 and 56.3% in group 2 needed a blood glucose value <50 mg/ml to notice symptoms. 43% of patients in group 1 and 66.7% in group 2 considered their symptoms hardly ever or never warned them about the presence of hypoglycaemia. There have not been any significant differences between both groups in diabetic microangiopathy, duration of disease, eating disturbances and insulin regimens (basal-bolus vs biphasic).
Conclusions
We have observed a high prevalence of unawareness hypoglycemia in patients with T1DM. Educational strategies are needed to improve their perception of hypoglycaemia symptoms.

Glycaemic control is comparable in patients with or without significant hepatic fibrosis as assessed by NAFLD fibrosis score

Jun Liong Chin, Grace Chan, Phyllis Sea-Pui Sin, Zeshan Siddiqui, Eoin O'Rathallaigh, Abdur Rahman Aftab, Garry Courtney & Colm McGurk
St. Luke's General Hospital, Kilkenny, Ireland.

Background and aims
Non-alcohol fatty liver disease (NAFLD) is increasingly recognised in diabetic patients with metabolic syndrome. Patients with poorly-controlled diabetes and metabolic syndrome are likely to have significant liver inflammation leading to fibrosis. NAFLD fibrosis score (NFS) is a validated non-invasive scoring system that identifies liver fibrosis in patients with NAFLD. The aim of this study is to examine the glycaemic control in patients with or without significant hepatic fibrosis as assessed by NFS in routine clinic.
Methods
All patients with type 2 diabetes or impaired glucose tolerance/fasting glucose, attending the diabetic clinic from March to June 2014 were included retrospectively. Patients with type 1 diabetes and gestational diabetes were excluded. Data were obtained from laboratory database and electronic patient record (Cellma). NFS was calculated for each patient based on age, BMI, diabetes, AST/ALT, platelet, and albumin.
Results
521 patients were screened and only 29.4% (153) of patients with complete laboratory data were studied. In our cohort of 153 patients, 64.1% (98) of patients were male and the median age was 63 (IQR 56.0–71.5) years. Using the NAFLD fibrosis score, almost a quarter of our patients (24.2%, $n=37$) had significant fibrosis with a median score of 1.169 (0.898–1.563) while the rest of the patients were indeterminate (66.0%, $n=101$) or had no significant fibrosis (9.8%, $n=15$). The median BMI for patients with significant hepatic fibrosis was 30.0 (27.8–34.5) kg/m^2 while for patients without significant fibrosis (including indeterminate score based on NFS), the median BMI was 34.8 (30.3–43.2) kg/m^2 ($P<0.01$) . Interestingly, there were no significant differences in the mean HbA1c readings in patients with or without significant hepatic fibrosis (55.2 ± 15.3 mmol/mol vs 56.6 ± 17.9 mmol/mol; $P=0.639$).
Conclusion
In conclusion, we did not observe any significant differences in glycaemic control in patients with or without significant hepatic fibrosis, as assessed by NAFLD fibrosis score.

Targeting optimal metabolic parameters in type 1 diabetes and concomitant coeliac disease: an extra challenge

Clifford Kiat[1], Tom Cotter[1], Sean Dinneen[1,2] & Esther O'Sullivan[1,2]
[1]University Hospital Galway, Galway, Ireland; [2]National University of Ireland, Galway, Ireland.

Patients, especially children, with type 1 diabetes (T1D) have an increased risk of developing other autoimmune disorders including coeliac disease (CD). While the general population prevalence of CD is ~1%, in patients with T1DM the prevalence of CD is higher (0.6–16%). Gluten free diet (GFD) imposes limitations in dietary options. Many of the gluten-free foods have a high glycemic index. This can influence glycemic values and metabolic parameters. We selected the subgroup of pts with T1D attending our service between June 2011 and June 2013 who have concomitant CD ($n=30$). To determine whether differences exist in their metabolic parameters compared to those of the total cohort of patients with T1D attending our service in the same time-period ($n=905$), we did a cross-sectional analysis of clinic measurements of weight, BMI, BP, HbA1c, lipid profiles, albumin creatinine ratios, and tissue transglutamine IgG antibody titres (TTG) (as a marker of adherence to a GFD). The CD+T1D group consisted of 18 (60%) females and 25 (83%) adults (>18 years) and had a mean age of 37 (s.d. 19). The T1D group consisted of 431 (48%) females and 798 (88%) adults (>18 years) and had a mean age of 37 (17). HbA1c in the CD+T1D group was 76.4 mmol/mol (s.d. 17.4) vs 70.3 (17.7) in the T1D group ($P=0.04$). Children overall had higher HbA1c values (83.6 and 75.7, $P<0.05$). In the CD+T1D group, lipid profiles showed lower total cholesterol (4.0 vs 4.6), LDL cholesterol (2.0 vs 2.4), triglycerides (1.0 vs 1.3), and higher HDL cholesterol (2.0 vs 1.7) mmol/l levels than the T1D group ($P<0.003$). There was no significant difference in the proportion taking cholesterol lowering drugs (35% vs 31%). The CD+T1D group had a lower average BMI (24.0 vs 26.4, $P<0.004$). CD+T1D presents a challenge to achieving target HbA1c but confers some benefits for lipid profiles.

Modulation of metabolic parameters and antioxidant enzymes in diabetic ageing female rat brains: beneficial role of metformin

Pardeep Kumar, R K Kale & N Z Baquer
Jawaharlal Nehru University, New Delhi, India.

Objective
The objective of this study was to investigate beneficial effects of metformin on membrane bound enzymes (monoamine oxidase, Na^+K^+ ATPse) and antioxidant enzymes (sueroxidase dismutase and glutathione *S*-transferases), lipid peroxidation, neurolipofuscin, and DNA degradation in diabetic aging female rats.
Methods
Young (3 months) adult (12 months) and aged (24 months) rats will be diabetic by using alloxan monohydrate. Metformin was administered i.p. at a dose of 200 mg/kg per day for 30 days to both control and diabetic aging rats. Learning was tested in a Morris water maze. A detailed study was carried on membrane linked enzymes, membrane fluidity, neurolipofuscin, antioxidant enzymes, and DNA degradation to identify the antidiabetic and antiaging role of metformin using biochemical, molecular, and histiochemical study.
Results
Present study shows that there was a similar pattern of increased lipid peroxidation, neurolipofuscin, DNA degradation, and monoamine oxidase activity and a decrease in membrane fluidity, Na^+K^+ ATPse, antixodant enzymes activities in both aging and diabetes. Metformin was found to be an effective treatment in stabilizing and normalizing the membrane functions; therefore this therapy can be considered an alternative to be explored further as a means of diabetic and aged related disorders control. Metformin treatment also helped to reverse the age-related changes studied, to normal levels, elucidating an anti-aging, antidiabetic, and neuroprotective action.
Conclusions
The results of this study will be useful for pharmacological modification of the aging process and applying new strategies for control of age-related disorders including metabolic syndrome.

Obstructive sleep apnoea and type 1 diabetes mellitus

Hiang Leng Tan[1], Feaz Babwah[2], Najeeb Waheed[2] & Muhammad Imran Butt[3]
[1]Weston General Hospital, Weston Super Mare, UK; [2]Hereford County Hospital, Hereford, UK; [3]Peterborough City Hospital, Peterborough, UK.

Introduction
Obstructive sleep apnoea (OSA) is common and frequently found in patients with obesity and type 2 diabetes mellitus. This case report shows the infrequently documented link between OSA and type 1 diabetes and highlights the need to confirm the type of diabetes especially in complex and atypical cases.
Case report
A 44-year-old gentleman, with a BMI of 34, was diagnosed with type 2 diabetes and was treated with metformin and given lifestyle advice. One year later, he became unwell with 2.5 stone weight loss, polyuria, and polydipsia. The history pointed towards a diagnosis of type 1 diabetes and he was commenced on basal bolus insulin regimen. During one of his clinic consultations, he described symptoms of OSA and both Epworth Sleepiness Scale and formal sleep studies performed subsequently confirmed the diagnosis of OSA. Anti-GAD antibody was positive, confirming the diagnosis of latent autoimmune diabetes of adult (LADA), a subset of type 1 diabetes. Metformin was re-initiated and within 6 months, his insulin requirement was reduced by about 50%. He only had minimal weight loss during this period.
Conclusion
There are now studies showing an unexpectedly high prevalence of OSA in type 1 diabetes patients independent of weight and this case serves as a reminder the importance of screening for OSA in this patient group due to its serious implications. Secondly, this patient showed a remarkable reduction in insulin requirement after metformin initiation although he had type 1 diabetes. Most studies showed only an average of 20% insulin sparing effect.

Efficacy of sitagliptin added on to intensive insulin therapy in type 2 diabetic patients

Bengur Taskiran & Guven Baris Cansu
Yunus Emre State Hospital, Eskisehir, Turkey.

Aim
Despite multiple dose injections some patients still fail achieving HbA1c target. We aimed to evaluate the effect of sitagliptin add on therapy to multiple dose insulin injections.
Method
Data of 47 (seven males and 40 females) type 2 diabetic patients who had HbA1c over 7% were retrospectively evaluated. They were already treated with premix lispro or aspart insulin ($n=28$), glargine plus premeal regular or aspart or lispro insulin ($n=15$), and detemir plus premeal aspart insulin ($n=2$), and glargine plus premix lispro insulin ($n=2$) for at least 3 months before sitagliptin add on therapy. The insulin scheme was intensified (glargine plus premeal regular or aspart or lispro insulin ($n=32$), and detemir plus premeal aspart insulin ($n=2$), and NPH twice daily plus regular or lispro insulin ($n=13$)).
Results
The patients were aged 56.26 ± 8.69 years. Mean duration of diabetes was 14.41 ± 7.57 years. Mean BMI 37.75 ± 6.08 kg/m^2 (28.81–53.78 kg/m^2). One patient had sleeve gastrectomy and still continued sitagliptin afterwards. Duration of insulin therapy before sitagliptin therapy ranged between 3 months and 22 years. Before sitagliptin therapy total daily dose was 91.13 ± 34.22 units (32–204 units) ($n=46$). HbA1c level within 6 months preceding sitagliptin therapy was $9.65\pm1.70\%$ (7.25–14.37%). Duration of sitagliptin therapy ranged between 1 and 25 months. The patients who used sitagliptin <6 months were the ones who were lost follow-up. Neither of them discontinued sitagliptin due to side effects. Weight change was 3.01 (gain) $\pm$ 3.47 kg (-2.30 to 15.00). Only 43 had follow-up total daily insulin dose data. Mean change was 20.72 units increment $\pm$ 29.86 (-48 to 90 units). According to the available follow-up records, mean HbA1c change was $0.95\pm1.48\%$ (-4.32 to 2.58%). When data of the patient who had undergone sleeve gastrectomy was deleted, mean weight change was 2.63 (gain) $\pm$ 2.74 kg (-2.30 to 6.60). Mean total daily insulin dose change was 23.90 units increment $\pm$ 30.68 (-48 to 90 units). Mean HbA1c change did not differ significantly ($0.93\pm1.48\%$; range: -4.32 to 2.58%). HbA1c change was correlated neither with total daily insulin dose change nor with weight change.

Total daily insulin dose change also did not correlate with weight change.
Conclusion
Adding sitagliptin to intensive insulin therapy do not cause consistent significant change in terms of weight change, HbA1c change, and total daily insulin dosage change.

Is vitamin D a predictor of premature atherosclerosis in type 2 diabetic patients?

Nehal Hammdy[1], Nagwa Abd El Gaffar[2], Randa Abdo[1] & Mary Wadia[1]
[1]Cairo University, Cairo, Egypt; [2]National Research Center, Cairo, Egypt.

Introduction
A poor vitamin D status has been related to an increased risk of cardiovascular disease. Carotid intima–media thickness (IMT) has shown to be an early marker of subclinical atherosclerotic Therefore, we aimed at examining the association between vitamin D status and the extent of carotid IMT in type 2 diabetics.
Subjects and methods
In a cross sectional study 78 type 2 diabetic patients attending the Diabetes and Endocrinology Clinic in Kasr El Ani Hospital were subjected to: full history, physical examination, anthropometric measurements (BMI and waist circumference), fasting glucose, HOMAIR, serum cholesterol, triglycerides, LDL, HDL, 25(OH) vitamin D, and carotid Doppler.
Results
Diabetics with normal CIMT ($n=26$) all with sufficient vitamin D, diabetic with increased CIMT ($n=52$) (40 sufficient 76.9% and 12 insufficient 23.1%). Six patients with increased CIMT had carotid plaque. Only one patient had vitamin D insufficiency, all other five patients had sufficient vitamin D. Vitamin D negatively correlated with Rt IMT, however, not statistically significant ($r=-0.003$, $P=0.981$). Negative correlation between fasting blood glucose and vitamin D statistically significant ($r=-0.415$, $P<0.001$). Negative correlation between cholesterol and Rt intima ($r=-0.340$, $P=0.002$).
Conclusion
Low serum 25(OH)D has no consistent association with mean IMT. Thus could not predict subclinical atherosclerosis in diabetics, the contribution of the local activated vitamin D system within atherosclerotic plaque has not been appropriately investigated yet. Therefore, both basic research studies and clinical trials are needed for better elucidating the therapeutic and path physiological role of vitamin D in atherogenesis and CV diseases.

Long-term use of insulin pump vs pens in treating young children with type 1 diabetes

Ashraf Soliman[1,2], Fawzia Alkhalaf[1], Mahmoud Alzyoud[1], Noura Alhumaidi[1], Ahmed Elawwa[1,2], Aml Sabt[1], Fawzia Alyafie[1] & Nagwa Aldersy[1]
[1]Hamad Medical Centre, Doha, Qatar; [2]University of Alexandria, Alexandria, Egypt.

Introduction
Unequivocal evidence for the benefit of MDI, the analogs and CSII-treatment in children is lacking. This study assesses the effects of insulin pump (CSII) vs pens in treating children with type 1 diabetes for more than 2 years.
Research design and methods
Diabetes control and anthropometric data of 94 children with type 1 diabetes who were on continuous s.c. insulin therapy using insulin pump were compared with those for 40 children with type 1 diabetes mellitus who were on multiple injections using basal insulin (Lantus) and prandial insulin (Novo-rapid) (three to four shots/day) for more than 2 years. Mean HbA1c, mean blood glucose (MBG), hypoglycemia and DKA frequency were recorded.
Results
Patients using pump therapy were older than patients on pen injections. However, the duration of diabetes did not differ between the two groups. Patients on CSII had significantly lower HbA1c, MBG, and insulin dose/kg compared with children using insulin pens. The frequency of severe hypoglycemia, ketoacidosis, or hospitalization was similar between groups at this time period. The majority (90/94) of patients on CSII expressed their desire to continue on CSII and appreciated its value as easier way to adjust insulin dose to their variable daily requirements.
Discussion
CSII is safe and well tolerated in young children with diabetes and may have positive effects on QOL. In addition, CSII improved diabetes control using less insulin/kg compared with pen injections. However, children on CSII had higher weight gain and BMI.
Conclusion
Our data indicate that CSII is safe and well tolerated in this population. The proper use of CSII in children with type 1 diabetes mellitus appears to improve glycaemic control using less s.c. insulin/kg per day and their quality of life. However, excessive weight gain should be avoided.

Effect of liraglutide 1.8 mg in patients with non-controlled type 2 diabetes mellitus at an endocrinology clinic: LIED-2 Study

Alvaro J Muriel[1], Alvaro A Herrera[2] & Alin Abreu Lomba[2]
[1]Universidad Libre Cali, Cali, Valle del Cauca, Colombia; [2]Centro Médico Imbanaco, Cali, Valle del Cauca, Colombia.

Background and aims
To describe the characteristics of patients with non-controlled type 2 diabetes mellitus with liraglutide treatment.
Materials and methods
Retrospective descriptive study. 85 outpatients (women 49, ages 18–86 years old with non-controlled type 2 diabetes mellitus were evaluated between July 2013 and March 2014 and received treatment with liraglutide 1.8 mg Q18/day (0.6 mg Q18 during the first week, 1.2 mg Q18 during the send week and 1.8 mg during the third week and the rest of the treatment). Age, sex, diagnosis time, weight, HbA1c, fasting glucose, systolic and diastolic blood pressure, pharmacological treatment during 6 months were extracted for analysis.
Results
Patients treated with liraglutide 1.8 mg as monotherapy or in conjunction with a therapeutic scheme decreased HbA1c values at 3 and 6 months (1.02% 95% CI $\pm$ 0.93 $P<0.0001$ y 2.08% 95% CI $\pm$0.8 $P<0.0001$); fasting glucose at 3 and 6 months (37 mg/dl 95% CI$\pm$33 $P<0.0001$ y 68 mg/dl 95% CI$\pm$26 $P<0.0001$); weight at 3 and 6 months (3 kg 95% CI$\pm$10 $P<0.0001$ y 5 kg 95% CI$\pm$10 $P<0.0001$); SBP at 3 and 6 months (9 mmHg 95% CI$\pm$15 $P<0.0001$ y 16 mmHg 95% CI$\pm$16 $P<0.0001$); DBP at 3 and 6 months (3 mmHg 95% CI$\pm$6 $P<0.0001$ y 6 mmHg 95% CI$\pm$6 $P<0.002$). 40% of patients reached HbA1c <7.0; 20% reduction of HbA1c, 39% reduction in fasting blood glucose, 6% reduction in mean weight (1–18%, 1–12 kg), 95% reached SBP <140 mmHg; 100% reached DBP <90 mmHg. Reported adverse events during treatment were nausea (27%), abdominal pain (18%), hypoglycaemia (14%), diarrhoea (9%), respiratory symptoms (7%). Metformin was present in 65% cases of nausea, 55% cases of diarrhoea and 43% of cases of abdominal pain. No fatal adverse events occurred.
Conclusion
Patients treated with liraglutide 1.8 mgQ18/day in monotherapy or in conjunction with a therapeutic scheme showed a decrease in HbA1c, fasting glucose, weight, SBP, DBP during a 6 month treatment.

Correlation of left ventricular hypertrophy and left ventricular diastolic dysfunction with HbA1c in newly diagnosed type 2 diabetics

Manish Gutch[1], Syed Mohd Razi[1], Abhinav Gupta[1], Sukriti Kumar[2] & Keshav Gupta[1]
[1]LLRM Medical College, Meerut, India; [2]SGPGI, Lucknow, Uttar Pradesh, India.

Introduction
Diabetes is associated with dysfunction, and failure of different organs, especially the eyes, kidneys, nerves, heart, and blood vessels. Diabetic macrovascular complications are the leading cause of deaths in diabetics. The correlation between LVH and LVDD with HbA1c is not clear in newly diagnosed T2DM Indian diabetics.
Aims and objective
To study the frequency of left ventricular hypertrophy (LVH) and left ventricular diastolic dysfunction (LVDD) in normotensive newly diagnosed type 2 diabetic patients by using 2D echocardiography and correlation with HbA1c.
Materials and methods
The present study is an observational cross sectional study in which 100 newly diagnosed normotensive type 2 diabetes mellitus patients between 30 and 60 year of age were enrolled from endocrine OPD of a tertiary care centre during a period of 1 year. All cases were subjected to thorough clinical history, examination and 2D echocardiography along with HbA1c.
Observations and results
Out of 100 patients of newly diagnosed normotensive type 2 DM; 41% patients had LVDD and 37% patients had LVH. The mean HbA1c of population with LVDD was $7.67 \pm 0.90\%$ and that with LVH was $7.74 \pm 0.91\%$. The LVDD and LVH were positively correlated with HbA1c (P value $= 0.0057$ and 0.0011) respectively.
Conclusion
LVDD and LVH were positively correlated with HbA1c in newly diagnosed T2DM population.

DOI: 10.1530/endoabs.37.EP405

The frequency of fall and risk factors in elderly patients with type 2 diabetes

Pelin Tutuncuoglu[2], Fulden Sarac[1], Sumru Savas[1], Asli Kilavuz[3] & Fehmi Akcicek[1]
[1]Department of Geriatrics Medicine, Ege University Medical Faculty, Izmir, Turkey; [2]Department of Endocrinology and Metabolism, Atatürk Training and Research Hospital, Izmir, Turkey; [3]Department of Internal Medicine, Ege University Medical Faculty, Izmir, Turkey.

The aims of the study were to determine the frequency of falls in elderly patients with type 2 diabetes mellitus and to evaluate the risk factors for falls. In the study, 100 (mean age 64.9 ± 11.0 years) (65 females, 35 males) elderly patients with type 2 DM were enrolled. Medical record abstraction of sociodemographic, clinical, and laboratory data was performed retrospectively. Medication characteristics, comorbidities, location and height of fall, associated injuries and outcomes were obtained from patients history with questionnaire-based interviews. A fall was described to patients as 'landing on the floor or ground, or falling and hitting an object like a table or stair.' The frequency of falls found to be 21% in elderly diabetic patients, particularly in women. Mean duration of diabetes was 18.7 ± 3.1 years in elderly who had fall. In this group, neuropathy, retinopathy, nephropathy, stroke, coronary heart disease, arthritis, difficulty with instrumental activities of daily living and lowgrip strength and low walking speed were found to be in 20, 18, 5, 7, 5, 9, 4 and 5 patients respectively. Eleven patients reported using triple oral antidiabetic drug (OAD), three patients reported using OAD and insulin, seven patients reported using only insulin. Sedative treatment was seen in 11 patients. Mean duration of diabetes was 7.9 ± 5.1 years in elderly patients who had no fall. Non-ground level falls (non-GLF) were recorded in six patients. Significantly higher injuries such as hip fracture were found in two patients. Mean levels of fasting and postprandial glucose and HbA1c were found to be 200.1 ± 61.0 and 210.9 ± 43.9 mg/dl and 11.1 ± 0.1, respectively, in elderly patients who had fall. Falls are significant health problem among the diabetic elderly. Non-GLF account for 6% of patients and are associated with chronic diabetic complications, comorbidities, medications, difficulty with instrumental activities of daily living and low grip strength and low walking.

Factors influencing prognosis in patients hospitalised with diabetic ketoacidosis

Manish Gutch[1], Sukriti Kumar[2], Syed Mohd Razi[1], Abhinav Gupta[1] & Keshav Kumar Gupta[1]
[1]LLRM Medical College, Meerut, Uttar Pradesh, India; [2]SGPGI, Lucknow, Uttar Pradesh, India.

Background
Diabetic ketoacidosis is characterised by biochemical tired of hyperglycemia, acidosis, and ketonemia. It remains a life threatening condition despite improvement in diabetic care, timely identification and intervention remains the backbone of treatment.
Aim and objectives
i) To evaluate the clinical and biochemical prognostic markers in diabetic ketoacidosis. ii) To correlate the various prognostic markers with mortality in diabetic ketoacidosis.
Settings and design
A prospective multicenteric observational study done at tertiary care centre.
Methods and materials
Two hundred and seventy patients hospitalised with diabetic ketoacidosis over a period of 1 year were evaluated clinically and by laboratory tests. Serial assays of serum electrolytes, glucose and blood pH, and clinical outcome of either discharge home or death were evaluated.
Statistical analysis
Data were analysed by SPSS version 17 and were presented in the values of mean, median, and percentages. The P value of < 0.05 was considered significant.
Results
The significant predicators of final outcome obtained were further regressed together and subjected with multivariate logistic regression (MLR) analysis. The MLR analysis further revealed that the male sex had 7.93-fold higher favourable outcome as compared to female sex (OR = 7.93, 95% CI 3.99–13.51) while decrease in mean APACHE II score (14.83) and S. PO_3^- (4.38) at presentation may lead 2.86 (OR = 2.86, 95% CI 1.72–7.03) and 2.71 (OR = 2.71, 95% CI 1.51–6.99) fold better favourable outcome respectively as compared with higher levels (APACHE II score: 25.00; S. PO_3^-: 6.04).
Conclusions
Sex, baseline biochemical parameters like APACHE II score, and phosphate level, were important predicator of mortality from DKA.

Microalbuminuria in children and adolescents with type 1 diabetes mellitus: predictive factors

Joana Nunes[1,2], Ricardo Monteiro[3], Daniela Amaral[4], Rosa Pina[4], Lurdes Lopes[4] & Catarina Limbert[4,5]
[1]Endocrinology, Diabetes and Metabolism Department, Centro Hospitalar São João, Porto, Portugal; [2]Faculty of Medicine, Porto University, Porto, Portugal; [3]Pediatrics Department, Centro Hospitalar Leiria Pombal, Leiria, Portugal; [4]Pediatric Endocrinology Department, Hospital D. Estefânia, Lisboa, Portugal; [5]Faculty of Medicine, Lisboa University, Lisboa, Portugal.

Objective
Microalbuminuria is usually the first microvascular complication of type 1 diabetes mellitus (T1DM). We aimed to identify its frequency, time of occurrence and related risk factors.
Methods
Clinical reports of 201 children followed in our institution were retrospectively analysed (diabetes duration 3.8 ± 3.6 years, age at diagnosis 8.1 ± 3.7 years, HbA1c value $9.0 \pm 1.7\%$). Statistical analysis was performed with SPSS version.21 for Windows. Results are expressed in frequencies and means $\pm$ S.D. Statistical significance was considered as P value < 0.05.
Results
Seventeen (ten females; seven males) patients (8.5%) presented microalbuminuria in a mean time of 5.5 ± 3.8 years: five children (29.4%) 2 years after diabetes onset and nine children (52.9%) 5 years after it (four children between 2 and 5 years of diabetes duration). In the logistic regression analysis, longer diabetes duration (6.3 ± 3.7 years vs 3.5 ± 3.5 years, $P = 0.005$, OR = 1.38), higher total cholesterol (TC) (180.6 ± 57.5 mg/dl vs 159.1 ± 31.0 mg/dl, $P = 0.03$, OR = 1.26), higher LDL (125.5 ± 36.3 mg/dl vs 110.9 ± 24.7 mg/dl, $P = 0.04$,

OR = 1.44), higher TG (133.3 ± 39.3 mg/dl vs 78.6 ± 38.4 mg/dl, $P = 0.006$, OR = 1.63), higher HbA1c (9.6 ± 1.9% vs 8.9 ± 1.7%, $P = 0.02$ OR = 1.88) and higher BMI (23.1 ± 4.9 kg/m^2 vs 20.3 ± 4.1 kg/m^2, $P = 0.02$, OR = 1.13) were associated with microalbuminuria. There were no statistical significant differences regarding gender, puberty and HDL-C.

Conclusions

In children, nephropathy can occur soon after T1DM onset. Besides poor metabolic control and longer diabetes duration, obesity and dyslipidemia seem to play a significant role. According to our results, we suggest yearly screening of microalbuminuria after T1DM onset and early treatment of dyslipidemia and obesity.

DOI: 10.1530/endoabs.37.EP408

EP409

Assessment of iodine status and thyroid structure changes in a cohort of patients with diabetes mellitus type 1 and comorbid chronic kidney disease in Belarus

Alena Sazonava[1], Tatiana Mokhort[1], Marina Astapovich[1] & Sergei Petrenko[2]
[1]Belarusian State Medical University, Minsk, Belarus; [2]International Sakharov Environmental University, Minsk, Belarus.

The aim was to assess iodine status and thyroid structure changes in a cohort of patients with diabetes mellitus type 1 (DM1) at different stages of comorbid chronic kidney disease (CKD) after achievement of adequate iodine status in Belarus. We examined 62 patients (20m; 42f; age 42.1 ± 12.07 years; BMI 26.14 ± 5.27 kg/m^2; duration of DM1 22.9 ± 8.67 years; age at DM1 onset 19.89 ± 12.72 years) at CKD stages 1, 2, 3, 5 ($n = 28$; 21; 12; 1 respectively). Urinary iodine excretion (UIE) in urine morning sample (UMS) was measured with the use of cerium–arsenite method approved WHO as a standard. Iodine deficiency (ID) is defined as a median urinary iodine concentration < 50 μ/l in a population. All data concerning ultrasound structure of thyroid gland (ThG) were determined as normal, reduced, increased volume (NVol, redVol, incrVol), homogeneity (hypo-, hyper-, homogeneous), local pathology (abs, single, multiple). In the examined group evaluating iodine supplementation in UMS lack of ID was registered – a median UIE at the time of survey was 115.5 mkg/l. Comparative analysis of patients in the subgroups according to CKD stages revealed reliable differences in level of UIE ($P = 0.0133$), total volume of ThG ($P = 0.0325$),and in homogeneity ($P = 0.040$).UIE in UMS correlates with urea plasma level ($r = -0.309$), GFR ($r = 0.420$), CKD stage ($r = -0.323$). Total volume of ThG correlates with plasma urea ($r = 0.313$) and creatinine levels ($r = 0.259$). Strong correlation was revealed between homogeneity and age at DM1 onset ($r = 0.292$). According to the ultrasound study of patients an incrVol was detected only in two patients (3.23%), in 33 revealed NVol (53.22%) and redVol in 27 patients (43.55%). Structural changes in ThG such as hypoechoic structure were reported in 24 patients (38.71%). Single and multiple pathology was recorded in 16 and seven patients respectively (25.81 and 11.29%). ID was not registered in examined population of patients that demonstrates the effectiveness of iodine prophylaxis. Revealed a direct correlation between level of UIE and CKD stage can lead to a variety of structural changes in ThG which requires close monitoring of patients with reduced renal function.

Introduction

Atherosclerotic complications are the leading causes of morbidity and mortality among patients with DT2.

Aim

To investigate the possible role of dyslipidaemia, hypertension and chronic kidney disease (CKD) on the characteristics of carotid atherosclerosis (presence of plaque, carotid IMT and total plaque area) in patients with DT2.

Material and methods

Patients aged 60–75 years with DT2 were included in this study. Control group included 24 healthy subjects the same age. Other atherosclerosis risk factors of subjects, including smoking, hypertension, dyslipidaemia, and CKD, were identified with a questionnaire and a blood test. The IMT was measured using automated edge detection software as the distance between the lumen–intima interface and the media–adventitia interface. Atherosclerotic plaque was defined as a focal structure encroaching into the arterial lumen of 0.5 mm or 50% of the surrounding IMT value or IMT of > 1.5 mm. Total plaque area (TPA) was calculated as the sum of all plaque areas.

Results

We divided all patients (DT2 and control) into three groups: Group 1 ($n = 24$) – patients did not have any additional atherosclerosis risk factor, Group 2 ($n = 25$) – patients had one additional atherosclerosis risk factor, and Group 3 ($n = 43$) – patients had two or three additional atherosclerosis risk factors. Using multiple linear regression analysis adjusted for confounding factors, IMT and TPA were significantly correlated with age > 60 years ($\beta = 0.359$, $P < 0.0001$; $\beta = 0.263$, $P < 0.0001$), hypertension ($\beta = 0.041$, $P = 0.003$; $\beta = 0.126$, $P < 0.0001$), dyslipidemia ($\beta = 0.066$, $P = 0.0001$; $\beta = 0.125$, $P < 0.0001$) and CKD ($\beta = 0.054$, $P = 0.003$; $\beta = 0.165$, $P < 0.0001$), respectively. However, gender (men) was not significantly correlated with IMT ($P = 0.171$) and TPA ($P = 0.112$).

Conclusion

The presence of dyslipidaemia, hypertension, and different CKD status were predictors of carotid plaque.

Validation of self-reported oral health measures for predicting periodontitis among adult Filipinos with type 2 diabetes mellitus

Tom Edward Lo, Ma. Cristina Lagaya-Estrada, Cecilia Jimeno & Gabriel Jasul
Philippine General Hospital, Manila, The Philippines.

Diabetes mellitus is currently being recognised as a global health problem. The likelihood of periodontal disease among diabetics is thrice and progresses rapidly when uncontrolled. Diabetics were less likely to see a dentist than to seek consult with a doctor for diabetes care. A cheap and easy way of clinical assessment via self-reported oral health questionnaire would be of great use especially in a developing country like The Philippines. This study aims to validate self-reported oral health measures, socio-demographic and medical variables in predicting the severity of periodontitis in Filipino adults with type 2 diabetes. The validated self-reported oral health questionnaires created by the CDC Periodontal Disease Surveillance Project was translated into Filipino and used. A cross-sectional study of 180 participants was conducted in a single institution. Multivariable logistic regression analyses was used to determine significant predictors of serious periodontitis. Socio-demographic and medical variables considered to be significantly predictive of serious periodontits were male sex (OR = 2.17), low educational status (OR = 2.98), poor glycaemic control (OR = 2.58), less frequent dental visits (OR = 2.77) and teeth loss > 6 (OR = 5.02). Self reported oral health variables shown to be significantly predictive of serious periodontitis included gum disease – Q1 (OR = 8.33), state of gum health – Q2 (OR = 0.39), loose teeth – Q3 (OR = 63.0), brushing of teeth – Q4 (OR = 0.65), use of mouthwash – Q4 (OR = 0.69) and poor tooth appearance – Q5 (OR = 48.42). A recommended set of questions and proposed scoring system based on the logistic regression analysis of each predictors' strength was then formulated. The use self-reported oral health questions appears to be a potentially useful screening tool for predicting the presence of serious periodontitis among type 2 diabetics locally where resources are limited and routine clinical oral examinations are not feasible. This will provide a cost-effective and rapid method of identifying patients who are in need of immediate dental evaluation and would benefit most to a dental referral.

The effect of MCP-1 A-2518G polymorphism on development of diabetic coronary artery disease

Gokhan Bagci[1,2], Binnur Bagci[1] & Bedia Cakmakoglu[2]
[1]Cumhuriyet University, Sivas, Turkey; [2]Istanbul University, Istanbul, Turkey.

Introduction
Inflammatory markers play an important role in the development of type 2 diabetes and coronary artery disease. Monocyte chemoattractant protein-1 (MCP-1) is a member of the C-C chemokine family and a potent chemotactic factor for monocytes.

The aim of our study was to investigate the effect of MCP-1 A-2518G polymorphisms on the development of diabetic coronary heart disease.

Subjects and methods
53 diabetic patients with coronary heart disease, 64 diabetic patients without coronary heart disease and 61 healthy controls were genotyped. Diabetes was diagnosed according to the criteria of the American Diabetes Association (ADA) and the non-diabetic subjects were selected according to no past history of diabetes mellitus or impaired glucose tolerance. PCR–RFLP method was used for genotyping.
