Joint Congress of the European Society for Paediatric Endocrinology (ESPE) and the European Society of Endocrinology (ESE) 2025: Connecting Endocrinology Across the Life Course

10–13 May 2025, Copenhagen, Denmark

Joint Steering Committee (JSC)

JOINT CHAIRS:
Anita Hokken-Koelega (The Netherlands) ESPE President and **Jérôme Bertherat** (France) ESE President

ESPE Representatives
Peter Kühnen (Germany)
Chair of the ESPE Programme Organising Committee
Mohamad Maghnie (Italy)
Chair of the ESPE Corporate Liaison Board
Rasa Verkauskiene (Lithuania)
Chair of the ESPE Strategic and Finance Committee
Nils Krone & Mehul Dattani (UK)
ESPE Programme Organising Committee Members

ESE Representatives
Cynthia Andoniadou (UK)
ESE Congress Committee Chair
Wiebke Arlt (UK)
ESE President-Elect
Sebastian Neggers (The Netherlands)
ESE Treasurer

Joint Scientific Programme Committee (JSPC)

JOINT CHAIRS:
Peter Kühnen (Germany) Chair of the ESPE Programme Organising Committee and
Cynthia Andoniadou (UK) ESE Congress Committee Chair

ESPE Representatives
Nils Krone (UK)
Mehul Dattani (UK)
Anders Juul (Denmark)
Katharina Main (Denmark)
Zdeněk Šumník (Czech Republic)

ESE Representatives
Frederic Castinetti (France)
Aylin Hanyaloglou (UK)
Martin Fassnacht (Germany)
Aleksandra Buha Djordjevic (Serbia)
Peter Lommer Kristensen (Denmark)

ESPE Programme Committee
Jacques Beltrand (France), Stefano Cianfarani (Italy), Sasha Howard (UK), Rachel Reynaud (France), Paul van Trotsenburg (The Netherlands), Malgorzata Wasniewska (Italy), Ram Weiss (Israel)
Young Endocrinologists (YES) Group Representative:
Hussain Alsaffar (Oman)

ESE Programme Committee
Krystallinia Alexandraki (Greece), Matthias Bluher (Germany), Sheerazad Boulkroun (France), Philippe Caron (France), Pauliina Damdimopoulou (Sweden), Silvia Grottolli (Italy), Mojca Jensterle (Slovenia), Gudmunder Johannsson (Sweden), Tim Korevaar (The Netherlands), Raul Luque (Spain), Luis Perez-Rivas (Germany), Flavia Prodram (Italy), Nadia Schoenmakers (UK), Elena Tsourdi (Germany), Elizabeth Winter (The Netherlands), Lina Zabuliene (Lithuania)
ESE Young Endocrinologists and Scientists (EYES) Representative: Barbara Altieri (Germany)
Nurse Representative: Kirsten Davidse (The Netherlands)

Joint Local Organising Committee (JLOC)
Anders Juul (Denmark)
Katharina Main (Denmark)
Peter Lommer Kristensen (Denmark)
Dorte Glintborg (Denmark)
Stina Willemoes Borresen (Denmark) (Chair of the Danish Society of Young Endocrinologists)

Learning from rare diseases: from corticotroph deficiency to corticotroph adenomas

Thierry Brue[1]
[1]Conception Hospital Marseille, France

Founded 3 decades ago, the Genhypopit network, an international consortium to identify genetic causes of hypopituitarism (such as mutations in pituitary transcription factor genes like *POU1F1*, *PROP1* or *LHX3/4*), allowed to decipher several phenotype-genotype correlations in various presentations of congenital pituitary hormone deficiencies. These include congenital isolated **corticotroph deficiency (ACTHD)**, the focus of this presentation. In collaboration with the group of Jacques Drouin (Canada), which discovered Tpit as the main regulator of mouse corticotroph development, we identified in patients referred to this network the first two families with ACTHD caused by mutations of *TPIT*, currently known as *TBX19*, demonstrating its major role in corticotroph function in humans also (Cell 2001). When further characterizing ACTHD patients with or without TBX19 mutations, we recognized in the latter group 3 families with both ACTHD and variable immunodeficiency, an association that we first described as DAVID syndrome (JCEM 2012) and found to be due to *NFKB2* gene mutations (JCEM 2014). Using a model of in vitro differentiation of mature human pituitary cell types from human induced pluripotent stem cells (3D culture of hypothalamo-pituitary organoids with or without pathogenic variations of *NFKB2*), we recently demonstrated the role of this gene in corticotroph differentiation (eLife 2024). Bridging from ACTHD to **Cushing's disease**, we were the first to show that TPIT/TBX19 immunostaining could be used to characterize adenomatous corticotroph cells (JCEM 2003), currently one of the main criteria for defining corticotroph tumors in the WHO classification of pituitary tumors. In terms of pathophysiology of this disease, further collaborative works with the group of J. Drouin led to the involvement of CABLES1 inactivation or Brg1 loss of function, and the roles of cyclin E or Pax7. Recently, in collaboration with Guido Kroemer in Paris, we found that plasma ACBP/DBI - Acyl coenzyme A binding protein that stimulates food intake and lipo-anabolic reactions - was elevated in both patients and mice with Cushing's syndrome. In mice, ACBP/DBI inhibition abolished manifestations of Cushing's syndrome such as weight gain or type 2 diabetes, which opens promising therapeutic avenues (Nature Metab 2024). These studies highlight the role of rare diseases in the identification of important physiological mechanisms and the added value of collaborative work between adult or pediatric specialists and experimental researchers. Hypothalamo-pituitary organoids represent a unique model for several genetically determined pituitary diseases affecting pituitary development and/or proliferation and for the study of developing or mature human pituitary cells.

MODY and Beyond: The Changing Face of Monogenic Diabetes

Kashyap Patel[1]
[1]Institute of Biomedical and Clinical Science, University of Exeter, UK

European Journal of Endocrinology Maturity Onset Diabetes of the Young (MODY) is the most common form of monogenic diabetes, where a genetic diagnosis can guide personalised treatment. However, accurate diagnosis depends on testing the right genes. This talk highlights the need to refine gene panels by including genes with strong evidence for MODY and removing those with insufficient support. This ensures more patients receive a correct diagnosis while avoiding misdiagnosis and inappropriate treatment. Optimising the cost-benefit of genetic testing also requires careful patient selection. The talk discusses clinical and familial criteria that increase the likelihood of identifying a monogenic cause of diabetes. Additionally, reduced penetrance—where individuals with pathogenic variants do not develop diabetes—is increasingly recognised in MODY and other monogenic disorders. This has important implications for interpreting genetic results, particularly in unaffected individuals. Emerging evidence suggests that polygenic risk may influence penetrance, challenging the traditional view of MODY as a purely monogenic disease. This talk explores recent findings on the interplay between monogenic and polygenic factors, shedding light on the genetic complexity of MODY. These insights have significant implications for diagnosis, management, and genetic counselling, paving the way for more precise and effective care for patients with MODY and other forms of diabetes.

Tackling adrenocortical cancer: a clinician perspective

Massimo Terzolo[1]
[1]University of Turin - Department of Clinical and Biological Sciences, Italy

During my talk I will address the following issues concerning treatment of patients with adrenocortical carcinoma (ACC):

- Indication of mitotane therapy in the adjuvant setting.
- Indication of mitotane therapy in the advanced disease setting.
- Managing mitotane therapy and the accompanying supportive therapy to improve patient compliance and adherence to treatment.
- The challenges of conducting clinical trials in ACC.
- Future perspectives for personalized treatments.

Disorders of thyroid hormone action: insights from human genetics

Krishna Chatterjee
University of Cambridge, Institute of Metabolic Science, Cambridge, United Kingdom

In my lecture, I will present notable contributions of our group in the field of thyroid hormone action. We have defined a multisystem disorder, often presenting in childhood, caused by mutations in SECISBP2, a factor which controls the synthesis of proteins (including deiodinase enzymes) which contain the aminoacid selenocysteine. This syndrome is associated with disordered thyroid hormone metabolism and phenotypes (e.g. muscular dystrophy, azoospermia) due to deficiency of selenoproteins in specific tissues plus features (e.g. photosensitivity, progressive hearing loss, aortic aneurysm) secondary to the lack of selenoenzymes which breakdown reactive oxygen species in cells. This disorder is a unique exemplar of the adverse consequences of oxidative stress in humans. We have discovered diverse mutations in THRB, causing Resistance to Thyroid Hormone (RTH) beta. We were first to discover homologous mutations in THRA causing RTHalpha - a form of congenital hypothyroidism which is underdiagnosed because thyroid function tests are near-normal; we first described and dominant negative mutations in PPARG, causing lipodystrophic insulin resistance. In these disorders, I will show that heterozygous mutant receptors inhibit the function of their normal cellular counterparts in a dominant negative manner - a unifying pathogenetic mechanism in these conditions and some other nuclear receptormediated disorders. Insights gained from the properties of unique receptor mutations and corresponding clinical phenotypes of prismatic cases, have enabled us to elucidate the molecular basis of dominant negative inhibition, informing approaches to treatment of these disorders.

Importance of gut microbiota for the effectiveness of weight loss – role of glucocorticoids

Ana Djordjevic[1]
[1]Institute for Biological Research "Siniša Stanković" - National Institute of the Republic of Serbia, Serbia

The global prevalence of obesity is increasing and there is growing evidence of a link between the gut microbiota and obesity. However, the specific bacterial strains and mechanisms involved in the development and treatment of obesity are not fully understood. We are investigating how probiotics modulate the gut microbiota to improve metabolic health in animal models of obesity and how dietary interventions remodel the gut microbiota to support weight loss in children with obesity. To investigate the role of the gut microbiota in obesity, we analyzed its composition using 16S rRNA gene amplicon sequencing in obese and obesity-resistant mice, while therapeutic effect of probiotics were examined in obese mice. We also examined the changes in the gut microbiota of children with obesity before and after a hypocaloric diet. In obesity-resistant mice, increased *Lactobacillus* abundance was negatively correlated with blood triglycerides, which, together with decreased expression of hepatic and intestinal free fatty acid transporters, suggests a role for the gut microbiota in preventing ectopic lipid accumulation. We have also shown that oral administration of a specific *Lactobacillus* strain to obese mice normalizes their gut microbiota, reduces hepatic steatosis and improves gut barrier integrity (patent pending), suggesting the gut microbiota as a potential therapeutic target. In children with obesity, a linear regression model showed that higher abundance of *Blautia* and *Anaerostipes* correlated with greater weight loss, while higher abundance of *Erysipelotrichaceae* UCG-003 and *Faecalibacterium* was negatively correlated with weight loss efficacy. Based on the above findings and our previous research on glucocorticoids as important mediators in obesity, whose availability and metabolism may be regulated by the activity of the gut microbiota, our future research aims to identify glucocorticoid-metabolizing gut bacteria and elucidate the molecular mechanisms by which they influence gut permeability and adipose tissue metabolism, thus contributing to the alleviation of obesity.

Association between premature ovarian insufficiency and biological aging: evidence from the UK Biobank and NHANES population-based surveys

Jinting Zhou[1], Menglin Fan[1,2], Aaron Aaron M. Lett[3], Qiqi You[1,2], Jingjing Zeng[2], Bo Chen[2], Yucen Wu[3], Hui Xing[1] & Shaoyong Xu[1]
[1]Xiangyang Central Hospital, Affiliated Hospital of Hubei University of Arts and Science, Department of Endocrinology, Xiangyang, China, 2Xiangyang Central Hospital, Affiliated Hospital of Hubei University of Arts and Science, Center for Clinical Evidence-Based and Translational Medicine, Xiangyang, China, 3Imperial College London, London, United Kingdom

Background
Premature ovarian insufficiency (POI), defined as menopause occurring before the age of 40 years, causes physiological changes in organs and health disorders. The issue of whether patients with POI have accelerated aging is important but epidemiological studies were lacking. This study aimed to analyze whether POI is associated with accelerated biological aging, and whether menopausal hormone therapy (MHT) in the POI population is associated with reduced biological aging.
Methods
This study analyzed 229,779 female aged 40 years and older from the UK Biobank (2006–2010) and NHANES (1999–2018). Menopause information such as age at menopause, cause of menopause, and use of MHT was collected through

a questionnaire. Biological age acceleration was defined by the Klemera–Doubal method, which was calculated through biomarkers, in reference to chronological ageing. Biological age acceleration >0 was defined as biological aging. Association between POI and biological aging was analyzed using multivariate linear regression and logistic regression models.

Results

In the UK Biobank and NHANES, a total of 6,105 (3.7%) and 1,882 (15.9%) female with POI were recorded, respectively. The results showed participants with POI had an increased risk of biological aging (UK Biobank: OR = 1.50 [95% CI: 1.24- 1.82]; NHANES: OR = 1.20 [95% CI: 1.07- 1.34]) and decrease in leukocyte telomere length (LTL) (UK Biobank: 0.0109 [95% CI: 0.0079- 0.0109]), compared with those without POI. Restricted cubic spline showed linear relationship between age at menopause and biological aging. With every 5-year increase in menopausal age, the risk of biological aging decreased by 11% and 2%, respectively (UK Biobank: OR = 0.89 [95%CI: 0.85- 0.93]; NHANES: OR = 0.98 [95%CI: 0.95- 1.00]). In the UK Biobank, participants with natural and surgical POI had a 48%, 55% increased risk of biological aging compared without POI, respectively. In the NHANES, the risk of biological aging was increased by 17%, 27%, respectively in female with natural and surgical. Participants with POI who underwent MHT had reduced risk of aging compared with those who did not (UK Biobank: OR = 0.63 [95%CI: 0.43- 0.92]; NHANES: OR = 0.75 [95%CI: 0.61- 0.92]).

Conclusion

Female with POI had a significantly increased risk of biological aging compared with those without POI. Participants with POI who received MHT had a reduced risk of aging compared with those who did. This study suggests patients with POI should be informed about the risks of aging and the potential benefits of early MHT.

USP8 genotype is associated with recurrence risk in Cushing's disease: an international, retrospective, multicenter cohort study

Qilin Zhang[*1,2], Yixin Cai[2], Ana Paula Abreu[1], Michael Buchfelder[3], Boyuan Yao[2], Felicia A Hanzu[4], Yuyu Liu[2], Jun Thorsteinsdottir[5], Zengyi Ma[2], Jörg Flitsch[6], Shuo Zhang[2], Jürgen Honegger[7], Rona Carroll[1], Hongying Ye[2], Zhaoyun Zhang[2], Ursula Kaiser[1], Martin Reincke[8], Marily Theodoropoulou[8], Yao Zhao[2] & Luis Gustavo Perez-Rivas[*9]

[1]Brigham and Women's Hospital, Division of Endocrinology, Diabetes and Hypertension, Boston, United States; [2]Huashan Hospital, Fudan University, Shanghai Pituitary Tumor Center, Department of Neurosurgery, Shanghai, China; [3]Universitätsklinikum Erlangen, Neurochirurgische Klinik, Erlangen, Germany; [4]Hospital Clinic Barcelona, Department of Endocrinology, Barcelona, Spain; [5]LMU Klinikum, Neurochirurgische Klinik und Poliklinik, Munich, Germany; [6]Universitätskrankenhaus Hamburg-Eppendor, Department of Neurosurgery, Hamburg, Germany; [7]University of Tübingen, Department of Neurosurgery, Tübingen, Germany; [8]LMU Klinikum, Medizinische Klinik und Poliklinik IV, München, Germany; [9]LMU Klinikum, Med. Klinik und Poliklinik IV, Munich, Germany

Background

The recurrence rate of Cushing's disease (CD) after surgery varies between 5–50%. About 30–60% of CD tumors carry somatic *USP8* variants. Prior studies on small cohorts have reported opposite association between *USP8* variants and recurrence. Here, we analyzed *USP8* genotype and recurrence risk in a large, international cohort of patients with postoperative remission and long follow-up.

Methods

Retrospective analysis across seven neuroendocrine centers from China, Europe, and the U.S. All patients had *USP8* genotype, demographic, clinical, biochemical, and follow-up data. Patients with prior pituitary intervention or bilateral adrenalectomy were excluded. We estimated the recurrence risk with Kaplan-Meier curve, long-rank test, and Cox regression.

Results

Among 435 patients (82.8% female; median follow-up: 5.61 years), *USP8* variants were identified in 195 (44.8%) tumors. Variants were more prevalent in younger ($P<0.001$) and female ($P<0.001$) patients and were associated with a lower incidence of cavernous sinus invasion ($P=0.021$) and reduced post-operative cortisol levels ($P=0.004$). Of these, 371 initially reached post-op remission, but 71 recurred during follow-up. *USP8* variants significantly increased recurrence risk in microadenomas (HR 2.36, $P=0.025$), while in macroadenomas, no significant association was observed (HR 0.58, $P=0.126$). Stratification by *USP8* genotype and tumor size produced four subgroups. However, due to similar recurrence risks (HR 1.08, $P=0.824$) and comparable clinical characteristics between *USP8* variant microadenomas and macroadenomas, these two variant subgroups were merged into a single category, resulting in three distinct categories: wild-type microadenomas, *USP8* variant adenomas, and wild-type macroadenomas, with 5-year cumulative recurrence rates of 6.45%, 12.53%, and 31.16%, respectively. The log-rank test revealed significant differences in recurrence risk among these 3 categories ($P<0.001$). Further evaluation of postoperative 1-week nadir cortisol levels showed category-specific recurrence risks. For wild-type microadenomas, cortisol levels ≥ 2 μg/dl were associated with increased recurrence risk (HR 7.26, $P=0.016$). In *USP8* variant adenomas, recurrence risk was elevated only at cortisol levels ≥ 5 μg/dl (HR 6.11, $P<0.001$). Postoperative cortisol levels were not significantly associated with recurrence in wild-type macroadenomas. We further identified additional, varied factors associated with recurrence risk across the three categories.

Conclusions

USP8 genotype, combined with tumor size, is associated with different risk of recurrence in CD. This study highlights the heterogeneity of CD recurrence patterns and underscores the importance of combining tumor size and somatic *USP8* genotype to guide follow-up strategies.

Thyroid Cancer Across the Lifespan: Similar yet Different

Steven Waguespack[1]
[1]The University of Texas MD Anderson Cancer Center, USA

Both follicular cell- and C cell-derived thyroid carcinomas affect patients of all ages. Although similar in many aspects across the lifespan, there are also significant differences in cancer pathogenesis, clinical behavior, and management depending on the age at diagnosis. This plenary will provide an up-to-date overview of thyroid cancer across the age continuum, including cutting-edge advances in research and therapy.

Adverse effects of endocrine disrupting chemicals though life course

Tina Kold Jensen[1]
[1]University of Southern Denmark, Department of Clinical Pharmacology, Pharmacy and Environmental Medicine, Odense, Denmark

Endocrine disrupting chemicals (EDCs) are natural or human-made chemicals that can interfere with the synthesis, secretion, transport, binding, action or elimination of natural hormones in the body. They are found in numerous household and industrial products and we are therefore all exposed to a cocktail of these chemicals through food, indoor air and dust, personal care products and clothing. EDCs are measurable in serum or urine from almost all. Exposure to even low doses of EDCs at vulnerable time windows during fetal life and early childhood, when the organs are rapidly developing have long-term impact on future health and disease. Examples on adverse health effects will be provided from the Odense Child Cohort, in which 2500 pregnant women were enrolled from 2010-12 in early pregnancy and serum and urine samples were collected. Their offspring are being followed through the age of 18 years with extensive repeatedly collected information from both questionnaires, biological sampling and clinical examinations in order to study the importance of EDCs exposure on metabolic syndrome, immune system, reproduction, growth pattern and neuropsychological development. We have measured perfluroalkyl substances (PFAS), phthalates, phenols, parabens and pesticides in serum and urine from more than 7000 mothers and children and have information on anogenital distance, weight and height and blood pressure, language development, asthma and allergy, infections, antibodies towards infections, ADHD, IQ, DXA, VO2 max and puberty.

Bullet points

- Endocrine disrupting chemicals (EDCs) can interfere with hormones in the body
- We are all exposed to EDCs
- Fetus and child are vulnerable to EDC exposure
- EDC exposure during development have long term implications for health and disease
- In the Odense Child Cohort we have measured EDCs in serum and urine from more than 7000 mothers and children
- Maternal EDC exposure is associated with metabolic syndrome, immune system, reproduction, growth pattern and neuropsychological development in the offspring

Unlocking the secrets of exercise: A pathway to enhanced insulin sensitivity and metabolism in type 2 diabetes

Juleen R. Zierath[1]
[1]Karolinska Institutet, Stockholm, Sweden

Skeletal muscle is a central player in locomotion and systemic metabolism, particularly in glucose regulation. Type 2 diabetes and obesity are associated with insulin resistance and muscle dysfunction, often exacerbated by sarcopenic obesity. Exercise is a proven intervention to counteract these declines, yet the molecular mechanisms underlying its benefits remain incompletely understood. Emerging research highlights the dynamic and time-dependent molecular responses in skeletal muscle following exercise, including waves of transcriptional, proteomic, and metabolic changes. Integration of multi-omics approaches is revealing new insights into how skeletal muscle interacts with other organs to maintain energy homeostasis. However, individual variability in exercise responses underscores the need for precision exercise strategies tailored to genetic, epigenetic, environmental, and phenotypic factors. By mapping the molecular landscape of exercise adaptation, researchers aim to identify therapeutic targets to enhance insulin sensitivity, prevent metabolic dysfunction, and inform personalized interventions. Despite ongoing challenges, understanding the intricate biology of exercise holds promise for innovative strategies to combat Type 2 diabetes and related disorders, supporting the mantra that "exercise is medicine."

Transition for Prader Willi Syndrome

Maithé Tauber[1]
[1]CHU de Toulouse - Hôpital des Enfants, France

Prader-Willi syndrome (PWS) is a complex neurodevelopmental genetic disorder with a specific trajectory leading to early obesity with hyperphagia, psychiatric disturbances, endocrine and metabolic disorder. Global incidence is approximately 1 in 20,000 births in Europe. PWS is usually diagnosed early in life and then managed by pediatric teams. Transition is defined as "a process of organized and coordinated change of adolescents and young adults with a chronic medical condition from a pediatric system of care to the adult system of care". Transition is a process, whereas ‘transfer’ is the actual moment of the first appointment at adult care. A European endocrinologist expert group examined in 2015 the gap in metabolic and endocrine care of patients during transition (2). They highlighted the necessity of multidisciplinary collaboration across health sectors for endocrine diseases, the need for pediatric and adult endocrinologists to work together, early involvement of adolescents in their disease, and also of parents in the transition process. The transition of patients with PWS from adolescence to adult life is particularly challenging for medical care because of multiple comorbidities and specific skills required for the medical team but also management of behavioral problems that may preclude socialization. This period of profound changes is thus prone to disruptions, the main risks being the worsening of the medical situation and losing the follow-up of patients. The MTG5 “Growth and obesity” of the EndoERN organized a webinar on 16th of November 2021 and convened experts of the disease to address the transition of care in PWS. Speakers brought their knowledge of this peculiar period on psychiatric and endocrinological aspects but also examined the complementary points of view as pediatricians and adult specialists. The experience of parents and patients was also presented. In this presentation I will show the adaptations our team made based on our long term experience to optimize the transition of care of adolescents to young adults with PWS and the challenges to face to give them the best chance of having a satisfactory quality of life.

A data-based campaign on reducing exposure to Endocrine Disruptors in mother-infant dyads: the Life Milch Project

Paola Palanza[1]
[1]University of Parma, Italy

The Life MILCH project -"Mother and Infant dyads: Lowering the impact of endocrine disrupting chemicals in milk for a Healthy Life" (www.lifemilch.eu) is a pilot study aimed at reducing the impact of environmental endocrine disruptors (EDs) on human health by assessing exposure and effects on mother-child pairs, with breastmilk as a main biomarker of exposure. The first screening phase of the project on 500 mother-child pairs enrolled in three different Italian locations, showed significant associations between mothers' lifestyle and diet and ED levels in maternal urine, breastmilk, and infant urine samples at different timepoints (1, 3, 6, 12 months of age), and identified possible main sources of maternal exposure to EDs to establish a risk assessment model. Based on this evidence-driven model, the project has developed a specific prevention/awareness campaign and interventions for reducing maternal exposure to EDs. Our hypothesis is that a change in food habits and lifestyle would reduce the levels of specific EDs in the mothers, their breastmilk and, consequently, in the infants. These prevention activities were carried out in the three project locations and with three specific targets: first involving pregnant woman and breastfeeding mothers, and then woman of childbearing age and health professionals. The efficacy of the prevention campaign and intervention was assessed by a subsequent biomonitoring of ED levels in the breast milk of 150 women who have participated in the campaign during pregnancy/nursing, including an assessment of their infants' ED exposure levels and development at 6 months of age (second screening – currently ongoing). Finally, we will compare the results obtained in the 2nd screening with those obtained in the 1st screening to clarify whether specific interventions could effectively reduce and prevent exposure to some EDs. (LIFE18 ENV/IT/000460).

Management of bone fragilty and osteoporosis in children and adolescence

Outi Mäkitie[1]
[1]University of Helsinki, Finland

Osteoporosis, a skeletal disorder with bone fragility, is rare in children and adolescents. The diagnosis is based on low BMD (Z-score $<$-2.0, appropriately adjusted for height and skeletal maturity) and a fracture history indicative of higher-than-normal bone fragility. Compared with primary osteoporosis (various genetic forms), secondary osteoporosis is more common and poses major treatment challenges in various pediatric subspecialties. Many chronic diseases and their treatment can impair childhood bone mass development and lead to osteoporosis. In the absence of a known chronic disease, fragility fractures and low BMD should prompt extensive screening for secondary causes. Genetic skeletal fragility disorders should be considered when no secondary cause can be identified. Management consists of treatment of the underlying illness and optimizing calcium and vitamin D intake and physical activity. Treatment with bone-active medication should be considered on a personalized basis, depending on the severity of osteoporosis and the underlying disease and its anticipated prognosis versus the absence of evidence of anti-fracture efficacy and potential harmful effects of pharmacotherapies. Only few large-scale studies with pharmacological treatment have been performed in childhood osteoporosis and most of them had BMD and not fractures as a primary outcome. When treatment of the underlying cause is not possible or effective and fracture risk appears high, antiresorptive drugs should be considered. Treatment with bisphosphonates has been shown to improve BMD in several underlying conditions but data on fracture prevention are mostly lacking. Rebound hypercalcemia after denosumab use limits its benefits in children. Anti-sclerostin antibody and other osteoanabolic treatments will hopefully in the future be available for selected pediatric patient groups. The management of children and adolescents with osteoporosis and fragility fractures requires a patient-centered multidisciplinary approach.

Key learning points

- Secondary osteoporosis has emerged as an important pediatric disease and involves all pediatric subspecialties.
- Evaluation of skeletal health should be part of chronic illness management for early diagnosis and timely treatment of pediatric osteoporosis.
- Pharmacotherapy, usually antiresorptives, needs to be determined on individual basis, considering the severity of osteoporosis, the underlying disease and its anticipated prognosis.
- Treatment options are limited and their efficacy inadequately established.
- There is need for osteoanabolic treatment options both in primary and secondary childhood osteoporosis.

Novel therapies in osteogenesis imperfecta

Jörg Semler[1]
[1]University of Cologne, Faculty of Medicine and University Hospital, Germany

For a period of nearly 2 decades the use of intravenous bisphosphonates was the only recommended medical treatment for children and adults with osteogenesis imperfecta (OI). In adults some small trials using PTH have been performed showing some osteoanabolic effect. During the last 10 years short acting antiresorptive agents like denosumab have been investigated. Due to the severe rebound after cessation of the treatment and fluctuations in calcium levels this strategy is not recommended. All antiresorptive agents increase bone mass by accumulating "old bone" which has a poor quality due to the structural collagen defect in most patients. Osteoanabolic agents like anti sclerostin antibodies or TGF-beta increase activity of osteoblasts and produce new collagen, which needs to be mineralized. Trials are currently on the way but it will remain unclear how long the treatment needs to be given and what happens after stopping the treatment. In adults a trial assessing the effect of PTH and zoledronic acid is currently performed pathing the way to a sequential therapy of osteoanabolic and antiresorptive treatments in the future. However, all these treatments will not correct the structural collagen defect. A first trial with embryonic mesenchymal stem cells has shown that this approach is safe in children with OI. These stem cells will produce normal collagen and might be able to replace the structural impaired bone in the patients. This might be a treatment alternative in the future while a gene therapy, correcting the mutation, is still not on the horizon currently. In addition to these drugs, the care for patients with OI will remain an interdisciplinary challenge which require surgeons, physiotherapist, pain nurses and many other specialists to provide a treatment adapted to the individual patient with this heterogenous disease.

Current Challenges and New Perspectives in Cyclic Cushing's Syndrome

Elisabeth Nowak[1]
[1]LMU Hospital, Germany

Variability is common, if not omnipresent, in cortisol excess. So-called "cyclic Cushing's syndrome" (cCS) refers to a subset of patients in whom periods of glucocorticoid excess (peaks) spontaneously alternate with periods of low or normal cortisol concentrations (troughs). cCS is marked by diagnostic errors, and possibly poorer outcomes. In this talk, I will provide an overview of different cortisol secretion kinetics, with a particular focus on the diagnostic challenges encountered in both adult and pediatric patients. Drawing on new data from our international patient cohort – collected from expert centers worldwide – I will offer practical guidance for improving diagnosis and patient care. Using case-based examples, I will highlight common diagnostic pitfalls and how to avoid them. I will present novel findings on cortisol secretion patterns and explore associated clinical and biochemical outcomes in patients with cCS. Finally, I will discuss potential underlying mechanisms of cyclicity and offer an outlook on ongoing and future research directions.

Key questions addressed in this talk

- *To cycle or not to cycle*:(How) can we distinguish cortisol variability from true cyclic Cushing's syndrome?
- What are the main diagnostic pitfalls in cyclic Cushing's syndrome, and how can we avoid them?
- What is the optimal treatment approach for patients with (suspected) cyclic Cushing's syndrome?
- Is cyclicity unique to the corticotroph axis, and what mechanisms might explain it?

What are the future directions of research on cyclic Cushing's syndrome?

Population screening of early stage Type 1 diabetes

Emanuele Bosi[1]
[1]Diabetes & Endocrinology Unit, Diabetes Research Institute, San Raffaele Hospital and San Raffaele Vita-Salute University, Milan, Italy

One of the most important advances in type 1 diabetes (T1D) research has been the identification of a long incubation period, starting months to years prior to the appearance of disease symptoms and progressing in a complete asymptomatic way. This pre-symptomatic phase can be recognized by the detection in the blood of autoantibodies against multiple islet antigens, including GAD, insulin, IA-2 and ZnT8. In children and adolescents the detection of two or more among these autoantibodies is highly predictive of future clinical T1D, approaching nearly certainty within 10-15 years. The pre-symptomatic disease staging and risk estimate of further progression is based on the assessment of glucose status: Stage 1, associated with normoglycemia; Stage 2, associated with dysglycemia; Stage 3, associated with hyperglycemia and need to start insulin therapy (corresponding to clinical T1D). These stages have been recently assigned the ICD-10 codes E10.A1, E10.A2 and E10.9, respectively. Therefore, measurement of islet autoantibodies has been increasingly adopted as the basic tool for screening programs, implemented initially in families and other cohorts of genetically predisposed individuals, and then more and more in the general population of pediatric ages. The identification of T1D at an early pre-symptomatic stage has several clinical benefits: opportunity for education and monitoring of at risk individuals to support a smooth transition to clinical diabetes and insulin therapy; reduction of the incidence of diabetic ketoacidosis and minimization of clinical manifestations at onset; potential access to disease modifying treatments (e.g. Teplizumab) and clinical trials. Conversely, the impact of screening the general population for T1D need to be assessed for ethical, psychological, socioeconomic and financial aspects. Particularly, anxiety and distress related to screening have been reported in association with communication to families of significant risk of future T1D. The new and growing discipline of pre-symptomatic/early T1D needs in depth investigations and overarching approaches such as that accomplished by EDENT1FI, a large European consortium conducting: screening children from the general population; evaluating the associated psychological impact and providing support and education to families; implementing protocols for monitoring and follow up of at risk people; and proving information and opportunities for disease modifying therapies.

Novel targets and sequential therapies in neuroendocrine neoplasms

Beata Kos Kudla[1]
[1]Department of Endocrinology and Neuroendocrine Tumors, Medical University of Silesia, Poland

Neuroendocrine tumors (NENs) are a diverse group of malignancies characterized by diverse clinical behaviors and responses to treatment. Despite significant advances in therapies, there is still an urgent need for new therapeutic targets and optimized sequential treatment strategies to improve patient outcomes. Recent developments in NEN treatment are discussed, focusing on innovative approaches such as molecular targeting, peptide receptor radionuclide therapy (PRRT), and combinations of available therapeutic approaches. Current therapeutic options, including somatostatin analogs, targeted therapies, chemotherapy, and PRRT, were reviewed while investigating their efficacy and limitations. It also highlights the potential of emerging molecular targets, including mTOR inhibitors, angiogenesis regulators, and epigenetic modulators, which offer hope for better disease control. An essential aspect of modern NEN treatment is the sequencing of therapy to maximize survival and reduce toxicity. Clinical evidence supporting rational choice of first-line and subsequent therapies was evaluated. Advances in PRRT were also highlighted, such as alpha- and beta-emitting radionuclides, combination regimens, and new radiopharmaceuticals. In conclusion, the role of precision medicine, a cutting-edge approach, and the importance of genomic and transcriptomic profiling in guiding the choice of therapy is emphasized. It addresses challenges such as resistance to treatment, the need for extended clinical trials, and integrating multidisciplinary care models. Ultimately, there is a need for continuous research and international collaboration to refine NEN treatment paradigms and improve patient outcomes.

Molecular basis of short stature

Andrew Dauber[1]
[1]Division of Endocrinology, Children's National Hospital, USA

In this talk, we will describe the spectrum of genetic variants that affect height. We will differentiate between common genetic variants identified by genome-wide association studies which have very small effects on height versus rare genetic variants with larger effects causing monogenic causes of short stature. We will then review two specific genetic causes of short stature, mutations in the ACAN gene and NPR2 gene. These genes both affect growth at the growth plate. We will discuss clinical trials of agents targeting these genetic defects and pathways. We will then explore the utility of genetic testing in identifying an etiology of short stature in the clinical setting.

Intratumoral glucocorticoid secretion in adrenocortical carcinoma and its implication for CAR-T cell targeting

Marc Philipp Schauer[1]
[1]University Hospital Wuerzburg, Department of Internal Medicine I & II, Division of Endocrinology & Diabetes, Germany

Glucocorticoids (GC) confer a profound immunosuppressive effect and are extensively used in autoimmune diseases and cancer therapy for their anti-inflammatory properties. However, this mechanism is also exploited by multiple endocrine and non-endocrine cancers that secrete GCs either by active production or metabolite recycling to modulate immune-recognition and –therapy. In this talk, the speaker will provide data on adrenocortical carcinoma (ACC) as perfect exemplary cancer entity to explore the impact of autocrine GC signaling in hormonally active cancers on cancer progression as well as the expression of cancer antigens that can be targeted with CAR-T cell immunotherapy. He will further provide transcriptomic and mechanistic insights in ACC tumor biology, will show how cancer antigens can be modulated to increase CAR-T cell recognition thresholds by GC signaling and demonstrates clinically relevant intratumoral biomarkers for GC secretion and disease progression in ACC. While GC secretion negatively affects conventional CAR-T cell efficacy the presenter will provide further selective T cell engineering capabilities to alleviate the detrimental effects on T cell efficacy on the one hand, while exploiting the exalted GC driven cancer antigen expression on the other. He will provide data that show how GC-resistant CAR-T cells exceed autocrine GC cancer signaling for effective immunotherapeutic targeting while inducing complete and sustained remission in steroidogenic ACC mouse models. Due to the promising curative potency of CAR-T cells in preclinical ACC mouse models, ROR1 CAR-T cells will enter

phase I clinical trial at our center, where we will assess safety and tolerability of ACC-directed CAR-T cells in human ACC patients.
Key findings
- Autocrine glucocorticoid (GC) cancer signaling induces cancer progression and antigen expression that can be targeted with genetically modified CAR-T cells.
- ROR1 is an extracellular oncogenic protein that is a suitable CAR-T cell target which further acts as new biomarker for intratumoral glucocorticoid secretion due to its tight regulation by GC signaling.
- Glucocorticoid-resistant CAR-T cells exploit autocrine GC signaling for effective CAR-T cell therapeutic targeting while inducing complete and sustained remission in ACC bearing mice.
  ROR1 CAR-T cells will be evaluated in human ACC patients in phase I clinical trial.

Testicular adrenal rest tumors in congenital adrenal hyperplasia: clinical, biochemical, and molecular aspects

Katja Dumic Kubat, MD, PHD
University Clinical Center Zagreb, Zagreb, Croatia

With advancements in diagnosis and treatment, most patients with congenital adrenal hyperplasia (CAH) now reach adulthood, and we are increasingly faced with long-term complications. A common complication in both male and female patients with classic CAH is gonadal dysfunction, which can lead to subfertility or infertility. In male patients, gonadal failure may be caused by testicular adrenal rest tumors (TART). These tumors are typically found bilaterally and can obstruct the seminiferous tubules due to their central location within the rete testis, resulting in either oligospermia or azoospermia. Furthermore, TART can cause irreversible damage to the surrounding testicular tissue. Current research indicates that the type and severity of CAH, which are closely associated with genotype, as well as disease duration and poor disease management, are significant factors contributing to the development of TART. However, there are also reports of TART arising in young children and in patients who have good control or milder forms of the disease. Signs of gonadal dysfunction may become apparent already during puberty; therefore, regular endocrine gonadal function assessment and imaging in male patients with CAH should start at an early age. Early detection of TART and optimization of treatment can prevent potentially irreversible gonadal dysfunction and infertility.

Overview of non-CAH forms of primary adrenal insufficiency in childhood

Domenico Corica[1]
[1]University of Messina, Italy

Primary adrenal insufficiency (PAI) is a relatively rare but life-threatening clinical condition caused by dysfunction or destruction of the adrenal cortex resulting steroid hormones deficiencies, including cortisol and aldosterone. Although rare, PAI is a potentially lethal disease that requires early recognition and treatment. However, symptoms are often unspecific and diagnosis can be difficult, frequently causing a delay in diagnosis. Congenital and acquired causes of PAI can be recognized. Congenital causes, other than CAH, include other defects of steroidogenesis (e.g., congenital lipoid adrenal hyperplasia), conditions of adrenal hypoplasia and ACTH resistance. Acquired causes include autoimmunity, adrenal injury of hemorrhagic, infectious and infiltrative nature, and transient forms (e.g., medical induced PAI). Autoimmune cause is the second most frequent cause of PAI in children after CAH, either as an isolated disease or as a manifestation of polyendocrinopathy. Congenital AI usually presents early in life with signs of adrenal crisis or hypoglycemic seizures. Acquired PAI can have an insidious onset characterized by the slow and progressive onset of nonspecific symptoms, such as anorexia, weight loss, morning sickness or vomiting, and fatigue; this could result in diagnostic delay and danger to the child's life. The finding of these signs and symptoms should alert the physician to the possibility of PAI. The purpose of this talk is to present an overview of the main causes of PAI, other than the better-known congenital adrenal hyperplasia (CAH), in order to highlight epidemiological, clinical, and laboratory features that can lead to a timely diagnosis and appropriate treatment of these conditions.

Safety of GH replacement in adults with hypopituitarism

Philippe Touraine[1]
[1]AP-HP Sorbonne Université, Hôpital Universitaire Pitié Salpêtrière-Charles Foix, France

Growth hormone deficiency (GHD) observed in adults either presents in childhood and persists into adulthood (childhood-onset GHD [CO-GHD]) or arises in adulthood (adult-onset GHD [AO-GHD]). GHD in adults is most frequently caused by hypothalamic/pituitary lesions, often due to a pituitary adenoma or its associated treatments by surgery or radiotherapy. Adult GHD is linked to a wide spectrum of clinical features, including abnormal body composition, reduced bone mineral density, decreased muscle strength and exercise capacity, unfavorable metabolic profile, and impaired physiological well-being and quality of life. Data from some studies also suggest that hypopituitary patients with untreated GHD may be predisposed to decreased life expectancy due to cardiovascular and cerebrovascular diseases, although an association between GHD and increased mortality has not been definitively proven. Since recombinant human GH was first introduced in the mid-1980s, clinical studies have shown that GH therapy increased lean body mass and

decreased body fat, improved bone health, enhanced patient-reported quality of life, and reduced total cholesterol (TC) and low-density lipoprotein (LDL) cholesterol in adults with GHD, although its effects on cardiovascular risks and mortality have been inconclusive. Administration of long-term GH replacement in adults with GHD is overall well-tolerated, but concerns regarding potential risks of diabetes mellitus, new malignancy, tumor recurrence, and cardiovascular diseases still remain and will be discussed. Long-term surveillance studies of large cohorts and adequate controls are therefore needed for a better benefit-risk assessment. Finally, GHD across transition period appears as a specific situation which needs to be managed and discussed in a proper way.

Endocrine disruptors affect male reproductive disorders in fetal and early postnatal life

Jorma Toppari[1]
[1]University of Turku, Turku, Finland

Male reproductive development depends on normal testicular hormones that induce masculinization in fetal and early postnatal life. Genetic and environmental factors that disrupt reproductive hormone production or action cause congenital reproductive organ defects, such as undescended testes, hypospadias, and short anogenital distance, while in adult life the adverse effects may appear as poor semen quality or testicular germ cell cancer. This spectrum of reproductive disorders has been named testicular dysgenesis syndrome (TDS), and it can present as one or multiple disorders of TDS. Congenital cryptorchidism or hypospadias have been associated with exposure to several endocrine disruptors that can be classified as antiandrogens, dioxin-like or estrogenic compounds. Concomitant exposure to a large mixture of endocrine disruptors raises concern, although exposure levels to single chemicals might seem safe. Legislation to secure chemical safety and international agreements, such as Stockholm convention have made our environment cleaner, but constant emergence of new chemicals poses a challenge to preventive medicine. We are acting often only after the harm has occurred.

S13.3

The evolutionary pressure on humans and other mammals to be reproductively successful

Kristian Almstrup[1]
[1]Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark

Spermatogenesis is crucial for our ability to reproduce. However, it also represents an evolutionary battleground. Genes that emerge during evolution are first expressed in the testis and spermatogenesis heavily depends on the rapidly evolving sex chromosomes. The evolution of spermatogenesis is also reflected by a great variation in testis size among primates and even among our closest relatives – the great apes.To explore the evolution of spermatogenesis we collected testicular specimens and reproductive data on more than 100 species of apes, including all great apes. This extensive resource allows us to assess the efficiency of spermatogenesis among these species quantitatively and to evaluate differences in reproductive hormones. To better understand the molecular processes that affect the evolution of spermatogenesis, we also generated single-nuclei gene-expression data from ~100k testicular cells from 11 species. We identified both evolutionary conserved and divergent patterns of gene expression. Notably, we observed a rapid molecular evolution in late post-meiotic germ cells. In addition, we were able to identify sex-chromosome-specific gene expression in spermatids, indicating recent meiotic drive processes, which are known to impair spermatogenesis. I will highlight our major findings from this extensive dataset and other comparative data on spermatogenesis across primates, with a particular emphasis on human spermatogenesis. The evolution of spermatogenesis can provide valuable insights into the molecular processes critical for its efficiency, potentially shedding light on why human spermatogenesis is relatively poor.

Calcium sensing receptor and its function in health and disease

Fadil Hannan[1]
[1]Nuffield Department of Women's & Reproductive Health, UK

The calcium-sensing receptor (CaSR) is a critical modulator of mineral homeostasis. This cell-surface class C G-protein coupled receptor binds extracellular calcium, phosphate and amino acids, and is the target of calcimimetic and calcilytic drugs. The CaSR is expressed on the cell surface as a homodimer and is most highly expressed in the parathyroid glands and the thick ascending limb of the Loop of Henle, where it acts to maintain a near-constancy of circulating calcium concentrations by regulating parathyroid hormone (PTH) secretion and urinary calcium excretion, respectively. The other major calcitropic role of the CaSR involves regulating mammary gland PTH related peptide (PTHrP) secretion during lactation. The importance of the CaSR for calcium homeostasis is highlighted by the identification of germline loss- and gain-of-function CaSR mutations, which cause familial hypocalciuric hypercalcaemia (FHH) and autosomal dominant hypocalcaemia (ADH), respectively, and also by the efficacy of CaSR-targeted drugs for the treatment of parathyroid disorders. The CaSR also has non-calcitropic roles and is highly expressed in pancreatic beta-cells, where it regulates insulin secretion and may also influence glucose homeostasis. In addition, abnormal expression or function of the CaSR is implicated in the pathogenesis of chronic lung diseases and also malignancies such as carcinoma of the breast. This has led to CaSR targeted drugs being evaluated for non-calcitropic disorders. Novel strategies such as utilising inhaled calcilytic drugs for asthma may help to minimize adverse effects arising from inappropriate modulation of the CaSR in calcitropic tissues.

Recent advances in the diagnosis and management of Hypophosphatasia

Maria Luisa Brandi[1]
[1]FIRMO Foundation, Italy

Hypophosphatasia (HPP) is a rare inherited metabolic disorder characterized by deficient activity of tissue-nonspecific alkaline phosphatase (TNAP) caused by variants in the ALPL gene. Disease manifestations include: reduced skeletal mineralization, rickets, lung hypoplasia, vitamin B6-dependent neurological manifestations, craniosynostosis, premature loss of deciduous teeth, and muscle pain. The clinical presentation can comprise failure to thrive with muscular hypotonia, delayed motor development, and gait disturbances later in childhood. In adults, pseudofractures are a characteristic indicator of severely compromised enzyme activity. However, non-classical symptoms like generalized musculoskeletal pain, weakness, and fatigue, frequently accompanied by neuropsychiatric and gastrointestinal problems are increasingly recognized as key findings in patients with HPP. The diagnosis is based on clinical manifestations in combination with persistently low alkaline phosphatase (ALP) activity, elevated levels of ALP substrates, specifically inorganic pyrophosphate (PPi), pyridoxal 5'-phosphate (PLP) or urine phosphoethanolamine (PEA), and genetic confirmation of a causative *ALPL* variant. Considering the wide range of manifestations, treatment must be multimodal and tailored to individual needs. The multidisciplinary team for comprehensive management of HPP patients should include expertise to ensure disease state metabolic and musculoskeletal treatment, dental care, neurological and neurosurgical surveillance, pain management, physical therapy, and psychological care. Asfotase alfa as first-in-class enzyme replacement therapy (ERT) for HPP was shown to improve survival, rickets, and functional outcomes in severely affected children. However, we need to know more the effects of the enzyme replacement therapy on emerging manifestations of the disease. The understanding of the pathophysiology behind the diverse clinical manifestations of HPP is instrumental for improving the diagnostic process, working on novel means to substitute enzyme activity, and developing an integrative care of the HPP patient.

Molecular basis of Pseudohypoparthyroidism

Harald Jueppner[1]
[1]Massachusetts General Hospital and Harvard Medical School, Boston, USA

The *GNAS* complex locus on chromosome 20q13.3 encodes the alpha-subunit of the stimulatory G protein (Gsα) and several splice variants thereof. With the exception of the transcriptional start site giving rise to Gsα, at least four *GNAS* regions undergo parent-specific epigenetic changes. Several human disorders are caused by mutations in *GNAS* or adjacent genomic regions. Thus, pseudohypoparathyroidism type Ia (PHP1A) is caused by heterozygous inactivating mutations involving the maternal *GNAS* exons 1-13 that lead to PTH-resistant hypocalcemia and hyperphosphatemia. Affected patients furthermore can present with resistance to TSH and other hormones, and typically develop characteristic abnormalities referred to as Albright's Hereditary Osteodystrophy (AHO). The same or similar mutations on the paternal allele also cause some of these AHO features, but without mineral ion changes, and this disorder is therefore referred to as pseudopseudohypoparathyroidism (PPHP). Other heterozygous mutations on the maternal allele (including deletions, duplications, insertions, and inversions) lead to epigenetic changes at one or several *GNAS* DMRs (Differentially Methylated Regions), thereby causing autosomal dominant pseudohypoparathyroidism type Ib (AD-PHP1B). The genetic defect(s) responsible for sporadic PHP1B (sporPHP1B) remains unknown for most cases, yet characteristic epigenetic changes at the *GNAS* DMRs can be readily detected. Thus, multiple genetic or epigenetic *GNAS* abnormalities impair Gsα function thereby reducing cAMP-dependent signaling events down-stream of various G protein-coupled receptors.

Regulation of HPT-axis in maternal-foetal health - Thyroid and Fertility

David Unuane[1]
[1]Universitair Ziekenhuis Brussel, Belgium

Thyroid autoimmunity (TAI) and thyroid dysfunction are prevalent among women of reproductive age, significantly impacting fertility and pregnancy outcomes. This talk explores the intricate relationship between thyroid health and female reproductive function, emphasizing the role of thyroid hormones in ovarian regulation. The discovery of thyroid-stimulating hormone (TSH) and its receptors on ovarian surface epithelium and oocytes underscores the importance of thyroid hormones in reproductive physiology. While overt hypothyroidism is widely recognized as a risk factor for infertility and adverse pregnancy outcomes, the association between subclinical hypothyroidism (SCH) and infertility remains inconsistent across literature. This inconsistency is partly due to varying TSH cut-offs and a lack of robust prospective studies. The talk will address the current lack of consensus on initiating levothyroxine treatment for SCH to prevent fertility issues, highlighting the methodological limitations and small sample sizes of existing studies. Additionally, the diverse population of women with thyroid autoimmunity and dysfunction, influenced by factors such as age and co-existing health conditions, complicates uniform treatment recommendations. The presentation will delve into thyroid hormone-dependent mechanisms, including ovarian function regulation and endometrial quality, as well as thyroid hormone-independent mechanisms like immunological dysfunction and direct infiltration of reproductive organs by thyroid autoantibodies. Understanding these mechanisms is crucial for developing targeted treatment strategies to improve fertility outcomes in women with TAI. This talk aims to provide a comprehensive overview of the current state of research, identify gaps, and propose directions for future studies.

International Diabetes Transition Recommendations- a joint initiative between ISPAD- ADA- EASD

May Ng[1]
[1]Faculty of Health, Social Care and Medicine, Edge Hill University, UK

Transition from pediatric to adult diabetes care is a critical period associated with increased risk of adverse health outcomes, disengagement from healthcare services, and psychosocial challenges. This consensus report, developed jointly by the International Society for Pediatric and Adolescent Diabetes (ISPAD), the European Association for the Study of Diabetes (EASD), and the American Diabetes Association (ADA), provides recommendations to optimize transition care for young people with diabetes. A systematic review, along with a global survey of 372 healthcare professionals and 146 individuals with diabetes or carers, identified significant variability in transition models, with many lacking structured readiness assessments, dedicated transition personnel, or formal education programs. Only 32.8% of healthcare centers utilized a transition readiness checklist, and less than 25% had structured transition education or dedicated staff to support transition efforts. Identified barriers included poor communication between pediatric and adult teams, lack of psychosocial support, and uncoordinated care transfers.

The consensus framework recommendations outline three key phases of transition:

1. Pre-transition: Early preparation (12–24 months before transfer), structured education, transition readiness assessments, and active family/carer involvement.
2. Transfer of care: Timely scheduling of the first adult care visit, provision of a written medical summary, structured communication between care teams, and encouragement of peer support.
3. Post-transfer: Ongoing assessment of diabetes knowledge and psychosocial well-being, flexible care models (e.g., telehealth, young adult clinics), and education on emergency care management.

Despite limited high-quality evidence on transition outcomes, structured programs have shown improvements in engagement, care satisfaction, and self-management skills. This report underscores the need for adaptable, resource-sensitive strategies tailored to diverse healthcare settings. Future research should evaluate long-term clinical and psychosocial outcomes to further refine best practices. Implementing these global recommendations will help ensure a seamless, supportive transition, ultimately improving long-term health and well-being for young people with diabetes.

Recombinant antibody fragments as new modulators of gonadotropin receptor activity

Eric Reiter[1,2]
[1]NRAE, CNRS, Université de Tours, PRC, Nouzilly, France, [2]Université Paris-Saclay, Inria, Université Paris-Saclay, Inria, Inria Saclay-Îllede-France, Palaiseau, 91120 France, Nouzilly, France

G Protein-Coupled Receptors (GPCRs) constitute the most abundant receptor family in the genome and also represent the primary class of therapeutic targets. Gonadotropins and their receptors play a central role in the control of both male and female reproduction. Gonadotropins (i.e. FSH, LH, hCG) are extensively used in assisted reproduction technologies (ART). However, no pharmacological tool allowing to tightly control gonadotropin receptors' activity through competitive antagonism or allosteric modulation is available in clinics. Therefore, some therapeutic needs remain unmet. Despite the tremendous success of antibodies as therapeutic agents, very few therapeutic antibodies targeting GPCRs have been approved to date. VHHs are small antibody fragments derived from the variable domain of heavy-chain antibodies (HcAbs) in camelids. Their small size (12 ~ 15 KDa) combined with their unique structural features (i.e., long CDR3, the ability to interact with concave surfaces, and access to cryptic epitopes that classical immunoglobulins cannot reach) make them intriguing tools for targeting GPCRs. In particular, VHHs have demonstrated their ability to modulate some GPCRs in an allosteric manner and have also proven to be valuable tools in structural biology for this receptor class. We have developed VHHs specific to gonadotropin receptors by phage display from immune and synthetic libraries. The selection and screening processes for identifying high-affinity/selectivity VHHs have been optimized to deal with high attrition rates and identify VHHs with specific pharmacological profiles. We have demonstrated novel biochemical and pharmacological properties of these VHHs that allow the modulation of fertility in mice without using exogenous hormones.

The long-term effects of duchenne muscular dystrophy and its treatment on bone strength

Leanne Ward[1]
[1]University of Ottawa, Canada

Duchenne muscular dystrophy (DMD) is a relentlessly progressive dystrophinopathy arising from pathogenic, loss of function variants in the *DMD* gene. Corticosteroid (CS) monotherapy is the mainstay of DMD treatment in many

countries around the world; even dystrophin-targeted treatments such as gene therapy do not relinquish patients from CS. On daily CS therapy, walking is prolonged by two years (with loss of ambulation typically experienced around 14 years of age), and life expectancy is typically extended into the late 20's and early 30's. Daily CS therapy is also characterized by well-known endocrine and bone co-morbidities including excess weight gain, short stature, delayed puberty, adrenal insufficiency, and bone fragility due to osteoporosis. In an effort to attenuate the adverse effects of CS therapy in DMD, regimens alternative to daily CS have been implemented (such as prednisone 10 days on/off); however, this saltatory approach comes at a cost to muscle strength. Recently, a novel steroid (vamorolone) has been studied in DMD. Data to nearly three years post-exposure suggest efficacy parity of high-dose vamorolone relative to classic CS regimens, along with improved growth velocity + serum bone turnover markers, and fewer vertebral fractures. However, excess weight gain, adrenal insufficiency and bone fragility can still occur on vamorolone, necessitating their ongoing, anticipatory prevention. DMD represents a serious secondary osteoporosis condition due to the high frequency of fractures, their devastating consequences, and limited potential for medication-unassisted recovery from osteoporosis. Lower extremity fractures are associated with premature, permanent loss of ambulation, while fat embolism syndrome after long bone injuries has been linked to acute respiratory distress syndrome and unexpected mortality. Vertebral fractures, often silent, occur at an alarmingly high rate in daily, classic CS-treated DMD, necessitating periodic surveillance with lateral spine imaging. Current management strategies centre around early detection of vertebral and non-vertebral fractures, with a single low-trauma vertebral or long bone fracture providing clear rationale for instituting bone protection therapy. At the same time, the high fracture rates of DMD combined with the devastating consequences of bone fragility have sparked interest in osteoporosis treatment *prior* to first fractures. Intravenous bisphosphonates remain the cornerstone of osteoporosis therapy in DMD. In an effort to improve the convenience of osteoporosis treatment and minimize first exposure adverse events, denosumab has been tried in this setting. However, even the low bone turnover of DMD does not protect against the denosumab-induced rebound phenomenon, leading to recommendations against the routine use of this agent in pediatric DMD. Overall, it is recognized that DMD is the ideal setting to consider not only prevention of first-ever fractures but also osteoanabolic agents, given the limitations of bisphosphonate monotherapy in low bone turnover states such as DMD. Strategic planning for primary osteoporosis prevention is currently underway by members of The OPTIMIZE DMD Consortium, an international working group dedicated to education, advocacy and research in endocrine and bone health care for people with DMD.

Transition from boy to man - Puberty/testosterone

Claire Wood[1]
[1]Newcastle University, Newcastle, UK

Glucocorticoids reduce inflammation and preserve muscle function in Duchenne muscular dystrophy (DMD) but cause pubertal delay. Consideration of testosterone treatment for the induction of puberty was introduced as part of the International Care Considerations in DMD in 2018 but the timing of this and methods used to induce puberty vary. It also remains unclear what happens to endogenous testosterone levels once testosterone supplementation is stopped, particularly in the context of ongoing GC therapy.
The aims of this session are to understand:
The cause and impact of delayed puberty in DMD
Assessment and treatment of delayed puberty in DMD
Follow-up after pubertal induction in DMD
Conversations surrounding sexual health and fertility in DMD
The causes of pubertal delay in DMD will be summarised and the evidence base for pubertal induction reviewed, which confirms that testosterone is safe and well tolerated in this population and may also be associated with an increase in contractile muscle bulk. The variations in international practice will be highlighted using results from a recent survey and in particular, with respect to ongoing surveillance of hypogonadism after pubertal induction. Finally, the views of young men regarding some of the awkward conversations surrounding sexual health and fertility in DMD will be shared from a recent qualitative study.

Genital Surgery in Disorders of Sex Development

Hedi Claahsen - van der Grinten[1]
[1]Radboud University Medical Centre, Netherlands

The European Reference Network on Rare Endocrine Conditions (Endo-ERN) wants to take a cautious and evidence-based position regarding genital surgery in individuals with Disorders/Differences in Sex Development (DSD). Given its focus on rare endocrine conditions, including DSD, Endo-ERN's position aligns with the broader European emphasis on human rights, ethical medical practices, and patient-centred care. ENDO ERN wants to address the ethical, medical, and legal considerations surrounding genital surgery in individuals with DSD in Europe and acknowledges intersex as a part of human diversity while providing clarity in a medical or scientific context. It advocates for a shift towards patient-

centred care that prioritizes the rights and well-being of individuals with DSD, particularly children. Recommendations emphasize deferring non-urgent, irreversible surgeries until the individual can provide informed consent whenever possible, strengthening support systems for families, and promoting a standardized European framework that respects human rights, with clearly defined quality indicators for surgery.

Novel genetic causes for CHI

Sarah Flanagan[1]
[1]University of Exeter Medical School, UK

Congenital Hyperinsulinism is the most common cause of persistent hypoglycaemia in childhood. The condition is clinically and genetically heterogeneous with over 35 different disease genes identified. Routine screening of these genes in individuals living with congenital hyperinsulinism identifies a pathogenic variant in ~50% of cases. Understanding the genetic cause of an individual's hyperinsulinism is critical as it will help to guide medical management. In recent years, genetic discovery efforts in congenital hyperinsulinism have focussed on screening for germline coding variants within genes known to have an important role in the pancreatic beta-cell. Much less attention has been afforded to the non-coding genome. This is largely because of the difficulties in interpreting the impact of non-coding variants on gene regulation. The Exeter Genomics Laboratory is an international referral centre for congenital hyperinsulinism, having received samples from over 4000 individuals living with this condition for genetic testing. Using state-of-the-art technology, we are improving our understanding of the genetics of this condition, which is leading to new knowledge of the pathways governing insulin secretion and importantly is providing more families with a genetic diagnosis. During this lecture I will show how we have developed methods to identify somatic variants in the known hyperinsulinism genes that are present in the pancreas but have remained undetected in leukocyte DNA. Results will also be presented from our genome sequencing studies which show how non-coding variants that disrupt the regulation of genes not normally expressed within the beta-cells, are a common cause of hyperinsulinism. These findings demonstrate, that for some, hyperinsulinism can present for the first time in adulthood- broadening the phenotypic spectrum associated with some monogenic forms of hyperinsulinism.

What is new in CHI therapeutics - Alpelisib

Khalid Hussain[1]
[1]Sidra Medicine, Qatar

Congenital hyperinsulinism (CHI) is a disorder of unregulated insulin secretion, leading to severe and persistent hypoglycemia especially in the newborn period. Mutations in the *ABCC8* and *KCNJ11* genes (which encode the SUR1 and the KIR subunit of KATP channels, respectively) are the commonest genetic cause of CHI. These mutations impair KATP channel function, leading to persistent depolarization of pancreatic beta cells and excessive insulin release. Patients with *ABCC8* or KCNJ11mutations present with severe, medically refractory hypoglycemia, necessitating aggressive interventions such as partial or near-total pancreatectomy. The first line drug therapy for CHI is diazoxide, however most patients with *ABCC8*/*KCNJ11* mutations do not respond. Other treatment options include octreotide (both short and long acting), nifedipine and sirolimus but even with these therapies most patients will continue to have episodes of hypoglycemia. Alpelisib, a selective phosphatidylinositol3-kinase (PI3K) inhibitor plays a crucial role in regulating cell growth, insulin signalling, and glucose metabolism. Originally approved for treating PIK3CA-mutated, hormone receptor-positive advanced breast cancer and overgrowth syndromes, alpelisib has also shown efficacy in managing non-islet-cell tumor hypoglycemia.The major side effect of alpelisib in patients with PIK3CA-mutated, hormone receptor-positive advanced breast cancer is hyperglycemia (with diabetic ketoacidosis reported in a few patients). Given the hyperglycemic effect of alpelisib we describe our observations in three patients with severe genetic forms of CHI where we re-purposed Alpelisib therapy for treating the hypoglycemia. Treatment was initiated at 12.5mg orally daily, with gradual dose adjustments based on clinical responses. Outcome measures included blood glucose variability, frequency of hypoglycemic episodes, need for supplemental feeding, and treatment safety. Alpelisib significantly improved glycemic control, reducing the frequency of hypoglycemic episodes in all three patients. This allowed for the tapering of other medications and in two patients discontinuation of all other medications (diazoxide and octreotide) and facilitated a transition to bolus gastrostomy-tube/oral feeding. No significant adverse effects were reported, growth and weight of all the patients remained normal. These observations suggest that alpelisib may be used for treating patients with CHI who are refracotry to all other forms of medical therapy. Randomized controlled trials are needed to assess its long-term safety and efficacy for CHI.

The relevance of Epigentics variability on Phenotype variation

Andrew Pospisilik[1]
[1]Van Andel Institute, USA

Our goal is to elucidate mechanisms underpinning developmental programming of disease. Focusing on non-genetic and non-environmental triggers, we've identified Trim28 and Nnat as novel 'probabilistic' regulators of disease outcomes. Loss-of-function mutations, in either gene triggers a unique developmental phenomenon known as 'polyphenism', in which genetically identical animals take on one of several meta-stable phenotypic programs, during development. These models represent the first formal demonstrations of mammalian polyphenism and carry profound implications for our understanding of the origins of disease risk in that they suggest that each individual may have several preferred multi-trait disease susceptibility states. I will share data that (i) characterize the phenotypic and epigenetic distinctions between these states in mice, in the contexts of cancer, obesity and food-addiction; (ii) first dissections of the mechanisms underpinning the developmental disease susceptibility state decision; (iii) provide evidence for alternate developmental trajectories in humans, including a high-dimensional analyses of monozygotic twin discordance and a panUKBB deconvolution that reveals human obesity endotypes. Collectively, these data alter our understanding of the fundamentals of the origins of metabolic disease heterogeneity.

Senolytics and senomorphics: new treatments on the door?

Cristina Aguayo-Mazzucato [1]
[1]Joslin Diabetes Center/Harvard Medical School, Boston, MA, USA

Cellular senescence is a stress response marked by the upregulation of anti-apoptotic pathways and loss of cellular function while maintaining an active secretory profile. Senescent pancreatic β-cells contribute to the development of Type 2 Diabetes and secrete a unique senescence-associated secretory phenotype (SASP) with potential effects on surrounding cells. Removing senescent β-cells leads to their functional recovery. scRNASeq analysis of mouse and human islets identified different subpopulations of senescent β-cells based on the expression of two cyclin-dependent kinase inhibitors: *Cdkn1a*$^+$ β-cells had reduced expression of functional and hallmark identity genes. In contrast, *Cdkn2a*$^+$ β-cells had a specific SASP profile. *In vitro*, SASP factors induced senescence and impaired insulin secretion, making senescent cells and its SASP a therapeutic target. JAK inhibitors were used to inhibit SASP secretion (senomorphic effect) and were compared to ABT263, which induced apoptosis in senescent cells (senolytic effect). SASP inhibition was confirmed with proteomic analysis of conditioned media from human β-cells, while senolytic action was shown through morphological analysis. In a mouse high-fat diet model of insulin resistance, senomorphic drugs improved blood glucose levels, increased insulin levels, restored glucose responsiveness, and decreased senescence and SASP genes while restoring the β-cell specific transcriptome. Human islets from donors with and without T2D were treated in vitro with senomorphic drugs, which preferentially decreased the *CDKN1A*$^+$ human subpopulation, increased survival, decreased SASP secretion, and improved GSIS in humans. In conclusion, the non-cell autonomous effects of SASP in β-cells can be pharmacologically inhibited to restore β-cell function and identity.

Genetic determinants of normal pubertal timing

Alexander Busch[1]
[1]University of Münster, University of Münster, Germany

Pubertal timing varies widely and influences lifelong health. We conducted a multi-ancestry GWAS in ~800,000 women, identifying 1,080 genetic signals for age at menarche (AAM), explaining 11% of trait variance. Extreme polygenic scores correlated with significantly altered puberty timing. Exome-wide analyses in 220,000 women identified rare variants, including in *ZNF483*, which nullified polygenic effects. Functional analyses implicated 665 genes, including *GPR83*, a GPCR enhancing *MC3R* signaling, a key puberty regulator. Shared genetic signals with menopause and DNA damage response genes suggest ovarian reserve integrity may influence pubertal onset. We also identified body size-dependent and independent pathways linking puberty timing to metabolic disease risk. These findings illuminate the genetic architecture of puberty, highlighting interactions between common and rare variants and their impact on reproductive health and disease susceptibility.

Definition of puberty onset in boys - secular changes?

Petur Juliusson[1]
[1]Haukeland University Hospital, Bergen, Norway

In clinical practice, the preferred method for assessing pubertal onset in boys is the orchidometer, introduced by Andrea Prader in 1966. Puberty is typically defined as beginning when the testicular size reaches 4 ml. However, several studies suggest that a testicular size of 3 ml is strongly associated with the activation of the hypothalamic-pituitary-gonadal axis and subsequent pubertal development. Recent publications indicate a secular trend toward earlier pubertal onset in girls, but data for boys are more limited. This talk will provide an overview of the physical and hormonal changes during puberty and various methods for assessing the onset and progression of puberty in boys. In addition to the orchidometer, the use of ultrasound for measuring testicular volume will be described, with examples from the Bergen Growth Study 2. The Tanner stages for genital and pubic hair development will be presented, as well as hormone measurements. Furthermore, the literature suggesting the relevance of a testicular size of 3 ml in defining the onset of puberty will be discussed. Lastly, we will address the question of whether secular changes are occurring in the age of pubertal onset in boys.

AMH as reproductive marker in healthy females and Turner syndrome patients from birth to adulthood

Caspar Hagen[1]
[1]Rigshospitalet Copenhagen, Denmark

The majority of patients with Turner Syndrome suffer from primary ovarian insufficiency (POI). This is a major concern for the patients and their families. To counsel the patients, we need markers of ovarian activity as well as predictors of POI. At centers offering ovarian cryopreservation, this assessment is essential when selecting relevant candidates for the procedure. AMH is a unique marker of ovarian function. In contrast to inhibin B and estradiol produced by mature ovarian follicles, AMH is produced by granulosa cells surrounding small antral follicles. This characteristic expression pattern is essential for the clinical use of AMH in pediatric endocrinology. In adulthood, POI is characterized by amenorrhea and hypergonadotropic hypogonadism. However, many TS girls are diagnosed prenatally due to ultrasound findings, or in mid childhood due to short stature. Due to central inhibition of the HPG axis, it is a challenge to assess ovarian activity in prepubertal girls. However, ovarian activity in prepubertal girls is not shut down completely. Infant minipuberty is characterized by a transient surge of ovarian activity. Even in mid childhood, there is subtle ovarian activity from small antral follicles growing independently from FSH stimulation. Activity from theses follicles contributes to detectable levels of circulating AMH in all healthy girls. Interestingly, each girl maintains her relative AMH during childhood, and AMH in minipuberty correlates therefore with AMH in adolescence. Based on data of circulating levels of reproductive hormones from infancy to adulthood in healthy females and patients with Turner Syndrome, I will discuss the clinical use of markers and predictors of POI.

The biochemical and clinical significance of 11-oxygenated androgens

Karl Storbeck[1]
[1]Department of Biochemistry, Stellenbosch University, Stellenbosch, South Africa

For decades, endocrinology has recognised testosterone and 5α-dihydrotestosterone (DHT) as the only potent androgens in human physiology. However, the discovery of adrenal-derived 11-oxygenated androgens, notably 11-ketotestosterone (11KT), has challenged this established view, leading to a reassessment of the androgen pool. In the last decade, 11-oxygenated androgens have been implicated in several disease states, including polycystic ovary syndrome, congenital adrenal hyperplasia, and castration-resistant prostate cancer. This presentation will provide an overview of the adrenal biosynthesis and peripheral metabolism of 11-oxygenated androgens, including their conversion to 11-oxygenated oestrogens. It will also summarise their emerging roles in human health and disease, highlighting the need to incorporate these androgens into routine steroid profiling, particularly in an era when LC-MS/MS is more accessible.

S27.2

New therapeutic steroid sparing options for Congenital Adrenal Hyperplasia

Richard Auchus[1]
[1]University of Michigan, Ann Arbor, MI, USA

Since the pioneering work of Lawson Wilkins in the 1950s, glucocorticoids have been the cornerstone of therapy for patients with congenital adrenal hyperplasia, particularly classic 21-hydroxylase deficiency (21OHD). Glucocorticoids are used both to replace the cortisol deficiency and to provide the missing negative feedback to the hypothalamic-pituitary-adrenal (HPA) axis, to lower the production of unwanted precursors, which are metabolized to androgens. Substantially higher than physiologic glucocorticoid dosing with late-day dosing is often required to correct the adrenal-derived androgen excess, allow normal growth and development, and maintain fertility. This glucocorticoid exposure, however, leads to long-term complications in adults, such as obesity, mood disorders, bone loss, and cardiometabolic dysfunction. Alterative pharmacologic targets have been explored to reduce glucocorticoid exposure in 21OHD. Crinecerfont, a corticotropin-releasing factor type 1 receptor (CRF1) antagonist was trialed in placebo-controlled studies for children and adults with 21OHD. The pediatric trial showed a reduction in androstenedione (A4) of ~50% after 4 weeks, which allowed glucocorticoid dose reduction of 18%, with ~25% A4 reduction by week 28. In the adult trial, A4 also fell ~50% after 4 weeks, which enabled a 27.3% (17% placebo-controlled) glucocorticoid dose reduction, while maintaining A4 at or below baseline. Additional therapeutics targeting the HPA axis are in trials, particularly atumelnant, an orally administered MC2R (ACTH receptor) antagonist, and Lu AG13909, an antibody to ACTH. These treatments might allow simplified and less toxic glucocorticoid regimens for children and adults with 21OHD, to improve short- and long-term outcomes.

S27.3

Novel approaches to glucocorticoid replacement

Eystein Husebye[1]
[1]University of Bergen, Norway

Despite optimal replacement therapy with corticosteroids, patients with adrenal insufficiency continue to experience reduced quality of life and face elevated risks of mortality and morbidity. A significant challenge lies in our inability to replicate the precise, dynamic secretion patterns of cortisol and aldosterone, coupled with the absence of reliable biomarkers to ensure adequate corticosteroid dosing. Conventional hydrocortisone formulations possess short half-lives (approximately 90 minutes), necessitating multiple daily doses. Recently, extended-release hydrocortisone (ER-HC) formulations have been developed, allowing for once or twice daily administration, which are more user-friendly and have demonstrated beneficial effects. Emerging evidence suggests that subcutaneous administration of hydrocortisone via a pump may offer additional advantages. These recent advancements will be presented and discussed.

Diabetes mellitus and Bone fragility: Pathophysiological aspects

Martina Rauner[1]
[1]Tu Dresden, Dresden, Germany

The incidence of diabetes, a disease characterized by high blood glucose levels, is increasing worldwide. Besides the well-known complications of diabetes including cardiovascular disease, retinopathy, nephropathy, and neuropathy, also bone fragility has recently been recognized as a complication of diabetes. In fact, type 1 diabetes is associated with a 6-fold increase in hip fractures with a marked loss of bone mineral density, while type 2 diabetes is associated with a 1.5-fold increase of hip fractures even in the presence of a higher bone mineral density. In both cases, diabetic bone disease is characterized by a low bone turnover and an increased incorporation of advanced glycation end-products into the collagenous matrix, rendering it stiff and inflexible. Moreover, bone vascularization is reduced in diabetic animals; in particular the number of pro-osteogenic H-type vessels is diminished. Experimental evidence shows that elevated ROS production, senescence, and suppressed Wnt signaling contribute to diabetic bone disease. Suppressed Wnt signaling also stimulates the differentiation of adipocytes in the bone marrow, which contribute to an inflammatory, pro-osteoclastogenic milieu. Finally, several miRNAs are differentially expressed any may contribute to diabetic bone disease

Sleep disturbances in patients with pituitary tumours

Peter Bisschop[1]
[1]Amsterdam UMC, Netherlands

Suprasellar tumors that compress the optic chiasm can lead to disturbances in sleep-wake rhythms, possibly due to damage to the brain's biological clock, the suprachiasmatic nucleus (SCN). Studies have shown that pituitary tumors with suprasellar extension impair circadian regulation and thermoregulation. In patients with a history of optic chiasm compression, there is reduced expression of arginine vasopressin (AVP) in the SCN, while vasoactive intestinal peptide (VIP) levels remain unchanged. This suggests selective impairment of the SCN, which may contribute to sleep disturbances. Additionally, patients with a history of chiasm compression show altered skin temperature regulation. Specifically, these patients exhibit lower proximal skin temperature and an absent association between pre-sleep skin temperature gradient and sleep onset latency, indicating disrupted hypothalamic control of both vigilance and thermoregulation. Furthermore, patients with hypopituitarism and optic chiasm compression demonstrate impaired photosensitive retinal ganglion cell (ipRGC) function, as evidenced by a weaker post-illumination pupil response (PIPR) compared to those without chiasm compression. This diminished PIPR is associated with delayed sleep timing but no significant differences in sleep duration or quality. Taken together, these findings support the hypothesis that damage to the hypothalamus, particularly the SCN and associated nuclei, impairs both circadian rhythms and thermoregulatory functions, contributing to sleep disturbances in patients with pituitary tumors compressing the optic chiasm.

Insufficient sleep in obesity: An eating jet lag

María Fernanda Zerón Rugerio[1]
[1]University of Barcelona, Barcelona, Spain

In contemporary society, modern lifestyles adversely impact our sleep and eating routines, particularly the timing of these activities. For example, the access to artificial light at night enables us to eat and stay awake at almost any time, leading to late sleep onset, short sleep duration, and circadian misalignment. In the general population, the most extreme example of circadian disruption is observed among shift workers. However, even non-shift workers who delay activities face mild circadian misalignment, known as social jet lag. This arises from accumulated sleep debt during the week, prompting extended sleep on weekends and resulting in inconsistent sleep patterns. Social jet lag is a potential risk factor for obesity and unhealthy eating habits, primarily due to insufficient sleep. In addition, our research group has shown that social jet lag is associated with breakfast skipping which could also be associated with circadian misalignment and obesity. Considering the aforementioned, we proposed the eating jet lag as a novel marker to study the irregularity in meal timing and its association with obesity. In this talk, we will explore the complex relationship between circadian misalignment and obesity, emphasizing how social and eating jet lag can lead to metabolic dysregulation and weight gain. Circadian misalignment induced from eating jet lag could have a negative impact on glucose metabolism and insulin sensitivity, increasing obesity risk. By examining these mechanisms, we will discuss the broader implications of eating jet lag in health. Although specific clinical recommendations remain inconclusive, we will discuss strategies to mitigate the adverse effects of sleep deprivation on metabolic health, including promoting regular sleep and meal timing.

Thyroid Hormone Resistance

Carla Moran[1]
[1]Beacon Hospital, Ireland

The syndromes of Resistance to Thyroid Hormone (RTH) are a group of rare disorders that cause relative tissue resistance to the effect of thyroid hormone (TH). Each syndrome has a genetic basis, unique phenotype, and most have a distinct biochemical profile, but nonetheless they remain difficult to diagnose. In this session, I will focus on the presentation, diagnosis and management of two forms of RTH, in childhood and adulthood. RTH beta is characterised by raised thyroid hormones, non suppressed TSH and variable tissue sensitivity to thyroid hormone, often with thyrotoxic features. RTH alpha, more recently identified, causes profound tissue hypothyroidism, despite normal TH levels. At the end of the talk, the audience will be familiar with the presenting features, typical biochemical profile and underlying pathogenic basis RTH alpha and beta, and will be aware of the therapeutic options available for affected patients.

>50 years of neonatal screening - where do we stand?

Anita Boelen[1]
[1]Amsterdam UMC, Vrije Universiteit Amsterdam and University of Amsterdam, Netherlands

Thyroid hormone (TH) is essential for brain development in utero and during the first two to three years of life. The negative effects of TH deficiency on brain development are irreversible. Early detection of TH deficiency in neonates (congenital hypothyroidism (CH) through newborn screening (NBS)) allows for early treatment, thereby preventing brain damage. Research in the 19th century highlighted the importance of early detection and treatment of CH to prevent growth and mental development issues. Newborn screening began in Buffalo, New York, in 1960 with Dr. Robert Guthrie's blood test for PKU. By the 1970s, the thyroid gland's production of thyroxine (T4) and triiodothyronine (T3) was known, and radioimmunoassay enabled detection of thyroid hormone deficiencies. Screening for CH began in 1973 with the measurement of total T4 in dried blood spots. In 1982, an international conference on neonatal thyroid screening with representatives from 34 countries led to widespread screening. Annually, 7-9 million newborns are screened in industrialized countries. Primary CH affects about 1 in 3800 to 1 in 4000 newborns, mainly due to thyroid dysgenesis (90%). The conference recommended focusing on detecting increased TSH levels and screening premature infants due to often low T4 levels. Currently, worldwide, the majority of NBS programs for CH employ TSH as the primary screening marker although a select few programs still utilize T4 as the primary marker, enabling the detection of both primary and central CH. However, neonatal screening for CH remains challenging, with continuous efforts to improve algorithms by adapting testing protocols, and using reference intervals for screening parameters. New developments, such as machine learning, and DNA-based screening, are being explored to enhance screening performance and reduce the number of false positive referrals. This presentation provides an overview of the aspects of the screening on CH from the start of screening to the present.

Germline variants in non-medullary thyroid cancer'

Karin van der Tuin
[1]Leiden University Medical Center, Netherlands

Recognizable features of a genetic predisposition to cancer are the development of 1 or more malignancies at an earlier than expected age and/or familiar clustering of cancer. Although nonmedullary thyroid carcinoma (NMTC) meets these characteristics (eg, 16% diagnosed below 35 years, increased risk for a second primary tumour and a 3- to 10-fold increased risk in relatives), most NMTC cases remain genetically unexplained. Familial nonmedullary thyroid cancer constitutes 3% to 9% of all thyroid cancers and is recognized as a distinct clinical entity, with heritability partially attributable to tumour predisposition syndromes such as PTEN hamartoma tumour syndrome, Carney complex, familial adenomatous polyposis, DICER1 syndrome, and Werner syndrome. In addition, genome-wide association studies and family-based case series have suggested a variety of possible associated genes (eg, DIRC3, FOXE1, NRG1, SMAD3, SRGAP1, SRRM2, and TITF-1/NKX2.1). Furthermore, recent studies indicate that NMTC heritability may be partly polygenic. Besides important clinical implications for the index patient, identification of a causative germline variant also facilitates cascade testing and surveillance of relatives, allowing early identification of (pre)malignant conditions. Currently no clear guidelines for genetic testing for NMTC are available. An important unanswered question is whether patients with NMTC should undergo genetic testing and, if so, which type of genetic test (eg, single gene/gene panel/whole exome or genome sequencing) should be performed. Recent genetic screening of a large, unbiased paediatric NMTC cohort detected a relatively high prevalence (13%) of P/LP germline variants in well-known tumour predisposing genes. This prevalence led us to recommend genetic counselling for all patients with childhood NMTC.

Pregnancy following bariatric surgery

Annuziatta Lapolla[1]
[1]Padova University, Padova, Italy

With the rising worldwide incidence of obesity, particularly in the young, bariatric surgery offers an effective method of meaningful and sustained weight loss. So, pregnancy after bariatric surgery is now a common scenario. Most women have good pregnancy outcomes, with reduced rates of pre-eclampsia and gestational diabetes, however, rates of stillbirth and small-for-gestational-age babies are increased,In this talk some unresolved questions in the management of pregnancy after bariatric surgery as the modification of glucose homeostasis, the diagnosis of diabetes,the importance of a strict follow up during pregnancy, the assesment and correction of micronutrient and/or macronutrient deficiencies management of preexisting obesity related complications will be underlined.

Don't mess with my iodine! chemical-induced perturbation in synthesis and metabolism of thyroid hormone impairs brain development

Mary E. Gilbert[1]
[1]Office of Research and Development, Center for Public Health and Environmental Assessment, US Environmental Protection Agency, Research Triangle Park, NC, USA

The complexity of thyroid hormone (TH) signaling pathways presents a myriad of targets for potential interference by environmental contaminants. Many of these sites of action can be detected by alterations in T3 and T4 concentrations in the blood. Iodine is essential for production of TH, severe deficiencies leading to hypothyroidism. Given the importance of TH in brain development, maintaining iodine status is especially critical during pregnancy - pregnant women with iodine deficiency (ID) and their progeny may be particularly susceptible to environmental exposures that impact the TH system. In this presentation, a rodent pregnancy model on perchlorate, an environmental contaminant that interferes with the iodine transport, and iopanoic acid (IOP), a chemical that interferes with TH metabolism will be described. Perchlorate, when combined with dietary ID induces structural defects in developing brain, alters synaptic transmission, and impairs behavioral measures of sensory gating. Reductions in serum TH in the fetus that persist to the first week of life are required to induce these changes, changes that were greatly exacerbated under conditions of ID. *Decreases* in serum TH induced by perchlorate stand in stark contrast to *increases* in serum T4 observed in response to exposure to IOP. IOP blocks deiodinases, enzymes responsible for activating and deactivating TH and maintain optimal receptor-level concentrations for T3-mediated gene transcription. Despite a peripheral state of hyperthyroidism, brain T3 is reduced in the newborn pup and a neuroanatomical defect similar to that reported for perchlorate was present in the brains of offspring. Together, the dissociation of peripheral vs central TH effects by IOP demonstrate the criticality of tissue levels TH while the combined effects of perchlorate and ID underscore the need to consider additional environmental stressors when determining the impact of chemical exposure on brain function. *Does not reflect EPA policy*.

Neurodevelopmental effects of thyroid hormone system disruption – insights from the ATHENA project

Marta Axelstad[1]
[1]Technical University of Denmark, Denmark

The aim of the ATHENA project was to develop new test methods for detecting thyroid hormone (TH) system disruption. The primary objective of the *in vivo* studies was to identify new sensitive and specific neurodevelopmental endpoints that may serve as reliable indicators for such disruption. Several neurological endpoints were examined in rat offspring exposed to two thyroid peroxidase (TPO) inhibiting substances: the drug methimazole and the pesticide amitrole, followed by studies examining effects from additional substances with different modes of action. Developmental exposure to the two TPO-inhibiting substances induced a range of adverse neurodevelopmental effects, including changes in cortical gene expression, altered motor activity levels, formation of periventricular heterotopia, reduced parvalbumin-positive cells in the cortex and hippocampus, and decreased TH concentrations in the brain. These effects were consistently observed when TH concentrations in serum were reduced by 50% or more during foetal and postnatal development. By including transcriptomic analyses of the hippocampus, the project also aimed to identify candidate biomarker genes that may be more sensitive indicators of TH system disruption than the identified morphological endpoints. Exposure to chemicals affecting the TH system through other modes of action caused variable effects on TH levels. In most cases, the observed TH reductions were not substantial enough to adversely affect the newly identified TH-specific neurological endpoints, indicating that these methods may lack the sensitivity needed to protect human brain development from adverse effects caused by TH system disruptors. In light of these findings, the ATHENA consortium recommends that, in a regulatory context, changes to serum and brain TH concentrations in rodents should be recognized as predictors of adversity in their own right. Overall, the ATHENA project has provided critical insights into the impacts of TH system disruption on brain development and has suggested improved regulatory measures, for better protection of human health.

EDC targets of the thyroid hormone system - HTS and in vivo assays for identification of potential reference compounds'

Josef Köhrle[1]
[1]Charité-Universitätsmedizin Berlin, Germany

The thyroid hormone system (THS) is a main target of endocrine-disrupting chemicals (EDC), natural or human-made chemicals that may interfere with hormonal systems during development, adolescence or adulthood. EDC interference, especially during sensitive developmental windows of susceptibility, may lead to irreversible setpoint changes of hormonal feedback regulation, inadequate function of hormone-regulated processes or predispose to disease development in adulthood or subsequent generations. Human, especially, brain development critically depends on adequate provision of maternal T4, particularly during first trimester fetal thyroid development and maturation, lessons learned from impact of iodide deficiency and genetic disorders affecting development and function of the THS. *In silico*, *in vitro*, *in vivo* test systems and animal experimental models allow the systematic, hypothesis-free or targeted interrogation of potential interference of single or groups of chemicals with relevant functional components of the THS system. ~70 000 low molecular weight chemicals, representing 1/5 of the current chemical universe, were screened for five THS targets (hr DIO1-3, DEHAL1, MCT8) of EDC using non-radioactive high throughput screening assays photometrically detecting iodide by the Sandell-Kolthoff reaction. Identified inhibitors are further prioritized with respect to their potency, target specificity, cytotoxicity and potential biological, medical or environmental relevance. Prioritized chemicals undergo testing in selected (established, validated, novel) *in vitro* test methods (reporter assays, cellular models, organoids) applicable for regulatory purposes by comparison with reference compounds affecting the respective THS target. Top hits are functionally characterized *in vivo* using mechanistically meaningful and biologically-informative experimental models for living organisms, which reflect intact function and regulation of the THS during and/or after completion of development (*Xenopus* amphibian metamorphosis, zebrafish, rodent). Application of 3R principles, development of New Approach Methodologies (NAM), and such data-based focused *in vivo* testing for prioritized relevant chemicals will accelerate EDC characterization, increase hazard-predictive power and chemicals safety for environmental and human health.

Genetic regulation of osteoarthritis pathogenesis

Natalie Butterfield[1]
[1]Imperial College London, London, UK

Osteoarthritis causes debilitating pain and disability, resulting in a considerable socioeconomic burden, yet no drugs are available that prevent disease onset or progression. Osteoarthritis is a complex trait, and the currently reported genome-wide associated loci explain only a small proportion of its heritability. We previously developed and validated a rapid-throughput imaging pipeline to detect signs of osteoarthritis in the mouse knee joint. We utilised this pipeline to phenotype mutant mice generated by the International Knockout Mouse Consortium. We identified genes with functional involvement in osteoarthritis pathogenesis, including the homeobox gene *Pitx1* as a potential key regulator of disease progression. Using this pipeline, we were able to functionally characterize human osteoarthritis candidate genes in mouse models. Finally, we utilised this pipeline to phenotype mice with an osteoarthritis-associated polymorphism in the *Dio2* gene and demonstrated a protective role in disease onset, with significant public health implications. This work aims to both accelerate functional gene discovery in osteoarthritis and facilitate drug discovery opportunities for this common, incapacitating chronic disease.

Deficient anterior pituitary with common variable immune deficiency (DAVID syndrome)

Thierry Brue[1]
[1]Conception Hospital Marseille, France

Deficient Anterior pituitary with common Variable Immune Deficiency (DAVID) syndrome results from heterozygous mutations of the nuclear factor kappa-B subunit 2 (*NFKB2*) gene, causing adrenocorticotropic hormone deficiency (ACTHD) and primary hypogammaglobulinemia. Only a few cases of DAVID syndrome have been reported since its first description by our team through the international multicenter GENHYPOPIT network (Quentien MH et al. JCEM 2012). We analyzed 28 cases with ACTH deficiency published from 2012 to 2022 (Mac TT et al. J Neuroendocrinol. 2023). ACTH deficiency was the only hormone deficiency in 79% of patients, but some patients harbored growth hormone (GH) and thyroid stimulating hormone (TSH) deficiencies. The first presenting symptoms were sinus/pulmonary infections (82%, mean age of 3 years) and alopecia (mean age of 4.7 years). ACTH deficiency was the third presenting condition (mean age at diagnosis: 8.6 years). All patients had hypogammaglobulinemia (decreased IgA and IgM levels), and 57% of patients had at least one autoimmune manifestation. Heterozygous mutations at the 3' end of the *NFKB2* gene, coding for the C-terminal domain of the protein, were identified in all cases. While NFKB signaling plays a crucial role in the immune system, its connection to endocrine symptoms is unclear. We established a human disease model to investigate the role of NFKB2 in pituitary development by creating pituitary organoids from CRISPR/Cas9-edited human induced pluripotent stem cells (hiPSCs). Introducing homozygous $TBX19^{K146R/K146R}$ missense pathogenic variant in hiPSC, an allele found in congenital isolated ACTHD, led to a strong reduction of corticotrophs number in pituitary organoids. Then, we characterized the development of organoids harboring $NFKB2^{D865G/D865G}$ mutations found in DAVID patients. $NFKB2^{D865G/D865G}$ mutation acted at different levels of development with mutant organoids displaying changes in the expression of genes involved on pituitary progenitor generation (*HESX1*, *PITX1*, *LHX3*), hypothalamic secreted factors (*BMP4*, *FGF8*, *FGF10*), epithelial-to- mesenchymal transition, lineage precursors development (*TBX19*, *POU1F1*) and corticotrophs terminal differentiation (*PCSK1*, *POMC*), and showed drastic reduction in the number of corticotrophs (Mac TT et al. Elife. 2024). Our results provide strong evidence for the direct role of *NFKB2* mutations in the endocrine phenotype observed in DAVID syndrome patients and demonstrate the role – to be further analyzed - of NFKB2 in pituitary differentiation, especially for the corticotroph lineage.

The genetic spectrum of PA: from monogenic disorders to aldosterone dysregulation in hypertension

Maria-Christina Zennaro[1]
[1]PARCC, INSERM, Université Paris Cité, France

Primary aldosteronism is the most common form of secondary arterial hypertension. Its prevalence increases with the severity of hypertension, reaching up to 25% in patients with treatment resistant hypertension. Due to the difficulty of its diagnosis, only a minority of patients are tested for PA and even less are appropriately treated. Somatic and germline mutations have been identified in a majority of aldosterone producing adenoma and in familial forms of primary aldosteronism. In most cases, genetic abnormalities are found in genes coding for ion channels (*KCNJ5*, *CACNA1D*, *CACNA1H*, *CLCN2*, *SLC30A1*, *MCOLN3*) or pumps (*ATP1A1*, *ATP2B3*). They occur as somatic mutations in aldosterone producing adenoma and as germline mutations in familial forms of the disease. Mutations in these genes affect intracellular ion homeostasis and/or cell membrane potential, leading to increased intracellular calcium concentrations and activation of calcium signalling, the main regulator of aldosterone biosynthesis. Double mutations in *CTNNB1* and *GNAQ/GNA11* have been identified in aldosterone producing adenoma presenting in puberty, pregnancy and menopause, while somatic mutations in *CADM1* in APA have revealed novel mechanisms of regulation of aldosterone biosynthesis. Beyond categorically overt PA, recent evidence suggests a continuum of dysregulated aldosterone production which affects a substantial proportion of patients with hypertension. Genome-wide association studies suggest that common genetic variation may underlie dysregulated aldosterone production in the general population, leading to PA in extreme cases. Remarkably, PA susceptibility loci have been associated with hypertension related traits and are in part shared between unilateral and bilateral forms of PA. This represents a paradigm shift in our understanding of PA, suggesting a genetically determined continuum between dysregulated aldosterone production and PA in hypertension.

Precision medicine in diabetes

Ewan Pearson[1]
[1]University of Dundee, Dundee, UK

People are all different, and this is no different when we consider people with diabetes, yet the current approaches to management of diabetes tend to treat everyone the same. The field of precision medicine aims to recognise these differences – whether at the level of their phenotype or at the molecular level. Faced with multiple, and increasing, treatment options for diabetes as well as increasing healthcare costs there is a clear need to target therapy to maximise benefit and reduce harm for every patient with diabetes. This talk will discuss advances in precision medicine and pharmacogenetics in diabetes. I will highlight recent work on how phenotypic variation matters, and how this maps to genetic variation, and will provide an overview of how genetic variants alter glycaemic response to commonly used diabetes drugs and how these inform on disease and drug mechanism. I will finish with an overview of iDiabetes – an intelligent diabetes platform that we will be using to implement precision diabetes care in Tayside in 2024.

The impact of rare gene variants in common diabetes and obesity

Amélie Bonnefond[1]
[1]Inserm/CNRS UMR 1283/8199, Pasteur Institute of Lille, France

The boundary between monogenic and polygenic type 2 diabetes (T2D) or oebsity is more fluid than previously thought. Emerging research has revealed an intermediate oligogenic form of T2D/obesity, which serves as a crucial genetic bridge between these two extremes. In this presentation, I will discuss recent scientific advances supporting the classification of genes involved in oligogenic T2D/obesity. While polygenic T2D/obesity research has significantly advanced our understanding of genetic susceptibility, it has faced limitations in pinpointing direct causal relationships between genetic signals and the molecular mechanisms driving the disease. In contrast, studies on oligogenic T2D/obesity have provided clearer causal links between specific genes and disease risk, uncovering novel therapeutic targets. By recognizing oligogenic T2D/obesity as a distinct genetic entity, we open new avenues for research and precision medicine, moving beyond broad genetic risk scores toward targeted therapeutic interventions.

Central regulation of body weight

Serge Luquet[1]
[1]Université Paris Cité, CNRS, Unite′ de Biologie Fonctionnelle et Adaptative, Paris, France

Brain lipid sensing and adaptive response to modern food environment: a culprit in obesogenic environment? While the over-consumption of energy-dense foods is now clearly identified as one of the main causes of obesity, there is a large body of evidence supporting that the development of obesity and related disorders is also the result of an interaction between specific genetic polymorphisms and the modern food environment. High circulating triglyceride (TG) and reward-dysfunction re common hallmark of obesity and obesogenic environment. In the reward dopaminergic circuit, neurons specifically express the lipoprotein lipase (LPL), an enzyme able to hydrolyze TG, suggesting that circulating TG might modulate the activity of dopaminergic and dopaminoceptive neurons. W have discovered that circulating TG act directly onto DA-D2 (DR2) receptors expressing neurons modulating the reinforcing and motivational values of feeding. In humans, we discovered that the neural responses to food cues show a significant correlation between postprandial increases in TG and the presence of Drd2/Taq1A genetic polymorphism. TaqIA is located in the gene that codes for the Ankyrin repeat and kinase domain containing 1 kinase (ANKK1) near the dopamine D2 dopamine receptor (DR2) gene. It affects 30 to 80% of the population and its homozygous expression of the A1 allele correlates with a 30 to 40% reduction of striatal DR2, a typical feature of addiction, over-eating and other psychiatric pathologies. Using genetic approaches, we revealed that Ankk1 loss-of-function in dorsal and ventral striatum leads to alteration in learning, impulsive, and flexible behaviors resembling the endophenotypes described in A1 carriers. We also observed an unsuspected role of ANKK1 in striatal DR2-expressing neurons in the regulation of energy homeostasis and documented differential nutrient partitioning in humans with versus without the A1 allele. Altogether, our data indicates that genetic variant of TaqIA greatly influence how the reward system response to modern food environment and particularly nutritional lipids to control behavior and metabolism.

Pharmacological treatment of obesity in adults and its impact on comorbidities

Rodrigo O. Moreira[1]
[1]Instituto Estadual de Diabetes e Endocrinologia, Brazil

Pharmacological treatment of obesity is passing through many changes in the last decades; different agents have been approved, and newer options are leaning towards higher efficacy and a more favourable safety profile; however, medications approved for a longer time are still available and useful for many patients. This presentation will focus on the 2024 Update Position Statement of Specialists from the Brazilian Association for the Study of Obesity and Metabolic Syndrome (Abeso) and the Brazilian Society of Endocrinology and Metabolism (SBEM), with the aim of reviewing all the approved medications for the management of obesity in Brazil (sibutramine, orlistat, liraglutide, semaglutide and bupropion/ naltrexone fixed dose), with the addition of tirzepatide. The presentation will focus on efficacy, safety profile and the impact of drugs on different comorbidities.

Epigenetic memory of fat cells: the role in weight regain

Ferdinand von Meyenn[1]
[1]Eth Zürich, Schwerzenbach, Switzerland

Reducing body weight to improve metabolic health and other comorbidities is a primary goal in treating obesity. However, maintaining weight loss is a considerable challenge, especially as the body is believed to retain an obesogenic memory via biological imprinting of prior obese states that contributes to the defence of body weight. Yet, overcoming this hurdle to long-term effective treatment is difficult because the molecular mechanisms underpinning this phenomenon remain largely unknown. Here, by using single-nuclei RNA-sequencing, we show that both human and mouse visceral adipose tissue retain a cellular transcriptional memory after appreciable weight loss. Furthermore, we observed that the mouse adipocyte epigenome continues to bear obesity-induced alterations, negatively affecting adipocyte function. In mice adipocytes carrying this obesogenic epigenetic memory respond differently to nutritional stimuli, resulting in accelerated rebound weight gain. We find that the epigenetic memory can explain future transcriptional deregulation in response to further high-fat diet feeding. Together, our data suggests the existence of an obesogenic memory in adipocytes, and likely other cells, largely based on stable epigenetic changes. These changes appear to prime cells to respond in a pathological manner to an obesogenic environment and may contribute to the problematic "yo-yo" effect on body weight observed with dieting. Targeting these changes could potentially improve long-term weight management and health outcomes

Metformin is not effective and safe during pregnancy in women with PCOS

Marianne Andersen[1]
[1]Odense University Hospital, Denmark

Metformin therapy induces weight loss and improves insulin resistance in women with PCOS. In pregnancy, gestational diabetes mellitus (GDM) is more prevalent in women with PCOS and overweight compared to women without PCOS. Disappointingly, GDM incidence was similar in women with PCOS treated with metformin or placebo, initiated late in 1st trimester. Furthermore, no significant longterm beneficial effect was seen in metabolic health of women treated with metformin versus placebo. Pregnancy is a window of sensitivity in offspring, and metformin may pose a risk, metformin passes placenta and maternal metformin intake results in therapeutic metformin concentrations in umbilical cord blood, hence metformin exposure of offspring is quite high. However, metformin therapy had potentially beneficial, lowering effect on maternal testosterone, in women with PCOS carrying a boy. Testosterone is elevated during healthy pregnancy, but women with PCOS have significantly higher testosterone levels than women without PCOS. Moreover, boys have been reported more susceptible to maternal testosterone regarding risk of neurodevelopmental disorders, autism spectrum disorder, but there is no data on maternal metformin treatment and autism spectrum disorder in PCOS. However, available data regarding metformin and neurodevelopment are not fully reassuring, as metformin therapy in pregnancy may be linked to borderline reduced cognitive function in children. Overall, metformin therapy cannot be recommended for pregnant women with PCOS due to lack of effect and offspring safety concerns, supporting previous guidelines.

Breaking down signalling in hypogonadotropic hypogonadism

Anna Cariboni[1]
[1]University of Milan, Italy

Human reproduction is regulated by a small number of hypothalamic neurons secreting the neurohormone GnRH. During development, GnRH neurons migrate from the nasal placode to the hypothalamus by following the terminal nerve to position into the medial preoptic area of the hypothalamus. Once there, GnRH neurons project to the median eminence where the decapeptide is released and transported to the pituitary for the production of gonadotropins, which in turn regulate the production of gonadal sex steroids. Defects in the development or funciton of GnRH neurons lead to hypogonadotropic hypogonadism (HH), a genetic class of disorders due to GnRH deficiency. The genetics of HH is complex and not fully understood with 50% of the cases still unexplained. During the seminar, I will illustrate how Semaphorins, a class of molecules that play key roles during embryonic development and cancer progression, play distinct but essential roles for the correct functioning of the GnRH neuronal system. During the seminar I will also explain how dysfunctional semaphorin signalling can be causing related genetic forms of infertility.

Senescence in peadiatric pituitary tumours

Juan Pedro Martínez-Barbera[1]
[1]GOS UCL Institute of Child Health, UK

Background
Senescence is a cellular process that is normally associated with ageing. In fact, senescent cells are rare in the tissues of children and young adults. However, our research has shown that adamantinomatous craniopharyngioma (ACP), a clinically aggressive paediatric pituitary tumour, contain cells that express the hallmarks of cellular senescence and senescence associated secretory phenotype (SASP). Moreover, we have hypothesised that these senescent cells, through their SASP, promote tumourigenesis in both mouse and human ACP. To test this hypothesis, we have analysed the effects of the ablation of senescent cells and modulation of their SASP using genetic ACP mouse models and pharmacological approaches.
Methods
Genetic murine ACP models that mimic human ACP (*Hesx1*$^{Cre/+}$; *Ctnnb1*$^{loxex3/+}$ and the inducible adult *Sox2*$^{CreERT2/+}$; *Ctnnb1*$^{loxex3/+}$ models) were used. ACP models were combined with a novel *p21-stop-FDR* mouse model, which expresses a fusion protein of diphtheria toxin receptor (DTR) with a fluorescent mCherry reporter from the *Cdkn1a* (p21) locus. This mouse model can report and ablate p21-expressing cells, including the senescent cluster cells in the ACP models. The ACP models were also combined with a new *R26-stop-mBRF1* model, which allows attenuation of the SASP by degrading the mRNAs of many inflammatory SASP factors. In-vivo survival studies, ex vivo culture and immunohistochemical characterizations were carried out.
Results
Ablation of senescent cluster cells or attenuation of the SASP using genetic mouse models, leads to asignificant reduction in ACP tumour burden and increased mouse survival. In addition to inhibitors of anti-apoptotic proteins, we show that a new senolytic compound targeting the ER-Golgi protein transport machinery can also ablate senescent cluster cells in ACP mouse models ex-vivo.
Conclusion
Our results demonstrate a critical role of senescent cells in ACP tumourigenesis and identify these cells as potential targets for senotherapies.

Beta is better: current progress in preserving and restoring beta cell function

Lorenzo Piemonti[1]
[1]IRCCS Ospedale San Raffaele, Italy

Preserving and restoring beta cell function is a key objective in efforts to modify the progression of type 1 diabetes (T1D). This *Meet the Expert* session will feature a leading expert who will discuss the latest advances in beta cell preservation, regeneration, and replacement therapies. Given the autoimmune nature of T1D, strategies aimed at protecting residual beta cells from immune attack remain crucial. Additionally, regenerative approaches seek to enhance beta cell survival and proliferation through small molecules, gene editing, and reprogramming strategies. Recent progress in stem cell-derived beta-like cells and islet transplantation offers potential solutions for restoring insulin production. Advances in encapsulation technologies and immune evasion strategies aim to improve the long-term survival and function of transplanted cells. Despite these promising developments, challenges remain, including immune rejection, the need for lifelong immunosuppression, and the difficulty of achieving full functional integration of beta cells. In this session, the expert will provide insights into current research, clinical applications, and the future of beta cell-directed therapies in T1D. Attendees will have the opportunity to engage in discussions on the most promising approaches and ongoing clinical trials, as well as the challenges that must be addressed to achieve durable beta cell function and a potential cure for T1D.

Fertility matters: exploring the impact of lipodystrophy

Rebecca Brown[1]
[1]NIDDK, NIH, USA

Lipodystrophy syndromes are rare diseases characterized by deficiency of subcutaneous adipose tissue. This may affect the entire body (generalized lipodystrophy) or large portions of the body (partial lipodystrophy). Decreased body fat leads to both low levels of the adipokine leptin, and severe insulin resistance due to ectopic lipid storage. Reproductive consequences of lipodystrophy stem from two distinct mechanisms. In patients with severe leptin deficiency (usually generalized lipodystrophy), low leptin leads to an energy conservation state, resulting in partial hypogonadotropic hypogonadism. In patients with both generalized and partial forms of lipodystrophy, insulin resistance leads to hyperinsulinemia as a compensatory response. High insulin acts on the ovaries to create a phenotype comparable to polycystic ovary syndrome (PCOS), with ovarian enlargement, hyperandrogenism, and anovulatory cycles. Hyperinsulinemia also may lead to excess production of 11-oxygenated androgens by the adrenal glands by upregulating *CYP11B1*. As a consequence of both hypogonadotropic hypogonadism and PCOS, fertility is greatly diminished in women with generalized lipodystrophy and is moderately reduced in women with partial lipodystrophy. Leptin replacement ameliorates both hypogonadotropic hypogonadism and insulin resistance with consequent hyperandrogenism and restores fertility in many women with generalized lipodystrophy. However, pregnancies in women with lipodystrophy have high complication rates, including miscarriage in 34-48%, diabetes (either preexisting or gestational) in over 50%, and preeclampsia in 39-45%. For patients with lipodystrophy in need of contraception or hormone replacement, use of oral estrogens, as in combination oral contraceptive pills, is contraindicated due to the risk of severe hypertriglyceridemia that may precipitate acute pancreatitis. Instead, progestin only or non-hormonal contraceptives are preferred, and transdermal estrogen should be used if estrogen replacement is needed.

Management of ACC during the ages

Darko Kastelan[1]
[1]University Hospital Centre Zagreb, Croatia

Adrenocortical carcinoma (ACC) is a rare but highly aggressive endocrine tumor with a relatively poor prognosis, which depends on disease stage, resection status, and tumor grading. Surgery remains the cornerstone of treatment and the only realistic chance for cure. However, even after complete resection, a significant proportion of patients remain at high risk for recurrence. Beyond surgery, treatment options are limited, with scientific evidence often based on small retrospective studies, leading to considerable uncertainty in clinical decision-making. This lack of robust data is even more pronounced in pediatric patients, whose management is largely extrapolated from studies in adults. Recent guidelines have provided recommendations for the clinical management of ACC, yet the supporting evidence for many of these recommendations remains weak. From a clinical perspective, some critical questions need to be addressed, such as identifying patients who will benefit most from different adjuvant therapies, as well as refining the management of patients with recurrent disease, where treatment strategies remain uncertain. Additionally, managing patients with advanced ACC presents a significant challenge, as responses to the best available systemic therapy, EDP plus mitotane, remain limited. This presentation will explore the current state of ACC management, highlight ongoing challenges, and discuss potential strategies to improve outcomes.

Hot-Topic Osteoanabolic therapies: when to choose what

Athanasios Anastasilakis[1]
[1]424 General Military Hospital, Greece

Osteoanabolics, i.e., agents that stimulate the osteoblast to form new bone, are the most efficacious among antiosteoporotic regimens and are considered as the spearhead of severe osteoporosis management. Currently available osteoanabolic agents can be divided into molecules that bind and stimulate the receptor type 1 of parathyroid hormone (PTH1R), teriparatide (TPTD) and abaloparatide (ABL), and monoclonal antibodies against sclerostin, with romosozumab (ROMO) to be the only representative of the class in clinical practice. Osteoanabolic agents increase BMD and bone strength while being more effective than antiresorptives in reducing fracture risk in postmenopausal women. Osteoanabolic agents typically serve as a second line therapy in case of antiresorptives' failure. However, they could (and should) also be used as a first line treatment in patients at high fracture risk, given that they perform better when given in treatment-naïve patients and that in patients at very high/imminent fracture risk, a rapid fracture risk reduction is critical to prevent new fractures. Among osteoanabolics, ROMO was more effective than TPTD in increasing BMD in treatment-naïve women and in women previously treated with bisphosphonates but there is no direct comparison of the antifracture benefits of the two agents. In contrast, in a head-to-head comparative study ABL achieved greater BMD increases at the hip than TPTD and led to a greater reduction of major osteoporotic fractures but with no differences in vertebral or non-vertebral fracture risk. There is no direct comparison of ROMO with ABL at present. With PTH1R agonists, stimulation of bone formation is maintained for as long as their administration is continued, the increase of bone formation with ROMO seems to be transient, lasting only for the first few months of treatment, with suppressed bone formation for the remainder of therapy. ROMO might have an advantage over PTH1R agonists in patients with renal insufficiency as well as in patients with hypercalcemia, hypercalciuria or nephrolithiasis, and hyperuricemia. On the opposite, PTH1R agonists may have an advantage over ROMO in low-bone turnover states and in cases of rare complications associated with prolonged bone turnover suppression, such as the osteonecrosis of the jaw and the atypical fractures. ROMO is contraindicated in patients with a history of myocardial infraction or stroke and should be used with caution in patients with cardiovascular risk factors. Among osteoanabolic agents only TPTD is approved for the treatment of male osteoporosis and glucocorticoid-induced osteoporosis. Finally, convenience of administration, reimbursement by national health systems and length of clinical experience may influence the decision of which osteoanabolic agent to use.

Management of endocrinopathies induced by cancer therapy

Anna Koumarianou[1]
[1]4th Dept of Internal Medicine, Attikon University Hospital, Greece

Cancer therapies, including chemotherapy, radiation, immune checkpoint inhibitors (ICIs), and targeted agents, can lead to significant endocrine dysfunctions, impacting patient outcomes and quality of life. Endocrinopathies such as hypothyroidism, adrenal insufficiency, diabetes, hypophysitis, and hypogonadism are frequently observed, necessitating early detection and comprehensive management. Thyroid dysfunction, commonly triggered by radiation and ICIs, requires regular thyroid function monitoring and appropriate levothyroxine replacement. Immune-related hypophysitis, often associated with CTLA-4 inhibitors, necessitates hormone replacement, including glucocorticoids, to prevent adrenal crisis. Similarly, ICI-induced adrenalitis warrants prompt glucocorticoid therapy, with stress dosing during acute illness. Cancer therapy-related diabetes, particularly from ICIs and glucocorticoid use, may require insulin therapy and close glucose monitoring. Hypogonadism, resulting from chemotherapy, radiation, or androgen deprivation therapy, should be assessed with hormonal evaluations and managed with hormone replacement where appropriate. Additionally, osteoporosis is a concern in patients receiving androgen deprivation or aromatase inhibitors, necessitating bone mineral density monitoring and interventions such as bisphosphonates or denosumab. Effective management of therapy-induced endocrinopathies involves a multidisciplinary approach integrating oncologists, endocrinologists, and primary care providers. Regular endocrine assessments, individualized hormone replacement, and patient education play pivotal roles in optimizing long-term outcomes. As cancer survival rates improve, proactive identification and management of these endocrine complications are essential to enhancing patient well-being and treatment success.

Management of the child with ambiguous genitalia

Christa Flück[1]
[1]Inselspital University Children's Hospital Bern, Switzerland

Managing ambiguous genitalia in newborns requires a multidisciplinary approach, involving pediatric endocrinologists, geneticists, neonatologists, urologists, and psychologists. A DSD team provides individualized psychosocial support to families. A structured evaluation is crucial to identify the underlying cause and assess any associated health risks. Initial workup includes clinical, biochemical, and genetic investigations to guide diagnosis. The clinical evaluation includes a thorough history (maternal drug use, family history of disorders/differences of sexual development (DSD), unexplained neonatal deaths) and physical examination (including anogenital measurements). Urgent investigations should rule out life-threatening adrenal insufficiency in cases of suspected congenital adrenal hyperplasia (CAH), requiring immediate glucocorticoid (GC) and mineralocorticoid (MC) therapy. Biochemical tests include measurement of sex steroids, adrenal hormones, gonadotropins, and anti-Müllerian hormone (AMH) to assess gonadal function. Genetic testing, including karyotyping and next-generation sequencing panels, helps determine the molecular diagnosis, guiding management decisions. Treatment of children with adrenal insufficiency requires the immediate initiation of GC and MC replacement. Hormone therapy may also be required for androgen excess or deficiency at follow-up. Sex assignment involves shared decision-making with parents and a DSD team, considering long-term outcomes. Psychological support is essential. Surgical intervention remains controversial and is increasingly delayed to preserve bodily autonomy, with early surgery discouraged unless medically necessary. Long-term care consists of lifelong follow-up to ensure hormonal balance, fertility potential, and psychosocial well-being. Support from DSD network teams helps families navigate challenges, fostering acceptance and inclusivity. A comprehensive, ethical, and individualized approach ensures the best outcomes for children with ambiguous genitalia. In this MTE, the management of two teaching cases, one manifesting at birth and one presenting in prepuberty, will be discussed.

Diagnosing and managing AVP excess

Ewout Hoorn[1]
[1]Erasmus MC, Rotterdam, Netherlands

Hyponatremia often presents significant challenges in both its differential diagnosis and management. This presentation will address key concepts and recent developments to assist clinicians in overcoming these challenges. Pathophysiologically, hyponatremia is marked by an excess of arginine vasopressin (AVP), which can be "appropriate" in response to hypovolemia or "inappropriate" due to underlying conditions, medications, or other triggers. The most common cause of inappropriate AVP secretion is the syndrome of inappropriate antidiuresis (SIAD). This presentation will offer a practical diagnostic approach to hyponatremia, aiming to differentiate its various underlying causes, including SIAD. In terms of treatment, the key distinction is whether hyponatremia is acute and symptomatic—requiring immediate intervention with hypertonic saline—or chronic, where overcorrection must be avoided to prevent osmotic demyelination. The management of chronic hyponatremia should focus on the underlying cause while also addressing the water excess. Fluid restriction remains the first-line treatment for SIAD, although additional therapies are often needed to promote free water excretion. Recent years have seen the emergence of new treatment options, such as oral urea, high-protein diets, SGLT2 inhibitors, and tolvaptan. This presentation will review the scientific evidence supporting these developments and provide practical guidance for clinicians on how to implement them.

Hormone treatment in transgender teenagers

Sabine Hannema[1]
[1]Amsterdam UMC, Amsterdam, Netherlands

An increasing number of transgender adolescents seek hormone treatment because they wish to align their body with their gender identity in order to reduce gender dysphoria. Medical care for adolescents should be offered by a multidisciplinary team, including mental health professionals as well as medical specialists. First a psychological and clinical assessment is performed, followed by counselling about medical treatment options and alternatives and their benefits and risks. The possible impact of treatment on fertility and options for fertility preservation are important topics in counselling. Several treatment options exist to suppress sex hormones and to induce sex characteristics consistent with gender identity. Care should be tailored to the specific needs of the adolescent. Current guidelines on hormone treatment and treatment monitoring will be reviewed. The transition from paediatric to adult care is an important phase to ensure adolescents receive appropriate long-term follow-up. This phase also requires attention to topics such as education, employment, relationships and sexual functioning. Transgender care, especially for adolescents, has become the subject of political and societal debate. Reviews have concluded there is a lack of high-quality evidence in this area. An increasing body of outcome data of hormonal treatment for transgender adolescents is available from observational studies, including data on mental health, development of secondary sex characteristics, growth and adult height, body composition, bone mineral accrual, and treatment continuation/discontinuation. However, long-term data are still limited. Therefore care is ideally combined with collection of data for research purposes.

Management of Adrenal incidentaloma

John Newell-Price[1]
[1]The Medical School, University of Sheffield, UK

Definition
Adrenal incidentalomas are masses found on imaging performed for reasons other than investigating adrenal pathology.
Prevalence
Rare in childhood Prevalence increases with age - around 10% of the population aged >70y have adrenal incidentaloma.
Aetiology
Most are benign adrenocortical adenoma, but there is a wide differential for unilateral and bilateral lesions. In children any adrenal mass is likely to be clinically relevant and require investigation and intervention.
Investigation:has two main aims:
1. *Is the lesion(s) benign?* Imaging with non-contrast CT is the most reliable means to determine is a lesion is a benign adrenocortical adenoma, but if indeterminate an interval follow up scan may be needed. Urine steroid metabolomics holds promise to assist in the discrimination between benign and malignant disease. Clearly malignant lesions need urgent investigation and management. Biopsy is infrequently needed
2. *Is the lesion(s) hormonally functioning?* Examination of the patient may reveal features of hormonal hypersecretion. For unilateral adrenocortical adenoma the 1mg overnight dexamethasone suppression test is used to establish if there is Mild Autonomous Cortisol Secretion (MACS) and if the patient is hypertensive additionally a plasma renin to aldosterone ratio assessed. For all other masses assessment of these parameters and plasma or urinary metanephrines is also needed. For bilateral lesions consistent with hyperplasia, screening with 17 hydroxyprogesterone is also needed. If bilateral metastases or infiltrative disease is suspected urgent assessment of cortisol reserve is needed.
Management
Unilateral benign lesions causing clinically apparent hormonal excess usually require resection by minimally invasive surgery by an expert surgeon. Surgery for MACS may be indicated where basal ACTH is suppressed there are clear co-morbidities that can be driven by cortisol – e.g. hypertension, diabetes mellitus. Benefit is likely to be greater in younger patients. Malignant and indeterminant disease need careful multi-disciplinary discussion to discuss surgical approach and adjuvant therapies.

Type 1 diabetes in athletes

Esben Thyssen Vestergaard[1]
[1]Aarhus University Hospital, Denmark

Introduction
Exercising benefits individuals with type 1 diabetes (T1D) by improving overall health, glycemic control, and body composition. However, managing blood glucose fluctuations during and after exercising remains a significant challenge, preventing many individuals with T1D from meeting the recommended physical activity level of 30 minutes per day. In particular, the fear of hypoglycemia leads to reduced physical activity.
Aim
The objectives of this session are to equip the audience with essential knowledge on exercise physiology in athletes with T1D and provide the participants with the latest recommendations for optimizing blood glucose management during exercise. Additionally, I will share insights into our clinic supporting athletes with T1D in training and competition, helping them perform at their highest potential.
Methods
To address these challenges, the *Clinic for Athletes with Type 1 Diabetes* was established in 2019 at Steno Diabetes Center Aarhus, Denmark. Our clinic's goal is to power athletes with T1D compete on par with their peers without diabetes by refining their diabetes management strategies for training and competition. In doing so, we also support them optimize their athletic performance.
Results
Our "Plan, Do, Study, Act" (PDSA) change model will be presented. Moreover, baseline and follow-up data will be reported on diabetes-related metrics from our athletes, including time-in-range and HbA1c, as well as patient-reported outcomes (PROs) such as WHO-5, SF-12, PAID, patient involvement in treatment, and the HFS-II Short Form (behavior and worry).
Conclusion
Our preliminary findings indicate that athletes in our clinical program reported a reduction in diabetes-related distress and fear of hypoglycemia, while we observed improvements in glycemic control. Furthermore, this talk outlines a method for implementing clinical guidelines for both recreational and elite athletes with T1D.

Pre-Congress Courses

PCC1.1

Introduction: Case Mentimeter

Jens Pedersen[1] & Lena Bjergved Sigurd[1]
[1]Denmark

This pre-congress thyroid ultrasound course is designed for trained endocrinologists seeking to refine their skills in thyroid imaging and intervention. The course will cover how to perform a thyroid ultrasound, how to assess and grade thyroid nodules, and how to conduct a fine needle aspiration biopsy (FNAB). Additionally, the course will introduce minimally invasive techniques for managing thyroid pathology. The program will include case presentations, expert-led lectures, and a hands-on training session to ensure practical skill development.

Sonographic assessment of the thyroid gland, diffuse thyroid illness including autoimmune disease

Steen J. Bonnema[1]
[1]Department of Endocrinology, Odense University Hospital, Denmark

Thyroid ultrasound is a highly valuable tool for assessment of the thyroid volume, texture, echogenicity, and nodule evaluation and risk stratification. The method is preferably performed by the decision-making clinician. Due to the superficial location of the thyroid gland in the neck, the resolution of the ultrasound images is very high, and even small lesions in the thyroid can be detected. If a large part of the thyroid extends into the thorax, as can be seen in older individuals, this hinders a complete thyroid ultrasound examination. Thyroid autoimmunity, whether reflecting presence of autoimmune thyroiditis or Graves' disease, appears hypoechogenic on ultrasound. The degree of hypoechogenicity correlates to some extent with plasma levels of thyroid autoantibodies. In Graves' disease, the chance of remission can be predicted based on the ultrasound appearance, i.e., marginal/normal echogenicity, pseudonodularity, marked hypoechogenicity. In addition, assessment of the thyroid volume is highly valuable in assessing the chance of remission in Graves' disease, in parallel with the thyroid echogenicity. The thyroid volume can be sonographically calculated from the ellipsoid formula, and with a reasonably precision unless the gland is grossly disconfigured due to thyroid nodularity. Thyroid planimetry is even more precise for volume estimation, but this method is rarely employed. Thyroid ultrasound can also be used to diagnose subacute thyroiditis, in which case the gland is tender, and ultrasound will show patchy avascular areas of marked hypoechogenicity in one or both thyroid lobes. Thyroid ultrasound, using the Doppler signal, may help differentiating between amiodarone-induced type 1 and type 2 thyrotoxicosis. the latter being an inflammatory condition.

Welcome

Paolo Giacobini[1] & Elisabet Stener-Victorin[2]
[1]INSERM U1172, France; [2]Karolinska Institutet, Sweden

Polycystic ovary syndrome (PCOS) is the most common reproductive and cardiometabolic disorder in women. It is a complex disorder involving the reproductive and endocrine systems, marked by a dysregulation in the hypothalamus-pituitary-gonadal (HPG) axis, affecting communication between the brain and reproductive organs. Additionally, the gut-brain axis contributes to the metabolic disturbances in PCOS, with altered gut microbiota interacting with neuroendocrine pathways to worsen both metabolic and reproductive symptoms. This altered brain-body communication also influences the central nervous system, impacting cognitive function and mood. The 2025 AE-PCOS Update Meeting will explore these interconnected topics to advance our understanding of PCOS.

Session 2: PCOS and the HPG axis: Alterations of the hypothalamo pituitary-gonadal axis in animal models of PCOS

Aleisha Moore[1]
[1]Kent State University, Kent, OH, USA

Polycystic ovary syndrome (PCOS) is a distressing condition and a prevalent cause of anovulatory infertility in individuals of reproductive age. Although PCOS is characterized by ovary dysfunction, growing evidence suggests that the brain plays a crucial role in the development and pathophysiology of the syndrome. In PCOS patients, there is an impairment in gonadal steroid hormone negative feedback to the hypothalamus, which contains the gonadotropin-releasing hormone (GnRH) neuronal network that governs fertility. This leads to an increase in GnRH and pituitary luteinizing hormone (LH) pulsatile release, which, in turn, acts on the ovary to induce ovarian dysfunction and hyperandrogenism. Androgen excess may then act back on the brain to further promote GnRH secretion, resulting in a vicious cycle that continually promotes androgen secretion and reproductive symptoms. The location and mechanistic changes that underlie impaired steroid hormone feedback remain unknown due to the challenges of studying the human hypothalamus at the cellular level. However, in recent years, animal models generated using exposure to excess androgens during critical developmental periods have significantly advanced our understanding of the brain's role in PCOS. In this talk, I will discuss recent results that identify key neural circuits involved in controlling GnRH release, as well as evidence showing that disruptions in these circuits play a crucial role in the pathogenesis of PCOS symptoms in animal models. In particular, this talk will emphasize new evidence regarding the role of cells in the arcuate nucleus of the hypothalamus that express the neuropeptide kisspeptin, which constitutes the GnRH pulse generator, in the syndrome's pathogenesis. Overall, this talk will highlight that identifying and understanding central defects will be vital for establishing effective treatments for PCOS.

PCC2.11

Session 3: PCOS and the Brain: PCOS and the Brain

Aled Rees[1]
[1]University of Cardiff, UK

Polycystic Ovary Syndrome (PCOS) is a multi-system disorder characterized by cutaneous, reproductive and metabolic sequelae with the potential to affect brain structure and function. In a large retrospective study of women with PCOS in the UK, we confirmed a significantly increased prevalence and incidence of depression and anxiety, in addition to bipolar disorder and eating disorder compared with matched controls. Linkage analysis found an increased risk of a recorded diagnosis of autism spectrum disorder and attention-deficit hyperactivity disorder in children born to mothers with PCOS, raising the possibility that increased exposure to androgens *in utero* might affect neonatal brain development. Cognitive function may also be affected: compared with age- and BMI-matched controls, subjects with PCOS displayed subtle decrements across a broad range of cognitive tests, despite similar education and premorbid intelligence. Advances in MRI technology allow for interrogation of the potential underlying mechanisms in unprecedented detail: in a diffusion MRI study, PCOS was associated with a widespread reduction in axial diffusivity and increased tissue volume fraction in the corpus callosum. Alterations in brain structure and function may also contribute to long-term health risks beyond mental health and cognition. Epidemiological studies have confirmed an increased risk of cardio- and cerebrovascular disease among people living with PCOS, with hypertension representing an important modifiable target. Using blood oxygen level-dependent functional MRI, we found evidence of enhanced sympathoexcitation in women with PCOS, accompanied by increased brain activation in the right orbitofrontal cortex. Studies of neurovascular coupling, cerebrovascular reactivity, dynamic cerebral autoregulation, cerebral blood flow and metabolic rate of oxygen consumption in the resting state were not different between subjects with PCOS and age/BMI-matched controls. However, an exaggerated rise in blood pressure was unmasked in PCOS subjects in response to an acute exercise stimulus.

Session 4: periphery-brain communication in pcos and metabolic co morbidities: autonomic brain-liver communication in metabolic diseases

Alexandre Caron[1]
[1]Université Laval, Canada

The brain influences liver metabolism through many neuroendocrine and autonomic mechanisms that have evolved to protect the organism against starvation and hypoglycemia by maintaining energy and glucose homeostasis. Unfortunately, these sophisticated homeostatic processes can be impaired in metabolic diseases such as obesity, type 2 diabetes and metabolic associated steatotic liver disease (MASLD). However, the precise mechanisms by which the brain regulates hepatic metabolism, how autonomic dysfunctions can alter brain-liver communication, and whether alterations in the autonomic outflow to the liver contribute to disease progression, remain to be defined. Based on recent tissue clearing studies showing that neural innervations within the liver are of sympathetic nature, we hypothesized that adrenergic receptors expressed by hepatocytes directly mediate the autonomic control of liver metabolism. Our data indicate that liver adrenoceptors play a protective role in the progression of metabolic diseases. We found sex-dependent mechanisms by which the sympathetic nervous system regulates energy and glucose homeostasis through the liver. We believe that a better understanding of the receptors and pathways involved in the sympathetic outflow of the liver will help.

Diabetes from cardle to grave - Growing up with diabetes

Anna Lindholm Olinder[1]
[1]Karolinska Institute, Department of Clinical Sciences and Education, Södersjukhuset, Sweden

The incident of type 1 diabetes is increasing, especially among young children. There is no cure yet, treatment with insulin together with careful control of blood glucose is necessary. International guidelines recommend that youths with diabetes shall be offered the most advanced insulin delivery technology that is available, accessible and acceptable for them. At the onset of diabetes, most children are admitted to a paediatric in-patient-clinic for about a week. Insulin treatment and intensive training in self-management start there. After discharge from the ward, self-management takes place at home, with continuous support and education from the diabetes team at the clinic. Despite the development of technologically advanced products, self-management for diabetes is demanding. There are different challenges for different ages. Young children have a total dependence on parents and caregivers for self-management. Injections, infusion set and sensor insertions, and BG checks seen as pain inflicted by caregivers. Parents may feel increased stress, diminished bonding, and depressive feelings. Education for nursery and kindergarten staff is essential. As the child gets older and develop an independence a progressive stepwise transfer of responsibilities is actual. The goal is to be able to manage self-management independently before transfer to an adult clinic.

A nurse-led transition clinic: Good example and nurse roles in transitional care

Jane N.T. Sattoe[1], Jobert Sturm[1,2], Rhoda Akilapa[2] & Anne Loes van Staa[1]
[1]Rotterdam University of Applied Sciences, Research Centre Innovations in Care, Rotterdam, The Netherlands; [2]Erasmus Medical Centre - Sophia Children's Hospital, Department of Pediatric Gastroenterology

Background
Transition Clinics (TCs) are specialized, multidisciplinary healthcare settings that support young people with chronic conditions as they move from pediatric to adult care. These clinics are considered essential in ensuring continuity of care, fostering self-management skills, and preventing adverse outcomes such as medication non-adherence and loss to follow-up. This study aimed to identify best practices in nurse-led TCs and determine key nurse roles contributing to high-quality transitional care.
Methods
This study used a mixed-methods approach consisting of semi-structured interviews with nurse specialists in six transition clinics and surveys among young adults. . Additionally, an integrative review analyzed the roles and responsibilities of nurses and nurse practitioners, highlighting their impact in the transition process.
Results
Nurse-led TCs incorporated individualized transition plans (ITPs), transition coordinators (often nurses/nurse practitioners), and warm handovers to create a structured and seamless transfer of care. These elements contributed to high levels of satisfaction among young adults and increased their trust in healthcare providers. Nurses played a multifaceted role in the transition process, offering personalized guidance and self-management support. The review identified eight critical nurse roles in transitional care: service coordinator, innovator, researcher, advocate, coach, educator, clinician, and liaison to the community. Despite the effectiveness of nurse-led TCs, challenges persist. Resource limitations, gaps in interdisciplinary collaboration, and barriers to fully integrating transitional care into routine practice remain significant concerns. Addressing these challenges requires greater institutional support, encouraging nurses to take up advanced roles, youth participation, and system-wide collaboration. This would help to optimize long-term patient outcomes and ensure equitable access to transitional care.
Conclusion
Nurse-led TCs are vital in facilitating smooth transitions, not only by managing medical transitions but also by empowering young adults and supporting families. By fulfilling diverse roles, nurses enhance the effectiveness of transitional care programs. However, addressing financial constraints, engagement difficulties, and collaboration gaps with primary and mental healthcare services is essential for further improvement.

Fertility in Patients with CAH

Ann-Christin Welp[1]
[1]LMU Klinikum München, Germany

Fertility in patients with classic congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency (21-OHD) is lower compared to the general population, although with adequate glucocorticoid replacement treatment, comparable fecundity can be achieved. The causes of reduced fertility differ between men and women. In women with classic CAH elevated androgen and progesterone levels lead to menstrual irregularities, affecting endometrial development and ovulation. In addition, genital surgeries for virilization and urogenital anomalies can impact fertility and sexual function, resulting in fewer heterosexual relationships. Psychosexual issues also contribute to impaired fertility. Spontaneous pregnancies are less frequent, and the time to successful conception is often prolonged. Despite these challenges, with adequate glucocorticoid replacement therapy, women with classic CAH can conceive and fecundity is not impaired. In women with classic CAH achieving pregnancy is more complex than disease management during pregnancy. Successful pregnancy management necessitates a complex, individualized approach to treatment and support. In men with classic CAH, fertility is often affected by hypogonadotrophic hypogonadism and complications like testicular adrenal rest tissue (TART),

which can impair spermatogenesis. However, regular monitoring and optimized glucocorticoid therapy may restore spermatogenesis. Genetic counselling is crucial to understand transmission risks and the implications for prenatal care. To prevent virilization in affected female fetuses prenatal dexamethasone treatment can be used but raises ethical and safety concerns that require careful consideration.

Key learning points

- Patients with CAH due to 21-OHD have reduced fertility compared to the general population.
- With adequate replacement therapy, normal fecundity can be achieved in both female and male patients with CAH.
- Reduced fertility in women with classic CAH is caused by elevated androgen and progesterone levels, psychosexual factors and the consequences of genital surgeries for virilization.
- Women with classic CAH experience a prolonged time to conceive compared to healthy women.
- In men with classic CAH, fertility is impacted by hypogonadotropic hypogonadism and testicular adrenal rest tissue (TART), which impairs spermatogenesis.

How Do I Sessions

H1.1

How do I evaluate and manage arginine vasopressin deficiency and arginine vasopressin resistance?

Mirjam Christ-Crain[1]
[1]University Hospital of Basel, Switzerland

Arginine Vasopressin (AVP) deficiency belongs to the polyuria polydipsia syndrome, which is defined as polyuria of >40-50ml/kg BW per day and accompanying polydipsia. It is crucial to differentiate AVP deficiency from AVP resistance and primary polydipsia since treatment differs and a wrong treatment can have dangerous consequences. For decades, the "gold standard" for differential diagnosis has been the standard water deprivation test. However, this test has several limitations leading to an overall limited diagnostic accuracy. Direct measurement of Vasopressin upon osmotic stimulation was first shown to overcome these limitations, but failed to enter clinical practice mainly due to technical limitations of the AVP assay. New test methods based on stimulated measurement of copeptin, the surrogate marker of AVP, have shown promising results. The hypertonic saline stimulation test is currently the test with the highest diagnostic accuracy, but other test methods have either been tested (e.g. arginine) or are currently under investigation. **This talk will show how AVP deficiency can be diagnosed or excluded at the baseline exam and will highlight different stimulation tests in those patients in which the diagnosis at baseline can not be made.** Treatment of AVP deficiency is usually straight forward and consists of exogenous desmopressin orally or nasally, started at bedtime, and if symptoms persist during the day, a morning dose is added. The most common side effect is hyponatremia, and it is therefore important to inform patients about the risk of hyponatremia following desmopressin treatment and to instruct them about the Desmopressin escape method. Also, **data will be shown highlighting psychological comorbidities in patients with AVP deficiency, and the possibility of an oxytocin deficiency underlying these psychological comorbidities will be discussed**.

How do I diagnose and manage adolescence with PCOS?

Helena Teede[1]
[1]Monash University, Australia

PCOS is common and heterogeneous with reproductive, metabolic, dermatological and psychological features. Presentation is often in adolescence, yet diagnosis delays are common internationally, with patient dissatisfaction with care, inadequate provided information and resources and evidence of long-term health impacts. Gaps in clinician and patient knowledge are demonstrated, as are inconsistencies in care. The Australian Centre for Research Excellence in PCOS, funded to drive research and translation, has partnered with leading international societies including ESE and ESPE among 40 organisations. Together we have updated the International Evidence-based Guideline for Assessment and Management in PCOS and included a focus on the adolescent life stage. The Guideline was developed and updated using world's best practice processes leveraging an international network across six continents and widespread engagement and international partnership to drive awareness, patient self-management, improved, evidence-based practices and better health outcomes in PCOS. Here we will cover updated evidence in adolescents, apply this through a number of case studies on diagnosis and management and explore priority areas for research and care moving forward.

H1.3

How do I manage the adolescent with Congenital Adrenal Hyperplasia

Hedi Claahsen-van der Grinten[1]
[1]Radboud University Medical Centre, Netherlands

Congenital adrenal hyperplasia (CAH) remains a challenging condition to manage during adolescence due to the limitations of current treatments. A major issue is the inability to adequately suppress early morning androgen surges, requiring supraphysiological doses of glucocorticoids (GC) to suppress ACTH. This can lead to both over- and undertreatment throughout the day, particularly in childhood, where the available preparations are suboptimal. Adolescents with CAH are at risk of various complications. These include adrenal crises, salt-wasting crises, mainly due to noncompliance which can be life-threatening. Elevated androgens due to poor hormonal control may result in precocious puberty, pubertal disturbances, delayed menarche, and ultimately, a reduced final adult height. Additionally, gonadal dysfunction and testicular adrenal rest tumors (TART) are frequently described. Furthermore, mental health challenges can significantly impact quality of life. Despite advances in treatment, no curative therapy exists for CAH, and glucocorticoid therapy remains the mainstay of management. However, balancing effective androgen suppression while avoiding GC-related side effects remains difficult. The risk of adrenal crises persists, necessitating careful monitoring and education on stress-dose adjustments. Modified-release glucocorticoids offer a potential strategy to better mimic physiological cortisol rhythms and improve HPA axis suppression, but optimal treatment regimens in adolescence are still under investigation. Future advancements should focus on improving disease control while minimizing long-term complications and enhancing quality of life.

Biochemical profile, age at diagnosis and patient ancestry are associated with the risk for positive genetic testing for PPGL susceptibility genes

Reut Halperin[1,2], Gili Reznick-Levi[3], Ayat Khalaileh[3], Roni Svirsky-Frayden[4], Orit Reish[2,4], Karen Weiss[3,5] & Amit Tirosh[1,2]
[1]Sheba Medical Center, Tel Aviv University, Division of Endocrinology, Diabetes and Metabolism, Ramat Gan, Israel; [2]Tel Aviv University, Tel Aviv, Israel; [3]Rambam Health Care Campus, Genetics, Haifa, Israel; [4]Shamir Medical Center, Genetics, Zerifin, Israel; [5]Technion-Israel Institute of Technology, Medicine, Haifa, Israel

Approximately 30% of patients with pheochromocytoma and paraganglioma (PPGLs) have a genetic predisposition due to a germline pathogenic variant (PV) in a susceptibility gene. We aimed to assess the prevalence of PPGL-related hereditary syndromes based on a multi-center national-level study, and to identify risk factors for hereditary PPGL based on clinical and biochemical data.
Methods
This is a retrospective study of patients with a personal history of PPGL. All patients underwent germline DNA sequencing (whole exome or panel sequencing). Demographic, clinical, biochemical, and genetic data were gathered.
Results
Of a total of 225 patients, 90 were evaluated for personal history of PPGL and 135 for family history. Overall, 76 patients (33.8%) carried a likely\PV in a PPGL-related gene, including 43 of the 135 patients with family history (31.8%); 30 with *SDHB* (three different PVs), eight with *SDHD* (two variants) and five with *VHL* (three variants). We found higher risk for positive genetic testing in patients with family history of PPGL among patients of Arab ancestry: 46 patients (60.5%) from 6 kindreds, carried *SDHB* PV ($n=38$), *VHL* PV ($n=7$) and *SDHC* ($n=1$), compared with 22.4% ($n=17$) among Jewish patients and 17.1% ($n=13$) among patients of Druze ancestry. Ninety patients with personal history of PPGL underwent genetic evaluation (median age at diagnosis 47 [7-73], 35.6% males), of them 29 (33.7%) had a family history of PPGL. Forty-one patients had pheochromocytoma, 45 had paraganglioma, and four had both. Thirty-four patients (37.8%) carried a PPGL susceptibility gene PV, most often in *SHDB* (14 patients, 41.1%), followed by *SDHD* ($n=9$, 25.7%), *VHL* ($n=6$, 17.6%), *NF1* ($n=2$, 5.9%), *SDHC*, *SDHAF2*, and *RET* (one patient each, 2.9%). Age at diagnosis was significantly younger in the PV-carriers vs. non-carriers (31.63 ± 2.71 vs. 50.48 ± 2.41, $P<0.00001$). All 17 carriers with elevated plasma/urine catecholamines had purely elevated normetanephrine (NMN) levels (52.2% vs 10.0% pure normetanephrine secretion in hereditary vs. sporadic PPGL, respectively, $P=0.002$). NMN-only secretion was associated with a younger age at diagnosis vs. other secretion profiles (36.1 ± 3.7 vs. 48.85 ± 3.1 years, $P=0.0006$). Twelve patients (13.3%) had aggressive tumor behavior (recurrence\metastases), with a significantly higher rate of PV compared with patients with non-aggressive disease ($n=8$ [66.7%] vs. $n=10$ [27.0%], respectively, $P=0.01$).
Discussion
Among patients with family history of PPGL, those from Arab ancestry had higher risk for positive testing for hereditary syndrome.

Introduction
Adrenal tumours (ATs) encompass a wide differential diagnosis, necessitating a multi-step process for accurate identification. Liquid biopsy emerges as a promising non-invasive technique for distinguishing malignant from benign cases. Recent studies have highlighted the potential of microRNAs as circulating biomarkers; however, their clinical utility remains underexplored.
Aim
This study aims to validate the diagnostic performance of selected circulating microRNAs, (miR-483-5p, miR-210, miR-335), identified through microRNA profiling studies, as markers of malignancy in a cohort of patients with ATs.
Methods
We collected serum samples from 90 participants, including 75 patients with ATs and 15 controls. The ATs comprised 50 cases of adrenocortical adenomas (ACA) and 25 cases of adrenocortical carcinomas (ACC). In the ACC subgroup, 16 samples were obtained preoperatively or upon detection of recurrence (active ACC group), while the remaining from disease-free patients with long-term follow-up (disease-free ACC group). Quantitative real-time polymerase chain reaction was employed to analyze microRNA expression.
Results
Circulating levels of miR-483-5p and miR-210 were significantly elevated in patients with active ACC compared to both ACAs ($P<0.001$ and $P=0.004$, respectively) and controls ($P=0.002$ and 0.003, respectively). Notably, miR-483-5p serum levels were higher in the group of active compared to disease-free ACC patients ($P=0.01$). MiR-483-5p demonstrated the best diagnostic accuracy for distinguishing active ACC cases from ACAs (AUC=0.869, 95%CI: 0.761–0.978, $P<0.001$), achieving a sensitivity of 81.3% and a specificity of 88%, and from disease-free ACC patients (AUC=0.854, 95%CI: 0.672–1, 230 $P=0.004$), reaching sensitivity of 81.3% and specificity of 89%. In contrast, miR-335 levels were not sufficient to differentiate the groups. A sub-analysis within ACC cases revealed a trend toward higher marker levels in preoperative samples compared to recurrent cases, although the observed differences were not statistically significant.
Conclusion
Our study highlights the potential of circulating miR-483-5p and miR-210 as promising non-invasive biomarkers for distinguishing active ACC cases from ACA. The absence of miR-483-5p expression in disease-free ACC patients, in which tumor burden is low or absent, suggests that this biomarker may be useful not only for diagnostic purposes but also for disease monitoring. Future research should focus on analyzing serial serum samples from ACC patients to better understand miRNA dynamics throughout disease progression and in response to treatment.

Quantitative proteomics of pediatric adrenocortical tumors reveals a continuum of molecular alterations and identifies prognostically relevant subgroups

Andreas Metousis[1], Victoria Fincke[2], Stefan Wudy[3], Joern Pons-Kuehnemann[3], Marina Kunstreich[2] , Eva Jüttner[4], Pascal Johann[2], Antje Redlich[5], Lisa Schweizer[1], Matthias Mann[1], Rainer Claus[2] & Michaela Kuhlen[2]
[1]Max Planck Institute of Biochemistry, Planegg, Germany; [2]University of Augsburg, Pediatrics and Adolescent Medicine, Augsburg, Germany; [3]Justus Liebig University Giessen, Giessen, Germany; [4]University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany; [5]Otto-von-Guericke-University Magdeburg, Magdeburg, Germany

Introduction
Pediatric adrenocortical tumors (pACTs), comprising highly malignant carcinomas (pACCs) and less aggressive adenomas (pACAs), pose significant diagnostic and therapeutic challenges due to their molecular heterogeneity and variable clinical outcomes. In this study, we performed an extensive quantitative proteomic analysis of pACTs and matched normal adrenal tissue to delineate molecular alterations, identify deregulated proteins and pathways, and define novel prognostically relevant subgroups.
Methods
Bulk proteomes were extracted from 85 pACTs and 43 matched normal adrenal samples, macrodissected from H&E-stained sections. Following protein extraction, lysis, and enzymatic digestion, the samples were analyzed on a Thermo Orbitrap Astral mass spectrometer coupled to an Evosep One LC system operating at 60 samples per day. The resulting data were $\log_2$ transformed and Z-score normalized prior to further analysis.

Results
A total of 10,714 proteins were quantitatively identified. Protein counts were robust, with tumor samples yielding a median of 8,246 proteins (range: 7,312–8,806) and normal samples a median of 7,497 proteins (range: 4,128–8,578). Unsupervised hierarchical clustering and principal component analysis (PCA) effectively separated normal from tumor samples, yet revealed a proteomic continuum between these states. Notably, traditional histological subtypes (ACA, ACC, and ACX) did not segregate into distinct clusters in PCA or clustering analyses. Differential expression analysis identified approximately 3,400 significantly regulated proteins, with roughly four times more downregulated (2,766) than upregulated (628) in pACTs. Key steroidogenic enzymes such as 3β-hydroxysteroid dehydrogenase were consistently downregulated, supporting a common origin in the adrenal cortex's zona reticularis. Among the top hits were IGF2, CCNE, and SGCG, with significant enrichment of proteins involved in the IGFR signaling and β-catenin pathways. Further dimensionality reduction using PCA and UMAP followed by k-means clustering delineated four distinct tumor clusters (comprising 17, 25, 13, and 30 samples, respectively) that differed in protein signature enrichment, gene ontology profiles, and prognostic outcomes. Moreover, samples of these clusters grouped together in a pseudotime analysis, suggesting a cancer development–associated transition between the clusters.
Conclusions
Our high-sensitivity mass spectrometry approach enables an in-depth proteomic characterization of pACTs, uncovering a continuum of molecular alterations from normal to tumor tissue and identifying novel molecular subgroups with distinct prognostic implications. These findings advance our understanding of pACT pathophysiology and pave the way for refined diagnostic stratification and targeted therapeutic interventions.

Pediatric adrenocortical tumors (pACTs) reveal typical patterns of impaired relative activities of steroid metabolizing enzymes

Michaela Hartmann[1], Joern Pons-Kuehnemann[2], Marina Kunstreich[3], Antje Redlich[4], Michaela Kuhlen[3] & Stefan Wudy[1]
[1]Justus Liebig University, Center of Child an Adolescent Medicine, Division of Pediatric Endocrinology & Diabetology, Laboratory for Translational Hormone Analysis, Steroid Research & Mass spectrometry Unit, Giessen, Germany; [2]Institute of Medical Informatics, Justus Liebig University, Medical Statistics, Giessen, Germany; [3]University of Augsburg, Faculty of Medicine, Pediatric and Adolescent Medicine, Augsburg, Germany; [4]Otto-von-Guericke-University, Department of Pediatrics, Pediatric Hematology/Oncology, Magdeburg, Germany

Introduction
pACTs comprise adenomas (pACAs) and carcinomas (pACCs). They are functional and thus symptomatic with the latter having a poor prognosis. We investigated whether precursor/product ratios of steroid hormone metabolites were suitable to diagnose patients with adrenal tumors and to differentiate adenomas from carcinomas. Method: We investigated 46 patients (median 6.9; range 0.7-17 yrs; 36 females) with ACTs from the GPOH-MET Registry (German Society for Pediatric Oncology and Hematology for Malignant Endocrine Tumors) at the time of initial diagnosis. Patients were recruited between 2001 and 2024. $n=21$ were diagnosed with pACAs and $n=25$ with pACCs according to histopathological criteria. $n=145$ urines from healthy children served as controls. 36 steroid metabolites were quantified (µg/l) from spot urines by targeted GC-MS urinary steroid metabolome analysis. Relative enzyme activities were calculated according to typical precursor/product metabolite ratios. Data underwent computational analysis by Z-transformation of log transformed values followed by logistic regression and machine learning classifiers.
Results
Most expressed differences ($P<0.001$) between the group of ACTs and healthy controls concerned decreased activities of the following enzymes: 3β-hydroxysteroiddehydrogenase (3βHSD, e.g. ratio 5-pregnenetriol-17α/pregnanetriol, OR 5.01), 11β-hydroxylase (11OHase, e.g. ratio tetrahydro-11-deoxycortisol/cortisol metabolites, OR 5.35) and 21-hydroxylase (21OHase, e.g. ratio pregnandiolone-5β/tetrahydrocortisone, OR 3.54). Recursive partitioning and regression trees showed a sensitivity of 94% and a specificity of 87%. Differences between ACAs and ACCs were less expressed ($P<0.05$) and primarily showed reduced activities for 5α-reductase (5αR, e.g. pregnandiolone-5α/pregnandiolone-5β, OR 2.68) and 17-hydroxylase/17,20-lyase (17OHase, e.g. corticosterone-metabolites/cortisol-metabolites, OR 2.03). Recursive partitioning and regression trees revealed sensitivities of 84% for carcinomas and 86% for adenomas.
Conclusions
1) targeted GC-MS urinary steroid metabotyping from spot urine using metabolite precursor/product ratios is non-invasive and highly useful in delineating pACTs. 2) pACTs showed gross differences compared to controls. Most common was reduced activity of 3βHSD with dominance of 5-ene-steroids, a finding pointing to the zona reticularis as probable site of tumorigenesis. 3) pACCs and pACAs showed only subtle differences primarily impaired activities of 5αR and 17OHase. 4) pACTs behave differently from those in adults. Findings in adult ACT patients cannot be transferred to pediatric patients.

Background
Pharmacological treatment for advanced adrenocortical carcinoma (ACC) consists of mitotane alone or combined with cytotoxic chemotherapy. However, reliable predictors of response to therapy are lacking. We aimed to explore the predictive role of clinical parameters in a large cohort of patients with advanced ACC treated with systemic therapy.
Methods
We investigated a total of 418 patients with advanced ACC (61.5% = women, median age = 52 years) from 11 European centres, treated with mitotane monotherapy (mitotane cohort, $n=161$), etoposide + cisplatin ± doxorubicin ± mitotane (EDP cohort, $n=178$) or two different 2nd-line chemotherapy schemes (gemcitabine + capecitabine ± mitotane or temozolomide + mitotane $n=79$). Clinical parameters were collected at start of therapy including age, cortisol excess, ECOG-performance status (ECOG-PS), tumor burden (4 grades defined depending on size, number and site of metastasis), neutrophil-to-lymphocyte-ratio (NLR). Patients underwent regular radiological surveillance according to European and local guidelines. Our endpoints were overall-survival (OS) and time-to-progression (TTP) from treatment initiation and best objective response to treatment according to RECIST 1.1 criteria. Descriptive, contingency table, Kaplan-Meier survival and Cox regression analyses were performed using STATA version 17.
Results
At multivariable analysis tumour burden, cortisol excess, ECOG-PS and NLR ≥ 5 significantly and independently predicted shorter OS in all cohorts (HR between

1.55 and 2.68). We therefore calculated a combined **BUCEN**score as a sum of the following points: tumour **BU**rden (1 = 0, 2 = 1, 3/4 = 2), **C**ortisol excess (present = 1), **E**COG-PS (0 = 0, 1 = 1, 2/3 = 2), and **N**LR (≥5 = 1). A high BUCEN (≥3) resulted a significant predictor of shorter OS and TTP in all groups (mitotane cohort: OS HR = 3.05, 95%CI = 2.06-4.51, TTP HR = 2.68, 95%CI = 1.81-3.98, EDP cohort: OS HR = 3.38, 95%CI = 2.22-5.14, TTP HR = 2.53, 95%CI = 1.68-3.84, 2nd-lines cohort: OS HR = 3.96, 95%CI = 1.68-9.29, TTP HR = 3.08, 95%CI = 1.31-7.24). BUCEN score ≥ 3 also predicted best objective response to mitotane ($P < 0.01$) and 2nd line therapies ($P = 0.04$), without reaching significance for EDP ($P = 0.07$).
Conclusions
Our new proposed BUCEN score resulted a promising predictor of response to pharmacological treatment in patients with advanced ACC. This score can be calculated starting from readily available clinical and biochemical parameters and could be used in routine practice to pre-select patients who could most benefit from systemic therapy.

Single-cell, single-nucleus, and spatial transcriptomics reveal the cellular atlas and developmental mechanisms of aldosterone-producing micronodules and adenomas

Zhuolun Sun[1], Changying Jing[2], Martina Tetti[1], Siyuan Gong[1], Jia Wei[1], Yingxian Pang[1], Martin Reincke[1] & Tracy Ann Williams[1]
[1]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, Ludwig-Maximilians-Universität (LMU) München, München, Germany; [2]Institute of Diabetes and Regeneration Research, Helmholtz Munich, Neuherberg, Germany

Background
Primary aldosteronism is frequently caused by aldosterone-producing adenomas (APAs). Aldosterone-producing micronodules (APMs) are distinct histopathological lesions consisting of subcapsular clusters of *zona glomerulosa* (zG) cells. APMs have been proposed as potential APA precursors, but molecular evidence supporting this hypothesis remains limited.
Objective
This study aimed to create a comprehensive cellular atlas of APAs and APMs and elucidate their developmental mechanisms through integrated single-cell, single-nucleus and spatial transcriptomics analyses.
Methods
We performed single nucleus (sn) RNA-seq on two APA specimens and integrated publicly available single cell (sc) RNA-seq data from two APMs. To map spatial gene expression, we conducted spatial transcriptomics analyses on 12 captured areas from formalin-fixed paraffin-embedded adrenal glands from five patients with primary aldosteronism. Functional *in vitro* studies were performed in human adrenocortical cells (HAC15).
Results
Integration of sn and scRNA-seq transcriptome data revealed distinct phenotypic profiles and variable frequencies of major cell types between APM and APA. APAs exhibited an immunosuppressive tumour microenvironment, potentially driven by enhanced VISFATIN pathway activity promoting M2 macrophage polarisation. Gene regulatory network analysis identified APA-specific transcription factors *LEF1* and *FOXO1*, while *JUN* and *FOS* expression in APMs suggested their role in early tumour responses. Trajectory analyses revealed two main developmental pathways: direct progression from zG to APA, and stepwise progression from zG through APM to APA. Within APAs, we identified two distinct cellular states with different differentiation potentials: a progenitor-like state (low differentiation potential) and a mature state (high differentiation potential). Compared to the progenitor state, the mature state was characterised by increased *PCP4* and *CYP11B2* expression and high copy number variation. Functional enrichment analysis revealed a dynamic regulatory environment during APA development, involving pathways of oxidative stress (including mechanisms leading to cell death by ferroptosis) and focal adhesion (influenced by cell density). We demonstrate that RSL3-induced ferroptosis sensitivity is modulated by cell density. TAZ knockdown in low-density HAC15 cells conferred resistance to ferroptosis, mimicking the effect observed in high cell densities.
Conclusion
Our findings reveal an immunosuppressed tumour microenvironment in APAs, characterised by increased M2 macrophages. We demonstrate dynamic changes in molecular profiles and cell cluster composition during APA initiation and progression. These insights enhance our understanding of APA pathobiology and may inform the development of novel diagnostic and therapeutic strategies for primary aldosteronism.

War-provoked glycemic shift: 4-years dynamics of HbA1c levels in Ukrainian population

Yeva Ilkiv[1,2], Viktoriia Yerokhovych[1], Vitalii Gurianov[1], Anna Shcherbakova[3], Iuliia Komisarenko[1], Oksana Sulaieva[3,4] & Nazarii Kobyliak[1,3]
[1]Bogomolets National Medical University, Kyiv, Ukraine; [2]Institute of Gerontology Academy of Medical Sciences of Ukraine, Kyiv, Ukraine; [3]Medical Laboratory CSD, Kyiv, Ukraine; [4]Kyiv Medical University, Kyiv, Ukraine

Background
War is one of the strongest stressors that affects the physical and psychological heath. In Ukraine, full-scale military operations have led to significant deterioration in access to medical care, chronic stress, a shortage of vital medicines, changes in diet and the lifestyle. These can provoke metabolic disorders predisposing to insulin resistance and diabetes mellitus development. One of the important indicators for diabetes diagnosis and control is the level of glycated hemoglobin (HbA1c). In this study we assessed the impact of war on distirbution of HbA1c values at populational level with respect to gender of people tested at pre-war and 3-year war period.
Methods
This population-based study involved 106,883 participants who underwent HbA1c testing from over Ukraine at the period from 2021 to 2024. This sample included 68,696 males and 38,187 females, of different age.
Results
According to the data analysis, the start of full-scale aggression in 2022 significantly affected HbA1c levels, which differed substantially from 2021, 2023, and 2024 ($P < 0{,}001$). The prewar level of HbA1c in the Ukrainian population comprised 5.82%. The beginning of the war in Ukraine was associated with a sharp increase of HbA1c in males from 6.01% (5.47-8.54%) in 2021 to 6.88% (5.54-10.26%) in 2022 when the full-scale invasion began. In 2023 and 2024, HbA1c levels returned to prewar values reaching 5.98% (5.44-8.14) and 6.02% (5.58-7.43), respectively. In women, the highest levels of HbA1c were also noted in 2022, when the full-scale invasion began (6.24; 5.43-9.14%), compared with the pre-war period in 2021 (5.77; 5.33-7.15%). However, the following decline of HbA1c in 2023 and 2024 was insignificant, so HbA1c levels in 2023 (5.89%; 5.40-7.50%) and 2024 (5.98%; 5.54-7.10%) kept higher than in prewar period. Thus, females demonstrated long-term glycemic shifts induced by war-related factors. This data reflects gender differences in scale and length of HbA1c level changes in response to war.
Conclusions
The war significantly affects the health of Ukrainians, provoking acute and chronic shifts in carbohydrate metabolism and glycemic profile indicators. The start of the war was associated with a rise in HbA1c levels. While men demonstrated a sharp increase with further normalization of HbA1c, females showed prolongation of changes in HbA1c.

Early detection of type 1 diabetes through population-based antibody screening: design and initial results from the adir program in Israel

Tal Oron[1,2], Galia Gat-Yablonski[1,3], Irit Meivar Levy[1,3], Biana Shatif[1,3], Michal Foist[1,3] & Moshe Phillip[1,2]
[1]The Jesse Z and Sara Lea Shafer Institute for Endocrinology and Diabetes, National Center for Childhood Diabetes, Schneider Children's Medical Center of Israel, Petach Tikva, Israel, Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, The Jesse Z and Sara Lea Shafer Institute for Endocrinology and Diabetes, National Center for Childhood Diabetes, Petach Tikva, Israel; [2]Tel Aviv University, Faculty of Medicine, Tel Aviv, Israel; [3]Felsenstein Medical Research Center, Tel-Aviv University, Laboratory for Molecular Endocrinology and Diabetes, Petach Tikva, Israel

Introduction
Type 1 diabetes (T1D) demonstrates a distinctive early immunological signature, with approximately 80% of affected children developing multiple islet autoantibodies (IA) before age 5. These children face an 84% risk of progressing to symptomatic diabetes within 15 years. Population-based antibody screening presents a critical opportunity to identify preclinical T1D, enabling proactive intervention through family preparation for insulin therapy, prevention of diabetic ketoacidosis (DKA) at diagnosis, and timely initiation of disease-modifying treatments.

Research design and methods
The Antibody Detection Israeli Research (ADIR) program, launched in October 2021 with support from Breakthrough T1D, represents a comprehensive national screening initiative. The study targets 35,000 children aged 9 months to 5 years across Israel for IA screening, with longitudinal assessment planned for 5,000 participants through repeat screening. The program's infrastructure comprises 65 community-based screening sites, six specialized diabetes centers following the children detected with preclinical T1D, a dedicated central laboratory, and a coordinating center. ADIR distinguishes itself through two key innovations: its focus on early childhood screening and the implementation of Antibody Detection by Agglutination PCR (ADAP) technology for autoantibody detection performed in capillary blood.
Preliminary results
As of January 2025, the study has enrolled 17,000 children (median age: 19 months). Analysis of over 12,000 samples revealed 57 children (0.475%) with multiple IA. Following confirmatory testing per the study protocol, 15 children were diagnosed with preclinical T1D, while others are still evaluated. Additionally, 120 children were identified with single islet antibody positivity. A comprehensive analysis and progression patterns will be presented.
Conclusions and future directions
The ADIR program represents one of the largest population-based screening initiatives for preclinical T1D in young children. Our preliminary results demonstrate the successful implementation of a nationwide screening infrastructure and validate the feasibility of early autoantibody detection using the novel ADAP technology. Identifying children with preclinical T1D and over 120 with single islet antibody positivity underscores the program's potential for early intervention. These findings support the viability of large-scale screening programs for type 1 diabetes and establish a foundation for future preventive strategies. Long-term follow-up of this cohort will provide valuable insights into the natural history of T1D and create opportunities for early therapeutic intervention.

Novel insights in understanding the relation of glycemic excursions and concomitant sleep macro- and micro-architecture among adolescents with type 1 diabetes

Marianna Rachmiel[1,2], Dana Blatch[3], Avital Leshem[1], Caroline Weill[3,4], Mordechay Medvedovsky[3,4], Mirit Lezinger[5], Eli Heyman[5] & Dana Ekstein[3,4]
[1]Pediatric Diabetes and Endocrinology Institute, Shamir (Assaf Haroffeh) Medical Center, Beer Yaakov, Israel; [2]School of Medicine, Tel Aviv University, Tel Aviv, Israel; [3]Hadassah Medical Center,, Department of Neurology, the Agnes Ginges Center for Human Neurogenetics, Jerusalem, Israel; [4]Faculty of Medicine, the Hebrew University of Jerusalem, Jerusalem, Israel; [5]Department of Pediatric Neurology, Shamir (Assaf Haroffeh) Medical Center, Beer Yaakov, Israel

Background and objective
The bidirectional influence between glycemic variability and quality of sleep among patients with type 1 Diabetes (T1D) has not been fully elucidated yet. We aimed to characterize real-time interactions of sleep parameters, including electrical activity, with immediate glycemic excursions, among adolescents with T1D, compared to their healthy siblings.
Methods
Twenty-two patients with T1D, 50% males, median age 14.6 years (13.7,15.8), and 13 of their healthy siblings, 61.5% males, median age 14.8 years (13.2,16), were included in the study. They were divided to well-controlled (WC-T1D) and poorly controlled (PC-T1D), according to HbA1c cutoff 8.3%. All were monitored continuously and simultaneously with an actigraph, electroencephalogram (EEG) and continuous glucose monitoring system (CGMS) for interstitial glucose concentrations (IGC), for one night. EEG recordings were used to calculate EEG power at frequency bands from delta to high gamma, averaged over different brain regions. IGC was divided to near-normal glucose range of 61-180 mg/dl, and high glucose of >180 mg/dl.
Results
During awakening (WASO), the percentage of time spent in optimal range was significantly higher in the Healthy group compared with the T1D group, (100% vs. 45.4%, $P=0.001$), mainly the WC-T1D subgroup, in which longer time was spent at the higher glucose levels during WASO. Higher percentage of time spent in 61-180 mg/dl range, was associated with longer NREM3 $r=0.51$, $P=0.012$, but with a shorter TST $r=-0.49$, $P=0.03$, in the T1D group. A similar trend with negative correlation between percent of time spent in 61-180 mg/dl and TST was seen in the Healthy group, $r=-0.51$, $P=0.07$. Lower EEG power was demonstrated in T1D group compared with the Healthy group, mainly at frequency bands delta, theta and beta during NREM stage 1, and bands delta, beta and gamma during WASO. Significantly lower EEG power was detected during N1, REM and WASO when IGC was >180 mg/dl in the T1D group, compared with the Healthy group, at most frequency bands and brain regions. Those differences were not detected with near normal IGC. In contrast, higher HbA1c was associated with lower EEG power during all sleep stages and across most frequency bands and brain regions.
Conclusions
EEG power in various sleep stages is differently regulated by chronic glycemic control and by acute glucose excursions, explained physiologically according to reflective cortisol secretion and modulation of autonomous nervous system. Effective management goals among the pediatric population with T1D, should include both lower HbA1c and longer time spent with IGC <180 mg/dl.

JOINT865

Rebound hyperglycemia in children with type 1 diabetes using automated insulin delivery

Ajenthen Gayathri Ranjan[1], Katrine Tidemand[1], Jannet Svensson[1,2] & Kirsten Nørgaard[1,3]
[1]Steno Diabetes Center Copenhagen, Department of clinical and translational research, Herlev, Denmark; [2]Herlev University Hospital, Department of pediatrics, Herlev, Denmark; [3]University of Copenhagen, Copenhagen, Denmark

Background and aims
To investigate how rebound hyperglycemia (RH) affects CGM-assessed time-in-range and how different automated insulin delivery systems (AID) manage RH.
Methods
This cross-sectional study included children and adolescents with type 1 diabetes (T1D) using either Tandem Control IQ (CIQ) or Medtronic Minimed 780G (780G) at Steno Diabetes Center Copenhagen, Denmark. RH was defined as ≥ 1 sensor glucose value (SG) >10.0 mmol/l within two hours of a preceding SG <3.9 mmol/l, with RH-severity measured by area under the curve (AUC).
Results
Among 190 children and adolescents, 94 used CIQ and 96 used 780G. The median age (range) for CIQ and 780G was 11.9 (1.8-18.0) versus 11.3 (1.2-17.4) years ($P=0.49$), diabetes duration was 7.0 (1-16) versus 4.0 (0-13) years ($P<0.001$), and HbA1c was 53 (37-102) versus 53 (37-147) mmol/mol ($P=0.29$) . RH-severity (AUC) was inversely related to time-in-range (TIR: 3.9-10.0 mmol/l) ($P<0.001$), regardless of the AID systems ($P=0.57$). The frequency of hypoglycemia, frequency of RH, and the percentage of hypoglycemia leading to RH were similar for 780G and CIQ ($P>0.05$). However, CIQ-users had a significant increased RH-duration of 30% (95%CI:16-46%) and RH-severity of 34% (95%CI: 18-53%) compared with 780G-users, despite having a shorter duration of hypoglycemia leading to RH of 23% (95%CI:14-32%).
Conclusions
Even though the frequency of RH was similar between AID systems, the severity and duration of RH were less and shorter for children and adolescents with T1D using 780G than CIQ. The inverse association between RH-severity and TIR suggests that addressing hypoglycemia management in AID-users could improve glycemic outcomes.

In-hospital diabetes management by a diabetes team using insulin algorithms with continuous glucose monitoring or point-of-care testing in patients with type 2 Diabetes: the DIATEC RCT

Mikkel Thor Olsen[1], Carina Klarskov[1], Signe Jensen[1], Louise Rasmussen[1], Birgitte Lindegaard[1], Jonas Andersen[1], Hans Gottlieb[2], Suzanne Lunding[2], Ulrik Pedersen-Bjergaard[1], Katrine Hansen[3] & Peter Kristensen[1]
[1]Copenhagen University Hospital – North Zealand, Hilleroed, Denmark; [2]Herlev-Gentofte Hospital, Herlev, Denmark; [3]Steno Diabetes Center Copenhagen, Herlev, Denmark

Objective
The DIATEC trial investigates the glycaemic and clinical effects of inpatient continuous glucose monitoring (CGM)-guided insulin titration by diabetes teams.
Research design and methods

This two-centre trial randomised 166 non-intensive care unit patients with type 2 diabetes. Diabetes management was performed by regular staff, guided by diabetes teams using insulin titration algorithms based on either point-of-care glucose testing or CGM. The primary outcome was the difference in time in range (TIR) (3.9–10.0 mmol/l) between the two arms. Outcomes were assessed during the entire hospitalisation.
Results
The CGM-arm achieved a higher TIR (median, IQR) of 77.6% (24.4) vs 62.7% (31.5) in the POC-arm ($P < .001$). Time above range (TAR) >10.0 mmol/l was lower in the CGM-arm of (median, IQR) 21.1% (24.8) vs 36.5% (30.3) in the POC-arm ($P = .001$). Time below range (TBR) <3.9 mmol/l was reduced by CGM, with a relative difference to POC of 0.57 (95% CI 0.34–0.97) ($P = .042$). Prolonged hypoglycaemic events decreased (IRR 0.13, 95% CI 0.04–0.46) ($P = .001$), and the coefficient of variation (mean, SD) was lower in the CGM-arm of 25.4% (6.3) vs 28.0% (8.2) in the POC-arm ($P = .024$). Total insulin doses (mean, SD) were reduced in the CGM-arm with 24.1 IU/day (13.9) vs 29.3 IU/day (13.9) in the POC-arm ($P = .049$). A composite of complications was lower in the CGM-arm (IRR 0.76, 95% CI 0.59–0.98) ($P = .032$).
Conclusions
In-hospital CGM increased TIR by 15%-points, mainly by reducing TAR. CGM also lowered TBR, glycaemic variability, prolonged hypoglycaemic events, insulin usage, and in-hospital complications.

Objective
The relationship between delayed puberty in males and the risk of type 2 diabetes (T2D) in adulthood is unclear. We investigated the association between delayed puberty during adolescence and the likelihood of developing T2D in early adulthood.
Research design and methods
A nationwide, population-based study of 964,108 Israeli adolescent males (mean age 17.3 years) who were examined before military recruitment during 1992–2015 and were followed until December 31, 2019. The diagnosis of delayed puberty was made by board-specified specialists based on physical examination and laboratory evaluation. Data were linked to the Israeli National Diabetes Registry. Cox proportional hazard models were applied.
Results
Delayed puberty was diagnosed in 0.45% (4307 of 964,108) of adolescent males. Over a cumulative follow-up of 15,242,068 person yeas, T2D was diagnosed in 111 individuals (2.58%) with delayed puberty and in 6,259 individuals (0.65%) without delayed puberty. The incidence rate of T2D per 105 person-year was 140.3 (95%CI, 114.2–166.4) in the delayed puberty group versus 41.3 (95%CI, 40.3–42.3) of adolescents without delayed puberty. The hazard ratio (HR) for T2D among individuals with delayed puberty was 2.52 (95%CI, 2.09–3.04, $P = 4.7$×10-22), remaining materially unchanged after adjustment for birth year, socioeconomic status, cognitive function, education level and country of birth HR 2.47 (95%CI, 2.04–2.99). After additional adjustment to baseline BMI, the HR was 1.37 (95%CI 1.13-1.66). The association was further strengthened when restricted to individuals diagnosed at or before 35 years of age 1.65 (95%CI 1.22-2.23) and persisted after controlling for baseline health status. In a sensitivity analysis limited to adolescents with overweight and obesity, using those without hypogonadism as the reference group, the adjusted HR was 1.31 (95% CI 1.05–1.21).
Conclusions
Delayed puberty in adolescent males is associated with a significantly increased risk of T2D in early adulthood, independent of baseline BMI and other confounders. These findings highlight delayed puberty as a potential marker of metabolic risk, warranting further investigation.

Fecal microbiota transplantation improves diabetic kidney disease by regulating gut tryptophan metabolism
Yan Zeng[1,2], Man Guo[1], Qi Wu[2,3], Fangyuan Teng[1], Betty Yuen-Kwan Law[2], Yang Long[1] & Yong Xu[2,4]
[1]The Affiliated Hospital of Southwest Medical University, Department of Endocrinology and Metabolism, Luzhou, China; [2]Macau University of Science and Technology, State Key Laboratory of Quality Research in Chinese Medicine, Faculty of Chinese Medicine, Macau, China; [3]The Affiliated Hospital of Southwest Medical University, Department of Pathology, Luzhou, China; [4]The Affiliated Hospital of Southwest Medical University, Lzuhou, China

Objective
Diabetic kidney disease (DKD) is a major microvascular complication of diabetes, with complex pathogenesis and limited effectiveness of current prevention and treatment strategies. Identifying novel therapeutic approaches and their molecular targets is therefore of critical clinical significance. This study aims to investigate the therapeutic effects and underlying mechanisms of fecal microbiota transplantation (FMT) in the prevention and treatment of DKD.
Methods
This study was conducted across population, animal, and cellular levels. Metagenomics, serum metabolomics, and tryptophan-targeted metabolomics were employed to analyze changes in gut microbiota composition and serum metabolic flux in both human subjects and DKD mouse models. An 18-week FMT treatment was administered to db/db mice, during which dynamic changes in glucose and lipid metabolism, renal function, and inflammatory markers were evaluated. Renal tissues were collected for transcriptomic sequencing and pathological analysis. Molecular biological techniques, including western blotting, immunoprecipitation, luciferase reporter assays, and gene over-expression/knockdown, were used to further explore the molecular mechanisms underlying the effects of FMT in ameliorating DKD.
Results
FMT effectively improved glucose and lipid metabolism disorders, reduced urinary microalbumin levels, delayed renal function decline, and alleviated renal inflammatory infiltration in db/db mice. In addition, FMT normalized the altered gut microbiota composition and structure in db/db mice, particularly restoring microbial populations associated with gut tryptophan metabolism. This intervention significantly modulated the abnormal serum tryptophan metabolic flux observed in db/db mice. Elevated serum levels of indole-3-acetic acid (IAA) in the DKD state were closely associated with metabolic disorders and renal dysfunction. Mechanistically, IAA promoted NEMO SUMOylation, leading to activation of the NF-κB signaling pathway, which further exacerbated renal inflammatory damage. FMT reduced IAA production, suppressed the activation of the miR-145a-5p/SENP2 signaling axis, inhibited NEMO SUMOylation, and mitigated the excessive activation of the NF-κB inflammatory signaling pathway.
Conclusion
In DKD, increased NEMO SUMOylation activates the NF-κB signaling pathway, resulting in renal inflammatory injury. The gut-derived tryptophan metabolite IAA upregulates renal miR-145a-5p expression, which further enhances NEMO SUMOylation via the miR-145a-5p/SENP2 axis, aggravating inflammatory damage. FMT alleviates DKD and its associated inflammatory injuries by regulating gut tryptophan metabolism, reducing IAA production, and inhibiting the miR-145a-5p/SENP2/NEMO-SUMOylation axis.

The sex chromosome aneuploidies Turner syndrome (45,X; TS) and Klinefelter syndrome (47,XXY; KS) are associated with aging-related comorbidities, reduced life expectancy and genome-wide DNA methylation changes. The objective of this study was to investigate whether the aging-related comorbidity pattern and the reduction in lifespan was associated with epigenetic aging. We assessed epigenetic age and age acceleration using six different epigenetic clocks predicting chronological age, phenotypic age, aging pace and telomere length. DNA methylation was obtained from existing cohorts of TS (TS, $n=47$; female controls, $n=33$) and KS (KS, $n=65$; male controls, $n=63$). In addition, we evaluated correlations between epigenetic aging and clinical variables, aiming to identify clinical aging markers in TS and KS. Epigenetic age and age acceleration based on predictors of chronological age were increased in both TS and KS compared to respective controls ($P<0.015$). Epigenetic age and age acceleration based on predictors of phenotype were increased in TS ($P<0.019$), as well as aging pace ($P<0.001$). Telomere length was decreased in TS ($P<0.001$) and slightly increased in KS ($P=0.06$). Markers of body composition and muscle mass were correlated to age acceleration in TS, while these traits were correlated to chronological and epigenetic age in female controls. Similarly, markers of body composition were more consistently correlated to aging pace in KS than male controls, while an age-dependent increase in triglyceride levels and body fat percentage seemed to be diminished in KS. We demonstrated that biological aging was clearly increased in TS and, to some extent, in KS. This could explain some of the excess mortality observed in these syndromes. Additionally, unfavorable changes in body composition, which are common in both syndromes, particularly if left untreated, could result in accelerated aging – or be the result hereof.

Role of clock gene Bmal1 in mitochondrial function and lipid metabolism in skeletal muscle

Mariarosaria Negri[1], Feliciana Amatrudo[1], Giovanna Trinchese[2], Fabiano Cimmino[2], Roberta Patalano[3], Donatella Paola Provvisiero[4], Rosario Pivonello[3,5], Maria Pina Mollica[2], Annamaria Colao[3,5] & Claudia Pivonello[6]
[1]Università Telematica Pegaso, Dipartimento di Psicologia e Scienze della Salute, Naples, Italy; [2]University of Naples Federico II, Department of Biology, Naples, Italy; [3]Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Università Federico II di Napoli, Naples, Italy; [4]Università Federico II di Napoli, Dipartimento di Sanità Pubblica, Naples, Italy; [5]UNESCO Chair for Health Education and Sustainable Development, Università Federico II di Napoli,, Naples, Italy; [6]Università Federico II di Napoli, Dipartimento di sanità Pubblica, Naples, Italy

Bmal1 is the key transcription factor of the molecular circadian clock, whose cyclic expression influences energy metabolism and regulation of cell growth and maintenance. The current study aims to elucidate the role of Bmal1 muscle metabolism regulation, with a focus on mitochondrial activity and lipid accumulation. The murine C2C12 cells differentiated into myocytes (C2C12 WT), and C2C12 in which the Bmal1 gene was deleted through CRISPR/Cas9 genome editing technology (C2C12 KOBmal1) were used. Mitochondrial oxidative capacity and efficiency were evaluated using Seahorse assays and MitoTracker Red CMXRos staining, respectively, in both cells. Simultaneously, the expression levels of DRP-1 protein, a key marker of mitochondrial fission, as well as the subcellular localization of myogenin, a transcription factor involved in muscle differentiation, and of HSP70, a molecular chaperone regulating stress response, were investigated via immunofluorescence. In addition, Bodipy staining was performed in both cell models to monitor potential ectopic lipid accumulation, while gene and protein expression levels of the mTOR pathway, myogenin, C/EBPα and PGC1α, key regulators of muscle anabolism, lipogenesis and mitochondrial biogenesis, were assessed by RT-qPCR and western blot, respectively. Furthermore, irisin levels, a myokine involved in mitochondrial function and muscle health, were quantified in both cell models through ELISA assay. Compared to C2C12 WT , basal respiration was significantly lower ($P=0.03$) while maximal respiration and reserve respiratory capacity were significantly higher ($P=0.009$; $P=0.003$) in C2C12 KOBmal1cells. Morphologically, C2C12 KOBmal1 cells showed a reduction in mitochondrial branching (-18.22%) and a significant decrease in mitochondrial branch length ($P=0.01$) compared to C2C12 WT cells. These changes were associated with increased DRP1 protein levels (+17%) and a significant reduction in PGC1α gene ($P=0.01$) and protein ($P=0.03$) levels. These mitochondrial alterations in C2C12 KOBmal1 were accompanied by significantly increased lipid accumulation ($P=0.03$) and C/EBPα protein expression ($P=0.03$), indicating a shift toward lipid storage. A marked downregulation of mTOR (-42.86%), p70S6K (-61.43%), and 4E-BP1 (-38.82%) genes was observed in C2C12 KOBmal1 cells compared to C2C12 WT , alongside reduced levels of myogenin (-27.70%). Immunofluorescence revealed perinuclear distribution of myogenin protein in C2C12 KOBmal1 , unlike its nuclear expression in C2C12 WT concomitantly with increased HSP70 nuclear expression, potentially linking reduced myogenic signalling to cellular stress. Lastly, C2C12 KOBmal1 showed significantly decreased irisin levels ($P=0.03$), reinforcing the impairment in metabolic balance. Concluding, Bmal1 deletion in myocytes disrupts mitochondrial morphology and function, promoting lipid accumulation and suppressing mTOR-driven anabolism through nuclear HSP70 accumulation.

Nuclear resident AMPK ?2 enhances adipose tissue browning through Neuregulin 4

Ping Gu[1] & Hannah Hui[2]
[1]Nanjing Jinling Hospital, Nanjing, China; [2]School of Biomedical Sciences, The Chinese University of Hong Kong, Hong Kong, China

AMP-activated protein kinase (AMPK) is a heterotrimeric serine/threonine kinase playing a key role in metabolic regulation. The γ subunit of AMPK is the regulatory subunit responsible for binding and sensing the adenine nucleotides and the most understudied subunit. We found the expression of AMPK γ2 subunit, encoded by *Prkag2* gene, is abundantly expressed in the mature adipocytes and its expression was significantly downregulated in obesity while boosted by cold exposure. Adipocyte-selective deletion of *Prkag2* exacerbates diet-induced obesity and compromises adipose tissue browning in mice. Notably AMPK γ2 contains a unique nuclear localization signal (NLS). Mutation of the NLS mitigates the nuclear localization of AMPK γ2 along with its biological function in potentiating adipose browning. WT but not mutant AMPK γ2 stimulates the transcription of Neuregulin 4 (*Nrg4*). Additionally, CUT&Tag analysis reveals a direct binding of AMPK γ2 on *Nrg4* gene locus, suggesting AMPK γ2 acts as a transcriptional co-activator of *Nrg4*. Supplementation of NRG4 reverses the compromised adipose browning in Prkag2 AKO mice. In human, NRG4, and other adipokines are tightly correlated with adipose AMPK γ2 expression. Our findings unravel the previously unrecognized function of AMPK γ2 as a transcriptional co-regulator independent of AMPK kinase activity in adipocytes.

Modeling adipose tissue dysfunction in polycystic ovary syndrome in vitro using 2D and 3D cell culture systems

Anja Dekanski[1], Congru Li[1], Lena Schobloch[1], Eva Lindgren[1], Shane Wright[1], Duarte Ferreira[1], Volker Lauschke[1], Nayere Taebnia[1] & Elisabet Stener-Victorin[1]
[1]Karolinska Institutet, Stockholm, Sweden

Background
Polycystic ovary syndrome (PCOS), characterized by hyperandrogenism, is the leading cause of female infertility and is associated with insulin resistance and type 2 diabetes. Impaired adipose tissue function is a key determinant of the metabolic phenotype in PCOS, with dysfunction evident in altered lipid metabolism, energy homeostasis, and adipokine production. Our group has identified enlarged fat cells as drivers of insulin resistance and linked aberrant genetic and epigenetic expression in adipose tissue to PCOS-related metabolic disturbances. However, the molecular mechanisms remain poorly understood and are not addressed by current drug development. Treatment for insulin-resistant PCOS primarily focuses on symptom management through lifestyle changes, diet, exercise, and antidiabetic drugs, including metformin and GLP1 receptor agonists. Yet, their direct effects on adipocytes in PCOS remain unclear. To address this, we are generating a single-nuclei transcriptome atlas of subcutaneous adipose tissue from women with and without PCOS to identify

disease- and cell type-specific signatures and treatment responses (see abstract Li *et al*). In parallel, we are developing and characterizing 2D and 3D *in vitro* adipose tissue cultures to investigate adipogenic differentiation, adipose dysfunction, and drug responses, focusing on metformin and GLP1-RA (semaglutide).
Methods
We collect subcutaneous white adipose tissue from hyperandrogenic, insulin-resistant women with PCOS and age and BMI-matched controls. Fresh biopsies are used to isolate adipose stem cells (ASCs) to assess adipogenic capacity, tissue recapitulation, and responses to metformin and semaglutide. We perform bulk RNA sequencing at day 0 (ASC), day 6 (preadipocytes), and day 12 (mature adipocytes). Moreover, we analyse lipid accumulation ad lipid droplet size, basal and stimulated lipolysis, and bioenergetics using Seahorse XFe96. Additionally, 3D adipocyte spheroids are generated and characterized.
Results & Future Perspectives:
Preliminary data indicate that 2D-differentiated PCOS adipocytes retain larger lipid droplets, mimicking tissue biopsies. PCOS adipocytes exhibit lower basal oxygen consumption and higher basal lipolysis, both partially reversed by metformin and semaglutide. Bulk RNA sequencing reveals persistent PCOS-specific differential gene expression related to mitochondrial function throughout differentiation. Preliminary 3D spheroid data suggest similar lipid droplet enlargement. Ongoing work includes profiling the secretome and extracellular vesicles and comparing transcriptomic data from *in vitro* and freshly isolated mature adipocytes for model validation and with single nuclei RNA-seq data. Future efforts aim to develop advanced *in vitro* PCOS models, such as microfluidic co-culture systems integrating adipose and reproductive tissues, including endometrial epithelial organoids and stromal cells, to study tissue interactions in PCOS.

Sedentary behavior, physical activity, and risk of mortality in adults with obesity

Shaoyong Xu[1], Qingying Tian[1], Yanyan Jia[1] & Wenxiang Yu[1]
[1]Xiangyang Central Hospital, Affiliated Hospital of Hubei University of Arts and Science, Department of Endocrinology, Xiangyang, China

Background
Obese individuals tend to lead sedentary lifestyles and avoid physical activity (PA). It remains unclear whether increasing PA can offset the health risks associated with sedentary behavior (SB), as well as the intensity of PA required to achieve such an effect.
Objectives
This study aimed to evaluate the joint and stratified associations of SB and PA with all-cause, cancer, and cardiovascular disease (CVD) mortality, and to estimate the theoretical effects of replacing SB with sleep or PA.
Methods
A total of 90,971 adults with obesity from the UK Biobank were included in the analysis. Information on sedentary time (sum of television watching, computer using and driving behavior) and PA (measured by International Physical Activity Questionnaire) were collected by self-reported at baseline. Participants were followed up for mortality events according to the ICD-10 code using linkage to national health records until 2021. Cox proportional hazards regression models were used to calculate multivariable-adjusted hazard ratios (HRs) for each SB-PA combination group and within SB strata. The isotemporal substitution model was applied to investigate the impact of replacing SB with sleep, walking, moderate physical activity (MPA), and vigorous physical activity (VPA), adjusting for potential confounders.
Results
During a median follow-up of 12.7 years, 8,357 deaths occurred, including 1,784 from CVD and 2,673 from cancer. Among groups with no PA, reducing sedentary time was not significantly associated with all-cause or cancer mortality. Compared with the reference group (no PA and SB >8 h/day), the group with VPA and 4–8 h/day of SB exhibited the lowest all-cause mortality risk (HR 0.70, 95% CI 0.65–0.75). The group with VPA and <4 h/day of SB showed the lowest cancer mortality risk (HR 0.68, 95% CI 0.60–0.78), while the group with VPA and >8 h/day of SB had the lowest CVD mortality risk (HR 0.66, 95% CI 0.57–0.78). Across SB subgroups, increased PA was significantly associated with reduced all-cause and cause-specific mortality, demonstrating an almost dose-response relationship. Replacing SB with walking or VPA showed stronger associations, with mortality risk declining as the replacement duration increased. For example, replacing 3 h of SB with an equivalent amount of VPA reduced all-cause mortality (HR 0.80, 95% CI 0.77–0.84).
Conclusions
In adults with obesity, reducing sedentary time and increasing PA of any Intensity are significantly associated with lower risks of all-cause and cause-specific mortality. Increasing PA or replacing SB with PA attenuates the association between SB and mortality.

Differential temporal onset of kisspeptin action following intranasal and intravenous administration supports a novel human olfactory-reproductive pathway

Jovanna Tsoutsouki[1], Edouard G Mills[1,2], Maria Phylactou[1,2], Sophie Clarke[1], Layla Thurston[1], Lisa Yang[1], Bijal Patel[1], Pei Eng[1], Chioma Izzi-Engbeaya[1,2], Emma Alexander[1], Muhammad Choudhury[1], Paul Bech[1], Magda Swedrowska[3], Ben Forbes[3], Ali Abbara[1], Alexander Comninos[1,2] & Waljit Dhillo[1]
[1]Imperial College London, Department of Metabolism, Digestion and Reproduction, London, United Kingdom; [2]Imperial College Healthcare NHS Trust, Department of Endocrinology, London, United Kingdom; [3]Institute of Pharmaceutical Science, King's College London, London, United Kingdom

Background
The most characterised pathway for kisspeptin's activation of the reproductive axis involves the stimulation of kisspeptin receptors on GnRH neurones *within the hypothalamus*. However, recent rodent evidence reveals an *extra-hypothalamic* population of GnRH neurons in the olfactory bulb that also express kisspeptin receptors. Intranasal kisspeptin administration could directly activate these olfactory bulb-GnRH neurones, triggering reproductive hormone release and unveiling a novel olfactory-reproductive pathway. Herein, we compare the reproductive hormone responses to intranasal and intravenous kisspeptin administration in humans for the first time, providing mechanistic insights and highlighting a non-invasive clinical route of kisspeptin administration.
Methods
Healthy male participants received 12.8 nmol/kg of kisspeptin-54 via either intranasal delivery ($n=12$) or intravenous bolus injection ($n=5$). Reproductive hormone levels were measured at 15 minute intervals over 6 hours following administration. The mean maximum increase in reproductive hormones from baseline and the median time to peak response between the two groups were analysed using an unpaired t-test and Mann-Whitney test, respectively.
Results
Both intranasal and intravenous kisspeptin-54 elicited significant gonadotrophin and testosterone responses. Although the peak LH response was lower with intranasal, compared to intravenous, administration (mean $\pm$ SEM [IU/l]: 4.5 ± 0.6 above baseline for intranasal vs. 11.3 ± 1.4 for intravenous, $P<0.0001$), intranasal kisspeptin-54 induced a notably earlier LH peak, with a median time of 38 minutes, compared to 300 minutes for intravenous administration ($P=0.0002$) . Similar patterns were observed for FSH, with a peak (mean $\pm$ SEM [IU/l]) of 0.7 ± 0.2 above baseline at 38 minutes (IQR: 30–79) following intranasal administration, compared to 2.3 ± 0.22 above baseline at 345 minutes (IQR: 345–360) following intravenous kisspeptin-54 ($P=0.0003$ for magnitude, $P=0.0002$ for timing). The peak testosterone responses did not differ significantly following intranasal and intravenous kisspeptin-54 ($P=0.1864$), but the median peak was attained earlier following intranasal administration (165 minutes; IQR: 109–240), compared to intravenous administration (345 minutes; IQR: 240–360, $P=0.0116$). Neither intranasal nor intravenous kisspeptin-54 administration were associated with any adverse effects.
Discussion
The remarkably faster onset of reproductive hormone responses following intranasal compared to intravenous kisspeptin-54 suggests that this route leverages a direct olfactory-reproductive pathway mediated by kisspeptin receptors on olfactory GnRH neurones. These findings have significant clinical implications for the therapeutic use of kisspeptin for common reproductive and psychosexual disorders, whilst also providing evidence for a newly identified kisspeptin mediated olfactory-reproductive pathway in humans.

B2R overexpression in resistant prolactinomas promotes B2R-D2R dimerization, with B2R precluding D2R signalling generating resistance to D2R agonists

Alejandra Inés Abeledo-Machado[1], Josep Argerich[2], Dana Bornancini[1], Agustin Yaneff[3], Carina Shayo[1], Mariela Gironacci[4], Francisco Ciruela[2] & Graciela Diaz-Torga[1,5]
[1]Instituto de Biología y Medicina Experimental, CONICET, Buenos Aires, Argentina; [2]Pharmacology Unit, Department of Pathology and Experimental Therapeutics, School of Medicine and Health Sciences, Institute of Neurosciences, University of Barcelona, 08907 L'Hospitalet de Llobregat, Spain, 08907 L'Hospitalet de Llobregat, Spain, Neuropharmacology & Pain Group, Neuroscience Program, Bellvitge Institute for Biomedical Research, Barcelona, Spain; [3]Instituto de Investigaciones Farmacológicas (ININFA-UBA-CONICET), Buenos Aires, Argentina; [4]Universidad de Buenos Aires, Facultad de Farmacia y Bioquímica, Departamento de Química Biológica and IQUIFIB (UBA-CONICET),, Buenos Aires, Argentina; [5]Instituto de Biologia y Medicina Experimental, Laboratorio de Fisiopatologia Hormonal, Buenos Aires, Argentina

Among the pituitary tumours PROLACTINOMAS, are the most frequently observed in the clinic. The dopamine receptor 2 (D2R) agonists represent a highly effective first-line therapy. However, between 15 and 20% of patients do not respond to the treatment or become resistant. These RESISTANT prolactinomas represent a major challenge for clinical management as there are no alternative treatments. During the last few years, our focus has been on why D2R doesn't work. Then we start studying whether D2R dimerization disrupts its signalling in lactotrophs promoting resistance to D2R agonists. The bradykinin receptor type 2 (B2R) is overexpressed in prolactinomas. We postulated that the increased B2R expression in prolactinomas could facilitate D2R-B2R dimerization disturbing D2R signalling, promoting resistance to D2R agonists. We first characterized the bradykinin receptors in the pituitary, and we found that B2R is the most expressed, mainly in lactotrophs cells. Then, the formation of B2R-D2R complexes in cultured cells transiently expressing both receptors was validated using the NanoBiT technology. Interestingly, while the stimulation of D2R did not alter B2R-induced intracellular calcium mobilization, B2R stimulation abolished D2R signalling (modulation of cAMP levels). The existence of B2R-D2R complexes in human pituitary adenomas biopsies was evaluated. B2R-D2R complexes were detected, using the ALPHALisa approach, in human prolactinomas and nonfunctioning pituitary adenomas (NFPA), but not in mixed (prolactin + growth hormone) secreting adenomas. These results suggest that overexpression of B2R in resistant prolactinomas may promote the formation of B2R-D2R complexes, with B2R disrupting D2R signalling, generating resistance to D2R agonists.

Pituitary tumors (PiTs) are heterogeneous intracranial neoplasms with limited personalized treatment options. Despite significant advances in understanding their genetics, epigenetics, and the cellular composition of their microenvironment, the underlying processes driving their tumorigenesis and heterogeneity remain poorly understood. The use of single-cell omics and tumour-derived cultures has confirmed the existence of various stem cell (SC) populations in all PiT-subtypes, raising questions about their role in tumorigenesis. Interestingly, while physio-pathological insults activate mouse pituitary SC (PSC) differentiation into endocrine pituitary lineages, their functional contribution has never been addressed in the context of murine tumours or human pituitary adenomas. Here, we questioned the heterogeneity and function of intratumoural PSCs using animal models, single cell-/spatial-omics, and patient-derived primary cultures. Through these approaches, we first confirmed that tumour growth, whether resulting from the orthotopic injection of tumour-cells or the consequences of aging, drives a remodelling of the SC-rich marginal zone (MZ). This was supported by the identification of MZ-budding structures containing SOX2+ cells and their expression of tumour-associated SCs (TA-SCs) markers. Following this observation, we confirmed the presence and the heterogeneity of SCs between 44 gonadotroph tumours (0.02%-4.78% SOX2+ cells). Bioinformatic analysis of single-nuclei sequencing (SnPatho-Seq) performed on three tumours with the highest SC numbers confirmed the presence of two SC populations with unique features and a series of differentiating stem-state identities. These findings were further confirmed by spatial-transcriptomic analysis (Visium/Xenium) and immunohistological validations, pointing to the existence of two major SOX2-expressing SC populations, respectively defined as Stem Cells and TA-SCs. Trajectory and pseudotime analyses confirmed that TA-SCs were differentiating into cell-states primed to the three major pituitary lineages: PIT1, TPIT and SF1, a result further validated by histological analysis. Finally, we addressed the mechanistic cues that control the TA-SC state. Regulon analysis identified STAT1/3 as a transcriptional pathway strongly activated in TA-SCs, a result supported by the identification of intratumoural SOX2-SCs showing a phospho-STAT3 activation. To assess the functional impact of JAK-STAT pathway modulation in vitro, we tested the effect of pharmacological inhibitors on SC-enriched cultures derived from patients. These inhibitors significantly decreased stemness markers while increasing the expression of endocrine differentiation markers. Altogether, these findings provide evidences that TA-SCs may contribute to pituitary tumorigenesis. Moreover, our results support that JAK-STAT inhibition impact SC maintenance and differentiation, suggesting this pathway as a potential therapeutic target to modulate TA-SC behaviour in PITs.Fundings: FRIEMM, Ligue-Cancer (CD26/CD69), HCL (PJC), ANR-23-CE45-0017, ANR-17-CONV-0002, ANR-18-CE45-0023, ANR-22-PESN-0002, CD24-00240, PRE2020-05930.

SDHB loss in anterior pituitary embryonic progenitors and postnatal SOX2+ stem cells is insufficient to drive pituitary tumorigenesis and results in pituitary hypoplasia in mice

James Kaufman-Cook[1], Yasmine Kemkem[1], Miriam Vazquez Segoviano[1], Olivia Sherwin[1], Bence Kover[1], Paul Carroll[2] & Cynthia Andoniadou[1,3]
[1]King's College London, Centre for Craniofacial and Regenerative Biology, London, United Kingdom; [2]Guy's and St. Thomas' NHS Foundation Trust, Department of Endocrinology, London, United Kingdom; [3]Technical University of Dresden, Medical School, Dresden, Germany

Succinate dehydrogenase (SDH) is an enzyme complex at the centre of aerobic respiration with a dual role in the Krebs cycle and electron transport chain. Mutations in any of the four SDH subunits (SDHA, SDHB, SDHC and SDHD) have been implicated in driving tumorigenesis of neuroendocrine tumours including phaeochromocytoma and paraganglioma, underscoring the link between metabolic dysregulation and tumorigenesis. Pituitary neuroendocrine tumours (PitNETs) associated with germline or somatic *SDHx* mutations, particularly in the *SDHB* subunit, can display clinically aggressive behaviour. The molecular pathogenesis, clinical behaviour and treatment outcomes of *SDHx*-mutated PitNETs remain poorly characterised. The role of *SDHx* mutations in driving tumour development, whether alone or in concert with other factors, and the cell-of-origin of these tumours are also unknown. Understanding these pathways is essential for developing targeted therapies for these tumours. Using *in vivo* mouse models, we assessed the consequence of mutating *Sdhb* during anterior pituitary (AP) embryonic development and in postnatal stages. We utilised two *Cre* drivers to delete Sdhb across Rathke's pouch in the embryo ($Hesx1^{Cre/+}$; $Sdhb^{fl/fl}$), as well as in the postnatal SOX2+ stem cell compartment ($Sox2^{CreERT2/+}$; $Sdhb^{fl/fl}$) using a tamoxifen-inducible model. We confirm a reduction in *Sdhb* expression and activation of pseudohypoxic signalling in the AP, with upregulation of *Hif1a* and its transcriptional targets, a pattern seen in other *SDHx*-mutated tumours. Through metabolic flux analyses, we observe metabolic reprogramming in pituitary stem cells, consistent with the Warburg effect (a metabolic switch that is a hallmark of cancer), in response to SDHB loss. Despite these changes, homozygous loss of *Sdhb* in our mouse models is not sufficient to lead to pituitary tumour formation. However, strikingly, loss of SDHB leads to pituitary hypoplasia, characterised by a reduction in AP volume,

with normal anterior pituitary lineage commitment and differentiation. Together, these findings support a potential two-hit tumorigenesis model. They also emphasise the potential role of altered cellular metabolism in hypopituitarism, which could inform regenerative medicine approaches in the future. These have important implications for the screening, diagnosis, and treatment of *SDHx*-mutated pituitary disorders.

Glucocorticoid negative feedback in regulating hypothalamic-pituitary-adrenal axis: the epigenetic role of miR-27

Claudia Pivonello[1], Roberta Patalano[2], Mariarosaria Negri[3], Donatella Paola Provvisiero[1], Feliciana Amatrudo[3], Nicola Di Paola[4], Erminio Massimo Crescenzo[4], Angelica Larocca[4], Chiara Simeoli[4], Annamaria Colao[4,5] & Rosario Pivonello[4,5]
[1]Università Federico II di Napoli, Dipartimento di Sanità Pubblica, Napoli, Italy; [2]DAI di Endocrinologia, Diabetologia, Andrologia e Nutrizione, AOU Federico II di Napoli, Naples, Italy; [3]Università Telematica Pegaso, Dipartimento di Psicologia e Scienze della Salute, Naples, Italy; [4]Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Università Federico II di Napoli, Naples, Italy; [5]UNESCO Chair for Health Education and Sustainable Development, Università Federico II di Napoli,, Naples, Italy

In a physiological state, activation of hypothalamic-pituitary-adrenal (HPA) axis induces the release of ACTH by pituitary and, in turn, of cortisol from adrenal glands according to a circadian rhythm. HPA axis undergoes negative feedback regulation due to the elevated circulating cortisol that induces negative feedback on the hypothalamus and pituitary. In corticotroph cells, the control is provided by the coordinated action of the co-chaperones FKBP4 and FKBP5, which regulate the cytoplasmic and nuclear localization of glucocorticoid receptor (GR) and, consequently, the action of glucocorticoids (GCs). Cortisol excess in Cushing's syndrome (CS) is associated with a complete loss of clock gene rhythmicity and reduced clock gene BMAL1 acrophase; therefore, the current study aimed at investigating the BMAL1 potential impacton GCs negative feedback on pituitary corticotroph cells. A wild-type murine corticotroph cell line, AtT20^{WT}, and AtT20 BMAL1 knockout (AtT20^{KO}), by CRISPR-Cas9, were used. GR, BMAL1, FKBP5, FKBP4 and POMC protein expression were evaluated by western blot (WB) in both cell models treated with or without dexamethasone 10^{-7}M (DEX) for 6 h and 24 h. Bioinformatic analysis predicted miRNAs targeting BMAL1, and concomitantly, the expression of these potential miRNAs was analyzed by RT-qPCR in both cell models treated with or without DEX and in 17 CS patients and 17 healthy subjects. AtT20^{KO} exhibited FKBP4 (91.2%, $P=0.04$ and FKBP5 (346%, $P=0.002$) higher expression compared to AtT20^{WT}. Interestingly, in AtT20^{WT}, DEX induced GR lower expression (52.2%, $P=0.01$) at 6 h, and FKBP5 higher expression (134%, $P=0.03$) and POMC lower expression (65.5%, $P=0.01$) at 24 h compared to untreated cells, while in AtT20^{KO} DEX effect on FKBP5 and POMC was lost and only lower expression of GR was observed at 6 h (40.7%, $P=0.005$) and 24 h (29.4%, $P=0.03$). Bioinformatic analysis revealed that miR-27a-3p and miR-27b-3p might target BMAL1. miR-27a-3p and miR-27b-3p circulating levels resulted upregulated in CS patients compared to healthy subjects ($P<0.0001$ respectively). AtT20^{KO} expressed miR-27b-3p lower levels ($P=0.03$) compared to AtT20^{WT}. Notably, 24 h DEX increased miR-27b-3p ($P=0.02$) in AtT20^{WT} but not in AtT20^{KO}. Even POMC could be a target of miR-27. Accordingly, AtT20^{WT} treated with 24 h DEX almost completely reduced POMC protein expression, but this effect was reverted when miR-27a-3p and miR-27b-3p inhibitors were added to DEX. In conclusion, these results added a small piece to the physiological knowledge by unveiling a new mechanism of negative feedback regulation of HPA at the pituitary level where BMAL1 expression allows DEX to increase miR-27b-3p levels, which in turn reduces POMC expression.

Cushing's disease (CD) is a rare disease caused by adrenocorticotropic hormone (ACTH) secreting pituitary tumors. Recurrent mutations in *USP8* have been identified as drivers of tumorigenesis in about 40% of cases. However, their direct impact at molecular level remains largely unknown. Therefore, our aim was to unveil the effect of USP8 mutations at chromosomal, genomic, transcriptomic and proteomic levels in patients' material. We gathered 26 cryo- and 90 formalin-fixed paraffin-embedded (FFPE) tumors from patients with CD and normal pituitaries (3 cryo, 10 FFPE). Mutational status was determined using Sanger sequencing. Chromosomal and genomic changes were studied using whole exome sequencing (WES) and shallow whole genome sequencing (sWGS). Transcriptomic changes were investigated using NanoString® nCounter® RNA analysis and single-nucleus RNA sequencing (snRNA-seq.). Protein expression was evaluated using immunohistochemistry. WES and sWGS identified low copy number variation (CNV) levels for *USP8* mutated tumors whereas *USP8* WT tumors showed variable CNV with higher CNV levels associated with higher recurrence rates. Immunity targeted nCounter® analysis revealed higher expression of inflammation and immune response transcripts in *USP8* wild type (WT) tumors. Consistently, snRNA-seq. confirmed enhanced percentage of T-cells in WT tumors and showed complement activation and higher protein secretion in corticotropes of *USP8* mutated tumors. Furthermore, *USP8* mutated tumors contained higher percentage of corticotropes in G2M and S cell cycle phases compared to WT tumors and normal anterior pituitaries. Interestingly, protein expression analysis revealed weaker staining of Prostaglandin E receptor PTGER4 and growth arrest regulator GADD45B in *USP8* mutated tumors, further indicating differences in cell proliferation. Higher staining of ubiquitin-like modifier SUMO1 and secreted protein Osteopontin were found in both tumor groups compared to normal anterior pituitaries, indicating converging roles in tumor progression. Surprisingly, no significant differences of galanin (GAL) and ACTH staining could be found between the tumor groups, however there was a positive correlation between GAL and ACTH solely in *USP8* mutated tumors ($r=0.411$, $P=0.03$). In addition, stronger staining of corticotroph marker TBX19 was found in *USP8* mutated tumors. As both GAL and TBX19 are known regulators of ACTH expression, these findings indicate distinct mechanisms of ACTH regulation in CD tumors based on mutational status, despite similar tumor ACTH levels. To conclude, our study presents extensive insights into Cushing's disease, highlighting higher genomic stability and cell proliferation in *USP8* mutated tumors, higher immune reaction in *USP8* WT tumors and differences in ACTH excess regulation based on mutational status.

Autoimmune diseases in 30,340 Danish women with polycystic ovary syndrome (PCOS) before and after PCOS diagnosis and in 151,520 controls. A national cohort study

Dorte Glintborg[1], Jens-Jakob Møller[1], Katrine Rubin[1], Louise Lehmann Christensen[1] & Marianne Andersen[1]
[1]Odense University Hospital, University of Southern Denmark, Odense, Denmark

Objective
Autoimmunity could be part of the pathogenesis of polycystic ovary syndrome (PCOS), but data regarding risk of autoimmune diseases in population based cohorts are limited.

Aim
To investigate incidence rates of autoimmune diseases in Danish women with PCOS before and after PCOS diagnosis compared to controls.
Design
National register-based study in Danish women with PCOS (PCOS Denmark, $n=30,340$) and age-matched controls ($n=151,520$). Type 1 diabetes, thyroid disease or other autoimmune diseases were study outcomes (defined by ICD10 diagnosis and/or medical treatment for type 1 diabetes or thyroid disease). Baseline was the date for PCOS diagnosis.
Results
The median age at PCOS diagnosis was 28 years (interquartile range (IQR) 23; 35). Before baseline (mean risk time 11.4 years), the incidence rate of type 1 diabetes (IRR = 2.18 (1.33; 3.55), thyroid disease (IRR = 1.81 (1.68; 1.96) and other autoimmune disease (IRR = 1.12 (1.03; 1.22) was significantly higher in women with PCOS compared to controls (all $P<0.001$). In PCOS, the prevalence of T1D before baseline was 0.09%, thyroid disorder 3.25% and other autoimmune disease 2.6%. The mean risk time after the index date was 9.8 years. After baseline, the incidence rate of type 1 diabetes (IRR = 3.41 (3.02; 3.86), thyroid disease (IRR = 1.49 (1.41; 1.59) and other autoimmune disease (IRR = 1.13 (1.04; 1.22) was significantly higher in women with PCOS compared to controls (all $P \leq 0.003$).
Conclusion
The incidence rate of autoimmune disease was higher in women with PCOS compared to controls before and after PCOS diagnosis.

PCOS-like hyperactivity in the reproductive axis following arcuate nucleus-specific progesterone receptor knockdown

Kelly Glendining[1], Melanie Prescott[1], Kyoko Potapov[1] & Rebecca Campbell[1]
[1]University of Otago, Department of Physiology and Centre for Neuroendocrinology, Dunedin, New Zealand

Mammalian reproduction and fertility rely on gonadal steroid hormone feedback within the hypothalamic-pituitary-gonadal (HPG) axis. In polycystic ovary syndrome (PCOS), diminished sensitivity to progesterone negative feedback contributes to impaired reproductive function, leading to increased pulsatile release of gonadotropin-releasing hormone (GnRH) and luteinizing hormone (LH). Although the precise mechanisms underlying progesterone negative feedback in the HPG axis remain unclear, both clinical and preclinical evidence suggest that progesterone signalling through progesterone receptors (PR) in the arcuate nucleus of the hypothalamus (ARC), and potentially GABAergic neurons, plays a key role. To pinpoint the critical site of progesterone negative feedback, we investigated whether selectively disrupting progesterone sensitivity in the ARC of adult females or in all GABA neurons from birth is sufficient to induce HPG axis hyperactivity. To disrupt PR in the ARC, bilateral injections of AAV-Cre or AAV-control were stereotaxically injected into the ARC of adult transgenic $PR^{fl/fl}$ mouse. To knock out (KO) PR in GABAergic neurons, $PR^{fl/fl}$ mice were crossed with vesicular GABA transporter (VGAT)-Cre mice to generate GABA-specific PRKOs. Immunohistochemistry was used to assess viral targeting and site/ cell-specific loss of PR. Vaginal cytology was monitored for 14 days before and 4 weeks after Cre-mediated PR knockdown and for 3 weeks in adult GABA-specific PRKOs. Lutienizing hormone (LH) pulsatility was assessed in serial blood samples by ELISA and analysed with Pulsar software. PR expression in the ARC of AAV-Cre injected animals was significantly reduced in comparison to controls ($P>0.001$) and PR expression was completely absent from VGAT+ neurons in GABA-specific PRKOs. PR knockdown specific to the ARC was found to significantly decrease estrous cycle frequency ($P>0.001$), increase cycle length ($P>0.01$), and reduce time spent in proestrus ($P>0.01$). ARC-specific PR knockdown also increased LH pulse frequency in comparison to controls ($P<0.05$). In contrast, although GABA-specific PRKOs demonstrated delayed first estrous ($P<0.05$) and decreased estrous cycle frequency ($P>0.001$), there were no significant differences in LH pulse parameters from controls. Using these different transgenic approaches, we have demonstrated that although GABA-specific PRKO does not impact LH pulse frequency, knockdown of PR exclusively in the ARC in adulthood is sufficient to drive LH hypersecretion and mimic other reproductive impairments common to PCOS. Together, this work supports neurons in the ARC as the critical site for progesterone negative feedback regulation of the reproductive axis.

Building 3D ovaroids to understand mechanisms of human ovary formation and its pathologies

Maeva Elzaiat[1], Somboon Wankanit[1,2], Laurene Schlick[1], Pierre-Henri Commere[1], Ken McElreavey[1] & Anu Bashamboo[1]
[1]Institut Pasteur, Paris, France; [2]Mahidol University, Department of Pediatrics, Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand

Background
Sex-determination (SD) is defined as differentiation of the bipotential anlage into either testes or ovaries. The gene networks and mechanisms involved in the cell fate decision that direct the precursor somatic cells to commit to either Sertoli (testis) or granulosa cells (ovary) in the human are poorly understood, in part, due to a lack of evolutionary conservation and the absence of a suitable *in-vitro* model.
Material and methods
Using only defined culture media, we have developed robust protocols to sequentially differentiate human XX iPSCs to granulosa-like cells (iGLCs) and primordial germ cell-like cells (PGCLCs).
Results
During differentiation lineage appropriate markers are expressed, with terminally differentiated cells expressing those for primary follicle (e.g. *FOXL2*, *RSPO1*) even in prolonged culture (>2 months), suggesting that they are *bona fide* ovarian somatic cell precursors. We also derived primordial germ cell-like cells (PGCLCs) from iPSCs, defined by expression of *SOX17*, *BLIMP1*, *TFAP2C* and *NANOS3*. To generate 3D ovarian organoids (ovaroids) we have co-cultured *in-vitro* derived PGCLCs with iGLCs to evaluate their ability to reconstitute follicular structures and development associated with primordial germ cell differentiation towards oogonia. Using genome editing, we are using this system to introduce variants we previously defined as causing *SRY*-negative 46,XX testicular or ovotesticular Disorders/Differences in Sex Development (e.g. NR5A1, NR2F2).
Conclusion
Ovaroids provide an infinite and powerful supply of material to define the mechanisms involved in directing and maintaining cellular identity in human gonadal cells. This system will lead to a better understanding of factors and mechanisms involved in human ovary formation and a wide range of ovarian pathologies, including infertility.

The effect of intranasal insulin on post prandial thermogenesis in obese women with and without polycystic ovary syndrome

Colin Duncan[1], Yuan Wang[1], Riada McCredie[1], Stephen Franks[2], Paul Fowler[3], Roland Stimson[1], Mick Rae[4,5] & Katarzyna Siemienowicz[4]
[1]The University of Edinburgh, Centre for Reproductive Health, Edinburgh, United Kingdom; [2]Imperial College, London, United Kingdom; [3]The University of Aberdeen, Aberdeen, United Kingdom; [4]Edinburgh Napier University, Edinburgh, United Kingdom; [5]Edinburgh Napier University, School of Applied Sciences, Edinburgh, United Kingdom

Polycystic ovary syndrome (PCOS) is a lifelong condition associated with reproductive and metabolic consequences. Obesity worsens PCOS and women with PCOS are more likely to be obese and find weight loss difficult. Women with PCOS have a reduced adaptive thermogenesis response to food meaning they don't burn off as many calories after eating. Previous studies conducted in a clinically realistic large animal model highlighted that this is due to a centrally-regulated defect in subcutaneous adipose tissue function. These studies have also suggested intranasal insulin (INI) as a novel therapeutic strategy with the hypothesis that it could help obese women with PCOS to regulate their metabolism and lose weight. This research was conducted as part of a single site basic experimental study looking at the effect of INI on postprandial energy expenditure (PPEE) in obese women with and without PCOS. Obese women with PCOS ($n=12$), and obese controls without PCOS ($n=12$) were fed a standard meal on two occasions with either intranasal saline placebo or 40iu INI in a random and blinded manner. A subset of PCOS patients ($n=6$) also underwent a third linked visit with 80iu INI to determine if there was a dose-response. The effect of INI on PPEE was assessed by indirect calorimetry. Area under the curve (AUC) of PPEE was used for statistical analysis. With 40iu INI participants with PCOS had significantly

greater postprandial energy (AUC 1580±166) expenditure than with saline placebo (AUC 1079±227), measured as a change in PPEE over time per kg of body fat ($P<0.05$). Within the subset group 80iu INI (AUC 1972±94) also caused a significant increase in PPEE vs saline placebo ($P<0.01$). There was a dose-response with 80iu INI increasing PPEE more than 40iu INI ($P<0.05$). In obese control women without PCOS 40iu INI (AUC 1314±154) had no effect in PPEE when compared to control (AUC 1393±173). There were no adverse effects on blood glucose concentrations. These results suggest proof of concept and provide additional safety data for INI in the improvement of PPEE in obese women with PCOS. There is still an unmet clinical need for accessible and cost-effective weight management treatment for patients with PCOS and this strategy warrants further investigation with proof of efficacy studies.

Gonadotropin rise following intranasal kisspeptin administration is heightened in women with hypothalamic amenorrhoea compared to healthy women

Edouard G Mills[1,2], Jovanna Tsoutsouki[1], Layla Thurston[1], Maria Phylactou[1,2], Bijal Patel[1], Lisa Yang[1], Sophie Clarke[1,2], Megan Young[1], Emma Alexander[1], Sandhi Nyunt[1], Arthur Yeung[1], Muhammad Choudhury[1], Anastasia Newman[1], Paul Bech[1], Ali Abbara[1,2], Magda Swedrowska[3], Ben Forbes[3], Alexander Comninos[1,2] & Waljit Dhillo[1,2]

[1]Imperial College London, Section of Endocrinology and Investigative Medicine, London, United Kingdom; [2]Imperial College Healthcare NHS Trust, Department of Endocrinology, London, United Kingdom; [3]King's College London, Institute of Pharmaceutical Science, London, United Kingdom

Background

Kisspeptin administration by *intravenous* or *subcutaneous* routes activates hypothalamic GnRH neurons to stimulate downstream reproductive hormone release and is under rapid development for treating common reproductive disorders, including hypothalamic amenorrhoea (HA). However, these invasive routes limit patient acceptability and clinical use. Intranasal offers a novel non-invasive delivery route, which would be clinically preferable to patients and clinicians. Herein, we compare the reproductive endocrine responses following *intranasal* kisspeptin administration in healthy women to women with HA.

Methods

Randomised, double-blinded, placebo-controlled, crossover study in 12 healthy (ovulatory) women during the follicular phase (mean age±SEM 22.1±0.9 yrs, BMI 22.1±0.8 kg/m^2) and 10 women with HA (age 25.8±2.7 yrs, BMI 19.9±1.3 kg/m^2). After intranasal administration of kisspeptin-54 (12.8 nmol/kg) or 0.9% saline (placebo), reproductive hormones were measured every 15 minutes for 4 hours. Groups were compared by unpaired t-tests.

Results

Intranasal kisspeptin-54 administration rapidly and robustly stimulated gonadotropin release in both study groups, without any side effects or adverse events encountered. However, LH and FSH release were significantly augmented in women with HA, compared to healthy women: mean area under the curve (AUC) for the change in LH across 4 hours 96.0±45.8 h·IU/litre (healthy women) vs. 600.6±146.7 h·IU/litre (women with HA) ($P=0.002$). Consistently, mean AUC for the change in FSH was -36.1±23.4 h·IU/litre (healthy women) vs. 474.9±237.3 h·IU/litre (women with HA) ($P=0.02$). The mean maximal increase in LH following kisspeptin-54 was over three-fold greater in women with HA at 4.4±0.2 IU/l vs. 1.4±0.3 IU/l in healthy women ($P<0.001$). Similarly, the mean maximal increase in FSH was over ten-fold greater in women with HA at 3.1±0.3 IU/l vs. 0.3±0.1 IU/l in healthy women ($P=0.03$).

Summary

Intranasal kisspeptin robustly stimulates reproductive hormone release in healthy women, with an even greater stimulation in women with HA. Therefore, intranasal kisspeptin offers not only a novel, effective, safe, and non-invasive route of administration for the management of reproductive disorders but also a potential simple diagnostic test to interrogate hypothalamic function and identify women with HA.

Bone mineral density and biochemical parameters after one year of treatment with denosumab or zoledronate in postmenopausal women with osteoporosis and primary hyperparathyroidism: a pilot study

Katarina Mlekus Kozamernik[1], Luka Ležaić[2], Marko Hočevar[3] & Tomaž Kocjan[1]

[1]UMC Ljubljana, Faculty of Medicine, University of Ljubljana, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia; [2]UMC Ljubljana, Faculty of Medicine, University of Ljubljana, Department of Nuclear Medicine, Ljubljana, Slovenia; [3]Institute of Oncology, Faculty of Medicine, University of Ljubljana, Department of Surgical Oncology, Ljubljana, Slovenia

Background

Optimal medical treatment of postmenopausal women with osteoporosis and primary hyperparathyroidism (PHPT) who decline surgery has not been determined. We compared the therapeutic effects of denosumab or zoledronate in this population.

Methods

Postmenopausal women with osteoporosis and PHPT were randomized 1:1 to treatment with either denosumab 60 mg sc every six months (DMAB group) or zoledronate 5 mg iv once a year (ZOL group) (ClinicalTrials.gov Identifier NCT04085419). Bone mineral density (BMD) at four standard sites and trabecular bone score (TBS) were measured by DXA at baseline and after twelve months (12M). Serum calcium (S-Ca), intact parathyroid hormone (iPTH), and bone turnover markers (C-terminal telopeptide (CTX), N-terminal propeptide of type I procollagen (PINP), and bone-specific alkaline phosphatase (BAP)) were determined at baseline, 3M, 6M, and 12M.

Results

Forty females (aged 73.0 (7.8 SD) years; 22.6 (10.0) years from menopause; BMI 27.77 (5.1) kg/m^2) were included. After one year of treatment, LS BMD was significantly and similarly higher in both groups (LS BMD 12M ΔDMAB +0.038 g/cm^2; $P<0.001$ and ΔZOL +0.040 g/cm^2; $P=0.003$). TH BMD was significantly higher only in the DMAB group (TH BMD 12M ΔDMAB +0.036 g/cm^2; $P=0.006$), while FN and 1/3R BMD did not change. All patients together had significantly higher TBS (ΔTBS 12M +0.066; $P=0.016$). There was a statistically significant decrease of 3M S-Ca in both groups (S-Ca 3M ΔDMAB -0.07 mmol/l; $P=0.045$, ΔZOL -0.08 mmol/l; $P<0.01$). The iPTH level increased significantly in both groups at 3M, remained high at 6M, and slowly decreased thereafter, with no statistically significant difference between the groups (iPTH 3M ΔDMAB +61.91 (126.93); $P=0.042$ vs. ΔZOL +30.24 (56.84) ng/l; $P=0.003$). CTX, PINP, and BAP decreased significantly in both groups at 3M (CTX 3M ΔDMAB -0.952 (0.639) vs ΔZOL -0.556 (0.439) µg/l; $P=0.03$; PINP 3M ΔDMAB -75.45 (33.9) vs ΔZOL -54.06 (32.06) µg/l; $P=0.003$; BAP 3M ΔDMAB -19.72 (8.12) vs ΔZOL -13.68 (9.55) µg/l; $P=0.685$), and remained low and unchanged thereafter. CTX and PINP at 3M were significantly lower in DMAB group.

Conclusion

One year of denosumab or zoledronate had similar effects on BMD and TBS in postmenopausal women with osteoporosis and PHPT. The effects on S-Ca, iPTH at 3M were also comparable between treatments. Denosumab had a more potent short-term effect on decreasing bone turnover than zoledronate.

Diagnostic performance of parathyroid 4d-ct in men1 syndrome-associated primary hyperparathyroidism

Anima Sharma[1], Nivedita Chakrabarty[2], Virendra Patil[1], Hemangini Thakkar[1], Padma Badhe[1], Mahadeo Garale[1], Saba Memon[1], Anurag Lila[1], Manjiri Karlekar[1], Rohit Barnabas[1], Ketki Ambulkar[1] & Tushar Bandgar[1]

[1]Seth G.S. Medical College and King Edward Memorial Hospital, Mumbai, India; [2]Tata Memorial Centre, Homi Bhabha National Institute, Mumbai, India

Background

In multiple endocrine neoplasia type 1 (MEN1) related primary hyperparathyroidism (PHPT), recognition of asynchronous parathyroid involvement has led to

consideration for targeted surgical approaches that require accurate preoperative localization modalities. However, data on parathyroid 4-dimensional computed tomography (4D-CT) in this context remains sparse.
Objectives
To assess 4D-CT diagnostic performance in MEN1 PHPT and report outcomes of parathyroidectomy where surgical extent was tailored as per the CT findings.
Study setting
Retrospective study in an endocrine referral center where 4D-CT is routinely used as first-line imaging for parathyroid localization.
Methods
CT scans of MEN1 PHPT patients from Jan 2008–Dec 2022 (20% clinical, 80% genetic diagnosis) were independently reviewed by two radiologists (15 & 11 years of experience) aware of MEN1 but blinded to original radiology reports, clinical/surgical details, histopathology, and outcomes. The per-patient analysis comprised the entire cohort. The per lesion analysis was limited to operated patients and used pathology/surgical outcome as the gold standard.
Results
Among 60 MEN1 PHPT patients, 43% were symptomatic and 93% had hypercalcemia at the time of CT (median calcium 11.7 mg/dl, PTH 248 pg/ml). The per-patient analysis included 61 4D-CT scans (53 previously unoperated, 8 for persistent/recurrent PHPT). The original report and radiologists identified abnormal glands in 96.7-100% of patients (mean 2.25 lesions per patient in unoperated, 1.71 in persistent/recurrent). In the per lesion analysis ($n=33$), 4D-CT had 85-89.5% sensitivity and 90-94% specificity, outperforming ultrasonography and Sestamibi scan ($P<0.001$ for both). There was good inter-observer agreement on CT for lesion quadrant localization in the overall cohort and operated subgroup (Cohen's kappa 0.64-0.91). In 24/33 patients, only CT-identified abnormal glands were resected, while glands not seen on CT were left unexplored (imaging-guided group). The remaining 9 had bilateral neck exploration (BNE) with subtotal/total parathyroidectomy and autotransplantation, regardless of CT findings. Both imaging-guided and BNE groups had similar baseline characteristics and number of lesions identified per patient on 4D-CT. The imaging-guided group had more adenomas and fewer hyperplasia (35% vs. 64%; $P<0.001$) and normal glands (2% vs. 17%; $P=0.01$) on pathology than BNE. Despite resecting fewer glands per patient ($P<0.001$), the imaging-guided group had comparable remission (91.7% vs 100%) and recurrence rates (9.5% vs 0%; $P=1.00$) to the BNE group over similar follow-up duration, with lower permanent hypoparathyroidism (4 vs. 44%; $P=0.01$).
Conclusion
4D-CT demonstrated good diagnostic performance and facilitated favorable operative outcomes in MEN1 PHPT, supporting its role in planning surgical extent.

JOINT1912

The prevalence of neurodevelopmental disorders in a large UK cohort of children with achondroplasia

Megan Baxter[1,2], Melita Irving[1], Sophie Emery[1], Johnathan Gibbins[1], Robyn Gilbey-Smith[1], Kathryn Johnson[1], Kathryn Philips[1], Naomi Pibworth[1], Emma Snow[1], Paul Watson[1], Alessandra Cocca[1] & Rhoda Akilapa[1]
[1]Guy's and St Thomas' Hospital, London, United Kingdom; [2]Center for Human Genetics, Oxford University, Oxford, United Kingdom

Objective
This project aims to better understand the rates of developmental delay and neurodevelopmental disorders in patients with achondroplasia. Achondroplasia is the most common genetic cause of short stature world-wide and is associated with a range of skeletal abnormalities and resultant chronic sequalae. Due to anthropomorphic differences, the developmental profile in achondroplasia is unique, particularly in the area of gross motor skills, with skills such as independent sitting and walking often being achieved later than other children. Achondroplasia it is not thought to be associated with neurodevelopmental abnormalities. It is noteworthy however that other conditions caused by variants in same gene (*FGFR3*) are associated with higher rates of neurodevelopmental abnormalities. There is also increasing anecdotal evidence of higher rates of neurodevelopmental disorders in achondroplasia patients. This relationship is however poorly explored and warrants further assessment.
Methods
Retrospective developmental milestones and neurodevelopmental data was collected from all individuals with a diagnosis of achondroplasia seen in the specialist achondroplasia clinic at the Evelina London Children's Hospital. Data regarding additional procedures and diagnosis was also collected. Developmental data was compared to the gold standard achondroplasia development charts (*Ireland et al*), using the 90th percentile cut-off for delays. Neurodevelopmental disorder rate, in particular Autism, ADHD and Special Education Needs in this cohort was compared to population prevalence.
Results
In this study, data from 240 children with achondroplasia was included. In total 52 children (21.6%) had a delay in one or more developmental domains with respect to achondroplasia milestones. Looking at specific milestones (Independent walking and first word), the proportion greater than the 90th centile cut-off for delay was not statistically different to that seen in the Australian cohort assessed by Ireland *et al*. When assessing neurodevelopmental disorders, statistically higher rates of autism (Bonferroni corrected $P=0.0032$) were seen in this cohort when compared to population prevalence. When assessing the rates of special education needs, the cohort as a whole did not have higher rates of special education needs compared to population prevalence. When specifically assessing those with a developmental delay there was a higher rate of long term special education needs when compared to population prevalence (Bonferroni corrected $P=0.031$).
Conclusions
This large cohort provides valuable insights into the extent of developmental delay and neurodiversity in achondroplasia patients. It offers further evidence of increased neurodevelopmental disorders, particularly autism, and highlights a potential link between early developmental delays and long-term special education needs in Achondroplasia patients.

Long-term height gain and maintenance of treatment effect in children with achondroplasia receiving vosoritide

Julie Hoover-Fong[1], Melita Irving[2], Paul Harmatz[3], Carlos Bacino[4], Ian Sabir[5], Hai Liu[6], Richard Rowell[6], Neil Lyon[5], Alice Huntsman Labed[5] & Ravi Savarirayan[7]
[1]John Hopkins University, Baltimore, United States; [2]Guy's and St. Thomas' NHS Foundation Trust, Evelina Children's Hospital, London, United Kingdom; [3]UCSF Benioff Children's Hospital Oakland, Oakland, United States; [4]Baylor College of Medicine, Houston, United States; [5]BioMarin (UK) Ltd, London, United Kingdom; [6]BioMarin Pharmaceutical Inc., Novato, United States; [7]Murdoch Children's Research Institute, Royal Children's Hospital, and University of Melbourne, Melbourne, Parkville, Australia

Achondroplasia (ACH) is a common form of disproportionate short stature caused by impaired endochondral bone growth. Vosoritide, a recombinant C-type natriuretic peptide, stimulates endochondral bone growth and is approved in 42 countries for children with ACH until the closure of epiphyses. Here, we demonstrate the effect of long-term vosoritide treatment on sustained annualized growth velocity (AGV) and estimate height gain compared to untreated children with ACH if vosoritide treatment was continuous from age 6 months until final adult height (FAH). Pooled mean AGV (cm/year) by integer age and sex while on treatment is reported from the phase 3 study 111-301 (NCT03197766) and its ongoing long-term extension (LTE) 111-302 (NCT03424018) and the phase 2 study 111-206 (NCT03583697) and its ongoing LTE 111-208 (NCT03989947). Study 111-301 evaluated 15 μg/ kg/day vosoritide in children with ACH aged ≥ 5 to <18 years at screening until FAH, and 111-206 evaluated 30 and 15 μg/ kg/day vosoritide in children with ACH from 4 months to <5 years until near-FAH. Untreated data from CLARITY served as an external ACH control population. Interval AGV for 6 ± 1 and 12 ± 3 months were derived from paired height assessments from age 4 months to 3 years and age 3 years to FAH, respectively. The midpoint of the 2 height assessments determined the associated age to summarize AGV. Total height gain was derived by subtracting the difference in AGV between the treated and untreated population per age. Confidence intervals (CIs) were estimated by bootstrap methods. By the data cutoff (February 25, 2024), mean treatment follow-up in 192 total participants was 4.7 (range, 1.8-7.1) years for those from 111-302 ($n=119$) and 3.8 (range, 1.1-5.7) years for those from 111-208 ($n=73$). Both studies provided mean AGV (95% CI) estimates at ages 5-9 years; CIs overlapped with no trend whether treatment started before or after age 5 years. Given these analyses, expected estimated height gain for children with ACH if continuously treated from 6 months to FAH was 21.7 cm (95% CI, 18.7-24.6) in females and 26.4 cm (95% CI, 22.9-29.8) in males compared to untreated children. In these results from the longest follow-up of a phase 3 study of children with ACH, vosoritide treatment sustained increases in AGV. For the first time, we predict total height gain for children with ACH if they

were to be treated continuously with vosoritide from age 6 months to FAH compared to untreated children.

Background

In children with achondroplasia (ACH), morphometric changes in the spine and lower extremities are associated with a range of orthopaedic and neurological complications. Increased rates of thoracolumbar kyphosis, lumbar lordosis, stenosis of the spinal canal, and genu varum may lead to pain, altered mobility, and the need for orthopaedic surgery. Navepegritide is an investigational prodrug of C-type natriuretic peptide (CNP), administered by subcutaneous injection once weekly and designed to provide a low Cmax through sustained release of active CNP. Continuous exposure to the released CNP stimulates natriuretic peptide receptor B (NPR-B) to counteract the constitutively active fibroblast growth factor receptor 3 (FGFR3) in ACH. We report radiographic findings from ApproaCH, a pivotal randomized, double-blind, placebo-controlled trial evaluating navepegritide in children with ACH.

Methods

Participants ($n=84$, aged 2-11 years) were stratified by age and sex and randomized 2:1 to receive navepegritide (100 µg/ kg/week) or placebo. The primary endpoint was annualized growth velocity (AGV) at week 52. Bone morphometry parameters were exploratory endpoints assessed by blinded central readers using spine and lower extremity radiographs, with data expressed as changes from baseline at week 52.

Results

Navepegritide demonstrated superiority over placebo in AGV at Week 52, with a least square (LS) mean AGV of 5.89 cm/year in children treated with navepegritide vs. 4.41 cm/year with placebo (LS mean treatment difference 1.49 cm/year [$P<0.0001$]). Safety and tolerability were comparable between treatment groups. Spinal canal dimensions were numerically improved with navepegritide compared to placebo across L1-L5, with a significant increase from baseline observed for interpedicular distance at L1 (LS mean difference of 0.618 mm, $P=0.0222$). No statistically significant changes were observed in thoracolumbar kyphosis or lumbar lordosis. Compared to placebo, navepegritide significantly reduced tibia femoral angle (LS mean difference of -1.814 degrees, $P=0.0094$) and mechanical axis deviation in the lower limbs (LS mean difference of -2.781 mm, $P=0.0063$). These changes corresponded to a normalization in fibular overgrowth, considered the key cause of leg bowing, as reflected in the reduced fibula-to-tibia ratio (LS mean difference of -0.016, $P=0.0001$).

Conclusion

In the ApproaCH trial, weekly administration of navepegritide demonstrated superiority over placebo in AGV and improved aspects of bone morphometry in children with ACH. These findings highlight that the design of navepegritide, which provides continuous exposure to active CNP, may deliver benefits that go beyond promoting linear growth – actively targeting and addressing critical aspects of skeletal dysplasia in ACH, which are key contributors to health-related complications.

JOINT1839

Hippocampal malrotation and transverse temporal sulcus abnoramlities: sensitive and specific neuroradiological markers of hypochondroplasia

Ruggero Lanzafame[1] , Felice D'Arco[2], Alessandra Cocca[3] & Moira Cheung[1]

[1]Great Ormond Street Hospital for Children NHS Foundation Trust, Pediatric Endocrinology Department, London, United Kingdom; [2]Great Ormond Street Hospital for Children NHS Foundation Trust, Neuroradiology Department, London, United Kingdom; [3]Evelina London Children's Hospital, Pediatric Endocrinology Department, London, United Kingdom

Introduction

Hypochondroplasia (HCH), caused by pathogenic variants in *FGFR3*, presents significant diagnostic challenges due to its phenotypic variability and subtle radiological findings. MRI findings, particularly hippocampal malrotation and abnormalities of the transverse temporal sulcus, have been identified as being more prevalent in conditions secondary to pathogenic variations in *FGFR3*, such as HCH. Hippocampal malrotation has a reported prevalence of 15-20% in the general population, and is more frequently observed in the left hemisphere (20%) than in the right (9%). We hypothesized that hippocampal malrotation and transverse temporal sulcus abnormalities are more common in HCH compared to the general population, and therefore could be helpful in the diagnostic workup of children with short stature.

Methods

A cohort of 29 children with genetically confirmed HCH was included in this study, involving Great Ormond Street Hospital and Evelina London Children's Hospital. Their high-resolution brain MRIs were anonymised and randomized with a cohort of 29 age-matched controls with short stature and suspected growth hormone deficiency. Two neuroradiologists (of 15 and 5 years' experience) were asked to separately assess the MRIs for hippocampal malrotation and transverse temporal sulcus abnormalities for each hemisphere. Significant differences from the age-matched cohort were calculated, and sensitivity and specificity in identifying HCH were evaluated. Inter-rater reliability was assessed using Cohen's kappa.

Results

The findings for each hemisphere in the HCH and age-matched control cohort are presented in the table. Overall, transverse temporal sulcus abnormalities showed the highest sensitivity and specificity in identifying children with HCH. Chi-squared test showed a significant association between hippocampal malrotation, transverse temporal sulcus abnormalities and HCH. Excellent inter-rater reliability was observed in evaluating hippocampal malrotation (Cohen's kappa: 0.83 right, 0.76 left) and transverse temporal sulcus abnormalities (Cohen's kappa: 0.93 right, 0.96 left).

	HCH % (*n*)	Age Matched Cohort % (*n*)	Sensitivity	Specificity	χ^2 (*P* value)
Hippocampal malrotation (Right)	86% (25/29)	10% (3/29)	89%	86%	33.42 (<0.05)
Hippocampal malrotation (Left)	90% (26/29)	14% (4/29)	86%	89%	33.42 (<0.05)
Transverse temporal sulcus abnormalities (Right)	97% (28/29)	3% (1/29)	96%	96%	50.27 (<0.05)
Transverse temporal sulcus abnormalities (Left)	97% (28/29)	7% (2/29)	93%	96%	46.68 (<0.05)

Conclusions

Our novel findings suggest that transverse temporal sulcus abnormalities and hippocampal malrotation are highly sensitive and specific biomarkers and may be important in the diagnosis HCH, especially in cases where skeletal findings are ambiguous. Future studies should explore whether these findings could also be useful for prenatal diagnosis through foetal imaging.

Sustained normalization of mineral homeostasis in autosomal dominant hypocalcemia type 1: results from a phase 2 study over 42 months of encaleret (cltx-305) treatment

Rachel Gafni[1], Iris Hartley[1], Kelly Roszko[1], Edward Nemeth[2], Karen Pozo[1], Rita Meadows[1], Elizabeth Ferguson[1], Arun Mathew[3], Mary Scott Roberts[3], Scott Adler[3] & Michael Collins[4]

[1]National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, United States; [2]MetisMedica, Toronto, Canada;

[3]Calcilytix Therapeutics, Inc., San Francisco, United States; [4]Consultant, Washington, DC, United States

Autosomal dominant hypocalcemia type 1 (ADH1), due to activating calcium-sensing receptor gene (*CASR*) variants, manifests as low PTH, hypocalcemia, hypercalciuria, hyperphosphatemia and hypomagnesemia. Calcium and active vitamin D treatment worsens hypercalciuria, which may induce renal complications. Calcilytics are negative allosteric modulators of the calcium-sensing receptor that decrease its sensitivity to extracellular calcium and normalize biochemical abnormalities in ADH1 mice. This Phase 2b open-label study (NCT04581629) of the oral investigational calcilytic encaleret included 2 5d inpatient periods followed by a 24W outpatient period and a long-term extension (LTE). Conventional therapy was stopped prior to encaleret initiation. After about 18 months in the LTE, participants continued encaleret in the Phase 3 LTE (NCT05680818). Thirteen adults with ADH1 received encaleret individually titrated to normalize albumin-corrected calcium (cCa). Encaleret was well-tolerated. There were 2 unrelated serious adverse events during the LTE: chest pain and post-surgical pain. There were no treatment discontinuations/withdrawals prior to the LTE. Mean ± SD values taken pre-dose at P3W24 and LTEM36 compared to baseline (BL) are presented. PTH was low at BL (6.3 ± 7.8 pg/ml [nl 10-65]) and normal at P3W24 (35.3 ± 10.2) and LTEM36 (23.7 ± 16.8 [$P < 0.01$]). Similarly, hypocalcemia at BL (cCa = 7.1 ± 0.4 mg/dl [nl 8.4-10.2]) had normalized at P3W24 (9.0 ± 0.5) and LTEM36 (9.0 ± 0.3 [$P < 0.01$]). BL hypercalciuria (395 ± 216 mg/d [nl <250-300]) normalized to 202 ± 83 at P3W24 and LTEM36 (162 ± 103 [$P < 0.01$]). BL blood phosphate (4.5 ± 1.1 mg/dl [nl 2.3-4.7]) decreased at P3W24 (3.7 ± 0.5) and LTEM36 (3.7 ± 0.7 [$P < 0.05$]). Blood magnesium rose (BL 1.7 ± 0.2 mg/dl [nl 1.6-2.6]); P3W24 2.0 ± 0.2; LTEM36 2.0 ± 0.2 [$P < 0.01$]). Bone turnover markers, adjusted for age, sex, and menopausal status by dividing by the ULN for each participant [nl 0-1], were low at BL and increased at P3W24 and LTEM36 [$P < 0.05$; $P < 0.01$]). Compared with screening, DXA Z-scores had decreased at LTEM24 but then stabilized at LTEM36 ($n = 10$-11). In patients with ADH1, encaleret corrected biochemical abnormalities and increased bone turnover, with stabilization of bone density by 42 months of continuous treatment. These consistent and sustained results are clinically meaningful and support ongoing efficacy and safety evaluation of encaleret as the first potential treatment for ADH1.

	Baseline	P3W24	LTEM12	LTEM24	LTEM36

Differential regulation of phosphate transport in epididymis and prostate: implications for sperm motility in mice and men

Zhihui Cui[1], Sam Yahyavi[1,2], Ida Boisen[1,3], Anne Jørgensen[1], Anders Juul[2,4,5] & Martin Blomberg Jensen[1,4]
[1]Division of Translational Endocrinology, Department of Endocrinology and Internal Medicine, Copenhagen University Hospital - Herlev and Gentofte, Herlev, Denmark, Copenhagen, Denmark; [2]Department of Growth and Reproduction, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark, Copenhagen, Denmark; [3]Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, Copenhagen, Denmark; [4]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark, Copenhagen, Denmark; [5]International Centre for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark, Copenhagen, Denmark

Seminal phosphate concentrations are several folds higher than serum levels in healthy men, which implies an active phosphate transport within the male reproductive system. However, phosphate regulation in the male reproductive organs remains poorly understood. This study investigated the expression profiles of the sodium-phosphate co-transporters (NPT2a, NPT2c, NPT2b, PIT1, and PIT2) and phosphate regulation in the epididymis and prostate using rodent models and human tissues. In rodents, high dietary phosphate intake increased epididymal phosphate transporter expression without affecting epididymal phosphate levels. In contrast, prostatic phosphate concentrations increased with serum phosphate, independent of transporter expression. Human tissues exhibited distinct transporter expression profiles compared to rodents, warranting further investigation. A retrospective analysis of 301 healthy men further demonstrated that high seminal phosphate levels correlated with improved sperm quality and elevated testosterone levels. In conclusion, this study revealed distinct expression profiles of phosphate transporters in the male reproductive organs, with species-specific differences between mice and humans. These findings highlight the distinct phosphate regulation in the epididymis and prostate, underscoring the critical role of phosphate in male reproductive health, particularly its association with sperm quality and testosterone levels. Together, these results provide novel insights into phosphate metabolism in male reproductive function and suggest presence of potential therapeutic targets for addressing male infertility.

[1]Unit of Metabolic Bone and Thyroid Disorders, Fondazione Policlinico Campus Bio-medico, Rome, Italy and Unit of Endocrinology and Diabetes, Campus Bio-medico University, Rome, Italy; [2]McMaster University, Hamilton, Canada; [3]Columbia University, New York, United States; [4]Rigshospitalet, Copenhagen, Denmark; [5]Mayo Clinic, Rochester, United States; [6]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, Italy; [7]Technische Universität Dresden Medical Center, Dresden, Germany; [8]University of Pisa, Department of Clinical and Experimental Medicine, Endocrine Unit, Pisa, Italy; [9]University of Chicago, Chicago, United States; [10]Ascendis Pharma Inc, Palo Alto, United States; [11]Aarhus University Hospital, Aarhus N, Denmark

Background
Hypoparathyroidism is an endocrine disease caused by insufficient levels of parathyroid hormone (PTH). Conventional therapy for hypoparathyroidism (active vitamin D, elemental calcium) aims to alleviate hypocalcemia but does not address insufficient PTH. Palopegteriparatide is a prodrug of PTH (1-34), administered once daily, designed to provide active PTH within the physiological range for 24 hours/day in adults with chronic hypoparathyroidism. It is approved by the EC, MHRA, and FDA. This analysis investigated the long-term efficacy and safety of palopegteriparatide in adults with chronic hypoparathyroidism through week 214 of the PaTH Forward trial.
Methods
PaTH Forward is a phase 2 trial with a 4-week randomized, double-blind, placebo-controlled period, followed by an ongoing open-label extension period. Renal function was assessed by estimated glomerular filtration rate (eGFR). Bone turnover markers C-terminal telopeptide of type 1 collagen (CTx) and procollagen type 1 N-terminal propeptide (P1NP), and bone mineral density (BMD) measured by DXA, were assessed at baseline and regular intervals through week 214. Safety assessments included 24-hour urine calcium and treatment-emergent adverse events (TEAEs).
Results
At week 214, 95% (56/59) of participants remained in the trial; of those, 93% were independent from conventional therapy (no active vitamin D and ≤600 mg/day elemental calcium) and 98% had normal albumin-adjusted serum calcium levels (2.07-2.64 mmol/l) with a mean (SD) of 2.24 (0.10) mmol/l. Mean CTx and P1NP increased from the low end of normal at baseline, peaked by week 26, and declined thereafter and remained stable above baseline levels through week 214. The elevated baseline mean BMD Z-scores trended towards age- and sex-matched norms at the lumbar spine, femoral neck, and total hip and largely stabilized after 26 weeks of treatment, remaining above zero through week 214. Changes in Z-scores were larger in participants with longer duration of hypoparathyroidism but were similar across the population when considering sex and age/menopausal status. Mean (SD) eGFR at week 214 was 86.0 (21.7) ml/min/1.73 m^2, reflecting a mean (SD) increase of 7.6 (13.7) ml/min/1.73 m^2 from baseline. Mean (SD) 24-hour urine calcium levels normalized with

palopegteriparatide treatment, remaining below the upper limit of normal (≤6.2 mmol/day) through week 214 (4.4 [2.1] mmol/day). TEAEs were mostly mild or moderate; no new safety signals were identified.
Conclusion
These results demonstrate sustained efficacy and safety of palopegteriparatide in adults with chronic hypoparathyroidism through week 214 of the PaTH Forward trial, highlighting continued benefits in skeletal dynamics and renal function.

Introduction and objective
Treatment strategies for pediatric Type 1 Diabetes (T1D) show substantial variation across countries. However, the role of national economic wealth interacting with gender differences on the outcome of care remains poorly defined. This study aims to assess these disparities using data from the worldwide SWEET registry.
Methods
We analyzed data from 54,285 pediatric patients with T1D (<25 years of age, diagnosed for >3 months) treated in 2022-2023. Participants (median age: 14.5 years; 52% male) were categorized into four groups based on their countries' GDP: low, lower-middle, upper-middle, and high income. Z-scores for height and BMI were calculated using the WHO reference standards. We performed linear and logistic regression analyses, adjusted for age, diabetes duration, and sex, to compare the outcomes across GDP groups. Gender-specific analyses were also conducted.
Results
Males consistently had higher height SDS across all income groups ($P<0.0001$). In contrast, females had higher BMI SDS, with the largest gender differences observed in the low-income groups ($P<0.0001$). HbA1c levels were highest in the low GDP group (8.7%) and lowest in the lower- and upper middle groups (7.5%). Overall, females had higher HbA1c levels ($P<0.0001$), with notable gender disparities in lower GDP quartiles (+0.07 to +0.15%), but no significant differences in the highest quartile. DKA episodes were most frequent in the high GDP group, and these were significantly more common in females ($P<0.001$). Females in the lower GDP quartiles had higher rates of severe hypoglycemia compared to males (0.10 vs. 0.07; $P<0.001$), with no gender differences in the highest GDP quartile. Insulin doses were found to be significantly higher in females ($P<0.001$). The use of diabetes technologies increased with GDP: insulin pump use ranged from 17% in low-GDP countries to 70% in high-GDP countries, CGM use from 36% to 91%, and AID systems from 11% to 38% (all $P<0.0001$). Females showed slightly higher adoption rates for both CGM and AID systems compared to males.
Conclusion
Females with T1D presented with shorter stature, higher BMI, and elevated HbA1c compared to males, particularly in lower-income settings. While they showed higher adoption rates of diabetes technologies, these advances did not fully close the gender gap, highlighting the need for targeted interventions addressing both gender and socioeconomic factors to ensure equitable outcomes in pediatric diabetes care.

Lipid profile in children living with Type 1 Diabetes: A novel approach using Z-scores for standardized comparison

Jens Greve[1,2] , Freja Barrett Mørk[1,2], Andreas Jensen[3], Jens Otto Madsen[1,2] & Jesper Johannesen[1,2,4]
[1]Steno Diabetes Center, Department of clinical research, Copenhagen, Denmark; [2]Herlev and Gentofte Hospitals, Department of pediatric and adolescent medicine, Herlev, Denmark; [3]Faculty of Health Sciences, University of Copenhagen, Section of Biostatistics, Department of Public Health, Copenhagen, Denmark; [4]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark

Background
Type 1 diabetes (T1D) is characterized by disrupted carbohydrate and lipid metabolism, predisposing individuals to cardiovascular disease and early death. Understanding lipid variations during childhood is crucial for assessing cardiovascular risk in T1D. A recent study from our team shows that lipid concentrations in healthy children vary across ages 5–17. Building on this, the current study aimed to assess the HDL, LDL, triglycerides, and remnant cholesterol profile in Danish children with T1D compared to healthy children, using age-adjusted z-scores.
Methods
Participants with type 1 diabetes (T1D) were recruited for the Copenhagen T1D 2016 cross-sectional cohort. Of the 256 participants diagnosed with T1D for at least one year, those younger than five or older than 17 years ($n=32$) were excluded to enable comparison with previously collected z-score data from a healthy control group, leaving 224 for analysis.
Results
The T1D cohort had significantly higher z-scores for total cholesterol in girls (median = 0.374, median control = 0.051; $P<0.001$) and LDL in girls (median = 0.287, median control = 0.019, $P=0.029$) as well as triglycerides in girls (median = 0.428, median control = 0.009, $P<0.001$) and boys (median = 0.356, median control = -0.018, $P=0.002$) and remnant cholesterol in girls (median = 0.651, median control = 0.049, $P<0.001$) and boys (median = 0.452, median control = 0.080, $P<0.$ 001). After adjusting for BMI z-score, the effect of BMI on all cholesterol z-scores was similar in both cohorts. Patients with T1D with an average weight (BMI z-score = 0), had significantly elevated total cholesterol z-scores compared to the control cohort in girls (Δz-score = 0.382, $P=0.002$), triglyceride in girls (Δz-score = 0.330, $P=0.006$) and boys (Δz-score = 0.314, $P=0.002$) and remnant cholesterol in girls (Δz-score = 0.489, $P<0.001$) and boys (Δz-score = 0.583, $P<0.001$). Non-compliance with the International Society for Pediatric and Adolescent Diabetes (ISPAD) LDL guidelines, whit an upper limit of 2.6 mmol/l, was 36% in the T1D cohort, compared to 31% in the control cohort.
Conclusions
This study highlights significant cholesterol differences in children with T1D through the novel application of age-adjusted z-scores, which provide a more precise comparison of lipid profiles between children with T1D and their healthy peers.

Introduction
Allogeneic islet-cell-transplantation (ICT) is an established treatment for hypoglycaemic unawareness for selected people living with Type-1 diabetes (T1D) available in Europe, the UK and Australia. As ICT is currently practiced, allogeneic human islets are transplanted into the liver via the portal vein. However, up to 75% of the transplanted islet mass is lost within the first 48 hours post-transplant, due to the Instant Blood Mediated Inflammatory Reaction.

Pt	Pre-Islet transplant Novosorb® integration period	Total IEQ transplant	3/12 c-pep	3/12 HbA1c reduction	3/12 insulin reduction	6/12 HbA1c reduction	6/12 insulin reduction	12/12 HbA1c reduction	12/12 Insulin reduction
1	25 days	485,584	pos	1.1%	21%	1.8%	22%	1.8%	28%
2	33 days	204,633	neg	1.1%	10%	0.6%	7%	0.8%	21%
3	76 days	276,026	pos	0.3%	44%	0.3%	44%	1.3%	62%

Furthermore, the hepatic transplant site is unable to be easily biopsied, transplanted islets are unable to be monitored or retrieved, limiting the ability to detect and treat islet graft rejection. In order to develop an alternative to intrahepatic ICT we pre-implanted a Biodegradable Temporizing Matrix (Novosorb®) into the inner-bicep of three trial participants prior to ICT as part of our **IN**tra-**C**utaneous **E**ctopic **P**ancreas **TR**ial – INCEPTR. Pre-implantation of Novosorb® created a fully functional dense vascular bed capable of supporting transplanted islets within the intracutaneous-transplant site (Diabetes 2023 PMID: 36929171). Unlike the hepatic site, intracutaneous islet grafts can be monitored *in vivo*, enable topical immunosuppression and removed in toto, thus creating an attractive site for gene modified, xenogeneic- and stem-cell-derived ICT.

Method

INCEPTR is a prospective first-in-human study of allogeneic ICT into a prevascularised intracutaneous transplant site : Australian and New Zealand Clinical Trials Registry (ACTRN12621001573842). The INCEPTR trial primary outcome was detectable c-peptide at 3 months post-transplant. Secondary outcomes included average daily exogenous insulin usage and HbA1c measured at baseline, 3, 6 and 12 months post-transplant.

Results

Three immunosuppressed kidney transplant patients with longstanding T1D (c-peptide negative) underwent Novosorb® implantation under local anaesthesia as outpatients prior to intracutaneous cadaveric human islet transplantation.

Conclusions

In this study two of three participants had positive c-peptide at 3 months with all patients showing improvement in glycaemic control over 12 months. One of the patients with positive c-peptide at 3 months has ongoing long-term detectable graft function out to 2.5 years post engraftment. The prevascularised Novosorb® neo-dermis is safe and supported human islet cell survival in an intracutaneous transplant site outside of the liver.

JOINT858 Crosstalk between neuronal mitochondrial dynamics and microglial activation during the hypoglycemic neuronal damage progression with cognitive deficit

Obin Kwon[1] , Jae-Young Joo[1], Soyun Lee[1] & Min Kyoung Shin[1]
[1]Seoul National University College of Medicine, Department of Biomedical Sciences, Seoul, South Korea

Severe hypoglycemia (HPG) is a critical adverse effect of insulin therapy in diabetes, potentially leading to brain damage and cognitive impairment. This risk is one of the major hurdles for enough glucose control and can be a fear to patients and healthcare providers. Our study investigates the crosstalk between mitochondrial dynamics and neuroinflammation to understand hypoglycemic neuronal damage mechanisms and identify potential therapeutic interventions. Male C57BL/6 mice were fasted for 24 hours and HPG (below 20 mg/dl) was induced by intraperitoneal (i.p.) injection of insulin. HPG was induced for 5 hours and terminated by glucose solution i.p. injection. Mice were then sacrificed on day 1, 4, and 7. Unbiased screening in cortex and hippocampus area revealed the retrosplenial cortex (RSC) as vulnerable to HPG among other cortex regions, evidenced by elevated oxidative stress with 4-hydroxynonenal immunohistochemistry on day 7. Progressive increases in oxidative stress and apoptosis, analyzed by terminal deoxynucleotidyl transferase dUTP nick end labelling staining, were observed in the RSC. While mitochondrial fragmentation, examined through transmission electron microscopy, immunoblotting, and immunohistochemistry, and inflammatory activation with IL-1β expression level were already significantly increased at day 1 whereas TNF-α and IL-6 expression levels were unchanged. Treatment with mitochondrial fission inhibitor [mdivi-1] or IL-1 receptor antagonist (IL-1ra) effectively mitigated hypoglycemic neuronal damage. Notably, elevated mitochondrial fission was only significantly increased in neurons, not microglia and astrocytes, as analyzed by co-localization of phosphorylated dynamin-related protein, a marker of activated mitochondrial fission, with markers specific to neurons, microglia, and astrocytes. In vitro experiments with cell-type-specific regulation using transwell co-culture system revealed that preventing mitochondrial fragmentation with mdivi-1 in neuronal cells [SH-SY5Y], and inhibiting IL-1 signaling with IL-1ra in either microglial cells [BV-2] or SH-SY5Y significantly prevented hypoglycemic damage. Morris water maze assessments confirmed the protective effects of these interventions against spatial memory impairment induced by HPG. These results suggest that direct regulation of neuronal mitochondrial fission, combined with indirect modulation through the crosstalk between neuroinflammation with IL-1 signaling, could prevent hypoglycemic neuronal damage and spatial memory impairment.

JOINT1881 Redefining islet adaptations in human pregnancy: insights from immunohistochemistry and proteomics

Faheem Seedat[1,2], Katie Holden[1], Simon Davis[3,4], Roman Fischer[3,4], James Bancroft[1], Edward Drydale[1], Neva Kandzija[2], John A Todd[1], Manu Vatish[1,2] & M Irina Stefana[1]
[1]Centre for Human Genetics, Nuffield Department of Medicine, University of Oxford, Oxford OX3 7BN, United Kingdom, Oxford, United Kingdom; [2]Nuffield Department of Women's and Reproductive Health, University of Oxford, Oxford OX3 9DU, United Kingdom, Oxford, United Kingdom; [3]Target Discovery Institute, Centre for Medicines Discovery, Nuffield Department of Medicine, University of Oxford, Oxford OX3 7FZ, United Kingdom, Oxford, United Kingdom; [4]Chinese Academy for Medical Sciences Oxford Institute, Nuffield Department of Medicine, University of Oxford, Roosevelt Drive, Oxford, OX3 7FZ, United Kingdom, Oxford, United Kingdom

Introduction

Pregnancy requires pancreatic islet adaptations to maintain glucose homeostasis. Human studies show that β-cell mass increases in pregnancy, murine studies suggest that prolactin receptor (PRLR) and serotonin 2B (5-HT2B) receptor signalling are key to these adaptations. However, little is known about the islet proteome and α cells in human pregnancy. This study investigates pregnancy-associated islet changes using rare human pancreatic tissues from pregnant women, focusing on proteomic alterations, whole islet, α- and β-cell metrics, and the expression of the PRLR, 5-HT2B receptor, and glucagon-like peptide-1 (GLP-1).

Methods

Formalin-fixed paraffin-embedded pancreatic tissue from pregnant human donors ($n=7$, third trimester) and non-pregnant controls ($n=7$) best-matched by age, race, and BMI were obtained from the Network for Pancreatic Organ Donors with Diabetes. Islets were isolated using laser-capture microdissection, and proteomic profiling performed using liquid chromatography-mass spectrometry (LC-MS/MS). Islets were labelled by immunofluorescence, and images acquired using spinning disc confocal microscopy. Unbiased, automated computational image analysis of whole pancreatic tissue sections was used to quantify whole islet, α- and β-cell areas, and the abundance of PRLR, 5-HT2B receptor, and GLP-1. For each metric, values were normalised to total tissue area prior to comparisons to account for the size differences between tissue sections.

Results

LC-MS/MS identified 7,546 proteins in human islets, generating the largest dataset of islet proteins from pregnant women to date. Four proteins—cathepsin Z, β1,4-galactosyltransferase 4, cyclin-dependent kinase 5, and laminin subunit alpha 4—were significantly more abundant in third-trimester islets. In pregnancy, whole islet area increased 1.9-fold (3.0% vs. 1.6%, $P=0.0145$), α-cell area 4.3-fold (0.44% vs. 0.1%, $P=0.0206$), and β-cell area 1.9-fold (1.26% vs. 0.65%, $P=0.0241$), driven by increased cell numbers. In pregnant islets, PRLR expression was upregulated in α cells (302.3 vs. 267.7 AU/mm^2, $P=0.0398$) but not β cells ($P=0.0610$). The 5-HT2B receptor was absent in β cells, confirmed by colocalisation analysis and positive ductal staining as an internal control for antibody functionality. Additionally, GLP-1 abundance in α cells increased 2.9-fold (0.69% vs. 0.24%, $P=0.0184$).

Conclusion

Human islet adaptations in pregnancy differ from those in mice. While α- and β-cell areas expand, the absence of β-cell 5-HT2B receptor expression and minimal proteomic changes suggest alternative regulatory mechanisms. The increased α-cell area and GLP-1 expression highlight the potential role of α-cell-derived paracrine signals in supporting β-cell function. These findings underscore the need for human-based studies to further elucidate mechanisms driving islet plasticity in pregnancy and their relevance to gestational diabetes.

68Ga-Exendin-4-guided surgery in children with congenital hyperinsulinism (CHI)

Laurina Bühner[1], Karin Rothe[2], Kathrin Hauptmann[3], Marti Boss[4], Nicola Beindorff[5], Martin Gotthardt[6], Steven Warmann[2], Winfried Brenner[7], Paniz Akbarzadeh Taghavi[7], Julian Rogasch[7], Oliver Blankenstein[1] , Peter Kühnen[1] & Vikas Prasad[8]
[1]Charité Universitätsmedizin Berlin, Department of Pediatric Endocrinology and Diabetology, Berlin, Germany; [2]Charité Universitätsmedizin Berlin, Department of Pediatric Surgery, Berlin, Germany; [3]Charité Universitätsmedizin Berlin, Institute of Pathology, Berlin, Germany; [4]Radboud University Medical Center, Department of Medical Imaging, Nijmegen, Netherlands; [5]Charité Universitätsmedizin Berlin, Berlin Experimental Radionuclide Imaging Center – BERIC, Berlin, Germany; [6]Radboud University Medical Center, Department of Radiology, Nijmegen, Netherlands; [7]Charité Universitätsmedizin Berlin, Department of Nuclear Medicine, Berlin, Germany; [8]Washington University St. Louis, Division of Nuclear Medicine, St. Louis, United States

Congenital hyperinsulinism (CHI) is a critical condition predominantly manifesting in neonates through severe hypoglycemic episodes. This can lead to severe brain damage and retardation of cognitive development if not detected and treated in time. Importantly, CHI is differentiated into focal and diffuse forms based on the distribution of affected pancreatic beta cells. Focal CHI typically arises from a paternally inherited heterozygous mutation in the ATP-sensitive potassium channel (*ABCC8, KCNJ11*) and can be identified by ^{18}F-DOPA or ^{68}Ga-Exendin-4 PET scan. However, intra-operative localization of focal CHI remained challenging until recently. This proof-of-concept study expands on previous work investigating the suitability of ^{68}Ga-Exendin-4, a GLP-1 receptor-binding tracer, as a diagnostic tool and as a tracer for radio-guided surgery to improve preciseness of intraoperative detection and resection of focal CHI lesions[1]. We describe a cohort of 27 patients with CHI. Preoperative imaging included ^{18}F-DOPA CT and ^{68}Ga-Exendin-4 PET MRI scans. During surgery, approx. 45 MBq of ^{68}Ga-Exendin-4 were administered intravenously. Beginning one minute after tracer application a handheld, cable-free positron probe was used at intervals of one minute to five minutes to intraoperatively locate the lesion by detecting positron emissions from the radiotracer. In 26 out of 27 cases, it was possible using ^{68}Ga-Exendin-4 to identify the CHI focus localization correctly. Additionally, the radio-guided surgery approach successfully facilitated the identification and resection of focal CHI lesions in 23 of 27 cases. Except for a significant increase in heart rate 1 min (mean = 125 ± 18/min vs. 139 ± 20/min, $P < 0.001$) and 30 min (mean = 141 ± 19/min, $P < 0.001$) after the administration of ^{68}Ga-Exendin-4, no adverse effects were observed. We compared the data with 12 patients with CHI, which were operated on without radio-guidance. The radio-guided approach reduced time of surgery (mean = 343 ± 83 min vs. 280 ± 107 min), though the difference was not statistically significant ($P = 0.072$), while also minimizing surgical complications (58.3% vs. 20%, $P < 0,05$). In conclusion this study confirms the efficacy of ^{68}Ga-Exendin-4 as both a diagnostic and intraoperative tool for focal CHI. Radio-guided surgery using ^{68}Ga-Exendin-4 improves lesion localization and reduces operative time, offering a promising advancement in the management of focal CHI.

Cellular tumor microenvironment cross-talk in pediatric adrenocortical tumors: insights from single-nucleus RNA sequencing

Victoria Fincke[1] , Maurice Loßner[1], Marina Kunstreich[1], Irmengard Sax[2], Marlena Mucha[1], Felix Dorn[1], Stefan Wudy[3], Christian Vokuhl[4], Christoph Slavetinsky[5] , Jörg Fuchs[6] , Michael Frühwald[1], Matthias Schlesner[2], Antje Redlich[7], Rainer Claus[1], Michaela Kuhlen[1] & Pascal Johann[1]
[1]University of Augsburg, Pediatrics and Adolescent Medicine, Augsburg, Germany; [2]Faculty of Applied Computer Sciences, University of Augsburg, Augsburg, Germany; [3]Justus Liebig University Giessen, Giessen, Germany; [4]University Hospital Bonn, Bonn, Germany; [5]University Childreńs Hospital Tuebingen, Tuebingen, Germany; [6]University Childreńs Hospital Tuebingen, Tübingen, Germany; [7]Otto-von-Guericke-University Magdeburg, Magdeburg, Germany

Pediatric adrenocortical tumors (pACTs) are rare adrenal cortex neoplasms, often presenting with Cushing's syndrome, virilization, or both. These tumors range from benign pediatric adrenocortical adenomas (pACAs) to aggressive pediatric adrenocortical carcinomas (pACCs). Our prior research identified four DNA methylation-based risk groups correlating with survival outcomes, yet their tumor microenvironment characteristics remain poorly understood. We performed single-nucleus RNA sequencing on 29 pACT samples to characterize immune infiltration and cell-cell communication across these risk groups. Cellular identities were determined using clustering and marker gene expression analysis. Low Risk 1 tumors exhibited significantly greater lymphoid (8.72%) and macrophage (19.75%) infiltration than High Risk tumors (lymphoid: 0.41%; macrophage: 3.6%), suggesting a more active immune environment in lower-risk tumors. Ligand-receptor analysis revealed distinct cell signaling patterns. High Risk tumors demonstrated increased fibroblast-to-endothelial signaling, particularly through collagen-related pathways (COL1A1, COL1A2, COL3A1-ITGA10_ITGB1), indicative of extracellular matrix remodeling and a pro-tumorigenic microenvironment. The MMRN2-CLEC14A interaction emerged as a dominant signal in High Risk tumors, suggesting increased endothelial activation and angiogenesis potential. In contrast, Low Risk 1 tumors showed homeostatic endothelial-fibroblast interactions, with COL1A2-CD93 and COL1A1-CD93 signaling likely contributing to extracellular matrix stabilization and tissue integrity. Notably, immune infiltration and cellular signaling patterns correlated more strongly with DNA methylation-based risk groups than with clinical manifestations such as Cushing's syndrome or virilization, emphasizing the limitations of clinical features in predicting tumor biology. These findings reveal distinct tumor microenvironment landscapes across pACT risk groups, with High Risk tumors exhibiting a pro-tumorigenic, angiogenic profile, while Low Risk tumors maintain a structured, immune-active microenvironment. The identification of key signaling pathways, such as MMRN2-CLEC14A, suggests potential targets for future therapeutic interventions. Our study underscores the importance of molecular profiling in risk stratification and treatment planning for pediatric adrenocortical tumors.

Characterization of metastatic dissemination in Znrf3/Trp53 double knock-out mouse model

Diana Garcia-Garcia[1], Allison Voisin[1], James Wilmouth[1], Antoine Martinez[1], Rachel Guiton[1] & Pierre Val[1]
[1]iGRED, Clermont-Ferrand, France

Adrenocortical carcinoma (ACC) is a rare endocrine malignancy with very poor prognosis due to the lack of successful therapies for patients with metastatic or recurrent tumors. However, the urgent need for the development of new therapies clashes with the lack of preclinical models that accurately represent ACC. Using Cre-loxP technology to mimic inactivation of *ZNRF3* and *TP53*, the most commonly found alterations in ACC patients from the most aggressive subgroup, we developed a new clinically relevant mouse model allowing for the study of the molecular basis of metastatic ACC. Using a combination of Kaplan Meier analysis, bulk RNA sequencing and immunohistochemistry, we demonstrate that adrenal cortex specific ablation of *Trp53* and *Znrf3* results in development of metastatic and lethal ACC over a 6-month time course. This is associated with other characteristics observed in most aggressive ACC patients, as the molecular signature of C1A subgroup, immune poor, steroidogenic high, and proliferation high signatures or the overexpression of the EZH2 methyltransferase and a constitutive activation on WNT pathway. Single nucleus RNA sequencing of primary tumors showed that acquisition of aggressive features is associated with amplification of a population of proliferative cells characterized by expression of *Dab2*, *Wnt4*, *Lef1*, *Mki67*, *Rad51* and *Ezh2*. These molecular features are also found in lung metastases, as assessed by both immunohistochemistry and spatial transcriptomic analysis, suggesting that these originate from dissemination of this set of cells. In addition, metastatic dissemination is associated with upregulation of senescence-related signatures. Immunolabeling for P16 and SA-β-galactosidase revealed the presence of senescent macrophages in the most aggressive primary tumors and their corresponding metastases. Single cell transcriptomic analysis of the immune compartment showed that senescent macrophages also express immune-checkpoint and pro-tumoral signatures, suggesting a role for senescent cells in promoting metastatic progression by inhibiting the anti-tumor response. Interestingly, multi-omics analyses of TCGA data have correlated senescence with poor prognosis and survival, highlighting this process as a new ACC therapeutic target. We are therefore currently evaluating the therapeutic potential of senolytics in our ACC mouse model. Altogether, these data shed light on the underpinnings of metastatic dissemination and establish these mice as a good *in vivo* model to investigate novel therapeutic options.

Genetic and functional heterogeneity in aldosterone producing adenomas

Maria Maldifassi[1,2], Jiayi Wang[3], David Colameo[1], Qin Zhang[4], Anna Bratus-Neuenschwander[4], Agnieszka Wengi[5], Hubert Rehrauer[4], Igor Delvendahl[6], Mark Robinson[3], Felix Beuschlein[7] & David Penton Ribas[1]

[1]University of Zurich, Electrophysiology Facility, Zurich, Switzerland; [2]University of Zurich, Electrophysiology Facility, Zurich, Switzerland; [3]University of Zurich, Department of Molecular Life Sciences, Zurich, Switzerland; [4]University of Zurich, Functional Genomics Center Zurich, Zurich, Switzerland; [5]University Hospital Zurich, Department of Endocrinology, Diabetology and Clinical Nutrition, Schlieren, Switzerland; [6]University of Freiburg, Institute of Physiology, Freiburg im Breisgau, Germany; [7]University Hospital Zurich, Department of Endocrinology, Diabetology and Clinical Nutrition, Zurich, Switzerland

Primary aldosteronism (PA), the most common secondary form of hypertension, results from excessive and autonomous aldosterone production by the adrenal cortex. Gain-of-function mutations in genes encoding ion channels or transporters underlie both inherited and acquired forms of PA. These mutations typically promote cell depolarization and increase intracellular Ca^{2+} levels, driving the overexpression and activity of the aldosterone synthase. Cellular heterogeneity is thought to be an intrinsic feature of PA, modulating its presentation and severity. However, understanding this complexity at the single-cell level has been challenging due to the limitations of traditional methods and lack of functional read-outs. To overcome this, we have combined single-cell long-read RNA sequencing (scRNA-seq), PatchSeq and high-throughput automated patch-clamp (HT-APC) techniques. This approach was applied to freshly dissociated cells from adrenal tissues resected from patients with aldosterone-producing adenomas (APA) or adrenal hyperplasia at the University Hospital Zurich. Preliminary analysis of 2,177 adrenocortical cells from seven patient samples (from normal, tumor and hyperplasia tissues) revealed over 100 likely pathogenic variants, as per ClinVar. These include known PA-driver mutations in KCNJ5, CLCN2, CACNA1D, and CACNA1H, along with novel mutations in potential steroidogenesis-related genes such as WNK1, VDR, PEX1, and KCNJ1. Interestingly, some genetic variants co-occur with known PA-driver mutations, offering insights into the one- or two-hit models of APA development. For future functional analysis, we have developed an automated pipeline that integrates high-content imaging with HT-APC electrophysiological data to identify recorded cells using steroidogenesis markers. The use of PatchSeq enables correlation of cellular functional data with mutation status and transcriptomic profiles, contextualizing the datasets derived from scRNA-seq and HT-APC. Additionally, transcriptomic analysis is anticipated to uncover novel cell markers associated with increased steroidogenesis. This innovative approach provides a detailed understanding of PA's molecular and functional heterogeneity at the single-cell level. The tools developed in this study could be broadly applied to other tissues where alterations in electrophysiological properties drive disease progression.

Instituto de Salud Carlos III, Madrid, Spain; [7]University of Córdoba, Córdoba, Spain; [8]Department of Hepatology and Liver Transplantation, Reina Sofía University Hospital, Córdoba, Spain

Background and aims

With the increasing incidence of metabolic dysfunction-associated steatotic liver disease (MASLD) and its association with hepatocellular carcinoma (HCC) development, novel potential clinical strategies are required. We have demonstrated that aminoacyl-tRNA synthetases (ARSs), which catalyze the transfer of amino acids to tRNAs, are altered in MASLD/HCC. Here, we explore the potential of aspartyl-tRNA synthetase (DARS1) as diagnostic biomarker and therapeutic target, as its molecular implication in MASLD/HCC.

Method

Tissular DARS1 levels were analyzed in *in silico* cohorts (mRNA/protein) of MASLD and HCC and in cytosolic/nuclear protein fractions of HCC patients ($n=42$). DARS1 levels were measured in plasma samples of two cohorts (Cohort1: 21 controls, 15 MASLD, 14 cirrhosis, 32 HCC; Cohort2: 8 controls, 8 HCC). Functional assays were performed in liver-derived cell lines (HepG2, Hep3B, SNU-387) after DARS1 modulation (silencing, overexpression, pharmacological inhibition). DARS1-overexpressing Hep3B cells were used for *in vivo* xenograft and orthotopic tumor formation. DARS1 immunoprecipitation and quantitative proteomics were performed in cytosolic/nuclear Hep3B fractions.

Results

DARS1 abundance was reduced in MASLD but increased in HCC tissues (mRNA/protein) and plasma [Area Under Curve (AUC) of plasma levels: HCC vs. controls: 0.8376; HCC vs. MASLD: 0.9016; HCC vs. cirrhosis: 0.8095]. DARS1 levels were higher in aggressive tumors (i.e. invasive, dedifferentiated), in patients with adrenal/lung metastasis, and in patients with metabolic disease. Consistently, *DARS1* silencing/pharmacological inhibition reduced, while *DARS1* overexpression increased, functional parameters of aggressiveness *in vitro*. In fact, xenograft and orthotopic tumors formed by *DARS1*-overexpressing cells had increased establishment capacity *in vivo*. Mechanistically, DARS1 protein levels were higher in nuclear, but not cytosolic, samples of HCC. An immunoprecipitation assay revealed 132 nuclear DARS1 interactors, three of the latter being members of the Spt-Ada-Gcn5 acetyltransferase (SAGA) complex, which regulates MYC acetylation and stability. This non-canonical interaction was confirmed by *in silico* docking of DARS1/SAGA crystal structures. Additionally, *DARS1* modulation regulated MYC protein levels and phosphorylation, and the expression of MYC targets was reduced in RNA-seq data of *DARS1*-silenced liver cells. Consistently, *DARS1* silencing reduced drug-induced senescence (Gemcitabine, Etoposide, Cisplatin), suggesting a link between DARS1-SAGA interaction and MYC-regulated senescence.

Conclusion

DARS1 is reduced in MASLD and overexpressed in HCC tissues and plasma samples, especially in metabolic disease patients. DARS1 could be implicated in the development of MASLD and its progression to HCC, wherein it could serve as biomarker or therapeutic target.Fundings: ISCIII (PI20/01301, PI23/00652; co-funded by the European Union), MINECO (FPU20/03957), JdA (PEMP-0036-2020, BIO-0139), FSEEN and CIBERobn/ehd.

Medicine, Örebro University Hospital, Örebro, Sweden; [13]Faculty of Health and Medical Sciences, Örebro University, Örebro, Sweden

Introduction
Growth hormone (GH) excess and elevated levels of insulin-like growth factor-1 (IGF-1) in acromegaly are associated with cell proliferation and cancer promotion. We aimed to investigate the incidence of cancer and the cancer-related mortality in patients with acromegaly.
Methods
A register-based cohort study was performed in patients with acromegaly diagnosed 1991-2018, and identified in the Swedish Pituitary Register and in the National Patient Register. For each patient we included ten controls from the genereal population matched by sex, age and municipality of residence. Cancer diagnoses were obtained from the National Cancer Register. A Cox proportional hazard regression model adjusted for age, sex and comorbidity was used to estimate adjusted Hazard Ratio (aHR) and 95% CIs.
Results
We included 1035 patients with acromegaly (median age at diagnosis 52 years (Q1-Q3: 40-62.5), 49.5% female) and 10 261 control subjects. Median follow up time was 10.8 years (Q1-Q3: 5.2-17.5). Eighty percent underwent surgery and 13.5% radiation therapy. In the National Prescribed Drug Register from 2005 pharmacological treatment with Somatostatin analogs was reported in 41%, and GH receptor antagonist in 10% of the patients diagnosed from 2005. At 10 years follow-up 83% had biochemical control. Cancer was more common in the patients with acromegaly (aHR 1.33 (95% CI: 1.14-1.56), $P < 0.001$). The highest aHR was found in the subgroups of colorectal cancer (aHR 1.73 (95% CI: 1.16-2.58), $P = 0.007$) and lung cancer (aHR 1.92 (95% CI: 1.18-3.11), $P = 0.008$). The aHR for these two cancer diagnoses was higher already from five years before acromegaly diagnosis until study end, which was also seen for breast cancer in women. Pituitary surgery, radiation therapy, hypopituitarism or biochemical control were not associated with cancer when they were included as covariates in a Cox regression model. The overall mortality rate was increased in the patients (aHR 1.19 (95% CI: 1.03-1.37), $P = 0.019$), which was associated with cardiovascular disease (aHR 1.76 (95% CI: 1.22-2.53), $P = 0.002$), but not with cancer, diabetes, hypertension or cerebrovascular disease. Biochemical control was associated with lower mortality (aHR 0.67 (95% CI: 0.49-0.91), $P = 0.011$) compared to patients not biochemically controlled.
Conclusions
This matched nationwide study indicates an increased risk of cancer in patients with acromegaly even years before the diagnosis was established, with colorectal and lung cancer showing the highest increase in hazard ratios. Our findings underscore the importance for clinicians to be vigilant for early signs of cancer in patients with acromegaly.

Single-nucleus multiome profiling of the arcuate-median eminence complex in male marmosets provides molecular insights into the postnatal dynamics of the hypothalamic-pituitary-gonadal axis

Amadeusz Odroniec[1], Lynn Ogoniak[1], Stefan Schlatt[1], Gerd Meyer zu Hörste[1], Astrid Jeibmann[1] & Alexander S. Busch[1]
[1]University Hospital Münster, Münster, Germany

Introduction
Minipuberty, a transient activation of the Hypothalamic-Pituitary-Gonadal (HPG) axis in early infancy, plays a crucial role in early gonadal maturation and serves as a diagnostic window for future reproductive function. Despite its critical importance, particularly in males, the molecular mechanisms and dynamics underlying minipuberty remain poorly understood. Rodent models offer limited insights, as they lack an activity phase comparable to human minipuberty. To address this gap, we aimed to investigate cell-specific expression and chromatin accessibility dynamics in the hypothalamus, specifically the arcuate nucleus/median eminence (ARC/ME) region, using male marmosets (*Callithrix jacchus*) as a translational model during this critical developmental phase.
Objectives and methods
We profiled a total of 9 animals from 3 developmental stages: newborn (0–1 day), 3-week-old (during minipuberty), and 12-week-old (post-minipuberty). In addition to brain tissues, serum was collected and androgen levels were measured via liquid chromatography-tandem mass spectrometry (LC-MS/MS) to further validate the selection of these developmental stages.
Results
Single-nucleus RNA sequencing (snRNA-seq) of the hypothalamus generated a comprehensive dataset of over 70,000 nuclei, allowing for the identification of distinct neuronal and non-neuronal populations. Analysis revealed stage-specific transcriptomic shifts across major cell types during early postnatal development, highlighting dynamic changes in hypothalamic function. We successfully profiled key HPG axis-regulating neurons, including KISS1-expressing populations, which play a central role in GnRH signaling. Additionally, hormonal measurements confirmed significant differences in androgen levels between developmental stages, supporting the physiological relevance of the selected time points.
Conclusions
These findings provide high-resolution insights into hypothalamic neuroendocrine regulation, emphasizing its role in growth and reproductive hormone dynamics during postnatal maturation. The observed stage-specific transcriptomic shifts and hormonal differences contribute to a deeper understanding of HPG axis activation and suppression, offering a framework for studying minipuberty and its implications for reproductive development.

PSA as a marker of androgen activity during pubertal transition in healthy boys

Andrés Felipe Fritzbøger[1,2], Ruth Frikke-Schmidt[3], Jørgen Petersen[2,3,4], Anders Juul[1,2,4] & Lise Aksglaede[1,2]
[1]Copenhagen University Hospital - Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark; [2]Copenhagen University Hospital - Rigshospitalet, International Centre for Research and Research Training Centre in Endocrine Disruption of Male Reproduction and Child Health ((EDMaRC), Copenhagen, Denmark; [3]Copenhagen University Hospital - Rigshospitalet, Clinical biochemistry, Copenhagen, Denmark; [4]University of Copenhagen, Faculty of Health and Medical Sciences, Clinical Medicine, Copenhagen, Denmark

Context
Prostate specific antigen (PSA) is an androgen-responsive biomarker regulated by testosterone (T) and dihydrotestosterone (DHT), with its expression tightly linked to androgen receptor activation. While PSA is primarily used in clinical practice for prostate cancer screening and monitoring, its physiological role as an androgen regulated protein suggests it may serve as a marker for androgen bioactivity in male pubertal development.
Objective
To evaluate PSA as an androgen-responsive biomarker in healthy boys during pubertal transition and to establish age-specific reference intervals for serum PSA concentrations.
Methods
This longitudinal study included 104 boys (corresponding to 890 serum samples) from The Copenhagen Puberty Study II conducted from 2006 to 2011. Serum PSA was measured using a commercially available assay with a limit of quantification (LOQ) of 0.014 µg/l. Age-specific RIs were developed using the generalized additive model for location, scale, and shape (GAMLSS). Total T was measured using a radioimmuno assay with a limit of detection (LOD) of 0.23 nmol/l. Free T was calculated using the Vermeulen equation. Pubertal onset was defined as a genital staging of G2.
Results
PSA concentrations were undetectable in prepubertal boys (G1) and at pubertal onset (G2). A significant increase in median PSA concentrations was observed from G2 to G3 (0.042 [0.009 - 0.104] µg/l, $P < 0.001$). This upward trend continued into later stages (G4: 0.215 [0.116 - 0.357] µg/l, $P = 0.005$; G5: 0.294 [0.204 - 0.447] µg/l, $P = 0.003$). The increase between G3 and G5 was significant ($P = 0.003$), whereas no significant difference was found between G3 and G4 ($P = 0.005$).
Conclusion
Serum PSA concentrations increase progressively with pubertal development, mirroring the rise in bioactive androgens. While PSA remains undetectable in early puberty, its significant rise from G3 onward suggests a threshold effect, where androgen levels must reach a critical point before inducing measurable PSA production. These findings confirm PSA as an androgen-responsive

biomarker, with its increase reflecting androgen receptor activation by testosterone and DHT. Our study provides clinically relevant reference intervals for PSA in the assessment of boys during pubertal transition.

Nuclear factor I/B interaction with PROP1 and its role in pituitary cell differentiation

Lucía Iglesias García[1], María Florencia Mercogliano[1], Claudio Schuster[2], Valentina Michan[1] , Marcelo Martí[2], Sally Camper[3] & María Inés Pérez Millán[1]
[1]Laboratorio de Genética y Endocrinología Molecular, IB3-UBA, Ciudad Autónoma de Buenos Aires, Argentina; [2]Laboratorio de Biofisicoquímica de Proteínas, IQUIBICEN-CONICET, Ciudad Autónoma de Buenos Aires, Argentina; [3]Department of Human Genetics, University of Michigan, Ann Arbor, Michigan, Ann Arbor, United States

The transcription factor PROP1 is necessary to trigger the onset of pituitary development by promoting the differentiation of stem cells into hormone-producing cell lineages by an epithelial-to-mesenchymal transition-like (EMT-like) process. Biallelic loss of function mutations in PROP1 cause deficiencies in growth hormone, thyroid stimulating hormone, and prolactin. PROP1 target genes have been identified, but little is known about interacting protein partners. We genetically engineered mouse pituitary GHTF1 cells to express biotin-tagged PROP1 and performed Rapid Immunoprecipitation and Mass spectrometry Experiments (RIME) to identify PROP1 interacting proteins. From 43 candidate proteins detected, we selected Nuclear Factor I/B (NFIB) for further studies based on the role of this gene family (NFIA, NFIB, NFIC, and NFIX) in development of other tissues. This family plays a role in developing the central nervous system, lungs, hair follicles, and skeletal muscle tissue. Notably, NFIB is involved in promoting EMT in various types of cancer. Using immunostaining, we observed that the pattern of NFIB and NFIA expression during mouse pituitary development was similar to SOX2 from e12.5 to e16.5. NFIB and NFIA also colocalized early on (e12.5) with PROP1. NFIB and NFIA have overlapping function in some organ systems and biallelic loss of function causes embryonic lethality. Thus, we generated a pituitary-specific knockout mice of *Nfib* and *Nfia*:*Hesx1Cre*/+; $Nfia_{Flox/Flox}$; $Nfib_{Flox/Flox}$. At postnatal day 1 these mice have an increase in the number of alpha-GSU and TSH-positive cells (with normal corticotrophs and somatotrophs). The stem cell population expressing SOX2 was not different between mutant and controls. We found increased double-positive GH and TSH-producing cells, suggesting that NFIB and/or NFIA are required to maintain proper cell lineage differentiation during pituitary organogenesis. Together, our findings expose NFIA/NFIB as important factors for pituitary lineage confinement. Further research is needed to understand the molecular mechanisms underlying these processes.

Unravelling the core regulatory network controlling stem cell fate in the anterior pituitary

Miriam Vazquez Segoviano[1], Bence Kover[1], Emily Lodge[2], James Kaufman-Cook[1], Yasmine Kemkem[1], Olivia Sherwin[1], Marika Charalambous[1,3], Stuart Sealfon[4], Frederique Ruf-Zamojski[5] & Cynthia Andoniadou[1,6]
[1]King's College London, London, United Kingdom; [2]University College London, London, United Kingdom; [3]Francis Crick Institute, London, United Kingdom; [4]Icahn School of Medicine at Mount Sinai, New York, United States; [5]Cedars-Sinai Medical Center, Los Angeles, United States; [6]Technical University of Dresden Medical School, Dresden, Germany

The anterior pituitary is a primary endocrine organ responsible for orchestrating major physiological processes including growth, metabolism, reproduction and our response to stress through hormone secretion. This dynamic gland contains a tissue-specific population of stem cells marked by the expression of the transcription factor (TF) SOX2, which are required for homeostasis throughout life. Although pituitary stem cells (PSCs) are highly proliferative during early postnatal life, their regeneration capacity declines with age, remaining largely quiescent during adult homeostatic conditions as a long-lived population. Knowing the genetic mechanisms of stem cell regulation is necessary to enable their exploitation in regenerative approaches for pituitary disorders. Previous research has demonstrated a central role for YAP/TAZ signalling in PSCs to promote self-renewal and proliferation while repressing differentiation *in vivo*, thereby positioning YAP as a key component of PSC regulation, acting through TEAD TFs. We carried out single nuclei (sn) multiome sequencing of anterior pituitaries from an inducible YAP overexpression model, where overexpression of non-degradable mutant YAP protein instigates self-renewal of PSCs. snMultiome studies enable gene expression profiling and chromatin accessibility simultaneously from individual cells. Transcription factor fingerprinting analyses revealed Nuclear Factor I (NFI) A, NFIB, NFIC and NFIX TFs as highly relevant to PSC regulation. The NFI family of TFs are important for cell fate of stem cell populations in other tissues, yet their role or possible involvement in pituitary disease has not been previously investigated. Here, we characterise NFI expression in the murine and human pituitary gland and demonstrate *in silico*, *in vitro* and *in vivo* data supporting that NFIs, together with YAP/TEADs and SOX2 are a core regulatory network driving stem cell self-renewal in the anterior pituitary.

Background
The pituitary gland is the hub of our endocrine system as it is responsible for the production of hormones that drive and regulate important physiological processes including body growth, lactation and stress. Organoids are complex 3D structures that mimic the biological functions of the target organ and allow the study of physiopathological mechanisms. The development of *in vitro* models using human induced pluripotent stem cells (hiPSC)-derived pituitary organoids has helped gain knowledge on pituitary biology and disorders[1,2]. However, up to date the generation of hormone-secreting organoids remains challenging because of the paucity of cells that differentiate into hormone-secreting cells.
Objective
In this study, we aimed to generate pituitary organoids with an improved ratio of hormone-secreting cells.
Methods
AG08h and KOLF2.1J hiPS cell lines were both derived from healthy donors, and 10742L from a patient with Leber hereditary optic neuropathy. All three hiPS cell lines underwent to genomic characterization prior to their differentiation towards pituitary organoids. hiPSCs were differentiated into pituitary organoids as previously described 3. Cells were maintained in culture up to 108 days and the expression of pluripotency markers and pituitary differentiation markers as well as those of *ACTH*, *GH* and *PRL* was measured via real time- quantitative PCR (RT-qPCR). Protein levels of ACTH, GH and PRL were measured by immunofluorescence (IF) and ELISA.
Results
We observed the presence of an epithelial layer as early as day 10 in all hiPS cell lines. In line with this, as of day 30 mRNA levels of *EpCAM* increased. Whereas the expression of pluripotency markers (*SOX2* and *NANOG*) strongly decreased along with differentiation, mRNA levels of *POU1F1*, *PITX1* as early pituitary differentiation markers increased. In addition, we found increased levels of *HESX1* between day 30–48 suggesting proliferation of pituitary progenitors, followed by increased *TBX19* and *PROP1* between day 48-60 pointing at further differentiation towards both corticotroph and somato-lactotroph cell lineages. Consistently, from day 60 onwards, we found an increase of *ACTH*, *GH* and *PRL* mRNA levels.
Conclusion
Here, we induced pituitary differentiation using three different hiPS cell lines. Of note, all three hiPS cell lines showed variable basal levels of ACTH secretion in culture media, and 10724L showed also secretion of prolactin, thus representing an interesting model to study both pituitary development and diseases.

Hydroxytyrosol mitigates high-fat diet-induced precocious puberty in rats through gut microbiome remodeling

Huimin Kang[1,2] & Ruimin Chen[1]
[1]Fuzhou First General Hospital Affiliated with Fujian Medical University, Fuzhou Children's Hospital, Department of Endocrinology, Genetics and Metabolism, Fuzhou, China; [2]Fujian Medical University Union Hospital, Department of Pediatrics, Fuzhou, China

Background
Precocious puberty (PP) may lead to multiple adverse outcomes. Growing epidemiological evidence implicates that a high-fat diet (HFD) is closely related to precocious puberty (PP). Emerging evidence suggests that PP is a gut–brain axis disorder involving microbial-endocrine crosstalk. Hydroxytyrosol (HT) demonstrates multiple bioactive properties, yet its impact on PP remains unexplored. We aimed to investigate the effects of HT on PP and gut microbiota (GM) in animals.
Objective
This study aimed to explore the therapeutic potential of HT in HFD-induced PP through modulation of the gut microbiota (GM)-hypothalamic-pituitary-gonadal (HPG) axis.
Study design and methods
A PP model was established in feeding female Sprague-Dawley rats through HFD administrated from postnatal day 21, and with HT by gastric until virginal opening. Four experimental groups were evaluated: normal diet control (NC) group, HFD group, NC + HT group, and HFD + HT group. Puberty onset was monitored via vaginal opening timing. Blood, fecal, and hypothalamic samples were harvested to evaluate potential mechanistic pathways. Furthermore, fecal microbiota transplantation (FMT) was conducted to confirm the causality between HT and PP risk.
Results
Administration of HT in female offspring rats delayed vaginal opening and extended the first estrous cycle, accompanied by reduced serum estrogen, serum luteinizing hormone (LH) and follicle stimulating hormone (FSH). The 25 mg kg^{-1} HT treatment significantly downregulated hypothalamic expression of gonadotropin-releasing hormone (GnRH) and kisspeptin proteins. These benefits were achieved through the modulation of the gut microbiome, which functionally suppressed the HPG axis and prevented PP progression. Notably, FMT experiments indicated that the causal correlation between HT intake and PP is mediated by the gut microbiome alterations.
Conclusion
Our findings establish HT as a novel microbiota-modulating agent that attenuates HFD-induced PP through gut microbiome-mediated regulation of neuroendocrine pathways. This suggests potential clinical applications of dietary polyphenols in PP prevention strategies.

Retrospective, multicentre evaluation of the clinical features and associated diagnostic challenges of central congenital hypothyroidism in the UK

Catherine Peters[1], Claire Wood[2,3], James Law[4,5], Chloe Stevens[6], Fatemah Alhusaini[1], Darla Rigby[2], Hannah Hornby[5], Tim Cheetham[2,3] & Nadia Schoenmakers[7,8]
[1]Great Ormond Street Hospital for Children, London, United Kingdom; [2]Newcastle University, Newcastle upon Tyne, United Kingdom; [3]Great North Children's Hospital, Newcastle upon Tyne, United Kingdom; [4]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom; [5]Nottingham University, Nottingham, United Kingdom; [6]Institute of Metabolic Science, University of Cambridge, University of Cambridge, United Kingdom; [7]College of Medicine and Health, University of Birmingham, Birmingham, United Kingdom; [8]Institute of Metabolic Science, University of Cambridge, Cambridge, United Kingdom

Introduction
Central congenital hypothyroidism (CeCHT) is a rare disorder occurring due to defective TSH-mediated stimulation of the thyroid, usually as part of multiple pituitary hormone deficiency (MPHD). CeCHT is not targeted by the UK TSH-based neonatal screening programme, in contrast to countries operating primary T4 ± TSH-based screening methodologies. Arguments in favour of CeCHT screening include the potential to prevent illness and associated neurodevelopmental sequelae through earlier management of otherwise undiagnosed pituitary hormone deficiencies. However, routes to detection and clinical consequences of CeCHT have not been evaluated in the UK, precluding predictions of whether neonatal screening could be beneficial.
Method
We assessed biochemical and clinical characteristics in 118 CeCHT cases diagnosed between 1996 and 2022 at 4 tertiary UK centres and considered diagnostic challenges in the context of the clinical picture, baseline biochemistry and the potential impact of screening. Pseudonymized, electronic case records were reviewed retrospectively, recording markers of neurodevelopmental outcome and comparing percentages or median values in patients with early ('ED', < 15 days, i.e. within a typical newborn screening window) versus late diagnosis ('LD') for whom definitive data was available.
Results
26% cases were preterm, and 96% exhibited MPHD. Early treatment was commenced in only 19% ('ED'). Neonatal symptoms included hypoglycaemia, (95% ED, 66% LD) consistent with more frequent ACTH deficiency in ED cases (96% ED, 64% LD) and prolonged neonatal jaundice (61% ED, 62% LD). Hypothyroidism was usually moderate (FT4 SDS -2.4 and -2.6 in 'ED' and 'LD' groups). FT4 was initially checked at 54 days in LD cases, but fell within the laboratory reference range in 29%, and was first defined as abnormal on testing a median of 474 days later. In 24% cases, levothyroxine commencement was delayed (median 169 days, max. 7 yrs) after the first abnormal biochemistry. Significant neurodevelopmental concerns were noted in 37% patients (36% ED, 38% LD) of whom 75% had concomitant ACTH deficiency and in whom midline defects were common (56% vs 18% cases without significant concerns).
Conclusions
This is the largest evaluation of clinical features and pathways to diagnosis in a UK CeCHT cohort. Our findings demonstrate a vulnerable group of children, in whom frequent, MPHD-associated neurodevelopmental concerns mandate optimal management of thyroid status. However, despite neonatal symptoms, challenges in interpreting thyroid biochemistry and delays in testing frequently impede prompt diagnosis. There is a clear need both for systematic identification of CeCH in early life and for improved biochemical diagnostic tools.

Functional non-coding variants in a TTTG microsatellite on chromosome 15q26.1 are a common genetic etiology of congenital hypothyroidism, and present with a mild phenotype

Hirohito Shima[1], Tomohiro Nakagawa[1], Kanako Kojima-Ishii[1,2], Akinobu Miura[1], Ikuma Fujiwara[1,3], Satoshi Narumi[4], Atsuo Kikuchi[1] & Junko Kanno[1]
[1]Tohoku University Graduate School of Medicine, Department of Pediatrics, Sendai, Japan; [2]Fukuoka Children's Hospital, Department of Endocrinology and Metabolism, Fukuoka, Japan; [3]Sendai City Hospital, Department of Pediatrics, Sendai, Japan; [4]Keio University School of Medicine, Department of Pediatrics, Tokyo, Japan

Introduction
Variants affecting a microsatellite on the non-coding region of chromosome 15q26.1 are associated with familial non-autoimmune thyroid abnormalities that are characterized by mild congenital hypothyroidism (CH) with elevated thyroglobulin (Tg) levels. Individuals harboring these variants may develop multinodular goiter (MNG) in the absence of treatment. Although these variants have been recognized as genetic etiologies of CH, nongoitrous, 3 (CHNG3), the associated severity of CH remains unclear.
Methods
A cohort of 63 participants diagnosed with CH at Tohoku University underwent screening for genetic variants on 15q26.1. We subsequently analyzed the clinical phenotypes of the variant-carrying participants.
Results
We identified five 15q26.1 variant carriers from four families among the cohort. Family histories of thyroid abnormalities were documented in three particpants of these two families. The variant carriers exhibited mild CH phenotypes, with two discontinuing levothyroxine treatment and the others requiring relatively low doses (1.33–1.89 μg/ kg/day) at their final visit. Notably, the patients' elevated neonatal TSH levels decreased spontaneously within weeks. This suggests that congenital

thyroid hormone synthesis capacities are compensated for during early infancy in a subgroup of patients with CHNG3. All the variant carriers presented with ectopic and normal-sized thyroid glands. During levothyroxine treatment, serum thyroglobulin and thyroid-stimulating hormone (TSH) levels were within the reference ranges at the majority of the evaluation points. Three of the five participants continued treatment into adulthood, whereas the other two discontinued treatment and maintained their serum TSH levels within the reference range. All five participants demonstrated normal intellectual development and stature. Notably, in our sister participants who discontinued their treatments at puberty after 5 and 13 years of levothyroxine treatment, respectively, one of them with a short treatment period exhibited significantly higher Tg levels following treatment. This observation may be attributed to the fact that levothyroxine replacement can prevent thyroid gland enlargement resulting elevation in serum Tg levels, suggesting that levothyroxine treatment may prevent thyroid enlargement and lead to MNG requiring surgical intervention.

Conclusion

These findings provide further evidence supporting the role of 15q26.1 variants as a common genetic etiology of CH, with clinical phenotypes including transient CH. Early genetic evaluation may facilitate the identification of 15q26.1 variant carriers among patients who are diagnosed with CH.

Subclinical hyperthyroidism, cardiovascular disease and all-cause mortality: insights from a large DUTCH primary care cohort study

Stan Ursem[1], Raymond Noordam[2], Jesse van den Berg[3], Anita Boelen[1], Petra Elders[4], Wendy den Elzen[5] & Annemieke C Heijboer[1]
[1]Amsterdam UMC, Endocrine Laboratory, Laboratory Medicine, Amsterdam, Netherlands; [2]Leiden University Medical Center, Internal Medicine, Section Gerontology and Geriatrics, Leiden, Netherlands; [3]Pharmo Institute, Utrecht, Netherlands; [4]Amsterdam UMC, General Practice, Amsterdam, Netherlands; [5]Amsterdam UMC, Laboratory of Specialized Diagnostics & Research, Laboratory Medicine, Amsterdam, Netherlands

Background

Subclinical hyperthyroidism (SHT) has previously been associated with adverse cardiovascular outcomes, yet the magnitude and consistency of risk and its demographic variation remain unclear due to limited sample sizes of subgroups in previous cohorts.

Objectives

To evaluate the association between SHT and the risk of atherosclerotic complications, atrial fibrillation (AF), heart failure (HF), and all-cause mortality in a large primary care population.

Methods

This retrospective cohort study analyzed data from the PHARMO Dutch GP database. SHT was Based on thyroid hormone levels available in the dataset. Outcomes were compared between SHT patients ($n=11,163$) and a euthyroid reference group ($n=46,058$) using multivariable Cox regression models.

Results

SHT was not significantly associated with atherosclerotic complications. However, the risk of AF was markedly increased (multivariate HR 1.4; 95% CI, 1.2–1.6), particularly in patients with TSH <0.1 mU/l and younger patients (aged 30–49 years). HF risk was modestly elevated (multivariate HR 1.2; 95% CI, 1.0–1.4), with a stronger effect in younger patients (aged 30–49 years) and in women. All-cause mortality risk was also higher in the SHT group (multivariate HR 1.5; 95% CI, 1.4–1.6), especially in men and with younger age.

Conclusion

SHT is associated with increased risks of AF, HF, and all-cause mortality, with some notable demographic differences. Younger patients exhibited a higher relative risk, particularly for AF and all-cause mortality, challenging the traditional focus on older populations. These findings highlight the need for careful monitoring and individualized risk assessment in patients with SHT.

Introduction

Evidence consistently points against the use of thyroid hormones (TH) in euthyroid patients. It is unclear to what extent this therapeutic approach is adhered with.

Objectives

Questionnaires documenting the frequency of thyroid specialists' TH use in euthyroid individuals.

Methods

Data collected 2019-2022 by THESIS (Treatment of Hypothyroidism in Europe by Specialists; An International Survey), a large-scale survey of European, Australian and Latin American thyroid experts focused on the use of TH for hypothyroidism and non-hypothyroid indications. Eight questions explored respondent characteristics, and 23 the use of TH. Here we report on the use of TH in euthyroid female infertility with high level of thyroid antibodies, simple goiter growing over time, obesity resistant to lifestyle interventions, depression resistant to anti-depressant medications, severe hypercholesterolemia as complementary treatment, and unexplained fatigue.

Results

Of 18,543 endocrinologists invited, 5,863 valid responses were obtained (938 from 6 countries in Western Europe, 1,679 from 9 countries in Eastern Europe, 2,053 from 6 countries in Southern Europe, 713 from 5 countries in Northern Europe, 312 from 2 countries in Western Asia, 87 from Australia, 81 from Latin America). Between 35-55% stated that TH are never indicated for euthyroid patients. TH were more frequently suggested in female infertility (34-48%), and in growing goiter (10-41%); in other scenarios less frequently [obesity (0-7%), depression (4-17%), hypercholesterolemia (3-8%), unexplained fatigue (3-9%)]. TH were more frequently suggested in female infertility by female endocrinologists younger than 60 years managing a high number of thyroid patients, whereas in growing goiter by non-endocrinologists older than 60 years practicing in areas with present or former insufficient iodine intake (uni-multivariate analysis).

Conclusion

This large scale international survey shows that thyroid experts would use TH in different clinical scenarios in euthyroid individuals, particularly in female infertility and goiter. This finding is concerning and needs to be addressed.

Purpose

Veligrotug (VRDN-001), a full antagonist humanized monoclonal antibody to the IGF-1 receptor (IGF-1R), is an investigational treatment for thyroid eye disease

(TED). Clinical and preclinical evidence indicate a central role for IGF-1R antagonism in reducing the inflammation and proptosis that occur in TED. Topline efficacy and safety results at 15 weeks were assessed from an ongoing phase 3 randomized double-masked placebo-controlled trial of veligrotug vs placebo in patients with active TED (THRIVE, NCT05176639).
Methods
Adults with moderate-to-severe active TED (onset $\leq$15 months, proptosis $\geq$3 mm, and clinical activity score [CAS] $\geq$3) were randomized to receive 5 IV infusions 3 weeks apart of either 10 mg/kg veligrotug or placebo. Outcomes included proptosis responder rate (PRR), defined as $\geq$2-mm reduction vs baseline by Hertel exophthalmometry, PRR by MRI/CT, complete resolution of diplopia, and mean changes from baseline in proptosis and CAS. Treatment-emergent adverse events (AEs) were assessed through 15 weeks, with follow-up ongoing through 52 weeks.
Results
A total of 113 patients were randomized to veligrotug ($n=75$) or placebo ($n=38$) and included in the intent-to-treat population. At baseline, mean proptosis was 23.2 mm in each group; CAS was 4.5 vs 4.8 and diplopia was present in 67% vs 68% of patients for veligrotug vs placebo. At 15 weeks, PRR by Hertel was 70% vs 5% ($P<0.0001$) for veligrotug vs placebo, with a mean proptosis reduction of 2.9 mm vs 0.5 mm ($P<0.0001$). PRR by MRI/CT was 69% vs 9% ($P<0.0001$) for veligrotug vs placebo, with a mean proptosis reduction of 2.9 mm vs 0.6 mm ($P<0.0001$). Mean CAS decreased by 3.4 vs 1.7 ($P<0.0001$) for veligrotug vs placebo. In patients with diplopia, complete resolution of diplopia occurred in 54% (27/50) vs 12% (3/26) ($P<0.0001$) for veligrotug vs placebo. AEs occurred for 66 (88%) veligrotug vs 24 (63%) placebo patients, and most were mild; 4 patients (veligrotug) had serious AEs (all unrelated to treatment). Hearing impairment AEs were reported for 12 (16%) veligrotug vs 4 (11%) placebo patients.
Conclusions
Topline results from the THRIVE phase 3 trial show 5 IV infusions of 10 mg/kg veligrotug were well tolerated and led to significant and clinically meaningful improvements in proptosis, CAS, and diplopia at 15 weeks. Additional follow-up through 52 weeks is ongoing.

[1]Chung-Ang University Hospital, Pediatrics, Seoul, South Korea; [2]Seoul National University Children's Hospital, Pediatrics, Seoul, South Korea; [3]Seoul National University College of Medicine, Pediatrics, Seoul, South Korea; [4]Seoul National University College of Medicine, Radiology, Seoul, South Korea; [5]Seoul National University Hospital, Radiology, Seoul, South Korea; [6]Seoul National University College of Medicine, Pathology, Seoul, South Korea; [7]Seoul National University Hospital, Pathology, Seoul, South Korea; [8]Seoul National University College of Medicine, Internal Medicine, Seoul, South Korea; [9]Graduate School of Convergence Science and Technology, Molecular Medicine and Biopharmaceutical Siences, Seoul, South Korea

Background
A pediatric-specific biopsy cutoff for the Thyroid Imaging Reporting and Data System (TIRADS) is lacking.
Purpose
We investigated the utility of repeat biopsy by analyzing the initial and follow-up TIRADS and biopsy results. We analyzed a pediatric-specific biopsy cutoff considering clinical risk factors using the 2021 Korean (K) and American College of Radiology (ACR) TIRADS.
Methods
Pediatric patients who underwent thyroid nodule biopsy at Seoul National University Hospital between January 2010 and December 2021 were analyzed retrospectively. The diagnostic performance of TIRADS considering risk factors such as Hashimoto's thyroiditis, previous radiotherapy, a family history of thyroid cancer, or hereditary tumor syndromes was estimated.
Results
A total of 200 patients (median age, 16 years; 17 children $<$10 years and 183 adolescents 10–19 years; 153 females; 92 with risk factors) with 223 nodules (142 malignant nodules [64% of total; 86% of 166 resected nodules]) were analyzed. Repeat biopsies due to large size, interval growth, or TIRADS 4–5 category revealed that 6/21 (29%) nodules categorized as benign on initial biopsy were postoperative malignant. Compared to the current guideline, applying a modified pediatric-specific biopsy cutoff for both K-TIRADS and ACR-TIRADS (0.5 cm/1.5 cm for TIRADS 4 with/without risk factors and 0.5 cm for all TIRADS 5) improved sensitivity (85% vs. 78% for K-TIRADS, 84% vs. 60% for ACR-TIRADS, both $P<.005$), missed malignancy rate (33% vs. 39%, 30% vs. 46%, both $P<.05$), and accuracy (74% vs. 71%, 77% vs. 67%, $P=.30$ and.002).
Conclusion
For pediatric patients, especially adolescents, with either TIRADS 4 nodules with risk factors or TIRADS 5 nodules, the cutoff size for biopsy needs to be lowered to 0.5 cm. Repeat biopsy is required if clinical and ultrasound findings are discordant, even if the initial biopsy indicates a benign.

Hydrocortisone treatment only partially restores systemic dysregulations caused by cortisol deficiency in a 21-hydroxylase deficient zebrafish model

Irina A Bacila[1,2], Nan Li[2], Vincent Cunliffe[2,3] & Nils P Krone[1,2]
[1]The University of Sheffield, School of Medicine and Population Health, Division of Clinical Medicine, Sheffield, United Kingdom; [2]The Bateson Centre, Sheffield, United Kingdom; [3]Department of Biomedical Science, Sheffield, United Kingdom

Background
It is known that conditions causing cortisol deficiency, such as congenital adrenal hyperplasia, lead to systemic dysregulations that are associated to the development of co-morbidities. We wanted to test to what degree dysregulations caused by cortisol deficiency are corrected by a physiological dose of hydrocortisone (HC) treatment in a 21-hydroxylase deficient zebrafish model (*cyp21a2-/-*).
Methods
We used wild-type (WT) and *cyp21a2-/-* zebrafish larvae, comparing between four groups: WT untreated, *cyp21a2-/-* untreated, WT treated and *cyp21a2-/-* treated on day 4 post-fertilisation with hydrocortisone 10μM solution for 24 hours. Following RNA sequencing, transcriptomic analysis including differential gene expression (DGE), and Gene Set Enrichment Analysis (GSEA) was performed.
Results
DGE and principal component analysis showed that 50% of the variance related to hydrocortisone treatment, and 16% to genotype. HC treatment in WT led to 3153 differentially expressed genes (DEG). GSEA showed that in WT larvae, HC caused the suppression of multiple biological processes pertaining to innate and adaptive immunity. ATP synthesis, provision of energy precursors, lipid and protein metabolism were among the most upregulated processes. In untreated *cyp21a2-/-* mutants there were 1096 DEG compared to WT, while in treated mutants only 334 DEG compared to treated WT. In untreated *cyp21a2-/-*, the majority of downregulated biological processes pertained to ribosomal biosynthesis and mitochondrion organisation, and the most upregulated ones to the mitotic cell cycle. In treated mutants, the dysregulation of ribosomal biosynthesis was no longer present, however, there was downregulation of the cell cycle processes which had been upregulated in untreated mutants. Treated *cyp21a2-/-* mutants shared 185 significantly supressed biological processes with treated WT, of which the majority related to the immune response. There were 195 processes upregulated following HC treatment in both mutants and WT, including ATP synthesis, fatty acid beta-oxidation and several other metabolic processes. However, 89 processes were upregulated by HC only in *cyp21a2-/-*, of which only 9 had been downregulated in untreated mutants, the remaining 79 representing additional dysregulations and including metabolic processes such as lipid synthesis, localisation and transport.
Conclusion
HC treatment administered in zebrafish larvae restored only some of the biological dysregulations caused by cortisol deficiency. However, it also overcorrected processes and resulted in additional dysregulations. Interestingly, HC treatment caused the upregulation of several lipid metabolic processes only in the cortisol deficient zebrafish. Translated to human cortisol deficiency, these findings highlight the challenge of adequate glucocorticoid replacement and the need for further research aimed at optimising treatment.

Towards durable genomic editing for the treatment of congenital adrenal hyperplasia

Lara Graves[1,2,3], Lakshmy Viswanath[1], Eva van Dijk[1,3], Samantha Ginn[1,3] & Ian Alexander[1,3,4]

[1]Children's Medical Research Institute, Gene Therapy Research Unit, Westmead, Australia; [2]The Children's Hospital at Westmead, Institute of Endocrinology and Diabetes, Westmead, Australia; [3]The University of Sydney, Faculty of Medicine and Health, Sydney, Australia; [4]Sydney Children's Hospitals Network, Westmead, Australia

Despite life-saving corticosteroid treatment, individuals with congenital adrenal hyperplasia (CAH) have increased morbidity and mortality. Gene therapy has the potential to restore physiological corticosteroid production, however, optimisation of the technology is required. Recombinant adeno-associated virus (rAAV) is the most common vector used in *in vivo* gene delivery. rAAV-based gene addition strategies have been explored in CAH, however due to adrenocortical cellular renewal, resultant phenotypic changes were temporary. Here, we introduced targeted editing events in the 21-hydroxylase locus (*Cyp21a1*) in the murine adrenal gland *in* vivo through rAAV-delivered genomic editing, with phenotypic effect to 15 weeks. Homology-independent targeted integration was utilised. A single-guide RNA (sgRNA) was designed targeting the first intron and a matching donor cassette was designed capturing the endogenous Cyp21a1 promoter. Both vectors were pseudo-serotyped with AAV-Rh10. Adult 21-hydroxylase deficient mice (C57BL/10SnSlc-H-2^{aw18}) were treated intravenously with the *Staphylococcus aureus* Cas9 (SaCas9)/sgRNA (2.5×10e12vg/mouse) and/or donor (1×10e12vg/mouse) vectors and harvested 4 (short-term) or 15 (long-term, dual vector only) weeks later. Sanger sequencing demonstrated editing events at the desired locus within the *Cyp21a1* gene in the dual vector-treated mice. Correctly oriented donor inserts were detected in 7% of total *Cyp21a1* alleles and 39% of total *Cyp21a1* transcripts in the short-term mice. Treated mice had improved corticosterone production, with 6.7-fold (males) and 9-fold (females) increases. There was no phenotypic benefit in the control groups that received a single vector. Four female mice were harvested at 15 weeks after treatment to determine durability of effect, as the adrenocortical turnover period has been estimated at 3 months. Correctly oriented donor inserts accounted for 5% of the total alleles and 25% of the total expressed transcripts in the adrenal. These mice had persistence of improvement in corticosterone, with no statistical difference between the serum corticosterone level in the group harvested at 4 weeks compared with the group harvested at 15 weeks. Renin expression was lower in the long-term group compared with the short-term group. There was no statistically significant difference in serum aldosterone, serum progesterone, aldosterone synthase expression or adrenal size between these treated groups. We demonstrated that rAAV delivery of genomic editing reagents to the adrenal gland resulted in targeted editing events that conferred durable phenotypic benefit. Targeted editing events in the *Cyp21a1* gene is possible despite challenges faced with the homologous pseudogene. This strategy could be adapted for use in the human locus once rAAV tropism for the human adrenocortical progenitor cells is determined.

Background

Primary aldosteronism (PA) is common, affecting 5-20% of the hypertensive population and is associated with an increased cardiovascular risk and incidence of metabolic disease when compared with primary hypertension. To date, establishing a correct diagnosis is hampered by laborious and time-consuming protocols unable to capture the pulsatile variability of aldosterone across the day. In this study we applied a dynamic hormone profiling technique to study the dynamics of aldosterone and other corticosteroids in patients with established PA to lay the foundation for new diagnostic procedures and criteria.

Methods

Sixty PA patients were recruited, 26 unilateral, 24 bilateral, and 10 with undetermined PA subtype. Ambulatory 24-hour profiles of corticosteroids including aldosterone and the hybrid steroids 18-hydroxycortisol and 18-oxocortisol were quantified in subcutaneous tissue microdialysate by liquid chromatography tandem mass spectrometry and compared with 215 healthy participants. Specific dynamic features were extracted and used to develop a machine learning model to distinguish PA profiles from healthy normal variation.

Results

PA profiles under unstimulated conditions were characterised by a pulsatile secretion and diurnal rhythmicity of aldosterone, cortisol, intermediary steroids and hybrid steroids. Nocturnal and early morning hypersecretion of aldosterone, 18-hydroxycortisol and 18-oxocortisol was prominent in unilateral PA. 18-oxocortisol was seen almost exclusively in unilateral PA, both with and without somatic *KCNJ5*-mutations. 24-hour cortisol concentrations did not differ between PA and healthy participants. Applying dynamic hormone profiling with a machine learning classifier algorithm resulted in a diagnostic sensitivity of 88% and specificity of 80% in predicting PA. Normalisation of aldosterone hypersecretion was observed after adrenalectomy for unilateral PA.

Conclusions

24-hour tissue corticosteroid profiling in the home setting is achievable and reveals new insights into the pathophysiology of PA, characterised by nocturnal hypersecretion of aldosterone and hybrid steroids. The technique holds promise for faster and more accurate PA diagnosis with identification of unilateral cases.

[1]Institute of Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, Department of Pediatrics, Göteborg Pediatric Growth Research Center (GP-GRC), Gothenburg, Sweden; [2]Ryhov County Hospital, Region Jönköping County, Department of Pediatrics, Jönköping, Sweden; [3]Copenhagen University Hospital—Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark; [4]International Centre for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health, Copenhagen University Hospital—Rigshospitalet, Copenhagen, Denmark; [5]Mental Health Center, Copenhagen University Hospital, Sexological Clinic, Copenhagen, Denmark; [6]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; [7]Mental Health Services, Capital Region of Denmark, Child and Adolescent Mental Health Centre, Hellerup, Denmark

Background

Transgender adolescents may be treated with gonadotropin-releasing hormone analog (GnRHa) and sex steroids. Hormone therapy (HT) may affect cardiovascular risk factors such as overweight, obesity and dyslipidemia.

Objective

To evaluate weight, body mass index (BMI), and lipid profiles at start and during HT in a Danish national cohort of transgender adolescents who started HT before 18 years of age.

Patients and methods

The cohort consisted of 164 trans boys and 55 trans girls. GnRHa was initiated before ($n=102$ trans boys and $n=43$ trans girls) or simultaneously with testosterone ($n=62$) or estradiol ($n=12$). Weight, BMI and lipid profiles were assessed at routine visits. Changes in the estimate (95% confidence intervals) were analyzed for weight standard deviation score (SDS), BMI SDS, and lipid profiles, using mixed model analyses.

Results

Before HT, overweight (BMI $\geq$1SDS) and obesity (BMI $\geq$2SDS) were found in 29.9% and 22.0% of the trans boys and in 5.7% and 5.7% of the trans girls,

respectively. Lipids profiles outside normal range were found in both trans boys and girls; total cholesterol ≥5.0 mmol/l (12.5% and 6.1%), low-density lipoprotein (LDL) ≥3.0 mmol/l (20.4% and 8.2%), high-density lipoprotein (HDL) ≤1.0 mmol/l (10.3% and 18.4%), and triglycerides ≥2.0 mmol/l (4.1% and 6.3%), respectively. During GnRHa monotherapy, weight SDS declined after one year of treatment ($n=56$, -0.2(-0.3–-0.0), $P=0.017$) in trans boys and after one ($n=28$, -0.3(-0.5–-0.1), $P=0.010$) and two years ($n=9$, -0.4(-0.7–-0.1, $P=0.013$) in trans girls. No consistent trends were observed in BMI SDS or the lipid profiles. During sex steroid therapy, weight SDS declined in trans boys only; after two ($n=70$, -0.4(-0.6–-0.2), $P<0.001$) and three years of treatment ($n=13$, -0.7(-1.2–-0.2), $P=0.006$). No consistent trends were observed in BMI SDS. During the first three years of sex steroid therapy, HDL decreased ($n=104$, -0.1(-0.2–-0.1), $P<0.001$, $n=62$, -0.2(-0.2–-0.1), $P<0.001$, $n=25$, -0.2(-0.3–-0.1), $P<0.001$), and triglycerides increased ($n=104$, 0.2(0.1–0.4), $P=0.003$, $n=62$, 0.3(0.2–0.5), $P<0.001$, $n=26$, 0.4(0.2–0.6), $P=0.002$) in trans boys, while HDL increased in trans girls; ($n=28$, 0.3(0.1–0.4), $P<0.001$, $n=19$, 0.3(0.2–0.5), $P<0.001$, $n=7$, 0.4(0.0–0.7), $P=0.038$).

Conclusion

The prevalence of overweight, obesity and dyslipidemia before HT was high compared with normal range. BMI SDS did not deteriorate during HT, but dyslipidemia worsened slightly during testosterone treatment. The results suggest that some transgender adolescents may benefit from lifestyle interventions and treatment of dyslipidemia to reduce the long-term cardiovascular risk.

Background

Adrenal crisis is a life-threatening emergency in patients with adrenal insufficiency. Despite preventive measures, previous studies indicate a rising incidence, yet detailed and validated investigations are lacking.

Methods

We included 743 patients with autoimmune primary adrenal insufficiency (Addison's disease) identified through the Norwegian National Addison Registry. All medical records were reviewed for admissions between January 1, 2000, and December 31, 2023. Overt adrenal crisis was defined as an acute deterioration of health status associated with hypotension (systolic blood pressure<100 mmHg), hyponatremia (<130 mmol/l), hyperkalemia (>5 mmol/l) or hypoglycemia (<3.5 mmol/l). Incipient adrenal crisis was defined as marked and typical symptoms in the absence of objective features.

Results

After a median follow-up of 15 years, 64% of the patients had one or more crisis-related admissions. The incidence of overt adrenal crisis was 4.4 per 100 person years, while the incidence of incipient adrenal crisis was 7.0 per 100 person years. Over time, admission rates with incipient crisis increased, while admission rates with overt adrenal crisis remained stable. At admission, s-sodium<130 mmol/l and s-potassium>5 mmol/l was found in 17% and 13% of the cases, respectively. Four percent had serum glucose below 3.5 mmol/l and 1.8% below 2 mmol/l. Infection was the most common precipitating cause (52%). In 29% of cases, patients had administered oral stress dosing before admission, and 24% had injected hydrocortisone. These treatments were associated with a reduced odds of having crisis on arrival to hospital (oral, OR 0.44; 95% CI, 0,33-0,58, $P=<0.001$ and injection OR 0.64; 95% CI, 0.49-0.85, $P=0.002$). Crisis-related admissions were highest among the youngest patients and those with type 1 diabetes. Out of 1254 admissions, 13 patients (1%) died during the hospital stay. Adrenal crisis was deemed as a contributing case of death in four cases (0.3%).

Conclusions

The incidence of overt adrenal crisis is low, and in-hospital crisis-related mortality nearly absent. Wider use of oral stress dosing and pre-emergency hydrocortisone injections is needed to further reduce the risk of overt adrenal crises.

A double-blind study of modified-release hydrocortisones, chronocort versus plenadren, in adrenal insufficiency (CHAMPAIN)

Alessandro Prete[1], Verena Theiler-Schwetz[1], Wiebke Arlt[2], Irina-Oana Chifu[3], Birgit Harbeck[4], Catherine Napier[5], John Newell-Price[6], Aled Rees[7], Nicole Reisch[8], Gunter Stalla[9], Helen Coope[10], John Porter[10], Jo Quirke[10] & Richard Ross[6]
[1]University of Birmingham, Birmingham, United Kingdom; [2]MRC Laboratory of Medical Sciences, London, United Kingdom; [3]University Hospital of Würzburg, Germany, Wurzburg, Germany; [4]Amedes MVZ Hamburg, Hamburg, Germany; [5]Newcastle University, Newcastle, United Kingdom; [6]University of Sheffield, Sheffield, United Kingdom; [7]Cardiff University, Cardiff, United Kingdom; [8]Ludwig-Maximilians-Universität München, Munchen, Germany; [9]Ludwig-Maximilians-Universität, Munchen, Germany; [10]Neurocrine UK, Cardiff, United Kingdom

Background

Patients with adrenal insufficiency (AI) have impaired quality of life (QoL), low energy and increased mortality. Immediate-release hydrocortisone is first-line replacement therapy, however, fails to restore the physiologic diurnal cortisol rhythm. There are two modified-release hydrocortisone formulations: 1) Plenadren®, taken in a single morning dose, and 2) Chronocort® delayed release, taken twice daily in a toothbrush regimen (last thing at night, first thing in the morning). Chronocort but not Plenadren mimics the physiologic rise in early morning cortisol. We compared Plenadren to Chronocort to test the hypothesis that waking with physiological cortisol levels will reduce fatigue and improve QoL.

Methods

double-blind, double-dummy, two-way cross-over, randomised, study comparing Chronocort vs Plenadren, one month on each treatment at 25mg/24 hours. Inclusion criteria were primary AI with morning pre-dose cortisol <50 nmol/l (1.8 μg/dl). The primary endpoint was the difference in 07:00 h cortisol after 4 weeks of treatment. The key secondary outcome was the Multidimensional Assessment of Fatigue (MAF) score after 4 weeks. Other secondary outcomes included the disease specific questionnaire AddiQol, the fatigue questionnaire PROMIS 7b, and QoL as measured by SF36 and EQ-5D-5L.

Results

Of 49 evaluable participants, 45 achieved a physiological morning cortisol (>140 nmol/l, 5ug/dl) with Chronocort compared with 2 on Plenadren (median serum cortisol 417.0 (15) vs 6.04 (0.2) nmol/l (μg/dl), $P<0.0001$). The MAF score was not significantly different between the two treatments; however, a sensitivity analysis showed that in the first treatment period Chronocort reduced MAF Score ($P=0.008$) suggesting a carry-over effect from period 1 to 2. The majority of the other QoL measures in the secondary efficacy analysis showed significant benefit for Chronocort including: The disease specific questionnaire AddiQol ($P=0.03$), the fatigue questionnaire PROMIS 7b ($P=0.02$), SF36 physical functioning ($P=0.03$) and EQ-5D-5L ($P=0.02$). The sensitivity analysis for all these measures showed greater benefit for Chronocort and patients showed a preference for the Chronocort treatment period. The safety profiles were similar, as expected for patients with AI, with no new safety signals identified.

Conclusions

In adrenal insufficiency Chronocort provides physiological waking cortisol levels and is associated with reduced fatigue and improved QoL as compared to Plenadren.

Background
The majority of children diagnosed with idiopathic isolated growth hormone deficiency (IIGHD) shows normal growth hormone (GH) secretion when retested at near adult height (NAH; height velocity <2cm/y). The question is whether continuing recombinant human GH (rhGH) treatment affects NAH if normal GH secretion is observed in mid-puberty.
Aim
To investigate if withdrawing rhGH treatment from mid-puberty onwards had no negative effect on attained NAH in adolescents who no longer fulfilled a diagnosis of GH deficiency.
Methods
Adolescents diagnosed with IIGHD in childhood (GH peak at diagnosis 1.7-10 µg/l) who started rhGH treatment between 2005-2018 and tested GH sufficient (GH peak >6.7 µg/l) at mid-puberty were included in this prospective multi-center SEENEZ-trial. Mid-puberty was defined as Tanner stage G3/4, testicular volume >12 ml, bone age 13-16 years in males and Tanner stage B3/4, bone age 11-14 years in females. Study participants had the choice to discontinue or continue rhGH treatment until NAH. Primary outcome was NAH-SDS minus target height (TH) SDS. Secondary outcomes were NAH-SDS and total pubertal growth. Additionally, attained versus predicted height gain from mid-puberty to NAH was calculated using a prediction model, developed from retrospective data of an IIGHD cohort who were GH sufficient upon retesting at NAH.
Results
A total of 127 patients (95 male, 75%) participated. Forty-four patients (35%) continued rhGH treatment until NAH (GHcont), and 83 patients (65%) stopped GH treatment (GHstop). Baseline height SDS and age at mid-puberty did not differ significantly between groups. Mean (SD) NAH-SDS minus TH-SDS was -0.16 (0.60) in the GHcont and -0.19 (0.62) in the GHstop group ($P=.78$). Mean NAH-SDS was -0.91 (0.76) (GHcont) vs -0.79 (0.76) (GHstop) ($P=.42$). Mean (SD) total pubertal growth in males was 27.4 cm (7.1) (GHcont) vs 25.9 cm (6.2) (GHstop) ($P=.30$) and in females 20.5 cm (5.7) (GHcont) vs 21.2 cm (7.6) (GHstop) ($P=.82$). The predicted vs attained height gain based on the prediction model did not differ between groups.
Conclusions
In IIGHD adolescents who tested GH-sufficient in mid-puberty, NAH is comparable between those who continued rhGH treatment until NAH and those who stopped rhGH treatment at mid-puberty. In transient IIGHD adolescents, rhGH treatment can be stopped at mid-puberty. Implementing these results in guidelines reduces the duration of rhGH treatment by 2-3 years in most children with IIGHD, leading to a substantial decrease in patient burden, need for medical care and healthcare costs.

Chemogenic activation of growth hormone-releasing hormone neurons stimulates the luteinizing hormone secretion

Lígia de Sousa[1], Vanielle Vicente[1], Stephanie Rusew[1] & Jose Donato Junior[1]
[1]University of Sao Paulo, Sao Paulo, Brazil

Neurons expressing growth hormone-releasing hormone (GHRH) are found in the arcuate nucleus of the hypothalamus (ARH), and they play a key role in stimulating GH secretion. Conversely, neurons expressing gonadotropin-releasing hormone (GnRH) and kisspeptins are stimulators of the luteinizing hormone (LH) secretion. Previous studies have shown that a subpopulation of GHRH neurons co-expresses kisspeptins in adult female mice but not in adult males or prepubertal animals. Thus, whether GHRH neurons can influence other endocrine axes beyond the somatotropic axis is unclear. The objective of this study was to evaluate whether the chemogenetic activation of GHRH neurons is able to modulate LH secretion in addition to GH. Initially, mice that constitutively express the cholinergic muscarinic receptor type 3 (hM3Dq) in GHRH neurons were produced. These animals were generated by crossing GHRH-Cre mice with a Cre-dependent hM3Dq-expressing strain. For acute stimulation of GHRH neurons, mice received an intraperitoneal injection of clozapine N-oxide (CNO) or vehicle solution (as control). Serial blood samples were collected before and after injection for subsequent hormonal dosage by ultra-sensitive enzyme-linked immunosorbent assay. Our findings indicate that the activation of GHRH neurons led to a robust GH secretion. Remarkably, a statistically significant increase in LH secretion was also observed in both male and female mice, either in adult (2-3 months) or prepubertal (~21 days of life) animals. Subsequently, GHRH-Cre and Kiss1-Cre adult mice received a bilateral injection in the ARH of an adeno-associated virus, inducing the expression of hM3Dq in Cre-positive cells. The chemogenic activation of either GHRH- or Kiss1-expressing cells also increased GH and LH circulating levels. Our findings indicate a crosstalk between the somatotropic and reproductive axis via ARH neuroendocrine neurons.

Insulin promotes the expression of aromatase in growth plate chondrocytes by activating the PI3K/AKT signaling pathway and enhancing the activity of the CYP19A1 specific promoter

Sicui Hu[1,2], Rongxiu Zheng[1] & Tang Li[2]
[1]General Hospital of Tianjin Medical University, Tianjin, China; [2]Qingdao women and children's hospital, Qing dao, China

Objectives
The mechanisms behind the increased height velocity and accelerated epiphyseal growth plate maturation since early childhood aren't well-defined.Hyperinsulinemia has been implicated as one of the causative factors.The aim of this study is to explore the mechanisms by which insulin regulates the expression of local aromatase in the growth plate,thereby leading to accelerated epiphyseal closure.
Methods
Culturing and identification of primary chondrocytes from the growth plate of 20 - day - old Sprague - Dawley rats were performed.The CCK8 assay procedure was utilized to identify the optimal concentrations of leptin antagonist and PI3K inhibitor. After culturing primary chondrocytes for 4 days and subjecting them to serum starvation for 24 hours,the leptin antagonist and insulin were sequentially added. qPCR and Western blot were employed to analyze the effects of different action durations and concentrations of insulin on the mRNA and protein expression of CYP19A1. This step was to determine the optimal action time and concentration of insulin for subsequent signal pathway studies. The phosphorylation of AKT in chondrocytes was analyzed by Western blot, and the changes in AKT phosphorylation, CYP19A1 mRNA and protein levels following the addition of a PI3K inhibitor were examined. After the construction, the four recombinant plasmids (pGL3.0-CYP19A1-I.3, pGL3.0-CYP19A1-II, pGL3.0-CYP19A1-I.4, and pGL3.0-CYP19A1-I.6) containing different lengths ofthe aromatase promoter fragments were co-transfected with the the dual-luciferase reporter system (firefly luciferase and Renilla luciferase) into the target cells. The activity of each promoter was quantitatively evaluated by the Dual-Luciferase Reporter Assay Kit.
Results
qPCR and Western blot analysis showed that 12-hour treatment with 20 nmol/l insulin maximally upregulated CYP19A1 mRNA and protein expression in a dose and time dependent manner ($P<0.01$).Western Blot was employed to detect the phosphorylation of AKT at specific time points,namely 1, 5, 15, 30, and 60 minutes. The results indicated that AKT phosphorylation reached its peak at 30 minutes.In the PI3K inhibitor group, the degree of AKT phosphorylation was significantly decreased at 30 minutes ($P<0.01$). After insulin (20 nmol/l) acted for 12 hours, the expression of CYP19A1 mRNA and protein in the PI3K inhibitor group was significantly reduced ($P<0.01$). Luciferase reporter gene analysis showed that after 12 hours of incubation, insulin significantly increased the activity of aromatase promoters I.4/I.6.
Conclusions
Insulin not only promotes the expression of aromatase within growth plate chondrocytes through the PI3K/AKT signal transduction pathway, but also significantly upregulates the activity of aromatase promoters I.4/I.6.

Background
Adult growth hormone deficiency (aGHD) is characterized by metabolic abnormalities due to insufficient growth hormone (GH) production. Lonapegsomatropin was designed to provide release of unmodified somatropin, and once-weekly injection reduces the burden of daily GH replacement therapy.
Methods
ForesiGHt was a randomized, parallel-3-arm, placebo-controlled (double-blind) and active-controlled (open-label) trial to establish the efficacy and safety of lonapegsomatropin in aGHD. 259 adults with GHD across 21 countries who were GH treatment-naïve or not treated with GH in the prior year, randomized 1:1:1 to receive lonapegsomatropin, once-weekly placebo, or daily somatropin. Fixed dosing was based on age and oral estrogen intake, designed to be comparable across lonapegsomatropin and somatropin arms. Following a 12-week (w) titration to target maintenance dose, fixed doses were administered for 26w.
Results
Baseline characteristics were similar between arms. Lonapegsomatropin demonstrated superiority on the primary efficacy endpoint of change from baseline (CFB) in trunk percent fat at 38w vs placebo (lonapegsomatropin -1.7%, placebo 0.4%, LS mean difference -2.0%, $P<0.0001$) and key secondary efficacy endpoints of CFB in total body lean mass (lonapegsomatropin 1.6 kg, placebo -0.1 kg, LS mean difference 1.7 kg, $P<0.0001$) and CFB in trunk fat mass (lonapegsomatropin -0.5 kg, placebo 0.2 kg, LS mean difference -0.7 kg, $P=0.0053$). Mean total exposure and maintenance doses were similar for lonapegsomatropin and somatropin arms, with larger CFB in average IGF-I SDS mean at 38w in the lonapegsomatropin arm (1.4) vs somatropin arm (0.5). To assess outcomes at comparable weekly IGF-I exposure, a post-hoc analysis was done in participant subsets with average IGF-I SDS $\leq$1.75 SDS at 38w. Mean IGF-I SDS for these subsets were similar (lonapegsomatropin -0.1, somatropin -0.5), with comparable effects in fat and lean tissue compartments (CFB in trunk percent fat mean -2.4% and -2.6% respectively; CFB in total body lean mass mean 1.7 kg and 1.4 kg respectively). In the safety population, the incidence of severe AEs was low (lonapegsomatropin, 3.4%; placebo, 1.2%; somatropin, 2.3%) and the incidence of treatment-related AEs was similar (lonapegsomatropin 24.7%, somatropin 22.1%). Injection site reaction incidence was low and similar for lonapegsomatropin (4.5%), somatropin (5.8%) and placebo (4.8%), and A1c levels remained stable in all treatment arms.
Conclusions
The results of the foresiGHt trial indicate that lonapegsomatropin is an efficacious and tolerable replacement for endogenous GH. Once-weekly dosing may be impactful for adults with GHD who typically manage multiple other medical therapies.

Background
The spectrum of genes associated with Noonan syndrome (NS) is growing and the real-life experience with management of these children is increasing; however, the genotype-phenotype correlation and a tailored management await further refinement.
Aim
To evaluate patient characteristics and the response to growth hormone (GH) therapy in a genetically defined large multicentre cohort of NS patients from a single country.
Patients and methods
Eighty-eight patients with NS (51 males) from five participating centres were included. Of these, 63 had a (likely) pathogenic variant in *PTPN11*; 10 in *SOS1*; and 15 in other genes (*BRAF* [2], *HRAS* [2], *KRAS* [3], *LZTR* [1], *MAP2K1* [1], *NRAS* [1], *RAF1* [3] and *SHOC2* [2]). All completed at least the first year of GH therapy while fifteen patients had already achieved their final height following GH administration.
Results
Not surprisingly, parental height was shorter than the population mean (fathers, -0.33 SDS [-1.33;0.57; median and IQR; $P=0.001$], mothers, -0.60 SDS [-1.47;0.12; $P<0.0001$]. The *SOS1*-patients were born earlier (GW 38 [32.5;38.3]) if compared to *PTPN11*-patients (GW 39 [38;40]; $P<0.001$). In the whole cohort of children, birth length was apparently lower (-1.26 SD [-1.78;-0.55] than the birth weight (-0.35 SD [-1.14;0.55; $P<0.0001$] demonstrating intrauterine bone growth restriction. Interestingly, both birth length and weight were lower in the *PTPN11* and *SOS1* patients if compared to the non- *PTPN11*-non- *SOS1* subcohort ($P<0.05$). GH stimulation testing was performed in 47/88 patients, with a peak GH of 7.8 mg/l [5.0;10.4]. Subsequently, GH therapy was started at age 5.7 years (3.8;9.3) with height-SDS -3.09 (3.74;2.59). The median annual height-SDS increments were 0.61 (year 1; $n=88$); 0.29 (year 2; $n=70$); 0.21 (year 3; $n=57$); 0.11 (year 4; $n=51$); and 0.09 (year 5; $n=34$), and were similar regardless the causative gene. The subcohort with final height already known ($n=15$) started GH therapy later (at 9.0 years [5.8;11.8] with height-SDS -3.48 (-3.86;-3.05). Following similar height increments, they reached height-SDS -2.00 (-3.26;-1.63) at pubertal onset (aged 12.5 years [11.5;14.3]), and final height-SDS -2.07 (-2.65;-1.08; aged 18.0 years [16.0-18.9]).
Conclusions
Growth restriction in NS has a prenatal component that is apparent in *PTPN11*- and in *SOS1*-patients, but not in the non- *PTPN11*-non- *SOS1* subcohort. GH therapy leads to a clinically significant improvement of statural height in all genetic subcohorts. In those with a known final height, the height increment occurred prior to pubertal onset; the pubertal portion of growth did not further improve final height. Thus, earlier initiation of therapy within childhood may optimize growth outcomes.

Background
Navepegritide is an investigational prodrug of C-type natriuretic peptide (CNP), administered subcutaneously once weekly and designed to provide a low C_{max} through sustained release of active CNP. Continuous exposure to the released CNP stimulates natriuretic peptide receptor B (NPR-B) to counteract the constitutively active fibroblast growth factor receptor 3 (FGFR3) in achondroplasia (ACH). ApproaCH is a pivotal, randomized, double-blind, placebo-controlled trial evaluating navepegritide in children with ACH.
Methods
Children with ACH ($n=84$, aged 2-11 years) were stratified by age and sex and randomized 2:1 to receive navepegritide (100 μg/ kg/week) or placebo for 52 weeks. The primary endpoint was annualized growth velocity (AGV) at week 52. Secondary endpoints included ACH-specific height Z-scores. Safety and tolerability were evaluated through treatment-emergent adverse events (TEAEs), including injection site reactions (ISRs), and changes in bone age.
Results
The trial met its primary endpoint, demonstrating superiority of navepegritide over placebo in AGV at week 52. Children treated with navepegritide achieved a least square (LS) mean AGV of 5.89 cm/year compared with 4.41 cm/year in children who received placebo (LS mean treatment difference 1.49 cm/year, $P<0.0001$). Change from baseline in ACH-specific height Z-score at 52 weeks was also significantly greater in the navepegritide group than the placebo group (LS mean treatment difference 0.28, $P<0.0001$). In subgroup analyses of children aged ≥5 years ($n=53$), participants treated with navepegritide had a higher AGV at Week 52 (LS mean treatment difference 1.78 cm/year, $P<0.0001$) and a greater change from baseline in ACH-specific height-Z-score (LS mean treatment difference 0.31, $P<0.0001$) than those who received placebo. Most TEAEs were mild or moderate, with a low event rate of ISRs (all mild) across groups (0.41 events per person year of exposure with navepegritide vs. 0.15 with placebo). The incidence of treatment-related AEs was similar between the navepegritide (21.1%) and placebo (25.9%) groups. The mean bone age to chronological age ratio remained relatively unchanged from baseline (change of 0 in the navepegritide group and -0.01 in the placebo group).
Conclusion
Navepegritide demonstrated superiority over placebo in AGV at week 52 of the ApproaCH trial. Statistically significant improvements in ACH-specific height Z-scores in children treated with navepegritide compared with placebo were also observed. These findings suggest that the design of navepegritide – to provide continuous exposure to active CNP – improves growth in children with ACH while maintaining a safety and tolerability profile comparable to placebo.

Introduction
Acquired hypothalamic obesity (aHO) results from physical hypothalamic damage due to trauma, tumours, treatment-related injuries, or inflammation, which can disrupt the melanocortin-4 receptor (MC4R) signalling pathway. aHO is characterized by rapid and excessive weight gain following the damage. A 16-week Phase 2 open-label trial, treating aHO with the MC4R agonist setmelanotide produced consistent and clinically significant responses, maintained or improved over a 12-month follow-up period. This report presents real-world data for 25 patients in France with aHO treated with setmelanotide under pre-marketing early access authorization.
Methods
For patients with aHO in France under early access treatment with setmelanotide for a minimum of 3 months changes in BMI are reported.
Results
Twenty-five patients (14 females), including 9 children, aged 7-42 years old, were included. Seventeen patients had craniopharyngioma, 3 astrocytoma, and 1 each AQP4 antibody encephalitis, ganglioma, Langerhans cell histiocytosis, neuroglial tumour or viral inflammation affecting the pituitary region. Patients started treatment at 0.25 to 2 mg/day. Depending on the duration of treatment, treatment response, and adverse events, patients received 1 to 3 mg/day at last included visit. For all 25 patients, mean BMI (SD) decreased from 40.6 (8.7) kg/m^2 to 36.2 (7.9) kg/m^2 after 3-month treatment, indicating a 10.8% decrease from baseline. For patients with 6-month data ($n=12$), mean BMI decreased from 42.5 (7.9) kg/m^2 to 37.6 (6.6) kg/m^2 to 34.9 (5.7) kg/m^2 after 3- and 6-month treatment, respectively, representing an 11.6% and 18.0% decrease from baseline. For patients with 9-month data ($n=7$), BMI decreased from 43.7 (7.9) kg/m^2 to 38.8 (7.0) kg/m^2 to 35.7 (6.0) kg/m^2 to 34.5 (6.0) kg/m^2 after 3-, 6- and 9-month treatment, respectively, indicating an 11.4%, 18.3% and 21.0% decrease from baseline. All patients except 1 had a lower BMI at each included time point. The patient with an increase in BMI, at Month 6, had surgery after 3 months due to disease progression and stopped treatment for 10 days. No new safety signals were observed.
Conclusions
This real-world evidence of 25 patients with aHO, including 3 with non-tumour-related causes, who received at least 3 months of setmelanotide under pre-marketing early access authorization in France showed consistent improvements in BMI in the majority of patients. Efficacy and safety outcomes are consistent with Phase 2 trial data that demonstrate beneficial outcomes of setmelanotide treatment in patients between 6 and 40 years of age with aHO.

[1]Barts and the London Medical School, London, United Kingdom; [2]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, United States; [3]Fulbourn Hospital Cambridge, Cambridge, United Kingdom; [4]Vanderbilt University, Nashville, United States; [5]The Research Institute at Nationwide Children's Hospital, Columbus, United States; [6]Soleno Therapeutics, Inc, Redwood City, United States; [7]University of Florida, Gainesville, United States

Background
Prader-Willi syndrome (PWS) is a rare genetic neurobehavioural-metabolic disorder characterised by hyperphagia and behavioural/psychological complications. No approved therapy exists for treating hyperphagia in patients with PWS. DCCR is an oral, once-daily medication currently under development for treating patients with PWS who have hyperphagia.
Objective
The objective of this analysis was to characterise the long-term efficacy of DCCR on DBC2 questionnaire total and subscale scores and the relationship between

changes in behaviours and changes in hyperphagia in participants with PWS from 2 completed studies encompassing > 3 years of exposure to DCCR.
Methods
The population included 125 participants ≥4 years old with genetically-confirmed PWS who received DCCR in either of 2 sequential studies: a 13-week, placebo-controlled study (Study C601) followed by an open-label extension (OLE) study (Study C602-OLE). Baseline was defined as the last assessment prior to the first DCCR dose. The primary endpoint was change from baseline in hyperphagia assessed by Hyperphagia Questionnaire for Clinical Trials (HQ-CT) Total Score. Behavioural changes were assessed using the DBC2 questionnaire which evaluates behaviours using total score and 6 subscales: Anxiety, Communication Disturbance, Disruptive Behaviour, Self-Absorbed, Social Relating and a subscale associated with PWS. The relationship between change in HQ-CT and changes in behaviour were evaluated using correlations.
Results
At baseline, the median age of participants was 12.0 (range 4, 44) years, 69 (55.2%) were female, and the mean (SD) HQ-CT Total Score was 21.5 (6.7). Over 3 years of DCCR administration, there was a clinically and statistically significant improvement in HQ-CT total score at all assessments [LS mean change (SE, *n*) at 3 years -10.7 (0.76; 81); $P<0.0001$]. Administration of DCCR was also associated with significant improvements in DBC2 total score at all timepoints [LS mean change (SE, n) at 3 years -15.5 (2.06, 71); $P<0.0001$] and all subscales at all timepoints (all $P<0.0001$). At 3 years, improvements in DBC2 subscale scores ranged from 29% to 39%. The correlation between HQ-CT change and DBC2 total score change at 52 weeks was 0.53 ($P<0.0001$), and the correlations between HQ-CT changes and changes in DBC2 subscales ranged from 0.25 ($P=0.0159$, anxiety subscale) to 0.56 ($P<0.0001$, self-absorbed subscale).
Conclusions
Long-term administration of DCCR for up to 3 years in participants with PWS was associated with clinically significant improvements in hyperphagia and behaviours. Behavioural improvements appeared to be independent of hyperphagia improvements. These hyperphagia and behavioural improvements should benefit patients with PWS and their families.

Introduction
Prader Willi Syndrome (PWS) is a rare genetic disorder (1:20,000 live births) characterized by hypothalamic dysfunction, leading to endocrine complications including early-onset, and life-threatening obesity. Controlling weight is particularly challenging due to behavioural disorders and an intense hyperphagic drive. In cases of progressive obesity, bariatric surgery, such as laparoscopic sleeve gastrectomy (LSG), may be considered. While LSG is effective in non-syndromic adolescents and young adults with severe obesity, evidence of its long-term efficacy in PWS remains limited.
Patients and methods
We enrolled 16 patients affected by genetically confirmed PWS, and 32 sex-, age- and BMI-matched non-syndromic control subjects (OB) with severe obesity (BMI-standard deviation score [SDS] > 3), who underwent LSG. The whole cohort included 24 males (50%), with a median age at surgery of 16.2 years [range: 8.1-26.7]. All subjects underwent comprehensive endocrine and metabolic evaluation, received personalised nutritional counselling, as well as psychological assessment and multidisciplinary support before and after surgery.
Results
Baseline median weight, BMI and BMI-SDS were 117.6 [IQR 97.3-131.9] vs 122.3 [111.5-144.0] Kg ($P=0.130$), 47.0 [41.1-53.4] vs 44.3 [40.7-49.5] Kg/m^2 ($P=0.252$), and +5.2 [4.3-6.3] vs +4.5 [4.0-5.0] ($P=0.032$) in the PWS and OB groups, respectively. Patients were followed-up for a median of 4.8 [3.6-7.1] years. Changes in mean BMI-SDS at each year were significantly lower in PWS compared to OB patients: year 1 (-30.6±19.9% vs -55.7±23.6%, $P=0.008$), year 2 (-29.8±31.2% vs -65.5±28.5%, $P=0.008$), year 3 (-8.4±31.8% vs -65.0±33.4%, $P=0.006$), year 4 (-9.1±31.6% vs -62.1±30.4%, $P=0.006$), year 5 (-18.5±34.5% vs -58.5±35.1%, $P=0.014$). The number of comorbidities (intermediate hyperglycaemia or diabetes mellitus, hypertension, hypercholesterolemia, hypertriglyceridemia and obstructive sleep apnea) decreased from 2.6±1.5 to 1.9±1.2 in the PWS group ($P=0.051$), and from 1.1±0.9 to 0.5±0.2 in the OB group ($P=0.125$).
Conclusions
LSG results in less sustained weight loss in PWS than in OB over a 5-year period. LSG should be considered in PWS selected patients with complicated obesity when a rapid weight loss is needed. However, these findings highlight the need for alternative or adjunctive therapeutic strategies to address the complex pathophysiology of obesity in PWS and improve long-term outcomes.

FetuinA connects hepatic steatosis and islet lipid accumulation in HFD mice: inhibiting TLR4 to protect beta cell function therein

Samanwita Mandal[1], Oindrila Mukherjee[1], Nandita Das[1] & Rakesh Kundu[1]
[1]Visva-Bharati University, Department of Zoology, Siksha Bhavana (Institute of Science), Santiniketan, India

Introduction
We and others have linked intracellular lipid accumulation in pancreatic islets with beta-cell dysfunction. Here, we report the effects of advancing hepatic steatosis on islet lipid accumulation during hyperlipidemic conditions. Increase in circulatory free fatty acids (FFA) enhances the expression and secretion of FetuinA (FetA) from the liver into the circulation. FetA, in combination with FFAs, activates TLR4, which induces insulin resistance and islet inflammation. This study thus targets TLR4 using its inhibitor C34 to investigate the regulation of islet lipid accumulation and beta cell function during the progression of hepatic steatosis.
Methods
C57BL/6J male mice were divided into 6 groups and given a standard diet (SD) for 20 weeks or a high-fat diet (HFD) for 4, 8, 12, 16 and 20 weeks. Another experiment had three groups receiving SD, HFD, HFD + TLR4 inhibitor C34 (1 mg/kg/day, i.p.) for 12 weeks. To assess the effects of FetA, mice on 4-week HFD received FetA i.p. injection for 5 days. Pancreatic islets from treated mice were subjected to immunoblot, qPCR and Nile Red staining. Immunofluorescence and H&E staining were performed on liver and pancreatic sections. Serum FetA level was measured using ELISA. Beta-cell function was evaluated by in-vivo GSIS.
Results
Results showed progressive increase in intracellular lipid accumulation in the pancreatic islet, along with hepatic steatosis and serum FetA levels, with HFD treatment from 4-16 weeks. However, in the 20-week HFD group, significant islet mass reduction with damage in islet morphology was observed. Increase in vesicular steatosis was seen in the liver with prominent adipocyte infiltration in the 20-week HFD, as evident from H&E-stained liver sections. Confocal images revealed higher lipid accumulation in islets of FetA-injected 4-week HFD mice compared to HFD (4-week) alone (~2-fold), suggesting the involvement of FetA in aggravating lipid accumulation. A concomitant increase in TLR4 expression and reduction in insulin content in the islet was observed in the HFD + FetA mice. TLR4 inhibition by C34 administration in HFD mice significantly reduced islet lipid accumulation and lowered circulating FetA (~0.4-fold) and IL-1β levels. Both lipid uptake and de-novo lipogenesis markers CD36 and SREBP1 were reduced in the islet of C34-treated HFD mice. Inhibiting TLR4 improved in-vivo GSIS, insulin gene expression and Pdx1 levels in HFD islets.
Conclusion
Elevated serum FetA level with advancing hepatic steatosis poses a significant increase in islet lipid accumulation and consequent dysfunction of beta cells in obese mice and could be prevented by early inhibition of TLR4.

SMG7 as a potential contributor to the progression of chronic liver disease to hepatocellular carcinoma

Betsaida Ojeda-Pérez[1,2,3] , Víctor J. Fernández-Ramírez[1,2,3], Jose Cordoba-Chacon[4] , Manuel Rodríguez-Perálvarez[2,3,5] , Raul M. Luque[1,2,3] , Juan Luis López-Cánovas[1,2,3] & Manuel D. Gahete[1,2,3]

[1]Department of Cell Biology, Physiology and Immunology, University of Cordoba, Córdoba, Spain; [2]Reina Sofia University Hospital (HURS), Córdoba, Spain; [3]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Córdoba, Spain; [4]Department of Medicine of the University of Illinois at Chicago, Chicago, Ilinois, United States; [5]Department of Hepatology and Liver Transplantation, Reina Sofía University Hospital, Córdoba, Spain

Background
The SMG7 factor plays a key role in the nonsense-mediated mRNA decay (NMD), a cellular pathway that removes mRNAs containing common errors, such as premature termination codons (PTCs), to prevent their translation. Numerous NMD targets are involved in cellular stress responses. Additionally, SMG7 supports cell survival following genotoxic stress by activating the ATR-Chk1 pathway. Chronic exposure to lipotoxic free fatty acids (FFAs) in liver disease contributes to cellular stress and liver damage. This study focuses on investigating the role of SMG7 in the progression of metabolic dysfunction-associated steatotic liver disease (MASLD), metabolic dysfunction-associated steatohepatitis (MASH) , and hepatocellular carcinoma (HCC).
Method
Expression (mRNA) of 22 NMD components was analyzed in two retrospective HCC cohorts (cohort 1 [$n=89$ HCC and non-tumor paired adjacent tissues (NTAT)] by microfluidic-based qPCR array and cohort 2 [$n=31$ HCC and $n=31$ NTAT] by RNA-seq), and validated in six external cohorts with healthy, MASLD, MASH, HCC, and/or NTAT samples. GSEA enrichment analysis was performed. Human (THLE2) and mouse primary hepatocytes (MPH) were treated with FFAs. Pharmacological (NMDI14, which blocks SMG7-UPF1 interaction) and genetic modulation of SMG7 were carried out in two liver-derived cell lines (Hep3B and SNU-387) to explore the functional effects in vitro.
Results
SMG7 is consistently overexpressed in samples of MASH, HCC, and MASH-derived HCC. In addition, hallmark pathways related to proliferation (mitotic spindle, G2M checkpoint, and E2F targets) are enriched in tumor samples with high SMG7 expression in the retrospective cohort 2 and an external cohort (TCGA or GSE164760). Furthermore, SMG7 (mRNA) expression was stimulated by FFAs (palmitate) in THLE2 and MPH cells, and its overexpression in liver cell lines enhances proliferation, as well as colony and tumorspheres formation. In contrast, SMG7 silencing reduced the proliferation and migration of SNU-387 cells, while having minimal functional effects on Hep3B cells, possibly due to a compensatory increase in UPF1, another key NMD factor. Notably, co-silencing SMG7 and UPF1 decreased tumor aggressiveness in both HCC cell lines. Consistently, treatment with NMDI14 led to a reduction in the aggressiveness of the HCC cell lines, while having no impact on MPH viability but reducing THLE2 proliferation.
Conclusion
The SMG7 factor could have a key role in the progression of MASLD-HCC, potentially opening new avenues for identifying biomarkers and/or therapeutic targets for these conditions.

Sex-specific molecular effects of semaglutide on cardiac and hepatic mitochondrial respiration and cellular redox state in HFpEF and MASLD

Niklas Geiger[1,2], Michael Kohlhaas[2], Alexander Nickel[1], Palina Zytner[1,2], Simon Kloock[1], Michael Matz[1,2] , Mia Külzer[2], Jessica Ulrich[3], Vasco Sequiera[2], Martin Fassnacht[3], Andreas Geier[4], Christioph Maack[1] & Ulrich Dischinger[1,2]
[1]University Hospital Würzburg, Department of Endocrinology and Diabetes, Würzburg, Germany; [2]University Hospital Würzburg, Comprehensive Heart Failure Center, Würzburg, Germany; [3]University of Würzburg, Pharmacology and Toxicology, Würzburg, Germany; [4]University Hospital Würzburg, Department of Hepatology, Würzburg, Germany

Background
Glucagon-like peptide (GLP)-1 receptor agonists, such as semaglutide, are known to have beneficial effects on obesity-related diseases such as heart failure with preserved ejection fraction (HFpEF) and metabolic dysfunction-associated steatotic liver disease (MASLD). However, cellular mechanisms underlying these effects remain poorly understood. Moreover, the gender-specificity of these effects is unclear.
Methods
Male and female wistar rats were fed either standard chow **(CO)** or a high-fat/fructose **(HFD)** diet combined with L-NAME for 8 weeks to induce obesity, hypertension and associated comorbidities like HFpEF and MASLD. Following this regimen, the rats received either semaglutide **(SEMA)** or saline **(HFD)** for additional 8 weeks, with ad libitum access to either HFD or a low-fat/high-fructose diet. Echocardiography (ECG) was conducted at the end of treatment. Histological assessment for H.E., OilRed and CD3 was performed in hepatic tissue. Isolated cardiomyocytes were evaluated for mitochondrial redox state, while isolated cardiac and hepatic mitochondria were subjected to high-resolution respirometry to assess oxygen consumption (with carbohydrates and fatty acids as substrates) and redox state with an Oroboros Oxygraph-2k.
Results
In ECG, the male HFD group exhibited a significantly reduced E/A-ratio with preserved ejection fraction, indicating diastolic dysfunction and an HFpEF phenotype when compared to the healthy CO group. SEMA normalized the E/A-ratio, in line with a significantly improved mitochondrial redox balance compared to HFD. Cardiac mitochondrial respiration, was significantly reduced in the HFD group, and was fully restored by SEMA. In female HFD rats, ECG showed a significantly reduced E/A-ratio. However, the mitochondrial redox state remained similar to CO. Here, SEMA did not normalize the E/A-ratio and mitochondrial respiration was unaffected. Characteristic for MASLD, hepatic histological assessment in the male HFD group indicated increased lipid storage and inflammation. Hepatic mitochondrial respiration in males was significantly higher in the HFD group compared to CO. While SEMA improved histological parameters, only a partial reduction of mitochondrial respiration could be detected. In females, mitochondrial respiration was also significantly increased compared to CO. Here, SEMA treatment significantly reduced cellular respiration and redox state.
Conclusion
Semaglutide exhibits sex-specific effects in a diet-induced model of HFpEF and MASLD, improving cardiac mitochondrial function in males while providing less pronounced effects in females. Regarding hepatic mitochondrial respiration, semaglutide treatment led to stronger effects in females. These results highlight the critical need to incorporate sex-based analyses in research on HFpEF and MASLD, given the variations in responses to semaglutide between genders, potentially having implications for treatment strategies.

Human sex-determination and associated pathologies as a model to understand developmental gene regulation

Estelle Talouarn[1], Maeva Elzaiat[1], Somboon Wankanit[1,2], Laurene Schlick[1], Anu Bashamboo[1] & Ken McElreavey[1]
[1]Institut Pasteur, Paris, France; [2]Mahidol University, Department of Pediatrics, Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand

Background
Our analysis of patients with 46,XY gonadal dysgenesis and 46,XX DSD (Disorders/Differences in Sex Development) has identified many genes involved in mammalian sex-determination (SD) and gonadal differentiation. Despite extensive exome studies >50% of all cases remain idiopathic. We hypothesize that unexplained cases are due to variants in gene regulatory elements (GREs) that may define gene regulatory networks (GRNs). Consistent with this hypothesis, recently we defined a novel *SRY* enhancer and identified SNVs in it, associated with a spectrum of phenotypes including 46,XY gonadal dysgenesis and under virilized male (PMID: 38555298). We have extended this work to develop a multi-omic genome-wide approach to identify functional GREs in human SD and predict GRNs.
Methods
Single-cell RNAseq and ATACseq data from human fetal gonad atlas (PMID: 35794482) was reanalysed by Scenic+, to define candidate GREs (cGREs). Transcription factor (TF) binding-site enrichment and mutational constraint in cGREs were determined using pycistarget and Gnocchi respectively. We defined cGREs corresponding to human accelerated regions (HARs, PMID: 27667684). Rare/novel variants from genome sequences of >160 individuals with unexplained DSD were mapped to cGREs and functional variants prioritized using CADD, FinSurf and Fabian.
Results
We defined 18,932 and 18,200 cGREs in Sertoli and pre-granulosa cells with a mean Gnocchi score of 7.90 and 7.88 respectively. Using our pipeline, we observed an enrichment of binding-sites for known SD TFs in cGREs: e.g: SOX9

(Normalized Enrichment Score (NES) = 12.95), NR5A1 (NES = 10.98) in Sertoli and LHX9 (NES = 5.66) in pre-granulosa cells. As proof of principle, we identified a previously reported *SOX9* GRE (eSR-A (PMID: 30552336)).
Conclusions
Our approach dissects the role of GREs and GRNs in SD providing a unique model to further understand developmental gene regulation. This approach also provides a unique pipeline to understand the genetic causes of unexplained DSD due to gene regulatory variants.

Characterising the metabolism of 11Oxy-androgens in placental cell models, tissue homogenates and explants

Therina Du Toit[1], Suzanne Smit[2], Christiane Albrecht[3] & Christa Flück[4]
[1]University Hospital Bern, Department of Biomedical Research (Translational Hormone Program), Nephrology and Hypertension, Bern, Switzerland; [2]University of Bern, Department of BioMedical Research, Bern, Switzerland; [3]University of Bern, Institute of Biochemistry and Molecular Medicine, Bern, Switzerland; [4]University Hospital Bern, Inselspital, Division of Pediatric Endocrinology, Diabetology and Metabolism, Department of BioMedical Research, Bern, Switzerland

Maternal and fetal adrenal derived androgen precursors are trafficked through the placenta throughout human fetal development. Most of these androgen precursors are steroid substrates for the biosynthesis of estrogens in the placenta, which evades harmful androgen excess. The placenta therefore serves as a key organ in the fetal-(adrenal and liver)-placental unit. Androgens in the 11oxy-pathway have recently been profiled in placental tissue, amniotic fluid and in maternal and newborn serum, which underscores their importance during fetal development, but also their potential to cause damage if in excess. Adrenal androgen excess readily occurs in classic congenital adrenal hyperplasia (CAH), with CAH marked by 11oxy-androgen (11OxyA) excess. 11OxyAs are in addition not readily converted to estrogen metabolites. Therefore, the dynamic of 11OxyA metabolism in placental steroidogenesis requires investigation to better understand their role in fetal development, especially in the developing CAH fetus. In this study, 11OxyA metabolism was traced in placental cells models (BeWo and Jeg-3 choriocarcinoma cells), and in healthy term placental S9 fractions and explants. Steroid profiling using liquid chromatography-mass spectrometry enabled the quantification of precursor and downstream steroid metabolites following the addition of steroid substrates (1 μM) after 48 hrs in cells, 24 and 48 hrs in explants, and 15 min in S9 fractions. Looking at the cell models, directional 11β-hydroxysteroid dehydrogenase type 2 (11βHSD2) activity was favoured, producing 11-ketoandrostenedione (11KA4). 11KA4 was in turn converted to 11-ketotestosterone (11KT), while the opposite reaction did not readily occur. Conversions in placental S9 fractions showed the rapid metabolism of 11KA4 (92%), similar to the classic- and 16-hydroxyandrogens, however 11KT was not readily metabolised (25%). Furthermore, the 11βHSD2 activity in placental explants firstly converted 11β-hydroxyandrostenedione to 11KA4 (after 24 h), after which 11KT was produced (after 48 h). To summarise, our data show that the placenta is an active 11OxyA metabolising organ, favouring the biosynthesis and metabolism of 11KA4. We show that while 11βHSD2 and aromatase activities normally safeguard the fetus from glucocorticoid and classic androgen excess, these enzymatic activities either 'activate' or do not apply to the 11OxyAs, respectively. Therefore, if in excess, as in CAH, the 11OxyAs would be suitable steroid substrates for placental steroidogenesis, potentially producing active metabolites which prevail over classic androgens.

Exposure to phthalates at the masculinization programming window is associated with longer anogenital distance and reduced birth weight in healthy children: A COPANA cohort study of 589 infants

Gylli Mola[1,2], Margit Bistrup Fischer[1,2], Emilie Zeuthen[1,2], Hanne Frederiksen[1,2], Jørgen Petersen[1,2], Anders Juul[1,2,3], Casper Hagen[1,2,3] & Anna-Maria Andersson[1,2]

Background
Phthalates are used widely in several consumer products. Previous studies suggest that phthalate exposure during the male programming window (MPW), gestational week (GW) 8-14, may disrupt gonadal and genital development with persistent effects. Most consistently, prenatal exposure to phthalates has been associated with reduced anogenital distance (AGD) in human and animal studies.
Primary aim
Exploratory assessment of prenatal exposure to phthalates was associated with changes in reproductive parameters in infancy.

Table 1

af = ano-fourchette. ac = ano-clitoral. as = ano-scrotal. ap = ano-penile.

Design
Prospective, observational pregnancy and birth cohort; The Copenhagen Analgesic Study (COPANA) (ClinicalTrials.gov NCT04369222).
Setting
Copenhagen University Hospital - Rigshospitalet (2020-2022).
Methods
Healthy, singleton pregnant women ($n = 685$) were enrolled during the first trimester, and 589 (287 boys) infants were examined. Metabolites of 15 phthalates and two substitutes were measured by LC-MS/MS in maternal urine samples collected in the first trimester (GW 14.1 ± 1.8 (mean ± SD)). Third-trimester ultrasound (GW 29-34): Fetal AGD and estimated fetal weight (EFW). Child examination (boys, mean age 3.1 months; girls, mean age 3.5 months): AGD by TIDES method, penile width and length, anthropometrics.
Statistics
Linear regression adjusted for maternal age, BMI, education level, and parity. Non-normally distributed data were ln2-transformed.
Results
Prenatal exposure to several phthalates in the first trimester was associated with longer fetal and infant AGD (raw and adjusted for weight), Table 1. In addition, exposure was associated with increased penile width and length. Metabolites of five different phthalates were associated with reduced birth weight and length in boys.
Conclusion
The results suggest endocrine-disrupting effects of phthalate exposure affecting early fetal development. We provide unique human data on phthalate exposure at MPW indicating androgenic effects. This may explain discrepancies with previous studies reporting reduced AGD after phthalate exposure in fetal life.

Testosterone therapy and the risk of atrial fibrillation, venous thromboembolism and cardiovascular events in cisgender men with hypogonadism and transgender men

Fabrice Bonnet[1], Patricia Vaduva[1,2], Beverley Balkau[3] & Laurent Fauchier[4]

[1]University of Rennes, CHU of Rennes, Endocrinology, Rennes, France; [2]CHU Rennes, Rennes, France; [3]Inserm U1018, Villejuif, France; [4]CHU of Tours, University of Tours, Tours, France

Aim
Cardiovascular safety of testosterone therapy has been a subject of controversies. A recent trial showed an increased risk of pulmonary embolism and atrial fibrillation in men with hypogonadism. The issue of cardiovascular safety of testosterone therapy also concerns female-to-male transgenders, for whom there are limited evidence. The aim was to assess in a real-life setting the safety profile and cardiovascular risk of testosterone therapy in these two different clinical settings: cisgender men with hypogonadism and transgender men.
Methods
We used TriNetx Research Collaborative network, a global federated health research network with access to electronic medical records from participating health care organizations, to identify and included participants. Diagnosis was done using the International Classification of Diseases, Ninth Revision and Tenth Revision, Clinical Modification (ICD-10-CM) codes, and medications. We used a 1:1 propensity-score matching for age and baseline characteristics to compare 117,908 cisgender men with hypogonadism treated with testosterone to 117,908 untreated cisgender men without a diagnosis of hypogonadism. Similarly, we compared matched 9,714 transgender men treated with testosterone to 9,714 untreated cisgender women treated with a contraceptive pill.
Results
After 5 years of follow-up, in cisgender men testosterone therapy was associated with a lower risk of myocardial infarction (HR: 0.94 95%CI [0.89-0.99], $P=0.01$) with no difference for stroke or total mortality. There was an increased risk of both atrial fibrillation (1.27 [1.22-1.32], $P<0.0001$) and acute pulmonary embolism/deep vein thrombosis (1.26 [1.18-1.34], $P<0.0001$). Transgender men treated with testosterone had a higher risk of acute myocardial infarction (2.82 [1.12-7.03], $P=0.02$) without significant difference for total mortality, stroke or atrial fibrillation compared to matched cis women treated with a contraceptive pill. Transgender men had a lower incidence of pulmonary embolism/deep vein thrombosis (0.46 [0.22-0.93], $P=0.03$) compared to matched cisgender women.
Conclusions
Testosterone treatment was associated in cisgender men with hypogonadism with a lower risk of myocardial infarction, but a higher risk of atrial fibrillation and venous thromboembolism as compared to men not treated with testosterone. Transgender men with testosterone therapy were at increased risk of myocardial infarction, without increased risk for atrial fibrillation or venous thromboembolism as compared to cisgender women.

Histological markers of testicular health and spermatogenesis in transgender adolescent girls following puberty suppression and subsequent gender-affirming hormone therapy

Henri Couckuyt[1], Koen Van de Vijver[2], Julie Van de Velde[3,4,5], Irem Kaya[2], Malaïka Van der Linden[2], Sofie Verbeke[2] & Martine Cools[5,6]
[1]Ghent university, Ghent, Belgium; [2]Ghent University Hospital, Department of Pathology, Ghent, Belgium; [3]Ghent University Hospital, Center for Medical Genetics Ghent, Ghent, Belgium; [4]Ghent University, Department of Biomolecular medicine, Ghent, Belgium; [5]Ghent University Hospital, Department of Pediatric Endocrinology, Ghent, Belgium; [6]Ghent University Hospital, Department of Internal Medicine and Pediatrics, Ghent, Belgium

Background
Gender incongruence is a marked and persistent incongruence between an individual's experienced gender and their sex registered at birth. This may lead to a desire to medical transition. For adolescents, this usually includes puberty suppressing drugs and subsequent gender affirming hormone therapy (GAHT). For trans girls, pubertal hormones can be suppressed with GnRH analogues (GnRHa) or cyproterone acetate (CA), and subsequent feminisation induced with 17β-estradiol (E2). It is currently not known if long-term use of these medications may cause testicular damage or irreversibly affect gamete number and quality hampering evidence-based fertility preservation counselling.
Aim of this study
To assess the effect of puberty suppression and subsequent GAHT on markers of testicular health and fertility in trans girls via histological analysis of testicular tissue obtained at orchidectomy. Differences in outcomes between those who received GnRHa versus CA are explored.
Methods
The primary outcome was the developmental stage of the most mature germ cell visible by routine histological examination and overall advancement of spermatogenesis, expressed as a modified Johnsen score (MJS). Secondary outcomes were basal membrane thickness (BMT), open lumen, peritubular myoid cell pattern (α-SMA staining), edema, fibrosis, Leydig cell presence and Sertoli cell maturity (podoplanin staining). Serum levels of E2, follicle stimulating hormone, luteinizing hormone and Inhibin B at the last pre-operative follow-up consultation were obtained from the patient files.
Participants
Sixty-seven participants were identified; 21 had received GnRHa and 46 CA. GnRHa were generally started at Tanner stage II-III, while CA was started at Tanner stage IV-V. The median total treatment duration for those who had GnRHa+E2 was 67 (IQR: 57-73) months and for those who had CA+E2 33 (IQR: 28-44) months. All participants had received E2 for a median duration of 27 (IQR: 20-34) months. All treatments were interrupted 2 weeks prior to orchidectomy.
Results
As expected, most participants showed spermatogenic arrest at orchidectomy, although full spermatogenesis was observed in a small minority, all treated with CA. All but one had spermatogonial stem cells. A disconnected α-SMA staining pattern and (moderately or severely) increased BMT, both likely indicating testicular damage, were observed in 49,3% and 55,2%, respectively. MJS inversely correlated with BMT. GnRHa were associated with a more immature testicular morphology when compared to CA.
Conclusion
Long-term puberty suppression and subsequent GAHT induces testicular immaturity and spermatogenic arrest in most trans girls. It may in addition cause testicular damage, visible as increased BMT, which adversely correlates with MJS.

Testicular function in young men and risk of cardiometabolic disease up to 20 years later – a register-based follow-up study of more than 5000

Laura Hansen[1,2], Astrid Beck[1,2], Julie Abildgaard[1,2,3], Anders Juul[1,2,4], Jørgen Petersen[1,2,5], Niels Joergensen[1,2] & Lærke Priskorn[1,2]
[1]Department of Growth and Reproduction, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark; [2]International Center for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark; [3]The Centre for Physical Activity research, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [4]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [5]Section of Biostatistics, Department of Public Health, University of Copenhagen, Copenhagen, Denmark

Background
The role of testicular function may extend beyond reproduction, potentially serving as a biomarker of general health. In fact, poor semen quality has been linked with increased risk of cardiovascular morbidity, hospitalization, and mortality.
Objective
To investigate testicular function and its associations with cardiometabolic health from a longitudinal perspective by utilizing baseline data from a well-characterized cohort of Danish young men from the general population, coupled with register-based follow-up.
Material and methods
This register-based follow-up study includes 5,265 men from the Danish Young Men Study (DYMS), a cohort established to investigate reproductive function in young adulthood. At baseline, participants completed a questionnaire, provided a blood sample for the assessment of reproductive hormones and health markers, delivered a semen sample, and underwent physical examinations. After a median follow-up of 12.1 years (5th–95th percentile: 2.1–20.8), the men had a median age of 32.4 years (5th–95th percentile: 22.4–40.9). Baseline data were linked to the nationwide Prescription Register and National Patient Register to obtain information on cardiometabolic prescriptions and diagnosed diseases. Men were divided into quartiles based on semen quality parameters. The associations between semen quality in early adulthood and later cardiometabolic disease were analyzed using Cox regression analyses, with follow-up from baseline until the first cardiometabolic prescription or diagnosis, or censoring. Results are expressed as hazard ratios (HR).

Results

After adjustment for period of ejaculation abstinence, smoking and BMI, we observed that the lower the quartile of baseline total sperm count, the higher the risk of cardiometabolic conditions (Q4: reference, Q3: HR = 0.97, Q2: HR = 1.06, Q1: HR = 1.16; *P*-trend = 0.21). A similar dose-dependent pattern was observed for total progressive motile sperm count (Q4: reference, Q3: HR = 1.06, Q2: HR = 1.14, Q1: HR = 1.21; *P*-trend = 0.14). BMI modified the association, which was less pronounced in men with normal BMI but more pronounced and statistically significant in men with BMI $\geq$ 25 kg/m^2 (n = 898) (total sperm count: Q4: reference, Q3: HR = 0.93, Q2: HR = 1.34, Q1: HR = 1.59, *P*-trend = 0.01, and total progressive motile count: Q4: reference, Q3: HR = 0.72, Q2: HR = 1.20, Q1: HR = 1.47, *P*-trend = 0.01, respectively).

Conclusion

Semen parameters in youth were significantly associated with risk of cardiometabolic health in men with BMI $\geq$ 25 kg/m^2. Thus, semen quality could serve as an additional biomarker for future cardiometabolic health, enabling earlier intervention and prevention. Men seeking help for infertility may be a relevant target group for such preventive initiatives.

Background
The concept of primary aldosteronism (PA) as a categorical disease has recently been revised; instead, PA may be considered as a continuous spectrum of disease, characterized by renin-independent aldosterone excess. The role of confirmatory tests in the diagnostic process of PA is still controversial. Among them, the postural stimulation test (PST) was proposed in the past for PA subtyping, however results were contradictory.
Objective
To assess PST role in differentiating from PA to low-renin hypertension (HTN).
Patients and methods
190 patients with arterial hypertension and at least one positive aldosterone to renin ratio (ARR) underwent confirmatory tests (saline infusion test and/or captopril challenge test). 80 were confirmed PA and 110 PA were identified as low-renin HTN. Baseline clinical and biochemical data and PST response were assessed. Principal component analysis (PCA), Partial Least Square-Discriminant Analysis (PLS-DA) and K-means clustering network were used to compute an integrated analysis.
Results
PST response showed 56/190 patients (29%) with suppressed renin levels both in clinostatism (clino) and orthostatism (ortho), 56/190 (29%) with desuppression of renin levels from clino to ortho, and 78/190 (42%) with non-suppressed clino renin which remained measurable in ortho. In the category of *always suppressed renin* 54/56 (92%) patients were PA, while 45/56 (80%) of patients in the category *renin from suppressed to measurable* were identified as low-renin HTN. Multivariable regression analysis showed increasing K levels (OR 12.5, 95% CI 3.4-42.5, $P<0.001$) and measurable ortho_renin (OR 351.6, 95% CI 31.35-3921, $P<0.001$) as significant predictors of low-renin HTN. Cluster analysis was able to distinguish PA from low-renin HTN. Cluster 1 correctly included 57/80 PA and Cluster 2 correctly included 104/110 low-renin HTN. Cluster 1 PA patients showed a higher frequency of suppressed renin levels at baseline and during PST, with a prevalence of clino_renin$_{suppressed}$ of 100% and a prevalence of ortho_renin$_{suppressed}$ of 95%. Cluster 1 low-renin HTN patients had lower potassium levels and a higher frequency of suppressed renin levels at diagnosis and during PST, compared to Cluster 2. LS-DA and PCA confirmed that ortho_renin, renin response to PST and presence of hypokalemia were the most accurate parameters to distinguishing PA from low-renin HTN.
Conclusion
PST demonstrated his role in the differential diagnosis of suspected PA, in particular regarding renin response during the test.

Introduction
Primary aldosteronism (PA) is the leading cause of secondary hypertension, strongly linked to left ventricular hypertrophy (LVH) and systolic dysfunction. Compared to essential hypertension, PA results in worse cardiac remodeling. However, data on factors influencing LVH at PA diagnosis remain scarce.
Methods
SPAIN-ALDO is a multicenter, national registry of patients with PA from 37 Spanish hospitals. This subgroup analysis included patients with an echocardiography within 24 months before or after diagnosis, excluding those who underwent PA surgery. Biochemical and clinical data at diagnosis were analyzed to identify independent factors associated with LVH.
Results
343 patients were included (women $n=119$, 35%) with a mean diagnosis age of 56 ± 12 yo. 188 patients (55%) had LVH from which, 108 (57%) had mild LVH severity, 69 (37%) moderate, and 11 (6%) a severe degree. Random forest analysis adjusted for age and sex identified patients with LVH as having longer durations of high blood pressure, a higher basal aldosterone index, higher BMI, elevated serum HbA1c levels, and increased 1mg overnight dexamethasone suppression test (ONDST) cortisol, along with lower glomerular filtration rates. Additionally, they were more likely to be male, active smokers, and have dyslipidemia and hypokalemia ($P=0.011$, $R^2=50.2\%$, $Q^2=0.73$, correctly predicted group: 73.9%). However, only glomerular filtration (OR = 0.12 [0.01 – 0.92]), active smoking (OR = 15.6 [1.79 – 37.2]), and hypokalemia (OR = 6.0 [1.3 – 16.8]) remained independent factors associated with LVH ($P=0.001$, $R^2=42.1\%$). The presence of type 2 diabetes mellitus (DM) was associated with LVH severity, with percentages of DM patients per group being 20%, 36%, and 46% in mild, moderate and severe LVH, respectively ($P<0.01$). Similarly, hypertensive retinopathy proportion of patients (mild = 4%, moderate = 17%, severe = 27%) and microalbuminuria (mild = 23%, moderate = 53%, severe = 67%) increased with LVH severity ($P<0.01$). Finally, basal aldosterone levels (ng/dl) increased with LVH severity: mild = 19.4 [13.9–31.5], moderate = 29.2 [20.7–47.6], severe = 27.6 [22.8–47.5] ($P=0.005$), as did ONDST cortisol levels (μg/d): mild = 1.5 [1.17–185], moderate = 2.10 [1.51–4.35], severe = 3.30 [1.40–4.50] ($P=0.014$).
Conclusion
Among patients with PA, those with active smoking, lower glomerular filtration and hypokalemia at diagnosis are at higher risk of developing LVH while higher levels of aldosterone and ONDST cortisol are associated with LVH severity.

Background
The efficacy of adrenalectomy in adenomas associated with Mild Autonomous Cortisol Secretion (MACS) is poorly investigated. A few small randomized trials and retrospective studies showed beneficial effects of adrenalectomy on hypertension. Long-term data on cardiovascular outcomes are missing.
Aim
To investigate cardiovascular outcomes in patients with unilateral adrenal adenomas and MACS after adrenalectomy.
Methods
Patients with MACS due to unilateral adrenal adenomas (serum cortisol after dexamethasone suppression test [DST] >1.8 mg/dl) from 14 ENSAT centers were included. Clinical data were retrieved at the time of initial evaluation (before adrenal surgery) and at last follow-up. From each center, MACS patients with and without surgery were matched 1:1. The control group belonged to a previously published study on long-term outcomes of MACS[1]. Matching was performed by propensity score using age and sex. We considered the following outcomes (occurring after adrenalectomy or after initial diagnosis in non-operated patients): new cardiovascular events (CVE), CVE and death from cardiovascular causes (composite-CVE), and death from all causes. We performed survival and multivariable Cox-regression analyses.
Results
We included 616 patients: 308 were treated by adrenalectomy and 308 underwent follow-up. Mean age was 58.1 ± 10.5 years for both groups ($P=0.927$). Prevalence of female sex was 67.2% ($n=207$) vs 67.9% ($n=209$) ($P=0.931$). The prevalence of hypertension and diabetes at baseline was not different between groups ($P=0.127$ and $P=1.000$, respectively). Values of post-DST cortisol were higher in operated patients than in non-operated ones (4.6 ± 3.7 vs 3.7 ± 3.2 mg/dl; $P<0.001$). After a median follow-up of 5 years (range 1 to 15 years), survival analysis showed significant differences between operated and non-operated patients for both new-CVE (HR: 0.554, 95%CI: 0.333-0.922, $P=0.023$) and composite CVE (HR: 0.581, 95%CI: 0.402-0.839, $P=0.004$). No significant differences were detected for all-cause mortality (HR: 0.772, 95%CI: 0.496-1.202, $P=0.251$). The multivariable Cox-regression analysis confirmed the significant beneficial effect of surgery on new CVE and composite-CVE after adjustment for cortisol after DST (HR: 0.565, 95%CI: 0.335-0.951, $P=0.032$ and HR: 0.573, 95%CI: 0.394-0.835, $P=0.004$, respectively).
Conclusion
Treatment of unilateral adenomas and MACS with adrenalectomy improves long-term cardiovascular outcomes.

Background
Adrenocortical carcinoma (ACC) is a rare cancer with heterogeneous clinical outcome. Close disease monitoring is essential but relies on radiological imaging that comes with significant radiation exposure. Circulating cell-free DNA (ccfDNA) can contain tumour-derived somatic variants, representing a non-invasive tool for cancer monitoring. Similarly, tumour-derived steroid hormone metabolites can be detected in urine from patients with ACC and may provide an additional post-operative surveillance tool.
Aim
Evaluate the role of combined ccfDNA sequencing and urine steroid metabolomics (USM) to monitor disease recurrence in ACC.
Methods
We investigated 6 patients (1M/5F, median age 37.5yrs) with histologically confirmed ACC. Plasma and 24 h urine samples were collected before primary tumour resection (baseline), early post-operatively (28-42 days) and on 3-monthly follow-ups. ccfDNA and germline DNA (gDNA) were isolated with commercially available kits. Tumour DNA (tDNA) was isolated from paraffin-embedded tissue. ccfDNA/gDNA/tDNA were sequenced using a customized ACC-specific panel and by shallow (0.1×) whole genome sequencing (sWGS). Genetic alterations (including gene variants and copy number variations, CNV) were called following standard bioinformatic protocols. gDNA was used to discriminate somatic variants. 32 distinct adrenocortical steroid metabolites were quantified using gas chromatography/mass spectrometry and a previously developed generalised matrix learning vector quantisation algorithm was used to detect the presence of ACC.
Results
at tDNA level, 3/6 cases (50%) presented point mutations while all 6 cases (100%) had an altered CNV pattern at sWGS. tDNA-derived somatic alterations were detected in baseline ccfDNA from 4/6 patients (71%). USM demonstrated steroid profiles for ACC in 5/5 patients at baseline. Three patients developed radiological recurrence at 3 or 6 months, which coincided with detection of somatic alterations in follow-up ccfDNA samples in 2/3 cases (67%). In one case, sWGS gave a clear signal for recurrence that would otherwise be missed by targeted sequencing alone. USM detected ACC-diagnostic steroids at recurrence in all cases with available urine samples, one 3 months before radiological evidence of relapse. The other three patients remain tumour free at 2-year follow up. One case presented somatic alterations at baseline tDNA/ccfDNA that disappeared in follow-up ccfDNA. USM reliably showed no evidence of ACC-diagnostic steroids in both cases with available samples during the entire follow up.
Conclusion
Integrating molecular signatures from ccfDNA and USM could complement standard radiological surveillance in monitoring of patients with ACC. sWGS

seems to have an additional value beyond targeted sequencing alone. Validation in a larger cohort is required to confirm our promising findings.

Non-aldosterone producing-adrenal-adenomas (NAPACAs) and polycystic ovaries syndrome (PCOS) are associated with hyperinsulinemia and insulin-resistance and thereby with increased prevalence of several aspects of the metabolic syndrome. Whether the co-existence of the two disease entities leads to accentuated prevalence of the metabolic syndrome remains unclear. Aim of the present study is the assessment of cardiovascular risk factors and insulin resistance indices in women with NAPACAs with and without PCOS. We conducted a retrospective multicenter study including adult premenopausal women categorized as NAPACA ($n=44$), PCOS ($=19$) or NAPACA+PCOS ($n=24$), excluding women with hormonally active adenomas other than mild autonomous cortisol excess (MACS), congenital adrenal hyperplasia, diabetes, systemic steroid medication or active malignancy and analyzed clinical, biochemical and hormonal data of the respective patients. As expected from the disease natural history, NAPACA patients were significantly older than the other two groups (NAPACA 41.02 ± 1.1, PCOS 31.05 ± 1.5, NAPACA+PCOS 33.83 ± 1.4 years old, $P<0.001$). PCOS patients displayed the lowest (26.88 ± 1.8 kg/m^2) and NAPACA+PCOS the highest body-mass-index (31.83 ± 1.9 kg/m^2, $P=0.05$), but patients of the three groups did not differ in their waist-to-height ratio ($P=0.12$), systolic ($P=0.51$) and diastolic blood pressure ($P=0.16$), HbA1c ($P=0.49$) and fasting plasma glucose levels ($P=0.51$). Interestingly, NAPACA+PCOS patients displayed significantly higher fasting insulin levels (NAPACA 9.38 ± 1.1, PCOS 12.93 ± 2.9, NAPACA+PCOS 25.52 ± 9.1 μU/ml, $P<0.05$). NAPACA+PCOS patients displayed significantly increased insulin resistance as calculated by the glucose-to-insulin ratio (GIR, $P<0.05$), the HOMA index ($P<0.05$) the QUICKI index ($P<0.05$) and the MATSUDA index ($P<0.05$). NAPACA+PCOS patients also presented lower HDL levels (NAPACA 58.67 ± 2.6, PCOS 58.21 ± 3, NAPACA+PCOS 48.05 ± 2.5 mg/dl, $P<0.05$). Although the cortisol levels upon 1 mg-dexamethasone suppression test (DST) did not differ among the groups ($P=0.1$), the DHEA-S ($P<0.05$), androstenedione ($P<0.01$) and testosterone levels ($P<0.01$) were significantly higher in the two groups including PCOS patients. Free androgen index levels positively correlated with the insulin resistance in NAPACA (GIR R -0.56, $P<0.01$, HOMA R 0.52, $P<0.05$, QUICKI R -0.52, $P<0.05$, MATSUDA R -0.49, $P=0.09$) and PCOS patients (GIR R -0.68, $P<0.01$, HOMA R 0.67, $P<0.01$, QUICKI R -0.67, $P<0.01$, MATSUDA R -0.82, $P<0.001$), while cortisol after 1mg-DST positively correlated with the insulin resistance in the NAPACA+PCOS group (GIR R -0.48, $P=0.05$, HOMA R 0.58, $P<0.05$, QUICKI R -0.58, $P<0.05$, MATSUDA R -0.67, $P<0.05$). These data provide hints that NAPACA+PCOS patients represent a distinct phenotype compared to NAPACA or PCOS patients, with a worse metabolic profile, and further studies with larger patient cohorts will be necessary to elucidate this observation.

Introduction

Diabetic ketoacidosis (DKA), a serious metabolic complication resulting from near-total insulin deficiency, is often associated with the initial presentation of type 1 diabetes (T1D) in children. Although DKA is transient at the time of diagnosis, it is associated with both medium- and long-term adverse outcomes. The incidence of DKA varies between countries. It is influenced by multiple factors including age, socioeconomic status and public awareness. The aim of this study is to evaluate for the first time the evolution of inaugural DKA in France over the past ten years.

Materials and methods

Data were collected from the national AJD (Aide aux Jeunes Diabetiques) registry, which collects data on paediatric patients with new-onset T1D (aged 0-15 years) from approximately 70% of the national clinics between 2010 and 2023. DKA was defined according to ISPAD criteria. Student's t-test, chi-squared test, or their non-parametric equivalents (Mann-Whitney U test and Fisher's exact test, Kruskall-Wallis) were used for statistical comparisons between groups and time periods.

Results

A total of 23108 children (46.7% female) were diagnosed with T1D at a mean age of 7.9 ± 5 years. The age at diagnosis and the distribution of patients across age groups (i.e., <5 years, 5-10 years and >10 years) remained stable over time. There was no significant increase in diagnoses in very young children (<5 years) (all $P>0.05$). DKA occurred in 39.1% of participants, with 43.2%, 36.1% and 39.5% in children <5, 5-10 and >10 years respectively. Between 2010 and 2019, the incidence of DKA remained consistently high in all years ($36.7\%\pm1.7\%$), with $12.9\%\pm0.9\%$ of children presenting with severe DKA ($P>0.05$). In participants without a first-degree relative (FDR) with T1D, DKA increased significantly after the COVID-19 pandemic (2016-2019 vs 2020-2023) from 39.7% to 46.5% ($P<0.0001$). This was accompanied by a significant increase in severe DKA (14.1% to 19.6%, $P<0.00001$). Children with FDR ($n=2523$) had a lower rate of DKA than children without FDR (18.8% vs. 41.6%, $P<0.000001$), but severe DKA persisted at diagnosis in 6.3% of this group.

Conclusion

Over the past decade, the age at diagnosis of T1D has remained stable. The incidence of DKA remains stable and elevated, with almost half of children with new-onset T1D who do not have an FDR presenting with DKA. While the rate of DKA was significantly lower in children with a FDR, there were still cases of severe DKA in this group. Increasing awareness for pediatric DKA is thus mandatory.

Introduction
Certain ethnicities – as native Americans and non-Hispanic Blacks in American cohorts- are known to have a higher risk to develop type 2 diabetes (T2D). As European cohorts differ substantially in migration background from American cohorts, we examined the migration background (mb) in a large pediatric German-Austrian-Suisse-Luxemburgish cohort.
Methods
The analysis was based on the DPV registry. Patients documented 2000-2023 with either type 1 (T1D) or T2D, younger than 18 years and diagnosed at the age of 6- 18 years were included. Mb is defined as either the child or one of the parents being born in another country. Mb was divided in the following groups: no mb, Turkish, African, East European, South European and Syrian/Iran/Irak/Jemen/Afghanistan (SIIJA). Statistical analysis was performed using the Wilcoxon rank sum test for continuous and Chi-square test for qualitative variables with adjustment for multiple testing (Bonferroni step-down). For longitudinal observations, adjusted regression models were used.
Results
70866 children with T1D and 2796 with T2D were included. Between 2000 and 2023, the rate of migration background increased in the total cohort from 3.2 to 29%. In the T2D group more children than in the T1D group had a migration background (33.7 vs 20.2%, $P=0.00$). Distribution of countries of origin differed between the two groups: More patients with T2D came from Turkey (8.9 vs 2.7%) , Africa (2.9 vs 1.7%), SIJJA (2.7 vs 1.6%) and Southern Europa (3.7 vs 2.6%) compared to T1D (all $P<0.0005$). At diagnosis, Turkish T2D patients were not more obese than patients with no mb, HbA1c and age were similar. In regression models adjusted for age, gender, diabetes duration and HbA1c, there was no significant difference in BMI between Turkish and no mb T2D patients ($P=0.48$).
Conclusion
Mb increased corresponding to the overall increase of mb in the general population (29% in Germany in 2023). We observe distinct differences in migration background between pediatric T1D and T2D cohorts. Pediatric T2D had more often a Turkish background. This difference could not be explained by differences in BMI. We hence postulate, that Turkish patients seem to have a higher genetic risk to develop T2D.

Islet cell autoimmunity and preclinical phase of type 1 diabetes in general population of 1-9 year old children in north-eastern region of Poland – a summary of the first 18 months of the study

Artur Bossowski[1], Milena Jamialkowska-Sztabkowska[1], Klaudyna Noiszewska[1], Agnieszka Polkowska[1], Aneta Zasim[1], Filip Bossowski[1], Magdalena Skorupska[1], Angelika Buczynska[1], Adam Kretowski[1] & Piotr Trzonkowski[2]

[1]Medical University in Bialystok, Department of Pediatric Endocrinology and Diabetes with a Cardiology Unit, Bialystok , Poland; [2]Medical University in Gdansk, Department of Medical Immunology, Faculty of Medicine, Gdansk, Poland

Aims
Assessment of islet autoimmunity and the prevalence of presymptomatic type 1 diabetes among children aged 1 to 9 years in a general population of North-Eastern Poland through a stepwise islet autoimmunity screening programme.
Methods
3575 children aged 1-9 years participated in the study. Venous blood samples have been collected and analysed in a stepwise procedure starting with 3 Screen Islet Cell Autoantibody ELISA and IAA ELISA. In the next step, samples found positive in either 3 Screen or/and IAAs, were verified for individual autoantibodies. Children with confirmed islet cell autoimmunity were invited for the first follow-up stage, that consisted of laboratory testing, metabolic staging and education.
Results
Among 3575 tested children 4.84% were found positive in 3 Screen test and 4.73% for IAA. Detailed antibody testing confirmed islet cell autoimmunity in 7.78% participants and 1.17% of the total number presented multiple positive islet autoantibodies (IAb). IAAs were the most frequently reported autoantibodies (50.75%), while IA-2As were the least frequent (8.4%). IAAs were observed more frequently in individuals with T1D family history compared to those without T1D in relatives ($P=0.04$) and in children aged 1-3 years compared to older ones ($P=0.02$). The frequency of IA2-As and ZnT8As increased with age ($P=0.035$ and $P=0.02$, respectively) and ZnT8As were observed more frequently in females than males ($P=0.024$). The prevalence of GADAs was similar in all age groups ($P=0.54$). The prevalence of multiple positive IAbs was almost 2.5-times higher among children with T1D family history than in other peers. 113 children with confirmed islet cell autoimmunity participated in metabolic staging. Within individuals with dysglycaemia (stage 2) almost 67% presented only a single autoantibody. Two participants (1.77%) presented stage 3 diabetes – both were diagnosed before DKA occurred.
Conclusions
Results of the study confirm the importance of screening for IAbs in general paediatric population as a method of prediction of T1D development. The study also shows that patients with a single positive islet autoantibody may have already developed dysglycaemia and need monitoring.

Introduction and objective
There is limited understanding of the heterogeneity in transfer of care from pediatric to adult services for youth with type 1 diabetes (T1D).
Aims
This study aims to examine T1D transition among European SWEET centers.
Methods
The SWEET (Better control in Pediatric and Adolescent diabete**S**: **W**orking to cr**E**ate **C**ent**E**r**T**ers of Reference) database was analyzed (2016-2023, >20

patients, > 5-year data). Transfer was assumed in patients 14-24 years without visits for ≥2 years. Age at transfer and sex, metabolic control, BMI-SDS, comorbidity, technology use (pump, continuous glucose monitoring [CGM], closed loop [CL], telemedicine [TM]) were evaluated across Western and Eastern Europe.

Results

19,123 patients (58 centers) were transferred (51% male, 93% T1D, mean DM duration 7.6 years). The median age at transfer was 18.7 years [Q1-Q3: 17.9-19.6]. Large centers transferred later, at 19.3 years [18.0-22.0], without gender differences. At patient level, the last visit mean age was 17.5 years [Q1-Q3: 13.6-18.9]. Mean HbA1c was 8% [6.9-8.7], BMI-SDS (WHO) 0.5 [-0.2-1.2]; 4% of patients had celiac disease (CD) and 3.8% Hashimoto thyroiditis. 5% of T1D patients were treated by CL, 41% with pump and 46% used CGM. Technology (as telemedicine, CGM, pump) was used by 60% of patients. Compared to patients not transferred ($n=23,947$), HbA1c was higher (7.6% vs 8%; $P<0.0001$), without differences in BMI-SDS. T1D females left earlier (-0.13 years; $P<0.0001$), patients with longer T1D and followed at larger centers left later. CD and thyroiditis did not affect age at transfer. Higher BMI z-score was associated with earlier transfer (-0.07, $P<0.0001$) as well as worse metabolic control (-0.1, $P<0.0001$). A model including interactions showed that only metabolic control, center size and diabetes duration remained associated with age at transfer. Pump, CL, CGM users were transferred earlier (-0.2, -0.3, -0.2; $P<0.0001$), while telemedicine was associated with later transfer (+0.7, $P<0.0001$). The interaction between technology use, HbA1c and BMI-SDS did not change the results. Age at transfer was similar in East and West Europe, with some differences in transition-related factors. For West Europe CGM was not associated to age at transfer. Considering East Europe, gender and metabolic control didn't affect age at transfer, while CL and technology use were associated with earlier transfer (-0.1, p 0.03).

Conclusion

This study highlights the significant heterogeneity of age at transfer of youth with T1D across Europe and some notable differences between European regions that warrant further exploration.

[1]Queen Elizabeth Hospital, Birmingham, United Kingdom; [2]Attikon University Hospital, Athens, Greece; [3]Sandwell and West Birmingham NHS Trust, Birmingham, United Kingdom; [4]Northwick Park Hospital, London Northwest NHS Trust, London, United Kingdom; [5]Royal Free Hospital, London, United Kingdom; [6]Dudley Group NHS Foundation Trust, Dudley, United Arab Emirates; [7]National and Kapodistrian University of Athens, Athens, Greece; [8]Ipswich Hospital, Ipswich, United Kingdom; [9]Norfolk and Norwich University Hospital, Norwich, United Kingdom; [10]University of Birmingham, Department of Applied Health Sciences, Birmingham, United Kingdom; [11]Institute of Metabolism and Systems Research, University of Birmingham, UK, Birmingham, United Kingdom

Background

Despite guidelines, significant variation in Hyperosmolar hyperglycaemic syndrome (HHS) diagnosis, management, and outcomes persists due to inconsistent protocol adherence. We developed and implemented a multicentre surveillance system to evaluate HHS management across hospitals, identify barriers to guideline adherence, and provide real-time feedback to optimise care pathways.

Methods

We conducted a prospective multicentre study (January 2021–November 2024) across 12 hospitals. Data were collected on demographics, precipitating factors, biochemical profiles, treatment practices, and outcomes. The surveillance system was modelled on the DEKODE (Digital Evaluation of Ketosis and Other Diabetes-related Emergencies) framework, incorporating standardised electronic data collection tools aligned with Joint British Diabetes Societies guidelines. The surveillance system facilitated the comparison of data from a hospital with median values from all participating hospitals and against a hospital of similar size and capacity. We assessed variations in management and mortality outcomes. Structured surveys and focus groups involving clinicians, diabetes specialist nurses, and acute care teams explored barriers and facilitators to guideline implementation.

Results

A total of 245 HHS episodes were captured, with 218 cases meeting diagnostic criteria (median age: 77 years (IQR 64–85)). Participation varied across the 12 hospitals due to various logistical and capacity issues. The leading precipitating factors were intercurrent illnesses (49.5%) and infections (16.0%). The median time to diagnosis was 2 hours, with 7.8% of cases diagnosed > 24 hours post-admission. Fluid resuscitation and insulin regimens varied widely, contributing to discrepancies in HHS resolution time (48.2 hours (IQR 24.9–74.2), [$n=149$]) and hospital length of stay (10.3 days (IQR 6.0–17.0), [$n=156$]). Mortality was 16.1% overall but significantly lower at Hospital A (2.3%) vs Hospital B (16.3%, $P=0.024$). Interestingly, Hospital A had higher insulin use and more frequent glucose monitoring than Hospital B. Key barriers to guideline adherence included reported staffing shortages, inconsistent glucose/ketone monitoring, and interdepartmental coordination issues. Facilitators included diabetes specialists' early involvement during acute admission, structured educational programs, and continuous real-time feedback throughout the year. Staff in one of the NHS trusts participating in the surveillance reported that a simplified, colour-coded HHS management algorithm improved adherence.

Conclusions

A standardised multicentre surveillance system identified care variations in HHS management, reinforcing best practices and refining guideline implementation. Integrating such surveillance into routine quality improvement frameworks could facilitate national benchmarking to drive improvements in management and future updates to HHS guidelines.

Background

Identifying populations at risk for early-onset type 2 diabetes (T2D) is crucial due to its rising incidence, delayed diagnosis, aggressive course, and deleterious socioeconomic sequelae.Isolated glucosuria is an uncommon but well-recognized hereditary condition caused by variants in *SLC5A2* encoding sodium-glucose co-transporter 2. Data regarding its long-term glycemic outcomes are scarce.

Objective

To assess the risk of developing T2D in young adulthood among adolescents with isolated glucosuria in a large nationwide cohort of 1.61 million adolescents.

Research design and methods
Israeli adolescents (ages 16–19 years) examined prior to compulsory military service between 1993 and 2015 were included. Evaluations comprised medical and socio-demographic assessments. Isolated glucosuria was defined based on persistent findings in at least two repeated urine dipstick tests and normal results from a comprehensive evaluation, including a morning fasting glucose test, a 2-hour 75-gram oral glucose tolerance test, and a biochemistry panel. Data were linked with the Israeli National Diabetes Registry, where incident T2D was defined as an outcome. Cox proportional hazard models were applied.
Results
The study included 1,611,467 individuals (42.5% women), of whom 755 (0.05%) were diagnosed with glucosuria during adolescence. Adolescents with versus without glucosuria were predominantly male (75.0% vs. 57.5%; $P<0.001$) and had lower rates of overweight and obesity (10.4% vs. 16.3%; $P<0.001$). During a cumulative follow-up of 23,848,350 person-years, 10,328 T2D cases were recorded, with a mean age at the end of follow-up of 32.6 years (SD 6.8). Ten (1.3%) and 10,318 (0.6%) T2D cases were observed among those with and without glucosuria, respectively, with incidence rates per 100,000 person-years of 87.5 and 43.3. No significant differences in mean BMI ($P=0.11$) or eGFR ($P=0.67$) at T2D diagnosis were observed between groups. Individuals with isolated glucosuria had an HR of 2.17 (95% CI, 1.17–4.04) following adjustment for sex, BMI, age, year of study entry, and sociodemographic confounders. The association was accentuated in individuals with lean BMI (i.e. BMI<85th percentile) at baseline and in those without coexisting illness at baseline. Results were consistent in sub-analyses limited to T2D before age 40, stricter outcome definition, and logistic regression [adjusted OR of 2.33 (95% CI, 1.26–4.27).
Conclusions
Isolated glucosuria during adolescence is associated with an increased risk of early-onset T2D, particularly in populations with lean BMI and unimpaired health at baseline. This suggests caution in viewing isolated glucosuria strictly as a benign condition.

Genotype-histotype-phenotype correlations in atypical congenital hyperinsulinism

Klaus Brusgaard[1], Annette Larsen[1], Eugenia Globa[2], Ditte Andersen[3], Catarina Limbert[4], Åsa Mattsson[5], Anne Nielsen[3], Michael Mortensen[3], Eva Hejbøl[6], Sönke Detlefsen[3] & Henrik Christesen[3]
[1]Department of Regional Health Research, Vejle Sygehus, Department of Clinical Genetics, Vejle, Denmark; [2]Ukrainian Center of Endocrine Surgery, Department of pediatric endocrinology, Kyiv, Ukraine; [3]Odense University Hospital, University of Southern Denmark, Department of Clinical Research, Odense, Denmark; [4]NOVA Medical School, Hospital Dona Estefania, Unit for Pediatric Endocrinology and Diabetes, Lisboa, Portugal; [5]Helsingborg Hospital, Department of Pediatrics, Helsingborg, Sweden; [6]University of Southern Denmark, Department of Regional Health Research, Sønderborg, Denmark

Background
Hyperinsulinaemic hypoglycaemia (HH) is a heterogeneous disease entity characterized by failure to suppress insulin secretion from the pancreatic beta cells during hypoglycaemia. Persistent non-syndromal CHI can be caused due to inherited mutations in a number of known genes. But in 40 – 50% of affected patients the genetic basis is unexplained. The two main histologically forms are diffuse and focal CHI. The diffuse form is an apparently normally structured islet. The focal form is characterized by the presence of a small endocrine lesion in the pancreas. The histology in some patients differ from these main forms. This form is referred to as CHI with atypical histology. We present molecular characterization of variants in this latter group. Atypical congenital hyperinsulinism (CHI) is characterized by distinct pancreatic histology that differs from classical KATP-channel diffuse or focal CHI and Beckwith-Wiedemann Syndrome (BWS). Its genetic basis remains largely unclear.
Aim
To explore genotype-histotype-phenotype correlations in atypical CHI within a single-center cohort.
Methods
Genetic analysis involved sequencing CHI-related genes in blood and pancreatic tissue, with BWS testing when appropriate. For negative cases, a targeted 140-gene panel, including the non-coding *HK1* region, was performed on blood, pancreatic tissue, and laser-microdissected (LCM) islets. Pancreatic tissue was evaluated through histological, immunohistochemical, and morphometric studies.
Results
Atypical CHI was observed in 5/70 (7.1%) surgically treated patients. Median birth weight was 2965 g (range: 2650–3385 g), with disease onset at a median of 93 days (range: 1–259 days). 18F-DOPA PET/CT showed diffuse labeling in all cases. Genetic findings revealed low-grade mosaic *HK1* intron 2 mutations in three patients: de novo germline, somatic mosaic in the whole pancreas, or isolated islets. One patient had a *CACNA1D* frameshift mutation of uncertain significance, while no abnormalities were identified in another. Histological analysis revealed lobule-specific enlarged islets with increased insulin-producing cell volume, interspersed with diffusely distributed shrunken islets. Nuclear enlargement was observed in isolated islets from one patient.
Conclusion
This is the first study to describe how low grade de novo variants in the beta-cell of the pancreatic islet can explain the atypical form of Hyperinsulinaemic hypoglycaemia. Rare atypical CHI cases display unique histological patterns restricted to specific lobules and are frequently associated with *HK1* intron 2 mosaic variants. Detection of low-grade mosaicism may necessitate laser-microdissected islet analysis.

An ongoing phase 2 study of efpegerglucagon: promising results on safety and efficacy in subjects with congenital hyperinsulinism

Antonia Dastamani[1], Indraneel Banerjee[2], Susann Empting[3], Mala Puri[4], EunJi Gwak[5], Seohyun Kang[5], JinHee Byeon[5], Moon Hee Lee[5] & Diva D. Leon-Crutchlow[6]
[1]Great Ormond Street Hospital, London, United Kingdom; [2]Royal Manchester Children's Hospital, Manchester, United Kingdom; [3]Otto-von-Guericke-Universität Magdeburg, Magdeburg, Germany; [4]Fortrea Inc., Durham, United States; [5]Hanmi Pharm. Co., Ltd., Seoul, South Korea; [6]Children's Hospital of Philadelphia, Philadelphia, United States

Introduction
Congenital hyperinsulinism (CHI) is a rare disease affecting 1 in 25,000 to 50,000 newborns, characterized by severe hypoglycemia that can lead to neurological damage or death. Current treatments, which include dietary management, medications, and surgical interventions, are often limited by suboptimal efficacy and significant side effects, highlighting the urgent need for novel therapeutic approaches.
Methods
Efpegerglucagon (HM15136), a long-acting glucagon analogue, is being evaluated in a Phase 2 open-label, multicenter trial across five countries (ACHIEVE, NCT No. 04732416, EUCT No. 2024-515290-98-00). The study targets CHI patients aged two years and older with recurrent hypoglycemia (>3 episodes/week) despite standard care. The trial includes two dosing cohorts: Cohort 1 (0.04 mg/kg) and Cohort 2 (0.06 mg/kg). Each cohort consists of 8 subjects receiving weekly subcutaneous injections over an 8-week period. Enrollment for Cohort 1 ($n=8$, median age: 16 years, equal male-to-female ratio) has been completed, and Cohort 2 is currently ongoing.
Results
The most frequent adverse events were gastrointestinal (e.g., upper abdominal pain, diarrhea, vomiting, nausea) and metabolic(e.g., hyperglycemia, decreased appetite) in nature. These events were predominantly mild or moderate, with no treatment discontinuation, adverse events of special interest, or deaths reported. Efficacy analysis based on the data from eight patients in Cohort 1 showed significant reductions in level 1 or level 2 hypoglycemia events (blood glucose< 70 mg/dl [<3.9 mmol/l]). After 8 weeks of treatment, the mean weekly level 1 or level 2 hypoglycemia events measured by 7-point self-monitored blood glucose (SMBG) decreased from 10.1 ($\pm$8.5, standard deviation) at baseline to 2.8 ($\pm$ 2.3), representing a 72.3% reduction. Home monitoring SMBG data also reflected a significant decline in weekly level 1 or level 2 hypoglycemia events decreasing from 16.0 ($\pm$19.4) at baseline to 3.6 ($\pm$6.5) at Week 8, indicating a 77.5% reduction. Notable improvements were demonstrated, including reductions in the weekly number and rate of level 2 hypoglycemia events (blood glucose<54 mg/dl [<3.0 mmol/l]) at Week 8, as measured by 7-point SMBG, and improvements in nutritional parameters such as total carbohydrate intake during treatment compared to baseline.
Conclusion
Efpegerglucagon demonstrated a favorable safety profile and clinically meaningful efficacy. After eight weeks of treatment, CHI patients experienced significant reductions in hypoglycemia events. These findings emphasize its therapeutic potential as a safe and effective treatment for CHI and support the continued enrollment of Cohort 2.

JOINT157

Modulation of SIRT1-related microRNAs in differentiating adipocytes and their relationship with inflammation

Mahdieh Tamkini[1], Mitra Nourbakhsh[2], Monireh Movahedi[1] & Abolfazl Golestani[3]
[1]Islamic Azad University, Biochemistry, Tehran, Iran; [2]Iran University of Medical Sciences, Clinical Biochemistry, Tehran, Iran; [3]Tehran University of Medical Sciences, Clinical Biochemistry, Tehran, Iran

Background
Chronic low-grade inflammation in adipose tissue is closely linked to metabolic diseases and organ complications in overweight and obese individuals. Dysfunctional adipocytes that release inflammatory adipokines are responsible for initiating and maintaining this inflammation. Although it is a low-grade inflammation, it adversely affects distant organs and contributes to obesity-related complications. Sirtuin 1 (SIRT1), a crucial nutrient-sensing histone deacetylase, is enhanced by caloric restriction and attenuated by overfeeding. When SIRT1 levels drop, inflammatory factors are produced in white adipose tissue, suggesting that reduced SIRT1 connects overnutrition with adipose tissue inflammation.
Aim
This study aimed to identify microRNAs that negatively regulate SIRT1 expression and are upregulated in differentiated and hypertrophied adipocytes and explore their relationship with inflammatory parameters.
Methods
A bioinformatics study was conducted to discover microRNAs conserved among mammals, targeting the 5'-UTR of SIRT1. 3T3-L1 cells were cultured in DMEM medium containing 10% FBS and differentiated into mature and hypertrophied adipocytes using MDI induction medium (comprising 1-methyl-3-isobutyl-xanthine, dexamethasone, and insulin). The differentiation cycle continued for 14 days in a culture medium containing 10% FBS. The expression of selected miRNAs was evaluated by real-time PCR. The microRNA with the highest expression was selected for subsequent experiments. Transfection of 3T3-L1 cells was performed using polyethyleneimine (PEI) and confirmed by fluorescence microscopy. Real-time PCR and Western blotting analyzed SIRT1 gene and protein expression levels, respectively. Luciferase reporter gene assay assessed the direct interaction between microRNA and SIRT1. The gene expression of inflammatory cytokines was measured by real-time PCR.
Results
Bioinformatics analysis identified mmu-miR-448, mmu-miR-181-5p, mmu-miR-186-5p, mmu-miR-653-5p, and mmu-miR-199-5p aligning with the 5'-UTR of SIRT1. Among these, miR-186 had the highest expression in differentiated and hypertrophied adipocytes. Upregulation of miR-186 by its mimic oligonucleotide led to decreased SIRT1 levels, while inhibition by miR-186 anti-sense sequence increased SIRT1 expression. miR-186 caused a significant elevation in the expression of inflammatory genes, including IL-6, IL-1β, TNF-α, and MCP-1, indicating a strong relationship between miR-186-induced SIRT1 inhibition and inflammation.
Conclusion
Differentiation and hypertrophy of adipocytes are accompanied by changes in microRNA expression, affecting various biological outcomes. Notably, inhibition of SIRT1 by microRNAs such as miR-186 may contribute to the increased inflammation observed in obesity. These findings suggest that overcoming the negative regulation of SIRT1 by miR-186 could be a promising strategy to alleviate obesity-associated inflammation.

Martino" of Messina, Department of Human Pathology of Adulthood and Childhood "G. Barresi", Messina, Italy

Background
Glomerular hyperfiltration (GHF) is an early manifestation of obesity-related glomerulopathy, with an estimated prevalence of 7 to 31% in childhood. GHF in obesity has been hypothesized to be a physiological adaptation mechanism to the changes the organism undergoes, including increased absolute mass of adipose tissue and body mass, increased cardiac output, increased glomerular pressure. A reduction in GFR has been correlated with a modification in sensitivity to thyroid hormones (THs), particularly a reduction in central sensitivity to THs, both in adults and youths with obesity. However, no data are available regarding the possible correlation between GHF and sensitivity to THs.
Objective
The aim of this study is to evaluate the association between sensitivity to TH and GHF in euthyroid non-diabetic youths with overweight (OW) and obesity (OB).
Material and methods
This cross-sectional study included 654 Caucasian youths with OW or OB (aged 6-18 years) recruited at seven Italian centers for the care of OW/OB. Inclusion criteria were: THs within the normal range in each center, anti-thyroid antibody negativity. Exclusion criteria were: diabetes mellitus, thyroid diseases, renal disease, subclinical hypothyroidism, genetic or endocrine obesity, chronic diseases, pharmacological treatment. Estimated glomerular filtration rate (eGFR) was calculated using Pottel's formula. Youths with reduced eGFR ($<$ 90 ml/min/1.73 m^2) were excluded. GHF was defined by eGFR $>$ 120 ml/min/1.73 m^2. Pulse pressure (PP) was calculated as: systolic blood pressure (BP) minus diastolic BP. The fT3/fT4 ratio was evaluated to assess peripheral sensitivity, while TSH index (TSHI), Thyrotroph T4 Resistance Index (TT4RI), Thyroid Feedback Quantile-based Index (TFQI) and Parametric TFQI (PTFQI) were calculated to assess central sensitivity.
Results
Youth with GHF ($n=203$) had significantly higher values of peripheral sensitivity to THs (FT3/FT4 ratio 0.46 ± 0.11 vs 0.44 ± 0.09 vs; $P=0.004$), fasting glucose (89.2 ± 9.0 mg/dl vs 85.5 ± 9.6 vs; P0.0001) and PP (47.5 ± 11.8 vs 45.4 ± 12.8 vs mmHg; $P=0.047$) compared to youths with normal eGFR. No significant differences were observed for indices of THs central sensitivity. Odds ratio of hyperfiltration rose of 1.04– and 13.16–fold for each increase of 1 mg/dl of fasting glucose ($P<0.0001$) and 1 mIU/l in FT3/FT4 ratio ($P=0.004$), respectively, independently of centers, PTFQI and PP.
Conclusions
GHF was associated with an increased peripheral sensitivity to THs in youths with OW/OB. GHF could be an allostatic adaptation mechanism in obesity and may represent early expression of obesity-related glomerulopathy. Further studies are needed to confirm these results.

Background

Epidemiological studies suggest that delivery mode is associated with numerous long-term conditions, including atopy and asthma, potentially associated with altered levels of cortisol. Emergency caesarean section is associated with increased levels of cortisol in the umbilical cord, and animal studies suggests that perinatal stress cause persistent changes in hypothalamic-pituitary-adrenal (HPA) axis activity. However, human data on the long-term impact of delivery mode on steroid hormone profiles during infancy remain limited.

Objectives

To evaluate the association between delivery mode and circulating levels of steroid hormone metabolites in healthy infants at three months of age.

Design

Prospective, observational pregnancy and birth cohort; The Copenhagen Analgesic Study (COPANA) (ClinicalTrials.gov NCT04369222).

Setting

Copenhagen University Hospital – Rigshospitalet, Denmark (2020-2022).

Methods

Healthy, singleton pregnant women recruited early in pregnancy ($n=685$) and 589 infants (287 boys) were examined (age 3.31 months (0.67) mean ($\pm$SD)). Infants with available hormone values and information on delivery mode ($n=508$) were included and stratified according to delivery mode: 1) emergency caesarean section (ECS), $n=50$ (26 males), 2) vaginal delivery (VD), $n=437$ (207 males), 3) elective caesarean section (ELCS), $n=21$ (10 males). Steroid hormones: progesterone (PRO), 11-deoxycorticosterone (DOC), corticosterone (CORT), aldosterone (ALDO), 17alfa-hydroxypregnenolone (17-OHPreg), 17-hyroxyprogesterone (17-OHP), 11-deoxycortisol (11-DOC), cortisol, cortisone, dehydroepiandrosterone (DHEA), androstenedione (Adion), testosterone (T) and dihydrotestosterone (DHT) were analyzed (LC/MS-MS), and age-related standard deviation scores (SDS) were calculated. Statistics: Kruskal-Wallis (KW) and Mann-Whitney U (MWU) tests.

Results

In boys, ECS was associated with consistently lower levels of: CORT, 17-OHPreg, 17-OHP, 11-DOC and cortisol compared to both VD and ELSC at three months of age (Table 1). Delivery mode was not associated with steroid hormone levels in girls.

Conclusions

The present study suggests that delivery mode has long-term impact on HPA axis activity. Whether effects on steroid hormone levels contribute to adverse long-term health outcomes associated with delivery mode remains to be examined.

Background

GSDIa is a rare, potentially life-threatening inborn error of carbohydrate metabolism caused by biallelic *G6PC* pathogenic variants, resulting in glucose-6-phosphatase deficiency. DTX401 is an investigational adeno-associated virus serotype 8 vector containing the human *G6PC* gene.

Methods

DTX401-CL301 (GlucoGene Study; ClinicalTrials.gov: NCT05139316), is an ongoing, pivotal, phase 3, double-blind, randomized, placebo-controlled trial in patients $\geq$8 years old with GSDIa. Participants were randomly assigned (1:1) to receive blinded DTX401 or placebo. At Week 48, participants entered a 48-week Crossover Period when, in a blinded manner, those randomized to DTX401 received placebo and placebo received DTX401. The primary endpoint was change from Baseline to Week 48 in daily cornstarch intake, DTX401 versus placebo.

Results

The study met the primary endpoint: at Week 48, the Primary Efficacy Analysis Period (PEAP), DTX401 treatment resulted in a mean (standard deviation [SD]) daily cornstarch intake reduction of 41.0% (18.4) versus a 10.1% (18.0) reduction with placebo; P <0.0001 based on mixed model of repeated measures. In the Crossover Period, greater reductions in total daily cornstarch were observed in both the ongoing DTX401 group and the Crossover Placebo to DTX401 group (Table). Glycemic control was maintained in participants treated with DTX401 despite significant reductions in daily cornstarch intake. Patient experience data support cornstarch reduction clinical meaningfulness, with Week 48 Patient Global Impression of Change Moderately or Much Improved corresponding to a 34% mean reduction in daily cornstarch intake. Anticipated vector-induced liver enzyme elevations were manageable with prophylactic corticosteroids. Elevations in triglycerides were observed in individual participants, requiring adjustments of cornstarch and dietary intake.

Conclusion

Treatment with DTX401 resulted in statistically significant and clinically meaningful reductions in cornstarch intake in the 48-week PEAP versus placebo. Greater reductions in cornstarch were observed in both groups in the Crossover Period after Week 48. Experience with disease management post-gene therapy and confidence that all participants had been treated with DTX401 likely contributed to improvements in the Crossover Period (Year 2) versus the PEAP (Year 1). DTX401 had an acceptable safety profile.

Mean (SD)	Week 96 *n*	DTX401	*n*	Crossover Placebo to DTX401*
Daily cornstarch, % change from baseline	13	-60.9 (18.9)	13	-64.7 (24.9)
Nighttime cornstarch, % change from baseline	12	-66.1 (33.5)	10	-74.2 (26.5)
Percent glucose values <70 mg/dl, change from baseline	17	3.78 (4.96)	16	2.33 (3.23)
Percent glucose values <54 mg/dl, change from baseline	17	0.85 (0.88)	16	0.27 (0.47)

*Data at 48 weeks after DTX401 treatment

Background

Chronic hyponatremia is associated with increased mortality and rehospitalization rates, but it remains unclear whether this relationship is causal. The aim of this study was to evaluate the effects of targeted hyponatremia correction versus routine care on mortality and rehospitalization rates.

Methods

Pragmatic, randomized controlled, parallel-group, international multicenter trial with blinded outcome assessment. Hospitalized participants with plasma sodium <130 mmol/l from nine European centers were assigned to undergo either targeted correction of hyponatremia according to guidelines (intervention) or routine care for hyponatremia (control). The primary outcome was the combined risk of death or rehospitalization within 30 days of study inclusion.

Results

2173 patients were included in the primary analysis of whom 1079 (49.7%) were randomized to the intervention and 1094 (50.3%) to the control group. Normonatremia was reached in 641 (60.4%) patients in the intervention group compared to 492 (46.2%) patients in the control group. Within 30 days after inclusion, the primary outcome occurred in 20.5% (218/1065 patients) in the intervention group and 21.8% (234/1073 patients) in the control group (estimated absolute difference in proportions [95% CI] -1.3% [-4.9, 2.2], $P=0.45$). Death occurred in 86 (8.0%) and rehospitalization in 141 (13.2%) patients in the intervention group compared to 88 (8.0%) and 151 (14.1%) patients in the control group. These findings were consistent in the per-protocol analysis and no evidence of effect modification was found for hyponatremia etiology and severity.

Conclusion

In hospitalized patients with chronic hyponatremia, targeted correction of plasma sodium did not reduce 30-day mortality and rehospitalization rates.

Introduction

Emerging evidence supports the presence of oxytocin deficiency (OXT-D) in patients with hypopituitarism and hypothalamic damage (HHD). However, the lack of reliable diagnostic tests for OXT-D remains a critical gap. Melatonin might be a candidate for such a test as melatonin receptors are located in the hypothalamus where OXT is synthesized, and melatonin regulates OXT release in animals. This study aimed to examine plasma OXT dynamics in response to oral melatonin in patients with HHD compared to healthy controls (HC) and explore its associations with psychopathology, sexual function, and quality of life (QoL).

Methods

This proof-of-concept study (NCT05319301) included 20 participants with HHD (11 females) and 20 HC (11 females). Melatonin (1.95 mg) was administered sublingually between 8-9 am. Blood samples were collected over 120 minutes. Additionally, participants were asked to complete questionnaires to assess psychopathology, sexual function and QoL. Linear mixed-effects regression model controlled for body mass index (BMI) was used to evaluate the change in OXT over time in HHD compared to HC.

Results

Both groups were comparable in age and gender distribution. The median BMI was higher in the HHD compared to the HC group (30.20 (3.79) vs. 22.91 (7.34) kg/m^2, $P=0.02$). Baseline OXT levels were similar across groups (HHD 56.75 ± 4.13 vs. HC 57.05 ± 3.99 pg/ml, $P=0.86$). In HC, melatonin significantly increased OXT at T90 vs. T0, whereas no such increase was observed in the HHD group (68.95 ± 4.37 vs. 54.07 ± 4.37 pg/ml, respectively; difference 14.57 pg/ml 26% increase, 95%IC 1.90 to 27.23, $P=0.02$); however, with high interindividual variability. Similar results were found in the subgroup of patients with HHD and arginine vasopressin deficiency (AVP-D) ($n=17$), with HC showing a greater OXT increase at T90 (HC 68.95 ± 4.37 vs. AVP-D 55.52 ± 6.85 pg/ml; difference 13.30 pg/ml, 95%CI 0.95 to 25.65, $P=0.03$). HHD group had more depression and alexithymia symptoms, impaired sexual function and worse QoL in comparison with HC. The mean percentage change in OXT from T0 to T90 was negatively associated with depressive and alexithymia symptoms in HHD and anxiety in both groups.

Conclusion

The reduced OXT response to melatonin in HHD, supports the existence of an impaired OXT response in a subset of patients with HHD. The associations between OXT changes and psychopathology suggest its role in mood and QoL. These findings provide support for a clinically significant OXT-deficient state in HHD. Future studies could examine different doses of melatonin as a diagnostic tool to address OXT-D.

Introduction
Tissue-specific 11β-hydroxysteroid dehydrogenase type 1 (HSD-1) reactivates glucocorticoids increasing binding to intracellular receptors. HSD-1 deficiency suppresses Cushing syndrome (CS) phenotype despite hypercortisolism.[1-3] Treatment with clofutriben (C), a potent and specific inhibitor of HSD-1, might improve CS comorbidities by decreasing intracellular cortisol.
Methods
Seventeen adults with ACTH-dependent CS (16 pituitary, 1 ectopic), and type 2 diabetes (T2D), impaired glucose tolerance (IGT), hypertension (HTN), hyperlipidemia, or osteopenia were randomized to a total of 12 weeks of oral C 6mg/d and 12 weeks of matching placebo (P) in 2 blinded sequences (PCCP, CCPP; "P" or "C" representing 6-week periods). Patients were offered open-label C treatment on completion. Primary endpoint was urinary ratio of cortisol and cortisone metabolites at Week 6 (hepatocellular HSD-1 activity biomarker). Key exploratory endpoints (and applicable population) at Week 6 were HbA1c (T2D), systolic blood pressure (>120 mmHg), LDL cholesterol (>100 mg/dl), osteocalcin (<7.5 mg/l), and normalization of elevated (>1.5×ULN) urinary free cortisol.
Results
Mean baseline HSD-1 ratio was 1.95±0.171. At Week 6, mean ratio was 0.21±0.091 with C and 2.01±0.263 with P. HbA1c decreased by 0.6% for C and 0.2% for P. Systolic blood pressure in C and P decreased by 8 and 3 mmHg. LDL in C decreased by 25 mg/dl but increased in P by 29 mg/dl. Osteocalcin increased by 6 mg/l for C and by 0.1 mg/l for P. Urinary free cortisol normalized with C in 3 of 8 patients, but in none of 6 patients with P. Concomitant medications for T2D were reduced in 4 C-treated, but increased in 2 P-treated patients. For HTN there were also 4 reductions for C-treated and 1 increase for P-treated patients. One patient succumbed to ectopic Cushing's due to cervical carcinoma after trial discontinuation. Four patients discontinued for non-adverse event (AE) reasons. One serious AE of vomiting (possible glucocorticoid withdrawal syndrome per investigator) led to temporary drug interruption. Common AEs (≥ 3 patients) included Arthralgia, Fatigue, Headache, and Nausea, but only Headache was more common in C during the P-controlled period. There was no evidence of adrenal insufficiency, clinically or biochemically (low cortisol). All 13 patients completers elected to enter the open-label extension (current treatment duration 3-15 months).
Conclusions
Clofutriben decreased hepatic HSD-1 activity adequately to confer clinical benefit while maintaining safety and overall tolerability. These limited data support clofutriben's potential for clinical improvement without adrenal insufficiency.

Background
Effective biochemical control of excess insulin-like growth factor-I (IGF-I) and growth hormone (GH) is essential to alleviate symptoms and associated conditions of acromegaly. CAM2029, an octreotide subcutaneous depot designed with FluidCrystal® technology to be long-acting, is conveniently self-administered using an autoinjector pen. In ACROINNOVA 1, a 24-week, Phase 3 trial (NCT04076462), CAM2029 demonstrated superior biochemical control versus placebo (72.2% vs 37.5%; $P=0.0018$) in patients previously controlled (IGF-I ≤ upper limit of normal [ULN]) on standard-of-care somatostatin receptor ligands (SoC; octreotide long-acting repeatable/lanreotide Autogel). ACROINNOVA 2 (NCT04125836), a 52-week, open-label, Phase 3 trial (plus 52-week extension), assessed long-term safety and efficacy.
Methods
ACROINNOVA 2 included patients from ACROINNOVA 1 (prior-placebo and prior CAM2029 groups) and directly-enrolled patients with IGF-I ≤2×ULN (on SoC for ≥3 months). Patients received CAM2029 20 mg every 4 weeks (±1 week) for 52 weeks (prior-placebo: week [W] 24–52). The primary endpoint characterised safety; secondary endpoints included the proportion of patients with IGF-I ≤ULN (W50/52 mean) and both IGF-I ≤ULN (W50/52 mean) and GH < 2.5 µg/l (W52 mean).
Results
In total, 135 patients were enrolled: 54 completing ACROINNOVA 1 (prior-placebo, $n=18$; prior-CAM2029, $n=36$) and 81 directly-enrolled. Overall, 127 patients (94.1%) completed treatment (prior-placebo, $n=18$; prior-CAM2029, $n=35$; directly-enrolled, $n=74$). CAM2029 was well tolerated; no new safety signals were identified. The most common adverse events (AEs) were injection-site erythema and injection-site swelling, occurring in 27.4% (37/135) and 14.8% (20/135) of patients, respectively. All injection-site AEs were mild-to-moderate (Grade 1–2); new injection-site AEs decreased throughout the study. AEs leading to treatment discontinuation occurred in 1.5% (2/135) of patients. The proportion of patients with biochemical control are presented in the Table.
Conclusions
CAM2029 treatment resulted in biochemical control being regained in prior-placebo and sustained in prior-CAM2029 patients. Biochemical control was notably improved in directly-enrolled patients previously uncontrolled on SoC. These long-term findings support CAM2029 as an effective new treatment for acromegaly with a safety profile consistent with SoC.

Table Proportion of patients with biochemical control

Endpoint(s)	Timepoint	Prior-placebo	Prior-CAM2029 n/NaII* (%)	Directly-enrolled
	SoC baseline	17/18 (94.4)	33/36 (91.7)	12/81 (14.8)

Objective
To evaluate the efficacy and safety of once-weekly somatrogon, a long-acting recombinant human growth hormone, in adults with growth hormone deficiency (GHD) (NCT01909479). Somatrogon has been approved in many countries for treatment of pediatric GHD.
Methods
This randomized, double-blind, placebo-controlled Phase 3 study enrolled adults with GHD across 52 sites in multiple countries. The study included a 26-week double-blind period (Period 1), a 26-week open-label extension (OLE; Period 2) (Main Study = Periods 1 and 2, lasting up to 60 weeks, including a 2–8-week washout period), and a multi-year long-term OLE (Period 3) to evaluate long-term safety. In Period 1, patients were randomized 2:1 to somatrogon or placebo, with dosing based on gender, age, and estrogen therapy. During Periods 2 and 3, all patients received somatrogon. The primary endpoint was change (baseline–Week 26) in trunk fat mass (FM). Secondary endpoints included changes (baseline–Weeks 26 and 52) in total FM, lean body mass (LBM), percentage change in trunk FM, and trunk FM (baseline–Week 52 only). A post-hoc supplemental efficacy analysis evaluated changes (baseline–Week 26) in percent trunk FM relative to the total trunk mass (FM + LBM), trunk LBM, and appendicular skeletal muscle mass. Safety assessments included adverse events (AEs), vital signs, and laboratory evaluations.
Results
In Period 1, 389 patients were screened, 202 randomized and 198 received treatment (somatrogon:133; placebo:65). Change in trunk FM from baseline to Week 26 (primary endpoint) was not significantly different between somatrogon vs placebo (-0.37 vs 0.03 kg; $P = 0.0821$). Change in LBM from baseline to Week 26 was significantly higher in somatrogon vs placebo (1.35 vs 0.02 kg; $P < 0.0001$). The somatrogon group showed significant improvements in percentage change in trunk FM (baseline-Week 26) and the 3 supplemental endpoints (baseline-Week 26). Mean IGF-1 SDS at baseline was $\leq$-2.6 in both groups; IGF-1 SDS normalized following initiation of somatrogon in either Period 1 or 2. The incidence of all-causality AEs was similar between patients originally randomized to somatrogon vs placebo (Period 1: 63.9% vs 69.2%; Period 2: 56.4% vs 60.0%; Period 3: 64.9% vs 60.0%); most AEs were mild to moderate in severity. The most frequently reported AEs (somatrogon vs placebo) were injection site pain (9.0% vs 13.8%) in Period 1, and nasopharyngitis in Periods 2 (7.5% vs 6.2%) and 3 (11.7% vs 10.0%).
Conclusions
Once-weekly somatrogon treatment significantly improved most body composition parameters and was well tolerated in adults with GHD.

Comparison of long-acting and short-acting GLP-1 receptor agonists on copeptin in euvolemic participants - a secondary analysis of three prospective trials

Svenja Leibnitz[1,2], Sarah Baumann[1,2], Cihan Atila[1,2], Christina Romberg[2], Matthias Hepprich[2,3], Kwadwo Antwi[4], Bettina Winzeler[2], Emanuel Christ[1,2] & Mirjam Christ-Crain[1,2]
[1]University Hospital of Basel, Department of Endocrinology, Basel, Switzerland; [2]University Hospital of Basel, Department of Clinical Research, Basel, Switzerland; [3]Cantonal Hospital Olten, Olten, Switzerland; [4]St. Claraspital Basel, Department of Nuclear Medicine, Basel, Switzerland

Introduction
Glucagon-like peptide-1 (GLP-1) plays an important role in regulating sodium and water balance. Long-acting GLP-1 receptor agonist (RA) treatment reduces fluid intake, diuresis, and copeptin levels, a surrogate marker for vasopressin. In contrast, short-acting GLP-1 RA induces natriuresis, but their effects on copeptin remain unknown. The aim of this analysis was to compare the effects of long-acting and short-acting GLP-1 RA on copeptin levels.
Methods
This analysis combined data from three prospective trials conducted at the University Hospital Basel, Switzerland. The primary objective was to compare the effect of a three-week treatment with dulaglutide (GOLD & GATE trials) to a single dose of exenatide (FAST trial) on plasma copeptin release in euvolemic adults. In the GOLD & GATE trials, 34 and 20 participants were randomly assigned, respectively, to first receive a three-week treatment with either dulaglutide (1.5 mg) or placebo (0,9% sodium chloride) subcutaneously once a week. After a wash-out period of at least three weeks, participants received the opposite intervention. In the FAST trial, 10 participants received a single dose of Exenatide (10ug) intravenously.
Results
In total, 64 participants in the three trials were included. The median age was 27 (IQR, 24 to 37) years in the GOLD & GATE cohorts, whereas participants in the FAST cohort were modestly older with 38 [33 to 41] years. The body mass index (BMI) was 23 (IQR 20.8-24.8) in the GOLD & GATE cohorts, compared to 27(IQR 24.8-30.4) in the FAST cohort. Participants in the FAST cohort were predominantly male (72%), whereas gender distribution was more balanced in the GOLD & GATE cohorts.Long-term treatment with dulaglutide resulted in a significant suppression of copeptin in both GOLD & GATE trials ($P = 0.04$) compared to placebo [GATE: treatment effect: -1.4 pmol/l and GOLD: treatment effect: -0.4 pmol/l]. In contrast, short-term treatment with exenatide in the FAST trial resulted in an increase of copeptin ($P = 0.06$) compared to baseline [FAST: treatment effect: + 0.34 pmol/l]
Conclusion
Long- and short-acting GLP-1 RA differ in their effects on copeptin regulation. Long-acting GLP-1 agonists significantly suppress copeptin, likely through a synergistic mechanism, while short-acting GLP-1 RAs appear to stimulate copeptin release. These differing effects may also extend to other GLP-1-related mechanisms with potential high clinical relevance.

Excess adrenal androgen secretion is a consequence of in utero androgen excess in an ovine model of PCOS

Mick Rae[1], Seshadri Ramaswamy[1], Katarzyna Siemienowicz[1], Alan McNeilly[2], Forbes Howie[2], Kirsten Wilson[2], Kirsten Hogg[2] & W. Colin Duncan[2]
[1]Edinburgh Napier University, School of Applied Sciences, Edinburgh, United Kingdom; [2]University of Edinburgh, Centre for Reproductive Health, Edinburgh, United Kingdom

Background
Exogenous androgenic steroid applied to pregnant sheep, or directly to developing sheep fetuses, programmes a PCOS-like metabolic phenotype in female offspring. We hypothesised that such androgen excess during development would alter postnatal adrenal steroidogenic capacity.
Methods
Using both indirect androgenic overexposure (Prenatal androgen excess; PA) (maternal testosterone propionate treatment (100 mg twice weekly) from day (d) 62 to d102 of gestation; maternal injection – M-PA) and direct fetal androgen treatment (from d62, F-PA), we examined postnatal female adrenal gland function. A subset of animals directly treated during fetal life with estrogen receptor agonist DES (F-DES), or synthetic glucocorticoid dexamethasone (F-DEX) were studied to examine specificity of androgenic effects observed. Adrenal function testing, and qPCR measurement of adrenal steroidogenic genes were the outcome measurements.
Results
During fetal life, in terms of a panel of steroidogenic and related genes examined in the adrenal cortex, we observed some sexual dimorphism, but there was no evidence of prenatal androgen excess causing masculinisation of the developing female adrenal. Prior to puberty, (11 weeks postnatal age), we observed no functional alterations in terms of either cortisol or testosterone secretion in response to synthetic (Synacthen) ACTH stimulation. However, in post-pubertal female offspring (11 months old) from both M-PA and F-PA models, we observed increased expression of *StAR*, *HSD3B1* and *HSD17B* mRNA in animals exposed to excess androgens during fetal life ($P < 0.05 – 0.001$ compared to vehicle treatment). These post-pubertal adrenal gene expression changes were

accompanied by a markedly exaggerated testosterone secretory response to ACTH stimulation in M-PA and F-PA animals as compared to vehicle controls ($P < 0.05$), in the absence of any alterations in cortisol secretion. This effect was specific to prenatal androgen excess alone.

Conclusion

We conclude that the postnatal, post pubertal adrenal gland develops a hyperandrogenic phenotype as a consequence of prenatal androgen excess. The adrenal cortex may be a secondary source of increased androgens found in PCOS due to excess androgen exposure during development.

Comparison of oxytocin and incretin dynamics in response to food intake in women with polycystic ovary syndrome and healthy controls

Irmak Güneşli[1], Elif Uluğ[2], Aylin Açıkgöz Pınar[2], Oytun Portakal[3] & Bülent O. Yıldız[4]

[1]Hacettepe University, Department of Internal Medicine, Ankara, Türkiye; [2]Hacettepe University, Department of Nutrition and Dietetics, Ankara, Türkiye; [3]Hacettepe University, Department of Biochemistry, Ankara, Türkiye; [4]Hacettepe University, Division of Endocrinology and Metabolism, Department of Internal Medicine, Ankara, Türkiye

Objective

The role of oxytocin and its potential relation with incretin hormones in regulation of food intake is not known in polycystic ovary syndrome (PCOS). This study aims to investigate the dynamics of oxytocin and incretins (GLP-1, GIP) in response to a mixed meal test (MMT) in women with PCOS compared to healthy controls and to examine their associations with appetite regulation, including hunger, satiety, and food craving behaviors.

Methods

Thirty-six women with PCOS (mean age: 21.6 ± 2.6y; mean BMI:25.5 ± 4.6 kg/m^2) and 36 age- and BMI-matched healthy controls were included. Each participant underwent a standardized MMT with blood samples collected at baseline and at 30, 60 and 120 minutes after meal ingestion to measure plasma concentrations of oxytocin, GLP-1, GIP, insulin, and glucose. All tests were performed during early follicular phase of the menstrual cycle. Appetite regulation was assessed using validated tools, including the Visual Analog Scale (VAS) to measure hunger and satiety levels during the test, and the "Food Craving Questionnaire" to evaluate the urge to overeat.

Results

Baseline oxytocin levels were significantly lower in the PCOS group compared to controls(1294 ± 92.5 pg/ml vs 1580 ± 83 pg/ml respectively; $P = 0.024$). Oxytocin levels showed a significant decrease within the first 30 minutes after food intake in the control group, whereas in the PCOS group this physiological decrease was absent and no significant change in oxytocin levels were detected throughout the test. Baseline GLP-1 and GIP levels were significantly lower in the PCOS group compared to controls ($P < 0.001$, $P = 0.022$ respectively) and remained consistently lower throughout the test. The AUC values for GLP-1 and GIP were also significantly reduced in the PCOS group, indicating impaired incretin responses ($P < 0.001$, $P = 0.033$ respectively). Significant correlations between oxytocin and GLP-1 levels were observed both at baseline and during the test in the entire cohort. In the control group, the 0–30 minute change in oxytocin correlated negatively with the hunger score ($r = -0.361$, $P = 0.031$) and positively with the satiety score ($r = 0.370$, $P = 0.027$). However, this pattern was not observed in the PCOS group. Notably, women with PCOS exhibited higher scores on the Food Craving Questionnaire, reflecting a greater propensity for food cravings ($P < 0.001$).

Conclusion

Women with PCOS show lower fasting oxytocin, GLP-1 and GIP levels and impaired response of these hormones to food intake. Altered dynamics of oxytocin, incretins and their interactions might play a role in regulation of appetite and weight in PCOS.

The kisspeptin/nNOS/GnRH (KiNG) neuronal network: regulating reproductive function through a dual activation-inhibition mechanism

Virginia Delli[1], Marie Moulinier[2], Sooraj Nair[1], Charles-Antoine Seux[1], Tori Lhomme[1], Damien Lemoine[1], Alan Carleton[2] & Konstantina Chachlaki[1,3]

[1]Inserm, University of Lille, Lille Neuroendocrinology, Lille, France; [2]University of Geneva, Department of Basic Neurosciences, Faculty of Medicine, Geneva, Switzerland; [3]University Research Institute of Child Health and Precision Medicine, National and Kapodistrian University of Athens, Athens, Greece

Gonadotropin-releasing hormone (GnRH) is the master regulator of the hypothalamic-pituitary-gonadal (HPG) axis, orchestrating reproductive function through its pulsatile and surge release patterns. While kisspeptin has been extensively studied as a primary excitatory input to GnRH neurons, the precise mechanisms regulating GnRH pulsatility remain debated. We have previously proposed a theoretical model of the Kisspeptin/nNOS/GnRH (KiNG) network as a critical regulatory circuit, in which neuronal nitric oxide (NO) acts as a dynamic modulator of GnRH secretion—opposing kisspeptin's excitatory drive and providing an essential "OFF" signal for pulse generation. This study aimed to experimentally validate the KiNG network, examining the interplay between kisspeptin, NO, and GnRH neurons in the preoptic hypothalamic area, in shaping the pulsatile and surge release of GnRH/lH. By employing a combination of neuroanatomical, genetic, chemogenetic, and pharmacological approaches, including a novel viral tool for highly sensitive NO/cGMP detection, we extensively assessed the functional role of NO signaling in GnRH pulse generation. Our study reveals the existence of a functional network formed between the nNOS-expressing neurons of organum vasculosum of the lamina terminalis (OV) and the median preoptic nucleus (MePO), and the kisspeptin and GnRH neurons. Kisspeptin directly stimulates GnRH neurons while simultaneously engaging nNOS neurons to induce NO release. NO, in turn, is necessary to fine-tune the kisspeptin response, shaping both the GnRH pulse and surge. Our findings reveal that NO production from nNOS neurons is not merely a modulatory factor but an essential component of the network, acting as a gatekeeper for the dynamic regulation of GnRH secretion in a cycle- and sex-dependent manner. This study provides experimental validation of the KiNG network as a fundamental mechanism governing GnRH/lH pulsatility. By acting as the Yin to kisspeptin's Yang, NO ensures the proper balance between excitation and inhibition, allowing for the precise control of reproductive hormone release. Understanding this interplay offers new perspectives on the neuroendocrine control of fertility and potential targets for reproductive disorders.

Kisspeptin-54 accurately identifies the cause of delayed puberty

Maria Phylactou[1,2], Kanyada Koysombat[1,2], Megan Young[1,2], Sandhi Nyunt[1,2], Jovanna Tsoutsouki[1,2], Arthur C. Yeung[1,2], Pei Eng[1,2], Sophie Clarke[3], Edouard Mills[1,2], Ruben H. Willemsen[4], Jayanti Rangasami[5], Evelien Gevers[4,6], Alexander Comninos[1,2], Sasha Howard[4,6], Ali Abbara[1,2] & Waljit Dhillo[1,2]

[1]Imperial College London, Metabolism, Digestion and Reproduction, London, United Kingdom; [2]Imperial College Healthcare NHS Trust, Endocrinology, London, United Kingdom; [3]University College London Hospital, Reproductive Endocrinology, London, United Kingdom; [4]Barts Health NHS Trust, Paediatric Endocrinology, London, United Kingdom; [5]Chelsea and Westminster NHS Foundation Trust, Paediatrics, London, United Kingdom; [6]Queen Mary University of London, London, Centre for Endocrinology, William Harvey Research Institute, London, United Kingdom

Background

Most young people with delayed puberty have self-limited delayed puberty (SLDP), but ~10% have congenital hypogonadotrophic hypogonadism (CHH). Differentiating between these two conditions is challenging, with the diagnosis typically made retrospectively, particularly in the absence of 'red flag' features of CHH e.g. anosmia. Kisspeptin stimulates hypothalamic GnRH neurons, and in turn LH release in healthy individuals, however patients with CHH have a minimal hormonal response to kisspeptin. Early evidence suggests that kisspeptin-10 could differentiate the cause of delayed puberty, however no data exists using kisspeptin-54, which could be advantageous. Kisspeptin-54 is reported to cross the blood brain barrier to access GnRH neuronal cell bodies, and a single bolus induces a greater LH rise than kisspeptin-10. We therefore investigated whether kisspeptin-54 could differentiate children with SLDP from those with CHH.

Methods

Fourteen young people with delayed puberty (12 boys and 2 girls) were categorised into three groups (Group 1: likely SLDP, Group 2: likely CHH, Group 3: indeterminate pending follow-up) according to pre-determined criteria including clinical history, auxology, and longitudinal Tanner staging. Participants received an intravenous bolus of kisspeptin-54 and GnRH on two separate occasions. Reproductive hormone levels were assessed every 15 min for 6 h (kisspeptin visit) , and for 2 h (GnRH visit). LH rises between the three groups were compared by Kruskal Wallis test with post-hoc Dunn's multiple comparisons. The LH rise between SLDP and CHH was compared by Mann Whitney U test.

Results
The mean age (±SD) of participants at time of assessment was 15.9±1.8 years. Five boys had likely diagnosis of SLDP, four young people (2 boys and 2 girls) had likely CHH, whilst the remaining five were indeterminate (Group 3). Kisspeptin-54 induced different maximal LH rises in the three groups (SLDP: 3.91±1.38, CHH: 1.29±0.91, Indeterminate 2.46±0.70 IU/l; *P*-value<0.0001). By contrast, the LH responses following GnRH were not significantly different between the groups (*P*-value=0.36). The LH-rise at two hours following administration of kisspeptin-54 fully differentiated participants with SLDP from those with CHH (area under ROC curve 1.0; *P*-value 0.0094). LH at both 30 and 60min post-GnRH had a poorer performance (auROC 0.58; *P*-value 0.72).Summary: Kisspeptin-54 demonstrates promise as a diagnostic test and performs better than GnRH, in young people with delayed puberty to help differentiate SLDP from CHH. Accurate and early identification of the cause of delayed puberty would remove uncertainty, aid in counselling, and could direct prompt appropriate management.

The predictive value of AMH and FSH concerning spontaneous vs induced puberty: a retrospective, longitudinal study of 50 girls with Turner Syndrome

Christine Baggesgaard[1,2], Margit Bistrup Fischer[1,2], Marie Ljubicic[1,2,3], Anette Tønnes Pedersen Pedersen[3,4], Katharina M. Main[1,2,4] & Casper Hagen[1,2,3,4]
[1]Copenhagen University Hospital, Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark; [2]Copenhagen University Hospital, Rigshospitalet, International Center for Research and Research Training in Endocrine Disruption of Male Repro-duction and Child Health (EDMaRC), Copenhagen, Denmark; [3]Copenhagen University Hospital, Rigshospitalet, Department of Gynaecology, Fertility and Obstetrics, Copenhagen, Denmark; [4]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark

Background
Turner syndrome (TS) is characterized by early onset of premature ovarian insufficiency (POI). In prepubertal patients, predicting ovarian function is essential for counselling of puberty guidance and potential ovarian cryopreservation. During infant minipuberty, HPG axis activation allows ovarian function assessment, with FSH remaining elevated in 45,X patients until around age 6 yrs. AMH, produced by small antral follicles, is unaffected by central HPG axis inhibition, keeping circulating levels measurable in all healthy prepubertal girls. While low AMH and elevated FSH are established markers of POI in adolescence, their predictive value in childhood for ovarian function at pubertal onset remains unexplored.
Aim
To evaluate the predictive value of AMH and FSH for POI in TS.
Setting
Copenhagen University Hospital – Rigshospitalet (1995-2022).
Design
Single-center, retrospective, longitudinal study.
Method
Turner syndrome (TS) patients (ICD10 Q96–Q96.9) were categorized into a) spontaneous puberty (*n*=13) or b) induced puberty by hormone replacement therapy (HRT) due to POI (*n*=37). Karyotypes: 45X (*n*=20), 45X/46XX (*n*=16), miscellaneous (*n*=14). AMH and FSH levels were analyzed by immunoassays. We assessed the predictive value of low AMH (<3pmol/l) as well as elevated FSH (>+2SDS) concerning induced pubertal onset (Tanner B2) at different timepoints prior to pubertal onset. ROC curves were used for data analysis.

Table 1. AMH<3 pmol/l and FSH >+2SD as predictors of the requirement for HRT to induce puberty

	Age (yrs)	*n* (total patientsin this age range)	Sensitivity	Specificity	PPV	NPV
AMH <3 pmol/l	0-1	4	NA	NA	NA	NA
AMH <3 pmol/l	1-6	11	100	75	88	100
AMH <3 pmol/l	>6 *	38	100	100	100	100
FSH >+ 2SD	0-1	6	NA	NA	NA	NA
FSH >+ 2SD	1-6	22	88	60	88	60

*age 6yrs to time of pubertal onset (spontaneous or induced by HRT)

Results
50 patients had blood samples prior to pubertal onset: 221 blood samples (mean 4, range 1–14 per patient). ROC curves: AMH cut off <3pmol/l provided the best combination of sensitivity and specificity.
Conclusion
From the age of 6yrs, AMH accurately predicted the patients who required HRT to induce puberty and the patients who underwent spontaneous pubertal onset. Thus, prepubertal AMH is a valuable clinical tool for guiding puberty management as well as future fertility counseling in TS girls. Further follow up is necessary to evaluate the predictive value of hormone levels in minipuberty.

Low prolactin levels as a risk factor for gestational diabetes mellitus: a longitudinal cohort study

Roberta Scairati[1,2], Renata Simona Auriemma[1], Sara Di Meglio[1], Enrica Mastantuoni[3], Chiara Graziadio[1], Guendalina Del Vecchio[1], Antonia Legnante[3], Christine Newman[2], Fidelma Dunne[2], Rosario Pivonello[1,4], Attilio Di Spiezio Sardo[3] & Annamaria Colao[1,4]
[1]"Federico II" University of Naples, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Diabetologia, Andrologia e Nutrizione, Naples, Italy; [2]University of Galway, HRB Clinical Research Facility Galway, Galway, Ireland; [3]"Federico II" University of Naples, Department of Public Health, Naples, Italy; [4]"Federico II" University of Naples, UNESCO Chair for Health Education and Sustainable Development, Naples, Italy

Rationale
Pregnancy induces profound metabolic adaptations to support fetal development, including increased insulin resistance and significant hormonal changes. However, when insulin production is inadequate to overcome pregnancy-induced insulin resistance, glucose impairment may occur thus increasing the risk of developing gestational diabetes mellitus (GDM). Emerging evidence highlights the role of early biomarkers, including hormonal profiles, in predicting GDM risk. Prolactin (PRL) plays a pivotal role in these adaptive changes, particularly in glucose homeostasis.
Objective
This study aimed to investigate the trajectory of PRL levels during pregnancy and their association with metabolic and glycemic outcomes.
Methods
A total of 120 pregnant women (67 with GDM, and 53 healthy controls) were assessed for anthropometric, hormonal (serum PRL) and metabolic parameters, including HbA1c, fasting glucose and glucose levels during the oral glucose tolerance test (OGTT). Women diagnosed with GDM underwent a follow-up OGTT between 4 and 12 weeks postpartum.
Results
PRL levels progressively increased across pregnancy but were significantly lower in patients with GDM, particularly in the third trimester (*P*=0.027). Early pregnancy PRL levels negatively correlated with fasting glucose (*P*=0.02; *r*=-0.4), whereas second-trimester PRL levels were inversely correlated with HbA1c levels in both the second (*P*=0.035; *r*=-0.5) and third trimesters (*P*<0.001; *r*=-0.9), respectively. Lower third-trimester PRL levels were associated with higher pre-pregnancy (*P*=0.02; *r*=-0.3) and postpartum weight (*P*=0.01; *r*=-0.6), whereas higher PRL levels correlated with better metabolic outcomes and longer breastfeeding duration. Subsequently, women were stratified into two groups based on the median third-trimester PRL level (183.8 μg/l). Ninety-six % of women with PRL<183.8 μg/l developed GDM, compared to 62% of those with PRL>183.8 μg/l (*P*<0.001). A one-unit decrease in third-trimester PRL predicted a 0.301-unit increase in 2-hour OGTT glucose (*P*=0.016; t=-2.81), reinforcing its potential role in GDM risk prediction. Adverse outcomes, including preterm delivery<37 weeks (5%) and infants large (LGA, 2.5%) or small (SGA, 5%) for gestational age, rarely occurred. No significant difference emerged between groups in breastfeeding duration, neonatal weight or length. Among patients retested after pregnancy, 22.3% had impaired glucose regulation, including 1 (1.5%) with type 2 diabetes mellitus, 7 (10.4%) with IFG and 7 (10.4%) with IGT.
Conclusions
PRL might represent a valuable biomarker for GDM risk stratification and maternal cardiometabolic health assessment during pregnancy. A sustained increase in PRL levels appears to support glucose homeostasis, whereas lower PRL levels are associated with increased GDM risk. Early monitoring of PRL levels could help identify women at high-risk, enabling timely interventions to improve maternal and fetal outcomes.

Study of predictive markers determining poor response to finerenone therapy in the management of diabetic kidney disease

Ipsita Mishra[1]
[1]IMS & SUM II, Endocrinology and Metabolism, Cuttack, India

Background
Diabetic kidney disease (DKD) is a leading cause of end-stage renal disease. Finerenone, a non-steroidal mineralocorticoid receptor antagonist (MRA), has demonstrated renoprotective effects in patients with DKD. However, not all patients respond equally to finerenone therapy. Identifying predictive markers for poor response is crucial for personalized management. This study aimed to investigate potential predictive markers associated with suboptimal response to finerenone in patients with DKD.
Methods
This prospective cohort study included 140 patients with DKD (estimated glomerular filtration rate [eGFR] 25-75 ml/min/1.73 m^2 and urinary albumin-to-creatinine ratio [UACR] $\geq$30 mg/g) who were initiated with finerenone therapy. Patients were followed for 12 months. Poor response was defined as a less than 15% reduction in UACR or a decline in eGFR of more than 5 ml/min/1.73 m^2 at end of one year. Baseline clinical and laboratory parameters, including age, sex, HbA1c, blood pressure, eGFR, UACR, serum potassium, sodium, uric acid, and inflammatory marker (high-sensitivity C-reactive protein [hs-CRP]), were analyzed as potential predictors. Univariate and multivariate logistic regression analyses were performed to identify independent predictors of poor response.
Results
Of the 140 patients, 45 (32.14%) were classified as poor responders to finerenone therapy. Univariate analysis revealed that baseline eGFR (OR 0.95, 95% CI 0.92-0.98, $P=0.001$), UACR (OR 1.001, 95% CI 1.000-1.002, $P=0.03$), hs-CRP (OR 1.25, 95% CI 1.08-1.45, $P=0.003$), and uric acid (OR 1.15, 95% CI 1.02-1.30, $P=0.02$) were significantly associated with poor response. In multivariate analysis, baseline eGFR (OR 0.96, 95% CI 0.93-0.99, $P=0.01$) and hs-CRP (OR 1.20, 95% CI 1.03-1.40, $P=0.02$) remained independent predictors of poor response to finerenone.
Conclusion
This study suggests that baseline eGFR and hs-CRP are independent predictors of poor response to finerenone therapy in patients with DKD. These findings highlight the importance of considering these markers in clinical practice to identify patients who may require closer monitoring or alternative treatment strategies. Further prospective studies are needed to validate these findings and explore the underlying mechanisms contributing to the observed associations.

Background
Finerenone significantly reduced cardiovascular and kidney risk versus placebo in patients with chronic kidney disease and type 2 diabetes in FIDELITY, a prespecified pooled analysis of the FIDELIO-DKD and FIGARO-DKD trials. Whether the benefits of finerenone on cardiovascular and kidney outcomes are observed independently of the number of American Diabetes Association-recommended treatment goals (HbA1c $\leq$7.0%, SBP $<$130 mmHg and DBP $<$80 mmHg, LDL cholesterol $<$70 mg/dl, and use of SGLT-2is or GLP-1RAs) achieved by patients at baseline remains to be determined.
Methods
Patients included in FIDELITY were on optimised RASi and were randomised 1:1 to finerenone or placebo. Composite cardiovascular (cardiovascular death, non-fatal myocardial infarction, non-fatal stroke or hospitalisation for heart failure) and kidney (kidney failure, sustained $\geq$57% estimated glomerular filtration rate [eGFR] decrease from baseline over $\geq$4 weeks, or kidney-related death) outcomes, and treatment-emergent adverse events (TEAEs) were assessed according to the number of treatment goals achieved at baseline.
Results
At baseline, 29%, 40%, 24% and 7% of patients achieved 0, 1, 2 and $\geq$3 goals, respectively. Larger proportions of patients achieved a higher number of goals in Asia and Western Europe versus other regions. Median urine albumin-to-creatinine ratio and mean eGFR at baseline decreased with an increasing number of goals achieved. No significant heterogeneity in the effect of finerenone versus placebo on the composite cardiovascular or kidney outcomes was observed between treatment goal achievement subgroups ($P_{interaction}$ of 0.75 and 0.61, respectively; Table). The safety profile of finerenone (versus placebo) was generally similar across treatment goal attainment subgroups, although patients who achieved a higher number of treatment goals tended to have slightly higher TEAE rates.

Table. Effect of finerenone versus placebo on efficacy outcomes by number of treatment goals achieved at baseline (Cox proportional hazards model)

		Treatment goals (*n*)			
		0 (*n*=3732)	**1 (*n*=5208)**	**2 (*n*=3091)**	**≥3 (*n*=959)**
			Composite cardiovascular outcome		
Incidence (n/N)	**Finerenone**	295/1905	299/2534	182/1568	47/491
	Placebo	307/1827	388/2674	194/1523	49/468
HR (95%CI)		0.90 (0.76–1.05)	0.79 (0.68–0.92)	0.88 (0.72–1.08)	0.89 (0.59–1.37)
$P_{interaction}$	0.75				
			Composite kidney outcome		
Incidence (n/N)	**Finerenone**	128/1905	144/2534	63/1568	21/491
	Placebo	155/1827	202/2674	89/1523	19/468
HR (95%CI)		0.77 (0.60–0.97)	0.71 (0.57–0.88)	0.70 (0.50–0.97)	1.11 (0.56–2.18)
	$P_{interaction}$	0.61			

CI, confidence interval; HR, hazard ratio.

Conclusion
Overall, the beneficial effect of finerenone on the composite cardiovascular and kidney outcomes was observed irrespective of the number of treatment goals achieved by patients at baseline.

management. Despite their established protocols, deviations from these guidelines remain prevalent, primarily due to errors in insulin administration. One significant consequence of these errors is severe hypoglycaemia, a potentially life-threatening condition affecting 5–25% of patients annually.

Aims

1. To evaluate adherence to JBDS guidelines in DKA management.
2. To explore the characteristics of severe hypoglycemia associated with DKA treatment.

Methods

This study was conducted at a large tertiary care centre from October 2024 to January 2025. A retrospective analysis was performed using data from all DKA episodes between August 2023 and September 2024. Episodes where severe hypoglycaemia (blood glucose <3.9 mmol/l) did not occur were excluded from the analysis. Patient demographics, episode characteristics, adherence to JBDS guidelines, and details regarding the hypoglycaemic events were extracted from electronic health records. Statistical analysis was conducted using Microsoft Excel and results are presented as frequencies or proportions as appropriate.

Results

Of the 304 DKA episodes during the study period, 68 hypoglycaemic episodes across 32 patients met the eligibility criteria for inclusion in this study. The median age of the patients was 42 years, with an equal male-to-female distribution. 68.8% had Type 1 Diabetes Mellitus (T1DM) (median age:38.8 years, CCI:1.5). 75% of the episodes lacked hourly glucose monitoring, 28% did not initiate the correct insulin infusion rate (0.1 unit/ kg/hour), 54% failed to introduce 10% dextrose when glucose levels fell below 14 mmol/l, and 69% did not halve the insulin infusion rate under these conditions. 60% of hypoglycaemic episodes were attributed to multifactorial causes. 19.1% of the episodes were classified as level three hypoglycaemia.

Conclusions

This audit underscores the substantial deviations from JBDS guidelines in managing DKA, particularly in relation to insulin administration, glucose monitoring, and dextrose supplementation. These gaps contribute to the high incidence of severe hypoglycaemia in DKA patients. The findings highlight the urgent need for targeted interventions, such as implementing standardised checklists and reinforcing clinical protocols, to improve adherence to guidelines and ultimately optimise patient outcomes. These interventions could be crucial in reducing hypoglycaemic events and enhancing the safety and effectiveness of DKA management.

Congenital hyperinsulinism and diabetes later in life –dominant variants causing both phenotypes

Jonna M E Männistö[1,2], Aparajita Sriram[1], Luke Sharp[1], Jasmin J Bennett[1], Matthew B Johnson[1], Sarah Flanagan[1] & Kashyap Patel[1]
[1]University of Exeter Medical School, Department of Clinical and Biomedical Science, Exeter, United Kingdom; [2]Kuopio Pediatric Research Unit (KuPRu), University of Eastern Finland, Kuopio, Finland

Background & aim

It is unclear which genes causing congenital hyperinsulinism (HI) can also cause diabetes later in life due to possible beta-cell exhaustion from excess insulin secretion. To test this, we screened for pathogenic variants in the three most common dominant HI genes in a large cohort of individuals with diabetes referred for MODY testing and in a large population cohort.

Methods

We examined dominantly acting pathogenic HI-causing variants in *ABCC8*, *GCK*, *GLUD1* in 2,413 individuals with early-onset diabetes (<40 y) referred for MODY genetic testing. We repeated the analyses in 24,203 individuals with late-onset diabetes from the UK Biobank (UKB). We examined enrichment of pathogenic variants in these cohorts compared to total of 395,625 controls.

Results

We did not find pathogenic HI-causing *GCK* or *GLUD1* variants in individuals with early- or late-onset diabetes, suggesting these etiologies do not increase diabetes risk. In contrast we found a significant enrichment of dominant *ABCC8* HI variants in the MODY cohort compared to control population (odds ratio 43, 95%CI 4–375, $P=0.0023$). The phenotype of the 9 individuals with diabetes and a dominant *ABCC8* HI variant in MODY cohort was not suggestive of type 1 or 2 diabetes and they lacked pathogenic variants in all known monogenic diabetes genes. They were diagnosed at median age of 16 years [IQR, 12.5;16.0]. All were negative for islet auto-antibodies and had low Type 1 diabetes Genetic Risk Score (<15thcentile). Their median BMI was 26.7 kg/m^2, seven (78%) had family history of diabetes, and only 2 (22%) neonatal-HI. A dominant *ABCC8* HI variant was detected in only 1 of 24,203 individuals with diabetes in the UKB.

Conclusion

Our results suggest that dominant loss-of-function HI variants can cause diabetes later in life but this is limited only to the *ABCC8* gene. Although further understanding is needed about treatment, these variants should be screened to determine the aetiology of early-onset diabetes.

Assessment of derangements in glucose metabolism in children with transfusion dependent thalassemia: a cross sectional analytical study

Pooja Meena[1], Anju Seth[1], Preeti Singh[1], Mukesh Dhankar[1] & Ritu Singh[1]
[1]Lady Hardinge Medical College, Paediatric, Delhi, India

Introduction

The mechanisms of abnormal glucose homeostasis in children with transfusion dependent thalassemia (TDT) are complex and multifactorial.

Objective

To assess the prevalence and spectrum of deranged glucose metabolism in children with TDT in comparison with age and sex matched controls.

Methods

Cross-sectional analytical study conducted in 110 children (aged 5-18 years) with TDT (cases) and equal number of age and sex matched controls. Proportion of children with deranged fasting blood glucose and fasting insulin levels were assessed in both cases and controls. Impaired glucose tolerance and insulin resistance were evaluated using oral glucose tolerance test (OGTT) and Homeostatic model assessment of insulin resistance (HOMA-IR) levels respectively in children with TDT.

Results

Altered glucose metabolism was observed in 33.6% children with TDT. Prevalence of impaired fasting glucose (IFG), impaired glucose tolerance and diabetes was 31.8%, 5.45% and 1.8% respectively. Proportion of children with IFG [31.8% vs 0], fasting insulin deficiency [19% vs 5.5 %] and raised HOMA-IR [17.3% vs 1.82%] were higher in cases as compared to controls ($P<0.001$). The mean fasting glucose, fasting insulin, 30-minute insulin on OGTT and HOMA-IR were significantly higher in children with TDT and altered glucose metabolism than with normal glucose tolerance (table 1). Significant predictors of altered glucose metabolism in TDT cases were delayed puberty, raised ALP and high BMI for age.

Conclusions

1/3rd of children with TDT had altered glucose metabolism. Underlying mechanisms include both insulin resistance and insulin deficiency.

Inherited stress vulnerability exacerbates obesity-induced metabolic alterations through dysfunctional adipose tissue

Saumya Mehta[1], Michaella Ben-Shachar[1], Amiel Lerner[1], Albert Pinchasov[1] & Tovit Rosenzweig[1]
[1]Ariel University, Molecular Biology, Ariel, Israel

Background
Obesity is a significant risk factor for developing cardio-metabolic diseases and is associated with increased mortality. However, there is substantial variability in the severity of metabolic abnormalities among obese individuals. The exact mechanisms contributing to this heterogeneity remain unclear.
Objective
This study aims to investigate whether differences in stress response affect metabolic health and to explore underlying mechanisms, hypothesizing that impaired stress resilience affects adipose tissue function.
Methods
The study utilized a selectively bred mouse model with inherent social dominance (Dom) and submissiveness (Sub), representing stress resilience and vulnerability, respectively. Mice were fed either a high-fat diet (HFD) or standard diet (STD), followed by physiological and molecular analyses. To manipulate stress response, a stress inoculation paradigm involving chronic mild stress (CMS) was employed (14 days of 5-minute daily restraint)[1]. Epididymal and inguinal white adipose tissue (eWAT and iWAT, respectively) were isolated for RNA-seq analysis, insulin sensitivity assessment, and determination of adipogenic potential.
Results
HFD-fed Sub mice exhibited hyperinsulinemia, hyperleptinemia, severe glucose intolerance, and fatty liver, whereas Dom mice showed minimal effects. CMS reduced HFD-induced glucose intolerance in stress-vulnerable mice, with similar positive effects observed in C57BL/6 mice. Adipose tissue analysis revealed impaired adipokine expression in HFD-fed Sub mice, with higher leptin and lower adiponectin mRNA levels compared to Dom mice. Additionally, an impaired pro-inflammatory gene expression profile was observed in Sub mice. Further investigation focused on differences in adipose tissue function between Sub and Dom mice, showing impaired insulin-induced Akt phosphorylation and glucose uptake in Sub mice. RNA-seq analysis demonstrated distinct clustering of genes in WAT of Sub and Dom mice, even under STD-feeding conditions, indicating fundamental differences in adipose tissue function between strains. Pathway analysis revealed that adipogenic pathways were enriched in eWAT but reduced in iWAT of lean Sub mice, suggesting impaired adipogenic potential in iWAT of Sub. Functional analysis of adipogenesis in isolated stroma-vascular fraction (SVF) from iWAT confirmed lower proliferation and differentiation rates in Sub mice compared to Dom mice. Furthermore, differentiated adipocytes from Dom mice exhibited a higher UCP1 and adiponectin-to-leptin expression ratio, compared to adipocytes from Sub.
Conclusion
Stress vulnerability contributes to increased susceptibility to metabolic alterations, with impaired adipogenic potential and impaired function in stress-vulnerable mice, potentially exacerbating metabolic abnormalities observed in this model.

Hereditary duodenopancreatic neuroendocrine tumors, what genetic analysis? a retrospective analysis on 410 patients

Theo Charnay[1], Camille Gianetti[2], Nicolas Sahakian[3], Magalie Haissaguerre[4], Marie Puerto[4], Patricia Niccoli[5], Olivier Gilly[6], Bénédicte Découdier[7], Arnaud Lagarde[2], Anne Barlier[1] & Pauline Romanet[8]
[1]Aix Marseille Univ, APHM, MMG, La Timone University Hospital, Molecular Biology Department GEnOPé, Marseille, France; [2]APHM, La Timone University Hospital, Molecular Biology Department GEnOPé, Marseille, France; [3]Aix Marseille Univ, APHM, Inserm, MMG, MarMaRa, La Conception University Hospital, Department of Endocrinology, Marseille, France; [4]Haut Leveque University Hospital, Department of Endocrinology, Bordeaux, France; [5]Institut Paoli Calmette, Oncology Department, Marseille, France; [6]Université Montpellier, Department of Metabolic and Endocrine Disease, CHU Nîmes, Nîmes, France; [7]CHU of Reims, Department of Endocrinology, Hôpital Robert Debré, Reims, France; [8]Aix Marseille Univ, APHM, INSERM, MMG, La Timone University Hospital, Laboratory of Molecular Biology GEnOPé, BIO-GENOPOLE, Marseille, France

Background
Duodenopancreatic Neuroendocrine Tumors (dpNETs) have an estimated prevalence of approximately 5 per 100,000, with less than 5% presenting as hereditary cases. Tumor growth is generally slow, but metastases can appear quickly. DpNETs can sometimes be the first symptom of syndromic diseases, diagnosed thanks to the identification of a pathogenic genetic variants. In France, the last recommendations of germinal genetic analysis in case of dpNETs focused only on *MEN1* and *VHL* analysis in isolated and familial cases or in isolated dpNETs before 50 years except for gastrinomas.
Objectives
Objectives was to update the list of candidate genes and to estimate the prevalence of these newly identified genes in order to update the decision tree for genetic analyses in dpNETs.
Methods
We conducted a literature review of genes implicated in dpNETs. Once identified, we performed a retrospective analysis of genetic and clinical data of patients diagnosed with dpNETs and analyzed using the Endocrine Tumor library at the laboratory of molecular biology APHM between 2018 and 2024.
Results
The literature review identified 3 additional syndromic diseases including dpNETs : neurofibromatosis type 1 (*NF1*), multiple endocrine neoplasia type 4 (*CDKN1B*), and tuberous sclerosis (*TSC1*, and *TSC2*). We include 410 patients, 306 with isolated dpNET and 104 syndromic dpNETs. A total of 15 had familial of dpNETs and 395 were sporadic. All (likely) pathogenic variants ((L)PV) of *MEN1*, *VHL*, *NF1*, *CDKN1B*, *TSC1* and *TSC2* identified by NGS in the 410 patients were collected. Overall, 36 (L)PV were identified, including 27 in *MEN1* (75%), 6 in *NF1* (16,7%), 3 in *VHL* (8,3%), and none in *CDKN1B* and *TSC1/2*. A (L)PV was identified in 28.8% (30/104) of patients with syndromic dPNETs while in only 2% (6/306, 5 *MEN1* and 1 *NF1*) of patients with isolated dpNETs. Among the 6 *NF1* cases, 3 (50%) had pancreatic gastrinomas, and in one case, dpNET was the first manifestation of the disease. An earlier onset of dpNET was observed in *VHL* patients with a mean age of 23 years, compared to 44 years for *MEN1* and *NF1* patients.
Conclusion
In patients with dpPNET, not only MEN1 and VHL but also *tuberous sclerosis*, and NF1-related lesions should be assessed to identify syndromic genetic predisposition. In case of isolated and sporadic dpNET, mutation detection rate is very low ($<2\%$); a better definition of the targeted population remains required to avoid an over genetic exploration.

Dysregulation of a RNA exosome component: a driving force behind prostate cancer progression

Francisco Porcel-Pastrana[1,2,3], Prudencio Sáez-Martinez[1,2,3], Antonio J Montero-Hidalgo[1,2,3], María Ortega-Bellido[1,2,3], Enrique Gómez-Gómez[1,3,4], Rafael Sánchez-Sánchez[1,3,5], Miguel A Japón-Rodriguez[6], Carmen Sáez-Torres[6], Manuel D Gahete[1,2,7] & Raul M Luque[1,2,7]
[1]Maimonides Institute for Biomedical Research of Córdoba (IMIBIC), Cordoba, Spain; [2]Department of Cell Biology, Physiology, and Immunology, University of Córdoba, Cordoba, Spain; [3]Hospital Universitario Reina Sofía (HURS), Cordoba, Spain; [4]Urology Service, HURS/IMIBIC, Córdoba, Spain; [5]Anatomical Pathology Service, HURS, Córdoba, Spain; [6]Department of Pathology, Hospital Universitario Virgen del Rocío, Sevilla, Spain; [7]Centro de Investigación Biomédica en Red de Fisiopatología de la Obesidad y Nutrición, (CIBERobn), Madrid, Spain

New diagnostic, prognostic and therapeutic strategies for different endocrine-related cancers are urgency required, especially in highly common types of malignancies affecting millions of subjects worldwide. Prostate cancer (PCa) represents a major endocrine health issue, with its progression influenced by intricate molecular factors, being the acquisition of an androgen-independent phenotype by prostate cancer cells a death sentence for patients [metastatic PCa (mPCa)]. In this context, recent evidence from our group indicates a profound

dysregulation in the RNA-Exosome complex (REC), a molecular machinery responsible for 3′-5′ RNA processing and degradation, in PCa vs. non-tumoral samples which might be implicated in driving oncogenic processes associated with tumour progression and aggressiveness. This study focuses on characterizing the levels and pathophysiological role of a REC component (REC-C) in PCa. Analysis of seven independent cohorts of patients with PCa and/or mPCa (three internal and four external) revealed that REC-C was consistently up-regulated in PCa and mPCa vs. control tissues, being this overexpression directly correlated with different clinical features of aggressiveness, including high Gleason scores, recurrence, and metastasis. Functional studies in different preclinical models, both *in vitro* [using normal-like prostate (PNT-2) and mPCa (LNCaP, DU145, and 22Rv1) cells] and *in vivo* (xenografted mice) demonstrated the impact of REC-C silencing in critical cancer hallmarks, including significant reductions in cell proliferation, migration, colonies or tumourspheres formation and tumor growth. Mechanistically (employing RNAseq and phosphoarray approaches), REC-C actions were mediated through the modulation of key inflammatory-related RNAs (e.g., interferon-gamma response) and critical oncogenic signalling pathways (e.g., MAPK and TGFβ). Remarkably, microscopy studies indicated that REC-C was predominantly localised in the nucleolus of normal and low-aggressiveness mPCa cells, whereas it was found to be enriched in the nucleoplasm of highly aggressive mPCa cells suggesting a cellular localization-dependent role of REC-C in prostate cells. In fact, this study demonstrated that the general expression and nucleoplasmic-guided accumulation of REC-C in the PNT2 normal prostate cell model induced metastasis-associated morphological changes (e.g. loss of nucleolar circularity) and increased cellular aggressiveness, including enhanced migration and invasion capacity. Finally, cross-linking and analysis of cDNA (CRAC) technique revealed **that** the enhanced aggressiveness features linked to REC-C might be associated to its potential interaction with critical long non-coding RNAs. These findings underscore REC-C as a driving force behind prostate cancer progression and as a promising therapeutic target for PCa/advance-state PCa.

Defining the clinical value of circulating splicing factors in prostate cancer: SRRM1 as a novel predictive biomarker and exploitable therapeutic target

Antonio Prats-Escribano[1], Antonio Jesús Montero-Hidalgo[2], Enrique Gómez-Gómez[3], Manuel Galán-Cañete[2], Ignacio Gil-Duque[2], Francisco Porcel-Pastrana[2], Jesús Miguel Pérez-Gómez[2], María Ortega-Bellido[2], Teresa González-Serrano[3], Rafael Sánchez-Sánchez[3], André Sarmento-Cabral[2], Manuel David Gahete-Ortiz[2], Juan Manuel Jiménez-Vacas[2] & Raúl Miguel Luque-Huertas[2]
[1]Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain, Department of Cell Biology, Physiology, and Immunology, Córdoba, Spain; [2]Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain, Hospital Universitario Reina Sofía (HURS), Cordoba, Spain, Department of Cell Biology, Physiology, and Immunology, University of Córdoba, Cordoba, Spain, Córdoba, Spain; [3]Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain, Hospital Universitario Reina Sofía (HURS), Cordoba, Spain, Córdoba, Spain

Prostate cancer (PCa) is the second most prevalent endocrine-related cancer among men worldwide. The main screening method, based on prostate-specific antigen (PSA) determination, exhibits significant limitations, including poor specificity and restricted prognostic value. Thus, the identification of accurate non-invasive diagnostic biomarkers, with potential prognostic and therapeutic applications, remains a critical need in PCa. In this context, dysregulation of the splicing process has emerged as a hallmark in PCa development and progression, with several splicing factors (SFs) playing key roles in PCa pathophysiology. However, despite discrete SFs have been reported to be potentially secreted by cancer cells, this event has not been addressed in PCa. Therefore, we aimed to explore the presence and potential clinical value of SRRM1, SNRNP200, and SRSF3 (previously reported SFs with a key pathophysiological role in PCa) in human plasma samples. Thus, plasma levels of these SFs were measured (using ELISAs) in control individuals ($n=40$) and PCa patients ($n=166$). We identified, for the first time, that these SFs were detectable in human plasma samples, being corroborated in an independent cohort of healthy individuals ($n=313$). Notably, plasma levels of SRRM1 and SNRNP200, but not SRSF3, were significantly elevated in PCa patients compared to controls. Furthermore, plasma and tissue SRRM1 levels were associated with relevant features of castration-resistant PCa (CRPC), a lethal disease stage, and positively correlated with androgen-receptor (AR) and AR-splicing variant 7 (AR-V7) expression and activity in PCa tissues. Furthermore, *in vivo* SRRM1 silencing in CRPC-derived xenografted tumors reduced aggressiveness features and AR/AR-V7 activity. Taken together, our findings suggest that circulating SRRM1 levels could serve as a valuable non-invasive diagnostic and prognostic biomarker in PCa. Additionally, SRRM1 may hold a promising therapeutic value, offering a clinically relevant opportunity for further exploration in human studies. Also, this study set the groundwork to thoroughly evaluate the presence and clinical utility of circulating SFs for clinical management of PCa patients.

Adipsic arginine vasopressin deficiency in CNS tumour patients: clinical management challenges

Catarina Regala[1], Sofia F. Silva[1], Leonor Pinto[1], Sofia Avelino[1], Margarida Oliveira[2], Carlos Marques[1], Daniela Cavaco[1], Sara Pinheiro[1], Margarida da Silva Vieira[1], Sara Donato[1] & Joana Simões Pereira[1]
[1]Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal; [2]Hospital Egas Moniz, Centro Hospitalar Lisboa Ocidental, Lisbon, Portugal

Introduction
Arginine vasopressin deficiency (AVP-D), formerly central diabetes insipidus, results from inadequate production of arginine vasopressin (AVP), also called antidiuretic hormone (ADH). It can be congenital or acquired, often resulting from tumours affecting the hypothalamic-pituitary region. The condition is marked by excessive urine output (polyuria), usually offset by increased water intake. Adipsic arginine vasopressin deficiency (AAVP-D), a rare form affecting hypothalamic osmoreceptors, impairs thirst perception, leading to an increased risk of dehydration and hypernatremia. This study retrospectively analyses patients with AAVP-D among those diagnosed with central nervous system (CNS) tumours in our centre.
Cases
Among 383 paediatric patients with CNS tumours, 34 were diagnosed with AVP-D, including 4 with AAVP-D. Of these, 2 (50%) were male. In most cases, AAVP-D was identified shortly after the CNS tumour diagnosis, except for one patient who developed symptoms 9 years later. Case 1: A girl diagnosed with a germinoma at 3 years, treated with multiple surgeries and chemotherapy, presented at age 12 with somnolence, hypernatremia (serum sodium: 157 mmol/l, osmolarity: 311.3 mOsm/kg), and concurrent panhypopituitarism. Given the potential influence of adrenal insufficiency on ADH secretion, she was hospitalized for initiation and titration of desmopressin therapy, followed by hydrocortisone. Case 2: A 13-year-old female with a hypothalamic germ cell tumour treated with radiotherapy developed adipsia, anorexia, and hypernatremia (serum sodium: 159 mmol/l, osmolarity: 325 mOsm/kg). Panhypopituitarism was diagnosed, requiring desmopressin, hydrocortisone, and levothyroxine. Due to persistent inadequate hydration, nasogastric tube feeding was attempted but ineffective, necessitating chlorpromazine therapy, which successfully improved hydration and thirst perception. Case 3: An 18-year-old male with a germinoma developed panhypopituitarism and AAVP-D following CNS radiotherapy but achieved good sodium control after initiating desmopressin. Case 4: An 6-year-old male presenting with vomiting, severe headache, and hydrocephalus due to intraventricular haemorrhage developed polyuria and hypernatremia (serum sodium: 155 mmol/l). Initial management was difficult due to high sodium from low water intake. Increasing desmopressin and setting a fixed water intake plan with school teacher support improved symptoms.
Conclusion
AAVP-D is a rare form of arginine vasopressin deficiency, in which the lack of polydipsia poses a challenge for both diagnosis and management. Effective treatment requires a personalized approach, with acute management involving fixed doses of ADH analogues and carefully controlled water intake. For patients with concurrent endocrine deficiencies, hormone replacement is essential. In refractory cases, chlorpromazine may be considered to enhance thirst perception, offering a potential adjunctive therapy.

Preclinical development and first clinical use of a radioiodinated CYP17 inhibitor for adrenal theranostics

Andreas Schirbel[1], Philipp Maier[1,2,3], Wiebke Schlötelburg[1], Carmina Teresa Fuss[2], Philipp Hartrampf[1], Britta Heinze[2] & Stefanie Hahner[2]
[1]Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, Germany; [2]Division of Endocrinology and Diabetes, Dept of Medicine I, University Hospital Würzburg, Würzburg, Germany; [3]Clinic for Radiology and Nuclear Medicine, Otto von Guericke University, Magdeburg, Germany

Background
The CYP11B1/2-selective tracers iodometomidate and IMAZA have been used for theranostics in adrenocortical carcinoma (ACC), but only ~40% of ACC patients show sufficient uptake, limiting their diagnostic and therapeutic utility. Since CYP17 is more frequently and highly expressed in ACC than CYP11B1/2, we designed several radiolabeled CYP17 inhibitors.
Methods
We designed and synthesised fluorinated and iodinated derivatives of known CYP17 inhibitors and evaluated their adrenostatic potential on CYP17-related enzymatic steps in NCI-H295 cells. Steroid concentrations of 17-OH-progesterone, DHEA and androstenedione were measured by LC-MS in supernatant after coincubation with the respective compounds and IC50 values were calculated. After successful establishment of the radiochemistry, the tracers were investigated in cell uptake experiments, cryosection binding studies and biodistribution analyses in hsCYP17-humanised mice.
Results
Ten derivatives of the known CYP17-inhibitor CFG920 showed single-digit nanomolar inhibition of at least one target steroid. Tracers showed up to 40% intracellular uptake, accumulating mainly in the endoplasmic reticulum fraction. Cryo-binding studies identified several tracers with high and specific tissue binding, with the radioiodinated compound IPIMA standing out. In animal studies, IPIMA exhibited high, sustained accumulation in CYP17-expressing tissues. Initial clinical studies in IMAZA-negative ACC patients showed that IPIMA effectively visualized tumor lesions undetected by IMAZA.
Conclusion
The CYP17-targeting radioiodinated compound IPIMA is a promising theranostic agent for adrenocortical tumors.

Recessive truncations in a previously uncharacterized gene, CCDC149, are a novel cause of congenital hypopituitarism

Louise Gregory[1], Shoshana Rath[2], Hanna Mandel[3], Ghadir Elias-Assad[4], Nadra Samra[3], Michael Parker[5], Paul Dimitri[6], Naresh Hanchate[1] & Mehul Dattani[1]
[1]UCL Great Ormond Street Institute of Child Health, Genetics and Genomic Medicine Research and Teaching Department, London, United Kingdom; [2]Tzafon Medical Center, Bar -Ilan University, Azrieli Faculty of Medicine, Nazareth, Israel; [3]Ziv Medical Center, Department of Genetics and Metabolic Disorders, Safed, Israel; [4]Saint Vincent de Paul Hospital, Bar - Ilan University, Pediatric endocrine unit, Azrieli Faculty of Medicine, Nazareth, Israel; [5]Sheffield Children's NHS Foundation Trust, Sheffield Clinical Genomics Service, Sheffield, United Kingdom; [6]Sheffield Children's NHS Foundation Trust, Department of Paediatric Endocrinology, Sheffield, United Kingdom

Background
Congenital Hypopituitarism (CH) is a complex developmental disorder characterized by a variable combination of defects in pituitary function, including deficiencies in growth hormone (GHD) (most frequent), gonadotropins, ACTH, TSH, prolactin and vasopressin. To date, a molecular basis has been identified in ~10-15 % of patients, but the majority remain unexplained.
Methods
Next generation sequencing was performed in two unrelated pedigrees including three patients with GHD, hypogonadotropic hypogonadism, and developmental delay/autism. MRI studies were performed to visualize morphological defects in the spinal cord and the pituitary. In situ hybridisation was conducted to generate an expression profile of *CCDC149* in the human embryonic brain at different Carnegie stages of development. A null *Ccdc149* mouse model was generated for phenotypic characterization.
Results
Two novel homozygous frameshifts were identified in *CCDC149*, c.832G>T p.G278* and c.665T>A, p.L222* respectively, in the two unrelated pedigrees with CH. Severe scoliosis was present in two out of the three patients, with the third unrelated patient having a small anterior pituitary on MRI. *CCDC149* mutations have not been reported previously. Human embryonic expression of *CCDC149* was localised to the developing hypothalamo-pituitary (HP) region at Carnegie stages (CS) 16, 19, 20 and 23. Preliminary murine data suggest that *Ccdc149*-knockout mice exhibit growth impairment and reduced fertility compared to their wildtype littermates.
Conclusion
We report the first genetic variant in a novel gene, *CCDC149*, associated with CH, scoliosis and learning difficulties/autism. We present clinical and molecular data in two pedigrees with CH, as well as gene expression in human embryonic sections and murine data to confirm the association between *CCDC149* variations and CH. *CCDC149* is therefore a novel candidate gene that should be considered for analysis in patients with unsolved CH. Previous studies in C.elegans report expression of the *CCDC149* orthologue in the basal bodies of ciliated neurons, supporting the possibility of impaired ciliary function as an underlying mechanism in this complex disorder.

Transcriptomic classification of PIT1-lineage PitNETs reveals distinct molecular groups associated with tumor differentiation and treatment resistance

Fabio Bioletto[1,2], Nesrine Benanteur[1], Chiara Villa[1,3], Maria Francesca Birtolo[1,4], Victor Gravrand[1], Anne Jouinot[1], Franck Letourneur[1], Jean-François Emile[5], Jérôme Bertherat[1,6], Bertrand Baussart[1,3] & Guillaume Assié[1,6]
[1]Université Paris Cité, Institut Cochin, Institut Cochin, Paris, France; [2]University of Turin, Department of Medical Sciences, Turin, Italy; [3]Assistance Publique–Hôpitaux de Paris, Hôpital Lariboisière, Paris, France; [4]Humanitas University, Pieve Emanuele - Milan, Italy; [5]Assistance Publique-Hôpitaux de Paris, Hôpital Ambroise Paré, Paris, France; [6]Assistance Publique–Hôpitaux de Paris, Hôpital Cochin, Paris, France

Objective
PIT1-lineage PitNETs are the most common pituitary tumors, encompassing lactotroph, somatotroph and thyrotroph tumor types. At a molecular level, several questions about their biology remain open. Among these, the molecular mechanisms of resistance to medical treatments remain largely unknown. The aim of this study was to better characterize PIT1-lineage PitNETs based on bulk transcriptome analysis, refining their molecular classification and deciphering molecular signatures associated with treatment resistance.
Methods
The transcriptome of 121 patients with PIT1-lineage PitNETs was evaluated. Clinical and histological data were collected, including those about response to dopamine agonists in prolactinomas, and to first-generation somatostatin analogs in acromegaly. Unsupervised transcriptome classifications were generated, both in the overall cohort and within subtypes, and tested for association with clinical data and treatment response.
Results
Unsupervised classification mainly discriminated PIT1-lineage PitNETs according to tumor histopathology (χ_2 $P<10_{-22}$ and $P<10_{-4}$ for WHO 2017 tumor type and granulations, respectively), secretion (χ_2 $P<10_{-22}$), and *GNAS* mutational status (χ_2 $P<10_{-6}$). Compared to previous classifications, a clear separation between sparsely granulated somatotroph PitNETs and thyrotroph/plurihormonal PIT1 PitNETs emerged. Moreover, a majority of aggressive PitNETs cumulated in a distinct transcriptomic subgroup, defined by a signature of mesenchimal differentiation, irrespective of histotype. Among prolactinomas, sensitivity to

dopamine agonists was the main driver of transcriptomic classification. Sensitive tumors cumulated in a distinct molecular subgroup. Resistant tumors were classified into three different clusters, with specific expression profiles (dedifferentiated, proliferative, and immune-rich). Among tumors causing acromegaly, three main transcriptomic groups were observed: sparsely granulated somatotrophs, densely granulated somatotrophs with *GNAS* somatic mutation, and densely granulated somatotrophs with PIT1/SF1 co-expression. Moreover, three smaller clusters were also observed, lacking the hallmark features of the three main ones: one of proliferative tumors with aggressive behavior; one of giant invasive tumors with atypical histology but otherwise indolent growth; and one of smaller tumors with limited extrasellar extension. Sensitivity to first-generation somatostatin analogs was associated with these molecular classes, with resistant tumors grouping within the sparsely granulated, proliferative, and giant invasive tumor clusters.

Conclusions

This transcriptomic study unravels important new aspects of the biology of PIT1-lineage PitNETs and further refines their molecular classification. The transcriptomic classification of prolactinomas recognizes the sensitivity to dopamine agonists as its main driver. The transcriptomic classification of tumors causing acromegaly primarily reflects their histological heterogeneity and identifies distinct molecular clusters associated with treatment response.

TNIP1 as a key regulator in sparsely granulated somatotropinomas: a combined proteomics and bioinformatics approach

Vaishali Kaur[1], Debajyoti Chatterjee[1], Apinderpreet Singh[1], Sivashanmugam Dhandapani[1], Soham Mukherjee[1], Sandeep Mohindra[1], Dibyajyoti Banerjee[1], Ashutosh Rai[2] & Pinaki Dutta[1]
[1]PGIMER-CHANDIGARH, Chandigarh, India; [2]Panjab University, Chandigarh, India

Background

Histopathologically somatotropinomas are classified as sparsely granulated (SG) and densely granulated (DG). Compared to DG, SG displays aggressive clinical behaviour, including a younger presentation, a higher percentage of invasiveness, therapy resistance, and recurrence (after total removal). A quantitative proteomics-based approach can dissect the signalling pathways between SG and DG subtypes and can potentially leads to new therapeutic targets in SG subgroups.

Method

Surgically resected 8 sporadic somatotropinoma (SG ($n=4$) and DG ($n=4$)) were subjected to high-throughput label-free quantitative mass spectrometry-based (Orbitrap Exploris mass spectrometer, Thermo Scientific) proteomics analysis in triplicates. Functional enrichment was conducted to identify the biological pathways and functions of the identified proteins. Topmost significantly differentially expressed proteins (cut-off = 1.5 fold-change) were considered for validation by immunofluorescence (IF) ($n=10$; SG = 5, DG = 5) and western blot ($n=8$ SG = 4, DG = 4).

Results

Mass spectrometry analysis identified 41,786 peptides corresponding to 5,163 proteins. Of these, 4,037 proteins were detected with ≥ 2 unique peptides. Statistical analysis showed significant differential expression of 1014 proteins, with overexpression of 44 proteins and under expression of 970 proteins. TNIP1($P=0.0001$) was the most overexpressed followed by PRSS29P ($P=0.001$), HPN ($P=0.001$) and DTNP ($P=0.002$) while COQ6 (0.00004) was the most under expressed protein. Functional enrichment analysis showed significant enrichment of glutathione synthesis pathway ($P=0.004$) and integrin signalling pathway ($P=0.004$) for overexpressed while mRNA processing ($P<0.0001$) and splicing ($P<0.0001$) pathways were significantly enriched for under expressed proteins. TNIP1 plays important role in EGFR mediated signalling cascade and inhibition of ERK2 mediated trancription[1,2]. ELK, a transcription factor regulated by ERK2, was found to be significantly enriched in our dataset ($P=0.04$). Notably, 122 proteins identified as targets of ELK exhibited under expression, suggesting a potential ELK-mediated transcriptional repression by TNP1. Furthermore, western blot analysis showed 5.9-fold increase ($P=0.007$) in TNIP1 expression in SG tumours as compared to DG tumours while there was no significant difference in the COQ6 levels between two groups. Immunofluorescence showed overexpression and nuclear localisation of TNIP1 in SG tumours as compared to DG.

Conclusion

Our findings suggest a potential role of TNIP1 in modulating ERK2-ELK signalling in SG tumours.

Sustained DNA methylation changes despite biochemical remission in cushing's disease

Ticiana Paes[1], Anand Iyer[1], Fadime Dogan[1], Peter van Koetsveld[1], Leo Hofland[1] & Richard Feelders[1]
[1]Erasmus Medical Center and Erasmus MC Cancer Institute, Rotterdam, Netherlands

Background

Glucocorticoids (GC) modulate the epigenetic machinery, thereby influencing gene expression. In cases of Cushing's disease (CD) in remission, the persistence of some comorbidities, such as hypertension, obesity, and diabetes, may be related to epigenetic changes. Our objective was to evaluate a) the reversibility of GC-induced changes in DNA methylation (DNAm) in patients with CD after at least one year of disease remission and b) the impact of DNAm on the persistence of comorbidities.

Methods

Forty-six patients diagnosed with CD and 59 BMI and gender-matched control subjects were included. Blood samples were collected during the active phase of CD (active_CD) ($n=40$) and at least one year of remission (remission_CD) ($n=30$, mean 49.76 ± 20.02 months), including 24 paired samples. Methylation levels of leukocyte-derived DNA were assessed using the Illumina Infinium Human Methylation 850K array. A difference in beta values of 0.05 with a Benjamini-Hochberg adjusted p-value of <0.05 was used to define differentially methylated probes/CpGs (DMPs).

Results

A total of 4264 DMPs were detected between control and active_CD (hypomethylated $n=2195$ and hypermethylated $n=1349$), 184 in control vs remission_CD (hypomethylated $n=150$ and hypermethylated $n=34$), and 2384 in active_CD vs remission_CD (hypomethylated $n=453$ and hypermethylated $n=1931$). Unsupervised hierarchical clustering revealed 3 main clusters; Cluster 1 comprised almost entirely of controls, the adjacent Cluster 2 included predominantly remission_CD, whereas most active_CD clustered in the distal Cluster 3. Analysis of DMPs associated with gene promoter regions yielded similar results. These results suggest that differences in methylation persist between the control and remission groups despite disease remission. Gene set enrichment analysis (GSEA) using DMPs revealed enrichment of cellular metabolic processes by comparing active CD or remission with controls, whereas immune processes were primarily enriched by comparing active CD and remission. A sub-analysis of 24 patients with paired samples from active disease and remission showed similar results. No association was observed between DMPs and comorbidities, such as diabetes, hypertension, obesity, and dyslipidemia. Using a random forest model, we could classify control, active, and remission samples in our cohort with an overall error rate of 14% (%; controls = 0, active_CD = 23.5, remission_CD = 22).

Conclusion

Cortisol excess in active CD is associated with a spectrum of methylation changes in leukocyte-derived DNA, which are not completely reversible after long-term remission. This indicates that cortisol has sustained effects on the epigenetic machinery. Future studies should explore prolonged epigenetic changes in other cell types in CD and examine their relation to persistent morbidities.

Histotype is not associated with short- or long-term remission of somatotroph tumours

Alexandra Monnot[1], Mirela-Diana Ilie[2], Camille Sergeant[1], Alexandre Vasiljevic[3], Emmanuel Jouanneau[4] & Gerald Raverot[1]
[1]Hospices Civils de Lyon (HCL), Fédération d'endocrinologie, Lyon, France; [2]"C.I. Parhon" National Institute of Endocrinology, Endocrinology Department, Bucharest, Romania; [3]Hospices Civils de Lyon, Service de Pathologie et Neuropathologie, Lyon, France; [4]Hospices Civils de Lyon, Service de Neurochirurgie, Lyon, France

Introduction
Pituitary surgery is the first-line treatment for acromegaly in most cases. While clinical and radiological predictors of remission have been extensively evaluated, few studies have analysed pathological prognostic factors, and evidence regarding histotype remains conflicting. Acromegaly histotypes mainly include pure GH adenomas, which can be either densely (DG) or sparsely granulated (SG), as well as GH-PRL adenomas.
Objectives
The primary objective was to assess the impact of histotype on acromegaly remission, defined as normal IGF-1 levels without treatment 3 months after surgery and at last follow-up. The secondary objective was to evaluate the influence of histotype on acromegaly control at last follow-up, defined as IGF-1 $\leq 1.2\times$ the upper limit of normal (ULN) with or without medical treatment.
Methods
Monocentric retrospective study including 162 patients with GH or GH-PRL adenomas who underwent endoscopic transsphenoidal surgery performed by an expert surgeon between 2012 and 2022.
Results
Among 162 patients, 63 (38.9%) had GH-PRL adenomas, while 99 (61.1%) had pure GH adenomas, including 59 DG (36.4%) and 40 SG (24.7%). Median age (48 years [IQR: 34-58]), IGF-1 (2.9×ULN [IQR: 2.1-3.7]), maximum tumour diameter (14 mm [IQR: 10-21]), and invasion rate (38%) did not significantly differ between GH and GH-PRL groups. Compared to pure GH adenomas, GH-PRL adenomas were more frequently p53-positive ($P<0.01$), had a higher mitotic count ($P<0.05$), and higher SST2 expression ($P<0.01$). Trouillas grade did not differ significantly between GH and GH-PRL adenomas. Compared to SG adenomas, DG adenomas had a lower Trouillas grade ($P<0.05$), lower SST5 expression ($P<0.01$), higher SST2 expression ($P<0.001$), and were more frequently SF1-positive (50% versus 0%, $P<0.01$). The 3-month remission rate was 52% for pure GH and 49% for GH-PRL adenomas, with no significant difference. At last visit, after a median follow-up of 33 months [IQR: 17-61], remission rates remained comparable between pure GH (63%) and GH-PRL adenomas (62%). The control rate at last follow-up for pure GH (89%) was not significantly different from GH-PRL adenomas (95%). Among patients requiring medical treatment, all controlled pure adenomas received monotherapy, while 35% of GH-PRL adenomas required combined therapy. In pure GH adenomas, no significant difference in remission was observed between DG and SG adenomas at 3 months or last follow-up. Similarly, control rates did not differ significantly.
Conclusion
Our results indicate that histotype is not significantly associated with remission or control of acromegaly and do not support the WHO classification, which considers SG high-risk pituitary adenomas.

Hypothalamic obesity following craniopharyngioma surgery; what is the role of hypothalamic inflammation?

Doga Yurddas[1], Rutger Nievelstein[1,2], Brigitte Bison[3], Marta Fiocco[4], Sanne Hulsmann[1], Julia Beckhaus[5], Eelco Hoving[1], Hermann Muller[5] & Hanneke van Santen[1,6]
[1]Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands; [2]Department of Radiology and Nuclear Medicine, University Medical Center Utrecht/Wilhelmina Children's Hospital, Utrecht, Netherlands; [3]Department of Neuroradiology, University Hospital Augsburg, Augsburg, Germany; [4]Mathematical Institute, Leiden University, Leiden, Netherlands; [5]Department of Pediatrics and Pediatric Hematology/Oncology, University Children's Hospital, Carl von Ossietzky Universität, Klinikum Oldenburg AöR, Oldenburg, Germany; [6]Department of Pediatric Endocrinology, University Medical Center Utrecht/Wilhelmina Children's Hospital, Utrecht, Netherlands

Background
Childhood craniopharyngioma (cCP) poses significant risks of hypothalamic damage, leading to severe obesity in up to 75% of survivors. Despite hypothalamus-sparing surgical techniques, hypothalamic obesity remains a prevalent issue. Emerging evidence suggests a link between hypothalamic inflammation (HI) and obesity. In this study, we aimed to investigate the presence of HI before and after cCP surgery using MRI and to study the association between HI and BMI change.
Methods
We conducted a retrospective analysis of two childhood craniopharyngioma cohorts; the Dutch cohort (diagnosed between 2018-2023, $n=40$), and the German cohort (diagnosed 2019-2023, $n=67$). Preoperative and postoperative MRI scans were scored, focusing on increased T2 signal intensity (SI) changes on FLAIR, indicative of hypothalamic inflammation(HI). Change of SI in the hypothalamus after surgery was tested and the effect of clinical and radiological variables on post-operative SI was evaluated. In addition, we estimated the correlation between the change in SI and the change in BMI at 3 months postoperatively and quantified the effect of clinical and radiological variables on BMI change at 3 months with a multivariate linear regression model. Lastly, in a subgroup of patients ($n=40$), post-op signal intensity ratios were compared between patients with or without hypothalamic syndrome (HS) at 6 months.
Results
Both left ($P<0.001$) and right ($P<0.05$) hypothalamic SI increased after surgery, indicative of HI. High post-operative SI was associated with increased pre-operative SI, older age, less cystic tumors, and post-operative grade of hypothalamic lesions (Muller score). A positive correlation was found between the change in SI and BMI change at 3 months ($r=0.56$, 95% CI: 0.29–0.74). SI increase was associated with an increase in BMI Z-score ($\beta=1.02$, SE$=0.35$) after adjusting for age, tumor composition, and postoperative Muller score. Post-operative SI ratios of patients with hypothalamic syndrome ($n=17$) were found significantly higher than in those without hypothalamic syndrome ($n=23$, $P<0.01$).
Conclusion
Our data suggests that HI may contribute to the BMI increase and development of hypothalamic dysfunction observed after CP surgery. These insights offer a valuable step toward understanding the pathophysiology underlying hypothalamic dysfunction. Prospective studies are needed to confirm our findings.

Medullary thyroid carcinoma and pathogenic ret proto-oncogene variants in children: clinical outcomes following prophylactic/therapeutic thyroidectomy

Cansu Koc[1], Yaprak Ece Yola Atalah[1], Melek Yildiz[1], Semen Onder[2], Gulcin Yegen[2], Nihat Aksakal[3], Yasemin Giles[3], Asli Derya Kardelen Al[1], Sukran Poyrazoglu[1], Firdevs Bas[1] & Feyza Darendeliler[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Department of Pediatric Endocrinology, Istanbul, Türkiye; [2]Istanbul University, Istanbul Faculty of Medicine, Department of Pathology, Istanbul, Türkiye; [3]Istanbul University, Istanbul Faculty of Medicine, Department of General Surgery, Istanbul, Türkiye

Introduction
Medullary thyroid carcinoma (MTC) is a rare but aggressive endocrine malignancy, often associated with variants in the *RET* proto-oncogene. *RET* variants are responsible for multiple endocrine neoplasia (MEN) syndromes (MEN2A, MEN2B). In addition to MTC, these patients may develop other MEN components, including pheochromocytoma and primary hyperparathyroidism. This study aims to evaluate the clinical outcomes of pediatric patients with MEN syndromes who has undergone either prophylactic or therapeutic thyroidectomy; and their long-term surveillance for pheochromocytoma and hyperparathyroidism.
Methods
Retrospective review of medical records of patients (aged <18 years) diagnosed with a pathogenic variant in the *RET* proto-oncogene between 2000-2024. Collected data included clinical information, biochemical markers, genetic analysis, imaging, and long-term outcomes. Histopathological evaluation classified patients as having benign (benign findings, C-cell hyperplasia) or malignant (micromedullary, multicentric MTC) pathology. Risk stratification was based on *RET* mutation status according to the 2015 American Thyroid Association (ATA) guidelines for MTC, and recurrence was defined by elevated calcitonin levels and/or radiological evidence of disease.

Results
Twenty-two *RET* variant carriers were included in the study; 54.5% ($n=12$) were male. Mean age at presentation was 6.8 ± 0.9 years (95% confidence interval [CI]: 4.8-8.9). According to risk stratification, 22.7% ($n=5$) were identified as moderate risk, 72.7% ($n=16$) as high risk, and 4.5% ($n=1$) as highest risk. All patients underwent total thyroidectomy at a mean age of 8 ± 0.9 years (95% CI: 5.9-10). Histopathological evaluation revealed benign findings in 22.7% ($n=5$), C-cell hyperplasia in 13.6% ($n=3$), micromedullary MTC in 50% ($n=11$), and multicentric MTC in 13.6% ($n=3$). No statistically significant difference was found between preoperative calcitonin levels and postoperative pathology outcomes in the benign and malignant groups ($P=0.111$). During postoperative follow-up, 27.3% ($n=6$) experienced recurrence. A significant association was found between pathology results (benign vs. malignant) and recurrence status ($P=0.041$), indicating a higher recurrence rate in malignant cases. During the follow-up period (mean: 5·9 $\pm$ 0·8 years) no cases of pheochromocytoma or hyperparathyroidism were observed.
Conclusions
Close monitoring of *RET* variant carriers is essential for early detection and management of MTC. Despite prophylactic thyroidectomy and subsequent diagnosis of MTC, recurrence occurred in some patients, highlighting the necessity of long-term follow-up. Preoperative calcitonin levels did not serve as a reliable predictor of malignancy, thus further research is needed to identify alternative biomarkers. Family screening enables the early identification of at-risk children, allowing prophylactic thyroidectomy to effectively prevent MTC.

Background
Thyroid dysfunction is associated with adverse reproductive outcomes including pregnancy loss. Approximately 55% of pregnancy losses are due to lethal chromosome abnormalities (aneuploid losses), whereas fetuses with a normal number of chromosomes (euploid) are potentially viable. Euploid pregnancy loss is suspected to be due to maternal comorbidity, e.g. thyroid dysfunction, although this has not previously been studied. We investigated if thyroid function and autoimmunity were associated with the risk of euploid pregnancy loss.
Methods
Prospective cohort study of women experiencing pregnancy loss at three Danish University hospitals (2020–2024). Blood was drawn at the time of pregnancy loss and at follow-up four to eight weeks after. Analyzes included thyroid stimulating hormones (TSH), free and total thyroxine (FT4, TT4), total triiodothyronine (TT3), human chorionic gonadotropin (hCG), thyroid peroxidase and thyroglobulin antibodies (TPOAb, TgAb). Antibody positivity: >60 kIU/l. Fetal chromosome status was determined by cell-free fetal DNA or fetal tissue sequencing to detect aneuploidy. Logistic regression models were adjusted for age, gestational week, body mass index, and thyroid medication use.
Results
A total of 1,031 out of 2,018 (51%) pregnancy losses were euploid. The euploid pregnancy loss risk did not differ according to TSH (adjusted odds ratio (aOR) 0.9, 95% confidence interval (CI) 0.8;1.1), FT4 (aOR 1.0, 95%CI 1.0;1.0), TPOAb positivity (aOR 0.99, 95%CI 0.68;1.43), or TgAb positivity (aOR 0.96, 95%CI 0.66;1.41). In contrast, the euploid loss rate was higher in women with TT3 >2.6 nmol/l (laboratory cut-off) vs TT3 ≤ 2.6 nmol/l ($n=61/85$, 71.8% vs. $n=470/1,521$ 48.6%, $P<0.001$) and TT4 >140 nmol/l (laboratory cut-off) vs ≤ 140 nmol/l ($n=248/425$ 58.4% vs. $n=552/1,180$ 46.8%, $P<0.001$). Also, in the adjusted regression models the euploid pregnancy loss risk was positively associated with TT3 concentration (aOR) 2.0, 95%CI 1.5;2.6) and TT4 concentration (aOR 1.09, 95%CI 1.05;1.13). This remained significant when further adjusting for TSH, TPOAb, TgAb, and hCG concentrations (TT3 aOR 2.7, 95%CI 1.44;5.33, and TT4 aOR 1.16, 95%CI 1.06;1.27). Noteworthy, 15 of 18 (83%) women with high TT3 and TPOAb- or TgAb-positivity had a euploid pregnancy loss. The majority of women with high TT3 or TT4 at inclusion had normalized hormone concentrations at follow-up ($n=49/52$, 94.2% for TT3 and $n=256/291$, 88.0% for TT4).
Conclusion
Women experiencing a euploid pregnancy loss have higher TT3 and TT4 concentrations at the time of the loss, but not outside of pregnancy. The mechanisms, including a potential interplay with thyroid antibody-positivity, needs further exploration.

JOINT2350

Proteomics-based identification of novel biomarkers for assessing severity and predicting recurrence in graves' thyrotoxicosis

Geriolda Topi[1,2] & Tereza Planck[1]
[1]Lund University, Skane University Hospital, Department of Clinical Sciences, Diabetes and Endocrinology, Malmö, Sweden; [2]Lund University, Skane University Hospital, Dep of Endocrinology, Malmö

Background
Graves' disease (GD) is an autoimmune disorder causing hyperthyroidism, primarily assessed by TSH-receptor-stimulating antibodies (TRAb). However, TRAb variations (blocking or neutral) can lead to misjudgments in disease severity and treatment duration. This study aims to identify novel biomarkers for GD severity and recurrence using proteomics analysis of blood samples.
Methods
We analyzed 121 plasma samples from 63 patients diagnosed with GD (first-time or recurrent after ≥ 2 years remission) between March 2019 and June 2023 at Skåne University Hospital, Sweden. Proteomics analysis was performed at baseline, 3- and 12-months post-antithyroid drug (ATD) treatment.
Results
A total of 758 proteins were identified. Independent of GD severity and recurrence status, the following proteins were significantly upregulated at 3 and 12 months post-treatment: SERPINA7 (Thyroxine-binding globulin, TBG) – a key thyroid hormone transport protein; Transthyretin (TTR) – essential for thyroid hormone and vitamin A transport; Apolipoprotein D (APOD) – involved in lipid transport; Adipocyte plasma membrane-associated protein (APMAP) – associated with metabolic processes. Conversely, significantly downregulated proteins at 3 and 12 months included: Cadherin 5 (CDH5) – vital for endothelial cell adhesion; Factor H-related protein 5 (FHR5) – regulator of the complement immune system; Coagulation Factor XIII B chain (F13B) – a key component in blood coagulation; Sex hormone-binding globulin (SHBG) – regulates sex hormone bioavailability.
Conclusion
Proteomics analysis identified significant protein alterations post-ATD treatment in GD patients. Upregulated proteins are linked to hormone transport and metabolism, while downregulated proteins are associated with vascular integrity, immune regulation, and hormone bioavailability. These findings suggest potential biomarkers for monitoring GD progression and treatment response, warranting further validation.

The role of ferroptosis as a novel alternative cell death model in thyrocytes from Hashimotós thyroiditis patients

Pablo Sacristán-Gómez[1], Susana Delgado-Martín[2], Ana Serrano-Somavilla[1], Sánchez de la Blanca Carrero Nuria[1], Andrea Álvarez-Rodríguez[1], Jose Luis Muñoz de Nova[3], Miguel Antonio Sampedro-Nuñez[1], Antonio Martínez-Ruiz[2], Monica Marazuela[1] & Rebeca Martínez-Hernández[1]
[1]Instituto de Investigación Sanitaria la Princesa (IIS-IP), Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER GCV14/ER/12), Endocrinología, Madrid, Spain; [2]Instituto de Investigación Sanitaria la Princesa (IIS-IP), Hospital Santa Cristina, Unidad de Investigación, Madrid, Spain; [3]Instituto de Investigación Sanitaria la Princesa (IIS-IP), Cirugía General y Digestiva, Madrid, Spain

Introduction
Autoimmune thyroid disorders (AITD) are organ-specific diseases that result from the dysregulation of the immune system homeostasis, leading to an immune response against self-thyroid antigens. The main AITD are Hashimotós thyroiditis (HT) and Graveś disease (GD). Ferroptosis is an intracellular iron-dependent form of cell death that involves the generation of reactive oxygen species, which increases oxidative stress and lipid peroxidation. Glutathione peroxidase 4 (GPX4) has a key role in reducing lipid peroxides into lipid alcohols, preventing ferroptosis. The high oxidative stress and the thyroid folicular cells (TFCs) death that takes places in HT patients suggests that ferroptosis could represent an alternative cell death pathway in HT pathogenesis.
Methodology
We analyzed lipid peroxidation with a sensor for lipid peroxidation (BodipyTM 581/591 C11) in a human thyroid follicular cell line stimulated with HT-associated proinflammatory cytokines (IFN-γ and TNF-α), ferroptosis inductors (RSL3 and erastin) and inhibitors (ferrostatin-1). At the same time, we evaluated cell death with the 7-AAD Staining Solution. We evaluated the levels of ferrous ion (Fe^{2+}), a ferroptosis inductor, in cellular models with an iron sensing dye (FerroOrange). We measured the expression of GPX4 and lipid peroxidation products, such as 4-hydroxynonenal (4-HNE) and malondialdehyde (MDA) in thyroid tissue and *in vitro* models by Western Blot (WB) and image.
Results
We observed an increase of lipid peroxidation and cell death in thyrocytes stimulated with IFN-γ and TNF-α. This increase was similar with the ferroptosis inductors RSL3 and erastin and, interestingly, this effect was reverted by ferrostatin-1. Furthermore, IFN-γ and TNF-α decreased GPX4 expression and increased Fe2+ levels. In thyroid tissue, GPX4 expression was downregulated in TFCs from HT patients compared to controls or GD. Although MDA expression did not change between conditions, the levels of 4-HNE, a lipid peroxidation product, were increased in HT, suggesting a relationship between ferroptosis and HT pathogenesis.
Conclusions
Our data indicates that ferroptosis may constitute a novel alternative cell death model in HT pathogenesis because of the proinflammatory microenvironment.

Thyrosense – a sensing device for monitoring of thyroid-stimulating hormone

Alemnew Mekonnen[1], Kumaravel Shanmugavel[1], Dan Hogdall[1], Jesper Kimer[1], Winnie Svendsen[1], Martin Overgaard[2], Steen Bonnema[3] & Jaime Castillo[1]
[1]HEI Therapeutics ApS, Copenhagen, Denmark; [2]Odense University Hospital, Department of Clinical Biochemistry, Odense, Denmark; [3]Odense University Hospital, Department of Endocrinology, Odense, Denmark

Introduction
Hypothyroidism affects 200 million people globally, with 4 million new diagnoses annually. Despite thyroid-stimulating hormone (TSH)-guided levothyroxine (LT4) replacement therapy, many patients experience persistent symptoms and impaired quality of life. TSH monitoring is recommended every 4-8 weeks upon diagnosis or treatment modification, with increased frequency during pregnancy and 1-2 times per year for maintenance. However, up to 50% of patients show TSH levels outside the reference range, increasing the risk of symptoms, pregnancy complications, and comorbidities associated with dysregulation. Current laboratory-based testing is costly and inconvenient, limiting patient compliance, and delaying treatment adjustments.
Objective
We present data on the ThyroSense prototype, a point-of-care (POC) home monitoring device that provides real-time, quantitative TSH measurements. This technology aims to improve disease self-management, reduce healthcare visits, and enhance treatment precision.
Methods
The ThyroSense system comprises a handheld reader, a single-use cartridge containing a test strip, and a companion mobile application. It utilizes a novel proprietary sensing chemistry for TSH detection. Analytical performance was assessed using electrochemical impedance spectroscopy, ELISA (for the selectivity tests), and anonymous clinical plasma samples. Clinical samples were pooled for biological normalization to TSH concentrations of 1, 5, and 10 mIU/l, respectively.
Results
The ThyroSense sensor demonstrated high specificity for TSH, with no significant cross-reactivity to luteinizing hormone, follicle stimulating hormone, and human chorionic gonadotropin hormone, showing relative signal levels of 3%, 4%, and 3%, respectively, at equivalent TSH concentrations. TSH was quantified within a range of 0-10 mIU/l with a detection limit of 0.2 mIU/l and a coefficient of variation of 10.7-13.0%. Results were obtained within 5 minutes of sample application.
Conclusions
There are currently no quantitative home-based TSH monitoring devices available. ThyroSense offers a cost-effective (aimed at <5£/test), user-friendly solution that can enhance treatment adherence and personalized care, particularly for newly diagnosed patients, before and during pregnancy, treatment adjustments, and long-term monitoring. Additionally, this device may facilitate research on TSH kinetics and treatment responses, potentially improving hypothyroidism management.

Evaluation of congenital hypothyroidism cases diagnosed through newborn screening and predictive factors for transient forms

Ummahan Tercan[1], Melek Yildiz[1], Asli Derya Kardelen Al[1], Sukran Poyrazoglu[1], Feyza Darendeliler[1] & Firdevs Bas[1]
[1]Istanbul University Istanbul Faculty of Medicine, Department of Paediatrics, Division of Paediatrics Endocrinology, Istanbul, Türkiye

Introduction
Congenital hypothyroidism (CH), a leading cause of preventable intellectual disability in children, can be identified early in life through newborn screening (NBS) programs. This study aims to analyze the clinical and biochemical characteristics of CH patients and identify predictive factors for transient CH (T-CH) in children diagnosed through NBS.
Methods
This retrospective study included a total of 322 term neonates (M/F = 163/159) diagnosed through NBS and initiated on levothyroxine therapy between 2006 and 2020. Patients were classified as thyroid dysgenesis (TD) or gland in situ (GIS) (dyshormonogenesis, DH) based on ultrasonography. Exclusion criteria included T-CH due to maternal factors, prematurity; syndromic and central CH. Cases with T-CH and permanent CH (P-CH) were compared based on gender, baseline thyroid hormone levels, and levothyroxine dosage at presentation and during follow-up (at 6 months, 1 year, 2 and 3 years). P-CH was diagnosed in patients whose TSH >10 μIU/ml following the discontinuation of levothyroxine therapy after at least 3 years of follow-up. Predictive factors for T-CH were identified.
Results
Among the cases, 22.7% ($n=73$) were categorized as TD, and 77.3% ($n=249$) as DH. Overall, 60.2% ($n=194$) of the patients were identified as having T-CH, while 39.8% ($n=128$) were classified in the P-CH group. Ultrasonography revealed thyroid agenesis in the majority (53.4%, $n=39$) of cases in the TD group. Screening TSH levels, initial venous TSH levels, initial treatment doses, and treatment doses at 6 months, and at 1, 2, and 3 years were significantly higher in the TD group ($P=0.001$ for all except the initial treatment dose, $P=0.006$). In DH group, after re-evaluation, 55 patients (23%) required restarting levothyroxine treatment and were diagnosed of P-CH. Among DH cases, mean heel blood TSH levels were significantly higher in the P-CH group (50.4 ± 30.7 mIU/l) compared to the T-CH group (28.2 ± 20.4 mIU/l) ($P=0.001$). Furthermore, in the P-CH group, treatment doses at the 1st, 2nd, and 3rd years were significantly higher than in the T-CH group ($P<0.001$ for all). ROC analysis identified levothyroxine dose thresholds for predicting T-CH as 2.1, 1.9, and 1.5 mg/kg/day at 1, 2, and 3 years, respectively.
Conclusion
This study identifies levothyroxine dose thresholds during first 3 years of life, to distinguish transient and permanent CH. Systematic re-evaluation, especially in DH cases at 3 years or even earlier, is crucial for minimizing unnecessary treatments and optimizing long-term follow-up plans. These findings support a tailored approach to CH management.

Objective

Constitutional duplications of the *PRKACA* gene locus (encoding the catalytic subunit of the Protein Kinase A) have been described in rare cases of Cushing's syndrome due to bilateral nodular adrenocortical diseases (BNAD). The pathological description according to the current WHO definition of adrenal tumors still needs to be reported. The objective here was to evaluate the results of the systematic screening of PRKACA constitutive duplication in BNAD and to specify the associated hormonal and pathological phenotype.

Methods

Between 2020 and 2024, 781 index cases diagnosed with BNAD: bilateral macronodular adrenal disease (BMAD) ($n=693$) or primary pigmented nodular adrenocortical disease (PPNAD) ($n=88$) (14% of isolated PPNAD) were genotyped with a targeted Next Generation Sequencing (NGS) panel including the exonic and intronic flanking regions of the *ARMC5*, *KDM1A*, *MEN1*, *PRKAR1A* and *PRKACA* genes, or by whole genome sequencing. Familial screening was offered to relatives. In situ Hi-C libraries were generated from three patients' tumors and chromatin conformation analysis were performed.

Results

Constitutional duplications of *PRKACA* were identified in 8 index cases and 7/11 screened relatives (sex-ratio = 1 male/2.5 female), supporting the involvement of the *PRKACA* oncogene through a constitutional copy gain mechanism. The whole genome sequencing performed on 4 index cases did not find any other gene involved in human pathology in the duplicated region, nor any other alteration in genes implicated in adrenal pathology. *PRKACA* tandem duplications generated neo-Topologically Associating Domains (TADs) (150kb), self-interacting genomic regions, in patient derived tumor Hi-C maps compared to Micro-C data from human embryonic stem cell line. All index cases and 6/7 relatives had PPNAD responsible for ACTH-independent hypercorticism, diagnosed at a median of 21 years old (range 9-35) and treated by bilateral adrenalectomy. The resected adrenals contained micronodules, composed mainly of large eosinophilic cells containing lipofuscin vacuoles, separated by patches of atrophic cortex, making the diagnosis of PPNAD. Similar staining was found with PRKACA and PRKAR1A antibody in these nodules and adjacent cortex, whereas in patients with PRKAR1A pathogenic variants, PRKAR1A staining was decreased in the nodule, compared to adjacent cortex.

Conclusion

Constitutional duplication of PRKACA is causing PPNAD (9% of index cases with PPNAD in this cohort), but no other forms of BNAD. Immunohistochemistry may differentiate the genetic background of PPNAD (*PRKAR1A* pathogenic variants *versus PRKACA* duplications). *PRKACA* tandem duplications generated neo-TADs in patient derived tumor Hi-C maps, pointing to specific regions of gene expression dysregulation induced by *PRKACA* duplication in BNAD.

Imaging bias in patients with adrenal adenomas

Ashley J. Han[1], Sara J. Achenbach[2], Elizabeth J. (Beth) Atkinson[2] & Irina Bancos[1]

[1]Mayo Clinic, Internal Medicine, Rochester, United States; [2]Mayo Clinic, Rochester, United States

Background

Although an association between adrenal adenomas and various cardiovascular and metabolic risk factors has previously been noted, it is suspected that patients with pre-existing comorbidities are more likely to be diagnosed with incidental adrenal adenomas due to increased frequency of imaging.

Methods

Historical case-control population study was performed. Patients diagnosed with adrenal adenoma between 2005-2017 with no evidence of overt hormone excess were paired with two different age- and sex-matched control groups without diagnosis of adrenal adenoma. To represent the general population, the first control group was randomly chosen from the same population matched on age and sex. The second control group only included patients who had a CT/MRI scan performed within 5 years prior to the index date (date of adrenal adenoma diagnosis). The prevalence of various social and metabolic risk factors present within 10 years prior to index date was compared across groups.

Results

Total of 670 cases identified. Patients with adrenal adenoma had a higher median body mass index (BMI) at 10 years prior to index date compared to the general population as well as the control group with prior imaging (30.1 kg/m^2 vs 27.4 kg/m^2 and 28.2 kg/m^2, respectively $P<0.001$). Cases were in a lower socioeconomic (SES) percentile based on Area Deprivation Index (ADI) at 10 years prior to index compared to controls (36.7% in poverty (ADI national percentage 51-100) vs 34.4% in the general population group and 31.1% in the control group with imaging, $P=0.116$). Compared to the general population control group, patients with adrenal adenoma were found to have higher prevalence of tobacco use, substance use, obesity, hypertension, dyslipidemia, pre-diabetes, and diabetes at 5-10 years prior to index date. However, when compared to the control group with prior cross-sectional imaging, the only differences that persisted were higher prevalence of obesity, tobacco use, and diabetes in patients with adrenal adenoma.

Conclusions

Previously noted associations between some cardiovascular/metabolic risk factors and adrenal adenomas are likely confounded by imaging bias. When compared to controls who had cross-sectional imaging performed within the past 10 years, patients with adrenal adenomas still had higher prevalence of obesity, tobacco use, and diabetes prior to index date.

Background

//tgcqSudden death is a high-priority public health concern, affecting at least 249,500 individuals each year in the European Union. Unidentified cardiovascular risk factors may account for approximately half of sudden deaths, a devastating event with limited preventive tools. We investigated whether adrenal histopathology suggestive of primary aldosteronism could explain part of the risk for disease-induced sudden death (DSD).

Methods

In this cross-sectional study, autopsies and histopathological analyses, including aldosterone synthase staining of adrenal glands, were performed on 403 consecutive individuals who experienced sudden death. These individuals were classified into 258 cases of DSD and 144 deaths caused by trauma, suicide, or intoxication, i.e., non-disease-induced sudden death (nDSD). Histopathological analysis followed the HISTALDO consensus. A four-grade classification of CYP11B2 positivity was used in the analyses with the following categories:1) aldosterone-producing adenomas

(APA) or nodules (APN), 2) aldosterone-producing micronodules (APMs) <20, 3) APMs ≥20, or 4) diffuse CYP11B2 positivity. This trial was registered at ClinicalTrials.gov (NCT05446779).

Findings

Adrenal histopathology revealed changes in 31 (7·7%) subjects of the cohort. Of these, the most prevalent findings [25 (6·2%)] were APA or APN, which were associated with myocardial infarction and atherosclerosis at autopsy. Individuals in the DSD group and the subgroup with sudden cardiac death (SCD) were more likely to have APA or APN than individuals in the nDSD group [23 (8·9%) vs. 2 (1·4%), $P=0·002$; 16 (8·8%) vs. 2 (1·4%), $P=0·003$, respectively]. Among all study subjects, heart weight, left ventricular wall thickness and the degree of aortic atherosclerosis showed an increasing trend with decreasing CYP11B2 continuity. In logistic regression analyses APA or APN were explanatory factors for DSD (odds ratio [OR] 6·47, 95% confidence interval [CI] 1·40-29·88, $P=0·017$) and SCD (OR 10·68, 95% CI 2·02-56·43, $P=0·005$).

Conclusions

Histopathological findings of APA or APN were observed more frequently in DSD and SCD cases than in nDSD cases and emerged as significant independent predictors of sudden death. The presence of APA or APN, along with a reduction in CYP11B2 continuity indicative of potential autonomous aldosterone production, was associated with markers of cardiovascular morbidity at autopsy. Timely diagnosis and effective treatment of PA may help extend the lifespan of individuals with CYP11B2-positive adrenal pathology. However, whether systematic biochemical screening for PA, targeted MRA therapy, or a combination of both should be implemented to reduce the risk of sudden death requires further investigation.

Primary adrenal insufficiency in the young, consider APS-1

Isil Kucuka[1], Lars Breivik[1,2], Marianne Øksnes[1,2], Marianne Grytaas[2], Kari Lima[3], Anders Jørgensen[4,5], Bergithe Oftedal[1,2], Anette Bøe Wolff[1,2] & Eystein Sverre Husebye[1,2]

[1]University of Bergen, Faculty of Medicine, Department of Clinical Science, Bergen, Norway; [2]Haukeland University Hospital, Department of Medicine, Bergen, Norway; [3]Akershus University Hospital, Endocrinology, Akershus, Norway; [4]Oslo University Hospital, Department of Endocrinology, Oslo, Norway; [5]University of Oslo, Faculty of Clinical Medicine, Oslo, Norway

Background

Autoimmune polyendocrine syndrome type-1 (APS-1) is a rare severe organ-specific autoimmune disease often presenting in childhood. A clinical diagnosis is made by the presence of at least two of the main manifestations: chronic mucocutaneous candidiasis, hypoparathyroidism, and primary adrenal insufficiency (PAI). Other relatively specific manifestations are enamel hypoplasia and severe alopecia. The phenotypic variation is huge overlapping with the much more common autoimmune polyendocrine syndrome type-2 (APS-2). Thus, there is a significant risk of delayed or missed diagnosis.

Objective

We investigated presentation of PAI in patients with APS-1 and -2 and isolated PAI to look for overlapping features, and to see if the diagnosis APS-1 had been missed.

Methods

Forty-eight Norwegian patients with APS-1 (age range 2-79 years) were compared with 1001 patients with isolated PAI or APS-2 (age range 5-100 years). APS-1 was confirmed by presence of disease-causing mutations in the autoimmune regulator gene (*AIRE*). Clinical examinations and assay of autoantibodies were conducted longitudinally.

Results

PAI was present in 35/48 (73%) APS-1 patients with a mean onset of 14.9 years (range 4-55 years) compared with 35 years (range 1-86 years) in the isolated PAI/APS-2 group. PAI was diagnosed after 20 years of age in 5 APS-1 patients and 55 years of age in one patient. Three of these already had developed hypoparathyroidism and therefore were clinically diagnosed with APS-1. The other three had no apparent APS-1-like manifestations, but they were positive for interferon omega autoantibodies on screening. The APS-1 diagnoses were subsequently confirmed by finding disease-causing mutations in *AIRE*.

Conclusions

PAI can present late in APS-1 without the other main manifestations. In patients younger than 30 years of age at PAI debut, APS-1 should be suspected by searching for other autoimmune manifestations and ideally by testing for interferon omega autoantibodies.

Crinecerfont improves reproductive hormones in classic congenital adrenal hyperplasia: 1-year results from the phase 3 CAHtalyst™ adult study

Deborah Merke[1,2], Sonal Vaid[1], Maamoun Salam[3], Duarte Pignatelli[4], Andrea Isidori[5], Nicole Reisch[6], Lee Ann Keener[1], Thom Board[7], Vivian Lin[7], Robert Farber[7], Eric Jen[7], Julia Sturgeon[7] & Jean Chan[7]

[1]National Institutes of Health Clinical Center, Bethesda, United States; [2]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, United States; [3]Washington University School of Medicine, St. Louis, United States; [4]Hospital S João, Universidade do Porto, Porto, Portugal; [5]Sapienza University of Rome, Rome, Italy; [6]Ludwig Maximilians Universität München, Medizinische Klinik IV, Munich, Germany; [7]Neurocrine Biosciences, Inc., San Diego, United States

Background

//tgcqGonadal dysfunction with classic congenital adrenal hyperplasia (CAH) is due to testicular adrenal rest tumors and/or poor hormonal control (males) and to high adrenal androgens and progesterone (P4) (females). Crinecerfont, a corticotropin releasing factor type 1 receptor (CRF1) antagonist, is FDA-approved for adjunctive treatment to glucocorticoid (GC) replacement to control androgens in patients with CAH. In CAHtalyst™ Adult (NCT04490915), least-squares mean (LSM) percent changes in GC dose at Week 24 (end of double-blind placebo-controlled period) indicated a significant reduction with crinecerfont (-27.3% vs -10.3% for placebo; LSM difference -17.0%; $P<0.0001$) while androstenedione (A4) was maintained/improved relative to Day 1 baseline (BL). At Month 12 (end of open-label period), mean percent decreases from BL were -24.6% in participants continuing crinecerfont (CFT/CFT) and -29.7% in those switching from placebo (PBO/CFT).

Objective

To evaluate reproductive hormone changes in adults with CAH who received up to 1 year of crinecerfont, in the context of substantial GC dose reductions.

Methods

Analyses conducted at Week 24 and Month 12 were as follows: luteinizing hormone (LH), follicle stimulating hormone (FSH), A4-to-testosterone ratio (A4/T) in males; testosterone (T) and P4 in females. Males included for analysis had abnormal (low or high) LH, abnormal FSH, or A4/T ≥0.5 at BL. Females had elevated T or P4 at BL, with analysis conducted without regard to menstrual cycle phase. In participants with abnormal values at BL, results are presented as % (n/N) (n=number achieving normalisation; n=number with available assessments).

Results

The percentages of males achieving normal/target levels at Week 24 with crinecerfont vs placebo were: LH (47.4% [9/19] vs 22.2% [2/9]); FSH (13.3% [2/15] vs 14.3% [1/7]); A4/T (18.9% [7/37] vs 4.5% [1/22]). Results at Month 12 for CFT/CFT and PBO/CFT were: LH (64.7% [11/17], 44.4% [4/9]); FSH (35.7% [5/14] , 14.3% [1/7]); A4/T (23.5% [8/34], 23.8% [5/21]). The percentage of females achieving normal levels at Week 24 were: T (10.7% [3/28] vs 0% [0/11]; P4 (13.5% [5/37] vs 5.9% [1/17]). Results at Month 12 for CFT/CFT and PBO/CFT were: T (3.7% [1/27], 9.1% [1/11]); P4 (8.6% [3/35], 18.8% [3/16]).

Conclusion

Crinecerfont has been shown to reduce ACTH, androgens, and androgen precursors in paediatric and adult patients with CAH. These analyses from CAHtalyst Adult indicate potential normalisation of reproductive hormones with crinecerfont, even with substantial GC dose reductions. CRF1 antagonism may be a promising therapeutic approach for improving reproductive hormones in adults with CAH.

Crinecerfont enables glucocorticoid dose reductions while maintaining/improving androstenedione in paediatric patients with congenital adrenal hyperplasia: subgroup analyses from CAHtalyst™ paediatric

Oksana Lekarev[1], Ayca Erkin-Cakmak[2], Maria Vogiatzi[3], Erik Imel[4], Maria Clemente[5], Régis Coutant[6], Thom Board[7], Gelliza Rosales[7], Eiry Roberts[7], George Jeha[7], Robert Farber[7] & Jean Chan[7]

[1]Weill Cornell Medical College and NewYork-Presbyterian Hospital, New York, United States; [2]University of California San Francisco, San Francisco, United States; [3]Children's Hospital of Philadelphia, Philadelphia, United States; [4]Indiana University School of Medicine, Indianapolis, United States; [5]University Hospital Vall d'Hebron and Biomedical Research Networking Center on Rare Diseases (CIBERER), Barcelona, Spain; [6]CHU d'Angers, Pediatric Endocrinology Unit, Angers, France; [7]Neurocrine Biosciences, Inc., San Diego, United States

Background
Crinecerfont, a corticotropin releasing factor type 1 receptor antagonist, is a first-in-class medication that is FDA-approved for adjunctive treatment to glucocorticoid (GC) replacement to control androgens in patients with classic congenital adrenal hyperplasia (CAH). In phase 3 trials, crinecerfont significantly reduced excess androgens, enabling subsequent GC dose reductions in paediatric and adult patients with CAH.
Objective
To analyse changes in androstenedione (A4) levels and GC dose reductions while maintaining/improving A4 in subgroups of participants from CAHtalyst™ Paediatric (NCT04806451).
Methods
Participants were randomised 2:1 to double-blind treatment with crinecerfont (25, 50, or 100 mg BID based on weight) or placebo for 28 weeks. GC doses were kept stable for 4 weeks to evaluate the impact on androgens and then reduced to a target of 8-10 mg/m^2/d in hydrocortisone equivalents (HCe) by Week 28 while maintaining/improving A4 relative to baseline (BL). Least squares (LS) mean changes from BL in A4 (before morning GC dose) at Week 4 and in GC dose at Week 28 were analysed in the overall population and in subgroups defined by: region (US, outside US); sex (male, female); race (white, non-white); age (<12, 12-17 years); weight (<55, ≥ 55 kg); body mass index (BMI) (<85th, ≥ 85th percentile); pubertal stage (Tanner 1-2, 3-5); BL A4 ($\leq$ULN [upper limit of normal], $>$ULN); and BL GC dose (<16, ≥ 16 mg/m^2/d HCe, for GC change only).
Results
Among 103 participants (crinecerfont = 69, placebo = 34), mean age ($\pm$SD) was 12.1 $\pm$ 3.5 years; 51% were male. Mean A4 at BL was 15.0 $\pm$ 16.1 nmol/l; mean GC dose was 16.4 $\pm$ 3.9 mg/m^2/d. At Week 4, A4 was significantly reduced with crinecerfont but increased with placebo (-6.9 vs. +2.5 nmol/l; LS mean difference [LSMD]: -9.3 nmol/l; $P = 0.0002$). LSMDs of the point estimates for A4 change at Week 4 favoured crinecerfont in all subgroups. At Week 28, GC dose was significantly reduced with crinecerfont (while maintaining or improving A4) but increased with placebo (-18.0% vs. +5.6%; LSMD: -23.5%; $P < 0.0001$). LSMDs of the point estimates for percent change in GC dose at Week 28 favoured crinecerfont in all subgroups. All subgroup results were consistent with the overall population.
Conclusion
Crinecerfont enabled GC dose reductions while maintaining/improving A4 in paediatric patients with CAH across multiple subgroups. These results demonstrate that paediatric patients with CAH can derive the androgen-lowering and GC-lowering benefits of crinecerfont regardless of region, sex, race, age, weight/BMI, pubertal stage, or pretreatment A4 level or GC dose.

Long-term efficacy and safety of once-weekly somapacitan in children with growth hormone deficiency: 7-year results from the randomised REAL 3 trial

Lars Savendahl[1], Tadej Battelino[2], Michael Højby Rasmussen[3], Tina Lund Leunbach[3], Paul Saenger[4], Lawrence Silverman[5] & Reiko Horikawa[6]
[1]Pediatric Endocrinology, Karolinska University Hospital, and Department of Women's and Children's Health, Karolinska Institutet, Solna, Sweden; [2]Faculty of Medicine, University of Ljubljana, and University Medical Center Ljubljana, Ljubljana, Slovenia; [3]Clinical Drug Development, Novo Nordisk A/S, Søborg, Denmark; [4]NYU Langone Health, Mineola, New York, United States; [5]Goryeb Children's Hospital, Atlantic Health System, Morristown, United States; [6]National Center for Child Health and Development, Tokyo, Japan

REAL 3 (NCT02616562) is a phase 2, randomised, multinational, open-label, active-controlled trial designed to determine treatment efficacy and safety of somapacitan, a long-acting growth hormone (GH) derivative, vs daily GH (Norditropin®, Novo Nordisk). Results after 4 years have been published (Sävendahl *et al*. *JCEM* 2023;108(10):2569-78). Here, we report final results at 7 years (364 weeks), representing the longest analysis of patients treated with somapacitan to date. Prepubertal children were recruited to three cohorts (I: GH-naïve, 2.5 to 9/10 years for girls/boys respectively; II: <2.5 years; III: 9/10 to 17 years for girls/boys, respectively). In cohort I, participants were randomised 1:1:1:1 to somapacitan (0.04 vs 0.08 vs 0.16 mg/kg/week) or daily GH 0.034 mg/kg/day. After 52 weeks, participants on somapacitan were all switched to the 0.16 mg/kg/week dose, while participants on daily GH continued unchanged. After 156 weeks, all participants, including those previously on daily GH, received somapacitan 0.16 mg/kg/week during a further 208-week long-term safety extension. Cohorts II and III only participated between weeks 156–364 and received somapacitan 0.16 mg/kg/week. In cohort I, 33 of 45 participants randomised to somapacitan (somapacitan-only group) and 10 of 14 participants randomised to daily GH (switch group) completed the long-term safety extension. Completion was similarly high in cohorts II ($n = 1/1$) and III ($n = 11/16$). Two participants in cohort I achieved near adult height by week 364. Efficacy results (mean [SD]) are reported for cohort I at week 364. Height velocity (HV) was 5.7 (2.2) cm/year in both groups and HV standard deviation scores (SDS) were 0.47 (1.13) and 0.57 (1.16) in the somapacitan-only and switch groups, respectively. Height SDS was -0.39 (1.15) in the somapacitan-only group and -0.54 (0.76) in the switch group. Year-on-year increases in height SDS were observed after week 156 in both groups. Insulin-like growth factor-I (IGF-I) SDS was 0.64 (1.68) and 0.79 (1.02) in the somapacitan-only and switch groups, respectively. Safety was assessed across all cohorts and no new safety signals were observed. Total patient-years of exposure to somapacitan 0.16 mg/kg/week was 327.4. After 7 years (364 weeks) of treatment, height SDS and IGF-I SDS were within the reference range (-2 to $+2$ SDS). Similar responses were observed in patients treated with somapacitan throughout the trial and in those who switched from daily GH after 156 weeks. No side effects for somapacitan outside the known safety profile of daily GH were identified.

Unexpected unbalanced upregulation of genes in gene replacement therapy with a constitutively active promoter and growth hormone receptor (GHR) in mice with nonfunctional GHR (laron mice)

Kok Onn Lee[1], Joshua Tay[1], Kian Sia[1], Siti Rodhi[1], Shu Gan[1], Zhen Fu[1], Max Pyatkov[2], John Kopchick[3], Michael Waters[4] & David Waxman[2]
[1]National University of Singapore, Medicine, Singapore, Singapore; [2]Boston University, Boston, United States; [3]Ohio University, Athens, United States; [4]University of Queensland, Institute for Molecular Bioscience, Brisbane, Australia

Gene replacement therapy where a dysfunctional or non-functional gene is treated with *in vivo* delivery of a functional gene almost always utilizes a constitutively active promoter/enhancer to enable expression of the therapeutic gene product. These promoters typically lack the complex regulation that is normally present in the endogenous gene. We have treated growth hormone (GH) resistant dwarf GHR-/- (Laron) mice with nonfunctional GH-receptors, with an adeno-associated virus (AAV) with a constitutively liver specific promoter (HLP) and mouse GHR (Sia et al, 2021). A single injection of the AAV-HLP-GHR construct resulted in significant but limited increase in length and weight, of a similar order to previously reported studies of IGF-1 treatment in mice or human Laron syndrome. In the present study, we have compared the total gene expresssion profiles from the mice in that previous study. Profiles of total RNA extracted from fresh frozen livers from the 4 groups of mice (3 male and 3 female in each group) were sequenced (Novogene-AIT Genomics, Singapore) and compared: Untreated GHR+/+, and GHR-/- (Laron); GHR-/- treated with AAV-HLP-GHR (AAV-GHR), and control GHR-/- treated with AAV-HLP-luciferase (AAV-luc) only. Gene expression differed significantly in only 4 genes comparing control AAV-luc and untreated GHR-/- (Laron), indicating minimal effect of the AAV-HLP promoter. Gene expression between GHR+/+ and GHR-/- (Laron) differed significantly in 2913 genes. In contrast, treatment with AAV-GHR compared with AAV-luc showed that only 448 genes were differentially expressed significantly. There was significant upregulation of key genes involved in IGF signaling; GHR, insulin-like growth factor-1 (IGF-1) and acid-labile subunit (ALS). However, of the significant upregulated 201 genes in AAV-GHR compared to AAV-luc, growth/cancer-related genes were upregulated/rescued significantly more than metabolism-related genes towards the normal gene expression levels in the wild type mice (GHR+/+). This unexpected unbalance upregulation is most probably the result of the absence of the normal complex regulation of the GH-receptor.
Conclusion
Gene replacement therapy utilizing a consitutively active promoter/enhancer may have unexpected unbalanced changes in gene expression.

AKT and PI3K inhibitors are more efficient in inhibiting growth of Proteus syndrome patient cells compared to mTOR inhibition

Anna Kirstein[1], Sandy Richter[2], Julia Hentschel[2], Diana Le Duc[2], Steffen Syrbe[3] & Antje Garten[1]
[1]Leipzig University, Hospital for Children and Adolescents, Center for Pediatric Research, Leipzig, Germany; [2]Leipzig University, Institute of Human Genetics, Leipzig, Germany; [3]Heidelberg University Hospital, Department of Neurological Diseases, Heidelberg, Germany

Background
Patients with somatic activating variants in the *AKT1* gene (Proteus syndrome) show symptoms like segmental overgrowth, increased tumor risk and vascular malformations. AKT is a central signaling molecule in the growth-promoting phosphoinositide-3- kinase (PI3K)/mTOR pathway and different pathway inhibitors are used for cancer therapy or related overgrowth syndromes. While there is no approved therapy for Proteus patients, benefits of treatment with the mTOR inhibitor rapamycin were described. We aim to evaluate the therapeutic potential of rapamycin as well as the PI3K inhibitor alpelisib and the AKT inhibitor capivasertib in a patient-derived cell model.
Methods
Fibroblasts from a 3-year old patient with segmental overgrowth, harboring an activating AKT1 (E17R) variant, were treated with rapamycin, alpelisib, and capivasertib *in vitro*. We evaluated cell proliferation, viability, and signaling via automated cell counting, WST-1 cell viability assays, and Western blots. Nuclei size was measured using the Spark Cyto multimode imaging plate reader.
Results
While all inhibitors significantly decreased cell count after 72 h of treatment, there were observable differences between mTOR and AKT/PI3K inhibition. Rapamycin reduced growth of the patient cells by 20% already at concentrations of 1 nM, but higher doses could not further reduce proliferation. In contrast, alpelisib reduced proliferation in a dose-dependent manner by 44% at 10 µM and 55% at 50 µM and capivasertib by 23% at 2 µM and 46% at 10 µM. We observed that all inhibitors had direct effects on cell viability already after 1 h of treatment (1 nM rapamycin reduced viability by 8%, 50 µM alpelisib by 56% and 10 µM capivasertib by 12%), indicating an immediate inhibition of cellular metabolism as detected in WST-1 assays. Nuclei size of patient fibroblasts was increased by 8% compared to control fibroblasts, which was reversed by inhibitor treatment. As observed in Western blots, each of the inhibitors effected cellular signaling differentially: While rapamycin was most effective in blocking activation of downstream mTOR signaling components p70S6K and ribosomal protein S6, it increased AKT1 activation. Alpelisib was less effective in blocking mTOR downstream signaling, but highly effective in reducing AKT activation and downstream GSK3β phosphorylation. Capivasertib reduced S6 and GSK3β phosphorylation.
Conclusion
Inhibitors of the PI3K/mTOR pathway effectively reduce growth of patient-derived fibroblasts with an activating *AKT1* variant. While rapamycin is effective in nanomolar doses, alpelisib and capivasertib decrease cell growth further. This might indicate a higher efficiency of these drugs in patients with overgrowth related to *AKT1* variants.

Neurodevelopmental outcomes in silver russell syndrome: the impact of molecular causes

Suparna Jain[1], Tyler Salem[2], Jennifer Salem[3], Catherine Bresee[4], Yvette Getch[5], Madeleine Harbison[6] & Irene Netchine[7]
[1]Cedars-Sinai Medical Center, Department of Pediatrics, Los Angeles, CA, United States; [2]Geisel School of Medicine at Dartmouth, Hanover, NH, United States; [3]The MAGIC Foundation RSS/SGA Research & Education Fund, Warrenville, IL, United States; [4]Cedars-Sinai Medical Center, Biostatistics Shared Resources, Los Angeles, CA, United States; [5]University of South Alabama, Dept of Counseling and Instructional Sciences, Mobile, AL, United States; [6]Icahn School of Medicine, Mount Sinai, Department of Pediatrics, New York City, NY, United States; [7]Sorbonne Université, INSERM, Centre de Recherche Saint Antoine, APHP, Hôpital Armand Trousseau, Explorations Fonctionnelles Endocriniennes, Paris, France

Background
Silver Russell Syndrome (SRS) is a rare imprinting disorder associated with prenatal and postnatal growth restriction, relative macrocephaly, feeding difficulties, protruding forehead and asymmetry. Primary molecular causes are loss of methylation within 11p15.5 imprinting control region (*H19/IGF2*), [11p15LOM] and maternal uniparental disomy of chromosome 7, [upd(7)mat]. There is limited research on neurodevelopmental outcomes in SRS patients.
Objective
Determine prevalences of neurodevelopmental disorders in a large cohort of molecularly-confirmed SRS patients and compare these prevalences among the SRS diagnostic groups and US general population [genUS].
Methods
297 subjects > 2 years old were divided by SRS molecular cause (including 11p15LOMn = 164, upd(7)matn = 99). Questionnaires about neurodevelopmental disorder diagnoses and treatments were completed by guardian or adult self. Reported diagnoses were confirmed by a qualified specialist.
Results
Speech articulation disorder prevalence was greater in upd(7)mat group (68%) than 11p15LOM group (24%), and both prevalences were significantly greater than in genUS (9%). Childhood speech apraxia was more prevalent in upd(7)mat group (24%) compared to 11p15LOM (3%) group, and both prevalences were greater than in genUS (0.1%). More upd(7)mat subjects had delayed onset of speech (> 18 mos) than 11p15LOM subjects (52% versus 20%). Two individuals > 6 yrs were non-verbal in each molecular group. Autism spectrum disorder (ASD) was more prevalent in upd(7)mat group (28%) than both 11p15LOM group (5%) and genUS (2.8%). The male to female distribution of ASD was ~1:1 in the upd(7)mat group, compared to 4.8:1 in the 11p15LOM group and 4:1 in genUS. Attention Deficit Hyperactivity Disorder prevalence was not statistically different between upd(7)mat (29%) and 11p15LOM (16%) groups, although the upd(7)mat prevalence was significantly greater than genUS (11.4%). Prevalences of intellectual disability, (IQ < 75), and learning disorders were 22% and 39%, respectively, in upd(7)mat group, significantly higher than rates observed in 11p15LOM group (2% and 7%), and genUS (2.20% and 9%). However, upd(7)mat group had a normal distribution in academic performance, compared to classmates, whereas 11p15LOM subjects were skewed with 69% performing in the top third of their classes.
Conclusion
Our study shows SRS upd(7)mat individuals are at higher risk for neurodevelopmental disorders than 11p15LOM individuals and/or genUS. Aside from speech disorders, SRS 11p15LOM individuals are overall neuro similar to genUS. Understanding the prevalence of neurodevelopmental disorders in children with SRS allows for better surveillance, diagnosis and intervention. Given the 1 in 4 chance of ASD in upd(7)mat, careful monitoring for ASD could increase opportunities for early intervention.

Introduction
Pituitary gigantism and acromegaly, both resulting from excessive growth hormone (GH) production, share the same pathophysiology. The main differences are the age of onset and the patient's height at diagnosis. However, due to the rarity of pituitary gigantism, it remains unclear whether their clinical course and comorbidities are the same. This study aimed to assess how early-onset GH oversecretion in pituitary gigantism affects disease progression, treatment strategies, and life expectancy.
Methods
From the UK Acromegaly Register (UKAR) and the International Familial Isolated Pituitary Adenoma Consortium, we extracted patients ($n=290$) meeting criteria for the pituitary gigantism (pituitary gigantism group, PGG). The remaining group from UKAR patients provided the acromegaly group (AG, $n=2,954$).
Results
Pituitary gigantism comprised 7.8% of GH-excess patients. The equal sex distribution observed in AG does not apply to PGG, where a male predominance is evident (61%). When analysing the onset of disease in AG, we found that the age of diagnosis in women was approximately 5 years later than in men. A similar trend was observed in PGG, where first symptoms (22.6 vs. 27.7 years) and diagnosis (26.9 vs. 31.0 years) occurred earlier in males than in females, with a greater final height in males (3.1 vs. 2.6 SD). AG patients had a similar height to the general population, with a trend for greater height before the age 50 years and lower height afterwards. In PGG patients, a more aggressive clinical disease course is seen: more invasive adenomas – significantly more macroadenomas (75.9% vs. 69.2%) and extrasellar extension (46.8% vs 33.9%), more aggressive surgical approach – more interventions (88.9% vs 83.7%), repeat surgery (23.3% vs 8.4%), and transcranial surgery (12.6% vs 5.0%), and more axis deficiencies per patient at post-treatment assessment (1.5 vs 1.0). The time from diagnosis to disease control was longer in the PGG group. PGG patients have a shorter life expectancy and higher mortality compared to patients with acromegaly (65.0 vs. 73.6 years, adjusted hazard ratio 2.09, 95% CI 1.46-3.04). Their mortality is twice as high compared to the general population (standardised mortality ratio 1.94).
Summary
PGG presents a more aggressive disease course, requiring more treatment modalities, with a greater risk of hypopituitarism and higher mortality compared to patients with acromegaly. Therefore, early diagnosis and a concentrated multi-disciplinary effort are essential to reduce long-term morbidity and mortality in patients with pituitary gigantism.

Identification of novel genetic variants associated with short stature using whole exome sequencing: insights from a pediatric cohort

Ting Chen[1,2] & Bingyu Yang[1,2]
[1]Suzhou Clinical Center for Rare Diseases in Children, Children's Hospital of Soochow University, Suzhou, Jiangsu, China; [2]Department of Endocrinology, Genetics and Metabolism, Children's Hospital of Soochow University, Suzhou, Jiangsu, China

Background
Short stature is a common pediatric condition with diverse etiologies, including genetic factors, endocrine disorders, and malnutrition. However, up to 70% of cases remain undiagnosed despite extensive clinical evaluation. Recent advances in genomic technologies, such as whole exome sequencing (WES), offer new insights into the genetic causes of unexplained short stature. This study aims to identify novel genetic mutations associated with short stature, particularly those not detectable by traditional diagnostic methods.
Methods
We analyzed 212 pediatric patients with short stature, 352 healthy controls, and 4327 East Asian samples from the ExAC database. WES was performed on all patients and their parents, with variants filtered for quality and rarity (gnomAD_MAF <0.001). Gene-based burden testing was conducted using the TRAPD method, and gene ontology (GO) and kyoto encyclopedia of genes and genomes (KEGG) pathway enrichment analyses were applied to identify biological processes and pathways associated with the identified genetic variants.
Results
Our analysis identified 263 genes with significant associations to short stature under a dominant inheritance model ($P<1\times10^{-5}$), and 63 genes with strong associations in both dominant and recessive models. Notably, genes such as FCGBP, FRAS1, MPDZ, and OBSCN, which were previously not associated with short stature, were identified as potential genetic contributors. The top 10 genes with the strongest associations included FCGBP ($P=5.06\times10^{-14}$), FRAS1 ($P=1.97\times10^{-10}$), and OBSCN ($P=3.62\times10^{-10}$). Pathway analysis revealed that these genes were involved in processes such as muscle development, steroid hormone biosynthesis, and sarcomere organization, with significant enrichment in Z discs, myosin filaments, and retinoic acid binding.
Conclusion
This study identifies several novel genetic variants that may contribute to short stature, underscoring the value of WES in identifying genetic causes in cases where traditional methods fail. The findings highlight the importance of expanding genetic testing in the diagnostic workup of short stature and provide new insights into the molecular mechanisms underlying this common pediatric condition.

Key words: short stature, whole exome sequencing, gene-based burden testing

Introduction
The melanocortin-4 receptor (MC4R) pathway plays a crucial role in regulating hunger, caloric intake, and energy expenditure. Genetic variants in this pathway can lead to hyperphagia and early-onset obesity. Raising awareness about genetic testing can help diagnose and identify patients who might benefit from innovative precision therapies. To improve access to genetic testing for individuals with suspected rare MC4R pathway diseases, the Rare Obesity Advanced Diagnosis™ (ROAD) genetic testing program was created, using a gene panel including 79 genes and 1 chromosome region including the most frequently tested genes associated with obesity. Here, we analysed ROAD data to identify prognostic factors for a positive genetic test.
Methods
Genes from individuals with early-onset obesity were sequenced. Analysis focused on biallelic variants in *POMC*, *PCSK1*, or *LEPR*, or in BBS genes (*BBS1-BBS22*). Variants were categorized as pathogenic, likely pathogenic, or of uncertain significance (P/lP/VUS) based on the criteria established by the American College of Medical Genetics.
Results
Overall, 6,169 individuals (54.5% female) from Germany, Greece, Ireland, Israel, Italy, Spain, Türkiye, UK, and the United Arab Emirates were sequenced, who had a mean age of obesity onset of 5.2 (3.8) years. A total of 1,830 P/lP/VUS variants were found in 1,755 unique individuals (28.4%), including 17 biallelic

variants in *LEPR*, 3 in *POMC*/*PCSK1* and 112 in any of the tested BBS genes. Mean age of onset of hyperphagia and of obesity in individuals with any of these biallelic variants was 2.7 (2.7) and 4.0 (3.6) years, respectively. In individuals in whom no variant from the gene panel was found, the ages were 4.6 (4.3) and 5.4 (3.8) years, respectively. When assessing the correlation between a positive test for biallelic *LEPR*, *POMC*, *PCSK1* or BBS and no identified variant, age of onset of hyperphagia ($P=0.0001$) and age at onset of obesity ($P=0.0007$) are key predictors for a positive genetic test, with BMI at time of testing ($P=0.0232$) and BMI z-score at time of testing (0.0661) showing potential predictive value.

Conclusions

A positive correlation was observed for individuals with biallelic variants in *POMC*, *PCSK1*, *LEPR*, or in any of the tested BBS genes, indicating that the age of onset of hyperphagia and obesity are key predictors for a positive test result for these genes. Hence, individuals presenting with early-onset hyperphagia and obesity are more likely to test positive for the disease, highlighting the importance of these factors as key predictors.

Introduction

The melanocortin-4 receptor (MC4R) pathway regulates energy balance, hunger, and satiety. DAYBREAK (NCT04963231) was a two-stage clinical trial evaluating setmelanotide in individuals carrying a variant in ≥ 1 of 31 genes involved in the MC4R pathway, including *PHIP*, which enhances *POMC* transcription. Heterozygous deleterious *PHIP* variants are associated with intellectual disability/developmental delay, behavioral disorders, obesity/overweight, and dysmorphic features. We report a post hoc analysis of individuals with *PHIP* variants and obesity.

Methods

Individuals from the DAYBREAK trial aged 6-65 years carrying a *PHIP* variant, classified as variant of unknown significance (VUS) or pathogenic/likely pathogenic (P/lP) according to American College of Medical Genetics criteria, and body mass index (BMI) ≥ 40 kg/m^2 (≥ 18 years) or $\geq$97th percentile (6-17 years) and hyperphagia were included. Individuals meeting age-related weight loss criteria with setmelanotide after the 16-week open-label stage 1 (S1) could enter the 24-week, double-blind, randomized, placebo-controlled stage 2 (S2). Participants could reinitiate open-label setmelanotide if BMI increased $\geq 5\%$ from S2 entry (switch to setmelanotide within S2 or transition early to bridging). Primary analyses were performed at S1. Hunger was assessed in individuals aged ≥ 12 years. The S2 analyses were exploratory/ad hoc.

Results

Sixteen individuals with *PHIP* variants were enrolled (age range, 7-58 years; 50% female; 81% White). At baseline, the mean (SD) BMI in adult participants ($n=10$) was 45.34 (7.01) kg/m^2, and pediatric BMI Z score ($n=6$) was 2.46 (0.45). For S1 BMI data, 9 of 16 participants (56.3%) met age-related weight loss criteria. The mean (SD) BMI percent change in the 13 participants who completed S1 was -6.12% (3.62%). For S1 hunger data, 8 of 11 participants with baseline "most hunger" data had Week-16 follow-up for daily most hunger scores and exhibited a mean (SD) score reduction of -3.87 (1.41); 7 participants achieved a score reduction of ≥ 2. Nine participants entered S2 (5 adult and 4 pediatric). Participants receiving setmelanotide maintained consistent weight loss, whereas those receiving placebo did not. For post S2 data, 8 participants continued on treatment, with a mean (SD) bridging duration of 48.7 (14.1) weeks; 5 adult and 3 pediatric participants exhibited a final mean (SD) percent change in BMI of -14.18% (7.66%) and in BMI Z score of -0.71 (0.27), respectively.

Conclusions

Clinical response to setmelanotide, a highly selective MC4R agonist, suggests the MC4R pathway is a key biologic driver of obesity in individuals with *PHIP* variants of interest and merits further investigation.

Premature aging in alström syndrome: a model of monogenic syndromic obesity

Sadaf Ali[1], Patricia Thomas[2], Niharika Duggal[3], Gabriela Xavier[2] & Tarekegn Hiwot[4]

[1]University Hospital Birmingham NHS Foundation Trust, Institute of Metabolism and Systems Science,University of Birmingham, Endocrinology and Metabolic Medicine, Birmingham, United Kingdom; [2]Institute of Metabolism and Systems Science ,University of Birmingham, Birmingham, United Kingdom; [3]Institute of Inflammation and Aging ,University of Birmingham, Birmingham, United Kingdom; [4]University Hospital Birmingham NHS Foundation Trust, Institute of Metabolism and Systems Science, Birmingham, United Kingdom

Cellular senescence has been increasingly recognized as a key driver of metabolic syndrome (MetS) and its complications, including obesity and type 2 diabetes (T2D). Alström syndrome (AS), a monogenic form of obesity with extreme insulin resistance and T2D has previously been associated with increased biological aging. This study investigates AS as a model of accelerated aging through cellular senescence markers in metabolic tissues. Patients with AS ($n=10$) were matched with healthy control volunteers ($n=10$) based on gender, BMI, and age. Clinical assessments were conducted alongside adipose tissue (AT) and skeletal muscle (SM) biopsies. β-galactosidase staining and RNA sequencing (RNA-Seq) with SanMayo analysis were performed on subcutaneous adipose tissue (AT), while reverse transcription polymerase chain reaction (RT-PCR) assessed senescence associated gene expression in SM. The IMM-AGE metric, analysed via fluorescence-activated cell sorting (FACS) was used to evaluate immune aging in peripheral blood mononuclear cells (PBMCs). Patient with AS exhibited a 55.4 ± 11.3-fold increase in β-galactosidase staining in adipocytes compared to controls. RNA-Seq analysis identified a gene expression signature associated with senescence in adipocytes. Quantitative RT-PCR of SM revealed overlapping gene expression changes in at least half of these senescence associated pathways in AT. Additionally, a significant increase in the IMM-AGE score indicated an increase in immunological age relative to chronological age in AS patients ($P<0.01$). These findings demonstrate a widespread senescence phenotype in adipose and skeletal muscle tissues in AS, supporting accelerated aging as part of the pathological presentation of AS. While the precise mechanisms remain unclear, our results suggest that senotherapies, combined with pharmacological and lifestyle interventions, could offer novel therapeutic strategies for obesity related metabolic dysfunction in AS.

Long-term weight gain in children who underwent adenotonsillectomy

Reut Zvi[1], Alon Haim[1], Guy Hazan[1], Itai Hazan[1] & Eli Hershkovitz[1]

[1]Soroka University Medical Center, Padiatric Endocrinology, Beer Sheva, Israel

Background

Adenotonsillectomy (AT) is one of the most common pediatric surgeries, primarily indicated for obstructive sleep apnea (OSA) and recurrent infections. Although effective, prior studies have mainly examined the association between AT and short-term weight gain, with limited focus on the potential for long-term obesity following the procedure.

Objective

This study aimed to investigate the long-term association between AT and BMI changes, focusing on a 10-year follow-up in a large, nationwide cohort.

Methods

This retrospective cohort study utilized Clalit Health Services' electronic medical records. A total of 2,166 pediatric patients (aged 0-18) were included, with 1,083 children undergoing AT, matched 1:1 to a control group based on sex, ethnicity, and birth year. Baseline BMI and BMI Z-scores were recorded prior to surgery, with follow-up measurements collected over a 10-year period. To minimize bias,

children with severe chronic conditions and diseases known to affect weight regulation were excluded. This ensured that BMI changes reflected the impact of surgery rather than underlying medical factors. Statistical analyses included propensity score matching and inverse probability weighting to adjust for potential confounders such as socioeconomic status and preoperative health conditions.
Results
At baseline, BMI values were comparable between groups, with no statistically significant differences (mean BMI Z-score: 0.14 ± 1.31). At the 10-year follow-up, children in the AT group demonstrated a significantly higher mean BMI Z-score (0.65 ± 1.45) compared to the control group (0.43 ± 1.44, $P < 0.001$). The proportion of children classified as obese increased from 12% to 26% in the AT group, compared to an increase from 12% to 22% in the control group ($P = 0.04$). Furthermore, the odds ratio (OR) for developing overweight or obesity in the AT group was 1.23 (95% CI: 1.01, 1.50; $P < 0.001$). Growth curve analysis revealed that weight gain in the AT group followed a distinct pattern, occurring in phases rather than as a continuous trend, highlighting a sustained post-surgical weight increase.
Conclusion
This study is among the few to highlight the long-term association between AT and the risk of obesity. The findings emphasize the importance of ongoing follow-up and comprehensive support for children undergoing AT to help mitigate potential weight gain.

A metabolomic signature of maternal BMI is associated with pregnancy complications: insights from the COPSAC2010 and VDAART mother-child cohorts

David Horner[1], Rebecca Kofod Vinding[1], Tingting Wang[1], Mina Ali[1], Mario Lovric[1], Nicole Prince[2], Jessica Lasky-Su[2], Klaus Bønnelykke[1], Jakob Stokholm[1], Bo Chawes[1] & Morten Rasmussen[1]
[1]COPSAC clinical research unit, Copenhagen, Denmark; [2]Channing Division of Network Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, United States

Introduction
Pregnancy complications such as gestational diabetes, preeclampsia, and caesarean section are more common among individuals living with higher BMI, likely due to metabolic disturbances. Blood metabolomics may offer mechanistic insights into these disturbances.
Methods
This study utilised data from the COPSAC2010 ($n = 684$) and VDAART ($n = 881$) mother-child cohorts, leveraging untargeted blood metabolomics and machine learning (sparse partial least square modelling) to investigate the association between pre-pregnancy BMI and pregnancy complications. A BMI-metabolite score was trained in the COPSAC2010 cohort and externally validated in VDAART.
Results
In the COPSAC2010 cohort, individuals with higher pre-pregnancy BMI (per 1 SD increase) had increased odds of gestational diabetes (OR 1.90, $P < 0.001$), caesarean section (OR 1.23, $P = 0.023$), and birth induction (OR 1.42, $P < 0.001$). A BMI-metabolite score predicted preeclampsia (OR 1.54, $P = 0.030$) and other pregnancy complications more effectively. Validation in VDAART confirmed the metabolite scores predictive value for gestational diabetes (OR 2.10, $P < 0.001$) and preeclampsia (OR 2.12, $P = 0.002$). Mediation analysis identified 16 metabolites mediating BMI's link to gestational diabetes. These mediators showed stronger predictive value for gestational diabetes in VDAART during early (OR 1.81, $P < 0.001$) and late gestation (OR 2.26, $P < 0.001$) than the full-metabolite score. Pathway enrichment analysis revealed that sphingomyelins and metabolites associated with Vitamin A metabolism were significantly enriched with higher pre-pregnancy BMI (FDR < 0.05)
Conclusion
Metabolomic profiling enhances understanding of how higher BMI during pregnancy may impact complications, offering opportunities for personalised risk assessment. These findings underscore the value of integrating metabolomics into prenatal care to optimise maternal and child health outcomes.

Brown adipose tissue as nutrient buffer through diet-induced thermogenesis

Claudine Netzhammer[1], Jael Senn[1], Giorgio Morandi[1], Aninja Isenrich[1], Christian Wolfrum[2], Matthias Betz[1] & Laila Füchtbauer[1]
[1]Department of Endocrinology, Diabetes & Metabolism, University Hospital Basel, Basel, Switzerland; [2]Department Laboratory of Translational Nutrition Biology, IFNH, ETH Zürich, Schwerzenbach, Switzerland

Background
Brown adipose tissue (BAT) dissipates energy into heat when activated, classically after cold exposure. While there is clear evidence for the correlation between the presence of active BAT and a lean phenotype as well as lower prevalences of cardiometabolic diseases the exact mechanisms of these beneficial effects remain unclear. Especially, since BAT contribution to the total energy expenditure is small. In this study we test the hypothesis that BAT operates as a nutrient buffer and prevents unfavourable postprandial peaks of glucose, free fatty acids, or branched-chain amino acids.
Objective
The primary objective is to compare postprandial increases of metabolites in subjects with functional BAT to those without. Moreover, we assess how the beforementioned macronutrients and BAT-activity contribute to diet-induced thermogenesis (DIT).
Methods
This single center prospective observational study involves 30 healthy, normal weight volunteers and will be completed by May 2025. Participants are screened for presence or absence of cold induced BAT activity by a mild cold stimulus over two hours, followed by a 18F-FDG-PET/CT. BAT metabolic volume (BMV = SUVmean x BAT volume) > 200 ml was chosen as cut-off value to discriminate between BAT-positive and BAT-negative subjects. At each of the following study visits the participants consume an iso-caloric test meal containing exclusively either carbohydrate, protein, or fat. We perform indirect calorimetry hourly and blood samples half-hourly before and during five hours after the test meal.
Results
At the ECE we will present the first analysis of the complete study. Preliminary data of 22 subjects, 10 BAT-positive (BMV = 562.10 ± 210.11 ml), 12 BAT-negative (BMV = 79.18 ± 29.84 ml) show no DIT after intake of fat. A 15-20% increase in energy expenditure was observed persistently for at least 5 hours after intake of protein and for 3-4 hours after glucose. No difference was seen between BAT-positive and BAT-negative subjects in this respect. The average fasting blood glucose level of all study visits was 4.92 ± 0.38mmol/l with no difference between the groups. While all had similar glucose curves after the 100g OGTT, we see consistently lower blood glucose values in BAT-positive subjects following the challenge with fat and protein.
Conclusion
Our data show the impact of different macronutrients on DIT and contradict the notion that BAT status has an impact on DIT. Interestingly blood glucose seems to be lower in BAT-positive subjects after intake of protein and fat while glucose tolerance in our healthy subjects does not correlate to BAT status.

WT1 germline variants are known to generate renal and gonadal conditions, including Differences in sex development (DSD), chronic kidney disease and early kidney and gonadal tumors. GONADVENIR is a French national, retrospective study partly designed to investigate the genotype phenotype correlation in renal and gonado-genital conditions according to genetic groups recently defined by a genetic consortium. Eighty patients were included, at a median age of 14.2±5 years. Among those, 33 (41.3%) had a missense variant of exons 8 or 9 (MS E8-9), 24 (30%) had a variant generating WT1 truncated protein (TP), 14 (17.5%) had a donor splice site variant in intron 9 (DSS I9), and 9 patients had rarer variants. Patients from MS E8-9 group developed mostly (94%) congenital or early steroid-resistant nephrotic syndrome (SRNS), at a median age of 0.7 years (0.3-1.7), significantly earlier than patients from DSS I9 group ($P < 0.0001$) who developed SRNS (64%) around 3.7 years (2.5-10.8). Histologically, biopsies revealed diffuse mesangial sclerosis in 77% of patients from MS E8-9 group, a pathognomonic renal signature. In addition, we found that 88% of TP group developed nephroblastoma at a median age of 1.3 years (0.8-1.6) compared to only 30% in MS E8-9 and 14% in DSS I9 groups. Regarding gonado-genital conditions, 95% of XY patients had DSD, significantly more severe in the MS E8-9 group with External Genitalia Score (EGS) around 4 or 5 and the DSS I9 group with 90% of severe DSD (EGS <7) including 50% of female phenotype, compared to the TP group ($P=0.01$) where 70% had moderate DSD (EGS >7). Interestingly, we found uterus malformations in 9 patients with XX karyotype (39%), of whom 8 (89%) were from MS E8-9 group. In addition, patients with XX caryotype developed more frequently premature ovarian insufficiency in the MS E8-9 group than in the DSS I9 group ($P=0.026$). Finally, we found that patients from the MS E8-9 group had more risk over time than in the TP group to develop gonadal function impairment and premature testicular insufficiency with respective Hazard Ratio at 3.3 ($P < 0.001$) and 3.5 ($P < 0.01$). In conclusion, WT1 germline variants generate, rather than syndromes, a spectrum of renal and gonadal damages. Our study is the largest cohort reported to date and contributes to a better knowledge of the genotype-phenotype correlation, which may help practitioners to better understand their patients' diseases and provide a more individualized follow-up.

Steroidogenesis and CYP17A1 inhibition: development of potent inhibitors for adrenal and gonadal steroid biosynthesis

Jibira Yakubu[1], Tomasz M. Wróbel[2], Angelika Grudzińska[2], Therina du Toit[1], Katyayani Sharma[1], Jeremiah C. Harrington[3], Natalia Dycha[2], Fredrik Björkling[3], Flemming Jørgensen[3] & Amit Pandey[1]
[1]University of Bern, Department of Biomedical Research, Bern, Switzerland; [2]Medical University of Lublin, Department of Synthesis and Chemical Technology of Pharmaceutical Substances, Lublin, Poland; [3]University of Copenhagen, Department of Drug Design and Pharmacology, Copenhagen, Denmark

Steroidogenesis, the biosynthesis of steroid hormones, is a critical process in the development and regulation of various physiological functions, including growth, metabolism, and reproductive health. One of the key enzymes involved in this process is CYP17A1, which catalyses two essential steps in the production of androgens. Given its role in both adrenal and gonadal steroid hormone production, CYP17A1 is a key target for disrupting abnormal steroidogenesis. Only approved CYP17A1 inhibitor is abiraterone, which has numerous side effects, including inhibition of CYP21A2, and is metabolized into a potent androgen, which renders the treatment futile in long term. In this study, we focused on the development of novel potent inhibitors of CYP17A1 to modulate steroid biosynthesis. Using a previously identified hit compound as a starting point, we synthesized a series of analogs, including a novel di-cyano derivative, which demonstrated enhanced potency against CYP17A1. These compounds were tested in the human adrenal NCI-H295R cell line, a well-established model for studying steroidogenesis. Biological assays confirmed that these compounds significantly inhibited CYP17A1 enzymatic activity, leading to changes in steroid hormone profiles. Among the compounds tested, compound 11 exhibited the highest potency ($IC_{50}=4$ nM) in inhibiting CYP17A1 activity, showing a strong disruption of both hydroxylase and lyase functions of the CYP17A1 enzyme. Compound 14 also showed considerable potency and emerged as a promising lead for further development. Structure-activity relationship (SAR) analysis revealed that compounds containing an indole moiety (e.g., compound 11) were more potent than those with a benzotriazole fragment, suggesting that the indole structure is more effective for CYP17A1 inhibition. These findings indicate that targeting CYP17A1 can be a powerful strategy for modulating steroidogenesis. The compounds developed in this study offer a potential avenue for therapeutic interventions aimed at regulating steroid hormone production in both adrenal and gonadal contexts. Elevated androgen levels in congenital adrenal hyperplasia can be targeted by these potent inhibitors of CYP17A1 and for treatment of hyperandrogenic conditions like polycystic ovary syndrome.

Testicular contributions to masculinization in HSD17B3 deficiency: the critical role of HSD17B12

Yunpeng Wang[1], Jing Zhu[2] & Min Zhu[1]
[1]Children's Hospital of Chongqing Medical University, Chongqing, China; [2]Children's Hospital of Chongqing Medical University, chongqing, China

Background
46, XY disorders of sex development (DSD) caused by 17-beta-hydroxysteroid dehydrogenase type 3 (HSD17B3) deficiency disrupt male sexual development, often resulting in undervirilization due to impaired testosterone synthesis. However, some patients experience masculinization, which is the main reason for the visit. This study investigates the molecular mechanisms underlying this phenomenon through clinical observations and protein expression analysis in patients with HSD17B3 deficiency.
Methods
Six patients with 46, XY DSD due to HSD17B3 deficiency were enrolled. Clinical phenotypic and hormonal profiles, were collected and analyzed. Bioinformatics analysis was used to identify candidate enzymes involved in androgen conversion. Immunofluorescence multi-marker staining was performed on tissue samples to examine the expression of HSD17B1, HSD17B5, and HSD17B12 in testicular tissues.
Results
The index patient was referred to our clinic after testicular-like tissue was discovered during an inguinal hernia repair. Genetic testing confirmed HSD17B3 deficiency, and the patient was assigned female sex. Despite this, no testicular tissue was present at follow-up during adolescence, and no signs of masculinization were observed. Retrospective analysis of other patients revealed that masculinization occurred exclusively in those with testicular tissue, indicating that the testis, rather than the adrenal glands or prostate, is the primary organ involved in episodic masculinization. Bioinformatics analysis revealed that HSD17B12 was the most highly expressed isozyme among HSD17B1, HSD17B5, and HSD17B12 in normal testes. Only HSD17B12 showed distinct spatiotemporal expression patterns, with low levels in infants and adults but significantly higher levels in adolescent boys. These changes were likely influenced by the elevated levels of luteinizing hormone during puberty, which stimulate testosterone production by Leydig cells in the testes. Similarly, in HSD17B3 deficiency, impaired testosterone synthesis leads to high gonadotropin levels, which is similar to puberty state and might contribute to masculinization. Immunofluorescence staining confirmed that HSD17B12 expression was the highest among the three enzymes in testicular tissue. Molecular docking studies further demonstrated that HSD17B12 had strong affinity for androstenedione, supporting its key role in the conversion to testosterone.
Conclusion
This study identifies the testis as the main organ responsible for episodic masculinization in patients with HSD17B3 deficiency, highlighting the importance of testicular tissue in the masculinization process. HSD17B12 emerges as the key enzyme involved, with its spatiotemporal expression patterns and high affinity for androstenedione suggesting a critical role in testosterone synthesis. These findings contribute to the understanding of the molecular mechanisms driving masculinization in HSD17B3 deficiency and may inform future therapeutic strategies targeting HSD17B12.

Semen quality and lifespan – a study of 78,284 men followed for up to 50 years

Lærke Priskorn[1], Lindahl-Jacobsen Rune[2], Jensen Tina[3], Stine Holmboe[1], Laura Smidt[1], Margit Kriegbaum[4], Bent Lind[4], Volkert Siersma[4], Christen Andersen[4] & Niels Jørgensen[1]
[1]Rigshospitalet, Dept. of Growth and Reproduction, Copenhagen, Denmark; [2]University of Southern Denmark, Unit of Epidemiology, Biostatistics and Biodemography, Dept. of Public Health, Odense, Denmark; [3]University of Southern Denmark, Dept. of Clinical Pharmacology, Pharmacy and Environmental Medicine, Odense, Denmark; [4]University of Copenhagen, The Research Unit for General Practice and Section of General Practice, Dept. of Public Health, Copenhagen, Denmark

Background
Male infertility and semen quality have been suggested to be markers of morbidity and thus mortality, but the role of underlying disease present at time of semen quality evaluation has not been thoroughly assessed.
Objective
To determine the association between semen quality and mortality and to assess the impact of the health of the man prior to semen quality assessment.
Participants, study design, size
The study was based on 78,284 men who had their semen quality assessed 1965-2015 at the public semen analysis laboratory in the Copenhagen area, Denmark, due to reported couple infertility. Thus, the included men covered a wide range of semen quality. Semen quality assessment included semen volume, sperm concentration and the proportion of motile and morphologically normal sperm, from which total sperm count, and total number of motile sperm was calculated. Utilizing the unique national registers, follow-up of the men regarding all-cause mortality was performed with a median follow-up of 23 years (5-95th percentile: 8-45 years) during which 8,600 (11.0%) deaths occurred.
Methods
Life expectancy was calculated according to semen quality. Furthermore, the relative differences in mortality were estimated using Cox regression analyses and presented as hazard ratios (HR) with 95% confidence intervals (CI). For a subpopulation of 59,657 men (sample delivery 1987-2015), information on diseases prior to semen sampling and educational level was available and adjusted for in Cox regression analyses.
Results
Men with a total motile count >120 mill. could expect to live 80.3 years, compared to 77.6 years among men with total motile count >0-5 mill. In Cox regression analyses, all semen parameters were negatively associated with mortality in a dose-response manner both in the total and the subpopulation (p-trend for all semen parameters <0.001), and adjustment for educational level and prior diagnoses did not change the estimates. Looking at total motile count as an example, for which men with total motile count >120 mill. served as the reference, adjusted HRs were: azoospermia: 1.39, >0-5 mill.: 1.61, >5-10 mill.: 1.38, >10-40 mill.: 1.27, >40-80 mill.: 1.16 and >120 mill.: 1.19, p-trend< 0.001).
Conclusion and implications
We observed clear negative dose-response associations between all semen parameters and all-cause mortality, which were not explained by disease registered at the time of semen evaluation. Thus, some men with impaired semen quality may experience less healthy aging than men with better semen quality and could benefit from being identified at time of semen quality evaluation.

Smart menstrual health monitoring patch: a non-invasive ai-driven solution for cycle tracing

Tinatin Kutchukidze[1]
[1]New vision University, New Anglia University, UK, Endocrinology, Tbilisi, Georgia

Objectives
The primary objective of this study was to evaluate the feasibility, accuracy, and clinical relevance of the Smart Menstrual Health Monitoring Patch(SMHMP), a non-invasive newly designed wearable device designed to continuously monitor menstrual cycle biomarkers. The study aimed to assess its effectiveness in predicting ovulation, detecting cycle irregularities, and identifying potential menstrual disorders such as PCOS, endometriosis, and infertility.
Design
A prospective, multi-centered study was conducted to validate the SMHMP's biosensor technology and AI-driven analytics. The study followed a longitudinal observational design, comparing SMHMP data with conventional menstrual tracking methods (eg: basal body temperature chart and hormone assays) and clinical diagnosis.
Methods
500 participants, aged 18-40 with varying menstrual health profiles, were recruited from gynecological clinics. Participants wore SMHMP continuously for six menstrual cycles. The patch collected basal body temperature, hormone fluctuation data (estrogen and progesterone levels via interstitial fluid analysis), and other biomarkers data were analyzed using machine learning algorithms to detect cycle trends, ovulation windows, and potential menstrual disorders. Clinical validation was performed through physical assessments, blood hormone assays, and ultrasound confirmation where necessary.
Results
The SMHMP demonstrated a 92.3% accuracy in ovulation prediction compared to standard luteinizing hormone tests. It successfully detected menstrual irregularities in 87.5% of participants previously diagnosed with PCOS and identified 78.9% of cases with suspected endometriosis. User compliance and satisfaction rates exceeded 85% with participants reporting improved menstrual health awareness and ease of use compared to traditional tracking methods.
Conclusion
The findings suggest that SMHMP is a viable, non-invasive solution for menstrual health monitoring, offering real-time insights that can aid in the early detection of menstrual disorders. This technology has to potential to transform gynecological practice by providing an accessible, AI-driven approach to reproductive health management. Future research should focus on expanding clinical trials, refining AI algorithms for increased diagnostic accuracy, and exploring integration with border women's health initiatives.

Examining factors associated with androgen abuse withdrawal symptoms during the first year of cessation: a cross-sectional study of 286 men

Bonnie Grant[1], Joseph Kean[2], Nipun Lakshitha de Silva[1,3], Maha Gumssani[1], Oliver Quinton[1], Paul Bassett[4], Anne Lingford-Hughes[1], Suks Minhas[5], Waljit Dhillo[1] & Channa Jayasena[1]
[1]Imperial College London, London, United Kingdom; [2]Bradford Metropolitan District Council, Bradford, United Kingdom; [3]General Sir John Kotelawala Defence University, Department of Clinical Sciences, Faculty of Medicine, Ratmalana, Sri Lanka; [4]Statsconsultancy Ltd, Amersham, United Kingdom; [5]Imperial College Healthcare NHS Trust, London, United Kingdom

Background
Androgens are widely abused by men worldwide to enhance muscle size and physical performance. Recent studies have quantified the recovery of cardiovascular and testicular function post-cessation. Qualitative studies demonstrate that low mood, anxiety, suicidal ideation, and sexual dysfunction are common following androgen abuse cessation. However, no previous study has focused on quantifying symptoms within the first year of cessation, nor investigated independently associated factors for these symptoms.
Methods
Cross-sectional, observational study of 286 men in 3 groups; non-use ($n=50$); current-use ($n=125$); past-use ≤ 1 year ($n=111$). All participants completed questions on substance misuse, Beck Depression Inventory-II (BDI-II), International Index Erectile Function-15 (IIEF-15), General Anxiety Disorder (GAD-7), Quality-of-life (SF-36), and underwent fasting, morning blood sampling with urine toxicology.
Results
Current-use had lower gonadotropins and elevated serum total testosterone compared with past-use and non-use. Sexual function measured using IIEF-15 was impaired in past-use compared with current users: (1) total: 69.0 [IQR 61.0, 73.0], current-use; 62.0 [IQR 47.0, 71.0], past-use; $P=0.0002$; (2) erectile function: 30.0 [IQR 27.0, 30.0], current-use; 27 [IQR 20.0, 30.0], past-use; $P=0.0002$; (3) sexual desire: 9.0 [IQR 7.0, 10.0], current-use; 7.0 [IQR 5.0, 9.0], past-use; $P<0.0001$; (4) intercourse satisfaction: 12.0 [IQR 10.0, 15.0], current-use; 12.0 [IQR 8.0, 14.0], past-use; $P=0.0445$; (5) overall satisfaction: 10.0 [IQR 8.0, 10.0], current-use; 8.0 [IQR 6.0, 10.0], past-use; $P=0.0001$. Multivariable analysis suggested that psychiatric comorbidity (coefficient -6.5 [95% CI -13.0, -1.3]; $P=0.03$) and androgen cessation (coefficient -10.8 [95% CI -5.6, -17.2]; $P<0.001$) were associated with lower total IIEF-15 scores. Depression scoring

was worse in the past-use compared with non-use and current-use: BDI-II 3.0 [IQR 0.0, 8.0], non-use; 6.0 [IQR 2.0, 11.0], current use; 8.0 [IQR 2.0, 18.0], past-use; $P=0.0005$. Multivariable analysis suggested that psychiatric comorbidity (OR 2.39 [95% CI 1.60, 3.57]; $P<0.001$) and lower serum total testosterone (OR 0.85 [95% CI 0.88, 0.94]; $P=0.002$) were associated with higher BDI-II scores. Anxiety scoring was worse in the past-use compared with the non-use: GAD-7 1.0 [IQR 0.0, 3.0], non-use; 2.0 [IQR 0.0, 6.0], past-use; $P=0.0271$. Energy and fatigue measured using SF-36 was lower in past-use compared with non-use and current-use: 70 [IQR 60, 76], non-use; 65 [IQR 50, 75], current-use; 55 [IQR 40, 50], past-use; $P=0.0009$.

Discussion

We report the first, detailed quantification and modelling of symptoms in men currently misusing and stopping androgens within the previous year. These data reveal potentially treatable factors to improve symptoms of androgen abuse cessation if proven within interventional studies.

Stimulated peak cortisol in healthy paticipants measured during the insulin tolerance test: defining cut-off limits for adrenal insufficiency with two generations of Roche cortisol immunoassays

Sema Okutan[1], Stina Willemoes Borresen[1], Linda Hilsted[2], Ulla Feldt-Rasmussen[1] & Marianne Klose[1]

[1]Copenhagen University Hospital, Rigshospitalet, Department of Endocrinology, Copenhagen, Denmark; [2]Copenhagen University Hospital, Rigshospitalet, Departmen of Clinical Biochemistry, Copenhagen, Denmark

Introduction

The cortisol concentration varies depending on the measurement method. Monoclonal immunoassays demonstrate greater specificity than their predecessor polyclonal immunoassays for the assessment of cortisol. This necessitates assay-specific cut-off limits for defining adrenal insufficiency (AI). A cortisol cut-off of 500 nmol/l has been recommended for the older cortisol immunoassay, while lower cut-off of 420 nmol/l for newer immunoassays. However these values are defined using the ACTH test and not specified for the insulin tolerance test (ITT).

Purpose

To conduct a direct comparison between the 1st and 2nd generation Roche Elecsys cortisol immunoassays and to establish test- and assay-specific cortisol cut-off limits for the ITT using a cohort of healthy participants.

Methods

Ninety healthy participants underwent an ITT after an overnight fast (60 men, median age 46 years (IQR 24.5–49.5)). Blood samples were collected before, 15, 30, 45, 60, 75 and 90 min after insulin injection. The samples were analyzed on the 1st and 2nd generation Roche Elecsys cortisol immunoassays. The cut-off limit for a normal cortisol response to the ITT was defined as the 2.5th percentile of the peak cortisol level for 1st and 2nd generation Roche Elecsys cortisol immunoassays, respectively. The percentage of participants failing the currently used cut-offs derived from the 250 µg ACTH test of 500 nmol/l (ElecsysCortisol I), and 420 nmol (ElecsysCortisol II) were calculated.

Results

ElecsysCortisol II measured peak cortisol concentrations on average 29 nmol/l (95% CI: −64 to 9 nmol/l) lower than ElecsysCortisol I. The median peak cortisol was 607 nmol/l (range 320–1020 nmol/l) with ElecsysCortisol I and 510 nmol/l (range 240–964 nmol/l) with ElecsysCortisol II. The 2.5th percentile cortisol cut-off limits for a normal cortisol response in the ITT were 379 nmol/l with ElecsysCortisol I and 312 nmol/l with ElecsysCortisol II. Sixteen (17.8%) of the healthy controls had a peak cortisol below 500 nmol/l when measured by ElecsysCortisol I, whereas 19 (21%) of the healthy controls had a peak cortisol below 420 nmol/l with ElecsysCortisol II.

Conclusion

The 2nd generation Roche Cortisol immunoassay systematically reported lower cortisol concentrations. Based on healthy controls, we defined a cut-off limit for the ITT of 312 nmol/l which is considerably lower than commonly applied cut-off limits to confirm or reject AI. Our data emphasize the importance of knowledge of the method used, especially in patients with low apriory likelihood of adrenal insufficiency where the diagnosis may be challenging and at risk of false positive results.

Neonatal screening in subjects with non-classic congenital adrenal hyperplasia (NCCAH)

Anat Segev-Becker[1,2], Liat Perl[1,2], Hussein Zaitoon[1,2], Asaf Oren[1,2], Ori Eyal[1,2], Erella Elkon Tamir[1], Galit Israeli[1], Yael Lebenthal[1,2], Shlomo Almashanu[3] & Naomi Weintrob[1]

[1]The Institute of Pediatric Endocrinology, Diabetes and Metabolism, Dana-Dwek Children's Hospital, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; [2]Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [3]The National Newborn Screening Program, Ministry of Health, Tel-Hashomer, Israel

Background

Newborn screening (NBS) for congenital adrenal hyperplasia (CAH) primarily targets the detection of classical forms, with limited sensitivity for the milder non-classic form (NCCAH). Data on the predictive value of NBS 17-hydroxyprogesterone (17OHP) levels for later diagnosis of NCCAH, particularly in relation to specific genotypes, remain scarce.

Aim

To compare NBS 17OHP levels among children with NCCAH carrying mild/severe genotypes, those with mild/mild genotype, and healthy controls (HC).

Methods

Between 2020 and 2024, children evaluated for precocious pubarche/puberty, growth acceleration, or advanced bone age in a pediatric endocrinology clinic underwent ACTH stimulation testing. Eligible participants were born at or after 2008, following the implementation of NBS. Children with a history of early prematurity or perinatal complications were excluded. The study included 60 children with NCCAH (peak stimulated 17OHP $\geqq$ 40 nmol/l) and 59 healthy controls (stimulated 17OHP $\leq$ 25 nmol/l). NBS 17OHP levels were retrieved from the national NBS laboratory. CYP21A2 mutations were screened using a nine-mutation panel and multiplex ligation-dependent probe amplification in individuals diagnosed with NCCAH.

Results

Median NBS 17OHP levels were significantly higher in NCCAH patients compared to HC (6.3 nmol/l [IQR: 4.6–8.2] vs. 5.1 nmol/l [IQR: 3.6–7.0], $P=0.012$). Within the NCCAH cohort, no significant difference in NBS 17OHP levels was observed between the mild/severe and mild/mild genotype subgroups ($P=0.43$). ROC curve analysis identified an NBS 17OHP cutoff of $\geqq$5.9 nmol/l as a potential predictor for future NCCAH diagnosis; however, the sensitivity and specificity were low (AUC = 0.633).

Conclusions

The current NBS recall threshold ($\geqq$35 nmol/l) is substantially higher than the median NBS 17OHP levels observed in NCCAH patients, limiting its effectiveness in identifying NCCAH. Interestingly, the identified cutoff of 5.9 nmol/l aligns with basal 17OHP thresholds proposed for ACTH testing in older NCCAH patients. Furthermore, no differences in NBS 17OHP levels were observed between genotype subgroups, contrasting with previously reported findings in older individuals.

In the phase 3 GRACE study, treatment with the selective glucocorticoid receptor modulator relacorilant improved blood pressure and other cortisol-related comorbidities in patients with endogenous hypercortisolism. The objective of this phase 3 open-label extension study (OLE, NCT03604198) was to assess the long-term efficacy and safety of relacorilant. Patients were eligible to enter the OLE if they completed a Corcept-sponsored parent relacorilant study, including either GRACE (NCT02804750), GRADIENT (NCT03697109), or the phase 2 study (NCT04308590), and in the investigator's opinion, might benefit from further treatment. As of September 8, 2024, there were 116 patients enrolled in the OLE. Patients' blood pressure continued to improve during relacorilant treatment. The mean (standard deviation) change in systolic and diastolic blood pressure from OLE baseline to month 24 was −10.0 [9.51] mmHg ($P=0.012$) and −7.3 [7.36] mmHg ($P=0.016$), respectively. Daytime and nighttime blood pressure

also improved during the OLE. In GRACE, patients who switched to placebo during the randomized-withdrawal phase experienced a deterioration in blood pressure. When relacorilant treatment was resumed in the OLE, their blood pressure improved. Improvements in body weight, glycemic control, and other cortisol-related comorbidities that were observed in the GRACE study were maintained in the OLE. Relacorilant was well tolerated in the OLE, consistent with the parent studies. No new safety signals were identified during up to 6 years of treatment. Long-term treatment with relacorilant led to significant and durable cardiometabolic improvements in patients with hypercortisolism and was well-tolerated.

Initial findings of the study into the health status of adults with CAH in the UK and Ireland – CaHASE2

CaHASE2 Investigators Society for Endocrinology UK
Society for Endocrinology, Bristol, UK

Background
Congenital adrenal hyperplasia (CAH) is one of the commonest forms of primary adrenal insufficiency with an incidence of about 1 in 15,000. Previous studies have highlighted the suboptimal health status and care provision in adults with CAH and these were associated with significant co-morbidities. In 2023, we implemented CaHASE2 (https://www.endocrinology.org/clinical-practice/research-projects/cahase-2/) to develop a strategy for prospective collection of longitudinal data. Our recent CAH service evaluation suggested significant differences in the approach to CAH patients.
Aim
To identify specific unmet needs in the care of people living with CAH, through standardised phenotyping across all participating centres.
Methods
In September 2023, PIs agreed a minimal dataset for the collection of real-world data for participating centres. The data is collected using the international CAH registry (I-CAH; https://sdmregistries.org/). CaHASE2 was launched in November 2023.
Results
To date, 351 adults (213 females, 138 males) with CAH have been recruited and 1213 clinic visits were available for analysis. There is a preponderance of younger to middle-aged adults in the currently available datasets (median age 42 years, range 23–88). Preliminary analysis suggests a temporal change in glucocorticoid choice over time with an increased use of hydrocortisone and a decreased use of prednisolone. Analysis of 17OHP concentrations shows that a significant proportion of patients are overtreated. A significant proportion of patients are overweight or obese. Currently 18 centres are actively recruiting and 5 are awaiting local approval to use the I-CAH registry. The data will be analysed in 12-month cycles, to assess the current level of care provision and inform the development of CAH standards. In addition, we will establish a report that will provide centres with information about their local care provision in relation to other centres.
Conclusions
The CaHASE2 project will provide important information about the health status of adults with CAH and how this might be related to differences in health care provision. Ultimately, such data should lead to a higher degree of equality of service provision in all parts of the UK and Ireland.

JOINT3812

is imaging alone sufficient for lateralising PA in younger patients?

Zin Htut[1], Namir Asmar[2], Joshua Agilinko[1], Florian Wernig[2] & Ali Alsafi[2]
[1]Imperial College London, London, UK; [2]Imperial College Healthcare NHS Trust, London, UK

Background
The role of adrenal vein sampling (AVS) in younger patients with primary aldosteronism (PA) remains debated. Endocrine Society (ES) Guidelines suggest that AVS may be avoided in patients ≤35 years with marked PA (aldosterone > 831 pmol/l, spontaneous hypokalaemia), and a solitary adrenal lesion consistent with an adenoma. While some centres adopt this approach, others, including ours, perform AVS routinely on all patients with PA. However, imaging alone may misclassify laterality in a significant proportion of younger patients.
Aim
To assess the accuracy of imaging alone in distinguishing unilateral from bilateral PA in patients ≤35 years and evaluate the added diagnostic value of AVS.
Method
We retrospectively analysed 364 patients who underwent AVS for PA between 2011 to 2024, including 39 patients aged ≤35 years. Of these, 38 underwent either CT or MRI prior to AVS. Two radiologists independently reviewed imaging blinded to AVS results, while two endocrinologists blinded to imaging findings analysed AVS. Concordance between imaging and AVS was assessed.
Results
The mean age was 32 years, with 60% female. Median hypertension duration was 1.5 years (IQR: 1–5 years). All patients had biochemically confirmed PA with spontaneous hypokalaemia and were on two to three antihypertensive medications. AVS was successful in all cases. Among 39 patients, four were excluded due to inconclusive AVS results and missing imaging data. In the remaining 35, imaging identified unilateral adenomas (6–25 mm) in 82.9% (29/35) patients, bilateral adenomas in 8.6% (3/35), and normal adrenal glands in 8.6% (3/35). Among 29 unilateral cases on imaging, 13.8% (4/29) had discordant AVS findings, indicating bilateral disease. Discordant cases had lateralisation index <2 (range: 1.3–2.0) and/or contralateral suppression index >1, suggesting bilateral PA. Only one discordant case met ES criteria for marked PA, while the other three had milder disease. All discordant cases were managed medically, while 86.2% (25/29) underwent unilateral adrenalectomy, with histological confirmed adenoma.
Conclusion
While imaging alone correctly lateralised PA in 86.2% of cases, 13.8% of patients with unilateral adenomas had discordant AVS findings, indicating bilateral disease. Only one discordant case met the ES criteria for marked PA, supporting AVS omission in these patients. However, AVS remains essential for those with milder PA to prevent misclassification and unnecessary adrenalectomy.

Challenges in the interpretation of cortisol response during insulin tolerance test: prevalence of secondary adrenal insufficiency and predictive factors

Federico Borghi[1], Andrea Ballaben[1], Maura Marin[1], Viviana Vidonis[2], Giada Vittori[2], Daniela Slama[2], Elena Faleschini[2], Gianluca Tamaro[2] & Gianluca Tornese[1,2]
[1]Department of Medicine, Surgery and Health Sciences, University of Trieste, Trieste, Italy; [2]Institute for Maternal and Child Health IRCCS "Burlo Garofolo", Trieste, Italy

Background
The insulin tolerance test (ITT) is the gold standard for assessing the integrity of growth hormone (GH) and cortisol axes. While ITT is essential for diagnosing growth hormone deficiency (GHD) and secondary adrenal insufficiency (SAI), its interpretation can be challenging due to variability in thresholds and individual responses.
Methods
This retrospective study analyzed ITTs performed at the Institute for Maternal and Child Health IRCCS "Burlo Garofolo," Trieste, Italy, from January 1, 2019, to December 31, 2024. Tests were conducted to confirm GHD after a blunted response to arginine stimulation or for retesting at the end of GH treatment. Regular insulin (0.1 IU/kg intravenously) was administered, and adequate hypoglycemia was defined as a ≧50% decrease in basal glucose or a nadir glucose <40 mg/dL.
Results
Of 212 ITTs performed, adequate hypoglycemia was achieved in 186 (88%), including 157 diagnostic tests and 29 retests. The prevalence of SAI varied widely depending on the threshold used: Between 14% and 27% of individuals meeting these thresholds were not diagnosed with GHD. Peak cortisol levels positively correlated with basal cortisol ($\rho = 0.490$, $P < .001$), nadir glycemia ($\rho = 0.307$, $P < .001$), basal ACTH ($\rho = 0.255$, $P < .001$), ACTH after hypoglycemia ($\rho = 0.332$, $P < .001$), and peak GH ($\rho = 0.312$, $P < .001$). No significant correlation was found with age, sex, or BMI SDS. Multivariate analysis identified lower basal cortisol ($P < .001$), lower ACTH after hypoglycemia ($P < .001$), and nadir glycemia ($P = .012$) as significant predictors of cortisol peak, with a moderate model fit ($R^2 = 0.354$).
Conclusions: The prevalence of SAI during ITT ranged from 13% to 80% depending on the diagnostic thresholds. Between 14% and 27% of individuals

Threshold for SAI	*n* (%)	Of which with no GHD
Peak cortisol <400 nmol/l	32 (17%)	6 (19%)
Delta cortisol <200 nmol/l	75 (40%)	20 (27%)
Peak cortisol <400 nmol/l and delta <200 nmol/l	24 (13%)	5 (21%)
Peak cortisol <550 nmol/l	129 (69%)	18 (14%)
Delta cortisol <250 nmol/l	102 (55%)	22 (22%)
Peak cortisol <550 nmol/l or delta <250 nmol/l	149 (80%)	28 (19%)

meeting SAI thresholds were not diagnosed with GHD, complicating interpretation. Significant predictors of cortisol peak include basal cortisol, nadir glycemia, and ACTH after hypoglycemia. These findings highlight the need to consider clinical context alongside hormonal thresholds to ensure accurate SAI diagnosis and avoid overdiagnosis.

The relationship between androgens and autistic traits: a comparative study in children with congenital adrenal hyperplasia

Hande Turan[1], Göktug Zorbay Eyupoğlu[1], Enes Karaca[1], Gizem Durcan[1], Elvan Bayramoglu[1], hasan karakas[1], Ilayda Altun[1], Mert Uçar[1], Gökçe Velioglu Haslak[1], Abdurrahman Güney[1] & Olcay Evliyaoğlu
Istanbul University-Cerrahpasa, Cerrahpaşa Faculty of Medicine, Istanbul, Türkiye

Purpose
Autism Spectrum Disorder (ASD) is a neurodevelopmental condition characterized by difficulties in social interaction, communication, restricted interests, and repetitive behaviors. ASD is more prevalent in males than females, with some studies suggesting a possible association with prenatal androgen exposure. Congenital Adrenal Hyperplasia (CAH), a genetic disorder causing increased prenatal androgen levels, provides a suitable model to investigate this relationship. This study aims to evaluate the potential link between early androgen exposure and autistic traits by comparing children and adolescents with CAH to healthy controls.
Method
The study included 49 participants: 25 children diagnosed with CAH (13 males, 12 females) followed by Istanbul University-Cerrahpaşa Medical Faculty Pediatric Endocrinology Clinic, and 24 age- and sex-matched healthy controls (12 males, 12 females) aged 2–18 years. Autism symptoms were assessed using the Childhood Autism Rating Scale (CARS), the Autistic Behavior Checklist (ABC), and the Strengths and Difficulties Questionnaire (SDQ).
Results
The total CARS score was significantly higher in the CAH group compared to the control group ($P<0.001$). The CAH group also had higher scores in the following CARS subtests: Relating to People ($P=0.027$), Body Use ($P=0.031$), Visual Response ($P=0.017$), Listening Response ($P=0.028$), Taste/Smell ($P=0.033$), Verbal Communication ($P=0.049$), Activity Level ($P<0.001$), and Intellectual Response ($P=0.003$). However, there was no significant difference between the groups in motor skills, language skills, and general autism scores ($P>0.05$). When the participants were evaluated with ABC, it was found that the sensory behavior score ($P=0.037$) was higher, and the relating behavior score ($P=0.001$) was lower in the CAH group compared to the control group.This finding indicates difficulties in social communication. In the SDQ assessment, emotional problems ($P=0.043$), behavioral issues ($P=0.043$), hyperactivity/attention deficit ($P=0.025$), and peer relationship problems ($P=0.001$) were significantly higher in the CAH group. The general difficulties score was also higher, indicating an increased psychosocial risk. No correlation was found between current androgen levels (17-OH, DHEA-S, 1,4) and CARS and ABC scores ($r < 0.4$)
Conclusion
Children diagnosed with CAH had higher scores regarding autism symptoms and had more difficulties with social communication. Additionally, increased behavioral and attention problems were observed in these children, which indicates emotional fragility. No direct correlation between androgen levels and autism symptoms was found, but it is thought that there might be indirect effects of prenatal androgen exposure. Further investigations are needed, with broader samples required to clarify this relationship.

Adrenal dysfunction and cardiometabolic comorbidities associated with weight cycling in postmenopausal conditions

Linghui Kong[1], Coralie Frimat[2], Nicolo Faedda[1], Bakhta Fedlaoui[1], May Fayad[1], Isabelle Giscos-Douriez[1], Fabio Fernandes-Rosa[1], Bruno Feve[3], Antoine Ouvrard-Pascaud[2], Maria-Christina Zennaro[1,4] & Sheerazed Boulkroun[1]
[1]INSERM U970 – PARCC, Université Paris Cité, Paris, France; [2]Inserm U1096, UFR santé, Rouen, France; [3]Sorbonne Université-Inserm, Centre de Recherche Saint-Antoine UMR_S938, Paris, France; [4]Service de Génétique, Assistance Publique Hôpitaux de Paris (AP-HP), Hôpital Européen Georges Pompidou, Paris, France

Overweight and obesity are major public health issues. ∼20% of overweight people achieve sustainable weight loss with a risk of repeated weight loss and regain. Obese patients exhibit high plasma leptin levels, but are resistant to its anorectic action. Leptin, and other adipokines, directly regulates adrenal aldosterone biosynthesis, while aldosterone has been implicated in obesity-induced suppression of adiponectin, an insulin sensitizing adipokine, suggesting a central role for aldosterone in the development of overweight-associated comorbidities. Interestingly, aldosterone levels are associated with the development of metabolic syndrome. Weight cycling is associated with fluctuations in blood pressure, heart rate and glomerular filtration, leading to increased risk of developing metabolic syndrome, type-2 diabetes, chronic kidney disease and heart failure, inducing higher mortality, particularly in women. The menopausal transition is associated with a 60% increase in the incidence of metabolic syndrome, which is associated with higher cardiovascular mortality. We hypothesize that adrenal dysfunction, in a postmenopausal context may play a role and has a lasting impact on the increased cardiometabolic risk induced by weight cycling. The aim of our study was to evaluate the impact of weight cycling on adrenal gland function and the impact on the development of cardiometabolic complications in postmenopausal conditions. We established an experimental protocol in which female mice were either ovariectomized (OVX, post-menopause) or not (non-OVX, pre-menopause) and subjected to three weight cycles of high fat diet/standard diet (Yoyo) or maintained on a standard diet throughout. At the end of each phase of the weight cycling protocol, blood samples were collected to assess various metabolic parameters and perform steroid profiling. A variety of tissues (adrenal, heart, adipose tissue…) were collected for further analyses. The yoyo diet led to a greater weight gain in OVX mice compared to non-OVX mice. After ovariectomy, mice exhibited higher fasting blood glucose and circulating leptin levels, an effect that was exacerbated in response to Yoyo diet. Additionally, OVX mice on Yoyo diet chowed impaired glucose tolerance and insulin resistance. These mice developed heart failure with preserved ejection fraction, which was prevented by the use of the mineralocorticoid receptor antagonist, finerenone. Surprisingly, OVX mice on Yoyo diet displayed an increase in adrenal gland weight, accompanied by significant morphological and functional remodeling of the adrenal cortex. The absence of estrogen leads to cardiometabolic disorders that are worsened by the Yoyo diet, as well as adrenal dysfunction, which could, in turn, contribute to the worsening of cardiometabolic comorbidities.

Introduction
Medical treatment for Cushing's syndrome (CS) primarily aims to lower daily cortisol levels, while often overlooking the restoration of circadian rhythm. Indeed, no approved treatment regimens are specifically designed to achieve this goal. We aimed to assess the efficacy and safety of a timed, once-daily Osilodrostat regimen in optimizing circadian cortisol profile in patients with CS.
Methods
We conducted a prospective, multicenter study evaluating patients with well-controlled CS who were on a stable twice-daily Osilodrostat regimen before and 60–90 days after transitioning to an equivalent once-daily dose administered at 19:00 ± 1 hour. Circadian steroid profiles were analyzed in saliva, serum, and urine using UHPLC-MS/MS. A cosinor-based analysis on salivary cortisol and cortisone measurements was performed to capture changes in their daily profiles. Additional evaluations encompassed cardio-metabolic markers, quality of life, sleep function, and safety outcomes.
Results
Sixteen patients (4 males; 7 pituitary, mean age 53.3 ± 11.8 years) were enrolled. At baseline, CS was well-controlled with a mean Osilodrostat dose of 4.2 mg (range 2–22). After the chronotherapy intervention, transitioning to once-daily dosing at 19:00 ± 1 hour, salivary cortisol exposure decreased significantly during the afternoon-to-early morning period [$AUC_{16:00–08:00}$: −6.1 (−0.15 to −12.1) ng/mL/h, $P = .029$; $AUC_{16:00–04:00}$: −4.6 (−1.2 to −8.1) ng/mL/h, $P = .009$]. Quality of life and sleep improved [CushingQoL: +4.2 (−0.1 to -8.6), $P = .029$; PSQI: −1.7 (−3.7 to 0.4), $P = .049$]. Serum steroid precursors, including 11-deoxycorticosterone ($AUC_{08:00–20:00}$: −3.1 ng/mL/h, $P = .008$) and 11-deoxycortisol ($AUC_{08:00–20:00}$: -17.8 ng/mL/h, $P = .005$), as well as total testosterone in women ($AUC_{0800–2000}$: = −0.8 ng/mL/h, $P = .039$), showed a decrease in the global day exposure. A subsequent salivary analysis involved 8 patients that advanced dosing to 16:00 ± 1 hour (T_{OD2}), showing comparable reductions (cortisol $AUC_{16:00–08:00}$: −5.5 ng/mL/h, $P = .036$). Once-daily OS was generally well tolerated and preferred by 93.4% of patients to the twice daily regimen in terms of overall appeal, ease of use in daily routine and future choice. No patients developed adrenal insufficiency, liver toxicity, ECG abnormalities, or loss of disease control.
Conclusions
This is the first evidence that chronotherapy with once-daily Osilodrostat effectively and safely treats CS, leading to improvements in circadian cortisol rhythms, quality of life, and sleep. These results warrant further exploration of chronotherapy-based approaches in CS management.

Assessment of adrenal function after oral prednisolone therapy in children with epileptic spasms

Ram Tapela[1], Preeti Singh[2], Anju Seth[2] & Suvasini Sharma[2]
[1]Lady Hardinge Medical College, Lady Harding Medical College, Pediatrics, New Delhi, India; [2]Lady Hardinge Medical College, Lady Harding Medical College, Pediatrics, New Delhi, India

Background
Epileptic spasms, including West syndrome, are severe pediatric neurological disorders associated with developmental delays and neurocognitive impairment. High-dose oral prednisolone is a first-line treatment but carries a risk of adrenal insufficiency (AI). Evaluating adrenal function post-treatment is crucial, particularly in resource-limited settings where routine testing may not be feasible.
Objectives
This study aimed to determine the proportion of children with AI at 5 days and 6–8 weeks after stopping prednisolone. Additionally, it assessed adrenal recovery at 6–8 weeks in those diagnosed with AI at 5 days, examined treatment-related adverse effects, and identified potential AI risk factors.
Methods
A prospective analytical study was conducted on 40 children (6–19 months, mean age: 10.10 ± 3.69 months) who completed high-dose oral prednisolone therapy (4 mg/kg/day for 2 weeks, followed by a 4-week taper). Adrenal function was evaluated using basal cortisol and ACTH stimulation tests at 5 days and 6–8 weeks post-treatment completion. Adrenal recovery was defined as a stimulated cortisol level ≧18 µg/dL.
Results
At 5 days post-therapy, all children exhibited AI as confirmed by ACTH stimulation testing, with 97.5% having inconclusive basal cortisol levels (3–18 µg/dL). By 6–8 weeks, 72.5% showed adrenal recovery. One child experienced an adrenal crisis at 2 weeks but recovered by the second assessment. Cushingoid facies was observed in 85% at 5 days, decreasing to 72.5% by 6–8 weeks. Elevated blood pressure was noted in 70%, reducing to 55%, with 5% developing persistent hypertension. No cases of hyperglycemia, cataracts, or glaucoma were detected. All children exhibited global developmental delay, which was unrelated to adrenal function. AI was not significantly associated with age, gender, socioeconomic status, stunting, hypertension, or cumulative prednisolone dose.
Conclusions
AI is universal following high-dose prednisolone therapy in children with epileptic spasms but shows significant recovery within 6–8 weeks. Routine adrenal function testing is essential to identify at-risk children, minimizing the risk of adrenal crisis and guiding the rational use of stress-dose steroids.

Keywords: Adrenal insufficiency, ACTH stimulation test, Cortisol.

Table 1 Baseline and ACTH stimulated serum cortisol levels at the first and second assessments.

	Mean (s.d.)			
	First assessment (5 days post-therapy)	Second assessment (6–8 weeks post-therapy)	Mean difference [95% CI]	*P*-value
Basal serum cortisol (ug/dl)	7.15(2.34)	14.72(2.26)	7.58[6.86 to 8.29	<0.001*
ACTH stimulated serum cortisol at 1 hr. (ug/dl)	9.08(2.58)	18.03(2.24)	8.95[8.28 to 9.61]	<0.001*

P value <0.05 – significant

Brain and behavior in primary adrenal insufficiency – with emphasis on the precuneus & orbitofrontal cortex

Diana Kancsar[1], Annelies van't Westeinde[1] & Svetlana Lajic[1]
[1]Karolinska Institute, Women's and Children's health, Paediatric Endocrinology Unit, Stockholm, Sweden

Context
Primary adrenal insufficiency (PAI), including congenital adrenal hyperplasia (CAH) and autoimmune Addison's disease (AAD), result in low cortisol levels and abnormal sex hormone levels due to adrenal cortex dysfunction. Previous studies on PAI found that the hormonal imbalance can alter brain structure and connectivity, affecting multiple brain areas including the left precuneus and the orbitofrontal cortex. These brain areas are major hubs in the brain, and alterations may lead to changes in structural and functional connectivity between the hub and other networks, which in turn could contribute to cognitive impairments and mental health issues. *Objective*: This study analyzed changes in structural and functional connectivity of the left precuneus and orbitofrontal cortex between patients with PAI and control subjects.
Design, setting, and participants
A total of 150 participants were included in the analysis: 29 individuals with CAH (18 females), 55 patients with AAD (33 females), and 66 healthy controls (37 females), aged 16 to 43 years, from a single research institute. All subjects underwent functional and structural magnetic resonance imaging (MRI).
Results
In patients with AAD, the resting-state functional connectivity analyses showed a decreased connectivity between the left precuneus and the left insula compared with the healthy controls. The analyses also showed a decreased connectivity between the orbitofrontal cortex and the left insula compared with the healthy controls. No such differences in functional connectivity were found in patients with CAH compared to controls. In contrast, CAH patients had impaired white matter microstructure in the left precuneus and orbitofrontal cortex, while patients with AAD did not.
Conclusions
The results suggest that long-term cortisol imbalances in primary adrenal insufficiency led to altered functional connectivity of the precuneus and orbitofrontal cortex in AAD, but not CAH. The underlying effects of these differences remain unexplained. Further research is needed to investigate the influence of the changes in functional connectivity and white matter and their relevance to cognitive functioning and mental health.

Background
Individuals with *NR5A1*/SF-1 variants encompass a wide spectrum of phenotypes, ranging from asymptomatic carriers to severe forms of differences of sex development (DSD). The mechanisms contributing to this wide variability of observed phenotypes remains elusive. Oligogenicity has been suggested as a potential mechanism. We aimed to investigate the oligogenicity patterns in individuals with *NR5A1*/SF-1 variants from the international SF1next study cohort, shedding light on how multiple genetic variants collectively influence DSD phenotypes.
Methods
DNA samples and comprehensive DSD phenotype data from individuals carrying *NR5A1*/SF-1 variants, and available family members, were collected from the SF1next study cohort. Whole exome sequencing (WES) data of 30 individuals/families were utilised. WES data were analysed using a tailored filtering algorithm to identify rare variants in SF-1- and DSD-related genes. Identified variants were assessed for potential pathogenicity based on American College of Medical Genetics and Genomics (ACMG) and clinical disease associations in related databases. Oligogenic combinations between the additional variants and the specific *NR5A1*/SF-1 variants were tested using Oligogenic Resource for Variant Analysis (ORVAL). Genotype–phenotype correlations were explored by integrating these findings with the phenotype data.
Results
Novel genetic workup of 30 individuals detected rare, additional variants in SF-1- and DSD-related genes. The phenotype of these individuals, all with 46,XY karyotype, ranged from severe to opposite-sex DSD. Using ORVAL, oligogenic pathogenic combinations were found in 73% (22/30) individuals, with one to seven additional variants per individual, predominantly in DSD-related genes. We found identical variants in eight unrelated individuals with DSD in DSD-related genes (e.g., *TBCE, FLNB, GLI3* and *PDGFRA)* and different variants in eight genes frequently associated with DSD (e.g., *CDH23, FLNB, GLI2, KAT6B, MYO7A, PKD1, SPRY4* and *ZFPM2*) in 15 index cases. Our study also identified combinations with *NR5A1*/SF-1 variants and variants in novel candidate genes.
Conclusion
Our study shows that in 3 out of 4 individuals with a *NR5A1*/SF-1 variant and a 46,XY DSD, additional genetic variants may explain the broad variability of the DSD phenotype, indicating oligogenicity. Thus, the genetics explaining the DSD phenotype in many individuals and their families might be more complex than previously thought.

Background
Approximately 25% of patients with primary aldosteronism (PA) exhibit mild autonomous cortisol secretion (MACS). Patients with PA and MACS have an increased incidence of cardiovascular events compared to patients with PA without MACS. However, the characterization of aldosterone lateralization, histopathology, and outcomes among patients with PA and MACS is not well established.
Aims
To evaluate the origins of aldosterone and cortisol secretion in patients with PA and MACS who underwent adrenalectomy, and to compare clinical and biochemical aspects, histology and outcomes between PA patients with and without MACS.
Methods
We conducted a cohort study including 197 patients with PA who underwent investigation for MACS using a 1 mg dexamethasone suppression test at a single tertiary center. MACS was characterized by cortisol $\geqq$ 1.8 mcg/dL with dexamethasone levels $>$ 130 ng/dL. Histology was investigated using CYP11B2 and CYP11B1 immunostaining in adrenal lesions.
Results
MACS was diagnosed in 52 (26.4%) out of 197 patients with PA. Among the 52 patients with MACS, 29 (55.8%) underwent adrenal venous sampling (AVS) under cosyntropin stimulation, and 25 (48.1%) underwent surgical treatment. Patients with PA and MACS were statistically significantly older at the time of PA diagnosis compared to patients with isolated PA (57.15 [range] vs. 52.58 [range] years; $P=$X). Other clinical and biochemical features at diagnosis and PASO outcomes were not different between the two groups. Moreover, the frequency of unilateral and bilateral PA was X% and Y% in patients with PA and MACS, respectively. Interestingly, aldosterone and cortisol were produced by different adrenal lesions in 7 (38.9%) out of 18 cases with immunostaining (unilateral cortisol secretion and bilateral PA): a unilateral cortisol-producing adenoma (positive for CYP11B1 and negative for CYP11B2) and bilateral aldosterone-producing nodules or micronodules (positive only for CYP11B2). Eleven (61.1%) out of 18 patients had an aldosterone lesion (adenoma or nodule?) producing both aldosterone and cortisol.
Conclusion: For the first time, we demonstrate that aldosterone and cortisol originate from distinct adrenal lesions in nearly 40% of patients with PA and MACS. This finding has critical implications for the interpretation of AVS and the planning of surgical treatment. Support: Sao Paulo Research Foundation (FAPESP) grant 2019/15873-6 (to M.Q.A.)

Ready, steady, go: an exploration of the knowledge and self-management skills of patients with congenital adrenal hyperplasia during transition

Judith van Eck[1], Kirsten Davidse[2,3], Erica van den Akker[1] & Laura De Graaff[2,3,4]

[1]Erasmus University Medical Centre – Sophia Children's Hospital, Department of Paediatric Endocrinology, Rotterdam, Netherlands; [2]Erasmus University Medical Centre, Department of Internal Medicine, Division of Endocrinology, Rotterdam, Netherlands; [3]Erasmus University Medical Centre, Department of Internal Medicine, Centre for Rare Genetic Syndromes, Rotterdam, Netherlands; [4]Radboud University Medical Centre, Department of Internal Medicine, Division of Endocrinology, Nijmegen, Netherlands

Introduction
In the past years increasing priority is given to the transition from child to adult care. Goals during the transition process focus on the knowledge about the

chronic condition, the ability of adolescents and young adults to manage their chronic condition, effectively utilize healthcare services, and ensure an organized and structured transfer of care and integration into adult care. In 2017 the transition service Young Adult Clinic (YAC) is launched in the Erasmus University Medical Centre. One of the tools used in the transition service is the generic transition questionnaire Ready Steady Go (RSG), for identifying gaps in knowledge, self-management skills, social skills and general health management. Since 2022, the RSG age-appropriate questionnaire has been sent annually to patients in the transition phase. For patients with adrenal insufficiency, for example congenital adrenal hyperplasia (CAH), a questionnaire regarding corticosteroid use and sick day rules is added.

Methods

We evaluated RSG questionnaires sent to eleven patients with CAH who made the transfer since the start of the annual RSG in our YAC.

Results

Two of the 11 patients started with the questionnaire in the paediatric department, at the age of 16, another two at the age of 17. In seven of the 11 patients the questionnaire was first sent when they were already in the adult care, varying in age between 18 and 21 years. One of the seven patients did not respond. At the age of 16 the two adolescents with CAH had sufficient knowledge about corticosteroid replacement therapy, but insufficient knowledge about causes and presenting symptoms of an acute adrenal crisis. After transfer to the adult clinic patients are eager to know more about their condition and are open for education, for example about side effects of medication and how to prevent an acute adrenal crisis. Most of the patients who completed the questionnaire at the age of 20 or 21 indicate to have adequate knowledge and self-management skills to manage their condition.

Conclusion

A generic questionnaire like the RSG can help identify gaps in knowledge and self-management skills in patients with CAH. Disease specific questionnaires about corticosteroid replacement therapy helps to gain specific self-management skills. The patients had comparable topics they wanted to address during consultations and showed adequate knowledge and self-management skills around the age of 21. These findings endorse the importance of starting transition early in adolescence and continuing well into adulthood.

Background

Aldosterone-producing adenoma (APA) is a major cause of primary aldosteronism (PA), the most prevalent form of secondary hypertension. While significant progress has been made in identifying somatic mutations in genes driving aldosterone secretion, the pathophysiology of PA remains partially understood. Recent studies have revealed that Substance P (SP), a neuropeptide encoded by the *TAC1* gene, stimulates aldosterone production by activating the neurokinin type 1 receptor (NK1R) in the adrenal cortex. The aim of this study was to explore the expression and distribution of SP and NK1R in APA tissues and to evaluate their role in aldosterone hypersecretion.

Methods

56 APA tissues were analyzed using quantitative RT-PCR, immunohistochemistry, and functional studies. The expression levels of *TAC1* and *TACR1* mRNAs were quantified to assess transcription of SP and its receptor NK1R. Immunohistochemical staining was performed to determine localization and protein expression of SP and NK1R. Functional studies were performed on primary APA cell cultures and perifused APA explants to evaluate the effects of SP on aldosterone secretion and the inhibitory potential of the NK1R antagonist aprepitant. Aldosterone pulsatility was analyzed in perifusion profiles by assessing the mean aldosterone levels, the nadir levels, the pulse frequency, the mean pulse interval, the pulse amplitude, and the integrated aldosterone secretion (area under the curve, AUC).

Results

Quantitative RT-PCR revealed significant expression levels of *TAC1* and *TACR1* mRNAs in APA tissues. Immunohistochemistry detected SP-positive nerve fibers in 90% of APA samples, with granular SP staining observed in a subset of adenoma cells. NK1R expression was identified in both adenoma cells and adjacent adrenal tissue with co-localization of NK1R and aldosterone synthase (CYP11B2) noted in 60% of adenomas. SP dose-dependently increased aldosterone secretion in 6 out of 10 APA cell primary cultures (EC$_{50}$ = 1.7 ± 0.3 nM; $P<0.01$). The NK1R antagonist aprepitant, significantly inhibited SP-induced aldosterone secretion in 3 out of 4 responsive APA samples ($P<0.01$). In perifusion experiments, SP administration increased the integrated aldosterone response, as measured by the area under the curve (AUC) by 153% ($P<0.05$).

Conclusion

These findings demonstrate that SP stimulates aldosterone production in APAs, through neurocrine and paracrine mechanisms, by activating the NK1 receptor. Targeting the SP-NK1R axis with NK1R antagonists, such as aprepitant, represents a promising therapeutic approach for a subset of patients with primary aldosteronism.

Molecular mechanisms of glucocorticoid sensitivity: insights from a novel transgenic mouse model

Margaux Laulhé[1,2], Yann Pelloux[3], Sarah Djellout[1], Thivya Rajkumar[1], Julie Perrot[4], Andrea Arzel[1], Peter Kamenicky[1,4], Say Viengchareun[1] & Martinerie Laetitia[1,2]

[1]Université Paris-Saclay, Inserm, Physiologie et Physiopathologie Endocriniennes, Le Kremlin Bicêtre, France; [2]APHP, Department of Pediatric Endocrinology, Reference Center for Growth and Development Endocrine Diseases, Hôpital Universitaire Robert-Debré, Paris, France; [3]Université Paris-Saclay, Inserm, Mood-Cesp, Le Kremlin Bicetre, France; [4]APHP, Department of Endocrinology and Reproductive Diseases, Bicêtre Paris-Sud Hospital, Le Kremlin Bicetre, France

Synthetic glucocorticoids are extensively prescribed. Although they improved the management of chronic inflammatory diseases, these treatments are also associated with numerous adverse effects, with an inter-individual variability that remains poorly understood. Glucocorticoids exert their effects *via* the glucocorticoid receptor (GR), encoded by the *NR3C1* gene. Only few variants associated with glucocorticoid sensitivity have been described and the molecular mechanisms involved are not fully understood. The N363S variant, which encodes for substitution of an asparagine with a serine at amino acid 363, has been associated with increased glucocorticoid sensitivity, but has never been further characterized. Performing *in vitro* studies, we demonstrated that maximal transactivation activity (GR_{WT} 93,8% ± 5.1 *vs* GR_{N363S} 142.6% ± 9,0, $n=38$, $P<0.0001$) and target gene expression were higher in response to dexamethasone in HEK 293T cells expressing the variant. Next, we aim to assess the impact of the N363S variant *in vivo* using a novel mouse model expressing the variant. As the mutated amino acid is conserved across species, we introduced a point mutation into the coding sequence of the mouse *Nr3c1* gene (c.1139 A>G), using the CRISPR/Cas9 system. The genotype (Wild type: WT; heterozygous: HET; homozygous: HOM) was assessed by PCR. First, we evaluated the impact of the variant on weight, glucose metabolism, and HPA axis activity without any glucocorticoid treatment. Next, we studied its impact on glucocorticoid-induced adverse effects after treatment with dexamethasone (1 mg/kg/d) for 28 days *via* osmotic pumps. The viability and fertility of the mice were not affected by the genotype. In absence of dexamethasone treatment, we observed no genotype-based differences in adrenal gland weight, corticosterone secretion levels after a single intraperitoneal administration of dexamethasone (WT 9.4 ng/ml [3.5;12.2]; HET 4.4 ng/ml [2.6;6.2]; HOM 9.6 ng/ml [4.8; 12.6], $n=4$), glucose metabolism (fasting glycemia, WT 117 mg/dL[90;145], HET 107 mg/dL [95;121], HOM 96 mg/dL [83;138], $n=3$) or behavioral outcomes. The impact of the N363S

variant on the development of adverse effects, such as glucocorticoid-induced adrenal insufficiency, impaired glucose metabolism and depressive features, is currently being investigated after prolonged dexamethasone treatment. Overall, we developed a novel mouse model expressing the N363S variant of the *Nr3c1* gene that will improve scientific knowledge on glucocorticoid sensitivity. Further, the N363S variant could be used as a predictive tool for personalized medicine.

Real word incidence of adrenal insufficiency after long-terme use os systemic and inhaled corticosteroids

Patricia Vaduva[1], Fabrice Bonnet[1], Gregoire Fauchier[2], Gerald Raverot[3], Jérôme Bertherat[4] & Laurent Fauchier[5]

[1]Department of Endocrinology, Diabetes, Nutrition; Rennes University Hospital, Rennes, France; [2]Department of Endocrinologi, Diabetes and Nutrition, Orleans University Hospital, Orleans, France; [3]Department of Endocrinology, Groupement Hospitalier Est, Hospices Civils de Lyon, Bron, France; [4]Department of Endocrinology, Cochin Hospital, APHP, Paris, France; [5]Department of Cardiology, Tours University Hospital, Tours, France

Aim

The incidence of adrenal insufficiency following chronic use of both systemic and inhaled corticosteroids remains poorly known. The aim of our study was to assess the incidence of hospitalization for adrenal insufficiency (AI) after long-term use of systemic and inhaled corticosteroids in a large population-based cohort.

Methods

We used TriNetx Research Collaborative network, with access to electronic medical records from a number of participating health care organizations, to identify participants. Diagnosis was done using the International Classification of Diseases codes, and data on medications were studied. We included individuals who were treated with long-term systemic or inhaled only corticosteroids. We excluded those with a past history of causes of primary and secondary adrenocortical insufficiency. We used a 1:1 propensity-score to compare matched subjects treated by long term systemic ($n=243{,}430$) or inhaled ($n=315{,}237$) steroid to subjects treated by NSAID only.

Results

Mean age of the population studied was 56.5 ± 18 years, with 40% of men. Over a mean follow-up of 2.4 ± 1.9 years, long-term systemic corticosteroids use was associated with a more frequent diagnosis of AI (0.20% vs 0.04% per year; HR: 6.32, 95%CI [5.50–7.26], $P<0.001$) and a greater incidence of hospitalization for AI (0.02% vs 0.008% per year; HR: 3.52, 95%CI [2.57–4.84], $P<0.001$) as compared to individuals treated with NSAID. Long-term inhaled corticosteroids use was associated with a more common diagnosis of AI (0.05% vs 0.04% per year; HR: 1.55, 95%CI [1.34–1.80], $P<0.001$), without increased risk of hospitalization for AI (0.01% vs 0.01% per year; HR: 1.26, 95%CI [0.91–1.76], $P=0.17$) as compared to NSAID therapy.

Conclusions

Long-term use of systemic corticosteroids was associated with an increased risk of diagnosed AI with a greater incidence of hospitalization for AI over a 2.4-year follow-up. Inhaled corticosteroids use was associated with an increased incidence of diagnosed AI. These findings from a large real world-based cohort underscore the importance of preventing the onset of corticotropic insufficiency among individuals with long-term corticosteroids treatment.

Background

Identification of unilateral disease in most patients with primary aldosteronism (PA) currently relies on invasive adrenal vein sampling (AVS). Positron emission tomography (PET) of the adrenal glands is emerging as a non-invasive alternative for treatment selection. The C-X-C chemokine receptor type 4 (CXCR4) tracer ^{68}Ga-PentixaFor has shown potential in visualising aldosterone-producing adenomas. However, real-world data for this novel method are still scarce. Here we present the currently largest European single-centre series of ^{68}Ga-PentixaFor PET/CT in patients with PA.

Methods

Between 11/2023 and 01/2025 35 patients underwent ^{68}Ga-PentixaFor PET/CT. The likelihood of unilateral disease was assessed qualitatively (visual inspection) and quantitatively (calculation of SUVmax-ratio). Treatment decisions were based on a combination of PET and AVS (where available). Subsequently, an expert centre for molecular imaging reviewed all PET scans blinded to AVS results. Postoperative outcomes were analysed based on the Primary Aldosteronism Surgery Outcome (PASO) criteria.

Results

PET was successfully completed in 35/35 patients and was reported as suggestive of unilateral disease by the local team in 18 (51%) patients. Of 22 patients who also underwent AVS, 12 (55%) had successful bilateral cannulation; 8 of these (36% of 22) demonstrated unilateral disease (6 were also identified on PET). When (partial) AVS data was combined with PET, high confidence to diagnose unilateral disease was reached for 12/22 (55%) patients who had both investigations. There was good agreement between the initial local and external expert reports in 28/35 (80%) cases. Following a second round of local reading with harmonized criteria (blinded to external reports), concordance increased to 33/35 (94%) cases; in two patients, intermediate probability of unilateral disease was only diagnosed by one centre. At the time of this analysis nine patients had undergone adrenalectomy, two informed by AVS, one informed by PET and AVS, and six informed by PET. Outcome data indicate complete biochemical remission in 2/2 operated patients based on AVS, 5/6 operated patients informed by PET, and 1/1 guided by both. The remaining patient showed partial remission. In two AVS, adverse events were reported (retroperitoneal hematoma, infection) while no adverse events were associated with PET.

Conclusion

Our initial experience with ^{68}Ga-PentixaFor PET/CT highlights its potential as a non-invasive additional modality to AVS for PA subtyping. Combining data from AVS and PET can expand achievement of definitive cure. Further studies are needed to validate PET interpretation criteria and better identify cases in which PET alone might suffice for PA subtyping.

JOINT2036

A retrospective longitudinal study on the association between urine metanephrines and cardiovascular events in patients in primary prevention without chromaffin tumors

Mirko Parasiliti Caprino[1], Martina Bollati[1], Elisa Febbraro[1], Daniele Giuseppe Candela[1], Matteo Procopio[1], Stefano Arata[1], Chiara Lopez[1], Fabio Bioletto[1], Federico Ponzetto[1], Giulio Mengozzi[2], Ezio Ghigo[1] & Mauro Maccario[1]

[1]Endocrinology, Diabetes and Metabolism, University of Turin, Turin, Italy; [2]Clinical Biochemistry Laboratory, University of Turin, Turin, Italy

Background

Previous studies have suggested that urine metanephrines (metanephrine, dU-MT, and normetanephrine, dU-NMT), metabolites of catecholamines used in the

diagnosis and follow-up of pheochromocytomas and paragangliomas (PPGL), may serve as markers of sympathetic nervous system (SNS) hyperactivation. SNS overactivity has been observed in various cardiometabolic disorders such as hypertension, heart failure, and metabolic syndrome. However, the predictive role of metanephrines in cardiovascular events (CVE) remains unexplored.
Objectives
This retrospective longitudinal study aims to assess the association between urine metanephrine levels and the development of CVE in patients in primary prevention without PPGL.
Methods
Adult patients who underwent measurement of 24-hour urine fractionated metanephrines at the Clinical Biochemistry Laboratory of the City of Health and Science University Hospital of Turin between 2007 and 2015 were included in the analysis. Patients were stratified into tertiles based on dU-MT and dU-NMT levels. Exclusion criteria encompassed a diagnosis of PPGL, prior CVE, interfering therapies, acute conditions at the time of testing, and stage IV-V chronic kidney disease. CVE development (coronary artery disease, stroke, symptomatic peripheral artery disease, arrhythmias, and heart failure) was assessed by retrieving pertinent discharge diagnoses from a regional database, restricting the evaluation to hospital admissions that occurred after the measurement of urine metanephrines.
Results
The final population consisted of 1,170 individuals (41.5% male, mean age 54 $\pm$ 14 years), 86% of whom had arterial hypertension. During a mean follow-up period of 11.7 $\pm$ 4.1 years, 14.7% of patients experienced a CVE. In univariate analysis, patients in the 2nd and 3rd tertiles of dU-NMT showed lower CVE-free survival compared to those in the 1st tertile ($P=0.020$ and $P < 0.001$, respectively). Multivariate Cox regression analysis revealed that patients in the 3rd tertile of dU-NMT had a 1.76-fold increased risk of CVE compared to those in the 1st tertile ($P=0.010$), regardless of traditional cardiovascular risk factors (age, sex, smoking status, family history of CVE, hypertension, and diabetes mellitus), renal function, number of antihypertensive drugs, and lipid-lowering therapy. Tertiles of dU-MT, however, did not show a significant difference in CVE risk.
Conclusions
This study reveals an association between higher dU-NMT levels and increased long-term risk of CVE, regardless of traditional risk factors, within a primary prevention cohort of patients without PPGL. These findings suggest that such metabolites could serve as a valuable tool for cardiovascular risk stratification.

Background
Adrenal insufficiency (AI) under glucocorticoid replacement therapy, adrenocortical tumors with mild autonomous cortisol secretion (MACS), and Cushing syndrome (CS), are characterized by different patterns of dysregulation of cortisol circadian rhythm. Despite the relationship between cortisol and energy metabolism is established, little is known about circadian-specific metabolic derangements in any of these conditions.
Aim
To characterize circadian fluctuations of acylcarnitines, sphingomyelins, glycerophospholipids, amino acids, and biogenic amines in healthy subjects (HS), and in patients affected by AI, MACS, and CS in dried blood spots (DBS).
Methods
We enrolled patients with AI ($n=8$) under dual-release hydrocortisone, and subjects with MACS ($n=12$) and CS ($n=9$) at diagnosis. HS ($n=10$) were drawn from the general population. All subjects underwent a 7-days standardized isocaloric Mediterranean diet. On day 7th, subjects collected DBS samples 30 minutes before and 2 hours after each meal (breakfast, lunch, and dinner), and at 11 pm. We measured 21 amino acids, 21 biogenic amines, 40 acylcarnitines, 15 sphingomyelins, and 90 glycerophospholipids by a targeted metabolomics LC–MS/MS method previously validated for DBS. Data were explored by a two-step approach. Firstly, a BORUTA algorithm trained on disease groups separation was performed. According to an all-features-matter approach, permutations of features were tested in a random forest classifier, pruning out uninformative features and keeping features describing differences among groups. Secondly, Factor Analysis (FA) was applied to reduce data dimensionality. To characterize the circadian fluctuation of interesting molecular patterns, the linear combination of selected molecule concentrations and FA-derived coefficients was evaluated along the 7 time-points.
Results
Two molecular patterns were highlighted. In pattern A, phosphatidylcholine (PC)-ae-C34:2, PC-ae-C34:3, PC-aa-C34:2, PC-aa-C36:2 and PC-aa-C36:0 differentiated HS from patients with AI, MACS, and CS. Overall, higher concentrations were detected in HS with respect to disease groups, with maximum difference at 2 hours after lunch ($P<0.05$). In pattern B, PC-aa-C38:4, PC-aa-C36:4, lysoPC-a-C20:4, PC-aa-C36:5 and Met differentiated HS and patients with AI from those with MACS and CS. In particular, patients with CS and MACS showed higher concentrations than HS and patients with AI, with maximum differences at 2 hours after lunch and 30 minutes before dinner ($P<0.05$ for both). At the same time-points, patients with AI had lower levels of compounds of pattern B than HS ($P<0.05$).
Conclusions
The phosphatidylcholine system is predominantly affected in different states of glucocorticoid replacement and cortisol excess. Dysregulation is mostly evident in the afternoon. Phosphatidylcholines appear relevant biomarkers of cortisol-related metabolic alterations.

Cardiac function and morphology in patients with adrenal incidentalomas: a longitudinal study

Dario De Alcubierre[1], Davide Ferrari[1], Alessandra Tomaselli[1], Federica Moscucci[1], Aurora Francia[1], Ilaria Bonaventura[1], Valeria Hasenmajer[1], Marianna Minnetti[1], Riccardo Pofi[2] & Andrea Isidori[1]
[1]Sapienza University of Rome, Department of Internal Medicine and Medical Specialties, Rome, Italy; [2]University of Oxford, Churchill Hospital, Oxford, Oxford Centre for Diabetes, Endocrinology and Metabolism, NIHR Oxford Biomedical Research Centre, Oxford, UK

Background
Emerging evidence suggests that mild autonomous cortisol secretion (MACS) might be directly associated with increased cardiac mass and diastolic dysfunction compared to non-functioning adrenal incidentalomas (NFAI). Nevertheless, the reversibility of these alterations following appropriate treatment has never been investigated. This study evaluated cardiac morphology in patients with adrenal incidentalomas over a 5-year follow-up period, comparing the effects of active surveillance to adrenalectomy in patients with MACS.
Methods
This prospective longitudinal case–control study included 60 patients with adrenal incidentalomas. After stratification based on cortisol levels post-dexamethasone suppression test, 34 patients with MACS and 26 with NFAI were evaluated for clinical, biochemical, and echocardiographic parameters at baseline and after 1 and/or 5 years of follow-up. Patients with MACS were managed either with active surveillance (AS, $n=23$) or unilateral adrenalectomy (ADRX, $n=11$), according to current recommendations.
Results
At baseline, patients with MACS showed higher left ventricular mass index (LVMi, $P=0.021$), interventricular septal (IVS) ($P=0.007$), and posterior wall (PW) thickness ($P=0.004$) compared to NFAI, along with higher prevalence of diastolic dysfunction and left ventricular hypertrophy ($P=0.050$ and $P=0.013$). Patients undergoing ADRX presented with larger adrenal mass diameters, higher prevalence of arterial hypertension, and lower ACTH levels ($P<0.001$ for all). After 1 year, the ADRX group showed a significant reduction in LVMi ($P=0.031$), IVS ($P=0.042$), and PW thickness ($P=0.037$), followed by a progressive increase to baseline values at the 5-year timepoint. The AS group showed overall long-term stability in cardiac parameters, while the NFAI group showed a significant, progressive increase of cardiac indexes through the 5-year follow-up. Accordingly, the ADRX showed a significantly higher decrease in

LVMi and PW thickness compared to the other two groups at the 1-year follow-up, even adjusting for sex and age ($P<0.001$, $P=0.003$). No significant inter-group differences were detected at the 5-year follow-up. In patients with MACS, linear regression analysis showed that unilateral adrenalectomy was the element most strongly associated with the 1-year improvement in LVMi ($R^2=0.423$, $P=0.017$) and PW thickness ($R^2=0.422$, $P=0.023$). The overall progression of the main cardiometabolic comorbidities remained comparable among the three groups.

Conclusions

Patients with MACS exhibit early cardiac remodelling compared to NFAI, independent of conventional risk factors. Unilateral adrenalectomy induced short-term improvement in cardiac parameters, which was not maintained on the long-term. Active surveillance in MACS resulted in long-term cardiac stability, likely reflecting the more intensive cardiovascular monitoring compared to NFAI, and underscoring the importance of cardiovascular monitoring to pursue individualized treatment strategies.

Correlation of morning cortisol with HPA axis response to insulin-induced hypoglycemia in children

Nattakarn Numsriskulrat[1,2], Khomsak Srilanchakon[3] & Vichit Supornsilchai[1]

[1]Department of Pediatrics, Faculty of Medicine, Chulalongkorn University, Pediatrics, Bangkok, Thailand; [2]Division of Academic Affairs, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [3]Division of Pediatric Endocrinology, King Chulalongkorn Memorial Hospital, Pediatrics, Bangkok, Thailand

Background

Diagnosis of adrenal insufficiency (AI) in children requires formal cortisol stimulation test which is time-consuming and costly. While morning cortisol levels has been proposed to predict hypothalamic–pituitary–adrenal (HPA) axis integrity in adults, data on children are limited. This study aimed to investigate the association between basal morning cortisol and peak cortisol response to the insulin tolerance test (ITT), the gold standard for diagnosing adrenal insufficiency, and to establish morning cortisol cutoff values for predicting AI in children.

Method

This retrospective study includes all children aged <18 years who underwent ITT to evaluate the cause of short stature. Subjects with prior steroid use and known pituitary or adrenal diseases were excluded. We collected data on age, sex, anthropometry, Tanner stages, glucose levels, baseline and peak cortisol levels, and cortisol increment (peak–baseline) during ITT. AI was defined as a peak cortisol level from ITT <18 mcg/dL measured by Chemiluminescence Immunoassay. The Mann–Whitney U test compared data between AI group and normal HPA group (nHPA). Spearman's rho correlation assessed association between variables. ROC analysis determined optimal cortisol cutoff values for predicting AI.

Result

Of the 108 subjects, 70 (64.8%) were male. The median age was 9.4 years (4.3–17.2). AI was diagnosed in 50 (46.3%) of the subjects. Compared to the nHPA, the AI showed significantly lower baseline morning cortisol (9.7 [4.7] vs. 12.6 [6.4] mcg/dL, $P=0.018$), and a significant smaller cortisol increment during ITT (3 [7.9] vs. 9.7 [10.7] mcg/dL, $P<0.001$). Baseline morning cortisol levels were positively associated with peak cortisol levels from ITT ($r=0.336$, $P<0.001$), particularly in the AI group ($r=0.535$, $P<0.001$). Peak cortisol levels correlated with cortisol increment ($r=0.45$, $P<0.001$), but not with age, anthropometry, Tanner stage, or gender. Regarding the morning cortisol levels, the cutoff of $<$ 6.3 mcg/dL showed highest sensitivity (34%) and specificity (86.2%), although the best cutoff to predict AI was <4.8 mcg/dL (sensitivity 22%, specificity 91.4%), and the best cutoff to predict nHPA was >16.7 mcg/dL (sensitivity 90% and specificity 31%)(AUC 0.632, $P=0.013$). The cortisol increment cutoff of $<$ 8.7 mcg/dL from ITT showed the best sensitivity (82%) and specificity (60%) to predict AI in children (AUC 0.737, $P<0.001$).

Conclusion

Basal morning cortisol levels and cortisol increment were well correlated with peak cortisol response to ITT and could be used to predict AI in children, potentially reducing the need for further unnecessary procedures. Further investigation in larger cohorts is warranted to validate these findings.

JOINT1137

Pseudohypoaldosteronism in infantile atopic dermatitis: a case series

Aimee Jacquemot[1], David Taylor[2], Emily Derrick[3] & Ritika R Kapoor[4,5]

[1]Evelina Children's Hospital, Paediatric Nephrology, London, UK; [2]King's College Hospital NHS Foundation Trust, Department of Clinical Biochemistry (Synnovis), London, UK; [3]University Hospital Lewisham, London, UK; [4]Variety Children's Hospital, King's College Hospital NHS Foundation Trust, Department of Paediatric Endocrinology, London, UK; [5]King's College London, Faculty of Medicine and Life Science, London, UK

Recent literature has highlighted a potential association between severe atopic dermatitis (AD) in infancy and biochemical disturbances resembling pseudohypoaldosteronism (PHA), though the mechanisms behind these disturbances remain poorly understood. We present a case series of three children, aged three to seven months, who were admitted with severe exudative eczema and were found to be hyponatraemic (sodium levels 115–129 mmol/l) and hyperkalaemic (potassium levels 6.3–7.4 mmol/l) on routine blood testing. Screening for PHA revealed elevated aldosterone levels with hyperreninaemia and increased urinary corticosterone and aldosterone metabolites providing further evidence of activation of the renin–angiotensin system (RAS). In each case, these biochemical and hormonal disturbances resolved after optimising dermatological and nutritional management of their atopic presentations. Trans-epidermal sodium loss driving volume depletion has commonly been hypothesised to determine both hyponatraemia and RAS activation in severe eczema, but direct evidence in support of this mechanism remains sparse. In all three cases, the patients exhibited low urinary sodium levels despite elevated aldosterone and renin, suggesting a compensatory response to hypovolaemia rather than renal tubular resistance to aldosterone. We also explore other potential contributing factors, including gastrointestinal protein and sodium loss due to increased permeability in the gastrointestinal tract, which is common in children with severe eczema and food allergies. Chronic inflammatory states associated with severe AD may also induce dilutional hyponatraemia and disrupt potassium handling in the kidneys. Furthermore, age-related factors such as low muscle mass and the physiological unresponsiveness to aldosterone in infancy may exacerbate electrolyte imbalances and complicate the clinical picture. This case series contributes to the sparse but growing body of literature on pseudohypoaldosteronism-like disturbances in severe infantile atopic dermatitis. The findings underscore the multi-system impact of severe eczema, highlighting the importance of considering not only dermatological management but also biochemical and hormonal factors in the comprehensive treatment of infantile AD. These cases reinforce the need for a holistic, multidisciplinary approach to early management in order to prevent severe complications, including electrolyte imbalances and nutritional deficiencies, that can arise in the context of this chronic inflammatory condition.

[1]Unit of Pediatric Endocrinology, Department of Medical and Translational Sciences, University of Naples Federico II, Naples, Italy; [2]Department of Pediatrics, IRCCS San Raffaele Scientific Institute, Milan, Italy; [3]Department of Pediatrics, Hospital of Bolzano (SABES-ASDAA)Italy; Teaching Hospital of Paracelsus Medical University, Bolzano, Italy; [4]Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, University of Genoa, Pediatric Endocrinology Unit, Department of Pediatrics, IRCCS Istituto Giannina Gaslini, Genoa, Italy; [5]Department of Medicine and Surgery, University of Parma, Parma, Italy; [6]Unit of Paediatrics, University Hospital of Parma, Parma, Italy, Department of Medicine and Surgery, University of Parma, Parma, Italy; [7]Pediatric Unit, Department of Precision and Regenerative Medicine and Ionian Area (DiMePre-J), Medical School, University of Bari Aldo Moro, Bari, Italy; [8]Regina Margherita Children's Hospital, Pediatric Endocrinology, Department of Public Health and Pediatric Sciences, University of Turin, Turin, Italy

Background
Modified-release hydrocortisone (MR-HC) has been developed to mimic the cortisol rhythm and has recently been approved to improve the disease control in children with Congenital Adrenal Hyperplasia (CAH) due to 21-hydroxylase deficiency (21OHD), older than 12 years. Aim of this multicenter study is to assess the efficacy and safety of MR-HC in a national cohort of children.
Study population and methods
71 children with 21OHD (25M/46F; age 15.3 ± 2.4 years) were evaluated before and after 6 months of MR-HC. Fifty-four (76.1%) had classic form of 21OHD (66.2% salt wasting) and 17 (23.9%) the non-classic form. Before to switching to MR-HC, all patients were receiving conventional HC at an average dose of 16.0 ± 4.0 mg/m^2 per day. General wellbeing, adverse effects (AE), frequency of adrenal crisis (AC), Body Mass Index (BMI), systolic (SBP) and diastolic blood pressure (DBP), ACTH, 17-Hydroxyprogesterone (17OHP), Androstenedione, Renin, Insulin, HOMA IR levels and lipid profile were assessed before and after 6 months of MR-HC. Primary outcome was the change in 17OHP levels at 9.00 am; secondary outcomes included changes in other adrenal precursors, body mass index (BMI), insulin sensitivity, general wellbeing and the frequency of AE and AC.
Results
After 6 months of MR − HC, 17OHP (12.5 ± 26.0 vs 25.5 ± 35.0 ng/ml, $P = 0.005$) and ACTH (37.8 ± 56.9 vs 141 ± 233 pg/ml, $P = 0.001$) levels significantly decreased compared to pre − treatment values, despite the HC dose remained unchanged (15.80 ± 3.68 vs 16.0 ± 4.0 mg/m^2/day). Androstenedione (2.2 ± 1.8 vs 2.7 ± 1.9 ng/ml) and Renin (61.6 ± 54.0 vs 82.3 ± 85.0, pg/ml) levels also decreased, but these changes were not statistically significant. Insulin (14.9 ± 6.0 mcUI/ml vs 16.2 ± 7.0) and HOMA − IR (2.8 ± 1.56 vs 3.02 ± 1.7) showed slight, but not significant reductions. No significant changes were observed in BMISDS, SBP, DBP and lipid profile during MR-HC treatment. General wellbeing improved significantly from 77.5% to 96.6% after 6 months of MR-HC ($P = 0.005$). No severe AEs were reported, and the frequency of AC remained unchanged compared to conventional treatment.
Conclusions
Preliminary results suggest that MR-HC treatment improves general wellbeing and biochemical disease control in children with 21OHD, with no significant adverse effects. The findings also indicate beneficial effects on insulin sensitivity, although these results need to be confirmed in a larger cohort with a longer treatment duration.

WHAT...IF? Organizing a focus group for young adults with congenital adrenal hyperplasia who underwent feminizing surgery in childhood and/or adolescence

Lena Van de Wynkele[1], Aube Tylleman[1], Martine Cools[1,2] & Arianne B Dessens[1,3]
[1]Ghent University, Department of Internal Medicine and Pediatrics, Ghent, Belgium; [2]Ghent University Hospital, Pediatric Endocrinology Service, Department of Pediatrics, Ghent, Belgium; [3]Erasmus Medical Center, Department of Child and Adolescent Psychiatry, Rotterdam, Netherlands

Background
Congenital adrenal hyperplasia (CAH) is a rare genetic disorder caused by an enzyme deficiency in the adrenal glands, resulting in insufficient cortisol and aldosterone production and high androgen levels. Girls with CAH are often born with virilized genitalia. For long, early feminizing surgery has been proposed to manage the situation. This practice has become a subject of medical and ethical debate while experiences of those who are directly impacted remain underrepresented in research.
Objective
To understand the perception of adult females diagnosed with CAH, who underwent genital surgery in childhood, on early feminizing surgery.
Methods
We organized a focus group, complemented with two individual interviews; all audio-recorded. The group discussion focused on participants' experiences with the surgery they had and their perception in the present debate. The recorded discussion was transcribed. The transcribed discussion was uploaded in NVivo, a software for data analysis. Thematic analysis, a structured method to identify and analyze discussions, elucidated themes across the data set on participants' experiences, views, opinions and values.
Results
Arguments pro early feminizing surgery — with the number of respondents who mentioned the argument between brackets — were societal participation (4), psychological well-being (4), reduced medical burden (3), body acceptance (3), potential need to explain their gender (3), align external genitalia with the experienced gender (3), challenge of determining the appropriate cut-off age (2), easier recovery at a younger age (2), preserving fertility and pregnancy (2), and reduced decisional distress (2). Arguments against feminizing surgery were autonomy (4), bodily integrity (2), complications (2), minimizing surgical interventions (2) and irreversibility (1). If their own daughter would have CAH, three women expressed a preference for surgery as early as possible.
Discussion
Participants underscored the importance of psychosocial support and the influence of family and societal acceptance on mental health, a positive self-image, and social participation. Participants proposed a preference for management of CAH that balances respect for patient autonomy and sensitivity to societal and medical contexts. The results indicated a divergence between the complex lived experiences of patients and the perspectives brought by activist movements, underscoring a gap in research on patient-reported outcomes in CAH.
Conclusions
This study highlights the necessity for more patient-centered management and further investigation into both surgical and non-surgical management options for CAH.

Background
The effectiveness of histopathological classification using CYP11B2 immunostaining in unilateral primary aldosteronism (PA) for predicting clinical and biochemical outcomes following adrenalectomy remains a topic of debate. To date, no studies have conclusively shown that HISTALDO influences hypertension remission, and its effect on biochemical success varies among different ethnic groups.
Methods
We conducted a cohort study involving 131 consecutive patients with unilateral PA who underwent unilateral adrenalectomy. Aldosterone-producing adrenal lesions were classified according to the HISTALDO criteria. Biochemical and clinical outcomes were assessed using the PASO criteria.
Results
Among the 131 adrenal lesions, classical and non-classical histology were identified in 101 (77.09%) and 30 (22.91%) cases, respectively. In the classical group, 89 cases were classified as aldosterone-producing adenoma (APA), and 12 as aldosterone-producing nodule (APN). Within the non-classical group, 27 cases (90%) had multiple aldosterone-producing micronodules (APM), and 3 cases (30%) had multiple APNs. Patients with classical histology were younger ($P = 0.028$) and predominantly female ($P = 0.028$) compared to those with non-classical histology. Classical histology was associated with higher rates of complete biochemical success (97.03% vs. 68.97%, $P < 0.001$) and complete hypertension remission (34.34% vs. 10.71%, $P < 0.001$) compared to non-classical histology. Although clinical and biochemical outcomes were similar between APA and APN, their immunohistological characteristics differed (fewer clear cells and stronger CYP11B2 staining in APN). In multivariable analysis, classical histology remained independently associated with complete biochemical ($P < 0.001$) and clinical ($P = 0.037$) success.
Conclusion
Classical histology was an independent variable associated with more severe PA, complete biochemical and hypertension remission in surgically treated patients

with unilateral PA. Moreover, the distinction between APA and APN did not differentiate outcome.

High prevalence of CYP11B2-positive aldosterone-producing micronodules in subjects without known adrenal diseases

Juhani Isojärvi[1], Antero Ylänen[1,2], Antti Virtanen[3], Helena Leijon[4], Tiina Vesterinen[4], Heini Huhtala[5], Ilkka Pörsti[1,2], Marianna Viukari[6], Eeva Kokko[1], Niina Matikainen[6] & Pasi I Nevalainen[1,2]

Background
The zona glomerulosa (ZG) of the adrenal cortex synthesizes aldosterone, a key hormone involved in blood pressure regulation. Previous studies have shown an inverse correlation between age and both the continuity of aldosterone synthase (CYP11B2) expression and the area expressing CYP11B2. However, the significance of CYP11B2 discontinuity in the development of primary aldosteronism remains unclear. This study aimed to investigate patient demographics and explore the localization, symmetry, and clinical relevance of adrenal cortical lesions expressing CYP11B2.
Methods
This cross-sectional study included 145 consecutive autopsied cases from southern Finland without known adrenal diseases, all of whom had died from exogenic causes (trauma, suicide, or intoxication). Immunohistochemical CYP11B2 staining was performed on both adrenal glands and analyzed following the HISTALDO consensus guidelines. A four-grade classification system was used to assess CYP11B2 continuity: 1) diffuse CYP11B2 positivity (normal), 2) twenty or more aldosterone-producing micronodules (APMs $\geq$20), 3) APMs $<$ 20, and 4) aldosterone-producing nodules (APNs). Autopsy findings were recorded, and clinical data including diagnoses of hypertension and antihypertensive medication prescriptions from the past 10 years were obtained from national registries. This sub-study was registered at ClinicalTrials.gov (NCT05446779).
Results
The study cohort included 104 males (71.7%) and 41 females (28.3%), with a mean age of 53.7 years (range: 26.1–76.4 years). Among the participants, 12 (8.3%) exhibited bilateral diffuse CYP11B2 positivity, while APMs were identified in 131 subjects (90.3%). Of these, 42 cases (29.0%) had APMs $\geq$20 and 89 cases (61.4%) had APMs $<$20. Two cases (1.4%) with APNs were detected. Both APMs $\geq$20 and APMs $<$20 showed notable symmetry between the two adrenals, with concordant CYP11B2 continuity in 76.2% and 68.5% cases, respectively. CYP11B2 continuity did not associate with age, diagnosis of hypertension, or use of antihypertensives. Heart weight was significantly higher in subjects with APMs $<$20 compared to those with APMs $\geq$20 or diffuse CYP11B2 positivity ($P=0.048$ and $P=0.021$, respectively).
Conclusions
Bilateral diffuse CYP11B2 positivity, considered as normal ZG structure, was surprisingly rare. APMs were frequently observed in the adrenal glands, showing notable side-to-side symmetry. Heart weight was significantly associated with decreased CYP11B2 continuity. However, neither the diagnosis of hypertension nor the use of antihypertensive medications was related with the CYP11B2 continuity categories. Contrary to previous studies, age did not associate with CYP11B2 discontinuity. Our cross-sectional results indicate that bilateral CYP11B2 discontinuity is a frequent finding.

Advancing adrenal tissue analysis: A comprehensive guide to immunohistochemical evaluation, RNA-scope, and digital pathology with QuPath

Victoria Louise Marnet[1], Marianne Hetzl[1], Britta Heinze[1], Martin Fassnacht[1], Stefanie Hahner[1] & Carmina Teresa Fuss[1]
[1]Department of Internal Medicine I, Division of Endocrinology and Diabetes, University Hospital Wuerzburg, Wuerzburg, Germany

Background
Histological analysis of adrenal tissue, particularly through immunohistochemical (IHC) staining and modern RNA-scope techniques, is pivotal in adrenal disease research and diagnosis. Traditionally, IHC evaluation relies on semi-quantitative methods such as the H-score, which offers the advantage of a straightforward, flexible, and numerical scaling system that integrates both the intensity and distribution of staining. However, these manual approaches are time-intensive, subjective, and prone to inter- and intraobserver variability, resulting in limited reproducibility.
Methods and results
To address these challenges, we developed a widely applicable protocol for adrenal tissue analysis based on automated cell detection using QuPath, an open-source digital pathology platform. Our method was evaluated for accuracy, robustness, and reproducibility and will additionally be assessed in direct comparison to the H-score. The protocol includes optimized cell detection strategies tailored to specific adrenal tissue types (normal gland ($n=3$), adenomas ($n=39$) and carcinomas ($n=240$), non-adrenal controls $n=40$)), adaptations for various unique staining patterns, assessment of tissue microarrays, and practical solutions for scenarios with restricted computational capacity. Furthermore, QuPath provides advanced AI tools to detect the presence of potentially confounding cells, such as blood cells, connective tissue or fat. We optimized these tools for adrenal tissue, offering practical insights to enhance analytical precision. QuPath is also capable of analyzing RNA-scope stainings ($n=59$ specimens, assessed for three targets respectively), which is traditionally performed semi-quantitatively, whereby a subset of cells and RNA spots are counted to calculate a spots-per-cell ratio. To enhance efficiency and reproducibility, the manufacturer recommends the use of software-based analysis. Utilizing QuPath's capabilities for automated cell detection and RNA spot identification significantly streamlines the evaluation process, providing a more representative and reliable assessment of RNA expression across entire tissue sections. Finally, we conclude our protocol by showcasing some of QuPath's visualization features on the adrenal gland, providing the necessary tools to get the most out of staining experiments.
Conclusion
Computational techniques have the potential to fundamentally revolutionize the assessment of adrenal tissue. With automated image analysis, large amounts of data can be evaluated more efficiently, reproducibly, and objectively, especially regarding marker expression. The additional use of artificial intelligence opens up the possibility of specifically recognizing distinct cell types and accounting for interfering tissue.

Long-term outcomes and prognostic value of LC–MS/MS hormone profiling in the largest single-center cohort of adrenocortical carcinoma: a cohort study since 2000

Barbara Altieri[1,2], Felix Megerle[1], Otilia Kimpel[1], Mario Detomas[1], Stefan Kircher[3], Ulrich Dishinger[1], Matthias Kroiss[1], Stefanie Hahner[1] & Martin Fassnacht[1]
[1]Division of Endocrinology and Diabetes, Department of Internal Medicine I, University Hospital, University of Würzburg, Würzburg, Germany; [2]Bavarian Cancer Research Center (BZKF), University Hospital, University of Würzburg, Würzburg, Germany; [3]Institute of Pathology, University of Würzburg, Würzburg, Germany

Background
Adrenocortical carcinoma (ACC) is a rare cancer with limited population-based studies. This study aimed to analyze the largest single-center ACC cohort over a 20-year period, investigating prognostic factors for clinical outcomes and the relevance of liquid chromatography tandem mass spectrometry (LC–MS/MS) for hormone measurement.
Methods
We conducted a cohort study of patients treated at our referral center from January 2000 to May 2024. Clinicopathological characteristics, including sex-

and age-related differences, were analyzed. Overall survival (OS) was assessed using Kaplan–Meier and Cox regression analyses. Hormone profiling via LC–MS/MS including 15 steroids was performed in a subgroup and compared with standard hormone assays.

Results

1516 ACC patients (median age 51 years, IQR 39–62; 62% female) were included. Median OS was 59 months (95%CI = 50.1–87.9), with ENSAT tumor stage, resection status, Ki67-index confirmed as independent prognostic factors ($P < 0.001$). No significant sex-related differences were found in OS, age at diagnosis, tumor stage, or metastasis patterns. However, men had larger tumors (median 12 (8–16) vs 10 (7–14) cm) that were more frequently incidentally diagnosed (39% vs 26%, $P < 0.001$, $\chi^2 = 23.06$). Young patients (< 16 years-old) had significantly longer OS (median not-reached) compared to young/adult (91 months, 95%CI = 69.3–122.7), adult (63 months, 95%CI = 48.6–77.8) and old patients (35 months, 95%CI 28.7–41.3) at multivariate regression (HR between 0.8 and 0.3, $P < 0.001$). Endocrine-inactive and androgens-secreting tumors were associated with significant better survival (111 months, 95%CI = 60.6–161.4, HR = 0.56, $P > 0.001$; and 105 months, 95%CI = 56.6–153.5, HR = 0.63, $P = 0.01$) than other hormone-secreting tumors (36 months, 95%CI = 30.3–41.6) at Cox regression. At diagnosis, metastases in liver, lymph nodes, and bone were associated with worse outcomes ($P < 0.01$), while lung metastases had no significant impact. In 78 patients evaluated with LC–MS/MS, a median of 3 (IQR 2–5) elevated steroids *per* patient was found and only 3 (3.8%) had complete negative hormonal profiles compared to 7 (8.9%) classified as inactive by standard immunoassays. Especially 11-deoxycortisol and 11-deoxycorticosterone were frequently detected (82% and 48%, respectively), also in patients with apparently inactive tumors. Increase of ≥4 steroids were associated with poorer OS (15 months, 95%CI = 7.6–22.4) than those with ≤3 increased steroids (31 months, 95%CI = 21.9–40.1; HR = 1.9, 95%CI = 1.1–3.8, $P = 0.04$) at multivariate regression.

Conclusion

While ACC is more frequent in women, our study suggest that sex-dimorphism has no impact on clinical outcome. Younger age, endocrine-inactive, and androgen-secreting tumors are associated with better survival. LC–MS/MS steroid panel diagnostic enhances hormonal detection and demonstrates that virtually all ACCs are endocrine active, improving diagnosis and potentially impacting patient management.

Adrenalectomy reduces the risk of vertebral fractures in patients with adrenal adenoma and mild autonomous cortisol secretion

Valentina Morelli[1], Vittoria Favero[2,3], Sofia Frigerio[4], Carmen Aresta[3], Flavia Pugliese[5], Antonio Salcuni[6], Alessandro Risio[2], Cristina Eller Vainicher[4], Serena Palmieri[4], Elisa Cairoli[1], Sabrina Corbetta[1,7], Alfredo Scillitani[5], Giovanna Mantovani[4,8] & Iacopo Chiodini[2,3]

[1]IRCCS Istituto Auxologico Italiano, Endocrinology Department of Endocrine and Metabolic Diseases, Milann, Italy; [2]Department of Medical Biotechnology and Translational Medicine, Milan, Italy; [3]ASST Grande Ospedale Metropolitano Niguarda, Unit of Endocrinology, Milan, Italy; [4]Fondazione IRCCS Cà Granda-Ospedale Maggiore, Unit of Endocrinology, Milan, Italy; [5]IRCCS Ospedale Casa Sollievo della Sofferenza, Unit of Endocrinology and Diabetology, San Giovanni Rotondo (FG), Italy; [6]University-Hospital S. Maria della Misericordia, Unit of Endocrinology and Metabolism, Udine, Italy; [7]University of Milan, Department of Biomedical, Surgical and Dental Sciences, Milano, Italy; [8]University of Milan, Department of Clinical Sciences and Community Health, Milano, Italy

Objective

Mild autonomous cortisol secretion (MACS) is associated with increased risk of vertebral fractures (VFx). However, the impact of recovery from MACS on bone health remains unclear.

Design

Retrospective Longitudinal Intervention Study (Study 1): A total of 53 patients with MACS were followed for 35.2 ± 18.6 months (mean ± S.D.). Among these, 31 patients underwent surgery (Study 1-GroupA), while 22 patients received conservative treatment (Study 1-GroupB). Prospective Randomized Study (Study 2): Fifty-one outpatients with MACS were randomly assigned to either adrenalectomy (Study 2-GroupA, 21 patients, 67% females, age 63 [56.5–72.5]) or a conservative approach (Study 2-GroupB, 28 patients, 78% females, age 69 [61–73]) and were followed for 24 months.

Methods

MACS was diagnosed in patients with adrenal incidentalomas > 1 cm and cortisol after 1-mg dexamethasone suppression test (F-1 mgDST) ≥ 1.8 μg/dL. At baseline and at the end of the follow-up we assessed: mineral metabolism, bone mineral density (BMD) at the lumbar spine (LS), total hip (TH) and femoral neck (FN) using Dual-energy X-ray Absorptiometry, and clinical and morphometric vertebral fractures (VFx).

Results

Study 1: Study 1-GroupB showed an increased incidence of VFx ($n = 11$) at the end of the follow-up when compared to Study1-GroupA ($n = 3$, $P < 0.05$). In both groups, BMD at LS, FN and TH were similar at baseline and at the end of follow-up. In Study 1-GroupB, a new VFx occurred in 50% of patients, including 2 out of the 5 patients treated with bisphosphonates; in GroupA, 3 patients (9.7%) experienced incident VFx, all having a prevalent VFx at baseline. Study 2: Patients in both groups were comparable for demographic features (age, sex, BMI), adenoma's size, cortisol secretion parameters (F-1 mgDST, urinary free cortisol, ACTH), prevalent VFx and BMD at baseline. After 24 months, in Study 2-GroupA, we observed significant increases in calcium and phosphate levels compared to baseline ($P = 0.03$ and $P = 0.04$, respectively). In Study 2-GroupB, no significant changes were noted when comparing baseline values with those after 24 months. Additionally, at the end of follow up, BMD remained stable across both groups. However, Study 2-GroupB showed a significantly higher incidence ($n = 7$, 25%) of VFx by the end of the follow-up period compared to Study 2-GroupA ($n = 1$, 4.8%, $P = 0.04$).

Conclusions

In patients with unilateral adrenal incidentalomas and MACS, adrenalectomy significantly reduces the risk of vertebral fractures.

Objective

Adrenal incidentalomas (AIs) are asymptomatic adrenal masses with a diameter of ≥1 cm that are detected incidentally during imaging without suspicion of adrenal gland disease. Most studies have focused on the characteristics of adult AIs and the recommendations for their diagnosis. However, the clinical characteristics of AIs in childhood differ greatly from those in adulthood. This multicenter study aimed to examine the clinical, laboratory and imaging characteristics of AIs in children to guide the clinical diagnosis and treatment.

Methods
The clinical data of pediatric AI cases admitted to participating hospitals from 2010 to 2024 was collected and analyzed retrospectively. The data analysis included the patient's sex, age; initial presentation, imaging, composition, size and site of the mass; tumor function; intervention/surgery and pathological/clinical diagnosis. All patients' radiographic images were reviewed by an experienced radiologist of the coordinating center. The determination of a malignant/benign tumor was primarily based upon histological findings from surgical resections.
Results
Nineteen children (68.4% male) were included,with a mean follow-up of 3.05 ± 2.83 years and mean age of 10.69 ± 4.24 (3.9–17.5) years. Abdominal ultrasound revealed almost all of the AIs (94.7%), while only one mass was detected with abdominal computed tomography. Most masses were <4 cm (68.4%), hormonally non-functional (84.2%) and excised (89.4%) by laparoscopic/laparotomic adrenalectomy. Seventeen cases (89.4%) were biopsy-confirmed, two (hemorrhage sequelae calcification and benign adrenal mass) were diagnosed clinically. These two cases who followed up without adrenalectomy remained clinically stable, with no increase in size. One patient who had adrenalectomy for bilateral pheochromocytoma developed adrenal insufficiency during follow-up. Among all the AIs, ganglioneuroma was the most common (63.2%). The mean age at ganglioneuroma diagnosis was 10 ± 4.64 years, most cases were male patients (75%) and most of them sized <4 cm (66.6%). The other diagnosed conditions were two adrenocortical neoplasia and one case each of pheochromocytoma, hemorrhagic sequela calcification, gastric duplication cyst, benign adrenal mass and adrenocortical-medullary hemorrhage. Both adrenocortical neoplasia cases were evaluated as suspicious for malignancy by the radiologist due to their heterogeneous internal structures, presence of hemorrhagic/calcific components, >4 cm size and heterogeneous contrast enhancement outside of adenoma characteristics.
Conclusion
Generally, most AIs are benign and poorly functional; often do not show any physical signs of excess/insufficient hormone secretion. In our multicenter study, ganglioneuroma was the most common type of pediatric AI. All of these cases were hormonally non-functional. Sixteen patients (84.2%) were regularly followed and all remained stable throughout the surveillance period.

Adrenomedullary stem cells can instigate the formation of steroidogenic adrenal cortex through paracrine signalling

Yasmine Kemkem[1], Alice Santambrogio[1,2], James Kaufman-Cook[1], Bence Kover[1], Miriam Vazquez Segoviano[1], Olivia Sherwin[1,2] & Cynthia Andoniadou[1,2]
[1]King's College London, London, UK; [2]Technical University of Dresden Medical School, Dresden, Germany

Adrenal disorders, such as congenital adrenal hyperplasia or Addison's disease, can require lifelong hormone replacement therapy and may result in potentially life-threatening complications. Although steroid cell replacement strategies could be attractive therapeutical approaches, the generation of steroid hormone-producing cells *in vitro* remains inefficient. The adrenal glands consist of two interdependent tissues of distinct developmental origin: the adrenal cortex, which arises from the intermediate mesoderm during development, and the adrenal medulla, which originates from the trunk neural crest, migrating from the neural folds. We recently demonstrated that SOX2+ cells of the postnatal adrenal medulla have stem cell properties throughout life, generate new chromaffin cells, and promote chromaffin cell proliferation through paracrine secretion of WNT6. It is not known if this inductive potential of neural crest-derived adrenomedullary stem cells (AMSCs) extends to the influence of cell fate and regulation in the cortex. We present here that altering the metabolic activity of AMSCs through genetic mutation in the succinate dehydrogenase complex, leads to changes in their paracrine secretion properties. Mutant AMSCs of postnatal mice influence surrounding mesenchyme, leading to the generation of new accessory adrenal structures *in vivo*, that include a capsule and adrenal cortex expressing steroidogenic markers. These results confirm that postnatal mesenchyme can remain competent to generate new adrenal cortex *in vivo,* and that key signals, secreted from mutant AMSCs, can influence steroidogenic differentiation. Taken together, these findings can be harnessed to improve the efficiency of regenerative approaches for adrenal disorders relying on the generation of steroid-producing cells.

Adrenal insufficiency associated with mutations in haem biosynthesis genes

Ahmed Al-Salihi[1], Chris Smith[1], Cristina Pérez-Ternero[1], Adam Jackson[2], Andreas Janecke[3], Elisabeth Steichen[3], Denise Darby[2], Liezel Griffin[4], Siddharth Banka[2], Solaf Elsayed[5], Neila Talbi[6], Laurent Gouya[6], Brigitte Delemer[7], David Taylor[8], Li Chan[1] & Louise Metherell[1]
[1]Queen Mary, University of London, London, UK; [2]University of Manchester, Manchester, UK; [3]University Hospital of Innsbruck, Innsbruck, Austria; [4]Salford Royal Hospital, Dermatology Centre, Manchester, UK; [5]Ain Shams University, Medical Genetics Department, Cairo, Egypt; [6]The National Institute of Health and Medical Research (INSERM), Paris, France; [7]Centre Hospitalier Universitaire De Reims, Reims, France; [8]King's College Hospital NHS Foundation Trust, London, UK

Mutations in the 8 haem biosynthetic pathway genes are traditionally known to cause a group of diseases known as porphyria. While Primary Adrenal Insufficiency (PAI), an intrinsic adrenal defect in glucocorticoid synthesis ± mineralocorticoid synthesis, is linked to mutations in more than 25 genes. Over the last few decades, there have been tantalising case reports linking porphyria with defects in steroidogenesis. We identified seven families (11 individuals) with defects in haem biosynthetic enzymes who exhibit flagrant adrenal insufficiency (AI), with or without porphyria. 1) a kindred ($n=4$) from Egypt with biallelic mutations in protoporphyrinogen oxidase (*PPOX*) p.(Glu339Lys), who have variegate porphyria along with severe AI. 2) Three kindreds with mutations in coproporphyrinogen oxidase (*CPOX*), with variable presentations (i) a female with p.(Pro367Ala) mutation, (ii) siblings of Kurdish descent homozygous for p.(Ser28*) mutation, one of which had no clinical manifestations of HCP but has severe AI, and (iii) a patient with HCP from France who presented with AI aged 64. 3) Three adult patients with mutations in Hydroxymethylbilane Synthase (*HMBS*) who presented with AI during acute hepatic porphyria attacks. We hypothesized that reduced enzyme activity may cause AI through reduction in the level or activity of steroidogenic CYP450 enzymes due to the lack of haem, toxicity of accumulated intermediate porphyrins, and/or the increased oxidative stress these may cause. We investigated the underlying mechanism, employing knockdown and knockout *PPOX* and *CPOX* human adrenal cell lines (H295R) plus an animal model of *PPOX* deficiency to measure steroid perturbations, enzyme activity and levels of oxidative stress. PPOX knockdown significantly reduces cortisol output in our cell model, whereas CPOX knockdown does not, likely due to differences in residual enzymatic activity. CRISPR knockout of these genes was unsuccessful, consistent with the lethal nature of homozygous null mutations in humans and other mammals, highlighting their essential role in survival. In heterozygous PPOX mice, mimicking an acute porphyria attack by administering 5-aminolevulinic acid (ALA) blunted the Synacthen response in both WT and mutant animals.
Conclusion
Although we have not fully delineated the mechanism, our finding of a link between mutations in haem biosynthesis genes and PAI indicates that testing adrenal function in porphyria patients and their families might be warranted. Furthermore, haem biosynthesis genes should be considered for inclusion in genetic testing panels for isolated adrenal insufficiency.

Lipoid congenital adrenal hyperplasia due to mutations in StAR: Genotype and phenotype in 10 Vietnamese patients

Dung Vu Chi[1], Ha Nguyen[1] & Thao Bui[1]
[1]Vietnam National Children's Hospital, Vietnam National University, Center for Endocrinology, Metabolism, Genetics/Genomics and Molecular Therapy, Hanoi, Other

Background
Lipoid congenital adrenal hyperplasia (LCAH) is the most severe form of congenital adrenal hyperplasia. It is characterized by severe adrenal insufficiency and gonadal steroidogenesis impairment. Most cases of lipoid CAH are caused by recessive mutations in the gene encoding a steroidogenic acute regulatory protein (*StAR*).
Objectives
To identify variants of *StAR* and to describe the phenotype and genotype of patients with LCAH.

Patients and methods
This is a case series study of 10 cases from 9 unrelated families. The study included mutation analysis using whole exome sequencing or panel sequencing, description of clinical manifestations, karyotyping, and biochemistry tests.
Results
Seven of 10 cases have a female appearance. Among them, 4 have a karyotype of 46,XX, ovaries, and uterus on pelvic ultrasound; 3 have a karyotype of 46,XY and testis. 2 of 10 have a male-typical appearance and 46,XY, and testis. 1 of 10 has bilateral cryptorchidism, truth micropenis, hypoplasia of the scrotum, and 46,XY. Six of ten patients presented with severe adrenal insufficiency in early infancy (under 6 months old). Remain cases presented the first adrenal crisis from 15 months to 6.5 years of age. The investigations showed very high plasma ACTH levels (440–1551 pmol/l), and salt losing with hyponatremia (117–127 mmol/l) on admission, while the plasma 17OHP level was normal or decreased. All patients have good responses to glucocorticoid and mineral corticoid replacement therapy. Nine different pathogenic/like pathogenic variants in the *StAR* gene were identified including c.577C>T (p.R193X), c.649A>G (p.R217G), c.545G>A (p.R182H), c.562C>T (p.R188C), c.496A>T (p.I166F), c.11C>G (p.A4G), c.784del (p.Q262RfsX59), c.466ã 11T>A, and Del exon 1-3. Homozygous mutations were identified in 6 probands and compound heterozygous mutations were identified in 3 probands.
Conclusions
The phenotype of LCAH can be classic or non-classical form. The clinical manifestations include early/severe or later onset of adrenal insufficiency and female external genitalia or male-typical genitalia in 46, XY. Molecular testing using next-generation sequencing helps confirmation of the LCAH – a rare cause of adrenal insufficiency, with effective treatment and genetic counseling.

Introduction
Individuals with congenital adrenal hyperplasia (CAH) often experience reduced final adult height due to androgen excess (AE). AE induces early puberty, accelerates bone age, and leads to premature epiphyseal fusion. Growth-promoting therapies aim to mitigate sex-steroid effects and improve height outcomes. We aim to evaluate the use of growth-promoting therapies in CAH patients and their impact on height outcomes using real-world data from the I-CAH registry.
Methods
A retrospective analysis was conducted on 162 CAH patients from I-CAH registry from 33 centres in 19 countries, who were on growth-promoting therapies. Data on types of treatment agents, dose, and age at treatment initiation were analysed. Height outcomes were assessed using change of height standard deviations (s.d.s) corrected for bone age (BA), and height deviation from the mid-parental height (MPH) after treatment.
Results
The cohort included 162 patients (93 males, 57%; 69 females,43%) diagnosed at a median age of 0.22 years (IQR: 0.04–3.55), with growth-promoting therapy initiated at a median age of 7.75 years (IQR: 5.73–9.14). Median average hydrocortisone equivalent glucocorticoid (GC) dose before treatment was 13.56 mg/m^2/day (IQR: 11.41–16.4), with 113 patients (70%) receiving fludrocortisone in combination with GC. Adherence issues with GC therapy were reported in 40%. Growth-promoting therapies included GnRH analogues ($n=104$, median initiation age: 8.01 years), aromatase inhibitors (AIs) ($n=54$, 7.68 years), growth hormone (GH) ($n=34$, 7.45 years), cyproterone acetate ($n=38$, 6.83 years), and spironolactone ($n=8$, 8.83 years), administered alone or in combination. Seventeen different drug combinations were used. Letrozole was the most used AI (69%, $n=36$) at a dose of 2.5 mg (97%, $n=35$). GH was administered at a median dose of 40 mcg/kg/day (range: 25–50), while median doses for cyproterone acetate and spironolactone were 50 mg/day (range: 25–200) and 100 mg/day (range: 25–150), respectively. After a mean treatment duration of 3.83 years (s.d. 2.14), significant improvements in height outcomes were observed. Mean height s.d. adjusted for BA increased significantly from -2.36 pre-treatment to -1.44 post-treatment (Δ height s.d.: 0.92, $P<0.00001$). Similarly, height s.d.s deviation from MPH improved significantly from -1.64 pre-treatment to -0.65 post-treatment (Δ height deviation: 0.65, $P<0.00001$).
Conclusion
This real-world study demonstrates the diverse use of growth-promoting therapies in CAH management and their potential to improve height outcomes by reducing the height deficit relative to BA and MPH. However, lack of a unifying approach emphasizes the need for standardized treatment strategies to improve patient outcomes through establishing evidence-based guidelines.

Influence of glucocorticoid replacement and dosage on infection rates and adrenal crises in patients with adrenal insufficiency

Richard Lampe[1], Catharina Bullmann[2] & Birgit Harbeck[1,2]
[1]University Medical Center Hamburg-Eppendorf, III. Department of Medicine, Hamburg, Germany; [2]Amedes Experts, Hamburg, Germany

Introduction
Patients with adrenal insufficiency (AI) have been shown to suffer from an increased susceptibility to infections. Conventional hydrocortisone replacement therapy may be the main cause as it is associated with temporary cortisol under- and overexposure leading to immunodysregulation and -suppression. Both effects may be reduced with dual-release hydrocortisone (Plenadren®), which improves the adaption to the circadian rhythm of cortisol. Aim of this study was to assess the effect of different hydrocortisone preparations on infection rates and thus also on the number of adrenal crisis (AC).
Material and methods
Patients with AI were contacted via a group practice for endocrinology, several self-helping groups in Northern Germany and the online network 'Glandula'. The test subjects were given a self-developed questionnaire regarding their infections in the past year, AC since their diagnosis and their glucocorticoid replacement dosage. The results were analyzed using Excel and SPSS.
Results
Eighty-eight patients (84% women, 16% men) with primary (53.4%), secondary (43.2%) and tertiary (3.4%) AI participated in this study. The results showed a 56.8% reduction in infections over 12 months in patients with Plenadren® compared to conventional hydrocortisone ($P=0.012$). Furthermore, patients with secondary AI had 56.4% more infections than those with primary AI ($P=0.04$). Overall, even though patients with Plenadren® had significantly higher medication doses (23.2 vs. 25.7 mg; $P=0.022$), no dosage-effect could be shown on the frequency of infections. Regarding the ACs, no differences were observed between the medications.
Conclusions
Our study suggests that the improved cortisol exposure under Plenadren® may indeed lead to fewer infections. However, this did not result in a lower rate of AC. The impact of glucocorticoid replacement dosage in the prevention of infections and AC remains unclear underlining the need of further confirmatory studies.

JOINT3423 Systemic treatment and outcomes in metastatic pheochromocytomas and paragangliomas of a multicenter Spanish cohort

Lorena Hernandez[1], Jorge Eduardo Contreras Saldarriaga[2,3], Jorge Hernando Cubero[4], Alejandro García-Álvarez[4], Stephan Prado[5], Ángel Segura Huerta[6], Anna Casteras[7], Marc Simó[8], Amparo García-Burillo[8], Jaume Capdevila[4] & Maria Isabel Del Olmo Garcia[1]
[1]Hospital Universitari i Politècnic La Fe, Department of Endocrinology, Valencia, Spain; [2]University of Antioquia, Department of Endocrinology, Medellín, Colombia; [3]University of Antioquia, Endocrinology, Medellin, Colombia; [4]Vall d'Hebron University Hospital, Department of Medical Oncology, Barcelona, Spain; [5]Hospital Universitari i Politècnic La Fe, Department of Nuclear Medicine, Valencia, Spain; [6]Hospital Universitari i Politècnic La Fe, Department of Medical Oncology, Valencia, Spain; [7]Vall d'Hebron University Hospital, Department of Endocrinology, Barcelona, Spain; [8]Vall d'Hebron University Hospital, Department of Nuclear Medicine, Barcelona, Spain

Introduction
Pheochromocytomas (PHEOs) and paragangliomas (PGLs), collectively known as PPGLs, are rare endocrine tumors with significant clinical variability. Around 10–15% of PHEOs and 35–40% of PGLs exhibit metastatic behavior. Due to their heterogeneity, treatment must be tailored to each patient individually.
Methods
This study aim to describe the general characteristics, treatments strategies, and response in a cohort of 49 patients with metastatic PPGLs. It is a retrospective study (2010–2024) conducted at two reference NET centers in Spain.
Results
Among the 49 patients, 51% with a mean age of 52.7 years (s.d.:8.4). The mean age at diagnosis was 40.9 years (s.d. 19.1). PHEO was the primary tumor in 25 patients. The most common reasons leading to diagnosis were incidental findings (23.1%), hypertension (20.5%), cervical mass (15.4%), and abdominal pain (15.4%). A total of 51% of cases were functional, with the majority exhibiting a noradrenergic phenotype (76%). At diagnosis, 44.9% of patients had metastases, with the most frequent metastatic sites being bone (32.7%), lymph nodes (26.5%), liver (22.4%), and lungs (14.3%). Systemic treatment was not administered to 14.3% of patients. Among those treated, the main indications were disease progression (PD)(59.5%), high tumor burden (31%), and tumor functionality (9.5%). Most patients (43.2%) received only one line of treatment. The remaining patients received more than one line: 23.8% received two, 16.7% three, 9.5% four, 4.8% five, and 4.8% seven First-line treatments included somastotin analogs (SSA)(40.5%), radionuclide therapy (33.3%), and chemotherapy (26.2%).No significant differences were observed between the reason for treatment initiation and the choice of first-line therapy ($P=0.316$). However, differences were found between the reason for starting treatment and the best radiological response achieved ($P=0.01$), with a higher partial response (PR) rate in patients with a high tumor burden compared to those with disease progression (38.4% vs 8%). PR was seen in 27.2% of the patients receiving chemotherapy and 28.5% of those treated with radioligands, compared to 5.88% with SSA ($P=0.14$). After first-line treatment, 63.1% of patients experienced disease progression, with a median progression-free survival of 25.6 months (s.d. 21.2). Significant differences were observed depending on the type of treatment received (SSA:11 months, radionuclide therapy:16.4 months, chemotherapy:7.2 months)($P=0.02$).
Conclusions
The most common indication for initiating systemic treatment in PPGLs is radiological disease progression. However, initial tumor burden appears to be the most influential factor in predicting radiological response. Prospective studies are needed to determine the optimal timing for initiating systemic treatment in PPGLs.

Factors influencing the time to achieve target mitotane concentration

Nikolina Vučenović Bašić[1], Anja Barač Nekić[2], Ivana Kraljević[2,3], Tina Dušek[2,3] & Darko Kaštelan[2,3]
[1]General Hospital Šibenik, Šibenik, Croatia; [2]University Hospital Centre Zagreb, Zagreb, Croatia; [3]University of Zagreb, School of Medicine, Zagreb, Croatia

Mitotane is an adrenolytic drug used as adjuvant therapy in patients with adrenocortical carcinoma (ACC) at high risk of recurrence or as first-line treatment for unresectable tumors. Its antineoplastic efficacy correlates with plasma concentration, making the early achievement of the therapeutic threshold (14 mg/l) crucial. However, interindividual variability in mitotane pharmacokinetics poses challenges in reaching this target concentration within an optimal timeframe. This study aimed to identify factors influencing the time required to achieve therapeutic mitotane levels.
Methods
We retrospectively analyzed 51 patients with ACC aged 18 to 72 (median 54 years) ENSAT stage I–IV treated with mitotane for at least 6 months. In stage I there was 1 patient, stage II 17 patients, stage III 17 patients and in stage IV 16 patients. 34 patients recived mitotane monotherapy and 17 of them recived combination of mitotane with chemoterapy (EP or EDP protocol). In 82% of the patients we used high dose approach, and in 18% low dose approach of mitotane therapy. Mitotane concentrations were obtained from Lysosafe service which provides a centralized analysis of mitotane levels using high-performance liquid chromatography (HPLC).
Results
The median time to achieve the target plasma mitotane concentration was 89 days (30–300, IQR 49–129). There was no significant difference in the time required to reach the target mitotane concentration between patients treated with the high-dose and low-dose approaches (median 86 days (range 26–300 days) vs. 92.5 days (range 32–275 days), respectively). Similarly, the time to reach the target mitotane concentration was not influenced by age at diagnosis, body mass index, ENSAT stage, tumor size, or tumor hormonal activity. Although patients receiving mitotane in combination with chemotherapy reached the target concentration more slowly than those receiving mitotane monotherapy (median 113 days (range 32–174) vs. 85 days (range 32–300)), this difference was not statistically significant.
Conclusion
No clinical parameter was found to significantly impact the time required to achieve therapeutic mitotane levels. However, given the relatively small sample size, our study may have been underpowered to detect subtle differences. Larger, multicenter studies with a greater number of patients are needed to more comprehensively evaluate this issue.

HELIOS Clinic Berlin-Buch, Department of Cardiology and Nephrology, Berlin, Germany (R.D.), Berlin, Germany; [6]Institute for Molecular Medicine, University of Southern Denmark, Odense, Denmark, Odense, Denmark

Background
Offspring blood pressure (OBP) may be programmed during pregnancy. Accordingly, maternal third trimester 24-hour (24 h) urine (u-) aldosterone levels are associated with feto-placental trophic effects. Furthermore, high potassium and low sodium intakes are generally recommended in adults with normal renal function. We hypothesized that maternal 24 h u-aldosterone levels were positively associated with OBP and maternal intake of potassium and sodium may influence the association.
Objectives
To investigate associations between maternal third trimester 24 h u-aldosterone, potassium and sodium intakes and OBP.
Methods
In the prospective Odense Child Cohort, 475 mother–child dyads had 24 h u-aldosterone from gestational week 29 and OBP (systolic (SBP) and diastolic (DBP)), at ages 3 and 18 months and 3 and 5 years. Maternal potassium and sodium intakes were calculated from 24 h u-potassium and u-sodium excretions.
Results
Increased maternal 24 h u-aldosterone associated with higher SBP in offspring at ages 3 months ($\beta = 0.54$ mmHg (95% CI: 0.29; 0.79)) and 18 months ($\beta = 0.24$ mmHg (95% CI: 0.03; 0.44)). One thousand mg/day increase in maternal potassium intake was associated with an average increase in offspring SBP of 0.68 mmHg (95% CI: 0.02; 1.34) up to 5 years of age (pooled), with significant associations only in girls ($\beta = 1.14$ mmHg (95% CI: 0.21; 2.08)). No significant association was seen between maternal sodium intake and OBP.
Conclusions
Elevated maternal 24 h u-aldosterone and higher dietary potassium intake were associated with higher OBP, but within normal range, in young children, and girls were more susceptible to maternal potassium intake.

Activation of calcium signaling, using chemogenetic tools, leads to the development of hyperaldosteronism and adrenal remodeling in mice

Bakhta Fedlaoui[1], Rania Hadri[1], Nicolo Faedda[1], May Fayad[1], Isabelle Giscos-Douriez[1], Chris Magnus[2], Scott Sternson[2], Stephanie Baron[3], Fabio Fernandes-Rosa[1], Maria-Christina Zennaro[1,4] & Sheerazed Boulkroun[1]
[1]INSERM U970 – PARCC, Université Paris Cité, Paris, France; [2]Howard Hughes Medical Institute & Department of Neurosciences, University of California, San Diego, USA; [3]Service de Physiologie, Assistance Publique Hôpitaux de Paris (AP-HP), Hôpital Européen Georges Pompidou, Paris, France; [4]Service de Génétique, Assistance Publique Hôpitaux de Paris (AP-HP), Hôpital Européen Georges Pompidou, Paris, France

Primary aldosteronism (PA) is the most frequent form of secondary hypertension and is due to autonomous aldosterone production by the adrenal gland. The most frequent genetic cause of aldosterone producing adenoma (APA) are somatic mutations in the potassium channel KCNJ5. They affect the ion selectivity of the channel, with sodium influx leading to cell membrane depolarization and activation of calcium signaling, the major trigger for aldosterone biosynthesis. To investigate how *KCNJ5* mutations lead to the development of APA, we developped a mouse model expressing specifically in the adrenal cortex, using a Cyp11b2-Cre mice generated in our laboratory, a chimeric ion channel receptor named α7-5HT3-R formed by the ligand binding domain of the α7 nicotinic acetylcholine receptor fused to the ion pore domain of the serotonin receptor 5HT3a. (Cyp11b2-Cre::α7-5HT3-R). The activation of the α7-5HT3-R by a selective agonist, the uPSEM-817, leads to sodium entry into the cells. In an adrenocortical cell model (H295R-S2 cells), we previously demonstrated that the expression of α7-5HT3-R leads to an increase of sodium entry into the cells, resulting in cell membrane depolarization, the opening of voltage-gated calcium channel, an increase in intracellular calcium concentration, and an upregulation of *CYP11B2* expression and aldosterone biosynthesis. Additionally, we found that this sodium influx reduces cell proliferation and promote apoptosis. Moreover, RNA sequencing and steroidome analyses revealed unique profiles associated with sodium entry, with only partial overlap with changes induced by angiotensin II and potassium. These findings suggest that additional events may be required for the development of an APA with *KCNJ5* mutation. In Cyp11b2-Cre::α7-5HT3-R mice, four weeks of treatment with uPSEM-817 induces, in both male and female, an increase in plasma aldosterone and 18-hydroxycorticosterone concentrations associated with an increase in *Cyp11b2* expression and to a lesser extent, a disorganization of the adrenal cortex. After four weeks of treatment, we did not observe an increase in blood pressure or cardiac remodeling. Further investigations and longer treatments are ongoing to thoroughly characterize this mouse model. This mouse model, in which we can modulate calcium entry, provides a valuable tool for dissecting the mechanisms underlying APA development and assessing new therapeutic strategies.

Investigating the role of insulin and adipose tissue in regulating adrenal steroidogenesis in response to metabolic diseases

Diana Cozma[1,2,3], Panagiota Siatra[1,2], Ioannis Oikonomakos[1,2], Mirko Peitzsch[4], Ulrike Friedrich[5], Stefan Bornstein[1,2,3], Cynthia Andoniadou[1,2,3] & Charlotte Steenblock[1,2]
[1]TUD University of Technology, Faculty of Medicine, Dresden, Germany; [2]University Hospital Carl Gustav Carus, Medical Clinic III, Dresden, Germany; [3]King's College London, Centre for Craniofacial and Regenerative Biology, London, UK; [4]University Hospital Carl Gustav Carus, Institute for Clinical Chemistry and Labarotory medicine, Dresden, Germany; [5]Center for Molecular and Cellular Bioengineering (CMCB), DRESDEN-concept Genome Center, Dresden, Germany

Metabolic syndrome is characterized by the hyperactivation of the hypothalamic–pituitary–adrenal (HPA) axis, leading to increased steroidogenesis. The molecular signaling mechanisms underlying HPA axis alterations in metabolic diseases remain poorly understood. In this study, our objective was to investigate how changes in signaling molecules within both plasma and adipose tissue contribute to the regulation of adrenal steroidogenesis in metabolic diseases and elucidate the modified response of adrenocortical and pituitary cells. Using a mouse model of obesity induced by a high-fat diet (HFD), we aimed to pinpoint the onset of changes in steroid hormone response. We investigated the adrenal glands and plasma of mice at different time points up to 16 weeks of HFD. We observed a significant increase in adrenal gland weight along with increased levels of corticosterone in mouse plasma. These changes were preceded by elevated insulin concentrations in the mouse plasma as early as 8 weeks of HFD. Further, our findings revealed increased expression of *Lep* (leptin), and decreased expression of *Adipoq* (adiponectin) in the adipose tissue surrounding the adrenal upon 16 weeks of HFD. To explore the direct impact on adrenocortical cells, we treated primary adrenocortical cell-derived spheroids with insulin and adiponectin. We observed that insulin induced an increase in spheroid diameter along with an increase in mRNA expression of steroidogenic genes, indicating enhanced cell expansion and steroidogenesis, while adiponectin decreased the spheroid diameter, indicating an inhibitory effect on steroidogenesis. We have previously shown that insulin can enhance ACTH secretion in primary pituitary cells. To elucidate the underlying mechanism of how insulin acts in these *in vitro* systems, we performed bulk RNA sequencing of adrenocortical and pituitary cells with and without insulin stimulation. When comparing insulin-induced

differentially expressed genes (DEGs) in both cell types, we observed upregulation of genes related to cholesterol biosynthesis and fatty acid transport. This could indicate that insulin stimulates *de novo* cholesterol biosynthesis, the precursor for steroid synthesis. In adrenocortical cells, insulin-induced DEGs were uniquely attributed to cholesterol transport, inner mitochondrial membrane and respiratory chain, and steroid synthesis. Hence, an overall effect of insulin on cholesterol metabolism could be crucial for regulating cholesterol transport for subsequent steroid synthesis in adrenocortical cells. Together, our results underscore the crucial role of insulin and adipose tissue in regulating adrenal gland function in metabolic diseases contributing to a comprehensive understanding of HPA axis activity in these conditions.

Relacorilant is a selective glucocorticoid receptor modulator in development for the treatment of patients with endogenous hypercortisolism. The objective of the phase 3, randomized-withdrawal (RW) GRACE study (NCT03697109) was to assess the efficacy and safety of relacorilant in patients with hypercortisolism and hypertension and/or hyperglycemia (diabetes/impaired glucose tolerance). Patients who achieved prespecified response criteria in the 22-week open-label (OL) phase were then eligible to enter the 12-week, double-blind placebo-controlled RW phase. The primary endpoint was defined as loss of response in hypertension control between relacorilant and placebo and was assessed at the end of the RW phase. There were 152 patients enrolled in GRACE ($n=31$ with hypertension; $n=50$ with hyperglycemia; $n=71$ with both). During the OL phase, rapid and sustained improvements in hypertension and hyperglycemia were observed, along with improvements in several other cortisol-related comorbidities. Patients who continued to receive relacorilant in the RW phase maintained significant improvements in blood pressure and glycemic measures. The primary endpoint was met with an odds ratio of 0.17 (95% confidence interval: 0.04–0.77; $P=0.02$) in favor of relacorilant. The most common adverse events (AEs) observed were back pain, headache, arthralgia, insomnia, and pain in extremity; these AEs were mostly mild to moderate in severity. No cases of relacorilant-induced irregular vaginal bleeding with endometrial hyperplasia, adrenal insufficiency, or QT prolongation were reported. Significant and sustained improvements in hypertension, hyperglycemia, and other manifestations of cortisol excess were observed during relacorilant treatment. Treatment with relacorilant was well tolerated in both the OL and RW phases of GRACE.

Background

Adrenocortical carcinomas (ACC) are highly aggressive malignancies with limited treatment options. Polo-like kinase 1 (*PLK1*) and cyclin-dependent kinases (*CDKs*) 1/2/4 are among the most overexpressed genes in ACC human samples. We have previously demonstrated the efficacy of PBD-targeting PLK1 inhibitor (PLK1i) poloxin in ACC cell lines (H295R, MUC-1, CU-ACC2).

Aims and methods

We tested the efficacy of 1) two PLK1i, i.e. the polo-box domain (PBD)-targeting poloxin and the kinase domain (KD)-targeting plogosertib; 2) two CDK inhibitors (CDKi), i.e. dinaciclib (targeting preferentially CDK1/2) and the CDK1-cyclin B1 inhibitor cucurbitacin E (CurE); 3) the combination of plogosertib and dinaciclib. Their efficacy was evaluated in four ACC cell lines, including H295R, MUC-1, and the newly generated TVBF-7 and JIL-2266. Increasing drug concentrations for 72 h. Cell proliferation and apoptosis were assessed by BrdU incorporation and caspase 3/7 activity, respectively, compared to basal condition. The "SynergyFinder" tool was used to analyse two-drugs combinations.

Results

PLK1i poloxin reduced proliferation at very high doses, achieving a maximum effect at 100μM ($P<0.01$ in MUC-1 and TVBF-7; $P<0.001$ in H295R and JIL-2266), and increased apoptosis at 10μM ($P<0.05$ for all). At considerably lower concentrations, plogosertib dose-dependently reduced cell proliferation ($P<0.05$ at 100 nM in MUC-1 and JIL-2266; $P<0.01$ at 750 nM in H295R and TVBF-7) and increased apoptosis ($P<0.05$ for H295R, TVBF-7, and JIL-2266 at 1μM). CDKi dinaciclib markedly reduced cell proliferation at low nanomolar doses ($P<0.05$ at 20 nM in

MUC-1 and JIL-2266, and at 100 nM in TVBF-7; $P<0.01$ at 100 nM in H295R), and increased apoptosis ($P<0.05$ in MUC-1, TVBF-7, and JIL-2266 at 200 nM). CurE dose-dependently reduced proliferation in all ACC cells, but its effects were less pronounced than dinaciclib ($P<0.05$ at 100 nM in MUC-1 and TVBF-7; $P<0.01$ at 100 nM in H295R and JIL-2266). In line with the observed differences in treatment sensitivity among cell lines, qRT-PCR analysis showed that CDK1/2 and PLK1 mRNA expression was particularly high in MUC-1 and JIL-2266. Synergistic suppression of cell proliferation by combined treatment with PLK1i plogosertib and CDKi dinaciclib was observed in H295R ($P<0.05$) and TVBF-7 ($P<0.01$) cell lines.

Conclusion

Plogosertib and dinaciclib were the most effective inhibitors in all cell lines, representing interesting novel targeted treatment options for ACC. Moreover, the combination of these drugs showed a synergistic effect, suggesting a potential benefit of using both PLK1i and multi CDKi that need to be further investigated *in vivo*.

Is muscle strength an overlooked parameter in patients affected by mild autonomous cortisol secretion (MACS)? A prospective study

Martina Romanisio[1], Chiara Mele[1], Sara Sturnia[1], Carola Ciamparini[1], Rosa Pitino[1], Alice Ferrero[1], Lorenza Scotti[2], Gianluca Aimaretti[1], Paolo Marzullo[1], Flavia Prodam[1,3] & Marina Caputo[1,3]

[1]Endocrinology, Università del Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [2]Università del Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [3]Department of Health Sciences, Università del Piemonte Orientale, Novara, Italy

Background

Adrenal incidentalomas are a growing clinical concern due to their increased prevalence in imaging studies. While most are non-secreting adenomas (NFAA), a significant proportion are associated with mild autonomous cortisol secretion (MACS), linked to various comorbidities, including metabolic and musculoskeletal alterations. The specific impact of MACS on skeletal muscle health, body composition, and quality of life (QoL) remains poorly understood.

Objective

To evaluate the effects of mild cortisol excess on skeletal muscle health, body composition, and QoL in patients with adrenal incidentalomas associated with MACS compared to those with NFAA and healthy controls.

Participants and methods

This cross-sectional case–control study enrolled 62 participants: 21 with MACS, 21 with NFAA, and 20 controls. Skeletal muscle strength was assessed using hand-grip strength, sit-to-stand test and the MRC scale. Body composition was analyzed through bioelectrical impedance analysis (BIA), measuring fat free mass (FFM), muscle mass (MM), and fat mass (FM). QoL was evaluated using EQ-5D and SARC-F questionnaires. Statistical comparisons were performed between groups, and correlations with cortisol levels were explored.

Results

Participants were demographically and anthropometrically comparable across groups. Patients with MACS exhibited a higher prevalence of osteopenia and osteoporosis than NFAA and controls (61.9% vs. 28.6% and 25%, respectively; $P=0.036$). Although no significant differences were observed in FFM, MM, or FM, MACS patients demonstrated lower muscle strength scores on the MRC scale for biceps and quadriceps than controls ($P=0.040$ and $P=0.0397$, respectively). Cortisol levels positively correlated with adenoma size ($r=0.347$, $P=0.0243$) but not with muscle strength parameters, despite a clear trend towards less suppression of cortisol values. QoL measures revealed trends toward greater functional impairments in MACS patients, though without statistical significance.

Conclusion

Mild cortisol excess in MACS patients is associated with subtle impairments in muscle strength and a higher prevalence of skeletal health issues, highlighting the potential subclinical impacts on musculoskeletal health and QoL. These findings underscore the clinical significance of MACS and highlight the need for multidisciplinary management strategies for the disease.

[1]University Hospital, University of Würzburg, Division of Endocrinology and Diabetes, Department of Internal Medicine I, Würzburg, Germany; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [3]Humanitas University, Division Department of Biomedical Sciences, MIlan, Italy; [4]Max Delbrück Center for Molecular Medicine, Berlin, Germany; [5]Central Laboratory University Hospital Würzburg, Würzburg, Germany; [6]University of Würzburg, Institute of Pathology, Würzburg, Germany; [7]University of Birmingham, Department of Metabolism and System Science, Birmingham, UK; [8]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [9]University Hospital, University of Würzburg, Bavarian Cancer Research Center (BZKF), Würzburg, Germany

Background

Prevalence of M2-macrophages has been described in normal and tumor adrenal tissues, likely modulated by cortisol autocrine/paracrine effects. However, their infiltration in adrenocortical adenomas (ACA) and comparison with normal adrenal glands (NAG) remain poorly characterized. This study aimed to evaluate tumor-associated macrophages (TAM) in ACA and assess the impact of ACA-pathogenic variants (PVs) and cortisol hypersecretion on their polarization.

Methods

Immunohistochemistry for CD163 and CD206 (M2-specific markers), and CD68 (pan-macrophage marker) was performed. Immunostaining was quantified using QuPath-0.5.1 pixel classification (thresholds 0.15–0.30) and expressed as mean percentage of positive pixels. PV in *CTNNB1, PRKACA,* and *GNAS* were detected by Sanger sequencing from matched fresh-frozen ACA. Associations between TAM, clinicopathological features, PV status, hormone levels and circulating monocytes were analyzed. Additionally, myeloid transcriptomic profiles from single-nucleus RNA sequencing (snRNA-Seq) data (DOI:10.1002/ctm2.1798) were examined using Seurat R package and differential gene expression analysis.

Results

A cohort of 103 ACA and 8 NAG-adjacent to ACA was analyzed. In ACA, CD163 staining was higher than CD206 and CD68 (6.83% vs. 1.62% and 1.71%, $P<0.001$). Conversely, in NAG CD206 was higher than CD68 (8.41% vs. 5.6%, $P=0.008$), but similar to CD163. Matched ACA-NAG comparisons revealed in ACA reduced CD206 (2.3% vs. 7.46%, $P=0.008$) and CD68 (2.14% vs. 4.43%, $P=0.012$), while CD163 remained unchanged, resulting in an increased CD163/CD206 ratio in ACA (2.28% vs. 0.76%, $P=0.017$). Same result was found at snRNA-Seq levels for CD206 (1.21 in ACA vs 1.48 in NAG, $P<0.001$), without difference in CD163. ACA harbouring *CTNNB1* and *PRKACA/GNAS* PVs had a higher CD163/CD68 ratio compared to PV negative cases (60% vs 33%, $P=0.022$), an association observed exclusively in women, suggesting potential sex-specific differences in macrophage infiltration. ACA with *PRKACA* PVs showed lower CD206 (0.5% vs. 1.79%, $P=0.003$) and, consequently, higher CD163/CD206 ratio (17.4% vs 3.2%, $P=0.002$) than those without. These results were consistent when considering cortisol-producing ACA only. Similarly, low CD206 was found also at snRNA-Seq in ACA with *PRKACA* PV (0.73 vs 1.27, $P=0.003$). Finally, CD68 inversely correlated with 24 h-urinary free cortisol ($\rho=-0.245$, $P=0.04$), with lower CD68 in patients with overt Cushing's syndrome ($P=0.018$). No correlation between number of circulating monocytes and TAM was found.

Conclusion

This study provides a comprehensive characterization of M2-like TAM in ACA, revealing distinct macrophage infiltration with higher CD163/CD206 ratio compared to NAG. TAM polarization is influenced by PVs and cortisol excess, with sex-specific differences, offering new insights into ACA microenvironment

Diagnostic accuracy of urinary free cortisol and cortisone excretion for the diagnosis of neoplastic hypercortisolism

Karlijn Koops[1,2], Peter Bisschop[2,3], Annemieke C Heijboer[1,2,4] & Jacquelien Hillebrand[1,2]

[1]Amsterdam UMC, Vrije Universiteit Amsterdam, University of Amsterdam, Department of Laboratory Medicine, Endocrine Laboratory, Amsterdam, Netherlands; [2]Amsterdam Gastroenterology, Endocrinology & Metabolism, Amsterdam, Netherlands; [3]Amsterdam UMC, University of Amsterdam, Department of Endocrinology and Metabolism, Amsterdam, Netherlands; [4]Amsterdam Reproduction & Development Research Institute, Amsterdam, Netherlands

Background
Quantification of urinary free cortisol excretion is one of the recommended initial screening tests for diagnosing hypercortisolism. The use of liquid chromatography–tandem mass spectrometry (LC–MS/MS) allows for the simultaneous quantification of both urinary cortisol and cortisone. This study aims to determine the optimal cut-off values for urinary free cortisol (UFCortisol) and urinary free cortisone (UFCortisone) in the diagnosis of neoplastic hypercortisolism and to determine whether either one has superior diagnostic accuracy.
Methods
In this retrospective study, we analyzed data from subjects who were screened for endogenous hypercortisolism at Amsterdam UMC between December 2015 and February 2022. Subjects had been instructed to collect urine for 24 hours on two consecutive days. UFCortisol and UFCortisone concentrations were measured using an in-house developed LC–MS/MS method. The average of both collections was used to determine the diagnostic accuracy. Confirmation of the diagnosis of neoplastic hypercortisolism was based on (postoperative) clinical parameters and histopathology, while the diagnosis was excluded based on a lack of progression of clinical signs during follow-up of at least 12 months. The diagnostic accuracy was evaluated by ROC-curve analysis.
Results
We included 426 subjects without neoplastic hypercortisolism (test indication: 136 clinical signs/symptoms, 274 adrenal incidentaloma, 9 pituitary incidentaloma, 2 genetic predisposition, 5 unclear) and 27 subjects with neoplastic hypercortisolism (test indication: 23 clinical signs/symptoms, 2 adrenal incidentaloma, 2 pituitary incidentaloma) in which UFCortisol was measured. In a subgroup of 304 subjects without and 17 subjects with neoplastic hypercortisolism UFCortisone was measured as well. The median UFCortisol concentration was 369 nmol/24 h (range 47–8987) for subjects with and 63 nmol/24 h (1.3–614) for subjects without neoplastic hypercortisolism ($P<0.001$). The median UFCortisone concentration was 606 nmol/24 h (131–1174) for subjects with and 190 nmol/24 h (13–863) for subjects without neoplastic hypercortisolism ($P<0.001$). For UFCortisol, a cut-off value of 120 nmol/24 h provided optimal diagnostic accuracy with a sensitivity of 88.9% (95% CI 0.771–1.000) and specificity of 85.9% (0.826–0.892). The optimal cut-off value for UFCortisone was 300 nmol/24 h with a sensitivity of 94.1% (0.829–1.000) and specificity of 87.8% (0.841–0.915). The sum of UFCortisol and UFCortisone provided a slightly higher diagnostic accuracy at a cut-off of 460 nmol/24 h with a sensitivity of 94.1% (0.829–1.000) and specificity of 93.0% (0.901–0.959).
Conclusion
We established cut-off values for UFCortisol and UFCortisone for the diagnosis of neoplastic hypercortisolism. UFCortisone had similar diagnostic accuracy to UFCortisol, but the sum UFCortisol + UFCortisone seemed to perform slightly better.

Introduction
Primary adrenal insufficiency (PAI) is mainly due to autoimmune adrenalitis in developed countries and the most common inherited form is congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency. There is controversy on long-term outcomes in PAI, with earlier studies showing that mortality was not different from the general population and more recent studies showing higher mortality. The primary aim of this study is therefore to synthetise the evidence on long-term mortality in PAI. The secondary aims are to analyse mortality due to cardiovascular and infectious diseases, along with time trends in mortality.
Methods
A database search of Medline, Cochrane, Embase and Web of Science was conducted for studies on mortality in PAI, including CAH. Two reviewers conducted an initial screening of the titles and abstracts. Thereafter, each reviewer examined the selected articles in full text. Observational studies reporting all-cause mortality in comparison with a control group or general population were included. The extracted data was systematically synthetised. The study quality was assessed independently by two reviewers, following the Newcastle-Ottawa quality assessment scale. The protocol for this systematic review complies with the preferred reporting items for systematic review and meta-analysis (PRISMA) guidelines and was registered in PROSPERO (CRD42023416253)[1].
Results
Totally, 5463 articles were identified. After title and abstract screening, 54 articles were reviewed in full text and nine were included in the systematic review. Cardiovascular disease, infections, neoplasms and adrenal crises were the most common causes of death. Of the nine studies, two were removed due to overlapping population. The meta-analysis included therefore 7 studies and in total 10211 patients (6178 with autoimmune PAI and 4033 with CAH). Four studies were cohort studies (6085 patients), assessing mortality using hazard ratios (HR), with a pooled HR of 2.51, 95% CI: 1.47–4.31, $I^2=86.1\%$. Three studies were population-based (4126 patients) that assessed mortality using standardised mortality ratios (SMR), with a pooled SMR of 2.49, 95% CI: 0.99–6.28, $I^2=97.9\%$. Cause-specific mortality and time-trend analyses were not performed due to lack of data or small sample size.
Conclusions
This is the first systematic review and meta-analysis studying mortality in patients with PAI. The analysis shows a 2.5 times higher mortality among patients with PAI compared to controls or general population.

JOINT1304

Prediction of lateralisation in primary aldosteronism – a decision tree model for bypassing adrenal vein sampling in bilateral disease

Julia Beck[1], Christoph Zech[2] & Matthias Betz[1]
[1]University Hospital Basel, Endocrinology, Basel, Switzerland; [2]University Hospital Basel, Interventional Radiology, Basel, Switzerland

Background
Subtyping primary aldosteronism (PA) into unilateral and bilateral disease is essential for effective treatment, as unilateral PA can be treated with adrenalectomy, while bilateral PA is managed medically. The gold standard, adrenal vein sampling (AVS), is creating a bottleneck because it is technically challenging and only available in specialized centers.
Aim
To create a predictive score for identifying bilateral PA with a high specificity to bypass AVS, while ensuring a high sensitivity for unilateral disease.
Methods
Retrospective observational study of patients, who underwent AVS at the University Hospital Basel, Switzerland between 2015 and 2023. A decision tree

model, using *rpart* (R version 4.4.2), was used to predict the likelihood of bilateral disease.
Results
A total of 164 patients with PA underwent AVS. 20 patients were excluded due to insufficient selectivity of AVS, leading to a total of 144 patients that were included in the analysis (38% female, median age 51[45;59]). Final diagnosis, based on AVS results, was unilateral in 68% ($n=98$) and bilateral in 32% ($n=46$) of patients. The classification decision tree with the highest accuracy was built based on the following predictors: *unilateral adrenal mass, potassium, diastolic blood pressure, age, glomerular filtration rate (GFR).* The model achieved an overall accuracy of 81%, with a specificity of 95% and sensitivity of 52% for bilateral disease. Assuming a distribution of 50% of uni- and bilateral disease, this decision model would allow to bypass AVS in 50% of bilateral diseases, translating into 25% total reduction in AVS exams. This comes with a price of 5% of patients with unilateral disease not undergoing AVS and surgery (benefit ratio 8:1). Feature importance analysis indicated diastolic blood pressure, GFR, unilateral adrenal mass, and potassium as most influential variables, while age contributed minimally to the model.
Conclusion
Our findings indicate that a decision tree model, based on variables: *unilateral adrenal mass, potassium, diastolic blood pressure, age, and GFR* can serve as an effective tool for predicting bilateral PA. Importantly, our model works with robust clinical parameters and is not dependent on variables from validation tests (e.g. saline loading test) This classification model has the potential to **first**, minimize the need for complex AVS procedures in patients with bilateral disease, **second**, optimize AVS resources for patients with unilateral disease, and **third** reduce health care costs associated with AVS diagnostics. Prospective validation of this score is necessary.

The genetic and functional analysis of CYP21A2 mutants in congenital adrenal hyperplasia

Yingtong Xu[1,2,3] & Amit Pandey[1,2,4,4]
[1]University Children's Hospital Bern, Department of Pediatrics, Division of Endocrinology, Diabetology and Metabolism, Bern, Switzerland; [2]University of Bern, Translational Hormone Research Program, Department of Biomedical Research, Bern, Switzerland; [3]University of Bern, Graduate School for Cellular and Biomedical Sciences, Bern, Switzerland; [4]Translational Hormone Research Program, Department of Biomedical Research, Faculty of Medicine, University of Bern, Bern, Switzerland

Congenital adrenal hyperplasia (CAH) is a genetic disease inherited in an autosomal recessive manner. Over 90% of CAH cases are caused by reduced activity of 21-hydroxylase encoded by *CYP21A2*, a cytochrome P450 protein which catalyzes the conversion of 17-hydroxyprogensterone (17-OHP) to 11-deoxycortisol and progesterone to 11-deoxycorticosterone (11-DOC), leading to the production of cortisol and aldosterone. Clinically, three distinct phenotypes are identified: the salt-wasting, the simple virilizing, and the nonclassical (NC) phenotype. Typically, the phenotype is dictated by the specific variant present in the milder allele. Therefore, the presence of a severe mutation cannot always be inferred from the phenotype in some cases of NC-CAH, which may lead to the severe symptom associated with significant neonatal mortality and morbidity. Furthermore, discordance between the phenotype and the identical genotype can be observed within families. Protein stability, enzymatic function, and gene expression regulation may contribute to this mechanism. It is necessary to obtain sufficient experimental evidence using computational and functional analysis of mutants to elucidate the molecular pathogenic mechanisms and improve clinical diagnosis. Five novel disease-associated mutants in CYP21A2 were selected from ClinVar by analyzing their positions on the surface of protein structure in PyMOL. Conservation and chemical properties of these amino acid substitutions were predicted using ConSurf, PolyPhen-2, SNAP2, Meta-SNP, Predict SNP, and MutPred2. The structure stability of CYP21A2 variant was calculated by the FoldX tool. Changes in enzymatic activity were measured by the conversion of 17-OHP to 11-deoxycortisol and progesterone to 11-DOC in HEK293T cells. The expression levels of CYP21A2 were determined by Western Blot. Three selected mutations showed less than 50% of WT activity: L308V, R401G, and R436C exhibited 30%, 40%, and 26% of WT activity, respectively. These three mutations showed similar reductions in enzyme activity for both 17-OHP and progesterone conversion: for 17-OHP conversion, L308V, R401G, and R436C exhibited 11%, 43%, and 12% activity, respectively; and for progesterone conversion, L308V, R401G, and R436C exhibited 20%, 27%, and 12% activity, respectively. Mutations E162G and S373N showed 58% and 99% of WT activity, respectively. E162G showed increased expression compared to WT, while the other mutations showed decreased expression. The reduced activity observed for variants L308V, R401G, and R436C shows their potential pathogenicity in CAH. The observed differences in protein expression may be related to gene expression regulation, mRNA degradation, or protein stability. These findings contribute to our understanding of the molecular mechanisms underlying CAH caused by CYP21A2 deficiency.

The impact of alternative treatment approaches on final adult height in patients with congenital adrenal hyperplasia

Sabina Sharifova Mirzayev, Hasan Yanik, Cansu Koc, Asli Derya Kardelen Al, Melek Yildiz, Sukran Poyrazoglu, Hulya Gunoz, Firdevs Bas & Feyza Darendeliler
Istanbul University, Istanbul Faculty of Medicine, Department of Pediatric Endocrinology, Istanbul, Türkiye

Introduction
Congenital adrenal hyperplasia (CAH) is an autosomal recessive disorder, most commonly caused by 21-hydroxylase deficiency (21-OHD). Chronic androgen excess in CAH patients accelerate epiphyseal maturation, and may cause early puberty and epiphyseal fusion which negatively affects growth potential. While conventional therapies help to manage hormonal imbalances, alternative therapies may optimize growth outcomes. This study aimed to evaluate the effects of additional treatment strategies on final height in CAH patients.
Methods
We retrospectively reviewed records of 57 patients (F/M=31/26) with molecularly confirmed classical CAH due to 21-OHD. Among these, 38 patients with predicted adult height (PAH) shorter than target height (TH), due to early puberty and/or advanced bone age, received additional therapies, including anastrozole, cyproterone acetate, GnRHa, and growth hormone (GH) (Group 1). The remaining patients received only conventional hydrocortisone/mineralocorticoid therapy (Group 2). Anthropometric data were compared between groups.
Results
The median age at diagnosis of CAH was 0.1 (range:0–10.3) years and; age at the initiation of alternative therapies in group 1 was 9.2 (range:4.6–11.1) years. In Group 1, 55% received cyproterone acetate, 45% anastrozole, 77.5% GnRHa, and 15% GH. The median treatment duration in Group 1 was 2.3 (range:0.6–7.3) years. Thirty-two patients (82.4%) in Group 1 and 11 (64%) in Group 2 have reached adult height. A significant difference in pre-treatment height SDS was observed between the groups (0.97 [range:−1,1 to 5.3] vs. 0.64 [range:−1.5 to 2.7], respectively; $P=0.02$), with an accelerated somatic growth noted in Group 1. Before alternative therapies, the median PAH SDS was −1.5 (range:−5.5 to 1.9) in Group 1 and −2.3 (range:−4.3 to 3.7) in Group 2, with no significant difference. As expected, the bone age/chronological age ratio before treatment was significantly higher in Group 1 (1.3 [range 1–2.5] vs. 1.0 [range 1.3–1.1], $P<0.001$) with accelerated somatic growth. The comparison of the difference between target height SDS and final height SDS revealed a median of 0.8 (range:−2.8 to 2.4) in Group 1 and 0.1 (range:−2.6 to 2.5) in Group 2, with no statistical significant difference. Final height SDS was −1.5 (range:−3.9 to 0.9) in Group 1 and −1.5 (range:−4.2 to 1.4) in Group 2. It was similar in both groups, and somatic growth acceleration regressed with alternative therapies.
Conclusion
Our data suggest growth-promoting therapies such as aromatase inhibitors, cyproterone acetate, GH and GnRHa appear to be effective in enhancing adult height in appropriately selected cases.

Background

Paediatric Adrenocortical Tumours (pACTs) are potentially devastating neoplasms of the adrenal cortex. The incidence of pACTs is about 0.2–0.3 cases per million children per year in most countries. Most pACTs are hormonally active and most often present with androgen excess. Data suggest that pACTs that solely produce androgens have better survival than tumours that concomitantly produce other steroid classes. Although a thorough endocrine work-up is recommended, there is no consensus on how this should be performed, nor is there guidance on imaging modalities or the extent of genetic investigations.

Aim

To seek international consensus on the initial diagnostic work-up in children and young people with pACTs.

Methods

A modified three-step Delphi consensus method was applied to develop statements from an international group of pACT experts (Delphi panel), comprising 28 participants from Europe, the Americas, and Asia selected by their clinical merit and peer-reviewed publications in the field of pACTs. Electronic surveys were created by the steering committee (members of the European Network for the Study of Adrenal Tumours [ENS@T], KIDS working group) and circulated to the panel. Levels of agreement and disagreement were rated on a six-point Likert response scale with the opportunity to give feedback. After each round, results were discussed within the ENS@T-KIDS group, and questions were reformulated if no consensus (defined as agreement by at least 70%) was reached.

Results

Of the 28 voting members, 24 participated in round 1 (86%), 23 in voting round 2 (82%) and 24 in round 3 (86%). Based on a literature review, 45 statements were formulated by the steering committee and electronically distributed to the Delphi panel for voting. The statements cover four categories: (I) General Aspects and Clinical Assessment (17 statements); (II) Endocrine Work-up (including methodology and assessment of hormone excess; 15 statements); (III) Radiology (7 statements) and (IV) Genetics (6 statements). Of the 45 statements voted upon in round one, only eight did not reach consensus. These eight statements were revised and voted upon in round two, with seven reaching consensus. One statement was further revised based on panel/committee feedback and reached a consensus on round three.

Discussion and conclusion

The diagnostic work-up of rare pACTs varies amongst different centres and countries and partly depends on local resources and individual experiences. For the first time, we have developed expert-based consensus statements formulating a diagnostic pathway to guide a unified approach with practical considerations for the work-up of pACTs.

Once-daily low-dose prednisolone has lower cardiovascular risk than conventional hydrocortisone replacement therapy in adrenal insufficiency: A double-blind randomised controlled trial

Sirazum Choudhury[1,2,3], Kate Lazarus[1,2], Angelica Sharma[1,2], Kavita Narula[1,2], Cara Go[2], Suzie Cro[4], Thilipan Thaventhiran[1,2], Bernard Khoo[5], Tricia Tan[1,2,3] & Karim Meeran[1,2]

[1]Imperial College Healthcare NHS Trust, 1Department of Endocrinology, London, UK; [2]Imperial College London, Division of Diabetes, Endocrinology and Metabolism, London, UK; [3]North West London Pathology, Clinical Biochemistry, London, UK; [4]Imperial College London, Imperial Clinical Trials Unit (ICTU), London, UK; [5]University College London, Endocrinology, London, UK

Background

Current Endocrine Society guidelines recommend thrice-daily hydrocortisone for the management of adrenal insufficiency. Prednisolone is suggested as a second-line treatment but previous studies have evaluated its use at greater than 5 mg. We have safely used low-dose prednisolone (2–4 mg) for over 10 years, culminating in this study to address the current vacuum of evidence.

Methods

Patients with adrenal insufficiency were recruited to this double-blind, randomised crossover study. Participants received 4 months of low-dose prednisolone (2–4 mg) with matching placebo at noon and in the afternoon, or 4 months of standard regimen hydrocortisone (10 / 5 / 2.5 mg). They were then crossed over to the alternative medication for the second study period. Observations (including weight, waist–hip circumference, blood pressure), biochemical data for cardiometabolic health and bone turnover, and subjective health data (SF-36 and Addisons Quality of Life (Addi-QoL)) were collected. Baseline and end-point data were collected at days 1, 30 and 120 of each study period, on both medications.

Results

A significant treatment difference of -1.87 Kg ($P=0.002$) in weight was detected in association with prednisolone treatment. There were further significant reductions in waist circumference and HbA1c of -2.26 cm ($P=0.010$) and -1.23 mmol/mol ($P=0.001$). Bone formation markers were suppressed on prednisolone with a treatment difference of -1.22 µg/l ($P=0.035$) in osteocalcin levels and -13.8 ng/l ($P<0.001$) in Procollagen 1 N-Terminal Propeptide. Bone resorption was also suppressed with Urinary N-telopeptide levels, decreasing by -9.34 nmol/mmol ($P=0.002$) with prednisolone. There was no significant difference in blood pressure, high-sensitivity troponin and CRP, between the treatments. Data from SF-36 survey and Addi-QoL questionnaire demonstrated that subjective health outcomes were unaffected by both hydrocortisone and prednisolone.

Discussion

We demonstrate evidence that low-dose prednisolone is associated with weight loss and reductions in HbA1c, suggesting superior cardiovascular outcomes compared to standard hydrocortisone treatment. This study is limited by the use of short-term markers, but is an important stepping-stone in normalising the use of prednisolone in adrenal insufficiency. Importantly, there were no adverse effects on wellbeing. These results could be explained by the reduced steroid exposure seen with low-dose prednisolone treatment. Alternatively, once-daily dosing may mimic the normal diurnal rhythm of physiological cortisol secretion better than thrice-daily hydrocortisone.

Conclusion

Once-daily low-dose prednisolone is an alternative to standard-regimen hydrocortisone. Further studies should be completed using low-dose prednisolone, focussing on longer term outcomes such as bone-mineral density and real-world mortality.

Evaluation of the overnight dexamethasone suppression test in a large cohort of patients with incidentally discovered adrenal nodules

Hassan Ibrahim, Muhammad Faheem, Sue Parsons, Lisa Yang, Sue Oddy, James Macfarlane, Andrew Powlson, Mark Gurnell & Ruth Casey

Cambridge University Hospitals NHS Foundation, Diabetes and Endocrinology, Cambridge, UK

Introduction

Incidentally discovered adrenal nodules are detected in 1–7% of abdominal imaging studies. The 2023 ESE guidelines recommend the 1-mg overnight

dexamethasone suppression test (ODST) for screening autonomous cortisol secretion (ACS). Previous studies suggest 20–50% of adrenal nodules patients will fail an ODST which, in the absence of clinical evidence of Cushing's syndrome (CS), is termed mild autonomous cortisol secretion (MACS). Herein, we report findings from a large cohort of patients with adrenal nodules.
Methods
512 patients (239 males, 273 females) referred between 2019 and 2023 were included. Patients with a positive ODST (cortisol $\geq$50 nmol/l) had dexamethasone level measured on the same sample to rule out false positives (defined as dexamethasone $\leq$3.7 nmol/l). Patients with abnormal ODST and dexamethasone levels >3.7 nmol/l were investigated for additional evidence of ACS defined as at least two of the following: elevated 24-hour urinary free cortisol, elevated late-night salivary cortisol, 0900 h plasma ACTH <10 pg/mL, suppressed DHEAS level.
Results
Of 512 patients, 52 were excluded due to incomplete data, leaving 460 participants. ODST was normal in 292 (63.5%) and abnormal in 168 (36.5%). Among the abnormal ODST group, 18/168 false positives were identified through dexamethasone measurement, while 150/168 with adequate dexamethasone levels were referred to the specialist adrenal multidisciplinary team (MDT) for further evaluation. Of the 150 patients, 40/150 were not recommended for further investigation by the MDT, and 14/150 declined additional assessment. Among the remaining 96 patients, 65 had no further clinical or biochemical evidence of ACS, while 31 had findings suggestive of ACS, including 3 with overt Cushing's syndrome (CS). The median cortisol level in patients with additional positive biochemical evidence of ACS was significantly higher at 102 nmol/l compared to 79 nmol/l in the abnormal ODST-only group who had no other clinical or biochemical evidence of ACS ($P=0.0019$).
Conclusion
This study highlights the need to consider new biomarkers to better detect MACS and stratify those at highest cardiovascular risk. Furthermore, a revision of the current ODST cortisol cut-off with further analysis needed to improve diagnostic accuracy and evaluate the clinical and economic impact of MACS screening.

Thyroid hormone regulation of adrenal androgens: Observations from the H295R cell model and pediatric CAH patients

Philipp Augsburger[1,2], Therina du Toit[2,3], Suzanne Smit[1,2] & Christa Flück[1,2]
[1]Department of Pediatric Endocrinology, Diabetology, and Metabolism, Inselspital, Bern University Hospital, Bern, Switzerland; [2]Department of BioMedical Research (DBMR), Bern, Switzerland; [3]Department of Nephrology and Hypertension, Bern University Hospital, Bern, Switzerland

Introduction
Thyroid hormones (THs) play an essential role in the development, cellular differentiation and metabolism of the human body. Although TH action on various tissues has been well-described, the effect on the adrenal glands remains less understood. Recent studies have indicated a regulatory role for THs in adrenal cortex development and function. However, the regulation of adrenal androgen production by THs has yet to be clarified.
Aim
To investigate the regulatory role of THs on androgen synthesis in human adrenocortical carcinoma H295R cells and to correlate TH levels to circulatory androgens in pediatric patients with congenital adrenal hyperplasia (CAH).
Methods
H295R cells were incubated with triiodothyronine (T3) [10^{-9} M] in serum-free media for either 48 h or 72 h. Gene expression was assessed by mRNA-sequencing (cutoff value for padj < 0.001), and steroid profiling of cell supernatants was examined via liquid chromatography–mass spectrometry (LC–MS). In addition, serum samples of pediatric CAH patients with 21-hydroxylase deficiency were analyzed, obtained from a prospective, observational multi-center cohort study. At 1 or 2 consecutive visits, a targeted and untargeted panel of conventional adrenal and additional peripheral steroids were measured by LC–MS. Data of 83 visits from 70 children (39 boys, 31 girls; 33 prepubertal, 37 postpubertal) were available. Mean age was 11.0 [1.2; 18.9] years and BMI z-score was 0.51 [−1.84; 2.91]. Free thyroxine (fT4) was measured via chemiluminescence immunoassays. Regression analyses were adjusted for age, sex, BMI-z-score, pubertal status (pre- and postpubertal), CAH subtype (salt-wasting, simple-virilizing, late-onset) and treatment quality (under-, over- and well-treated).
Results
T3 downregulated dehydroepiandrosterone (DHEA) and DHEA-sulfate production in H295R cells (fold changes 0.71 and 0.63 respectively; $P<0.01$), reflecting changes in the transcriptome profile of upregulated *HSD3B2* (log2FC = 1.24) and downregulated *CYP17A1* (log2FC = −0.42) and *PAPSS2* (log2FC = −0.49) gene expression. Likewise, in our CAH patients, we found a weak negative correlation for fT4 and serum DHEA (R^2 =0.251; $P=0.014$), androstenedione (R^2 =0.368; $P=0.018$) and androsterone (R^2 =0.323; $P=0.036$).
Discussion
We show that T3 downregulates adrenal androgen secretion in H295R cells, mediated by changes in the expression of key steroidogenic enzymes. Furthermore, we found weak negative correlations between fT4 levels and serum androgens in pediatric patients with CAH. Together, these results indicate that THs may play a role in adrenal androgen production.

24-hour blood pressure profiles in patients with adrenal insufficiency

Irina Chifu[1], Laura Heger[1], Marcus Quinkler[2], Hanna F Nowotny[3], Georgiana Contsantinescu[4], Christina Pamporaki[4], Nicole Reisch[3] & Stefanie Hahner[1]
[1]University Hospital of Wuerzburg, Division of Endocrinology and Diabetology, Department of Internal Medicine I, Wuerzburg, Germany; [2]Endocrinology in Charlottenburg, Berlin, Germany; [3]LMU University Hospital, Department of Medicine IV, Munich, Germany; [4]University Hospital Carl Gustav Carus, Dresden, Germany

Background
Patients with adrenal insufficiency (AI) have an increased risk of cardiovascular diseases, largely attributed to supraphysiological hormone replacement therapy.
Objective
This study evaluated 24-hour blood pressure (BP) profiles in patients with primary (PAI) and secondary AI (SAI) based on ESC/ESH hypertension thresholds and dipping status. BP profiles were correlated with glucocorticoid (GC) and mineralocorticoid (MC) replacement, cumulative GC dose/week (calculated from daily GC dose and frequency of dose adjustments), plasma steroid profiles, salivary cortisol (SC) day profiles, urinary cortisol as well as routine clinical and biochemical parameters.
Methods and results
We analysed 246 patients (76% PAI; mean age 50±15 years; 69% female). 52% of the subjects either had a preexisting diagnosis of arterial hypertension (22%) or exhibited pathologically elevated blood pressure on 24-h BP measurement (30%). Among patients on antihypertensive treatment ($n=53$, 22%), 60% had elevated 24 h-BP, compared to 41% of untreated patients ($n=187$) ($P=0.01$). The prevalence of elevated 24 h-BP was higher among SAI compared to PAI (58% vs. 41%, $P=0.02$). Nighttime hypertension was more frequent than daytime hypertension (48% vs. 35%), even in patients without previously diagnosed hypertension (42% vs. 30%). One-third were non-dippers, regardless of antihypertensive therapy. No significant differences in GC or MC dose regimens or GC preparations were observed between patients with elevated or normal 24 h-BP. However, both 24-hour diastolic BP and extent of nocturnal dipping positively correlated with cumulative GC dose/week ($r=0.2$, $P<0.01$; $r=0.14$, $P=0.03$). Inverse dippers were more frequent with evening GC use (20% vs. 6%, $P=0.02$). Morning SC levels were significantly higher in patients with elevated 24 h-BP, particularly in patients on short-acting GC and in patients with quantifiable steroid precursors. Logistic regression analyses identified AI etiology, glomerular filtration rate (GFR), body weight, and the frequency of GC dose adjustments as significant predictors of elevated 24-hour BP in the entire cohort. Except for AI etiology, these factors remained significant predictors in subgroups of patients not on antihypertensive treatment and in those with PAI.
Conclusion
Of the subjects, 52% either had a preexisting diagnosis of arterial hypertension or exhibited elevated 24-h BP levels. Frequency of GC dose adjustments was a consistent predictor of hypertension, implying a negative impact of recurrent cortisol spikes on BP regulation. The higher morning SC levels observed in hypertensive patients on short-acting GC and in those with quantifiable steroid precursors suggest that delayed cortisol metabolism and/or residual adrenal function may additionally contribute to increased blood pressure.

JOINT1642

GC–MS urinary steroid metabotyping of aldosterone deficient states

Huijie Li[1], Joern Pons-Kuehnemann[2], Michaela Hartmann[1] & Stefan Wudy[1]
[1]Justus Liebig University, Center of Child an Adolescent Medicine, Division of Pediatric Endocrinology & Diabetology, Laboratory for Translational Hormone Analysis, Steroid Research & Mass spectrometry Unit, Giessen, Germany; [2]Institute of Medical Informatics, Justus Liebig University, Medical Statistics, Giessen, Germany

Introduction
Disorders of isolated deficient aldosterone action involve insufficient production of aldosterone (aldosterone synthase defects type 1 and type 2 (corticosterone methyl oxidase (CMO) I and II)), as well as pseudohypoaldosteronism (PHA) featuring end-organ hormone resistance. Aldosterone is a key regulator of sodium–potassium homeostasis and blood pressure. Deficient action is characterized by hypotension, hyponatremia, hyperkalemia, and dehydration. We investigated whether gas chromatographic–mass spectrometric (GC–MS) urinary steroid metabolome analysis allows for delineation of these entities.
Method
We quantified 44 urinary steroid metabolites from spot urine (μg/l) by targeted GC–MS from 124 infants with aldosterone deficient states (24 CMO I, 26 CMO II, 74 PHA; aged 3–348 days) and 138 matched controls. Relative enzymatic activities were calculated from precursor/product metabolite ratios. Data preprocessing included log2 transformation, Z-score standardization, and quantile normalization, followed by logistic regression and decision tree analysis.
Results
Male patients dominated in all diseases (68%). All entities peaked around the end of the neonatal period (wk4) with CMO manifesting up to six months and PHA extending until the end of the first year of life. Elevated corticosterone metabolite levels distinguished patients best from controls. PHA showed grossly elevated metabolites of aldosterone and its precursors. The ratio between corticosterone and aldosterone metabolites discriminated best between CMO subtypes and PHA. The ratio between 18-hydroxylated corticosterone and aldosterone metabolites differentiated CMO II from CMO I. Decision tree (rpart) analysis identified various sequential classifiers distinguishing controls, PHA, CMO I and CMO II, with high specificity (94%) and sensitivities (96%, 92% and 77%), respectively.
Conclusions
GC–MS urinary steroid metabotyping from spot urine provides a non-invasive and highly reliable new diagnostic tool for delineating aldosterone deficient states in young infants. Various metabolites and metabolite ratios effectively discerned controls, patients with CMO I, CMO II and PHA. The quantitative biomarkers we found allow for a steroid metabolomics based precision medicine approach.

JOINT317

Metabolic associations of premature adrenarche 4 years after menarche

Ana Pereira[1], German Iñiguez[2], Gordon Cutler[3] & Veronica Mericq[2]
[1]University of Chile, Institute of Nutrition and Food Technology (INTA), santiago, Chile; [2]University of Chile, Faculty of Medicine, Institute of Maternal and Child Research, santiago, Chile; [3]consultation LLV, Deltaville, Virginia, USA

Premature adrenarche (PA) is associated with increased adiposity and adverse metabolic profiles at presentation. Recent LC–MS/MS studies have demonstrated adrenal production of potent 11-oxygenated C19 androgens. However, evidence is conflicting about whether girls with PA are at higher risk of developing permanent metabolic dysfunction.
Objective
Does hyperandrogenism in childhood resulting from PA lead to metabolic dysfunction in young adulthood?
Methods
Girls from the prospective observational Growth and Obesity Chilean Cohort Study (GOCS, all with normal birth weight) who had DHEAS measured at age ∼7 ($n=504$, 68%) were studied at 4 years after menarche (4yPM, age ∼16 yr). Subjects were classified by DHEAS concentrations at age 7 into HD ($>75^{th}$ percentile) or normal DHEAS (ND, $\leq 75^{th}$ percentile) subgroups. This definition of PA subgroups allowed identification of PA independently from factors influencing clinical manifestations (*e.g.,* ethnicity or tissue sensitivity).
Results
At 4 YPM girls with HD at 7 years ($n=96$) exhibited higher BMI SDS ($P<0.01$), waist circumference (WC)/height ($P<0.05$), WC/hip ratio ($P<0.05$), and a 47% higher mean DHEAS concentration compared to ND girls. Nevertheless, glycemia, insulin, HOMA-IR, total cholesterol and its subfractions, triglycerides, testosterone, SHBG, FAI, LH, FSH, AMH, and all C19 11-oxo steroids (11-OHA4, 11-OHT, 11-KA4,1-KT) did not differ between the groups. Girls with HD 4YPM did not show greater frequency of metabolic syndrome score in the crude and adjusted models (covariates: birth weight SDS, age at menarche, and BMI at age ∼7) but a higher blood pressure. Furthermore, there was no correlation between HD at age ∼7 and C19 11-oxo concentrations at 4 YPM nor with concentrations of C19 11-oxo above the 75^{th} percentile. Linear regression analysis showed inverse correlations of 11-KA and 11-KT with metabolic score, WC, and triglycerides that were lost after adjustment for covariates. 11-KA4 showed an inverse correlation with glycemia in raw and adjusted models (β −0.02, 95%CI −0.04 to −0.006).
Discussion
Our observations indicate that girls with HD at the age of adrenarche continue to display higher levels of DHEAS after puberty completion but not of the more bioactive 11-oxygenated adrenal androgens. Apart from trends, the unfavorable metabolic signature at adrenarche appeared to diminish at 4 yr post menarche.

Myocardial microcirculation and left ventricular function in former and current female androgenic anabolic steroid users: A cross-sectional study

Anders Kløve Petz[1], Yeliz Bulut[1,2], Niels Brandt-Jacobsen[1,3], Rasmus Westergaard Madsen[1], August Nielsen[1], Jon Jarløv Rasmussen[1] & Caroline Kistorp[1,2]
[1]Department of Nephrology and Endocrinology, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark; [2]Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark; [3]Department of Clinical Physiology and Nuclear Medicine, and Cluster for Molecular Imaging, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark

Background and aim
Impaired myocardial microcirculation, measured by myocardial flow reserve (MFR) has recently been demonstrated in male androgenic steroid (AAS) users. Illicit use of AAS has disseminated to women, though the knowledge on the impact on cardiac function is virtually none. Therefore, the purpose of this study was to investigate cardiac microcirculation and systolic function in current and former female AAS users and compare with female controls with no former AAS use. Coronary artery calcium score was assessed as a secondary outcome.
Methods
This cross-sectional study included recreational strength trained females who were grouped according to their history of illicit AAS use. MFR was investigated using rest and adenosine stressed cardiac rubidium 82 (^{82}Rb) positron emission tomography/ computed tomography (PET/CT). Impaired and subclinical impaired myocardial microcirculation was evaluated using cutoffs of MFR less than 2 and less than 2.5, respectively. Left ventricular ejection fraction (LVEF) was evaluated at rest and during stress, and as LVEF-reserve, calculated as LVEF-stress minus LVEF-rest. Coronary artery calcium score was determined from a non-contrast breath-hold CT.
Results
A total of 54 women, 20 current users (mean (s.d.): 34 (10) years), 17 former users (37 (9) years) and 17 controls (37 (8) years) were included. The accumulated use of AASs were similar between current users (median (IQR): 58 (13–166) weeks) and former users (58 (33–117.5) weeks, $P=0.67$). There were no differences in mean MFR between groups ($P=0.79$). Further, the prevalence of impaired MFR (current users: $n=1$ (5.0%), former users: $n=1$ (5.9%), controls: $n=0$ (0.0%), $P>0.99$), and subclinical impaired MFR (current users: $n=3$ (15.0%), former users: $n=2$ (11.8%), controls: $n=3$ (17.6%), $P>0.99$) did not differ between groups. Mean (s.d.) LVEF-rest and LVEF-stress was reduced in current users (64 (7) % and 72 (7) %) compared to controls (70 (6) %, $P=0.01$ and 78 (19) %, $P=0.01$). In contrast, no significant differences were observed in LVEF-rest and LVEF-stress between former users (68 (5) %, $P=0.47$ and 75 (4) %, $P=0.47$) and controls. No differences were detected in LVEF-reserve ($P=0.92$) and coronary artery calcium score (median (range): current users: 0 (0–2.5), former users: 0 (0–44), controls: 0 (0–0), $P=0.14$) between the three groups.
Conclusion
In this study, there were no group differences in MFR and coronary artery calcium score. However, an impaired left ventricular function demonstrated by a reduced LVEF-rest and LVEF-stress, was found among current female users of AASs compared to female controls.

JOINT1444

Predictors of increased vulnerability for adrenal crises in patients with chronic adrenal insufficiency – long-term follow-up of an initial prospective study

Irina Chifu[1], Anna Lynn Schreiber[1], Marcus Quinkler[2], Holger S Willenberg[3], Nicole Reisch[4], Felix Beuschlein[5] & Stefanie Hahner[1]
[1]University Hospital Wuerzburg, Endocrinology, Würzburg, Germany; [2]Endokrinologiepraxis am Stuttgarter Platz, Endocrinology, Berlin, Germany; [3]Rockstock University Medical Center, Endocrinology, Rostock, Germany; [4]Klinikum der Universität München, Endocrinology, München, Germany; [5]Universitätsspital Zürich, Endocrinology, Zürich, Switzerland

Background
Despite increasing patient education, the prevalence and mortality of adrenal crises (AC) remain high in individuals with adrenal insufficiency (AI). Effective prevention is limited by the absence of established risk profiles. A previous 2-year prospective study identified a positive history of AC as the sole significant risk factor for future AC.
Objective
This study aims to reassess the frequency and predictors of AC over a long-term follow-up period (14 years) within the original study population.
Materials and methods
Patients from the initial prospective study ($n=423$) were re-contacted for a 14-year follow-up via questionnaire. AC prevalence was calculated per 100 patient-years (py). Parameters assessed included glucocorticoid (GC) and mineralocorticoid (MC) replacement therapy, dose regimen, possession of an emergency card and hydrocortisone injection, education status, regular GC dose adjustments, comorbidities, and co-medications.
Results
A total of 200 patients responded (70% female, 55% primary AI). AC prevalence increased from 8.8 AC/py to 11.6 AC/py. Seventeen (8.5%) patients died during the observation period. No significant differences were observed in disease duration, GC replacement dose, or changes in GC dose/preparation between patients who experienced AC and those who did not during the observation period. The highest risk for recurrent AC was observed in patients with a history of AC at baseline compared to those without prior AC (OR 7.1, 95% CI 2.3–21.6). Logistic regression identified AI etiology, prior AC history, type 2 diabetes mellitus, hypothyroidism, and frequency of regular GC dose adjustments as significant predictors of AC. Except for AI etiology, these factors remained significant predictors of AC in the subgroup of patients primary AI.
Conclusion
This study confirms previous findings that a history of AC is the strongest predictor of future AC and identifies additional risk factors contributing to individual vulnerability. These results support the development of personalized risk assessment and prevention strategies for AC.

JOINT2906

Treatment of children and adolescents with congenital adrenal hyperplasia with hydrocortisone modified-release hard capsules

Erwin Lankes[1], Levin Wiebelt[2], Kathrin Helge[1], Oliver Blankenstein[1] & Uta Neumann[1]
[1]Clinic for paediatric endocrinology and diabetology, Charité – Universitätsmedizin, Berlin, Germany; [2]Institute of Biometry and Clinical Epidemiology, Charité – Universitätsmedizin, Berlin, Germany

Context
The standard treatment for congenital adrenal hyperplasia (CAH) in childhood includes hydrocortisone and, for salt-wasting CAH, fludrocortisone supplementation. Regular monitoring and dose adjustments are essential to prevent over- or under-dosing during growth and puberty. Conventional fast-acting hydrocortisone often fails to adequately suppress the early morning surge of 17-OH progesterone (17OHP), and the requirement for three daily doses poses adherence challenges. In 2021, the European Medicines Agency approved hydrocortisone modified-release capsules (HMRC, Efmody®) for children aged 12 and older with CAH. Its modified release allows for twice-daily dosing, with the highest dose at bedtime, better replicating physiological cortisol secretion by achieving peak levels in the early morning.
Objective
To investigate growth, pubertal development, safety, long-term disease control and dosage of hydrocortisone and fludrocortisone in children and youth with CAH treated with HMRC and monitored by 17OHP saliva profiles.
Methods
This study is a retrospective, descriptive analysis of CAH patients treated at a single-center outpatient clinic. Linear mixed models (LMMs) are used to compare the average growth rate of parental target height and BMI before and after switching to hydrocortisone modified-release capsules (HMRC). Additionally, average dosage, blood pressure, and 17OHP level before and after switch are calculated using LMMs. The LMMs account for patient heterogeneity in time-dependent changes. Pubertal status is assessed using breast stage in females and testicular stage in males.
Results
Since September 2021, 42 children with CAH (22 males) have been treated with hydrocortisone modified-release capsules (HMRC). At the time of treatment switch, the median age was 11 years (IQR 8–14), with 16 children classified as prepubertal, 17 as pubertal, and 9 as postpubertal. Prior to the switch, growth rates were accelerated (0.10 z-scores/year, CI: 0.04–0.15, $P<0.001$), whereas a deceleration was observed afterward (-0.05 z-scores/year, CI: -0.15 to 0.04), particularly in (pre-)pubertal patients (0.13 vs. -0.12). The average hydrocortisone dosage increased by 3.25 mg/m^2 per day upon switching from immediate-release hydrocortisone to HMRC. Morning 17OHP levels suggested underdosage before the switch (323 ng/l, CI: 250–396) and improved control afterward (228 ng/l, CI: 167–289, $P<0.01$). No increase in adrenal crises was observed.
Conclusion
HMRC treatment in children with CAH improves morning pre-dose 17OHP levels, while growth rates align more closely with the parental target height. No significant adverse effects or severe complications were observed. Further research is needed to assess long-term outcomes and quality of life.

AZD1775: effect of monotherapy or EDP-M combination in the treatment of ACC preclinical models

Emma Nozza[1,2], Rosa Catalano[1], Genesio di Muro[1], Sonia di Bari[1,2], Gianluca Lopez[3,4], Giusy Marra[1], Emanuela Esposito[1], Federica Mangili[5], Donatella Treppiedi[5], Michele Battistin[6,7], Giovanna Mantovani[1,5] & Erika Peverelli[1,5]
[1]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [2]PhD Program in Experimental Medicine, University of Milan, Milan, Italy; [3]Pathology Unit, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy; [4]Department of Biomedical, Surgical, and Dental Sciences, University of Milan, Milan, Italy; [5]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [6]Center for Preclinical Research, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy; [7]Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy

Adrenocortical carcinoma (ACC) is a rare and aggressive endocrine cancer. The current treatment for advanced ACC is represented by EDP-M (etoposide, doxorubicin, cisplatin + mitotane), but its efficacy is limited and new therapeutic approaches are needed. Previous *in vitro* findings of our group showed that AZD1775, an inhibitor of the G2/M checkpoint gatekeeper Wee1, reduces proliferation and increases apoptosis in ACC cell lines and primary cultured cells. Aim of this study was to test in vitro, in vivo, and ex-vivo the effects of the combined AZD1775+EDP-M therapy, as well as to validate AZD1775 antitumoral efficacy in a preclinical mouse model of ACC. In human ACC H295R cells the coincubation of AZD1775 and EDP-M showed synergistic effects in reducing both cell viability and cell proliferation (HSA Synergy Score 11.86 and 17.63, respectively). The growth of H295R-derived tumor xenografts in athymic nude mice was significantly reduced after single or combined treatment vs. control group (tumor volume increase in untreated +168(32–253)% after 21 days, +24.5(7–75)% in AZD1775 group, +53(6–116.8)% in EDP-M group, and +45.5(13–84.5)% in AZD1775+EDP-M group). All treatments were well tolerated and histological examination of hearts and kidneys of treated animals did not reveal signs of toxicity. Interestingly, AZD1775 was the most efficient drug in inducing tumor cell necrosis. At last, ex vivo primary cultures of untreated and AZD1775+EDP-M treated tumor xenografts were incubated with single or combined drugs. Cell proliferation assays demonstrated that cells derived from mice treated with combination therapy for 21 days were less responsive to AZD1775 or to EDP-M compared to cells derived from untreated mice, suggesting the possible onset of resistance mechanisms. Interestingly, the co-incubation of these cells with AZD1775+EDP-M maintained a strong inhibitory effect (−60.7% of cell proliferation in pre-treated cells vs −80.7% in naïve cells). In conclusion, we showed the high efficiency of AZD1775 therapy on H295R xenografts, which resulted comparable to EDP-M monotherapy, without

any off-target toxicity. Furthermore, the combined therapy AZD1775 + EDP-M synergistically reduced cell proliferation and viability in vitro, impaired tumor growth of H295R xenografts, and was efficient even upon re-exposure of cells derived from treated mice. Our data support AZD1775 as a novel therapeutic option for ACC, as well as its combination with EDP-M as a useful strategy to enhancing drug efficacy, possibly reducing the therapeutic dose, minimizing side effects and preventing the development of drug resistance.

Adrenalectomy ameliorates cardiovascular profile in patients with mild autonomous cortisol secretion: results of a RCT

Valentina Morelli[1], Maria Strata[2], Serena Palmieri[2], Carmen Aresta[3], Vittoria Favero[4], Sofia Frigerio[2], Flavia Pugliese[5], Antonio Musolino[4], Alberta Dall'Antonia[4,6,6], Sabrina Corbetta[4], Maura Arosio[4], Alfredo Scillitani[5] & Iacopo Chiodini[3,4]
[1]Istituto Auxologico Italiano IRCCS, Milan, Italy; [2]Fondazione IRCCS Cà Granda, Milan, Italy; [3]Ospedale Niguarda, Unit of Endocrinology, Milan, Italy; [4]University of Milan, Milan, Italy; [5]Ospedale Casa Sollievo della Sofferenza, IRCCS, San Giovanni Rotondo (FG), Italy; [6]Milan, Milan, Italy

Context
The best therapeutic approach in patients with mild autonomous cortisol secretion (MACS) is debated.
Objective
To evaluate the effect of adrenalectomy on blood pressure (BP), glycometabolic control, cardiac structure and coagulation factors in patients with MACS.
Design
Prospective randomized controlled trial.
Setting
Outpatients.
Patients
Patients with adrenal incidentaloma (AI) >1 cm and cortisol after 1 mg dexamethasone suppression test (F-1 mgDST) between 1.8 (50 nmol/l) and 5 μg/dL (138 nmol/l).
Intervention
Randomization to adrenalectomy (Arm-A) or conservative approach (Arm-B).
Main outcomes measure
BP, coagulation factors, echocardiography and glycemic control, parameters and medical therapy changes assessed at baseline and 12 months after recovery or observation, in Arm-A and Arm-B, respectively.
Results
Fifty-one subjects (23/28 in Arm-A/Arm-B) were enrolled. At follow-up the prevalence of BP improvement was higher in Arm-A (43.5%) than in Arm-B patients (14.3%, $P=0.020$). The improvement of BP control was 5.4-fold more frequent in Arm-A patients (CI, 1.16–24.9 $P=0.031$), regardless of confounding factors. Left ventricular (LV) mass and Left atrial (LA) area decreased at follow-up in Arm-A (96.4 ± 28.8 vs 87.6 ± 25, 6 g/m^2, $P=0.039$; 28.4 ± 9.9 vs 22.6 ± 12.4 cm^2, $P=0.037$, respectively), whereas they remained stable in Arm-B. At the end of follow-up, Arm-A patients had a lower prevalence of altered anti-coagulant parameters (10% vs 50%, respectively, $P=0.005$). The improvement of ≥ 1 out of hypertension, LV hypertrophy or LA dilatation and coagulation state was observed in 82.5% of patients of Arm-A and in 49.1% of Arm-B group ($P=0.015$)
Conclusion
In patients with MACS surgery ameliorates BP, cardiac structure, and coagulation factors

Assessing hypothalamus–pituitary–adrenal axis in Prader-Willi syndrome: experience in a tertiary care centre

Carmen Bucolo[1], Agnese Solmi[1], Beatrice Volpe[1], Maria Rosaria Galati[1], Roberta Pajno[1] & Gianni Russo[1]
[1]IRCCS San Raffaele Hospital, Milan, Italy

Background
Central adrenal insufficiency (CAI) is a severe endocrinological manifestation reported in Prader Willi Syndrome (PWS). To date there is no consensus on the most reliable dynamic test to assess the adrenal function or whether to treat CAI. We aimed to evaluate adrenal function using morning plasma cortisol (MPC) and Low-Dose Tetracosactrin Stimulation Test (LDTST) in a paediatric PWS cohort; we also evaluated the usefulness of Glucagon stimulation test (GST) in those in transitional age who reached adult height.
Methods
We retrospectively analysed MPC and ACTH levels in 94 GH-treated PWS patients (48:M, 46: F), aged 0.5–17.9 years, followed at San Raffaele Hospital over the past 16 years. An MPC level of ≥ 60 ng/mL was considered normal; a LDTST test was performed if MPC was lower than 60 ng/ml on two MPC measurements. A cortisol peak <180 ng/mL after LDTST was suggestive of CAI. We also assessed hypothalamic–pituitary–adrenal (HPA) function in those patients undergoing GST during transitional age at adult height achievement; in this case adrenal insufficiency was considered as peak of cortisol <167 ng/mL, according to prior studies.
Results
The median MPC and ACTH levels were 75.5 ng/mL [54; 109] and 16 pg/ml [12; 22.38], respectively. No patients showed laboratory abnormalities suggestive of CAI, such as hypoglycaemia, hyponatremia, or hyperkalaemia. Only one patient (1%) presented abnormal weight loss, albeit in absence of anorexia, fatigue or salt cravings. Eight subjects (8.5%) underwent LDTST: median basal and peak cortisol levels were 40 ng/ml [30.5; 55.75] and 185 ng/ml [149.3; 217.3], respectively. Four out of eight patients (50%) showed a pathological test response, although the cortisol peak was not indicative of severe CAI. These patients were advised to take hydrocortisone only during acute illness or stressful events. Total of nine patients (9.5%) underwent GST during transitional age, all showing an adequate cortisol response (median peak 198 ng/ml [172.5; 216]).
Conclusions
This study suggests that CAI, despite rare, is a potentially life-threatening endocrinological manifestation in PWS. Considering its subtle presentation, monitoring adrenal function in PWS patients is crucial. Morning basal cortisol alone has a limited diagnostic value for CAI, but it appears useful as an initial step in CAI screening. To improve diagnostic accuracy, we believe that a dynamic stimulation test should be performed in every PWS patient at least once. Further studies are needed to establish defined criteria for diagnosis and treatment of CAI.

Intraocular pressure and risk of glucocorticoid-induced ocular hypertension are increased in children with congenital adrenal hyperplasia

Kübra Yüksek Acinikli[1], Özlem Ural Fatihoğlu[1,2], Özlem Kayır Kurt[3], Gözde Akın Kağızmanlı[1], Özge Yıldırım Şalbaş[1], Deniz Özalp Kızılay[3], Gül Arıkan[2], Damla Gökşen[3], Korcan Demir[1], Ece Böber[1] & Ayhan Abacı[1]
[1]Dokuz Eylül Medical Faculty, Pediatric Endocrinology, izmir, Türkiye; [2]Dokuz Eylül Medical Faculty, Pediatric ophtalmology, Izmir, Türkiye; [3]Ege University Medical Faculty, Pediatric Endocrinology, Izmir, Türkiye

Background
Children with classical congenital adrenal hyperplasia (CAH) require lifelong glucocorticoid (GC) treatment. An important side-effect of steroids is GC-induced ocular hypertension, which may cause irreversible blindness known as GC-induced glaucoma.
Aim
This study aimed to evaluate the intraocular pressure (IOP) and the risk of GC-induced ocular hypertension in pediatric patients with congenital adrenal hyperplasia (CAH), a condition requiring long-term GC therapy due to impaired adrenal steroid synthesis.
Method
The study included patients aged 4–21 years diagnosed with salt-wasting or simple virilizing CAH and receiving hydrocortisone therapy, along with age-matched healthy controls. Data including GC dosages, auxological parameters, and levels of serum androstenedione (AS) and 17-hydroxyprogesterone (17-OHP) over the past year for all patients. IOP was measured using an Icare tonometer, with intraocular hypertension defined as a peak IOP of ≥ 21 mmHg in either eye. IOP levels were compared among CAH patients based on hydrocortisone dosage (≥ 15 mg/m^2/day as high dose; <15 mg/m^2/day as maintenance dose).
Results
The median ages of CAH patients ($n=26$) and controls ($n=45$) were 12 ± 5 and 11.5 ± 2.9 years, respectively ($P=0.63$). No difference was observed between the groups in terms of age and gender ($P=0.63$, $P=0.8$, respectively). IOP levels were significantly higher in CAH patients (20 ± 3 mmHg) compared to healthy controls (13.8 ± 3 mmHg) ($P<0.001$). Fourteen of CAH patients (53%) had intraocular hypertension; among these, three were treated with dexametasone

(daily doses were 0.25 mg, 0.375 mg, and 0.5 mg). Age, gender, mean 17-OHP and AS levels over the past year of patients with intraocular hypertension were similar with those of normotension subgroup. However, the change in BMI SDS over the past year was significantly higher in patients with intraocular hypertension ($P=0.005$). Median IOP levels were similar ($P=0.5$) between the high dose hydrocortisone ($n=9$) and maintenance dose ($n=14$) groups. The correlation analyses revealed no significant associations between IOP and age, disease duration, AS, or 17-OHP levels. However, a positive significant correlation was observed between BMI SDS change over last year and IOP ($r=0.5$, $P=0.008$).

Conclusion

In patients with CAH, systemic GC can cause increased IOP which indicates the need for IOP screening of these children. Increase in BMI can be an additional risk factor.

Analysis of novel ventricular repolarization parameters in Cushing's syndrome: A comparative study

Caglar Keskin[1], Çağrı Yayla[2], Ekin Yiğit Köroğlu[1], Muhammed Saçıkara[1], Didem Özdemir[3], Oya Topaloglu[3], Reyhan Ersoy[3] & Bekir Cakir[3]

[1]Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, ankara, Türkiye; [2]Ankara Bilkent City Hospital University of Health Sciences, Department of Cardiology, Ankara, Türkiye; [3]Ankara Yıldırım Beyazıt University Faculty of Medicine, Department of Endocrinology and Metabolism, ankara, Türkiye

Introduction

Cardiovascular complications are leading causes of morbidity and mortality in Cushing's disease, including hypertension, myocardial infarction, stroke, dilated-hypertrophic cardiomyopathy, heart failure, pulmonary embolism, and arrhythmias. Electrocardiography (ECG) remains one of the most reliable methods for assessing cardiac electrical activity. The Tpeak-end (Tp-e) interval, which represents the time from the peak of the T wave to its end, is a repolarization parameter that reflects both global and transmural repolarization. An increased Tpe interval has been shown to predict in-hospital and long-term mortality in patients with acute myocardial infarction. These ECG parameters have been associated with poor prognosis and mortality in various diseases beyond cardiovascular conditions. This study aimed to evaluate changes in ventricular repolarization parameters on ECG in patients with Cushing's syndrome.

Methods

This study included 45 patients with ACTH-dependent or ACTH-independent Cushing's disease, along with a control group matched for age and gender. Patients with known cardiovascular diseases, those using antiarrhythmic drugs, and those with electrolyte disturbances were excluded. All participants underwent a standard 12-lead ECG (filter 40 Hz, 25 mm/s, 10 mm/mV). An experienced cardiologist measured heart rate, P-wave duration, QRS complex, T-wave duration, PR interval, Tp-e interval, and QT interval.

Results

A total of 83 participants were included, comprising 41 patients with Cushing's syndrome (Female/Male: 32/9) and 42 healthy controls. Among the patients, 27 had ACTH-independent and 14 had ACTH-dependent Cushing's disease. P-wave duration, Tp-e interval, and Tp-e/QT and Tp-e/QTc ratios were significantly increased in the Cushing's group compared to controls ($P<0.001$). Additionally, the QTc interval and P-wave duration showed a significant negative correlation with midnight salivary cortisol levels.

Conclusion

Our study found that P-wave duration, Tp-e interval, and Tp-e/QT and Tp-e/QTc ratios were elevated in patients with Cushing's syndrome compared to control subjects. These findings suggest that ECG changes linked to ventricular arrhythmias and mortality may be present in Cushing's syndrome, highlighting the need for further investigation and monitoring of these patients.

JOINT2103

Assessment of adrenal function after glucocorticoid therapy for childhood onset first episode nephrotic syndrome

Palak Garg[1], Anju Seth[1], Abhijeet Saha[1], Preeti Singh[1] & Ritu Singh[2]

[1]Kalawati Saran Children Hospital, Lady Hardinge Medical College, Paediatrics, New Delhi, India; [2]Lady Hardinge Medical College, Biochemistry, New Delhi, India

Background

Adrenal insufficiency (AI) is a significant concern in children having prolonged glucocorticoid therapy for childhood onset first-episode nephrotic syndrome. As AI results in impaired cortisol response during stressful conditions, which can lead to life-threatening adrenal crisis if stress dose of corticosteroid is not administered on time. Therefore, this highlights the need for regular monitoring of adrenal function after discontinuing steroid therapy.

Objectives

1. To assess the proportion of children having adrenal insufficiency within 5 days after discontinuing steroid therapy for first episode nephrotic syndrome and again after 6–8 weeks.
2. To assess features of steroid toxicity at both time points.

Methods

This study included 40 children with first-episode nephrotic syndrome who received standard corticosteroid therapy as per ISPN guidelines. Adrenal function was assessed within 5 days and again at 6–8 weeks after discontinuing steroids by measuring 0800 h basal and 1-hour post ACTH stimulation serum cortisol levels (obtained after 25 IU I/M injection of Acton Prolongatum). Basal serum cortisol < 3 µg/dL were considered low and suggestive of adrenal insufficiency. Confirmed adrenal insufficiency was defined as post-stimulation serum cortisol $<$ 18 µg/dL. Steroid toxicity features were also assessed at both time points.

Results

Mean basal and post-stimulated cortisol levels increased significantly from first to second assessment ($P<0.001$ for both) indicating progressive adrenal recovery with time after discontinuing steroid therapy. Low basal cortisol was present in 42.5% cases at first and 2.5% cases at second assessment. Adrenal insufficiency was present in 52.5% within 5 days of stopping steroids which decreased to 27.5% at 6–8 weeks. Steroid toxicity at first assessment included moon face (97.5%), buffalo hump (25%), hirsutism (42.5%), pre-hypertension (25%) and hypertension (12.5%) which was reduced to 72.5%, 10%, 22.5%, 7.5%, and 5% respectively by the second assessment. Impaired fasting sugar was seen in 17.5% at first and 12.5% at second assessment. No children were overweight, obese, diabetic or showed clinical symptoms of adrenal insufficiency during study period. Hypertension and impaired blood sugar were significantly associated with adrenal insufficiency at the first assessment, but not at the second.

Conclusion

Over half of the children had adrenal insufficiency soon after stopping steroids, with more than a quarter still affected at 6–8 weeks. This highlights the need for regular adrenal function monitoring post-steroid therapy to prevent adrenal crisis and optimize the use of stress-dose steroids. The study also demonstrates the reversible nature of steroid-related side effects after treatment cessation.

Manchester Children's Hospital, Manchester, UK; [18]University of Cambridge, Cambridge, UK

Background
Congenital adrenal hyperplasia (CAH) is one of the commonest forms of primary adrenal insufficiency, around 70 children being diagnosed every year in the UK. Our national survey indicated variations among clinicians in the management of children and young persons with CAH. We wanted to use the SDMregistries to gain further insight regarding the current practice of CAH clinical management in children in the UK.
Methodology
We launched a 5-year-project in 03/2022, collecting annually longitudinal data from the SDMregistries platform on UK patients under 18 with 21-hydroxylase deficiency, the most common form of CAH.
Results
The first data extraction in 09/2022 provided data from 44 eligible patients (5 centres), with a median of 8 patients per centre (range 3–15). The second data extraction in 03/2024 showed an increase in participation, including 96 patients from 15 centres, with a median of 4 patients per centre (range 1–20). Of these, only 68 (70%) had sufficient data to allow an analysis of the replacement medication. We analysed information related to medication and height standard deviation scores (SDS) for age and sex. The mean daily glucocorticoid (GC) dose was 12.0 ($\pm$3.8 S.D.) mg/m^2 per day hydrocortisone-equivalent, with broad variations between centres ranging from 7.7 ($\pm$1.2) to 19.1 ($\pm$7.7) mg/m^2 per day. The dose decreased with age by 0.2 mg/m^2 per day per year, and depended upon centre; it also varied with sex, doses used in girls being lower by 1.1 mg/m^2 per day compared to boys. We identified different GC administration regimes, with variation in the time of administration of the first daily hydrocortisone dose between 04:00 and 09:00, and six centres using midnight doses. Total daily fludrocortisone doses ranged between 50 and 300 μg/day, with significant variation between centres ($R^2=0.44$, $P<0.01$). Generalised additive model fit showed height SDS fluctuated with age, starting from -0.6 in infancy increasing to 0.7 at 10 years and then decreasing to -1.0 at 17.5 years.
Conclusions
These preliminary findings warrant further investigation to establish potential different approaches and analyse outcomes. Thus, we are implementing a strategy to increase recruitment by actively engaging UK centres involved in the management of CAH patients under 18 into recording their data in I-CAH. Data will be collected and analysed annually, to assess the current level of care provision and inform the development of national CAH standards. This work will help to develop a standardised approach to hormone replacement in CAH and create a framework for benchmarking management at national and international level.

Increased prevalence and incidence of psychiatric and sleep disorders in patients with non-functional adrenal tumors

Hadis Mirzaei[1], Jonatan Lindh[2], Buster Mannheimer[1] & Henrik Falhammar[3]
[1]Karolinska Institutet, Department of Clinical Science and Education, Södersjukhuset, Stockholm, Sweden; [2]Karolinska Institutet, 3Laboratory Medicine, Division of Clinical Pharmacology, Stockholm, Sweden; [3]Karolinska Institutet, Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden

Importance
Current research has yet to elucidate the potential relationship between non-functional adrenal tumors (NFATs) and various mental health conditions, including psychiatric and sleep-related disorders. An increase could be hypothesized due to very mildly abnormal cortisol secretion in patients with NFATs.
Objective
To investigate the prevalence and incidence of psychiatric and sleep-related disorders in individuals diagnosed with NFAT.
Design, setting, and participants
A national retrospective register-based study was conducted on patients diagnosed with NFAT in Sweden from 2005 to 2019 and controls without adrenal tumor diagnosis, followed until death or the conclusion of 2020. Individuals diagnosed with adrenal hormonal excess were excluded from the study.
Exposures
NFAT diagnosis.
Main outcomes and measures
Primary study outcomes were the prevalence and incidence of any psychiatric and sleep disorders after adjustment for sex and age. The secondary outcomes were sleep disorders, substance abuse disorders, psychotic disorders, mood disorders, anxiety and stress-related disorders.
Results
Among 33 348 cases, 18 510 (55.5%) were women, and the median (IQR) age was 68 (59; 74) years. Among 144 983 controls, 80 942 (55.8%) were women, and the median (IQR) age was 67 (59; 74) years. Previous psychiatric and sleep disorders were more prevalent in patients diagnosed with NFAT compared to controls (odds ratio (OR) 1.74, 95% CI 1.69–1.80, adjusted OR 1.71, 95% CI 1.66–1.77). Similar increases were found in all secondary outcomes. During the follow-up period (5.4 years (IQR 2.5–8.8)), the incidence of psychiatric and sleep disorders was higher in patients with NFAT than in controls (hazard ratio (HR) 2.06, 95% CI 1.97–2.15, adjusted HR 2.03, 95% CI 1.94–2.13). Similar increases were found in all secondary outcomes.
Conclusion and relevance
NFAT was associated with an increased risk of psychiatric and sleep disorders.

Macrophage polarisation in patients with autonomous cortisol excess

Ana Crastin[1], Ezra Leander Onesimu[1], Oskar Podstawka[1], Mengjie Xu Mengjie[2], Vittoria Favero[1,3], Chiara Parazzoli[1,4], Alessandra Mangone[1,4], Alessandro Prete[1,5], Rowan Hardy[1] & Cristina L Ronchi[1,5]
[1]Metabolism and Systems Science, Institute of Biomedical Research, University of Birmingham, Birmingham, UK; [2]Taihe Hospital, Hubei University of Medicine, Shiyan, China; [3]Department of Biotechnology and Translational Medicine, University of Milan, Milan, Italy; [4]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [5]Department of Endocrinology, Queen Elizabeth Hospital, Birmingham NHS Trust, Birmingham, UK

Background
Adrenal Cushing's syndrome (CS) is characterized by chronic, endogenous cortisol excess, which disrupts innate and adaptive immune functions. This dysregulation is observed as increased monocyte and reduced lymphocyte counts. However, the effects of "subclinical" CS in patients with cortisol-producing adenomas (CPA) and mild autonomous cortisol secretion (MACS) remain insufficiently understood. We hypothesize that macrophage polarization and activation may be altered in these patients, potentially leading to significant immune dysfunction.
Methods
Our cohort included 14 patients, i.e. 5 with CPA-MACS, 4 with CPA and overt CS (CPA-CS), and 5 sex- and age-matched patients with endocrine-inactive adenomas (EIA) as controls. Serum samples were collected during standard visits, centrifuged within 1–2 hours from collection, and stored at -80 °C. Primary human macrophages were polarized to an M1-like inflammatory state by adding TNFα (10 ng/ml) and IFNγ (20 ng/ml), followed by co-treatment with 10% serum from patients with adrenocortical adenomas. The macrophages were incubated for 24 hours, and inflammatory and anti-inflammatory cytokine levels and gene expression were measured using ELISA and RT-qPCR techniques. Cytokines and gene expression levels were correlated with clinical parameters (e.g. age, sex, tumour size) and degree of cortisol secretion (e.g. cortisol after overnight dexamethasone test, ACTH, and DHEAS levels).
Results
Pro-inflammatory markers such as TNFα exhibited a slight decrease in M1-polarized macrophages exposed to serum from both CPA-MACS ($P=0.1916$) and CPA-CS ($P=0.1217$) patients when compared to controls. A similar pattern was observed for IL6, with significant reductions noted in CPA-MACS ($P=0.0389$) and CPA-CS ($P=0.0283$) serum-treated macrophages compared to EIA. Gene expression data indicated non-significant trends in IL6 reduction in both CPA groups (CPA-MACS: $P=0.0794$, CPA-CS: $P=0.1302$). Additionally, GILZ (glucocorticoid-induced leucine zipper) gene expression was modestly elevated in CPA-CS patients ($P=0.2830$), though no change was observed in CPA-MACS ($P=0.9921$). The pro-resolving M2-like marker CD163 showed slight increases in gene expression in both CPA-MACS ($P=0.1761$) and CPA-CS ($P=0.1545$) groups compared to EIA controls. Notably, CD163 expression was strongly correlated with GILZ ($P<0.0001$) and the anti-inflammatory marker

CD64 ($P=0.0038$). The ratio of IL6 to CD163, reflecting M1-to-M2 polarization, was elevated in CPA-CS samples ($P=0.0614$). Additionally, CD163 expression correlated with post-ONDST cortisol levels ($P=0.0153$) and tumour size ($P=0.08$).

Conclusions

Both CPA-MACS and CPA-CS patients demonstrated suppression of M1-like inflammatory markers and a shift towards M2-like polarization, which could contribute to immune dysregulation. Further experiments with a larger cohort and additional functional assays are ongoing to identify the mechanisms driving these immune alterations.

Aldosterone, renin and their ratio (ARR) in patients with newly diagnosed and untreated hypertension

Harpa Gunnarsdottir[1], Gudmundur Sigthorsson[2], Isleifur Olafsson[2], Thor Aspelund[3], Vilmundur Gudnason[3] & Helga Sigurjónsdóttir[1]
[1]Landspitali University Hospital, Internal Medicine, Reykjavik, Iceland; [2]Landspitali University Hospital, Clinical biochemistry, Reykjavik, Iceland; [3]Icelandic Heart Associations, Reykjavik, Iceland

Background

Primary hyperaldosteronism (PA) is more prevalent than previously recognized. The prevalence of PA in patients with undiagnosed and untreated hypertension (HT) is less known. In a prior population-based study, REFINE-REYKJAVIK study (RRS), carried out in Iceland 2005–2006, 8815 men and women born between 1935 and 1985, and living in the Reykjavik area, were randomly drawn from the Icelandic national registry. Of those, 6941 (73%) individuals attended the study. Thereof, 420 participants were diagnosed with previously unrecognized and untreated HT. The aim of the presented study is to evaluate serum aldosterone (s-aldosterone), plasma renin (p-renin) and their ratio (ARR) taken at baseline and the difference between participants with HT in comparison to normotensive (NT) counterparts.

Methods

As part of RRS, systolic (SBP) and diastolic (DBP) blood pressure was measured at baseline, and HT diagnosed if SBP was over 140 mmHg and/or DBP over 90 mmHg. Blood samples were collected between 08 and 10 AM (68%), 10–12 AM (30%) and few after 12 PM (1.5%). The specimens, initially cooled for up to maximum of 6 hours before being frozen at -80°C and stored. S-aldosterone and p-renin was measured in the 402 HT patients and the 207 NT participants. A Mann–Whitney U test was implemented in comparing the groups. Statistics were performed by using datatab.net.

Results

The mean value for s-aldosterone was 253.09 pmol/l $\pm$ 167.58 in HT ($n=402$) and 267.5 pmol/l $\pm$ 170.8 in NT ($n=207$), the difference was not significant ($P=0.817$). The mean value for p-renin was 11.15 mIU/l $\pm$ 11.32 in HT and 13.56 mIU/l $\pm$ 11.2 in NT. The difference was significant $P<0.001$. The ARR in the HT group was 39.95 $\pm$ 39.11 and 29.64 $\pm$ 23.49 in the NT group, the difference was significant, $P=0.005$. Mean serum potassium levels for the groups was 4.22 mmol/l $\pm$ 0.28 in HT and 4.19 mmol/l $\pm$ 0.27 in NT, the difference was not significant $P=0.952$.

Discussion

These findings show that p-renin was significantly lower in the HT group compared to the NT group and ARR was thus significantly higher in individuals with newly diagnosed and untreated HT compared to NT counterparts. These findings emphasize the importance of using aldosterone, renin and ARR in patients with newly diagnosed HT. As PA seems to be largely underdiagnosed; these findings support the need to screen for PA at the time of diagnosis of HT.

Incidental adrenal nodules: A single-center study on the prevalence and radiological predictors of phaeochromocytoma

Muhammad Faheem[1], Hassan Ibrahim[1], James McFarlane[1], Sue Parsons[1], Sue Oddy[2], David Halsal[2], Mark Gurnell[1] & Ruth Casey[1]
[1]Cambridge University Hospitals, Endocrinology, Cambridge, UK; [2]Cambridge University Hospitals, Biochemistry, Cambridge, UK

Introduction

Phaeochromocytomas are increasingly diagnosed incidentally during cross-sectional imaging for other indications. Biochemical confirmation can be obtained via plasma free metanephrines or a 24-hour urine collection for normetanephrine and metanephrines. However, recent ESE guidelines suggest biochemical testing may not be necessary for patients with clear radiological features of an adrenal adenoma.

Methods

A retrospective analysis was conducted on the radiological and biochemical data of patients with incidentally discovered adrenal nodules reviewed at Cambridge University Hospital from 2019 to 2024.Only cases with formal radiological characterization of the adrenal nodule via unenhanced CT, dedicated CT adrenal imaging, or MRI were included. Data collected included age, gender, plasma metanephrines, laterality, tumour size, histology, genetics, and follow-up.

Results

A total of 631 patients were included, with 296 males (47%) and 335 females (53%). Of these, 507 (80.34%) had nodules with attenuation <10 Hounsfield units (HFU) or signal dropout on MRI. 61 patients (9.66%) had densities between 10 and 20 HFU, and 63 (10%) had densities >20 HFU. Most nodules (94.45%) were <4 cm in size, with 35 (5.55%) >4 cm. 521 nodules (82.56%) were unilateral and 110 (17.43%) bilateral. The mean age was 66 years (range 21–91). Two patients (0.4%) with radiologically characterized lipid-rich adenomas had abnormal plasma metanephrine results (<2 times the upper reference range), one of whom was on Venlafaxine. Both cases are pending further evaluation, with a low clinical suspicion for phaeochromocytoma. Among the 631 patients, 7 (1%) were diagnosed with phaeochromocytoma, all of which had nodules with densities >20 HFU on unenhanced CT scan adrenal glands. 4 were females and 3 males. It is important to mention that two ($\sim$28%) were reported as adenomas on washout studies but later confirmed as non-secretory pheochromocytomas. Histological analysis showed retained SDHB immunoreactivity in all cases. Genetic testing in five patients revealed an NF1 gene mutation in one with composite pheochromocytoma.

Conclusion

This study found a 1% prevalence of phaeochromocytoma in patients with incidentally discovered adrenal nodules. All confirmed cases had unenhanced nodules with densities >20 HFU. Histological analysis showed retained SDHB immunoreactivity, and genetic testing revealed an NF1 mutation in one patient. Two patients with lipid-rich adenomas had equivocal plasma metanephrine results, with further testing pending. Washout characteristics were unreliable in distinguishing benign from indeterminate lesions. These findings support the ESE guidelines, suggesting biochemical testing can be excluded in patients with radiologically characterized lipid-rich adrenal adenomas on unenhanced CT imaging of adrenal glands.

Effects of prednisolone administration on clock gene expression and indices of circadian rhythms in healthy human subjects

Simon Bøggild Hansen[1,2,3], Jelena Stankovic[1,2,3], Henrik Oster[4], Niels Jessen[3] & Jens Otto Jørgensen[1,2]
[1]Aarhus University Hospital, Department of Medical Endocrinology and Internal Medicine, Aarhus N, Denmark; [2]Aarhus University, Institute of Clinical Medicine, Aarhus N, Denmark; [3]Steno Diabetes Centre Aarhus, Aarhus University Hospital, Aarhus N, Denmark; [4]University of Lübeck, Center of Brain Behaviour and Metabolism, Lübeck, Germany

Background

States of glucocorticoid (GC) excess and circadian clock disruption disorders – as observed in shift workers and following chronic stress and sleep deprivation – both confer an increased risk of developing abdominal obesity, type 2 diabetes and cardiovascular disease. Animal studies have demonstrated that GCs regulate circadian clocks providing a potential mechanism for GC side effects however, experimental data in human models are sparse.

Objective

To investigate the impact of exogenous GC exposure in human subjects on clock gene expression in muscle and fat in concomitance with assessment of circadian variations in peripheral interstitial glucose levels, blood pressure, cortisol levels and sleep quality.

Design

Randomized double-blinded crossover trial with ten healthy males aged 18–34.

Intervention

Prednisolone 25 mg/day in two daily doses or placebo in random order for five days with 6 week washout.

Results
During placebo treatment, an expected large difference was observed between morning and evening expression levels of all four clock genes investigated in adipose tissue and skeletal muscle (table). Prednisolone profoundly flattened the diurnal change in expression levels of all genes. Prednisolone treatment led to increased nocturnal interstitial glucose (placebo 6.6±0.8 vs prednisolone 8.2±0.9 mmol/l, $P<0.001$) and elevated nocturnal nadir of systolic blood pressure (placebo 116±7 vs. prednisolone 123±14, $P=0.05$).
Conclusion
Prednisolone twice daily abolished the normal fluctuations in the expression levels of core clock genes in skeletal muscle and adipose tissue. This was accompanied by disturbed sleep, and altered daily patterns of glucose levels and blood pressure. Our findings add important human data supporting GC-induced circadian disruption in metabolic tissues.

The mechanisms and regulatory factors underlying adrenarche, the development of the zona reticularis in the adrenal cortex, remain largely unknown. Children with premature adrenarche (PA) are typically taller and have a higher body fat percentage compared to peers with normally timed adrenarche. Notably, their growth acceleration and rapid weight gain can often be traced back to infancy, suggesting the possibility of early metabolic programming as a contributing factor. To explore this, we compared 16 girls with PA and 27 control girls, at the mean ages of 7 and 9 years, in a longitudinal study using a liquid chromatography mass spectrometry (LC–MS)-based untargeted metabolomics approach. PA was defined by at least one clinical sign of androgen action, accompanied by a serum DHEAS concentration exceeding 1 µmol/l, with other causes of androgenic signs ruled out. Both groups were comparable regarding background characteristics, including standardized body size at birth and diagnosis (length/height and BMI), basic biochemical parameters (glucose, insulin, and lipids), and dietary nutrient intake. Metabolites were analyzed from serum samples using LC–MS. Metabolomics data from PA girls at age 7 was compared to control girls at age 7 ('age-matched' comparison) and in addition also at age 9, when the control group exhibited adrenarchal signs ('event-matched' comparison), using linear mixed-effects models. In the age-matched comparison, 93 metabolite features differed significantly between the groups, with 74 being higher and 19 lower in PA girls. In the event-matched comparison, 128 metabolite features differed significantly between the groups, with 95 being higher and 33 lower in PA girls. Notably, 23 metabolites were identified in both comparisons, including 22 being consistently higher and 1 lower in PA girls. Among the 22 metabolites that were higher in PA girls, acylcarnitine metabolites were predominant, along with several fatty acid and steroid metabolites. The sole metabolite that was lower in the PA girls was a sulfate conjugate of the bacterial metabolite p-cresol. These findings suggest a potential involvement of fatty acid beta-oxidation in mitochondria and/or peroxisomes, and gut microbiome in the development of PA.

[1]Team 'Genomics and Signaling of Endocrine Tumors', Institut Cochin, INSERM U1016-UMR8104-Université Paris-Cité, Paris, France; [2]Pathology department, Hôpital Cochin, Paris, France; [3]Endocrinology department, Hôpital Cochin, Paris, France; [4]Hormonology department, Hôpital Cochin, Paris, France; [5]Biochemistry department, Hôpital Cochin, Paris, France; [6]Visceral and Digestive Surgery department, Hôpital Cochin, Paris, France; [7]Institut de Chimie Physique, Université Paris-Saclay-CNRS, UMR8000, Orsay, France

Introduction
Bilateral adrenocortical lesions, either primary including macronodular adrenocortical disease (BMAD) and pigmented nodular adrenocortical dysplasia (PPNAD), or secondary to Cushing's disease (CD), are responsible for steroid hypersecretion of variable intensity, evaluated by plasma or urine assays. In a subgroup of BMAD, *ARMC5* pathogenic variants are associated with more severe clinical, radiological and biological phenotypes. The aim of our work was to better describe steroidogenesis alterations in these bilateral lesions by directly assessing steroid content in the adrenocortical tissue.
Material and methods
An intratissular profile of 14 steroids (4 glucocorticoids, 3 mineralocorticoids, 5 androgens, 2 precursors) was determined using LC–MS/MS (*Thermo Fisher* ™) on 38 fresh-frozen tissue samples collected from patients undergoing adrenalectomy (6 *ARMC5*-WT BMAD, 7 *ARMC5*-altered BMAD, 9 PPNAD including 8 with *PRKAR1A* pathogenic alteration, 7 from adrenal hyperplasia due to CD), and 9 normal adrenals (NA) as controls).
Results
CD presented higher intratissular glucocorticoids and androgens concentrations than NA, in accordance with circulating levels. Intratissular steroids levels were globally lower in *ARMC5*-altered BMAD than in *ARMC5*-WT BMAD (cortisol: median [IQR] =5976 [3201–16741] vs. 26971 [18069–44509] nmol/kg of tissue, $P=0.02$). Surprisingly, intratissular testosterone was elevated (between 256 and 595 nmol/kg vs. 40.3 [15.6–99.7] nmol/kg of tissue in NA) in 4/9 PPNAD (2F/2M) despite neither evidence of clinical nor biological hyperandrogenism. Intratissular concentrations of mineralocorticoids precursors in BMAD were higher than in PPNAD.
Discussion
Our results confirm the hypothesis of a less efficient steroidogenesis in *ARMC5*-altered BMAD, in which the higher tumoral mass may contribute to systemic hypercortisolism. Despite normal plasmatic concentrations, we observed elevated intratissular levels of testosterone in some PPNAD, as well as mineralocorticoid precursors in BMAD. These discrepancies between intratissular and circulating steroid concentrations might reflect the underlying and little-known mechanisms leading to steroidogenesis alterations in these bilateral adrenocortical nodular diseases, and also raise the question of a specific steroid export dysregulation.

Circulating GDF-15 is elevated in adrenal cushing's syndrome but not in cushing's disease

Ilaria Bonaventura[1,2], Elisabeth Nowak[1], Marceli Chojnacki[1], Júnia Schweizer[1], Isabel Stüfchen[1], Friederike Völter[1], Paul Schwarzlmüller[1], Isabel Weigand[1], Alexandra Triebig[1], Tanja Maier[1], Isabella Kinker[1], Stephanie Zopp[1], Andrea Isidori[2], Felix Beuschlein[1,3,4], Matthias Kroiss[1] & Martin Reincke[1]
[1]LMU University Hospital, LMU Munich, Department of Medicine IV, Munich, Germany; [2]Sapienza University of Rome, Experimental Medecine, Rome, Italy; [3]University Hospital Zurich (USZ) and University of Zurich (UZH), Zurich, Switzerland; [4]The LOOP Zurich – Medical Research Center, Zurich, Switzerland

Context
Growth/differentiation factor 15 (GDF-15) is a cytokine involved in immunosuppression and anorexia and secreted primarily in response to mitochondrial dysfunction. Recent studies suggest its potential implication in the hypothalamic–pituitary–adrenal axis.
Objective
To investigate the potential role of GDF-15 in adrenal steroid dysregulation in Cushing's syndrome (CS).
Design
Case–control study.
Methods
Circulating GDF-15 concentrations were assessed in plasma from 25 patients with confirmed overt CS (16 pituitary, 9 adrenal) and 30 age-, BMI-, and sex-matched patients in whom CS was ruled out.
Results
Plasma GDF-15 was significantly higher in CS compared to the control group (644 pg/ml [487.3–797.6] *vs* 520.9 pg/ml [353.2–665.9], $P=0.033$). GDF-15 plasma concentrations were positively correlated with age ($r=0.423$, $P<0.001$), HbA1c ($r=0.329$, $P=0.014$), serum cortisol following dexamethasone suppression test (DST) ($r=0.484$, $P<0.001$), and late-night salivary cortisol ($r=0.334$, $P=0.014$), while negative correlations were observed with ACTH ($r=-0.310$, $P=0.023$) and DHEA-S ($r=-0.538$, $P<0.001$). In multivariate linear regression, age ($B=8.955$, $P=0.045$), DST ($B=7.980$, $P=0.050$) and DHEA-S ($B=-58.215$, $P=0.035$) emerged as independent predictors of GDF-15 concentration ($R^2=0.311$, $P=0.002$). Plasma GDF-15 was significantly higher in adrenal CS compared to pituitary CS (797.6 pg/ml [723.0–1212.2] *vs* 523.2 pg/ml [441.3–668.1], $P=0.002$). Binomial logistic regression identified GDF-15 as an independent predictor of adrenal CS diagnosis (OR = 1.005, $P=0.040$). ROC analysis revealed that the diagnostic accuracy of GDF-15 approached that of DHEA-S and ACTH.
Conclusion
This study identified elevated GDF-15 concentrations in patients with adrenal CS. This observation may reflect cellular stress in response to adrenal steroid dysregulation and could be an additional contributor to immunosuppression in CS.

Unravelling the sexually dimorphic role of adrenocapsular progenitor cells during stress adaptation of the adult adrenal gland

Panagiota Siatra[1,2], Timothé Benoit[3], Diana Cozma[1,4], Leonie Hobohm[1], Ioannis Oikonomakos[1], Yasmine Neirijnck[3], Stefan Bornstein[1,4], Andreas Schedl[3] & Charlotte Steenblock[1]
[1]Technische Universität Dresden, University Hospital Carl Gustav Carus, Department of Internal Medicine III, Dresden, Germany; [2]Université Côte d'Azur, Inserm, CNRS, Institut de Biologie Valrose, Nice, France; [2]Université Côte d'Azur, Inserm, CNRS, Institut de Biologie Valrose, Nice, France; [4]King's College London, Centre for Craniofacial and Regenerative Biology, London, United Kingdom

Chronic stress is a pervasive concern in the modern society. The HPA axis dysregulation in chronic stress and psychiatric disorders is tightly linked with hypertrophy and hyperplasia of the adrenal gland. These stress-induced cellular adaptations might employ and could be a result of capsular progenitor behaviour. However, little is known about the contribution of resident progenitor cells to these stress-induced cellular changes. In this study, we aim to unravel the mechanisms involved in the regulation of adreno-capsular progenitors during acute and repeated restraint stress. To that aim, we used a tamoxifen inducible *Gli1:CreERT2/R26R:eYFP* mouse line to lineage trace and monitor *Gli1*$^+$ adrenocortical progenitors during restraint stress in the adult adrenal cortex *in vivo* using both sexes. Our results reveal migratory patches of *Gli1*$^+$ spindle-like cells towards zona glomerulosa (zG) in the cortex of stressed male mice. These patches resemble the adrenocortical neoplasms previously described in literature and express GATA4, a common marker of the adrenogonadal primordium. Further, significant upregulation of the capsular markers *Nr2f2* and *Rspo3*, a signaling molecule involved in the control of cell renewal in the tissue, was noted in the adrenal cortex of those mice. Concerning female mice, it is already known that *Gli1*$^+$ cells contribute to the tissue renewal under homeostatic conditions. Preliminary results suggest that the subcapsular patches of *Gli1*$^+$-derived eYFP$^+$ cells are rather reduced in the cortex of stressed female mice compared to the control group. Overall, this may suggest that in female mice the process of capsular progenitor cell recruitment is reduced when the need for increased steroid production occurs. Notably, beside the reduced recruitment of capsular progenitor cells, we additionally observed significant upregulation of *Cyp11b2*, *Dab2* and the Wnt target *Lef1,* which may indicate a higher response of the zG in female compared to male mice. Lastly, our preliminary results from single-cell RNA sequencing data from stressed and non-stressed mice from both sexes confirm the sexually dimorphic response of the capsule during restraint stress. By further analysing these data, we aim to shed light on molecular factors involved in the paracrine communication between the capsule and the rest of the cortex in stress that could potentially regulate directly or indirectly the stress response and the steroid production.

Diagnostic genotyping of CYP21A2 gene employing Short Read-NGS: Benefits and Limitations

Irene Fylaktou[1], Faidon-Nikolaos Tilemis[2], Anny Mertzanian[1], Christina Kanaka Gantenbein[1] & Amalia Sertedaki[1]
[1]Laboratory of Molecular Endocrinology, Division of Endocrinology, Diabetes and Metabolism 'Aghia Sophia' Children's Hospital ENDO-ERN Center for Rare Paediatric Endocrine Diseases, First Department of Pediatrics, Medical School, National and Kapodistrian University of Athens, 'Aghia Sophia' Children's Hospital,, Athens, Greece; [2]Laboratory of Medical Genetics, Medical School, 'Aghia Sophia' Children's Hospital, National and Kapodistrian University of Athens,, Athens, Greece

Introduction
Short Read Next Generation Sequencing (SR-NGS) has been widely applied in the genetic diagnosis of several mendelian disorders. Nevertheless, one of the major disadvantages remains the inability to fully discriminate genes from their pseudogenes/homologous genes. To date, SR-NGS is not widely used in the diagnostic genotyping of the *CYP21A2* gene due to its highly homologous pseudogene, thus rendering the PCR-based sequencing and MLPA analysis the recommended *CYP21A2* genotyping methodologies. The aim of this study is to assess one of the first SR-NGS assays developed for the genotyping of the *CYP21A2* gene and to present the results of 151 samples referred to the Laboratory of Molecular Endocrinology for *CYP21A2* genotyping employing the above-mentioned technique.
Patients and methods
A total of 172 subjects were studied. Subjects were categorized in 2 groups; the Pilot and the Study Group. The Pilot Group, employed for the assessment of the SR-NGS assay, consisted of 21 samples, previously analyzed using PCR-based sequencing and MLPA analysis. The Study Group consisted of 151 subjects referred for *CYP21A2* genotyping. Both Groups underwent Long Range PCR followed by SR-NGS. Two different bioinformatic pipelines for variant calling (varscan mpileup2cns and GATK HaplotypeCaller functions) were employed in the Study Group. Filtration of the data was performed using VarAFT v2.17. In cases with suspicion of *CYP21A2* gene duplication/deletion MPLA analysis was also employed.
Results
The pilot study assessment of the SR-NGS assay resulted in a sensitivity and precision of 100%. Minor differences were observed in the use of the two different bioinformatics pipelines. No alteration was observed in the frequencies of cases harboring duplication of the gene when compared to cases carrying two copies of the *CYP21A2* gene. Advantage of this methodology is the identification of variants in regions with heterozygous deletions/insertions that could not be covered by PCR-based sequencing. In the Study Group, pathogenic variants were identified in 54.3% of cases while duplications in 4.6%.
Discussion
This study verifies that the application of the SR-NGS assay for *CYP21A2* genotyping presents high sensitivity and precision, short turnaround time and cost effectiveness compared to the PCR based sequencing. Both bioinformatic pipelines can be employed for the SR-NGS data analysis although the GATK algorithm exhibits higher accuracy. MLPA analysis is still required for the

identification of deletions/duplications of the *CYP21A2* gene. Hence, the presented SR-NGS assay and MLPA can be employed for the *CYP21A2* diagnostic genotyping.

Elevated bone turnover in primary aldosteronism: a role for aldosterone-dependent phosphate changes?

Vittoria Favero[1,2], Alessandro Risio[1], Chiara Parazzoli[1,2], Erika Grossrubatscher[2], Stefano Testa[1], Alfredo Scillitani[3], Renato Cesare Cozzi[2], Elena Valassi[4,5] & Iacopo Chiodini[1,2]
[1]Department of Medical Biotechnology and Translational Medicine, Milan, Italy; [2]ASST Grande Ospedale Metropolitano Niguarda, Unit of Endocrinology, Milan, Italy; [3]IRCCS Ospedale Casa Sollievo della Sofferenza, Unit of Endocrinology and Diabetology, San Giovanni Rotondo (FG), Italy; [4]Universitat Internacional de Catalunya (UIC), Barcelona, Spain; [5]Endocrinology Department, Germans Trias i Pujol Hospital and Research Institute, CIBERER Unit 747, Badalona, Spain

Background
Aldosterone excess has been implicated in the regulation of bone metabolism, with different studies indicating reduced bone mass in patients with primary hyperaldosteronism (PA) compared to those with essential hypertension (EH). Some authors suggest that these alterations may be linked to aldosterone-induced parathyroid hormone (PTH) release. Additionally, increased levels of 24-hour urinary calcium have been proposed as a mechanism contributing to bone loss. However, it remains unclear whether this 24-hour urinary calcium is a direct effect of aldosterone or a compensatory response to elevated PTH levels. Existing data on bone turnover in PA patients are limited and often conflicting. This study aimed to investigate calcium–phosphorus metabolism and bone turnover markers in PA patients compared to a cohort of EH controls.
Methods
We conducted a retrospective, multi-center study involving 37 patients with PA and 46 EH controls. PTH, 24-hour urinary calcium, alkaline phosphatase (ALP), C-terminal telopeptide (CTX), calcium, phosphate, 25-OH vitamin D, plasma aldosterone concentration, plasma renin activity, and the aldosterone-to-renin ratio were measured in all participants. Bone turnover has been evaluated in the absence of interfering anti-hypertensive medications in both PA and EAH patients.
Results
The two study groups were comparable in terms of age, gender, and BMI. Serum ALP levels were similar between the groups (73 U/L [62–91] in PA vs. 70 U/L [55–73] in EH, $P=0.26$), as were 25-OH vitamin D levels (27.6 ng/ml [15–34] in PA vs. 19.9 ng/ml [16–28.5] in EH, $P=0.33$) and PTH levels (52 pg/ml [41–61] in PA vs. 59 pg/ml [44–71] in EH, $P=0.25$). As expected, 24-hour urinary calcium was significantly higher in PA patients (201 mg/kg/day [149–299]) compared to those with EH (165 mg/kg/day [107–230]). Notably, the PA group exhibited significantly elevated CTX levels compared to EH controls (617 ng/ml [447–779] vs. 410 ng/ml [280–560], $P<0.005$). Additionally, calcium levels were higher (9.3 mg/dl [8.9–9.6] vs. 9.1 mg/dl [8.8–9.3], $P=0.03$), while phosphorus levels were lower in PA patients (3.0 mg/dl [2.6–3.5] vs. 3.5 mg/dl [3.2–3.7], $P<0.001$).
Conclusion
Patients with PA demonstrate increased skeletal turnover compared to EH controls, which does not appear to be linked to elevated PTH levels. These findings suggest that alterations in bone metabolism among PA patients may be partially PTH-independent and potentially driven by other factors, such as changes in phosphorus metabolism induced by aldosterone, as indicated by the lower phosphorus levels observed in this cohort.

Serum inflammation-based scores in adrenal incidentalomas: the role of salivary cortisol rhythm dysregulation

Kimberly Coscia[1,2], Flaminia Fanelli[2,3], Lorenzo Tucci[1,2], Valentina Bissi[2,3], Greta Galante[2,3], Francesca Donnarumma[1,2], Giada Ramundo[1,2], Giacomo Colombin[1,2], Valentina Vicennati[1,2], Uberto Pagotto[1,2] & Guido Di Dalmazi[1,2]
[1]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [2]Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, Italy; [3]Center for Applied Biomedical Research, Department of Medical and Surgical Sciences, Alma Mater Studiorum University of Bologna, Bologna, Italy

Background
Alteration of serum inflammation-based scores, used as surrogate markers of systemic inflammation, has been associated with hypercortisolism in recent studies. However, the role of altered circadian rhythm of cortisol in the context of mild autonomous cortisol secretion (MACS) has not been investigated so far.
Aim
To evaluate the association between inflammation-based scores and salivary cortisol daily rhythm in patients with MACS and non-secreting (NS) adrenal tumors.
Methods
We included 85 benign adrenal tumors, classified as NS ($n=25$) and MACS ($n=60$) according to the cortisol values after 1 mg dexamethasone suppression test (DST) $\leq$ or >1.8 mcg/dl, respectively. On an ordinary day, each subject collected saliva samples at the following times: 0700 (awakening), 0715, 0730, 1000, 1230, 1400, 1600, 1930, 2100, and 2300 (bedtime). Salivary cortisol was measured by liquid chromatography–tandem mass spectrometry. The following serum inflammation-based scores were calculated: neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), lymphocyte-to-monocyte ratio (LMR), and systemic immune-inflammation index (SII; platelet count * NLR). Cortisol AUC (AUC) was used as a surrogate marker to assess overall (0700–2300), morning (0700–1600) and evening (1600–2300) cortisol exposure. Student *T*-test, Pearson's correlation and generalized linear models adjusted for sex, age, body mass index, presence of altered glucose metabolism, and smoking status were used to analyze the relationship between serum inflammation-based scores and cortisol measures.
Results
Evening cortisol AUC was positively correlated with post-DST cortisol levels ($R=0.23$; $P=0.037$). Cortisol levels at 1930 and 2100, and evening AUC were higher in patients with MACS than in those with NS tumors ($P<0.001$ for all). NLR and SII were positively associated with cortisol overall ($R=0.29$, $P=0.010$), morning ($R=0.26$, $P=0.024$) and evening ($R=0.29$, $P=0.009$) AUCs, while PLR only directly correlated with evening AUC ($R=0.23$, $P=0.043$). Generalized linear models showed that higher post-DST cortisol levels were significantly associated with increased NLR ($B=0.160$; 95% CI: 0.011–0.308; $P=0.035$) and reduced LMR ($B=-0.160$; 95% CI: -0.271 to -0.048; $P=0.005$). Increasing overall and evening cortisol AUCs were significantly directly associated with NLR ($B=0.285$, 95% CI: 0.0.059–0.510, $P=0.013$, and $B=0.306$, 95% CI: 0.100–0.512, $P=0.004$; respectively). Additionally, evening cortisol AUC directly associated with SII values ($B=0.406$, 95% CI: 0.107–0.705, $P=0.008$). Active smoking showed an independent direct contribution over NLR ($P<0.001$) and SII ($P=0.006$).
Conclusion
Cortisol exposure, particularly in the evening, is associated with surrogate markers of increased systemic inflammation in patients with benign adrenal incidentalomas.

Spectrum of Presentation of 46,XY Sex Reversal and Adrenal Insufficiency: Case Report with Literature Review

Nourah Almutlaq[1] & Muhammad Alshuhayeb[2]
[1]Ministry of Interior, Riyadh, Saudi Arabia; [2]Security Forces Hospital, Riyadh, Saudi Arabia

Introduction
CYP11A1 (P450scc) deficiency is a rare and complex disorder associated with primary adrenal insufficiency and 46,XY disorders of sex development (DSD).
Objective
This study delineates the clinical spectrum and genetic underpinnings of 46,XY sex reversal and adrenal insufficiency, using a detailed case presentation and comprehensive literature review.
Methods
We present a case of congenital adrenal hyperplasia (CAH) due to P450scc deficiency in a patient with complete 46,XY DSD. This case prompted a review of similar reported cases focusing on the onset of adrenal insufficiency (AI), clinical presentations, and gonadal management.

Results
Our index case involves a 4-year-old child, assigned female at birth, presenting with recurrent vomiting, hypoglycemia, fatigue, and hyperpigmentation of the lips and hand creases. Clinical examination revealed clitoromegaly. Laboratory tests indicated mild hyponatremia, low cortisol, elevated ACTH, diminished steroidogenesis across all pathways, low aldosterone, and elevated renin. Diagnosis of primary adrenal insufficiency was established, and treatment with hydrocortisone and fludrocortisone was initiated. Chromosomal analysis confirmed a 46,XY karyotype. Pelvic MRI showed no female internal genitalia and bilateral inguinal gonads. Whole exome sequencing revealed a homozygous variant in CYP11A1, confirming P450scc deficiency. The literature review included 25 cases, all demonstrating mutations in the CYP11A1 gene. The mean age at presentation of AI was 3.7 years, ranging from neonates to 18 years. The most common clinical presentations involved ambiguous genitalia or undervirilization (90%) and signs of adrenal crisis or insufficiency (50%). Genital appearances varied, with micropenis, cryptorchidism, and bifid scrotum being prevalent. Approximately 60% had non-palpable or undescended testes. Gonadal management typically involved surveillance or gonadectomy, based on malignancy risk and anatomical findings, with no established timing for surgery.
Conclusion
This case report and literature review underscore the heterogeneity in presentation and genetic variability of 46,XY sex reversal and adrenal insufficiency. Importantly, mutations in the CYP11A1 gene were present in all cases reviewed, highlighting the critical role of genetic analysis in diagnosis. Early genetic screening and multidisciplinary management are crucial for optimizing patient outcomes, suggesting a need for further research into tailored therapeutic approaches.

JOINT2864

Diagnostic accuracy of urinary aldosterone, independent of sodium intake, for the diagnosis of primary aldosteronism

Tatiana Rojas López[1], Paola Parra Ramírez[2], Jorge Escobar Gómez[2], Beatriz Barquiel Alcalá[1], Daniel Álvarez Martín[2], Patricia Martín Rojas-Marcos[2], Isabella Mantellini González[1], Sime Rogic Valencia[1], Maria Luisa González Casaus[2] & Cristina Álvarez Escolá[1]
[1]Hospital Universitario La Paz, Endocrinology and Metabolism, Madrid, Spain; [2]Hospital Universitario La Paz, Madrid, Spain

Introduction
Primary aldosteronism (PA) is an underdiagnosed cause of secondary hypertension. Diagnosis is typically performed in three steps: screening, confirmatory testing (CT), and subtype classification. Twenty-four-hour urinary aldosterone (uAldo) after an oral sodium load is one of the available confirmatory tests. This test requires an intake of 6 grams/24 hours of sodium for three days to achieve urinary sodium (uNa) >200 mmol/24 hours. However, in some cases, intravenous (IV) or oral sodium administration may have detrimental effects on the cardiovascular system.
Objective
To assess the diagnostic utility of uAldo in PA, independent of sodium loading.
Materials and methods
We carried out an observational study of patients suspected of having PA based on an aldosterone-to-renin ratio (ARR) $\geqq$ 30 ng/dl/ng/ml/h or an aldosterone-to-direct renin concentration ratio $\geqq$ 3.7 ng/dl per mU/l between 2018 and 2024. All patients underwent a confirmatory test (either the captopril test or IV saline infusion, depending on physician preference and/or comorbidities), and antihypertensive treatment change, and were advised to follow a normal-sodium diet for the three days preceding the confirmatory test. Additionally, uAldo and uNa were measured from a 24-hour urine sample collected the day before. The diagnostic performance of uAldo was analyzed independently of uNa levels.
Results
77 patients were included, 47 (64.9%) of whom were women; 94.8% had hypertension. A total of 39 individuals (50.6%) had a positive confirmatory test for PA. Baseline renin was suppressed in 76.6% of patients at the beginning of the confirmatory test, and 33.8% had uNa >200 mmol/24h. The group with a negative confirmatory test had a lower median uAldo than the group with a positive confirmatory test (8.3 μg/24h, IQR [4.5–12.1] vs. 11.7 μg/24h, IQR [8.5–19.3], $P<0.05$). A uAldo cutoff of >6.6 μg/24h had a sensitivity of 87.1% and a specificity of 36.8%. A uAldo >14 μg/24h had a sensitivity of 46.1% and specificity of 84.2%. The area under the ROC curve (AUC) was 0.70 (95%CI 0.59–0.81).
Conclusions
uAldo, regardless of uNa levels, showed acceptable diagnostic performance. Despite the absence of prior sodium loading, most patients had suppressed renin, ensuring independent aldosterone production. A uAldo >14 μg/24h strongly suggests the diagnosis of PA in patients with a positive screening test and a normal sodium diet, while a uAldo <6 μg/24h makes PA unlikely.

Adrenocortical carcinoma following long-term stable adrenocortical adenomas: a rare phenomenon in a large cohort

Giacomo Cristofolini[1,2], Otilia Kimpel[1], Mario Detomas[1], Stefan Kircher[3], Wiebke Schlötelburg[4], Martin Fassnacht[1] & Barbara Altieri[1,5]
[1]Division of Endocrinology and Diabetes, Department of Internal Medicine I, University Hospital, University of Würzburg, Würzburg, Germany; [2]Department of Biomedical Sciences, Humanitas University, Pieve Emanuele (MI), Italy; [3]Institute of Pathology, University Hospital, University of Würzburg, Würzburg, Germany; [4]Department of Nuclear Medicine, University Hospital, University of Würzburg, Würzburg, Germany; [5]Bavarian Cancer Research Center (BZKF), University Hospital, University of Würzburg, Würzburg, Germany

It remains debated whether adrenocortical adenomas (ACAs) might represent a precursor to adrenocortical carcinomas (ACCs) or whether ACCs arise 'de novo' from adrenocortical tissue. Sporadic cases of malignant transformation of pre-existing ACA after prolonged latency have been reported, highlighting the unpredictable malignant potential of few benign tumors. This study retrospectively investigates the prevalence of prior imaging-based ACA diagnosis in the largest single-center ACC cohort, including 1516 patients referred to our center since January 2000. We identified 3 patients (0.2%) with documented ACA that remained stable for $\geqq$2 years but were later histologically confirmed as ACC. All 3 patients were female, with a median age of 33 years at ACA diagnosis and 40 years at surgery. Tumors averaged 3.3 cm initially, and median follow-up was 7 years (range:4–14 years).
Case 1: A 39-year-old woman was diagnosed with a 4.5 cm left ACA in 2003. The lesion remained stable during the first 8 years of regular follow-up. However, following a 5-year gap in surveillance, the lesion grew to 6 cm and exhibited a new inhomogeneous appearance at CT imaging. Surgical tumor resection confirmed a high-grade ACC (Ki67:20%; Weiss score:9) with p53 positivity at immunohistochemistry. She died 2 years later from synchronous lung adenocarcinoma.
Case 2: A 33-year-old woman had a diagnosed of 3.7 cm non-functioning right ACA in 2014. After 3 years, although the lesion did not significantly change in size, the patient underwent adrenalectomy because of the development of hypercortisolism (cortisol after 1 mg-DST:16.6 μg/dl). Histology revealed low-grade ACC (Ki67:2–5%; Weiss score:3). She remains disease-free under active surveillance.
Case 3: A 33-year-old woman was diagnosed with a 1.6 cm left ACA in 2014, which remained stable until 2016. Hormonal evaluation was incomplete at diagnosis. By 2021, the lesion had grown significantly to 7.5 cm and hypercortisolism was detected (cortisol after 1-mg-DST:17 μg/dl). Adrenalectomy confirmed a high-grade ACC (Ki67:10–40%; Weiss score:8). A somatic pathogenic variant in *CTNNB1* (p.Ser45Ala) was found. Since 2021, she has been undergoing mitotane and systemic therapies due to disease progression. Determining whether these ACCs arose from the malignant transformation of pre-existing ACAs, developed de novo, or were initially misdiagnosed remains challenging. However, these cases emphasize the exceptionally low likelihood of malignant transformation in benign-appearing, size-stable adrenal lesions, despite the high prevalence of benign adrenal tumors. Additionally, one case describes a rare occurrence of hormonal hypersecretion developing over time.

Metabolic syndrome in patients treated for primary adrenal insufficiency

Marta Fichna[1], Anita Rogowicz-Frontczak[2], Hanna Komarowska[2] & Marek Ruchała[2]
[1]Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznań, Poland; [2]Poznan University of Medical Sciences, Department of Internal Medicine and Diabetology, Poznań, Poland

Primary adrenal insufficiency (PAI) requires lifelong steroid substitution however, standard replacement regimens do not perfectly mimic the physiological glucocorticoid secretion. Under-replacement is life-threatening, while long-term steroid excess leads to adverse effects, including metabolic consequences, which may contribute to increased mortality. The current study was designed to assess the frequency of the metabolic syndrome (MS) in patients conventionally treated for PAI. General Polish population displays 33% and 39% prevalence of MS in women and men, respectively. This cross-sectional analysis comprised 239 individuals (69 males, 170 females) suffering from PAI. Their mean age was 48.2 ± 14.8 years and mean disease/treatment duration 10.8 ± 11.2 years. All patients were on hydrocortisone (HC): mean daily HC dose was 23.1 ± 7.1 mg, adjusted for body mass 0.34 ± 0.12 mg/day/kg, and cumulative HC dose was 94.6 ± 98.1 g during treatment. Central obesity (waist circumference 94/80 cm) was found in 148 (61.9%) patients (123 females and 25 males), hypertension in 37 (15.5%), decreased circulating HDL cholesterol in 64 (26.8%), elevated triglycerides in 90 (37.6%), and hyperglycemia in 57 (23.8%) individuals (19 prediabetes, 15 type 2 diabetes, 23 type 1 diabetes). Overall, 62 (25.9%) subjects displayed MS, including 54 (31.8%) females and 8 (11.6%) males ($P = 0.0013$), however, mean age in the studied women was also significantly higher (51.7 ± 13.8 *vs.* 39.7 ± 13.7 years; $P < 0.0001$). Female were older, but their PAI onset was also later than males (40.7 ± 13.2 years *vs.* 30.1 ± 12.0 years; $P < 0.0001$), therefore mean treatment duration remained similar in both sexes ($P = 0.3717$). Once pre- and postmenopausal women were considered, the proportion of MS reached 14.7% and 43.1%, respectively ($P < 0.0001$). Daily HC doses were similar in patients with and without MS ($P = 0.3382$), however, once total HC dose was evaluated, MS patients displayed significantly higher cumulative HC intake (123.4 ± 112.4 *vs.* 84.5 ± 90.8 g, $P = 0.0088$), which supports the primordial role of disease duration. Finally, in a multiple linear regression model comprising age, disease duration, gender, PAI form (isolated or polyglandular) and HC dosage, only age appeared significant predictor of MS ($P < 0.001$). In conclusion, MS does not specifically affect patients with PAI, however, post-menopausal women seem at increased risk. This is mainly due to their advanced age, and obviously lack of protective estrogen effects, while HC treatment within the current dose recommendations does not seem primordial for MS development. Therefore, conventional but still reasonable HC dosage in PAI does not imply considerably elevated risk for MS, although postmenopausal women should be carefully monitored with this regard.

Background

Androgen excess in 21-hydroxylase deficiency (21OHD) remains challenging. Combined oral contraceptives (OCs) containing ethinylestradiol and progestin are known to affect both ovarian and adrenal androgen levels. In a pilot study, we observed a positive effect of combined OCs on the androgen status in women with classic congenital adrenal hyperplasia (CAH). Therefore, we aimed to prospectively investigate how combined OCs affect the steroid metabolome in young women with classic 21OHD.

Methods

We enrolled women aged 11-26 with classic 21OHD treated with hydrocortisone and mostly fludrocortisone from eight international centres who planned to start combined OCs. The study comprised three visits, including blood-drawing and 24-h-urine sampling: baseline (Visit-1, prior to OCs), three cycles post-OC-initiation (Visit-2), and six cycles post-initiation (Visit-3). Liquid chromatography-mass spectrometry (LC–MS) and gas-chromatography mass spectrometry (GC–MS) were utilized for steroid analysis. Differences in steroid metabolite levels across the three visits were assessed using the Friedman-test.

Results

The 17 participating young women had a median age of 18.7 years (range 11-26 years). Compared to before OC-intake, we saw a substantial decrease in plasma 17α-hydroxyprogesterone, androstenedione, dehydroepiandrosterone, testosterone (all $P < 0.001$) and 11-ketotestosterone ($P = 0.004$) under OCs, whilst cortisol levels increased. The levels of relevant urinary androgen metabolites, including 11-oxo-pregnanetriol, also showed a significant decrease (Table 1). Between visits 1 and 3, seven out of 17 (41%) women could reduce their hydrocortisone doses.

Conclusion

Our results suggest that combined oral contraceptives have a significant potential in lowering androgen levels, thereby improving the steroid metabolome in women with classic 21OHD. OC-treatment could therefore serve as an effective supplementary therapy in women with 21OHD, particularly in those with an unsatisfactory steroid profile.

Table 1: Urine metabolites (nmol/24h).

	Median (P25-P75)			
Urine metabolites	**Visit-1**	**Visit-2**	**Visit-3**	**P-value**
Androsterone	767.9 (398.5–1619.2)	131.6 (39.0–632.1)	77.9 (35.3–537.0)	<0.001
Etiocholanolone	469.7 (310.8–781.8)	83.1 (32.1–473.8)	57.3 (31.4–405.0)	0.002
11-Oxo-etiocholanolone	258.8 (187.9–359.0)	98.5 (77.4–166.9)	97.7 (60.1–173.2)	0.002
11β-OH-androsterone	740.3 (367.8–1474.5)	112.1 (73.1–480.8)	106.4 (61.8–278.8)	<0.001
11β-OH-etiocholanolone	169.9 (114.4–211.5)	100.7 (60.1–181.8)	100.9 (72.7–139.2)	0.029
11-Oxo-pregnanetriol	233.4 (64.7–402.6)	23.3 (6.2–183.9)	18.3 (10.8–59.2)	<0.001

Exploring the role of glucocorticoids and androgens in the regulation of brain immunity using zebrafish models of impaired steroidogenesis

Irina A Bacila[1,2], Lara Oberski[1,2,3], Vincent Cunliffe[2,4] & Nils Krone[1,2]

[1]The University of Sheffield, School of Medicine and Population Health, Division of Clinical Medicine, Sheffield, United Kingdom; [2]The Bateson Centre, Sheffield, United Kingdom; [3]Imperial College, Department of Infectious Diseases, Faculty of Medicine, London, United Kingdom; [4]Department of Biomedical Science, Sheffield, United Kingdom

Background

The role of steroid hormones in the pathophysiology of neurological problems is well established, however, the mechanisms involved in their development are not well understood. More recently, there has been increasing evidence on the important involvement of brain immunity in health and disease. We aimed to study the role of steroid hormones in the regulation of neuro-immunity, using established zebrafish models of cortisol deficiency.

Methods

We analysed adult brains from two zebrafish lines with differentially impaired steroidogenesis: 21-hydroxylase deficiency (*cyp21a2*−/−), which are cortisol deficient and have normal sex hormones, and side-chain cleavage enzyme deficiency (*cyp11a2*−/−), which are deficient in both cortisol and sex hormones, developing as infertile males. We extracted brain RNA and conducted paired-end sequencing, followed by transcriptome study by Gene Set Enrichment Analysis (GSEA) to identify dysregulated biological processes.

Results

In the *cyp21a2*−/− zebrafish, we found that cortisol deficiency impacted on the regulation of immune processes within the brain in a sex-specific manner. When compared to wild-type (WT) siblings the brains of mutant males showed wide upregulation of the immune response, including biological processes involved in the immune cell chemotaxis, response to cytokines, response to other organisms. By contrast, these processes were downregulated in the *cyp21a2*−/− female brains and in the *cyp11a2*−/− brains. In addition, granulocyte activation and leukocyte

differentiation were also upregulated in the *cyp21a2−/−* male brains, however, they were not found to be dysregulated in the other groups. We then compared male against female brain transcriptomes within the WT and *cyp21a2−/−* groups. Immune processes including the major histocompatibility (MHC) complex assembly, immune cell differentiation, activation, T-cell proliferation, response to biotic stimulus, macrophage migration, were downregulated in males compared to females only in WT fish, but not in cortisol deficient mutants. Moreover, leukocyte chemotaxis and migration were downregulated in WT males but upregulated in *cyp12a2−/−* males compared to females.
Conclusion
Our results indicate that cortisol deficiency has a different impact on the regulation of brain immunity in male zebrafish compared to females, or to androgen-deficient males. The differential dysregulation of the immune response in the brains of our mutant lines would indicate that androgens have a cortisol-dependent suppressive effect on brain immunity in zebrafish. Further research into the role of sex hormones and their relationship with glucocorticoids in regulating the immune response is warranted to better understand sex-specific patterns in the development of neurological conditions, and the relevance of replacement therapies in patients with steroid deficiencies.

Effect of very low LDL cholesterol levels on steroid metabolome
Tereza Foglarová[1], Václav Hána[1], Drahomíra Springer[2], Marcela Kotasová[2], Martin Hill[3] & Lukáš Zlatohlávek[1]
[1]3rd Department of Medicine, 1st Faculty of Medicine, Charles University and General University Hospital, Prague, Prague, Czech Republic; [2]Institute of Medical Biochemistry and Laboratory Diagnostics, 1st Faculty of Medicine, Charles University and General University Hospital, Prague, Prague, Czech Republic; [3]Steroid Hormone Unit, Institute of Endocrinology, Prague, Prague, Czech Republic

Introduction
Recommended cholesterol levels in cardiovascular prevention are continuously being lowered by clinical guidelines. Cholesterol is an essential substrate for the synthesis of steroid hormones. The aim of the study was to explore the adrenal glands' ability to adapt to cholesterol deficiency as a substrate.
Methods
Thirty-six male patients on high-intensity hypolipidemic therapy with LDL-C levels of 0.5±0.3 mmol/l, documented for at least one year, were selected. Exclusion criterion was corticosteroid therapy, including local application, in the previous year and ageless than 18 years. The Synacthen (1-24 ACTH) test (10 μg) was performed, and 17 steroid hormones were measured at baseline and following stimulation at 0, 30, and 60 minutes. Additionally, baseline levels of ACTH, TSH, fT4, insulin, C-peptide, fasting blood glucose, and glycated hemoglobin were determined. All steroid measurements at baseline and after stimulation were performed using Liquid Chromatography-Mass Spectrometry (LCMS). The data obtained were statistically processed.
Results
Results showed a correlation between steroid hormones (sex hormone-binding globulin, testosterone, cortisol, 11-deoxycortisol, 11-deoxycorticosterone, 17α-hydroxyprogesterone) and LDL cholesterol levels, but no adrenocortical insufficiency was observed. These findings prove a correlation between LDL cholesterol and adrenal steroids, and highlight the safety of hypolipidemic therapy in clinical practice. We also, unexpectedely observed the association between various hormones (androstenedione, dehydroepiandrosterone, cortisol, cortisone, 11-deoxycorticosterone, 17α-hydroxyprogesterone, dihydrotestosterone) and HDL cholesterol levels.
Conclusion
The adrenal glands are capable of full adaptation to a profound cholesterol deficiency using it as a substrate for steroid hormone synthesis. Long-term hypolipidemic therapy does not induce adrenocortical insufficiency.

Performance of plasma renin assays in guiding mineralocorticoid dosing in children with adrenal insufficiency
Alice Stephenson[1], Indraneel Banerjee[1], James M. Hawley[1] & Timothy Morris[1]
[1]Manchester University NHS Foundation Trust, Manchester, United Kingdom

Background
Plasma renin is measured in paediatric patients with salt-wasting adrenal insufficiency (AI) to assess the efficacy of mineralocorticoid (MC) replacement. Plasma renin is recommended as a useful marker to monitor MC replacement and can be measured as either plasma renin concentration (PRC) or activity (PRA). Our department currently measures PRC using immunoassay in paediatric patients, and PRA using LC-MS/MS in adults.
Objective
Here, we sought to compare the clinical utility of PRC and PRA concentrations in paediatric patients with AI taking MC replacement.
Methods
Samples from patients less than 18-years old ($n=129$, m:f=69:60) requested for PRC were selected randomly. PRC was measured using the IDS-iSYS chemiluminescence immunoassay, PRA was measured by LC–MS/MS. The PRC and PRA values for each sample were reviewed using published reference ranges and categorised into low, normal and high results. Samples which showed disagreement between PRC and PRA results were divided into patient groups. Samples collected from patients attending the adrenal clinic were clinically reviewed by local endocrinologists to determine if MC dosing would differ based on PRC or PRA results.
Results
Of the samples analysed, 96 (74%) exhibited concurrence between their PRC and PRA interpretation. Samples that displayed disagreement ($n=33$, 26%) included 17 collected from adrenal clinic patients. Of these, eight resulted in a different clinical decision concerning MC replacement based on PRA compared to PRC. In each of these instances, adjustments to MC dose was strongly supported by serum sodium and blood pressure centiles when based on PRA. In several instances, PRC had been overlooked by clinicians and MC dose had been adjusted in preference to other conventional parameters such as blood pressure and serum electrolytes. Thus, PRA provided reassurance that clinicians had correctly assessed MC replacement.
Conclusions
Using the current methodology and normative ranges, our investigation found PRA performed superiorly to PRC for assessing MC replacement in paediatric patients, based on supporting biochemical and clinical parameters. Our results indicated that use of PRA may help to standardise practice when assessing MC replacement, which would have immediate patient benefit through improved blood-pressure and electrolyte control. Further work is planned to corroborate these results in a wider pool of patients.

Familial hypercholesterolemia in Chinese children and adolescents: a multicenter study
Mengna Huang[1]
[1]Department of Endocrinology, Children's Hospital of Zhejiang University School of Medicine, National Clinical Research Center for Child Health, Hangzhou, China

Background
Familial hypercholesterolemia (FH) is an inherited disorder mainly marked by increased low-density lipoprotein cholesterol (LDL-C) concentrations and a heightened risk of early-onset arteriosclerotic cardiovascular disease (ASCVD). This study seeks to characterize the genetic spectrum and genotypeã phenotype correlations of FH in Chinese pediatric individuals.
Methods
Data were gathered from individuals diagnosed with FH either clinically or genetically at multiple hospitals across mainland China from January 2016 to June 2024.
Results
In total, 140 children and adolescents (mean age of 6.00 years) with clinically and genetically diagnosed FH were enrolled in the study, with 87 distinct variants identified in the *LDLR*, *APOB* and *PCSK9* genes. Among the variants, 11 variants were newly identified worldwide, with 9 classified as 'pathogenic' or 'likely pathogenic', and 2 classified as 'variants of uncertain significance'. Additionally, the 5 most common variants in the study were c.1448G>A (p.W483*), c.1879G>A (p.A627T), c.1216C>A (p.R406R), and c.1747C>T (p.H583Y) in the *LDLR* gene, as well as c.10579C>T (p.R3527W) in the *APOB* gene, accounting for 49.29% (69/140) of all patients. These variants are primarily observed in the Asian or Chinese population and are distinct from those present in Caucasian groups. In this cohort, 105 patients were diagnosed with heterozygous FH (HeFH), while 35 were diagnosed with homozygous FH (HoFH). Finally, only 28.57% of the patients (40/140) were using lipid-lowering medications with 33.33% of HoFH patients

initiating treatment after the age of 8. Additionally, only 3 compound heterozygous patients (2.14%) underwent liver transplantation because of significantly high lipid levels.
Conclusion
This study reveals the variable genotypes and phenotypes of children with FH in China and illustrates that the genotypes in the Chinese population differ from those in Caucasians, providing a valuable dataset for the clinical genetic screening of FH in China. Furthermore, the older age at diagnosis and treatment highlights the underdiagnosis and undertreatment of Chinese FH pediatric patients, suggesting that early identification should be improved through lipid or genetic screening, and that more timely and regular pharmacological treatments should be implemented.

Effect of cholecalciferol and calcium supplementation on blood pressure in young Infertile but otherwise healthy men

Claudia Paredes[1], Sam Kafai Yahyavi[1,2], Mads Jorsal[1] & Martin Blomberg Jensen[1,3]
[1]Division of Translational Endocrinology, Department of Endocrinology and Internal Medicine, Copenhagen University Hospital, Herlev and Gentofte, Denmark; [2]Group of Skeletal, Mineral and Gonadal Endocrinology, Department of Growth and Reproduction, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; [3]Department of Clinical Medicine, Copenhagen University Hospital, Copenhagen, Denmark

Introduction
Vitamin D plays a crucial role in bone and mineral homeostasis, but its effect on cardiovascular health and blood pressure (BP) in particular remains unclear with studies presenting conflicting results. Most studies have focused on hypertensive patients, but this study aims to assess the effect of cholecalciferol supplementation on BP in young men.
Materials and methods
The Copenhagen Bone-Gonadal Study, a double-blinded RCT (NCT01304927), included 330 healthy infertile men with $25(OH)D_3$ insufficiency who received either cholecalciferol supplementation or placebo for 150 days. The primary endpoint was semen quality. BP was measured using standardized conditions after five minutes of rest, with an average of three consecutive measurements used for analysis. Correlations between vitamin D metabolites and BP were assessed using Pearson's correlation, and intervention effects were analyzed using *t*-tests and ANOVA.
Results
The cohort consisted of 300 men (mean age 35 years), and no correlations were found between systolic BP and $25(OH)D_3$ ($r=0.037$, $P=0.53$) or $1,25(OH)_2D_3$ ($r=-0.0042$, $P=0.94$) at baseline. There was no difference between the treatment and placebo groups after 150 days in systolic BP (127 mmHg vs 127 mmHg, $P=0.87$) or diastolic BP (81 mmHg vs 82 mmHg, $P=0.23$). Even in men with vitamin D deficiency (<25 nmol/l), supplementation with cholecalciferol and calcium did not affect BP (127 mmHg vs 127 mmHg, $P=0.85$). No differences were found in subgroups when stratifying according to baseline $25(OH)D_3$ levels, SCORE2 categories, or changes in in serum $25(OH)D_3$ (all $P>0.05$).
Conclusion
There was no correlation between vitamin D metabolites and BP. Cholecalciferol supplementation for 150 days did not significantly affect BP in infertile men, regardless of baseline $25(OH)D_3$ status or cardiovascular risk using SCORE2, implying that high-dose supplementation is not beneficial for BP regulation in young and overall healthy men.

Persistent renin suppression after unilateral adrenalectomy in patients with primary aldosteronism

Isabel Stüfchen[1], Júnia Ribeiro de Oliveira Longo Schweizer[1], Friederike Völter[1], Stephanie Zopp[1], Denise Bruedgam[1], Petra Zimmermann[2], Tracy Ann Williams[1] & Martin Reincke[1]
[1]Department of Medicine IV, Endocrinology, Diabetology and Metabolism, LMU University Hospital, LMU Munich, Munich, Germany; [2]Department of General, Visceral and Transplantation Surgery, LMU University Hospital, Ludwig Maximilian University of Munich, Munich, Germany

Background
Suppressed renin levels in medically treated patients with primary aldosteronism (PA) are associated with a worse cardiometabolic outcome. This study investigates the prevalence and outcome of persistent renin suppression after adrenalectomy in patients with unilateral PA.
Methods
We included 77 patients that underwent adrenalectomy for PA and evaluated postoperative renin recovery. Patients were divided into tertials based on their renin concentration at the first follow-up, approximately six months after adrenalectomy. We compared histopathology using CYP11B2 staining according to histopathology of primary aldosteronism consensus (HISTALDO), biochemical and clinical outcomes according to the PASO (Primary Aldosteronism Surgical Outcome) criteria and improvement of comorbidities and end-organ damage at short- and long-term follow-up ranging from six months to three years postoperatively.
Results
Renin concentrations were <8mU/l, between 8 and 16mU/l, or >16mU/l at first follow-up in the respective groups. Patients with renin concentrations <8mU/l had twice as often non-classical histopathology, comprising multiple aldosterone-producing nodules, aldosterone-producing micronodules and aldosterone-producing diffuse hyperplasia, as the other two groups together (8/26 (30.8%) vs. 1/25 (4%) vs. 3/26 (11.5%); $P=0.024$) and less frequently complete biochemical remission (normalisation of aldosterone-to-renin ratio and correction of hypokalaemia) at their first follow-up ($P<0.01$). There were no differences in the clinical outcome, long-term biochemical outcome, and improvement of end-organ damage and comorbidities.
Conclusions
In our study, suppressed renin concentrations <8mU/l occurred in one third of PA patients six months after adrenalectomy. Despite a worse short-term biochemical outcome, long-term biochemical and clinical outcomes, including comorbidities and end-organ damage, do not appear to be associated with postoperative renin concentrations.

Establishing the prevalence of non-classical congenital adrenal hyperplasia using serum 21-deoxycortisol concentrations

Romy de Kroon[1], Renée de Mutsert[2], Raymond Noordam[3,4], Frits Rosendaal[5], Wjera Wickenhagen[1], Jacquelien Hillebrand[1], Martin den Heijer[6] & Annemieke C Heijboer[1,7]
[1]Amsterdam University Medical Center, location University of Amsterdam, Endocrine Laboratory, department of Laboratory Medicine, Amsterdam, Netherlands; [2]Leiden University Medical Center, Department of Clinical Epidemiology, Amsterdam, Netherlands; [3]Leiden University Medical Center, Department of Internal Medicine, Section of Gerontology and Geriatrics, Leiden, Netherlands; [4]Leiden University Medical Center, Health Campus The Hague/Department of Public Health and Primary Care, Leiden, Netherlands; [5]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, Netherlands; [6]Amsterdam University Medical Center, location Vrije Universiteit Amsterdam, Department of Internal Medicine, Division of Endocrinology, Amsterdam, Netherlands; [7]Amsterdam University Medical Center, location Vrije Universiteit Amsterdam, Endocrine Laboratory, department of Laboratory Medicine, Amsterdam, Netherlands

Background
The prevalence of non-classical congenital adrenal hyperplasia (NCCAH) is estimated to be 0.1–0.2% in the Netherlands, mostly established using serum 17-hydroxyprogesterone (17-OHP) concentrations. However, it could be questioned whether this prevalence is accurate as 17-OHP measurement does not reflect optimal sensitivity and specificity for the diagnosis of NCCAH. Recently, 21-deoxycortisol (21-DOCL) has been proposed to be a valid diagnostic discriminator for both classical and non-classical CAH.

Objectives
To establish the prevalence of NCCAH in the Netherlands using serum 21-DOCL concentrations.
Methods
Steroid hormone concentrations were measured using LC–MS/MS in participants from the Netherlands Epidemiology of Obesity (NEO) study, which contained an oversampling of participants with overweight and obesity. We examined 21-DOCL concentrations in participants not using corticosteroids (3416 women and 3096 men) and used a cut-off value of 0.5 nmol/l for the diagnosis NCCAH. To rule out potential selection bias of our overweight population, prevalence rates were calculated by weighing toward distribution of body mass index in the general population.
(Preliminary) results
Based on 57 participants with a 21-DOCL concentration ≧0.5 nmol/l, the weighted prevalence was 0.94% [95% CI 0.65%–1.35%] in this population. A sub analysis showed a prevalence of 0.86% [95% CI 0.49%–1.50%] in women and 1.04% [95% CI 0.65%–1.66%] in men. When comparing the groups of participants with 21-DOCL concentrations ≧0.5 nmol/l to those with lower 21-DOCL concentrations, mean testosterone, androstenedione and 17-OHP concentrations were higher in participants with 21-DOCL concentrations ≧0.5 nmol/l.
Conclusions
The prevalence of NCCAH established based on serum 21-DOCL concentrations seems to be 5- to 10-fold higher than the previously estimated prevalence based on serum 17-OHP concentrations in the general population. This is relevant information since, in women particularly, there might be an underdiagnosis of NCCAH and possibly overdiagnosis of polycystic ovary syndrome (PCOS) due to overlapping clinical symptoms between NCCAH and PCOS.

Can the plasma aldosterone/potassium ratio predict primary aldosteronism in patients scheduled for confirmatory testing?

Kübra Durmuş Demirel[1], Fatma Dilek Dellal Kahramanca[1], gulsum karahmetli[1], cevdet aydin[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara City Hospital, Ankara, Türkiye; [2]Ankara City Hospital, Yildirim Beyazit University, Ankara, Türkiye

Introduction
Primary aldosteronism (PA) is a common cause of endocrine hypertension, yet there are some difficulties in diagnosing the disease. A single normal or low aldosterone/plasma renin activity (PRA) ratio (ARR) alone may not be sufficient to exclude the diagnosis of primary aldosteronism (PA) (3–5). The saline infusion test (SIT), a standard confirmatory test, has limitations such as contraindications, need for hospitalization and high cost (6). This study evaluates the potential of the plasma aldosterone/potassium (A/K) ratio in predicting PA.
Methods
Between 2019 and 2023, 118 patients admitted to our Endocrinology outpatient clinic who underwent SIT with a prediagnosis of PA due to hypertension, as well as hypokalemia and/or elevated ARR were retrospectively included in the study. Patients who were pregnant, <18 years of age, had adrenal surgery and used diuretics were excluded. Demographic data, laboratory and adrenal imaging results were evaluated retrospectively. Aldosterone and concurrent potassium levels at the time of admission were obtained and A/K ratio was calculated. The diagnosis of PA was made according to the results of SIT, captopril confirmation test if available, adrenalectomy results and clinical judgment of the multidisciplinary council (7). All parameters were compared between the groups of patients with and without PA.
Results
A total of 118 patients who underwent SIT were included in the study. PA was diagnosed in 57 patients based on clinical and laboratory results. Male sex ratio was higher in the PA group (52.6% vs. 23.0%; $P=0.001$) (Table 1). Patients with PA had higher aldosterone levels ($P<0.001$) and ARR ($P<0.001$), but lower potassium levels ($P<0.001$) and PRA ($P=0.01$). The A/K ratio was significantly higher in the PA group ($P<0.001$). ROC analysis showed that an A/K ratio cut-off of 5.4 could distinguish PA patients from non-PA patients [AUC (95% CI) =0.811 (0.733–0.890), $P<0.001$], with 73.7% sensitivity and 77.0% specificity (Default 1). When this cut-off point was applied to the group of patients with indetermine SIT results, sensitivity was 71.4% and specificity 77.8%. Univariate and multivariate analyses indicated that a high A/K ratio increased the likelihood of a PA diagnosis, with an A/K ratio above 5.4 associated with a 4.585-fold higher risk (95% CI: 1.181–17.799, $P=0.028$) (Table 2).
Conclusion
The A/K ratio may predict PA. It offers advantages such as no need for pretest potassium or hospitalization, making it a useful supplementary parameter for diagnosing PA, particularly in patients for whom confirmatory tests are unsuitable.

Significance of plasma catestatin and relaxin-2 levels in patients with primary hypertension and type 2 diabetes mellitus

Olena Pankova[1] & Oleksii Korzh[1]
[1]Kharkiv National Medical University, Department of General Practice – Family Medicine, Kharkiv, Ukraine

Background
Arterial hypertension (AH) and type 2 diabetes mellitus (T2DM) are potent risk factors for cardiovascular diseases. Cardiovascular and metabolic effects of catestatin (CST) and relaxin-2 (RLN-2) indicate their involvement in AH and T2DM pathogenesis and suggest their diagnostic potential.
Objective
To determine plasma CST and RLN-2 levels, evaluate their associations with parameters of glucose metabolism and investigate the prognostic potential of CST and RLN-2.
Materials and methods
The present study was an observational prospective cohort single-center by design with a 12-month follow-up. This study was performed in accordance with all ethical principles of the Declaration of Helsinki. All participants signed a written informed consent form prior to any protocol procedures. 106 patients with AH and 30 healthy volunteers were enrolled in the study. 55 hypertensive patients had comorbid T2DM. Plasma CST levels were measured by ELISA (E4996Hu, BT Lab, China), RLN-2 (E-EL-H1582, Elabscience, USA). The data are presented as a mean±S.D. or a median and interquartile range. Statistical significance was defined as $P<0.05$. Statistical data were analyzed using SPSS statistical software (SPSS 25.0 for Windows, IBM, Armonk, NY, USA).
Results
Patients with AH and T2DM had decreased CST (4.47±1.16 vs. 5.61± 0.61 ng/ml; $P<0.001$) and RLN-2 levels (5.11 [4.97; 5.38] vs. 6.71 [6.00; 7.14] pg/ml; $P<0.001$) compared with hypertensive patients without T2DM. Both CST and RLN-2 had negative correlations with parameters of glucose metabolism, particularly HbA1c ($r=-0.535$; $P<0.001$ and $r=-0.673$, $P<0.001$), glucose ($r=-0.450$; $P<0.001$ and $r=-0.543$; $P<0.001$), HOMA-IR ($r=-0.481$; $P<0.001$ and $r=-0.392$; $P<0.001$). CST (0.175 [0.099 − 0.312; $P<0.001$) and RLN-2 levels (0.196 [0.095 − 0.405]; $P<0.001$) were established as significant predictors of impaired glucose metabolism by univariate binary logistic regression. Kaplan–Meier curve analysis revealed a significantly higher incidence of MACE in patients with CST levels <5.44 ng/ml ($P=0.01$). Cox proportional hazard model indicated CST levels (0.486 [0.285 – 0.830]; $P=0.01$) as an independent predictor of MACE in the study population as well as presence of T2DM (3.578 [1.102 – 11.619]; $P=0.03$), HOMA-IR (1.157 [1.023 – 1.309]; $P=0.02$), insulin levels (1.049 [1.006 – 1.094]; $P=0.02$).
Conclusions
In the present study, we established reduced plasma CST and RLN-2 levels in hypertensive patients with T2DM and their negative relationships with parameters of glucose metabolism. CST and RLN-2 were determined as significant predictors of impaired glucose metabolism. These findings allow us to suggest CST and RLN-2 as perspective biomarkers of AH and T2DM.

Education of sick day management of paediatric adrenal insufficiency: a national survey of paediatric endocrine nurse specialists

Jennifer McKechnie[1,2], Anna Bradford[1,2], S Abdelrahman[1], Talat Mushtaq[3], Sze May Ng[4,5,6], Sally Tollerfield[7], Peter Laing[8] & SC Wong[1,2]
[1]Bone, Endocrine, Nutrition Research Group in Glasgow (BEN-G), Human Nutrition, University of Glasgow, Glasgow, United Kingdom; [2]Department of Paediatric Endocrinology, Royal Hospital for Children Glasgow, Glasgow, United Kingdom; [3]Leeds Children's Hospital, Leeds, United Kingdom; [4]Mersey and West Lancashire Teaching Hospitals, Paediatrics, Ormskirk, United Kingdom; [5]Faculty of Health, Social Care and Medicine, University of Liverpool, Liverpool, United Kingdom; [6]Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom; [7]Department of Women's and Children's Health, University of Liverpool, Liverpool, United Kingdom; [8]Department of Paediatric Endocrinology, Alder Hey Children's NHS Foundation Trust, Liverpool, United Kingdom

Background
A critical component of health provision for a young person with adrenal insufficiency (AI) is education for the family and young person regarding management during sick day episodes. Deficits in patient education have been identified as a contributor to adrenal crisis risk.
Aim
The aim of this online survey distributed via the British Society for Paediatric Endocrinology (BSPED) paediatric endocrine nurse specialists (PENS) mailing list is to explore current clinical practice on provision of education in the United Kingdom.
Methods
An online survey of 25 questions was circulated to BSPED PENS between January-February 2024. These were multiple answer questions and there was also free text space for additional comments.
Results
The survey was circulated to eighty-eight PENS; fifty-one(58%) responses were received. In relation to the provision and structure of the initial education of sick day management, all provide individual face-to-face education of parents/guardians. In addition, eighteen (35%) provide online individual face-to face education, two (4%) provide group face-to-face and two (4%) group online education. Twenty-six (51%) have local departmental guidance on content of the AI education. All PENS provide education on symptoms of adrenal crisis, and management during moderate and severe sick day episodes. Forty-nine (96%) would discuss the underlying pathophysiology of AI and forty (78%) would discuss management during minor procedures. Fifty (98%) would educate and demonstrate injection of hydrocortisone at the first educational session, with forty-nine (96%) offering a practice injection. Fifty (98%) would provide written information to take away after the initial education; 43 (84%) provide a steroid emergency card whilst 25 (50%) provide information leaflets. Thirty-two (63%) do not provide any written information to non-English speaking families. Seven (14%) do not assess understanding after the initial education and twenty-five (49%) do not provide routine follow-up after the initial education. Twenty-one (41%) do not provide routine, regular refresher educational sessions. Twenty (39%) PENS do not educate the young person themselves in preparation for transition.
Conclusion
This national survey of PENS identified a consistent approach to the initial education of parents/guardians of a young person with AI. However, we identified variability in provision of routine refresher sessions and education of the young person themself prior to transition. Additionally, non-English speaking families may be at a disadvantage as written information is not provided in over 60%. These results will help with the development of national standards of education for young people with adrenal insufficiency.

A validated liquid chromatography mass spectrometry method for comprehensive urinary steroid profiling: applications in hypertension research and diagnostic studies

Joshua Bain[1], Fozia Shaheen[1], Lorna Gilligan[1], Alessandro Prete[1] & Angela Taylor[1]
[1]Metabolism and Systems Science, University Of Birmingham, Birmingham, United Kingdom

Steroids are crucial for numerous biological processes, and their dysregulation is linked to various endocrine disorders from hypertension to adrenocortical carcinoma. Accurate steroid profiling is essential for understanding these conditions. Here we present a validated method (EMA/FDA criteria) for urinary steroid profiling using liquid chromatography-tandem mass spectrometry (LC-MS/MS) which quantifies 29 steroids, including steroid precursors, mineralocorticoids, glucocorticoids, and androgens. Steroids were extracted from urine via C_{18} solid-phase extraction after deconjugation from their sulfate and glucuronide esters. Quantification was performed using a Waters Acquity UHPLC and Xevo® TQ-XS mass spectrometer. Chromatographic separation of 27 steroids was achieved in 16 minutes using a Waters HSS T3 column, with a second injection onto a BEH C_{18} column to separate and quantify THF and 5αTHF in 4 minutes. The lower limits of quantification ranged from 2 to 20 ng/ml, with accuracy (bias) between 12.6% and 19.9% and precision (%CV) from 4.0% to 18.6%. Imprecision assessed at three concentrations was within acceptable limits for all steroids, ranging from 3.4% to 14.1%. Accuracy (bias) ranged from −14.9% to 14.9%, (excluding 5PD). Recovery was 76–103%, with matrix effects within the ideal range (< 15%) for 15 steroids and the acceptable range (<20%) for the rest. Inter- and intra-assay imprecision (%CV) ranged from 0.8% to 14.9%. In a proof or principle cohort of 40 healthy volunteers, all steroids were detectable, with DHEA, α-cortol, THAldo, 5PD, and PTONE quantifiable in 86%, 84%, 72%, 43%, and 38% of samples, respectively. Steroid excretion was higher during the day and in men compared to women. This LC-MS/MS method enables high-throughput, comprehensive multi-steroid quantification across multiple steroid classes, offering a valuable tool for clinical research and diagnostic applications. This method will be implemented in the multi-centre European clinical research study, HT-Advance, where it will be combined with other technologies to rapidly measure urinary steroid excretion, evaluate the diagnostic performance of MOMICS (multi-omics) technologies in identifying endocrine causes of hypertension, and predict treatment responses in patients with newly diagnosed hypertension.

JOINT1596

Space Oil Vapours: Endocrine Risks and the Adolescent Challenges

Clara Ngai[1] & Antony Fu[1]
[1]Princess Margaret Hospital, Hong Kong, Hong Kong, Hong Kong

Introduction
There is an increasing concern regarding the misuse of etomidate, a drug traditionally used as a general anaesthetic, which is now being abused within the community through vaping with electronic cigarettes. Beyond its immediate effects on the central nervous system, etomidate presents substantial risks due to its adrenal toxicity and the potential for long-term impairments in cognitive and endocrine functions. The rising prevalence of adolescent use of electronic cigarettes is also becoming a pressing issue.
Objectives and methodology
We hereby report a retrospective cohort review of all paediatric patients, who are defined as age at or below 18 years old, with etomidate detected in their urine toxicology analyses upon admissions to Princess Margaret Hospital between 1 January 2024 and 31 December 2024 inclusively.
Results
Thirteen adolescents (7 females) were identified (age 14.1–17.9 years). They reported to have vaped etomidate for an average of two months (range: 1–8 months) before presenting to the hospital. Seven of them admitted to having taken other substances. Common presenting complaints included confusion and dizziness (3/13), unsteady gait (2/13), suicidal attempt/deliberate self-harm (2/13). At presentation, five of them had hypertension (systolic blood pressure range: 94–160 mmHg). All did not manifest signs of hyperandrogenism. One patient was treated in the paediatric intensive care unit (ICU) for inhalation injuries resulting from a fire incident due to vaping. Morning cortisol was low in 3 out of 8 patients (range: 44–83; reference >133 nmol/l). Short synacthen test showed adrenal insufficiency in 3 out of 6 patients (peak cortisol range: 74–238; reference >376 nmol/l). Baseline ACTH levels were elevated in three cases (range: 28–55; reference 1.6–13.9 pmol/l). Renin and aldosterone were both undetectable in six of the patients. 11-deoxycortisol, the precursor hormone accumulated right above the inhibition of 11β-hydroxylase (range: 72.4–564; reference ≤4.3 nmol/l) and 17-OHP (range 8.7–11; reference <4 nmol/l) along

the glucocorticoid pathway of steroidogenesis were found elevated in four patients.
Conclusion
These alarming consequences have heightened awareness among healthcare professionals and the broader community, underscoring the urgent need to identify, intercept, and prevent the proliferation of this harmful substance. Safeguarding our younger generations from the devastating effects of such abuse is a collective responsibility that demands concerted efforts in education, intervention and policy development.

Implementing a neonatal screening programme for Congenital Adrenal Hyperplasia using liquid chromatography–tandem mass spectometry in a Northern Spanish region

Claudia Cifuentes Zamalloa[1], Amaia Sanchez Arlegui[1], Nerea Ferrero[2], Maria Unceta[3], Amaya Vela Desojo[1], Nancy Portillo[1], Itxaso Rica[1] & Gema Grau Bolado[1]
[1]Hospital Universitario Cruces, Pediatric endocrinology, Barakaldo, Spain; [2]Public Health Department Osakidetza, Bilbao, Spain; [3]Hospital Universitario Cruces, Biochemistry Laboratory, Barakaldo, Spain

Introduction
Screening of Congenital Adrenal Hyperplasia (CAH) due to 21-hydroxylase deficiency reduces neonatal morbidity and mortality. The quantification of 17-hydroxyprogesterone (17-OHP) using Delayed Fluorescence Immunoassay (DFI) on filter paper blood samples is the standard screening strategy. However, it is associated with a high number of false positives (FP), especially in premature infants. To optimize the positive predictive value (PPV), most screening programs establish cutoff points for 17-OHP based on gestational age (GA). Currently, it is considered more efficient to determine 17-OHP and other adrenal analytes using LC-MS/MS, which may also allow the diagnosis of other types of CAH. In June 2023, CAH screening was implemented in our region.
Objectives
To evaluate the effectiveness of our screening strategy for diagnosing classic CAH. To determine the prevalence and impact of FP by including the measurement of 17-OHP via LC–MS/MS.
Methodology
At 48 hours of life, filter paper samples with 17-OHP values exceeding the 99.95th percentile (p99.95) by DFI are considered positive. Three groups are differentiated based on GA: <33 weeks (weighted p99.95), 33–37 weeks (p99.95 corresponding to the group with the highest gestational age), and >37 weeks (p99.95). All positives are retested using both DFI and LC–MS/MS. The established cutoff points for various adrenal analytes and diagnostic ratios by LC–MS/MS are: 17-OHP >15.1 nmol/l + 21-deoxycortisol >2.9 nmol/l or 17-OHP >15.1 nmol/l + ratio of [17-OHP + Androstenedione]/cortisol >2 + ratio 17-OHP/11-deoxycortisol >10. In neonates <33 weeks and/or <1500 grams, a second filter paper determination by DFI is done at 15 days of life, as done for congenital hypothiroidsm screening. This allows for a single cutoff point in this population. We analyzed the positive cases from the CAH screening (June 1, 2023 – December 31st, 2024). Data were obtained from the neonatal screening program and clinical records.
Results
Out of 21 411 screenings performed, 40 were positive by DFI (55% male). Three out of 40 neonates died early due to other causes. 37 cases were retested, confirming one true positive (a 5-day-old male neonate) by both DFI and LC-MS/MS. Outpatient treatment was started at 7 days of life. In the 36 cases considered false positives (75% from the group 33–37 weeks, 58% male), retesting using LC–MS/MS allowed ruling out classic CAH.
Comments
In the short duration of CAH screening, one male was diagnosed before one week of life. The inclusion of LC–MS/MS in this screening strategy raises the PPV to 100%, avoiding unnecessary interventions in the few false positives.

Morning serum cortisol predicts short synacthen test response during glucocorticoid weaning in children and adults

Muhammad Fahad Arshad[1], Aneeq Ahmed[2], Sian Beddows[2], Arwa Mullamitha[2], John Newell-Price[1], Richard Ross[3], Charlotte Elder[2] & Miguel DeBono[1]
[1]University of Sheffield, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom; [2]University of Sheffield, Sheffield Children's NHS Foundation Trust, Sheffield, United Kingdom; [3]University of Sheffield, Sheffield, United Kingdom

Introduction
Tertiary adrenal insufficiency (AI) resulting from glucocorticoid-induced hypothalamic-pituitary-adrenal (HPA) axis suppression is the commonest cause of AI. The morning serum cortisol levels recommended by recent National Institute for Health and Care Excellence (NICE), UK guidelines (1) to predict adrenal insufficiency (AI) are not derived from studies in patients with AI due to glucocorticoids, as such studies using modern immunoassays are scarce. The aim of this study was to identify morning cortisol cut-off that predict the 30-minute post-Synacthen cortisol, to safely use in clinical practice in children and adults without requiring an SST.
Materials and methods
A retrospective cohort study of paediatric and adult patients on long-term glucocorticoids with suspected or confirmed tertiary AI undergoing a short synacthen test (SST). The main outcome of the study was morning serum cortisol cut-offs with 95% and 99% specificity and sensitivity determined via receiver operating characteristic (ROC) curve analysis. A pass for the SST was defined as a post-synacthen 30-minute cortisol of $\geqq 430$ nmol/l using immunoassays, Vitros 5600 (Ortho Clinical Diagnostics) in paediatric cohort, and Elecsys II (*Roche)* in the adult cohort.
Results
One hundred and seventy three and 443 SSTs were included in the paediatric and adult cohorts, respectively, of which 32% and 36% were normal. The ROC curve analysis demonstrated that basal morning cortisol performed well in both cohorts with area under curve (AUC) of 0.77 (95%CI 0.70,0.85) and 0.89 (95%CI 0.85,0.92), respectively. Morning serum cortisol cut offs to predict a normal SST in children and adults were 280 and 285 nmol/l at 95% sensitivity, and 316 and 349 nmol/l at 99% sensitivity, respectively. In a longitudinal safety analysis carried out in the adult cohort, using the 95% cut off, 54 of 57 patients with morning serum cortisol values $\geqq 285$ nmol/l were weaned from glucocorticoids within three months.
Conclusion
This study shows that morning serum cortisol performs well in predicting SST outcome in both children and adults on glucocorticoids, with two different immunoassays. A cut off of $\geqq 285$ nmol/l can be safely used to wean glucocorticoids without the need for synacthen testing.

Metabolic disorders in pheochromocytoma: A retrospective multicenter study of pre- and post-operative profiles

Eleftheria Kakargia[1], Aikaterini Themis Vyllioti[1], Anastasia E. Markatseli[2], Stelios Tigas[2], Georgios Kostopoulos[3], Zoi Efstathiadou[3], Foteini Adamidou[3], Nektarios Adamopoulos[4], Alexandra Bargiota[4], Athanasios Fountas[1], Athina Markou[1] & Labrini Papanastasiou[1]
[1]Department of Endocrinology and Diabetes Center, Center of Excellence of Rare Endocrine Adrenal Disorders, 'Georgios Gennimatas' General Hospital of Athens, Athens, Greece; [2]Department of Endocrinology and Diabetes Center, Ioannina University Hospital, Ioannina, Greece; [3]'Hippokration' General Hospital of Thessaloniki, Department of Endocrinology, Thessaloniki, Greece; [4]University of Thessaly, Department of Endocrinology and Metabolic Diseases, Larissa, Greece

Introduction
Pheochromocytomas/paragangliomas (PPGLs) are a group of rare neuroendocrine tumors with an incidence of approximately 0.8 per 100 000 person-years. Due to their rarity, the metabolic dysregulation of patients with PPGL and metabolic evolution after tumor resection are still under investigation.
Aim
To compare the baseline characteristics of patients across catecholamine phenotypes and investigate post-operative changes in the metabolic profile.
Methods
This is a multicenter, retrospective study conducted at four Endocrinology departments of Greek tertiary general hospitals. Comparisons were performed at diagnosis between catecholamine phenotypes (adrenergic versus noradrenergic) and incidentalomas versus non-incidentalomas. Correlations between metabolic and pheochromocytoma-related characteristics (tumor size, PASS) were performed and metabolic profile evolution after adrenalectomy was assessed.
Results
Overall, 83 individuals [58% females, median age 51 years] diagnosed and treated for pheochromocytoma over the past twenty years were included. Pheochromocytomas were found incidentally in the majority of patients (64%) , with 74% of the total cases being secreting tumors. Among those, 28% had adrenergic and 46% noradrenergic phenotype, respectively. The majority of patients (69%) had hypertension which was paroxysmal in 37% of cases. Metabolic disorders at baseline were common with a 74% prevalence of diabetes and prediabetes, 65% of dyslipidemia and 20% of obesity. Adrenergic phenotype was predominant in older individuals ($P=0.003$) and required significantly higher daily doses of phenoxybenzamine ($P=0.002$). Metabolic and tumor parameters did not differ between catecholamine phenotypes. Patients diagnosed with incidentalomas exhibited a higher prevalence of diabetes in comparison to their non-incidentaloma counterparts ($P=0.021$) while the lipid profile did not vary. Hypertensive patients had larger tumors (53.7 vs 42.1 mm, $P=0.023$) with worse PASS ($\geqq 4$) ($P=0.022$). Furthermore, univariate correlations demonstrated that greater tumor size was associated with higher number of anti-hypertensive drugs at diagnosis ($P=0.044$) and increased PASS in histology ($P=0.007$). Positive correlations between daily phenoxybenzamine dose and BMI ($P=0.002$) as well as between HbA1c and number of anti-hypertensive drugs ($P=0.029$) were observed. Seventy- five patients were followed-up after adrenalectomy for a median period of 24 months. Metabolic assessment revealed improved HbA1c, fasting glucose and LDL levels ($P<0.02$) despite no significant change in post-operative BMI.
Conclusion
This population-based study, spanning two decades, offers valuable insights into the clinical characteristics of PPGLs patients. Metabolic and tumor parameters showed no variation across catecholamine phenotypes. On the other hand, metabolic disorders demonstrated improvement after adrenalectomy while BMI was not a contributing factor in this context as it remained stable.

Prognostic factors for cardiovascular complications induced by catecholamines in pheochromocytomas and paragangliomas: A systematic review and meta-analysis

Eleftheria Kakargia[1], Charalampos Tsentidis[2], Athanasios Fountas[1], Georgia Kanti[1], Athina Markou[1] & Labrini Papanastasiou[1]
[1]Department of Endocrinology and Diabetes Center, Center of Excellence of Rare Endocrine Adrenal Disorders, 'Georgios Gennimatas' General Hospital of Athens, Athens, Greece; [2]'Agios Panteleimon'General Hospital of Nikaia, Department of Endocrinology, Piraeus, Greece

Introduction
Pheochromocytomas and paragangliomas (PPGLs) can cause serious cardiovascular events induced by the unpredictable release of large amounts of catecholamines.
Purpose
The aim of this study was to determine possible prognostic factors of catecholamine-induced cardiovascular events for timely diagnosis, better risk stratification and optimal treatment strategy in patients diagnosed with PPGL.
Methods
A literature search for eligible studies on PubMed and the Cochrane Library from January 1980 until November 2024 was performed. The primary endpoint was any serious cardiovascular event (Takotsubo syndrome, acute coronary syndrome, acute heart failure, cardiogenic shock, stroke or fatal arrhythmias) in PPGL patients. Meta-analysis of potential prognostic factors of major adverse cardiovascular events (MACEs) after assessment of clinical, laboratory, imaging, histological and genetic parameters was performed on the pooled data.
Results
Quantitative data from nine retrospective cohort studies, involving 1566 patients with PPGL were included in the analyses. MACEs were manifested in 302 patients [pooled estimate 21% (95% C.I. 14–29%)], among whom there were 95 patients with Takotsubo syndrome [pooled estimate 39% (23–54%)] of overall cardiovascular events. There was no sufficient data to determine the prevalence of the other types of cardiovascular events while significant heterogeneity was detected for all effect estimates. An increased risk of MACEs was noted in patients presenting with tumors with necrosis/hemorrhage (71%; 95C.I. 27–115%) and in those with diabetes (56%; 95C.I. 2–109). As expected, dyspnea and chest pain were prominent risk factors for MACE as they were associated with a 5 (95% C.I. 3.3–7.4) and 2.7 (95% C.I. 1.5–4) times increased risk of serious cardiovascular event development, respectively. The pooled results did not demonstrate any association between age, adrenergic phenotype, metastatic disease or familial PPGLs on serious cardiovascular outcomes. In conclusion, smaller sizes do not serve a protective factor, as MACEs are associated with a mean difference of only 8.3mm (95% C.I. 0.9–15.7 mm) in tumor size between the two groups.
Conclusion
To our knowledge, this is the first meta-analysis of cohort studies of catecholamine-induced MACEs in patients with PPGL. Our study shows that 21% of PPGL cases will develop MACE. Necrosis/hemorrhage, dyspnea, chest pain and diabetes are associated with an increased likelihood of development of serious cardiovascular events. However, these results should be interpreted with caution due to statistical and methodological heterogeneity.

Surgical outcomes and histochemical analysis in primary aldosteronism: a 10-year cohort study

Emaad Mohammad[1], Naji Touma[1,2], Christopher Davidson[1,2] & Sara Awad[1,2]
[1]Queen's University, Kingston Health Sciences Centre, Internal Medicine, Kingston, Canada; [2]Kingston Health Sciences Centre, Endocrinology, Kingston, Canada

Introduction and objectives
Primary aldosteronism (PA) is a leading cause of hypertension, affecting up to 11.2% of new cases due to excessive aldosterone production. It typically results from bilateral adrenal hyperplasia or unilateral conditions like aldosterone-producing adenomas (APA). While laparoscopic adrenalectomy is a common treatment for unilateral cases, some patients remain hypertensive due to lingering hyperplasia in the other adrenal gland. Research suggests that staining adrenal tissue for enzymes such as CYP11B2, CYP11B1, and CYP17A1 can help identify aldosterone-producing cells and predict surgical outcomes, highlighting the need for improved diagnostic methods to enhance treatment success.
Methods
Patients undergoing adrenalectomy for PA at one center were identified over a 10-year period. Clinical parameters such as patient demographics, lab results, imaging features, adrenal vein sampling results, and clinical outcomes were recorded. Pathology specimens were stained with aldosterone synthase (CYP11B2). Patterns of histochemistry were then described.
Results
A cohort of 30 patients diagnosed with primary aldosteronism (PA) who underwent adrenalectomy over a span of 10 years was examined. Preoperative adrenal vein sampling was performed on 27 patients. On average, patients were taking 3.03 antihypertensive medications prior to surgery, which decreased to 0.92 medications per patient postoperatively. Hypokalemia was present in 23 patients before surgery, with none exhibiting it afterward. Surgical outcomes

revealed that 21 patients were completely cured, 4 showed improvement, and 5 did not experience a cure. Immunostaining analysis was performed on 19 cases, revealing the following distribution of patterns: 12 (63.2%) showed consistent staining, 4 (21.0%) showed variable staining, 2 (10.5%) displayed aldosterone-producing micronodules (APM), and 1 (5.2%) had no staining. Preoperative imaging did not identify adenomas in either of the APM cases, in 2 out of 12 cases with consistent staining, or in 1 out of 4 cases with variable staining. The case with no staining revealed an adenoma on the ipsilateral side, as well as one on the contralateral side. No definitive link was observed between histochemical findings and cure rates.
Conclusion
This study highlights the effectiveness of adrenalectomy in treating primary aldosteronism (PA), with significant improvements in blood pressure, potassium levels, and reduced antihypertensive use. While immunostaining identified distinct histochemical patterns, no clear correlation with outcomes was found. Despite this, most patients experienced a cure or improvement, supporting adrenalectomy as a viable treatment. Further research is needed to refine diagnostics and identify factors influencing surgical success.

Determination of cortisol cut-off limits in the overnight dexamethason suppression test using roche elecsys® cortisol II immunoassay

Nanna Thurmann Jørgensen[1], Stina Willemoes Borresen[1], Linda Hilsted[2], Kasper Brødbæk[2], Randi Ugleholdt[3], Claus Feltoft[3], Ulla Feldt-Rasmussen[1] & Marianne Klose[1]
[1]Copenhagen University Hospital, Rigshospitalet, Department of Kidney and Hormone Diseases, Copenhagen, Denmark; [2]Copenhagen University Hospital, Rigshospitalet, Department of Clinical Biochemistry, Copenhagen, Denmark; [3]Copenhagen University Hospital, Herlev, Department of Medicine, Copenhagen, Denmark

Background and aim
Mild autonomous cortisol secretion (MACS) is defined as excessive cortisol secretion but without the clinical phenotype of Cushing's syndrome in the context of an adrenal incidentaloma. Still, MACS has been associated with increased mortality and risk of type 2 diabetes, hypertension, obesity, and osteoporosis. Diagnostic tests capable of detecting MACS are lacking, but cortisol concentrations in plasma after a 1 mg overnight dexamethasone suppression test (1 mg DST) has the highest sensitivity of available biochemical analyses. A cut-off of 50 nmol/l has been recommended in the recent guidelines from ESE/ENS@T, but as measurement of cortisol concentrations is method dependent, this study aimed to establish the assay-specific cut-off of the 1 mg DST using the Roche Elecsys® Cortisol II immunoassay (ElecsysCortII) in a cohort of patients with adrenal incidentalomas.
Methods
Healthy participants ($n=101$, 57 women, median [range] age 60 [19–81] years) and patients with incidentalomas ($n=106$, 56 women, median [range] age 63 [40–85] years) underwent a 1 mg DST (dexamethason was taken between 2300 and 2400 h, and blood samples were collected between 0800 and 0900 h the following day) with plasma cortisol samples analyzed using ElecsysCortII. Cut-off limit for a normal response to the 1 mg DST was defined as the 97.5th percentile in the healthy participants.
Results
Two healthy participants were referred to the endocrinology department due to high 1 mg DST plasma cortisol levels (336 and 415 nmol/l, respectively), and thus excluded from the analyses. In the remaining healthy participants, the 0800 to 0900 h cortisol cut-off limit for the 1 mg DST was 68.9 [CI 63.1–75.3] nmol/l (ElecsysCortII). Forty-four percent of patients with an incidentaloma had a 1 mg DST cortisol above the recommended cut-off of 50 nmol/l, whereas 15% had a cortisol concentration above the assay-specific cut-off of 68.9 nmol/l.
Conclusion
ElecsysCortII-specific cortisol cut-off in healthy participants demonstrated a higher cut-off compared with previous recommendation of 50 nmol/l, and fewer than half as many patients exceeded the cut-off 68.9 nmol/l. As the number of referred patients suspected of MACS depends on the cut-off, the present findings may provide evidence for always adjusting the normal cut-off according to the local cortisol method.

[1]Centre of Postgraduate Medical Education, EndoLab Laboratory, Department of Endocrinology, Warsaw, Poland; [2]Children's Memorial Health Institute, Department of Clinical Biochemistry, Warsaw, Poland; [3]The Children's Memorial Health Institute, Clinical Biochemistry, Laboratory for the Diagnosis of Metabolic Disorders and Steroidogenesis, Warsaw, Poland; [4]Centre of Postgraduate Medical Education, Department of Cell Biology and Immunology, Warsaw, Poland; [5]Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznań, Poland; [6]Medical University of Warsaw, Department of Internal Medicine and Endocrinology, Warsaw, Poland; [7]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland

Introduction
The application of metabolomics studies of determining the profile of steroid hormones or their metabolites in blood or urine opens new research directions in the diagnosis of adrenal diseases. In addition, studies of new biomarkers in the form of proteins, peptides, neuropeptides can be useful at various stages of the diagnostic and therapeutic process. Proteins and peptides of the granin family are produced and secreted into blood from endo- and neuroendocrine cells, along with hormones. The aim of the projects was the clinical and analytical evaluation of new biomarkers: urinary steroid hormone profiles and selected proteins and neuropeptides from granin family.
Materials and methods
The study included 61 patients with various adrenal tumors (mean age 48 years, 55% females; 26 MACS, 7 CS, 9 PA, 19 NFAA). All patients with adrenal tumors were analyzed for 41 different steroid hormone metabolites in a 24-hour urine samples. In addition, CgA, WE-14, Catestatin, Serpinin and proSAAS concentrations were determined in blood. Analyses were performed by GC/MS and ELISA methods.
Results
In the study groups (CS, MACS, PA, NFAA), urinary steroid profile analysis and profile testing of selected granin family proteins and peptides were performed. Comparison of CS vs. NFAA group revealed significant differences for: ET/AN ($P=0.010$), THS ($P=0.003$), THF ($P=0.007$), Free cortisol ($P=0.004$) and CgA ($P=0.002$) with higher level in CS group in all cases. Significant difference for MACS vs. NFAA was confirmed for: AN ($P=0.008$), An-3-ol ($P=0.002$), with higher level in NFAA group and for THS ($P=0.009$) with higher level in MACS group. For PA vs. NFAA there was a significant difference for THAldo ($P=0.026$) with higher level in PA group. The next stage of the project was the analysis of selected urinary steroid profile biomarkers (ET/AN, THS, THF, Free cortisol) and protein – chromogranin A in a group of patients with CS in order to assess the usefulness of this diagnostic tool. In the study of a panel of biomarkers (ET/AN + CgA, THS + CgA, THF + CgA, Free cortisol + CgA), the sensitivity and specificity rates were over 80–100%.
Conclusions
The study of urinary metabolomic profile and chromogranin A concentration has shown high usefulness in the diagnosis of Cushing's syndrome. The analysis of combined metabolomic and immunochemical studies may be useful in the in-depth biochemical diagnosis of adrenal tumor lesions.

Does the cutoff point of 1.8 μg/dl in the 1 mg dexamethasone suppression test differentiate the cardiometabolic risk attributed to MACS?

Joanna Kokoszka[1], Marta Opalinska[2], Magdalena Kolasa[1], Katarzyna Sitarz[3], Aleksandra Banas[4], Gabriela Pabian[4], Jolanta Bugajska[5], Krystyna Sztefko[5] & Alicja Hubalewska-Dydejczyk[2]
[1]Department of Endocrinology, Oncological Endocrinology, Nuclear Medicine and Internal Medicine, University Hospital in Krakow, Kraków, Poland; [2]Chair and Department of Endocrinology, Jagiellonian University Medical College, Kraków, Poland; [3]Department of Genetics, Institute of Psychiatry and Neurology, Warsaw, Poland; [4]Students Scientific Group of Endocrinology, Jagiellonian University Medical College, Kraków, Poland; [5]Department of Clinical Biochemistry, Institute of Paediatrics, Jagiellonian University Medical College, Kraków, Poland

Introduction
About 20–50% of adrenal tumors in patients without symptoms of overt Cushing's syndrome are associated with mild autonomous cortisol secretion (MACS) based on 1 mg dexamethasone suppression test (DST) (cortisol concentration $>1,8$ ug/dl). Some clinical data shows that patients with MACS are at a higher risk of developing obesity, hypertension, hyperlipidemia, nonalcoholic fatty liver disease, cardiovascular diseases, prediabetes, type 2 diabetes, osteopenia, osteoporosis, and vertebral fractures as compared to patients with non-functioning adrenal tumor (NFAT). The prevalence of hypertension in MACS varies between 35% and 92% across different studies, compared to 43% to 73% in patients with NFAT or controls. Many studies reveal that patients with a higher degree of cortisol excess have a lower quality of life and survival rate.
Objectives: The aim of the study was to assess whether the cut-off point of 1.8 μg/dl in the 1 mg dexamethasone suppression test differentiates the cardiometabolic risk attributed to MACS in adrenal incidentalomas.
Methods
The results of cortisol suppression test of 347 incidentaloma patients (141 operated patients with confirmed of adenoma and 206 non-operated with homogenous adrenal mass <10 HU) were analyzed. 100 men and 247 women with median age 63.5 and 64 respectively were included to the analysis. Primary hyperaldosteronism, pheochromocytoma and Cushing's syndrome were excluded. Patients with negative (serum cortisol concentration $\leq 1,8$ ug/dl) and positive dexamethasone suppression test (serum cortisol concentration $>$ 1,8 ug/dl) were analyzed in relation to the presence of diabetes, obesity, hypertension, ischemic heart disease and chronic heart failure.
Results
In patients with a negative (serum cortisol concentration $\leq 1,8$ ug/dl) and positive dexamethasone suppression test (serum cortisol concentration $>1,8$ ug/dl) the percentage of the diseases were as follow: hypertension: 72.22% vs. 77.88% ($P=0.02$); ischemic heart disease: 11.54% vs. 18.58% ($P=0.15$); chronic heart failure: 4.27% vs. 7.08% ($P=0.16$); diabetes: 23.93% vs. 32.74% ($P=0.06$) and obesity: 32.49% vs. 31.69% ($P=0.88$). No differences between male and female regarding the frequency of accompanying diseases were noted.
Conclusion
In patients with MACS, a cortisol cutoff of 1.8 μg/dl in the 1 mg dexamethasone suppression test may help differentiate those at higher risk for hypertension and diabetes, and appears to be an independent and significant factor in the development of these conditions.

Efficacy and safety of corticosteroid replacement therapies in pediatric congenital adrenal hyperplasia: insights from hydrocortisone, prednisone, and dexamethasone studies

Ashraf Soliman[1], Ahmed Elawwa[1], Shayma Ahmed[1], Noor Hamed[1], Nada Alaaraj[1], Fawzia Alyafei[1] & Ahmed Khalil[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Congenital Adrenal Hyperplasia (CAH) is a genetic disorder requiring lifelong corticosteroid replacement to manage cortisol insufficiency and androgen excess. Hydrocortisone, prednisone, and dexamethasone are the primary glucocorticoids used, yet dosing, timing, and long-term impacts vary.
Objectives
This review evaluates the effectiveness and safety of hydrocortisone, prednisone, and dexamethasone replacement therapies in pediatric-CAH patients, focusing on their impact on growth, androgen suppression, and cognitive outcomes.
Methods
We synthesized findings from 25 studies published between 2000 and 2024 that assessed corticosteroid replacement therapies in children and adolescents with CAH. Data were collated on drug type, dose, patient age, and primary outcomes, including growth metrics, metabolic health, androgen control, and cognitive effects.
Results
1. Hydrocortisone (10–20 mg/m^2/day in divided doses) was the most frequently studied replacement therapy. Monitoring of 17-hydroxyprogesterone was critical for dose optimization to prevent overtreatment. Studies revealed:
• Optimal Dosing: Three- or four-times-daily regimens closely mimic natural circadian rhythms, effectively reducing androgen excess and avoiding adrenal crises.
• Growth and Metabolism: Higher doses correlated with reduced adult height predictions but minimized androgen excess when appropriately adjusted.
• Advancements: Granule formulations allowed precise dosing in younger children, enhancing growth outcomes.
2. Prednisone (1–5 mg/day, single or twice-daily dosing) showed:
• Growth Impact: Comparable linear growth to hydrocortisone in lower doses but increased growth suppression during puberty.
• Androgen Suppression: Adequate suppression of 17-OHP and androstenedione, with fewer metabolic side effects than dexamethasone.
• Clinical Use: Prednisone offered convenience in older children requiring less frequent
3. Dexamethasone (0.1–0.27 mg/m^2/day or prenatal dosing) provided robust androgen suppression but raised concerns about cognitive and metabolic effects:
• Growth: Low doses-controlled androgen secretion effectively while maintaining normal bone age progression.
• Cognition: Prenatal exposure in CAH-unaffected fetuses resulted in verbal working memory issues and social anxiety, highlighting the need for cautious use.
• Novel Approaches: Ultra-low doses preserved endogenous cortisol production in nonclassical CAH patients.
Discussion
Hydrocortisone remains the preferred corticosteroid for pediatric CAH due to its safety and ability to replicate physiological cortisol rhythms closely. Prednisone offers convenience for older children but may compromise growth during puberty. Dexamethasone, while effective for androgen suppression, warrants caution due to cognitive risks, particularly with prenatal exposure.
Conclusion
Tailoring corticosteroid therapy is critical in CAH management. Hydrocortisone remains the gold standard, while prednisone and dexamethasone serve specific roles, requiring precise dosing to balance efficacy and safety.
This synthesizes the need for individualized treatment strategies and monitoring to optimize outcomes in pediatric CAH patients.

Evaluating 24-hour urine aldosterone levels with suppressed renin activity as a practical diagnostic tool for primary aldosteronism: a comparison with conventional confirmatory tests

Gökhan Rıza Baykal[1], Berna Evranos Ogmen[2], Sevgul FAKI[1], Fatma Dilek Dellal Kahramanca[1], cevdet aydin[3], Oya Topaloglu[3], Reyhan Ersoy[3] & Bekir Cakir[3]
[1]Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Türkiye; [2]ankara yildirim beyazıt university, ANKARA BİLKENT CITY HOSPITAL, endocrinology and metabolism, Ankara, Türkiye; [3]Ankara Yıldırım Beyazıt University Faculty of Medicine, Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Türkiye

Background
Primary aldosteronism (PA) is the most prevalent cause of secondary hypertension. The prevalence of PA is high and often overlooked using current diagnostic approaches. Screening for the disease involves measuring the aldosterone–renin ratio (ARR). Aldosterone secretion is pulsatile and variable. PA also exhibits intraindividual variability in aldosterone concentrations. The 24-hour urine aldosterone levels are unaffected by diurnal and pulsatile changes in plasma aldosterone levels. Complications can occur during the confirmatory tests. The diagnosis of primary aldosteronism requires new approaches. This study used 24-hour urine aldosterone with suppressed renin activity to compare classical confirmatory methods.

Methods
The study included twenty-one patients with suspected primary aldosteronism. After correcting the patients' hypokalemia and bringing their hypertension under control, we collected 24-hour urine before proceeding with other confirmatory tests. We applied classical confirmatory tests like saline infusion ($n=20$) and the captopril test ($n=1$) to the patients. We did not perform an oral salt loading test on the patients. Plasma renin activity of all patients was below 1 ng/ml/h. Patients were divided into three groups according to 24-hour urine aldosterone levels: group 1 (<6 mcg/24 h), group 2 (6–12 mcg/24 h), and group 3 (>12 mcg/24 h).
Results
Mean 24-hour urine aldosterone levels were 4.03 mcg/24 h in group 1, 8.32 mcg/24 h in group 2, and 23.36 mcg/24 h in group 3 ($P < 0.001$), respectively. Classical confirmatory tests excluded PA in 10 patients. In groups 1 and 2, there were no patients with hypokalemia. In Group 3, all patients were hypokalemic. In group 1, standard confirmatory tests ruled out PA. There was no need for further workup of PA for patients in group 2. All patients in this group received antihypertensive agents during the follow-up, and no adrenal venous sampling or surgery was required. All patients in group 3 received confirmation of their PA diagnosis. Adrenal venous sampling was performed in 5 patients, and five underwent surgery in this group.
Conclusions
PA is a disease that can result in significant cardiovascular morbidity and mortality. Early and accurate diagnosis of the disease is crucial. We have demonstrated that 24-hour urine aldosterone with suppressed plasma renin activity measurements is an alternative and more practical diagnostic method than other classical confirmatory methods. It can help avoid complications of classical confirmatory tests and help achieve diagnosis and treatment more accurately and in a shorter time.

Serum orexin ghrelin and adropin levels in patients with congenital adrenal hyperplasia due to 21 hydroxylase deficiency

Ilker Tolga Özgen[1], Semra Bahar Akın[2], Yasar Cesur[3] & Fatma Başak Çilesiz[4]
[1]Biruni University, Faculty of Medicine Department of Pediatrics, Division of Pediatric Endocrinology, istanbul, Türkiye; [2]Derince Training And Research Hospital, Department of Pediatrics, Division of Pediatric Endocrinology, kocaeli, Türkiye; [3]Bezmialem Vakif University, Department of Pediatrics, Division of Pediatric Endocrinology, Faculty of Medicine,, istanbul, Türkiye; [4]Bezmıalem Unıversıty Faculty Of Medıcıne, Department of Pediatrics, istanbul, Türkiye

Introduction
In congenital adrenal hyperplasia (CAH) due to 21 hydroxylase deficiency, steroid treatment at supraphysiologic doses is recommended. However, the effects of steroids on food intake and energy homeostasis have been previously demonstrated. Moreover, many patients with CAH have increased body fat and insulin resistance. This study aimed to investigate the impact of the supraphysiologic dose of hydrocortisone on adropin, orexin, and ghrelin levels, which are peptides associated with food intake regulation and insulin resistance in patients with CAH.
Material and methods
Thirty-five patients with CAH receiving hydrocortisone treatment for at least three years and attending regular follow-ups and 35 age- and body-mass index-matched healthy children for the control group were included in the study. Anthropometric measurements of the patients were recorded. Glucose, insulin, serum lipid profiles, adropin, orexin, and ghrelin levels were compared between the two groups.
Results
Seven patients (20%) in the patient group had a body mass index (BMI) above +2 SDS. Adropin (208.37±186.03 ng/l vs. 143.97±50.31 ng/l, *P*: 0.049), ghrelin (1.59±1.32 ng/ml vs. 1.10±0.41 ng/ml, *P*: 0.036), and orexin (234.25±220.25 pg/ml vs. 123.83±50.02 pg/ml, *P*: 0.005), were higher in the patient group compared to the control group. Total cholesterol and LDL cholesterol levels were also increased in the patient group.
Conclusion
Serum ghrelin, orexin, and adropin levels have been found to be elevated in patients with CAH treated with supraphysiologic doses. The findings of this study suggest that these changes may play a role in the pathophysiology of increased body fat and food intake in these patients.

Evaluation of the frequency of Hashimoto's thyroiditis and thyroid cyto/histopathological findings in patients with Connshing Syndrome

Fatma Dilek Dellal Kahramanca[1], Kübra Durmuş Demirel[1], Sevgül Fakı[1], Ayça Dilşad Çağlayan[2], Husniye Baser[3], Oya Topaloglu[3], Reyhan Ersoy[3] & Bekir Cakir[3]
[1]Ankara City Hospital, Ankara, Türkiye; [2]Ankara City Hospital, Pathology, Ankara, Türkiye; [3]Ankara City Hospital, Yildirim Beyazit University, Ankara, Türkiye

Introduction
Connshing syndrome (CS) is characterized by concomitant cortisol excess in patients with primary aldosteronism (PA). There is only one study in the literature on the relationship between CS and thyroid and this study reported that anti-TPO and anti-Tg levels were similar in CS and PA patients and anti-TPO levels increased only in CS patients after adrenalectomy. The aim of this study was to evaluate thyroid autoantibody levels, ultrasonography (USG) features and cyto/histopathology results in CS and to compare the findings with PA and adrenal Cushing's syndrome patients.
Methods
Between 2019 and 2023, patients admitted to our Endocrinology outpatient clinic and diagnosed with CS, PA or adrenal Cushing's syndrome were retrospectively reviewed. Patients with PA who also exhibited autonomous cortisol secretion (ACS) were classified as having CSIf any of the 24-hour urinary cortisol, nocturnal salivary cortisol or 1 mg DST values were elevated, the patient was diagnosed with OCS. Demographic data, thyroid autoantibody levels, thyroid function tests, plasma aldosterone, renin activity (PRA) and cortisol levels were recorded. Additionally, chronic thyroiditis and nodules on USG and cyto-histopathological features were documented. All parameters were compared among the three patient groups.
Results
A total of 125 patients with CS ($n=21$), PA ($n=62$), and adrenal Cushing's syndrome ($n=42$) were included in the study. Thyroid autoantibody levels, autoantibody positivity rates and thyroid function tests were similar among the groups. Plasma aldosterone, PRA and aldosterone/PRA ratios were lower in the Cushing's syndrome group than in the CS and PA groups, whereas no significant difference was observed between the PA and CS groups. Basal cortisol levels were similar in all groups. No significant differences were found in the presence, number or characteristics of nodules on USG, but chronic thyroiditis was significantly lower in CS ($P=0.021$). A total of 66 patients had 252 nodules, of which 52 underwent fine-needle aspiration biopsy. The cytologic results of the nodules were similar.
Conclusions
Thyroid autoantibody titers and positivity rates in CS are not different from those in patients with PA and adrenal Cushing's syndrome, but the appearance of chronic thyroiditis on USG is significantly lower. The groups were similar in other USG features. Prospective studies with a larger number of cases are needed to elucidate the pathophysiologic mechanisms involved in the potential effects of CS on the thyroid.

JOINT2270

The prevalence and the diagnosis of glucocorticoids-induced adrenal insufficiency: a systematic review

Andrew Gerges[1] & Atul Kalhan[2]
[1]Doncaster Royal Infirmary, Diabetes and Endocrinology, Doncaster, United Kingdom; [2]Royal Glamorgan Hospital, Llantrisant, United Kingdom

Introduction
Glucocorticoid-induced adrenal insufficiency (GC-induced AI) remains a common although under-recognised cause of morbidity in patients on chronic steroid therapy for a wide array of therapeutic indications.
Objectives
This systematic review of literature was carried out to evaluate prevalence of GC-induced AI by dose, duration and route of administration. An approach to screen and manage such patients (which can was be adapted to clinical practice) was critically appraised.
Methods
A systematic review of literature published between 2015 and 2024 was carried out using PubMed, Cochrane, Embase, Google Scholar, and EBSCOhost databases. Studies with strong evidence, including systematic reviews, randomized controlled trials, and observational studies, were included. Case

reports and studies without full texts were excluded. Data were extracted on GC dose, duration, route, and diagnostic tests.
Results
Twenty-one studies met the inclusion criteria, reporting AI prevalence ranging from 7.8% for inhaled GCs to 63% for oral high dose GCs used on short-term. Oral prednisolone doses $\geq$15 mg/day for $>$3 months carried the highest risk of developing iatrogenic AI. Inhaled fluticasone $>$800 mcg/day and super-potent topical clobetasol $>$50 g/week posed significant clinical risks. Diagnostic tests included early morning cortisol and Short Synacthen Test (SST), with SST providing the most reliable results. Measurement of salivary cortisol in outpatient settings remains a useful non-invasive test (with sensitivity 97%, specificity 97%) to assess ACTH-cortisol axis function. The results of this systematic review were compared to the recent European guidelines which were published in May 2024. This review provided more granular dose-specific data, evidence on short term risk compared to recent European guidelines.
Conclusions
GC-induced AI remains a clinically under-recognised condition associated with significant morbidity. Patients at high-risk of developing AI (based on potency, route and duration of steroid therapy) need to be closely monitored using 0900 h cortisol +/− SST. Salivary cortisol measurement can be used to improve diagnostic accuracy. It is important to educate patients at risk of developing iatrogenic AI regarding sick day rules and given back-up support (e.g. sign post to self-help groups, steroid alert card and hydrocortisone emergency use kit).

Lowering the day 5 postoperative cortisol cutoff value to avoid over-diagnosis of secondary adrenal insufficiency following pituitary surgery

Daniella Bae[1], Emmanuel Lawal[1], Sirazum Choudhury[1,2,3], Kavita Narula[1,2], Katharine Lazarus[1,2], Tricia Tan[1,2,3], Debbie Papadopoulou[1,2], Niamh Martin[1,2] & Karim Meeran[1,2]
[1]Division of Diabetes, Endocrinology and Metabolism, Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom; [2]Department of Endocrinology, Imperial College Healthcare NHS Trust, London, United Kingdom; [3]Department of Clinical Biochemistry, Northwest London Pathology, London, United Kingdom

Background
It is essential to identify patients who develop secondary adrenal insufficiency (SAI) following trans-sphenoidal pituitary surgery (TSS) to avoid life-threatening Addisonian crises. An early morning day 5 cortisol value may reliably assess hypothalamo-pituitary-adrenal (HPA) axis functioning following surgery.
Method
This was a retrospective cohort study of 54 patients undergoing TSS at Imperial Healthcare NHS Trust between 2019 and 2023. Receiver Operating Characteristic (ROC) curves were generated to evaluate the different predictive values of day 5 postoperative cortisol levels, using the Abbott Alinity cortisol immunoassay. Area Under the curve (AUC) was calculated from the ROC curve.
Results
The prevalence of SAI was 31%. The currently used cortisol cut-off value of $>$ 358 nmol/l to exclude SAI demonstrated 100% sensitivity and a specificity of 53.85%. Lowering this threshold to $>$308 nmol/l maintained 100% sensitivity but improved the specificity to 75.86%. A Day 5 cortisol value of $<$206 nmol/l predicts poor HPA function with a sensitivity of 70.59% and 100% specificity. Day 5 cortisol values (AUC 0.9645) provided better predictive values for SAI compared to values taken on Day 2/3 post-operatively (AUC 0.8095).
Conclusion
A day 5 serum cortisol value of $>$308 nmol/l reliably indicates an intact HPA axis. Values $<$206 nmol/l reliably detect SAI. Patients with Day 5 serum cortisol measurements between 206 and 308 nmol/l should be discharged on glucocorticoid therapy and undergo a dynamic test post-operatively to ascertain their true HPA function.

The genetics of adrenal insufficiency, evolution of methodologies over 35 years in a single centre

Chris Smith[1], Rathi Prasad[1], Claire Hughes[1], Avinaash Maharaj[1], Younus Qamar[1], Saptarshi Maitra[1], Claire Hutchison[1], Lucia Marroquin Ramirez[1], Luqman Fauzi[1], Jordan Read[1], Charlotte Hall[1], Marwa Mohammedali[1], Ashwini Maudhoo[1], Helen Storr[1], Adrian Clark[1], Li Chan[1] & Louise Metherell[1]
[1]Centre for Endocrinology, William Harvey Research Institute, Queen Mary University of London, London, United Kingdom

Background
Primary adrenal insufficiency (PAI) is life-threatening and can present alone or in combination with other co-morbidities. Paediatric primary adrenal insufficiency (PPAI) is most commonly congenital adrenal hyperplasia (CAH) caused by mutations in CYP21A2, but there are $>$25 other genetic aetiologies.
Methods
We investigated 369 families (probands 43% female, 57% male) from 36 countries with non-CAH PAI between 1990 and 2025 using candidate gene and next generation sequencing (NGS) techniques including targeted panel [TPS], whole exome [WES] and whole genome sequencing [WGS]. Challenges in coverage between different capture/sequencing methodologies were minimised by repeat sequencing and recent reanalysis of NGS data using the Genome Analysis Toolkit (GATK) and Exomiser as well as CNV assessment building towards a novel in house pipeline for diagnosis. Further analyses to assess pathogenicity included in silico e.g. SQUIRLS and functional analyses involved splice assays and heterologous expression of mutants vs wild-types.
Results
Although mean age of presentation was 3y it ranged from neonatal to 81y with a median age of 1.5y. Eight novel genetic causes of PAI were discovered with genes responsible for isolated glucocorticoid deficiency (*MC2R, MRAP*), with/without additional mineralocorticoid deficiency (*NNT, TXNRD2*) or as part of a syndrome (*MCM4, SGPL1, PPOX, CPOX*). Overall, a genetic diagnosis was achieved in 245/369(66.3%) families, 109 were diagnosed by CGS, 35 by TPS and 101 by WES, with WGS useful as an adjunct to define the co-ordinates of deletion mutations but adding no new diagnoses. Pathogenic variants occurred in 17 genes: *MC2R* (20%), *MRAP* (15.9%), *NNT* (14.2%), *CYP11A1* (9.8%), *STAR* (9%), *ABCD1* (7.4%), *AAAS* (5.3%), *NR0B1* (DAX-1; 2.9%), *TXNRD2, SGPL1, AIRE CYP11B1, CYP11A2, HSD3B2, POMC, POR* and *PPOX*. *MC2R/MRAP* were most prevalent, responsible for 23.9% of cases, with the UK variant of *MC2R* (S74I) very common (49% of *MC2R* diagnoses) and for *MRAP* the majority of mutations were at the splice junction of exon1/intron 1. We have evolved a novel pipeline whereby sequencing of small frequently mutated genes/exons is followed by NGS where these prove negative.
Conclusion
PPAI is most commonly congenital, and, with our serial sequencing and analysis pipeline, a genetic diagnosis is achievable for $>$65% of cases in a cost-effective and timely manner. Distinguishing between isolated and syndromic adrenal insufficiency means treatment, ongoing management and genetic counselling can be personalised.

JOINT3654

Single daily dose prednisolone has a lower cardiovascular risk compared to multiple daily hydrocortisone doses in patients with adrenal insufficiency

Emmanuel Ssemmondo[1], Kate Lazarus[2], Milly Newham[1], Kavita Narula[2], ZIN HTUT[2], Thozhukat Sathyapalan[1], Sirazum Choudhury[2] & Karim Meeran[2]
[1]Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom; [2]Imperial College Healthcare NHS Trust, London, United Kingdom

Background
Multiple daily doses of hydrocortisone are traditionally used as glucocorticoid replacement in patients with adrenal insufficiency. The Endocrine Society guideline suggests 3–5mg of prednisolone as an alternative. Prednisone is a pro drug that is converted to prednisolone by first pass metabolism in the liver. We compared the metabolic profile of patients taking multiple doses of hydrocortisone before and after switching to a single daily low-dose of prednisolone 2–5mg.
Methods
Patients with adrenal insufficiency were switched from multiple-daily dose hydrocortisone to 2–5mg of prednisolone and followed up after 4 months. We assessed cardiovascular risk using weight, blood pressure, waist and hip circumference, lipid profile and high sensitivity C-reactive protein. Quality of life was assessed using a modified SF-36 questionnaire. Baseline and follow-up data were compared using a paired *t*-test.
Results
Sixty-two participants were enrolled, of whom 48 completed the study. Eight (16.8%) had a diagnosis of primary adrenal insufficiency. The mean duration of glucocorticoid use was 11.4$\pm$8.6 years. After at least four months of prednisolone,

we observed significant reductions in mean weight from 90.6 kg to 89.6 kg ($P=0.007$) and a significant reduction in systolic blood pressure (BP) of 6 mmHg ($P=0.027$). There was no difference in the waist to hip ratios between the two treatments ($P=0.183$). The use of prednisolone was associated with no change in total, LDL, HDL, or non-HDL cholesterol, triglycerides or hs-CRP. Use of once-daily low-dose prednisolone demonstrated an improvement in the energy/fatigue and total quality of life scores ($P=0.003$ and $P=0.019$ respectively). Patients reported prednisolone to be more convenient compared to hydrocortisone ($P=0.002$).
Conclusion
Single dose daily low-dose prednisolone has a lower metabolic risk profile to multiple daily doses of hydrocortisone given the lower blood pressure and weight. It is more convenient and improves subjective energy levels. We recommend low dose prednisolone or prednisone as a first line treatment for patients with adrenal insufficiency.

Clinical characteristics and outcomes in 31 pediatric cases of x-linked adrenoleukodystrophy: a retrospective study at SCMC

Juan Li[1], Lingwen Ying[1], Guoying Chang[1], Yu Ding[1], Tingting Yu[1], Jing Chen[1] & Xiumin Wang[1]
[1]Shanghai Children's Medical Center, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Objective
To investigate the clinical characteristics, treatment approaches, and prognosis of X-linked adrenoleukodystrophy (ALD) in children.
Methods
This study included 31 male pediatric patients diagnosed with ALD and treated at our hospital from 2015 to 2023. Loes score were assessed in all participants with cerebral ALD (cALD).
Results
Of the 31 patients, 24 presented with cALD, while 7 exhibited the adrenal-only type. Clinical manifestations in cALD primarily involved central nervous system symptoms, including visual/hearing impairment (9/24), seizures (7/24), cognitive deficits (4/24). Adrenal cortical insufficiency developed in 62.5% of cALD cases during follow-up. Patients with adrenal-only type primarily exhibited hyperpigmentation. Genetic analysis identified 29 distinct *ABCD1* mutations, with missense mutations accounting for 75.9%, frameshift mutations for 20.7%, and 1 large deletion that containing *ABCD1* gene. Three novel mutations were identified: c.77C > G, c.1119_1120 insTC, and c.1291C > T. Allogeneic hematopoietic stem cell transplantation (all-HSCT) was the primary treatment for early cALD, achieving a 5-year overall survival (OS) rate of 78.0% (64.0 ~ 86.6%) compared to 29.0% (95%CI 11.7 ~ 48.2%) in non-HSCT patients. A pre-transplantation Loes score < 10 was strongly associated with improved outcomes.
Conclusion
Early intervention with allo-HSCT significantly improves survival in pediatric cALD, particularly in patients with a Loes score < 10 before transplantation. Close monitoring is essential for progressive adrenal insufficiency, which remains a key phenotype of ALD.

Key words: X-linked adrenoleukodystrophy; *ABCD1*; gene mutation; Loes score

ESPE school: sharing knowledge to save lives – developing and standardizing education for clinicians and families with children with adrenal insufficiency in Kazakhstan

Gulmira Abduakhassova[1], Aliya Zetova[2], Malika Alimussina[3] & Elena Lundberg[4]
[1]Astana Medical University, Astana, Kazakhstan; [2]Al-Farabi Kazakh National University, Almaty, Kazakhstan; [3]Office for Rare Conditions, School of Medicine, Dentistry and Nursing, University of Glasgow, Glasgow, United Kingdom; [4]Inst of Clinical Sciences, Pediatrics, Umeå University, Umea, Sweden

Introduction
Adrenal insufficiency (AI) is a severe disorder characterized by a deficiency in the synthesis and release of cortisol or/and aldosterone. The prevalence of AI is estimated to range from 20–50 per 100 000 individuals in Europe. However, studies on AI in Central Asia (CA) have only recently begun. Kazakhstan, a vast country with a population of 20 million, faces challenges in delivering consistent specialized outpatient care due to sparse clinics and variable healthcare standards. Since 2014, the ESPE Caucasus & Central Asia School has been instrumental in providing pediatric endocrinology education. This initiative marks the first structured effort to implement an organized educational program for medical professionals and families dealing with AI in Kazakhstan.
Aim
To develop and implement a standardized, systematic educational program in Kazakhstan for clinicians, families, and patients with AI.
Methods
Healthcare professionals involved in managing AI were identified by contacting healthcare authorities across all regions of Kazakhstan. Additionally, project information was disseminated through Facebook groups for families with children diagnosed with AI. To enhance care standards, the European Emergency Card (EEC) for AI was translated into Kazakh and Russian and will be integrated into emergency response protocols in the future.Structured educational programs were designed for healthcare professionals, and individualized treatment plans (ITP) were created for patients. These programs aimed to establish continuity of care across all 17 regions of Kazakhstan. All materials, including educational content and treatment templates, were prepared in both Kazakh and Russian.
Results
A total of 134 patients with AI were identified, with detailed information on age and gender available for 72 individuals. Among them, 43 (61%) were girls, and 29 (39%) boys with a median age of 10.5 years (range: 1–18). The translated EEC and the structured educational program were introduced to clinicians during face-to-face and digital conferences held nationwide. Patient organization representatives participated in these events, sharing expertise.ITP templates were developed and adapted to the local healthcare infrastructure. These plans are now being implemented to ensure comprehensive, patient-centered care for individuals with AI.
Conclusion
The implementation of an organized and standardized educational approach across Kazakhstan significantly enhances the quality of care for patients with AI. By ensuring consistent medical care and education, this initiative bridges geographical barriers and aligns medical practices across all regions. Furthermore, equipping healthcare professionals with tailored educational resources fosters a deeper understanding of AI management and improves patient outcomes.

Smoking and alcohol use plays a mediating role on the social determinants of high blood pressure: evidence from nationally representative sample in India

Arivarasan Barathi[1], Yuvaraj Krishnamoorthy[2] & Rajan Rushender[3]
[1]ESIC Medical College and Hospital, Community Medicine, Chennai, India; [2]PROPUL Evidence, Evidence Synthesis, Chennai, India; [3]St.Joseph Medical College, Hosur, India

Background
Hypertension remains a global health concern, with its prevalence influenced by socioeconomic determinants and modifiable risk factors. Understanding the interplay between these factors is vital for targeted interventions. This study aimed to investigate the mediating roles of smoking and alcohol consumption in the association between socioeconomic factors (education, wealth index, gender) and blood pressure using data from the National Family Health Survey-5 (NFHS-5) in India.
Methods
We carried out a secondary analysis of data collected from a nationally representative survey (NFHS-5 data) in India. We included 19 23 504 people aged 18 years and above having all the necessary information for analysis. We performed a mediation analysis using structural equation modelling to estimate the natural direct effect (NDE), total effects, and natural indirect effect (NIE) of sex, education and wealth index on systolic and diastolic blood pressure keeping the behavioural habits (smoking and alcohol use) as mediator variables. The analysis was carried out in Stata 16.1.
Results
The sample had a nearly equal distribution of males (51.4%) and females (48.6%). Alcohol use and tobacco consumption were reported by 13.2% and 27.6% of participants, respectively. Women exhibited lower systolic ($\beta=-4.59$) and diastolic ($\beta=-2.07$) blood pressure compared to men. Lower education levels and higher wealth indices were significantly associated with

variations in blood pressure. Mediation analysis showed partial mediation by alcohol and tobacco which were statistically significant ($P<0.001$). For instance, 17.8% of the reduction in systolic blood pressure associated with being female was mediated by alcohol use, while tobacco accounted for 22.1%. Education's effect on systolic blood pressure was mediated by 29.7% through alcohol and 27.3% through tobacco. The analysis also revealed that the people in the richer and richest quintiles had significantly higher level of systolic and diastolic blood pressure when compared to those in the poorer and poorest quintiles.

Conclusion

The study highlights the significant mediating roles of smoking and alcohol in the relationship between socioeconomic factors and blood pressure. These findings underscore the importance of integrating behavioural interventions into public health strategies to address hypertension and its risk factors effectively. Targeted approaches considering socioeconomic disparities and behavioral risks are crucial for improving cardiovascular health in diverse populations.

Management practices in Italy on adrenal insufficiency in young people with Duchenne muscular dystrophy on steroid treatment

Gianluca Tornese[1,2], Sze Choong Wong[3,4], Anne Marie Sbrocchi[5,6], David Weber[7] & Tommaso Aversa[8,9]
[1]Department of Medicine, Surgery and Health Sciences, University of Trieste, Trieste, Italy; [2]Institute for Maternal and Child Health IRCCS 'Burlo Garofolo', Trieste, Italy; [3]Department of Paediatric Endocrinology, Royal Hospital for Children, Glasgow, United Kingdom; [4]Bone, Endocrine, Nutrition Research Group in Glasgow, University of Glasgow, Glasgow, United Kingdom; [5]Department of Pediatrics, Montreal Children's Hospital, McGill University Health Centre, Montreal, Canada; [6]Shriners Hospital for Children, Montreal, Canada; [7]Division of Endocrinology and Diabetes, The Children's Hospital of Philadelphia, Philadelphia, United States; [8]Department of Human Pathology of Adulthood and Childhood, University of Messina, Messina, Italy; [9]Pediatric Unit, 'G. Martino' University Hospital, Messina, Italy

Background

The cornerstone of current pharmacologic management of Duchenne muscular dystrophy (DMD) is glucocorticoid (GC) therapy initiated at a young age. Chronic high-dose daily GC treatment causes adrenal suppression that can result in potentially life-threatening adrenal insufficiency (AI). Despite the potential severity of this complication, it is not known what guidance pediatric endocrinologists and neurologists in Italy provide regarding the risk of AI.

Methods

Online survey distributed via email to Italian endocrinologists and neurologists involved in the care of young people with DMD.

Results

A total of 35 physicians responded to the survey (57% endocrinologists, 43% neurologists). Most respondents (57%) managed between 11 and 50 patients, with neurologists caring for a greater number of patients than endocrinologists ($P=0.013$). The most commonly used GC regimen was daily deflazacort (86%), followed by daily prednisone (26%), intermittent deflazacort (14%), and intermittent prednisone (3%). For minor stress (e.g., cold without fever), most respondents (80%) did not recommend any additional treatment, with a significant difference between neurologists and endocrinologists (93% vs. 70%, $P=0.027$). For moderate stress (e.g., febrile illness, vomiting, diarrhea but able to take oral intake), 31% recommended oral hydrocortisone (HC), 17% suggested an additional dose of deflazacort/prednisone, and 9% recommended parenteral HC. In cases of major stress (e.g., painful long bone fracture, vomiting or diarrhea with inability to take oral intake, general anesthesia, surgery), 77% recommended parenteral HC, yet 14% still did not advise any additional treatment. Although 82% of respondents reported providing education on AI management (from endocrinology team in 41%, neurology team in 26%, both in 15%), only 43% supplied a prescription and instructions on how to administer intramuscular HC. Furthermore, while 71% provided a written emergency plan for steroid management during illness or stress, only 37% had an alert in the hospital system, and 31% recommended wearing a steroid-dependent alert bracelet/card.

Conclusions

To our knowledge, this is the first survey addressing AI management practices among physicians caring for individuals with DMD in Italy. Most physicians involved in DMD care manage fewer than 50 patients. There are notable differences in approach for minor, moderate, and major stress, with nearly a quarter of respondents not prescribing parenteral hydrocortisone in major stress situations. Additionally, the majority of patients do not receive practical education or prescriptions for parenteral hydrocortisone. There is a clear need for enhanced education on AI risk in DMD, particularly regarding specific situations common in DMD patients (e.g., fractures, bisphosphonate infusion).

Increased arterial stiffness and short QTc interval are associated to androgen levels in classical congenital adrenal hyperplasia due to 21 hydroxylase deficiency

Lorenzo Campioni[1], Maria Chiara Di Carlo[1], Beatrice Bergoglio[1], Chiara Sola[1], Ezio Ghigo[1], Mirko Parasiliti Caprino[1] & Roberta Giordano[2]
[1]Endocrinology, Diabetes and Metabolism; City of Health and Science University Hospital; Department of Medical Sciences; University of Turin;, Turin, Italy; [2]Department of Biological and Clinical Sciences; University of Turin;, Turin, Italy

Context

Congenital Adrenal Hyperplasia (CAH) is a group of autosomal recessive disorders characterized by impaired cortisol synthesis and hyperandrogenism, current treatment of CAH mainly rely on glucocorticoids (GC) to suppress androgen hypersecretion and to mimic endogenous cortisol secretion. GC therapy, however, often needs to be administered at supra-physiological doses, with an increased risk of long-term complications.

Objective

To evaluate the cardiovascular and metabolic risk in a group of adult patients affected by CAH caused by 21β-hydroxylase deficiency.

Subjects and methods

A cross-sectional study was conducted in a group of 32 adult patients affected from classical CAH due to 21β-hydroxylase deficiency in treatment with different formulations of glucocorticoids (Hydrocortisone HC, Double-release Hydrocortisone DR-HC, Hydrocortisone and dexamethasone HC+DEX), compared with 73 unaffected controls. Anthropometric and metabolic biochemical parameters were collected for each of the subjects, as well as a 24-hour dynamic blood pressure monitoring (ABPM) and an EKG.

Results

The univariate analysis showed a higher weight ($P=0.006$), systolic blood pressure ($P<0.001$), glycemia ($P=0.031$), triglycerides ($P=0.025$), LDL cholesterol ($P<0.001$) in the control group when compared to CAH patients; however, the latter being significantly younger than the control group ($P=0.035$). The CAH group also exhibited a shorter QTc ($P=0.006$), RR ($P=0.045$) and QRS ($P=0.004$) interval. The Ambulatory Arterial Stiffness Index (AASI), derived from the 24-hour ABPM, showed statistically significant higher values in the CAH group ($P=0.006$), the two groups were matched 1:2 through a propensity score matched analysis, confirming a higher AASI score ($P< 0.001$) and a shorter QTc interval ($P=0.004$). Through a multivariate analysis we found the AASI score to be related to CAH diagnosis (coeff. 1.131; $P<0.001$), Age (coeff. 1.004; $P=0.034$), BMI (coeff. 1.008; $P<0.001$) and 17 OHP levels (coeff. 1.001 $P=0.049$); while a shorter QTc interval seems to be related to CAH diagnosis (coeff. 0.977; $P=0.039$) and ACTH levels (coeff. 0.999; $P=0.021$). Patients treated with HC+DEX showed higher AASI ($P=0.026$) and triglycerides levels ($P=0.04$) when compared to patients treated with HC only or DR-HC, however no differences in hormonal levels and comorbidities were found between the groups.

Conclusion

The metabolic profile of CAH patients did not differ from unaffected controls, however androgens levels seem to be related to cardiovascular alterations in subjects affected by CAH, especially those in treatment with dexamethasone.

Investigation of alternative hormones for evaluating selectivity of adrenal vein sampling in the subtype diagnosis of primary aldosteronism

Federico Ponzetto[1], Giulia Montesano[2], Matteo Procopio[1], Laura Leoni[2], Fabio Settanni[3], Ezio Ghigo[1], Giulio Mengozzi[2,3] & Mirko Parasiliti Caprino[1]
[1]Endocrinology, Diabetology and Metabolism; University of Turin, Turin, Italy; [2]Clinical Biochemistry Laboratory; University of Turin, Turin, Italy;

[3]Clinical Biochemistry Laboratory; City of Health of Science University Hospital, Turin, Italy

Background-Aim
International guidelines recommend adrenal venous sampling (AVS) for subtype diagnosis of primary aldosteronism (PA), which is crucial for suggesting surgical or medical treatment. Successful cannulation of adrenal veins is assessed using the cortisol (F) ratio between adrenal and peripheral veins (selectivity index, SI). Given the limitations associated with F measurements, this study aimed to evaluate whether the measurement of other hormones could improve SI calculation.
Methods
The study included 122 PA patients undergoing unstimulated and sequential AVS. Concentrations of F, catecholamines (noradrenaline, NA, adrenaline, AD), metanephrines (normetanephrine, NMT, metanephrine, MT, normetanephrine, NMT), and other steroids (DHEA, DHEAS, androstenedione, A4, 11-deoxycorticosterone, DOC, 17-hydroxyprogesterone, 17OHP, and progesterone, P) were measured in both adrenal vein and peripheral vein samples using CLIA, HPLC, and LC–MS/MS, respectively. Hormone-specific SI cut-offs were calculated along with the percentage of selective procedures identified based on each marker. Additionally, differences in SI values of all hormones were compared between the selective and non-selective procedure groups.
Results
Using as reference cut-off SI = 3 for F, ROC curve analysis revealed the following SI cut-offs for MT (11.90, AUC = 0.640), NMT (1.65, AUC = 0.640), NA (1.40, AUC = 0.598), AD (1.50, AUC = 0.557), DHEA (1.10, AUC = 0.850), DHEAS (22.00, AUC = 0.831), A4 (16.66, AUC = 0.825), DOC (4.49, AUC = 0.950), 17OHP (4.62, AUC = 0.944), and P (4.75, AUC = 0.829). All markers, except P, improved the rate of selective procedures compared to F (74.1%). Notably, only steroid hormones exhibited significantly higher SI values in the group of selective procedures, with increases of up to 10-fold for DOC and 17OHP.
Conclusions
The monitoring of alternative hormones and the use of hormone-specific SI cut-offs increased the rate of selective AVS procedures, with steroids demonstrating the best diagnostic accuracy compared to metanephrines and catecholamines. In the evaluation of successful cannulations, the highest increases in SI were observed for DOC and 17-OHP, highlighting the latter as a promising additional marker due to its easily measurable levels in both adrenal and peripheral veins.

Dose the GH IGF-1 Axis serve as a determinant of prognosis in Acute Ischemic Stroke?

Yuki Tsujimoto[1], Kenji Yamashiro[1], Motohiro Okumura[2], Takeo Sato[2], Yuki Suzuki[1], Takahiro Shimada[1], Yasuyuki Iguchi[2] & Rimei Nishimura[1]
[1]The Jikei University School of Medicine, Division of Diabetes, Metabolism and Endocrinology, Department of Internal Medicine, Tokyo, Japan; [2]The Jikei University School of Medicine, Department of Neurology, Tokyo, Japan

Background
In acute ischemic stroke (AIS), low IGF-1 levels are associated with unfavorable prognosis; however, the relationship with GH levels remains unclear. On the other hand, some reports suggest that elevated GH levels in cardiovascular disease are associated with increased mortality. Therefore, in this study, we investigated the relationship between post-stroke GH and IGF-1 levels and the modified Rankin Scale (mRS) at three months from the onset of AIS.
Methods
Between October 2020 and December 2022, patients admitted to our hospital with AIS were included in the study. GH and IGF-1 levels were measured on or after the 7th day of hospitalization. At three months post-stroke, patients were classified into a favorable outcome group (FOG: mRS ≤ 1) and an unfavorable outcome group (UOG: mRS ≥ 2), and the relationship between GH and IGF-1 levels and prognosis was analyzed.
Results
A total of 130 participants were enrolled in this study, and 124 cases were included in the final analysis (95 males [77%], median age 62 years). Among them, 25 patients (20%) were classified into the unfavorable outcome group. The Mann–Whitney U test revealed that GH levels were significantly higher in the unfavorable outcome group ($P = 0.02$), whereas there was no significant difference in the IGF-1 SD score (IGF-1 SDS) between the two groups. Next, a ROC-analysis was performed to determine the optimal cutoff value for GH in distinguishing the two groups, which was estimated to be 0.2 ng/ml. Based on these findings, the 124 patients were categorized into four groups using GH 0.2 ng/ml and IGF-1 SDS -2.0 as cutoff values: 'high GH – high IGF-1,' 'high GH – low IGF-1,' 'low GH – high IGF-1,' and 'low GH – low IGF-1.' Logistic regression analysis, FOG/UOG as dependent variables, revealed that both the NIHSS score ($P < 0.001$, OR 1.12 [1.05–1.20]) and the 'high GH – low IGF-1' group (compared with the 'low GH – high IGF-1' group, $P = 0.02$, OR 6.23 [1.32–28.54]) were significantly associated with unfavorable prognosis.
Conclusion
Our study demonstrated that patients with high GH levels and low IGF-1 SDS are associated with poorer stroke outcomes. These findings suggest that a state of 'GH resistance,' characterized by elevated GH levels without a corresponding increase in IGF-1, may be a prognostic factor for poor outcomes. Further studies are currently planned to investigate the impact of 'GH resistance' as a determinant of prognosis in AIS.

Impact of gender-affirming hormone therapy on cardiovascular risk factors in transgender individuals

Francisca Palma[1], Miguel Saraiva[2] & Lia Ferreira[2]
[1]Unidade Local de Saúde de Matosinhos, Matosinhos, Portugal; [2]Unidade Local de Saúde de Santo António, Porto, Portugal

Introduction
Transgender individuals exhibit a higher cardiovascular risk compared to the general population. Gender-affirming hormone therapy (GAHT), used to align physical characteristics with gender identity, has an unclear impact on cardiovascular risk factors. Some evidence suggests that GAHT may exacerbate cardiovascular risk through changes in blood pressure, insulin resistance, lipid profile, and body composition.
Objective
This study aims to evaluate the impact of GAHT on lipid profile, blood pressure, and body mass index (BMI) in transgender individuals.
Methods
A retrospective longitudinal study was conducted at a multidisciplinary clinic of transgender medicine from October 2021 to January 2024. The study collected and analysed sociodemographic data, lifestyle behaviours, medical history, and clinical data from all individuals observed during this period. From this population, a subset of participants with sufficient data at two or more time intervals was studied to evaluate changes in lipid profiles, blood pressure, and BMI from baseline up to one year after starting GAHT. Statistical analysis was performed using IBM SPSS Statistics 28.0.1.0 with a significance level of 0.05.
Results
The study included 232 transgender individuals (152 trans men and 80 trans women; median age 23) who showed high rates of tobacco use (37.3%) and illicit substance use (11.5%). Among trans feminine individuals, there were consistent but non-significant decreases in systolic blood pressure (SBP) and triglycerides (TG) at 3, 6, and 9 months. Trans masculine individuals exhibited a trend of increasing SBP, though no changes reached statistical significance. Trans masculine individuals experienced a significant increase in BMI at 3, 6, and 9 months (Δmax of 1.01 kg/m^2; $P < 0.01$) and a significant decrease in HDL cholesterol at all time points (Δmax of -10.47 mg/dl; $P < 0.001$).
Conclusion
The observed trends suggest that GAHT may influence lipid profiles. Although these changes are statistically significant, their magnitude is typically not considered clinically relevant. As such, our data indicates that GAHT appears to be safe in the short term. However, the prevalence of other cardiovascular risk factors highlights the need for routine monitoring in this population. Further research is essential to address existing knowledge gaps regarding the long-term cardiovascular effects of GAHT.

Cortisol response to coffee, tea, and caffeinated drinks: A comparative review of studies

Aml Sabt[1], Fawzia Alyafei[2], Nada Alaaraj[2], Noor Hamed[2], Shayma Ahmed[2] & Ashraf Soliman[3]

[1]Sidra Medicine, Doha, Qatar; [2]Hamad Medical Corporation, Doha, Qatar; [3]Hamad Medical Coropration, Pediatric Endocrine and Diabetes, Doha, Qatar

Background
Cortisol, a stress hormone regulated by the hypothalamic–pituitary–adrenal (HPA) axis, plays a crucial role in maintaining physiological balance. Caffeinated beverages, such as coffee, tea, and energy drinks, are widely consumed worldwide and are known to influence cortisol secretion. Understanding the effect is vital for assessing the health implications of caffeine intake, particularly regarding stress regulation and overall well-being.
Objective
To evaluate and compare the effects of coffee, tea, and other caffeinated drinks on cortisol secretion, highlighting the magnitude of cortisol increase, caffeine content, and beverage-specific characteristics.
Methods
A comprehensive review of 15 studies conducted between 2000 and 2024 was performed. The studies assessed cortisol secretion in response to caffeine consumption, including coffee, tea, and energy drinks, across diverse populations. The analysis focused on the percentage increase in cortisol, number of participants, and caffeine content in each beverage category.
Results
The studies revealed notable differences in cortisol responses based on beverage type and caffeine content:
• Coffee: Represented in 10 studies with ∼2500 subjects, coffee, with a typical caffeine content of 80–120 mg per 8-ounce cup, caused the strongest cortisol increase of 50% above baseline. Examples include espresso, Americano, cold brew, and drip coffee.
• Tea: Covered in 3 studies with ∼800 subjects, tea (20–60 mg caffeine per serving) showed a milder cortisol increase of 20%. Examples include black tea (e.g., Earl Grey, English Breakfast), green tea, matcha, and iced tea. Tea's effects are moderated by L-theanine, which promotes relaxation.
• Other Caffeinated Drinks: Represented in 2 studies with ∼300 subjects, energy drinks (e.g., Red Bull, Monster) and sodas (e.g., Coca-Cola, Pepsi) exhibited a moderate cortisol increase of 30%, with caffeine content ranging from 30 to 300 mg per serving. Additional ingredients like sugar and taurine may influence cortisol responses.
Discussion
Coffee elicited the highest cortisol response due to its high caffeine concentration, while tea's effects were milder, likely due to L-theanine's calming properties. Other caffeinated drinks exhibited intermediate effects, depending on caffeine dosage and additional ingredients. Habitual caffeine consumers showed attenuated cortisol responses, suggesting tolerance over time.
Conclusions
Caffeine consumption significantly impacts cortisol secretion, with coffee showing the strongest effect, followed by other caffeinated drinks and tea. Tea's stress-buffering properties and moderate cortisol response make it a suitable option for individuals sensitive to stress. Future studies should explore the long-term implications of caffeine-induced cortisol elevation and its role in stress and health management.

Short-term effect on tissue sodium distribution in hypertensive patients following sodium loading test: A sodium MRI study

Sven Gruber[1], Mustafa Cavusoglu[2], Isabella Sudano[3], Cristina Rossi[2] & Felix Beuschlein[1,4]
[1]University Hospital Zurich, University of Zurich, Department of Endocrinology, Diabetology and Clinical Nutrition, Zurich, Switzerland; [2]University Hospital Zurich, University of Zurich, Institute of Diagnostic and Interventional Radiology, Zurich, Switzerland; [3]University Hospital Zurich, University of Zurich, University Heart Center, Cardiology, Zurich, Switzerland; [4]Klinikum der Universität München, Medizinische Klinik und Poliklinik IV, Munich, Germany.

Background
Emerging research suggests that tissue Na^+ accumulation plays a role in blood pressure control, yet the mechanisms underlying the regulation of sodium storage remain unclear to date.
Methods
In 31 hypertensive patients with a mean age of 49 years, of whom 61% were women, a sodium infusion test (SIT) was conducted to confirm or exclude the diagnosis of primary aldosteronism (PA). For this purpose, 2000 ml of isotonic saline were intravenously infused over 4 hours. Both before and immediately after the sodium infusion, each patient underwent sodium magnetic resonance imaging (^{23}NA-MRI), a specialized noninvasive imaging technique that focuses on visualizing the distribution and concentration of sodium ions within tissues.
Results
The mean sodium content in skin and muscle tissue in the study cohort was 45 ± 3.4 mmol/l and 17.9 ± 2.8 mmol/l, respectively, prior to the intervention. Following salt loading, in both compartments a significant increase in salt accumulation (+18%, $P<0.001$; +4.4%, $P=0.004$) could be observed. Based on the SIT, PA was diagnosed in 17 cases (54.8%) and excluded in four cases (12.9%), while remaining inconclusive in ten cases (32.3%). Across diagnostic categories, the aldosterone-to-renin ratio (ARR) correlated positively with the level of baseline salt content in the skin ($P=0.03$). While a similar trend was evident in muscle tissue, it did not reach statistical significance. Muscle salt accumulation was significantly less pronounced in patients with a post-SIT aldosterone level above the median of 135 ng/l compared to those with lower aldosterone values (Δ1.48% versus Δ7.23%, $P=0.016$).
Conclusions
This study demonstrates a significant increase in sodium accumulation within skin and muscle tissues among hypertensive individuals following short-term sodium loading. In addition, we demonstrate a positive correlation between ARR and sodium stores in the skin prior to intervention. In muscle tissue, we observe a negative correlation between post-SIT aldosterone levels and the percentage of sodium accumulation. The data may provide an indication of a potential influence of aldosterone on sodium dynamics within body tissues. Increasing patient numbers and further investigation is required to assess whether differences in tissue sodium distribution before and after loading could serve as a discriminating factor between endocrine forms of hypertension and essential hypertension.

Impact of Val334Ile and Val472Leu variants on cytochrome P450 oxidoreductase activity

Isabel S Barata[1,2,3], Erica Lucato[1,2], Maria Natalia Rojas Velazquez[1,2,3], Louise Metherell[4] & Amit Pandey[1,2,3]
[1]Translational Hormone Research Program, Department of Biomedical Research, University of Bern, Bern, Switzerland; [2]Pediatric Endocrinology, Diabetology and Metabolism, University Children's Hospital, Bern, Switzerland; [3]Graduate School for Cellular and Biomedical Sciences, University of Bern, Bern, Switzerland; [4]Centre for Endocrinology, William Harvey Research Institute, Queen Mary University of London, London, UK.

Several different human diseases are caused by mutations in the NADPH:cytochrome P450 oxidoreductase (POR) that may severely impair its electron transfer ability. As the energy provider to microsomal cytochrome P450 (CYP) enzymes, effects of mutations in POR reach far beyond steroid biosynthesis. Human variants in POR manifest with a very broad phenotype affecting steroid and drug metabolism. POR is composed of a NADPH-binding domain and FAD and FMN-binding domains, linked by a hinge region. This hinge region allows the protein to undergo the conformational changes needed for the electron transfer from the electron donor to the final acceptor, either a CYP, another protein partner, or a small molecule. Variations in different regions of the protein contribute to the heterogeneous effects of POR variants in multiple pathologies. We report two POR variants, Val334Ile and Val472Leu, located in the FAD-binding domain and identified, respectively, in patients with primary adrenal insufficiency and familial glucocorticoid deficiency. Both variants were found to have been reported in population genetics databases, with a higher allele frequency in individuals with South Asian ancestry. The variants were expressed in bacterial systems and partially purified. CYP electron transfer activity was assessed using standard fluorescent or radiolabelled substrates, and small molecule reduction was assessed spectrophotometrically following cytochrome *c* reduction. Both variants resulted in a decrease in activity of drug metabolizing CYPs 2C9, 2C19, and 3A4, more pronounced for the Val334Ile variant, which maintained only approximately 20% of CYP2C9 and CYP2C19 activity and 70% of CYP3A4 activity. Moreover, preliminary data suggests a pronounced effect for the Val334Ile POR variant in the steroidogenic activity of CYPs 17A1 and 21A2, with approximately 35% of activity compared to wild-type POR. Cytochrome *c* reduction by POR was also impaired more severely by the Val334Ile variant. In silico predictions of stability and conservation highlighted the Val334 amino acid residue as more conserved and predicted a more deleterious effect of Val334Ile compared to Val472Leu, in accordance with the experimental data.

Education of sick day management in young people with adrenal insufficiency: Online survey and focus groups involving young people and parents

J Kirkby[1], J McKechnie[2,3], T Mushtaq[4], S Tollerfield[5], SM Ng[6,7,8], P Laing[9], SC Wong[10] & L Bray[1]
[1]EdgeHill University, Glasgow, UK; [2]University of Glasgow, Glasgow, UK; [3]Royal Hospital for Children, Department of Paediatric Endocrinology, Glasgow, UK; [4]Leeds Children's Hospital, Leeds, UK; [5]Great Ormond Street Hospital for Children NHS Foundation Trust, Department of Paediatric Endocrinology, London, UK; [6]Mersey and West Lancashire Teaching Hospitals, Paediatric Department, Ormskirk, UK; [7]EdgeHill University, Faculty of Health, Social Care and Medicine, Liverpool, UK; [8]University of Liverpool, Department of Women's and Children's Health, Liverpool, UK; [9]Alder Hey Children's NHS Trust, Department of Paediatric Endocrinology, Liverpool, UK; [10]University of Glasgow, Bone, Endocrine, Nutrition Research Group in Glasgow, Human Nutrition, Glasgow, UK

Background
Education of parents and young people (YP) with adrenal insufficiency (AI) in relation to sick day management is crucial and may help prevent adrenal crisis. In the UK, there is currently no national standards on education of sick day management in YP with AI.
Aims
To investigate the perceptions of YP with AI and their parents regarding experiences of and preferences for education and information on sick day management.
Methods
Online surveys and online focus groups with YP with AI (11–16 years), and their parents. Recruitment UK wide was facilitated through patient support groups. Survey responses were analysed using descriptive statistics and content analysis. Focus group data were analysed using thematic analysis.
Results
Twelve YP with AI, and 108 parents shared their views in the online survey. Five YP and 12 parents took part in online focus groups. YP reported gaps in their sick day management knowledge via the survey: 'I know a bit' (6/12, 50%) or 'I do not know much' (3/12, 25%). Some YP had not received education. Some received education at diagnosis when the YP were very unwell. YP in the surveys and focus groups reported that information and education should be more age-appropriate with child friendly leaflets and videos addressed to them (not just their parents) and covering injection technique. Some parents on the survey (34/108, 32%) reported that education did not equip them with the knowledge and skills needed to manage their child's sick day episodes. Despite education, some parents expressed uncertainty around how to spot signs of adrenal crisis (40/108, 37%) and did not feel they had the knowledge or skills to manage their child's sick days (36/108, 33%). The majority of parents (76/108, 70%) had received no refreshers following initial education. Parents wanted to gain information by talking with health professionals (88/108, 82%) or via instructional videos (72/108, 67%). Parents in the focus groups felt that education should be delivered separately to the time of diagnosis or acute illness and should include a follow-up appointment or regular refresher. Parents would like the choice of whether education is conducted on their own or with their child so they can ask difficult questions and access more opportunities for peer support.
Conclusion
This study highlights that many parents and YP with AI have unmet information needs regarding sick day management. Developing national standards of education of sick day management of AI should be prioritized.

JOINT3187

Post adrenalectomy hyperkalemia in primary aldosteronism. A case series of a not well-defined complication

Carlien de Herdt[1], Pieter-Jan Van Gaal[2], Christophe De Block[1] & Eric Gheuens[2]
[1]Antwerp University Hospital, Endocrinology, diabetology and metabolic diseases, Edegem, Belgium; [2]ZAS Cadix, Nephrology, Antwerp, Belgium

Introduction
Hyperkalemia post adrenalectomy can develop in primary aldosteronism (PA) due to chronic suppression of renin–angiotensin–aldosterone system (RAAS). There is too much uncertainties concerning this complication in terms of prevalence, risk factors, aetiology and treatment. We present the postoperative course of PA cases who underwent adrenalectomy.
Methodology
Inclusion of cases with unilateral PA confirmed by adrenal venous sampling (at the Antwerp University Hospital) who underwent unilateral adrenalectomy. Blood results were retrospectively evaluated 1–4 weeks and 2–12 months postoperatively.
Results
13 cases ($M=9$) with a mean age of 56 ± 11 years were included. 3 cases developed hyperkalemia <4 weeks postoperatively and persisted in 2 cases. Both were men, had a history of arterial hypertension >10 years and a normal kidney function. One case had a preoperatively hypokalemia. The first case developed a grade 3 hyponatremia and grade 1 hyperkalemia with a 45% increase of the serum creatinine level. Plasma aldosterone and renin levels were low. Kidney function and potassium level normalized under treatment with Kayexalate, but hyponatremia and suppression of RAAS persisted. The second case developed a grade 2 hyperkalemia and grade 3 hyponatremia with a 75% increase of the serum creatinine. Under treatment with Fludrocortisone, potassium and sodium levels improved. Plasma aldosterone was low-normal with an inappropriate normal renin level. Early postoperative suppression of RAAS was present in 5/13 cases and led to hyperkalemia in 2 cases. In the 3 cases without electrolyte disturbances, RAAS recovered.
Conclusion
Post adrenalectomy hyperkalemia in PA is stated to be a well–documented entity with a variable prevalence (4.5–7%). In our cohort of 13 cases, 1 case had a transient and 2 cases persistent hyperkalemia. Both cases with persistent electrolyte disturbances had a suppression of RAAS. Risk factors described in the literature and met by these 2 cases were older age (>53 years) and longer duration of hypertension. Early postoperative, 5/13 cases had a suppression of RAAS, leading to hyperkalemia in only 2 cases. Reviewing the literature, there is no difference in early postoperative plasma aldosterone or renin levels in cases with and without hyperkalemia. However, case series are small (largest including 9 cases with persistent postoperative hyperkalemia) and timing of blood sample varies. It is unknown why in most cases, postoperative suppression of RAAS is not associated with hyperkalemia. We state post adrenalectomy hyperkalemia is a not well-documented entity. Larger case series are needed to compare cases with and without post adrenalectomy hyperkalemia.

Metabolic risk following gender affirming hormone therapy, a prospective cohort study

Louise Lehmann Christensen[1], Camilla Viola Palm[2], Marianne Andersen[1], Pernille Ravn[2], Rikke Hjortebjerg[3], Tine Taulbjerg Kristensen[1] & Dorte Glintborg[1]
[1]Odense University Hospital, Department of Endocrinology, Odense, Denmark, [2]Odense University Hospital, Department of Gynecology and Obstetrics, Odense, Denmark, [3]Odense University Hospital, Odense, Denmark

Introduction
Gender affirming hormone treatment (GAHT) may associate with higher risk of cardiovascular-metabolic disease and screening is recommended as part of clinical care. Long term prospective data are requested to tailor individual follow-up.
Objectives
To evaluate prospective changes in metabolic syndrome during 24 months of masculinizing or feminizing GAHT.
Methods
Prospective audit with patient's informed consent conducted at a public center of gender identity with annual clinical and biochemical evaluation. GAHT regimen followed international guidelines, and feminizing estradiol treatment was combined with cyproterone acetate. Study outcomes were BMI, waist, hip, blood pressure, lipid status, and HbA1c at baseline, 12 and 24 months. Metabolic syndrome was defined by obesity (BMI >30 kg/m^2, waist ≥80 cm, or waist–hip-ratio (WHR) >0.9), elevated triglycerides (TG) ≥1.7 mmol/l, HDL <1.0 mmol/l, blood pressure (BP) $\geq140/90$ mmHg, and HbA1c $\geq$ 5.6%.
Results
The cohort included 438 persons, 220 were undergoing masculinizing GAHT (TransM_TN, treatment naïve $n=113$, TransM_TO, treatment ongoing $n=107$) or feminizing GAHT (TransF_TN, treatment naïve $n=137$, TransF_TO, treatment ongoing $n=81$. At baseline, the median age was 22 years (19–28) and 26 years (24–37) in TransM_TN and TransF_TN, respectively. In transM_TN, waist, WHR, systolic BP, TG, and HbA1c increased from baseline to 12 months, whereas HDL decreased. Total cholesterol increased from 12 to 24 months. ≥2 metabolic syndrome criteria were present in $40/110=36\%$ at baseline and in $16/34=47\%$ at 24

months. In TransF_TN, weight, BMI, waist, hip, and WHR increased from baseline to 12 months whereas HbA1c, cholesterol, and TG decreased. From 12 to 24 months, BMI, waist, and hip increased. ≥2 metabolic syndrome criteria were present in 71/134=53% at baseline and in 17/42=41% at 24 months.

Conclusion

Metabolic and cardiovascular risk factors increased after GAHT, especially within the first year of GAHT initiation.

Patient-reported outcomes in patients with primary adrenal insufficiency – A study from the register for organ-specific sautoimmune diseases (ROAS)

Sandra Steintorsdottir[1,2,3], Marianne Grytaas[1], Marianne Øksnes[1,2], Lars Breivik[1], Anders Jørgensen[3,4] & Eystein Sverre Husebye[1,2]
[1]Haukeland University Hospital, Department of Internal Medicine, Bergen, Norway; [2]University of Bergen, Department of Clinical Science, Bergen, Norway; [3]Oslo University Hospital, Department of Endocrinology, Morbid Obesity and Preventive Medicine, Oslo, Norway; [4]University of Oslo, Faculty of Medicine, Oslo, Norway

Background

Despite modern evidence-based treatment, patients with primary adrenal insufficiency (PAI) experience reduced quality of life, increased fatigue, and diminished work capacity compared to healthy individuals. Patient-reported outcome measures (PROM) can provide better insights into patients' own experiences and perceptions, which can lead to improved follow-up and treatment.

Methods

Patients included in the Register for Organ-Specific Autoimmune Diseases (ROAS) with autoimmune PAI, aged 18 and older, completed annual electronic PROM questionnaires from 2018 to 2023. Patients answered questions regarding disease progression, medication use, work capacity, stress dosage, incidence of adrenal crises, symptoms of cortisol deficiency, and quality of life. The latter was evaluated using AddiQoL, a validated questionnaire for PAI.

Results

The number of responses increased from 179 in 2018 to 478 in 2023 (response rate 54%). At the time of diagnosis, the most common symptoms were fatigue (92%), increased pigmentation (79%), and weight loss (75%). The most frequent time interval from the first symptom to diagnosis was 3–12 months (35%, $n=169$), while 25% ($n=119$) reported symptoms occurring 1–3 years before diagnosis. In 2023, 308 patients (65%) reported using cortisone acetate tablets (median daily dose 37.5 mg), while 136 (29%) used Plenadren (median daily dose 25 mg). Plenadren use increase from 20% in 2018. A majority (70%) reported temporary dose increases in the past year. Most patients (94%) felt they had received adequate information about stress dosing of glucocorticoids, and 80% had access to hydrocortisone injections. The median daily dose for fludrocortisone was 0.13 mg. Fifty-nine patients (12%) experienced an adrenal crisis in the past year. In 2023, 267 patients (56%) had paid employment, 111 (23%) were retirees, and 123 (26%) had sick pension. A total of 131 patients (49%) reported no sick leave days, while 47 (18%) had more than 30 days of sick leave. The mean AddiQoL-30 score was 86±12 in 2023, unchanged from 2018 (86±13). The AddiQoL-8 score was also unchanged (21±5 for both years).

Conclusion

Patient-reported data provide valuable insights into the health and quality of life of patients with autoimmune PAI. The triad of fatigue, increased skin pigmentation, and weight loss were the most common symptoms at onset. Nearly one-third of patients are now treated with modified release hydrocortisone (Plenadren), and over 50% are employed. Quality of life in patients with PAI remains diminished but unchanged over the 6-year observation period.

JOINT376

Clinical characteristics and genetical analysis of HSD11B2 in three Chinese children with apparent mineralocorticoid excess: A case series

Yuan Ding
Beijing Children's Hospital, Department of Endocrinology, Genetics, Metabolism, Beijing, China

Background

Apparent Mineralocorticoid Excess (AME) is a rare autosomal recessive disorder, characterized by a notably complex diagnostic process. To date, the majority of documented cases have been presented as individual case reports. This article aims to enhance the understanding of the course and prognosis of AME, by detailing the management protocols employed for patients with genetically confirmed diagnoses.

Methods

An analysis comprising three cases and a review of relevant literature were conducted to synthesize the insights and experiences derived from gathering clinical and laboratory data on patients.

Results

All three patients were born to non-consanguineous parents, were small for gestational age and exhibited severe hypokalemia, metabolic alkalosis, hypertension, nephrocalcinosis, and hypercalciuria. The glomerular filtration rate was normal in all cases. One patient experienced complications related to hypertension. Genetic analysis revealed biallelic recessive variations in the HSD11B2 gene in all three patients. Treatment with oral spironolactone and potassium chloride resulted in the normalization of both blood pressure and serum potassium levels in all patients.

Conclusion

This study presents the diagnostic and treatment experiences of three Chinese pediatric patients with AME type I. Through our analysis, four novel variants of the HSD11B2 gene were identified, thereby enhancing the genotype–phenotype spectrum associated with AME. Early genetic testing in patients suspected of having AME is beneficial for facilitating prompt diagnosis and the implementation of standardized treatment protocols. Such measures are essential for the prevention or mitigation of target organ damage, as well as for the reduction of associated morbidity and mortality.

Establishment of an adult mouse adrenal *ex vivo* tissue culture model

Sara Kyhn[1], Ida Marie Boisen[1], Nadia Krarup Knudsen[1], Anne Jørgensen[1] & Martin Blomberg Jensen[1,2]
[1]Copenhagen University Hospital – Herlev and Gentofte, Department of Endocrinology and Internal Medicine, Herlev, Denmark; [2]Copenhagen University Hospital, Department of Clinical Medicine, Copenhagen, Denmark

Introduction

Dysregulation of adrenal steroidogenesis can cause imbalances in the secretion of mineralocorticoids, glucocorticoids, and androgens, leading to various endocrine disorders. We have previously established and extensively validated a human fetal adrenal *ex vivo* culture model, but no comparable model exists for adult human adrenal tissue. Developing an adult adrenal tissue culture model could facilitate studies of de novo and altered adrenal steroidogenesis in normal adrenal glands and hormone-producing adenomas, providing valuable insights towards establishing clinically relevant functional models. Despite important species-specific differences between human and mouse adrenals, we initially aim to establish an adult mouse adrenal *ex vivo* tissue culture model.

Materials and methods

Three *ex vivo* culture techniques were evaluated using adult mouse adrenal tissue: hanging drop, porous membranes, and agarose gel fragments. Adrenal tissue was cultured for 24 hours, 48 hours, or 5 days. Following each culture period, tissue was fixed, paraffin-embedded, and assessed for morphology (hematoxylin and eosin staining), proliferation (BrdU incorporation), and apoptosis (cleaved PARP staining). Subsequently, adrenal tissue will be treated with ACTH (1 nM) or ketoconazole (1 μM) to stimulate or inhibit steroidogenesis, respectively and effects on steroidogenesis will be determined by analyzing the production of selected adrenal steroid metabolites in the collected culture media.

Results

Analysis of the three different culture approaches and culture periods are currently ongoing. The optimal culture method will be determined based on preservation of tissue morphology (including intact cortical zones), minimal apoptosis, sustained cell proliferation, and functional responses to steroidogenic stimulation and inhibition.

Conclusion

Preliminary findings suggest that *ex vivo* culture of adult mouse adrenal tissue is feasible. Ongoing analyses will identify the most effective culture approach, providing a critical framework for future investigations into adrenal steroidogenesis. This model represents a significant first step toward enabling studies on both normal and pathological adrenal function in adult adrenal gland tissue.

Paediatric peripheral adrenal insufficiency: Rare causes in an observational cohort

Mathilde Schermesser-Sicard[1], Dinane Samara-Boustani[1,2], Roucher Florence[3,4], Graziella Pinto[1,2], Jean-Claude Carel[2,5,6], Adrien Nguyen Quoc[1], Gaëlle Vermillac[1], Sibylle Rovani[1,6], Caroline Thalassinos[1], Sabrina Da Costa[1,7], Maria Beatriz Arrom Branas[1], Isabelle Flechtner[1], Yamina Dassa[1], Laura González-Briceño[1], Magali Viaud[1,2], Alix Besançon[1], Jacques Beltrand[1,6], Athanasia Stoupa[1,6,8], Michel Polak[1,6,8] & Kariyawasam Dulanjalee[1,2,6]

[1]Necker-Enfants Malades University Hospital, Pediatric Endocrinology, Diabetology and Gynecology Department, Paris, France; [2]Centre Maladies Rares de la Croissance et du Développement, Paris, France; [3]Hospices Civils de Lyon, LBMMS, Service de Biochimie et Biologie moléculaire, Centre de Biologie et de Pathologie Est, Lyon, France; [4]Université Claude Bernard Lyon 1, Lyon, France; [5]Robert Debré University Hospital, Pediatric Endocrinology and Diabetology Department, Paris, France; [6]Paris Cité University, Paris, France; [7]Centre de Référence des Pathologies Gynécologiques Rares, Paris, France; [8]Paris regional Newborn Screening Program Department, Paris, France

Objective

Peripheral adrenal insufficiency (PAI) is a rare, chronic condition causing life-threatening complications. The main cause is 21-hydroxylase deficiency. Identifying other rare causes is difficult but crucial to ensure timely diagnosis and optimal management. The objective of this study was to describe rare causes of paediatric PAI.

Design

Observational, retrospective, single-centre, cohort study

Methods

Descriptive analysis of data from patient files

Results

Of 213 patients younger than 18 years who were diagnosed with PAI between 1980 and 2023, 172 had assessable data, including 113 with 21-hydroxylase deficiency and 59 (52%) with rare causes of PAI. Rare causes included monogenic diseases ($n=38$, 64%, such as non 21-hydroxylase deficiency congenital adrenal hyperplasia(CAH), X-linked adrenoleukodystrophy, Triple A syndrome, MIRAGE syndrome, Xp21 continuous gene deletion syndrome, *NNT* deficiency), auto-immune disorders ($n=15$, 25%), and bilateral adrenal haemorrhage ($n=3$); in 3 patients, no cause was identified. Median age at diagnosis varied greatly depending on the aetiology: from 4 days of life for MIRAGE syndrome to 10.5 years for isolated auto-immune PAI. Symptoms of chronic and/or acute adrenal insufficiency were noted at presentation in 39 (66%) patients, including half with both chronic and acute symptoms. Median follow-up was 7.6 years and 28 (48%) patients attained adult height at last visit. The mortality rate was 6/59 (10%), with MIRAGE syndrome as the most common cause of death (4/6 deaths). Acute adrenal crisis occurred in 26 (45%) patients, usually due to poor treatment adherence. Excess weight was a common complication (16/59, 27%), not correlated with the daily hydrocortisone dosage. Data on puberty were available for 37 patients: puberty was normal in 26 (72%), early in 6 (17%), and delayed in 5 (14%). Of the 9 patients with CAH in post-pubertal ages, 3 (33%) experienced either precocious or advanced puberty and 2, both females, required puberty-inducing hormonal therapy (P450 oxidoreductase deficiency and P450scc deficiency, respectively). All 3 patients with *NNT* deficiency experienced precocious puberty, which was initially peripheral (Leydig cell adenoma, testicular adrenal inclusions) at about 5 years of age then central puberty. Statural growth outcomes were satisfactory: mean final height was -1.1 SDS in males and -0.4 SDS in females and median height in the 27 patients who did not attain their adult height during follow-up was -0.4 SDS.

Conclusion

The wide range of rare causes of PAI raises diagnostic challenges. In most cases, however, the cause can be determined, allowing optimal therapy. Treatment adherence deserves careful attention.

Contribution of immunohistochemistry and *in situ*hybridization in BMAD and correlations with patient genotype

Florian Violon[1,2], Lucas Bouys[1], Annabel Berthon[1], Bruno Ragazzon[1], Anne Anne Jouinot[1], Patricia Vaduva[1,3], Louis Vaquier[2], Karine Perlemoine[1], Benoît Terris[2], Jérôme Bertherat[1,4] & Mathilde Sibony[1,2]

[1]Institut Cochin, Genomic and signaling pathway in endocrine tumors, Paris, France; [2]Cochin Hospital, Pathology, Paris, France; [3]CHU Rennes, Rennes, France; [4]Cochin hospital, Endocrinology, Paris, France

Introduction

Bilateral macronodular adrenocortical disease (BMAD), formerly known as PBMAH for primary bilateral adrenocortical hyperplasia is an uncommon disease responsible for about 2% of overt Cushing's syndrome. The disease is clinically, biologically and radiologically heterogeneous. Our team has described four microscopic subtypes based on macronodule architecture and cell type proportion (clear, eosinophilic and oncocytic). Subtypes 1 and 2 correlate with the presence of pathogenic variants in *ARMC5* and *KDM1A* genes, respectively. *ARMC5* inactivation leads to accumulation of the A subunit of RNA polymerase II (POLR2A). We have also shown that bi-allelic inactivation of *KDM1A* occurs via loss of heterozygosity with deletion of the short arm of chromosome 1. The aim of this study is to describe the immunohistochemical and *in situ*hybridization characteristics of BMAD subtypes.

Patients and methods

Immunohistochemistry and *in situ*hybridization were performed on 4 patients of each subtype from the cohort of 35 patients previously described at our center. We performed immunohistochemistry (IHC) using antibodies targeting alpha inhibin, DAB2, HSD3B1, HSD3B2, CYP11B1, CYP11B2, CYP17A1, KDM1A and POLR2A proteins. Fluorescent *in situ*hybridization (FISH) was performed with 1p36/1q25 commercial probe.

Results

In each subtype, HSD3B2 preferentially stains clear cells whereas CYP17A1 stains eosinophilic cells contrary to cortisol producing adenomas (CPA) that co-express CYP17A1 and HSD3B2 (*Kubota Hum Pathol 2016*). HSD3B2 uniformly stains clear cells only in patients with a pathogenic variant of *ARMC5*, in BMAD. HSD3B1 and CYP11B1 stain all cell types in each subtype. In subtype 1 (*ARMC5*), there is a population of columnar eosinophilic cells expressing DAB2 without expressing CYP11B2. In patients with a pathogenic variant of *ARMC5*, contrary to other subtypes, all nodular cells strongly express POLR2A in contrast with non-nodular adrenal gland. In subtype 2 (*KDM1A*), alpha inhibin is highly expressed in eosinophilic cells, and KDM1A immunoexpression is lower than in the adjacent adrenal gland. Similarly, this subtype is the only one in which a deletion of the short arm of chromosome 1 is demonstrated by the 1p36/1q25 FISH probe.

Conclusion

The absence of HSD3B2 and CYP17A1 co-expression appears to distinguish BMAD from CPA, and these IHCs could provide a diagnostic marker for BMAD. HSD3B2 and POLR2A are strongly correlated with *ARMC5* pathogenic variants and, KDM1A IHC and 1p36/1q25 FISH probe distinguish *KDM1A* altered BMAD. These markers could be used to guide genetic investigations or to confirm the pathogenic nature of germline variants of undetermined significance.

Direct detection of urinary free cortisol: Analytical and clinical validation of a new fully automated chemiluminescence assay

Júnia Ribeiro de Oliveira Longo Schweizer[1], Pierre Lukas[2], Andrea Osswald[1], Stephanie Zopp[1], Katrin Ritzel[1], Emanuele Persichetti[3], Etienne Cavalier[2], Martin Reincke[1] & Martin Bidlingmaier[1]

[1]LMU Klinikum Innenstadt, Medizinische Klinik und Poliklinik IV, München, Germany; [2]Department of Clinical Chemistry, University of Liege, CHU de Liege, Liege, Belgium; [3]Department of Research and Development, Diametra S.r.l., Spello, Italy

Background

Measurement of 24-hour urinary free cortisol (UFC) is recommended for biochemical diagnosis of Cushing's syndrome (CS). However, measured cortisol concentrations differ depending on the test method. Results of chemiluminescence immunoassays (CLIA), in contrast to liquid chromatography–mass spectrometry (LC–MS/MS), may be impacted by the presence of cortisol metabolites in urine. Poor agreement across CLIA methods is primarily attributable to cross-reactivity and to whether or not an extraction procedure is performed. Accordingly, the Endocrine Society recommends using the upper limit of the method-specific reference interval (RI) as a cut-off in diagnosis of CS. We assessed the performances of a new automated CLIA that does not require extraction, and compared clinical performance to two other CLIAs and a LC–MS/MS method.

Methods
Analytical performance of the IDS Urinary Cortisol CLIA (Immunodiagnostic Systems Ltd, UK) was verified. Clinical performance was studied in 24-hour urine samples from 24 CS patients and 50 patients in which the diagnosis of CS was clinically suspected, but finally excluded. Results obtained by the IDS assay were compared to those from Beckman Access Cortisol CLIA (Beckman Coulter Inc, USA) without extraction, DiaSorin Liaison Cortisol CLIA (DiaSorin Spa, Italy) after extraction with dichloromethane and an in-house LC–MS/MS (CHU of Liege, Belgium). Analytical agreement across methods was estimated using Passing–Bablok regression and diagnostic performances were compared using clinical sensitivity, specificity, and accuracy.
Results
UFC concentrations measured with IDS were lower compared to Beckman (slope: 0.81, intercept: 0.31 µg/dl; R^2: 0.96), but higher than DiaSorin (slope: 1.45, intercept: 1.68 µg/dl; R^2: 0.75) and LC–MS/MS (slope: 4.09, intercept: 1.44 µg/dl; R^2: 0.73). At the RI-based cutoff (µg/24 h: IDS 324, Beckman 403, DiaSorin 83, LC–MS/MS 45), the IDS CLIA results exhibited 92% sensitivity and 100% specificity (Beckman: 83% sensitivity, 98% specificity; DiaSorin: 100% sensitivity, 56% specificity; LC–MS: 96% sensitivity, 82% specificity). At an optimized, method-specific cut-off providing 100% sensitivity (µg/24 h: IDS 306, Beckman 266, DiaSorin 171, LC–MS 44), specificity was 98% with IDS and DiaSorin CLIAs, 84% with Beckman CLIA and 80% with LC–MS/MS.
Conclusions
The new IDS CLIA is a clinically accurate automated method for measuring UFC concentration. As expected, due to the omission of an extraction procedure, the assay measures higher concentrations compared to LC–MS/MS and other CLIA methods. Comparison of 3 immunoassays and an LC–MS/MS method demonstrated acceptable correlation but significant differences in absolute concentrations. Using method-specific cut-offs are used, the new CLIA provides similar or better clinical sensitivity and specificity.

Characterization of ferroptosis activation in primary mouse spheroids

Agnès Wlodarczyk, Uta Lehnert, Stefan Bornstein & Waldemar Kanczkowski
University Hospital Carl Gustav Carus, Internal Medicine III, Dresden, Germany

Background
Bacterial sepsis is a serious threat to homeostasis and is the most common cause of mortality in non-coronary intensive care units (ICUs). It is characterized by compromised function of several vital organs, including the adrenal glands. However, little is known about the mechanisms involved. Recently, it has been reported that iron overload and ferroptosis might be involved in sepsis-induced multiorgan damage. Our previous results indicated that the human adrenocortical cell line, NCI-H295R, is sensitive to ferroptosis induced by inhibiting glutathione peroxidase 4 (GPX4) and can be enhanced by active steroidogenesis. However, whether primary adrenal cells are also sensitive to ferroptosis and whether bacterial LPS can modulate this process remains unexplored until now.
Objectives
The main objective of this study was to investigate whether primary adrenal cells are susceptible to ferroptosis induction by known ferroptosis inducers or in septic conditions *in vitro* in 3D culture.
Methods
Primary adrenal cells were isolated from mouse adrenal glands and cultivated as 3D spheroids using AggreWell microwell plates and low attachment conditions. The sensitivity of 3D spheroids was tested by pharmacological inhibition of GPX4 using RSL3 and incubation with bacterial LPS. Spheroid diameter, cell viability (FDA/PI staining), lipid peroxidation (C11-BODIPY), and necrosis induction (LDH release) were measured 24 h thereafter.
Results
Our study demonstrated that administration of RSL3 negatively affected the morphology and size of primary adrenal spheroids, which were associated with enhanced lipid peroxidation and necrosis induction. These changes were mitigated by ferroptosis inhibitor, ferrostatin-1. Our preliminary data based on spheroids isolated from mice with adrenocortical cell-specific deletion of GPX4 support these results. However, no significant increase in lipid peroxidation or LDH release could be observed after LPS treatment.
Conclusions
In summary, our findings suggest that primary adrenal cells are susceptible to ferroptosis induction through direct inhibition of GPX4 but not bacterial LPS. Further experiments, including the detailed characterization of spheroids, especially those isolated from GPX4-deficient adrenal cells, are ongoing. Moreover, a more thorough molecular investigation of LPS effects on primary mouse spheroids is necessary to elucidate its potential involvement in adrenal necrosis.

Treatment of primary aldosteronism improves cardiac autonomic function

Denise Bruedgam[1], Daniel Heinrich[1,2], Christine Meyer-Zürn[3], Isabel Stüfchen[1], Paul Schwarzlmueller[1], Hediyeh Daneshpour[1], Erik Petersenn[1], Petra Zimmermann[4], Sinan Deniz[5], Martin Bidlingmaier[1], Tracy Ann Williams[1], Konstantinos Rizas[1], Felix Mahfoud[3], Martin Reincke[1] & Johannes Schier[3]
[1]LMU Klinikum, Medizinische Klinik und Poliklinik IV, Munich, Germany; [2]Hormon-und Stoffwechselzentrum München, Munich, Germany; [3]Universitätsspital Basel, Klinik für Kardiologie, Basel, Switzerland; [4]LMU Klinikum, Klinik für Allgemein-, Viszeral-und Transplantationschirurgie, Munich, Germany; [5]LMU Klinikum, Klinik für Radiologie, Munich, Germany

Introduction
Primary aldosteronism (PA) is among the most common causes for secondary hypertension. Cardiovascular mortality is influenced independently by aldosterone excess and sympathetic activation. Periodic repolarization dynamics (PRD) is an electrocardiographic marker of repolarization instability associated with sympathetic activity. It has shown promising results in predicting mortality and arrhythmias in patients with cardiovascular disease. Therefore, we analyzed PRD values of PA patients before and after specific PA treatment.
Methods
We included 85 patients, recruited from 2020 to 2022, who were part of the German Conn's Registry and retrospectively investigated PRD values using a high resolution ECG at baseline and at 6–12 months follow-up.
Results
Baseline PRD values could be significantly lowered after specific treatment at follow-up (2.39 deg2 vs. 1.66 deg2; $P=0.02$). MRA treated patients were the driver of this PRD reduction ($n=54$, 1.31 (0.81; 2.64)), as PRD reduction was not significant in the adrenalectomy group ($n=31$, 1.93(1.05; 5.13)). Baseline PRD correlated significantly with baseline aldosterone. Spironolactone dosage could not significantly be correlated to PRD reduction. In the MRA treatment subgroup, renin stimulation after treatment was not an independent factor in PRD reduction. Surprisingly, cortisol co-secretion was also not significantly correlated to PRD values at baseline.
Conclusion
PRD as marker of sympathetic activation could be shown to be reduced in PA patients after specific treatment, indicating a lower burden of sympathetic activation. The reduction was mostly due to patients treated with MRA. Further studies are necessary in order to determine whether PRD can be a long term prediction tool for cardiovascular mortality in patients with PA.

Background
Mild autonomous cortisol secretion (MACS) as well as non-functional adrenal incidentalomas (NFAI) are associated with increased metabolic and cardiovascular risk suggesting a subtle secretion of cortisol or of other precursors of steroidogenesis.

Aim
To investigate steroid metabolites levels in patients with MACS and NFAI benign adrenal tumours as well as in adrenocortical carcinomas (ACC). Controls were defined as patients with normal adrenals on imaging.
Methods
Liquid chromatography–tandem mass spectrometry (LCMS) was used for the steroidomics analysis of several steroid precursors [cortisol (F), corticosterone (B,CORT), 11-deoxycorticosterone (DOC), 11-deoxycortisol (11-DOC, compoundS), 21-deoxycortisol (21-DOF), aldosterone (ALDO), testosterone (T), dihydrotestosterone (DHT), androstenedione (A4), androsterone (AN), dehydroepiandrosterone (DHEA), dehydroepiandrosterone Sulfate (DHEAS), progesterone (P4), 17-hydroxyprogesterone (17-OHP4), pregnenolone (P5), 17-hydroxypregnenolone (17-OHP5), estradiol (E2), estrone (E1)] in the blood of 35 patients. The categorisation of patients in functional or NFAI was based on functional hormonal blood tests [1 mg overnight dexamethasone suppression test (ODST)] based on current guidelines. All ACC cases were confirmed histopathologically.
Results
A total of 29 patients (8 males) with adrenal tumors [($n=17$ with NFAI, $n=8$ with MACS and $n=4$ with ACC] and 6 controls were included. Tumor size was significantly higher in ACC compared to NFAI and MACS patients. Urinary-free cortisol (UFC) levels were 5-fold higher in ACC and 3-fold higher in MACS compared to NFAI patients (although within normal range for MACS) LCMS analysis showed that all the median blood steroid hormones levels were significantly higher ($P<0.05$) in ACC patients compared with NFAI, MACS and control patients except for aldosterone levels. Regarding patients with benign tumors, median levels of baseline morning cortisol, corticosterone, 11-deoxycorticosterone and 21-deoxycortisol were significantly higher in MACS compared with NFAI ($P=0.04$, $P=0.03$, $P=0.047$, $P=0.043$ respectively). Baseline median levels of cortisol, corticosterone, 11-deoxycorticosterone and progesterone levels were significantly higher in MACS compared with controls ($P=0.037$, $P=0.042$, $P=0.039$, $P=0.023$ respectively). Baseline median levels of 11-deoxycorticosterone were significantly higher in NFAI compared with controls ($P=0.01$) whereas progesterone and 17-OH progesterone were significantly lower in NFAI compared with controls ($P=0.002$, $P=0.04$). Among comorbidities hypertension, hyperlipidemia and diabetes mellitus prevalence was higher in patients with adrenal tumours compared to controls as well as between NFAI and controls.
Conclusions
All steroid hormones levels were significantly higher in ACC patients compared to patients with MACS and NFAI. Precursors such as 11-deoxycorticosterone, and 21-deoxycortisol could play a supplementary role to the routine hormones profile for the distinction of NFAI from controls or MACS.

Background
The tissue 'milieu' of cortisol, intended as cortisol secretion combined with its tissue sensitivity could have an impact on obesity and its comorbidities such as type 2 diabetes mellitus (T2DM), arterial hypertension (AH), depressive syndrome (DS) and cardiovascular disease (CVD), in subjects without Cushing Syndrome.
Objective
This study aimed at evaluating cortisol secretion together with glucocorticoids (GCs) receptor sensitivity through the determination of glucocorticoid receptor polymorphisms (GRp) in severely obese subjects, exploring their association with obesity's degree and comorbidities.
Methods
A total of 193 male subjects (age >18) suffering from severe obesity (BMI >35 kg/m^2) were consecutively enrolled in a cross-sectional observational study. For each patient we collected clinical history and presentation and performed blood tests for metabolic and gonadal function. We evaluated night-time cortisol blood levels and the morning cortisol after 1 mg of dexamethasone overnight suppresion test (OST); GRp (BclI, rs41423247; N363S, rs56149945 increasing the sensitivity and ER22/23EK, rs6189+ rs6190 reducing it) were evaluated using restriction enzymes. Both logistic regression analyses and a machine learning naive approach were used to explore the association of cortisol milieu with AH, T2DM, DS and CVD. Polysomnography was used to determine if decompensated obstructive sleep apneas were present, to adjust the analyses together with age, BMI and smoking habit (pack-years).
Results
In our cohort 74% of patients exhibited AH, 42% had T2DM, and 37% experienced varying degrees of DS according to the Beck Depression Inventory; the 17% had a history of CVD. At multivariate analyses cortisol levels after OST were associated with the presence of T2DM ($P=0.007$) and diabetic nephropathy ($P=0.025$), whereas GRp increasing sensitivity to cortisol were independently associated with AH ($P=0.04$) and CVD ($P=0.03$). Depression, did not show any significant correlation. Using 'Random Forest' machine learning analyses we found that the addition of GRp and hypogonadotropic hypogonadism to the known factors (such as hypertension, renal function, HOMA index, BMI and age) increased the prediction performance of CVD in obese patients.
Conclusions
The combined study of cortisol secretion and peripheral sensitivity to GCs in the absence of overt hypercortisolism seems to provide additional information on the mechanisms leading to the development of obesity comorbidities, both using classic statistical methods and machine learning naive approaches. If confirmed, this could have potential use in identifying subjects deserving specific treatments aimed at modulating GCs action.

Impact of adrenal insufficiency on quality of life: clinical insights from a retrospective study

Manal Bennani, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Ibn Rochd University Hospital, Clinical Neuroscience and Mental Health Laboratory Faculty of Medicine and Pharmacy – Hassan II University, Department of Endocrinology and Metabolic Diseases, Casablanca, Morocco

Objective
The objective is to evaluate the quality of life in patients with gradual-onset adrenal insufficiency and assess its overall impact.
Materials and patients
This is a descriptive study conducted in our department, using the AddiQOL questionnaire, involving 48 patients with adrenal insufficiency who experienced episodes of acute decompensation between January 2022 and December 2024.
Results
Our study included 48 patients, of which 17 were men and 31 were women. The average age was 37 years, with 40% being patients with Addison's disease. Overall health-related quality of life was impaired in 73% of cases, while physical, social, and emotional health were affected in 93%, 82%, and 75% of cases, respectively. The most common symptoms were fatigue (100% of cases), abdominal pain (83%), nausea and vomiting (41%), loss of appetite (75%), insomnia (66%), constipation (33%), and diarrhea (25%).
Conclusion
The impairment of quality of life in patients with adrenal insufficiency remains significant, with a variety of symptoms, the most common being fatigue, which persists despite substitution therapy.

11-Oxygenated androgens in healthy young men and women and the impact of hormonal contraceptives.

Torkild Pettersen[1], Ole Martin Fuskevåg[2], Yngve Figenschau[1,3], Elin Evensen[4], Christopher Nielsen[5,6], Anne-Sofie Furberg[7,8], Anne Winther[9] & Guri Grimnes[1,10]
[1]UiT Arctic University of Norway, Department of Clinical Medicine, Tromsø, Norway; [2]University Hospital of North Norway, Department of Laboratory Medicine, Tromsø, Norway; [3]University Hospital of North Norway, Diagnostic Clinic, Tromsø, Norway; [4]UiT Arctic University of Norway, Department of Health and Care Sciences, Tromsø, Norway; [5]Norwegian Institute of Public Health, Department of Chronic Diseases, Oslo, Norway; [6]Oslo University Hospital, Department of Pain Management and Research, Oslo, Norway; [7]University Hospital of North Norway, Department of Microbiology and Infection Control, Tromsø, Norway; [8]Molde University College, Department of Health and Social Sciences, Molde, Norway; [9]University Hospital of North Norway, Department of Neurosciences, Orthopedics and Rehabilitation Service, Tromsø, Norway; [10]University Hospital of North Norway, Division of Medicine, Tromsø, Norway

Introduction
A novel interest in 11-oxygenated adrenal androgens (11-ketotestosterone, 11KT; 11-hydroxytestosterone, 11OHT; 11-ketoandrostenedione, 11KA4; and 11-hydroxyandrostenedione, 11OHA4) has emerged due to their contribution to androgen signaling through binding androgen receptors or as precursor metabolites. These androgens are predominantly produced by the adrenal gland, although evidence on enzyme distribution suggests that the androgens may be interconverted in peripheral tissues. A recent article investigating the association between adrenal androgens and contraceptive use found no association, albeit with a smaller sample size and combined contraceptive users rather than investigating combined hormonal contraceptives and gestagen containing contraceptives individually. A well-known effect of combined hormonal contraceptives is lowering of serum concentrations of testosterone, which is utilized for instance in treatment of polycystic ovary syndrome.
Material and methods
This study utilized data from the Fit Futures Study, a population-based longitudinal study following participants from adolescence into adulthood through three waves performed in 2010–2011 and 2012–2013, and the most recent third held in 2021–2022. The study was composed of questionnaires, clinical interview, physical examinations, and sampling of biological material. Specifically, this study utilized data from the third Fit Future study, in which 705 participants attended. Descriptive statistics were used to describe distributions of 11-oxygenated androgens. Independent *t*-tests and chi-square tests were used to compare variables between the sexes. Relation to exposure variables were assessed through independent *t*-tests or Pearson correlations and general linear models.
Results
The study included 305 males and 350 females with mean age of 26.9 (1.1). Males had 13–17% higher concentrations of 11-oxygenated androgens. Among the females, 32.6% used combined hormonal contraceptives, 11.7% used gestagen containing contraceptives, and 55.7% used non-hormonal contraceptives or no contraceptives. Gestagen containing contraceptives was found to have no association with 11-oxygenated androgens and was hence combined with non-hormonal contraceptives. Users of combined hormonal contraceptives had significantly lower levels of 11-ketotestosterone (16.6% means difference, $P = < 0.001$), 11-hydroxytestosterone (16.6% means difference, $P = < 0.001$), and 11-ketoandrostenedione (19.4% means difference, $P = < 0.001$) than the non-users and gestagen users.
Conclusion
Lower levels of 11-oxygenated androgens in CHC users may have direct clinical impact for treatment of hyperandrogenic conditions like polycystic ovary syndrome, in which 11-oxygenated androgens are elevated.

Androgens as prognostic factors – the evaluation of septic patients

Aleksandra Czapla[1], Kasper Kuna[2], Magdalena Wujtewicz[3], Michał Okręgły[3] & Renata Świętkowska-Stodulska[1]
[1]Medical University of Gdansk, Department of Endocrinology and Internal Diseases, Gdansk, Poland; [2]Medical University of Łódź, Department of Biostatistics and Translational Medicine, Łódź, Poland; [3]Medical University of Gdansk, Division of Anaesthesiology & Intensive Care, Gdansk, Poland

Sepsis is a life-threatening disease posing a huge burden to healthcare systems. It remains one of the most frequent causes of the admissions to hospitals with high mortality of patients. Hence, early identification of patients threatened with worse course of the disease and death is crucial. The activation of hypothalamic–pituitary–adrenal axis is a very important part of organism's response to ongoing infection. The majority of published papers describes the role of cortisol in septic patients, however, the scarce data regarding androgens are inconclusive. For this prospective study 49 septic patients and 25 healthy controls were recruited. The concentrations of dehydroepiandrosterone (DHEA), dehydroepiandrosterone sulphate (DHEAS), androstenedione, testosterone, cortisol, sex hormone-binding globulin (SHBG) and 28-day mortality were assessed. The severity of the disease was described as APACHE II (Acute Physiology and Chronic Health Evaluation II) scale and SOFA (Sequential Organ Failure Assessment) score. The data were collected in three time points: up to 24 hours of hospital admission, on the 2nd day of hospital stay and after reaching hemodynamic stability/day of discharge/the day prior/ 8–10th day of prolonged hospitalization. The concentrations of all examined hormones were changing within the course of sepsis ($P < 0.01$). Assessing 28-day mortality, nonsurvivors had higher DHEA in all time points (P: 0.027–0.051) with higher cortisol ($p = 0.016$) and androstenedione ($P = 0.020$) in the first time point. Among indexes, only cortisol/testosterone ratio was different in the first time point ($P = 0.031$). SOFA and APACHE results were lower in survivors in comparison to nonsurvivors. In first time point in both groups – survivors and nonsurvivors – DHEA values were not age-dependent. In third time point in nonsurvivors, contrary to survivors, DHEA concentrations did not change with patients' age. Additionally, lower BMI ($P = 0.020$; $HR = 0.8533$), higher cortisol ($P = 0.044$; $HR = 1.001$) and higher cortisol/testosterone ratio ($P = 0.001$; $HR = 1.002$) were risk factors for death. In logistic regression, DHEA and cortisol were feasible prognostic factors with AUC 0.71 and 0.73, respectively. In conclusion, DHEA and cortisol can be used as prognostic factors in sepsis. Low BMI, high cortisol and high cortisol/testosterone ratio are the risk factors for death. Androgens show various changes during the course of sepsis that differ between survivors and nonsurvivors groups. Those changes might be used for more thorough assessment of septic patients. However, the role of androgens in severe infection still needs in-depth explanation. Our better understanding of the disease might help define the most time- and cost-effective regimens of sepsis management always having patients' health in mind.

INSM-1 – a new biomarker in the differential diagnosis of adrenal tumor lesions – a preliminary study

Alicja Szatko[1,2], Dorota Leszczynska[3], Urzula Ambroziak[4], Michał Łomiak[3], Malgorzata Bobrowicz[4], Lucyna Papierska[3], Wojciech Zgliczyński[3] & Piotr Glinicki[1,2]
[1]Centre of Postgraduate Medical Eduction, EndoLab Laboratory, Warsaw, Poland; [2]Centre of Postgraduate Medical Eduction, Department of Endocrinology, Warsaw, Poland; [3]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [4]Medical University of Warsaw, Department of Internal Medicine and Endocrinology, Warsaw, Poland

Introduction
Diagnosis of adrenal tumors is based on various diagnostic tests: determination of hormone levels, biomarkers, performance of various functional tests, molecular tests, imaging studies, pathomorphological studies, etc., which are useful at various stages of the diagnostic and therapeutic process. Biochemical studies focus on the search for new biomarkers in the blood, that could be useful for differential diagnosis of neoplastic lesions in adrenal glands (benign / malignant, hormonally active / inactive lesions). INSM-1 (Insulinoma-associated protein 1) is a new neuropeptide that may have applications in oncological endocrinology. The peptide is produced in endocrine and neuroendocrine cells of the human body. The goal of this project was to initially evaluate the usefulness of INSM-1 in the differential diagnosis of adrenal tumors and PGL tumors.
Materials and methods
The study included 104 patients with various adrenal tumors and PGL (mean age 52 years, 94 females): 30 MACS, 12 CS, 3 ACC, 9 PA, 10 Myolipoma, 7 PHEO, 30 NFAA and 3 PGL. Diagnosis of individual tumors was made within current guidelines and confirmed by postoperative testing and/or drug treatment. Plasma INSM-1 levels were determined by ELISA immunoassay in all patients.

Results
In the groups studied (MACS, CS, ACC, PA, Myolipoma, PHEO and PGL), the sensitivity and specificity rates of the biomarker INSM-1 were determined. In MACS, the sensitivity and specificity rates were 77% and 57%, respectively, while in Cushing's syndrome they were 58% and 37%. In tumors associated with aldosterone secretion (PA), the sensitivity and specificity of INSM-1 were 56% and 29%, while in adrenocortical carcinoma (ACC): 67% and 47%. In catecholamine-secreting tumors, the respective sensitivity and specificity rates were: PHEO 57% and 23%, while in PGL they were 67% and 40%. In benign myolipoma tumors, both rates were: 50% and 43%.
Conclusion
Preliminary studies have shown moderate usefulness of INSM-1 in the diagnosis of hypercortisolemia (MACS, ACC) in adrenal lesions and paraganglioma (PGL) tumors.

Endocrinological adverse effects of abiraterone acetate in the treatment of prostate cancer: Real-world prevalence

Carme Figueredo, Nerea Anton, Pol Candela, Mariona Estape, Karen Castillo, Felicia A Hanzu, Mireia Mora & Aida Orois
Hospital Clínic, Barcelona, Spain

Introduction
Abiraterone acetate (AA) is an approved treatment for advanced prostate cancer. As a CYP17A1 inhibitor, it suppresses adrenal androgen and cortisol biosynthesis, potentially leading to adrenal insufficiency (AI). In order to mitigate this risk, treatment regimens include prednisone (5 mg/day). Additionally, the accumulation of steroid precursors may, in some cases, result in mineralocorticoid excess syndrome (MES). However, real-world data on the incidence and management of endocrine adverse effects (EAE) associated with AA remain scarce.
Objectives
This study aimed to characterize the EAE associated with AA therapy, with a particular focus on MES, and to assess potential contributing factors to their development.
Materials and methods
We conducted a retrospective descriptive study of prostate cancer patients treated with AA, identified from the pharmacy dispensing registry at Hospital Clínic Barcelona (Spain) between January 1 and December 31, 2024. Clinical and biochemical parameters, medication use and cancer-related variables were analyzed.
Results
A total of 110 patients (mean age 74.9 years [range: 53–96], mean age at prostate cancer diagnosis 67 years [range: 49–94]) received AA during the study period. One confirmed case of MES (the only case referred to the Endocrinology Department) and nine probable but unconfirmed cases (characterized by new-onset or worsening hypertension, edema and three cases of hypokalemia) were identified, seven of which occurred within the first 12 weeks of treatment. No baseline or post-treatment aldosterone/renin measurements were available and cortisol was measured in only one case (3.2 µg/dl). No acute AI events were reported; however, two patients likely developed chronic AI after discontinuing AA due to disease progression (mean duration of AA and prednisone treatment: three months). Five deaths were recorded. No significant clinical or prognostic differences were observed between patients who developed probable ME and those who did not.
Conclusions
AA is an increasingly utilized agent in the management of prostate cancer, with potential EAE – including MES and AI – whose prevalence remains poorly characterized. Our findings contribute to the understanding of these adverse effects in a real-world setting. Recognizing and optimizing the preventive and therapeutic management of AA-associated EAE is essential to improving patient outcomes.

Diurnal pattern of secretion of cortisol, Aldosterone and 18-hydroxycortisol levels in four biological fluids in healthy volunteers

Adelina Ameti[1], Eder Zavala[2], Ali Gilani[3], Adamo Michela[1], Vionnet Nathalie[1], Raul Nicoli[4], Nicolas Niederlander[1], Paal Methlie[5], Thomas Upton[6], Adrian Ionescu[3] & Nelly Pitteloud[1]

[1]Centre Hospitalier Vaudois CHUV, Service of Endocrinology, Diabetology and Metabolism, Lausanne, Switzerland, [2]University of Birmingham, Department of Metabolism and Systems Science, Birmingham, UK, [3]EPFL, Nanoelectronic Devices Laboratory, Lausanne, Switzerland, [4]University of Lausanne, Swiss Laboratory for Doping Analyses, University Center of Legal Medicine, Lausanne, Switzerland, [5]University of Bergen, Department of Clinical Science, Bergen, Norway, [6]University of Bristol, Translational Health Sciences, Bristol, UK

Background
Cortisol, aldosterone, and 18-hydroxycortisol are key adrenal steroids involved in metabolism, fluids homeostasis, and stress responses. Their secretion follows complex diurnal and ultradian rhythms. Due to their rhythmicity, adrenal hormones analysis following a single time-point measurement provides limited information on the state of the HPA activity and fails to inform on the nadir to peak concentrations.
Objectives
The primary objective of the study was to compare and correlate concentrations of cortisol, aldosterone and 18-hydroxycortisol in saliva, sweat and interstitial fluid to plasmatic levels,. The secondary objectives were to investigate the circadian rhythm of steroid profiles, including cortisol, aldosterone and 18-OH cortisol, in healthy volunteers and assess the influence of physical activity and dietary intake on these profiles.
Methods
A prospective study of 8 healthy volunteers with repeated sampling of blood, ISF, saliva and sweat during a 27-hour period was conducted.
1) 24 h adrenal steroids profiles in blood, interstitial fluid, saliva and sweat were measured by liquid chromatography–tandem mass spectrometry and analyzed.
2) Influence of a moderate bout of exercise and of meals on Free cortisol, 18-hydroxycortisol, and aldosterone variations were also assessed.
Results
Cortisol displayed a clear circadian rhythm, peaking in the early morning (0600–0700 h) and declining at night, with a strong correlation between serum and ISF. Aldosterone, known to be regulated by the renin–angiotensin system, showed an unexpected strong correlation with cortisol, suggesting a stronger influence of ACTH than previously described. Further, peak of Aldosterone were depicted after lunch and exercise. Saliva showed good correlations with serum for cortisol. Sweat analysis was unreliable for aldosterone and 18-hydroxycortisol due to low detectability but showed some correlation with serum cortisol levels.
Discussion
Our findings confirm ISF as a promising biofluid for real-time cortisol monitoring, given its correlation with serum variations despite slight temporal shifts. The data also challenge the conventional understanding of aldosterone regulation, highlighting a significant ACTH influence as well as the impact of meals and exercise on aldosterone secretion. Finally, these results underscore the limitations of single-point hormone measurements.

Long-term impact of hypercortisolism on diabetes outcomes: A follow-up study

Baltagi Myriam, Ibtissem Ben Nacef, Sawsen Essayeh, Sabrine Mekni, Rihab Laamouri, Khiari Karima & Rojbi Imen
Hospital of Charles Nicolle, Tunis, Tunisia

Introduction
Chronic exposure to elevated cortisol levels in Cushing's syndrome (CS) is known to cause insulin resistance and hyperglycemia. While remission of CS often leads to improved glycemic control, some patients continue to experience persistent diabetes. This study aims to evaluate the long-term evolution of diabetes after the resolution of hypercortisolism.
Methods
A total of 22 patients previously diagnosed with CS were followed for an average of five years after achieving remission. Glycemic parameters, including fasting blood glucose (FBG) and glycated hemoglobin (HbA1c), were measured before and after treatment. In addition, insulin resistance (assessed using HOMA-IR) and beta-cell function (measured with HOMA-B) were evaluated. The occurrence of diabetes-related complications were also recorded.
Results
Most patients experienced a significant improvement in glycemic control following remission. On average, HbA1c decreased from 7.8% to 6.3% ($P=0.004$), and fasting blood glucose showed a similar decline. However, 41% of the patients (9 out of 22) remained diabetic five years after remission, with a mean HbA1c of 7.2% ($\pm$1.1%). This group displayed higher baseline cortisol levels ($P=0.02$) and greater insulin resistance (HOMA-IR: 4.1$\pm$0.9 vs. 2.3$\pm$0.7,

$P=0.01$) compared to patients who regained normoglycemia. Beta-cell function was also significantly lower in these patients (HOMA-B: 49.5±13.6 vs. 76.8±14.2, $P=0.03$). Among those with persistent diabetes, 33% developed microvascular complications, including two cases of diabetic neuropathy, one case of nephropathy, and one case of early-stage retinopathy.
Discussion
These findings suggest that although remission of Cushing's syndrome leads to significant improvements in glucose metabolism, a subset of patients continues to experience long-term metabolic dysfunction. The persistence of diabetes may be due to the prolonged effects of hypercortisolism on insulin sensitivity and pancreatic beta-cell function. Chronic exposure to high cortisol levels may induce irreversible metabolic changes, predisposing some patients to ongoing hyperglycemia despite normalization of cortisol levels.
Conclusion
This study highlights the importance of long-term metabolic follow-up in patients recovering from Cushing's syndrome. While many patients experience an improvement in glycemic control, a significant proportion remains at risk for persistent diabetes and associated complications. Identifying these patients early and implementing targeted interventions, such as lifestyle modifications and pharmacological treatment, may help mitigate the long-term consequences of hypercortisolism on glucose metabolism. Further research is needed to better understand the underlying mechanisms and to develop optimized management strategies for this patient population.

Triple a syndrome: phenotypic and genotypic diversity and a novel AAAS gene variant

Sabina Sharifova Mirzayev[1], Cansu Koc[1], Melek Yildiz[1], Asli Derya Kardelen Al[1], Ayca Aslanger[2], Volkan Karaman[2], Sukran Poyrazoglu[1], Firdevs Bas[1] & Feyza Darendeliler[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Department of Pediatric Endocrinology, Istanbul, Türkiye, [2]Istanbul University, Istanbul Faculty of Medicine, Department of Medical Genetics, Istanbul, Türkiye

Objective
Triple A syndrome (Allgrove syndrome), is a rare autosomal recessive disorder, characterized by achalasia, alacrima, and adrenal insufficiency due to adrenocorticotropic hormone (ACTH) resistance. This study aims to evaluate the phenotypic and genotypic characteristics of patients with Triple A syndrome.
Methods
This retrospective study included data from 10 patients from 7 families who were followed in the pediatric endocrinology clinic between 1996 and 2024. Demographic information, clinical findings, biochemical and genetic results of the patients were collected from their medical records.
Results
Ten patients (M/F=7/3) with a median age of 11 (range: 6–35) years were included. Consanguinity rate was 71% among 7 families. Alacrima was detected in all cases, while adrenal insufficiency and achalasia were observed in 9 patients (90%). Adrenal insufficiency and achalasia presented between 2–8 and 1.5–17 years of age, respectively. Additional clinical findings included mineralocorticoid deficiency (40%), epilepsy (40%), short stature (40%), osteoporosis (10%), osteopenia (10%), hypogonadotropic hypogonadism (10%), cryptorchidism (10%), anal atresia (10%), and congenital hip dysplasia (10%). Ectodermal and autonomic features included dry skin (60%), dry mouth (30%), hyperhidrosis (50%), and multiple dental caries (90%). Neurological findings included hyperreflexia (50%), quadriplegia (10%), speech delay (50%), mild intellectual disability (40%), and severe intellectual disability (10%). Dysmorphic features such as deep-set eyes, down-slanting palpebral fissures, prominent and large ears, pectus excavatum, arachnodactyly, and joint hyperextensibility were observed, along with thenar and hypothenar atrophy (40%). Genetic analysis identified the previously reported homozygous frameshift mutation c.1066_1067del (p.Leu356fs*) in the *AAAS* gene in 6 cases from 3 families. Despite having same mutation, two siblings from the same family exhibited phenotypic variability, with one not developing adrenal insufficiency. In another family, adrenal insufficiency and achalasia onset varied among affected siblings. One case had a 46,XY,inv(9)(p11q13) karyotype. Additionally, a novel pathogenic variant, c.145C>T (p.Gln49), was identified in the *AAAS* gene, leading to premature termination of the ALADIN protein. Notably, the coexistence of anal atresia, congenital hip dislocation, osteoporosis, hypogonadotropic hypogonadism, cryptorchidism, and dysmorphic features associated with this mutation has not been previously reported in the literature, suggesting a potentially unique phenotypic spectrum.
Conclusion
Phenotypic variability and genetic diversity in Triple A syndrome are noteworthy. The novel AAAS gene mutation is believed to cause a loss of ALADIN protein function, expanding the genetic spectrum of Triple A syndrome. This study highlights the critical importance of genetic analysis, particularly in patients presenting with core symptoms such as alacrima and adrenal insufficiency.

Reliability of morning cortisol in predicting the recovery of hypothalamic–pituitary–adrenal (HPA) axis in patients with glucocorticoid induced adrenal insufficiency

Prethivan Pillai Gopalakrishnan[1], Alan Mitan[1,2], Helmine Kejem[1], Katie Goodier[1], Muhammad Khan[1] & Sravan Thondam[1]
[1]Aintree University Hospital, Liverpool, UK, [2]Wirral University Teaching Hospital NHS Foundation Trust (WUTH), Endocrinology and Diabetes, Liverpool, UK

Introduction
Glucocorticoids (GC) are widely used in managing chronic inflammatory conditions. Long-term exposure to GC leads to HPA axis suppression. Recovery of HPA axis is highly variable among patients and often Short Synacthen test (SST) is used in standard practice to assess HPA axis and to assist wean off glucocorticoids. This test requires a day care investigation unit and has cost implications. The joint clinical guideline by European Society of Endocrinology and Endocrine Society published in May 2024 addresses the management of this condition. Our aim was to assess the applicability of criteria suggested in the guideline to our patient population, accepting there is variability in cortisol assays.
Method
This is a retrospective study of 48 patients with GC induced adrenal insufficiency who underwent outpatient morning SST (IM tetracosactide 250 µg) at Aintree University Hospital, Liverpool, UK from February 2022 to January 2024. Pass result for SST (HPA axis recovery) was determined as 30-minute cortisol ≥ 450 nmol/l. We use a competitive immunoassay (electrochemiluminescence – Roche Gen 2) for cortisol measurements.
Results
There was a significant and strong positive relationship between morning cortisol and 30-min cortisol on SST (rs[46]=0.82, P-value<0.001). Statistically significant difference (P-value<0.001) was observed in the 0900 h cortisol of those patients who passed SST (median 308 nmol/l) compared to those who failed (median 154 nmol/l). Morning cortisol >300 nmol/l is more likely to predict HPA axis recovery (P-value< 0.001, Specificity 96%, PPV 92%). Meanwhile morning cortisol of <150 nmol/l is highly likely to predict adrenal insufficiency (P-value=0.001, Specificity 95%, PPV 93%). Among patients with morning cortisol between 150 and 300 nmol/l, there was no significant difference noted as 59% failed SST and 41% passed the SST.
Conclusion
Our study shows a linear relationship between morning cortisol and 30-minute cortisol on SST and the likelihood of passing the SST. This supports the guideline's emphasis to interpret 0900 h cortisol as a continuum with higher values are more indicative of HPA axis recovery. Morning median cortisol in our study was significantly different in those who passed SST compared to those who failed. They were very reflective of the cut offs values suggested in the guideline. Morning cortisol threshold >300 nmol/l and <150 nmol/l were statistically significant in our study to predict HPA axis outcome with high specificity and positive predictive values. SST use may therefore be limited for selective patients with borderline cortisol results needing GC withdrawal soon based on their clinical needs.

WES as a Tool for Differential Diagnosis of Adrenal Insufficiency in Sudanese Children

Chris Smith[1], Mohamed Abdullah[2,3], Samar Hassan[2], Luqman Fauzi[1], Younus Qamar[1], Charlotte Hall[1], Saptarshi Maitra[1], Avinaash Maharaj[1],

Lucia Marroquin Ramirez[1], Jordan Read[1], Li Chan[1], Salwa Musa[2,4] & Louise Metherell[1]
[1]Centre for Endocrinology, William Harvey Research Institute, Queen Mary University of London, London, UK, [2]Department of Paediatric Endocrinology and Diabetes, Gaafar Ibn Auf paediatric Tertiary Hospital, Khartoum, Sudan, [3]Department of Paediatrics, Faculty of Medicine, University of Khartoum, Khartoum, Sudan, [4]Department of Paediatrics and Child Health Faculty of Medicine, Al-Neelain University, Khartoum, Sudan

Studies of adrenal insufficiency (AI) in African children are rare and diagnosis is challenging, especially in resource limited settings where biochemical and genetic testing are restricted. We describe the genetic characterisation of a cohort of Sudanese children, identifying founder effects and commonly mutated genes that will improve their treatment, expand our knowledge of AI, and expedite diagnosis of future patients. 48 patients from 43 families (31M:17F) with presentation of AI paired with biochemical finding of low cortisol ± high ACTH were included in this study. Exclusion criteria were clinical and/or genetic diagnosis of CAH or Triple A syndrome. Additional co-morbidities observed in some patients included white matter changes, muscular dystrophy, gait abnormalities, cataracts, obesity, and deafness. Whole exome sequencing (WES), copy number variation analysis (CNV), variant prioritisation (Exomiser/QCI) and splice predictions (SQUIRLS) were performed as a genetic diagnostic pipeline. Variants were confirmed by Sanger sequencing and possible splicing mutations were functionally assessed using the Exon Trap vector (MoBitech). Genetic diagnosis was achieved for 26/43 families, with mutations in *ABCD1* (7), *NNT* (5), *AIRE* (3) the most affected genes. CNV analysis identified a *CYP11B1-2* fusion event and a deletion incorporating 5-exons of *AIRE*, and 2 downstream genes. This *AIRE* deletion was identified in 2 unrelated families and 3 patients from 2 families had a splicing defect in *NNT* (c.9193G>A) which resulted in partial exon skipping. Incidental findings in *MC4R*, *ADGRV1*, and *CNDP1* are likely to be causative of the obesity, cataracts and deafness, and abnormal gait respectively observed in patients. This study has not only diagnosed 60% of our Sudanese cohort but also identified commonly mutated genes and 2 possible founder effects. Sanger sequencing of bespoke candidate genes might provide a cheaper alternative, increase, and hasten the diagnosis rate of at-risk patients in resource limited settings.

Cognitive function worsens with increasing age and glucocorticoid dose in classical congenital adrenal hyperplasia due to 21-hydroxylase deficiency

Nozomi L Yamashita[1], Edwin A Deras[1], Sharon H O'Neil[2,3], Ginger Simon[1], Sophia Dettweiler[1], Benjamin Hoffman-Kipp[1], Adriana Mockler[1], Mitchell E Geffner[1,2] & Mimi S Kim[1,2]
[1]Children's Hospital Los Angeles, Division of Endocrinology, Diabetes and Metabolism, Los Angeles, United States, [2]The Saban Research Institute of Children's Hospital Los Angeles, Los Angeles, United States, [3]Children's Hospital Los Angeles, Division of Neurology, Los Angeles, United States

Background
Classical congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency (21OHD) is the most common cause of primary adrenal insufficiency in youth resulting in impaired cortisol synthesis and excess androgen exposures starting *in utero*. Children with CAH exhibit increased risk for developmental delay compared to unaffected children. As well, adolescents and adults exhibit differences in cognitive function including decreased reward-based inhibitory control and working memory. However, more needs to be understood about how clinical factors (e.g., treatments and disease severity) in CAH affect cognitive function from early childhood through adulthood. Thus, we aimed to investigate the connection between cognitive function, age, glucocorticoid dose, and genotype-based severity in patients with CAH.
Methods
A cross-sectional study through various stages of development was performed in 56 patients (4–23 years; 11.7±5.4 years, 55% female) with classical CAH due to 21OHD. All patients completed iPad-based testing of cognitive function (NIH ToolBox Cognition Battery) including: inhibitory control (Flanker), cognitive flexibility (Dimensional Change Card Sort), and working memory (List Sort). Patients were compared to a normative population mean of 100 utilizing Welch's *t* test. Within the CAH group, Pearson's correlations between cognition scores and age or glucocorticoid dose (mg/m^2 per day) were analyzed. Disease severity was categorized by *CYP21A2* genotype ($n=38$): Null (0% enzyme activity including deletions, large gene conversions; $n=18$) and Non-Null (category A: <1% enzyme activity, $n=15$; category B: 1–2% enzyme activity, $n=5$). Data are presented as mean ± S.D..
Results
Overall, inhibitory control (90.9±16.3), cognitive flexibility (95.0±18.5), and working memory scores (94.6±11.6) were lower in patients with CAH compared to normative mean (P's<0.05). Within the CAH group, inhibitory control ($R=-0.7$) and cognitive flexibility ($R=-0.4$) scores were inversely correlated to age (P's<0.01). In addition, inhibitory control ($R=-0.6$) and cognitive flexibility ($R=-0.5$) scores were inversely correlated to glucocorticoid dose (P's<0.01). Finally, inhibitory control was lower in Null (87.3±14.0) vs Non-Null (103.6±21.2, $P<0.01$) patients.
Conclusion
Our findings suggest that patients with CAH have worse inhibitory control and cognitive flexibility scores compared to unaffected individuals, that is also seen with increasing age and glucocorticoid dose. In addition, inhibitory control scores are lowest in those most severely-affected (Null genotype). Thus, it is important to consider the effects of clinical factors inherent to CAH on cognitive function throughout the lifespan.

Evaluation of the metabolic impact of modified-release hydrocortisone in patients with congenital adrenal hyperplasia: an observational cohort study

Pierluigi Mazzeo[1,2], Irene Tizianel[1,2], Giulia Bovo[1,2], Chiara Sabbadin[1,2], Alessandro Bavaresco[1,2], Filippo Ceccato[1,2] & Mattia Barbot[1,2]
[1]Endocrinology unit, Padova University Hospital, Padua, Italy, [2]Department of Medicine-DIMED, University of Padova, Padua, Italy

Background
Congenital adrenal hyperplasia (CAH) is a genetic disorder characterized by impaired cortisol secretion and androgen excess. The mainstay of CAH treatment is glucocorticoid (GC) replacement, necessary to avoid adrenal crises and manage androgen excess. The delicate balance between GC under- and overtreatment is crucial to prevent metabolic and cardiovascular (CV) complications. The modified-release hydrocortisone (MRHC) formulation seems to improve hormonal control; however, there are few data on its metabolic impact.
Aim of the study
Evaluate the hormonal control and metabolic impact of MRHC treatment in patients with CAH.
Patients and methods
31 patients with CAH due to 21OH-deficiency (median age 28years) were included; clinical, metabolic and hormonal data were analyzed at baseline and after 6 and 12 months since MRHC switch. At baseline 10 patients were on long half-life GC treatment, 21 on immediate/dual-release hydrocortisone.
Results
During MRHC, there was a significant improvement in hormonal control, with a reduction in 17-OH-progesterone levels (median values: 474 nmol/l vs 61.5 nmol/l at 12 months, $P<0.001$) and androstenedione levels (22.2 nmol/l vs 10.7 nmol/l, $P<0.001$). Additionally, was observed a decrease in total testosterone in women (3.1 nmol/l vs 1.4 nmol/l, $P=0.001$) and an increase in the proportion of patients with good disease control (women 17% at baseline vs 36% at 12 months, $P=0.030$; men 23% vs 63%, $P=0.018$). Notably, there was a significant worsening in the lipid profile, with increases in total cholesterol (162 mg/dl vs 176 mg/dl at 12 months, $P=0.026$), LDL (90 mg/dl vs 104 mg/dl, $P=0.009$), and homocysteine levels (10.1 μ mol/l vs 12.6 μ mol/l, $P=0.044$) with only a slight improvement of triglycerides (70 mg/dl vs 59 mg/dl, $P=0.006$). Moreover, systolic ABP decreased in patients receiving long half-life GC therapy at baseline (125 mmHg vs 121 mmHg at 12 months, $P=0.007$). When assessing the CV risk profile, we observed a slight improvement in the VAI score, but no changes in the SCORE2, with 5 out of 11 patients remaining at high risk. No adrenal crises were reported and one patient discontinued MRHC due to insomnia.
Conclusions
MRHC was shown to improve hormonal control while maintaining a good safety profile. However, since patients with CAH are known to have a higher CV risk, the worsening of certain parameters should not be underestimated, although the clinical relevance of these findings requires further evaluation. In conclusion, we recommend evaluating the overall impact of available therapies to better tailor treatment for each patient.

Active steroidogenesis increases the vulnerability of human adrenocortical cells to SARS-CoV-2 infection

Waldemar Kanczkowski[1], Marlena Schlecht[2], Thomas Kurth[3], Marleen Hohnvehlmann[1], Agnès Wlodarczyk[1], Felix Beuschlein[4] & Stefan R Bornstein[1]

[1]Department of Internal Medicine III, University Hospital Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany, [2]Division of Nephrology, Department of Internal Medicine III, University Hospital Carl Gustav Carus at the Technische Universität Dresden, Dresden, Germany, [3]Center for Molecular and Cellular Bioengineering (CMCB), Technology Platform, Technische Universität Dresden, Dresden, Germany, [4]Klinik für Endokrinologie, Diabetologie und Klinische Ernährung, Zürich, Switzerland

Background
The COVID-19 pandemic, induced by infection with severe acute respiratory syndrome coronavirus 2 (SARS–CoV-2), resulted in a significant health burden worldwide. Previously, we demonstrated that SARS–CoV-2 could target human adrenal glands, increasing parenchymal inflammation and necrosis. However, little is known about the mechanisms that facilitate SARS–CoV-2 infection of adrenocortical cells and whether this coronavirus can directly affect the function of these cells.
Objectives
The current study examined the mechanisms involved in SARS–CoV-2 infection of adrenal cells. Furthermore, we investigate the hypothesis that COVID-19 conditions may alter the susceptibility of individual human adrenocortical cells to SARS–CoV-2 infection by affecting their entry receptors.
Methods
To this end, we infected the human adrenocortical cell line, NCI-H295R, with various strains of SARS–CoV-2 and compared the efficiency of infection through nucleocapsid staining and ultrastructural analysis of the infected cells. Moreover, we sought evidence of active replication and production of new viral particles in the adrenal cells using an additional plaque-forming assay. Finally, we induced steroidogenesis in the adrenal cells with forskolin (FSK) and examined its effects on the expression of SARS–CoV-2 receptors, infection efficiency, and coronavirus replication.
Results
Our results demonstrated that human adrenal cells are susceptible to coronavirus infection and support its replication. FSK activation of adrenal glucocorticoid production enhanced susceptibility, replication, and SARS–CoV-2 production in NCI-H295R cells. The latter was associated with increased expression of the primary SARS–CoV-2 entry receptor, ACE2, which involved the cAMP-PKA pathway. Furthermore, we observed that SARS–CoV-2 infection induced necroptosis and apoptosis in both infected and bystander cells.
Conclusions
To summarise, our results indicate that human adrenocortical cells are differentially affected by SARS–CoV-2 and that alterations in ACE2 expression, as demonstrated in the case of FSK-mediated steroidogenesis, may influence their susceptibility to coronavirus infection. Moreover, when supported by clinical evidence, this finding could elucidate the increased risk of complications in patients with GC overproduction, including those suffering from Cushing's syndrome.

Assessment of the association between cardiometabolic index (CMI) and metabolic dysfunction-associated steatotic liver disease (MASLD): A systematic review and meta-analysis

Alireza Azarboo[1], Amin Javidan[1], Parisa Fallahtafti[1], Sayeh Jalali[1] & Amir Anushiravani[2]

[1]School of Medicine, Tehran University of Medical Sciences, Tehran, Iran, [2]Associate Professor of Gastroenterology and Hepatology, Hepatopancreatobiliary Research Center, Digestive Diseases Research Institute, Tehran University of Medical Sciences, Tehran, Iran

Background
Metabolic dysfunction-associated steatotic liver disease (MASLD) is an emerging global health challenge, with cardiovascular mortality as its leading cause of death. The cardiometabolic index (CMI), a novel biomarker derived by multiplying the waist-to-height ratio (WHtR) with the triglyceride-to-high-density lipoprotein cholesterol (TG/HDL-C) ratio, shows promise as a predictive tool for MASLD. This study aims to systematically evaluate the association between CMI and MASLD.
Methods
We performed a systematic review and meta-analysis adhering to PRISMA guidelines. A comprehensive search of PubMed, Scopus, Embase, and Web of Science was conducted up to January 2025. Studies reporting the association between CMI and MASLD in adults were included. Effect sizes, odds ratios (OR), and standardized mean differences (SMD) were pooled. Heterogeneity was assessed using I^2, and publication bias was evaluated via Egger's test. Sensitivity analyses and meta-regressions explored sources of heterogeneity.
Results
Seven studies with 41,122 participants were included. Individuals with MASLD had significantly higher CMI (SMD [95%CI] $=1.24$ [1.00, 1.48]; $I^2=98.1\%$). Studies with higher smoking prevalence, female proportion, elevated FBG, SBP, DBP, TG, and AST levels, and lower TC and HDL levels showed a lower SMD of CMI in MASLD compared to non-MASLD patients, while meta-regression indicated that age, BMI, WC, ALT, and LDL were not significant sources of heterogeneity. Each 1-SD increase in CMI was associated with roughly 2-fold higher odds of MASLD (OR [95%CI] $=2.33$ [1.78, 3.04]; $I^2=96.8\%$). Patients in the highest CMI quartile had substantially greater odds of MASLD compared to the lowest quartile (OR [95%CI]$=7.44$ [4.28, 12.95]; $I^2=91.8\%$). The pooled area under the curve (AUC) for CMI in predicting MASLD was 0.82 (95%CI: 0.80–0.84).
Conclusion
CMI emerges as a non-invasive predictor of MASLD with elevated levels serving as an early indicator for identifying individuals at risk, even before significant liver fat accumulation occurs. Its strong association with liver fibrosis underscores the importance of identifying and managing elevated CMI to slow disease progression and prevent complications such as cirrhosis or hepatocellular carcinoma. Furthermore, emerging therapies for MASLD not only reduce liver fat but also improve CMI components, highlighting its potential as a marker for treatment response. Future research should focus on refining CMI cut-off values and validating its applicability across diverse populations.

Keywords: Cardiometabolic index, MASLD, Non-invasive biomarker

Is the 18 ng/ml cortisol cut-off at the 1 mg overnight dexamethasone suppression test effective with routine immunoassays? Comparison with LC–MS/MS

Laura Rotolo[1,2], Greta Galante[2,3], Kimberly Coscia[1,2], Valentina Bissi[2,3], Lorenzo Tucci[1,2], Marco Mezzullo[2,3], Alessandra Gambineri[1,2], Valentina Vicennati[1,2], Guido Zavatta[1,2], Uberto Pagotto[1,2,3], Guido Di Dalmazi[1,2,3] & Flaminia Fanelli[2,3]

[1]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, [2]Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, Italy, [3]Center for Applied Biomedical Research, Department of Medical and Surgical Sciences, Alma Mater Studiorum University of Bologna, Bologna, Italy

Background
The dexamethasone suppression test (DST) is essential for assessing hypercortisolism. The cut-off of normal cortisol response after DST was set at 18 ng/ml by an extractive radioimmunoassay in 1989. Since then, poor accuracy and reproducibility were documented for non-extractive automated immunoassays used in routine laboratories. The influence of automated immunoassay performance on assessment of hypercortisolism remains under-investigated. Liquid chromatography–tandem mass spectrometry (LC–MS/MS) is recommended for accurate and sensitive steroid measurement.
Aim
To compare cortisol measurements from two automated immunoassays with LC–MS/MS in paired sera collected at baseline and after DST. To evaluate immunoassay performance in detecting hypercortisolism by the DST.
Methods
We included 477 patients with suspected hypercortisolism or adrenal incidentalomas. Cortisol was measured by Elecsys gen I in 260 (cohort 1), and by Access in 217 (cohort 2) subjects. All samples were measured by a validated LC–MS/MS method. We compared cortisol measurements in all samples between immunoassays and LC–MS/MS, estimated the prevalence of hypercortisolism according to the established cut-off for cortisol after DST (18 ng/ml) with each method, and performed ROC analyses to determine ideal immunoassay-specific cut-off.
Results
Elecsys gen I measurements were 32.5% and 6.1% higher, whereas Access measurements were −4.7% and −5.9% lower than LC–MS/MS in basal and

post-DST samples, respectively. Considering the cut-off of 18 ng/ml, Access determined a lower prevalence of hypercortisolism than LC–MS/MS in the overall cohort 2 (30.4 vs 36.4%, respectively; $P=0.001$); similar results were obtained for Elecsys gen I only within the adenoma subgroup of cohort 1 ($n=112$, 26.8 vs 34.8%, respectively; $P=0.049$). Using LC–MS/MS as the reference, Elecsys gen I determined 3.8% possible false positives and 6.9% possible false negatives in cohort 1. In cohort 2, Access caused 0.5% possible false positives and 6.4% possible false negatives. Accordingly, sensitivity and specificity were 79.6 and 94.2% for Elecsys gen I in cohort 1, and 82.3 and 99.3% for Access in cohort 2, respectively. Ideal hypercortisolism screening effectiveness was obtained at 15 ng/ml for Elecsys gen I (sensitivity: 97.7%; specificity: 80.8%), and 12 ng/ml for Access (sensitivity: 97.5%; specificity: 78.3%).

Conclusions

We observed a variable performance between different immunoassays and sampling conditions. In basal samples, Elecsys gen I largely overestimated cortisol levels, whereas Access was accurate. In post-DST samples, both determined a remarkable under-detection of hypercortisolism when using the recommended 18 ng/ml cut-off. We provided novel immunoassay-specific cut-offs. However, LC–MS/MS should be preferred to improve DST specificity and to establish harmonized cut-off.

JOINT1711

Harmonization of serum cortisol methods for dynamic testing

Jacquelien Hillebrand[1,2], Annemieke Heijboer[1,2,3], Judith Bons[4] & Antonius van Herwaarden[5]

[1]Amsterdam UMC, University of Amsterdam, Department of Laboratory Medicine, Endocrine Laboratory, Amsterdam, Netherlands, [2]Amsterdam Gastroenterology, Endocrinology & Metabolism, Amsterdam, Netherlands, [3]Amsterdam UMC, Vrije Universiteit, Department of Laboratory Medicine, Endocrine Laboratory, Amsterdam, Netherlands, [4]Maastricht University Medical Center+, Department of Clinical Chemistry, Central Diagnostic Laboratory, Maastricht, Netherlands, [5]Radboud University Medical Center, Department of Laboratory Medicine, Nijmegen, Netherlands

Background

Dynamic tests are used in diagnosis and follow-up of endocrine disorders. Unfortunately, there is considerable variation in how these tests are performed, including the patient preparation and analytical methods used with different standardization. Despite these differences, the interpretation of dynamic tests is often based on fixed cut-off values. The (pre-)analytical variability means that dynamic test results are not similar between medical centers, leading to confusion and treatment delay. Dynamic testing for adrenal insufficiency or Cushing's syndrome includes measuring serum cortisol. Our aim is to explore whether the different serum cortisol methods used can be harmonized to improve the interpretation of dynamic tests.

Methods

Blood was collected from 45 participants. Females ($n=23$) were not using oral contraceptives. Sera were aliquoted, frozen and sent to 25 Dutch laboratories. Serum cortisol was measured using in-house LC–MS/MS ($n=5$), Roche Cobas ($n=4$), Siemens Atellica/Centaur ($n=6$), Beckman Coulter DxI/Access ($n=5$) and Abbott Architect/Alinity ($n=5$) cortisol assays. One of the LC–MSMS methods was checked against the IFCC Cortisol Reference serum Panel and set as the expert method. Passing-Bablok regression analyses were performed and within method variation was determined. Maximum allowable imprecision was set at 8%.

Results

Cortisol measurements in laboratories using the same cortisol assay showed an imprecision of $<8\%$ except for the Beckman Coulter assay (31% of samples $>$ 8%). Regression analyses showed good agreement between the LC–MS/ MS, Roche and Beckman Coulter and the expert method (slope 1.02, 0.99, 1.00 and intercept 1.1, 1.8, -7.0 nmol/L respectively), and slightly less for Abbott (slope 0.93, intercept 8.8 nmol/L). The Siemens assay showed significant deviation in slope (1.40) and intercept (-35 nmol/L).

Conclusions

This study shows that LC–MS/MS assays and Roche cortisol assays are well standardized and that harmonization is not necessary. Harmonization is possible for the Abbott assay whereas the Siemens assay requires re-standardization. The Beckman Coulter assay shows a high within–method variation that first needs improvement. Standardization or harmonization of serum cortisol assays along with aligning the preanalytical workup will pave the way for uniform interpretation of dynamic testing.

Prevalence and causes of negative genetic testing results in clinically diagnosed congenital adrenal hyperplasia: A research summary

Ashraf Soliman[1], Dina Fawzy[2], Shayma Ahmed[1], Ahmed Elawwa[1], Fawzia Alyafei[1] & Noor Hamed[1]

[1]Hamad Medical Corporation, Doha, Qatar, [2]Alexandria University Children's Hospital, Alexandria, Egypt

Background

Congenital adrenal hyperplasia (CAH) is an autosomal recessive disorder commonly caused by mutations in the CYP21A2 gene, leading to 21-hydroxylase deficiency. While genetic testing is pivotal in diagnosing and managing CAH, a substantial proportion of clinically diagnosed cases return negative results, posing challenges for accurate diagnosis and treatment. Understanding the prevalence and underlying causes of these negative results is crucial for advancing diagnostic strategies.

Objectives

This review aims to evaluate the prevalence of negative genetic testing results in clinically diagnosed CAH cases and explore the genetic, technical, and methodological factors contributing to these outcomes.

Methods

A systematic review of 12 studies (1999–2024) encompassing over 2,000 patients was conducted. Data on genetic testing results, prevalence of negative findings, and identified causes were extracted. Studies utilized techniques such as whole-genome sequencing (WGS), multiplex ligation-dependent probe amplification (MLPA), and PCR-based sequencing to investigate mutations in CYP21A2 and related genes.

Results

The prevalence of negative genetic testing in clinically diagnosed CAH cases ranged from 14.4% to 44%. Common causes included:

- Complex genetic architecture: High-sequence homology between CYP21A2 and its pseudogene CYP21A1P, leading to gene conversions and undetectable mutations (Doleschall et al., 2017; Belyeu et al., 2023).
- Technical limitations: Insufficient coverage of testing panels, inability to detect large structural rearrangements, and low sensitivity of standard sequencing methods (Mireia Tondo et al., 2021; Marino et al., 2011).
- Rare or novel mutations: Variants outside commonly tested regions and mild phenotypes contributing to undetected cases (Krone et al., 2013; Ohlsson et al., 1999).
- Population-specific variations: Regional genetic heterogeneity, such as RCCX copy number variations in certain populations (Umaña-Calderón et al., 2021; Dina Fawzi et al., 2023).

Discussion

High-sequence homology and structural complexity in the CYP21A2 gene region remain significant challenges. Emerging techniques like advanced WGS and targeted software tools (e.g., DRAGEN) demonstrate improved sensitivity for small variants and rearrangements. However, access to these technologies is limited in many settings. Novel diagnostic strategies integrating MLPA, PCR, and computational tools are crucial for accurate genotyping in complex cases.

Conclusion

Negative genetic testing in CAH reflects a combination of genetic complexity and technical limitations. Addressing these gaps through advanced diagnostic technologies and comprehensive testing panels is essential for improving diagnostic accuracy, treatment outcomes, and genetic counseling. Future research should focus on refining testing methodologies and exploring the clinical relevance of novel mutations.

Friedreich ataxia and impaired steroidogenesis

Ozge Bayrak Demirel[1], Ceyda Oney Yilmaz[2], Sinan Akbas[3], Tugce Kandemir[1], Ayca Dilruba Aslanger[3], Asli Derya Kardelen Al[1], Hulya Maras Genc[2], Melek Yildiz[1], Edibe Pembegul Yildiz[2], Sukran Poyrazoglu[1], Feyza Darendeliler[1] & Firdevs Bas[1]

[1]Istanbul University, Istanbul Faculty of Medicine, Department of Pediatric Endocrinology, Istanbul, Türkiye, [2]Istanbul University, Istanbul Faculty of Medicine, Department of Pediatric Neurology, Istanbul, Türkiye, [3]Istanbul University, Istanbul Faculty of Medicine, Department of Medical Genetics, Istanbul, Türkiye

Introduction

Friedreich ataxia (FA) is an autosomal recessive disorder caused by an expansion of GAA repeats in the *FXN* gene, leading to impaired iron-sulfur (Fe-S) cluster

biosynthesis and mitochondrial dysfunction. Fe-S clusters are essential for the activity of type 1 enzymes (CYP11A1, CYP11B1, CYP11B2) involved in steroidogenesis. Animal models and human cell culture studies have demonstrated reduced testosterone and progesterone levels in FA, particularly in males, which has been associated with a more severe disease course. However, no clinical studies in humans have been reported to date. This study aims to investigate potential steroidogenesis abnormalities in patients with FA.
Methods
This retrospective study analyzed data from four FA patients aged 13–17 years (3 males, 1 female). Data were obtained from patient records, including pubertal stages, basal steroid hormone levels, and standard-dose ACTH stimulation test results.
Results
At Tanner stage 5, basal cortisol levels were near the lower limit in three patients (2 males, 1 female). Progesterone levels were below the detection limit (<0.2 ng/ml) in the same patients. Androstenedione and DHEA-S levels were within normal ranges for all patients. Standard-dose ACTH stimulation tests showed adequate cortisol responses in all cases. Total testosterone levels were low in two male patients (2.06 and 2.88 ng/ml; Tanner stage 5 lower limit: 3.5 ng/ml) and near the lower limit in the third (3.65 ng/ml). The female patient had a normal estradiol level (54 pg/ml) in the follicular phase.
Conclusions
Potential steroidogenesis abnormalities in FA are characterized by reduced progesterone levels and testosterone deficiencies, particularly in males. These findings align with experimental data suggesting that impaired Fe-S cluster biosynthesis affects the activity of type 1 steroidogenic enzymes. Despite low basal cortisol levels, adequate responses to ACTH stimulation suggest preserved adrenal reserve. The normal estradiol level in the female patient supports the hypothesis that these abnormalities may be sex-specific. Further studies with larger cohorts and advanced techniques such as LC–MS to analyze steroidogenesis intermediates are needed to better understand the impact of FA on steroidogenesis and gonadal function. Investigating the effects of testosterone therapy on disease severity in males with FA through clinical trials could provide valuable insights.

JOINT3334

Less for more? Outcomes of adrenal vein sampling over a 5-year interval from a single operator in a specialist referral centre

August Palma[1], James Macfarlane[1], Lihua Hu[1], Nicholas Hilliard[2] & Mark Gurnell[1]
[1]Cambridge University Hospitals NHS Foundation Trust, Endocrinology, Cambridge, UK, [2]Cambridge University Hospitals NHS Foundation Trust, Radiology, Cambridge, UK

Purpose
Primary aldosteronism (PA) is the leading cause of endocrine hypertension. Adrenal vein sampling (AVS) is the recommended technique in lateralising PA to distinguish unilateral from bilateral disease. The success of AVS guides clinicians in making informed decisions to manage and treat PA effectively. Successful AVS requires a technically-skilled and experienced interventional radiologist and global success rates vary between 41.1% and 99.2%. The aim of this study was to assess the success rate of AVS by a single operator in a single centre.
Methods
A retrospective, single-centre study of AVS procedures performed by a single operator between January 2020 and January 2025. Aldosterone and cortisol levels were measured on samples collected from the right and left adrenal veins and low inferior vena cava (IVC). Successful adrenal vein cannulation was defined as selectivity index (SI) >3 with adrenocorticotropic hormone (ACTH) stimulation ($n=110$), and SI >2 without ACTH stimulation ($n=2$).
Results
A total of 112 patients underwent AVS: 70 (62.5%) were men and 42 (37.5%) were women, with a mean age of 52 years (range 27–74). Bilateral adrenal vein cannulation was achieved in 103 of 112 (91.96%) AVS procedures. In patients in whom bilateral cannulation was not achieved, this was due to an inability to sample the right adrenal vein in all nine patients. In addition, two patients who had previously undergone adrenal/para-adrenal surgery on the left also underwent AVS, with successful cannulation of the right adrenal vein, but the left adrenal could not be located (likely consequent on the previous surgery).
Conclusion
We have shown that adopting a standardised approach to AVS with a single experienced operator can deliver high rates of technically successful procedures. Our findings are therefore consistent with earlier published series and support the case for concentrating delivery of AVS in high volume specialist referral centres.

JOINT2155

The follow up of 3 patients with apparent mineralocorticoid excess after 32 years

Maryam Razzaghy Azar
Iran University of Medical Sciences, H. Aliasghar Hospital, Endocrinology Department, Tehran, Iran

Background
Apparent mineralocorticoid excess (AME) is a genetic disorder. It is caused by deficiency of 11 beta-hydroxysteroid dehydrogenase type-2 (11βHSD2) enzyme activity in the kidney. 11βHSD2 is a member of the short-chain alcohol dehydrogenase family, catalyzes the NAD^+-dependent dehydrogenation of cortisol so, converts cortisol to inactive cortisone. Circulating level of cortisol is 100- to 1,000-fold higher than aldosterone and it can occupy mineralocorticoid receptor and causes hypertension and hypokalemia with low renin and aldosterone
Case report
In this report, the success and pitfalls of medical therapy with spironolactone in 2 sisters and one brother after 32 years are described. At the time of diagnosis, the eldest sister was 14.2-years old. She had blood pressure (BP) of 260/140 mmHg, hypokalemia, retinopathy and left ventricular hypertrophy, polyuria and urinary incontinence. The brother was 11.6-years old and had general paralysis with blood pressure (BP) of 170/110 mmHg and serum potassium of 2 mEq/L. The younger sister was 4.16-years old with BP of 160/100 mmHg and serum potassium was 3.2 mEq/L. She had headache and occasional abdominal pain. Spironolactone treatment resulted in normal blood pressure and serum potassium level in all of the patients. They have lost from follow up for a long time. After 32 years, the eldest sister is 46 years old now, has two daughters. At the age of 36 years in her second pregnancy, she discontinued the medicine by herself. So, reduced left ventricular function with mitral and tricuspid regurgitation and renal failure were developed after child birth and renal transplantation became necessary. It resulted in cure of AME but she should take Immunosuppressant medicines lifelong. The brother is 43 years old. He has regularly taken one tablet of spironolactone twice daily all the time and is in good health without any complication. He has one 10-year-old son. The younger sister is 36 years old. She has not taken her medicine correctly and sometimes discontinued medicine for some period, so is taking medicines for her heart and hypertension, by administration of a cardiologist in her city.
Conclusion
Early and continuous treatment with appropriate dosage of spironolactone can improve hypertension and hypokalemia of apparent mineralocorticoid excess without end organ damage.

JOINT3258

Clinical significance of mild autonomous cortisol secretion associated with primary aldosteronism

Maja Jelinić[1], Mirjana áukić[2], Annemarie Balasko[3], Hrvoje Popovac[3] & Karin Zibar Tomšić[4]
[1]Special hospital for medical rehabilitation Krapinske Toplice, Krapinske Toplice, Croatia, [2]General hospital "Dr. Ivo Pedišić", Department of internal medicine, Sisak, Croatia, [3]University hospital centre Zagreb, Department of endocrinology and diabetology, Zagreb, Croatia, [4]University hospital centre Zagreb, Department of endocrinology and diabetology, Zagr, Croatia

Introduction
Primary aldosteronism (PA) is the most common cause of secondary hypertension and a known risk factor for cardiovascular and metabolic disease (1). It may be associated with autonomous co-secretion of cortisol, which may represent an additional risk factor for the development of cardiovascular and possibly metabolic complications (2).
Materials and methods
We searched the database of patients with PA who underwent adrenal vein sampling (AVS) at the University Hospital Centre Zagreb between 2016 and 2024. The total of 140 patients were divided into two groups: patients with mild autonomous cortisol secretion (MACS) and those with normal cortisol in the overnight dexamethasone suppression test (ODST) or cortisol in 24-hour urine. MACS was defined as a cortisol finding in the ODST > 50 nmol/L or a cortisol finding in the 24-hour urine > 416 nmol. Of the total number of patients, 16% had MACS. We compared whether there was a statistically significant difference in metabolic parameters or cardiovascular outcomes in the two patient groups.
Results
Univariate analysis showed that there was a statistically significant difference between patients with MACS and those without MACS in the value of eGFR (89 vs. 95 ml/min per 1.73 m^2, $P=0.013$), in the use of hypolipemic medications (43% of

patients with MACS vs. 18% of patients without MACS, $P=0.007$) and in the occurrence of cerebrovascular disease (9% of patients with MACS vs. 0.9% of patients without MACS, $P=0.018$). A possible association with albuminuria was observed but needs to be further validated (57% of patients with MACS vs. 32% of patients without MACS, $P=0.073$). No significant differences in metabolic parameters or other cardiovascular outcomes were observed. In a binary logistic regression analysis after adjustment for age, cerebrovascular disease and lipid-lowering medication use, only lipid-lowering medication use was an independent predictor of MACS ($P=0.03$, OR 0.331, 95% CI 0.121–0.902).
Conclusions
MACS is associated with an increased incidence of cerebrovascular adverse events in patients with PA, while an increased incidence of albuminuria cannot be excluded either, which should be verified in a larger patient population.

Salt wasting in infancy: Pseudohypoaldosteronism type 1 secondary to a novel genetic mutation

Sabrina Sheridan[1], Marah Shaikh Yousef[1] & Niamh McGrath[1]
[1]University Hospital Galway, Department of Paediatrics, Galway, Ireland

Background
Pseudohypoaldosteronism type 1 (PHA1) is a rare, primary form of mineralocorticoid resistance. Infants typically present in the neonatal period with salt wasting, failure to thrive, dehydration and the biochemical findings of hyperkalaemia, metabolic acidosis and elevated plasma aldosterone and renin levels.
Case presentation
We report the case of an 18 day old male infant born to non-consanguineous parents at term with a birth weight of 3.68kg. He presented with poor feeding, lethargy and 11% weight loss. Biochemical investigations revealed severe hyponatraemia (118mmol/L) and hyperkalaemia (9.2mmol/L). He was normoglycaemic (4.3mmol/L) and had a normal pH (pH 7.37). He was initially treated for suspected congenital adrenal hyperplasia with intravenous fluids, stress dose intravenous hydrocortisone and treatment of hyperkalaemia. Broad spectrum antibiotics were commenced for suspected sepsis. His CRP was elevated at 223mg/L and his urine and blood cultures grew E. coli. He was treated with IV antibiotics for 14 days. His cerebrospinal fluid culture was negative. He was switched to oral hydrocortisone, fludrocortisone and sodium supplements and his electrolytes normalised within 24 hours (Na 135mmol/L and potassium 5.9mmol/L). His cortisol returned at 2219 nmol/L. His 17-hydroxyprogesterone (17OHP) also returned normal at 1.9 nmol/L (<20 nmol/L), ruling out a diagnosis of congenital adrenal hyperplasia. His medications were discontinued by day of life 30 as transient pseudohypoaldosteronism was suspected secondary to urosepsis. On weaning of these medications, his sodium dropped to 129mmol/L and his potassium rose to 6.2mmol/L, therefore treatment was restarted pending the results of further investigations. He had a significantly elevated aldosterone > 3656 pmol/L (102–670) and a raised direct renin 199.7mIU/L (9.0–103.5). As he required ongoing sodium supplementation despite resolution of his urosepsis, genetic testing was performed. He was successfully weaned off sodium supplements at 6 months of age and is currently 3 years of age with normal electrolytes off treatment.
Results
Genetics testing revealed that he was heterozygous for a pathogenic variant in gene NR3C2 (varint c.2145dupA; p.Glu716Argfs*28) causative for pseudohypoaldosteronism type 1 due to defects in the mineralocorticoid receptor. This variant has not been described in scientific literature prior to this. Parental genetics were carried out and this infant's mum was also positive for the above mutation.
Discussion
This case describes a rare novel genetic mutation causing pseudohypoaldosteronism in our patient. The main differential for this presentation is transient pseudohypoaldosteronism secondary to urinary tract malformation or urinary tract infection. This patients electrolyte abnormalities persisted despite treatment of his urosepsis prompting genetic testing.

Introduction
Glucocorticoids act via the glucocorticoid receptor (GR) to exert pleiotropic effects on all tissues, with heterogeneity in cellular response, aimed at regulating cellular and metabolic homeostasis. Recent advances in our mechanistic understanding of the GR demonstrate a more complex interplay of functions than traditionally considered. Multiple splice variants and translational isoforms of GR have been elucidated which contribute to cellular glucocorticoid sensitivity and may have diverse functions. The aim was to assess the GR isoform expression in PBMCs of individuals with varying states of glucocorticoid exposure.
Methods
Peripheral blood mononuclear cells (PBMC) were isolated from whole blood of healthy volunteers (HV), patients with endogenous Cushing syndrome (CS), adrenal insufficiency (AI) and treated with exogenous glucocorticoids for other conditions (GC). GR protein isoforms were measured via western blot. RNA was extracted from PBMC aliquots and RNA-Seq libraries prepared using Illumina Ribo-Zero plus and sequenced using NovaSeq X.
Results
PBMC were collected from 42 HV (15 male, 12 pre-menopausal and 15 post-menopausal females), 10 CS, 10 AI and 16 GC. The cohort were 50 ± 1.8 years old, with the GC group being older, and had a mean BMI 27.2 ± 0.8 kg/m^2 (which was significantly greater in the CS group). GR isoforms GRα-A, α-C, α-D1-3, -A and -P were identified in both the cytoplasm and nucleus of PBMCs across all groups. Isoforms GRα-C and D3 were the most frequently expressed ($n=69$). Cytoplasmic expression of GRα-C ($P=0.005$), GR-P ($P=0.01$), and GR-A ($P=0.009$) were lower in the GC group. After adjusting for age, BMI and sex/menopausal status, the lower cytoplasmic expression in of GR-P ($P=0.002$) in GC remained significant. No other differences were detected between groups including in nuclear isoform expression. Preliminary data suggest that isoform expression is correlated with both shared and unique gene expression. Genes correlated with GRα-A were enriched in pathways involving functions associated innate and adaptive immune function including T cell-mediated responses; GRα-D2 correlated genes were enriched in pathways associated with ubiquitin-proteosome function and GRα-D2 and GR-A-gene correlations were enriched in pathways associated with ATP production and mitochondrial function.
Conclusion
Previously described GR isoforms are present in PBMC of humans regardless of glucocorticoid exposure state. There appears to be an in vivo difference in gene regulatory function of individual isoforms which may contribute to the variation in clinical sequelae of glucocorticoid perturbations.

Impact of cholesterol supplementation for critical illness-induced hypocholesterolemia in a mouse model of prolonged sepsis: Effect on muscle weakness and adrenal failure

Lauren De Bruyn[1], Fien Van Beek[1], Sarah Vander Perre[1], Inge Derese[1], Lies Pauwels[1], Sarah Derde[1], Greet Van den Berghe[1] & Lies Langouche[1]
[1]KU Leuven, Clinical division and Laboratory of Intensive Care Medicine, Department of Cellular and Molecular Medicine, Leuven, Belgium

Background
Hypocholesterolemia is a hallmark of sepsis, associated with adverse outcomes. Both serum HDL- and LDL-cholesterol rapidly drop from the onset of critical illness onwards. Whether hypocholesterolemia necessitates intervention or merely reflects a marker of disease severity is unclear. We hypothesize that low cholesterol levels are potential contributors to ICU-acquired muscle weakness and adrenal failure and that supplementation with cholesterol can improve tissue cholesterol availability, thereby improving muscle and adrenal integrity. Our hypothesis was tested in a clinically relevant mouse model of prolonged sepsis.
Methods
In a catheterized mouse model of cecal-ligation and puncture-induced, fluid resuscitated and antibiotics-treated prolonged (5 days) sepsis, septic mice

received continuous IV-infusion of a bovine serum cholesterol mixture containing predominantly LDL-cholesterol (*animal study 1;* $n=51$), or human plasma purified HDL-cholesterol (*animal study 2*; $n=47$), as compared to placebo. Healthy mice served as controls. Plasma HDL-, LDL-cholesterol, CORT, TNF-α and total bile acids were measured, in addition to *ex vivo* specific muscle force, and adrenal cholesterol content (Oil Red O staining) and structure (H&E staining). Gene expression markers of inflammation (*Tnf-α*) and cholesterol synthesis (*Hmgcs1, Hmgcr*, *Fdft1*) were measured in the liver.

Results

In both studies, mortality was not affected by the cholesterol supplementation. In *animal study 1*, five-day LDL-supplementation in septic mice increased plasma LDL-cholesterol but not HDL-cholesterol as compared to placebo ($P<0.0001$) and attenuated the sepsis-induced reduction of adrenal cholesterol content ($P=0.0004$) but without improving the distortion of adrenal structure. LDL-supplementation had no additional effect on sepsis-induced loss of muscle mass and force. In contrast, plasma total bile acids were elevated and hepatic gene expression markers of cholesterol synthesis were overall decreased with LDL-supplementation as compared to placebo, whereas *Tnf-α* expression was further increased ($P<0.05$). Elevated plasma CORT and TNF-α were not affected by LDL-supplementation. In *animal study 2*, five-day HDL-supplementation of septic mice substantially increased plasma HDL-cholesterol and even more so LDL-cholesterol as compared to placebo ($P<0.0001$). HDL-supplementation attenuated the sepsis-induced reduction of adrenal cholesterol content ($P=0.006$) but without improving adrenal structure. Also, HDL-supplementation did not attenuate the sepsis-induced loss of muscle mass and force. Additional analyses are currently ongoing to further assess the impact on cholesterol homeostasis and functional markers in muscle, adrenal and liver tissue.

Conclusion

Cholesterol supplementation reversed hypocholesterolemia in prolonged septic mice, but without reversing adrenal structural changes or muscle function. Tissue-specific effects on inflammation and cholesterol homeostasis require further investigation.

Suprarenal adenomas in adult Bulgarian CAH patients

Ivesta Kirova[1], Ralitsa Robeva[1,2], Desislava Yordanova[3], Iva Stoeva[4,5], Atanaska Elenkova[1,2], Maria Orbetzova[6,7] & Sabina Zacharieva[2,6]

Penchev", Sofia, Bulgaria, [7]Faculty of Medicine, Medical University-Plovdiv, Plovdiv, Bulgaria

Background

Several studies have shown an increased prevalence of adrenal adenomas in adult patients with congenital adrenal hyperplasia (CAH) (1). However, data on the topic are still scarce, especially in East European countries.

Methods

The data of all adult patients with proven congenital adrenal hyperplasia in a single Expert Center for Rare Endocrine Diseases for the last 15 years have been explored. The prevalence and characteristics of adrenal formations (AF) have been described.

Results

Seventy-two CAH patients (60 women and 12 men) were included in the study. Four women and three men (16.7% of all) presented with AF. Patients with AF were significantly older than the other CAH patients (median 39.0 years [36.0–56.0] vs. median 27.0 years [18.0–57.0], $P<0.001$]). In three patients, visualized adrenal adenomas led to CAH diagnosis, while in the other four patients, CAH was diagnosed in childhood, with 3 of them showing poor compliance to corticosteroid therapy. In 6 of the patients, the AF characteristics were benign, while in one patient, adrenal carcinoma was found. The median size of AF was 41 mm (16–67), the largest formation being considered adrenal carcinoma; 2 of the AF were left-sided, 1 – was right-sided, and 4 – were bilateral.

Conclusions

The development of AF in adult CAH patients is associated with late diagnosis or poor compliance with corticosteroid therapy. Most AF in undertreated CAH patients are bilateral. More efforts should be made to diagnose simple-virilizing and late CAH forms early, even in countries with appropriate CAH neonatal screening. The timely transition from pediatric to adult endocrine tertiary centers is crucial for preventing complications in CAH patients.

Congenital adrenal hyperplasia causing Gender dysphoria: The dilemma of being a boy or a girl?

Yasmine Abdelmeguid & Samar Elwan
Faculty of Medicine, Alexandria University, Pediatric Endocrinology and Diabetology, Alexandria, Egypt

Introduction

In developed countries, female patients with classic forms of congenital adrenal hyperplasia (CAH) are diagnosed at birth or in early childhood, allowing prompt treatment with correct gender assignment. The impact of late diagnosis or late interventions of CAH on gender identity, sexual orientation and function has been previously described. Hence, we-herein- describe an unusual case of an 18-year-old CAH girl with gender dysphoria and deciding to be a male.

Objective

To demonstrate the dilemma of gender identity in female CAH patients with delayed interventions due to social and cultural issues.

Case summary

An 18-year-old patient born to consanguineous parents had presented in a southern Egyptian city with persistent vomiting, electrolyte disturbance, atypical genitalia noticed since birth, and was diagnosed with salt-wasting congenital adrenal hyperplasia. Treatment with prednisolone and mineralocorticoid was started. No gonads were palpable, virilization Prader IV staging. Ultrasonography of the abdomen and pelvis was done showing uterus, no testes, bilateral ovaries. Due to social problems, the patient was lost to follow-up. At the age of 12.5 years, patient sought medical advice with breast enlargement and did laparoscopy showing female internal genitalia, and confirmed there were no testes. Before planning for surgery, the patient had his/her first menstrual cycle through a common urogenital sinus. They gave the decision to the patient after being reared for 11.5 years as a male, and his parents and they asked for doing bilateral salpingo-oophorectomy and hysterectomy at the age of 13 years. Hence, it was preferred to be an infertile male rather than a fertile female. Intramuscular testosterone was given for 3 months only for further virilization. The patient presented to us at the age of 18 years on subdose of prednisolone (1.4 mg/m^2 per day), stopped mineralocorticoid therapy since 5 years. On examination, she/he had short stature, Breast Tanner 5, penile hypospadias (not operated), SPL 6 cm, stria rubra, and chordae. Moreover, body image discomfort, depressive symptoms, and gender dysphoria.

Conclusion

Social and cultural issues play a major role in the management of female CAH patients, whether as physicians we agree with or disagree. Disregarding CAH patients' clinical condition, and deprivation of medical care have major consequences psychologically and physically.

A novel mutation in a female patient with congenital adrenal hyperplasia due to 11-hydroxylase deficiency: A case report

Mona Nourbakhsh[1], Maryamsadat Tabatabaei[2], Marziyeh Mojbafan[3], Marziyeh Zamany[2] & Maryam Razzaghy Azar[4]
[1]Aliasghar Clinical Research Development Center, Iran University of Medical Sciences, Pediatrics, School of Medicine, Tehran, Iran, [2]Iran University of Medical Sciences, Shahid Akbarabadi Clinical Research Development Unit (ShACRDU), Genetic, Tehran, Iran, [3]Iran University of Medical Sciences, School of Medicine, Medical Genetics, Tehran, Iran,

[4]Iran University of Medical Sciences, School of Medicine, H.Aliasghar Children Hospital, Pediatrics, Tehran, Iran

Background
11-Hydroxylase deficiency is a rare form of congenital adrenal hyperplasia (CAH) caused by mutations in the CYP11B1 gene. This mutation disrupts cortisol synthesis, leading to overproduction of ACTH. Elevated ACTH results in excessive deoxycorticosterone (DOC), a weak mineralocorticoid, causing hypernatremia, hypertension, and hypokalemia. Female patients may exhibit virilization at birth, while male patients are often diagnosed later with premature puberty and hypertension. This case report describes a novel mutation in the CYP11B1 gene identified in a patient presenting with vaginal stenosis and premature pubarche.
Case presentation
A 6-year-old girl was referred to the endocrinology clinic at 4 months of age due to ambiguous genitalia. Physical examination revealed normal blood pressure and no hyperpigmentation. Genital examination corresponded to Prader Stage 3; karyotyping confirmed a 46, XX profile. Neonatal screening indicated elevated 17-hydroxyprogesterone levels, leading to an initial diagnosis of 21-hydroxylase deficiency. Hydrocortisone therapy was initiated, and vaginal repair was performed under stress dosing. However, genetic testing for 21-hydroxylase was negative, prompting discontinuation of the medication. At 3 years and 9 months, signs of androgen excess emerged, including acne and Tanner Stage B1P3 pubic hair development, with an advanced bone age of 7.5 years. Laboratory analysis showed LH at 0.11 mIU/ml and FSH at 0.8 mIU/ml, inconsistent with central precocious puberty, and a 17-OHP level of 4.71 ng/ml. Whole exome sequencing revealed a mutation in the CYP11B1 gene: chr8:143960454A > G, c.389T > C (p.Phe130Ser). Both parents were carriers, confirming the diagnosis of 11β-hydroxylase deficiency. Currently, at 6 years old, she is receiving hydrocortisone treatment (10 mg/m^2). Her bone age is now 8 years, with normal growth velocity and cessation of signs of androgen excess, maintaining a prepubertal state.
Conclusion
The CYP11B1 gene is associated with over 100 mutations, including missense/nonsense mutations, splicing errors, and various deletions and insertions. This report highlights a patient with CAH due to a novel CYP11B1 mutation, resulting in reduced enzyme activity and androgen excess, leading to clinical manifestations such as virilization and hormonal imbalances. Hormone replacement therapy is essential, but achieving the right balance can be challenging.

Introduction
Familial hypercholesterolemia (FH) is a genetic disorder characterized by elevated levels of low-density lipoprotein cholesterol (LDL-c) from birth onwards, leading to an increased risk of premature cardiovascular events. Given that treatment for FH can start as early as 8 years of age, ideally, screening should be performed at a young age to enable early detection and intervention, leading to an optimal clinical outcome. However, universal screening for FH is not yet widely performed, and traditional biomarkers, including total cholesterol and LDL-c, leave considerable room for improvement in terms of sensitivity and specificity. Therefore, we explored the feasibility of using plasma free cholesterol as a potential screening marker for FH in children.
Methods
We developed and validated an LC–MS/MS method to quantify free cholesterol in plasma. Using this method, we analyzed plasma samples from three groups of children (aged 1 – 18 years): with a confirmed pathogenic FH gene variant ($n = 15$), those who tested negative for FH variants ($n = 9$), and a presumptively unaffected population ($n = 51$). Additionally, LDL-c, total cholesterol, HDL-cholesterol, non-HDL-cholesterol, triglycerides, lipoprotein(a), and apolipoproteins A1 and B were quantified.
Results
Free cholesterol and LDL-c levels were strongly correlated ($R^2 = 0.86$) in all children. Free cholesterol levels in children with FH (median (IQR): 1.76 (1.44–1.94) mmol/L) were significantly higher compared to unaffected children (1.32 (1.09–1.54) mmol/L) and the presumptively unaffected population (1.11 (0.94–1.23) mmol/L). Although free cholesterol levels were significantly higher in the FH group across all ages, this effect was more pronounced in children below 10 years old. To validate these findings and establish cut-off values for free cholesterol as a screening marker, further analyses will be performed in a larger cohort.
Discussion
Free cholesterol seems to perform comparably to LDL-c and total cholesterol in detecting FH and may offer several methodological advantages, such as a very small sample volume (5 μL) and high throughput. Therefore, free cholesterol may be a suitable biomarker for large-scale screening for FH in children, potentially improving early detection and treatment to prevent premature cardiovascular events.

Comparison between Romanian and Flemish cohort of patients with PPGLs

Sofia-Maria Lider-Burciulescu[1], Andrei Muresan[2], Monica Livia Gheorghiu[2,3], Elena Braha[2], Stanescu Laura-Semonia[2], Bruno Lapauw[4], Attila Patocs[5] & Corin Badiu[2,3]
[1]'Ana Aslan' National Institute of Geriatrics and Gerontology, Endocrinology, Bucharest, Romania, [2]'CI Parhon' National Institute of Endocrinology, Bucharest, Romania, [3]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania, [4]Ghent University Hospital, Ghent, Belgium, [5]Semmelweis University, National Institute of Oncology, Budapest, Hungary

Introduction
Pheochromocytomas and paragangliomas (PPGLs) are rare neuroendocrine tumors with a heterogenous clinical behaviour. Among solid tumors, PPGLs have the most strong genetic predisposition with a specific geographical distribution pattern.
Aim
To compare the genotype and phenotype characteristics from two cohorts of patients with PPGLs from two different geographical and historical regions of Europe: Romania and Belgium.
Material and methods
For Romanian cohort retrospective clinical, imaging and genetic (germinal) data was collected from electronic medical records of 140 patients consecutively diagnosed with PPGLs at 'C.I. Parhon' National Institute of Endocrinology between 1987–2020. For newly diagnosed patients the same data was prospectively collected between 2020 and February 2024. For the Flemish cohort, we retrospectively retrieve data of 67 consecutively registered patients diagnosed with PPGLs in Endocrinology, Pathology and Surgery Departments from Ghent University Hospital (Belgium) registry, between 2002 and 2020.
Results
In the Romanian cohort were included 140 patients with PPGLs, with a mean age at diagnosis of 47.9 ± 15.6 years. Ninety-seven (69.2%) were women, and 43 (30.7%) were men; 130 (92.8%) presented with PHEOs and 10 (7.2%) with PGLs. In the Flemish cohort were included 67 patients, with a mean age at diagnosis of

50 ± 19 years, 38 (56.7%) women, 29 (43.3%) men, most of them presented with PHEO 42 (63%) and 25 (37%) with PGL. Patients from Flemish cohort had a better access to genetic test (90% in Flemish vs. 63% in Romanian cohort) resulting a higher percentage of hereditary cases ($n=32$, 40% vs. $n=24$, 36%). Romanian patients presented most frequently with *RET – c.1902C>G (p.Cys634Trp)* ($n=22$, 68.7%), while Flemish patients with *SDHD – SDHD c.170-1 G>T* ($n=10$, 41.7%) pathogenic variant. Based on this genetic background, Romanian patients presented more frequently with bilateral PHEOs, compared to Flemish cohort (19.3%; $n=15$; vs. 7% $n=3$; $P=0.002$), while Flemish patients presented more often with multiple PGLs (24% vs. 0%).
Conclusion
We can conclude that the different prevalence of pathogenic variants related to hereditary PPGLs in Romania [*RET c.1902C>G (p.Cys634Trp)]* versus Belgium [*SDHx (SDHD c.170-1 G>T)*], could be considered as a founder effect. While Flemish patients are more frequently incidentally diagnosed and develop more often multiple PGLs, Romanian patients had a higher PHEO/PGL ratio and had higher proportion of bilateral PHEOs compared to Flemish population.

Research Unit. University Hospital of Tarragona Joan XXIII-Institut d'Investigació Sanitària Pere Virgili (IISPV), Tarragona, Spain, Endocrinology and Nutrition, Tarragona, Spain, [3]Grupo de investigación de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM)-Instituto de Salud Carlos III, Madrid, Spain, Tarragona, Spain

Introduction
In primary hyperaldosteronism (PH), differentiating between unilateral and bilateral secretion is essential for defining treatment. Adrenal-CT imaging has limitations to determine subtype classification and lateralization, being adrenal venous sampling (AVS) the current test of choice. In this study, we aim to analyse, in our series, the degree of concordance between adrenal CT and AVS at stablishing subtype classification and lateralization in PH, as well as biochemical remission followed by adrenal-CT or AVS-guided adrenalectomy.
Materials and methods
A retrospective observational study of a cohort of patients with PH who underwent AVS with or without ACTH stimulation. Clinical, analytical, radiological data, AVS results, and biochemical success parameters according to PASO criteria were collected.
Results
Out of 69 patients, 38 underwent AVS, with a mean age of 54.4 years (s.d. ±8), 76.3% male. Median follow-up post-adrenalectomy was 5 months (IQR 3–10). Concordance was observed between AVS and CT in the subtype classification in 12 (31.5%) of the 38 patients ($P=0.006$). Adrenalectomy was performed in 27 patients, 19 of whom had both AVS and CT (one patient was excluded due to loss of follow-up). Biochemical cure was reached in 14 (77.7%) patients with AVS-guided adrenalectomy, with a correlation between CT and AVS in 8 of them (57.1%, $P=0.007$). Out of 8 patients with CT-guided adrenalectomy, 6 (75%) achieved biochemical remission, with a mean age at the time of surgery of 54.8 years, and the relation between lateralization by CT and biochemical cure was statistically significant ($P<0.001$).
Conclusions
The correlation of adequate lateralization between adrenal-CT and AVS observed in our series aligns with current literature: less than 40% of adrenal-CT results agree with AVS in subtype classification, and approximately only 50% show correct lateralization guided by CT compared with AVS. A high rate of biochemical remission was observed in those who underwent CT-guided adrenalectomy, despite a median age of 54.8 years. This could be explained by the fact that these were mostly patients with marked PH and unilateral image on CT.

JOINT3879

Clinical, biological and genetic characteristics in congenital adrenal hyperplasia due to 11-beta hydroxylase deficiency in a Tunisian center

Wided Debbabi[1], Samah Allous[1], Hajer Marzouk[1], Mouna Elfarouki[1] & Issam Kharrat[1]
[1]Ibn Aljazzar University Hospital, Faculté de Médecine de Sousse, Endocrinology Departement, Kairouan, Tunisia

Introduction
11ß-hydroxylase deficiency is the most common deficiency after 21-hydroxylase deficiency, usually diagnosed following signs of virilization in a newborn or 46XX fetus, and later following hypertension with hypokalemia.
Patients and methods
This is a retrospective study of 19 patients with 11ß-hydroxylase block consulting the endocrinology department of Ibn Aljazzar Hospital Kairouan
Results
We report 19 cases; 12 male and 7 female, with a current mean age of 23 years. Parental consanguinity was found in 9 cases (47.4%). The mean age of diagnosis was 31 months. The circumstances of discovery were neonatal screening in one girl, hypertension in 5 patients, sexual ambiguity in two girls, precocious pseudo-puberty in two boys, and growth retardation in one case, renal failure in one patient, hemorrhagic stroke in one patient and infertility in one patient. 17 High blood pressure was diagnosed in 89,5% (17 cases/19). 17 hydroxy progesterone was elevated in all patients and corticosterone was elevated in four patients in whom it was performed. The genetic diagnosis showed a high prevalence of the p.G379 V mutation in the homozygous state in exon7 of theCYP11B1 gene. Surgical repair of sexual ambiguity was performed in 3 girls. The evolution was marked by the occurrence of left ventricular hypertrophy in two patients and hemorrhagic stroke in one patient. Testicular adrenal rest tumors were diagnosed in 7 males.
Discussion
11ß-hydroxylase enzyme deficiency is responsible for defective synthesis of cortisol and aldosterone, with accumulation of the upstream metabolites compound S and deoxycorticosterone (DOC), and excessive synthesis of adrenal androgens, resulting in different clinical forms depending on sex and age of onset. The hypersecretion of DOC and its metabolites, known for their mineralocorticoid action, can generate hypertension, which remains uncorrelated with DOC levels but can be responsible for serious complications.

Evaluation of cardiovascular risk and hepatic fibrosis scores in patients with pheochromocytoma

Kübra Durmuş Demirel[1], Ahmet Kurşat Soyer[1], Sevgül Fakı[1], Fatma Dilek Dellal Kahramanca[1], Ahmet Dirikoç[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara City Hospital, Ankara, Türkiye, [2]Ankara City Hospital, Yildirim Beyazit University, Ankara, Türkiye

Introduction
Pheochromocytoma (PHEO) is a rare tumor characterized by excessive release of catecholamines. Although improvements in metabolic parameters are observed after surgery, the relationship between serum catecholamine levels and these changes has not been thoroughly investigated. The aim of this study was to evaluate the changes in metabolic parameters, cardiovascular risk and hepatic

fibrosis in patients with PHEO and non-functioning adrenal masses (NFA) after adrenalectomy and the relationship between these changes and preoperative catecholamine levels.
Methods
Between 2019 and 2024, patients with PHEO and NFA (adenoma or hyperplasia) who were admitted to the Endocrinology and Metabolic Diseases Clinic of Ankara City Hospital and underwent adrenalectomy were included in the study. Pre- and post-adrenalectomy measurements of glucose, biochemistry, hemogram, lipids, insulin, HbA1c, systolic and diastolic blood pressures, weight and BMI were recorded and compared. Preoperative serum and 24-hour urine catecholamine levels were recorded. We used the SCORE calculation model recommended by the Endocrinology and Metabolism Society of Turkey for cardiovascular risk prediction in Turkey (7). For liver fibrosis assessment, we used the Non-Alcoholic Fatty Liver Disease Fibrosis Score (NFS), AST to Platelet Ratio Index (APRI) and Fibrosis 4 (FIB-4) scores (10–12). Changes in metabolic parameters, cardiovascular risk scores and hepatic fibrosis scores were analyzed and the associations between preoperative catecholamine levels and these parameters were evaluated.
Results
In this study, 61 pheochromocytoma (PHEO) and 37 non-functioning adenoma (NFA) patients who underwent adrenalectomy were evaluated. HbA1c ($P<0.001$), HDL levels ($P=0.007$), systolic and diastolic blood pressure ($P<0.001$) and SCORE cardiovascular risk ($P=0.001$) decreased after adrenalectomy in PHEO patients, while triglyceride levels increased ($P=0.057$). Postoperative NFS score was significantly elevated in PHEO ($P=0.03$). A negative correlation was found between preoperative systolic and diastolic blood pressure and preoperative urinary dopamine in PHEO ($P=0.041$, $P=0.045$, respectively). A negative correlation was also found between preoperative urinary dopamine levels and preoperative FIB-4 ($r=-0.373$, $P=0.021$) and NFS ($r=-0.358$, $P=0.038$), as well as between urinary metanephrine levels and APRI score ($r=-0.286$, $P=0.03$). Preoperative urinary metanephrine levels were higher in patients whose FIB-4 score did not improve ($P=0.25$).
Conclusıons
The reduced SCORE and blood pressure after surgery in patients with PHEO suggest that early diagnosis and surgery play a critical role in reducing cardiovasculer mortality and morbidity. Preoperative elevated catecholamine levels may have a protective effect on liver fibrosis and it will be important to confirm these findings with new studies for long-term follow-up.

Ensuring safety in adrenal insufficiency: A review of emergency hydrocortisone kit prescriptions

Alice Gatenby[1], Blaise Emery[1], Win Lei Yin[1] & Thinzar Min[1,2]
[1]Swansea Bay University Health Board, Department of Endocrinology, Swansea, UK, [2]Swansea University Medical School, Diabetes Research Unit, Swansea, UK

Background
Adrenal crisis is a life-threatening condition needing urgent injectable hydrocortisone. Without prompt treatment, it can lead to severe complications. NICE Guidance recommends educating patients on sick day rules and providing them with emergency hydrocortisone injection kits.
Aim
The project aimed to determine the percentage of adrenal insufficiency patients prescribed emergency hydrocortisone kits.
Methods
A retrospective review of case notes from secondary Endocrine Clinics within the Swansea Bay University Health Board was conducted, examining demographic data, causes of adrenal insufficiency, and emergency hydrocortisone kit prescriptions.
Results
118 patients with adrenal insufficiency (47% Male; Mean age 60.5 ± 16.7 years) were included. Causes of adrenal insufficiency included Addison disease 35 (30%); secondary adrenal insufficiency 57 (48%); iatrogenic 15 (13%) and Others [Bilateral adrenalectomy, congenital adrenal hyperplasia, immunotherapy related adrenalitis] 11 (%). 15 out of 118 had immunotherapy related adrenal insufficiency (13 patients had hypophysitis and 2 had adrenalitis). Majority (77%) were treated with hydrocortisone and the reminder treated with prednisolone. All patients received sick day rule education and 92% (108) were prescribed with emergency hydrocortisone kit. In the last 12 months, 15 patients (9 with secondary adrenal insufficiency, 4 with Addison disease, 2 with iatrogenic) were admitted with adrenal crisis. Precipitating factor for adrenal crisis was infection (gastroenteritis, COVID, pneumonia, urinary tract infection). Out of 15 patients with adrenal crisis, 2 patients were not prescribed with emergency hydrocortisone injection kit.
Conclusion
Most patients with adrenal insufficiency were prescribed injectable hydrocortisone, and adrenal crisis can occur in all types of adrenal insufficiency. Educating patients on sick day rules and ensuring they have emergency hydrocortisone is crucial in preventing adrenal crisis. Notably, 13% of patients with an adrenal crisis had not received injectable hydrocortisone. Ensuring all patients (and/or their family members) receive education and emergency hydrocortisone injection techniques is essential for effective management and prevention of adrenal crisis. This study emphasizes the importance of consistent and comprehensive patient education and access to emergency treatment to mitigate the risks associated with adrenal insufficiency.

Consistent reduction in rate of fracture with setrusumab therapy in patients with osteogenesis imperfecta: month 14 data from phase 2 of the orbit study

Luigi Picaro[1], Gary Gottesman[2], Thomas Carpenter[3], Danita Velasco[4], Maegen Wallace[5], Peter Smith[6], Erik Imel[7], Diana Luca[8], Heather Byers[8], Stanley Krolczyk[8] & E Michael Lewiecki[9]
[1]Mereo BioPharma, London, UK; [2]Washington University School of Medicine, St. Louis, Missouri, USA; [3]Yale University School of Medicine, New Haven, CT, USA; [4]Children's Nebraska, Omaha, NE, USA; [5]Phoenix Children's Hospital, Phoenix, AZ, USA; [6]Shriner's Hospitals for Children, Chicago, IL, USA; [7]Indiana University School of Medicine, Indianapolis, Indiana, USA; [8]Ultragenyx Pharmaceuticals Inc., Novato, CA, USA; [9]University of New Mexico Heath Sciences Center, Albuquerque, NM, USA

Osteogenesis imperfecta (OI) is a rare bone disorder characterize by increased fragility and low bone mass. Setrusumab is a fully human anti-sclerostin monoclonal antibody that has demonstrated improved bone mineral density (BMD), strength, and remodeling in adult patients with OI. Here, we assess the efficacy and safety of setrusumab in children and young adults with OI through Month 14 of Phase 2 of the Phase 2/3 Orbit study (NCT05125809). Participants with OI Types I, III, or IV aged 5 to <26 years randomized 1:1 received setrusumab at 20 or 40 mg/kg monthly doses intravenously. After all participants had received setrusumab for 6 months, the 20 mg/kg dose was selected and all participants switched to this dose through the end of the study. 24 participants were assessed: 12/24 (50%) are female, 18/24 (75%) are <18 years of age, and 17/24 (71%) and 7/24 (29%) have OI Types I and III/IV, respectively. Participants received setrusumab for a mean 16 months at the time of analysis, and most (18/24, 75%) received bisphosphonates prior to enrollment. Baseline assessments of BMD showed continued improvements through Months 6 and 12. A mean (S.E.) change from baseline in lumbar spine BMD of 14% ($\pm2\%$) was observed at Month 6 and continued to 22% ($\pm3\%$) at Month 12 ($P<0.0001$). This equated to an improvement from baseline in BMD Z-score of 0.9 (±0.1) at Month 6 and 1.2 (±0.2) at Month 12 ($P<0.0001$). The baseline median annualized rate of skeletal fracture (excluding fingers, toes, face, skull, and morphometric vertebral fractures) prior to treatment of 0.72 decreased to 0 ($P=0.0014$). A reduction in fracture rate of 67% was calculated. No safety concerns were identified at Month 14. Treatment-emergent adverse events (TEAE) were consistent with the anticipated safety profile of setrusumab. Most reported related TEAEs (11/12, 92%) were mild (Grade 1), with no related serious TEAEs. Importantly, no cardiovascular TEAEs were reported through Month 14, and none of the reported TEAEs led to discontinuation of the study by any participant, or disruption in setrusumab treatment. Data from Month 14 of Phase 2 of the Orbit study indicated notable improvements in BMD with setrusumab therapy in participants with OI. We report a meaningful reduction in the annualized rate of skeletal fractures (67%) with setrusumab therapy. Overall, the findings herein support those data reported after 6 months of setrusumab therapy, confirming the robust and durable response in participants with OI.

Rodolico", Catania, Italy; [5]Department of Biomedical, Surgical and Dental Sciences, University of Milan, Milan, Italy; [6]Department of Medicine, Surgery and Neurosciences, University of Siena, Siena, Italy; [7]Endocrine Unit, Fondazione IRCCS Ospedale Casa Sollievo della Sofferenza, San Giovanni Rotondo, FG, Italy; [8]Department of Clinical and Experimental Medicine, University of Catania, Catania, Italy; [9]Department of Medical Biotechnology and Translational Medicine, University of Milan, Milan, Italy; [10]Unit of Endocrinology, ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy

Objective

To assess the prevalence of hidden hypercortisolism (HidHyCo) in a large sample of patients with osteoporosis or osteopenia plus the comorbidities possibly associated with cortisol excess and to evaluate the characteristics predictive of HidHyCo

Methods

From April 2023 to January 2025 we enrolled, in 5 Italian hospitals, 1194 patients without clinically overt hypercortisolism or other secondary causes of osteoporosis. Patients were referred for evaluation of osteoporosis or fragility fractures, or for osteopenia associated with ≧1 of these conditions: hypertension (treated ≧2 drugs or not well controlled, severe-hypertension), diabetes, history of cardiovascular events (CVE).

Measurements

In all patients we collected data regarding history of fragility fractures, diabetes, hypertension and CVE. Bone mineral density was measured with DXA at lumbar spine and femur and the presence of vertebral fractures (mVFx) was evaluated with thoracolumbar X-ray and the Spinal Deformity Index (SDI) was calculated. All patients performed twice: 1 mg overnight dexamethasone suppression test (DST) and, as confirmatory, 2day low-dose DST (2day-ldDST) for HidHyCo diagnosis.

Results

The presence of HidHyCo was detected in 26 out of 1192 patients (2.2%). As for the characteristics predictive of HidHyCo, here we present a preliminary analysis on 318 patients. Within this group, 43 patients (13.5%) showed DST> 1.8 mcg/dl, and in 14 (4.4%) HidHyCo was confirmed. Patients with and without HidHyCo showed no difference in prevalence of osteoporosis (75.0 vs 80.8%, $P=0.708$), CVE (8.3% vs 2.8%, $P=0.314$), diabetes (8.3% vs 12.7%, $P=1.00$) and severe-hypertension (25.0% vs 20.6%, $P=0.710$). Patients with HidHyCo showed a higher prevalence of mVFX or major clinical fractures (MajorFX) (75.0% vs 37.6%, $P=0.014$) and higher SDI (4.1 ± 6.3 vs 1.2 ± 2.4, $P=0.001$). In two separated logistic analyses, adjusted for age, osteoporosis, diabetes, severe-hypertension, the presence of a mVFX or MajorFX (odds ratio, 4.5 [CI, 1.14 to 17.37], $P=0.031$) and SDI (odds ratio, 1.2 [CI, 1.05 to 1.38], $P=0.006$) were associated with HidHyCo.

Conclusions

HidHyCo may be more common than is generally recognized in patients with bone fragility in whom other secondary causes have been excluded. The presence of mVFX or MajorFX and the SDI are associated with a higher risk of HidHyCo.

Parathyroid surgery in children with sporadic and familial hyperparathyroidism

Philippa Prentice[1,2], Han Boon Oh[3], Tarek Abdel-Aziz[3], Colin Butler[3], Alexander Chesover[1,4], Caroline Brain[1], Jeremy Allgrove[1] & Tom Kurzawinski[1,3]

[1]Great Ormond Street Hospital, London, UK; [2]Evelina London Children's Hospital, London, UK; [3]University College London Hospital, London, UK; [4]Royal National Orthopaedic Hospital, London, UK

Introduction

Primary Hyperparathyroidism (PHPT) in children is very rare and arrival of better imaging, minimally invasive parathyroidectomy (MIP) and intra-operative parathyroid hormone (IOPTH) monitoring is changing current surgical practice.

Method

Retrospective case notes review of children with PHPT who had parathyroidectomy between 1977 and 2022 at a single tertiary endocrine centre.

Results:

A total of 49 children (0.2–17 years, 24 boys) had parathyroidectomy for PHPT; 30 (7–17 years) for sporadic (sPHPT), 10 (6–16 years) familial (fPHPT, 6MEN1, 2 MEN2a, 2JT-HPT)) and 9 (0.2–3 years) Neonatal Severe Hyperparathyroidism (NSHPT). Children with sPHPT presented most commonly with abdominal symptoms (54%), incidental hypercalcaemia was reported in 12%. 44% of children with fPHPT had abdominal symptoms; 33% hypercalcaemia on screening. All children with NSHPT presented with poor feeding, behavioural change and/or developmental delay, except one with incidental hypercalcaemia. Preoperative corrected calcium was 3.12 ± 0.47 mmol/l (mean $\pm$ S.D.) in sPHPT, 2.97 ± 0.31 mmol/l ($P=0.4$) in fPHPT and 4.6 ± 1.6 mmol/l ($P<0.05$) in NSHPT. Pre-surgical treatment was most commonly hyperhydration and bisphosphonates; cinacalcet was used in 3 sPHPT and 4 NSHPT; calcitonin in 1 sPHPT and 2 NSHPT. In children with sPHPT ultrasound identified abnormal parathyroid in 91%; Sestamibi was abnormal in 89%; both abnormal in 76%. Of those with discordant imaging, 2/4 had abnormal ultrasound and normal Sestamibi, and 2/4 had abnormal Sestamibi and normal ultrasound. In children with fPHPT 86% of ultrasound images were abnormal, with Sestamibi in agreement except for 1 case showing no uptake. When imaging was performed in NSHPT (66%), no abnormal parathyroids were identified. Seventy percent of sPHPT children (all but one in the last 15 years) had MIP and 90% removal of 1 parathyroid). IOPTH monitoring was used in all operations since 2016. 20% of children with fPHPT had MIP and others had neck exploration with removal of 1(20%) – 4(20%) parathyroids. Eight children with NSHPT had 4 and one 3½ parathyroidectomies. Recurrence rate in children with fPHPT was 40% and 0% in sPHPT. There were no surgical complications.

Conclusion

Most children with PHPT are symptomatic and have high levels of calcium meeting criteria for immediate surgery. Ultrasound correctly identifies abnormal parathyroids and should be first line imaging in children with sPHPT and fPHPT, with Sestamibi recommended only when US negative. Imaging parathyroids is not helpful in NSHPT. Parathyroidectomy in children is safe in experienced hands and MIP with IOPTH should be the operation of choice for sPHPT.

Bone microarchitectural degradation in hypertensive patients: a population study

Fabio Bioletto[1], Martina Bollati[1], Marco Barale[1], Chiara Lopez[1], Alessia Pusterla[1], Emanuela Arvat[1], Ezio Ghigo[1], Mauro Maccario[1], Massimo Procopio[1] & Mirko Parasiliti Caprino[1]

[1]University of Turin, Department of Medical Sciences, Turin, Italy

Background

Hypertension is associated with increased bone fragility. However, the underlying mechanisms remain partly obscure. Evidence on the association of hypertension with bone mineral density (BMD) is conflicting, and changes in BMD are insufficient to justify the observed increase in fracture risk. Data on bone microarchitectural quality in hypertensive patients are scarce. The *in vivo* effects of anti-hypertensive medications on bone quality are poorly explored.

Objective

The primary aim of this study was to evaluate whether trabecular bone microarchitecture, non-invasively assessed by trabecular bone score (TBS), is altered in hypertensive patients. The association between anti-hypertensive medications and TBS was also evaluated as a secondary endpoint.

Methods

We conducted a cross-sectional analysis on 7053 subjects extracted from the 2005-2008 cycles of the National Health and Nutrition Examination Survey (NHANES), in which lumbar spine dual-energy X-ray absorptiometry (DXA) scans were acquired. TBS values were calculated from DXA images using dedicated software. The association between hypertension, anti-hypertensive medications and bone outcomes was assessed by regression analyses. Generalized additive models with spline smoothing were used to evaluate systolic and diastolic blood pressure as continuous predictors. All analyses were adjusted for relevant confounders.

Results

Hypertension was independently associated with lower TBS values (adjusted β = –0.010, 95%CI: [–0.016, –0.003], P = 0.008); on the contrary, no association was observed between hypertension and BMD T-scores at lumbar spine (adjusted β =

+0.04, 95%CI: [–0.05, +0.13], $P = 0.362$), total hip (adjusted β = –0.03, 95%CI: [–0.10, +0.05], $P = 0.474$), or femoral neck (adjusted β = –0.03, 95%CI: [–0.10, +0.03], $P = 0.294$). When evaluating blood pressure as a quantitative measure, a significant inverse relationship was observed between systolic blood pressure and TBS values ($P < 0.001$); conversely, no correlation was found for diastolic blood pressure ($P = 0.616$). No class of anti-hypertensive medications was significantly associated with TBS. Thiazide diuretics and angiotensin receptor blockers were associated with higher BMD values, whereas loop diuretics and non-dihydropyridine calcium channel blockers with lower BMD values.

Conclusion

Hypertension is associated with degraded bone microarchitecture, while no association is observed with bone mass. No significant relationships between anti-hypertensive medications and TBS were found. Associations between anti-hypertensive medications and BMD were consistent with previous reports. Overall, these results provide further insight into the relationship between hypertension and bone health. The specific degradation of bone microarchitecture may offer a plausible explanation for the increased fracture risk observed in hypertensive patients, independent of BMD.

The effect of low-dose cyclic 17-ß-estradiol administration on bone turnover in healthy postmenopausal women: a randomized controlled trial

Esther M. Speksnijder[1], Sarah Siegelaar[1], Michael Tanck[2], Dirk Jan Stenvers[1,3] & Peter Bisschop[1]

[1]Amsterdam UMC, University of Amsterdam, Amsterdam Gastroenterology Endocrinology Metabolism, Department of Endocrinology and Metabolism, Amsterdam, Netherlands; [2]Amsterdam UMC, University of Amsterdam, Department of Epidemiology and Data Science, Biostatistics and Bioinformatics, Amsterdam, Netherlands; [3]Amsterdam UMC, VU University, Amsterdam Gastroenterology Endocrinology Metabolism, Department of Endocrinology and Metabolism, Amsterdam, Netherlands

Background

Hormone therapy (HT) containing estrogen is an effective treatment for the prevention of bone loss in low-estrogenic states. Apart from the inhibiting effect of HT on bone resorption, studies have demonstrated that 17-β-estradiol also increases bone formation in the first 4 weeks of treatment. We hypothesized that this initial increase in bone formation is driven by a rise in serum 17-β-estradiol concentrations, as seen during the menstrual cycle of premenopausal women. Therefore, we investigated whether restoring a monthly cycle in 17-β-estradiol levels is beneficial for bone formation.

Methods

We performed an open-label randomized controlled trial in healthy postmenopausal women aged 45-60 years (without history of hysterectomy). Participants were randomized to transdermal cyclic (4-week cycle consisting of 2 weeks 25 mg/24h, and 2 weeks 50 mg/24h), continuous low-dose (25 mg/24h), or continuous standard-dose 17-β-estradiol (50 mg/24h) for 16 weeks. All participants also received continuous oral micronized progesterone 100 mg once daily. Endpoints of the study were the interaction between treatment and time on serum P1NP concentrations (bone formation) and on serum CTX concentrations (bone resorption). We measured P1NP and CTX every two weeks.

Results

The 48 participants had a mean age of 53.5 (SD 3.3) and had their final menstrual period at 50.5 (SD 3.8) years. P1NP increased in all groups between baseline and week 4, followed by a decrease between week 4 and week 16. The median decrease in P1NP levels (bone formation) was lower in the cyclic (-12.6 µg/l (IQR -20.4 – -0.7), $P = 0.03$) and low-dose group (-12.0 µg/l (IQR -18.4 – 1.8), $P < 0.01$) compared to the standard-dose group (-15.2 µg/l (IQR -29.1 – -8.7)). CTX decreased between baseline and week 16 in all groups. The median decrease in CTX values from baseline until week 16 was similar in the cyclic group (-143 ng/l (IQR -221.3 – -71.2), $P = 0.45$) compared to the standard-dose group (-176.9 ng/l (IQR -218.9 – -123.2)). However, CTX values (bone resorption) remained higher in the low-dose group (-112.2 ng/l (IQR -192.6 – -67.9), $P = 0.04$) compared to the standard-dose group. After 16 weeks of treatment, the mean changes in P1NP and CTX no longer differed between the groups.

Conclusion

Cyclic 17-β-estradiol administration resulted in higher bone formation over time compared to continuous standard-dose administration, while bone resorption did not differ between the cyclic and continuous standard-dose group. Thus, cyclic estradiol may improve bone health in the short-term.

Assessing PTH dynamics following total thyroidectomy: an important tool for predicting hypoparathyroidism

Miguel Paja[1,2], Cristina Moreno[3], Josune Rodríguez-Soto[3], Natalia Iglesias[3], Laura Calles[3], Jon Garay[3], Jon Portu[3,3], Elena Cruz-Iglesias[3], Amaia Expósito[2,3] & Amelia Oleaga[2,3]

[1]OSI Bilbao-Basurto. Hospital Universitario de Basurto., Bilbao, Spain; [2]University of the Basque Country UPV/EHU, BIlbao, Spain; [3]Basurto University Hospital; OSI Bilbao-Basurto, BIlbao, Spain

Perioperative PTH (pOPTH) has been proposed as a predictor of postoperative hypoparathyroidism in TT. ATA Surgical Affairs Committee 2018 estimated that PTH >15pg/mL 20 min after thyroidectomy obviates the need for calcium supplementation, while others prefer day postoperative measurement. We evaluate the dynamics of pOPTH and its relationship to preoperative and intraoperative findings in a large series of patients over fourteen years. Excluding patients with concomitant primary hyperparathyroidism, we retrospectively evaluated PTH concentrations preoperatively (prePTH), immediately post-operatively (immPTH), and the day after surgery (24hPTH). We evaluated the PTH trend and its relation to clinical characteristics, extent of surgery, autoimmunity, intraoperatively identified parathyroid glands, and thyroid weight. A total of 638 thyroidectomies were included between 2010 and 2024, 145 with central neck dissection (CND) and 132 males. Mean(SD) prePTH, immPTH, and 24hPTH were 52.1(22.6), 23.7(26.8), and 25.2(19.9) pg/mL, respectively. Globally, 24hPTH was 1.21(0.73) times higher than immediate, but 236 patients (37%) had 24hPTH lower than immPTH. This trend of increasing PTH levels did not differ between males and females, patients older than 50 years or younger (61.6% vs. 65.1%; $P = 0.40$), cases with and without autoimmunity (63.3% vs. 62.2%; $P = 0.85$), preoperative thyroid hyperfunction (58.5% vs. 64.4%; $P = 0.45$), or patients with 0-2 identified glands vs. 3-4 identified glands (60.1% vs. 62.9%; $P = 0.55$). Patients undergoing surgery for radiological, biopsy or cytological suspicion were more likely to have 24hPTH > immPTH than those undergoing surgery for clinical reasons (68.8% vs. 57.1%; $P = 0.002$). This trend was also significantly higher in patients who received CND (73.8% vs. 59.8%; $P = 0.002$) than in those who received TT alone. Out of 283 cases with immPTH < 15 pg/ml, 152 (53.7%) had a higher 24hPTH, 76 of them (24.4%) > 15 pg/ml. Thus, 207 patients (32.4%) had both below 15 pg/ml. Of the 229 patients with 24hPTH < 15, only 22 of them (9.6%) had immPTH > 15 pg/ml. Patients with decreasing PTH (24h PTH < immPTH) had higher prePTH [median(IR): 49(29) vs. 46(20) pg/ml; $P = 0.003$] and heavier glands at surgery [median(IR): 35.4(54.5) vs. 29.0(37.6) g; $P = 0.009$]. [PTH] showed a general trend towards an increase at 24 hours after surgery in relation to immediate measurement, particularly in cases with CND and those operated on for suspicion of malignancy, but there are cases with inverse dynamics, particularly in those with higher basal PTH and heavier glands at surgery. An immPTH may not be helpful in predicting low PTH, as a quarter of them recover PTH above 15 pg/ml at 24h.

Quality of life assessed by HPES and HPQ28 questionnaires in patients with post-surgical hypoparathyroidism: correlation with biochemical and clinical features

Francesco Arcidiacono[1], Antonio Prinzi[1], Ignazio Barca[1], Andrea Palermo[2], Anda Mihaela Naciu[2], Gaia Tabacco[2], Francesco Frasca[1] & Pasqualino Malandrino[1]

[1]Endocrinology Unit, Department of Clinical and Experimental Medicine, University of Catania, Garibaldi-Nesima Medical Center, 95122, Catania, Italy; [2]Unit of Metabolic Bone and Thyroid Disorders, Fondazione Policlinico Universitario Campus Bio-Medico, Roma, Italy

Background

Patients with hypoparathyroidism (HPT) experience impaired quality of life (QoL) due to poorly understood reasons. While QoL has traditionally been assessed using generic instruments such as the SF-36 questionnaire, disease-specific instruments like the HPES (Validated in several countries) and HPQ28 (validated only in German) have recently emerged, although their use remains limited.

Aims of the Study

Primary aims: to validate an Italian version of HPQ28 questionnaire; to evaluate QoL in hypoparathyroid subjects using both HPES and HPQ28. Secondary aims: to correlate questionnaire scores with clinical, biochemical and general

characteristics of subjects; to establish potential thresholds for each questionnaire that can assist clinicians in identifying when HPT impacts QoL.
Materials and Methods
Cross-sectional study including 179 subjects divided into three groups. After applying exclusion criteria (other systemic or psychiatric diseases and TSH levels outside the normal range), the final study population included: 51 thyroidectomised subjects with HPT, 49 thyroidectomised subjects without HPT and 57 control subjects without HPT or hypothyroidism.
Results
The Italian version of HPQ28 demonstrated a high reliability at test-retest (Intraclass Correlation Coefficient > 0.70) and the results for total and domain scores were consistent with those obtained with the German validated version, allowing effective assessment of symptom burden. Patients with HPT showed a significantly impaired QoL at HPES-impact (20.5% vs 7.8%, $P = 0.023$) and higher symptom burden at both HPQ28 (29.8% vs 20.2%, $P = 0.042$) and HPES-Symptom (35.8% vs 16.2%, $P = 0.011$) compared to hypothyroid patients. Symptom burden was correlated with female gender in both HPQ28 ($P = 0.040$) and HPES-Symptom ($P = 0.037$) as well as with age at HPQ28 ($P = 0.042$), but not with biochemical parameters such as serum calcium or calcium-phosphorus product, whereas QoL, as measured by HPES-impact was unrelated to general, clinical, and biochemical characteristics. However, analysis of questionnaire results by calcium quartiles revealed a trend toward improved QoL in patients with calcium levels between 8.4 and 8.9 mg/dL ($P = 0.051$). Receiver operating characteristic (ROC) analyses and the Youden Index calculation identified provisional cutoffs (HPES-impact: 16.10%; HPES-Symptom: 18.22%; HPQ28: 22.61%) to better interpret scores after single administration. Questionnaire score below these cutoffs may identify patients with lower impact of HPT on QoL and symptom burden.
Conclusion
This study highlights the significant impairment of QoL in HPT, underlines the usefulness of disease-specific questionnaires, and confirms that QoL and symptom burden do not appear to be related to biochemical data.

JOINT2461 Switch from rhpth1-84 to transcon PTH with individual dose adjustment in adult hypoparathyroidism – results for 40 patients one month after treatment transition

Heide Siggelkow[1], Kim Peschke[1], Elena Tsourdi[2], Lorenz Hofbauer[2], Christina Berr[3], Stefanie Hahner[4], Christian Lottspeich[5], Ralf Schmidmaier[5] & Martina Blaschke[1]
[1]University Medical Center Göttingen, Research and Development, Department of Trauma, Orthopedics and Reconstructive Surgery, Göttingen, Germany; [2]Technische Universität Dresden, Department of Medicine III and Center for Healthy Aging, Dresden, Germany; [3]University of Augsburg, Department of Endocrinology, Augsburg, Germany; [4]University of Würzburg, Division of Endocrinology and Diabetes, Department of Medicine I, Würzburg, Germany; [5]Ludwig-Maximilians-Universität München, Medizinische Klinik und Poliklinik IV, München, Germany

Introduction
Parathyroid hormone (PTH) replacement therapy is a relatively new treatment option for chronic hypoparathyroidism (HypoPT). As the previously approved rhPTH1-84 is no longer manufactured, patients need to switch to an alternative replacement therapy. Palopegteriparatide (TransCon PTH) is a long-acting, slow-release molecule of PTH1-34 that was recently approved by the EMA and FDA. In this retrospective multicenter study, we describe our experience with the initial phase of switching from rhPTH1-84 to TransCon PTH.
Methods
We analyzed data from 40 patients with chronic postsurgical HypoPT ($n = 37$) or nonsurgical ($n = 3$) HypoPT during the change of treatment. In Germany, rhPTH1-84 treatment was only available for patients not adequately controlled through conventional therapy or with complications, and only few patients received the expensive treatment. TransCon PTH was available during a compassionate-use program or used after officially becoming available in Germany starting January 2024. Independently of the last prior rhPTH-1-84 dose, all patients were started on 18 µg of TransCon PTH with dose adaptation, and adverse events were documented.
Results
Within the first month of transition, 80% ($n = 32$) of patients needed individual adjustment of their TransCon PTH dose. Specifically, 38% needed a dose reduction to between 9 and 15 µg, while 43% ($n = 17$) required an increase to 21-27 µg. Adjustments by treating physicians was based on serum calcium levels with the goal of calcium in the lower normal range (in 62 % cases), or dependent on symptoms. The previous rhPTH1-84 dose correlated positively with the adjusted TransCon PTH dose ($r = 0.4$; $P = 0.01$). The treatment change was associated with moderate or mild symptoms. From 34 patients documented, 38% ($n = 13$) reported headache, 38% ($n = 13$) muscular spasms or arthralgia, 24% sleep disturbance or fatigue, 21% ($n = 7$) nausea, 21% palpitations, 15% injections site reactions, and 15% other gastrointestinal symptoms ($n = 5$). Ten patients reported no negative symptoms.
Conclusion
Switching treatment from rhPTH1-84 to TransCon PTH using the initial dose of 18 µg proved to be efficient independently of the prior rhPTH1-84 dose. Adverse events were frequent, albeit mild to moderate and no patient withdrew from treatment.

[1]University of Florence, Department of Health Sciences, Florence, Italy; [2]Guy's and St Thomas's NHS Trust, Clinical Genetics, London, United Kingdom; [3]Evelina London Children's Hospital, Paediatric Endocrine and Bone Service, London, United Kingdom; [4]Evelina London Children's Hospital, Pediatric Radiology Service, London, United Kingdom

Introduction
Cleidocranial dysplasia (CCD) primarily affects intramembranous ossification, causing hypoplastic/aplastic clavicles, delayed cranial suture closure and dental abnormalities. Endochondral ossification can also be altered with impairment of bone mineral density (BMD), but data are limited.
Methods
Three databases (Embase, Medline, Cochrane) were systematically screened for publications assessing BMD in CCD. We reviewed clinical records of our CCD cohort. Collected data included DEXA assessments (lumbar spine [LS]-BMD, total body less head [TBLH]-BMD), evidence of vertebral (VF) or long-bone fractures and bisphosphonate treatments. LS-BMD of patients with height $<$-2/$>$2 SDS was adjusted using BMAD.
Results
Literature review identified 29 patients (51.7% females, 62.1% children). DEXA scan was performed in 86.2% cases, Qualitative-Ultrasound and X-Rays in the remaining. The average LS-BMD Z-score was -1.91 ($\pm$1.16), with paediatric population displaying lower scores (-2.26$\pm$1.05), particularly in females (-2.53$\pm$1.14). Adults LS-BMD Z-score was -1.38 ($\pm$1.17). Fractures were reported in 27.6% patients. Our cohort consists of 30 paediatric patients. Twenty-four (75% males; 66.7% prepubertal; average-age 9.4 years, 5.2-17.2) had $\geq$1 DEXA scan performed. Median LS-BMD Z-score resulted -1.65 (IQR 1.84), being $\leq$-2 SDS in 41.7%. Similarly, TBLH-BMD Z-score was -1.75 (1.60) and $\leq$-2 SDS in 37.5%. Osteoporosis was diagnosed in 16.7%, always VF-related and treated with bisphosphonates. Two patients reported trauma-related long-bone fractures.
Discussion
Both literature and our cohort showed low LS-BMD Z-scores. Although the lack of height-adjustment of published cases may underestimate LS-BMD, our cohort supports these findings, as 41.7% had Z-score $\leq$-2 SDS. Additionally, LS-BMD was significantly lower in prepubertal patients, highlighting pubertal influence on BMD. Even TBLH-BMD resulted low: interestingly, paediatric females showed significant lower Z-scores than males. However, the lack of height-adjustment might have overestimated the Results. Although identification of pathological fractures in published cases is hindered by the lack of details, 16.7% of our cohort met osteoporosis criteria. Finally, there was no association between LS-/TBLH-BMD Z-scores and VF: these parameters might not independently predict VF.
Conclusion
Our work emphasizes the need of screening programs for low BMD in CCD patients. DEXA assessment and bisphosphonate treatment should be considered

Comparison of LS-BMD and TBLH-BMD Z-scores (Mann-Whitney test).

	Male vs female		Prepubertal vs pubertal	
	U-statistic	*P*-value	U-statistic	*P*-value
LS-BMD	69.5	0.32	31.5	0.049*
TBLH-BMD	86	0.035*	40.5	0.16

Association between LS-BMD or TBLH-BMD Z-scores and VF (logistic regression).

	B-coefficient	*P*-value
LS-BMD	-0.134	0.743
TBLH-BMD	-0.206	0.688

Serum phosphate as a marker of disease severity in primary hyperparathyroidism

Elisa Dinoi[1], Laura Pierotti[1], Simone Della Valentina[1], Anna Dal Lago[1], Elena Pardi[1], Chiara Sardella[2], Claudio Marcocci[1] & Filomena Cetani[1]
[1]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]University Hospital of Pisa, Pisa, Italy

Serum phosphate (P) is typically reduced or low-normal in patients affected by primary hyperparathyroidism (PHPT) because of the lower expression of sodium phosphate cotransporter type2a protein in the proximal renal tubule driven by elevated PTH levels. However, current guidelines on PHPT management do not specify a P level threshold or offer recommendation regarding this parameter. To our knowledge, few studies have explored the relationship between P levels and the clinical and biochemical features of PHPT. We retrospectively evaluated 425 consecutive patients, 350 females and 75 males, affected by sporadic PHPT referred to our outpatient clinic from 2018 to 2023. Eighty-six (20%) patients were classified as symptomatic and 339 (80%) as asymptomatic according to the Guidelines from the Fifth International Workshop. Hypophosphatemia (HypoP), defined as phosphate (P) levels <2,5 mg/dL, was found in 245/425 (57%) patients and it was mild (2-2,5 mg/dL), moderate (1-1,9 mg/dL) and severe (< 1 mg/dL) in 183 (75%), 62 (25%) and 0 cases, respectively. P levels were significantly lower in males than in females (2.14±0.43 *vs.* 2.50±0.43), in patients with symptomatic vs. asymptomatic PHPT (2.34±0.49 *vs.* 2.46±0.44) and in those with nephrolithiasis (2.31±0.44 *vs.* 2.50±0.44), but not in patients with osteoporosis at any site (lumbar, femoral sites and 1/3 distal radius) or fragility fractures. Patients were further divided into two groups based on the presence or absence of hypoP. According to the above data, hypoP patients were significantly more frequently males, symptomatic and stone formers, but not osteoporotic. Moreover, patients with hypoP had a more severe biochemical phenotype namely significantly higher PTH (82 *vs.* 65 ng/l), ionized calcium (1,51 *vs.* 1,43 mmol/l), total serum calcium (11,1 *vs.* 10,7 mg/dL) and 24-h urine calcium excretion (360 *vs.* 244 mg) and significantly lower 25(OH) vitamin D levels (28 *vs.* 32 mg/l). No significant correlation was found between P levels and bone turnover markers (alkaline phosphatase, osteocalcin and S-CTX), T-score at any site or trabecular bone score TBS values. All patients, except one, with moderate hypoP met at least one surgical criterion. In conclusion, hypoP is associated with a higher risk of nephrolithiasis but not osteoporosis in PHPT patients. The question of whether moderate hypoP could serve as a reliable, cost-effective, and easily accessible criterion for parathyroidectomy, particularly in cases where evaluating all systemic complications is challenging, remains an open question.

Classification of bone turnover and calcium metabolism markers based on the molecular subtypes of osteogenesis imperfecta

Aylin Gunay[1], Aylin Tugba Canbaz[1], Ilknur Kurt[1], Elif Kelestemur[1], Ahmet Kahveci[1], Busra Gurpinar Tosun[1], Didem Helvacioglu[1], Zehra Yavas Abali[1], Belma Haliloglu[1], Tulay Guran[1], Abdullah Bereket[1] & Serap Turan[1]
[1]Marmara University School of Medicine, Istanbul, Türkiye

Introduction and Aim
Osteogenesis imperfecta (OI) is a genetic disorder characterized by bone fragility, with molecular subtypes influencing its severity and clinical presentation. This study aims to investigate how bone turnover and calcium metabolism markers vary across these subtypes.
Method
The medical records of 125 OI patients were retrospectively reviewed. Patients without genetic results, and those without pre-treatment bone turnover markers (BTMs) were excluded. A total of 83 patients (43 females) were included. Patients were classified into five molecular subgroups: Group-1 (collagen synthesis, $n = 53$), Group-2 (collagen modification, $n = 9$), Group-3 (collagen folding, $n = 10$), Group-4 (bone mineralization, $n = 6$), and Group-5 (osteoblast development, $n = 5$). Pre-treatment measurements of calcium metabolism markers (serum calcium, phosphorus, alkaline phosphatase [ALP], parathyroid hormone [PTH], and urinary calcium/creatinine [uCa/Cr]) and BTMs (osteocalcin, C-terminal telopeptide [CTX] and deoxypyridinoline [DPD]) were analyzed, and each parameter's age- and sex-adjusted standard deviation score (SDS) was calculated for intergroup comparisons. DPD and CTX could not be evaluated in all patients.

Results
One-way ANOVA revealed significant differences in osteocalcin levels among five groups, with post-hoc analysis identifying the difference between group 1 and 2 as the primary contributor. Phosphorus levels also showed a significant difference, driven by differences between group 1 and 2 ($P = 0.02$) and group 1 and 3 ($P = 0.03$). No significant differences were observed between groups for serum calcium, ALP, PTH, and uCa/Cr. DPD levels differed between groups 2 and 3. CTX levels differed between Groups 1 and 3 (Table).
Conclusion
High osteocalcin and phosphorus indicate active bone formation and mineralization, with low CTX suggesting lesser collagen degradation in group 1. Low osteocalcin and high DPD in Group 2 suggest impaired formation and excessive collagen degradation. Group 3 had low DPD but high CTX, reflecting ongoing osteoclast activity and unstable collagen resorption due to impaired cross-links. These findings offer insights into OI pathophysiology and support subtype-specific therapeutic approaches.

Autosomal dominant hypocalcemia type 1 (ADH1) and type 2 (ADH2) are rare disorders caused by activating variants of the *CASR* and *GNA11* genes, respectively. The calcium-sensing receptor (CaSR) plays a critical role in calcium homeostasis by signaling parathyroid hormone (PTH) secretion and urinary calcium (uCa) reabsorption in response to variations in blood calcium. The CaSR signals by coupling to G-proteins, including *GNA11*-encoded Gα11. The CLARIFY disease monitoring study [NCT05227287] is an ongoing global, multicenter, longitudinal, observational study to characterize disease burden, management, and progression in children and adults with ADH1/2 over a 5-year period. Of 25 pediatric participants (birth to <18y) enrolled (Mar 2022 to Jun

2024), 22 were diagnosed with ADH1 and 3 with ADH2; 64% are females. Median age at enrollment was 9 years (IQR 5-13). Median age at hypocalcemia presentation and ADH1/2 diagnosis were 0. 8 years (IQR 0. 0-3. 0) and 1. 0 year (IQR 0. 5-3. 0), respectively. Family history of ADH1/2 was reported in 64% of participants. 16 unique *CASR* and 2 unique *GNA11* variants were present, with *CASR* E767K (3) and F788C (3) the most frequent. Treatment regimen varied at baseline (Day 1 study visit): 32% (8) were on Ca and active vitamin D, 24% (6) on Ca alone, 8% (2) on active vitamin D alone, 20% (5) on PTH replacement, 20% (5) on magnesium, 12% (3) on thiazide diuretics, 12% (3) on potassium, 12% (3) on phosphate binder, 32% (8) on cholecalciferol, and 20% (5) without treatment. At baseline, 92% (23) had hypocalcemia (0-<1y <2. 1 mmol/l; 1-17y <2. 15 mmol/l), 83% (20) had low iPTH (<15 ng/l), 84% (21) had hyperphosphatemia (0-<1y >2. 5 mmol/l; 1-12y >1. 9 mmol/l; 13-17y >1. 5 mmol/l), 8% (2) had hypomagnesemia (<0. 62 mmol/l), and 84% (21) had normal total 25-OH Vitamin D (50-125 nmol/l). 32% (6) of 19 participants with 24hr uCa collected were hypercalciuric (>0. 1 mmol/kg/day); and 0% of 5 participants with spot urine collections had Ca/Cr above the aged-defined reference range (7-18mo <1. 70 mmol/mmol; 19mo – 6y <1. 16 mmol/mmol; adults <0. 59 mmol/mmol). Baseline eGFR by Schwartz equation was 117±25 mL/min/1. 73m^2 (range: 69-175). Common (proxy) self-reported ADH1-related comorbidities were seizures (36%), nephrocalcinosis (32%), dental abnormalities (20%), and long QT syndrome (16%). This study represents the largest pediatric cohort of ADH1/2 described to date. Persistent hypocalcemia and hypercalciuria, along with the high prevalence of comorbidities, highlights the ongoing medical need in this population. Long-term prospective data are needed to better understand disease progression and burden of ADH1/2.

Caloric restriction exerts duration-dependent effects on marrow adiposity, bone structure, & metabolic health

Kuan-Chan Chen[1, 2], Richard Sulston[2] & William Cawthorn[2]
[1]Tri-Service General Hospital, Internal Medicine, Endocrinology & Metabolism, Taipei, Taiwan; [2]University of Edinburgh, Queen's Medical Research Institute, Cardiovascular Science, Edinburgh, United Kingdom

Introduction
Bone marrow adipose tissue (BMAT) is a distinct and metabolically active fat depot within the bone marrow. BMAT negatively correlates with bone mineral density (BMD) and increases in diseases such as osteoporosis and type 2 diabetes. Surprisingly, BMAT also increases in caloric restriction (CR), a well-established intervention for enhancing metabolic health. Despite inducing widespread metabolic and endocrine adaptations, CR also promotes bone loss; however, the extent to which these changes are associated with BMAT remains unclear. This study aims to investigate the effects of CR duration on BMAT expansion, bone microarchitecture, and metabolic adaptations in male and female mice, providing further insights into the interplay of bone metabolism and systemic metabolic regulation during CR.
Method
Male and female mice were fed either ad libitum (AL) or a CR diet (70% of daily AL intake) for 1, 2, 4, or 6 weeks. Oral glucose tolerance tests (OGTT) and body composition analysis were conducted to evaluate metabolic responses. Serum levels of adiponectin, leptin, corticosterone, and insulin-like growth factor 1 (IGF-1) were measured at each time point. Bone microarchitecture and BMAT volume were analyzed using micro-computed tomography and osmium staining.
Results
The effects of CR on BMAT accumulation were region-specific: the primary effect was on the tibia, followed by the femur, while effects on the humerus were negligible. These effects on BMAT were also duration-dependent, with CR's impact plateauing after 4 weeks of CR. Regarding bone microstructure, CR significantly decreased cortical bone area and thickness in both sexes but had a lesser influence on trabecular bone, decreasing only trabecular thickness in females. Notably, at the metaphysis, females exhibited greater CR-induced BMAT accumulation than males and this is accompanied by a reduction in trabecular thickness. CR improved glucose tolerance after only one week, and this effect persisted thereafter. During CR, adiponectin and corticosterone levels increased while leptin and IGF-1 levels declined. Notably, adiponectin levels plateaued around weeks 3–4 of CR, a pattern that coincided with BMAT expansion.
Conclusion
Our findings demonstrate that CR-induced BMAT expansion and bone architectural changes are influenced by CR duration, sex, and skeletal site. Moreover, the improvement in glucose tolerance observed with CR occurs independently of BMAT expansion, while BMAT accumulation may either contribute to or result from elevated adiponectin levels and cortical bone loss. Our findings highlight a potential interaction between BMAT and systemic metabolic adaptations.

A novel method for the detection of hypercalciuria in individuals with chronic hypoparathyroidism

Elvira O Gosmanova[1], Carol Zhao[2], Christopher Sibley[2], Michael Makara[2] & Kenneth R Phelps[3]
[1]Albany VA Medical Center, Albany Medical College, Medicine/Nephrology, Albany, United States; [2]Ascendis Pharma, Inc., Palo Alto, United States; [3]Albany VA Medical Center, Albany Medical College, Albany, United States

Background
Current guidelines recommend avoiding hypercalciuria to minimize the risk of renal complications during treatment of chronic hypoparathyroidism. Measurement of 24-hour urine calcium (24uCa) is the gold standard for diagnosing hypercalciuria; however, this method is inconvenient and susceptible to error. As an alternative, we evaluated calcium excretion per volume of filtrate (E_{Ca}/C_{cr}), which is calculated from measurements in simultaneous aliquots of serum and urine and does not require a timed urine collection.
Methods
This was a post-hoc analysis of the PaTH Forward trial (NCT04009291) of palopegteriparatide, in which 59 adults with chronic hypoparathyroidism were enrolled in a phase 2, randomized, double-blind, placebo-controlled 4-week trial followed by an ongoing open-label extension with palopegteriparatide. E_{Ca}/C_{cr} was calculated as $Ca_{u*}cr_s/cr_u$, where, Ca_u is urine calcium concentration, and cr_u and cr_s are urine and serum creatinine concentrations measured from simultaneous morning non-fasting samples. A 24-hr urine collection was performed 1-7 days (median 3 days) prior to E_{Ca}/C_{cr}. Paired 24uCa and E_{Ca}/C_{cr} evaluations were matched by visit. Hypercalciuria was defined as 24uCa > 300mg/day. Linear associations between E_{Ca}/C_{cr} and 24uCa were evaluated with the Pearson correlation (PC) method. Receiver operating characteristic (ROC) analysis was used to assess the diagnostic accuracy of E_{Ca}/C_{cr} in detection of hypercalciuria.
Results
There were 247 paired E_{Ca}/C_{cr} and 24uCa measurements collected through the 110-week follow-up, including 50 baseline measurements prior to palopegteriparatide initiation. At baseline, median (IQR) 24uCa was 381 (296-602) mg and 72% of individuals had hypercalciuria. Median 24uCa excretion declined to 149, 125, 108, and 150 mg/day during 26, 58, 84, and 110 weeks of open-label period. Baseline mean (SD) E_{Ca}/C_{cr} was 0. 25 (0. 13) mg/dL; it fell to 0. 13, 0. 10, 0. 10 and 0. 10 mg/dL during the same time points. E_{Ca}/C_{cr} strongly correlated with 24uCa (PC coefficient 0. 61, $P < 0.001$). $E_{Ca}/C_{cr} \geq 0.149$ mg/dL had 76% sensitivity, 85% specificity, and 84% accuracy for detecting 24uCa > 300mg/day (AUC 0. 837). E_{Ca}/C_{cr} of <0. 08 and >0. 21 mg/dL virtually excluded the presence and absence of hypercalciuria.
Conclusions
These results show that E_{Ca}/C_{cr} correlates with 24uCa in people with chronic hypoparathyroidism. Given the convenience and the accuracy of E_{Ca}/C_{cr} as compared with 24uCa, these findings suggest that E_{Ca}/C_{cr} may be useful for the detection of hypercalciuria in individuals treated for chronic hypoparathyroidism.

Cardiovascular disease in patients with post-surgical hypoparathyroidism

Sarah Thornhøj[1, 2], Line Underbjerg[1], Lene Ring Madsen[3 4 5], Simon Winther[2, 6], Morten Böttcher[2, 6] & Lars Rejnmark[1, 2]
[1]Aarhus University Hospital, Department of Endocrinology and internal medicine, Aarhus, Denmark; [2]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; [3]Aarhus University Hospital, Steno Diabetes Center Aarhus, Aarhus, Denmark; [4]Gødstrup Hospital, Department of Internal Medicine, Herning, Denmark; [5]Odense University Hospital, Danish Diabetes Academy, Odense, Denmark; [6]Gødstrup Hospital, Department of Cardiology, Herning, Denmark

Introduction
Hypoparathyroidism (HypoPT) is a rare disorder characterized by hypocalcemia with low levels of parathyroid hormone (PTH). The most common cause of HypoPT is due to neck surgery and is considered chronic if treatment is still needed a year after surgery. PTH has been recognized as a hormone with cardiovascular properties. However, effects of PTH on the cardiovascular system are not well-defined. A previous large retrospective cohort study of patients with chronic HypoPT showed that patients with HypoPT have a significantly higher risk of cardiovascular disease, compared to patients without HypoPT. We aimed to investigate the risk of cardiovascular disease in patients with chronic post-surgical HypoPT.
Methods
Pre-liminary data from a cross-sectional study on 50 patients with chronic post-surgical HypoPT compared to 50 randomly selected people from the general population matched on gender and age ($\pm$2 years). All participants underwent blood sampling, coronary computed tomography angiography (CCTA), measurements of pulse wave velocity (PWV) and office blood pressure (BP). Pulse wave velocity was measured using an applanation tonometer (AtCor SpygmoCor-XCEL).
Results
63 people have consented to participate in the study (35 patients and 28 controls). 56% of these have completed the entire protocol. Mean age of patients were 59 years (31-84 years), 86% female. Duration of HypoPT 13 years ($\pm$7 years). Risk factors of cardiac disease (hypertension, smoking, hypercholesterolemia, diabetes) did not differ significantly between groups ($p_{all} > 0.05$). Mean office BT was 124/76 mmHg in patients with HypoPT compared to 125/74 mmHg in controls, $P = 0.96$. Mean LDL cholesterol did not differ between groups, $P = 0.32$. Mean pulse wave velocity was 8. 49 m/s (95% CI 7. 84; 9. 14 m/s) in patients with HypoPT compared to 8. 88 m/s (95% CI 8. 24; 9. 52 m/s) in controls, $P = 0.42$. However, the proportion of HypoPT patients with one or more plaques present in the coronary arteries was 59% (95% CI 39; 78) compared to only 25% (95% CI 3; 65) of the controls, $P = 0.12$. The final results await.
Conclusion
Preliminary results suggest that patients with disturbances in calcium homeostasis due to post-surgical HypoPT may have an increased risk of coronary atherosclerosis.

Bone age assessment as a marker of skeletal maturation is a relevant biomarker in treatment decisions. Visual evaluation by the atlas methods according to Greulich-Pyle (GP) or Tanner-Whitehouse are standard procedures. However, these comparators are based on images from healthy children. Another disadvantage is the subjective nature of the procedure and in the evaluation of abnormal bone structure, e. g. skeletal dysplasia. BoneXpert was the first artificial intelligence (AI) radiology system to be marketed, but as outlined in the manual this tool excludes data analysis from subjects with bone dysplasia. To address this gap, we developed Deeplasia; an open-source prior-free deep-learning approach designed for bone age assessment, specifically validated on skeletal dysplasias incl. achondroplasia (Rassmann *et al*., 2023). To expand its validation scope, Deeplasia was integrated into the CrescNet auxological database (ClinicalTrials.gov ID: NCT03072537). All data were documented directly during the visit at participating endocrine centers. 953 images from different diagnoses were examined by both Deeplasia and by paediatric endocrinologists (Table) and analyzed using Bland-Altman plot. In particular, we included images from subjects with achondroplasia (305 images of 126 patients), hypochondroplasia (62/21), Noonan syndrome (83/16), SHOX deficiency (226/42), Silver-Russell syndrome (SRS, 24/5), Ullrich-Turner syndrome (UTS, 223/57), and others (38/23). Mean visual bone age was 8. 3 years (SD 4. 1) according to Greulich-Pyle and 8. 4 years (4. 2) according to Deeplasia. Analysis of the Bland-Altman plot between the two methods shows a high level of agreement across all ages, with few outliers.
In conclusion, our data support that Deeplasia might significantly aid in assessing BA in skeletal dysplasia.

	Achondroplasia	Hypochondroplasia	Noonan	SHOX	SRS	UTS
N	305	62	83	226	24	223
Mean difference Deeplasia vs. GP (years)	-0. 25	0. 26	0. 26	0. 47	0. 72	0. 03
SD (years)	1. 03	1. 66	0. 72	0. 88	0. 96	0. 85

Switch from rhPTH1-84 to transcon PTH in patients with hypoparathyroidism normalizes phosphate, magnesium metabolism, and bone turnover

Heide Siggelkow[1], Kim Peschke[1] & Martina Blaschke[1]
[1]University Medical Center Göttingen, Research and Development, Department of Trauma, Orthopedics and Reconstructive Surgery, Göttingen, Germany

Introduction
Hypoparathyroidism is a rare disease, 75% of cases are due to thyroid or parathyroid surgery. Conventional treatment of Hypoparathyroidism with active vitamin D and calcium is associated with high pill burden and long term complications associated with high phosphate values. Replacement therapy with recombinant human parathyroid hormone (rhPTH1-84) decreased phosphate levels, however did not normalize hypercalciuria. Palopegteriparaide (TransCon PTH) is a long-acting molecule with slow release of PTH1-34, which has recently received approval from the EMA and FDA. In this one center study, we describe the effect of treatment switch from rhPTH1-84 to TransCon PTH on bone metabolism after one, three and six months of treatment.
Methods
We analyzed data from 26 patients with chronic postsurgical HypoPT ($n = 23$) or nonsurgical ($n = 3$) HypoPT during the change of treatment. Patients were predominantly women (20f/6m) with a mean age of 56$\pm$14 years (range 33-84 years). Duration of hypoPT was 16. 6 $\pm$10 years (range 3. 9-44) and treatment with rhPTH 4. 2$\pm$1. 7 years (range1. 3-6. 5). Complications were 46% nephrocalcinosis, 11% renal insufficieny, 11% nephrolithiais, 11% Fahr's disease, and 11% cataract. TransCon PTH was available during a compassionate-use program or used after officially becoming available in Germany starting in January 2024. Independent of the last prior rhPTH-1-84 dose, all patients were started on 18 µg of TransCon PTH and doses adapted individually. Serum values and 24 h urine were collected before treatment change and after one month, three and six months. Until now 20 patients finished the six months treatment.

Results
Six months after change from rhPTH(1-84) more patients were in the normal range for calcium and phosphate (77% vs 90%) with normalization of FGF23 metabolism (64. 2±36. 1 vs 79. 1±24. 1; $P < 0.0001$). Hypercalciuria was also significantly reduced. Palopegteriparatide increased magnesium levels (0. 76±0. 07 mmol/l vs 0. 83±0. 08; $P = 0.0011$) by decreasing urinary excretion of magnesium already after one-month treatment (110. 2±61. 8 mmol/day vs 100. 7±71. 8 and 97. 0±59. 2 at six months). Treatment change significantly decreased the rhPTH(1-84)-induced high bone turnover for bone alkaline phosphatase, P1NP and desoxypyridinoline/urine. Conclusions Switching treatment from rhPTH1-84 to TransCon PTH was followed by significant changes towards normalization in calcium, phosphate, and magnesium metabolism and bone turnover during the first six months of treatment.

Risk of non-completion of sequential osteoporosis therapy after teriparatide treatment - real-life data from Hungary

Istvan Takacs[1, 2], Boglarka Szabo[1], Enikő Jókai[3], Szilvia Meszaros[1], Balint Mazzag[4], Robert Frigyesy[4] & Peter Lakatos[1]
[1]Semmelweis University, Internal Medicine and Oncology, Budapest, Hungary; [1]Semmelweis University, Internal Medicine and Oncology, Budapest, Hungary; [3]Gedeon Richter Plc, Budapest, Hungary; [4]Research-flow Ltd, Kaposvar, Hungary

The beneficial effect of antiresorptive treatment following anabolic treatment on bone fragility is well known, but there are no real-life data on the risk change in the absence of such treatment. In our retrospective longitudinal study, we examined the fracture data of patients receiving teriparatide therapy in Hungary between 1 January 2009 and 31 December 2023 using the databases of the National Health Insurance Fund Administration. There is a single health insurance fund in Hungary, so both prescription and fracture data are considered representative of the total population. We investigated the trend in hip fracture rates during and after teriparatide treatment as a function of adherence, depending on whether patients received sequential antiresorptive treatment. 13 774 patients with severe osteoporosis were treated with teriparatide during the study period. Of these, data were analysed for 8893 patients who had completed teriparatide treatment by the end of 2021 and had an adherence rate to teriparatide treatment of more than 20%. 91% of patients were female and 8. 7% of patients had a hip fracture during the entire observation period. Within 90 days of teriparatide treatment, 20% of patients received denosumab and 10% received a bisphosphonate. Even without sequential treatment three years after teriparatide treatment, the number of hip fractures was significantly lower in the group with more than 80% adherence than in the group with less than 20% adherence ($P < 0.01$). However, treatment with denosumab or a bisphosphonate after teriparatide discontinuation significantly reduced the risk of hip fracture compared with those who did not receive an antiresorptive agent. (RR: 0. 469, $P < 0.01$) The timing of treatment initiation also influenced the increase in fracture risk. If treatment was continued beyond 90 days, the relative risk increased significantly, with this delay almost doubling the risk of hip fracture if treatment was continued with denosumab (RR: 1. 48, $P < 0.01$). In conclusion, although the beneficial effect of teriparatide treatment can be demonstrated for years without continued treatment, antiresorptive treatment started within 90 days can achieve an additional fracture risk reduction of more than 50%. Our study provides fracture data to support a clear benefit of sequential therapy after teriparatide treatment.

Wide clinical spectrum of GCM2-related primary hyperparathyroidism

Reut Halperin[1, 2], Liana Tripto-Shkolnik[1, 2], Gil Goldinger[1, 2], Naama Peshes-Yaloz[1] & Amit Tirosh[1, 2]
[1]Sheba Medical Center, Tel Aviv University, Division of Endocrinology, Diabetes and Metabolism, Ramat Gan, Israel; [2]Tel Aviv University, Tel Aviv, Israel

Primary hyperparathyroidism (PHPT) is a prevalent endocrine disease, with up to 10% risk for genetic predisposition. The *GCM2* gene p. Y394S pathogenic variant (PV), found mostly in Ashkenazi Jews, leads to an autosomal dominant disorder of familial isolated hyperparathyroidism. We aimed to compare the biochemical phenotype of patients with various hereditary PHPT.

Methods
In this prospective study, we included patients that underwent next generation sequencing due to a diagnosis of neuroendocrine neoplasms, suspected multiple endocrine neoplasia syndromes or PHPT. We compared demographic, clinical and biochemical parameters, and surgical outcome data between pathogenic variant carriers vs. non-carriers.
Results
A total of 380 patients underwent genetic analysis, of them sixty patients diagnosed with PHPT (63. 3% females, mean age at diagnosis 45. 1±2. 1 years). Eleven (18. 3% of those with PHPT) carried a PV in a PHPT-relevant gene: four patients had *MEN1* PV (6. 7%), five - *GCM2* (8. 33%) and two - *CDKN1B* gene PV. Age at diagnosis, serum and urinary calcium levels were comparable between carriers and non-carriers. However, number of parathyroid glands involved was significantly higher in the carriers vs. non-carriers group ($P = 0.011$), with a trend toward increased rate of recurrence in the carrier group ($P = 0.06$). Twelve (3. 75%) patients evaluated for other clinical diagnoses were found to carry a PV in PHPT-related genes: six in *GCM2*, three in *CDKN1B*, two in *MEN1* and one in *RET*. In the entire cohort, eleven patients, all of Jewish ancestry, carried the *GCM2* p. Y394S PV, of them seven (63. 6%) had PHPT. Clinical presentation was various, most patients with GCM2-related PHPT had a mild disease. However, one patient had a post-surgical recurrence and another patient presented with hypercalcemic crisis at the age of 32 with a three-generation history of PHPT, and a maternal grandfather deceased due to hypercalcemic crisis at the age of 47. In contrast, three *GCM2* PV carriers did not develop hypercalcemia until their evaluation at the ages of 51, 59 and 81 years.
Conclusion
Based on a large cohort of patients with hereditary PHPT, we report various biochemical phenotypes in patients with the p. Y394S *GCM2* PV, ranging between absence of hypercalcemia in adulthood, and hypercalcemic crisis at a young age.

JOINT3319

Risk of atypical femoral fractures among osteoporotic patients on denosumab treatment in real-life setting: a population-based study

Uri Goldwaser[1], Uri Yoel[2], Liana Tripto-Shkolink[3] & Merav Fraenkel[2]
[1]Faculty of Health Scince Ben-Gurion University of the Negev, Goldman School of Medicine, Beer-Sheva, Israel; [2]Soroka University Medical Center, Faculty of Health Science Ben-Gurion University of the Negev, Endocrinology, Beer-Sheva, Israel; [3]Sheba Medical Center, Mineral and Bone Diseases Service, Division of Endocrinology, Diabetes and Metabolism, Tel-Hshomer, Israel

Background
Atypical femoral fractures (AFF) are rare but serious adverse events with distinct radiographic criteria but lack specific ICD-9 diagnostic codes. While the association between bisphosphonates (BP) treatment and AFF is well established, denosumab's (DMAB) risk profile remains unclear, particularly when used after BP.
Aim
To evaluate AFF risk in patients treated with DMAB after prior BP use.
Methods
This population-based study included Clalit HMO patients aged ≥50 years who received osteoporosis treatment between 2002 and 2024. Patients were classified as BPs only (at least one purchase of zoledronic acid or more than one oral BP purchase), or DMAB after BP (at least 2 purchases of DMAB following no more than 3 years from last BP purchase). AFF cases were identified using a validated algorithm combining specific femoral fracture diagnostic and surgical procedure codes, achieving 96. 88% sensitivity, 95. 10% specificity, and 38. 75% positive predictive value when validated against radiographically adjudicated cases meeting ASBMR 2014 criteria. Cases with concurrent pathological fractures, motor vehicle accidents, or peri-prosthetic fractures within 14 days were excluded. We used Cox regression with treatment status (e. g., BP, DMAB as second-line) being a time-varying covariate, to compare AFF risk between the groups. Hazard ratios (HR) were adjusted for age.
Results
262, 482 patients were included in the analysis: 242, 117 patients in the BP-only group (85% female, mean age 68. 8±10. 0 years), and 16, 629 patients in the DMAB-after-BP group (93% female, mean age 65. 9±8. 8 years). 2, 622 AFF cases occurred during 1, 866, 704 BP patient-years and 98 AFF cases occurred during 76, 743 DMAB patient-years. AFF risk was significantly lower during DMAB treatment after BP compared to BP treatment (HR: 0. 25, 95% CI: 0. 20-0. 31). Patients who developed AFF during DMAB treatment after BP had previously received BP therapy for a mean duration of 10. 8 ± 4. 6 years before switching to DMAB and had a mean DMAB exposure of 2. 9 ± 2. 4 years.

Conclusion
In our analysis, DMAB treatment following BP was associated with a lower risk of AFF compared to BP therapy. This finding is particularly relevant given the common clinical practice of transitioning patients from BP to DMAB therapy. A prospective study is needed to further support the safety of DMAB therapy after BP.

Histopathological and clinical differences in primary hyperparathyroidism: a retrospective analysis of parathyroid adenomas with severe and mild hypercalcemia

Irem Sonmezoglu Kutuk[1], Meral Uner[2], Cenk Sokmensuer[2], Suleyman Nahit Sendur[3] & Bulent Yildiz[3]
[1]Division of Endocrinology and Metabolism, Gazi University Faculty of Medicine, Ankara, Türkiye; [2]Department of Pathology, Hacettepe University Faculty of Medicine, Ankara, Türkiye; [3]Division of Endocrinology and Metabolism, Hacettepe University Faculty of Medicine, Ankara, Türkiye

Background and Aim
Primary hyperparathyroidism (PHPT), predominantly caused by parathyroid adenomas, exhibits a broad spectrum of clinical and histopathological manifestations, ranging from mild to severe hypercalcemia. Severe hypercalcemia (Ca $>$13 mg/dL) is linked with complications such as osteoporosis and nephrolithiasis, while mild hypercalcemia (Ca $<$12 mg/dL) is often asymptomatic. This study aimed to explore differences in tumor characteristics, clinical outcomes, and histopathological markers between these groups, providing insights into their pathophysiology and prognostic implications.
Subjects and Methods
A retrospective analysis was conducted on 66 patients with PHPT due to parathyroid adenomas. Patients were divided into two age-matched groups: 46 with mild hypercalcemia (Ca $<$12 mg/dL; mean age 54. 3 $\pm$ 11. 3 years) and 20 with severe hypercalcemia (Ca $>$13 mg/dL; mean age 51. 9 $\pm$ 17. 8 years). Immunohistochemical analyses for parafibromin, cyclin D1, TP53, and Ki67 were performed on pathological specimens. Tumor size, mitotic activity, fibrosis, and clinical, hormonal, and biochemical parameters were also evaluated.
Results
The severe hypercalcemia group demonstrated significantly higher median serum calcium and parathormone levels (13. 8 mg/dL [IQR: 13. 3–14. 5], 351. 4 pg/mL [IQR: 216. 9–487. 7]) compared to the mild hypercalcemia group (11. 2 mg/dL [IQR: 10. 9–11. 6], 152. 3 pg/mL [IQR: 121. 3–227. 6]). Despite these differences, no significant variations were found between the groups in tumor size (P = 0. 43), mitotic activity (P = 1. 0), fibrosis (P = 0. 12), or immunohistochemical markers such as parafibromin (P = 0. 47), cyclin D1 (P = 0. 7), beta-catenin (P = 0. 82), and Ki67 (P = 0. 63). Additionally, there were no significant differences in the prevalence of osteoporosis (Ca $<$12, n = 17; Ca $>$13, n=2; P = 0. 17) or nephrolithiasis (Ca $<$12, n = 18; Ca $>$13, n = 12; P= 0. 18).
Conclusion
Severe hypercalcemia in PHPT reflects greater biochemical disease severity, yet histopathological and molecular profiles of parathyroid adenomas remain comparable across calcium levels. These findings suggest that hypercalcemia severity may stem from factors beyond tumor pathology, including functional variations in adenomas or host-specific influences. Further research is required to uncover mechanisms contributing to disease severity and their clinical implications.

Introduction
ENPP1 is a critical enzyme involved in the generation of pyrophosphate, an inhibitor of skeletal mineralization, and adenosine, a regulator of vascular intimal proliferation. Patients with biallelic, loss of function *ENPP1* variants typically present at birth with severe arterial calcification and cardiovascular complications, a phenotype described as Generalized Arterial Calcification of Infancy Type 1 (GACI Type 1). Those who survive beyond infancy develop Autosomal Recessive Hypophosphatemic Rickets Type 2 (ARHR2), with deficient mineralization of the bone and growth plate leading to impaired growth and skeletal deformities.
Purpose
To describe Rickets Severity Score (RSS), height, bone age, Bone Health Index (a surrogate for bone strength), and treatments/interventions in pediatric patients with ENPP1 Deficiency under current standard of care.
Methods
Sub-group analysis of a multicenter longitudinal retrospective chart review, including patients with clinical and genetic diagnosis of ENPP1 Deficiency. In a post-hoc analysis, Bone Age and Bone Health Index were calculated using BoneXpert^{TM} software.
Results
Fourteen patients with ENPP1 Deficiency were enrolled. Two died in infancy, and 12 were enrolled at a median age of 19. 5 years (range: 4-33). Seven patients were diagnosed with GACI, and 10 with ARHR2 at a median age of 5 years (range 0. 3 – 21), including 3 with both phenotypes. All 7 with GACI required medication (n = 6) and/or respiratory support (n = 5) in infancy; 5/12 surviving patients (42%) received at least one antihypertensive in childhood or early adulthood. Nine surviving patients (75%) required medication for rickets (vitamin D analogs n = 9; phosphate supplements n = 8), 9 had at least one orthopedic surgery (epiphysiodesis n = 7, osteotomy n = 5), and 6 wore hearing aids. All 13 patients assessed were hypophosphatemic, and 11/13 had elevated alkaline phosphatase (ALP) levels. Median Global RSS in children $<$13 years of age (n = 8) was 1. 75 (range 0-3). Height Z scores tended to decline over time. At final follow up, 5 patients had short stature (Z score $\leq$-2) including 3 patients with stature Z scores more than 3. 0 standard deviations below the mean. Mean bone age was delayed by 0. 87$\pm$1. 28 years relative to chronological age (P $<$ 0. 01), as calculated by BoneXpert assessment of 33 hand X-rays across 9 patients. Mean Bone Health Index Z score was reduced at -1. 31$\pm$1. 33; P $<$ 0. 001.
Conclusions
Children with ENPP1 Deficiency under current standard of care exhibit considerable and heterogenous impairments in bone health, overlapping with other forms of genetic hypophosphatemias. In addition, surviving patients may require treatments/interventions for hypertension and hearing loss.

General Hospital, Athens, Greece; [6]Department of Endocrinology and Diabetes and Department of Medical Research, 251 Hellenic Air Force & VA General Hospital, Athens, Greece

Background
Chronic hypoparathyroidism (HypoPT) is a rare endocrine disorder characterized by deficient parathyroid hormone (PTH) levels, leading to hypocalcemia and dependency on calcium and active vitamin D., Trans-conPTH 1-34 formulation (Yorvipath), has emerged as a potential therapeutic option for patients with uncontrolled hypoparathyroidism or those previously treated with rhPTH(1-84). This study presents preliminary results from an ongoing prospective cohort-study evaluating the real-world effectiveness of Yorvipath.
Methods
Eligible patients were adults diagnosed with HypoPT who required trans-conPTH due to inadequate control on conventional therapy or as a replacement for prior treatment with rhPTH(1-84). All included patients started Yorvipath at 18 mg and were followed regularly during the titration period.
Results
Thirty-seven patients (aged 21–70years) were included. The majority (29/37) had surgical hypoparathyroidism, including eight cases related to thyroid cancer. Six patients had idiopathic hypoparathyroidism, one developed infiltrative hypoparathyroidism due to sarcoidosis, and another due to iron deposition from transfusion-dependent thalassemia. The mean disease duration was 12 ± 9. 7 years (range 1-44y). Before initiating Yorvipath, 21 patients (56%) had been treated with rhPTH (1-84) at doses ranging from 75 to 100 mg/day. Baseline conventional treatment included an average of 2000 mg/day of calcium-supplements (divided into 3–4 doses), 1. 5 mg/day of active vitamin-D, 1400 IU/day of cholecalciferol, and 746 mg/day of magnesium. Additionally, 15 patients (40%) were on hydrochlorothiazide for hypercalciuria. The mean duration of Yorvipath treatment was 90 ± 59 days (range 11-210). By the last study visit, albumin-corrected calcium levels had significantly increased compared to baseline (9. 0 ± 0. 58mg/dL vs. 8. 15 ± 0. 65mg/dL, respectively, $P < 0.001$), while phosphate levels had decreased (4. 0 ± 0. 59mg/dL vs. 4. 64 ± 1. 12mg/dL, respectively, $P = 0.004$). Notably, 60% of the cohort (23/37) achieved independence from both calcium and active vitamin D within the first 21 days of treatment (range:7–60 days). Among the remaining patients, eight continued with low-dose calcium supplements (<600 mg/day), and only five required ongoing activated vitamin D. No significant differences were observed between drug-naïve patients and those previously-treated with rhPTH(1-84). The median dose of Yorvipath was 21mg(range 12-30mg). No adverse events were reported during treatment with Yorvipath. Two patients (5%) experienced transient hypercalcemia during the titration period.
Conclusion
Preliminary findings suggest that Yorvipath is effective in reducing or eliminating the need for calcium and activated vitamin-D treatment in patients with HypoPT. Most patients achieved Ca/active VitD independence within the first few weeks of treatment. Further studies with longer follow-up are warranted to confirm the long-term efficacy and safety of Yorvipath in this patient population.

Relation of body composition with 3D-DXA parameters and trabecular bone score in women with anorexia nervosa

Iana Mizumukai de Araújo[1], Maria Victoria Rebolho[1], Vivian Suen[1, 2], Carlos Ernesto Salmon[3] & Francisco de Paula[1]
[1]Faculdade de Medicina de Ribeirão Preto - Universidade de São Paulo, Ribeirão Preto, Brazil; [2]Eating Disorder Support Group, Hospital das Clinicas, Faculdade de Medicina de Ribeirão Preto - Universidade de São Paulo, Ribeirão Preto, Brazil; [3]Faculdade de Filosofia, Ciências e Letras de Ribeirão Preto - Universidade de São Paulo, Ribeirão Preto, Brazil

Anorexia nervosa (AN) is a psychiatric disorder characterized by self-imposed fasting leading to significant weight loss and consequently nutrient deficiencies that disrupt the bone metabolism. Also, the catabolic processes in muscle and adipose tissue are associated with bone loss. Curiously, caloric restriction leads to marrow adipose tissue (MAT) expansion, which is associated with low bone mineral density (BMD). This cross-sectional observational study aimed to evaluate MAT in the tibia and explore the relationships between 3D shaper parameters, dual-energy-X-ray absorptiometry (DXA), body composition, and trabecular bone score (TBS). Both groups underwent blood sampling, DXA scans, TBS assessments, magnetic resonance ^{1}H spectroscopy of the tibia, and 3D shaper analysis. The study included 12 women with AN, monitored by a multi-disciplinary team, and 11 healthy controls (C), matched by age (C:25. 6 ± 8. 6; AN:24. 2 ± 10. 0 years) and height (C:1. 62 ± 0. 05; AN:1. 59 ± 0. 09 m). The total MAT was significantly higher in the AN (93. 2 ± 6. 4 %) than C (87. 0 ± 8. 5 %). Total hip (TH) BMD (C:0. 96 ± 0. 07; AN:0. 81 ± 0. 16 g/cm^2), TH Z-score (C:-0. 32 ± 0. 57; AN:-1. 49 ± 1. 18), femoral neck (FN) BMD (C:0. 98 ± 0. 06; AN:0. 81 ± 0. 17 g/cm^2), and FN Z-score (AN:-0. 35 ± 0. 57; C:-1. 21 ± 0. 99) were significantly lower in AN. Additionally, fat mass index was reduced in women with AN (C:7. 70 ± 1. 44;AN:5. 56 ± 1. 96 kg/m^2, $P < 0.01$), while the appendicular lean mass index (ALMI) was similar between both groups (C:5. 88 ± 0. 71; AN:5. 68 ± 1. 25 kg/m^2). The 3D shaper parameters tended to be lower in the AN [e. g. cortical sBMD total (C:151 ± 14; AN:129 ± 26 mg/cm^2) and trabecular vBMD total (C:194 ± 25; AN:153 ± 53 mg/cm^3)]. A negative association was observed between MAT and FNBMD (R^2=0. 3, $P = 0.02$). There was association between total cortical volumetric BMD (vBMD) ($P = 0.02$, R^2=0. 26), cortical surface BMD ($P = 0.01$, R^2=0. 31), integral vBMD ($P = 0.03$, R^2=0. 24), and TBS. FN Z-score had a trend of association with ALMI ($P = 0.05$, R^2=0. 19) and was related with FMI ($P = 0.04$, R^2=0. 20). In addition, it was observed a negative relationship of total cortical thickness with ALMI ($P = 0.04$, R^2=0. 21) and FMI ($P = 0.04$, R^2=0. 21). The results suggest that women with AN exhibit reduced BMD compared to healthy controls, beside compromised 3D-DXA parameters of the proximal femur and decreased TBS. The present study is the first to show that the tool 3D shaper potentially can detect bone impairment in AN. Moreover, it suggests that fat mass has a stronger association with FN BMD than lean mass in AN and confirms a negative relationship between MAT and bone mass in AN.

Treatment of hypercalciuria in patients with chronic hypoparathyroidism

Carmina Teresa Fuss[1], Philipp Hofmann[1], Christina Berr[2] & Stefanie Hahner[1]
[1]University Hospital Würzburg, Department of Internal Medicine I, Division of Endocrinology and Diabetes, Würzburg, Germany; [2]Funktionsbereich Endokrinologie und Stoffwechsel, I. Medizinische Klinik, Universitätsklinikum, Augsburg, Germany

Background
Chronic hypoparathyroidism (hypoPT) is characterized by insufficient production of parathyroid hormone, resulting in hypocalcemia and hyperphosphatemia. This condition can lead to hypercalciuria, which is a common finding in patients with chronic hypoparathyroidism and can contribute to long-term renal complications such as nephrocalcinosis, kidney stones, and impaired renal function. Current guidelines suggest adjustment of calcium and active vitamin D and/or treatment with thiazide diuretics to reduce hypercalciuria. However, data regarding their efficacy is lacking.
Methods
We retrospectively analyzed urinary calcium excretion in 244 patients with chronic hypoparathyroidism from two different German centers (Wuerzburg $n = 224$, Augsburg $n = 20$) between 1999 and 2024 (median age 52 years [IQR 19-82], 75% female, 91% postsurgical hypoPT). A total of 1231 patient-years were recorded with a median of 4. 2 [IQR 1-24] visits per patient and a median follow-up of 5 [IQR 0-23] years.
Results
At baseline (first recorded visit), 39% ($n = 95$) of patients presented with hypercalciuria, whereas concomitant treatment with thiazide diuretics occurred only in 13% of patients. During time of data collection, thiazide treatment was initiated in 97 cases. The majority of patients received hydrochlorothiazide (73%) at a median daily dose of 22 mg [IQR 12. 5-50]. Initiation of thiazide treatment led to a significant reduction of urinary calcium excretion (-2. 31 mmol/d, $P < 0.001$) at the next recorded visit. This effect was even more pronounced in case of hypercalciuria at treatment initiation (-3. 49 mmol/d, $P < 0.001$, $n = 68$). Interestingly, higher thiazide doses did not lead to a greater reduction of urinary calcium and 70% of patients remained hypercalciuric despite initiation of thiazide treatment. Serum albumin-corrected calcium remained unchanged during treatment. Reduction of oral calcium supplementation by 833 mg/d (median) led to a significant decrease of urinary calcium (-1. 79 mmol/d, $P < 0.001$ for the whole cohort, -2. 86 mmol/l, $P < 0.001$ for hypercalciuric patients at baseline), whereas a reduction of calcitriol by 0. 5 µg/d decreased urinary calcium excretion by 2. 8 mmol/d at the following visit.
Conclusion
Hypercalciuria frequently occurs in patients with hypoPT. Thiazides, as well as dose reduction of calcium or active vitamin D significantly reduce urinary calcium excretion. However, even the combination of both approaches was still not sufficient to lower urinary calcium into the normal range.

Effect of thiazide diuretics on bone turnover in osteoporotic postmenopausal patients with idiopathic hypercalciuria

Giacomo Fabio Antonio Grifoni[1], Vittoria Favero[1, 2], Alessandro Risio[1], Carmen Aresta[2], Elisa Cairoli[3], Sabrina Corbetta[4, 5] & Iacopo Chiodini[1, 2]
[1]Department of Medical Biotechnology and Translational Medicine, University of Milan, Milan, Italy; [2]Unit of Endocrinology, Azienda Socio Sanitaria Territoriale (ASST) Ospedale Niguarda, Milan, Italy; [3]Division of Endocrinology-Diabetology Dietetics, and Clinical Nutrition, Sant'Anna Hospital, ASST Lariana, Como, Italy; [4]Bone Metabolism Disorders and Diabetes Unit, Istituto di Ricerca e Cura a Carattere Scientifico (IRCCS) Istituto Auxologico Italiano, Milan, Italy; [5]Department of Biomedical, Surgical and Dental Sciences, University of Milan, Milan, Italy

Introduction
Idiopathic hypercalciuria (IH) - defined by 24 hours urinary calcium levels (CaUr24h/kg) >4 mg/kg - is a cause of secondary osteoporosis, affecting 30% of postmenopausal women. IH is thought to lead to a compensatory increase of bone turnover and, thus, to a bone loss. The reduction of hypercalciuria is achieved through low-dose thiazide diuretics (hydrochlorothiazide, HCT), whose effect on skeletal turnover is unknown. This study evaluates the effect of HCT on bone turnover in postmenopausal osteoporotic women.
Materials and Methods
82 postmenopausal women with a median age of 59 years (interquartile range 55-66), affected by osteoporosis and IH were retrospectively enrolled from a multicenter case series. All patients had normal calcium intake (by diet and/or supplements), were supplemented with cholecalciferol and were not taking antiresorptive medications. Patients with secondary hypercalciuria (i. e., primary hyperparathyroidism, endogenous or exogenous hypercortisolism) were excluded. At enrollment (T0), calcium, phosphate, 25OH-vitamin D, parathyroid hormone (PTH), C-terminal telopeptide (CTX), alkaline phosphatase (ALP), CaUr24h/kg, and creatinine clearance (ClCr) were measured; 6-12 months (T1) and 18-24 months (T2, $n = 48$) after the initiation of a treatment with HCT (12. 5 mg or 25 mg/day), the same parameters were reassessed. Normalization of CaUr24h/kg and reduction of CTX were considered as primary outcomes.
Results
A normalization of calciuria was observed in 43. 9% patients (36/82) at T1 and in 60. 4% (29/48) at T2. Moreover, the paired data obtained from the patients were analyzed longitudinally, showing a significant reduction at T1 and T2 compared to T0 in both CaUr24h/kg values (-1. 26±0. 19 mg/kg/24h, $P < 0.001$; -1. 23±0. 25 mg/kg/24h, $P < 0.001$) and CTX values (-140±32 ng/ml, $P < 0.001$; -90±29 ng/ml, $P < 0.005$). No significant differences were observed in CaUr24h/kg values (0. 03±0. 24 mg/kg/24h, $P = 0.91$) between T1 and T2, while a slight increase in CTX values was noted (49±22 ng/ml, $P = 0.031$). A slight increase in calcium levels was observed between T0 and T1 (0. 17±0. 06 mg/dl, $P < 0.005$) and T0 and T2 (0. 13±0. 07 mg/dl, $P = 0.08$), although not statistically significant, but not between T1 and T2 (-0. 04±0. 07 mg/dl, $P = 0.52$). No significant differences were found in the levels of phosphate, 25OH-vitamin D, PTH, ALP, or renal function among T0, T1, and T2.
Conclusion
the use of HCT in osteoporosis secondary to idiopathic hypercalciuria in postmenopausal women appears to reduce the bone resorption process. However, the sample size, the short duration and the design of the study do not allow for conclusive information on the persistent effects on turnover, bone mineral density, and fracture risk.

FGF23 in chronic hypoparathyroidism: clinical implications of phosphate regulation

Anna Piazza[1, 2], Matteo Malagrino'[1, 2], Nicolo' Bisceglia[1, 2], Sara Capra[1, 2], Cristiana Cantone[1, 2], Uberto Pagotto[1, 2] & Guido Zavatta[1, 2]
[1]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero- Universitaria di Bologna, Bologna, Italy; [2]Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, Italy

Introduction
Fibroblast Growth Factor 23 (FGF23) regulates phosphate homeostasis, but its systemic effects remain unclear in hypoparathyroidism. Elevated FGF23 levels have been linked to adverse renal, cardiovascular, and skeletal outcomes in patients without hypoparathyroidism. In chronic hypoparathyroidism, its role is not well defined, with limited evidence on its clinical implications.
Objective
To assess intact FGF23 levels in chronic hypoparathyroidism and their association with biochemical markers and clinical outcomes.
Methods
This observational study included 48 hypoparathyroid patients under regular follow-up at a university hospital. A cross-sectional analysis (2023–2024) evaluated clinical and biochemical parameters, complemented by a retrospective longitudinal analysis to identify predictors of FGF23 levels.
Results
The cohort (85. 4% women, 87. 5% postsurgical hypoparathyroidism, mean age 60. 6±16. 3years, disease duration 14. 8±12. 1years) was mostly on conventional therapy (44vs4 on teriparatide) and showed good biochemical control (mean serum calcium 8. 7±0. 8mg/dL, phosphate 4. 55±0. 82mg/dL, CaP product 39. 2±6. 8mg^2/dL^2). Despite this, 71% of patients had elevated FGF23 levels (157. 9±92. 4pg/mL; normal 23. 2–95. 4pg/mL), of whom only one patient on teriparatide. Higher FGF23 levels were associated with longer disease duration (19. 6±13. 1 vs 9. 6±8. 5years), reduced kidney function (49. 6±17. 3 vs 61. 5±16. 0mL/min/1. $73m^2$), higher CaP product (41. 3±7. 1 vs 37. 2±6. 0mg^2/dL^2), lower PTH (8. 7±8. 3 vs 14. 6±8pg/mL), and lower 1, 25OH vitamin D (30. 0±13. 0vs39. 8±13. 7pg/mL). However, treatments did not differ significantly in term of calcium doses (1801±1695mg/die vs 1359±1106mg/die) or calcitriol (0. 55±0. 46mg/die vs 0. 55±0. 33mg/die). Patients with higher CaP product had longer disease duration (19. 6±12. 8y vs 10. 0±9. 5 $P = 0.006$), elevated FGF23 (187. 0±111. 2 vs 128. 9±57. 5pg/mL, $P = 0.028$), and higher TmPO4/GFR (4. 4±0. 7vs3. 7±0. 7mg/dL, $P = 0.001$). Lower tertiles of CaP product levels correlated weakly with TmPO4/GFR, suggesting significant FGF23 kidney resistance (R^2=0. 082 and R^2=0. 022), whereas this association was stronger in the highest tertile (R^2=0. 268), suggesting a dose-dependent FGF-23 sensitivity. This mechanism, however, remains ineffective at inducing clinically-significant phosphate excretion. PTH level was associated with lower CaP product (34. 9±5. 6mg^2/dl^2 vs 40. 2±5. 9mg^2/dL^2 $P = 0.004$), higher serum magnesium (2. 0±0. 2mg/dl vs 1. 9±0. 2mg/dl $P = 0.047$) and lower calcium fractional excretion (1. 3±0. 5% vs 2. 2±1. 2% $P = 0.007$). Multivariate analysis identified female sex (β=88. 76±41. 38, $P = 0.032$) and mean CaP product (β=7. 99±2. 73, $P = 0.004$) as independent predictors of FGF23 levels, independent of PTH, 1, 25OH vitaminD, renal function, serum magnesium and disease duration.
Conclusions
This study is the largest in literature investigating FGF23 levels in hypoparathyroidism. Despite adequate biochemical control, most patients exhibited elevated FGF23, driven by female sex and CaP product. High FGF23 levels were ineffective in promoting phosphate excretion but contributed to reduced 1, 25OH vitamin D, complicating conventional therapy management. FGF23 is clinically relevant in hypoparathyroidism and warrants further investigation.

Clinical and phenotypic features of osteogenesis imperfecta caused by fkbp10 mutations: a study of skeletal deformities and cervical abnormalities

Aylin Tugba Canbaz[1], Aylin Gunay[1], Ilknur Kurt[1], Elif Kelestemur[1], Ahmet Kahveci[1], Sebati Baser Canbaz[2], Murat Kahraman[3], Abdullah Bereket[1] & Serap Turan[1]
[1]Marmara University School of Medicine, Department of Pediatric Endocrinology and Diabetes, Istanbul, Türkiye; [2]Kartal Dr. Lutfi Kirdar City Hospital, Department of Orthopaedics and Traumatology, Istanbul, Türkiye; [3]Bagcilar Training and Research Hospital, Department of Neurosurgery, Istanbul, Türkiye

Introduction and Aim
Osteogenesis imperfecta (OI) is a hereditary disorder of connective tissue characterized by increased bone fragility, recurrent fractures, and skeletal deformities. Mutations in *FKBP10* cause a rare and severe form of OI, known as OI type-XI. This study aims to investigate the clinical and phenotypic characteristics, as well as the skeletal deformities and cervical abnormalities, of patients with *FKBP10* mutations.
Methods
A retrospective follow-up study of 17 children (10 male) with *FKBP10* mutations (ten different biallelic variants) evaluated between 2000 and 2024 was undertaken.
Results
The patients were diagnosed at a mean age of 3. 2±4. 2 years (range: 0. 03-13. 5 years). Consanguinity was reported in 14 patients with a family history of OI in 11. Four had antenatal fractures, 9 had fractures within the first 3 months postnatally, and 4 experienced fractures within the first 3 years. The median follow-up duration was 4. 5±4. 7 years (range: 0-14. 5 years). Multiple fractures (more than 10) occurred in 70% ($n = 12$) of the patients. All patients had long bone fractures, with additional rib (82%, $n = 14$), sacrum-coccyx (64%, $n = 11$), clavicle (23%, $n = 4$), and pelvic fractures (17%, $n = 3$). Long bone deformities caused by recurrent fractures were detected in all

patients. Bone deformities included pectus excavatum/carinatum (70%, $n = 12$), pes equinovarus (35%, $n = 6$), and genu varum (29%, $n = 5$). Vertebral issues included vertebral compression (64%, $n = 11$), spondylolisthesis (58%, $n = 10$), pars defect (23%, $n = 4$), fusion defect (23%, $n = 4$), ossified longitudinal ligament ($n = 1$), and platybasia ($n = 1$). Scoliosis was present in 88% ($n = 15$). Basilar invagination was observed in 47%. Hip deformities included coxa vara (41%, $n = 7$), pelvic rotation anomalies (41%, $n = 7$), and acetabular protrusion (23%, $n = 4$). Other findings included Wormian bones (58%, $n = 10$), JOINT contractures (58%, $n = 10$), blue sclera (29%, $n = 5$), dentinogenesis imperfecta (41%, $n = 7$), epidermolysis bullosa (23%, $n = 4$), cardiac problems in 3, hyperlaxity in 3, and no hearing loss. Additionally, 70% ($n = 12$) were immobile, and all patients had short stature. All patients received intravenous bisphosphonate treatment for 7. 2±4. 1 years (range: 0. 25-15 years). Corrective surgeries for long bone deformities were performed in ten patients. The median height SDS was −2. 3±3. 4 at the initial examination and −3. 6±2. 0 at the last examination.

Conclusion

FKBP10 mutations result in a variety of severe clinical manifestations, including fractures, deformities, and spinal abnormalities. The majority of patients experience multiple fractures early in life, highlighting the need for early intervention and continuous monitoring.

JOINT2372

The role of FGF23 in phosphorus and calcium metabolism: lessons from diseases affecting serum phosphate levels

Ilknur Kurt[1], Mehmet Eltan[1], Busra Gurpinar Tosun[1], Belma Haliloglu[1], Abdullah Bereket[1] & Serap Turan[1]

[1]Marmara University School of Medicine, Department of Pediatric Endocrinology, Istanbul, Türkiye

Background and Objective

Fibroblast Growth Factor 23(FGF23) is a phosphate regulating hormone primarily produced by osteoblast and osteocytes. Under physiological condition, FGF23 secreting cells sense the serum phosphate and regulate it in strict range by modulating FGF23 secretion in coordination with parathyroid hormone (PTH). Additionally, FGF23 inhibits both the synthesis and secretion of PTH, while PTH stimulates FGF23 secretion, underscoring the complex interplay between these hormones. In this study, we aimed to evaluate interrelationship between FGF23 and phosphate metabolism, along with other key regulators, by analyzing their levels in various diseases conditions. Additionally, we sought to develop an FGF23-Phosphate nomogram to facilitate a better understanding of these interactions.

Methods

A total of 79 blood samples from 77 patients were evaluated. Patients with X-linked hypophosphatemia(XLH[$n = 22$]), fibrous dysplasia ($n = 3$) and tumor induced osteomalacia/nonosseous fibroma ($n = 3$) were classified under phosphate independent FGF23 secretion (PI-FGF23[$n = 29$]). Conversely, patients with nutritional rickets ($n = 6$), *SLC34A3/A1* mutations ($n = 8$), and nephrocalcinosis of unknown etiology, whose FGF23 levels were consistent with phosphorus levels, were classified under phosphate dependent FGF23 secretion (PD-FGF23[$n = 41$]). Additionally, patients with hypoparathyroidism/pseudohypoparathyroidism (HP/PHP[$n = 6$]) and hyperparathyroidism ($n = 3$) were evaluated as separate groups. Samples were collected from patients either before treatment or after the discontinuation of treatment. Serum FGF23 concentrations were measured using the Sandwich Immunoassay method.

Results

In PD-FGF23, FGF23 showed a positive correlation with P-SDS ($r = 0.634$, P=< 0. 0001) and Tmp/GFR ($r = 0.463$, $P = 0.002$); in contrast, no correlation was detected in PI-FGF23 group. Additionally, P-SDS demonsrated a negative correlation with ALP-SDS ($r = -0.554$, $P = 0.0002$) and PTH (r:-0. 585, P=< 0. 0001) in PD-FGF23 group, whereas a positive correlation was observed between P-SDS and PTH ($r = 0.573$, $P = 0.0053$) in XLH group. Additionally, the P/FGF23 nomogram demonstrated that FGF23 levels were undetectable when serum phosphate <-3 SDS. Between -2 SDS and -3 SDS, FGF23 cutoff value of 30 could differentiate PI-FGF23 from PD-FGF23. Furthermore, patients with a homozygous SLC34A3 mutation exhibited undetectable FGF23 levels despite normal phosphorus levels. In HP/PHP group, FGF23 levels were inappropriately low relative to phosphorus levels, whereas in the hyperparathyroidism, FGF23 levels were inappropriately high relative to phosphorus levels.

Conclusion

Our findings suggest that FGF23 plays a pivotal role in phosphorus metabolism, with distinct regulation patterns depending on the underlying etiology of hyperphosphatemia or hypophosphatemia. The interplay between FGF23 and PTH is essential in maintaining phosphate homeostasis, yet neither can fully compensate for the absence of the other.

Gain-of-function CASR variants identified as a major genetic contributor of non-surgical hypoparathyroidism: findings from over 300 participants in a sponsored genetic testing program

Michael Mannstadt[1], Arun Mathew[2], Ananth Sridhar[2], Lyndsay Smith[2], Mary Scott Roberts[2] & Scott Adler[2]

[1]Massachusetts General Hospital, Harvard Medical School, Endocrine Unit, Boston, United States; [2]BridgeBio, San Francisco, United States

Hypoparathyroidism is a rare condition characterized by insufficient production of parathyroid hormone, resulting in low serum calcium and an imbalance in mineral homeostasis. Hypoparathyroidism is most commonly caused by damage to or removal of parathyroid glands during surgery, however, genetic causes have become increasingly recognized with advances in genetic testing and growing awareness of non-surgical etiologies. Genetic forms of hypoparathyroidism can occur in isolation or as part of a syndrome, and include disorders related to the formation of parathyroid glands, secretion of parathyroid hormone, and autoimmune damage to the parathyroid glands. Individuals with a clinical diagnosis of non-surgical hypoparathyroidism, positive family history or suspicion of genetic hypoparathyroidism, are eligible to participate in a no-charge sponsored genetic testing program in the United States and Canada. The next-generation sequencing panel leveraging a whole exome backbone includes 26 genes associated with hypoparathyroidism: *ACADM*, *AIRE*, *ATP1A1*, *CASR*, *CHD7*, *CLDN16*, *CLDN19*, *CNNM2*, *DHCR7*, *EGF*, *FAM111A*, *FXYD2*, *GATA3*, *GCM2*, *GNA11*, *HADHA*, *HADHB*, *KCNA1*, *NEBL*, *PTH*, *SEMA3E*, *SLC12A3*, *SOX3*, *TBCE*, *TBX1* and *TRPM6*. A total of 327 samples were tested over four years (2020 – 2024) from participants with a mean age of 26. 7 years (range 0-81). 191 variants were identified in 149 individuals (46%) which were classified as pathogenic, likely pathogenic, or variants of uncertain significance. Among these 149 individuals with detected variants, *CASR* was the most frequently affected (35%), followed by *AIRE* (17%), *GATA3* (10%), *TBX1* (7%), *HADHA* (3%), *GNA11* (3%), *GCM2* (3%), *SEMA3E* (2%), *SLC12A3* (2%), *NEBL* (2%), *DHCR7* (2%), *HADHB* (2%), *FAM111A* (2%), *CHD7* (2%), *ACADM* (1%), *TRPM6* (1%), *EGF* (1%), *PTH* (1%), *KCNA1* (1%), *CNNM2* (1%), *CLDN19* (1%), and *TBCE* (1%). Notably, 36 individuals had variants identified in multiple genes. Genetic etiologies should be considered in all patients with hypoparathyroidism without a history of neck surgery as the identification of a genetic etiology can impact patient management and guide further medical evaluation. In our data, the most common genetic form of hypoparathyroidism was found to be autosomal dominant hypocalcemia type 1 (ADH1), caused by gain-of-function variants in the *CASR* gene (18. 4%; 60/327). An ongoing global Phase 3 study [NCT05680818] is investigating encaleret, an oral calcilytic, which has the

potential to be the first targeted treatment for ADH1. The sponsored genetic testing program offers an efficient pathway for diagnosing genetic causes in patients with non-surgical hypoparathyroidism and, in accordance with consensus guidelines, enables improved care for those with an identified genetic etiology.

JOINT1411

Skeletal characterization of patients with PLS3-associated early onset osteoporosis in comparison to patients with osteogenesis imperfecta type i

Oskar Windels[1], Alexander Simon[1], Julian Delsmann[2], Uwe Kornak[3], Michael Amling[1] & Ralf Oheim[1]
[1]University Medical Center Hamburg Eppendorf, Department of Osteology and Biomechanics, Hamburg, Germany; [2]University Medical Center Hamburg Eppendorf, Department of Orthopedics, Hamburg, Germany; [3]University Medical Center Göttingen, Göttingen, Germany

Introduction
PLS3-associated X-linked early-onset osteoporosis (EOOP) is a rare condition that was first described in 2013. Consistent with the X-linked inheritance, males are more severely affected, although varying degrees of severity have also been documented for females. The function of PLS3 and the effects of pathogenic *PLS3* variants are poorly understood. The aim of this retrospective analysis was to describe the clinical features of patients with EOOP due to variants in *PLS3* in comparison to patients diagnosed with Osteogenesis imperfecta type I.
Materials and methods
We retrospectively collected clinical data from patients diagnosed with EOOP who carry (likely) pathogenic genetic variants in the *PLS3* gene. The data were collected at the specialized outpatient clinic of the National Bone Board at the University Medical Center Hamburg-Eppendorf and include fracture history, treatment history, laboratory parameters, HR-pQCT and DXA data, as well as muscle function tests (Chair Rising Test, grip strength).
Results
Patients with variants in the *PLS3* gene had an increased number of fractures, low Z-scores and severely reduced microstructural parameters, with men being more affected than women. Compared with OI type I patients, there were no statistically significant differences in fracture frequency, but women with pathogenic variants in the *PLS3* gene had significantly higher Z-scores on DXA scans. In men with causative *PLS3* variants, HR-pQCT measurements showed a significant reduction in structural parameters compared to OI type I, especially in the cortical compartment. There were no significant differences regarding relevant laboratory parameters.
Discussion
The results of this study highlight the specific influence of pathogenic *PLS3* variants on the clinical presentation and bone structure of affected patients. In particular, the significantly reduced cortical thickness on HR-pQCT measurements in affected men suggests specific effects of the *PLS3* variants. These microstructural deficits may play a central role in the clinical presentation of patients with *PLS3*-associated X-linked early-onset osteoporosis. However, larger studies are needed to further elucidate the pathogenesis of this rare condition.

X-linked hypophosphatemic rickets and FGF23 levels: the importance of a correct reference range

Eugenio Trinati[1, 2], Sara Soldovieri[1, 2], Alessandro Barbato[1, 2], Renato Vaiasuso[1, 2], Elena Andreucci[3], Angela Peron[3, 4], Gaia Varriale[2] & Stefano Stagi[1, 2]
[1]Department of Health Sciences, University of Florence, Florence, Italy; [2]Diabetology and Endocrinology Unit, Meyer Children's Hospital IRCCS, Florence, Italy; [3]Medical Genetics Unit, Meyer Children's Hospital IRCCS, Florence, Italy; [4]Department of Biomedical, Experimental and Clinical Sciences "Mario Serio", University of Florence, Florence, Italy

Introduction
X-linked hypophosphatemic rickets (XLH) is caused by variants in the PHEX gene, leading to hypophosphatemia and significantly elevated FGF23 levels. However, there is limited data in the literature regarding reference values for FGF23 in healthy paediatric subjects and cut-off in patients with XLH.
Case report
We present the case of a 3-year-old female patient referred to our clinic for an abnormal gait, characterized by clumsy running and frequent falls. Blood tests showed normal calcium and magnesium levels, severe hypophosphatemia, elevated alkaline phosphatase and bone isoenzyme levels, normal parathormone levels, normocalciuria, and increased level of urinary phosphate. FGF23 levels were within the reference range at 24. 2 pg/mL (reference range: 23. 2–95. 4 pg/mL). X-rays revealed lateral bowing of the femurs and tibias, predominantly tibial varus deformity, widened metaphyses of the tibia and femur, irregular physeal contours, medial sclerosis, and bilateral femoral neck varus. Initial diagnosis of inherited non-FGF23-mediated hypophosphatemic rickets was made. Calcitriol and inorganic phosphate salts treatment was started. During follow-up, FGF23 levels progressively increased (44. 6 pg/ml at 3 months and 80. 6 pg/ml at 6 months). Alkaline phosphatase remained elevated while phosphate levels were low (2. 8 mg/dl at 6 months). Other blood tests showed no significant changes. Based on these clinical and laboratory findings, a genetic evaluation was performed. Genetic analysis identified the c. 1601C>T, p. Pro534Leu heterozygous variant in the PHEX gene, classified as pathogenic and associated with XLH.
Conclusions
Generally, FGF23 levels appear significantly elevated in patients with XLH, but they can sometimes appear falsely normal. Moreover, reference values for the paediatric age group have not yet been standardized: FGF23 levels exhibit diurnal fluctuations and vary based on age, pubertal stage, and clinical context, as demonstrated in a 2024 Italian monocentric study (Baroncelli *et al*.). Multicentric studies are needed to establish FGF23 reference values for paediatric patients and those with XLH genetically confirmed. In clinically and radiologically suspicious cases for XLH, without definitive laboratory tests, paediatric endocrinologists should frequently reassess the complete calcium-phosphorus profile, including FGF23 and urinary tests, while also considering genetic evaluation even when FGF23 levels continue to appear normal. A change in the diagnostic suspicion, awaiting the results of genetic investigation, and the early start of specific PHEX's treatment could improve the patient's clinical outcome.

Getting bone health right from the start: new tools for bone mineral density evaluation and determinants of BMD from pregnancy to 12 months of life

Malgorzata Wasniewska[1], Serafina Perrone[2], Anna-Mariia Shulhai[2], Virginia Beretta[2], Valentina Bianco[2], Elena Scarpa[2], Tommaso Aversa[1], Domenico Corica[1], Giorgia Pepe[1], Letteria Anna Morabito[1], Emanuela Falcone[2] & Maria Street[2]
[1]University of Messina, Pediatric Unit, University Hospital, Department of Human pathology of Adulthood and Childhood, Messina, Italy; [2]University of Parma, Medicine and Surgery, Parma, Italy

Introduction
Bone health begins with maternal well-being and nutrition, which influences skeletal mass and bone mineral density (BMD) in utero. BMD preservation during skeletal growth is a main goal of primary prevention of osteopenia and osteoporosis in adulthood. Bone health can be determined by fetal programming where oxidative stress, endocrine disrupting chemicals (EDCs), and microRNAs (miRNAs) play an important role. The radiofrequency echographic multi spectrometry (REMS) technique has been extensively used for the measurement of BMD in adults.
This project aims to evaluate skeletal status from the perinatal period up to 12 months of life, assessing the feasibility of REMS in newborns, and to explore new associations regarding oxidative stress, EDCs, and miRNAs between mother-infant dyads and BMD.
Methods
200 mother-infant dyads were enrolled in this ongoing prospective multicenter longitudinal study. We are assessing BMD of the proximal femur with REMS technology in mothers, fetuses, newborns, and infants at 1, 3, 6, and 12 months of life. Blood and urine samples have been collected for the assessment of oxidative stress, miRNAs, and EDCs, respectively. The creation of a reference database, including 100 fetuses/newborns, was required to apply REMS technology for the first time in this population.
Results
Preliminary data from the REMS reference database showed that the specific settings for acquiring structures located between 10- and 15-mm depth appeared suitable for children from 0 to 1 month but not for babies aged 3 months. Therefore, the final adopted configuration of REMS for the evaluation of children from 0 to 3 months

included the following: BeamFormer: Echo Blaster 128 Rev. C; Linear Probe 40 mm: HL9. 0/40/128Z-4; Focus: Dynamic Focus: No; Focus Number: 1; Focus Set 4; Focus Depth: 18 mm (Coverage: 0–25 mm); Depth: Fixed at 60 mm; Frequency: 5 MHz; Power: 54%; Gain: 58%.
Conclusion
REMS technology seems to be applicable for the assessment of BMD in infants. Further investigations will be performed to develop settings for children up to 1 year, by defining age-appropriate reference data, and to examine associations of oxidative stress, EDC exposure, and expression levels of miRNAs in cord serum with BMD obtained by REMS.

Genotype-phenotype insights and longitudinal outcomes in WNT1-related osteogenesis imperfecta type XV: a 14-year study of 44 chinese patients

Ting Chen[1] & Guangsha Ding[1]
[1]Children's Hospital of Soochow University, Suzhou, China

Background
Osteogenesis imperfecta (OI) type XV, caused by biallelic WNT1 variants, is a rare autosomal recessive skeletal dysplasia linked to impaired osteoblast differentiation. Despite growing recognition of WNT1-related OI, longitudinal clinical data on disease progression and treatment efficacy remain sparse.
Methods
This 14-year cohort study analyzed 44 Chinese patients from 42 unrelated families with OI type XV. The pathogenic mutations were detected by Whole-Exome Sequencing (WES) and verified by Sanger sequencing. Longitudinal assessments included fracture history, spinal radiography, dual-energy X-ray absorptiometry (DXA), and biochemical markers (serum β-CTX, P1NP, calcium, phosphate, ALP).
Results
Two hotspot variants, c. 677C>T(p. S226L) (19. 2%) and c. 301C>T(p. Arg101Cys) (11. 5%), predominated. Key phenotypic features included severe skeletal fragility (mean fracture rate: 19. 3±18. 9; range: 4–100), early-onset fractures (66. 7% within 1 year), universal thin cortical bone (100%) and metaphyseal enlargement (100%), spinal compression fractures (84. 2%), humeral curvature (64. 1%), and extraskeletal manifestations: ptosis (70. 0%), scoliosis (61. 0%), blue sclera (32. 4%), and intellectual abnormalities (28%). Bisphosphonate therapy, initiated at a mean age of 3. 7 years (duration: 7. 7±4. 0 years), improved vertebral height in 80. 9% of patients within 1 year. However, β-CTX and P1NP levels not decreased in 97. 7% of patients, with no long-term reduction in fracture risk or skeletal deformity progression. Two patients died during follow-up.
Conclusions
This study delineates the natural history of OI type XV, marked by profound skeletal fragility and distinct extraskeletal features. While bisphosphonates transiently improved vertebral architecture, their limited long-term efficacy highlights the necessity for WNT pathway-targeted therapies. Our findings expand the genotypic and phenotypic spectrum of OI and provide critical insights for mechanistic studies and genotype-phenotype correlations.

JOINT3340

Increased MMP13-bip interaction and activated ER stress contribute to SEMD in patient-ipsc-derived chondrogenic with MMP13 variant

Huifei Lu[1] & Chunlin Wang[1]
[1]zhejiang university, hangzhou, China

Background
Spondyloepimetaphyseal dysplasia (SEMD) is a rare developmental disorder of bone and cartilage with short stature and skeletal deformities affecting the extracellular matrix of cartilage. MMP13 (collagenase-3) has been considered to have an important role in skeletal biology in view of its exclusive presence in the skeleton during embryonic development in cartilaginous growth plates and primary centers of ossification. MMP13 takes part in catalyzing ECM components in the growth plate and at the same time cleaving and releasing biologically active molecules stored in the ECM, such as VEGFA, essential for chondrogenic differentiation, apoptosis, and matrix remodeling. Although previous studies had identified the association of $SEMD_{MO}$ with a missense *MMP13* mutation, the mechanism by which $SEMD_{MO}$ is associated with MMP13 is poorly understood.
Patient and Methods
The proband was a 5. 5years old male exhibiting short stature(-3. 27SD). His X-ray examination revealed ulnar and radial bones with widened metaphysis, "brush and cup-like"changes, irregular edges. The WES analysis showed the probably pathogenic variant c. 124T>G in heterozygosity in exon2 of the MMP13 gene, described in the literature in patients with SEMD. The proteins which possibly could interact with MMP13 were preliminarial identified through CoIP-MS method and a bioinformatic analysis has been made as well. CoIP-WB experiment was used to verify the *in vivo* interaction. We generated induced pluripotent stem cells (iPSCs) from peripheral blood mononuclear cells (PBMCs) via nucleofection with episomal plasmids. These iPSCs were further differentiated into chondrogenic via mesenchymal stem cells (MSCs). RT-PCR and Western blot methods were used to substantiate whether both transcription level and protein level of PERK, ATF6, IRE1a are upregulated by BiP.
Results
Cell lines harboring the variant displayed decreased amount of MMP13 proteins in culture medium and degraded misfolded protein fragments of approximately 30kDa of the mutant protein intracellular through the ubiquitin-proteasome system. The results of CoIP-MS experiments and related bioinformatics analysis showed that the *MMP13* Y42D variant increased the interaction between MMP13 and Bip and these proteins were mainly involved in several biological processes, including protein folding, protein processing in ER, response to ER stress. In patient-iPSC-derived chondrogenic, both transcription level and protein level of PERK, ATF6, IRE1a are upregulated by BiP.
Conclusion
Our study indicate that the variant in *MMP13* lead to increasing MMP13-Bip protein interaction, activating endoplasmic reticulum stress. Under ER stress, Bip could upregulate transcription and expression level of PERK, ATF6, IRE1a and promote cell death.

Burosumab, a fully human anti-FGF23 antibody is approved for treating X-linked hypophosphataemia (XLH), a rare, genetic, progressive, deforming bone disease. As part of the burosumab risk management plan, a post-authorisation safety study (PASS) was initiated, utilizing International XLH Registry (NCT03193476) data. The PASS is a 10-year multi-centre, non-interventional, observational study. Primary objectives assessed safety outcomes in children and adolescents with XLH, including participants with chronic kidney disease (CKD). The secondary objective compared burosumab and conventional therapy safety outcomes. Of participants enrolled by the 29-Sep-2023 datacut, 340 received burosumab

Table 1: Safety outcomes

	SAF participants				
n, (%)	Total (n = 340)	Normal: GFR ≥90 mL/min/1.73 m^2[n = 43]	CKD* (n = 51) Mild-to-moderate/severe: GFR ≥30–<90 mL/min/1.73 m^2[n = 6]	Severe CKD-to-kidney failure: GFR <30 mL/min/1.73 m^2 [n = 2]	CSAF participants (n =91)
Any AE	**127 (37. 4)**	**14 (32. 6)**	**3 (50. 0)**	**0**	**20 (22)**
Possibly/probably related to treatment	54 (15. 9)	9 (20. 9)	1 (16. 7)		5 (5. 5)
Possibly/probably related to burosumab	49 (14. 4)	8 (15. 7)	0		
Leading to death	0				0
Leading to treatment withdrawal	2 (0. 6)				1 (1. 1)
Possibly/probably related to treatment leading to treatment withdrawal	0	0			1 (1. 1)
Any serious AE	**12 (3. 5)**	**1 (2. 3)**			**0**
Possibly/probably related to burosumab	3 (0. 9)	0			
Hospitalisations	**244 (71. 8)**				**65 (71. 4)**
Hyperphosphataemia	**1 (0. 3)**				**0**
Elevated parathyroid hormone	**7 (2. 1)**				**1 (1. 1)**
Ectopic mineralisation	**5 (1. 5)†**				**1 (1. 1)**

*Defined as abnormalities of kidney structure or function, present for >3 months. †Nephrocalcinosis. AE, adverse event; CKD chronic kidney disease; CSAF, cohort SAF; GFR, glomerular filtration rate; SAF, safety analysis set.

(Safety Analysis Set [SAF]), 91 received conventional therapy (Cohort SAF [CSAF]). Of SAF participants, 51/340 (15. 0%) had CKD. SAF and CSAF adverse event (AE) reporting were solicited and unsolicited, respectively (Table). Hospitalisation data were separate and independent from AE reporting and not necessarily linked to AEs. Most common AEs in the SAF cohort were 'Pain in extremity, ' 'Headache' and 'Arthralgia. ' Of CSAF participants, most common AEs were 'Pain in extremity, ' 'Headache' and 'Abdominal pain. ' No deaths were reported in either cohort. Hospitalisations (inpatient and outpatient) were common in both cohorts; hyperphosphataemia, ectopic mineralisation and elevated parathyroid hormone were rare. The safety profile of burosumab was consistent with previous reports, with no new safety concerns. The most common AEs were typical of paediatric populations or frequent manifestations of XLH. AE frequency in CKD participants was similar compared with SAF participants. Long-term safety outcomes were similar between the SAF and CSAF cohorts.

CALIBRATE-PEDS: a phase 2/3, multicenter, single-arm study evaluating the pharmacokinetics, efficacy, and safety of encaleret in pediatric participants with autosomal dominant hypocalcemia type 1

Stefano Mora[1], Raja Padidela[2, 3], Todd Alexander[4], Peter Tebben[5], Mary Scott Roberts[6], Dingfeng Li[6], Scott Adler[6] & Rachel Gafni[7]
[1]Pediatric Endocrinology, Department of Pediatrics, IRCCS San Raffaele Hospital, Milano, Italy; [2]Department of Paediatric Endocrinology, Manchester University NHS Foundation Trust Hospital, Manchester, United Kingdom; [3]Faculty of Biology, Medicine and Health, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom; [4]Department of Pediatrics, University of Alberta, Edmonton, Canada; [5]Departments of Internal Medicine and Pediatrics, Section of Endocrinology, Yale University, New Haven, United States; [6]Calcilytix Therapeutics, Inc. a company of BridgeBio Pharma, Inc, San Francisco, United States; [7]National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, United States

Objectives
Autosomal dominant hypocalcemia type 1 (ADH1), caused by gain-of-function variants in the calcium-sensing receptor gene, is characterized by low/-inappropriately normal parathyroid hormone (PTH), hypocalcemia, and hypercalciuria. Standard-of-care (SoC) treatment (calcium and active vitamin D) worsens hypercalciuria, increasing renal morbidity. Encaleret, a negative allosteric modulator of the calcium-sensing receptor, is under investigation as a potential ADH1 treatment. In a Phase 2b study [NCT04581629] in 13 adults with ADH1, encaleret led to sustained normalization in PTH, albumin-corrected calcium (cCa), phosphorus, magnesium and 24-hr urine calcium (UCa) excretion over 24 weeks, without serious adverse events reported. A Phase 3 study [NCT05680818, CALIBRATE] in adults with ADH1 is ongoing. CALIBRATE-PEDS is a Phase 2/3 study evaluating pharmacokinetics (PK), efficacy, and safety of encaleret in children with ADH1.
Methods
Approximately 28 children (birth-18y) will be enrolled in 4 age cohorts sequentially, starting with the oldest cohort (12-18y). After 3-6 months of stable SoC/PTH treatment, eligible participants will enter Period 1, an inpatient stay lasting up to 6 days, for PK sampling and individualized dose titration. Period 2 follows, during which encaleret doses will be optimized to maintain target cCa while minimizing UCa over 20 outpatient weeks. Period 3 is a 4-week dose maintenance period, when the dose is intended to be fixed. Participants may then continue into a long-term extension period for safety monitoring and continued access to encaleret. PK data from Period 1 will be used to refine population-based PK modeling and inform dosage in younger cohorts.
Results
The primary endpoint is the composite endpoint of a) cCa within 2. 1 to 2. 6 mmol/l in participants aged ≥1year, and within 2. 0to 2. 8 mmol/l in participants aged <1year and b) UCa <0. 1 mmol/kg/d in toilet-trained participants or spot ratio of UCa/UCr within the age-specific reference range in non-toilet-trained participants. Participants meeting both criteria at the end of Period 3 will be considered responders. Key secondary endpoints include safety and tolerability, mineral homeostasis, renal ultrasound, bone density, and self-reported outcomes. The statistical analyses will be descriptive; no statistical testing is planned.
Conclusions
CALIBRATE-PEDS is the first pediatric study of encaleret. It is under development and is expected to be initiated globally in 2025.

Triptorelin effects on linear growth and bone mineral density in transgender adolescents: a longitudinal study

Julia Galhardo[1 2 3], Francisco Caetano[2], João Farela Neves[3] & Lurdes Lopes[2]
[1]Lisbon Clinical Academic Centre - Nova Medical School, Lisbon, Portugal; [2]Unit for Paediatric Endocrinology, Hospital de Dona Estefânia - ULSS José, Lisbon, Portugal; [3]Child and Adolescent Hospital - Luz Lisboa, Lisbon, Portugal

Background
Gonadotrophin-releasing hormone (GnRH) analogues are widely used to suppress puberty in adolescents with gender dysphoria. While effective in halting endogenous pubertal progression, concerns persist regarding their impact on linear growth and bone mineral density (BMD) during a crucial period of skeletal growth. Understanding this impact is essential to optimise care and mitigate potential long-term risks.
Objective
To assess the effects of triptorelin on linear growth and BMD in transfeminine and transmasculine adolescents followed in a paediatric endocrinology clinic.
Methods
This was a longitudinal study conducted in a paediatric endocrinology clinic between January 2020 and December 2024. The study included adolescents with gender dysphoria who were treated with triptorelin for at least two years. Growth parameters and BMD (measured by dual-energy X-ray absorptiometry, DXA) were evaluated at baseline and follow-up. BMD Z-scores were analysed using reference values based on sex assigned at birth. Biochemical markers of bone metabolism, including blood calcium, phosphate, vitamin D, parathormone (PTH), and alkaline phosphatase, were also assessed.
Results
22 adolescents were analysed: 15 transmasculine and 7 transfeminine; aged 14–19 years; referred to the clinic between 12 and 15 years old. Triptorelin use was associated with transient growth deceleration, with partial catch-up after discontinuation. Transmasculine individuals showed greater preservation of height SDS compared to transfeminine individuals. BMD Z-scores declined during GnRH analogue treatment in both groups, with more pronounced reductions in transfeminine individuals. Of the 15 individuals who commenced gender-affirming hormone therapy (GAHT), a partial recovery in BMD was observed; however, some remained below expected reference values for their age. Mean blood calcium levels were 2. 30 ± 0. 10 mmol/l, phosphate 1. 20 ± 0. 15 mmol/l, 25-hydroxyvitamin D 45 ± 10 nmol/l, PTH 4. 5 ± 1. 2 pmol/l, and alkaline phosphatase 150 ± 40 U/l, indicating transient bone turnover alterations.
Conclusion
Our findings highlight the effects of triptorelin on growth and bone health in adolescents undergoing puberty suppression. The observed decline in BMD

underscores the importance of regular monitoring and early interventions to support bone health. While GAHT appears to facilitate partial BMD recovery, further research is needed to establish optimal management strategies. These results contribute to a growing body of evidence guiding best practices in gender-affirming care for adolescents.

Vitamin D supplementation during pregnancy does not improve maternal bone mineral density at 4 years post-partum

Rebecca Moon[1, 2], Stefania D'Angelo[1], Elizabeth Curtis[1], Kate Ward[1], Keith Godfrey[1, 3], Cyrus Cooper[1 3 4] & Nicholas Harvey[1, 3]
[1]University of Southampton, MRC Lifecourse Epidemiology Centre, Southampton, United Kingdom; [2]Southampton Children's Hospital, University Hospital Southampton NHS Foundation Trust, Paediatric Endocrinology, Southampton, United Kingdom; [3]University of Southampton and University Hospital Southampton NHS Foundation Trust, NIHR Southampton Biomedical Research Centre, Southampton, United Kingdom; [4]University of Oxford, NIHR Biomedical Research Centre, Oxford, United Kingdom

Objectives
During pregnancy and lactation, mobilisation of the maternal skeleton ensures sufficient calcium is available for fetal skeletal mineralisation. Maternal bone mineral density (BMD) typically reduces during these stages of the life course, with subsequent recovery after lactation ends. Recent trials have shown that pregnancy vitamin D supplementation can increase offspring BMD in childhood, but the effect on the maternal skeleton is poorly described. We previously demonstrated reduced maternal bone turnover (measured by urinary c-telopeptide) in pregnant women supplemented with cholecalciferol compared to placebo, but an effect on maternal BMD immediately after delivery was not detected in a subset of the women. Here, we assessed the effect of pregnancy vitamin D supplementation on the maternal skeleton in the medium term.
Materials and Methods
MAVIDOS was a randomised placebo-controlled trial of 1000 IU/day cholecalciferol from 14-17 weeks gestation until delivery. Participants were invited to have a Dual-Energy Xray absorptiometry (DXA) scan of the whole-body (analysed less head: WBLH), lumbar spine (LS) and left hip at 4 years after delivery. A subset of the women also had a DXA scan within 2 weeks of delivery. BMD at 4 years postpartum was compared between groups using linear regression in unadjusted and adjusted models (age, further pregnancy, duration of lactation, height, weight). β (95%CI) represents the effect of cholecalciferol compared to placebo. In women with DXA at both time points, the effect of cholecalciferol was assessed using mixed effects modelling to account for repeated measures.
Results
DXA imaging was performed on 443 participants (225 placebo, 218 cholecalciferol) at a median of 4. 1 years (IQR 4. 0, 4. 2) after delivery. Late pregnancy serum 25-hydroxyvitamin D was higher in the supplemented women (placebo 42. 0 nmol/l (SD 21. 5), cholecalciferol 70. 4 nmol/l (SD 19. 0), $P < 0.001$). BMD measured 4 years after delivery did not differ between the two randomization groups in unadjusted or adjusted analyses (adjusted WBLH $\beta = 0.000$ g/cm^2 (0. 012, 0. 012), LS $\beta = 0.009$ g/cm^2 (-0. 010, 0. 027), total hip $\beta = 0.004$ g/cm^2 (-0. 014, 0. 022)). 223 women had DXA at birth and 4 years. BMD increased between the two scans in both groups (placebo WBLH 6. 3%, LS 1. 2%, hip 2. 2%; cholecalciferol WBLH 6. 2%, LS 1. 0%, hip 2. 4%, $P < 0.05$ for all). However, the randomisation group had no effect on BMD ($p > 0.05$ for all).
Conclusions
Despite previously demonstrated increases in offspring BMD in childhood in the same trial, in this study, pregnancy supplementation with 1000 IU/day cholecalciferol did not benefit maternal BMD measured by DXA.

Characterization of bone density, strength, and mineral metabolism in 20 adults with monoallelic ENPP1 pathogenic variants

David Weber[1, 2], Yves Sabbagh[3], Kevin O'Brien[3], Eva Partridge[1] & Michael A. Levine[1, 2]
[1]The Children's Hospital of Philadelphia, Philadelphia, United States; [2]The Perelman School of Medicine at the University of Pennsylvania, Philadelphia, United States; [3]Inozyme Pharma, Boston, United States

Background
Biallelic loss-of-function (LOF) *ENPP1* variants cause generalized arterial calcification of infancy type 1 (GACI1) and autosomal recessive hypophosphatemic rickets type 2 (ARHR2). *ENPP1* encodes an enzyme that generates inorganic pyrophosphate (PPi), a mineralization inhibitor. Loss of ENPP1 function leads directly to PPi deficiency and indirectly to fibroblast growth factor 23 (FGF-23) excess. Animal data support a role for ENPP1 as a regulator of bone mass; case reports suggest that humans with monoallelic *ENPP1* variants may develop osteoporosis. The objective of this study was to characterize bone density, strength, and mineral metabolism in adults with monoallelic *ENPP1* variants.
Methods
Symptomatic (atraumatic vertebral or long bone fractures, pain interference, early onset cardiovascular disease) and asymptomatic individuals with monoallelic *ENPP1* variants were eligible. Outcome measures included whole body, hip, lumbar spine, and forearm areal bone mineral density (aBMD) by dual energy X-ray absorptiometry (DXA, Hologic), cortical and trabecular volumetric BMD (vBMD) and strength (stiffness, failure load) of the radius and tibia by high resolution peripheral quantitative computed tomography (HR-pQCT, Scanco) expressed as Z-scores for age and sex. Mineral metabolism markers were determined by standard clinical assays, PPi by an ATP sulfurylase/luminescence-based enzymatic method (Inozyme).
Results
Twenty individuals (11 female, 10 symptomatic), median age 38 years (range 20-54) completed the study. Thirteen participants (65%) reported a total of 27 lifetime fractures. Within the symptomatic cohort, pain interfering with daily activities was the most prevalent symptom (80%); demographics did not differ by symptomatic status. Mean ($\pm$SD) aBMD-Z ranged from -0. 4$\pm$0. 8 (forearm) to 0. 3$\pm$0. 6 (whole body); no subjects had low aBMD at any site. HR-pQCT analysis revelaed relative deficits in trabecular vBMD vs cortical vBMD at distal radius (-0. 9$\pm$1. 1 vs 0. 3$\pm$0. 7, $P < 0.01$) with a similar trend at distal tibia (-0. 9$\pm$1. 1 vs -0. 3$\pm$1. 2, $P = 0.18$). Failure load and stiffness Z-scores were both -0. 4$\pm$0. 6 at the radius and -0. 8$\pm$0. 9 at the tibia. Blood phosphate and alkaline phosphatase were normal in all participants; FGF-23 was elevated in one male. PPi did not differ by symptomatic status and was not correlated with bone outcomes.
Conclusion
Fractures and musculoskeletal pain were common in this cohort of adults with monoallelic *ENPP1* variants. In contrast to prior reports, aBMD was normal in all participants. Mild deficits in trabecular vBMD and bone strength were found by HR-pQCT; however, these were not related to symptomatic status, serum PPi, or markers of mineral metabolism. Further genotype/phenotype studies may clarify the contribution of ENPP1 to bone health.

Estimating the risk of chronic kidney disease progression in chronic hypoparathyroidism: a retrospective matched cohort study, using real world data from England

Alden Smith[1], Narendra Reddy[2], Caoimhe T. Rice[3], Jennifer Davidson[3], Christopher Sibley[1], Wahidullah Noori[1] & Christopher Poole[4]
[1]Ascendis Pharma, Inc., Palo Alto, United States; [2]University Hospitals of Leicester NHS Trust, Leicestershire, United Kingdom; [3]CorEvitas, Cheshire, United Kingdom; [4]Cencora, London, United Kingdom

Hypoparathyroidism is an endocrine disease caused by insufficient levels of parathyroid hormone (PTH). Postsurgical hypoparathyroidism accounts for most cases; other etiologies include genetic, autoimmune, and idiopathic (non-surgical). Conventional therapy, active vitamin D and calcium, aims to alleviate hypocalcemia but does not address insufficient PTH levels and is associated with hypercalcemia which may increase chronic kidney disease (CKD) risk. We assessed CKD risk in patients with hypoparathyroidism compared to non-hypoparathyroid individuals using routinely collected healthcare data from England. English linked primary (Clinical Practice Research Datalink [CPRD] Aurum) and secondary care (Hospital Episode Statistics) data were used to identify patients aged $\geq$18 years with incident chronic postsurgical ($n = 215$) or prevalent chronic non-surgical ($n = 730$) hypoparathyroidism between 01/Apr/2008–22/Mar/2019. Patients were matched 1:10 to non-hypoparathyroid controls on 5-year age bands, gender, and $\geq$1 year overlap in CPRD registration periods. CKD progression was compared between patients with

Table 1: CKD progression in patients with hypoparathyroidism

Outcome	Post-surgical hypoparathyroidism N progressed (N considered)	HR (95%CI)	Adjusted HR (95%CI)	Non-surgical hypoparathyroidism N progressed (N considered)	HR (95%CI)	Adjusted HR (95%CI)
CKD1/2 to CKD3	13 (144)	2. 74 (1. 52-4. 94)	3. 02 (1. 67-5. 47)	56 (536)	3. 06 (2. 30-4. 07)	4. 05 (3. 03-5. 42)
CKD3 to CKD4	<5 (25)	1. 53 (0. 44-5. 33)	2. 21 (0. 59-8. 29)	17 (158)	2. 44 (1. 39-4. 29)	2. 94 (1. 54-5. 63)
CKD4 to CKD5	<5 (9)	2. 00 (0. 17-23. 18)	*	14 (57)	2. 30 (0. 99-5. 32)	1. 80 (0. 71-4. 56)
CKD4 to dialysis	<5 (9)	3. 67 (0. 21-63. 87)	*	6 (57)	2. 92 (0. 73-11. 71)	2. 13 (0. 45-10. 03)

*Insufficient sample CI = confidence intervals; HR = hazard ratios

hypoparathyroidism and controls using Cox proportional hazards regression adjusted for age (at surgery for postsurgical and follow-up start for non-surgical), gender, and cardiovascular disease presence. Progressions of CKD1/2 to CKD3, CKD3 to CKD4, CKD4 to CKD5, and CKD4 to dialysis were determined from recorded diagnoses. Patients without CKD at hypoparathyroidism diagnosis were conservatively assumed as CKD1/2. Each progression comparison was limited to patients with the starting CKD stage at hypoparathyroidism diagnosis or during follow-up, and censored at earliest of CKD progression, death, end of CPRD registration, or 22/Mar/2020. Patients with postsurgical hypoparathyroidism had a 3-fold increase in CKD1/2 to CKD3 progression compared to matched controls (Table 1). Patients with non-surgical hypoparathyroidism had a 4-fold and 3-fold increase in CKD1/2 to CKD3 progression and CKD3 to CKD4 progression, respectively. Our results show increased risks of early-stage CKD progression amongst patients with hypoparathyroidism compared to non-hypoparathyroid individuals. The small sample size in this rare disease precludes definitive analysis of late-stage risk difference.

Evaluation of ALP and PLP as a screening tool for ALPL mutations in hypophosphatasia: a study in chinese pediatric patients

Dandan Zhang[1] & Ting Chen[1]
[1]Children's Hospital of Soochow University, Suzhou, China

Background
Hypophosphatasia (HPP), an inherited metabolic disorder caused by ALPL gene mutations, manifests through deficient tissue-nonspecific alkaline phosphatase (TNSALP) activity, leading to skeletal complications and systemic morbidity. Persistent low serum alkaline phosphatase (ALP) activity is a hallmark biochemical feature, yet its non-specificity and overlap with other conditions often delay diagnosis. With the advent of enzyme replacement therapy, establishing a pediatric-specific diagnostic framework is imperative to prevent life-threatening sequelae and avoid mismanagement.
Methods
Based on the lower limit of the ALP reference interval for age-and gender-specific ranges in children, as outlined in the 'Health Industry Standards of the People's Republic of China', we included children and adolescents with persistently low ALP activity in this study. These participants underwent whole-exome sequencing (WES) and plasma pyridoxal-5′-phosphate (PLP) measurement. By analyzing the genetic mutation positivity rate in the low ALP population, we calculated the cutoff value for PLP using ROC curve analysis. Clinical phenotype data were collected to clarify the characteristics of hypophosphatasia (HPP) in the Chinese population and to explore the genotype-phenotype correlation.
Results
Among 94, 467 analyzed samples, 246 subjects had persistently low ALP activity. ALPL variants were detected in 76 of 246 individuals (30. 9%) by WES. ROC curve analysis identified a PLP cutoff value of 21. 3 ng/mL (sensitivity 74. 6%, specificity 84. 4%). When PLP $\geq$ 21. 3 ng/mL, the positive predictive values for ALP mutation was 62. 4% (58/93). Further analysis revealed that PLP (AUC = 0. 819, P < 0. 05) was a better predictor of ALPL gene positivity than ALP (AUC = 0. 784, P < 0. 05). The carrier frequency of ALPL heterozygous mutations was approximately 1/500 to 1/133, missense mutations accounted for 80. 7% of ALPL mutations, with the most common being p. Arg136His (10. 8%). Not all carriers exhibited clinical symptoms, genotype-phenotype correlation study showed that 100%, 88% and 77% of carriers with severe dominant negative effect (DNE) mutation, severe haploinsufficiency (HI) mutation and moderate HI mutation of ALPL gene had clinical symptoms. The proportion of severe DNE mutation carriers with 1 or 2 symptoms was the highest, 60% and 40%, respectively. p. Arg136His were recognized in patients with fractures and epilepsy.
Conclusion
Our study identified PLP as a cost-effective screening biomarker for HPP in children and as a reliable biomarker for predicting ALPL mutations. We found that the carrier frequency of p. Arg136His is relatively high in the Chinese population. These findings also provide valuable insights into the genetic and phenotypic characteristics of HPP in the Chinese population.

Renal safety of zoledronic acid infusion in osteoporosis patients: a retrospective analysis

Kubra Yildiz Comert[1], Elif Tuna Kuru[2], Adar Irmak[2], Deniz Turkum Atikcan Simsek[1], Merve Senay Ozcalik[1] & Ozlem Iyidir[1]
[1]Baskent University, Internal Medicine, Ankara, Türkiye; [2]Baskent University, Faculty of Medicine, Ankara, Türkiye

Introduction
Zoledronic acid (ZA) is a bisphosphonate used for osteoporosis and malignancy-associated hypercalcemia. It is given intravenous infusion annually. While generally safe, isolated cases of acute kidney injury (AKI) have been reported, particularly in cancer patients receiving high cumulative doses, those with pre-existing renal insufficiency, and those with nephrotoxic therapy history. Kidney function monitoring, especially in older adults, is essential as AKI can also occur in low-risk patients. ZA is not recommended for patients with creatinine clearance below 35 mL/min. Osteoporosis guidelines suggest using the Cockcroft-Gault formula to estimate renal function before infusion, though many labs now report eGFR using the 2021 CKD-EPI formula. This study evaluates changes in serum creatinine (SCr), AKI incidence, and renal safety using eGFR (2021 CKD-EPI).
Methods
We retrospectively analyzed data from patients receiving at least two ZA infusions. Changes in SCr before and after infusion and AKI incidence within one year were recorded.
Results
A total of 452 infusions from 226 patients met the criteria. The mean age was 74. 2 $\pm$ 9. 8 years, and 93. 4% were female. The baseline T-score was -2. 95 $\pm$ 0. 86. 11. 5% had a baseline GFR <60 mL/min/1. 73 m^2 (stage 3 CKD). The mean baseline SCr was 0. 80 $\pm$ 0. 18 mg/dL, with an average GFR of 78. 5 $\pm$ 14. 8 mL/min/1. 73 m^2. The mean SCr increase was 0. 04 mg/dL ($P < 0.0001$). Table 1 outlines renal outcomes. There was 5 (%2. 2) AKI, two of them progressed to chronic renal failure due to additional comorbidities. 124 of the patients were >75 years old. In older patients The average baseline SCr was 0. 83 ($\pm$ 0. 19) mg/dl, corresponding to an average GFR of 71. 8 ($\pm$ 13. 4) mL/min/1. 73 m2. The mean difference in SCr was 0. 06 (95% confidence interval, 0. 109–0. 02, $P = 0.002$) lower in the after-period which was statistically significant.
Discussion
Our study results show no clinically meaningful changes in serum creatinine (SCr) levels following zoledronic acid (ZA) infusions, and ZA-induced acute kidney injury (AKI) or renal failure was rare, occurring only in older patients receiving treatment for osteoporosis. While the 0. 04 mg/dL increase in SCr was statistically significant, we do not consider it clinically significant. Additionally, since the study had a maximum follow-up of one year, we cannot evaluate the long-term effects of treatment.

Real-world bone health outcomes in surgical, medical, and monitored patients with primary hyperparathyroidism

Nang Htwe[1], Eleanor Robinson[2], Felicity Burton[1], Rebecca Sagar[1] & Afroze Abbas[1]

[1]Leeds Centre for Diabetes and Endocrinology, Leeds Teaching Hospitals Trust, Leeds, United Kingdom; [2]Leeds Teaching Hospitals Trust, Leeds, United Kingdom

Background
Primary hyperparathyroidism (PHPT) leads to hypercalcemia and increased fracture risk due to parathyroid hormone overproduction. While surgery is the standard curative treatment, optimal bone health management strategies remain unclear. This study evaluates real-world bone mineral density (BMD) changes, fracture risk and treatment in PHPT patients undergoing surgical, medical, or monitoring-based management.
Methods
A retrospective analysis was conducted on patients diagnosed with PHPT between 2012-2019. Data collected included demographics, PHPT management, baseline and longitudinal BMD, fracture risk (assessed with Fracture Risk Assessment Tool, FRAX), and osteoporosis management. Statistical analysis was performed using Prism software.
Results
A total of 758 patients (81% female, mean age 65 $\pm$ 16 years) were included. Of these, 52% underwent parathyroidectomy, 14% received long-term cinacalcet (medical group), and 34% were monitored without active treatment. Baseline BMD at the spine, hip, and wrist was comparable across groups (wrist BMD: 0. 68 $\pm$ 0. 2 g/cm^2 vs. 0. 67 $\pm$ 0. 1 g/cm^2 vs. 0. 68 $\pm$ 0. 2 g/cm^2; $P > 0.9$). Mean follow-up duration for repeat DXA was 2. 8 years. The monitored cohort had the highest baseline major osteoporotic fracture (MOF) risk (35 $\pm$ 21%) compared to the medical (16. 3 $\pm$ 0. 1%, $P < 0.001$) and surgical groups (16 $\pm$ 0. 2%, $P < 0.001$). Hip fracture risk was highest in the monitored group (12. 7 $\pm$ 7%) compared to the medical (6. 7 $\pm$ 0. 1%, $P < 0.001$) and surgical groups (4. 8 $\pm$ 0. 2%, $P < 0.001$). On repeat DXA, the surgical group demonstrated the greatest BMD gains at all sites: **Spine BMD change:** +3. 1% (surgical) vs. -2. 78% (medical) vs. -0. 91% (monitored), $P < 0.001$. **Hip BMD change:** +1. 18% (surgical) vs. -5. 69% (medical) vs. -3. 87% (monitored), $P < 0.001$. **Wrist BMD change:** +4. 71% (surgical) vs. -4. 71% (medical) vs. -6. 17% (monitored), $P < 0.001$. There were no significant differences in BMD changes between the medical and monitored groups. As per National Osteoporosis Guideline Group thresholds, high/very high fracture risk was identified in 43% (medical & monitored) vs. 31% (surgical) of patients, $p < 0.02$. Despite this, only 42% (surgical), 57% (medical), and 56% (monitored) received osteoporosis treatment, indicating suboptimal management.
Conclusion
In this large cohort, surgical treatment resulted in significant BMD improvements at all sites, with the greatest gains at the wrist. No differences were observed between the medical and monitored groups, suggesting cinacalcet *alone* is insufficient to improve bone health in PHPT. A more proactive osteoporosis management strategy is needed, particularly for non-surgical cohorts.

Exploring parathyroid carcinoma: clinical and pathological observations from a two-decade review

Subhash Yadav[1], Ayushi Singhal[2], Ayush Gupta[2], Ayushi Chak[2] & Anjali Mishra[3]
[1]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Endocrinology, Lucknow UP, India; [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Endocrinology, Lucknow UP, India; [3]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Endocrine Surgery, Lucknow UP, India

Background
Parathyroid carcinoma is an extremely rare endocrine malignancy, comprising less than 1% of primary hyperparathyroidism cases and only 0. 005% of all cancers. Its clinical presentation and symptoms primarily result from hypercalcemia rather than from local invasion or distant metastasis.
Material and methods
A retrospective study was performed, analysing all histopathologically confirmed cases of parathyroid carcinoma identified among primary hyperparathyroidism cases between 2004 and 2024. The demographics and clinical characteristics of these parathyroid carcinoma cases were compared to a randomly selected group of parathyroid adenoma cases in a 2:1 ratio. Clinical and laboratory parameters of all parathyroid carcinoma cases were thoroughly evaluated.
Result
In our study, the prevalence of parathyroid carcinoma was 3% ($n = 16$) among all diagnosed cases of primary hyperparathyroidism. The mean age at presentation was 50. 3$\pm$11 years in the carcinoma group and 47$\pm$18 years in the adenoma group. Males were predominant in the parathyroid carcinoma group, while females were more prevalent in the adenoma group. Compared to parathyroid adenoma, carcinoma cases showed more palpable masses (82% vs. 6. 3%; $P < 0.001$), higher rates of gastrointestinal symptoms, nephrolithiasis, pancreatitis. One patient had reversible Mobitz Type 1 heart block in carcinoma group. Investigations showed that carcinoma group had lower albumin (3. 6$\pm$0. 8 g/dL vs. 4. 2$\pm$0. 7 g/dL; $P < 0.01$), and higher serum creatinine (1. 4$\pm$0. 6 mg/dL vs. 1. 1$\pm$0. 5 mg/dL; $P < 0.05$). In patients with parathyroid carcinoma mean levels of calcium, phosphorus, alkaline phosphatase, iPTH and vitamin D were 13. 7$\pm$2. 1 mg/dL, 2. 3$\pm$0. 6 mg/dL, 301$\pm$169 IU/l, 123. 3$\pm$137 pmol/l, 43. 5$\pm$32. 2 nmol/l respectively (no significant difference from parathyroid adenoma). Mean size of involved parathyroid gland in USG was 2. 7$\pm$1. 1 cm. Most involved gland was inferior parathyroid. Histopathology of the carcinoma group revealed capsular invasion (88%), vascular invasion (68%), necrosis (88%), mitotic figures (50%), and perineural invasion (63%). Predictor of risk factors for parathyroid carcinoma were palpable mass and gland size >3 cm. All patients underwent surgical resection, with additional treatments including cinacalcet 3 (19%), radiotherapy 3 (16%), and TACE 1 (6%). Recurrence was observed in 5 (31%) patients.
Conclusion
Palpable neck mass, gland size >3 cm were key predictors of parathyroid carcinoma, while recurrence was predicted by calcium >14 mg/dL, gland size > 3 cm, and extrathyroidal extension with recurrence rate of 31%.

Obesity and blunted FGF23 response associate with kidney impairment in patients with hypoparathyroidism

Luigi di Filippo[1], Agnese Allora[1], Anna Maria Formenti[1], Francesca Ferrari[1], Marta Villanova[1], Antonino Russo[2], Barbara Presciuttini[3], Massimo Locatelli[4], Maria Luisa Brandi[1], Giuseppe Vezzoli[5], Claudio Marelli[6] & Andrea Giustina[1]
[1]Institute of Endocrine and Metabolic Sciences, Università Vita-Salute San Raffaele, IRCCS Ospedale San Raffaele, Milan, Italy; [2]Internal Medicine Division, Santa Chiara Hospital, Provincial Health Care Agency (APSS), Trento, Italy; [3]Endocrinology Unit, Medical Department, ASST Mantova, Mantua, Italy; [4]Laboratory Medicine Service, IRCCS Ospedale San Raffaele, Milan, Italy; [5]Unit of Nephrology and Dialysis, Università Vita-Salute San Raffaele, IRCCS Ospedale San Raffaele, Milan, Italy; [6]Medical Pharma Consultant, Sestri Levante, Italy

Hypoparathyroidism is an endocrine disease characterized by low or insufficient parathyroid hormone secretion leading to alterations in calcium-phosphate and skeletal metabolism. Chronic kidney disease (CKD) is a common complication of patients affected by chronic hypoparathyroidism managed with conventional therapies. However, no data are currently available regarding the endocrine and metabolic determinants of renal function in these patients. This was a multicenter observational study performed in three health-care centres. Patients with hypoparathyroidism were consecutively enrolled during follow-up visits in 2022-2023. These exclusion criteria were adopted: patients managed with dialysis, proteinuria (>200 mg/24h), use of antihypertensive drugs including thiazides, ACE-inhibitors, angiotensin-II-receptor antagonists, alpha-beta blocking-agents, aldosterone-antagonists, and insulin-treated diabetes. A total of 46 patients were enrolled. Median age was 53 years, 34 (74%) were female and the median disease duration was 11 years. All patients were managed with conventional treatment with active vitamin D and calcium supplements, and the calcium-phosphate product was within the normal range in all patients. The 23. 7% of patients was obese (BMI $\geq$30 kg/m2) and CKD (defined with an eGFR<60 mL/min1. 73m2) was found in the 21. 7% of patients. Patients with CKD were older, affected by a longer-disease, and were more frequently obese (62% vs 13%, $P = 0.01$) and characterized by a non-significant trend toward higher BMI (30. 4 vs 24. 1 kg/m2, $P = 0.07$) as compared to those without. In multivariate analyses, obesity resulted as the only significant independent risk factor associated with CKD ($P = 0.035$, OR 3. 05, CI 1. 38–6. 77). In addition, a significant negative correlation was found between BMI and eGFR ($P = 0.034$; $r = 0.54$), and ROC analyses showed a significant global-performances of BMI to predict CKD with the best youden index of 27. 5 kg/m2 (75% sensitivity, 74% specificity and AUROC 77%, $P = 0.008$, CI 0. 42–0. 94). Patients with CKD were characterized also by higher FGF23 levels. A significant negative correlation was found between FGF23 and eGFR ($P < 0.001$; $r = 0.78$). However, evaluating separately patients with eGFR above and below 60 mL/min/1. 73m2, the correlation between FGF23 and eGFR remained statistically significant only in the first group ($P = 0.028$; $r = 0.61$) and not in those with CKD ($P = 0.7$; $r = 0.22$).

In conclusion, for the first-time, obesity was demonstrated to be independently associated with CKD in patients with hypoparathyroidism, and a blunted eGFR-related response of FGF23 was shown in patients with CKD potentially worsening the renal function in the context of hypoparathyroidism.

Effects of different dietary patterns on bone health: mouse models

Maria Felicia Faienza[1], Donatella Mentino[1], Alessandro Antonioli[2], Alessia Provera[2], Giacomina Brunetti[1], Salvatore Sutti[2] & Flavia Prodam[2]
[1]University of Bari "Aldo Moro", Bari, Italy; [2]University of Piemonte Orientale, Novara, Italy

Background
Bone is a dynamic tissue that undergoes continuous remodeling to maintain its shape and structural integrity. Bone remodeling, essential for maintaining bone health, involves the resorption of mineralized bone by osteoclasts, followed by the formation of new bone matrix by osteoblasts, which is subsequently mineralized. Various factors, including diet, influence this process.
Aim
Our aim was to evaluate the effects of different dietary patterns on bone health in mouse models. We fed mice for 16 and 20 weeks with normal diet (ND16w, ND20w) or Western diet (WD16w, WD20w), and for 20 weeks with combinations of normal diet + Western diet (ND20w + WD20w), normal diet + ketogenic diet (KD) (ND20w + KD20w) or Western diet + KD (WD20w+ KD20w).
Results
Micro-computed tomographical analysis of trabecular region of femoral bones showed that mice fed WD20w + KD20w had a decrease in bone volume to tissue volume ratio (BV/TV%) and trabecular thickness (Tb. Th) compared to mice fed only with western diet (WD20w) (P-values: 0. 04 and 0. 039, respectively). In cortical bone, a significant decrease in cortical thickness (Ct. Th%) comparing mice fed WD16w or WD20w with those fed ND16w or ND20w was observed (P= 0. 049 and P = 0. 0039, respectively). Interestingly, mice fed WD20w showed a significant decrease in Ct. Th% compared to mice fed the combined WD20w + ND20w (P = 0. 0011). Furthermore, mice fed the combined WD20w + KD20w diet showed a significant decrease in Ct. Th% with respect to mice fed the combined WD20w + ND20w diet (P = 0. 0018). An increase in the number of osteoclasts was observed in the trabecular bone in mice fed ND20w + KD20w vs ND20 (P = 0. 020), or WD20w + KD20w vs WD20w (P = 0. 028). In addition, the number of osteoblasts decreased significantly comparing ND + KD20w vs ND20w (P = 0. 041), as well as ND20w + KD20w vs WD20w + ND20w (P = 0. 020). An increase of osteoblast's number in mice fed WD20w + ND20w combined diet vs WD20w was observed (P = 0. 019).
Conclusions
The ketogenic diet causes an alteration of bone remodeling by shifting it towards an increase in the number of osteoclasts and a reduction in osteoblasts. The combination of the normal diet and the Western diet reduces the detrimental effects on bone of the Western di*et al*one.

JOINT2283

Efficacy of anastrozole in adolescent boys with limited growth potential: a retrospective analysis

Giulia Del Medico[1, 2], Nicolò Chiti[1], Alessandro Barbato[1, 2], Alessio Rossi[1, 2], Sara Soldovieri[1, 2], Matteo Pontone[1, 2], Emanuela Pignatone[1, 2], Gaia Varriale[1], Franco Ricci[1] & Stefano Stagi[1, 2]
[1]Endocrinology and Diabetology Unit, Meyer Children's Hospital IRCCS, Florence, Italy; [2]Health Sciences Department, University of Florence, Florence, Italy

Introduction
Managing short stature can be challenging, often due to delayed diagnosis, as many patients have already entered puberty by their first endocrinological assessment. During puberty, sex hormones accelerate epiphyseal fusion, restricting growth potential. In adolescent boys, aromatase inhibitors may slow estrogen-driven growth plate closure, potentially enhancing adult height.
Objectives
To retrospectively assess the effectiveness of Anastrozole in increasing height Standard Deviation Score (SDS) in adolescent boys with restricted growth potential.
Methods
Medical records of 53 adolescent boys who received Anastrozole for at least three months were reviewed, collecting data on diagnosis, previous treatments, pubertal stage, anthropometrics, and bone age (BA) at treatment initiation (TI) and conclusion (TC).
Results
Among 53 patients, 9 (17%) were born small for gestational age (SGA), 3 (5. 7%) had growth hormone (GH) deficiency, and 4 (7. 5%) had central precocious puberty. In this cohort, 11 (20. 7%) had prior treatment with recombinant human GH (rhGH), while 4 (7. 5%) received GnRH analogues. At TI, the mean (± standard deviation) age was 14. 7 (±1. 8) years, with a mean BA of 14. 7 (±1. 6) years, a mean height SDS of -1. 37 (±0. 83), and BMI SDS of -0. 33 (±1. 02). The average treatment duration was 1. 1 years. At TC, there was no significant change in height SDS (-1. 38 ± 0. 90) or BMI SDS (-0. 23 ± 0. 92). However, in the subgroup of 13 (24. 5%) patients with a BA below 14 years at TI (mean BA 12. 9 ± 1. 2, mean age 12. 9 ± 1. 9 years, mean duration 1. 4 years), height SDS significantly increased from -1. 19 (±0. 72) to -0. 90 (±0. 93) (P < 0. 005). Notably, one patient did not respond to Anastrozole (height SDS at TI -2. 18 and at TC -2. 53) and was later diagnosed with an *ACAN* mutation. Furthermore, treatment was less effective in SGA patients, as their mean height SDS decreased from -0. 99 (±0. 85) at TI to -1. 29 (±0. 83) at TC, likely due to accelerated puberty. During follow-up, one patient developed transient bilateral knee synovitis and discontinued Anastrozole, but no other adverse events were reported.
Conclusion
Anastrozole may be a promising intervention for improving height outcomes in adolescent boys with limited growth potential, particularly when initiated in those with a BA below 14 years. Further research is necessary to determine the efficacy of aromatase inhibitors in specific subgroups, such as individuals with ACAN mutations or those born SGA. Regular monitoring is essential to identify potential adverse effects.

Atypical parathyroid tumor in patients with primary hyperparathyroidism: predictive preoperative characteristics

Chiara Parazzoli[1], Stefano Testa[1], Vittoria Favero[1, 2], Gisele De Rezende[3], Federica Scolari[4], Paolo Salvatore Lorenzo Aiello[4], Iuliana Pauna[4], Sara Andreani[4], Marco Boniardi[4] & Iacopo Chiodini[1, 2]
[1]University of Milan, Department of Biotechnology and Translational Medicine, Milan, Italy; [2]ASST Grande Ospedale Metropolitano Niguarda, Unit of Endocrinology, Milan, Italy; [3]Niguarda Cancer Center, Department of Anatomic Histopathology and Cytogenetics, Department of Laboratory Medicine, Milan, Italy; [4]ASST Grande Ospedale Metropolitano di Niguarda, General Oncologic and Mini-invasive Surgery Department, Milan, Italy

Introduction
Atypical parathyroid tumor (APT) is a rare lesion of uncertain malignant potential with characteristics similar to parathyroid carcinoma, making early diagnosis crucial to adequately plan surgery and follow-up. To date, no predictive criteria exist to differentiate APT from typical adenoma (TA) before surgery.
Aims
To identify predictive preoperative characteristics of TA and APT and compare their biochemical response to parathyroidectomy.
Methods
We retrospectively analyzed patients who underwent parathyroidectomy for primary hyperparathyroidism in our center between March 2022 and August 2024. In patients with TA and TPA, we compared: i) pre-intervention: demographic characteristics, calcium-phosphorus metabolism tests, renal and bone complications, tumor site; ii) post-intervention: type and duration of surgery after excluding patients who also underwent other interventions contextual to parathyroidectomy, histological characteristics, calcium-phosphorus metabolism at discharge.
Results
150 patients were included (age 59. 5±10. 5 years; 113 females), of whom 14 (9. 3%) had TPA. These patients were predominantly male compared to TA (78. 6% vs. 19. 1%, respectively, P < 0. 001). TPA and TA patients were similar in age and had a higher prevalence of history of other malignancies (50% vs 22. 6%, respectively, P = 0. 02). APT patients had higher calcium levels than TA (11. 7

vs. 11. 2 mg/dL, respectively, $P = 0.03$), with no significant differences in other parameters or complications. SestaMIBI scintigraphy localized APT better than TA (100% vs 79. 2%, respectively, $P = 0.04$). APT had more frequently a right-sided parathyroid location than TA (92. 9% vs. 50. 7%, $P = 0.003$), with no differences in adenoma size. Logistic regression analysis showed that male sex (OR 11. 5, 95%CI 2. 7–47, $P < 0.001$) and right-side location (OR 12. 5, 95%CI 1. 4–111, $P = 0.02$) or their combination ($P < 0.001$) were independently associated with APT. APT patients underwent longer (70 ± 26. 5 vs 52 ± 18. 4 min, $P = 0.007$) and more extensive surgery, such as "en bloc" resections and neck exploration ($P < 0.001$). APT were heavier as compared with TA (2.8 ± 2.9 vs. 1.2 ± 1.4 g, respectively, $P = 0.04$) and had more fibrosis ($P < 0.001$), but no difference in Ki-67 values was found. Finally, APT patients had higher disease persistence and/or recurrence than TA patients (21. 4% vs. 1. 5%, respectively, $P < 0.001$).

Conclusion

These preliminary data suggest that TPA and TA have similar preoperative clinical and biochemical presentations. Male gender and/or right parathyroid location appear to be associated with TPA. These patients should be cautioned as they are at higher risk for longer and more complex surgery and postoperative persistence.

Does an aggressive onset affect prognosis? insights into atypical parathyroid tumors

Berna Evranos Ogmen[1], nurcan ince[2], aysegül aksoy altınboğa[3], gulsum karahmetli[3], Oya Topaloglu[3], Reyhan Ersoy[3] & Bekir Cakir[3]
[1]Ankara yildirim beyazit university, bilkent city hospital, endocrinology and metabolism, Ankara, Türkiye; [2]Artvin Public Hospital, internal medicine, Artvin, Türkiye; [3]Ankara yildirim beyazit university, bilkent city hospital, pathology, ankara, Türkiye

Introduction

Parathyroid tumors are the most frequent cause of primary hyperparathyroidism (PHPT), affecting approximately 0. 1% to 0. 3% of the general population. Most cases are attributed to benign parathyroid adenomas (PA), with hyperplasia being less common, while parathyroid carcinomas (PC) are rare, accounting for less than 1% of cases. Atypical parathyroid tumors (APT) are parathyroid tumors with uncertain malignant potential, distinguished by certain histological features commonly seen in PCs, such as a solid growth pattern, fibrous bands, and cellular atypia. However, they do not exhibit definitive signs of malignancy, such as capsular, vascular, or perineural invasion, or evidence of local invasion or metastasis. Due to the uncertain malignant potential of APT, long-term follow-up is recommended. We followed patients with PA or APT and compared the outcomes in this study.

Methods

This retrospective study includes patients who were followed up in 2 tertiary centres with PA or APT diagnoses between June 2007 and January 2025. Demographic data, including age and gender, along with biochemical parameters serum Ca, corrected calcium (cCa), phosphorus, albumin, alkaline phosphatase (ALP) parathormone (PTH), 24-hour urinary Ca, estimated glomerular filtration rate (eGFR), fractional calcium excretion (FECa), and 25-hydroxyvitamin D (25OHD) were collected. Renal imaging and dual-energy X-ray absorptiometry were used to assess nephrolithiasis and osteoporosis. The patients' data were compared at the time of diagnosis, preoperatively and at the last follow-up.

Results

47 patients with APT were compared with 596 patients with PA. Median age was similar (53 years for PA vs. 51 years for APT, $P=0.11$). PTH levels were significantly higher in APT (209 ng/l vs. 172 ng/l, $P=0.006$), while serum 25-hydroxyvitamin D levels were lower (9. 4 µg/l vs. 14. 9 µg/l, $P=0.03$). Other biochemical markers, including FECa, 24-hour urinary calcium, ALP, and corrected calcium, showed no significant differences ($P>0.05$). Osteoporosis was more prevalent in APT (64% vs 41. 9%, $P = 0.029$), while nephrolithiasis was similar ($P = 0.84$). Ultrasonographic tumor volume was significantly larger in APT (1. 65 cm^3 vs. 0. 53 cm^3, $P<0.001$). Follow-up data were available for 309 PA and 35 APT patients. The median follow-up period was 55 months for PA and 75 months for APT ($P=0.88$). Serum calcium levels remained similar (9. 12 mg/dL vs. 9. 13 mg/dL, $P=0.368$). The incidence of osteoporosis and nephrolithiasis during follow-up was comparable between groups ($P=0.31$ and $P=0.76$, respectively).

Conclusion

Despite elevated baseline PTH levels, larger tumor size, and suspicious pathological findings, APT demonstrated no significant differences in long-term outcomes compared to PA during follow-up.

Tumour induced osteomalacia in a teenager: successful tumour localisation (68-Ga DOTATE PET-CT), tumour genetics (FGFR1 fusion gene) and tumour removal

Aikaterini Perogiannaki[1, 2], Banupriya Sivasanker[1], Krishanantham Ambalawaner[3], Alessandro Vidoni[4], Rob Pollock[5], Adrienne Flanagan[6], Benjamin Jacobs[7] & Evelien Gevers[1, 8]
[1]Barts Health NHS Trust, Department of Paediatric Endocrinology and Diabetes, London, United Kingdom; [2]Leeds Teaching Hospitals NHS Trust, Department of Paediatric Endocrinology and Diabetes, Leeds, United Kingdom; [3]Barts Health NHS Trust, Royal London Hospital, Department of Radiology, London, United Kingdom; [4]Royal National Orthopaedic Hospital, Department of Radiology, London, United Kingdom; [5]Royal National Orthopaedic Hospital, Department of Orthopaedics, London, United Kingdom; [6]University College London, Pathology Department, London, United Kingdom; [7]Royal National Orthopaedic Hospital, Department of Paediatric Medicine, London, United Kingdom; [8]William Harvey Research Institute, Queen Mary University of London, Centre for Endocrinology, London, United Kingdom

Tumour induced osteomalacia (TIO) is rare and difficult to diagnose and treat in children. We report an adolescent with TIO, his diagnostic pathway, and recovery after surgery. A 14-year-old male presented with a one-year history of generalised bone pain with a prior distal radius/ulna fracture. He had normal growth, development and unremarkable family history. Examination was normal with no leg bowing. Investigations revealed severe hypophosphataemia (0. 48 mmol/l), renal phosphate loss (TMP/GFR 0. 26 mmol/l), mild hypocalcaemia (2. 15 mmol/l), high ALP (791U/l), high-normal PTH (6. 5pmol/l), undetectable urine calcium, elevated FGF23 [177RU/mL(<100)] and low 1, 25 vitamin D3 [38nmol/l(108-246)]. He had normal knee X-rays, renal ultrasound and urine aminoacids, and low bone mineral density (L1-4 BMD -2. 5 SD). TIO was diagnosed. He was started on oral phosphate, alfacalcidol and vitamin D. Genetic testing [hypophosphatemia panel (PHEX/renal phosphate wasting) and whole-genome sequencing] was normal, as expected. Imaging to identify the tumour was initiated. X-ray skeletal survey was normal. Whole body MRI suggested a 33mm ovoid lesion in the distal left femur. Ga-68 DOTATATE PET-CT was chosen for further imaging and confirmed the juxtacortical soft tissue lesion. A dedicated MRI showed the lesion was 35x14x9mm. Peripheral venous sampling from legs and arm showed very high FGF23 (898–1019mU/mL) but was unable to localise the FGF23 production. The lesion was surgically excised. Histopathology showed osteoclast-like cells and calcification, in line with a phosphaturic mesenchymal tumour. Tumour RNA analysis (TruSight RNA Pan Cancer panel) showed a *FN1-FGFR1* fusion gene. Postoperatively, phosphate supplementation was discontinued, and alfacalcidol tapered. FGF23 decreased rapidly (24RU/mL after 14 days), phosphate concentration improved, but with concomitant increase in PTH (14. 9pmol/l), 1, 25 vitamin D (919pmol/l), ALP (415 mmol/l), undetectable calciuria, and worsening bone pain suggestive of hungry bone syndrome. His symptoms improved after 2-3 months, and all medications were stopped. Three months after surgery, 1, 25 vitamin D was still high but other biochemical indices had normalised.

Conclusion

Localisation of the tumour in TIO is often unsuccessful. Whole body MRI, peripheral venous FGF23 sampling, octreotide scan and octreotide SPECT-CT are commonly used. Recently, Ga-68 DOTATATE PET-CT has shown better sensitivity in adults, although it has high radiation dose. Ga-68-DOTATATE PET-CT performed best in identifying our patient's tumour, whereas peripheral sampling for FGF23 was unsuccessful. Tumour RNA sequencing can reveal the underlying mechanism of TIO. Post-operatively, FGF23 drops rapidly, 1, 25 vitamin D rises, and hungry bone syndrome and bone pain can occur.

National Hospital, Washington DC, United States; [5]Universidade de São Paulo, São Paulo, Brazil; [6]Sunnaas Rehabilitation Hospital & Oslo University Hospital Rikshospitalet, Oslo, Norway; [7]Johns Hopkins University, Baltimore, United States; [8]National Institute Fernandes Figueira, Rio de Janeiro, Brazil; [9]ISEIKAI International General Hospital, Osaka, Japan; [10]BridgeBio Pharma, San Francisco, United States; [11]Murdoch Children's Research Institute, Melbourne, Australia; [12]Baylor College of Medicine & Texas Children's Hospital, Houston, United States; [13]Great Ormond Street Hospital, London, United Kingdom

Background
Hypochondroplasia (HCH) is a disproportionate short statured skeletal dysplasia caused by gain-of-function pathogenic variants in the fibroblast growth factor receptor 3 gene (*FGFR3*) that lead to reduced endochondral bone growth. HCH typically becomes clinically apparent after the first year of life, when growth velocity begins to decline and height discrepancy widens relative to average height peers. Reaching an initial suspicion of HCH can be challenging due to wide phenotypic variability and subtle clinical and radiographic features, which in turn can lead to delayed or missed diagnosis. Early diagnosis may facilitate implementation of appropriate clinical management and psychosocial support. However, there are currently no standardized diagnostic criteria for HCH nor are diagnostic pathways well described in the literature.
Methods
In October 2024, 14 experts across multiple specialties (pediatric endocrinology, medical genetics, maternal fetal medicine, pediatrics, family medicine, radiology, genetic counseling) completed an online survey on current clinical practices for diagnosing HCH. A subset of participants convened to discuss strategies to optimize clinical diagnostic pathways. Insights and recommendations were refined by the collective group during the drafting of this communication.
Results
Sonographic features of HCH may be detectable prenatally from approximately 20 weeks' gestation, becoming more pronounced in the third trimester, and typically include a short femur and a relatively larger head circumference. Prenatal diagnostic testing options include targeted *FGFR3* analysis via non-invasive prenatal testing or multi-gene sequencing in DNA from invasive procedures such as amniocentesis, which also allows wider exploration of other skeletal dysplasias when diagnostic uncertainty exists. Postnatally, features suggesting HCH include a sustained fall in height centiles over the first two years, macrocephaly, seizures, and specific radiographic and neuroimaging findings. Between ages 2-3 years, a characteristic growth pattern including body disproportion with shortened limbs may become evident. Occasionally a history of learning differences may become apparent. HCH should be considered in the differential diagnosis of idiopathic or isolated short stature in children. Genetic testing for growth disorders using panels that include *FGFR3* and evaluation of short statured parents are also useful to establish the diagnosis of HCH.
Conclusions
Early diagnosis of HCH is achievable by the detection of key clinical and radiological features and supported by molecular analysis using different diagnostic platforms. Timely diagnosis may enable interventions to reduce complications and potentially enhance vertical growth in the future. This work represents an important initial step towards consensus-based diagnostic criteria and guidelines for HCH.

The IMPACT survey: healthcare experiences reported by individuals with osteogenesis imperfecta and their caregivers

Luigi Picaro[1], Ingunn Westerheim[2], Frank Rauch[3], Tracy Hart[4], Lena Lande Wekre[5], Taco van Welzenis[2], Cathleen Raggio[6], Melanie Anderson[7], Samantha Prince[1, 7] & Oliver Semler[8]
[1]Mereo BioPharma, London, United Kingdom; [2]Osteogenesis Imperfecta Federation Europe, Heffen, Belgium; [3]mgill University, Montreal, Canada; [4]Osteogenesis Imperfecta Foundation, Gaithersburg, Maryland, United States; [5]TRS National Resource Center for Rare Disorders, Sunnaas Rehabilitation Hospital, Bjørnemyr, Nesodden, Norway; [6]Hospital for Special Surgery, New York, United States; [7]Wickenstones Ltd., Oxford, United Kingdom; [8]University of Cologne, Cologne, Germany

Introduction/Objectives
The healthcare journey of people with osteogenesis imperfecta (OI)—a rare genetic connective tissue disorder—is not completely understood. This study provides insights on self-reported healthcare experiences and barriers to care.
Materials and Methods
The IMPACT Survey, developed by the OI Federation Europe, the OI Foundation and an international steering committee of experts, explored the clinical, humanistic and economic impact of OI. The survey was fielded online from July–September 2021 and open to adults (aged ≥18 years) and adolescents (aged 12–17 years) with OI, caregivers (CGs; with or without OI) and other close relatives. This analysis presents self-reported findings from individuals with OI and CGs, who responded on behalf of their care recipients with OI: children (aged 0–11 years), adolescents (aged 12–17 years) and adults (aged ≥18 years). Data were analysed using Microsoft Excel.
Results
Among respondents with OI, 1, 440 were adults and 92 adolescents; CGs ($n = 700$) provided proxy data on 474 children, 171 adolescents and 118 adults with OI. Over 12 months, respondents reported visits to a wide range of healthcare professionals (HCPs; mean [standard deviation] visits 60. 0 [79. 4] children; 53. 9 [56. 5] adolescents; 40. 5 [78. 1] adults) including generalists, specialists and therapists. When asked about healthcare experiences, 41. 0% of adults and 15. 2% of adolescents felt unsupported in their transition from paediatric to adult care. CGs of children (85. 2%) and adolescents (86. 4%) reported worrying about their child's future care transition. Most adults (69. 9%) felt they needed to coordinate their own care, and many (32. 7%) felt care was not continuous. CGs of adults (27. 0%), adolescents (21. 2%) and children (19. 4%) felt care was uncoordinated; CGs of adults (27. 0%), adolescents (11. 8%), and children (10. 1%) felt care was not continuous. Many adults (34. 7%) and adolescents (26. 1%) avoided healthcare. The most common reasons given were past trauma/negative experiences (62. 0%, adults; 58. 4% adolescents), HCPs being unfamiliar with OI (66. 6%, adults; 66. 7% adolescents) or fear (46. 0%, adults; 41. 6% adolescents). CGs who avoided seeking care for their care recipient (18. 8% children; 24. 6% adolescents; 24. 7% adults) indicated this was driven by past trauma/negative experiences (67. 2% children; 48. 3% adolescents; 66. 6% adults), ability to provide better care themselves (52. 5%, children; 41. 3% adolescents; 52. 3% adults) or HCPs being unfamiliar with OI (62. 3%, children; 75. 9% adolescents; 61. 9% adults).
Conclusion
The IMPACT Survey highlights the need for integration of multidisciplinary paediatric and adult care, and increased awareness of OI and healthcare barriers across all life stages.

A case of heterozygous PTHLH deletion causing brachydactyly type E2

Ping Li[1], Jie Xing[1] & Meng Zhang[1]
[1]the Second Hospital of Jilin University, Department of Developmental Pediatrics, Changchun, China

Background
Brachydactyly type E (BDE), a rare skeletal dysplasia (OMIM: 113300), is characterized by metacarpal/metatarsal shortening and variable skeletal anomalies. BDE2 (OMIM: 613382), a distinct subtype, arises from pathogenic variants in the PTHLH gene (12p12. 1-p11. 22), which regulates endochondral ossification via parathyroid hormone-related protein signaling. Heterozygous loss-of-function variants in PTHLH are associated with a characteristic skeletal pleiotropy, classically manifesting as severe generalized bilateral brachydactyly, proportionate short stature, pectus carinatum deformity, and radiologically confirmed premature epiphyseal fusion.
Clinical Case
A 5-year-7-month-old girl presented with symmetrical brachydactyly. Her height(115 cm, 50th percentile), weight(19 kg, 50th percentile) and neurodevelopment were age-appropriate. Her hand radiographs showed dysplastic epiphyses in all digits, and her bone age was 6 years old with mild thoracolumbar scoliosis (Cobb angle 10°). Familial evaluation revealed no brachydactyly or skeletal anomalies. Trio-based whole-exome sequencing (WES) identified a de novo 1. 90 Mb heterozygous deletion at 12p12. 1-p11. 22 (GRCh37: chr12:26, 217, 430-28, 122, 427), encompassing PTHLH exons 3-4. Quantitative PCR confirmed the proband-specific deletion, absent in parental genomes. Decipher/ClinVar databases classified this CNV as pathogenic for BDE2. During 3-year follow-up, scoliosis remained stable (Cobb angle 10°), with height growth velocity of 6 cm/year. She did not yet exhibited signs of pubertal development at eight and half years old.
Conclusion
This study expands the mutational spectrum of BDE2 by identifying the PTHLH intragenic deletion. The absence of familial transmission supports de novo dominance. Notably, preserved stature and non-progressive scoliosis contrast with typical BDE phenotypes, highlighting the broad phenotypic spectrum of PTHLH-related skeletal dysplasias, and necessitating integrated genomic diagnostics to delineate genotype-phenotype correlations. Despite preserved anthropometric parameters (height Z-score: 0. 0) and age-appropriate neurodevelopment, structured surveillance protocols remain critical to monitor potential skeletal sequelae, including scoliosis progression and metaphyseal dysplasia.

JOINT3344

Insufficient bone mineralization to sustain mechanical load of weight in obese girls: a cross-sectional study

Chloe Ramandason[1], Regis Coutant[2], Amsellemn Jager Jessica[2], Bouhours-Nouet Natacha[2], Donzeau Aurelie[2], Rouleau Stephanie[2], Labarre Emmanuelle[2] & Levaillant Lucie[2]
[1]University Hospital, Tours, France; [2]University Hospital, Angers, France

Context
Despite an apparent increase in bone mineral content (BMC) and bone mineral density (BMD) in obese compared to lean children, the fracture risk is higher. On the one hand, mineralization measurements by dual-energy X-ray absorptiometry (DXA) may be falsely raised by the increase in height and width in obese children. On the other hand, the rise in BMC and BMD measured by DXA may not sustain the mechanical load associated with weight.
Objective
We described bone mineralization in overweight/obese girls and lean girls in relation to body composition.
Methods
This was a cross-sectional study in the Pediatric Endocrinology Unit of Angers University Hospital. Three hundred and twenty-eight overweight/obese girls aged 7-18 underwent DXA measurements. Using the same DXA model, their bone mineralization was compared with data from 441 lean girls of similar age and height from the NHANES 2011-2015 studies.
Results
The mean age- and height-adjusted difference in total-body-less-head BMC (TBLH BMC) between obese and lean girls was 186 ± 11 g (P <. 001). Each 1 kg/m2 increase in body mass index (BMI) was associated with a gain of +21 ± 2 g of TBLH BMC in lean girls vs +19 ± 1 g in obese girls (P <. 05 for the difference). Each 1 kg/m2 increase in lean BMI (LBMI) was associated with a gain of +63 ± 4 g of TBLH BMC with no difference between lean and obese girls, whereas fat mass index (FMI) did not have a significant effect on TBLH BMC.
Conclusion
The increase in bone mineralization in obese girls does not adapt to the rise in body mass.

Keywords: obese, girls, bone mineral content, mechanical load, lean mass, fat mass

Clinical significance of chloride-to-phosphorus and chloride-to-magnesium ratios in primary hyperparathyroidism

Beril Turan Erdogan[1], Esra Çopuroğlu[2], Gulsum Karahmetli[1], Fatma Dilek Dellal Kahramanca[1], Neslihan Çuhacı seyrek[2], Husniye Baser[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Türkiye; [2]Ankara Yildirim Beyazit University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Türkiye

Background
Primary hyperparathyroidism (PHPT) is a common endocrine disorder classified into hypercalcemic and normocalcemic subtypes. Traditional biochemical markers such as serum calcium, phosphorus, and parathyroid hormone (PTH) aid in diagnosis; however, additional markers may improve diagnostic accuracy. The chloride-to-phosphorus (Cl/P) and chloride-to-magnesium (Cl/Mg) ratios have been proposed as novel biomarkers for distinguishing PHPT subtypes and predicting skeletal and renal complications.
Methods
A retrospective observational study was conducted on 116 PHPT patients who underwent parathyroidectomy at Ankara Bilkent City Hospital from 2019 to 2022. Preoperative clinical and biochemical parameters, including serum Cl, P, and Mg levels, were analyzed. Cl/P and Cl/Mg ratios were calculated and correlated with PHPT subtypes and complications such as bone mineral density (BMD) loss and nephrolithiasis.
Results
The Cl/P ratio was significantly higher in patients with hypercalcemic PHPT compared to those with normocalcemic PHPT (median 42. 4 vs. 38. 3, $P = 0.0125$). ROC curve analysis determined that a Cl/P ratio greater than 43. 6 had a specificity of 80. 0% and a sensitivity of 43. 4% (AUC: 64. 1%) in distinguishing PHPT subtypes. Additionally, the Cl/P ratio was lower in patients with osteopenia and osteoporosis ($p < 0.0001$), suggesting its role in predicting skeletal complications. The Cl/Mg ratio, on the other hand, was significantly associated with nephrolithiasis risk. A cut-off value of ≤55 demonstrated 82. 4% sensitivity and 66. 7% specificity (AUC: 70. 5%, $P = 0.0002$) in identifying patients at risk for nephrolithiasis. However, the Cl/Mg ratio did not show a significant difference between PHPT subtypes.
Discussion
The Cl/P ratio demonstrated potential as a diagnostic adjunct for PHPT subtype differentiation and as a predictor of skeletal health. Its ability to identify normocalcemic PHPT cases, which often go undiagnosed due to normal serum calcium, highlights its clinical utility. The Cl/Mg ratio, while not useful for subtype differentiation, emerged as a valuable marker for nephrolithiasis risk assessment, reinforcing the role of chloride metabolism in PHPT complications.
Conclusion
Cl/P and Cl/Mg ratios are promising, cost-effective biomarkers for PHPT diagnosis and risk stratification. Their integration into clinical practice may enhance diagnostic precision and aid in early intervention strategies. Further multicenter studies are needed to validate these findings and establish standardized cut-off values.

Table 1: ROC Analysis of Cl/P and Cl/Mg Ratios

Parameter	Cut-off Value	Sensitivity (%)	Specificity (%)	AUC	p-value
Cl/P Ratio	>43.6	43.4	80.0	64.1%	0.0096
Cl/Mg Ratio	≤55	82.4	66.7	70.5%	0.0002

JOINT2644

Phenotypic heterogeneity and long-term bisphosphonate outcomes in osteogenesis imperfecta type V: an 8-year retrospective study of 143 chinese patients

Ting Chen[1] & Qisang Fan[1]
[1]Children's Hospital of Soochow University, Suzhou, China

Background
Osteogenesis imperfecta type V (OI-V), driven by the recurrent *IFITM5* c. -14C>T mutation, is characterized by fractures, hyperplastic callus formation, and progressive interosseous membrane calcification. Despite bisphosphonate use in OI management, their long-term efficacy in OI-V remains poorly defined. This study evaluates phenotypic variability and longitudinal bisphosphonate outcomes in the largest OI-V cohort to date.
Methods
This 8-year retrospective analysis included 143 molecularly confirmed OI-V patients from 105 unrelated families (median age: 12. 4 years; follow-up: 8. 4 years). Patients received intravenous bisphosphonates (zoledronic acid: 0. 05 mg/kg/6 months; pamidronate: 1 mg/kg/day ×3 days/4 months). Clinical, radiographic (spinal radiographs, DXA), and biochemical markers (β-CTX, P1NP, calcium, phosphate, 25-OH-vitamin D) were analyzed.
Results
All patients carried the *IFITM5* c. -14C>T variant. Phenotypic features included radial head dislocation (57. 8%; median onset: 10. 2 years), interosseous membrane calcification (85%; earliest onset: 4 years), and hyperplastic callus (52. 3%; onset: 4–8 weeks post-fracture). Bisphosphonate therapy (median initiation age: 5. 2 years) reduced annual fracture rates from 2. 1 to 0. 4, improved lumbar spine BMD Z-scores (−2. 6 to −1. 3), restored vertebral height in 68% (>15% increase), and elevated height Z-scores (−2. 5 to −1. 8). Bone turnover markers declined (β-CTX: ↓42%, P1NP: ↓38%). However, JOINT deformities and ectopic calcification progressed despite treatment: radial head dislocation prevalence increased from 24% (<10 years) to 82% (>15 years), correlating with reduced elbow mobility ($r = -0.71$, $P<0.001$).
Conclusions
Bisphosphonates significantly improve bone density and reduce fractures in OI-V but fail to halt ectopic calcification or JOINT degeneration. These findings underscore the need for early rehabilitation and novel therapies targeting pathological ossification. This study refines the clinical spectrum of OI-V and provides critical evidence for optimizing multidisciplinary management strategies.

JOINT3831

Solving pancreatic insufficiency as a clue to normal vitamin D serum concentrations in cystic fibrosis

Ondrej Soucek[1] & Kvido Malaska[1]

[1]Charles University in Prague and Motol University Hospital, Second Faculty of Medicine, Department of Pediatrics, Prague, Czech Republic

Introduction
Vitamin D deficiency has been repeatedly found in individuals with cystic fibrosis (CF). Therefore, substitution is recommended by all relevant professional societies. However, the effect of novel treatment strategies such as CFTR modulators on vitamin D metabolism in CF has not been extensively studied yet.
Methods
We have reviewed the medical records of all children and adolescents followed up at our tertiary care Cystic Fibrosis Center. The age, sex, pancreatic function status and CFTR modulators use were collected. The last three assessments of serum concentration of 25-hydroxyvitamin D (25-OHD) and forced expiratory volume within the first second (FEV1) were noted and the mean was calculated. Also the respective doses of vitamin D substitution in international units were recorded.
Results
There were 169 patients (89 females) actively followed at our center. Mean age was 9. 3 $\pm$ 5. 3 years. Eighty six percent (149/169) presented with pancreatic insufficiency and sixty two percent (105/169) were on CFTR modulators. The mean 25-OHD serum concentration was 74. 9 $\pm$ 18. 6 nmol/l and mean FEV1 (percent of the reference) was 100. 7 $\pm$ 14. 3. There was no difference in these two measures between pancreatic sufficient and insufficient patients and between treated and untreated with CFTR modulators. In the linear regression model, 25-OHD concentrations were only slightly negatively influenced by age (beta -1. 14 $\pm$ 0. 33, $P < 0.001$) but not CFTR modulator use or pancreatic sufficiency. However, vitamin D substitution dose was positively influenced by age (beta 97. 2 $\pm$ 17. 6, $P < 0.001$) and negatively by pancreatic sufficiency (beta -580. 6 $\pm$ 247. 7, $P = 0.020$) but not CFTR modulators.
Conclusion
It seems that patients with CF with pancreatic insufficiency need higher doses of vitamin D to keep their 25-OHD serum concentrations within reference range, as compared to patients with pancreatic sufficiency. Despite the expected positive effect of CFTR modulators on vitamin D metabolism in CF, we could not prove that in our study. Longitudinal studies collecting data before and after commencement of the CFTR modulators may elucidate whether vitamin D doses could be decreased or maybe completely discontinued in patients with CF treated with the modern drugs.

Predictors of long-term morbidity and mortality in patients with chronic post-surgical hypoparathyroidism

Line Underbjerg[1], Simon Kok Jensen[2], Thomas Rasmussen[2], Tanja Sikjaer[1], O Ayodele[3], F. Castriota[4], Claudio Marelli[4], Richard Finkelman[3], Christian Fynbo Christiansen[2] & Lars Rejnmark[1]
[1]Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark; [2]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark; [3]Takeda Pharmaceuticals U. S. A., Inc., Cambridge, MA, USA, Aarhus, United States; [4]Takeda Pharmaceuticals International AG, Zurich, Switzerland., Zurich, Switzerland

We aimed to examine factors associated with long-term morbidity and mortality for patients with post-surgical hypoparathyroidism (HypoPT), as a means of assisting healthcare providers in identifying patients at high risk of long-term adverse outcomes. We included 160 patients with post-surgical HypoPT and at least five years of follow-up from the Central Denmark Region. The majority were females (87. 5%) and the main indications for surgery were atoxic goiter and thyroid cancer. Median age was 46 years (interquartile range [IQR], 37-57 years). During the first year after surgery, the median ionized calcium level was 1. 18 mmol/l (IQR, 1. 14-1. 22). Thirty-nine percent of patients experienced episodes of hypocalcemia, whereas 31. 2% had episodes of hypercalcemia. Over a five-year period starting a year after surgery, 16. 4% of patients developed incident chronic kidney disease (CKD), 43. 8% had more than two hospitalizations, and 16. 3% had either a cardiovascular event, incident CKD or died. Patients with prevalent disease were excluded. Multivariable models were used to access factors associated with morbidity and mortality in patients with HypoPT. Higher age and more episodes of hypercalcemia were factors associated with of an increased risk of incident CKD. Elevated levels of phosphate and the presence of comorbidity were associated with a higher risk of two or more hospitalizations. In conclusion, episodes of hypercalcemia and higher age may be associated with the development of CKD. Furthermore, elevated levels of phosphate and comorbidity were linked to two or more hospitalizations. While this study provides new insight into the prognosis of postsurgical HypoPT, study findings should be validated externally in a larger cohort.

Effective management of rebound hypercalcemia during denosumab therapy in pediatric osteogenesis imperfecta through individualized calcium supplementation

Stefanie Stasek[1], Susanna Reincke[1], Mirko Rehberg[1], Jörg Semler[1] & Heike Hoyer-Kuhn[1]
[1]University of Cologne, Faculty of Medicine and University Hospital, Department of Pediatrics, Cologne, Germany

Context
Osteogenesis Imperfecta (OI) is a rare genetic condition, primarily caused by mutations in the *COL1A1* and *COL1A2* genes. Denosumab, a monoclonal antibody inhibiting the receptor activator of nuclear factor kappa-B ligand (RANKL), reduces osteoclast activity and bone resorption. Although it has demonstrated efficacy as an anti-resorptive treatment, its clinical utility is constrained by concerns regarding rebound hypercalcemia. This study was conducted as part of the multicenter trial NCT02352753, which was prematurely terminated due to calcium-related adverse events. At our center, we implemented a sub-study to monitor the dynamics of bone resorption markers and calcium levels during denosumab treatment in pediatric OI patients to prevent rebound-associated complications in this population.
Methods
A total of 40 children and adolescents aged 2 to 17 years with moderate to severe OI were treated with subcutaneous denosumab at a dose of 1 mg/kg body weight every six months. Urinary bone resorption markers (NTX and DPD) and calcium levels were measured at weeks 2, 8, 12, 16, 18, 20, and 22 post-injection. Calcium supplementation was individually adjusted based on age-specific thresholds.
Results
Bone resorption was effectively suppressed during the first two months following denosumab administration. However, levels of uNTX and DPD began to rise already after eight weeks, returning to baseline after three months, with a mild rebound observed at four months. No serious calcium-related adverse effects occurred in these patients.
Conclusion
Individualized monitoring of urinary calcium levels, along with timely adjustments to calcium supplementation, successfully prevented rebound hypercalcemia in children treated with denosumab for OI, without causing hypocalcemia shortly after administration.

The significance of gender regarding the effects of primary hyperparathyroidism on the cardiometabolic profile of the patients: a single-center experience

Efstratios Kardalas[1], Angeliki Mandrapylia[1], Vasiliki Antonopoulou[1], Dimitra Baikousi[1] & Marinela Tzanela[1]
[1]Evangelismos General Hospital, Department of Endocrinology "D. IKKOS", Diabetes Center European and National Center of Excellence for Rare Endocrine Diseases, Athens, Greece

Background and Aim
Emerging scientific data supports the theory that non-syndromic pHPT may be associated to increased risk for various cardiometabolic disorders. The aim of the present study was to decipher the potent role of gender with respect to the impact of pHPT on the lipid and glucose profile of the patients.
Material and methods
A cohort of 227 pHPT (61 male and 166 female) patients from our endocrinology outpatient clinics were included in the retrospective study. Demographic, clinical and laboratory data of these patients were evaluated retrospectively.
Results
The female-to-male ratio was 2. 7:1 with comparable mean age and body mass index among female and male patients (60. 5 vs 58. 4 years, $P = 0.3$ and 29. 3 vs 27. 1 kg/m^2, $P = 0.14$, respectively). No significant differences were recorded regarding the parameters of calcium metabolism between the 2 groups. Bone mineral density was lower in both the lumbar spine ($P = 0.033$) and the femur

neck ($P = 0.029$) for female patients. With reference to the lipid metabolism, male patients presented with significantly higher levels of LDL (127vs111 mg/dl, $P = 0.031$) and triglycerides (116vs100 mg/dl, $P = 0.04$) whilst LpA values were as well more elevated among the male compared to the female patients (38vs31 mg/dl, $P = 0.022$). Additionally, the prevalence of arterial hypertension was 55% among men compared to 52% among women ($P = 0.17$). Furthermore, diabetes mellitus was more often diagnosed among the male patients (20/61 [32%] vs 40/166 [24.1%], $P = 0.012$). The same observation applied for obesity ($P = 0.024$) and impaired fasting glucose ($P = 0.031$), which more frequently affected the male group of pHPT patients. Finally, mean uric acid levels were significantly higher among male pHPT patients compared to the female ones (7.7 vs 6.7 mg/dl, $P = 0.011$), contrary to the CRP levels, which were equal for both groups ($P = 0.24$). It should also be highlighted that parathormone levels were strongly and positively associated with both LDL, TGs and Lpa values in both groups of patients, implying no gender difference towards a plausible direct association of the abnormal parathyroid gland function to the lipid metabolism.

Conclusion

Non-syndromic pHPT may be associated with greater risk for concomitant glucose and lipid profile disorders, especially among the male population. Thus, clinicians should be alert and routinely evaluate pHPT patients for the previously mentioned pathological entities in order to promptly diagnose and treat the latter and preserve cardiometabolic health of these patients.

Histological and laboratory factors associated with negative 99mtc-sestamibi scintigraphy in primary hyperparathyroidism: insights from a retrospective analysis

Nuno Jesus[1,2], Andreia Martins Fernandes[3], Ana Rita Elvas[3], Joana Couto[3], Jacinta Santos[3], Raquel G. Martins[3], Teresa Martins[3] & Fernando Rodrigues[3]

[1]Unidade Local de Saúde de Gaia e Espinho, Endocrinology Department, Vila Nova de Gaia, Portugal; [2]i3S, University of Porto, Cancer Signalling & Metabolism, Porto, Portugal; [3]Portuguese Oncology Institute of Coimbra, Endocrinology Department, Coimbra, Portugal

Introduction

The 99mTc-sestamibi scintigraphy is commonly used for preoperative localization of the affected gland in primary hyperparathyroidism (PHPT) due to its affinity for well-perfused, mitochondria-rich tissues. However, false-negative results occur in 12-25% of cases. Several factors can affect the sensitivity of 99mTc-Sestamibi scintigraphy, including the size and location of the affected gland, the lesion's mitochondrial and fat composition, P-glycoprotein expression, the presence of multiglandular disease, and coexisting thyroid pathology.

Aim

To analyse the association between the histopathological and laboratory findings of patients who underwent parathyroidectomy and had false-negative results in 99mTc-Sestamibi scintigraphy.

Methods

A retrospective study was conducted on patients diagnosed with PHPT who underwent parathyroidectomy and had a 99mTc-Sestamibi scintigraphy performed.

Results

A total of 143 patients were identified and included in the study. The sample was predominantly composed of women (84.6%) with a mean age of 58.4 ± 13.7 years. The preoperative laboratory study revealed median values of ionized calcium of 1.41 mmol/l (IQR:1.37–1.50), phosphate of 2.6 mg/dL (IQR:2.2–3.0), PTH of 178.1pg/mL (IQR:138–291.2), and 25-OH vitamin D of 19.4 IU (IQR:14.0–27.4). The histopathological study revealed 104 (72.7%) typical adenomas, 5 (3.5%) atypical adenomas, 6 (4.2%) carcinomas, 20 (14.0%) hyperplasia, and 8 (5,6%) other histology. The 99mTc-Sestamibi scintigraphy allowed the localization of the affected glands in 123 (86.0%) cases. Comparatively, in the remaining 20 (14.0%) cases where the scintigraphy was negative, the frequency of typical adenoma was significantly lower (50.0% *vs*. 76.4%; $P=0.014$). However, no significant differences were found regarding hyperplasia (20.0% *vs*. 13.0%), atypical adenoma (0.8% *vs*. 3.3%), and parathyroid carcinoma (0% *vs*. 4.9%). In the scintigraphy-negative group, the lesions tend to be smaller (median weight 0.46g [AIQ: 0.61] *vs*. 0.74g [AIQ: 1.02]; $P=0.035$). The analysis of laboratory parameters related to phosphocalcic metabolism revealed that vitamin D levels were significantly higher in patients with a negative scintigraphy result (23.6 UI [AIQ: 19.3-23.6] *vs*. 17.6 [AIQ:13.9-25.7]]; $P=0.033$).

Discussion

PHPT is caused by benign single-gland adenoma in 85% of cases, and precise identification of the affected gland can be challenging. The lesions in the negative scintigraphy group were generally smaller. Both groups present a high prevalence of Vitamin D deficiency, which is linked to a higher volume of parathyroid adenoma. The group with negative scintigraphy showed a higher vitamin D level, which is consistent with the literature.

The complex link between obesity and bone mineral density: exploring the role of body composition

Bárbara Jesus[1], Margarida Sobral[1], Sofia Lopes[1], Leonor Rodrigues[2], Alice Monsanto[1], Tânia Carvalho[1], Gustavo Rodrigues[1], Dírcea Rodrigues[1] & Leonor Gomes[1]

[1]Coimbra Local Health Unit, Endocrinology, Diabetes and Metabolism, Coimbra, Portugal; [2]Aveiro Local Health Unit, Aveiro, Portugal

Introduction.

Traditionally, obesity was thought to be a protective factor against osteoporosis. This assumption has influenced clinical practice, as Body Mass Index (BMI) is incorporated into the Fracture Risk Assessment Tool (FRAX), where a higher BMI is associated with a lower fracture risk. However, recent studies have challenged this perspective, indicating that excess adiposity may be linked to osteopenia and osteoporosis. Other finding suggest that this relationship is more complex and site dependent. This study aims to assess the correlation between bone mineral density (BMD) and body composition parameters.

Methods

Inclusion of obese individuals followed in an Obesity Endocrinology appointment who underwent dual-energy X-ray absorptiometry (DEXA) scans to evaluate BMD at the spine, femur (neck and proximal regions), and forearm. Additionally, body composition was also assessed using DEXA. The relationship between BMD and body composition variables was examined.

Results

A total of 101 patients were included, of whom 81.2% were female and 18.8% were male. The mean age was 44.4 ± 12.1 years (between 18 and 67), with 62.4% being under 50 years. Mean BMI was $41.09 \pm 5.68 kg/m^2$. Mean total BMD was $1.097 \pm 0.11 g/cm^2$. BMD was significantly higher in males ($P < 0.001$) and in individuals younger than 50 years ($P = 0.019$). After adjusting for age and sex, no significant correlation was found between BMI and total BMD ($P = 0.859$), spine BMD ($P = 0.199$) and forearm BMD ($P = 0.131$). A weak positive correlation was observed for femoral neck ($r = 0.220$; $P = 0.031$) and proximal femur ($r = 0.282$; $P = 0.005$). A weak negative correlation was identified between fat mass percentage and total BMD ($r = -0.274$; $P = 0.013$), though no significant correlation was found at other sites. This correlation was stronger in males ($r = -0.581$; $P = 0.032$) compared to females ($r = -0.274$; $P = 0.013$) A weak positive correlation was observed between lean mass and total BMD ($r = 0.215$; $P = 0.032$), as well as at all analyzed skeletal sites. No correlation was found between BMD and visceral tissue adiposity index.

Conclusion

In this study, BMI did not demonstrate a protective effective on overall BMD, with only a weak positive correlation found for femoral neck and proximal femur. Additionally, fat mass percentage showed a weak negative correlation with total BMD, particularly in males. In contrast, lean mass exhibited a weak positive correlation with BMD across all analyzed segments, reinforcing its protective role in bone health. No significant relationship was identified between BMD and visceral tissue adiposity index. These findings highlight the complex interplay between body composition and bone health in obese individuals.

JOINT3970

The diagnostic incidence of normocalcaemic hyperparathyroidism decreases and diagnostic concordance of parathyroid hormone (PTH) assays improves with assay- and age-specific PTH reference intervals

Halimah Khalil[1], Anna Sanders[1], Jonathen Fenn[1], Clare Ford[1], Rousseau Gama[1,2] & Tejas Kalaria[1]

[1]The Royal Wolverhampton NHS Trust, Black Country Pathology Services, Wolverhampton, United Kingdom; [2]University of Wolverhampton, School of Medicine and Clinical Practic, Wolverhampton, United Kingdom

Background

Parathyroid hormone (PTH) assays lack standardization, leading to the interpretation of PTH results using manufacturer-specific reference intervals.

These intervals do not account for inter-assay differences, resulting in discordant diagnoses of normocalcaemic hyperparathyroidism (NCPHPT). PTH levels increase with age independently of vitamin D, renal function, phosphate, and ionized calcium. Variations in age-nonspecific PTH reference intervals may stem from differing age distributions in reference interval studies.
Aim
This study aimed to evaluate the effect of newly derived age-specific reference intervals for Abbott and Roche PTH assays on the diagnosis of NCPHPT, focusing on diagnostic concordance when applying age- and assay-specific intervals to previously identified cases of NCPHPT.
Methods
Age- and assay-specific intact parathyroid hormone (iPTH) reference intervals from recent studies were applied to serum samples from patients previously diagnosed with NCPHPT in a prior diagnostic test assessment. The study included adult outpatients ($\geq$18 years) with NCPHPT, whose serum samples were collected between February and June 2021. Serum samples were analysed using Abbott and Roche second-generation immunoassays. Patients with vitamin D deficiency ($<$50 nmol/l), impaired renal function (eGFR $<$60 mL/min/1. 73 m^2), malignancy, pregnancy, or medications influencing calcium/PTH levels were excluded. Reference intervals from previously published studies for both Roche and Abbott iPTH derived from large population datasets using the refineR algorithm were used to assess diagnostic concordance.
Results
Among the 46 individuals initially diagnosed with NCPHPT based on elevated Abbott PTH levels, only 16 (35%) remained concordant for NCPHPT by Roche method when the results were interpreted using the manufacturer provided method-specific reference intervals. The remaining 30 (65%) had normal PTH levels. However, when method- and age-specific reference intervals were applied, diagnostic concordance improved: 31 individuals (67%) were classified with normal PTH levels by both methods, 8 (17%) remained concordant for NCPHPT, and 7 (15%) were discordant (NCPHPT diagnosed by Abbott but normal PTH by Roche). This indicates that age- and assay-specific reference intervals significantly reduced NCPHPT diagnoses and improved agreement between the assays.
Conclusion
The use of age- and assay-specific reference intervals for PTH assays enhances diagnostic accuracy, reduces unnecessary NCPHPT diagnoses, and improves concordance between different commercially available assays. This approach minimises the risk of misdiagnosis, unnecessary testing, and inappropriate management, particularly for older patients.

Profile of patients initiating abaloparatide treatment

Laura Cánovas Noguera[1], María Del carmen andreo-lopez[1] & Victoria Contreras Bolivar[1]
[1]San Cecilio Clinical University Hospital, endocrinology and nutrition, Granada, Spain

Introduction and Objectives
Abaloparatide is part of the arsenal of osteoforming drugs, marketed in Europe since May 2024 for postmenopausal women at very high risk of fractures. Abaloparatide has been shown to reduce the risk of vertebral and non-vertebral fractures. However, there is scarce evidence in real life about the patient profile receiving this treatment. Therefore, this work aims to evaluate the clinical and analytical profile of the patient who is receiving abaloparatide in our center.
Material and Methods
Descriptive observational study of the profile of patients who started treatment with Abalopratide in the Endocrinology Service of the HUCSC of Granada in 2024. The results were analyzed in the SSPS 25. 0 program. Analytical variables, bone mineral density (BMD) and TBS were measured.
Results
Twenty women with mean age at diagnosis of osteoporosis of 62. 5 years were included. 20 % family history of hip fracture. 65% had a fragility fracture before treatment, 60% of which were vertebral and 10% hip fractures, with a mean number of fractures of 1. 9 +-1. 7 SD. 100% of the sample presented a very high risk of fracture. 55% received previous osteoporotic treatment. The mean T-SCORE value for femoral neck and total spine was -2. 3 and - 2. 6 respectively. The mean TBS level in the spine was 1. 17 and the mean Tscore was -3. The mean BMD value in the total spine was 0. 94 with a mean Tscore of -2. 6. The mean value of Creatinine, Calcium, Vitamin D and Parathormone was 0. 66 mg/dl, 9. 3 mg/dl, 30. 5 ng/mL and 68. 2 pg/mL respectively. The mean value of the remodeling markers C-terminal Telopeptide collagen type I and Procollagen I, N-terminal propeptide was 0. 51 ng/mL and 80. 3 ng/mL.
Conclusion
The patients who started Abaloparatide complied with the indications for treatment since they presented a high risk of fracture with greater involvement of trabecular bone in addition to presenting calcium and parathyroid hormone levels in the normal range.

JOINT3786

Birth outcomes and educational level among patients with post-surgical and non-surgical hypoparathyroidism

Line Underbjerg[1], Tanja Sikjaer[1] & Lars Rejnmark[1]
[1]Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark

Background
Hypoparathyroidism (HypoPT) is most often caused by complications following neck surgery, post-surgical HypoPT, but genetic or autoimmune causes are seen, called non-surgical HypoPT (Ns-HypoPT). Calcium is vital for the mineralization of the fetal skeleton. Studies have shown that inadequate managed maternal HypoPT may cause preterm labor, miscarriage and stillbirth. Patients with HypoPT often complain of impaired cognitive skills, i. e. confusion, brain fog and forgetfulness. Studies have found that HypoPT patients, regardless of etiology, have reduced executive functions, processing speed, visual – and auditory memory. However, the impact on education level are still unknown. We aimed to investigate birth complications and education level in patients with post-surgical HypoPT and Ns-HypoPT compared to controls from the background population.
Material and Methods
We conducted a case-finding study, identifying patients with postsurgical hypoparathyroidism between 1988-2012 and patients with Ns-HypoPT between 1977-2012. Patients with HypoPT were identified through the National Patient Registry on ICD-codes combined with the regional prescription database. Controls were randomly selected from the background population using the Danish Civil Registration System. These were matched by gender and year of birth ($\pm$ 2 years), using the incidence-density sampling technique. From Statistics Denmark registers we received all relevant information including fertility, childbirth and educational status.
Results
688 patients with post-surgical (88% female, median age 49 years, mean follow-up 8. 4 years)) and 180 patients with Ns-HypoPT were identified (53% females, 49. 7 years at time of follow-up, 21% genetically verified), and matched to 2604 controls. No differences in birth outcomes including length, weight, head-, abdominal circumference or placenta weight were seen. We found a trend towards a shorter gestational age among post-surgical patients, $P = 0.07$. Fewer patients with post-surgical HypoPT (80%) and Ns-HypoPT (32%) have completed an education, defined as vocational/short or higher, compared to controls (88% and 43%, respectively), $P < 0.01$. No differences in age when receiving a higher education were seen. Investigations on the level of education show that 50% of patients with NS-HypoPT have primary school as their highest completed education. This is opposite controls, where only 30% have primary school as their highest completed education. Grades in primary school are significantly lower among Ns-HypoPT patients compared to controls, this concerns both written and verbal grades, $P < 0.01$. In conclusion, no differences in birth outcomes were found. However, it seems that patients with HypoPT have a lower educational level compared to controls and grades among patients with Ns-HypoPT are significantly lower than controls.

Bone phenotype in infantile hypercalcemia-1 caused by CYP24a1 pathogenic variant

Anna Dal Lago[1], Laura Pierotti[1], Simone Della Valentina[1], Alessandro Brancatella[1], Chiara Sardella[1], Elena Pardi[1] & Filomena Cetani[1]
[1]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy

Infantile hypercalcemia-1 (HCINF1) is a rare disorder of mineral metabolism caused by homozygous loss-of-function variants of the *CYP24A1* gene which induce an increase of serum 1, 25$(OH)_2$D3 concentration, and consequently hypercalcemia, hypercalciuria, and low-to-undetectable plasma PTH levels. The aim of this study was

to evaluate the bone phenotype in a cohort of patients affected by HCINF1 disease followed at our outpatient clinic. We included 5 patients (1 female and 4 males) carrying homozygous (Group A) and 7 patients (3 females and 4 males) carrying heterozygous *CYP24A1* variants (Group B). In group A, the median age was 26 (IQR: 25-52), while in group B, it was 30 years (IQR 30-60). No patient experienced clinical fragility fractures or morphometric fractures as assessed by DXA. One male patient aged 69 years of the group A and another male patient aged 63 years of the group B exhibited osteoporosis at 1/3 distal radius, with T-score: -3 and -3. 3, respectively. Both patients did not have risk factors for osteoporosis. Two of the 5 patients of group A had osteopenia at femur (both total and neck regions) and 1 patient showed osteopenia at 1/3 distal radius. Conversely, 1 of the 7 patients in group B exhibited osteopenia at lumbar spine. The remaining patients had normal BMD at all sites and normal trabecular bone score values. Regarding bone turnover biomarkers, all values were in the normal range. Specifically, in the group A the value of bone-specific alkaline phosphatase (BAP) was 13 mg/l in the female and the median of BAP was 15 mg/l (IQR: 13-16, 5) in males, while in group B the median was 12 mg/l (IQR: 11, 65-12) in females and 13 mg/l (IQR 11, 25-16, 25) in males. Osteocalcin levels were 20, 45 mg/l (IQR: 19, 13-23, 63) in group A and 11 mg/l (IQR 9, 5-29, 45) in group B. In group A, the value of serum CTX was 0, 36 mg/l in the female and the median value was 0, 464 mg/l (IQR: 0, 344-0, 667) in males while in group B CTX was 0, 186 mg/l (IQR 0, 125-0, 199) in females and the median was 0, 14 mg/l (IQR: 0, 133-0, 234) in males. Our findings seem to suggest that the BMD in homozygous patients with HCINF1 tend to be lower compared to heterozygous patients. Moreover, the levels of BAP, osteocalcin and sCTX are in the half/lower half of the reference range, this could reflect a low bone turnover secondary to low PTH levels, as occurs in hypoparathyroidism.

JOINT2578

Pseudohypoparathyroidism type 1b diagnosed in adulthood: a novel family deletion in the GNAS locus

Margarida Sobral[1], Bárbara Jesus[1], Adriana Duarte[1], Leonor Rodrigues[1], Carolina Moreno[1, 2] & Leonor Gomes[1, 2]
[1]Endocrinology, Diabetes and Metabolism Department - Coimbra's Local Health Unit, Coimbra, Portugal; [2]Faculty of Medicine of the University of Coimbra, Coimbra, Portugal

Introduction
Pseudohypoparathyroidism type 1b (PHP-1b) is characterized by resistance to parathyroid hormone (PTH), primarily in renal tissues, leading to hypocalcemia, hyperphosphatemia, and elevated PTH levels. In some cases, it may also present with resistance to thyroid- stimulating hormone. Features of Albright hereditary osteodystrophy are usually absent. This condition is caused by genetic and epigenetic imprinting defects of the GNAS locus on chromosome 20q13. 32. It is typically sporadic, although familial cases with autosomal dominant inheritance have been reported. We describe a novel deletion in the GNAS-AS1 and GNASXL transcripts, which has not been previously documented in the literature in a family with PHP-1b.
Clinical Case
A 36-year-old male presented with massive calcifications of the basal nuclei and thalami, along with dispersed calcifications in both cerebellar hemispheres, identified on a head CT scan conducted due to his complaints of vertigo and headache. Subsequent testing revealed severe hypocalcemia (5. 6 mg/dL) and elevated PTH levels (260. 8 pg/mL). His medical history included cataract surgery at a young age and complaints of paresthesias since adolescence. He was referred to the Endocrinology department, where pseudohypoparathyroidism was suspected. The patient started calcium and vitamin D supplementation, with correction of the hypocalcemia (Ca2+ 8. 9 mg/dL) and persistent elevated PTH (273 pg/mL). Given the clinical presentation and imaging findings, genetic testing for mutations in the STX16 and GNAS genes was performed, but results were negative. Subsequently, a methylation-specific MLPA test was requested, revealing a heterozygous deletion of the GNAS-AS1 and GNASXL transcripts, as well as a hypomethylation pattern in the DMR A/B region of the GNAS gene, attributed to the deletion of the maternal allele. To this date, this deletion has not been previously documented in the literature or in polymorphism databases. The patient was referred for genetic counselling where his family was evaluated: his sister exhibited the same deletion and clinical manifestations and his mother also have the same deletion, although she has no clinical symptoms and no analytical or imaging abnormalities. The genetic study of his aunt and cousin are pending.
Conclusion
PHP-1b is a rare endocrine disorder with genetic aetiology. While some mutations have been described, the identification of new mutations, such as the one presented in this case, may enhance our understanding of the underlying genetic mechanisms and facilitate future diagnoses.

Objectives
Osteoporosis is a common complication in Duchenne muscular dystrophy (DMD) . Current clinical guidelines focus primarily on paediatric care, with limited guidance for managing osteoporosis during the transition to adulthood and long-term management of osteoporosis therapy initiated in paediatric care.
Methods
In 2023, a UK expert working group was formed with the task of developing national expert consensus on the management of osteoporosis in adults with DMD in the adult NorthStar Network. The working group included 13 adult and 5 paediatric bone specialists, 3 adult neuromuscular clinicians (2 with paediatric experience), a clinician-scientist/densitometrist, and 3 patient representatives. Systematic and scoping reviews of osteoporosis therapies for DMD, glucocorticoid-induced osteoporosis guidelines for adults, and DXA-based fracture predictions in DMD were conducted. A survey was distributed via patient organisations to paediatric clinicians managing DMD-related osteoporosis, with focus on care during transition. Feedback on bone health management was also gathered through a focus group of adults with DMD. Four online meetings of the expert working group were held. Using a modified Delphi approach, consensus clinical recommendations were developed.
Results
Consensus recommendations were established through three Delphi voting rounds, with 80% agreement required. Thirteen clinical guidance statements were developed. Key recommendations include:

- Adults with DMD should undergo osteoporosis and fracture risk assessments, including vertebral fracture (VF) assessment and DXA bone density, if expected to influence clinical decision making.
- VF reassessments are recommended every two years for those on glucocorticoids and should be individualised for those who are not on glucocorticoid treatment and/or, those with metal instrumentation for scoliosis.
- For young people on long-term bisphosphonate therapy (> 10 years) initiated in childhood and who have completed puberty, discontinuation of therapy should be considered at transition, depending on clinical risk factors. The clinical risk factors include glucocorticoid therapy, presence of VF at most recent evaluation, new VF and/or worsening VF during treatment with osteoporosis therapy or recent low trauma long bone fracture.
- Upon discontinuation of osteoporosis therapy, re-evaluation of the need to re-initiate osteoporosis treatment is recommended if low trauma fractures are sustained off treatment or if there is significant bone density decline, or at two years post-discontinuation.

Conclusion
Using a Delphi-based systematic process, this UK expert working group developed national consensus guidance for managing osteoporosis in adults with DMD. These recommendations address critical gaps in care during the

transition from paediatric to adult services, ensuring a comprehensive and individualised approach to bone health management.

JOINT2366

Vitamin d-dependent rickets type 2a in a 1-year-old girl: a rare case of alopecia and hypocalcemic jerking episodes

Praphawee Thanomtham[1] & Jittra Ruktrirong[1]
[1]Division of Endocrinology, Department of Pediatrics, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand

Background
Vitamin D-dependent rickets type 2A (VDDR2A) is a rare autosomal recessive disorder caused by mutations in the vitamin D receptor (VDR) gene, leading to resistance to 1, 25-dihydroxyvitamin D. It results in hypocalcemia, secondary hyperparathyroidism, and severe rickets. Alopecia is a hallmark feature, particularly in cases with mutations in the DNA-binding domain of the VDR gene. We report a case of VDDR2A in a 1-year-old girl presenting with jerking movements and alopecia.
Case Report
A previously healthy 1-year-old girl presented with brief jerking movements involving the trunk and upper extremities, initially occurring once daily and increasing in frequency. There was no history of seizures, consanguinity, or family history of epilepsy. She was born full-term with normal birth weight and had no perinatal complications. Growth parameters were within normal limits, but gross motor development was delayed. Physical examination revealed diffuse alopecia, frontal bossing, and absent teeth. Chvostek's sign was positive, suggesting hypocalcemia. Laboratory investigations showed hypocalcemia, low-normal phosphorus, elevated alkaline phosphatase (1, 677 U/l), and markedly elevated parathyroid hormone (565 ng/l). Her 1, 25-dihydroxyvitamin D level was strikingly high ($>$1, 500 pmol/l). Radiographs revealed classic rickets features. Whole-exome sequencing identified a homozygous c. 238C$>$T (p. Arg80*) mutation in the VDR gene, confirming VDDR2A. She was initially treated with intravenous calcium gluconate for symptomatic hypocalcemia, followed by high-dose oral calcium (up to 285 mg/kg/day) and calcitriol (0. 6 mg/kg/day). Over seven months, her biochemical markers and radiological features significantly improved. By 1 year and 11 months, healing was evident, and treatment was gradually reduced. However, alopecia persisted. Her motor development improved, and her height velocity increased from 2 cm over six months to 6. 2 cm in the following six months.
Discussion
This case highlights the importance of considering VDDR2A in infants with early-onset rickets, hypocalcemia, and alopecia. The key diagnostic clue is high 1, 25-dihydroxyvitamin D despite hypocalcemia and secondary hyperparathyroidism. Mutations in the DNA-binding domain of the VDR gene cause complete receptor dysfunction, resulting in severe disease and alopecia.
Conclusion
Early recognition and genetic confirmation of VDDR2A are crucial for timely intervention. High-dose calcium and calcitriol therapy improve biochemical markers and bone health, but alopecia remains irreversible. Long-term follow-up is necessary to adjust treatment as calcium homeostasis changes with age.

Design of the ACCEL study: a prospective clinical assessment study in children with hypochondroplasia

Ravi Savarirayan[1], Julie Hoover-Fong[2], Andrew Dauber[3], Liza Bakunina[4], Elena Muslimova[4] & Melita Irving[5]
[1]Murdoch Children's Research Institute, Melbourne, Australia; [2]Johns Hopkins University, Baltimore, United States; [3]Children's National Hospital, Washington DC, United States; [4]BridgeBio Pharma, San Francisco, United States; [5]Myriad Trials at the Portland Hospital, London, United Kingdom

Background
Hypochondroplasia (HCH) is a disproportionate short statured skeletal dysplasia caused by gain-of-function pathogenic variants in the fibroblast growth factor receptor 3 gene (FGFR3) that lead to reduced endochondral bone growth. The natural history of HCH is not well characterized and longitudinal growth data for this condition are limited. Management of HCH is currently focused on treating specific complications.
Methods
ACCEL (NCT06410976) is a non-interventional clinical assessment study designed to characterize the natural history of children with HCH aged 2. 5 to $<$ 17 years. The primary objective is to collect baseline height velocity measurements of children who may participate in an interventional study with infigratinib, an oral FGFR1–3 selective tyrosine kinase inhibitor in development for HCH. Secondary objectives are to collect other baseline growth measurements including height z-score and body proportion ratios, assess cognitive functions, evaluate HCH-related medical events and surgical procedures, and assess health-related quality of life. Evaluation of biomarker indicators of growth is an exploratory objective. Key inclusion criteria include diagnosis of HCH documented clinically by the presence of disproportionate short stature and confirmed with a molecular test. Participants will be assessed for a minimum of 6 months and a maximum of 2 years.
Results
The first participant enrolled in June 2024 and recruitment is ongoing in multiple countries.
Conclusion
Prospective data from this study will contribute to the characterization of the natural history of HCH and serve as a baseline for evaluation of infigratinib as a potential treatment option for children with HCH in future interventional studies.

The impact of parathyroid adenoma removal on the quality of life of patients with primary hyperparathyroidism

Sitora Muminova[1], Rustam Uzbekov[2] & Aziza Abdieva[1]
[1]Tashkent Pediatric Medical Institute, Endocrinology, Tashkent, Uzbekistan; [2]Republican Specialized Scientific and Practical Medical Center of Endocrinology named after Ya. Kh. Turakulova, Tashkent, Uzbekistan

Objective
To investigate the effect of surgical treatment (parathyroid adenoma removal) on the quality of life of patients with primary hyperparathyroidism.
Materials and Methods
Forty patients aged 38 to 65 who underwent parathyroid adenoma removal were examined. The patients were divided into three groups: asymptomatic (8 individuals), manifest (24 individuals), and hypercalcemic (8 individuals). The average parathyroid hormone level before surgery was 454. 7 pg/ml. The quality of life was assessed using the Primary hypoparathyroidism quality of life questionnaire (PHPQoL), which provided quantitative data on 16 indicators related to health status and functional limitations.
Results
Six months after surgery, quality of life assessments revealed that, despite the successful reduction in parathyroid hormone levels, most patients reported symptoms, including pain during prolonged walking 29 (72, 5%), and limitation of recreational activities detected in 24 patients, 67, 5 % patients complained to bone and JOINT pain during prolonged walking, Insomnia during the first three months post-surgery noted in 6 patients and difficulty concentrating at work 10 patients out of 40. These findings suggest that despite successful surgical intervention, a significant number of patients experience symptoms that impair their quality of life.
Conclusion
The study demonstrated that while parathyroid adenoma removal significantly reduces parathyroid hormone levels and improves the overall condition of patients with primary hyperparathyroidism, certain symptoms, such as bone and JOINT pain during prolonged walking, persist in the postoperative period. This indicates the need for further optimization of diagnostic and therapeutic approaches to PHPT to improve patients' long-term quality of life. Enhancing postoperative care and early rehabilitation may significantly improve the quality of life for these patients.

Denosumab treatment of two children with inoperable spinal aneurysmal bone cysts

Signe Beck-Nielsen[1], Henrik Hasle[2], Raja Padidela[3] & Amish Chinoy[3]
[1]Centre for Rare Diseases, Aarhus University Hospital, Aarhus, Denmark, Institute of Clinical Medicine, Aarhus University, Aarhus, Denmark,

Paediatrics and Adolescent Medicine, Aarhus University Hospital, Aarhus, Denmark; [2]Aarhus University Hospital, Institute of Clinical Medicine, Aarhus University, Paediatrics and Adolescent Medicine, Aarhus, Denmark; [3]Royal Manchester Children's Hospital, Manchester, United Kingdom

Background
Aneurysmal Bone Cysts (ABC) are rare, benign, osteolytic tumours of bone, characterized by locally aggressive and rapid growth, and treatment experience thus scarce. Despite its benign nature, ABC tends to regrow until end-of-growth and medical treatment is therefore suggested to be continued until final height. We present two childhood cases of inoperable ABC and their medical treatment. **Case 1:**A 6-year-old girl presented with a limp and muscle pain for some months. MRI revealed a large cystic process at the os sacrum, involving S2 and S3, embedding the ischiadic nerve. Biopsy revealed multinucleated giant cells of osteoclast appearance with no signs of malignancy, and by RNA NGS, a CTNNB1-USP6 fusion, confirming ABC. Fluorodeoxyglucose (FDG) PET/CT revealed increased uptake in ABC. Due to considerable risk for nerve damage/instability of the lower spine, surgical removal of ABC was impossible with medical treatment as the only option. Denosumab treatment was initiated, 70 mg/m^2 weekly, the first four weeks, thereafter 4-weekly. Pain disappeared rapidly. MRI after three months revealed ABC regression and some consolidation. **Case 2:**An 11-year-old boy presented with a previous history of lower limb weakness and back pain due to a T5 ABC, which had already required 3 surgeries in one year for recurrent symptoms. As further surgeries were with risk of permanent spinal cord damage, denosumab was initiated, 1mg/kg monthly, alongside zoledronate 0. 05 mg/kg 6-monthly to offset risk of rebound hypercalcaemia. ABC has shrinked with no further significant neurological episodes, and no calcium disturbance.
Discussion
Case 1: Continued treatment plan: denosumab 4-weekly for 6 months. If MRI shows continued ABC regression, and normal metabolic activity on FDG PET/CT, tapering of denosumab initially alternating with zoledronate 0. 025 mg/kg followed by extended dosing intervals is planned. As ABC growth is expected to continue until end-of-growth, medical treatment is suspected to continue at intervals permitting ABC control until end-of-growth. Case 2: As treatment has been ongoing for >2 years (planned to continue until end-of-growth), cautious stretching of dose frequency to 6-weekly has commenced, with ongoing biochemical and MRI monitoring. The dose of zoledronate has been reduced due to increased bone density.
Conclusion
As updated treatment advice describing the use of denosumab in ABC in children are warranted, we would like to invite colleagues treating children with ABC to share their experiences aiming to collaborate on the development of a statement publication on the treatment of ABC in children of different ages.

Bone mineralization in children aged 7-10 years born after assisted reproductive technology with frozen and fresh embryo transfer

Elisabeth Waldemar Grønlund[1], Anna Sophie Lebech Kjaer[1, 2], Louise Laub Asserhøj[1], Ikram Mizrak[1, 3], Tine D Clausen[4], Per Lav Madsen[3, 5], Anja Pinborg[1] & Rikke Jensen[2]
[1]Copenhagen University Hospital - Rigshospitalet, The Fertility Clinic, Department of Gynaecology, Fertility and Obstetrics, Copenhagen, Denmark; [2]Copenhagen University Hospital - Herlev Hospital, Department of Paediatrics and Adolescent Medicine, Copenhagen, Denmark; [3]Copenhagen University Hospital - Herlev Hospital, Department of Cardiology, Copenhagen, Denmark; [4]Copenhagen University Hospital - Rigshospitalet, The Obstetrics Clinic, Department of Gynaecology, Fertility and Obstetrics, Copenhagen, Denmark; [5]University of Copenhagen, The August Krogh Department of Physiology, NEXS, Copenhagen, Denmark

Background
Birth weight (BW) is positively associated with Bone Mineral Content (BMC) and Bone Mineral Density (BMD) later in life. Children conceived after assisted reproductive technology (ART) by frozen embryo transfer (FET) have an increased BW compared to naturally conceived (NC) children, while the opposite association is known for children born after ART by fresh-embryo transfer (fresh-ET). Bone health in children born after ART is scarcely explored and with inconsistent Results
Methods
This study was a retrospective cohort study as part of the 'Health in Childhood following Assisted Reproductive Technology' (HiCART) cohort, consisting of 606 children (292 boys) aged 7-10 years, conceived after FET ($n = 200$), fresh-ET ($n = 203$), and NC ($n = 203$) born from November 2009 to December 2013. The children were identified through Danish Medical Birth Registry and Danish IVF registry. The clinical examination involved anthropometric measurements, pubertal staging, fasting blood samples, and whole-body dual-energy x-ray absorptiometry scan (DXA). The three groups were compared pairwise using univariate linear regression model and possible confounders and mediators were adjusted for using multiple linear regression analysis.
Results
Crude values of BMC corrected for height did not differ between children born after FET, fresh-ET, or NC. When adjusted for relevant confounders children born after FET had a statistically significant higher BMC corrected for height compared with both fresh-ET and NC. After further adjustment for BW standard deviation score (SDS), the differences in BMC corrected for height disappeared, and no statistically significant differences in BMC corrected for height between any of the three groups was found. Factors potentially affecting bone mineralization, such as calcium, parathyroid hormone (PTH), insulin-like growth factor-I (IGF-I), lean mass, and physical activity in childhood did not differ between the three groups.
Conclusion
Increased BW in children conceived after FET was associated with increased BMC corrected for height at age 7-10 years when compared to children conceived after fresh-ET and NC. This difference was primarily mediated by the higher BW found in children conceived after FET compared with fresh-ET and NC. Longitudinal studies of pregnancies and newborns after FET are needed to explore the causes of the increase in BW and the possible effects on long-term bone health.

Machine learning model on opportunistic computed tomography for predicting vertebral fracture risk in women undergoing hormone deprivation therapy for breast cancer

Maria Francesca Birtolo[1, 2], Alberto Piasentier[1, 2], Riccardo Levi[1], Flaminia Carrone[3], Giovanni Savini[1], Massimo Battaglia[4], Lucrezia Gentile[1, 2], Sara Bodini[1, 2], Roberto Colle[1, 2], Alessandro Fanti[1, 2], Andrea Lania[1, 2], Letterio Politi[1, 4] & Gherardo Mazziotti[1, 2]
[1]Humanitas University, Department of Biomedical Sciences, Milan, Italy; [2]IRCCS Humanits Research Hospital, Endocrinology, Diabetology and Medical Andrology Unit, Milan, Italy; [3]Humanitas Mater Domini, Endocrinology Service, Varese, Italy; [4]IRCCS Humanitas Research Hospital, Radiology Department, Milan, Italy

Introduction
Women under hormone-deprivation therapies (HDTs) for breast cancer are at high fracture risk, but currently available fracture prediction tools are imprecise. Emerging evidence suggests that radiomics may contribute to fracture risk assessment in general population, but its application in this context is unknown.
Objective
To identify radiomic features (RFs) on opportunistic computed tomography (CT) associated with vertebral fractures (VFs) in women under HDTs, and to develop a radiomics-based model predictive of VFs.
Methods
Radiomics analyses were performed on CT scans of 109 women (median age 61. 1 years, range 27-85) exposed to HDTs (median 27. 1 months). Lumbar vertebrae were automatically segmented (convolutional neural network) for RFs extraction. Each feature was tested for its ability to predict VFs. Patients were randomly divided into training and test cohorts for the development and validation of the predictive model.
Results
Morphometric VFs were diagnosed in 23 women (21. 1%), in association with older age ($P = 0. 013$), lower total hip T-score ($P = 0. 041$) and higher FRAX score for major fractures ($P = 0. 045$). The machine-learning model based on 20 RFs showed a high ability to predict VFs (ROC 0. 832), outperforming that of T-score and FRAX score, even when lower thresholds than conventional ones were used (ROC 0. 77 and 0. 45, respectively). The RF "information measure of correlation" was the most relevant feature in the model, suggesting that a reduction in texture cross-correlation is positively associated with the development of VFs ($P < 0. 001$).
Conclusion
The radiomics-based machine learning model showed high potential in identifying women at high fracture risk during HDTs.

Nonsurgical hypoparathyroidism: insights from a single-center experience

Laura Pierotti[1], Chiara Sardella[2], Simone Della Valentina[2], Anna Dal Lago[2], Elena Pardi[2], Angela Michelucci[3], Maria Adelaide Caligo[1], Claudio Marcocci[2] & Filomena Cetani[2]
[1]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]University of Pisa, Unit of Endocrinology, Pisa, Italy; [3]University of Pisa, Laboratory of Molecular Genetics, Pisa, Italy

Hypoparathyroidism (HypoPT) is a rare endocrine disorder characterized by hypocalcemia and absent, low, or inappropriately normal PTH levels. The most common cause is neck surgery (75%), while nonsurgical forms, including idiopathic and genetically determined HypoPT, account for the remaining 25%. These forms are rarer and less well understood. This retrospective study investigates the clinical and biochemical characteristics, as well as complications, in 26 patients with idiopathic or genetically determined HypoPT followed at our Endocrinology Unit. We included 26 patients (15 women, 11 men) with a mean age at diagnosis of 22 ± 14 years (5–59) and a mean disease duration of 10. 8 ± 11 years (1–48). Genetic screening identified pathogenic variants in seven patients: five deletions of 22q11. 2 (DiGeorge syndrome), one GATA variant associated with hypoparathyroidism, sensorineural deafness, and renal dysplasia (HDR) syndrome, and one *AIRE* variant (APS type 1). Two variants of uncertain significance in *GCM2* and *AIRE* genes and one benign *GNAS* variant was identified. The remaining patients had no detectable mutations. The mean daily calcium and calcitriol supplementation was 1200 mg (0–3000) and 0. 9 μg/day (0. 5–1. 5), respectively. Despite treatment, 10 patients (38. 5%) experienced hypocalcemic symptoms. Baseline biochemical tests showed mean albumin-corrected serum calcium of 9. 04 ± 0. 6 mg/dL (7. 5–11. 3), phosphorus 3. 5 ± 0. 58 mg/dL (2. 2–6. 2), ionized calcium 1. 19 ± 0. 08 mmol/l (0. 93–1. 53), and magnesium 1. 9 ± 0. 14 mg/dL (1. 4–2. 5). Mean urinary calcium excretion was 255 mg/day (156–387). Corrected calcium, phosphorus, and magnesium levels were within target in 62%, 65%, and 53% of patients, respectively. Complications included basal ganglia calcifications (46. 2%), audiometric abnormalities (34. 6%), cardiac alterations (7. 7%), and recurrent infections (15. 4%). Renal involvement was observed in 46% of patients, with eight cases of nephrolithiasis and four of renal insufficiency. Reduced bone mass was documented in only one patient, and one vertebral fracture was reported. Bone evaluation showed a mean lumbar spine BMD of 1. 176 g/cm^2 (T-score 1. 2, Z-score 1. 2); a mean femoral neck's BMD of 1. 003 g/cm^2 (T-score 0. 5, Z-score 0. 7); a mean total hip's BMD of 1. 059 g/cm^2 (T-score 0. 5, Z-score 0. 7) and a mean one-third radius' BMD of 0. 705 g/cm^2 (T-score -0. 7, Z-score -0. 3). These findings highlight the heterogeneity of disease and its complications in patients with non-surgical HypoPT. Furthermore, many patients fail to achieve optimal biochemical targets despite treatment. This underlines the need for further studies to better understand this condition and develop improved therapeutic strategies to optimize patient outcomes.

JOINT3020

Association of size at birth and bone mineral density in adolescents

Indre Petraitiene[1], Kastytis Smigelskas[1, 2] & Rasa Verkauskiene[1]
[1]Lithuanian University of Health Sciences, Medical Academy, Institute of Endocrinology, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Faculty of Public Health, Health Research Institute, Kaunas, Lithuania

Introduction
Persons born small for gestational age (SGA) are more prone to various adverse growth and metabolic outcomes later in life. Previous studies showed worse body composition in adults born SGA compared to those born appropriate for gestational age (AGA). The data on bone mineral density (BMD) in subjects born SGA are inconsistent. We aimed to analyze BMD in adolescents born SGA in relation to body composition and size at birth.
Methods
We investigated 107 children from prospective cohort followed from birth (43 SGA and 64 AGA). Birth weight and/or length in SGA individuals were below 2 standard deviations (SD) of the mean according to sex and gestational age and in AGA - between -2 and + 2 SD score (SDS). Children were born at 32-42 weeks of gestation. The anthropometric data were obtained at birth, 5, 12, 24 months and 11-13 years of age. DXA scan and laboratory parameters were assessed in adolescence.
Results
Adolescents born SGA were shorter and leaner than AGA (height SDS: -0. 52 ± 1. 31 vs. 0. 36 ± 1. 01, $P < 0.001$; weight SDS: -0. 49 ± 1. 69 vs. 0. 59 ± 1. 57; $P = 0.010$; BMI SDS: -0. 20 ± 1. 30 vs. 0. 31 ± 1. 25, $P = 0.048$). There were no differences in waist to height ratio, lean and fat mass percent in adolescents born SGA vs. AGA. There were no difference in ionized calcium, phosphate, PTH and vitamin D levels in SGA and AGA adolescents. Additionally, there were no differences in IGF-1 and IGF-BP-3 levels ($P = 0.119$ and $P = 0.128$, respectively). IGF-1/IGF-BP-3 ratio was lower in adolescent born SGA (0. 11 ± 0. 07 vs. 0. 15 ± 0. 12, $P = 0.027$). There was no difference in BMD (g/cm2) and apparent BMD (BMAD, g/cm3) between the groups. BMD Z-score was lower in adolescents born SGA compared to AGA (-0. 22 ± 1. 10 vs. 0. 21 ± 0. 83, $P = 0.035$). BMD Z-score in adolescence was directly related to gestational age and birth weight, weight SDS and length ($P = 0.024$, $P = 0.011$, $P = 0.022$ and $P = 0.011$, respectively). Analyzing SGA and AGA data separately, significant relations remained only in the SGA group. BMD Z-score in adolescence correlated with height and weight gain during first 2 years of life, but in separated analysis, relations remained only in AGA group.
Conclusion
Adolescents born SGA were leaner and had lower BMD Z-score. In SGA subjects, birth size is more important for further bone mineral accrual than early postnatal growth. Ethics: The study was approved by Lithuanian University of Health Sciences Kaunas regional biomedical research ethics committee (Nr. BE-2-42, 2011. 06. 14). Informed written consent was obtained from all parents prior to the study.

Hypertension in primary hyperparathyroidism: predictive factors and post-parathyroidectomy outcomes

Mariana de Griné Severino[1], Carolina Peixe[1, 2], Catarina Isabel Lopes[1], José Vicente Rocha[1, 2], Mariana Lopes-Pinto[1], Marta Vaz Lopes[1], Miguel António Duarte[1], Ana Gomes[1, 2], Maria Inês Alexandre[1, 2] & Ema Paula Ricca Lacerda Nobre M Caetano[1, 2]
[1]Endocrinology Department, Hospital de Santa Maria, ULS Santa Maria, Lisbon, Portugal; [2]Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal

Introduction
Hypertension is common among primary hyperparathyroidism (PHPT) patients and may contribute to increased cardiovascular morbidity. The impact of parathyroidectomy on blood pressure and cardiovascular outcomes remains unclear and is not typically considered when evaluating a patient for surgery.
Objectives
This study aims to identify predictors of hypertension in PHPT and to assess the impact of parathyroidectomy on blood pressure regulation.
Methods
This observational, retrospective study included 178 PHPT patients at a tertiary center. Logistic regression, adjusted for age, was used to analyze the association between clinical and biochemical variables and hypertension risk.
Results
Our population (84. 8% women, mean age 63 years) showed a hypertension prevalence of 60. 1% ($n = 107$), with hypertensive patients being significantly older (mean age 67 vs. 57 years, $P < 0.001$). After adjusting for age, no significant associations were found between hypertension and calcium, phosphate, PTH, vitamin D, or magnesium levels. Neither chronic renal disease nor disease duration increased hypertension risk. Among hypertensive patients, 60. 7% ($n = 65$) underwent parathyroidectomy, achieving a PHPT remission rate of 81. 5% ($n = 53$). At 6 months post-surgery, 7, 5% of patients ($n = 4$) experienced hypertension remission, and antihypertensive medication usage decreased from 1. 79 to 1. 62 drugs on average ($P = 0.031$).
Conclusion
Hypertension is prevalent in PHPT patients, regardless of laboratory values, renal disease, or disease duration. Parathyroidectomy appears to modestly reduce hypertension prevalence and antihypertensive medication use, suggesting long-term cardiovascular benefits.

30 Years later: cracking the mystery of x-linked hypophosphatemic rickets

Esra Eraslan Aydemir[1], Şerife Özkarakoç Ertürk[2], Can Berk Leblebici[3], Halil Gürhan Karabulut[3] & Özgür Demir[4]
[1]Ankara University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Türkiye; [2]Ankara University Faculty of Medicine, Internal Medicine, Ankara, Türkiye; [3]Ankara University Faculty of Medicine, Medical Genetics, Ankara, Türkiye; [1]Ankara University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Türkiye

Introduction
X-linked hypophosphatemic rickets (XLH; OMIM 307800) results from renal phosphate wasting, impaired intestinal calcium and phosphate absorption, and abnormal vitamin D metabolism due to elevated fibroblast growth factor 23 (FGF23). Patients present with early-onset rickets, skeletal deformities, short stature, bone pain, craniosynostosis, and dental anomalies. XLH is the most common inherited rickets form, with a prevalence of 1 in 20, 000 to 60, 000 individuals. It is caused by dominant inactivating variants in the PHEX gene on XP22. 11. This report discusses two siblings initially diagnosed with achondroplasia but later confirmed to have XLH.
Patients
I. B., a 60-year-old female, had a history of achondroplasia and osteoporosis but had not sought medical care for years. She presented with widespread leg pain and walked with two crutches. Her height was 110 cm, weight 33 kg, and she exhibited genu varum deformity. She had multiple past fractures but was not on regular medication. N. B., a 52-year-old female, had achondroplasia, osteoporosis, bilateral hearing loss, and primary hyperparathyroidism (surgically treated 24 years ago). She sought evaluation due to body pain and walked with one crutch. Her height was 115 cm, weight 35 kg, and she also exhibited genu varum. She had a history of leg fractures and was not taking medication. Family history revealed their father's height was 110 cm, their mother's 140 cm, with no consanguinity. The family had six children (three females, three males); all females had short stature, while males were at least 160 cm tall. Both sisters were misdiagnosed with achondroplasia 30 years ago without genetic testing. Recent genetic analysis identified a heterozygous c. 207_212del (p. K69_V70del) variant in *PHEX* (NM_000444. 6), classified as a 'Variant of Uncertain Significance' (VUS) per American College of Medical Genetics (ACMG)guidelines. Genetic counseling and segregation analysis were recommended.
Conclusion
These cases highlight diagnostic challenges in distinguishing XLH from achondroplasia, stressing the importance of genetic evaluation for accurate diagnosis. Misdiagnosis can delay appropriate management, underscoring the need for increased awareness and thorough genetic assessments in such cases.

Table 1:

	Patient 1	Patient 2
Serum phosphate (2. 5-4. 5 mg/dl)	1. 76	1. 8
Serum calcium (8. 6-10. 2 mg/dl)	9. 4	9
Serum ALP (35-105 U/l)	73	95
Serum 25 (OH)D (20-120 μg/l)	21. 7	14
Serum PTH (15-65 pg/ml)	81	65
Serum creatinine (0. 5-0. 9 mg/dl)	0. 53	0. 5
TRP (%) %85-95		78. 2

Pediatric parathyroid adenomas: a single tertiary care center experience

Hasan Bora Ulukapi[1], Keziban Aslı Bala[1], Melikşah Keskın[1], Erdal Kurnaz[1], Yasemin Dere Günal[2], Çiğdem Üner[3], Nazlı Altun Yoloğlu[4], Tuğba Taşkın Türkmenoğlu[5] & Şenay Savaş Erdeve[1]
[1]Ankara Etlik City Hospital, Pediatric Endocrinology Clinic, Ankara, Türkiye; [2]Ankara Etlik City Hospital, Pediatric surgery clinic, Ankara, Türkiye; [3]Ankara Etlik City Hospital, Pediatric radiology clinic, Ankara, Türkiye; [4]Ankara Etlik City Hospital, Nuclear medicine, Ankara, Türkiye; [5]Ankara Etlik City Hospital, Pathology clinic, Ankara, Türkiye

Introduction
Parathyroid adenoma is a rare cause of primary hyperparathyroidism in children, with a prevalence of 2–5 per 100, 000. Pediatric cases have been reported to often present with more severe manifestations and higher rates of end-organ involvement, though symptoms may be nonspecific and lead to delayed diagnosis. This study evaluates the clinical characteristics, management, and outcomes of pediatric parathyroid adenoma at our center.
Methods
We retrospectively analyzed pediatric patients diagnosed with parathyroid adenoma at our hospital between 2022 and 2024. Patient records were reviewed for clinical presentation, laboratory findings, imaging studies, biochemical evaluations for MEN syndromes, perioperative management, and pathological assessments.
Results
Nine patients (4 females, 5 males; mean age 13. 80 $\pm$ 1. 69 years) were included. At diagnosis, the mean serum calcium was 12. 53 $\pm$ 0. 97 mg/dL and the mean PTH level was 203. 58 $\pm$ 127. 11 ng/l. Surgery was performed 19. 44 $\pm$ 14. 84 days after diagnosis, with an average follow-up of 8. 56 $\pm$ 7. 18 months. Preoperative imaging included parathyroid ultrasound (100%), sestamibi scintigraphy (88. 89%), and urinary ultrasound (88. 89%), with the left superior gland most commonly affected (44. 44%). Only one patient required a PTH washout study. Biochemical screening for MEN syndromes was performed in 66. 67% of patients, and genetic testing for MEN1, RET, and CDKN1B, performed in three patients, was negative. Notably, no patients had a family history of parathyroid adenoma or nephrocalcinosis. Clinically, 55. 56% of patients were asymptomatic with incidentally detected hypercalcemia, while 44. 44% presented with symptoms such as abdominal pain, gastrointestinal disturbances, and facial acne. Postoperative calcium levels normalized within 2. 33 $\pm$ 1. 41 days. No significant difference in preoperative calcium levels was found between symptomatic and asymptomatic groups ($P = 0.240$). All pathology was benign. Perioperative management included intravenous hydration (88. 89%), furosemide (88. 89%), pamidronate (22. 22%), calcitriol (44. 44%), and calcium supplementation (55. 56%), with two patients remaining on calcitriol therapy at 15-month follow-up.
Conclusion
Our findings underscore the sporadic nature of pediatric parathyroid adenoma, with no familial cases or nephrocalcinosis observed. Despite benign pathology, the variability in clinical presentation demands high diagnostic vigilance. Early surgical intervention resulted in rapid normalization of calcium levels, though prolonged calcitriol therapy in some patients suggests ongoing endocrine monitoring is essential. Further studies with larger cohorts and extended follow-up are warranted to refine management strategies for this uncommon pediatric condition.

Patient-reported outcomes and quality of life in children and adults with hpp treated with asfotase alfa

Kathryn M. Dahir[1], Lothar Seefried[2], Gabriel Ángel Martos-Moreno[3], Wolfgang Högler[4], Priya Kishnani[5], Cheryl Rockman-Greenberg[6], Keiichi Ozono[7], Peter R. Ebeling[8], Anna Petryk[9], Shona Fang[9] & Agnès Linglart[10]
[1]Vanderbilt University Medical Center, Nashville, United States; [2]University of Würzburg, Würzburg, Germany; [3]Hospital Infantil Universitario Niño Jesús, Madrid, Spain; [4]Johannes Kepler University Linz, Linz, Austria; [5]Duke University Medical Center, Durham, United States; [6]University of Manitoba, Manitoba, Canada; [7]Osaka University, Osaka, Japan; [8]Monash University, School of Clinical Sciences, Clayton, VIC, Australia; [9]Alexion, AstraZeneca Rare Disease, Boston, United States; [10]Paris-Saclay University, AP-HP and INSERM, Paris, France

Introduction
Hypophosphatasia (HPP) is a rare disease caused by deficient tissue-nonspecific alkaline phosphatase activity. The objective of this analysis was to assess the effectiveness of asfotase alfa enzyme replacement therapy on patient-reported outcomes and quality of life (QoL) in patients with HPP.
Methods
Patients in the Global HPP Registry (data cutoff: July 2024) who received asfotase alfa treatment for $\geq$6 months after age 2 years were included. Pediatric Quality of Life Inventory (PedsQL) was administered to children (2-18 years). Brief Pain Inventory-Short Form (BPI-SF) and Short Form-36 version 2 Health Survey (SF-36v2) were administered to adults ($\geq$18 years). Data from patients with baseline and $\geq$1 follow-up assessments within 2 years were analyzed. Significance of changes was assessed by 95% confidence intervals (calculated assuming normal distribution, $\alpha = 0.05$).
Results
The study included 136 children and 202 adults. The most common baseline manifestations were dental manifestations among children (61%) and pain among

adults (76%). Muscular manifestations were common (children: 49%; adults: 38%). Pain and/or QoL (PedsQoL/SF-36v2) data were available for 26 children and 63 adults, among whom mean scores improved significantly following treatment (**Table**). No mean scores worsened over time. Injection site reactions were the most common event of interest.

Conclusions

Pain in adults and QoL in children with HPP significantly improved following asfotase alfa treatment.

Hospitalizations in people with rare bone diseases across age groups: a population-based cohort study in switzerland

Pascal Gaechter[1, 2], Fahim Ebrahimi[3, 4], Christian Meier[5], Emanuel Christ[5], Alexander Kutz[6, 7] & Gabor Szinnai[1, 2]

[1]University Children's Hospital Basel, Pediatric Endocrinology and Diabetology, Basel, Switzerland; [2]University Hospital Basel, Department of Clinical Research, Basel, Switzerland; [3]Clarunis, Department of Gastroenterology & Hepatology, University Digestive Health Care Center, Basel, Switzerland; [4]Karolinska Institute, Medical Epidemiology and Biostatistics, Stockholm, Sweden; [5]University Hospital Basel, Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [6]Kantonsspital Aarau, Division of General Internal and Emergency Medicine, University Department of Medicine, Aarau, Switzerland; [7]Brigham and Women's Hospital and Harvard Medical School, Division of Pharmacoepidemiology and Pharmacoeconomics, Department of Medicine, Boston, MA, United States

Introduction

Rare bone diseases pose challenges for both affected people and healthcare systems, necessitating optimized multidisciplinary and individualized care. However, comprehensive data on age-specific hospitalization rates, associated clinical conditions, causes of hospitalization, and in-hospital outcomes across different age groups remain limited.

Design and Methods

This is a population-based nationwide cohort study using administrative claims data from Switzerland between January 1, 2012, and December 31, 2021. We identified individuals across all ages with a diagnosis of a rare bone disease: Achondroplasia, fibrous dysplasia (FD), fibrodysplasia ossificans progressiva (FOP), osteogenesis imperfecta (OI), pseudohypoparathyroidism, and X-linked familial hypophosphatemia (XLH). Incidence rates, main causes of hospitalization, and in-hospital outcomes were assessed and compared with those of the general population.

Results

Among 11, 103, 800 hospitalizations, 2, 878 involved individuals with at least one rare bone disease: 218 hospitalizations of people with achondroplasia, 436 with FD, 62 with FOD, 926 with OI, 87 with pseudohypoparathyroidism, 1, 148 with XLH, and one individual with both FD and pseudohypoparathoyroidism. Hospitalizations were disproportionately high in pediatric patients (ages 0-17 years) with achondroplasia (52. 1% vs. 7. 3% in the general population) and OI (41. 1% vs. 7. 3%). In contrast, most hospitalizations of people with XLH occured in adulthood (18-90 years), similar to the general population (95. 2% vs. 92. 7%). Locally estimated scatterplot smoothing (LOESS) plots highlight distinct hospitalization patterns across rare bone diseases, with fractures being a significantly more common cause, particularly in pediatric OI cases.

Conclusions

This study shows distinct age-specific hospitalization patterns across rare bone diseases, emphasizing the need for tailored management strategies. The findings highlight the importance of an age-inclusive approach to optimize care in this population.

Clinical features of pediatric hypophosphatasia and eight-year outcomes of enzyme replacement therapy in korea

Minhye Choi[1], Insung Kim[1], Minji Im[1], Juyoung Sung[1], Yunji An[1], Dong Hyun Lee[2], Yong Hee Hong[3], Chong Kun Cheon[4] & Sung Yoon Cho[1]

[1]Department of Pediatrics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea; [2]Department of Pediatrics, Dongsan Medical Center, Keimyung University School of Medicine, Daegu, South Korea; [3]Department of Pediatrics, Soonchunhyang University Bucheon Hospital, Soonchunhyang University College of Medicine, Bucheon, South Korea; [4]Department of Pediatrics, Pusan National University Children's Hospital, Yangsan, South Korea

Introduction

Hypophosphatasia (HPP) is a rare genetic disorder caused by loss-of-function mutations in ALPL, which encodes tissue-nonspecific alkaline phosphatase (ALP). HPP is classified into six forms according to the onset and severity of manifestations: perinatal lethal, perinatal benign, infantile, childhood, adult, and odontohypophosphatasia. Perinatal and infantile forms have high mortality, making early diagnosis and intervention critical. Enzyme replacement therapy (ERT) with human recombinant tissue-nonspecific ALP (asfotase alfa) became available in Korea since 2016. This study describes the clinical characteristics of Korean HPP patients and presents an 8-year ERT experience in two patients with perinatal lethal and infantile HPP, highlighting their clinical course and long-term outcomes.

Patients and Methods

HPP was suspected in patients with markedly low ALP levels, and the diagnosis was confirmed by mutations in ALPL. We collected information on patients' demographics, laboratory findings, radiographic features, genetic variants, and clinical courses. Among HPP patients (one perinatal lethal, one perinatal benign, one infantile, two childhood, one odontohypophosphatasia, and two siblings presumed to develop into adult HPP based on family history), six were followed without ERT due to the absence of severe skeletal deformities, motor dysfunction, or pain. Two patients with infantile and perinatal lethal HPP received ERT. Both patients received asfotase alfa (2 mg/kg 3 times per week subcutaneously, adjusted to 3 mg/kg 3 times per week if required) for 8 years.

Outcomes

Radiographic improvements were observed: in the infantile HPP patient, the Rickets Severity Scale (RSS) score decreased from 10 to 7, and the Radiographic Global Impression of Change (RGI-C) score was +2. 3; in the perinatal lethal HPP patient, the RSS improved from 8 to 0, with an RGI-C score of +3. 0. Growth also improved: height standard deviation score (SDS) increased from -6. 37 to -5. 08 (infantile) and from -3. 00 to -1. 84 (perinatal lethal). The perinatal lethal patient had no radiographic signs of rickets after 3 years of ERT. Mechanical ventilation and supplemental oxygen were discontinued after 4. 5 years (infantile) and 2 months (perinatal lethal). Despite a more severe initial condition, the perinatal lethal patient showed greater improvement, emphasizing the importance of early treatment.

Conclusion

HPP should be considered when serum ALP is consistently low. Early diagnosis is important to ensure appropriate monitoring of patients with HPP. In particular, patients with perinatal lethal and infantile HPP should receive prompt treatment to avoid premature mortality and improve long-term prognosis.

Persistent hypercalcaemia in trisomy 21: consider ABCD syndrome

Elisabeth Laurer[1], Alexandra Blaschitz[1], Marlene Wimleitner[1], Thomas Hörtenhuber[1], Wolfgang Högler[1], Rodrigo Montero-Lopez[1] & Julian Schirl[1]
[1]Johannes Kepler University Linz, Centre for Growth and Osteology, Department of Paediatrics and Adolescent Medicine, Linz, Austria

Background
The ABCD syndrome (ABnormal Calcium, Calcinosis, and Creatinine in Down syndrome) is a rare cause of persistent hypercalcemia in children with trisomy 21, which typically occurs in the first 2 years of life. To date, 12 patients have been reported. Here we present a new case and review the literature of this under-reported clinical entity. **Case**: A 21-month-old toddler with trisomy 21 presented with a 6-month history of recurrent vomiting, failure to thrive, and bilateral nephrocalcinosis grade IIb of unknown origin. Laboratory results revealed hypercalcaemia (3. 37 mmol/l), hypermagnaesemia (1. 16 mmol/l), normophosphataemia and impaired renal function (creatinine 0. 80 mg/dl, (normal range 0. 19-0. 39 mg/dl)). Further tests showed undetectable serum PTH, low 1, 25(OH) 2D, elevated urinary calcium/creatinine ratio (3. 6 mmol/mmol). Vitamin A and 25-hydroxyvitamin D (74. 3 ng/mL) were both outside toxic ranges. The patient had received only routine vitamin D supplementation, with no other medication or supplements and no special diet, without excess of milk products. Adrenal insufficiency and malignancy were excluded. Trio whole exome sequencing identified no pathogenic variants linked to hypercalcemia. Since intravenous fluids failed to normalize calcium levels, a single dose of pamidronate (1mg/kg) was administered and low-calcium diet commenced. Serum calcium levels and renal function subsequently normalized before discharge. Follow-up examinations at two and four weeks confirmed sustained normal values for calcium, phosphate, PTH and calcium excretion, under continued dietary calcium restriction.
Discussion/Conclusion
Most reported cases of ABCD syndrome had similar biochemical profiles of calcium overload of PTH-independent cause, such as hypercalcaemia, hypercalciuria, nephrocalcinosis and acute kidney injury. The rapid improvement of hypercalcaemia following calcium intake reduction suggests increased intestinal calcium absorption as a potential mechanism. The diagnostic approach requires exclusion of other causes of hypercalcemia. Our case and literature review highlight the importance of raising awareness about ABCD syndrome to ensure timely diagnosis and intervention. Early recognition can help reduce the risk of complications such as kidney injury and prolonged failure to thrive.

	Admission	*Follow-up (2 weeks)*	*Follow-up (4 weeks)*

JOINT2645

Genotype-phenotype correlations and therapeutic outcomes in osteogenesis imperfecta type vi: an 11. 5-year cohort study of 36 chinese pediatric patients

Ting Chen[1] & Xinlin Wu[1]
[1]Children's Hospital of Soochow University, Suzhou, China

Background
Osteogenesis imperfecta type VI (OI-VI), caused by biallelic *SERPINF1* mutations disrupting pigment epithelium-derived factor (PEDF) production, is a rare autosomal recessive skeletal disorder. Despite its distinct clinical profile, long-term therapeutic outcomes and genotype-phenotype relationships remain poorly characterized.
Methods
This retrospective cohort study analyzed 36 pediatric OI-VI patients from 33 families (median follow-up: 11. 5 years). Genetic testing identified *SERPINF1* variants, while clinical evaluations included bone mineral density (DXA), spinal radiographs, biochemical profiling (PEDF, β-CTX, P1NP, calcium, phosphate, 25-OH-VD), and treatment responses to bisphosphonates or denosumab with calcium/vitamin D supplementation.
Results
Thirty-eight *SERPINF1* variants (25 copy-number variations, 13 single-nucleotide variants) were identified, with recurrent pathogenic mutations c. 907C>T (p. Arg303Ter), c. 271_279dup (p. Ala91_Ser93dup), and c. 79G>T (p. Glu27Ter). Key clinical features included severe growth impairment (mean height Z-score: −2. 9), early-onset fractures (mean age: 1. 37 years), dentinogenesis imperfecta (82. 3%), blue sclerae (71. 4%), and vertebral compression fractures (51. 7%). Serum PEDF levels were universally deficient (mean: 0. 0017 μg/mL). All patients required surgical interventions (mean: 3. 79 procedures) combined with pharmacotherapy: 18 received bisphosphonates, and 18 switched to denosumab (11 after bisphosphonates). Hypercalcemia occurred in 5 denosumab-treated patients (mean onset age: 3. 6 years) . Fracture frequency decreased post-treatment, though detailed analyses of spinal deformity progression and biomarker trends are ongoing.
Conclusions
This study delineates the genotypic spectrum and phenotypic severity of OI-VI, emphasizing early fracture onset and multisystem involvement. While bisphosphonates and denosumab reduce fracture burden, denosumab-associated hypercalcemia in young children warrants cautious monitoring. Longitudinal data on spinal remodeling and bone turnover dynamics will further clarify therapeutic efficacy, guiding optimized management strategies for this ultrarare OI subtype.

Prediction of adult height is important in treatment decisions of children with short stature. However, an important contributing factor is the variable range of puberty start and duration. To calculate the residual growth during adolescence, age at onset of puberty is a valuable indicator. Holmgren *et al*. described a remaining growth potential after onset of puberty of 28. 8–29. 2 cm in healthy boys ($n = 1174$) and 26. 2 to 26. 6 cm in healthy girls ($n = 1165$) (Gothenborg study, 2022). In comparison, del Pino *et al*.

reported a mean residual growth of 17. 8 cm and 19. 7 cm, respectively in 17 girls and 10 boys, respectively with untreated achondroplasia (ACH) (JPEM, 2020). In achondroplasia (ACH), correction of lower limb axis deviation – in particular varus malalignment – is performed by a variety of methods. To avoid major surgical procedures, growth modulation using temporary hemiepiphysiodesis can be employed in children with sufficient residual leg growth. Precise timing of this procedure before onset of the pubertal growth spurt is crucial to achieve sufficient correction of the deformity. Vosoritide is a new growth promoting drug for ACH, approved in 2021, enabling higher growth rate with to date no waning of treatment response. To analyze the effect of late start of vosoritide treatment on residual growth potential we analyzed 297 children with ACH (139 girls) with proven FGFR3 mutation. Onset of puberty was defined as follows: testicle volume > = 4ml, pubic stage = P2, breast stage = B2, bone age in female 11–12 or male 13–14 years (y), which was documented in 60 children (26 girls). Vosoritide treatment had been started at puberty onset in 38 out of 225 treated patients who were suitable for analysis. Puberty started in untreated girls at age 11. 0 y with mean height-SDS of -5. 1 SDS (i. e. 110. 8 cm; SD 7. 2 cm) and in untreated boys at age 12. 8 y with a mean height-SDS of -4. 6 SDS (i. e. 118. 9 cm; SD 7. 5 cm). So far, only 1st year treatment data from 16 pubertal children (5 girls) with ACH were documented. In vosoritide treated children compared to untreated ACH children a constant higher growth rate after onset of puberty of 5. 8 cm/y (SD 0. 7) vs. 4. 2 cm/y (SD 1. 1) in females and 5. 5 cm/y (SD 1. 1) vs. 4. 7 cm/y (SD 1. 1) in males was identified. In conclusion, after onset of puberty vosoritide induced an accelerated growth rate, which may be of potential benefit for effective growth modulation to correct angular deformities.

Diabetes mellitus marginally impairs bone quality with chronic kidney disease

Sofie Dragoun Kolibova[1], Syazrah Salam[2], Lilian Gabel[1], Orla Gallagher[2], Richard Eastell[2], Björn Busse[1, 3] & Katharina Jähn-Rickert[1, 4]
[1]University Medical Center Hamburg-Eppendorf, Department of Osteology and Biomechanics, Hamburg, Germany; [2]University of Sheffield, Division of Clinical Medicine and Mellanby Centre for Musculoskeletal Research, School of Medicine and Population Health, Sheffield, United Kingdom; [3]University Medical Center Hamburg-Eppendorf, Interdisciplinary Competence Center for Interface Research, Hamburg, Germany; [4]University Medical Center Hamburg-Eppendorf, Mildred Scheel Cancer Career Center Hamburg, University Cancer Center Hamburg, Hamburg, Germany

Lately, various bone quality changes inflicted by diabetes mellitus (DM) have been linked to the elevated fracture risk with both type 1 and type 2 DM. Fracture risk is also elevated in patients with advanced chronic kidney disease (CKD), with DM being a key factor in CKD prevalence and CKD patients having an increased risk to develop DM. To decipher the contribution of bone quality parameters contributing to bone fragility, we assessed if diabetes mellitus has differential effects on bone quality in advanced CKD patients. Therefore, CKD stage 4-5D patients with (n = 11, age 58 ± 15 yrs, 10♂, 1♀) and without DM (n = 22, age 59 ± 12 yrs, 16♂, 6♀) were recruited. Double-label tetracyclines were used prior to trans-iliac bone biopsy. Quantitative bone histomorphometry was performed to determine bone turnover, mineralization, and bone structure. Bone quality was evaluated using quantitative backscattered electron imaging (qBEI) to assess bone mineral density distribution and 2D morphological analysis of the osteocyte lacunae. The osteocyte-lacunae network was visualized and quantified with Ploton silver precipitation on LR white resin sections. Additionally, bone matrix composition was analyzed using vibrational Raman spectroscopy to determine the mineral-to-matrix ratio (MMR) with a 50x objective at a laser wavelength of 785 nm. We determined that, trabecular bone volume/tissue volume (BV/TV) was lower in CKD + DM group (17. 5 (13. 9 – 19. 4) % vs. 21. 6 (18. 7 – 26. 1) %, P = 0. 02), with no differences in bone formation (BFR/BS) and bone resorption (Oc. S/BS) parameters on bone histomorphometry between the groups. Bone mineral density distribution as determined by qBEI, presented locally with lower mineral content and the presence of micropetrosis – mineralization of osteocyte lacunae. Raman spectroscopy identified a higher phosphate/amide III peak in the cortical bone in CKD + DM (1. 42 ± 0. 15 vs 1. 32 ± 0. 11 a. u., P = 0. 04), which indicates altered bone matrix composition. The results of our ongoing study point towards minor differences in bone quality between individuals with CKD with or without DM, whereby biopsies from CKD patients with DM had lower trabecular bone volume and slightly altered matrix composition. If and how these changes contribute to bone fragility will have to be explored in future studies.

Biochemical response kinetics in vitamin d resistant rickets (VDDR) type 1 and 2: 13-year retrospective analysis from a tertiary care centre

Archana K[1], Preeti Dabadghao[1], Vijayalakshmi Bhatia[1] & Archana Kumari[1]
[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Endocrinology, Lucknow, India

Background
Vitamin D-resistant rickets (VDDR) type 1 and 2 are rare genetic forms of rickets. A few genetically proven cases have been reported from India. The pragmatic treatment responses assessed over time in literature are scarce.
Method
Retrospectively, we identified a cohort of fifteen cases of VDDR, including 6 patients of VDDR 1A, 2 patients of VDDR 1B, 7 patients of VDDR 2. The biochemical parameters, treatment and outcomes were analyzed. Data are presented as median with inter-quartile range (IQR), and mixed effect analysis for statistical analysis was used.
Result
In VDDR1A, the median age of presentation and delay in diagnosis was 12 (IQR-8-13. 5) and 26 months, whereas for VDDR2 it was 12 (IQR-6-24) and 46 months (6-58) respectively. 50% of VDDR1A patients had severe calcipenic symptoms and serum calcium improved over time from baseline- 7. 75mg/dl to 9. 3mg/dl at 1 year, and 9. 9mg/dl at 5 years, requiring a calcium dose(mg/kg/d) of 62. 5(44-128. 75), which reduced to 26. 5(18. 5-56. 25). Likewise, calcitriol dose (ng/kg/d) reduced from 40(26. 25-63. 75) to 24(12. 5-30. 75). In VDDR2, alopecia was present in 6 out of 7 patients, however only 28. 6% had severe calcipenic symptoms. Serum calcium improved over time from baseline- 7. 4mg/dl to 8. 7mg/dl at 1 year to 9. 2mg/dl at 5 years. As expected, these patients required higher doses of calcium and calcitriol. They required a calcium dose (mg/kg/d) of 138(70-160), which reduced to 100(42-200). Similarly, calcitriol dose (ng/kg/d) reduced from 75(50-100) to 62(27-100). Time to biochemical improvement was 5. 5 and 12months for VDDR1A and VDDR2 respectively. Additionally, two siblings with VDDR1B presented in their infancy, with complete biochemical response (alkaline phosphatase, serum parathyroid hormone, serum calcium) in 3 months with adequate calcium and vitamin D supplementation.
Conclusion
Timely diagnosis of VDDR is lacking, but good symptomatic and biochemical response is seen once diagnosed and appropriately treated.

Severe short stature secondary to distal renal tubular acidosis with slc4a1 gene mutation in a nigerian adolescent

Oluwadamilola Oladipo[1], Elizabeth Oyenusi[1, 2] & Abiola Oduwole[1]

[1]Paediatric Endocrinology Training Centre for West Africa, Lagos, Nigeria; [2]College of Medicine, University of Lagos, Lagos University Teaching Hospital, Endocrinology and Metabolism Unit, Department of Paediatrics, Lagos, Nigeria

Introduction
Renal tubular acidosis is characterized by persistent normal anion gap metabolic acidosis. It may be hereditary(primary) or secondary to disease conditions or drug use. Hereditary distal renal tubular acidosis (dRTA) is a rare genetic disease caused by mutations in either SLC4A1, ATP6VOA4 or ATP6V1B1 genes that encode the chloride-bicarbonate exchanger (AE1) or subunits of the H-ATPase pump. Affected individuals typically present with rickets, growth failure due to metabolic acidosis. This disease condition remains undiagnosed in most cases. This report is to create awareness about dRTA as a possible cause of rickets and short stature and to avoid the confusion with hypophosphatemic rickets.
Case Summary
17-year female adolescent with bony deformity first noticed in infancy presented to an orthopaedic hospital where she commenced on oral calcium and vitamin D in treatment for rickets. In view of recurrent history of fractures following minimal impacts despite use of calcium and vitamin D, she was referred to paediatric endocrinology clinic for possible vitamin D resistant rickets. There was no history suggesting autoimmune diseases or chronic drug use. She attained menarche at 15years but menstrual cycles stopped. Her weight was 19kg; length was 106cm -(minus)8. 5, and body mass index was 16. 9kg/m^2 -(minus)1. 71. Upper to lower segment ratio was 0. 95:1. Musculoskeletal system examination revealed telephone shaped deformity of the long bones and fork deformity of the wrist. Serum calcium was normal; 2. 41 mmol/l (2. 10 -2. 55), serum phosphate was 0. 51 mmol/l ↓ (0. 97 -1. 68), 25 hydroxyvitamin D was 56. 5 nmol/l (normal), Alkaline phosphatase was elevated at 692μ/l (79-370), parathyroid hormone was remarkably low < 1. 2 pg/ml (18. 50 – 88. 0). Serum electrolytes showed acidosis and hypokalemia with a normal anion gap. Urinalysis showed specific gravity of 1. 050, pH:8, low urine calcium (0. 59 mmol/l) phosphate (4. 8 mmol/l). On evaluation for vitamin D resistant rickets, FGF23 was normal. Whole genome sequencing returned positive for de novo heterozygous pathogenic variants in SLC4A1 of distal renal tubular acidosis with autosomal dominant mode of inheritance. There was an improvement with acidosis and hypokalemia on commencement of baking powder, phosphate and potassium therapy. She is also on calcitriol and calcium.
Conclusion
Rickets and growth failure are established presentations of dRTA. Serum electrolytes and urinalysis check in evaluation of a child with features of hypohosphatemic rickets are necessary to rule out dRTA.

Localization imaging and postoperative outcomes in primary hiperparathyroidism (phpt): is less enough?

Daniela M. Soares[1], Henrique Carmona Alexandrino[2], Andreia Martins Fernandes[3], Leandro Augusto Silva[3], Sofia Lopes[4], Ana Rita Elvas[3], Raquel G. Martins[3], Jacinta Santos[3, 3], Teresa Martins[3], Joana Couto[3] & Fernando Rodrigues[3]
[1]Unidade Local de Saúde de Santo António, Endocrinology, Porto, Portugal; [2]Unidade Local de Saúde de Vila Nova de Gaia e Espinho, Vila Nova de Gaia, Portugal; [3]Instituto Português de Oncologia Francisco Gentil de Coimbra, Coimbra, Portugal; [4]Unidade Local de Saúde de Coimbra, Coimbra, Portugal

Background/Aims
Surgery is the first-line established treatment for pHPT; the performance of preoperative localization techniques (LT) increases the probability of a successful parathyroidectomy. Our aim was to characterize the use of two different LT (neck ultrasound (US) and ^{99m}Tc-sestamibi scintigraphy (Sci)) and their impact on postoperative outcomes.
Methods
Retrospective study including patients with sporadic pHPT diagnosed and submitted to parathyroidectomy between january 2003 and october 2023 at a tertiary center. Patients with normocalcemic pHPT, without preoperative LT records or whose pHPT was an intraoperative finding were excluded.
Results
119 patients were included, most of whom were females (86. 6%; n = 103). At diagnosis, median age was 62. 0 (IQR=51. 0-70. 0) years and median ionized calcium (iCa), serum calcium (sCa), and PTH levels were 1. 41 (IQR=1. 37-1. 51) mmol/l (reference 1. 14-1. 29); 11. 3 (IQR=11. 0-12. 0) mg/dL (reference 8. 6-10. 5) and 178. 1 (IQR=143. 3-275. 7) pg/mL (reference 18. 0-80. 0), respectively. US was performed in all patients and Sci in 117 patients (98. 3%). US and Sci located abnormal parathyroid(s) in respectively 75. 6% (n = 90) and 90. 6% (n = 106) of patients; when both were performed, 26. 5% of patients (n = 31) presented positive localization in only one of the techniques. Neck CT and ^{18}F-fluorocholine-PET-CT were additionally performed in 17. 0% (n = 19) and 1. 7% (n = 2) of patients, respectively. Postoperative complications were documented in 16. 8% of patients (n = 16), in which 2. 1% (n = 2) presented iatrogenic hypoparathyroidism. Surgery success rates among all patients globally, patients with positive US only, positive Sci only, both US/Sci positive, both US/Sci negative and one positive with the other negative were 98. 3% (116/118); 87. 5% (7/8); 96. 0% (24/25); 100% (84/84); 50. 0% (1/2) and 93. 5% (29/31), respectively. No statistically significant differences were found between patients with one positive vs two positive LT regarding postoperative complications (18. 5% vs. 16. 7%; P = 1. 000) and calcium levels normalization (96. 9% vs. 100%; P = 0. 276). Additionally, no statistically significant differences were documented between patients with positive US only vs positive Sci only regarding the same outcomes (16. 7% vs. 19. 0%, P = 1. 000; 100% vs. 96. 0%, P = 1. 000).
Conclusion
In this study, the performance of US vs Sci demonstrated no differences regarding postoperative complications or calcemia normalization. Additionally, our results also suggest that one positive imaging exam might be enough to ensure parathyroidectomy success with no differences in the evaluated postoperative outcomes, thus reducing futile use of more preoperative localization techniques.

Management of osteoporosis in a pediatric case of severe osteolysis

Shiga Chiaryath[1], Sharon Bout-Tabaku[1], Talaat Youssef[2], Rasha Amin[1], Marwa Ibrahim[1], Khalid Bureshad[1] & Khalid Hussain[1]
[1]Sidra Medicine, Endocrinology, Doha, Qatar; [2]Sidra Medicine, Radiology, Doha, Qatar

Introduction
Autosomal recessive genetic osteolysis disorders include Multicentric osteolysis nodulosis arthropathy (MONA), Winchester syndrome, Torg syndrome, infantile systemic hyalinosis and mandibulo-acral dysplasia. Winchester syndrome (WS), first described in 1969, is a rare disorder characterized by short stature, coarse facial features, corneal opacities, generalized osteolysis, progressive JOINT destruction, osteoporosis and debilitating painful arthropathy. It is due to a missense mutation in *MMP14*, encoding the membrane-bound matrix metalloprotease 14. Due to the rarity of WS, evidence-based guidelines for managing osteoporosis in pediatric osteolytic syndromes are not well defined. Here we present the case of a 2-year-old girl with clinical and radiological features suggestive of likely Winchester syndrome managed with intravenous bisphosphonate for osteoporosis and immunomodulation for inflammatory arthritis.
Case: The patient, first child of consanguineous parents presented to our center for evaluation of a probable osteoporotic fracture of the left ulna diaphysis after the parents observed left wrist swelling. She had an uneventful antenatal and postnatal history and developmental milestones included delayed walking and speech delay. Chronic bilateral hand and finger swelling with pain upon tactile pressure was reported since infancy. On physical examination the anterior fontanelle was open, normal sclera and dentition, fingers of both hands had flexion deformities. Investigation revealed a normal biochemical bone profile. Radiographic findings included severe carpotarsal and phalangeal osteolysis, diffuse osteopenia with near total loss of mineralization of the scaphoid, lunate, triquetrum and pisiform bones. Thoracolumbar spine imaging revealed collapse of the T6 vertebral body. MRI of the bilateral wrists showed advanced osteolysis with necrosis like infarcts in the left wrist, synovitis, tenosynovitis and JOINT effusion indicating ongoing inflammation in the right wrist. Initial management with analgesia was minimally effective in reducing the bone pain. In view of the vertebral collapse, she was given a dose of intravenous Zoledronic acid followed by second dose 6 months later. Immunomodulation with Adalimumab was initiated for coexisting arthritis and tenosynovitis leading to decreased hand pain. She has not developed further fractures after 2 doses of Zoledronic acid. The provisional diagnosis of WS in this case was based on characteristic osteolysis, osteoporosis and arthropathy with differential diagnoses including MONA and Torg syndrome. Whole exome sequencing has been done for the child and the parents and results are awaited. This case underscores the challenges of managing osteoporosis in rare osteolytic syndromes. It highlights the importance of multidisciplinary care and need for genetic confirmation for a definitive diagnosis.

Hereditary and acquired phosphopenic rickets: from childhood to adulthood

Selen Hürmüzlü Közler[1], Esra Koçyiğit[1], Gizem Böke Koçer[1], Sibel Tuğçe Aygün[1], Ayça Karakış[2], Jeremy Huw Jones[3], Gürkan Tarçın[1], Zeynep Cantürk[4] & Filiz Mine Çizmecioğlu Jones[1]
[1]Kocaeli University Faculty of Medicine, Pediatric Endocrinology & Diabetes, Kocaeli, Türkiye; [2]Kocaeli University Faculty of Medicine, Department of Radiology, Kocaeli, Türkiye; [3]Kocaeli University, Department of Academic Writing, Kocaeli, Türkiye; [4]Kocaeli University Faculty of Medicine, Department of Endocrinology, Kocaeli, Türkiye

Introduction
Phosphopenic rickets (FPR) is a group of disorders characterized by renal phosphate loss due to hereditary or acquired causes, leading to impaired bone mineralization. It affects both children and adults. This study presents the clinical data of patients diagnosed with FPR from a single center.
Patients and Methods
We present the clinical and genetic characteristics of pediatric (index) patients evaluated for hypophosphatemia and their subsequently diagnosed relatives between 2004 and 2024.
Results
A total of 33 cases (M:F = 21:12) from 26 families were identified. The median (range) age at diagnosis was 3. 9 (0. 6–31) years, serum phosphate (sP) was 2. 6(0. 5–3. 8) mg/dL, and the mean ± SD TmP/GFR 1. 7 ± 0. 9 mg/dL. Sixteen (48. 5%) had fibroblast-growth-factor-23 (FGF23)-dependent hypophosphatemic rickets (HPR) (14 hereditary, 2 acquired – both infants with liver failure), 10 (30%) from 8 families had vitamin D-dependent-rickets-(VDDR) [type 1 ($n = 8$)/type 2 ($n = 2$)], and 7(21%) had FGF23-independent-renal-tubular-dysfunction (RTD). In hereditary HPR, the age at diagnosis was 4. 8 (2-31) years, follow-up 14. 1(6. 6-21. 8) years. All patients had short stature, genu varum, and/or dental abnormalities. The Thacher score was 6. 1(5–8). While 4(28%) had enthesopathy, nephrocalcinosis was detected in 2(14%). Eight(57%) had corrective surgery, 2(%14) had history of fractures. Two(14%) were treatment naive while 6(42%) discontinued in adulthood. *PHEX* variant was identified in 4(28%). One was started on burosumab aged 10 years, resulting in significant improvement in genu varum. In VDDR age at diagnosis was 1. 6(1. 3-4) years. Nine(90%) presented with delayed walking and 9 had consanguineous parents. Wrist widening was observed in all, while genu varum was present in 7(70%). Height SDS at presentation was -2. 0(-0. 5/-4. 5) and sP 2. 9 mg/dL(1. 7-3. 3). In type 1 VDDR, *CYP27B1* variant was found in 6/8 (homozygous $n = 5$; compound heterozygous $n = 1$) while in type 2 VDDR a homozygous pathogenic variant in *VDR* was found in one. In RTD, age at diagnosis was 7(3-14. 3) years, height SDS -3. 5(-0. 6/-4. 3), sP 2. 6 mg/dL(0. 5-2. 9), and TmP/GFR 1. 7(0. 2-2. 5)mg/dL. Diagnosis included cisplatin toxicity (CT)($n = 1$, Pearson syndrome $n = 1$, cystinosis $n = 2$, and RTD $n = 3$. All but one (CT) had skeletal anomalies. In one with RTD, a pathogenic variant in the *SLC34A3* gene was identified.
Conclusion
These results highlight the wide range of clinical and genetic characteristics of patients with hypophosphatemia. Elucidation of etiology will enable early and correct diagnosis but delay causes severe morbidity. Burosumab, an FGF23 inhibitor, targeted therapy for X-linked hypophosphatemia improves skeletal deformities and growth in children, enhances fracture healing, reduces pain, and boosts physical activity in adults.

Parathyroid washout's role in accurate adenoma localisation and diagnostic cut-offs

Ekin Yiğit Köroğlu[1], Berna Evranos Ogmen[2], belma tural balsak[1], Mustafa Ömer Yazıcıoğlu[3], cevdet aydin[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism Diseases, Ankara, Türkiye; [2]Ankara Yıldırım Beyazıt University Faculty of Medicine, Endocrinology and Metabolism Diseases, Ankara, Türkiye; [3]Ankara Bilkent City Hospital, General Surgery, Ankara, Türkiye

Purpose
Accurate adenoma localisation is necessary for the application of minimally invasive surgery, which is preferred in the treatment of primary hyperparathyroidism. This study aimed to determine appropriate cut-off values for the parathormone-washout(PTH-WO) method.

Table 1: The demographical and biochemical parameters of the patients.

Parameters	n	Value
Age (years)	339	54. 00 (19. 00-81. 00)
Calcium (mg/dl)	339	11. 00 (8. 90-14. 90)
Corrected Calcium (mg/dl)	339	10. 60 (8. 30-14. 70)
Phosphorus (mg/dl)	339	2. 70 (1. 40-4. 70)
Alkaline phosphatase (U/l)	315	106. 09 ± 42. 09
Creatinine (mg/dl)	339	0. 74 ± 0. 14
Glomerular filtration rate (ml/min)	339	97. 00 (60. 00-134. 00)
Serum Parathormone (ng/l)	339	154. 00 (81. 00-738. 00)
24-hour urinary calcium (mg/day)	339	298. 50 (80. 00-947. 00)

Table 2. Locations of the parathyroid adenomas of the patients.

	Right	Left	Level VII lymph node compartment	Overall
Superior	11 (3.13%)	18 (5.12%)	N/A	29 (8.26%)
Inferior	149 (51.20%)	142 (40.45%)	N/A	291 (82.90%)
Intrathyroidal	16 (4.55%)	12 (3.41%)	N/A	28 (7.97%)
Level VII lymph node compartment	N/A	N/A	3 (0.85%)	3 (0.85%)
Overall	176 (50.14%)	172 (49.00%)	3 (0.85%)	351 (100.00 %)

Design
A total of 402 PTH-WO assays from 339 patients were included in the study. The diagnostic accuracy of the test was assessed by accepting as a positive result a PTH-WO result higher than the serum PTH level [PTH-WO/serum PTH(PTH ratio) > 1]. In addition, a cut-off value for the test was established by evaluating the PTH washout results obtained in comparison with postoperative histopathology. Undiluted test results were not included to obtain a clear numerical value in this evaluation. The results of parathyroid scintigraphy and fine needle aspiration biopsy(FNAB) were compared with postoperative histopathology.
Results
While 309(76. 86%) of the PTH-WO procedures were considered positive, 93(23. 13%) were considered negative if the PTH ratio was > 1. When these results were compared with the postoperative histopathology, the test's sensitivity was 92. 51%, and the specificity was 100. 00%. In the analysis of the remaining 292 PTH-WO samples after excluding the undiluted ones, the sensitivity and specificity of the method were 92. 3% and 94. 1%, respectively, with a PTH ratio > 0. 99. With a cut-off value of 99. 5 ng/l for PTH-WO value, 93. 1% sensitivity and 94. 3% specificity were obtained. The sensitivities of parathyroid scintigraphy and FNAB were 53. 4% and 15. 3%, respectively.
Conclusion
The PTH-WO method is safe and cheap, with high sensitivity and specificity in localising parathyroid adenoma. In cases where radiological methods cannot achieve localisation with specified cut-off values, it has high diagnostic accuracy.

Pubertal development in hypophosphatemic rickets: does it have an impact on growth?

Tugce Kandemir[1], Ozge Bayrak Demirel[1], Cansu Koc[1], Asli Derya Kardelen Al[1], Melek Yildiz[1], Sukran Poyrazoglu[1], Feyza Darendeliler[1] & Firdevs Bas[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Department of Pediatric Endocrinology, Istanbul, Türkiye

Background
Hypophosphatemic rickets (HR) is a rare disorder characterized by impaired phosphate metabolism, leading to skeletal deformities, short stature, and delayed bone mineralization. While its impact on childhood growth is well-documented, its effect on pubertal development and final height remains unclear. This study aims to evaluate pubertal progression, final height outcomes, and associated clinical factors in HR patients to provide insights into optimizing growth management strategies.
Methods
This retrospective study included HR patients diagnosed either clinically or genetically. Data including pubertal onset, progression, final height, and pubertal height gain were collected. Height SDS and BMI SDS were analyzed across different Tanner stages. Statistical analyses were performed to assess the association between pubertal onset and final height, sex-based growth differences, and predictors of target height.
Results
A total of 34 patients (F/M:18/16) were included. Genetic analysis was available for 13 patients, with mutations identified in *PHEX* ($n = 7$), *SLC34A3* ($n = 4$), *SLC34A1* ($n = 1$), and *DENT* ($n = 1$). At presentation, the mean age of the patients was 8. 4 ± 5. 2 years, and the mean height SDS was -2. 49 ± 1. 56. The mean age at pubertal

onset was 10. 6 (8. 4–13) years in females and 10. 7 (9. 4–15) years in males. The mean age at menarche was 13. 1 ± 0. 8 years, which was significantly delayed compared to the Turkish population (12. 2 ± 0. 9 years) ($P < 0.001$). The pubertal height gain was 20. 1 ± 6. 2 cmin girls and 29. 8 ± 15. 4 cm in boys, comparable to that observed in the Turkish population. The duration of puberty was 5. 3 ± 1. 0 yearsin girls and 5. 3 ± 1. 5 years in boys. Among 13 patients (F/M:6/7), who reached final height, the final height SDS (-2. 3 ± 1. 1) was significantly lower than the target height SDS (-1. 1 ± 0. 9) ($P = 0.0005$). The final height SDS was significantly higher in females compared to males (-1. 9 ± 0. 9 vs. -3. 1 ± 1. 1, $P = 0.045$).

Conclusion

Despite a normal or slightly increased pubertal height gain in females, final height remained significantly below the genetic target in both sexes. Menarche was delayed, and pubertal duration was slightly prolonged in HR girls compared to the general population. Notably, females had a significantly higher final height SDS than males, suggesting a greater growth deficit in male patients despite comparable pubertal height gain. These findings underscore the importance of early intervention, continuous growth monitoring, and individualized treatment strategies to optimize final height outcomes in HR.

Pregnancy management in ectonucleotide pyrophosphatase/phosphodiesterase family member 1 (ENPP1) deficiency: a case report and considerations for maternal medicine care

Mariyah Ahmed[1], Jenny Myers[2], Peter Selby[3] & Clare Mumby[4]
[1]Manchester Royal Infirmary, St. Mary's Hopital, Endocrinology and Diabetes and Obstetrics, Manchester, United Kingdom; [2]St Mary's Hospital, Obstetrics, Manchester, United Kingdom; [3]Manchester Royal Infirmary, Endocrinology and Diabetes, Manchester, United Kingdom; [4]Manchester Royal Infirmary, St. Mary's Hospital, Endocrinology and Diabetes and Obstetrics, Manchester, United Kingdom

Background

ENPP1 Deficiency is a rare autosomal recessive disorder with an estimated prevalence of 1 in 64, 000 pregnancies. It results in low inorganic pyrophosphate levels, leading to excessive soft tissue calcification, neointimal proliferation, and impaired bone mineralisation. Approximately 50% of affected infants succumb to generalised arterial calcification of infancy (GACI) within the first six months. Survivors may develop hypophosphatemic rickets, hearing loss, osteomalacia, vascular calcification, and cardiac complications. Pregnancy in women with ENPP1 Deficiency remains undocumented.

Case Presentation

We present a 32-year-old woman with ENPP1 Deficiency, currently in her second pregnancy. Her past medical history includes hypophosphatemic rickets managed with Alfacalcidol and phosphate replacement, congenital cervical spine fusion (C2-C3), and minor vascular calcification. Her twin brother died at six weeks from severe GACI. She has received lifelong metabolic bone and cardiology care. Her first pregnancy was managed in a Maternal Medicine Centre (MMC) with multi-disciplinary management. Her initial bone chemistry was within normal ranges and remained stable throughout pregnancy. The bone profile was monitored closely as the placenta can produce PTHrP in variable amounts, requiring potential dose adjustments of Alfacalcidol. She remained on Alfacalcidol 1 mg and Phosphate Sandoz 4 tablets daily. Due to increased risk of hypertension, pre-eclampsia, and fetal growth restriction, she was commenced on prophylactic aspirin (150 mg/day). Obstetric cardiology assessments showed normal ECG and echocardiogram findings. Low molecular weight heparin prophylaxis was initiated after MDT discussion. At 23 weeks, she had a positive placental screen with bilateral notches and a mean placenta pulsatility index of 1. 46 and she commenced home blood pressure monitoring and fetal growth surevillance. Normal fetal growth velocity was maintained and delivered at 36 + 4 weeks via elective cesarean section due to hypertension and abnormal placental growth factor (PIGF). In her second pregnancy, also managed at MMC, initial assessment revealed hypophosphatemia with mild secondary hyperparathyroidism (PTH 7. 8 pmol/l, PO_4^{2-} 0. 73 mmol/l, Adjusted Ca^{2+} 2. 34 mmol/l). She remains on the same dose of Alfacalcidol and Phosphate Sandoz. She is 23 weeks gestation with reassuring cardiology assessments. Placental screen shows no notches and borderline raised pulsatility index indicating a lower risk of placental pathology.

Conclusion

Pregnancy in women with ENPP1 Deficiency requires multidisciplinary care at a Maternal Medicine Centre. Pre-conception counselling should address potential complications, emphasising cardiovascular risk assessment. Close monitoring for metabolic bone disease, cardiac complications, and hypertensive disorders, along with individualised management plans, is crucial to optimising maternal and fetal outcomes.

JOINT2401

"Familial hypocalciuric hypercalcemia in adolescence: diagnostic challenges and the role of genetic testing"

Manju Chandwani[1], Muhammad Ahmad[1], Sumana Chatterjee[1] & Toby Candler[1]
[1]University Hospitals of Bristol and Weston, Paediatric Endocrinology, Bristol, United Kingdom

Introduction

Familial hypocalciuric hypercalcemia (FHH) is a benign, autosomal dominant condition with high penetrance. Heterozygous individuals typically present with mild hypercalcemia, hypocalciuria, inappropriately normal parathyroid hormone (PTH) levels, and elevated serum magnesium levels. FHH1, the most common form, results from inactivating mutations in the calcium-sensing receptor (CaSR) gene on chromosome 3q21. 1. Distinguishing FHH from asymptomatic primary hyperparathyroidism (PHPT) is critical, as FHH rarely requires parathyroidectomy and is not resolved by it. While typical biochemical findings can differentiate the two conditions, atypical presentations pose challenges. The calcium-creatinine clearance ratio (CCCR) aids diagnosis, with CCCR < 0. 01 indicating FHH and > 0. 02 suggesting PHPT. However, values between 0. 01–0. 02 create diagnostic uncertainty, and some PHPT cases may also present with CCCR < 0. 01, as reported by Moore *et al*. This report presents a 14-year-old girl diagnosed with FHH despite a CCCR > 0. 01, emphasizing the role of genetic testing in cases with overlapping biochemical features.

Case Presentation

A 14-year-old girl was referred for incidentally detected hypercalcemia during a routine evaluation. She had no history of polyuria, abdominal pain, weight loss, or bowel changes. Her clinical examination was normal, with no family history of hypercalcemia at initial assessment. Growth parameters were within normal limits (height: 163. 2 cm, weight: 58. 6 kg).

Investigations

- Adjusted Calcium: 2. 97–3. 20 mmol/l (elevated) (NR: 2. 20 – 2. 70)
- PTH: 7. 0–10. 1 pmol/l (unsuppressed in presence of hypercalcemia) (NR: 1. 3 – 9. 3)
- CCCR: 0. 0158
- Magnesium: 0. 89–0. 90 mmol/l (normal) (NR: 0. 7 – 1. 0)
- Vitamin D: 54 nmol/l (normal) (NR: 50 – 200)

Renal ultrasound showed no nephrocalcinosis. Normal neck ultrasound as well as Sestamibi scintigraphy scan ruled out parathyroid adenoma. Genetic testing identified a heterozygous pathogenic missense variant in the CASR gene, confirming FHH1. Following this, patient's father was also found to have asymptomatic hypercalcemia, and his genetic test results for the identified mutation are pending.

Discussion

FHH shares biochemical overlap with PHPT but is typically benign, with low urinary calcium excretion and a CCCR < 0. 01. Unlike PHPT, FHH does not lead to complications like osteoporosis or kidney stones.

Conclusion

This case underscores the importance of genetic testing in distinguishing FHH from PHPT, especially when CCCR results are inconclusive. A correct diagnosis ensures appropriate management, avoiding unnecessary procedures and anxiety.

"A diagnostic odyssey: camurati - engelmann syndrome presenting as childhood onset leg pains and stiffness"

Lisa Tharby[1], Manju Chandwani[1], Christopher Moudiotis[2] & Toby Candler[1]
[1]University Hospitals of Bristol and Weston, Paediatric Endocrinology, Bristol, United Kingdom; [2]Royal Devon and Exeter Hospital, Exeter, United Kingdom

A 10-year-old girl was referred to the paediatric rare bone disease service by neurology for persistent leg pain, stiffness, and an undiagnosed condition despite extensive evaluation. Born at term following an uneventful pregnancy, she met early milestones and walked independently at 12 months. Symptoms began at 2 years of age with unsteadiness and frequent falls. By 3 years of age, she struggled with running and fatigued easily. By 6 years of age, she had difficulty climbing stairs, used a one-foot-at-a-time approach, and could not jump. Her dystonia primarily affected her lower limbs, with no family history of similar conditions. Brain and spine MRIs were normal. At age 7, she was referred to the complex movement disorder service, initially suspected of primary dystonia. Extensive metabolic, neuromuscular, and genetic tests were inconclusive, and nerve conduction studies were normal. Due to needle phobia, sedation or general anaesthesia was required for testing. Multiple dystonia medications, including L-Dopa, clonazepam, and gabapentin, failed and caused side effects like anxiety, mood disturbances, and suicidal ideation. She was also enrolled in the 100, 000 Genomes Project. By age 9, her condition worsened; she developed a waddling gait with foot clawing and required a wheelchair for long distances. A paediatric neurologist questioned the dystonia diagnosis, and deep brain stimulation was not pursued. Following referral to rare bone disease service, radiographs and MRI of the lower limbs were obtained and these revealed cortical thickening, Erlenmeyer flask deformity of the femora, and bone marrow oedema, suggesting Camurati-Engelmann disease (CES). Whole genome sequencing confirmed a de novo heterozygous pathogenic TGFB1 missense variant, confirming CES. Her current management includes physiotherapy, hydrotherapy, regular analgesia, heat pads, and activity pacing. NSAIDs help control pain, with prednisolone or losartan as potential options. She is growing well and has entered puberty without issues. Audiology, ophthalmology, and DEXA scans remain normal, with a lumbar spine and Total Body Less Head BMD z-score of -0. 3. CES is a rare autosomal dominant disorder caused by TGFB1 mutations, leading to progressive diaphyseal dysplasia with bone pain, muscle weakness, and waddling gait due to cortical thickening of long bones. Skull thickening can cause CNS complications such as increased intracranial pressure, headaches, optic nerve compression, and cranial nerve dysfunction. CES should be considered in children with unexplained limb pain and stiffness, particularly with radiological features like cortical thickening, Erlenmeyer flask deformity, and bone marrow narrowing. Early diagnosis prevents unnecessary investigations and ineffective treatments.

Bone health index (BHI) in children with osteogenesis imperfecta: is it an accurate tool for predicting fracture risk?

Ruggero Lanzafame[1], Alistair D. Calder[2] & Moira S. Cheung[1]
[1]Great Ormond Street Hospital for Children NHS Foundation Trust, Pediatric Endocrinology Department, London, United Kingdom; [2]Great Ormond Street Hospital for Children NHS Foundation Trust, Radiology Department, London, United Kingdom

Introduction
Bone Health Index (BHI) is calculated from hand-wrist X-rays using BoneXpert® software: it assesses the average cortical thickness of the three middle metacarpal bones, adjusted for bone width and length. The software also provides a standard deviation score (BHI SDS) that allows comparison with healthy children with the same bone age. BHI has shown a significant correlation with fracture risk in a healthy pediatric population[1]; however, its correlation with fractures in OI has not been evaluated. We hypothesise that BHI would correlate with fracture risk in Osteogenesis Imperfecta (OI) and thus be helpful in the assessment of bone fragility.
Methods
The National OI service at Great Ormond Street Hospital (London, UK) currently looks after 276 children with OI and maintains a detailed and accurate record of fractures. We retrospectively reviewed their first hand-wrist X-rays, fracture history in the one-year window before and after hand-wrist X-ray was performed, lateral spine X-rays, and DXA scans. All selected patients underwent hand-wrist X-rays and DXA scans on the same day, with X-rays analyzed using BoneXpert® version 3. 0 or later. The 132 cases previously analyzed with earlier software versions are currently being reanalyzed using the latest version and are not included in this preliminary analysis.
Results
A statistically significant negative correlation was observed between BHI SDS and the total number of vertebral and non-vertebral fractures within the year before and after BHI assessment ($r = -0.702$, $P = 0.0001$). This correlation was particularly strong for vertebral fractures ($r = -0.759$, $P = 0.00002$). A statistically significant positive correlation was observed between BHI and DXA BMD absolute values ($r = 0.610$, $P = 0.0461$), but no correlation between BHI SDS and DXA SDS values was observed. Interestingly, no significant correlation was found between lumbar DXA measurements (BMD, BMD SDS and BMAD SDS) and fracture incidence, even when analyzing vertebral and non-vertebral fractures separately. Post-pubertal patients showed higher BHI values than pre-pubertal patients. Additionally, patients with an Asian geographical background had lower BHI scores and sustained more fractures compared to patients with a Caucasian and African background
Conclusion
This preliminary analysis suggests that, unlike DXA, BHI correlates more closely with fracture risk, particularly for vertebral fractures. BHI may offer a feasible, cost-effective tool for identifying OI children at higher fracture risk.

Clinical and laboratory characteristics of genetic rickets: a single-center experience with long-term outcomes

Özge Köprülü[1], Gülşen Özer[1], Ibrahim Mert Erbas[1], Özlem Nalbantoğlu[1], Semra Gürsoy[2] & Behzat Ozkan[1]
[1]University of Health Sciences Turkey, Izmir Dr. Behcet Uz Pediatric Diseases and Surgery Training and Research Hospital, Department of Pediatric Endocrinology, Izmir, Türkiye; [2]Dokuz Eylül University Faculty of Medicine, İzmir, Türkiye., Department of Pediatric Genetics, Izmir, Türkiye

Background
Rickets is a metabolic bone disease characterized by inadequate mineralization of growing bone tissue due to deficiency of calcium, phosphorus, vitamin D or resistance to vitamin D. Genetic causes of rickets are rare and accounts for 13% of all rickets cases. Genetic rickets can be divided into two groups: vitamin D-dependent rickets and hypophosphatemic rickets (HR). All of them present similar clinical manifestations of hypocalcemia and/or rickets. This study aimed to evaluate the clinical, laboratory and genetic features and long-term follow-up of the patients diagnosed with genetic rickets.
Materials and Methods
The study included patients diagnosed with genetic rickets between 2010 and 2024 in our clinic. Relevant data were collected retrospectively from medical records. The patients were evaluated in terms of clinical, laboratory, and genetic characteristics.
Results
Fifteen patients were included in the study. Eight of the patients (53. 3%) were male, and seven (46. 7%) were female. Of the patients, six had Vitamin D-dependent rickets type 1 (VDDR1), two had Vitamin D-dependent rickets type 2 (VDDR2), and seven had Hypophosphatemic Rickets (HPR). The most common presentation was leg deformities; followed by delayed walking, growth retardation, alopecia, delayed dental development and bone pain. The mean age at presentation was 3.5 ± 3.1 years. Physical examination findings included JOINT widening (40%), genu varum (33. 3%), short stature (33. 3%), genu valgum (26. 7%), rachitic rosary (26. 7%), caput quadratum (6. 7%), pectus carinatum (6. 7%), and frontal bossing (6. 7%). The diagnosis of all the cases with VDDR1 was confirmed by demonstration of the variant in the *CYP27B1* gene. One of the VDDR2 cases showed a variant in the *VDR* gene, while genetic analyses could not be performed in the other. Six patients with HPR had variants in the *PHEX*, and one had variant in the *CLCN5*. The mean follow-up period for the patients was 77. 9 months. The mean final height of the four patients, who reached final height, was 142.07 ± 11.19 cm (129-155 cm). No complications were observed in any of the patients during long-term follow-up.
Conclusion
This study provides valuable insights into the clinical and laboratory characteristics, as well as long-term follow-up outcomes, of 15 patients diagnosed with genetic rickets. The findings are important for expand the knowledge and increase the awareness of this rare condition and for encouraging further research in this area.

A novel case of macroprolactinoma in a patient with phenylketonuria

Sinéad Cadogan[1], James J. O'Byrne[2] & Siobhán McQuaid[1, 3]
[1]Mater Misericordiae University Hospital, Department of Diabetes and Endocrinology, Dublin, Ireland; [2]Mater Misericordiae University Hospital, National Centre for Inherited Metabolic Disorders, Dublin, Ireland; [3]University College Dublin, School of Medicine, Dublin, Ireland

Introduction

Phenylketonuria (PKU) is an autosomal recessive disorder that impairs phenylalanine (Phe) metabolism to tyrosine. We present a case of macroprolactinoma in a patient with PKU and explore potential mechanisms linking the conditions.

Case

A 36-year-old man with neonatal-diagnosed classical PKU (compound heterozygous *PAH* variants) presented to the endocrine clinic with fatigue, low mood, and erectile dysfunction. He had low lumbar spine BMD (Z-score -2. 5), managed with bisphosphonates. Phe concentrations were often above the 600 umol/l target, typically ranging from 550–800 umol/l. Examination showed BMI 32 kg/m^2, bilateral gynaecomastia, and sparse body hair. Labs confirmed secondary hypogonadism: total testosterone 6. 3 nmol/l, free testosterone 0. 15 nmol/l, LH 1. 23 IU/l, FSH 2. 3 IU/l. Prolactin was elevated at 11, 649 mIU/l (RR 73–407), with macroprolactin excluded. Remainder of pituitary function and calcium concentrations were normal. Family history was negative for pituitary disease. MRI revealed a 17 mm right-sided pituitary macroadenoma. Following initiation of Cabergoline 0. 25 mg weekly, prolactin declined to 1, 421 IU/l at four weeks and 590 IU/l at three months. Total testosterone rose to 10. 3 nmol/l after six months, with symptomatic improvement.

Discussion

Patients with PKU may have impaired neurotransmitter production due to low plasma and brain tyrosine. Elevated Phe levels further deplete brain tyrosine by competing for blood-brain barrier transport, reducing dopamine synthesis. PET studies confirm reduced dopamine production in PKU, even with mildly elevated Phe. Since dopamine inhibits prolactin secretion, low levels result in increased prolactin. Therefore, suboptimal metabolic control in PKU is typically associated with modest prolactin elevations (~1, 500 mIU/l). However, the marked hyperprolactinemia in this case suggests the alternative pathology of prolactinoma. Dopamine is thought to inhibit lactotroph proliferation, and animal models link chronic dopamine deficiency, possibly via reduced D2 receptor stimulation, to pituitary tumorigenesis. However, human data are lacking, necessitating further research on whether PKU-related dopamine deficiency could increase pituitary tumour risk. Bone health is an important concern in PKU. While PKU patients generally have lower BMD Z-scores than controls, most remain within the normal range. However, around 10% have a Z-score below -2, suggesting low BMD. These cases warrant further evaluation for secondary causes.

Conclusion

While mild hyperprolactinemia is common in PKU, markedly elevated prolactin levels should prompt further investigation. This case also highlights the importance of investigating low BMD in PKU, as its underlying causes may be multifactorial. Further research is needed to explore the link between PKU-related dopamine deficiency and pituitary tumorigenesis.

Trabecular bone score and risk of vertebral fracture in systemic lupus erythematosus children and adolescent who treated with glucocorticoids

Jittra Ruktrirong[1], Voraluck Phatarakijnirund[1], Parinya Samakkarnthai[2], Monthira Chowichian[3], Konggrapun Srisuwan[4], Trirat Boonya-ussadorn[5] & Kulisara Wangwarawut[6]
[1]Phramongkutklao College of Medicine, Division of Pediatric Endocrinology, Department of Pediatrics, Bangkok, Thailand; [2]Phramongkutklao Hospital and College of Medicine, Division of Endocrinology, Department of Medicine, Bangkok, Thailand; [3]Phramongkutklao College of Medicine, Division of Pediatric rheumatology, Department of Pediatrics, Bangkok, Thailand; [4]Phramongkutklao College of Medicine, Division of Pediatric Neprhology, Department of Pediatrics, Bangkok, Thailand; [5]Phramongkutklao College of Medicine, Division of Nuclear Medicine, Department of Radiology, Bangkok, Thailand; [6]Maharaj Nakhon Si Thammarat Hospital, Division of Pediatric Endocrinology, Department of Pediatrics, Nakhon Si Thammarat, Thailand

Background

Glucocorticoid-induced osteoporosis (GIO) is a common consequence in children and adolescents with systemic lupus erythematosus (SLE). Vertebral fractures (VFs), which are typically asymptomatic, occur in 4-28 percent of these patients, emphasising the importance of close monitoring. While bone mineral density (BMD), assessed by dual-energy X-ray absorptiometry (DXA), is the gold standard for evaluating bone health. its limitations are evident as many children with VFs show normal BMD Z-scores. Trabecular bone score (TBS) offers insight into bone quality and has been linked to fracture risk. Despite its potential, limit studies have explored TBS's role in identifying prevalent VFs among SLE children treated with glucocorticoids therapy.

Purpose

To evaluate the TBS in glucocorticoid-treated SLE children and adolescents with and without VF and the correlation between the TBS and BMD data.

Methods

The retrospective cohort study included 48 patients with SLE who had been treated with systemic glucocorticoids (GCs) for over three months. Both TBS and BMD were assessed between January 1, 2017 and December 31, 2024, at the Pediatric Department of Phramongkutklao hospital. TBS was analyzed using iNsight software (version 3. 0. 2. 0) and TBS Z-scores as well as BMD Z-scores were calculated using established reference values for children and adolescents. Patients were classified into two groups: VF and non-VF according to the Genant semi-quantitative method. A comparison of TBS Z-scores between the VF and non-VF groups was done.

Results

At baseline, the mean age (11 years [10. 5-14]), BMI (21. 49 kg/m^2 [18. 2-25. 99]), cumulative GCs dose (8, 083. 75 mg [5, 105-12, 800]) showed no significant differences between two groups. TBS L1-L4 and TBS L1-L4 Z-scores were lower in the VF group than in the non-VF group, although not significantly: [1. 16 (1. 14-1. 40) vs. 1. 36 (1. 30-1. 42), P 0. 117; 0. 05 (-2. 12 to 0. 38) vs. 0. 09 (-0. 6 to 0. 5), $P = 0.370$]. Both VF and non-VF groups had L1-L4 BMD Z-scores above -2: -1. 04 (-2. 57 to 0. 4) vs. 0. 26 (-1. 04 to 1. 02), P 0. 12. TBS L1-L4 Z-scores showed a moderate positive correlation with L1-L4 BMD Z-scores (r 0. 477, P 0. 001). TBS L1-L4 also exhibited moderate positive correlations with L1-L4 BMD (r 0. 686, $P < 0.001$) and BMAD L1-L4 Z-scores (r 0. 488, $P < 0.001$).

Conclusion

Lower TBS may indicate compromised bone microarchitecture, providing additional insight beyond BMD alone in childhood and adolescent patients with SLE.

Hypercalcaemia from primary hyperparathyroidism and CYP24a1 pathogenic variant: a coincidence or an underlying mechanism?

Simone Della Valentina[1], Giordano Paolucci[1], Chiara Sardella[1], Laura Pierotti[1], Anna Dal Lago[1], Angela Michelucci[2], Maria Adelaide Caligo[2] & Filomena Cetani[1]
[1]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]Molecular Genetics, University Hospital of Pisa, Pisa, Italy

The *CYP24A1* gene encodes the enzyme 24-hydroxylase, which plays a crucial role in the catabolism of 1, $25(OH)_2D_3$ and 25-hydroxyvitamin D [$25(OH)D_3$]. A deficiency in this enzyme results in elevated circulating levels of both $25(OH)D_3$ and 1, $25(OH)_2D_3$, leading to enhanced vitamin D activity. This, in turn, increases serum calcium levels due to heightened intestinal calcium absorption and renal calcium reabsorption. Biallelic pathogenic variants in this gene are responsible for infantile idiopathic hypercalcemia, whereas heterozygous individuals may either maintain normocalcemia or develop mild hypercalcemia. To date, only six cases of patients with a heterozygous CYP24A1 variant and primary hyperparathyroidism (PHPT) has been documented in the literature. Here, we present the cases of two unrelated patients evaluated at our outpatient clinic. The first patient is a man with a history of recurrent nephrolithiasis since the age of 16. At 26, he was referred to our clinic for evaluation after presenting with a serum calcium level of 12. 5 mg/dL (reference range: 8. 6–10. 2), PTH of 24 pg/mL (10–40), 25(OH)D of 72. 8 mg/dL, 1, $25(OH)_2D_3$ 64. 9 mg/dL and 24-hour urinary calcium of 558 mg/24h. Suspecting PHPT, a SPECT/CT scan revealed a hyperfunctioning parathyroid gland, leading to parathyroidectomy (PTx) with histological confirmation of a parathyroid adenoma. Six months postoperatively, the patient continued to have persistent hypercalcemia (10. 8 mg/dL) and suppressed PTH (7 pg/mL), raising suspicion for PTH-independent hypercalcemia. Genetic analysis revealed a heterozygous variant c. 1226T>C, p. (Leu409Ser) in the *CYP24A1* gene. The second patient is a 59 years-old woman who presented with severe hypercalcemia (14. 3 mg/dL), PTH of 47 pg/mL and 25(OH)D of 30. 9 mg/dL. Suspecting PHPT, she underwent PTx of the left lower and upper glands, with histological confirmation of parathyroid adenomas. Four years later, after missing follow-up appointments, she was admitted to the emergency department with nausea

and vomiting due to severe hypercalcemia (19 mg/dL) and an elevated PTH of 227 pg/mL. She was treated with hemodialysis, zoledronic acid, cinacalcet, and, subsequently, underwent PTx of the right lower parathyroid with histological confirmation of adenoma. Six months later, despite persistent hypercalcemia (10. 4 mg/dL) and suppressed PTH (7 pg/mL), genetic analysis revealed compound heterozygosity for the c. 428_430del, p. (Glu143del) and c. 245A > G, p. (Gln82Arg) variants in the *CYP24A1* gene. These two cases illustrate the clinical presentation of PHPT in patients with CYP24A1 mutations, showing that these individuals can develop severe hypercalcaemia challenging-to-manage hypercalcemia. Whether this association is just by chance or depends on specific mechanisms remains to be explored.

Effect of long-term treatment with teriparatide and vitamin k on bone density and bone markers, glucose metabolism and body composition in severe osteoporotic patients

Chiara Verdelli[1], Chiara Degradi[2], Giorgia Dito[3], Silvia Carrara[4], Veronica Sansoni[1], Giovanni Lombardi[1, 5] & Sabrina Corbetta[6]
[1]IRCCS Ospedale Galeazzi-Sant'Ambrogio, Laboratory of Experimental Biochemistry & Advanced Diagnostics, Milan, Italy; [2]IRCCS Istituto Auxologico Italiano, Centro Obesità, Centro Disturbi Alimentari e della Nutrizione, Milan, Italy; [3]Ospedale di Vimercate - ASST della Brianza, UOSD Malattie Endocrine, del Ricambio e della Nutrizione, Vimercate, Italy; [4]University of Milan, Department of Biotechnology and Translation Medicine, Milan, Italy; [5]Poznan University of Physical Education, Department of Athletics, Strength and Conditioning, Poznan, Poland; [6]University of Milan, Bone Metabolism Diseases and Diabetes Unit, IRCCS Istituto Auxologico Italiano, Department of Biomedical, Surgical, and Dental Sciences, Milan, Italy

Osteocalcin (OC) is emerging as a hormone regulating metabolic/endocrine functions including glucose metabolism and energy homeostasis. OC displays different carboxylation status modulated by vitamin K with different biological activities. Here, we investigated the role of carboxylated (γ_3OC) and uncarboxylated (γ_0OC) osteocalcin using a human model of severe osteoporotic patients treated with teriparatide (TPT) and randomized to supplementation with metaquinone (MK-7) 375 microg/die. Sixty-five normoglycemic patients (60 females, 5 males, aged 73. 9 ± 6. 0 years, BMI 24. 2 ± 3. 8 kg/m^2, mean ± SD) were enrolled, treated with 20 microg TPT daily sc and reevaluated after 18 months. Forty-three patients concluded the study, including 11 women supplemented with MK7 (TPT + MK-7). All patients experienced at least one fragility fractures (n = 3. 4 ± 1. 9), while during the follow up incident vertebral morphometric deformities occurred just in one patient. TPT increased the circulating bone formation markers γ_3OC, γ_0OC, bone-specific alkaline phosphatase (BALP), as well as the bone resorption markers C-terminal telopeptide of type 1-collagen (β-CTX-I) and tartrate-resistant acid phosphatase 5b (TRACP5b), while TPT reduced sclerostin. Of note, in patients treated with TPT + MK-7, circulating γ_3OC levels, but not γ_0OC, after 18 months were higher than those in non-supplemented patients (21. 1 ± 13. 1 vs 12. 7 ± 3. 7 ng/ml, P = 0. 0651; Δ + 94. 1 ± 0. 7% vs + 34. 5 ± 0. 5%, P = 0. 0313). TPT treatment significantly increased lumbar T-scores, with any difference in the amount of increase between the two groups (Δ17. 0 ± 14. 0% vs 18. 3 ± 15. 0%), while no changes were detected at neck and hip levels. By contrast, TPT + MK-7 induced a higher T-score Δ at hip level than TPT (22. 2 ± 0. 5% vs 0. 4 ± 0. 2%, P = 0. 0374). Long-term TPT as well as TPT + MK-7 did not prevent skeletal muscle mass reduction, evaluated as appendicular skeletal muscle index (ASMI; 5. 76 ± 0. 82 vs 5. 51 ± 0. 74 kg/m^2; P = 0. 0018; Δ − 3. 9% per year) and lean mass/height^2 (LMH; 14. 2 ± 1. 6% vs 13. 9 ± 1. 6%, P = 0. 0156) by DXA, as well as muscle strength loss by handgrip test (17. 5 ± 5. 8 vs 15. 7 ± 3. 9 kg, P = 0. 0715). Besides, the trunk/limb fat mass ratio increased, though circulating leptin levels decreased. Finally, TPT treatment induced a significant increase in insulin sensitivity evaluated by oral glucose tolerance test (OGIS index, 427. 7 ± 82. 7 vs 474. 0 ± 81. 4 μmol/min/m^2, P = 0. 0102). In Conclusions, long-term TPT increases γ_3OC and γ_0OC circulating levels and lumbar T-scores and prevents new fractures, improves peripheral insulin sensitivity and decreases leptin levels; however, it does not protect from aging-related loss of muscle mass and strength. MK-7 supplementation amplifies the TPT-induced increases of circulating γ_3OC levels and hip T-scores, but it does not affect glucose metabolism as well as body composition in normoglycemic severe osteoporotic elder patients.

Prevention and treatment of hypocalcaemia in children undergoing total thyroidectomy

Ariana Marques[1], Joana De Beir[1], Joana Lopes[2], Inês Rua[1], Joana Serra Caetano[1], Rita Cardoso[1], Isabel Dinis[1] & Alice Mirante[1]
[1]ULS Coimbra, Pediatric Endocrinology, Diabetes and Growth Unit of the Pediatric Hospital of Coimbra, Coimbra, Portugal; [2]ULS Coimbra, Pediatric Surgery and Burns Service of the Pediatric Hospital of Coimbra, Coimbra, Portugal.

Background
Hypocalcaemia due to hypoparathyroidism is one of the most common complications of total thyroidectomy in the paediatric population. Early screening and postoperative monitoring are crucial to minimise long-term complications.
Aim
To evaluate the incidence of hypocalcaemia in paediatric patients submitted to total thyroidectomy, to identify associated risk factors, and to improve the screening protocol implemented at our centre since 2020.
Methods
Retrospective cohort study including all children submitted to total thyroidectomy, at our centre, from 1st January 2020 to 30th June 2024, without any conditions affecting calcium homeostasis and with a minimum follow-up period of 6 months after surgery. Demographic, clinical, surgical and laboratory data were collected from the patient's medical records. A comparative statistical analysis was subsequently performed between children who developed hypocalcaemia and those who did not, using SPSS®, with a significance level set at $P < 0.05$. Transient hypocalcaemia (< 8. 5mg/dL) was defined as resolved within 6 months post-surgery.
Results
A total of 19 paediatric patients underwent total thyroidectomy, 68. 4% of whom were female, with a median age of 15. 2 years (IQR 3. 3). Indications for surgery included malignant neoplasm (n = 8), hyperthyroidism (n = 5), multinodular goitre (n = 3), and prophylactic thyroidectomy due to genetic risk of neoplasia (n = 3). The median hospital stay was 5 days (IQR 1. 25). Only 8 children had blood samples taken in the recovery room 60 minutes post-surgery, and only 8 received vitamin D supplementation at least one week prior (ranging from 10 to 435 days). Hypocalcaemia occurred in 68. 4% of the cases (n = 13), all within the first 24 hours post-surgery. Three patients developed paresthesia. Hypocalcaemia was transient in 9 cases (4 resolving during hospitalisation) and permanent in 4. Patients with hypocalcaemia had significantly lower preoperative vitamin D levels (19 vs 31 ng/mL, P = 0, 033) and a greater decrease in baseline calcium levels (-1. 3 vs -0. 8 mg/dL, P= 0, 046). ROC curve analysis to predict hypocalcaemia demonstrated an AUC of 0. 929 (P = 0. 040) for preoperative vitamin D (with an optimal cut-off using Youden Index of 25. 5 ng/mL) and 0. 788 (P = 0. 048) for calcium drop (cut-off of -1. 15 mg/dL).
Conclusion
The importance of screening and managing for post-total thyroidectomy hypocalcaemia is emphasised. This includes vitamin D supplementation for all children prior to elective surgery and monitoring calcium and PTH levels in the postoperative period, beginning in the recovery room, in order to identify at-risk patients early. We recommend multicentre studies to confirm these findings and enhance the intervention protocol.

X-linked hypophosphatemic rickets in children and adolescents - single centre expertise in romania

Iuliana Gherlan[1], Radomir Lidia[2], Madalina Boboc[2], Adelina Badici[3], Alexandru Oproiu[4] & Camelia Procopiuc[5]
[1]Carol Davila University of Medicine and Pharmacy, C. I. Parhon National Institute of Endocrinology, Pediatric Endocrinology, Bucharest, Romania; [2]C. I. Parhon National Institute of Endocrinology, Bucharest, Romania; [3]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [4]C. I. Parhon National Institute of Endocrinology, Radiological Department, Bucharest, Romania; [5]C. I. Parhon National Institute of Endocrinology, Bucharest, Romania.

Introduction
XLH is a rare, genetic, chronic, progressive, lifelong musculoskeletal disorder characterised by renal phosphate wasting caused by excess FGF23 activity. It has biological and clinical consequences since early childhood: hypophosphatemia, low active vitamin D, craniosynostosis, rickets, bone deformity, short stature, and nephrolithiasis. The inheritance pattern of XLH is X-linked dominant, and the total incidence of XLH (paediatrics and adults) is 1 in 20, 000. There are two main therapeutic options: conventional therapy (phosphate supplements and active vitamin D) and biological therapy (Burosumab, a specific antibody against FGF23, EMA approved since 2018).
Subjects and Methods
Between 2018 and 2024, 13 children (7 girls) (median age = 4. 1 years, 1. 8-6. 8 years) and 1 adolescent girl were diagnosed and treated for XLH in a tertiary centre of pediatric endocrinology. Clinical, biological and radiological parameters were measured every 3-6 months: height, bone deformity, cranial circumference, 6MWT, serum calcium, phosphate and alkaline phosphatase, serum 25 OHvitamin D, PTH, TRPh, rickets severity score (RSS) and mechanical and anatomical axis of the lower legs.
Results
The children were first treated with conventional therapy and then switched to biological treatment after a median time of 4. 2 years. The main reasons for therapeutic alternatives were unimproved short stature and low leg deformity needing orthopaedic correction. None of the children on conventional therapy developed nephrolithiasis. After a median time of 2. 3 years (0. 5-3. 5 years), Burosumab treatment (median dose 1 mg/kg) showed a clear improvement of the clinical, biological and radiological data: an average 0. 425 SDS at week 96 improvement of Z-score for height, a constant increase of serum phosphorus to low normal levels, a constant decrease of alkaline phosphatase. Minor local reactions at injection sites or flu-like symptoms were described in the first doses but without clinical significance. None of the children needed orthopaedic correction. None of the children developed hyperparathyroidism.
Conclusions
Although a rare disease, XLH can be easily identified, evaluated, and treated by multidisciplinary teams from specialised bone disorders children's centers.

From highs to lows: the challenge of hypocalcemia after parathyroid carcinoma surgery

Anca Matei[1], Ilona Stafie[2], Alina Schiopu[2], Stefana Bilha[1, 2], Diana Martiniuc[2] & Preda Cristina[1, 2]
[1]"Grigore T. Popa "University of Medicine and Pharmacy, Endocrinology, Iasi, Romania; [2]"Saint Spiridon"Hospital Iasi, Iasi, Romania

Background
Parathyroid carcinoma is a rare but aggressive cause of primary hyperparathyroidism (PHPT), accounting for <1% of cases. Its delayed diagnosis often results in severe phosphocalcic imbalance, leading to marked hypercalcemia, skeletal destruction, and end-organ damage. Surgical resection is the only curative treatment, but postoperatively hungry bone syndrome (HBS) frequently complicates recovery, prolonging hypocalcemia due to excessive mineral uptake by bones.
Case Presentation
A 36-year-old underweight female (body mass index = 16. 4 kg/m^2) with facial dysmorphia and feeding difficulties, presented after four years of progressive, uninvestigated right mandibular and left maxillary swellings, found to be large (10 cm) brown tumors with maxillary sinus invasion on cone beam computed tomography. Laboratory findings revealed severe hypercalcemia (Calcium = 14. 2 mg/dL), markedly elevated parathormone (PTH) (780. 8 pg/mL), and hypercalciuria (779 mg/24h), confirming PHPT. Ultrasonography identified a 1. 52 × 1. 74 × 4 cm hypoechoic, inhomogeneous left superior parathyroid lesion, with intense Technetium -99m MIBI uptake, highly suspicious for malignancy. PHPT complications included forearm osteoporosis and bilateral nephrocalcinosis with stage 3 chronic kidney disease. She underwent emergency total en bloc thyroidectomy with removal of three parathyroid glands. Histopathology confirmed parathyroid carcinoma (pT2N0L0V1Pn1) in the left superior gland, with hyperplasia in the left inferior and right superior glands. Despite preoperative vitamin D supplementation, intensive hydration, andavoiding bisphosphonates, severe HBS developed (Calcium=5, 1 mg/dl; Magnesium=1, 7 mg/dl; Phosphorus=2. 3mg/dl; Alkaline Phosphatase = 467 U/l, after the PTH postsurgical drop (2, 4 pg/ml). She required prolonged high-dose IV and per os calcium (up to 2500 mg calcium element daily), high doses of calcitriol, and magnesium supplementation with multiple dose adjustments for three months. MEN syndromes were excluded. A six-month follow-up is scheduled to assess brown tumor regression and determine if surgical correction for skeletal damage is necessary. Lifelong multidisciplinary follow-upwill monitor forrecurrence, phosphocalcic balance, and end-organ damage.
Conclusion
Delayed diagnosis led to severe pre- and postsurgical phosphocalcic imbalance and severe skeletal and renal complications. Identifying risk factors for malignancy guided the choice of an optimal surgical approach. However, despite close monitoring and intensive management, metabolic rebalancing was prolonged. Long-term multidisciplinary follow-up is essential for bone recovery, and recurrence monitoring.

Biochemical ratios for predicting primary hyperparathyroidism: revisiting simple yet powerful diagnostic tools

Fatma Tuğçe Şah Ünal[1], Özgür Demir[1], Rifat Emral[1] & Asena Gökçay Canpolat[1]
[1]Ankara University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Türkiye

Background
The differentiation of primary hyperparathyroidism (PHPT), normocalcemic primary hyperparathyroidism (NPHPT), and vitamin D deficiency-associated secondary hyperparathyroidism (VDSHPT) remains a diagnostic challenge. This study evaluates the diagnostic performance of biochemical markers in distinguishing these conditions.
Methods
This cross-sectional study included 437 participants categorized into PHPT (n = 161), NPHPT (n = 97), VDSHPT (n = 89), and control (n = 90) groups. Serum calcium (Ca), phosphate (P), chloride (Cl), parathyroid hormone (PTH), and vitamin D levels were analyzed, along with biochemical indices such as Cl/P, Ca/P, Ca × Cl/P ratios, and the PF Index (Ca × PTH/P). Patients with chronic kidney disease, malignancy, or medication use affecting calcium and PTH metabolism were excluded. Receiver operating characteristic (ROC) curve analysis was used to determine diagnostic accuracy.
Results
Calcium levels were highest in PHPT (2. 73 ± 0. 17 mmol/l, P < 0. 001), while phosphate levels were lowest (0. 70 ± 0. 19 mmol/l, P < 0. 001). PTH levels were significantly elevated in PHPT (164. 9 ± 73. 4 pg/mL), NPHPT (126. 0 ± 40. 4 pg/mL), and VDSHPT (134. 9 ± 49. 2 pg/mL) compared to controls (43. 2 ± 14. 0 pg/mL, P < 0. 001). The Ca/P ratio was highest in PHPT (4. 17 ± 1. 21), significantly differing from other groups (P < 0. 001). The Ca × Cl/P ratio was also significantly elevated in PHPT (448. 5 ± 133. 6) compared to controls and other hyperparathyroidism subtypes (P < 0. 001). No significant differences were observed between NPHPT and VDSHPT for Ca/P (P = 0. 63) and Ca × Cl/P (P = 0. 74) ratios. The Ca × Cl/P ratio exhibited the highest diagnostic accuracy for PHPT (AUC: 0. 876, 95% CI: 0. 834–0. 917), with a specificity of 89. 2% and PPV of 82. 2%. The Ca/P ratio had the highest sensitivity (77. 6%) and an NPV of 86. 6%. The PF Index (AUC: 0. 851, 95% CI: 0. 816–0. 886) and Cl/P ratio (AUC: 0. 766, 95% CI: 0. 711–0. 820) showed moderate accuracy. In contrast, all markers showed high sensitivity (100%) but extremely low specificity (1. 6–23. 2%) in NPHPT, with poor PPV (<27%) despite maintaining an NPV of 100%.
Conclusion
The Ca × Cl/P and Ca/P ratios demonstrate strong diagnostic value for PHPT, while biochemical markers have limited specificity in NPHPT. These findings highlight their role in screening but emphasize the need for additional diagnostic approaches.

Bone marrow stem cells derived exosomes for osteoporosis treatment

Simge Eren[1], Naz Ünsal[2], Merve Yıldırım[2] & Olcay Eren[3]
[1]Şişli Etfal Research and Training Hospital, Pediatric Endocrinology, İstanbul, Turkey, Pediatric Endocrinology, İstanbul, Türkiye; [2]Yeditepe University Biotechnology Department, Biotechnology Department, İstanbul, Türkiye; [3]Fatih Sultan Mehmet Research and Training Hospital, Department of Orthopedics and Traumatology, Yeditepe University, Department of Biotechnology, Biotechnology Department, İstanbul, Türkiye

Introduction
Osteoporosis is a systemic bone metabolic disorder caused by reduced bone formation and increased bone resorption. Currently, there are several anti-resorption drugs and osteosynthesis drugs that are effective in the treatment of osteoporosis, but their use is limited due to contraindications and side effects. In regenerative medicine, the unique repair ability of mesenchymal stem cells (MSCs) has gained significant attention from researchers. The exosomes secreted by MSCs possess signal transduction and molecular delivery mechanisms, which may have therapeutic effects.
Methods
MSCs were initially isolated from human bone marrow. After the surface antigen of MSCs was identified using flow cytometry, MSC-derived exosomes (MSC-Exo) were extracted. The osteogenic and adipogenic differentiation abilities of BMSCs were assessed using alizarin red staining and oil red O staining, respectively. Quantitative reverse transcriptase-polymerase chain reaction (qRT-PCR) was employed to analyze the mRNA expression of various genes. The cell viability of osteoblasts was determined using the Cell Counting Kit-8 (CCK-8) assay. Western blotting was used to measure the expression of specific surface markers in exosomes and the MAPK pathway-related proteins in osteoblast cells. Additionally, the cell cycle of osteoblasts was analyzed by flow cytometry.
Results
We found that surface antigens were positively expressed in MSCs, indicating a strong multipotent differentiation ability. The isolated MSC-Exo exhibited typical exosome morphology and particle size, with the detection of specific surface-labeled proteins being positive under electron microscopy. After co-culturing MSC-Exo with the osteoblast cell line, we observed that MSC-Exo could promote the proliferation of osteoblast cells. Additionally, mRNA and protein expression levels in the cells were increased, and the cell cycle was also enhanced.
Conclusion
MSCs-derived exosomes have the potential to promote osteoblast proliferation by inhibiting cell apoptosis, ultimately improving osteoporosis. We suggest that MSCs-derived exosomes could be a promising therapeutic approach for osteoporosis in the future.

Jaw tumor syndrome: a rare endocrine disorder with diverse clinical manifestations

Leonor Rodrigues[1], Margarida Sobral[2], Bárbara Jesus[2], Diana Catarino[2], Sofia Gouveia[2], Luís Cardoso[2], Miguel Melo[2] & Leonor Gomes[2]
[1]ULS Região de Aveiro, Aveiro, Portugal; [2]ULS Coimbra, Coimbra, Portugal

Jaw Tumor Syndrome (JTS) is a rare, autosomal dominant endocrine syndrome caused by pathogenic variants of the **CDC73 gene**. The most common manifestation is primary hyperparathyroidism (PHPT), due to adenoma or, more rarely, parathyroid carcinoma. Other manifestations include ossifying fibromas of the jaw, renal cysts and tumors, as well as uterine conditions. However, a concomitant diagnosis of pheochromocytoma has not been identified to date. The clinical case of a 56-year-old woman is presented. She was referred to the Endocrinology department in 2004 due to hypercalcemia and bilateral kidney stones. There were no other significant personal or family medical histories. After investigation, she was diagnosed with primary hyperparathyroidism and underwent a left inferior parathyroidectomy (pathological examination confirmed it was a parathyroid adenoma), along with a left lobectomy and isthmectomy (consistent with nodular thyroid hyperplasia). About two years after the parathyroidectomy, she presented with a progressively worsening expansive lesion of the right upper jaw, causing bone destruction. She underwent surgical intervention, and the diagnosis of a cemento-ossifying fibroma was made. There were no recurrent lesions throughout imaging follow-up. Additionally, the patient had a history of endometrial and endocervical polyps and uterine fibroids (she underwent partial endometrial ablation). In 2008, due to newly developed and difficult-to-control hypertension, further studies were performed, including the measurement of plasma, urinary metanephrines and an abdominal CT scan revealed a 3. 5 cm nodule in the right adrenal gland. She underwent a right adrenalectomy, which confirmed a benign norepinephrine-producing pheochromocytoma. She remained asymptomatic until 2016 when she was hospitalized with a suspected diagnosis of MEN or hereditary pheochromocytoma/paraganglioma. A genetic study was conducted to look for mutations in the **SDHAF2, SDHB, SDHC, SDHD, MAX, TMEM127 and VHL** genes, but no relevant mutations were found. Given her personal history, a diagnosis of **JTS** was suggested. A subsequent mutational analysis of the **CDC73 gene** revealed an 8-base deletion in exon 16, resulting in the substitution of lysine with proline at position 474, leading to the appearance of a premature stop codon. Following this result, genetic testing was performed on family members, including her sister(**CDC73+ and diagnosed with a 6mm angiomyolipoma in the upper third of the left kidney**)and her mother (**negative genetic test result**). Her father passed away at very young age. Currently, the patient continues to follow up with the Endocrinology consultation, monitoring potential complications related to the syndrome. This case describes the complexity of diagnosing this rare syndrome, which should be considered in the presence of hyperparathyroidism and ossifying jaw tumors. The concomitant presence of pheochromocytoma, not described in the syndrome, made the definitive diagnosis more challenging.

Heterozygous WNT1 variant causing severe, adult-onset hereditary osteoporosis

Eeva Ryhänen[1], Tuula Pekkarinen[1], Heikki Kröger[2, 3], Xiaoyu Tong[3], Riikka Mäkitie[4], Outi Mäkitie[5 6 7] & Camilla Schalin-Jäntti[1]
[1]Department of Endocrinology, Abdominal Center, Helsinki University Hospital and University of Helsinki, Helsinki, Finland; [2]Orthopedics and Traumatology, Kuopio University Hospital, Kuopio, Finland; [3]Kuopio Musculoskeletal Research Unit, University of Eastern Finland, Kuopio, Finland; [4]Otorhinolaryngology, Head and Neck Surgery, Helsinki University Hospital and University of Helsinki, Helsinki, Finland; [5]Children's Hospital, Helsinki University Hospital and University of Helsinki, Pediatric Research Center, Helsinki, Finland; [6]Faculty of Medicine, University of Helsinki, Reseach Program for Clinical and Molecular Metabolism, Helsinki, Finland; [7]Folkhälsan Research Center, Helsinki, Finland

Osteoporosis primarily affects postmenopausal women and several secondary causes may predispose to osteoporosis in premenopausal women or males < 50 years. If no secondary causes are found, possible genetic causes should be considered despite adult age. WNT1-mutation related osteoporosis, a genetic form of osteoporosis is characterized by early-onset fragility fractures in childhood and a rather mild disease course. We describe a novel family with a different phenotype, that presented at adult age with multiple fractures and severe, progressive disease. Patient 1 A 27-year-old man presented with multiple vertebral fractures and 7. 5 cm height reduction. Dual-energy absorptiometry (DXA) Z-scores in the lumbar spine, femoral neck and total hip were -4. 6, -2. 6 and -2. 9, respectively. Biochemistry including calcium, phosphate and bone turnover markers was normal. After exclusion of secondary causes, we performed a genetic analysis revealing a heterozygous pathogenic *WNT1* variant (p. Cys218Gly) in exon 4 of Chromosome 2. This variant is known to result in reduced WNT1 signaling and impaired bone mineralization. Patient 2 At the same time, a 59-year-old woman, mother of patient 1, was referred because of several years of back pain and 7 cm height reduction. At presentation, she had multiple vertebral fractures and severe kyphosis. The first vertebral fractures were diagnosed three years earlier. DXA T-scores in the lumbar spine, femoral neck and total hip were -3. 2, -2. 7 and -2. 1, respectively. Secondary causes were excluded and genetic testing revealed that she carried the same *WNT1* mutation as her son. Histomorphometry analysis of transiliac bone biopsy after tetracycline double labeling showed low bone turnover in both patients. Patient 1 was started on denosumab 60 mg twice a year. During 3 years of follow-up, he has not suffered from further fractures. Also in patient 2, denosumab was initiated. A year later, BMD had improved markedly, however, she then suffered low-energy hip and humerus fractures. Sequencing of treatments was as follows; denusomab 18

months, followed by 5 mg of zoledronic acid and, 9 months later, initiation of romosozumab. Romosozumab is an anabolic osteoporosis medication that acts via WNT-signaling. The results of 6 months of treatments are available in March 2025. In conclusion, hereditary WNT1-mutation related osteoporosis can present with an adult-onset, severe and progressive phenotype.

Infantile idiopathic hypercalcemia associated with heterozygous mutation of SLC34A1: a case series

Ayse Pinar Ozturk[1], Alina Oprea[1], Helen Jones[2], Laura Halpin[3] & Alessandra Cocca[1]

[1]Evelina London Children's Hospital, Paediatric Bone and Endocrinology, London, United Kingdom; [2]Evelina London Children's Hospital, Paediatric Nephrology, London, United Kingdom; [3]Maidstone and Tunbridge Wells NHS Trust, General Paediatrics, Maidstone, United Kingdom

Objective

Idiopathic infantile hypercalcemia (IIH) is a rare clinical disorder defined by hypercalcemia, typically presenting with symptoms such as failure to thrive, dehydration, vomiting, nephrocalcinosis, and elevated calcium levels. Mutations in *SLC34A1*, which encodes the sodium-phosphate cotransporter (NPT2A), lead to phosphate depletion and dysregulated production of 1, 25-dihydroxyvitamin D, resulting in subsequent hypercalcemia. Here, we present three cases of IIH associated with mutations in the SLC34A1 gene.

Methods

The clinical and laboratory findings of three patients with IIH were analyzed retrospectively.

Results

All patients were asymptomatic at presentation, and hypercalcemia was detected incidentally. The first two patients were twins, both presented with hypercalciuria and nephrocalcinosis. The third patient had hypercalciuria but did not show nephrocalcinosis. A targeted next-generation sequencing panel for nephrocalcinosis/nephrolithiasis was conducted to investigate the underlying aetiology. Genetic analysis revealed that the twins had compound heterozygous mutations in *SLC34A1* (c. 644+1G>A/c. 398C>T p. (Ala133Val)), one of which was a pathogenic variant and the other variant of uncertain significance (VUS). The third patient had a monoallelic variant in *SLC34A1* (c. 272_292del p. (Val91_Ala97del)), which was likely pathogenic (Table-1).

Table 1. Clinical and laboratory findings of patients

	Family-1		Family-2
	Patient-1	Patient-2	Patient-3
Sex	Female	Female	Male
Gestational-age, week	29+4	29+4	41+3
Birth-weight, gr	1174	1261	3445
Consanguinity	No	No	No
Family-history of renal calcification	No	No	No
Family-history of hypercalcemia	No	No	No
History of vitamin D application	600 U/day (from birth to 10w)	NA	400 U/day (from birth to 2 month)
Symptoms	Asymptomatic	Asymptomatic	Asymptomatic
Age at initial assessment, months	12	12	2
Initial assessmentAdjusted-Ca(mmol/l) (normal-range 2. 2-2. 7)	2. 91	2. 97	2. 71

Renal-function Imaging-examination	Normal	Normal	Normal
Nephrocalcinosis	+	+	-
Skeletal abnormality	-	-	-
Treatment	Potassium-citrate	Potassium-citrate	None
Gene-analysis	Compound-heterozygous mutation in *SLC34A1* gene c. 644+1G>A/c. 398C>T p. (Ala133Val)		Heterozygous mutation in *SLC34A1* gene c. 272_292del p. (Val91_Ala97del)

Conclusion

In the presence of hypercalcemia accompanied by hypercalciuria, DNA analysis for mutations in the *SLC34A1* gene should be conducted. Heterozygous patients typically exhibit milder clinical symptoms compared to homozygous patients due to haploinsufficiency of NTP2A. Despite having a mild phenotype, they remain at risk for kidney damage and chronic kidney disease due to nephrocalcinosis and require close monitoring. Gaining a better understanding of the phenotypic and genotypic characteristics of this rare disease may help clarify its full spectrum over time.

Analysis of symptoms in paediatric patients with familial hypocalciuric hypercalcaemia, a case series

Naomi Howard-James[1], Mikaela Griffin[1], Sami Alanazi[1, 2], Susan O'Connell[1, 3] & Declan Cody[1]

[1]Children's Health Ireland Crumlin, Department of Paediatric Endocrinology, Dublin, Ireland; [2]Imam Abdulrahman Alfaisal Hospital, Riyadh, Saudi Arabia; [3]Royal College of Surgeons (RCSI), Dublin, Ireland

Background

Familial hypocalciuric hypercalcaemia (FHH) type 1 is caused by mutations in the *CASR* gene which encodes the calcium sensing receptor (CaSR). It is inherited in an autosomal dominant pattern with high penetrance. CaSR is highly expressed in parathyroid glands and kidneys and is an important regulator of calcium homeostasis. Inactivating/loss-of-function mutations in *CaSR* result in a decreased sensitivity of CaSR to serum calcium, leading to inappropriate PTH release with respect to hypercalcaemia. This PTH effect leads to an increase in renal tubular reabsorption of calcium. The net biochemical effect is of hypercalcaemia, with inappropriately normal or mildly elevated PTH and low urinary calcium. Well described symptoms of hypercalcaemia include nephrocalcinosis, gastrointestinal symptoms and fatigue. Conversely patients with FHH are often asymptomatic and this condition is usually identified incidentally. In terms of management, calcimimetic medications are allosteric agonists at CaSR. By enhancing the effect of extracellular calcium at the CaSR they consequently reduce serum calcium levels. However given the benign natural history of FHH, the necessity of these medications is controversial. Particularly in a paediatric population where safety and efficacy are not well established. We aimed to review symptomatology in our patients with FHH1 to add to the debate of whether treatment is required.

Methods

We retrospectively reviewed cases of patients with FHH1 actively attending our endocrine clinic. Patient demographics, calcium measurements and documented symptoms were collected. Data are mean $\pm$ standard deviation unless otherwise stated.

Results

11 participants were identified over the last ten years. All patients had confirmed *CaSR* heterozygous mutations. (45%) $n = 5$ patients from same kindred and remainder ($n = 7$) were unrelated. Diagnosis was made at age 5. 75 years $\pm$ 6. 07 and resulted from an incidental finding of hypercalcaemia in 72% ($n = 8$) and screening due to family history in 27% ($n = 3$). Serum calcium at diagnosis 2. 95 mmol/l $\pm$ 0. 10. Range of serum calcium over time 2. 66 to 3. 1 mmol/l. The most common symptom reported was constipation in 36% ($n = 4$). One patient reported polydipsia, all other patients ($n = 6$) were asymptomatic. All patients had normal renal ultrasound.

Conclusions

The majority of patients with FHH1 attending our service are asymptomatic of hypercalcaemia. Constipation was the only consistently reported symptom and given the prevalence of constipation in a paediatric population, causality from hypercalcaemia alone is unlikely. Given these findings, we have not considered calcimimetic medication for any of our patients. Further prospective studies to correlate calcium concentrations with symptoms is warranted for this paediatric cohort.

Secretagogin deficiency leads to gut microbiome dysbiosis and impairs thermogenesis in age-related diabetes via reduced 12,13-diHOME

Shuai Tan[1], Gaohui Zhu[1], Qi Liu[2], Jingjing Tian[1] & Li Li[1]
[1]Children's Hospital of Chongqing Medical University, Chongqing, China; [2]University of Texas Southwestern Medical Center, Dallas, USA

\[Type 2 diabetes (T2D) is increasingly recognized as a global pandemic. Secretagogin (SCGN), an EF-hand calcium sensor, plays a crucial role in hormone secretion across the pancreas, enteroendocrine cells (EECs), and neural compartments. While pancreatic SCGN expression has been linked to T2D, its role in EECs remains underexplored. In this study, we show that SCGN is significantly downregulated in the intestinal epithelial cells of both T2D patients and diabetic mice. Scgn deficiency in EECs of mice leads to age-associated diabetes by impairing thermogenesis in brown adipose tissue, attributed to reduced circulating levels of 12,13-diHOME, as revealed by metabolomics. Notably, the diabetic phenotypes and impaired heat production are alleviated in germ-free mice receiving stool transplants from Scgn-deficient mice, highlighting the critical role of gut microbiota. Additionally, we find a significant correlation between circulating 12,13-diHOME levels and brown adipose tissue activity in both diabetic patients and mouse models, with 12,13-diHOME levels being substantially lower than in healthy controls. Through extensive data from T2D patient stool transplants, we confirmed the correlation between butyrate in fecal samples and 12,13-diHOME levels in plasma. Our findings suggest that butyrate-producing microbiota can restore 12,13-diHOME levels, offering a promising therapeutic strategy for T2D. In conclusion, our study highlights the role of SCGN in EECs as an important cause of intestinal hormone secretion disorders and provides new insights into the complex interplay between microbiota dysbiosis and T2D.]

Diabetes type 1 can induce testicular atrophy with Leydig cell hyperplasia and germ cell depletion and therefore negatively influence reproductive function in rats

Isabel Viola Frielitz-Wagner[1,2], Nora Kloeting[3], Alexandra E Kulle[4], Olle Soeder[5] & Olaf Hiort[1]
[1]University Hospital Schleswig-Holstein, Campus Lübeck, Department of Paediatrics and Adolescent Medicine, Lübeck, Germany; [2]Klinikum Bremen Nord, Paediatric Endocrinology and Diabetology, Bremen, Germany; [3]University Hospital Leipzig, Helmholtz-Institute Munich, Leipzig, Germany; [4]University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany; [5]Karolinska Institute, Stockholm, Sweden

Research aim
Diabetes type 1 can negatively influence testicular function and fertility but the pathomechanisms on the testicular level remains to be elucidated. Therefore, the aim of the study was to evaluate effects of diabetes mellitus type 1 disease on testicular function.
Material and methods
BB/OKL rats developed type 1 diabetes during adolescence. One group received sufficient insulin treatment with excellent HbA1c levels, a second group insufficient amounts of Insulin and had a poor glycaemic control (8 rats per group). Leydig-, Sertoli-, and Germ-cell function was analysed on RNA and protein level. Furthermore, androgens were measured in serum samples and after extraction from testicular tissue with LC–MS/MS. Immunhistochemistry was performed and the inflammatory status and apoptosis was evaluated.
Results
After diabetes manifestation 25–33% of the rats developed testicular atrophy compared to none in the healthy control group. In the atrophic testis, we found a strong reduction of elongated and round spermatids and spermatocytes by more than 80%. Leydig cells showed a hyperplasia with a strong and significant upregulation of steroidogenic enzymes on RNA and on protein level (Star by 106%/94%, 3beta-HSD by 177%/203%, 17Beta-HSD by 276%/134%, CYP11A1 by 66%/65% and CYP17A by 1859%/2202%; all $P<0.001$). Furthermore, we measured significantly higher concentrations of androgens and INSL3 levels in the atrophic testis. In contrast, germ cells showed a depletion with a strong downregulation of DDX4 (by 78,19%/) and Crem (by 51,54%). In addition, we found a strong increase of oxidative stress, apoptosis and inflammation. SF-1 (+965%) and DHH (by 2575%) pathways were strongly upregulated in the atrophic testis and might me a possible pathomechanism.
Conclusion
Diabetes type 1 can induce testicular atrophy with germ cell depletion, apoptosis and increased inflammation. In parallel, Leydig cell hyperplasia develops with an upregulation of steroidogenic enzymes, and higher intratesticular testosterone levels. Therefore, diabetes type 1 can negatively influence reproductive function and fertility in male rats.

Assessment of metabolic status in adolescents with type 1 diabetes: the utility of the SPISE index

Mert Uçar[1], Didem Güneş Kaya[2], İlayda Altun[1], Hasan Karakaş[1], Gökçe Velioğlu Haşlak[1], Abdurrahman Güney[1], Elvan Bayramoğlu[1], Olcay Evliyaoglu[1] & Hande Turan[1]
[1]Istanbul University- Cerrahasa Faculty of Medicine, Department of Pediatric Endocrinology, Istanbul, Türkiye; [2]Istanbul University Cerrahpaşa Faculty of Medicine, Department of Pediatrics, Istanbul, Türkiye

Background and objectives
Body mass index(BMI) has limitations in assessing metabolic status in adolescents. Insulin-based methods are not applicable in patients with type 1 diabetes(T1D). The SPISE index, calculated using BMI, HDL, and triglyceride levels, has been proposed as a potential tool for monitoring metabolic status in adolescents with T1D.This study aimed to evaluate the efficacy of the SPISE index in assessing metabolic status in this population.
Methods
A total of 83 adolescents(aged 12–18 years,Tanner stage 5) with T1D for at least one year were included. Participants were categorized into three groups: underweight(-UW:BMI SDS <-1), normal(NW: $-1<$BMI SDS <1), and overweight(OW:BMI SDS >1). Baseline anthropometric measurements, daily insulin doses, HbA1c levels, lipid profiles, and body fat percentages (BFP) by bioelectrical impedance were noted. The SPISE index(SPISE $=600 \times HDL^{0.185}/(Triglyceride^{0.2} \times BMI^{1.338})$) was also used to assess the metabolic status. Standardized diet and exercise recommendations were provided, and all parameters were re-evaluated after 12 months.
Result
The study included 24(28.9%) underweight,36(43.4%) normal,and 23(27.7%) overweight participants. The median age was 15.7(14.4;17) years, and the median duration of diagnosis was 4.1(3.1;6.1)years. The age,gender and insulin delivery mode distributions were similar between the groups. The baseline and follow-up metabolic parameters of the groups are presented in **Table 1.** Notably,BFP and triglyceride levels in the UW group were found to have significantly increased compared to the OW. The SPISE index levels significantly decreased in both UW and NW groups compared to the OW group. Despite the absence of significant differences in HbA1c and daily insulin doses, deterioration in metabolic control was observed in UW and NW groups. Finally, linear regression analysis found a significant negative correlation between the BFP and the SPISE index in ($P=0.001$, $R^2=0.26$).

	Baseline(0.month)			Control(12.month)

Long-term beta-cell function and GLP-1 secretion after sleeve gastrectomy vs gastric bypass in patients with type 2 diabetes: the oseberg clinical trial

Jostein Wågen Hauge[1, 2], Jøran Hjelmesæth[1, 2], Heidi Borgeraas[1], Jens Kristoffer Hertel[1], Milada Hagen[1], Rune Sandbu[1], Marius Svanevik[1], Kåre Inge Birkeland[2], Hanne Løvdal Gulseth[3], Bolette Hartmann[4], Jens Juul Holst[4] & Dag Hofsø[1]
[1]Vestfold Hospital Trust, Department of Endocrinology, Obesity and Nutrition, Tønsberg, Norway; [2]University of Oslo, Oslo, Norway; [3]Norwegian Institute of Public Health, Oslo, Norway; [4]University of Copenhagen, Copenhagen, Denmark

Introduction
Bariatric surgery improves beta-cell function and insulin sensitivity in people with type 2 diabetes short-term. Comparative long-term data on the glycaemic effects of gastric bypass vs sleeve gastrectomy remain limited.
Methods
Prespecified secondary analyses of a two-armed, single centre, RCT conducted at Vestfold Hospital Trust (Norway). Adult patients with obesity and type 2 diabetes were randomised (1:1) to undergo either gastric bypass or sleeve gastrectomy and were followed for 5 years. The study assessed changes from baseline in beta-cell glucose sensitivity (modelled from c-peptide deconvolution), postprandial GLP-1 hormone profile, and intestinal absorption rate of paracetamol, using a 25g 180-minute oral glucose tolerance test (OGTT). Acute insulin response to glucose (AIRg) and peripheral insulin sensitivity (Si) were estimated with a 180- minute intravenous glucose tolerance test (IVGTT). Outcomes were assessed according to intention to treat principles utilizing generalized linear mixed models for repeated measures using identity link. Statistical analyses; Stata (version 18).
Results
A total of 109 patients were randomised to gastric bypass ($n = 54$) or sleeve gastrectomy ($n = 55$). The baseline demographic characteristics were comparable between the groups (mean age 47. 7 years [SD 9. 6], BMI 42. 3 kg/m^2 [5. 3], HbA1c 8. 1% [1. 7], and 72 [66%] were women). At 5-year follow-up, 73 (67%) participants underwent an OGTT and an IVGTT. During follow-up, beta-cell glucose sensitivity increased three-fold following gastric bypass, compared with a two-fold increase after sleeve gastrectomy, between-group difference 0. 35 pmol/kg/min/mmol (95%CI [0. 01 to 0. 70]; $P = 0. 042$). The incremental area under the curve ($iAUC_{0-180}$) for GLP-1 increased after gastric bypass only, between-group difference 797 pmol/l*min (95%CI [172 to 1422]; $P = 0. 012$). AIRg increased two- to three-fold in both surgical groups (between-group difference: -54 mU/l per min [95%CI [-144 to 36], $P = 0. 239$]), and Si approximately doubled in each group (between-group difference: 0. 3 mU/l^{-1}*min^{-1} [95% CI -0. 4 to 1. 0, $P = 0. 358$]). Paracetamol peak concentration (C_{max}) was higher, whilst time to peak concentration (T_{max}) was shorter after gastric bypass than after sleeve gastrectomy, between-group difference 57 mmol/l (95%CI [44 to 71]; $P < 0. 001$) and -27 minutes (95%CI [-36 to -18]; $P < 0. 001$) , respectively.
Discussion
The insulin secretion and peripheral insulin sensitivity improved similarly during 5 years of follow-up after both surgical procedures. However, gastric bypass was associated with higher paracetamol and GLP-1 levels, and a greater insulin response to changes in glucose levels after an oral glucose-paracetamol load. This suggests accelerated gastric emptying, and a more pronounced influence on the entero-insular axis after gastric bypass as compared with sleeve gastrectomy.

Cathepsin s is elevated in pancreatic islets and plasma in new-onset type 1 diabetes and positively associates with systemic inflammatory cytokines

Simranjeet Kaur[1], Laila Ü. Demir[1], Caroline Frørup[1, 2], Jens Otto B. Madsen[3], Lars Krogvold[4], Ivan C. Gerling[5], Knut Dahl-Jørgensen[4], Martin Haupt-Jorgensen[6], Flemming Pociot[1], Joachim Størling[1], Jesper Johannesen[1, 3] & Tina Fløyel[1, 6]
[1]Steno Diabetes Center Copenhagen, Clinical & Translational Research, Translational Type 1 Diabetes Research, Herlev, Denmark; [2]Baker Heart and Diabetes Institute, Epigenetics in Human Health and Disease Program, Melbourne, Australia; [3]Herlev and Gentofte Hospital, Department of Pediatric and Adolescent Medicine, Herlev, Denmark; [4]Oslo University Hospital, Division of Paediatric and Adolescent Medicine, Oslo, Norway; [5]University of Tennessee, Department of Medicine, Memphis, United States; [6]Bartholin Institute, Rigshospitalet, Department of Pathology, Copenhagen, Denmark

BackgroundAccumulating data indicate that cathepsin proteases are implicated in the development and progression of type 1 diabetes (T1D). Several cathepsins are regulated by proinflammatory cytokines in human islets/β-cells and have functions in the β-cells. We recently showed that cathepsin S (CTSS) is induced and secreted from the β-cells during T1D, and that CTSS serum levels are elevated in children with new-onset T1D and autoantibody-positive siblings.
Aims
The aims were to investigate the pancreatic islet expression of the 15 human cathepsins during T1D and to further explore the biomarker potential of CTSS in new-onset T1D.
Methods
The cathepsin gene expressions were extracted from previously generated microarray data on laser-dissected pancreatic islets from individuals with new-onset T1D ($n = 5$) from the Diabetes Virus Detection (DiViD) study and donors with autoantibody-positivity (AAb+, $n = 12$), T1D ($n = 20$), type 2 diabetes (T2D, $n = 8$), and healthy controls ($n = 18$) from the network of Pancreatic Organ Donors (nPOD). Cathepsin expression levels were compared between the groups using one-way ANOVA and Fisher's LSD analyses. *P*-values were corrected for multiple comparisons. CTSS plasma levels were measured by ELISA at onset and 6 and 12 months after onset in a Remission cohort of children with new-onset T1D ($n = 73$) and analyzed for association with the inflammatory cytokines IFNγ, IL-1β, IL-6, IL-8, IL-10, IL-12p70, and TNFα, measured by MSD V-PLEX assays. A linear mixed effect model was used to evaluate changes between visits, and linear regression models were used to evaluate associations between CTSS and cytokines levels at the three time points. $P < 0. 05$ was considered statistically significant.
Results
Seven cathepsins were differentially expressed in islets from individuals with T1D as compared to healthy controls: *CTSD*, *CTSH*, *CTSL*, and *CTSS* in new-onset T1D, and *CTSA*, *CTSB*, and *CTSZ* after longer T1D duration (FDR-adjusted $P < 0. 05$). Only *CTSS* was induced in new-onset T1D. The CTSS plasma levels were decreased 12 months after onset compared to at onset ($P < 0. 05$) and 6 months after onset ($P < 0. 01$), after adjusting for age and sex. CTSS was positively associated with IFNγ (6 months, $P < 0. 001$), IL-10 (baseline, $P < 0. 05$; 12 months, $P < 0. 05$), and TNFα (baseline, $P < 0. 05$), after adjusting for age.
Conclusions
Several cathepsins are differentially expressed in the pancreatic islets during T1D. CTSS is elevated in both the islets and plasma in new-onset T1D and shows potential as an early biomarker of islet inflammation and T1D progression.

Challenges in managing MODY 12: a case report

Raghad M. Hussain[1], Bayan Alnassir[1] & Iman Algadi[1]
[1]College of Medicine, King Saud University, Division of Pediatric Endocrinology, Department of Pediatrics, Riyadh, Saudi Arabia

Introduction
Maturity-onset diabetes of the young (MODY) comprises a heterogeneous group of monogenic diabetes often misclassified as type 1 or type 2 diabetes. We describe a case of ABCC8-Mody with an atypical course and unexpected non-responsiveness to high-dose sulfonylurea therapy.
Case description
A 12-year-old girl initially presented at 8 years of age with polyuria, polydipsia, and weight loss. She had normal weight (10th percentile), and a BMI of 12 kg/m^2 with early puberty (Tanner stage II) and no signs of insulin resistance. Laboratory tests revealed severe hyperglycemia (29 mmol/l), normal pH (7. 37), mild-to-moderate ketonuria (+1–2), and HbA1c of 14%. She was diagnosed with new-onset type 1 diabetes (T1DM) and started intensive insulin therapy. During follow-ups, her diagnosis was reconsidered as a detailed family history uncovered early-onset diabetes in three maternal uncles and her grandmother, along with

hyperinsulinism in her younger brother—who had a confirmed ABCC8 mutation and underwent near-total pancreatectomy. Her insulin requirements were lower than expected (0. 6 – 0. 7 unit/kg/day at 10 months post-diagnosis) with an HbA1c of 8. 3%. Further evaluation showed mild positive insulin autoantibodies (0. 7 U/ml, cutoff <0. 4) while glutamic acid decarboxylase, zinc transporter 8, and islet cell antibodies were negative. Whole exome sequencing confirmed a pathogenic heterozygous autosomal dominant ABCC8 mutation, consistent with MODY 12. Given the typical sulfonylurea responsiveness in ABCC8-MODY, an inpatient trial of high-dose glibenclamide was initiated and titrated over 8 days to 2 mg/kg/day. However, she continued to require frequent insulin corrections (up to 1 unit/kg/day). After 3 days at the maximum dose, the trial was deemed unsuccessful. Over the subsequent year, her insulin needs increased to 1. 8 IU/kg/day (65% basal) amid factors such as pubertal insulin resistance, menarche, and insulin omission from diabetes burnout and psychosocial challenges. Her glycemic control deteriorated with HbA1c reaching to 10. 5%, compounded by an episode of severe diabetic ketoacidosis due to insulin omission. Emerging evidence supporting GLP-1 receptor agonists in ABCC8-MODY prompted a trial of liraglutide, which improved her time in range by 60% and allowed insulin dose reduction within 6 weeks. Gastrointestinal side effects led to a switch to weekly Semaglutide. Repeat autoantibody testing returned negative.

Discussion

This case underscores the management complexities of ABCC8-MODY in the presence of autoimmune positivity. The failure of sulfonylurea therapy suggests that autoimmunity may alter the therapeutic response, while GLP-1 receptor agonists show promise as an adjunct therapy in such complex cases.

Gut microbiota-derived indole-3-propionic acid alleviates diabetic kidney disease through its mitochondrial protective effect via reducing ubiquitination mediated-degradation of SIRT1

Yan Zeng[1, 2], Man Guo[1], Qi Wu[2, 3], Betty Yuen-Kwan Law[2], Yang Long[1] & Yong Xu[1, 2]
[1]The Affiliated Hospital of Southwest Medical University, Department of Endocrinology and Metabolism, Luzhou, China; [2]Macau University of Science and Technology, State Key Laboratory of Quality Research in Chinese Medicine, Faculty of Chinese Medicine, Macau, China; [3]The Affiliated Hospital of Southwest Medical University, Department of Pathology, Luzhou, China

Objective

Diabetic kidney disease (DKD) has a complex pathogenesis, and current therapies offer limited benefits. Gut-derived metabolites, particularly indole-3-propanoic acid (IPA), a deaminated derivative of tryptophan produced by gut bacteria, may play a role in DKD. This study aimed to assess serum metabolic alterations in DKD and explore the effects of IPA on glomerular endothelial cells (GECs) and mitochondrial function.

Methods

Untargeted metabolomics was employed to identify differentially expressed metabolites in DKD mouse serum, followed by validation in DKD patients using UHPLC-MRM-MS/MS. IPA supplementation was tested in high-fat diet combined with STZ-induced DKD mice to evaluate its effects on kidney morphology, glomerular filtration barrier integrity, fibrosis, and albuminuria. *In vitro*, high glucose-stimulated GECs were used to investigate IPA's impact on mitochondrial function, the PGC-1α pathway, and SIRT1 protein degradation.

Results

Metabolomics revealed significant alterations in tryptophan metabolism and its metabolites, including IPA. UHPLC-MRM-MS/MS analysis confirmed reduced IPA levels in DKD patients, which were negatively correlated with fasting blood glucose, HbA1c, and UACR, and positively correlated with eGFR. In DKD mice, IPA supplementation improved kidney structure, reduced fibrosis, enhanced glomerular filtration barrier integrity, and decreased UACR. IPA also alleviated mitochondrial abnormalities in GECs, increasing mitochondrial quantity and ATP, while reducing oxidative stress markers such as malondialdehyde (MDA). *In vitro*, IPA reduced ROS and MDA in GECs, improved mitochondrial membrane potential and ATP levels, and upregulated mtTFA and SOD2 expression. Additionally, IPA inhibited SIRT1 degradation via the ubiquitin-proteasome pathway, leading to increased SIRT1 levels and activation of the SIRT1/PGC-1α pathway, which enhanced mitochondrial biogenesis and antioxidant defense.

Conclusions

IPA, a gut-derived metabolite, is reduced in DKD and correlates with UACR. IPA supplementation alleviates albuminuria in DKD by improving mitochondrial function, reducing oxidative stress, and activating the SIRT1/PGC-1α signaling pathway. These findings suggest that IPA is a potential therapeutic target for DKD, offering new insights into renal protection through enhanced mitochondrial biogenesis and antioxidant capacity.

Leukocyte telomere length as a potential indicator of early kidney dysfunction in persons with type 2 diabetes

Viktoriia Yerokhovych[1], Yeva Ilkiv[1], Olena Karpenko[1], Vitalii Gurianov[1], Dmytro Krasnenkov[2], Tetiana Tsema[1], Oksana Sulaieva[3, 4], Maryna Bobryk[1], Iuliia Komisarenko[1] & Nazarii Kobyliak[1, 3]
[1]Bogomolets National Medical University, Kyiv, Ukraine; [2]Institute of Gerontology Academy of Medical Sciences of Ukraine, Kyiv, Ukraine; [3]Medical Laboratory CSD, Kyiv, Ukraine; [4]Kyiv Medical University, Kyiv, Ukraine

Background

Leukocyte telomere shortening can occur as a result of both natural age-related changes in the body and various damaging factors. The study of laboratory indicators reflecting age-related changes in chronic kidney disease (CKD) patients serves as an important tool for assessing disease progression and predicting future risk. The search for new markers of kidney damage and factors influencing CKD progression remains highly relevant. Recently, increasing research attention has been given to the role of leukocyte telomere length in various pathological conditions, including systemic inflammation, atherosclerosis, complications of infectious diseases, apoptosis, and aging processes.

Aim

In our study, we examined the relationships between early markers of kidney damage and relative leukocyte telomere length (RTL) in individuals with type 2 diabetes (T2D).

Methods

Our study involved 86 individuals with T2D, who were categorized into two groups on the basis of their estimated glomerular filtration rate (eGFR): Group I ($n = 21$) with an eGFR < 60 ml/min/m^2 and Group II ($n = 65$) with an eGFR ≥ 60 ml/min/m^2. The standardized method proposed by Cawthon *et al*. was used to measure RTL.

Results

The analysis of RTL in relation to the eGFR revealed a significant difference between the patient groups (1. 10 (0. 97–1. 18) vs 1. 18 (1. 06–1. 41) in group I and group II, respectively; $P = 0. 031$). A significant positive correlation between RTL and eGFR was observed only in the reduced eGFR group ($r = 0. 44$; $P = 0. 042$). In the multivariate logistic analysis, RTL, albumin-to creatinin ratio in daily urine, and T2D duration were found to be independent predictors of decreased eGFR (< 60 ml/min/m^2). The AUROC of the model was 0. 79 (95% CI 0. 684 - 0. 897; p <0. 001), with a sensitivity of 71. 4% and a specificity of 73. 8%.

Conclusion

RTL shortening, a longer duration of T2D, and the presence of albuminuria are early prognostic factors independently associated with a decline in renal function in patients with diabetic kidney disease (DKD). Early detection of DKD and an understanding of the predictors of eGFR impairment progression can help reduce the risk of severe complications that significantly impact patients' quality of life. Timely diagnosis can prevent or substantially slow irreversible changes in the eGFR and enable the initiation of treatment in the early stages of DKD.

Background
Individuals with schizophrenia face a 10 to 20-year reduction in life expectancy, primarily due to cardiovascular disease (CVD) and obesity-related type 2 diabetes (T2D). These risks may be exacerbated by treatment with second-generation antipsychotics (SGAs), which may cause obesity and thereby diminish quality of life (QoL). Semaglutide, a GLP-1 receptor agonist approved for obesity has demonstrated significant efficacy in promoting weight loss, and reducing the prevalence of T2D and risks for CVD. Therefore, this trial evaluated whether once-weekly semaglutide improves HbA1c, reduces weight, and enhances mental health and QoL in prediabetic, overweight/obese SGA-treated patients with schizophrenia.
Methods
We conducted a double-blind, randomized, placebo-controlled trial involving 154 adults, aged 18-60 years, with BMI $\geq$27 kg/m^2, SGA-treated schizophrenia, and prediabetes (HbA1c: 39–47 mmol/mol). Participants were randomized (1:1) to receive once-weekly semaglutide or placebo, titrated to 1. 0 mg or maximally tolerated dose, over 30 weeks.
Outcomes
In total, 151 participants completed randomization (semaglutide group: 74; placebo group: 77). Intention-to-treat analysis demonstrated that semaglutide reduced HbA1c by 5. 07 mmol/mol (95% CI: -6. 05 to –4. 09) and body weight by 9. 21 kg (95% CI: -11. 68 to -6. 75) compared to placebo. Furthermore, 81% in the semaglutide group vs. 19% in the placebo group obtained an HbA1c $<$39 mmol/mol ($P < 0.001$). The semaglutide group improved physical QoL scores (SF-36) by 3. 6 points (95% CI: 1. 4 to 5. 8), but changed neither mental QoL scores nor psychiatric symptoms outcomes. Finally, the semaglutide group had higher incidence of gastrointestinal symptoms, but experienced no worsening in somatic or mental serious adverse events.
Interpretation
Semaglutide appears safe as adjunct therapy for SGA-treated patients with schizophrenia, prediabetes, and overweight/obesity. During 30 weeks, semaglutide significantly improved glycemic control, promoted weight loss, and enhanced physical QoL without adversely affecting mental health. These findings highlight its potential role in mitigating cardiometabolic risks in this high-risk population.

Introduction
In 2022, type 1 diabetes (T1D) prevalence in youth was estimated at 1. 52 million, listing it among the most common pediatric chronic conditions. The T1D pediatric population has been identified to be at higher risk of cardiovascular morbidity and mortality. Lower cardiorespiratory fitness (VO_2 peak) has been associated with higher cardiovascular mortality in the adult population. However, no studies have examined the effect of VO_2 peak on early markers of cardiovascular disease in youth with type 1 diabetes.
Objective
To assess the association between VO_2 peak and early markers of CVD in adolescents with and without T1D and determine differences across groups.
Methods
This is a cross-sectional study conducted in the CARDEA cohort consisting of adolescents (14-18 years of age) with T1D ($n = 100$) and without T1D ($n = 97$). VO_2 peak was measured on an electromagnetic bicycle during an incremental exercise test. The morphological cardiac outcomes were assessed using cardiac magnetic resonance imaging. For vascular outcomes, flow-mediated dilation was used to evaluate endothelial function, and arterial stiffness was estimated using pulse-wave velocity. Multivariable linear regressions were adjusted for age, sex, ethnicity, diabetes, household income, physical activity (accelerometry), and heart rate. Differences between groups were tested using an interaction term between T1D status and VO_2 peak.
Results
In comparison to the control group, adolescents with T1D had a lower VO_2 peak, MVPA and familial income, while they had higher daily screen time. A higher VO_2 peak was associated with higher left ventricle (LV) papillary mass (0. 04 g; 95% CI: 0. 01; 0. 06) and LV end-systolic volume (0. 37 mls; 95% CI: 0. 07; 0. 67) . In contrast, higher VO_2 peak was associated with a lower LV wall thickness (-0. 10 mm; 95% CI: -0. 19, -0. 01). There were no meaningful associations between VO_2 peak and endothelial function or arterial stiffness. No differences in associations were found between T1D participants and controls.
Conclusion
Overall, adolescents with T1D had lower cardiorespiratory fitness and poorer lifestyle habits compared to controls. Our results indicate that higher cardiorespiratory fitness is linked to favorable cardiac morphology but not vascular function, irrespective of T1D status.

JOINT2673

Parental perception on immunotherapy for children at risk of type 1 diabetes and islet cell transplantation/stem cell therapy for children with type 1 diabetes

Candy Chan[1], Iris Poon[1], Irene Lok[1], Sarah Poon[1], Gloria Pang[1] & Joanna Tung[1]
[1]Hong Kong Children's Hospital, Department of Paediatrics and Adolescent Medicine, Hong Kong, China

Aim
This study aims to evaluate parental perception on immunotherapy to delay onset of diabetes for siblings at risk of type 1 diabetes (T1D), as well as examine parents' viewpoints on islet cell transplantation and stem cell therapy for children with established T1D. Understanding these viewpoints is essential for integrating novel treatments into clinical practice locally.
Method
A survey was administered to parents of children diagnosed with T1D at the Hong Kong Children's Hospital from October to December 2024. 9 questions assessing their awareness of these treatments, willingness to consent for their use, as well as concerns regarding long term safety were included.
Results
34 parents were surveyed in the study period. The mean age of their children (53% male) was 11. 7 and mean diagnosis duration was 5. 3 years. 70. 6% were on multiple daily injections while the rest were on insulin pump therapy. 73. 5% showed readiness for autoantibody screening for siblings, despite awareness on potential impact on insurance coverage. 47% of the parents were aware of immunotherapy for predisposed siblings, with 59% expressing readiness to consent to administration for their child if they were found to be at risk. Reasons for not considering immunotherapy included concern on side effects (71. 4%), unknown long-term side effects (71. 4%), inadequate knowledge about the therapy (35. 7%), doubts about its effectiveness (35. 7%), logistical issues related to time and transportation (21. 4%), and concern on required treatment duration of 14 days (21. 4%). Regarding novel methods of beta cell replacement, 55. 9% and 64. 7% of the respondents were aware of islet transplantation and stem cell therapy respectively. 67. 6% of the parents accepted these treatments for their child with diabetes. Reasons for not considering these therapies included safety concerns (60%), doubts about the effectiveness (60%),

inadequate knowledge about these options (50%) and a preference for lifelong insulin injections over immunosuppressant (40%).
Conclusion
Our findings showed that local parents had a moderate awareness on novel therapies for diabetes. While majority accepted these treatments, safety and efficacy profile were most concerning for them. These findings highlighted the importance of integrating parental perspectives into the development of treatment protocols for T1D. Future research should focus on creating targeted educational initiatives that empower parents in navigating innovative treatment options for their children.

Can diabetes self-management applications replace continuous glucose monitoring in low-resource environments?"
Nancy Samir Elbarbary[1], Mohamed Mohamed[1] & Yasmeen Fereig[1]
[1]Department of Pediatrics, Faculty of Medicine, Ain Shams University, Cairo, Egypt

Background
The "Rightest" app connected to Right test glucose meter via Bluetooth, helps to set blood glucose target and customize measurements. The app is provided with ketone alert when BG is $\geq$ 240 mg/dl.
Aim of the Work
To assess the role of the rightest app in improving glycaemic control as well as quality of life in a 6- month interval of its usage.
Patients and Methods
A case- control study included 40 participants with type 1 diabetes, mean age 14. 3 ± 1. 42 years and diabetes duration of 4. 5 ± 3. 6 years regularly following up at Diabetes Unit. Rightest app was installed on the participants' smart phone on enrollment and 6 months later. Assessment of the glycemic control was done by HbA1c and time in range. Results collected from app Quality of life (PedsQL) and user experience (UEQ) Questionnaires were applied at the end of the study.
Results
Using smartphone app yielded a significant reduction in mean BG level (-17. 64%, $P = 0.012$) that decreased HbA1c (-10.63%, $p = 0.000$). Increase of SMBG frequency was observed ($P = 0.04$). This is reflected on a 20 % increment time in range generated by app (P-value = 0. 002) and lower time above range (TAR > 180mg/dl, -18. 75%, $P = 0.001$) in intervention group compared to control. However, the number of hypoglycemic events ($P = 0.71$) or DKA($P = 0.59$) did not differ between groups. PedsQL questionnaire total score has improved (P-value = 0. 010) in favor of intervention group with good experience with app indicated by UEQ. The pragmatic total score (1. 425) of UEQ was above average while the hedonic total score was good (1. 250) and overall score was good (1. 338). The higher score of UEQ was inversely correlated with mean BG ($r = -0.414$, $P = 0.008$) and positively correlated to glycemic control ($r = 0.644$, $P = 0.002$).
Conclusion
Using mobile apps as an alternative for CGM in low resource settings can help improve glycemic control and quality of life for those who don't have access to diabetes. technology services because of unavailability or unaffordability.

Comparison of moderate intensity atorvastatin and ezetimibe with high intensity atorvastatin on cardiovascular events and diabetes in patients with angina pectoris
Seo Young Sohn[1], Yunjin Kim[2], Jae Hyuk Lee[1] & Sung Woo Cho[3]
[1]Myongji Hospital, Hanyang University College of Medicine, Division of Endocrinology, Department of Internal Medicine, Goyang, South Korea; [2]Hanyang University College of Medicine, Biostatistics Lab, Medical Research Collaborating Center, Seoul, South Korea; [3]Inje University Ilsan Paik Hospital, Inje University College of Medicine, Cardiology, Goyang, South Korea

Background
The beneficial effect of moderate-intensity statin with ezetimibe combination therapy compared to high-intensity statin monotherapy in patients with angina pectoris undergoing percutaneous coronary intervention (PCI) remains unclear. We aimed to investigate the effect of moderate-intensity atorvastatin with ezetimibe combination therapy in patients with angina pectoris in real-world practice.
Methods
This retrospective cohort study used Korean National Health Insurance Database. A total of 6, 784 patients underwent PCI between 2015 and 2018 and received either moderate-intensity atorvastatin (10 and 20 mg) and ezetimibe 10mg ($n = 4, 682$) or high-intensity atorvastatin (40 and 80 mg; $n = 2, 102$). The primary outcome was a composite event of cardiovascular death, myocardial infarction, coronary revascularization, and stroke. The secondary outcome was newly developed diabetes. Subgroup analyses were performed based on baseline comorbidities.
Results
During the mean follow up of 4 years, the incidence rates of the primary outcome were 70. 14 vs. 62. 05 per 1, 000 person-years in the moderate-intensity atorvastatin and ezetimibe group and the high-intensity atorvastatin group, respectively. There were no significant differences in the risk of primary outcome between the moderate-intensity atorvastatin and ezetimibe group and the high-intensity atorvastatin group [hazard ratio (HR): 0. 99, 95% CI: 0. 90-1. 10]. The risk of new onset diabetes was not different between the two-treatment groups (HR: 0. 99, 95% CI: 0. 88-1. 13). However, in patients with underlying chronic kidney disease (CKD), moderate-intensity atorvastatin with ezetimibe combination therapy was associated with lower risk of primary outcome compared to the high intensity atorvastatin therapy (HR: 0. 40, 95% CI: 0. 18-0. 86).
Conclusion
In real-world cohort study, there was no significant difference in the cardiovascular outcome and new onset diabetes between moderate-intensity atorvastatin with ezetimibe combination therapy and high-intensity atorvastatin monotherapy in patients with angina pectoris undergoing PCI. Moderate-intensity atorvastatin with ezetimibe combination therapy may be beneficial particularly in patients with CKD.

To study the effect of medical nutrition therapy on school-time hyperglycemia and the glycemic outcomes in childeren with type 1 diabetes mellitus
Siddhnath Sudhanshu[1, 2], Archana K[2], Preeti Dabadghao[2] & Vijayalakshmi Bhatia[2]
[1]All India Institute of Medical Sciences, Patna, Additional Professor, Patna, India; [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India

Background
In resource-limited settings, poor support and non-compliance for school-time insulin, coupled with carbohydrate-rich breakfast and school-snacks, school-time is the most vulnerable period for hyperglycemia. Thus, appropriate nutritional intervention is a practical solution to the aforementioned problem. Medical nutrition therapy (MNT) in type 1 diabetes (T1D) is associated with improved glycemic outcomes. Hence, this study examines the effect of MNT on the glycemic outcomes in school going children with T1D.
Aim
The aim of this open-label randomized controlled trial was to determine the effectiveness of MNT in the form of appropriate carbohydrate and calorie containing breakfast and school-snacks, on the glycemic control during school hours, in children with T1D.
Methods
At the baseline, for a total of 60 children and adolescents with T1D, glycemic parameters were recorded using a continuous glucose monitoring system (CGMS) for 14 days along with the dietary records. In the RCT, the intervention group ($n = 30$) received carbohydrate content of 45-55% during breakfast and school-snacks whereas, the control group practiced the routine diet, for four weeks and reassessed with CGMS for 14 days with dietary analysis. The CGMS derived glycemic variables for the school-time and the whole day as well, were analyzed along with the dietary analysis for average dietary records, during the 14 days of CGMS. The primary outcome was to determine the difference in the time in range (TIR) between the intervention and control group.
Results
After the dietary modification provided in the intervention group, the carbohydrate content reduced significantly from 59. 9% to 50. 1% ($P = 0.01$) in the breakfast, and from 65. 5% to 52. 1% ($P = 0.002$) in the mid-morning snacks during the school-hours. The TIR significantly improved ($P = 0.018$) whereas, the time above range (TAR) significantly reduced ($P = 0.039$), in the intervention group. The TIR showed

significant improvement in the 24-hour CGMS profile as well ($P = 0.037$). Multivariate regression showed insulin requirement and change in carbohydrate percentage in the midmorning snacks had significant association with TIR. The intervention was safe as there was no significant increase in time below range (TBR) and no episode of severe hypoglycemia was recorded in the intervention group.

Conclusion

An appropriate reduction in carbohydrate content in breakfast and midmorning snacks improves TIR and reduces TAR during school hours in children with T1D who do not administer pre-snack insulin at school, with benefits extending to 24-hour profile. The MNT intervention was very effective in improving the overall glycemic outcomes and was safe as well.

The impact of regulatory-approved and open-source automated insulin delivery systems on glycemic control: real-world data from a heterogeneous population

Karin Dreifuss[1], Floris Levy-Khademi[2, 3], Carmit Avnon Ziv[2] & Adi Auerbach[2]

[1]Shaare Zedek Medical Center, Department of Pediatrics, Jerusalem, Israel; [2]Shaare Zedek Medical Center, Division of Pediatric Endocrinology, Department of Pediatrics, Jerusalem, Israel; [3]Hebrew University, The Faculty of Medicine, Jerusalem, Israel

Background

Type 1 diabetes leads to absolute insulin deficiency and necessitates lifelong insulin therapy. Despite advancements in diabetes care, achieving optimal glycemic control remains challenging. Automated insulin delivery (AID) systems are a breakthrough in diabetes management, improving glycemic outcomes and quality of life. While regulatory-approved systems are available, open-source systems—developed by patients for self-installation—offer an alternative that requires technical expertise and active engagement with support networks. This study uniquely evaluated the efficacy and safety of both systems in a real-world, heterogeneous population, including patients with limited technological literacy and restricted internet access— groups assumed to benefit less from open-source AID systems.

Methods

This cross-sectional study was conducted at Shaare Zedek Medical Center and involved children with type 1 diabetes. Glycemic control was assessed while the children were using an AID system, compared to a sensor-augmented pump. The change in glycemic control following the transition to the automated system was compared between two systems: the regulatory-approved Medtronic G780 and an open-source system (Android APS).

Results

Sixty-one children were included in the study- 30 using the approved system and 31 using the open-source system. Both groups showed significant improvements in glycemic control, including an increase in time in range and reduction in mean blood glucose, estimated HbA1c/Glucose Management Indicator (GMI) and time spent in hypo and hyperglycemia. A trend toward greater reduction in mean blood glucose and estimated HBA1C/GMI was observed in the regulatory approved system group. No significant differences in rates of severe hypoglycemia or diabetic ketoacidosis were observed between the two systems and before and after the transition to an AID system.

Conclusions

Real world data from a heterogeneous population demonstrates significant improvement in glycemic control with both regulatory-approved and open-source AID systems, with an acceptable safety profile. Notably, even patients with limited technological literacy achieved meaningful improvements using open-source systems. These findings highlight the adaptability and effectiveness of AID systems across diverse patient populations, emphasizing the importance of preserving patient autonomy in choosing the system that best suits their needs. However, the observed trend favoring the regulatory-approved system warrants further evaluation in larger trials.

Can insulin level measured by oral glucose tolerance test be a guide in the diagnosis of prediabetes?

Nilüfer Uyar[1], Ibrahim Mert Erbas[1], Fatma Yavuzyılmaz Şimşek[1], Özge Köprülü[1], Özlem Nalbantoğlu[1], Huseyin Anil Korkmaz[1] & Behzat Özkan[1]

[1]Health Sciences University, İzmir Dr. Behçet Uz Pediatric Diseases and Surgery Training and Research Hospital, Pediatric Endocrinology, İzmir, Türkiye

Background

In our study, we aimed to show the role of insulin level obtained by oral glucose tolerance test (OGTT) and insulin resistance in indicating dysglycemia and their correlation with HbA1c level.

Material and methods

The data of the cases who administered OGTT in our clinic between 2014 and 2024 were examined retrospectively. For OGTT, 1. 75 g/kg (maximum 75 g) dextrose was administered perorally and serum glucose and insulin levels were measured at 0. and 120. minutes. Insulin resistance was defined in those with serum insulin level >75 mU/l at 120. minutes. Results were presented as mean$\pm$standard deviation or median (25-75p) depending on the normality of the distribution.

Results

Of the 512 patients included in the study [median age 13. 7 (12 – 15. 5) years], 53. 9% were female and 93. 9% were pubertal. When the OGTT results of the patients were examined, insulin resistance was detected in 58% ($n = 297$). While the HbA1c level didn't show a significant difference when the cases were grouped according to obesity or insulin resistance ($p>0.05$), it was significantly higher in those with impaired glucose tolerance ($P < 0.001$). HOMA-IR, 0. and 120. minute insulin levels were found to be higher in obese patients, those with impaired glucose tolerance and those with insulin resistance than those without ($P < 0.05$). Impaired glucose tolerance was detected in 8. 2% of the group with normal HbA1c. For the diagnosis of insulin resistance, when the basal insulin level is taken as 23. 4 mU/l; It was found to have 80% sensitivity and 74% specificity (AUC$=0.829$, $P < 0.001$). When the 0. minute HOMA-IR upper limit for the diagnosis of insulin resistance is taken as 5. 6; it was observed that it had 78% sensitivity and 73% specificity (AUC$=0.817$, $P < 0.001$), and when the 120th minute HOMA-IR upper limit was taken as 19, it had 96% sensitivity and 94% specificity (AUC$=0.985$, $P < 0.001$). There was no significant relationship between HbA1c and insulin levels at 0. or 120. minutes ($p>0.05$).

Conclusion

In this study, we showed that the insulin level measured by OGTT isn't guiding in the diagnosis of prediabetes. Additionally, we found that the upper limit of basal fasting serum insulin level, which is used for insulin resistance especially in the pubertal period, can be lowered to less than 30 mU/l, but HbA1c isn't compatible with OGTT for the definition of insulin resistance. We evaluated that HOMA-IR can be used with high specificity and sensitivity in the definition of insulin resistance in children.

HDL Lipidome remodeling is linked to diabetic kidney disease progression independent of albuminuria severity

Aniele Cristine Ott Clemente[1], Aécio Lopes de Araújo Lira[1, 2], Carlos André Minanni[1, 3], Monique de Fátima Mello Santana[1], Marcos Yukio Yoshinaga[4], Sayuri Miyamoto[4], Maria Lucia Correa-Gianella[5], Márcia da Silva Queiroz[6] & Marisa Passarelli[1, 6]

[1]Universidade de São Paulo, Laboratório de Lípides (LIM10), Clínica Médica, São Paulo, Brazil; [2]Centro Universitário Uninovafapi, Faculdade de Medicina, Teresina, Brazil; [3]Hospital Israelita Albert Einstein, São Paulo, Brazil; [4]Universidade de São Paulo, Laboratório de Lipídeos Modificados e Bioquímica Redox, Instituto de Química, São Paulo, Brazil; [5]Universidade de São Paulo, Laboratório de Carboidratos e Radioimunoensaio (LIM18), Clínica Médica, São Paulo, Brazil; [6]Universidade Nove de Julho, Programa de Pós-Graduação em Medicina, São Paulo, Brazil

Background and Aims

Diabetic kidney disease (DKD) is associated with alterations in lipid and lipoprotein metabolism, worsening kidney function and increasing cardiovascular disease (CVD) risk. Changes in HDL composition, proteomics, and functionality have been reported in DKD. This study analyzed HDL lipidome in non-dialysis DKD patients, categorized by estimated glomerular filtration rate (eGFR) and urinary albumin excretion rate (AER), to identify potential biomarkers for DKD progression and CVD risk.

Methods

DKD patients were classified into three groups: EA1A2 (early-stage DKD, AER A1–A2, eGFR ≥ 45; $n = 21$), AA1A2 (advanced DKD, AER A1–A2, eGFR < 45; $n = 9$), and AA3 (advanced DKD, AER A3, eGFR < 45; $n = 24$). Age-matched controls (C; eGFR > 60, AER < 30; $n = 7$) were included. The study was approved by the local ethics committee, and all participants provided written informed consent. HDL was isolated by ultracentrifugation ($D = 1.063$–1.21 g/mL) and analyzed via high-performance liquid chromatography-mass spectrometry (HPLC-MS). Lipidomic data were processed using MetaboAnalyst 6. 0, with statistical analyses conducted via Student's t-test, ANOVA, and Kruskal-Wallis test.

Results
The study population comprised 61% men and 39% women. Baseline characteristics, including age, body mass index, total cholesterol, LDL-C, HDL-C, and triglycerides (TG), were comparable across groups. No significant differences were observed in diabetes duration or glycated hemoglobin levels among DKD groups. Among 480 lipid species identified in HDL, six showed significant reductions across four groups, including four sphingomyelins (SM), one lysophosphatidylcholine (LPC) and one phosphatidylcholine (PC). Compared to controls, EA1A2 exhibited a reduction of 21 lipid species, primarily from the lipid core (cholesteryl esters, sterols and TG). AA1A2 and AA3 exhibited reductions in 132 and 86 lipid species, respectively, compared to controls, predominantly affecting surface lipids, including SM, PC, LPC and ceramides (Cer). Only four lipid species differed significantly between AA3 and AA1A2, whereas 70 species (41. 4% SM, 30% PC, 11% Cer, 7. 1% free fatty acids, 4. 3% plasmalogens, 2. 8% LPC, and 2. 8% prenol) were consistently reduced in advanced DKD, irrespective of albuminuria severity.
Conclusion
DKD progression is associated with extensive remodeling of the HDL lipidome, characterized by early reductions in core lipids and progressive depletion of surface lipids in advanced stages. These changes, independent of albuminuria, may impair HDL functionality and exacerbate cardiovascular risk. Further research is warranted to assess their potential as biomarkers for DKD progression and CVD risk stratification.

Relevance of PFKP lysine lactylation in coupling glycolytic adaptation and mitochondrial respiration in diabetic proximal tubules

Tong Shen[1], xuan Bo[1], Ying Zhang[1], chunlin Meng[2], Xiang Song[2] & Zhiming Wang[1]
[1]The First Affiliated Hospital of Zhenzhou University, Division of Endocrinology and Metabolic Diseases, henan, China; [2]The First Clinical School of Medicine, Zhengzhou University, Zhengzhou, China

Synopsis
Diabetic kidney disease (DKD) is a major burden and a predictor of mortality in diabetes, characterized by clinical heterogeneity. Hyperglycemia enhances glycolysis-driven pyruvate-to-lactate conversion in the proximal tubules. Lysine lactylation (Kla), a novel post-translational modification induced by intracellular lactate, may contribute to this heterogeneity. Here, we used lactylome analysis and experiments to explore its impact on biological processes with redirection of glycolytic flux.
Purpose
DKD is associated with altered metabolic patterns. Enhanced glycolysis and pyruvate-to-lactate conversion are common early adaptive features in the proximal tubules. Here we investigate the metabolic consequences and present a global lactylome profiling of lactate dehydrogenase(LDH) inhibition to characterize the landscape of lactylation in the human renal proximal epithelial tubular cell line(HK-2) under hyperglycemic conditions.
Methods
HK-2 cells were treated with 25 mM high D-glucose(HG) for 7 days, followed by 40 mM oxamate, the LDH inhibitor, for 24 hours. This induced metabolic reprogramming without affecting cell growth[1]. Global lactylome analysis using 4D label-free proteomics identified differentially lactylated proteins. Co-immunoprecipitation(Co-IP)and site-directed mutagenesis were used to verify modification sites. Respiratory measurements using Seahorse assay, alongside fluorescent probes, western blot, qPCR and cross-species sequence comparisons were performed.
Results
Integrative lactylome and proteome analysis identified 1, 149 Kla sites and 83 differentially expressed (DE) modified sites. Notely, three glycolytic enzymes contained DE sites: ATP-Dependent 6-Phosphofructokinase, Platelet Type (PFKP), Alpha-enolase (ENO1) and Aldolase (ALDOA). PFKP was the second most down-regulated DE site with P-value $= 4.86\times10^{-5}$and log2FC $= -0.66$, and only one lactylated lysine residue in PFKP (K688) was identified (modified sequence: NFGTK(1)ISAR). Subsequently, the lactylation modification of PFKP was verified by Co-IP, while neither those of ENO1 nor ALDOA. The modification site of PFKP (K688) was further confirmed by site-directed mutagenesis. The modification level of PFKP (K688) was downregulated by oxamate. During this process, mitochondrial membrane potential significantly increased, while the oxygen consumption rate revealed a decrease in ATP-linked respiration, a reduction in maximum respiration, and an increase in proton leak. Cross-species sequence comparison reveals both the conservation and diversity of the PFKP gene across various organisms, with the K688 site being highly conserved throughout evolution.
Conclusion
PFKP lactylation revealed a feedback loop among glycolysis, lactate, and lactylation in hyperglycemic proximal tubular cells. The high conservation of the PFKP K688 site, along with its dynamic modifications, coupled with glycolytic reprogramming and their impact on mitochondrial respiration in diabetic proximal tubules, may provide valuable insights into the study of heterogeneity in DKD.

Alpelisib therapy for patients with congenital hyperinsulinism

Khalid Albureshad[1], Rasha Amin[1], Hajar Dauleh[2], Marwa Ibrahim[2 3 4] & Khalid Hussain[2]
[1]Sidra Medicine, Endocrinology, Doha, Qatar; [2]Sidra Medicine, Doha, Qatar; [3]Sidra Medicine, Ar Rayyan, Qatar; [4]Sidra Medicine, Endocrine and Diabetes, Doha, Qatar

Background
Congenital hyperinsulinism (CHI) is a disorder of unregulated insulin secretion, leading to severe and persistent hypoglycemia. Current medical treatment options include Diazoxide, octreotide, nifedipine, and sirolimus. However, most patients with K_{ATP} channel gene (ABCC8 and KCNJ11) mutations do not respond to these medications and require a near total pancreatectomy. We previously described the adjunct use of Alpelisib therapy in a three-month-old patient with CHI avoiding the need for a near total pancreatectomy (N Engl J Med. 2024;390(4):379-380).
Aims
We describe our observations in two additional patients with severe CHI treated with Alpelisib therapy, which resulted in the complete discontinuation of all existing treatments and the normalization of feeding.
Case studies
Two children (aged 3 and 4 years) with severe CHI (homozygous *ABCC8* and *KCNJ11* mutations) who were unresponsive to all the conventional therapies were treated with Alpelisib. The 3-year-old patient was on continuous gastrostomy feeds, received four-weekly long-acting octreotide injections, and was on diazoxide. The 4-year-old was also on continuous gastrostomy feeds overnight and 2 hourly bolus feeds during the day As well as on four-weekly long-acting octreotide. Treatment was initiated at 12. 5mg daily of Alpelisib, with gradual dose adjustments based on clinical responses. Outcome measures included blood glucose variability, frequency of hypoglycemic episodes, need for supplemental feeding, and treatment safety. In both cases, Alpelisib significantly improved glycemic control, reducing the frequency of hypoglycemic episodes. This allowed for the tapering and discontinuation of other medications (diazoxide and octreotide) and facilitated a transition to bolus gastrostomy-tube/oral feeding. No significant adverse effects were reported in either patient.
Conclusions
Alpelisib therapy shows promise as both an adjunctive and primary therapy for CHI, improving glucose control and reducing dependence on continuous feeding and other medications. Randomized controlled trials are needed to assess its long-term safety and efficacy for CHI.

Hyperinsulinemic hypoglycaemia in small for gestational age neonates: clinical characteristics, biochemical features, treatment, and clinical outcome

Cristina Aguilar Riera[1], Angeles Linde Sillo[1], Núria González-Llorens[1], Eduard Mogas[1], Ariadna Campos Martorell[1], Diego Yeste[1, 2] & María Clemente[1, 2]
[1]Vall d'Hebron University Hospital, Barcelona, Spain; [2]CIBER Enfermedades raras. Instituto Carlos III., Madrid, Spain

Introduction
Hyperinsulinemic hypoglycaemia(HH) is a common cause of persistent hypoglycaemia in neonates. Risk factors for transient HH include small for gestational age(SGA) newborns, perinatal asphyxia, intrauterine infections,

preeclampsia, and maternal diabetes. In neonates with HH and SGA, hypoglycaemia frequently has good response to diazoxide despite persisting for several months.
Objective
to review a cohort of patients diagnosed with HH in the neonatal period with a history of SGA.
Patients and Methods
Descriptive and retrospective study conducted at a tertiary hospital.
Inclusion criteria
Newborns with SGA (birth weight or length ≤-2 SD Carrascosa 2010) and HH: glucose <50 mg/dL with detectable insulin and/or C-peptide, and/or low free fatty acids(<1800 µg/dL) and carbohydrate requirements >12 mg/kg/min.
Exclusion criteria
Neonates with infection or syndromic hypoglycemia. Medical records were reviewed. Genetic testing included the *ABCC8, AKT2, CACNA1C, FOXA2, GCK, GLUD1, HADH, HK1, HNF1A, HNF4A, INSR, KCNJ11, SLC16A1, UCP2, and PGM1* genes.
Results
Twenty patients met inclusion criteria and none of the exclusion criteria. Thirteen(65%) were male. The mean gestational age was 34. 8±2. 9 weeks, with 14(70%) being preterm. Birth anthropometry(Mean±SD): weight Z-score -1. 9±0. 6 and length Z-score -1. 7±1. The mean age at hypoglycaemia onset was 1. 3±0. 7 days. **Biochemical parameters during hypoglycaemia**(Mean±SD)**:** glucose 37. 3±11. 6mg/dL, cortisol 16±15. 8µg/dL, insulin 6. 8±8mU/l, and C-peptide 1±0. 8ng/mL. Five patients(33%) had prematurity-related complications. Three(15%) had left ventricular hypertrophy(LVH) on echocardiography, one with a patent foramen ovale(PFO) and one with an intraventricular communication.
Treatment
All patients required initial intravenous glucose and continuous nasogastric feeding, with an average carbohydrate intake of 18. 1±3. 6mg/kg/min. Seventeen(85%) needed additional enteral supplementation with dextrin-maltose with maximum concentration of 5±1. 1%. Fourteen(70%) were treated with diazoxide, with a mean dose of 10±4. 4mg/kg/day. Thirteen patients responded well except for one with partial response. Diazoxide was discontinued after a mean of 5. 1±3 months. Two preterm patients experienced complications from diazoxide: Reopening of the ductus arteriosus with no previous cardiopathy and pulmonary hypertension with previous PFO and LVH. The mean age to treatment (enteral and pharmacological) discontinuation was 5. 2±5. 4 months.
Genetics
NGS was performed in ten patients, with one showing heterozygous VUS variant in *UCP2*(c. 127-1G>T). The Array CGH and exome sequencing were normal in the two and three patients tested, respectively.
Conclusions
In our cohort of SGA patients, HH resolved in average of five months. Most responded well to diazoxide. Two preterm presented complications. Genetic studies might be not necessary in the first six month of live if there is clinical resolution of hypoglycaemia.

Predictive markers of insulin resistance and dysglycemia in children and adolescents with overweight or obesity before and after the COVID-19 pandemic

Emre Sarıkaya[1], Leyla Kara[2], Ebru Suman Gök[2], Uğur Berber[3], Ülkü Gül Şiraz[4, 5] & Nihal Hatipoğlu[6]
[1]Kocaeli City Hospital, Erciyes University Medical Faculty, Pediatric Endocrinology, Kocaeli, Türkiye; [2]Kayseri City Hospital, Erciyes University Medical Faculty, Pediatric Endocrinology, Kayseri, Türkiye; [3]Yozgat City Hospital, Erciyes University Medical Faculty, Pediatric Endocrinology, Yozgat, Türkiye; [4]Erciyes University Medical Faculty, Kayseri, Türkiye; [5]Erciyes University, Pediatric Endocrinology, Kayseri, Türkiye; [6]Erciyes University, Faculty of Medicine, Pediatric Endocrinology, Kayseri, Türkiye

Objective
Childhood obesity is a major global health concern, closely linked to insulin resistance, dysglycemia, and increased cardiometabolic risk. The COVID-19 pandemic has further exacerbated these issues, leading to a higher prevalence of obesity-related metabolic disorders. This study aimed to assess the predictive ability of fasting glucose, fasting insulin, HOMA-IR, HOMA-β, and HbA1c for insulin resistance and dysglycemia in children and adolescents with overweight or obesity before (BPD, 2019) and after (APD, 2021) the pandemic.
Methods
A total of 392 patients (146 BPD, 246 APD) aged 5–18 years underwent oral glucose tolerance tests (OGTT). Insulin resistance and dysglycemia were defined based on OGTT Results The 90th and 97. 5th percentiles for fasting glucose, fasting insulin, HOMA-IR, and HOMA-β, as established by Hammel *et al*., were evaluated as predictors of insulin resistance and dysglycemia. ROC analysis was conducted to determine optimal cut-off values for these markers.
Results
Insulin resistance was detected in 74. 7% of BPD and 83. 3% of APD patients, while dysglycemia was observed in 11. 6% and 19. 1%, respectively. We demonstrated that the 90th and 97. 5th percentiles for fasting insulin, HOMA-IR, and HOMA-β, as established by Hammel *et al*., effectively predict insulin resistance, while fasting glucose is an effective predictor of dysglycemia in youth with excess body weight. Additionally, an HbA1c level of ≥5. 7% was a reliable predictor of dysglycemia detected by OGTT. ROC analysis revealed optimal cut-offs for fasting insulin (13. 65–25. 05 µU/mL), HOMA-IR (3. 35–5. 30), and HOMA-β (156. 34–318. 41) in detecting insulin resistance, while fasting glucose (89. 50–94. 50 mg/dL) and HbA1c (≥5. 61%) were effective in identifying dysglycemia.
Conclusion
Fasting glucose, fasting insulin, HOMA-IR, HOMA-β, and HbA1c serve as valuable non-invasive markers for predicting insulin resistance and dysglycemia in children and adolescents with overweight or obesity. Their consistency before and after the pandemic highlights their clinical utility and potential as alternatives to OGTT for early detection. Integrating these markers into routine clinical practice could facilitate timely intervention and personalized management strategies, particularly in resource-limited settings, to address the growing burden of obesity-related metabolic disorders in pediatric populations.

Co-designing a multicentre quality improvement initiative for hypoglycaemia: the dekode model

Mariam Idrissi[1], Kalyaani Persad[1], Sam Sherratt-Mayhew[1], Aashritha Buchipudi[1], Charles Page[1], Amrit Rakkar[1], Samama Rafi[1], Ahmed Iqbal[2], Alexandra Lubina Solomon[3], Team DEKODE[1] & Punith Kempegowda[1, 4]
[1]University of Birmingham, Birmingham Medical School, School of Medical Sciences, Birmingham, United Kingdom; [2]University of Sheffield & Sheffield Teaching Hospitals, Sheffield, United Kingdom; [3]The Dudley Group NHS Foundation Trust, Dudley, United Kingdom; [4]University Hospitals Birmingham NHS Foundation Trust, Department of Diabetes and Endocrinology, Birmingham, United Kingdom

Background
Effective hypoglycaemia management requires adherence to standardized guidelines, yet implementation remains inconsistent across healthcare settings[1]. A structured monitoring system can improve compliance, but its success depends on user acceptability and integration into clinical workflows[2]. Codesigning such systems with end-users enhances usability and adoption, ultimately supporting better patient care[3].
Aims
This study aimed to develop and implement a multicentre, standardised data collection system co-designed with end-users, assessing its feasibility, scalability, and sustainability.
Methods
This multicentre observational study was conducted from October 2023 to July 2024 and involved nine hospitals across three NHS trusts. An online Google Form was created through collaboration between clinical experts, medical students, and resident doctors. The form was piloted by diverse team members to ensure its appropriateness and robustness. Data collection focused on various factors involved during the management of hypoglycaemia, with a two-tier system ensuring data security. The system was scaled across the hospitals, with regular training and quality control measures in place.
Results
The co-designed data collection system, iteratively refined based on end-user feedback, was implemented consistently through structured training. Overall, we collected data on 1, 881 hypoglycaemic episodes across nine hospitals in 10 months. The system was scaled across varied IT environments, making it a sustainable tool in continuous data collection by new cohorts of medical students and ensuring ongoing implementation. Users found the system easy to use, with seamless accessibility and robust data security.
Conclusion
The study successfully developed a scalable, sustainable, and standardised data collection system for hypoglycaemia management, addressing a critical gap in UK healthcare. Its sustainability across various IT environments highlights its long-term feasibility. Further refinement of the system through AI-driven analytics and real-time data integration could enhance its predictive capabilities

and clinical decision-making support. Future efforts should focus on expanding the system to additional healthcare settings and evaluating its impact on clinical outcomes and patient safety.

Prevalence of MASLD in children and adolescents with type 1 diabetes assessed by transient elastography

Julie Agner Damm[1, 2], Amalie Dalgas-Madsen[1, 2], Jon Nielen[3], Kasper Pilgaard[1, 4], Flemming Pociot[1, 2], Tine Hansen[1] & Jesper Johannesen[1 2 4]
[1]Steno Diabetes Center Copenhagen, Herlev, Denmark; [2]University of Copenhagen, Copenhagen, Denmark; [3]University Hospital of Copenhagen, Rigshospitalet, Herlev, Denmark; [4]Herlev University Hospital, Department of Pediatric, Herlev, Denmark

Aims
To evaluate the prevalence of liver steatosis, fibrosis, and Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) in children and adolescents with type 1 diabetes using transient elastography, and to identify associated clinical variables.
Material and Methods
Cross-sectional study including 192 children and adolescents aged 6–18 years with type 1 diabetes for at least 12 months, recruited from Pediatric Diabetes Departments across Eastern Denmark between May 2022 and June 2024. Transient elastography was used to measure controlled attenuation parameter (CAP) and liver stiffness measurement (LSM) to assess steatosis and fibrosis, respectively. MASLD was defined as the presence of steatosis or fibrosis in addition to at least one metabolic risk factor, such as overweight/obesity, insulin resistance, impaired glucose tolerance, low HDL cholesterol, elevated blood pressure, or high triglycerides. Moreover, alanine aminotransferase and aspartate aminotransferase levels were measured, and screening for celiac disease was performed.
Results
The prevalence of steatosis (CAP > 90th percentile) was 2%, fibrosis (LSM > 90th percentile) was 8%, and MASLD was 4%. Higher CAP values were associated with higher BMI z-scores ($P = 0.012$) and lower glucose time-in-range ($P = 0.029$). Fibrosis was more prevalent in males ($P = 0.0003$). None of the participants with steatosis, fibrosis or MASLD had elevated alanine aminotransferase and aspartate aminotransferase levels or celiac disease.
Conclusion
The prevalence of steatosis, fibrosis, and MASLD in children and adolescents with type 1 diabetes was low. Steatosis was associated with higher BMI and poorer glycemic control, while fibrosis was associated with male sex.

Portosystemic shunt as a cause of alternating ketotic hypoglycemia and hyperinsulinism in patients with associated anomalies

Henrik Christesen[1, 2], Marianne Jørgensen[3], Susanne Frevert[3], Pernille Greisen[1], Anne Benner[1, 2], Mathias Rathe[1, 2] & Mette Ørngreen[3]
[1]Odense University Hospital, Hans Christian Andersen Children's Hospital, Odense, Denmark; [2]University of Southern Denmark, Clinical Research, Odense, Denmark; [3]Copenhagen University Hospital, Rigshospitalet, Diagnostic Radiology, Copenhagen, Denmark

Background
Congenital porto-systemic shunt (CPSS) between the portal vein and the inferior vena cava is a very rarely described cause of alternating pathological fasting ketotic hypoglycemia (pKH) and hyperinsulinemic hypoglycemia (HH).
Methods
Case reports.
Results
In two male patients aged 14. 9y, and 7. 0y, respectively, a CPSS was identified. Patient 1 was diagnosed with fasting pKH age 5y. Glucose did not increase after i. m. glucagon. Unsuppressed serum insulin during hypoglycemia and chronic zink deficiency were recorded. Ammonia was persistently elevated (80-120 mcM); other liver counts were only slightly affected. Plasma amino acids indicated liver affection with increased tyrosine and methionine. IgF-1 and IgF-BP3 were low despite normal growth hormone (GH) stimulation test and IgF1 only increased to 120 mg/l upon IgF1 stimulation test. Synacthen test showed low cortisol response with low ACTH. MRI of the pituitary and related structures was normal. Other hormonal, extensive metabolic, and expanded genetic studies returned normal. Treatment variably included extended release cornstarch, diazoxide, long-acting somatostatin analogue, GH and hydrocortisone. Repeat abdominal ultrasound showed discrete hepatic changes. MRI and contrast CT identified an intrahepatic CPSS. Radiological shunt closure at the age of 15 y led to normalization of blood glucose, ammonia, zink deficiency and hormonal disturbances without further treatment. Patient 2 was diagnosed with pKH age 3y with later diagnosis of mild hyperinsulinism. Except for slightly decreased coagulation factors II-VII-X, liver biochemistry was normal including ammonia. He had persistent, unexplained iron deficiency anemia, refractory to oral supplementation. He had prominent veins on the anterior truncus and a tendency to declive edema. Blood pressure and echocardiography were normal. Synacthen test was flat with low ACTH. IgF1 and IgF-BP3 were low with low IgF1 response upon IgF1 generation test. GH stimulation tests, other hormonal tests, MRI of the brain and pituitary and intensive metabolic and genetic investigations were normal. Treatment included extended release cornstarch, diazoxide, GH, hydrocortisone and iron. Abdominal ultrasound identified a very narrow portal vein and an extrahepatic CPSS was diagnosed by contrast CT. A first trial of radiological shunt balloon occlusion was unsuccessful due to reduced portal venous flow with unacceptable elevation of pressure in the hepatic vein.
Conclusion
CPSS should be suspected in children with alternating pKH and HH, liver affection and variable other manifestations. Ultrasound followed by contrast CT of the abdomen is diagnostic. The hypoglycemia, low IgF1 and IgF-BP3 and blunted ACTH-cortisol axis can normalize after shunt closure.

Disparities in diabetes incidence and prevalence among koreans under 30 in 2008–2021: a greater burden on socioeconomically disadvantaged populations

Hwa Young Kim[1, 2], Eunjeong Ji[3], Hakyung Lee[4] & Jaehyun Kim[1, 2]
[1]Seoul National University Bundang Hospital, Pediatrics, Seongnam, South Korea; [2]Seoul National University College of Medicine, Pediatrics, Seoul, South Korea; [3]Seoul National University Bundang Hospital, Medical Research Collaborating Center, Seongnam, South Korea; [4]Seoul National University Bundang Hospital, Bundang, South Korea

Background
The burden of diabetes mellitus is increasing globally, with significant implications for younger populations. This study evaluated temporal trends in the incidence and prevalence of type 1 (T1DM) and type 2 diabetes mellitus (T2DM) among Korean individuals aged <30 years from 2008 to 2021.
Methods
Data from the National Health Insurance Service in South Korea were analyzed to assess trends by sex and age group. Sex- and socioeconomic status (SES)-adjusted rate ratios (aRRs) were calculated to evaluate annual changes in incidence and prevalence rates.
Results
For T1DM, incidence per 100, 000 persons increased from 3. 02 (95% CI, 2. 78–3. 27) in 2008 to 3. 75 (95% CI, 3. 45–4. 06) in 2021 (aRR: 1. 017, $P < 0.0001$). This increase was significant in the 0–14 age group (from 2. 65 to 5. 28, aRR: 1. 041, $P < 0.0001$), while the 15–29 age group showed no significant change (from 3. 32 to 2. 70, aRR: 0. 997, $P = 0.5069$). Females consistently had higher incidence than males (aRR: 1. 176, $P < 0.0001$). Prevalence increased from 21. 83 (95% CI, 21. 17–22. 49) in 2008 to 46. 42 (95% CI, 45. 34–47. 50) in 2021 (aRR: 1. 058, $P < 0.0001$), with increases observed across all age groups and sexes. For T2DM, incidence escalated from 27. 61 (95% CI, 26. 87–28. 36) in 2008 to 60. 45 (95% CI, 59. 22–61. 69) in 2021 (aRR: 1. 083, $P < 0.0001$). A sharp rise was observed in the 0–14 age group (from 4. 94 to 17. 59, aRR: 1. 105, $P < 0.0001$) and nearly doubled in the 15–29 age group (from 46. 05 to 89. 81, aRR: 1. 075, $P < 0.0001$). Females consistently had lower incidence than males

(aRR: 0. 800, $P < 0.0001$). Prevalence increased dramatically from 73. 30 (95% CI, 72. 09–74. 51) in 2008 to 270. 39 (95% CI, 267. 79–272. 99) in 2021 (aRR 1. 104, $P < 0.0001$), with higher rates among males (from 75. 51 to 298. 61, aRR: 1. 111, $P < 0.0001$) and the 15–29 age group (from 124. 99 to 430. 37, aRR: 1. 098, $P < 0.0001$). Significant SES-related disparities were evident, with lower SES individuals having higher incidence (T1DM: aRR 1. 483; T2DM: aRR 2. 282, $P < 0.0001$) and prevalence (T1DM: aRR 2. 861; T2DM: aRR 3. 699, $P < 0.0001$).

Conclusion

The rising incidence and prevalence of diabetes, particularly among younger age groups, underscore an urgent need for public health interventions to mitigate the growing diabetes burden among Korean youth and young adults.

JOINT3013

Influence of SARS-CoV-2 virus and COVID-19 pandemic on course of type 1 diabetes in children during the first year of disease

Lizete Braivo[1, 2], Alona Lavrenova[1], Jana Pavare[1, 2] & Iveta Dzivite-Krisane[1, 2]

[1]Children's Clinical University Hospital, Riga, Latvia; [2]Riga Stradins University, Department of Paediatrics, Riga, Latvia

Objectives

After several medical centres, including Children's Clinical University Hospital (CCUH) in Latvia, had reported increase in type 1 diabetes (T1D) incidence in children during COVID-19 pandemic, our aim was to analyse influence of SARS-CoV-2 and pandemic itself on the control and course of T1D during the first year of disease.

Materials and Methods

Patients were included prospectively from August 2022 till January 2024, retrospectively from January 2017 until August 2022 and further divided depending on previous COVID-19 history: exposed to SARS-CoV-2 before T1D and unexposed patients. Data about initial manifestation and compensation measures 3, 6 and 12 months after diagnosis were gathered via interviews and medical records. Partial remission (PR) was defined by insulin doses <0.5 IU/kg/day and HbA1c $<7\%$. Complete remission (CR) was referred in patients with no requirement of insulin. Metabolic compensation (HbA1c) was also compared between pandemic and non-pandemic periods.

Results

In total, 277 patients were included in this study: 122 (44%) in exposed group (53. 3% boys, median age 9. 54 (IQR_{1-3} 5. 98-13. 27)), 155 (56%) in unexposed group (56. 8% boys, median age 10. 58 (6. 67-13. 42)). Initial manifestation of T1D was significantly more severe in patients previously exposed to SARS-CoV-2 (pH 7. 29 (7. 13-7. 37) vs pH 7. 33 (7. 19-7. 39)), $P = 0.02$. SARS-CoV-2 exposed patients needed higher doses of insulin initially (0. 74 (SD $\pm$ 0. 27) IU/kg/day vs 0. 66 ($\pm$0. 27) IU/kg/day), $P = 0.02$, but in 3-, 6- and 12-months requirement for insulin was similar in both groups. During the first year of T1D, PR was observed in 48 (39. 7%) exposed patients and 50 (33. 8%) unexposed patients, showing no significant difference ($P = 0.58$). 2 patients in both groups had CR period. Overall patients who initially presented with diabetic ketoacidosis (DKA), had significantly lower prevalence of remission period during the first year (26. 1% vs 48. 9%, $P = 0.001$). There was significantly higher frequency of DKA during one-year period in patients previously exposed to SARS-CoV-2 (6. 1% vs 0. 7%, v = 0. 02). Comparison analysis of follow-up visits (3, 6 and 12 months after diagnosis) between pandemic and non-pandemic periods showed slightly higher HbA1c levels during COVID-19 pandemic, but results did not reach statistical significance.

Conclusion

New-onset T1D patients previously exposed to SARS-CoV-2 have more severe initial manifestation, but insulin dosages, prevalence of remission and HbA1c levels reach similar levels 3, 6 and 12 months after diagnosis. However, cause of significantly higher prevalence of DKA in SARS-CoV-2 exposed group during the first year of diabetes should be further analysed.

Correlation between visceral fat and estimated disposal glucose rate in patients with type 1 diabetes

Samir Mkaouer[1], Zeineb Rekaya[1], Meriem Yazidi[1], Elyes Kamoun[1, 2], eya azzouz[1, 2], Nadia Khessairi[1], Ibtissem Oueslati[1], Fatma Chaker[1] & Melika Chihaoui[1]

[1]CHU LA RABTA, Endocrinology Department, Tunis, Tunisia; [2]CHU LA RABTA, Radiology Department, Tunis, Tunisia

Introduction

Metabolic syndrome (MS), closely associated with visceral fat, is a growing global health concern that also affects individuals with type 1 diabetes (T1D). The estimated glucose disposal rate (eGDR) is a simple and validated tool for predicting MS in patients with T1D. This study aimed to assess the correlation between visceral fat and eGDR.

Methods

We conducted a cross-sectional study including 68 patients with T1D. The study subjects were young adults, aged between 18 and 45 years. Each patient underwent a physical examination (anthropometric parameters and blood pressure), a fasting biological sample collection for the measurement of HbA1c, and lipid parameters and an evaluation of body composition by DXA Scan to measure the visceral fat mass (VFM). Visceral fat mass proportion (%VFM) was calculated by the formula: [VFM (g)/Weight (g)] x 100. High visceral fat mass (HVF) was defined by a %VFM >1, 1 in men and >0, 7 in women. MS was diagnosed according to the International Federation of Diabetes (IDF) criteria.

Results

The study population consisted of 29 men (42. 6%) and 39 women (57. 4%). The mean age was 29. 4 $\pm$ 7. 23 years. MS was observed in 14 patients with T1D (20. 6%). HVF was present in 15 patients (23, 4%). The mean eGDR score was 8. 31 $\pm$ 1. 72 mg/kg/min, ranging from 2. 81 to 11. 8 mg/kg/min. T1D patients with HVF had lower eGDR (7, 06 $\pm$ 2, 01 *vs* 8, 80 $\pm$ 1, 31, $P < 0,001$). eGDR was negatively correlated with %VFM ($r = -0,516$, $P < 0,001$). Using ROC curve analysis, we evaluated the relationship between eGDR and HVF. The area under the curve (AUC) was 0. 775 ($P = 0.001$), indicating that an eGDR value below 8. 41 mg kg^{-1} min^{-1} was associated with HVF in individuals with T1D, with 71% sensitivity and 73% specificity.

Conclusion

Our study demonstrated that eGDR, with a cut-off value of 8. 41 mg kg^{-1} min^{-1}, is a reliable marker for estimating visceral fat and can serve as an alternative to DXA scans, especially in situations where DXA is unavailable.

[1]Ege University Faculty of Medicine Department of Pediatric Endocrinology and Diabetes, Izmir, Türkiye; [2]Ege University Faculty of Medicine, Department of Child and Adolescent Psychiatry, Izmir, Türkiye; [3]Ege University Faculty of Medicine, Department of Medical Microbiology and Immunology, Izmir, Türkiye; [4]Ege University Faculty of Medicine, Department of Public Health, Izmir, Türkiye; [5]Adnan Menderes University Faculty of Medicine, Department of Pediatric Endocrinology and Diabetes, Aydin, Türkiye; [6]Dokuz Eylül University Faculty of Medicine, Department of Pediatric Endocrinology and Diabetes, Izmir, Türkiye; [7]Dr. Behçet Uz Pediatric Diseases and Surgery Training and Research Hospital, Department of Pediatric Endocrinology and Diabetes, Izmir, Türkiye; [8]Afyon Kocatepe University Faculty of Medicine, Department of Pediatric Endocrinology and Diabetes, Afyon, Türkiye; [9]Izmir City Hospital, Department of Pediatric Endocrinology and Diabetes, Izmir, Türkiye

Objective

To screen first-degree relatives of individuals with type 1 diabetes (T1D) for diabetes-related autoantibodies(AAs), identify individuals at increased risk for T1D, and evaluate the psychological impact of screening on both children and their parents.

Methods

This multicenter study targeted the inclusion of 400 children and adolescents aged 2-18 years who were first-degree relatives of individuals diagnosed with T1D. Thus far, 262 participants were enrolled, and screening was completed for 176. Venous blood samples were tested for four autoantibodies (IAA, GAD, IA-2, ZnT8). Psychological assessments were performed using the Screen for Child Anxiety Related Emotional Disorders(SCARED) for children and the State-Trait Anxiety Inventory(STAI-I and STAI-II) for parents, before and after the disclosure of screening Results SCARED scores ≥ 30 indicated clinical anxiety, 25-30 mild anxiety, and <24 normal. STAI scores >41(state) and >44(trait) signified heightened anxiety.

Results
The mean age of the 176 individuals was 10. 1 ± 0. 34 years, with a gender distribution of 79(44. 9%) females and 97(55. 1%) males. Autoantibody positivity was detected in 17 participants(9. 7%), with one autoantibody identified in 9 individuals(5. 1%), three autoantibodies in 4 individuals(2. 3%), two autoantibodies in 3 individuals(1. 7%), and four autoantibodies in 1 individual (0. 6%). ZnT8 was positive in 13 individuals(7. 39%), anti-GAD in 11(6. 25%), IA-2 in 6(3. 41%), and anti-insulin in 1(0. 57%). SCARED assessment was completed in 61 patients. Anxiety levels increased by 100% in autoantibody-positive children(from 25 to 37, $p < 0.001$), while 72% of autoantibody-negative children showed a significant decrease(from 25 to 18, $p < 0.001$). The STAI was completed by 53 mothers and 8 fathers. In the autoantibody-negative group, both state(from 38 to 31, $p < 0.001$) and trait anxiety(from 39 to 37, $P = 0.007$) decreased significantly in parents. In the autoantibody-positive group, state anxiety in parents increased significantly(from 35 to 46, $p < 0.001$), while trait anxiety anxiety changed slightly(from 36 to 39, $P = 0.353$). Mothers had higher STAI scores than fathers for both state(38 vs. 35) and trait anxiety(35 vs. 28, $P = 0.245$).
Conclusion
Among 176 individuals, 4. 54% had two or more positive autoantibodies, which is consistent with findings reported in the literature. This is the first multicenter T1D autoantibody screening in Turkey. Psychological evaluations conducted before and after screening revealed significant anxiety reduction among autoantibody-negative children and their parents, while autoantibody-positive individuals experienced marked increases in anxiety levels. Findings highlight the need to educate at-risk individuals and provide psychological support.

"Urinary c-peptide to creatinine ratio (UCPCR) as a marker of insulin secretion: impact of glucose load and sex differences"

Sharmaine Reintar[1], Magdalena Pöchhacker[2], Anna Ramirez-Obermayer[3], Katharina Eberhard[4], Andreas Zirlik[5], Nicolas Verheyen[5], Dirk von Lewinski[5], Daniel Scherr[5], Barbara Hutz[1], Christoph Haudum[1], Thomas Pieber[1], Harald Sourij[1] & Barbara Obermayer-Pietsch[1]
[1]Medical University of Graz, Department of Internal Medicine, Division of Endocrinology and Diabetology and Endocrinology Lab Platform, Graz, Austria; [2]University of Vienna, Department of Food Chemistry and Toxicology, Faculty of Chemistry, Vienna, Austria; [3]Medical University of Graz, Clinical Department of Medical Psychology, Psychosomatics and Psychotherapy, Graz, Austria; [4]Medical University of Graz, Center for Medical Research, Core Facility Computational Bioanalytics, Graz, Austria; [5]Medical University of Graz, Department of Internal Medicine, Division of Cardiology, Graz, Austria

Background
Insulin resistance and prediabetes are growing risk factors for metabolic and cardiovascular sequelae in many populations worldwide. Early risk detection could be based on biochemical and functional biomarkers for individual diagnosis and monitoring. Therefore, the urinary C-peptide to creatinine ratio (UCPCR) is an emerging diagnostic approach based on a noninvasive tool for assessing and monitoring insulin secretion. This study aims to investigate changes in UCPCR values before and after a defined oral glucose tolerance test (OGTT) and explore potential differences between men and women.
Methods
This study investigated a subgroup of 169 volunteers from the BioPersMed cohort (Biomarkers in Personalized Medicine), with 1022 participants overall. A regular OGTT was performed, with spot urine samples taken before and after the glucose load. In parallel, glucose, insulin, and C-peptide measurements in blood serum or plasma were taken at baseline, 30, 60, and 120 minutes, and a large number of parameters related to metabolic and cardiovascular risk were measured.
Results
Our findings indicate a significant increase in UCPCR following the OGTT compared to fasting values, suggesting that the test induces a measurable change in insulin secretion. We observed no statistically significant difference in UCPCR values between men and women at baseline before the OGTT (P-value 0. 250). However, a notable difference in UCPCR values was found between genders after the OGTT, with women showing higher UCPCR values than men based on the Mann-Whitney U test (P-value <0. 001). Further analyses are ongoing.
Conclusion
These results highlight the dynamic nature of insulin secretion in response to glucose intake and suggest that gender influences UCPCR findings after an OGTT. Further studies in the larger BioPersMed cohort will refine the clinical potential of UCPCR as a biomarker for insulin secretion.

Single-cell analysis reveals plasticity of pancreatic β-cells during pregnancy and postpartum in mice

Shengda Tian[1], Jiajia Wang[2], Jing Li[1], Yunshan Li[1], Xiaohua Li[1], Wenyi Li[2] & Hongli Zhang[1]
[1]Seventh People's Hospital of Shanghai University of Traditional Chinese Medicine, Department of Endocrinology, shanghai, China; [2]Tongren Hospital, Shanghai Jiao Tong University School of Medicine, Department of Endocrinology, Shanghai, China

Background
During pregnancy, the pancreatic β-cell mass expands to meet the increased metabolic demands, and it subsequently regresses in the postpartum period as maternal glucose homeostasis returns to normal. The transcriptional changes underlying these adaptations remain unclear. This study seeks to explore the heterogeneity of pancreatic beta cell populations at various stages of pregnancy and postpartum involution, focusing on the molecular mechanisms driving their adaptive plasticity.
Methods
Islets were isolated from non-pregnant mice, pregnant mice at day 14. 5, and postpartum mice at day 4. Single-cell RNA sequencing (scRNA-seq) was performed to analyze the transcriptomic features of the β-cells. Bioinformatics analyses were conducted to identify heterogeneity within these cells. SCENIC analysis was employed to identify the transcription factors most active in proliferating β-cells. Immunofluorescence assays revealed that Pbx4 positivity significantly increased in pancreatic islets of pregnant mice and returned to baseline levels postpartum. *In vitro* functional assays were conducted on mouse β-cell lines to validate the role of Pbx4 in regulating the expression of cell cycle-related proteins, thereby promoting β-cell proliferation.
Results
Our single-cell transcriptomic analysis identified five functionally distinct β-cell subpopulations. We focused on three dynamically regulated clusters that exhibit stage-specific heterogeneity during gestational adaptation and postpartum recovery, we observed:A polyhormonal subpopulation co-expressing Gcg (glucagon), Sst (somatostatin), and Ppy (pancreatic polypeptide), indicative of endocrine plasticity, decreases during pregnancy and recovers in the postpartum. This suggests that the increased metabolic stress during pregnancy may drive this cell population to differentiate into mature beta cells. A pregnancy-enriched cluster marked by acinar-to-β cell transdifferentiation, with expression of Ctrb1 and Prss2, suggests that acinar cells transdifferentiate into β-like cells during pregnancy to alleviate insulin insufficiency; and a proliferative population marked by Mki67, potentially regulated by the transcription factor Pbx4. Overexpression of Pbx4 in mouse β-cell lines has demonstrated that Pbx4 can upregulate the expression of cyclins, thereby promoting β-cell proliferation.
Conclusion
Using single-cell RNA sequencing, we revealed transcriptomic changes of distinct β-cell subpopulations, including polyhormonal cells, acinar-like clusters, and a proliferative β-cell subset during pregnancy and postpartum. Our analysis reveal novel mechanisms of β-cell adaptation to metabolic challenges during pregnancy-related changes.

Influenza vaccine coverage and factors associated with vaccination in adults with type 1 diabetes - a danish register-based study

Vithiya Karunakaran[1, 2], Ida Pedersen[1, 2], Anders Isaksen[1] & Kurt Kristensen[1, 2]
[1]Steno Diabetes Center Aarhus, Aarhus, Denmark; [2]Department of Clinical Medicine, Aarhus University, Faculty of Health, Aarhus, Denmark

Background
20% of all confirmed influenza cases are admitted to hospitals in Denmark. Underlying conditions such as type 1 diabetes (T1D) can lead to increased risk of severe complications from influenza. In Denmark, influenza vaccination is recommended to all adults with T1D, and the World Health Organization (WHO) recommends an influenza vaccination coverage (IVC) of 75% in high-risk groups. This register-based, repeated cross-sectional study aims to investigate IVC among individuals with T1D and identify subgroups susceptible to non-vaccination.
Methods
Using nationwide Danish registers, we compiled a cohort of adults in Denmark aged 19-64 with T1D during influenza seasons 2015/16-2022/23. Vaccination status was assessed prior to every influenza vaccination season. We investigated associations between non-vaccination and gender, region of residence, age at T1D onset, T1D duration, hemoglobin A1c, socioeconomic status and events of severe hypoglycemia and/or ketoacidosis using robust Poisson regression to compute adjusted relative risk (RR).
Results
IVC was low in the 2015/16 season (IVC 17. 99%, 95% confidence interval (CI) (17. 44%, 18. 54%)), and increased slightly throughout seasons 2016/17-2020/21. In 2021/22, IVC increased significantly to 41. 13% (95% CI (40. 45%, 42. 18%)). Male sex was associated with not receiving influenza vaccination (RR 0. 75, 95% CI (0. 73, 0. 77)). Age at onset and T1D duration was also associated with vaccination status: As these increase, so does the likelihood of vaccination. Individuals with HbA1c $>$ 53 mmol/mol had a reduced RR of vaccination (RR 0. 97, 95% CI (0. 95, 0. 99)). Region of residence and socioeconomic factors were strongly associated to RR of vaccination. Diabetic ketoacidosis prior to season start showed a significant decrease in RR of vaccination by 12% (RR 0. 88, 95% CI (0. 83, 0. 92)).
Conclusions
This study reveals that IVC among individuals with T1D is suboptimal and does not meet the recommendations set by the WHO. Although IVC seems to be increasing, more intense and tailored vaccination strategies are needed to increase it further. We have identified several factors that are associated with non-vaccination, revealing specific subgroups that healthcare providers should prioritize in vaccination efforts.

Continuous glucose monitoring in paediatric residents with normal glucose metabolism: correlations to 24-hour duty schedule

Anastasia Proimou[1, 2], Georgia Sotiriou[1], Paraskevi Panagopoulou[3], Zoi Tsimtsiou[2, 4] & Athanasios Christoforidis[1]
[1]First Department of Pediatrics, School of Medicine, Faculty of Health Sciences, Aristotle University of Thessaloniki, Hippokratio General Hospital, Thessaloniki, Greece; [2]MSc "Social – Preventive Medicine and Quality in Health Care", School of Medicine, Faculty of Health Sciences, Aristotle University of Thessaloniki, Thessaloniki, Greece; [3]4th Paediatric Department, School of Medicine, Faculty of Health Sciences, Aristotle University, Papageorgiou General Hospital, Thessaloniki, Greece; [4]Laboratory of Hygiene, Social and Preventive Medicine and Medical Statistics, School of Medicine, Faculty of Health Sciences, Aristotle University of Thessaloniki, Thessaloniki, Greece

Intoduction
Glucose values in healthy humans are influenced by many factors like dietary habits, stress and hormonal signaling, lack of adequate sleep.
Aim
To quantify glucose fluctuations in healthy paediatric residents with the use of commercial continuous glucose monitoring systems (CGMS).
Methods
Eligibility criteria for participation in the research were: a)participation as a paediatric resident in the full on-call duty schedule of a Paediatric department in a teritiatory hospital, b)age: 25-40 years, c)absence of chronic disease or receiving treatment affecting glucose metabolism and d)willingness to participate in the study after providing signed consent.
Results
Fifteen sensors were placed in 13 residents (8 females). A total of 35 days of 24-hour duty shift in outpatient basis were covered. Additionally, 35 days were stratified as days after a 24-hour outpatient duty and 114 days were classified as being away from 24-hour outpatient duty shift. In the whole study group, mean glucose values were 99. 69 $\pm$ 20. 31 mg/dl, 97. 67 $\pm$ 19. 28 mg/dl and 97. 14 $\pm$ 16. 99 mg/dl on 24h outpatient duty days, on days after 24h outpatient duty and on days away from 24h outpatient duty respectively ($P < 0.001$). Males showed significantly higher glucose values on 24h outpatient duty days in compared to females (101. 22 $\pm$ 19. 42 mg/dl vs 99. 17 $\pm$ 20. 57mg/dl, $P = 0.006$), while on the days after and away from 24h outpatient duty shift, males displayed significantly lower glucose values compared to females (97. 25 $\pm$ 19. 24 mg/dl vs 97. 85 $\pm$ 19. 30 mg/dl, $P = 0.002$ and 96. 57 $\pm$ 15. 95 mg/dl vs 97. 12 $\pm$ 17. 60 mg/dl, $P < 0.001$). The analysis of the data per person individually, showed that the majority of participants significantly increased levels of glucose on the 24h outpatient duty shift (with the exception of 1 male and 1 female resident). Lower glucose values during the night compared to the whole 24 hours for the away from the 24h outpatient duty shifts, were recorded for the majority of participants with the exception of 1 male and 2 3 female participants. On the contrary, higher glucose values were recorded in the night compared to the whole 24 hours in 8 participants (4 males and 4 females) during the 24h outpatient duty shift.
Conclusions
24h outpatient duty shifts for Paediatric residents have shown that significantly affect glucose values. The stressful environment, lack of sleep and poor and unhealthy dietary habits contribute to this glucose disturbances. Further studies are warranted to confirm and further extent these preliminary data.

Acceptance of artificial intelligence by clinicians: a study on adoption and integration in medical practice

Bharat Saboo[1], Shweta Saboo[2], Alok Modi[3], Aniket Inamdar[4] & Shambo Samajdar[5]
[1]Prayas Diabetes Center, Diabetes and Obesity, Indore, India; [2]Prayas Diabetes Center, Indore, India; [3]Kewalya Hospital, Thane, India; [4]Samarpan Clinic, Omerga, India; [5]AHC Clinic, Kolkata, India

Aim
This study aims to evaluate the acceptance of artificial intelligence (AI) technologies by clinicians, focusing on factors influencing adoption, perceived benefits, challenges, and the impact on clinical decision-making and patient care.
Materials and Methods
A cross-sectional survey was conducted among 200 clinicians from various medical specialties across India. The survey included questions on familiarity with AI tools, perceived usefulness, ease of integration into clinical workflows, and concerns regarding AI's role in medical practice. The Technology Acceptance Model (TAM) was used as a framework to assess clinicians' attitudes and intentions to adopt AI. Data were analyzed to identify trends and correlations between clinician demographics, specialties, and AI acceptance levels.
Results
The study revealed that 68% of clinicians expressed a positive attitude towards adopting AI in their practice, citing improved diagnostic accuracy and efficiency as key benefits. However, 45% of respondents reported concerns about the reliability of AI tools and the potential for reduced clinical autonomy. Younger clinicians and those in tech-savvy specialties, such as radiology and pathology, showed higher acceptance rates compared to their peers. Additionally, 52% of clinicians indicated that lack of training and integration challenges were significant barriers to AI adoption.
Conclusion
While there is a growing acceptance of AI among clinicians, several barriers, including concerns about reliability, loss of autonomy, and insufficient training, hinder widespread adoption. Addressing these issues through targeted education, robust AI tool validation, and seamless integration into clinical workflows can enhance acceptance and utilization. The findings underscore the need for collaborative efforts between technology developers and healthcare professionals to ensure AI tools effectively support clinical practice and improve patient outcomes.

Postprandial glucose response to a novel low-sucrose chocolate spread in adults with type 1 diabetes: a randomized, double-blinded, cross-over, controlled trial

Naama Fisch-Shvalb[1, 2], Revital Nimri[2, 3], Moshe Phillip[1, 2] & Michal Yackobovitch-Gavan[3, 4]
[1]Institute of Endocrinology and Diabetes, Schneider Children's Medical Center, Petach Tikva, Israel; [2]Faculty of Medical & Health Sciences, Tel Aviv University, Tel Aviv, Israel; [3]Institute of Endocrinology and Diabetes,

Schneider Children's Medical Center, Petach-Tikva, Israel; [4]Epidemiology and Preventive Medicine, School of Public Health, Faculty of Medicine, Tel Aviv University, Tel-Aviv, Israel

Aims
Controlling postprandial glucose excursions remains a challenge for people with Type 1 diabetes (T1D). Novel advances in food technology enable the production of foods with significantly reduced sucrose without the use of additives. We aimed to test the postprandial glycemic response of subjects with T1D to a novel sucrose-reduced chocolate spread, as well as its acceptance and palatability.
Materials and Methods
A randomized, double-blind, crossover, active-controlled trial comparing the glycemic response to two test-meals: 20 grams of the sugar-reduced spread (8% sugar; 1. 6 grams sucrose), and 20 grams of control chocolate spread, (56% sugar; 11 grams sucrose) in people with T1D.
Results
Thirty adults (50% males), aged 18–28 years (mean 23. 0 ± 3. 0), mean HbA1C of 7. 2 ± 0. 9 % were recruited. Postprandial glucose excursions were significantly lower following consumption of the study spread compared to the control spread: pre-meal to peak glucose difference (mean 25. 8 ± 34. 9 mg/dL lower, $P < 0.001$), postprandial CGM iAUC (mean 2271 ± 3789 min × mg/dL, $P = 0.003$). Median time in range was higher for the study vs control spread (100% and 64. 6%, respectively, $P = 0.030$). In the sweetness scale questionnaire, the study spread rated higher than the control, with a "right degree of sweetness" 53. 3% and 26. 7% respectively, $P < 0.001$.
Conclusion
The study product with 80% less sucrose and 50% less carbohydrates showed a more favorable glycemic response, without compromising sweetness. This new technology could be a significant contributor to the ongoing effort to produce healthier, sugar-reduced foods, both for people with diabetes, and for the general population.

Prolonged hyperglycemia results in the formation and accumulation of complex and heterogeneous groups of compounds - advanced glycation end-products (AGEs) that increase oxidative stress and induce inflammatory reaction, which exacerbate the occurrence and progression of diabetic complications. The project "Integrated model for personalized diabetic retinopathy screening and monitoring using risk-stratification and automated AI-based fundus image analysis – PerDiRe" involved data on type 1 diabetes (T1D) and type 2 diabetes (T2D) patients from four countries - Latvia, Lithuania, Estonia, and Norway, on two consecutive annual visits. The project was funded by EEA-RESEARCH-60 grant. The objective of this substudy was to assess the relationship between AGE levels and diabetic retinopathy (DR) course in patients with diabetes across all four countries.
Methods
410 patients with diabetes attended the initial visit, and 226 patients returned for the 1st year follow-up. At both visits, the patients with diabetes underwent full ophthalmological and diabetes-specific clinical examinations. The patients were stratified according to the DR status as follows: no retinopathy, non-proliferative (simple) retinopathy, proliferative retinopathy, and diabetic macular edema. AGEs were measured non-invasively using an *AGE Reader* device (DiagnOptics Technologies B. V., SN 00010604, Netherlands). AGE z-scores were calculated with the formula: AGE z-score = AGE mean-(0. 024*age, years + 0. 83).
Results
During the initial visit, 47. 3% ($n = 194$) of the patients had some form of DR. By the second visit, 52. 2% ($n = 118$) presented with DR ($P = 0.23$). 9. 3% of the study subjects experienced progression to a more severe stage of DR ($P < 0.05$). A significant change in DR severity from first to second visit was found only within the T2D group ($P < 0.05$). During both visits, T2D patients had significantly higher median AGE values and z-scores, compared to T1D ($P < 0.001$). Patients with T1D exhibited a statistically significant increase in median AGE values and z- scores at the second visit compared to the first one ($P < 0.05$ for both measures). Conversely, patients with T2D showed no significant change in either AGE values or AGEs z-scores between the two visits. In both groups combined, marginal means of AGE values and z-scores increased significantly with progression of DR stages during both visits (general linear models' $P < 0.001$).
Conclusions
The results indicate a notable change in the distribution of DR stages between the first and second visits, especially in T2D. AGE levels were significantly higher in T2D patients and were directly related to more advanced stages of DR.

Randomized controlled trial on the effectiveness and usability of interactive diabetes management application: a multi-centre study

Phei Ching Lim[1, 2], Hadzliana Zainal[2], Jason Lye Hin Kam[1], Leong Seng Tan[3], Hooi Hoon Tan[4], Lay Ang Lim[5] & Chong Hui Khaw[6]
[1]Hospital Pulau Pinang, Pharmacy Department, Penang, Malaysia; [2]Universiti Sains Malaysia, School of Pharmaceutical Sciences, Penang, Malaysia; [3]Hospital Bukit Mertajam, Pharmacy Department, Penang, Malaysia; [4]Sungai Dua Health Clinic, Pharmacy Department, Penang, Malaysia; [5]Hospital Seberang Jaya, Medical Department, Penang, Malaysia; [6]Hospital Pulau Pinang, Medical Department, Penang, Malaysia

Introduction
Emerging trends insmartphone usage have led to integration of smartphone technologies in diabetes management via mobile application. Ideally, a newly-developed application should be evaluated in terms of its effectiveness and usability to ensure patients' and continuous engagement. However, majority of the applications are not evaluated on the effectiveness in improving in health outcomes.
Objective
We aimed to evaluate the effectiveness and usability of complementary interactive automated data entry diabetes management tool vs standard physician care.
Methods
Diabetes mellitus patients treated with insulin were randomly assigned to intervention (standard of care plus interactive mobile application) or control arms (standard physician care without mobile application). Every patient was provided with bluetooth-enabled glucometer and strips as well as blood pressure measuring set. Blood glucose and blood pressure data were automatically synced to the mobile application for the intervention arm and pharmacists monitored the patients remotely every month in addition to standard physician care. Meanwhile, patients in the control arm who received only standard physician care, recorded the glucose and blood pressure monitoring manually. Demographic data, haemoglobin A1c (HbA1c), systolic and diastolic blood pressure readings, insulin doses, hypoglycaemic episodes and usability of the interactive mobile application via questionnaire were collected at baseline and 3 months post-intervention.
Results
A total of 112 patients (63. 4% female, mean age 53. 1 years, mean duration of diabetes 16. 3 years) with similar baseline characteristics for intervention and control arms completed the study. Glycaemic control improved significantly, in the intervention arm as compared to control arm with HbA1c -1. 22 ± 1. 36% (95% CI -1. 59, -0. 84) and -0. 23 ± 1. 04% (95% CI -0. 50, 0. 04) respectively ($P < 0.001$). Blood pressure improved significantly in the control arm with systolic and diastolic blood pressure reduced by 6. 72 ± 17. 26 mmHg ($P = 0.005$) and 2. 95 ± 8. 97 mmHg ($P = 0.016$) respectively. There was no difference in insulin doses in both arms but hypoglycaemic episodes reduced significantly in the intervention arm, $P = 0.016$. Most of the patients (87. 8%) in the intervention arm reported good usability and were satisfied with the interactive mobile application.

Conclusion
The interactive diabetes management tool with automated glucose and blood pressure data entry improved glycaemic control and reduced hypoglycaemic episodes significantly with high satisfaction among users. This application has proven to be an effective tool for remote monitoring by healthcare professionals, providing timely oversight and serving as a valuable alternative for patient monitoring especially in the rural areas.

JOINT554
JAK/STAT and TRAIL signaling in latent autoimmune diabetes in adults: findings from single-cell transcriptomics
Ivan Golodnikov[1], Elizaveta Podshivalova[1], Vadim Chechekhin[1], Alina Matrosova[1], Anatolii Zubritskiy[1], Margarita Samsonova[1], Tatyana Nikonova[1] & Marina Shestakova[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation

Goal
Latent Autoimmune Diabetes in Adults (LADA) exhibits a hybrid autoimmune-metabolic phenotype, sharing features of both type 1 and type 2 diabetes. However, the molecular mechanisms underlying its slower β-cell decline remain poorly characterized. We aimed to clarify the role of two key immune signaling pathways, JAK/STAT (Janus Kinase/Signal Transducer and Activator of Transcription) and TRAIL (TNF-Related Apoptosis-Inducing Ligand), in shaping the autoimmune landscape of LADA compared to classic type 1 diabetes mellitus (T1DM).
Methods
Peripheral blood mononuclear cells (PBMCs) were collected from 15 individuals with LADA, 21 with T1DM, and 22 healthy controls. Single-cell RNA sequencing (10x Genomics platform) provided 5'single-cell transcriptomic profiling (scRNA-seq) of immune subsets (T-cells, B-cells, NK-cells, and monocytes). After quality control and batch-correction, pathway-centric analyses (PROGENy-based scoring) assessed relative JAK/STAT and TRAIL pathway activities across these groups, focusing on T- and NK-cell subpopulations.
Results
In T1DM, JAK/STAT showed robust hyperactivation across CD4+ and CD8+ T-cell subsets, often reaching 10- to 20-fold higher scores than in healthy controls. Concomitantly, TRAIL activity was markedly reduced 2- to 5-fold, suggesting a diminished apoptotic checkpoint against hyperreactive lymphocytes. This imbalance likely contributes to the rapid β-cell destruction typically observed in T1DM. LADA, however, demonstrated more moderate JAK/STAT activity 2- to 6-fold, consistently lower than T1DM but slightly above healthy levels. Notably, TRAIL signaling scores were significantly elevated in LADA 2- to 3-fold compared with T1DM. This pattern implies that, while JAK/STAT-driven inflammation persists, enhanced TRAIL-mediated apoptosis selectively eliminates the most aggressive immune clones. Hence, LADA appears to adopt an attenuated autoimmune response that slows β-cell decline. NK-cells (CD56dim) mirrored these findings, showing intense JAK/STAT upregulation in T1DM but a tempered response in LADA. TRAIL in LADA NK-cells was consistently higher than in T1DM, reinforcing the idea of apoptotic regulation limiting full-blown cytotoxicity. Collectively, these pathway-level distinctions align with LADA's milder clinical progression relative to T1DM.
Conclusion
Our single-cell profiling indicates that LADA's immunopathology is shaped by an interplay of moderately elevated JAK/STAT signaling and heightened TRAIL-mediated apoptosis. This contrasts sharply with T1DM, where excessive JAK/STAT activation and insufficient TRAIL-related cell death of autoregressive T-cells foster a more aggressive β-cell attack. These findings suggest that targeting JAK/STAT hyperactivation or enhancing TRAIL-mediated apoptosis may provide novel therapeutic strategies to modulate LADA's autoimmune trajectory and preserve β-cell mass. Pharmacological modulation of these pathways warrants further exploration as a potential strategy for LADA management.

Assessment of insulin-releasing and glucose-lowering effects of Piper guineense extracts in cellular and animal models of type 2 diabetes
Opeolu Ojo[1, 2], Mojisola Adie[1], Simren Heer[1], John Edeani[1], Ayokunle Falana[1], Ayodele Falobi[1] & Constance Ojo[3]
[1]University of Wolverhampton, UK, Diabetes Research Group, Research Institute in Healthcare Sciences, School of Life Sciences, Wolverhampton, United Kingdom; [2]IRiD Biosciences, Stokes-on-Trent, United Kingdom; [3]University of Wolverhampton, UK, School of Engineering, Wolverhampton, United Kingdom

Aim
Piper guineense is a plant used traditionally for the management of diabetes in many countries across West Africa. However, mechanisms underlying its actions are poorly understood. This study assessed phytochemical composition, insulin-releasing effects of aqueous extracts of the plant extract
Methods
The screening for common flavonoids and phenolic compounds in *P. guineense* was carried out. Actions of *P. guineense* extracts (0–1000μg/ml) on insulin release, cell viability and markers of cytotoxicity in BRIN-BD11 cells and in mice fed with a high-fat diet were assessed. The involvement of the ATP-dependent pathway in the actions of the plant extract was also assessed.
Results
Aqueous extract of *P. guineense* had total phenolic and flavonoids content of 1. 84±0. 18GE/g and 1. 72±0. 16QE/g respectively. The extract stimulated non-toxic insulin release from BRIN-BD11 cells at all concentrations tested (0. 01 – 1000μg/ml, 1. 2- to 2. 3-fold, $P < 0.05$ to $P < 0.001$). The observed insulinotropic effects was glucose-dependent (1. 8-fold, $P < 0.001$ at 1. 1mM to 5. 6mM; 1. 5-fold, $P < 0.01$ at 5. 6mM to 16. 7mM). Effects of *P. guineense* increased in the presence of KCl (30mM, 1. 5-fold, $P < 0.01$). Reduced effects were observed in the presence of verapamil (50nM, 43%, $P < 0.001$), diazoxide (300μM, 53%, $P < 0.001$) and absence of extracellular calcium (48%, $P < 0.01$). *P. guineense* improved glucose tolerance (24. 7 – 38. 4%, $P < 0.01$-0. 001 at 150 - 300mg/kg bw) and plasma insulin levels (1. 6 - 2. 8-fold, $P < 0.01$ at 150 - 300mg/kg bw) in high fat fed mice in a dose-dependent manner.
Conclusions
Observed anti-diabetic actions provide a basis for further research of the therapeutic potential of *P. guineense* extract as an anti-diabetic agent.

Liver androgen receptor knockout fails to prevent high-fructose diet-induced glucose dysregulation in female mice
Stanley Andrisse[1]
[1]Howard University College of Medicine, Washington, DC, United States

The liver androgen receptor (AR) plays a crucial role in metabolic regulation, particularly under dietary stress. This study examined the impact of a high-fructose diet (HFrD) on glucose metabolism in male and female liver androgen receptor knockout (LivARKO) mice. LivARKO and wild-type (WT) mice were fed either an HFrD or a control diet, and glucose tolerance and insulin sensitivity were assessed over two months. In female mice, LivARKO did not prevent HFrD-induced glucose intolerance, as LivARKO-HFrD females exhibited similar impairments in glucose tolerance as their WT counterparts. While insulin sensitivity improved slightly in LivARKO females at later time points, they displayed significant hyperinsulinemia relative to controls. In contrast, male LivARKO mice experienced exacerbated glucose intolerance and heightened hepatic insulin resistance under HFrD conditions, suggesting sex-specific effects of hepatic AR loss on metabolic function. These findings indicate that liver AR knockout does not protect against HFrD-induced metabolic dysfunction in females and may worsen glucose homeostasis in males, highlighting the differential role of AR in diet-induced metabolic dysregulation.

Experience with the use of dapagliflozin in patients with ckd of various etiologies
Olimkhon Sharapov[1, 2] & Sherzod Abdullaev[1, 3]
[1]Tashkent Pediatric Medical Institute, Internal diseases, nephrology and hemodialysis, Tashkent, Uzbekistan; [2]Republican Specialized Scientific Practical Medical Center of Nephrology and Kidney transplantation, Adult and Pediatric Nephrology, Tashkent, Uzbekistan; [3]Republican Specialized Scientific Practical Medical Center of Nephrology and Kidney transplantation, Immunogenetics, Tashkent, Uzbekistan

Background and Aims
Multiple trials have reported that SGLT2 inhibitors reduce the risk of its primary composite outcome of kidney disease progression or cardiovascular death in a wide range of patients with CKD. Our aim was to compare effects on kidney outcomes among the different types of kidney diseases.
Method
Eligible patients with eGFRs ≥30-45, or ≥45-90 ml/min/1. 73 m2 with a urinary albumin-to-creatinine ratio of ≥300 mg/g, and receiving renin angiotensin system inhibitor, where indicated and tolerated were randomized to dapagliflozin 10 mg once daily vs placebo. Kidney disease progression was defined as a sustained ≥30% eGFR decline from randomization or to <10 mL/min/1. 73 m2, start of maintenance dialysis or receipt of a kidney transplant, or renal death, and the effects of dapagliflozin were analyzed using a pre-specified Cox model. Testing for heterogeneity of effect between pre-specified kidney disease subgroups was performed, including exploratory analyses by specific glomerular disease etiologies.
Results
362 participants were followed for a median of 2. 0 years. 90 (24. 8%) had diabetic kidney disease, 126 (34. 8%) had glomerular disease, 94 (26%) had hypertensive or renovascular disease, and 52 (14. 4%) had other or unknown causes. Overall, dapagliflozin reduced the risk of kidney disease progression by 34% (dapagliflozin 29/178 vs placebo 48/184; hazard ratio 0. 62, 95% CI 0. 51-0. 78). This relative risk reduction appeared broadly similar in subgroup analyses by primary cause of kidney disease and by different types of glomerular disease.
Conclusion
Our study with a few numbers of patients with diabetic and non-diabetic causes of CKD showed that dapagliflozin reduced risk of kidney disease progression with relative risk reductions that were broadly similar across the different CKD etiologies.

Accuracy and cost saving using haemoglobin A1c and lipid profiles point-of-care testing: a multicentre study

Phei Ching Lim[1, 2], Leong Seng Tan[3], Jason Lye Hin Kam[1], Hadzliana Zainal[2] & Chong Hui Khaw[4]
[1]Hospital Pulau Pinang, Pharmacy Department, Penang, Malaysia; [2]Universiti Sains Malaysia, School of Pharmaceutical Sciences, Penang, Malaysia; [3]Hospital Bukit Mertajam, Pharmacy Department, Penang, Malaysia; [4]Hospital Pulau Pinang, Medical Department, Penang, Malaysia

Introduction
Measurement of glycosylated haemoglobin (HbA1c) and lipid profiles have been the standard monitoring for diabetes control and cardiovascular disease management respectively. Point-of-care testing (POCT) offers quick results with little blood sample needed compared to standard laboratory testing that requires additional time to hospital or health clinic.
Objective
We aimed to compare HbA1c and lipid profile POCT accuracy to the standard hospital laboratory testing and evaluate the potential cost savings from the patients' perspective.
Methods
Venous blood sample obtained from the diabetes mellitus patients were sent for standard laboratory testing. Simultaneously, capillary blood samples were collected for HbA1c and lipid profiles POCT using Quo-Lab® and PixoTest® respectively. Demographic data, time taken for blood tests, patients' salary, cost of travelling including distance from hospital, and absenteeism cost were collected. Intraclass correlation coefficient (ICC) and correlation coefficient analyses were employed.
Results
Seventy-three patients (mean age 53. 8±12. 4, 60. 3% female) were included. Patients spent median 5(IQR 4) hours for blood taking. HbA1c POCT using Quo-Lab® showed excellent correlation [ICC 0. 984 (95% CI 0. 975, 0. 990), rho=0. 97, $P < 0.001$] to the standard laboratory test. However, lipid profiles POCT using PixoTest® showed moderate correlation with the ICC for total cholesterol, triglycerides, low-density-lipoprotein cholesterol and high-density-lipoprotein cholesterol (0. 652, 0. 597, 0. 743 and 0. 704 respectively). POCT translated to cost saving from patients' perspective was RM61. 65 (IQR RM53. 55) or USD13. 70 (IQR USD11. 90) [1USD =RM4. 50].
Conclusion
The HbA1c POCT showed high reliability while the lipid profiles POCT had moderate reliability as compared to standardised laboratory testing. POCT is a cost saving alternative option for patients who have difficulty to travel or having to miss work for routine blood tests.

CGM as a useful tool providing deeper insights into the glucose metabolism of patients with transfusion dependent b-thalassemia

Iskra Modeva[1, 2], Atanas Banchev[3, 4], Margarita Archinkova[2, 5] & Iva Stoeva[1, 6]
[1]University Pediatric Hospital "Prof. Ivan Mitev", Screening and Functional Endocrine Diagnostics, Sofia, Bulgaria; [2]Medical University, Sofia, Bulgaria; [3]National Haematology Hospital, Sofia, Bulgaria; [4]Expert center for thalassemia, University Hospital "Tzaritza Giovanna - ISUL", Sofia, Bulgaria; [5]University Pediatric Hospital "Prof. Ivan Mitev", Pediatric Endocrinology and Metabolic Diseases, Sofia, Bulgaria; [6]State University "Professor Assen Zlatarov, Faculty of Medicine, Burgas, Bulgaria

Background
The iron overload occurring in patients with transfusion-dependent B-thalassemia causes a wide range of endocrine disorders, one of the most common being glucose dysregulation. Both insulin deficiency and resistance are reported in these patients. Current recommendations require assessment of glucose abnormalities by testing fasting blood glucose (BG) and performing oral glucose tolerance tests (oGTT) annually after a certain age. A new promising method for determining glucose disorders is the use of continuous glucose monitoring system (CGM).
Case reports
We present three cases of patients with transfusion-dependent B-thalassemia (TDT) with high ferritin levels (above 1000 ng/mL despite of the chelating therapy) and glucose dysregulation. Fasting blood glucose and extended oGTT were conducted to evaluate the glucose homeostasis along with the calculation of HOMA-IR. CGM (Dexcome One) was applied to each of them for a period of one week. MRI was conducted to evaluate the iron overload in the liver and pancreas. The first patient (14 years, male) had normal HOMA-Ir = 0. 88, but oGTT showed pronounced hyperinsulinism and impaired glucose tolerance – BG at 120'- 9. 2 mmol/l. CGM data showed postprandial glucose elevation up to 15. 3 mmol/l and mean BG 6. 2 mmol/l. The second patient (14 years, female) had insulin resistance according to HOMA-Ir = 3. 16, and normal BG and insulin levels during oGTT but the CGM showed postprandial BG up to 12. 5 mmol/l and mean blood glucose 8. 01 mmol/l. The third patient (8 years, female) had normal HOMA-Ir = 0. 7 and insulin levels during oGTT, no hyperglycemia. Three symptomatic episodes of hypoglycemia were observed with BG 3. 1, 2. 5 and 2. 0 mmol/l – two of them during the oGTT and one later the same day. CGM data showed postprandial glucose elevation up to 13 mmol/l, mean BG 6. 1 mmol/l.
Conclusions
The use of CGM seems to be more useful for diagnosing glucose dysregulation in patients with TDT than fasting BG and oGTT alone. More investigations and a longer follow up are needed.

KARLOTTA 2. 0 (kids + adolescents research learning on tablet teaching aachen) – study results of a digital educational app for pediatric patients with type 1 diabetes

Maria Tincheva[1], Saeed El Ahmadieh[1], Johannes Boy[1], Martin Lemos[1] & Angeliki Pappa[1]
[1]University Hospital RWTH Aachen, Pediatrics, Aachen, Germany

Objectives
Improvement of disease-specific knowledge in pediatric patients with type 1 diabetes using a digital app and individualized teaching.
Methods
We developed the KARLOTTA app (Kids + Adolescents Research Learning on Tablet Teaching Aachen), a game with knowledge-quiz and mini-games, designed for use before outpatient clinic appointments. The app provides immediate feedback on answers, mirrored for caregivers. The quiz-content is based on established educational programs in Germany. In our randomized-controlled pilot study, 57 patients were included to evaluate acceptance, transition-readiness, and changes in behavior and glycemic control (HbA1c). Of the 57, 27 were in the intervention group and 30 in the control group. The mean age at diagnosis was similar in both groups (8. 37 Intervention, 9 Control), as was the mean duration of T1D (5. 19/5. 05 years). The gender distribution, insulin therapy type, and HbA1c values were comparable between the two groups. We analyzed 26 patients in the intervention group and 24 in the control group. The intervention group used the game 3 times over 6 months, with 3-month intervals. They completed quality of life (Qol), satisfaction, and transition questionnaires before and after the intervention. The control group filled out the same

questionnaires at their first and final visits after 6 months. The median time between visits in the intervention group was 101. 5 days (IQR 91-111), $n = 50$. The average time between the first and last visits was 210 days (SD 27), $n = 25$. The 26 intervention group patients completed a satisfaction questionnaire after the last game, with 15 multiple-choice, 2 open-ended, and 1 transition question for adolescents over 16. Responses were analyzed descriptively using the Likert scale. The analysis of the feedback Questionnaire indicated that patients learned from using the App. The App encouraged them to pay more attention to their blood sugar levels and improve insulin bolus administration. Patients reported increased openness in discussing their therapy with our diabetes team and a greater overall concern for their condition. They enjoyed the game feature and planned to continue using it. Both groups (Intervention and Control) showed improved HbA1c levels. Evaluation of our Qol and transition questionnaire will be reported.

Conclusion

Individualized teaching is essential for managing chronic diseases like T1D, particularly for children and adolescents who require intensive communication and ask for modern and age-adequate tools. The KARLOTTA app identifies knowledge gaps, offers customized teaching, and is easily implementable in outpatient settings. Further studies are planned in multi-centric and international settings.

Incidence trends and seasonal variation of new cases of type 1 diabetes in lithuanian children in 2001-2022

Ingrida Stankute[1], Kastytis Smigelskas[1], Dale Marciulionyte[2], Rytas Ostrauskas[1] & Rasa Verkauskiene[1]

[1]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Microbiology and Virusology, Veterinary Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania

Introduction

Type 1 diabetes (T1D) incidence is rising globally, with significant regional variation, ranging from low rates in Asia (2. 4-3. 2 per 100, 000 person-years) to the highest in Scandinavia and Sicilia (up to 65 per 100, 000 person-years). Despite extensive research, the contributing factors — climate, genetic, environmental, or lifestyle-related, remain unclear. Therefore, data from highly homogeneous populations, such as Lithuanian, may contribute to a better understanding of these factors. This study examines 21-year trends in childhood T1D incidence and seasonal patters in Lithuania.

Methods

The current study relied on the incidence data sourced from the T1D Database of Lithuanian children, while population data were procured from the Lithuanian Department of Statistics. The annual incidence rates for more than two decades were computed utilizing established methodologies (per 100, 000 person-years in children aged 0-14 years (*from this point onward per 100, 000 person-years*). The study included 2, 472 (1221 boys) patients with T1D diagnosis before the age of 15, permanent residents of Lithuania.

Results

During 2001-2022, the mean standardized incidence rate (IR) was 24. 09 per 100, 000 person-years (95% CI 20. 89, 27. 28). The IR scaled from 11. 4 to 40. 8 per 100, 000 person-years, with the lowest in 2001-2002, reaching its peaks in 2017 (36. 3 per 100, 00 person-years), 2021 (40, 8 per 100, 000 person-years) and 2022 (34 per 100, 000 person-years). Analysis of the trends in age subgroups, showed the most rapid increase in young teenagers (10-14 years), with more steadily increasing incidence in younger groups (0-4 years and 5-9 years). No significant disparity in incidence trends was noticed between male and female cohorts. The boys-to-girls ratio varied from 0. 7 to 1. 53 during the study period, however, the overall ratio was 1. 00. The majority of new T1D cases (54, 5%) were diagnosed from October to March, and the lowest incidence rate was during late spring and summer months (May-July).

Conclusion

This study demonstrates arapidly increasing incidence of T1D in Lithuanian children over a 21-year period, with the incidence peaking at 40. 8 cases per 100, 000 person-years in 2021, rating Lithuania among the top three European countries. The seasonal distribution of new cases, with the majority occurring during the darker months of the year, suggests a potential role of reduced sunlight exposure and lower vitamin D levels, as well as increased school related stress and viral infections during autumn and wintermonths. However, additional contributing factors are likely involved, underscoring the need for further research to elucidate the underlying mechanisms driving this trend.

JOINT1822

Pilot screening program for early detection of type 1 diabetes in first-degree relatives in saudi arabia (VISION-T1D)

Noor Bawahab[1, 2], Raghad MohammedHussain[1, 2], Iman Al-Gadi[1, 2], Yazed AlRuthia[3], Muhammad Mujammami[1, 2], Khalid Aburisha[1], Metib Alotaibi[1, 2], Sharifah Al Issa[1, 2], Amal Al-Saif[4], David Seftel[5], Chengting Tsai[5] & Reem Al Khalifah[1, 2]

[1]Division of Pediatric Endocrinology, Department of Pediatrics, College of Medicine, King Saud University, Riyadh, Saudi Arabia; [2]The University Diabetes Centre, King Saud University Medical City, Riyadh, Saudi Arabia; [3]College of Pharmacy, King Saud University, Department of Clinical Pharmacy, Riyadh, Saudi Arabia; [4]College of Psychology, Imam Mohammad ibn Saud Islamic University, Riyadh, Saudi Arabia; [5]Enable Biosciences, South San Francisco, California, United States

Background

Type 1 Diabetes (T1D) is a growing global health concern, with a notable rise in incidence in Saudi Arabia. Despite the potential benefits of early detection through screening programs, such initiatives are currently lacking in Saudi Arabia and other Arab countries.

Objectives

To evaluate the feasibility, acceptability, and cost-effectiveness of a T1D screening program targeting high-risk individuals, specifically children with a first-degree relative diagnosed with T1D.

Methods

The VISION-T1D program is a prospective cohort study focused on the early detection of pre-symptomatic T1D by screening children aged 2–18 years. The primary screening method involves testing for islet autoantibodies, including insulin autoantibodies (IAA), glutamic acid decarboxylase autoantibodies (GADA), IA-2 autoantibodies (IA-2A), and Zn-transporter 8 (ZnT8) autoantibodies. Optional genetic testing, including HLA phenotyping and the Genetic Risk Score (GRS), is offered. Outcomes include the feasibility of the screening process, prevalence of early-stage T1D, psychological impacts, educational interventions effectiveness, progression rates to Stage 3 T1D, and the economic viability.

Results

The VISION-T1D program began in May 2024. As of December 2024, 210 families have been enrolled with 430 children. Data collection will continue until April 2025.

Conclusions

The VISION-T1D study provides a practical approach to T1D screening tailored to the healthcare landscape of Saudi Arabia. The insights gained from this pilot program will inform the development of a national, population-based screening initiative designed to reduce diabetic ketoacidosis (DKA) at diagnosis, improve long-term outcomes, and alleviate the economic burden of T1D. The VISION-T1D initiative could also serve as a scalable and sustainable model that can be adopted internationally, contributing to global efforts to manage and prevent T1D.

JOINT796

Impact of sex and BMI on A1C trajectory amongst children and adolescents with type 1 diabetes

Joseph Leung[1, 2], Melissa Braschel[3], Qian Zhang[3], Jeffrey Bone[1, 3] & Shazhan Amed[1, 3]

[1]University of British Columbia, Vancouver, Canada; [2]Vancouver General Hospital, Vancouver, Canada; [3]BC Children's Hospital Research Institute, Vancouver, Canada

Introduction

Glycemic control in type 1 diabetes is known to worsen significantly during adolescence and young adulthood. Female sex is known to be a risk factor for this worsening glycemic control, but the mechanisms of this are unclear. We hypothesized that body mass index (BMI) may be a factor that facilitates worsening A1C in female youth.

Methods

We have previously established the British Columbia Pediatric Diabetes Registry (BC-PDR). Using this registry, we graphed the trajectory of A1C by age according to sex. We conducted this same analysis stratifying by BMI categories: underweight/normal weight, overweight, and obese. Using regression modelling, we compared average A1C between the sex-BMI categories for each age, adjusting for total daily dose of insulin and presence of chronic comorbidities. Missing data was addressed with multiple imputation.

Results
There were 674 patients with type 1 diabetes diagnosed in childhood and adolescence from the BC-PDR who were included in this study (299 females and 375 males). At recruitment, 35. 5% of females and 31. 7% of males were in the overweight or obese BMI category. At age 7, the average A1C of underweight/normal weight males was 7. 53%, which was not significantly different compared to the average A1C of overweight males, obese males, and females of any BMI category. However, by age 17, there were significant differences in average A1C between the different sex-BMI categories. At this age, the average A1C of underweight/normal weight males was 8. 16%, but average A1C was 0. 84% lower (95% CI -1. 10, -0. 59, $P < 0.001$) in overweight males and 0. 94% lower (95% CI -1. 21, -0. 68, $P < 0.001$) in obese males. The average A1C of underweight/normal weight females was not significantly different from that of underweight/normal weight males (+ 0. 15%, 95% CI -0. 04, 0. 34, $P = 0.118$), but was 0. 78% higher (95% CI 0. 53, 1. 03, $P < 0.001$) in overweight females and 0. 35% higher (95% CI 0. 15, 0. 55, $P = 0.001$) in obese females.
Conclusions
There appears to be a differential effect of sex and BMI on A1C amongst adolescents with type 1 diabetes. Average A1C is highest amongst adolescent females who are in the overweight and obese BMI categories. These findings suggest that weight management (e. g. including the use of weight loss adjuncts), particularly in overweight and obese post-pubertal females, may be an important treatment modality for adolescents with type 1 diabetes. Further study is needed to determine the factors and mechanisms, whether biological or psychological, that contribute to elevated A1C amongst female youth living with type 1 diabetes.

JOINT2112

Incidence and burden of childhood diabetes in china from 1990 to 2021: findings from the global burden of disease study 2021

Bingyan Cao[1], Chunxiu Gong[2] & Guoshuang Feng[3]
[1]Children's Hospital Affiliated to Capital Institute of Pediatrics, Department of Endocrinology, Beijing, China; [2]Beijing Children's Hospital, Capital Medical University, Department of Endocrinology, Genetics and Metabolism, Beijing, China; [3]Beijing Children's Hospital, Capital Medical University, Big Data Center, Beijing, China

Background
Diabetes is emerging as a significant threat to human health in 21st-century China. Accurate data on diabetes prevalence, incidence, associated mortality, and life expectancy are crucial for informing public health policy, yet such data remain scarce, particularly among children in China.
Methods
Data from the Global Burden of Diseases, Injuries, and Risk Factors Study (GBD) 2021 were used to estimate the incidence, trends, disease burden, and regional distribution of type 1 and type 2 diabetes among children in China from 1990 to 2021. Children aged 0 to 19 years with diabetes were included in the analysis.
Results
In 2021, the national incident cases of diabetes in children were 342, 121 (95% uncertainty interval [UI], 265, 699-426, 246), with 204, 118 being male (60•0%) and 138, 003 being female (40•0%). The incidence was 102. 34 per 100, 000 (95% UI 79•48-127•50) for diabetes mellitus, 4•09 per 100, 000 (95% UI 2•82–5•64) for T1DM, and 98•25 per 100, 000 (95% UI 75•11-123•44) for T2DM. The incidence of T1DM in males was lower than in females (3•96 per 100, 000 vs. 4•24 per 100, 000), while the incidence of T2DM in males was higher than in females (110•30 per 100, 000 vs. 84•42 per 100, 000). From 1990 to 2021, the incidence of diabetes mellitus, T1DM, and T2DM in children increased by 156•5%, 24•68%, and 168•31%, respectively. T1DM-associated DALYs in children decreased by 70•23%, whereas T2DM-associated DALYs increased by 51•08%. Over the past 30 years, the number of diabetes-associated deaths in children decreased by 75%.
Interpretation
The growing trend of childhood diabetes in China, particularly type 2 diabetes, requires significant attention. Future measures should focus on reducing the incidence of type 2 diabetes and its complications in areas with high obesity rates.

JOINT2260

Elevated alanine aminotransferase predicts the risk of prediabetes/-diabetes and NAFLD in obese children: a cross-sectional retrospective study

Song Guo[1], Jun Zhang[1], Rujiang Zheng[1], Qiuli Chen[1] & Yanhong Li[1]
[1]First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background
The obese children and adults, NAFLD is associated with type 2 diabetes or prediabetes. However, it is unrealistic to have all obese children willing to complete all assessment items.
Objective
To detect the association of type 2 diabetes and prediabetes in obese children with MRI-PDFF proved NAFLD and assess useful screening factors for predicting obese children without NAFLD and prediabetes.
Method
We recruited a cohort of 149 Chinese children/adolescents who finished OGTT test, and 108 children/adolescents with MRI-PDFF evaluated liver fat content. The diagnosis of prediabetes and type 2 diabetes was based on either hemoglobin A1c, fasting plasma glucose or 2 h post-load glucose concentrations.
Result
The prevalence of prediabetes and type 2 diabetes in children/adolescents with obesity was 26. 17% and the OR increased with increasing serum GGT and morning cortisol. There was no significant difference in glucose concentrations at 0 and 120 min in both the prediabetic and non-prediabetic groups with different NAFLD grades. Among factors screened in the comparison between subgroup of NAFLD with prediabetes and subgroup without NAFLD and prediabetes, BMISDS/P90, PLT, ALB, UASDS, ALT, cortisol and HOMA-IR were included for logistic regression analysis. the OR for both NAFLD and prediabetes in obese children increased with increasing serum ALT and PLT. ROC analysis shows ALT lower than 18. 5IU/l had a sensitivity of 85% and specificity of 72. 7% for detecting patients without prediabetes and NAFLD in obese children (ROC AUC 0. 857).
Conclusion
Although prediabetes is highly prevalent among children/adolescents with obesity but was not consistent with the grades of NAFLD. ALT lower than 18. 5IU/l might be useful in deciding not to conduct OGTT test or liver MRI-PDFF after basic examination for children with obesity.

Background
Previously, Patient-Reported Experience Measures (PREMs) for children with type 1 diabetes (CwD) were developed in cooperation with parents and clinicians alone. This resulted in a lack of knowledge concerning children's experiences in meeting the health care system. It is a challenging task to obtain this information from children, who do not read and write. There exists no animated PREMs for CwD and their parents, teachers and health care professionals (HCP). Our overall aim is to develop an animated, diabetes specific Patient Reported Outcome Measures (PROMs) and PREMs instrument for CwD aged 4-12 years old. This work builds on the animated Child Health Rating Inventories (CHRIS) PROMs questionnaire.
Aims
The specific aims of this study were 1) To obtain the perspectives of CwD, parents, teachers and HCP on needs and experiences, when attending an outpatient pediatric diabetes clinic in Denmark and 2) To establish a minimal set of PREM domains as the first step in developing an animated PREMs questionnaire.
Materials and Methods
COSMIN guidelines for developing Patient reported Outcome measures (PROMs) were used. Three participatory design workshops were executed in

two regions in Denmark in the period August 2023 – April 2024. Relevant stakeholders partook in the workshops: 16 CwD, 36 Parents, 7 Teachers and 19 HCP and 27 facilitators. Play-based communication and storytelling tools were used to enable and engage CwD to participate in the workshop. All participants (but HCP) were systematically encouraged to describe what is of personal value in daily life with diabetes and also describe bio-psycho-social challenges and needs in the PREMs context. All workshops were video- and audio recorded, transcribed, and thematically analyzed.

Results

Four main PREM domains were identified. 1) Diabetes-specific expertise, where trust in the HCP's expertise played an important role. 2) The hospital environment, in which the consultation rooms were perceived as clinical and not child-friendly, resulting in children being more passive during the consultation. 3) The diabetes team's family-centered approach with emphasis on establishing and maintaining a relationship while considering the child's interests and developmental stage. 4) The family's preparation and planning prior to outpatient visits, which was described as important to create a more positive experience for the child.

Conclusion

This study describes four important PREM domains for a CwD, parents and HCPs attending an outpatient pediatric clinic. The next study is to develop animated PREM items specific to these four PREM domains in order to develop a PREM questionnaire.

Use of portable elastomeric pump for home-based continuous enteral carbohydrate administration through gastrostomy in children with congenital hyperinsulinism or ketotic hypoglycemia

Henrik Christesen[1, 2], Susan Nørregaard[1] & Rikke Jørgensen[1]
[1]Odense University Hospital, Hans Christian Andersen Children's Hospital, Odense, Denmark; [2]University of Southern Denmark, Clinical Research, Odense, Denmark

Background

Continuous enteral glucose infusion through gastric tube may be useful in patients with congenital hyperinsulinism (CHI) or pathological ketotic hypoglycemia (pKH). Home-based enteral treatment with infusion pump is, however, limited by impracticalities for patients and their caregivers.

Methods

We developed the novel use of enteral portable elastomeric pump (ePEP) therapy to deliver home-based continuous enteral carbohydrates through gastrostomy. The first pilot results of this novel treatment modality are presented.

Results

Ten pediatric patients (girls, $n = 7$) were enrolled. Six patients had pKH with unknown background ($n = 4$); Russel-Silver syndrome ($n = 1$), or clinical glycogen storage disease with digenic heterozygous *PYGL* and *GBE1* DNA variants ($n = 1$). Four patients had diffuse CHI with biallelic *ABCC8* mutations ($n = 2$), activating *GCK* mutation ($n = 1$), or CHI with associated organ malformations of unknown cause ($n = 1$). Prior surgical treatment for ABCC8-CHI included near-total or partial pancreatectomy ($n = 2$). All patients had a gastrostomy. Prior or concomitant treatment included continuous i. v. glucose ($n = 7$), continuous i. v. glucagon ($n = 3$) , diazoxide ($n = 8$), octreotide ($n = 8$) long-acting somatostatin analogue ($n = 5$), sirolimus ($n = 3$), dietary cornstarch ($n = 9$), extended-release cornstarch ($n = 9$), protein supplementation ($n = 8$), and/or overnight gastrostomy tube feeding with liquid full-dietary products ($n = 9$), glucose ($n = 8$), or maltose ($n = 8$). Home-based ePEP therapy with home-blended glucose 10-40% was initiated at the median (range) age of 5. 4 (0. 3-15. 1) years. Maltose or apple juice was used alternatively in two for shorter periods. The median (range) duration of ePEP was 1. 25 months (4 hours to 26 months). Three patients aged 1. 8 y (ABCC8-CHI), 5. 4 y (GCK-CHI) and 13. 9 y (pKH) still use ePEP therapy at present after 7, 19 and 26 months, with high satisfaction in terms of improved glucose control and ease of daily living. One patient (8. 7 y; pKH) reported improved and good glucose control, relief of abdominal pain after discontinuation of extended release cornstarch and normalization of appetite, after which glucose was stable on oral diet only. Reports of insufficient ($n = 3$) or no ($n = 2$) improvement in glucose control, or hyperglycemia ($n = 1$) was associated with early discontinuation. The ePEP therapy was reportedly easy to use in seven and difficult to use in three. One reported skin irritation.

Conclusion

ePEP therapy with carbohydrates is a promising supplement to selected patients with CHI or pKH, although not continued by all due to insufficient effect, hyperglycemia or difficulties. This should encourage to formal trials with long-term follow-up on dose, effect, quality of life and adverse effects, e. g. on the intestinal microbiome.

Association of the triglyceride/HDL cholesterol ratio with cholesterol efflux in adolescents with type 2 diabetes mellitus

Jose Antonio Orozco Morales [1], Margarita Torres Tamayo[2], Aída Xochitl Medina Urrutia[2], Juan Reyes Barrera[2], Esteban Jorge Galarza[2], Juan Gabriel Juárez Rojas[2], Angélica María Ballén Torres[1] & Patricia Guadalupe Medina Bravo[1]
[1]Children's Hospital of México Federico Gómez, Department of Endocrinology, Mexico City, Mexico; [2]Instituto Nacional de Cardiología Ignacio Chávez, Department of Endocrinology, Mexico City, Mexico

Background

Cardiovascular disease is a frequent cause of morbidity and mortality in patients with type 2 diabetes mellitus (T2D). In adult patients with T2D, it has been observed that the elevation of the triglyceride (Tg)/HDL-C ratio is positively correlated with cardiovascular disease, and that the capacity to promote cholesterol efflux from peripheral cells to HDL is decreased, which is inversely associated with the incidence of cardiovascular disease (CVD). Currently, there are no studies that relate the Tg/HDL-C ratio with the functionality of HDL particles (cholesterol efflux) in adolescent patients with T2D.

Objective

To evaluate the association of the Tg/HDL-C ratio with cholesterol efflux in adolescents with DM2.

Material and Method

This Cross-sectional study included a total of 70 adolescents, 47 of which had T2D treated at the Diabetes Clinic of the Federico Gómez Children's Hospital of Mexico and 23 healthy adolescents of the same age and sex were included. The protocol was approved by the local Ethics and Research Committees. Anthropometric and biochemical variables (HbA1c, lipid profile, aminotransferases) were determined. Cholesterol efflux capacity (CEC) was determined by measuring the efflux of fluorescently labeled cholesterol from J774 mouse macrophages cells.

Results

In Our study, differences were observed between both groups in the concentrations of glucose ($P < 0.001$), total cholesterol ($P = 0.043$), triglycerides ($P < 0.001$), c-HDL ($P < 0.001$), Tg/c-HDL ratio ($P < 0.001$), Apo A ($P = 0.029$) and GGT ($P = 0.010$). When evaluating cholesterol efflux in both groups, no significant difference was observed ($P = 0.600$).

Conclusions

In the present study, we found no association between the Tg/HDL-C ratio and cholesterol efflux in adolescents with T2D. Further studies are required to assess whether some cardiovascular risk indices that have already been evaluated in adults would be applicable to the pediatric population with T2D.

Effects of transition from basal insulin glargine 100 u/ml to 300 u/ml on glycemic control in children and adolescents with type 1 diabetes - real-world data

Fulya Mete Kalaycı[1], Deniz Özalp Kızılay[1], Günay Demir[1], Samim Özen[1] & Damla Gökşen[1]
[1]Ege University Faculty of Medicine, Division of Pediatric Endocrinology and Diabetes, İzmir, Türkiye

Introduction

Insulin glargine 300 U/mL (Gla-300), a second-generation basal insulin, has shown in phase 3 trials to provide better glycemic control than insulin glargine

Table 1: Glycemic Parameters Before and After Transition in the Patients

	Glargine U100	Glargine U300	p
Weight SDS	0. 35 ± 0. 99	0. 51 ± 1. 10	0. 113
Total Insulin Dose (IU/kg/day)	0. 75 ± 0. 24	0. 81 ± 0. 22	0. 082

Hypoglycemic Events	7. 38 ± 6. 22	6. 69 ± 4. 09	0. 622

100 U/mL (Gla-100), while reducing hypoglycemia risk and glycemic variability. However, real-world data in the pediatric age group is limited. This study aims to evaluate the impact of switching from Gla-100 to Gla-300 on glycemic control in children and adolescents with type 1 diabetes (T1D).

Methods

The study included 20 patients aged 8-20 years with T1D who were using continuous glucose monitoring (CGM) systems and transitioned from Gla-100 to Gla-300. Glycemic parameters assessed before and three months after the transition.

Results

Mean age and mean duration of diabetes was 13. 14 ± 2. 89, 4. 71±3. 26 years, respectively. The mean age at transition to Gla-300 was 12. 58 ± 2. 85 years. Glycemic data from the patients' CGM is shown in Table 1. Basal insulin ratio increased significantly ($P = 0.036$), and an increase in total insulin dose was also observed, although it was not statistically significant. No significant changes were found in glycemic parameters, nor was there a reduction in the number of hypoglycemic events or the time below range before and after the transition.

Conclusion

Gla-300 provides glycemic control similar to Gla-100, but with a higher basal insulin ratio, without significant differences in overall glycemic outcomes.

Early detection of peripheral and autonomic neuropathy in children and adolescents with type 1 diabetes mellitus

Yaprak Ece Yola Atalah[1], Volkan Taşdemir[2], Nermin Gorkem Sirin[2], Melike Cevikdizici[3], Ummu Mutlu[3], Aslı Derya Kardelen Al[1], Melek Yildiz[1], Sukran Poyrazoglu[1], Feyza Darendeliler[1], Kubilay Karsidag[3], Mehmet Baris Baslo[2], Firdevs Bas[1] & Elif Kocasoy Orhan[2]

[1]Istanbul University, Istanbul Faculty of Medicine, Department of Pediatric Endocrinology, Istanbul, Türkiye; [2]Istanbul University, Istanbul Faculty of Medicine, Department of Neurology, Istanbul, Türkiye; [3]Istanbul University, Istanbul Faculty of Medicine, Department of Endocrinology and Metabolism, Istanbul, Türkiye

Introduction

Clinical neuropathy manifestations emerge during the initial stages of diabetes in children with type 1 diabetes mellitus (T1DM). Early detection and intervention of these changes leading to neuropathy are crucial for the follow-up of patients diagnosed with T1DM. Our objective was to identify a more sensitive method that can be implemented in clinical settings for the early detection of neuropathy in children. The present data constitute initial findings from our pilot study.

Methods

Thirty-one children with T1DM aged 6-18 years were evaluated using nerve conduction studies (NCS) (motor and sensory), autonomic tests (sympathetic skin responses and R-R interval variability studies), Sudoscan®, and neuropathy screening questionnaires (Composite Autonomic Symptom Score-31 (COMPASS-31) and Michigan Neuropathy Screening Instrument (MNSI)).

Results

This study recruited 31 children (F/M: 15/16), two of whom were prepubertal. The mean age of the T1DM patients was 13. 8±2. 9 years and mean duration of diabetes was 6. 1±1. 8 years. Mean insulin requirement of the study population was 1. 1±0. 4 U/kg/day, while their mean HbA1c level in the preceding year was 9. 2%±1. 8. All nerve conduction studies were within normal ranges, except for one patient. The COMPASS-31 scores were within the normal range for all the patients. The Sudoscan® results were within the normal range for all patients, except for one patient who exhibited moderate risk. Although within normal ranges, the median, peroneus, and tibial nerve motor latencies and amplitudes of the medial plantar and sural sensory nerves were affected by the duration of diabetes ($P < 0.05$). Our research has demonstrated that prolonged diabetes duration correlates with diminished amplitudes and extended latencies in the aforementioned nerves. Multivariate regression analysis showed that T1DM duration was significantly associated with peroneus motor latency (β=5. 164, $P = 0.011$), tibial motor conduction velocity (β=-1. 748, $P = 0.006$), total COMPASS-31 score (β=0. 254, $P = 0.010$), Sudoscan® foot mean value (β=-0. 229, $P = 0.013$), and HbA1c level (β=-2. 069, $P = 0.004$) (R^2=0. 73). The results of this study suggest that duration of diabetes affects autonomic dysfunction and electrophysiological parameters in the pediatric population.

Conclusion

In children with T1DM, screening for diabetic neuropathy is recommended during the early stages. It may be possible to detect early changes in the pediatric population using nerve conduction studies, autonomic tests, Sudoscan®, and diabetic neuropathy screening. To detect early changes, it also seems important to determine normative data for NCS in the pediatric population.

Does celiac disease have an impact on hypoglycemia awareness in children with type 1 diabetes?

Gülşen Özer[1], Ibrahim Mert Erbas[1], Murat Karataş[1], Fatma Yavuzyılmaz Şimşek[1], Özge Köprülü[1], Özlem Nalbantoğlu[1] & Behzat Ozkan[1]

[1]University of Health Sciences, Dr. Behçet Uz Children's Hospital, IZMIR, Türkiye

Background

Hypoglycemia awareness is the ability to recognize when blood sugar is low, through the activation of counter-regulatory hormones and the perception of symptoms. It is a known fact that frequent hypoglycemic events can impair this awareness. Celiac disease increases the risk of hypoglycemia in type 1 diabetes (T1D). However, there is a lack of data in the literature regarding whether celiac disease leads to hypoglycemia unawareness in children with T1D. We aimed to investigate the possible effects of celiac disease on hypoglycemia awareness in pediatric patients with T1D.

Materials and Methods

This prospective cross-sectional study included children aged 5-18 years with T1D, who visited our clinic between November 2024 and January 2025. The participants were divided into two groups: one with both T1D and celiac disease, and another with T1D alone. The sample size was determined through a power analysis with a 3:1 case-to-control ratio. Hypoglycemia awareness was evaluated by the Clarke's questionnaire, and participants' knowledge about hypoglycemia management was noted. The results are presented as means (±standard deviation) or medians (25-75th percentile) depending on the distribution of the data.

Results

The study was conducted with 87 T1D patients (54% male, age 12. 5 ± 3. 5 years). The mean diabetes duration was 5. 1 (±3. 5) years, and the average HbA1c level was 8. 5% (±1. 8). The most common symptoms reported during hypoglycemic events were hand trembling (46. 5%), weakness (23. 3%), and dizziness (10. 5%). Celiac disease was present in 24. 4% ($n = 21$) of the participants, with a median disease duration of 3. 1 (1. 4 – 5. 3) years. No significant differences were found between the two groups in age, diabetes duration, HbA1c, or hypoglycemia knowledge ($p > 0.05$). Among the individuals with celiac disease, 19% ($n = 4$) had impaired hypoglycemia awareness, while 12% ($n = 8$) of those with only T1D had this issue. There was no significant difference between the two groups regarding hypoglycemia unawareness ($P = 0.476$). Additionally, there were no significant differences in age, HbA1c levels, diabetes duration, or knowledge about hypoglycemia between patients with and without impaired hypoglycemia awareness ($p > 0.05$).

Conclusion

To our knowledge, this is the first study to show that celiac disease did not affect hypoglycemia awareness in children with T1D. We also found no correlation between HbA1c levels and hypoglycemia awareness. These findings suggested

that while children with T1D and celiac disease, or those with poor metabolic control, may experience more frequent hypoglycemic events, the duration of hypoglycemia may be more critical in the development of hypoglycemia unawareness.

JOINT2840

Prognostic value of the neutrophil-to-lymphocyte ratio for acute appendicitis in children with acute abdominal pain and T1DM

Svitlana Suchok[1], Oleksandr Yakymenko[1] & Vladyslav Burmistrov[1]
[1]National Pirogov Memorial Medical University, Vinnytsya, Pediatric Surgery, Vinnytsia, Ukraine, Peadiatric surgery, Vinnytsia, Ukraine

Background
Abdominal pain is often associated with T1DM and DKA in children. Underlying causes include not only functional disorders and impaired motility of GIT but also common surgical emergencies, namely acute appendicitis (AA) and peritonitis. The neutrophil-to-lymphocyte ratio (NLR) has recently become a valuable tool for diagnosing DKA and endothelial dysfunction in T1DM. Moreover, several studies have shown that NLR serves as an indicator of systemic inflammation and reflects a balance between the latter and immunity. However, its prognostic discriminative role between surgical emergencies and abdominal pain in DKA in children with T1DM remains unclear.
Aim
We aimed to analyze the utility of NLR in the differential diagnosis of surgical (acute appendicitis and peritonitis) and non-surgical causes of acute abdominal pain in children with T1DM and/or DKA.
Material and Methods
102 pediatric patients were enrolled in this study and further divided into three groups: group I – patients with DKA and acute abdominal pain ($n = 21$); group II ($n = 70$) - patients with acute appendicitis; group III ($n = 11$) – patients with acute appendicitis and T1DM/DKA. Diagnosis of acute appendicitis was confirmed by pathology. All patients underwent routine workup. Additionally, blood gases were evaluated in groups I and III. NLR was calculated as a ratio between the neutrophil and lymphocyte counts measured in peripheral blood. Written informed consent was obtained from the parents.
Results
The mean level of NLR was significantly different between group I (5. 06 ± 3. 13) and two other groups with AA (group II – 9. 40 ± 8. 03; group III – 9. 95 ± 8. 6), $P = 0$, 01786; $P = 0$. 0254, respectively). However, there was no difference between groups II and III($P = 0$. 8348). It may be due to the leading role of intraabdominal infection in the development of inflammation in both groups. Further ROC analysis has shown that NLR may be used as a prognostic marker of intraabdominal surgical diseases (AUC = 0. 827; 95% CI = 0. 671-0. 983; $p < 0$. 01) at a cut-off value of 7. 81 with sensitivity = 72. 7% (CI = 43. 4-90. 2 %) and specificity = 85. 7% (65. 3-95. 0 %), Youden's index – 0. 58. We also found that NLR strongly inversely correlates with the LYM fraction of CBC ($r_s = -0.98$; $p < 0$. 0001). It shows the crucial role of immunity in the natural course of AA in children with T1DM.
Conclusion
NLR is significantly higher in children with T1DM and AA than in children with non-surgical acute abdominal pain. A cut-off value of 7. 81 may be used to predict the surgical cause of acute abdominal pain (AA) in children with T1DM and/or DKA.

Beyond glycemic control: managing rare complications in type 1 diabetes

Leonor Rodrigues[1], Hugo Marinho[1], Teresa Azevedo[1], Márcia Alves[1] & Joana Guimarães[1]
[1]ULS Região de Aveiro, Aveiro, Portugal

Effective metabolic control is crucial for preventing microvascular and macrovascular complications in patients with type 1 diabetes mellitus (T1DM). Here, we present a case of a young woman with T1DM who developed two rare complications: acute insulin neuritis and diabetic myonecrosis. A 45-year-old woman with T1DM since 2009, followed by the Endocrinology Department, experienced, since her diagnosis, irregular medical follow-up, poor adherence to treatment, and inadequate glycemic control. She developed severe microvascular complications, including proliferative diabetic retinopathy (treated with photocoagulation), diabetic nephropathy, and autonomic dysfunction with gastroparesis. Additionally, she suffered from significant macrovascular complications, such as an acute myocardial infarction in 2015 (managed with angioplasty) and peripheral arterial disease of the lower limbs. In 2022 and 2023, her adherence to treatment improved, leading to intensified insulin therapy and a rapid reduction in HbA1c from 14. 2% to 6. 6%. During this period, she reported paresthetic pain in the lower limbs along with mild-to-moderate paraparesis. Electromyography confirmed moderate sensorimotor axonal neuropathy, which later progressed to Charcot neuroarthropathy. The most likely cause was treatment-induced neuropathy, also known as acute insulin neuritis. She was started on tapentadol and pregabalin, resulting in significant pain relief. She was referred to a Diabetic Foot specialist and, in October 2024, underwent surgery to stabilize her left foot. In 2023, she had a prolonged hospitalization due to diabetic myonecrosis with abscess formation in the gastrocnemius muscles. She presented with pain, swelling, and redness in the right calf, along with functional impairment that lasted for two weeks, without fever or trauma history. MRI revealed multiple abscessed collections within the muscular planes of the right leg, with an extensive inflammatory process suggestive of abscessed hematomas. A muscle biopsy confirmed acute inflammatory infiltration and necrosis of skeletal muscle, consistent with spontaneous diabetic myonecrosis. She underwent surgical drainage of the abscesses and received broad-spectrum antibiotic therapy for 20 days. Currently, she remains under regular follow-up, with HbA1c levels ranging between 7. 6% and 8. 4%. This case underscores the complexity of managing T1DM and highlights the importance of recognizing rare complications early to minimize their impact on patients' quality of life.

The interplay of cortisol, trygliceride glucose index and microalbuminuria in type 2 diabetes: a prospective observational case-control study

Selma Jusufovic[1 2 3 4], Šefkija Balić[5], Amela Dizdarević-Bostandžić[6] & Bosanko Horozić[6]
[1]University Clinical Centre Sarajevo, Clinic for Endocrinology and Diabetes, Sarajevo, Bosnia and Herzegovina; [2]ASA Hospital, Department for Endocrinology, Sarajevo, Bosnia and Herzegovina; [3]Sarajevo School of Science and Technology, Medical School, Sarajevo, Bosnia and Herzegovina; [4]University Clinical Centre Sarajevo, Endocrinology and dijabetes, Sarajevo, Bosnia and Herzegovina; [1]University Clinical Centre Sarajevo, Clinic for Endocrinology and Diabetes, Sarajevo, Bosnia and Herzegovina; [6]Clinic for Endocrinology and Diabetes, University Clinical Centre Sarajevo, Sarajevo, Bosnia and Herzegovina

Background
Studies have suggested possible link between diabetic kidney disease (DKD) and cortisol levels. Relationship between DKD and triglyceride-glucose (TyG) index is currently investigating. However sole relationship between cortisol, TyG index and microalbuminuria in diabetic population is unknown. This study aims to investigate the potential association and interplay between microalbuminuria, cortisol, and TyG index in DMT2 patients.
Material and Methods
One hundred and seventy participants were enrolled in this study, comprising one hundred patients with DMT2 and seventy healthy volunteers. Anthropometric and biochemical characteristics were evaluated in all participants. Parameters measured included fasting blood glucose, HbA1c, 8h cortisol, cortisol after low-dose overnight dexamethasone suppression test (DEX cortisol), ACTH, urinary albumin-to-creatinine ratio (UACR), Trygliceride Glucose Index (TyG) (calculated as TYG = ln (fasting triglycerides × fasting glucose/2)). Microalbuminuria is defined as UACR > 30-≤ 300mg/g. Statistical analyses included correlation analysis, multiple regression, and subgroup analysis. The study protocol was approved by the Ethical Committee of the University Clinical Centre Tuzla, under the number 02-09/2-50/14.
Results
ROC analysis showed that cortisol (AUC: 0. 733, $p < 0$. 001) and TyG index (AUC: 0. 968, $p < 0$. 001) effectively discriminate between T2DM patients and controls, with optimal cut-off values of >342 for cortisol and >8. 49 for TyG. Strong correlations were found between TyG index and microalbuminuria ($r = 0$. 7463, $p < 0$. 0001) and cortisol and microalbuminuria ($r = 0$. 5151, $p < 0$. 0001), suggesting that higher levels of TyG index and cortisol are associated with more pronounced microalbuminuria. Median cortisol levels increased from 324. 0 (IQR: 233. 0–400. 0) in the normoalbuminuria group to 518. 7 (IQR: 424. 0–593. 2) in the microalbuminuria group, while the Tyg values increased from 8. 5 (IQR: 8. 2–8. 9) in normoalbuminuria to 10. 2 (IQR: 9. 8–10. 5) in microalbuminuria.

Additionally, the TYG index showed a correlation with cortisol ($r = 0.4071$, $p < 0.0001$), suggesting that higher cortisol levels are associated with higher TYG index values. We did not find a significant association of DEX cortisol and ACTH with the TyG index and microalbumin.

Conclusion

Elevated cortisol levels and the TyG index are strong predictors of microalbuminuria in patients with type 2 diabetes mellitus. Additionally, a higher TyG index is associated with higher cortisol levels. This connection is particularly important as it establishes a foundation for further research on how reducing the Tyg index may influence cortisol levels and decrease the risk of microalbuminuria.

JOINT2224

Unveiling the spectrum of mitochondrial diabetes – a single center, multidisciplinary case series analysis

Rutie Mamlok Sherf[1], Efrat Markus[1], Miriam Shtainsneider[1, 2], Peretz Shlomi[3] & Shlomit Koren[1, 2]

[1]Shamir Medical Center, Endocrine and Diabetes Institute, Zerifin, Israel; [2]Tel-Aviv University, Faculty of Medicine, Tel Aviv, Israel; [3]Shamir Medical Center, Neurologic ward, Zerifin, Israel

Introduction

Mitochondrial diabetes is a rare form of adult-onset diabetes mellitus (DM) caused by mutations in mitochondrial DNA, most commonly in the MT-TL1 (m.3243ANG) genotype. It manifests clinically as Maternally Inherited Diabetes and Deafness (MIDD) or Mitochondrial Encephalopathy with Lactic Acidosis and Stroke-like episodes (MELAS). The primary abnormality causing DM is inefficient and suboptimal glucose-stimulated insulin secretion. Treatment strategies for mitochondrial diabetes remain unclear due to sparse published evidence. Metformin therapy is generally avoided due to the high risk of lactic acidosis in this population.

Aim

To better define and understand the natural history of mitochondrial diabetes.

Results

A case series analysis was conducted on 14 patients treated at a multidisciplinary MELAS clinic over the past two years. Among them, 7 patients exhibited glucose homeostasis abnormalities: 6 were diagnosed with DM and 1 with Impaired Fasting Glucose. The mean age at DM diagnosis was 36.1 years, while MELAS was diagnosed at 44.3 years. Two patients were primarily diagnosed as type 1 DM despite negative anti GAD antibodies, and four patients were classified as type 2 DM on presentation. Treatment regimens included Insulin therapy (via Insulin pump or injections), GLP-1 agonists, SGLT2 inhibitors, Sulfonylurea and lifestyle modifications. Two patients had a history of lactic acidosis secondary to Metformin use, and one patient reported a history of Diabetic Ketoacidosis. The mean HBA1C level is 7.04%. Microvascular complication were observed in three patients and included nephropathy and neuropathy, while none developed macrovascular complications. Additional comorbidities included overweight, dyslipidemia and hypertension in 3/7 patients. Other MELAS manifestations were hearing loss, stroke like events and cardiac complications in 6/7, 1/7 and 3/7 patients respectively. When compared to the 7 MELAS patients with normal glucose homeostasis, the patients with DM tended to be older (47 vs 35 years), had higher BMI (23.8 vs 17.9) and more comorbidities.

Conclusion

Mitochondrial diabetes is underrecognized, often diagnosed before MELAS, leading to potential mismanagement and complications. A multidisciplinary approach is essential to improve diagnosis, treatment, and patient outcome. Our specialized MELAS clinic provides valuable insights into the natural history and therapeutic strategies for this rare condition.

JOINT3834

Diabetic foot recurrence: a study of predictive factors

Hajar Sabaoui [1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]

[1]CHU Ibn Rochd, Clinical Neuroscience and Mental Health Laboratory, Endocrinology, Diabetology, Metabolic Diseases and Nutrition Department, Casablanca, Morocco

Introduction

Diabetic foot recurrence involves lesions reappearing after completely healing, leading to serious complications like amputations and decreased quality of life. This study identifies characteristics and predictive factors for recurrence.

Patients and Methods

This is an analytical retrospective cohort study conducted among patients hospitalized in our department for diabetic foot, including those who presented a recurrence from January 2018 to December 2024. Data were analyzed using IBM SPSS Statistics 27.0.1, with chi-square and Student's t-tests used to identify significant associations with recurrence.

Results

Our study included 405 patients, 89 of whom had a recurrence (22%). The average age was 56.7 years, with 78.65% being over 50 years old. The male gender predominated with a sex ratio of 2.8.85.6% of the patients had type 2 diabetes. The average duration of diabetes was 14.35 years. The average Hba1c was 10.24%. 79% of patients were on insulin. 21.35% of cases had a history of amputation. Peripheral artery disease (PAD) was present in 46% of cases, diabetic retinopathy in 69.6%, peripheral neuropathy in 55%, and autonomic neuropathy in 28%. The average duration of progression was 72 days. 51.7% had a deformity. 40.5% of the cases had bone involvement. Statistical analysis of our sample revealed several factors significantly associated with the recurrence of diabetic foot lesions: Age over 50 ($P = 0.03$) has a notable impact on recurrence. Additionally, a longer duration of diabetes ($P = 0.019$), insulin treatment ($P = 0.02$), and glycemic imbalance ($p < 0.01$) are key factors. Complications such as peripheral artery disease (PAD) ($p < 0.01$), retinopathy ($p < 0.01$), and peripheral neuropathy ($p < 0.01$) play a crucial role. Bone involvement ($P = 0.03$), a history of amputation and deformities ($p < 0.01$) are also associated with recurrence.

Conclusion

Diabetic foot lesion recurrence is influenced by several factors, including age, duration of diabetes, treatment type, glycemic imbalance, presence of retinopathy, neuropathy, and peripheral artery disease (PAD), bone involvement, history of amputation, and foot deformity. Our study suggests that developing treatment strategies based on these factors could help prevent recurrences and improve patients' quality of life.

Simulation-based education enhances healthcare professionals' confidence in managing acute diabetes scenarios

Kalyaani Persad[1], Aqeelah Khatoon[1], Aashritha Buchipudi[1], Nevil Philip[2], Angelica Sharma[3], Amanda Ling Jie Yee[1], Akshat Sinha[1], Punith Kempegowda[4] & Team Dekode[4]

[1]University of Birmingham, Birmingham, United Kingdom; [2]Department of Diabetes and Endocrinology, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [3]Norfolk and Norwich University Hospitals NHS Foundation Trust, Norwich, United Kingdom; [4]Applied Health Sciences, School of Health Sciences, University of Birmingham, Birmingham, United Kingdom

Background

The JOINT consensus by the American Diabetes Association and the European Association for the Study of Diabetes emphasises the importance of practical and up-to-date training in acute diabetes care. Simulation via Instant Messaging for Bedside Application (SIMBA) is a Simulation-Based Learning (SBL) model that provides healthcare professionals hands-on learning for various medical conditions, including acute diabetes.

Objectives

- Measure the change in participants' confidence in managing acute diabetes post-SBL.
- Evaluate participants' satisfaction and the relevance of the intervention to clinical practice.

Methods

This mixed-methods study took place in the UK between July and October 2024. Clinical experts were interviewed to assess general needs in acute diabetes care, while students and resident doctors were interviewed to assess specific needs for focused simulation sessions. The team employed the SIMBA model to deliver SBL on nine acute diabetes-related conditions. Healthcare professionals interested in acute diabetes care were invited to participate in the session. After the session, participants were invited to post-simulation interviews to discuss their satisfaction with and perceptions of the case's relevance to clinical practice. Those who completed both pre- and post-SIMBA surveys were included in the analysis. Two independent authors performed inductive thematic analysis on the interviews.

Results
17 participants completed both pre- and post-session surveys and were included in the analysis. Confidence in managing acute diabetes scenarios improved significantly (pre- vs post-session: 33. 3% vs. 78. 4%, $P < 0.001$). All participants rated the SIMBA session as excellent or good. 94. 1% strongly agreed that the cases were relevant to their practice, and 82. 3% preferred this teaching method over traditional approaches. Post-session interviews and surveys revealed that experts and residents appreciated the benefits of simulation in promoting safer learning environments and enhancing guideline implementation. Future sessions desired by participants included antenatal and perinatal diabetic care, diabetes remission, hypoglycaemia, and perioperative diabetes care.
Conclusion
SIMBA significantly improved participants' confidence in managing acute diabetes conditions. Participants highly rated the model, which they found relevant to their clinical practice. This model shows great promise in enhancing training and education for healthcare professionals involved in acute diabetes management. Future sessions should include a broader range of acute diabetes scenarios, incorporating the wider multi-disciplinary team, to enhance holistic care for people with diabetes in the acute setting and better prepare healthcare professionals.

Development and validation of hba1c prediction models using CGM metrics in korean pediatric patients with type 1 diabetes: insights on average glucose and recent glycemic trends of CGM

Hakyung Lee[1], Mi Yang[2], Hwa Young Kim[2] & Jaehyun Kim[2]
[1]Seoul National University Bundang Hospital, Bundang, South Korea; [2]Seoul National University Bundang Hospital, Department of Pediatrics, Bundang, South Korea

Introduction
HbA1c has long been used as the gold standard marker for reflecting average blood glucose levels over the previous three months. As continuous glucose monitoring (CGM) systems are becoming a part of the standard care for type 1 diabetes (T1D), there is greater recognition of the limitations of HbA1c in revealing hyperglycemia, hypoglycemia, and glycemic variability. Meanwhile, CGM metrics such as Time in Range (TIR) have emerged as important parameters for glycemic control. In this study, we aimed to explore the relationship between CGM metrics and HbA1c in Korean pediatric patients with T1D and to develop and validate the HbA1c prediction models based on different CGM metrics and time intervals.
Methods
A total of 85 children and adolescents with T1D, using CGM (G6 or G7, Dexcom, USA), were included. Twelve weeks of CGM records were analyzed to evaluate the relationship between HbA1c and CGM metrics, including TIR, Time Above Range (TAR), Time Below Range (TBR), Coefficient of Variation (CV), and Average Glucose, across time intervals of 0–2 weeks, 0–4 weeks, 4–8 weeks, 8–12 weeks, and 0–12 weeks prior to HbA1c measurement. HbA1c prediction models were developed using Ridge regression modeling and cross validation with CGM metrics as the training data set. Additionally, to assess the performance of the HbA1c prediction models, a separate test data set comprising 12-week CGM records from 80 patients was used.
Results
Average Glucose had the greatest impact on A1c across all time periods, and was identified as the most suitable metric for HbA1c prediction with higher R^2 and lower AIC values than TIR and TAR. Validation using test data confirmed that regression models based on Average Glucose demonstrated the best performance, with the lowest MSE (MSE = 0.1425) and highest R^2 ($R^2 = 0.8444$). Among time periods, the 0–4 week interval consistently had the largest coefficients, suggesting it is the most predictive of HbA1c compared to other intervals.
Conclusion
Average Glucose, TIR, and TAR are highly related with HbA1c, with Average Glucose being the most predictive metric. The 0–4 week period showed the strongest association with HbA1c changes, highlighting the importance of closely reviewing recent glycemic data, especially in the 4 weeks preceding an HbA1c test, to better understand glycemic trends and inform clinical decisions.

Keywords: Continuous glucose monitoring; CGM metrics; HbA1c; prediction modeling

Challenges in transitioning from pediatric to adult diabetes care in armenia: patient experiences and systemic gaps

Irina Muradyan[1, 2], Yelena Aghajanova[1, 2], Shogher Grigoryan[1], Natela Navasardyan[3], Bayburdyan Gayane[1, 2], Lusine Arakelyan[1, 2], Marianna Gevorgyan[1] & Lusine Navasardyan[2, 4]
[1]"Muratsan" University Hospital Complex, Yerevan, Armenia; [2]Yerevan State Medical University, Chair of Endocrinology, Yerevan, Armenia; [3]"Muratsan" University hospital complex, Yerevan, Armenia; [4]"Arabkir" MC, Yerevan, Armenia

Background
The transition from pediatric to adult care for patients with type 1 diabetes mellitus (T1DM) is a vulnerable period marked by gaps in care continuity and self-management. Limited data exist on patient-reported experiences in low-resource settings.
Objective
To evaluate healthcare accessibility, quality of care, self-management support, and satisfaction during transition in Armenia.
Methods
A questionnaire-based study was conducted with 60 T1DM patients (30% male, 70% female; age 18–≥22 years), stratified by disease duration (≤5, 6–10, ≥11 years) and residence (60% urban, 40% rural). A 25-item survey compared care across four domains: accessibility, quality, self-management support, and outcomes. Qualitative feedback was thematically analyzed.
Results
Accessibility: Visit frequency declined post-transition:33. 3% visited pediatric endocrinologists biannually vs. 21. 7% in adult care, while 23. 3% attended adult clinics less than annually (vs. 3. 3% pediatric). Scheduling adult appointments was harder (28. 4% vs. 10% pediatric, $P < 0.05$), and provider accessibility dropped sharply (66. 7% pediatric vs. 28. 3% adult, $P < 0.01$). **Quality of Care**: Staff knowledge was rated "excellent" by 83. 3% in pediatric vs. 23. 3% in adult care ($P < 0.01$). Discussions on mental health, nutrition, and insulin management were less frequent in adult care (85% vs. 32% for mental health, $P < 0.01$). Specialist referrals declined from 75% (pediatric) to 35% (adult, $P < 0.01$). **Self-Management Support**: Education on critical skills (insulin devices, carbohydrate counting) declined from near-universal pediatric coverage to 30–50% in adult care. Support for patient independence dropped from 86. 7% ("very supportive" pediatric) to 30% (adult, $P < 0.01$). **Outcomes**: Post-transition, only 20% had HbA1c ≤7. 4%, 11. 7% - 7. 5–8. 4%, and 25%-≥8. 5%; 43. 3% did not even check HbA1c in the past year. Hyperglycemia worsened in 52% (vs. 18% improved). **Satisfaction**: Satisfaction dropped post-transition: 88% were "very satisfied" in pediatric care vs. 25% in adult care, and 97% vs. 63% would recommend their diabetes provider. Only 20% in adult care felt their needs were "always" met.
QualitativeThemes
- **Pediatric strengths**: Family-centered care, structured and continuous education, tight monitoring and contact with diabetes providers.
- **Adult gaps**: Fragmented communication, abrupt transitions, inadequate psychosocial support.
- **Patient priorities**: Financial subsidies for glucometer strips/CGMS and empathetic providers. One participant emphasized, *"Doctors must listen and discuss, not just prescribe. "*

Conclusion
T1DM patients in Armenia face significant declines in care quality, self-management education, and provider empathy post-transition, exacerbated by financial barriers and rural disparities. Systemic reforms—gradual transition protocols, subsidized diabetes technologies, and training to foster patient-centered communication—are urgently needed to address these gaps.

New criteria of 1-hour post-load plasma glucose for the diagnosis of intermediate hyperglycaemia and type 2 diabetes in adolescents

Caroline Pellicciari[1], Eduardo Caldana[1], Arthur Lyra[1], Barbara Aoto[1], André Ruzzi[1], Carlos Longui[1] & Cristiane Kochi[1]
[1]Irmandade da Santa Casa de Misericórdia de São Paulo, São Paulo (SP), Brazil, Pediatric Endocrinology Unit, São Paulo, Brazil

Introduction
According to the International Diabetes Federation (IDF) Position Statement, people with a 1-h G ≥ 155 mg/dL (8. 6 mmol/l) during an oGTT are considered to

have intermediate hyperglycemia (IH) and people with a 1-h G ≥ 209 mg/dL (11. 6 mmol/l) are considered to have type 2 diabetes (T2D). There are few papers that analyze those findings in children/adolescents. The aim of this study is to analyze the oGTT response in adolescents with overweight/obesity and compare the frequency of IH according to fasting glucose, 1-h and 2-h post-load.
Methods
This study comprised 195 pubertal adolescents with overweight/obesity who underwent oGTT. They were classified into 3 groups: Group 1: Fasting glucose > 100 mg/dL, Group 2: 1-h post-load (1hG) ≥ 155 mg/dL and group 3: 2-h post-load PG (2hG) >140 mg/dL. The Homeostasis Model Assessment of Insulin Resistance (HOMA-IR), and Oral Disposition Index (oDI) were calculated.
Results
A total of 195 curves were evaluated, 63 male and 132 female with a mean chronological age (SD) of 12. 5 years (2. 1). The mean zBMI and Waist-to-Height Ratio (WHtR) relation were 2. 7 kg/m^2 (0. 7) and 0. 61 (0. 06), respectively. No patient had diagnosis of T2D based on 2hG, but one patient was diagnosed as T2D after 1hG. 16 (8. 2%) patients had IFG, 10 (5. 1%) had 1hG ≥ 155 mg/dL and 8 (4. 1%) had IGT after 2hG. Compared to patients with normal oGTT, those in all 3 groups were older (P = 0. 002, 0. 022 and <0. 001, respectively), had higher HOMA-IR (P = 0. 031), but there were no differences in zBMI or waist/height ratio. Patients in groups 2 and 3, with higher 1hG and 2hG, had lower oDI value (p < 0. 05), suggesting worse β-cell function.
Conclusion
There is limited literature in adolescents indicating that an 1h post-load PG ≥ 155 mg/dL with NGT during an oGTT is highly predictive for detecting progression to T2D. However, our findings suggest worse β-cell function and that the same cut-offs could potentially be used in children/adolescents. Surprisingly, in this group of patients, the severity of obesity did not correlate with the presence of β-cell dysfunction, a fact that could be associated with duration of disease progression instead of the anthropometric parameter. Further studies are needed to confirm these findings.

Causal association between diabetes and herpesvirus infections: a bidirectional two-sample mendelian randomization study

ying liu[1], jin wu[1] & Chuanjie Yuan[1]
[1]West China Second University Hospital of Sichuan University, Chengdu, China

Objective
Diabetes, marked by elevated blood sugar, raises the risk of serious health issues, including heart and nerve problems, and is linked to a variety of diseases caused by herpesviruses. This study investigates the causal associations between genetically predicted diabetes, its complications, and herpesvirus infections.
Patients
Using summary data from genome-wide association studies (GWAS) on diabetes and herpesvirus infections, the population was primarily of European descent.
Measurements
We employed a bidirectional two-sample Mendelian Randomization (MR) design. Analyses were conducted using the Inverse Variance Weighted (IVW) method, weighted median, weighted mode, and MR-Egger regression. Sensitivity analyses included MR-Egger, MR-PRESSO, Cochran's Q test, and leave-one-out analysis.
Results
Our Mendelian Randomization study revealed no significant causal association between diabetes and herpesvirus infections. The forward analysis showed odds ratios for Type 2 diabetes and herpes zoster (OR: 0. 99, 95% CI: 0. 92-1. 08, P = 0. 855) and Type 1 diabetes and infectious mononucleosis (OR: 0. 98, 95% CI: 0. 92-1. 04, P = 0. 478) that were not statistically significant. Notably, the IVW analysis showed no significant association between diabetic polyneuropathy and herpesvirus infections, the Weighted Median method suggested a marginal association with herpes zoster (OR: 1. 08, 95% CI: 1. 00-1. 17, P = 0. 05), warranting further research. The reverse analysis also demonstrated non-significant. Sensitivity analyses, including MR-Egger, weighted median, and MR-PRESSO, confirmed these findings, indicating no pleiotropy or outliers affecting the Results
Conclusions
This rigorous MR study provides evidence against a direct causal association between diabetes or its complications and herpesvirus infections, highlighting the need for further exploration into this complex association.

Epidemiology of monogenic diabetes in the czech republic

Stepanka Pruhova[1], Marketa Pavlikova[2], Klara Vesela[1], Katerina Kolarova[1], Michaela Cermakova[1], Zdenek Sumnik[1], Jan Lebl[1] & Petra Dusatkova[1]
[1]Department of Paediatrics, Motol University Hospital and Second Faculty of Medicine, Charles University, Prague, Czech Republic; [2]Department of Probability and Mathematical Statistics, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic

Background
Monogenic diabetes results from a single-gene defect affecting pancreatic beta cells. Accurate diagnosis enables personalized treatment. While precise European prevalence data are lacking, the U. K., a global leader in monogenic diabetes research, reports an estimated prevalence of 24. 8/100, 000 and an observed prevalence of 5. 8/100, 000. This study assessed diagnostic trends and determined the minimum prevalence of monogenic diabetes in the Czech Republic. The clinical indication criteria for genetic investigation were: positive family history of diabetes, diagnosis of diabetes up to 25 years of age, positive C-peptide and negative pancreatic autoantibodies. Since 2011, milder criteria have been used without the necessity of a positive family history of diabetes and the age of diagnosis of diabetes up to 30 years of age.
Material and Methods
Clinical and genetic data were collected from individuals suspected of having monogenic diabetes referred for genetic testing and registered in the National Registry for Monogenic Diabetes between 1999 and 2023. Covariates were analysed using the t-test, and categorical variables with $\chi 2$.
Results
By 2023, we registered 1, 879 families (i. e., probands) with suspected monogenic diabetes, and 728 (39 %) received a confirmed diagnoses (1, 473 individuals from the Registry in total). The causative variant was identified in 13 different genes, most commonly in *GCK* (69 %), *HNF1A* (15 %), and *HNF4A* (8 %). The minimum prevalence of monogenic diabetes was 13. 6/100, 000. The number of referred probands increased from 42 per year between 1999-2001 to 142 in 2023. Between 1999 and 2011, stricter clinical criteria resulted in a detection rate of 67% while milder clinical criteria for genetic testing have led to a currently stable detection rate of 30- 40%. The average age of diabetes diagnosis was 15. 5 (± 9. 4) years, with 76 % of probands having a family history of diabetes.
Conclusion
We reported an increasing referral rate and stable detection rate of monogenic diabetes in the Czech Republic. However, considering the U. K. prevalence estimates, about half of the Czech patients with monogenic diabetes remain un- or misdiagnosed. Supported by Czech Ministry of Health (NW24-01-00160)

Closed-loop CamAPS system shows time-specific glucose variability and hypoglycemic patterns in very young children with type 1 diabetes

Pollé Olivier[1], Kevin Perge[2, 3], Cécile Godot[1], Alix Bensacon[1], Diletta Ingrosso[1, 4], Laura Arvis[2], Marc Nicolino[2, 3], Julie Pelicand[5] & Jacques Beltrand[1, 6]
[1]Hôpital Universitaire Necker Enfants-Malades, Pediatric Endocrinology and Diabetes, Paris, France; [2]Pediatric Endocrinology, Diabetology and Metabolism Department, Femme Mère Enfant Hospital, Hospices Civils de Lyon, Lyon, France; [3]Claude Bernard University, Lyon 1, Lyon, France; [4]University of Chiety, Department of Paediatrics, Chieti, Italy; [5]Children Hospital, Hopital Universitaire of Toulouse, Paediatric Gastroenterology, Hepatology, Nutrition and Diabetology Department, Toulouse, France; [6]Institut Cochin, Inserm U 10116, Paris, France

Introduction
Type 1 diabetes (T1D) incidence is increasing in very young children (i. e. under 6 years of age). Achievement of glycaemic targets in this subgroup is challenging due to their variable insulin needs, unpredictable eating habits, and activity levels. This leads to poor metabolic control and increased diabetes-related complications. Hybrid closed-loop (HCL) systems offer promising solutions to improve glycaemic outcomes. However, studies in very young children are scarce and show inconsistent results in reducing hypoglycemia and glycaemic variability. The aim of this study was to evaluate the impact of HCL on glycaemic control and more specifically the patterns of glycemic parameters throughout the day.
Materials and Methods
Data were collected from fifty children with T1D for ≥6 months who switched to HCL (CAM APS FX) before 6 years of age in two pediatric diabetes centre.

Clinical and continuous glucose monitoring (CGM) data were collected before (Pre-HCL) and at 1, 3, and 6 months post-HCL initiation. From the raw CGM data, metrics of hyperglycemia, hypoglycemia, euglycemia and glucose variability (global, intra-day and inter-day) were calculated. Comparisons between Pre-HCL and every post-HCL periods were performed using student t-tests.

Results

Time in range (TIR, 70-180mg/dL) significantly increased of 11. 9% ± 11% from 1 month after HCL ($P < 0.001$) with a concomitant decrease of target above range (TAR, >180 mg/dL) of -13% ± 13. 4% ($P < 0.01$). The improvement in glycemic control was sustained at 6 months with greatest differences observed during the night ($P < 0.001$). Hypoglycaemic episodes (< 70mg/dL and <54mg/dL) remained similar before and after HCL (all $p > 0.05$). However, hourly glycaemic patterns sustain that the morning period (7AM-1PM) was at significantly higher risk for hypoglycemia after HCL initiation with time below range (<70mg/dL) and LBGI peaking at respectively 6. 6% ± 7. 5% and 1. 5±1. 5 at 1 month compared to 1PM-7AM period ($P < 0.0001$). This risk of hypoglycaemia persisted for up to 6 months ($P < 0.01$). Finally, while the coefficient of variation remained stable at all time points ($p > 0.05$), a significant decrease in intra-day (MAGE) and inter-day glucose variability (CONGA, MODD) was observed from 1 month post-HCL (all $P < 0.05$).

Conclusion

In real life, HCL significantly improved the TIR and TAR in very young children with T1D from the first month after activation of the system. Morning time demonstrated to be a period at risk of hypoglycaemia in this age group, highlighting the importance of optimizing HCL therapy and informing parents of these specific times at risk of glycaemic instability.

Comprehensive genetic testing reveals a deep intronic variant in HNF1A in a family with early-onset diabetes mellitus

Eleni Z Giannopoulou[1], Abukabar Moawia[2], Joanna Lerner[2], Stefanie Zorn[1], Reiner Siebert[2], Christian Denzer[1] & Martin Wabitsch[1]
[1]Division of Pediatric Endocrinology and Diabetes, Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, Germany; [2]Institute of Human Genetics, Ulm University and Ulm University Medical Centre, Ulm, Germany

Maturity Onset Diabetes of the Young (MODY) is a form of diabetes characterized by autosomal dominant inheritance and early age at diagnosis. Pathogenic variants in HNF1A are associated with MODY3 and most of them are in the coding region. We describe the case of a patient with early-onset diabetes mellitus (DM). Comprehensive genetic testing, including whole-exome-analysis via next generation sequencing (NGS) performed due to multiple affected family members, revealed a heterozygous deep intronic variant in HNF1A, 14 years after DM diagnosis. The index patient (female, 10 years old) was admitted for further evaluation due to random hyperglycemia after a minor trauma. The girl mentioned no symptoms of polyuria, polydipsia or weight loss. At admission she had a HbA1c of 8. 1%, C-peptide was 0. 9 μg/dl and type 1 diabetes associated autoantibodies were negative. An oral glucose tolerance confirmed DM. Regarding her family history, her mother was suffering from DM since the age of 15 years and was treated at first with sulfonylureas and later on with insulin. Her maternal grandmother had kidney cysts and was suffering from DM since the age of 30 years and was treated with oral antidiabetic drugs. Three other family members from the mother's side were diagnosed with DM at a young age and were treated with sulfonylureas or insulin. None of them had a definite diagnosis regarding DM type. Sequencing of genes associated with MODY types 1-5 (incl. exon/intron boarders ± 20 bp) was performed of the index patient at diagnosis, but revealed no pathologic Results Treatment with sulfonylureas was started due to her strong family history, which was suggestive of monogenic diabetes. A good glycemic control with sulfonylureas was achieved until the age of 16 years, when HbA1c levels increased and treatment with prandial insulin injections was initiated. At the age of 18 years, targeted NGS panel including MODY types 6-14 was, also, negative. At the age of 24 years, whole-exome-sequencing via NGS and re-evaluation of the 14 MODY associated genes including deep intronic regions, revealed the heterozygous intronic variant c. 327-28A > G;p. ? in the HNF1A gene in the index patient, as well as in 4 other affected family members. The variant is absent from gnomAD and clinical databases. Expanding genetic testing, including re-evaluation for deep intronic variants, for young individuals with a strong family history of DM, non-autoimmune DM and negative routine genetic testing, is recommended as it can determine prognosis, treatment and family counseling.

Cross sectional and longitudinal study of arterial stiffness in pediatric patients with type 1 diabetes mellitus (T1DM), with glycemic metrics derived from continuous glucose monitoring (CGM) devices

Eirini Georeli[1], Georgia Sotiriou[2], Athanasia Chainoglou[2], Stella Stabouli[2], Assimina Galli-Tsinopoulou[3, 4] & Athanasios Christoforidis[2]
[1]General Hospital Kavala, Paediatric, Kavala, Greece; [2]School of Medicine Faculty of Health Sciences, Aristotle University of Thessaloniki, 1st Department of Paediatrics, Hippokratio General Hospital, Thessaloniki, Greece; [3]School of Medicine Faculty of Health Sciences, Aristotle University of Thessaloniki, Unit of Pediatric Endocrinology and Metabolism, 2nd Department of Paediatrics, AHEPA General Hospital, Thessaloniki, Greece; [4]School of Medicine, Faculty of Health Sciences, Aristotle University of Thessaloniki, 2nd Department of Pediatrics, University General HOspital AHEPA, Thessaloniki, Greece

Aim

To investigate early indicators of cardiovascular disease (CVD) in youths with type 1 diabetes mellitus (T1DM), focusing on pulse wave velocity (cfPWV) and augmentation index (AIx@75) and their associations with various glycemic parameters and new metrics derived from continuous glucose monitoring (CGM) systems.

Patients and Methods

The study had two parts: for the cross-sectional part, 124 youths with T1DM (58 boys, mean age: 10. 75 ± 3. 57 years and mean disease duration: 3. 09 ± 2. 91years) were assessed, whereas for the longitudinal part, 87 patients (44 boys, mean age 10. 72 ± 3. 35 years and mean disease duration: 3. 27 ± 2. 84 years at the first assessment), completed 3 visits with a six month interval. In each visit, cfPWV and AIx@75 were quantified using a validated non – invasive method, while glycemic parameters such as HbA1c, time in range (TIR), time above range (TAR) and time below range (TBR) were assessed during the last 3 months from the assessment. For the longitudinal part patients were divided in 2 groups: *TIR improvers*: patients with constantly TIR≥ 70% or constantly TIR ≥ 60% and improved by + ≥ 10% from the beginning of the study vs *TIR non-improvers* and *HbA1c improvers*: patients with constantly HbA1c ≤ 7% or constantly HbA1c ≤ 8% and improved by -≥0. 8% from the beginning vs *HbA1c non-improvers*. Univariate and multivariate linear regression were used to explore the association of cfPWV and AIx@75 with glycemic variables.

Results

In the cross-sectional study all arterial stiffness parameters were significantly correlated with systolic and diastolic blood pressure (SBP, DBP), whereas AIx@75 was negatively correlated with TIR ($r = -0.190$, $P = 0.034$) and positively correlated with TAR ($r = 0.212$, $P = 0.018$). In the longitudinal study, TIR improvers had lower PWV values ($P = 0.013$) at the 3rd assessment compared to TIR non-improvers and showed significant improvement in ΔPWV Z score according to age ($P = 0.022$) and ΔSBPindex ($P = 0.036$). Finally, no significant difference regarding arterial stiffness parameters was shown between HbA1c improvers and HbA1c non-improvers.

Conclusion

Higher AIx@75 values were significantly correlated to lower TIR and higher TAR values. Children and adolescents who had TIR in the suggested target or improved their TIR, showed significantly lower PWV values in their final assessment and significantly improved both PWV and SBP. Such a finding was not shown when HbA1c was used as a metric of glycemia, indicating TIR as a more sensitive index for CVD.

Development and validation of diabetes interpreter, a mobile application-based tool for point-of-care evaluation of children with diabetes

Alapan Mahapatra[1], Anurag Bajpai[1], Proteek Sen[1], Vibha Yadav[1], Dhvani Raithatha[1], Santosh Olety[2], Rishi Shukla[1], Jayati Jhala[3], Ankita S[4] & Piyush Sharma[1]
[1]Regency CDER, Pediatric Endocrinology, Kanpur, India; [2]Karnataka Institute of Endocrinology and Research, Bengaluru, India; [3]P D Hinduja Hospital and Research Center, Mumbai, India; [4]Venkateswara Institute of Medical Sciences, Gajraula, India

Background

Inappropriate classification of pediatric diabetes has significant short and long-term implications.

Aim
To develop and validate Diabetes Interpreter Application (DIA), a mobile tool for point-of-care guidance for classifying pediatric diabetes.
Methods
DIA provides suggestions for diagnosis and work-up based on clinical parameters (age at diagnosis, disease duration, presentation, and insulin requirement). The guidance of the DIA, an adult endocrinologist (AE), a senior Pediatric endocrinologist (SPE), a young pediatric endocrinologist (YPE), a pediatrician (PED), and a pediatric trainee (PT) were compared to the gold standard management and diagnosis of 302 children with diabetes (250 Type 1, 35 Type 2, six monogenic, and 11 neonatal).
Results
DIA had the highest concordance rate (score 596 out of 604, 98. 6%). The concordance score for SPE (546; 90. 4%) and YPE (491; 81. 3%) was higher than the AE (405; 67. 1%), PED (287; 47. 5%) and PT (258; 42. 7%). The proportion of correctly classified subjects with Type 1 diabetes was higher for the SPE (249, 99. 6%), DIA (247, 98. 8%), and AE (234, 93. 6%) compared to the YPE (214, 85. 6%), PED (229, 91. 6%) and PT (206, 82. 4%). Type 2 Diabetes was correctly classified by Diabetes Interpreter, YPE, AE, SPE, PED, and PT in 34 (97. 1%), 33 (94. 3%), 30 (85. 7%), 18 (51. 4%), 20 (57. 1%) and 14 (40%) subjects, respectively. The SPE classified 15 subjects (43%) with Type 2 Diabetes as Type 1 without autoimmune work-up in 5 (33. 3%). Work-up was suggested in a greater proportion of subjects not needing evaluation by PT (250, 100%), PED (245, 98%), and AE (124, 49. 6%) compared to SPE (8, 3. 2%), YPE (25, 10. 0%), and DI (3, 1. 2%). Autoimmunity work-up was not recommended in 28 (66. 7%) by the AE, 36 (85. 7%) by YPE, 11 (26. 2%) by SPE, and 1 (2. 4%) by Diabetes Interpreter where indicated.
Conclusion
The high concordance score of the Diabetes Interpreter suggests its role in point-of-care guidance for assessing children and adolescents with diabetes. Using the Diabetes Interpreter would have prevented diagnostic errors and unwarranted work-up. To the best of our knowledge, this is the first mobile application-based tool for pediatric and adolescent diabetes classification.

Fibrosis and severe steatosis contribute to liver dysfunction in patients with insulin resistance after hematopoietic stem cell transplantation

Haruki Yamano[1], Kei Takasawa[1], Reiko Kagawa[2], Yoko Saito[1], Ryosei Iemura[1], Eriko Adachi[1], Maki Gau[1], Takeru Yamauchi[1], Ryuichi Nakagawa[1], Akito Sutani[1], Shigeru Takishima[1], Fukiko Kitahata[3, 4], Miyako Murakawa[3], Takeshi Isoda[1], Takahiro Kamiya[1], Tomohiro Morio[1], Masatoshi Takagi[1], Satoshi Okada[2] & Kenichi Kashimada[1, 5]
[1]Institute of Science Tokyo, Department of Pediatrics and Developmental Biology, Tokyo, Japan; [2]Hiroshima University, Department of Pediatrics, Hiroshima, Japan; [3]Institute of Science Tokyo, Department of Gastroenterology and Hepatology, Tokyo, Japan; [4]Institute of Science Tokyo Hospital, Clinical Laboratory, Tokyo, Japan; [5]National Center for Child Health and Development, Division of Endocrinology and Metabolism, Tokyo, Japan

Background
Hematopoietic stem cell transplantation (HSCT) survivors can develop a unique form of diabetes mellitus (DM) characterized by severe insulin resistance (IR) and dyslipidemia, despite having a non-obese body habitus. These clinical features resemble those of partial lipodystrophy (PL), and have recently been conceptualized as HSCT-associated PL. In classic PL, liver fibrosis, notably metabolic dysfunction-associated steatohepatitis (MASH), is recognized as a crucial factor determining long-term outcomes. However, few studies have investigated the hepatic status of non-obese post-HSCT patients with DM, emphasizing the need for greater understanding of their underlying pathophysiology.
Methods
We examined 20 non-obese (BMI $<$ 25) HSCT recipients at two Japanese institutions (Institute of Science Tokyo and Hiroshima University). To reduce confounding influences, we excluded patients receiving ongoing corticosteroids or immunosuppressants, as well as those with drug-induced liver injury or hepatic graft-vs-host disease (GVHD). Participants were divided into two groups: those who developed DM with IR (DM group) and those who had not yet manifested DM (DM(-) group). We compared serum markers of liver fibrosis (type IV collagen, hyaluronic acid) alongside hepatic steatosis and fibrosis scores measured by ultrasound elastography, FibroScan® (controlled attenuation parameter [CAP] and liver stiffness measurement [LSM], respectively).
Results
Between the two groups, we found no significant differences regarding age at evaluation, BMI, intensity of conditioning regimens, or serum liver fibrosis markers (type IV collagen and hyaluronic acid). However, time since HSCT was significantly longer in the DM group. Although there was no statistically significant difference in serum fibrosis markers, FibroScan® measurements revealed that both hepatic steatosis and fibrosis scores were significantly higher in the DM group. (CAP: DM group 307 [261–343. 5] dB/m vs. DM(-) group 237 [216. 5–271] dB/m, $P = 0.041$, and LSM: DM group 6. 7 [5. 9–9. 9] kPa vs. 4. 1 [3. 5–4. 7] kPa, $P = 0.007$)
Discussion
These findings suggest that non-obese HSCT survivors with DM show a pattern of hepatic steatosis and fibrosis consistent with PL. Based on our results, FibroScan® surveillance may be more sensitive than conventional serum markers for detecting early hepatic abnormalities in this population. In a certain case, liver biopsy highlighted a form of fibrosis differing from typical MASH, underscoring the need for further investigation into disease mechanisms.
Conslusion
HSCT survivors can develop not only abnormal glucose and lipid metabolism, but also hepatic dysfunction probably due to PL. FibroScan® is an effective non-invasive tool for assessing liver dysfunction in post-HSCT patients.

Three-year OCT/OCTA follow-up of retinal neurovasculature in pediatric type 1 diabetes

Semra Tiryaki Demir[1], Ahmet Uçar[2], Tuğçe Dursun Yılmazşamlı[1], Emine Betül Akbaş Özyürek[1], Ecrin Çakır[1] & Aydilek Dagdeviren Cakir[2]
[1]University of Health Sciences, Şişli Hamidiye Etfal Health Practices and Research Centre, Ophthalmology, Istanbul, Türkiye; [2]University of Health Sciences, Şişli Hamidiye Etfal Health Practices and Research Centre, Pediatric Endocrinology and Diabetes, Istanbul, Türkiye

Purpose
To investigate three-year changes in retinal neurovascular structure in children and adolescents with type 1 diabetes (T1D) without clinical diabetic retinopathy using optical coherence tomography (OCT) and OCT angiography (OCTA).
Methods
This prospective, cross-sectional, observational study included T1D patients without DR, assessed between May and September 2022 (T1D-C group). Retinal neurovascular structures in the macular and peripapillary regions were quantitatively analyzed using OCT and OCTA and compared with data collected three years prior (T1D-P group). Associations with Tanner's pubertal stage, diabetes duration, and HbA1c were assessed. Statistical significance was set at $P < 0.05$.
Results
Ninety-two eyes from 46 T1D patients were included. The T1D-C group exhibited significantly lower vessel densities(VDs) in the foveal and parafoveal superficial capillary plexuses(SCP) and deep CP(DCP) compared to the T1D-P group. Conversely, central foveal thickness, central inner retinal thickness, peripapillary retinal nerve fiber layer thickness (pRNFLT), and nasal inferior disc VD were significantly higher in the T1D-C group ($p < 0.05$ for all). Tanner's pubertal stage was significantly and negatively correlated with SCP VDs ($r = -0.345$ to -0.166, $p < 0.001$) and inferior nasal and temporal disc VDs. HbA1c and diabetes duration negatively correlated with foveal avascular zone diameter($r = -0.346$ and -0.267; respectively, $p < 0.01$) and SCP/DCP VDs ($p < 0.05$).
Conclusion
In young T1D patients, while initial peripapillary microvascular changes may be more pronounced, macular microvasculature shows significant decline over three years. Concurrently, foveal retinal thickness and pRNFLT increase. These findings highlight the importance of longitudinal monitoring of retinal neurovascular structure in young T1D patients, even in the absence of clinical DR.

Factors affecting caregiver burden in families of children with type 1 diabetes

Ozge Bayrak Demirel[1], Tugce Kandemir[1], Cansu Koc[1], Hasan Yanik[1], Nevin Karaca[1], Asli Derya Kardelen Al[1], Melek Yildiz[1], Sukran Poyrazoglu[1], Feyza Darendeliler[1] & Firdevs Bas[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Department of Pediatric Endocrinology, Istanbul, Türkiye

Introduction
Managing type 1 diabetes (T1D) in childhood imposes significant burdens on families, influenced by factors such as the child's age, diabetes duration, glycemic control, and use of technologies like insulin pumps and continuous glucose monitors (CGMs). Caregiver burden in families of children with T1D has not been sufficiently explored. This study evaluates caregiver burden and its relationship with these factors.
Methods
This cross-sectional study included 100 children with T1D from a single pediatric endocrinology clinic. Demographic, clinical, and laboratory data were collected. The Zarit Burden Interview (ZBI) assessed caregiver burden across four subcategories: demands of care and social impact, control over the situation, psychological impact, and worry about caregiving performance. Participants were divided into three groups: non-users of diabetes technologies, CGM users, and insulin pump users. Statistical analyses were conducted using non-parametric tests.
Results
Among the children, 48% were girls ($n = 48$) and 52% were boys ($n = 52$), with a mean age of 12. 2 ± 4. 1 years (range: 2. 5–18. 3 years). The mean age at diagnosis was 7. 4 ± 3. 9 years, and the mean duration of diabetes was 4. 9 ± 3. 8 years. Of the participants, 32% were prepubertal, and 68% were pubertal. Regarding technology use, 44% did not use technology, 43% used CGMs, and 13% used insulin pumps. Mothers constituted the majority of primary caregivers (90%). The mean ZBI total score was 24. 8 ± 14. 2, indicating mild to moderate burden. No statistically significant differences were found in total caregiver burden or its subcategories based on gender or pubertal status ($p > 0.05$). Correlation analyses revealed no significant relationship between diabetes duration and caregiver burden ($r = -0.03$, $P = 0.774$). However, a significant negative correlation was observed between the child's age and total caregiver burden ($r = -0.2$, $P = 0.018$), as well as between age and caregiving demands and social life impact ($r = -0.3$, $P = 0.007$). No significant correlation was found between HbA1c levels and caregiver burden ($r = 0.1$, $P = 0.259$). Caregivers of children using diabetes technologies reported significantly lower total burdens compared to non-users ($P = 0.001$), with no notable differences between CGM and insulin pump users ($P = 0.954$).
Conclusion
Diabetes technologies were associated with reduced caregiver burden. Families of older children experienced less burden, while diabetes duration had no significant effect. Improving access to diabetes technologies and developing support strategies, especially for families with younger children, is essential.

Omnipod5 real-world data from the first paediatric users universal coverage under the united kingdom national health service

May Ng[1, 2], Zoe Tattersall[2], Violet Swain[2], Gursagar Sandhu[3], Katherine Quirk[3] & Astha Soni[3]
[1]Faculty of Health, Social Care and Medicine, Edge Hill University, Ormskirk, United Kingdom; [2]Paediatric Department, Mersey and West Lancashire Teaching Hospitals, Southport, United Kingdom; [3]Sheffield Children's Hospital, Sheffield, United Kingdom

Background
Hybrid closed-loop (HCL) systems combine continuous glucose monitoring (CGM) with insulin pumps to automate insulin delivery through specific algorithms and user input. The recent updated UK NICE Technology Appraisal (TA943) on HCLs for T1D was published in December 2023. It advocates for widespread National Health Service (NHS) adoption and access to these systems for all children with T1D. This represents a significant and positive move towards universal health accessibility to advanced diabetes technologies. The Omnipod 5 system (OP5) by Insulet Corp. is a tubeless automated insulin delivery system, and as of June 2023, was the latest HCL system to be introduced in the United Kingdom (UK). This real-world study aimed to evaluate the effectiveness of the Omnipod5 HCL system on HbA1c, time-in-range (TIR), hypoglycaemia frequency, and sensor glucose variability over 3 and 6 months in children and young people with type 1 diabetes at two NHS-funded paediatric diabetes centres in the North West of England.
Methods
Children under 18 years of age in two teaching hospital-based diabetes centres were started on Omnipod5 between August 2023 and January 2024. Sensor glucose metrics and HbA1c were collected within 3 months prior to Omnipod5 initiation and compared at 3 and 6 months post-initiation. Metrics included %TIR (sensor glucose 3. 9–10. 0 mmol/l), time above range (TAR) (sensor glucose $>$ 10. 0 mmol/l and $>$13. 9 mmol/l), and time below range (TBR) (sensor glucose $<$3. 9 mmol/l and $<$3. 0 mmol/l), with variability assessed by coefficient of variation (CV) and standard deviation (SD).
Results
A total of 144 children were included, with 46% males and a mean age of 7. 1 years (SD 4. 3). The cohort was predominantly white (80%), with diabetes duration averaging 4. 4 years (SD 3. 9). Prior to Omnipod5, 54% used multiple daily injections, 41% a non-integrated pump, and 5% another HCL system. At 3 and 6 months post-initiation, there were significant improvements in HbA1c (from 60. 2 mmol/mol to 54. 4 mmol/mol at 3 months, and 55. 2 mmol/mol at 6 months), TIR (from 53. 3% at baseline to 67. 4% at 3 months and 68. 8% at 6 months), and reductions in TAR and CV.
Conclusions
These findings highlight the Omnipod5 system's safety and effectiveness in improving glycaemic control for CYP with T1D in a real-world NHS setting. Further research is needed to explore the long-term benefits and cost-effectiveness of this tubeless HCL system in routine clinical care.

Navigating complexity and challenges in managing type 1 diabetes in children with neurodiverse diagnoses – a qualitative study

Zoe Tattersall[1], Violet Swain[1] & May Ng[1]
[1]Mersey and West Lancashire Teaching Hospitals NHS Trust, Ormskirk, United Kingdom

Background
Managing type 1 diabetes (T1D) in children with neurodiversity presents unique challenges. This population often faces difficulties with communication, sensory sensitivities, and adherence to complex medical regimens meaning that management of chronic disease can be difficult. These challenges are further compounded by variations in cognitive abilities and social understanding, requiring tailored strategies for effective diabetes care. However, they have also had to overcome significant barriers in day-to-day life and education and this resilience may help in self-management of complex management of T1D. We explore the impact of neurodiversity on diabetes self-management and caregiving dynamics, aiming to highlight evidence-based interventions, the importance of interdisciplinary collaboration, and the role of assistive technologies. Co-morbidity of autism spectrum disorder and T1D has been shown to have poorer outcomes of diabetic control, but there is little evidence available on how these patients show resilience in managing their diabetes and what challenges they face.
Methods
This qualitative study explores the lived experiences of children with co-occurring neurodiverse diagnosis and T1D, alongside their primary caregivers. We completed semi-structured interviews with 10 adolescents and parents to understand the unique barriers and how these families have shown resilience in managing these dual conditions. The interviews focussed on diabetes education, the interplay between neurodiversity and diabetes, diabetes technologies, personal management and transition, and the impact on daily life.
Results
Thematic analysis revealed five key themes: management and fear of hypoglycaemia, worries regarding future planning and transition, use of diabetes technology, sleep, and support structures and relationships. Both patients and their caregivers noted that diabetes technology, including continuous glucose monitoring (CGM), reduced anxiety and improved sleep quality. Patients also highlighted that they did not feel that their neurodiverse diagnoses impacted on their management of T1D. Families also recognised that there was a lack of general resources covering neurodiversity and T1D.
Conclusion
We have highlighted the resilience that families demonstrate in managing T1D alongside neurodiversity. This study underscores the need for personalised, neurodiversity-affirming care models that integrate behavioural strategies and caregiver training to optimise health outcomes. The findings highlight the importance of fostering collaborative care frameworks to address the dual

demands of neurodiversity and T1D, promoting improved quality of life for both children and their families.

JOINT2128

A longitudinal analysis of the impact of alarmed sensors on anxiety, depression, sleep quality, quality of life and treatment satisfaction in patients with type 1 diabetes

Michele Baldari[1, 2], Enrico Saudelli[1, 2], Simona Moscatiello[1], Sara Flamigni[1], Uberto Pagotto[1, 2] & Guido Di Dalmazi[1, 2]
[1]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria, Bologna, Italy; [2]Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, Italy

Introduction
Type 1 diabetes mellitus (T1DM) plays an important role on living standards in affected patients. The use of technologies has been shown to have important benefits on glycemic compensation, but studies regarding the impact on psychosocial indicators are currently limited in the literature.
Aim
To dynamically observe in a population of T1DM patients how living standards change in relation to new technology upgrades and clinical parameters
Subjects and Methods
In this longitudinal analytical study, the following questionnaires were administered to 143 patients with T1DM: Hospital Anxiety and Depression Scale (HADS), Pittsburgh Sleep Quality Index (PSQI), Diabetes Treatment Satisfaction Questionnaire (DTSQ), Diabetes Distress Scale (DDS), and Diabetes Quality of Life (DQOL). In the HADS scale, specifically, 3 categories were assigned: normal, borderline or pathological. The number of patients changing their category was considered as the primary endpoint. Questionnaires were collected at the Endocrinology Unit of IRCCS S. Orsola in April 2021 and then 3 years later in September 2024.
Results
The cohort enrolled in 2021 consisted of 77 men and 66 women: mean age 45 ± 14 years, HbA1c 56 ± 11 mmol/mol. During the period from 2021 to 2024, 83 patients switched from capillary glycemic monitoring to the use of a sensor equipped with low and high glucose alarms, 37 remained on capillary, and 23 maintained a sensor associated with or without a pump. A statistically significant improvement in HbA1c (57. 6 ± 10. 4 vs 56 ± 13 mmol/mol, $p < 0.001$) and TBR (3. 2 ± 4. 2 vs 1. 62 ± 1. 59%, $P = 0.009$) was confirmed in the cohort who had an alarmed sensor at 3 years. In the subgroup that upgraded to an alarmed sensor, there was no significant change in the degree of anxiety ($P = 0.780$), or depression ($P = 0.158$) on the HADS scale, nor a significant worsening of the PSQI sleep quality score ($P = 0.667$) and disease-related distress ($P = 0.831$), in contrast to treatment satisfaction, which instead appeared to be significantly reduced compared to baseline (26. 9 ± 5. 5 vs 28. 7 ± 4. 8, $P = 0.008$). Similar situation occurred for quality of life, which was found to be worse (30. 5 vs 30. 1, $P = 0.012$)
Conclusions
In individuals with type 1 diabetes, the introduction of sensors equipped with alarms seems likely to improve glucometabolic compensation and prevent hypoglycemia without leading to a deterioration in anxiety, depression, and sleep quality status, whereas it may worsen satisfaction with care and quality of life.

JOINT1800

The trend in hospitalizations for diabetes mellitus in brazilian children under 10 years of age: an analysis from 2013 to 2023

Renata Pinto[1] & Verônica Mendanha[1]
[1]Federal University of Goiás, Goiânia, Brazil

Introduction
Brazil occupies the third position both in the ranking of countries with the highest healthcare expenses related to Diabetes Mellitus (DM) and in an estimated number of prevalent cases of DM1, totaling 92, 300 diabetics aged 0 to 19 years. This scenario results in numerous annual hospitalizations due to complications such as diabetic ketoacidosis. This study aimed to determine the temporal trend of hospitalizations due to DM in Brazilians aged less than 10 years from 2013 to 2023.
Methods
This is an epidemiological, descriptive, and retrospective study with a quantitative approach to reported cases of hospitalizations for Diabetes Mellitus in children aged 0 to 9 years in Brazil. Data was obtained from the SUS Hospital Admissions System (SIH/SUS) and accessed electronically on the portal of the Department of Information of the Unified Health System (DATASUS) of the Ministry of Health. Hospitalization rates were calculated as expressed per 100, 000 inhabitants. For the temporal trend, raw hospitalization and population data per year were imported into the Joinpoint regression program version 5. 1. 0. 0., calculating the annual percentage change (APC) and the confidence interval (95% CI).
Results
In the analyzed period, 32, 184 hospitalizations due to DM were reported in children aged 0 to 9 years, with an annual average of 2, 925. 82. The trend of hospitalizations proved to be increasing, with an APC of 3. 38 (95%CI: 2. 30;4. 39; $P < 0.001$). From 2013 to 2019, there was a stationary trend, with APC = 1. 3% (95%CI: -2, 89;2. 78; $P = 0.41$), and from 2019 to 2023, an increasing trend was observed, with APC = 6. 58% (95%CI: 4. 08;12. 18; $P < 0.001$). The highest number of hospitalizations occurred in mixed-race female children aged 5 to 9 years in the Southeast region. The highest hospitalization rates were seen in the Central-West, South, and Southeast regions, respectively.
Conclusion
We observed high rates of hospitalization in the period analyzed for DM in children under 10 years of age, with an increasing temporal trend after 2019. This epidemiological profile agrees with the international literature that shows a significant increase in DM diagnoses after the COVID-19 pandemic. 19. Hospitalizations of northern, indigenous, and elective children were the minority. There is limited data regarding children with Diabetes in Brazil, highlighting the importance of more epidemiological studies to direct care and resources to groups at higher risk of hospitalization.

A novel GCK gene variant causing juvenile-onset adult-type diabetes in a family is reported for the first time

Ping Yi[1] & Xingxing Zhang[1]
[1]The Second Xiangya Hospital of Central South University, paediatrics, Changsha, China

Adult-onset diabetes mellitus (MODY) in adolescents represents a distinct category of autosomal dominant inherited monogenic diabetes disorders. It typically exhibits a subclinical onset and is characterized by clinical manifestations such as family-based, mild, and non-progressive fasting glucose hyperglycemia. Unfortunately, due to its relatively subtle and atypical features, it is often prone to misdiagnosis and excessive treatment. This report meticulously delineates a freshly diagnosed case of MODY that was triggered by a variant in the glucokinase (GCK) gene, specifically identified as p. A379L. The proband manifested the disease during adolescence, presenting with mild impairment in fasting glucose levels, negative insulin antibodies, and a moderately compromised pancreatic function. Intriguingly, both the proband and his father were found to carry a heterozygous variant in the ninth exon of the GCK gene at the genomic location of Chr7:44145614. Both of them maintained normal blood sugar levels through diet and health management. The GCK gene variant p. A379L was identified as the main pathogenic gene in this MODY2 family, which is the first report of its kind both at home and abroad.

Depressive symptoms in youths with diabetes mellitus and their associating factors: an observational study in a single centre in hong kong

Sin Yi Cindy Chan[1] & Chun-cheung Antony Fu[1]
[1]Princess Margaret Hospital, Department of Paediatrics and Adolescent Medicine, Hong Kong, Hong Kong

Objectives
Paediatric diabetes mellitus is of increasing prevalence over the past decade worldwide. It is a life-long endocrine illness that poses both physical and psychogical burdens to our affected youths. Up to 14% of youths with diabetes reported at least mildly depressed mood. Mental health screening in these

individuals, is therefore a standard of medical care in diabetes according to latest recommendations. Regular screening allows early identification of patients who are at risk of depression, and timely psychological intervention can lead to better diabetic control and overall well-being in these patients. The aim of our study is to evaluate the prevalence and severity of depressive symptoms in paediatric patients with diabetes mellitus, and identify factors associated with the development of depressive symptoms.
Research Design and Method
The Patient Health Questionnaire-9 (PHQ-9), a validated and efficacious self-reported tool recommended by the American Diabetes Association (ADA) and the U. S. Preventive Services Task Force (USPSTF) for screening depression, was completed by 90 paediatric patients with diabetes mellitus from year 2020- 2022 who received regular follow up in our hospital. Data including demographics and characteristics of patients were collected and analysed.
Results
Sixteen out of 90 patients (17. 8%, 95% CI: 9. 9%- 25. 7%) reported moderate or above severity of depressive symptoms as defined by a PHQ-9 score $\geq$10. 13. 7% and 12. 2% of patients had a PHQ-9 score $\geq$10 in year 2021 and 2022 respectively, compared to none in year 2020. Higher body mass index (BMI) (P=0. 048), presence of diabetic-related complications (P = 0. 049), greater number of hospital admissions related to poor diabetic control (P = 0. 003), poor family dynamics with parental marital conflicts (P = 0. 002) and parent-child relationship problems (P < 0. 001), known psychological or behavioural problems (P < 0. 001) were identified as factors associated with increased risk for developing depressive symptoms. Patients who used continuous glucose monitoring system (CGMS) (P = 0. 014) and had more frequent blood sugar monitoring (P = 0. 002) were associated with less risk for developing depressive symptoms. A higher haemoglobin A1c (HbA1c) value (P = 0. 023) was found to be positively related to depressive symptoms in the subgroup analysis for patients with type 1 diabetes mellitus but not type 2.
Conclusion
Depressive symptoms are common in youths with diabetes mellitus. Regular mental health screening by using a validated self-reported questionnaire is a cost-effective and reliable method that should be advocated in all eligible patients.

JOINT1814

Twenty-four hours glycemic profile of women with early gestational diabetes mellitus

Preeti Dabadghao[1], Bibhuti Bhusan Mohanta[1], Amita Padey[2] & Archana Tripathy[1]
[1]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Endocrinology, Lucknow, India; [2]King Georges Medical University, Obstetrics & Gynaecology, Lucknow, India

Introduction
Traditionally GDM has been diagnosed as hyperglycemia in 24-28 weeks of gestation. Glucose abnormalities seen before this period were attributed to pre-existing or undetected diabetes. However, the HAPO study has changed this understanding, recognizing that any degree of hyperglycemia at any gestational age can increase the risk of adverse outcomes for the mother, fetus, and newborn. Early GDM (eGDM) occurring before 20 weeks of gestation, likely represents an intermediate state between normal glucose metabolism and prediabetes/diabetes outside of pregnancy. The clinical impacts of eGDM are still debatable.
Materials & Methods
All eligible patients diagnosed with early GDM according to the World Health Organization (WHO 2013) criteria were prospectively followed after the placement of the Freestyle Libre Pro CGMS on the day of diagnosis between September 2021 and May 2023. The 24-hour glycemic profile of women with eGDM was compared with that of age- and gestational-age-matched normoglycemic pregnant women.
Results
Thirty-nine early GDM patients whose mean age was 29. 4 $\pm$ 2. 4 years with a gestational age of 12. 9$\pm$4. 2 weeks and 113 pregnant women with normoglycemia whose mean age was 27. 6 $\pm$ 3. 8 years and gestational age of 13. 4$\pm$4. 5 weeks were enrolled in the study. Glycemic variability indices like standard deviation of blood glucose, J index, and mean amplitude of glycemic excursions were also significantly higher in eGDM patients. Women with eGDM showed a similar "time in range"(93. 4% vs. 89. 1%, p=. 73) and a considerably higher "time above range"(2% vs. vs1. 7%, p=<0. 05) compared to those with normoglycemia. While in most cases glycemic targets could be achieved with lifestyle interventions, 2 out of 39 patients (5%) required insulin therapy. Forty-three percent of women with eGDM had a normal vaginal delivery, 23% experienced neonatal complications, and 10% had macrosomia. Maternal and fetal outcomes differed significantly between the early GDM and normoglycemia groups.

Comparison of CGMS parameters

Parameters	Early GDM (39)	Normoglycemia (113)	P value
Fasting Glucose (mg/dl)	79. 9$\pm$9. 9	73. 8$\pm$8. 9	0. 004
Premeal Glucose(mg/dl)	81. 5$\pm$9. 2	74. 8$\pm$8. 1	0. 001
1hr Post meal Glucose(mg/dl)	101. 8$\pm$17. 4	94. 8$\pm$12. 7	0. 031
2hr Post meal Glucose(mg/dl)	91. 2$\pm$13. 4	84. 1$\pm$10. 2	0. 006
24hr Glucose(mg/dl)	91. 9$\pm$10. 8	84. 1$\pm$8. 7	0. 002
Day time Glucose(mg/dl)	95. 2$\pm$11. 3	86. 1$\pm$10. 1	0. 001
Nocturnal Glucose(mg/dl)	83. 7$\pm$12. 2	78. 2$\pm$10. 1	0. 041

Conclusion
Women with early GDM, despite mild hyperglycemia, exhibit abnormal glycemic patterns on CGMS and higher rates of macrosomia and neonatal complications in a South Asian population, though the small sample size in the eGDM group remains a limitation.

JOINT2633

Association between serum lipid profile and glycemic control in adolescents with newly diagnosed type 2 diabetes: a single center study

Ji Won Park[1], Minkyu Seo[1], Eungu Kang[1], Hyo-Kyoung Nam[1], Young-Jun Rhie[1] & Kee-Hyoung Lee[1]
[1]Korea University College of Medicine, Pediatrics, Seoul, South Korea

Background
Worldwide prevalence of young onset type 2 diabetes (DM) is showing an increasing trend with the increase in prevalence of pediatric obesity. The prevalence of type 2 diabetes in young Korean population have reached more than 4. 4-fold when compared with the early 2000s. The aim of this study is to investigate factors associated with glycemic control in adolescents with type 2 diabetes to reduce the risk of complications.
Method
Data from adolescents aged 10–19 years who were newly diagnosed with type 2 diabetes mellitus from 2014 to 2023 and had at least one year of follow-up at Korea University Hospital were analyzed. The study compared trends in glycemic control and associated factors, including the patients' metabolic profile. Patients were classified into good and poor glycemic control groups based on HbA1c in which good glycemic control is HbA1c$\leq$7. 0% and poor glycemic control is HbA1c greater than 7. 0% in addition to those with subcutaneous(SC) insulin injection. Each group were further analyzed for differences in clinical characteristics and laboratory findings
Results
Total of 134 adolescents were newly diagnosed as type 2 DM over 10 years at Korea University Hospital, with mean age of 14. 4$\pm$1. 9 years and mean Body Mass Index of 27. 8$\pm$5. 5 kg/m2. Mean HbA1c at diagnosis was 10. 6$\pm$2. 6% and 81(60. 5%) patients required SC insulin combined with PO medication as initial treatment. Among 93 patients with follow-up duration of 2 years, 47(50. 5%) patients manifested good glycemic control with mean HbA1c of 5. 9$\pm$0. 5 and 46(49. 5%) patients had poor glycemic control with mean HbA1c of 8. 6$\pm$2. 5%. Patients with poor glycemic control at 2 years had higher AST/ALT, LDL cholesterol, and triglyceride compared with patients with good glycemic control(P < 0. 05). Total of 40 patients required SC insulin injection up to 2 years from diagnosis, and their SPISE index at 2 year was significantly lower than patients treated with PO medication alone or without any medication (4. 8($\pm$1. 3) vs 6. 1($\pm$2. 1), P < 0. 05).
Conclusion
Newly diagnosed type 2 diabetic adolescents showed poor glycemic control at 2 years from diagnosis and presented with metabolic problems confirmed by laboratory Results Close monitoring and proper management of lipid profile as well as glucose level is required to achieve good glycemic control in pediatric type 2 DM patients.

JOINT632

Fasting blood glucose as predictor in achieving glycemic control among patients with gestational diabetes mellitus on non-pharmacologic therapy: a retrospective cohort study

Lorain Ann Bumagat-Briones[1] & Jay Fonte[1]
[1]Ospital ng Makati, Department of Internal Medicine, Taguig, Philippines

Background
Gestational diabetes mellitus (GDM) is associated with adverse maternal and neonatal outcomes. There is currently no uniform guidelines for the management of GDM and the observation period when to progress from non-pharmacologic to pharmacologic treatment varies. This will lead to a delay in initiation of a definitive therapy which will probably increase risk of complication from GDM. This study aims to investigate the association between fasting blood glucose at diagnosis of GDM and glycemic control based on self-monitoring blood glucose (SMBG) after 2 weeks of non-pharmacologic therapy.
Methodology
We conducted a single-center observational retrospective cohort study of patients with GDM at Ospital ng Makati (OsMak) from 2013-2023. Included were patients with fasting blood sugar (FBS) values of 92-125 mg/dL who had their prenatal visits and delivery at OsMak. Medical records were reviewed and the following data were collected: current age, weight, height, BMI on initial prenatal visit, comorbidities such as hypertension, diabetes mellitus, autoimmune diseases (SLE, APAS) and obstetric history. FBS at initial visit or at 24-28 weeks AOG and SMBG values were recorded. Subsequent mode of therapy, either non-pharmacologic or pharmacologic, was assessed.
Results
We included a total of 112 patients with GDM in the study. 50% (95% CI: 40. 4-59. 6%) achieved glycemic control through non-pharmacologic therapy. There was no significant difference between the two groups (glycemic control achieved vs not achieved) in any of the variables except for FBS at the time of GDM diagnosis. Median FBS was significantly higher in patients who did not achieve glycemic control than those who did. Patients with FBS at GDM diagnosis of $>$ 99 mg/dl had about 23 times higher odds of non-achievement of glycemic control than those with FBS of $\leq$99 mg/dl.
Conclusion
The result of this study demonstrates that FBS at GDM diagnosis was significantly associated with glycemic control and showed excellent discriminative ability with a sensitivity of 87. 50% and specificity of 76. 79 %. Patients with FBS at GDM diagnosis of $>$99 mg/dl had about 23 times higher odds of non-achievement of glycemic control than those with FBS of $\leq$99 mg/dl.

Association between genetic variants of SLC30A8, CDKAL1 and HHEX and increased risk of gestational diabetes mellitus: implications for early detection and personalized management

Justyna Hryniewicka[1], Angelika Buczyńska[2], Witold Bauer[2], Natalia Wawrusiewicz-Kurylonek[3], Jacek Szamatowicz[4], Adam Krętowski[1] & Małgorzata Szelachowska[1]

[1]Medical University of Bialystok, Department of Endocrinology, Diabetology and Internal Medicine, Bialystok, Poland; [2]Medical University of Bialystok, Clinical Research Center, Bialystok, Poland; [3]Medical University of Bialystok, Department of Clinical Genetics, Bialystok, Poland; [4]Medical University of Bialystok, Department of Gynecology and Gynecological Oncology, Bialystok, Poland

Gestational Diabetes Mellitus (GDM) is a common pregnancy-related condition, affecting 14. 2% of women worldwide and 12. 2% in Europe. It increases the risk of long-term complications for both mother and child, including cardiovascular disease, obesity, and type 2 diabetes (T2D). Early diagnosis and appropriate management are crucial in minimizing these risks. Although the exact causes of GDM remain unclear, it is linked to insufficient insulin production and an inability to counteract pregnancy-induced insulin resistance. Genetic factors are increasingly recognized as contributors to GDM development. Variants in *SLC30A8* (rs13266634, rs11558471) and *CDKAL1* (rs10946398) have been associated with alterations in insulin secretion, beta-cell function, and glucose regulation. Additionally, SNPs near genes responsible for pancreatic development, such as rs1111875, rs5015480, and rs7923837 in *HHEX*, have been linked to an increased risk of GDM in several studies. This study investigates the association between the SNPs mentioned above and the risk of GDM in the Polish population and evaluates their impact on phenotypic traits using mathematical indices of insulin resistance (HOMA-IR), insulin sensitivity (Matsuda index), and beta-cell function (IGI, DI30, DI120, and AUC-based indices), calculated from a four-point glucose tolerance test. A total of 104 women diagnosed with GDM and 372 normoglycemic controls (NGT) were included in the study. Women with GDM exhibited higher glucose levels, greater insulin resistance (HOMA-IR), and reduced indices of beta-cell function ($P < 0.0001$). GDM was significantly associated with *SLC30A8* polymorphisms in both the dominant model (rs13266634: OR 1. 63 [1. 04-2. 53], rs11558471: OR 2. 02 [1. 28-3. 16]) and the allelic model (OR 1. 47 [1. 03-2. 09] and OR 1. 68 [1. 17-2. 41]). Additionally, rs10946398 in *CDKAL1* showed an association with GDM in both the genotypic (OR 1. 77 [1. 1-2. 83]) and allelic models (OR 1. 4 [1. 02-1. 91]) ($P < 0.05$). Carriers of the risk genotypes exhibited higher glucose levels and impaired insulin secretion in response to glucose, as reflected by the disposition index (DI), ΔAUCins/glc, and reduced beta-cell function (IGI index) across the study population ($P < 0.05$). This study confirms the association between *SLC30A8* and *CDKAL1* polymorphisms and an increased risk of GDM. Carriers of risk genotypes exhibited higher glucose levels and impaired beta-cell function, indicating a genetic influence on glucose metabolism during pregnancy. Identifying these SNPs could aid in early detection of GDM, enabling personalized management strategies to improve maternal and fetal outcomes and reduce the long-term risk of type 2 diabetes. These findings support the potential clinical use of genetic testing to identify high-risk individuals and implement targeted interventions.

Performance of an algorithms predicting mortality in medical vs surgical patient with diabetes

Pedro Caraballo[1], Karen Fischer[2], Ricky Rojas[2], Gyorgy Simon[3], Genevieve Melton[3], Hojjat Salehinejad[2], Bijan Borah[2] & M. Regina Castro[2]

[1]Mayo Clinic, Internal Medicine, Rochester, United States; [2]Mayo Clinic, Rochester, United States; [3]University of Minnesota, Minneapolis, United States

Introduction
Patients with diabetes have an increased risk of hospital complications including complications related to surgical treatment. Computer-based early warning systems (EWS) implemented in the hospital wards can identify patients at risk of deterioration, and trigger lifesaving interventions. In general, these systems often perform differently in subpopulations of patients. There is also concern with risk factors associated with chronic conditions that are usually not part of the variables used by these algorithms. We present preliminary data of the performance of an EWS in the general hospital wards in patients with diabetes assigned to medical vs surgical treatment.
Methods
Adult ($\geq$18 y-o) patients with diagnosis of diabetes, hospitalized in general wards were grouped based on medical vs. surgical treatment. We collected EWS scores generated every 15 min during the entire hospitalization. The scores estimated the probability of total mortality on scale 0 to 100. We compared the distributions of the Highest Score (at any time during the hospitalization) and calculated diagnostic accuracy using a cutoff of $\geq$60.
Results
There were 15, 727 patients with diabetes, 10, 234 in the medical group (age mean(SD) 68. 8(13. 9) years; female 44%; length of stay 5. 0(5. 7) days) and 5, 493 in the surgical group (age mean(SD) 67(12. 7) years; female 40%; length of stay 6. 3(8. 9) days). Hospital mortality in the medical vs. surgical group was 88 (0. 86%) vs. 6 (0. 1%). Using a score of $\geq$60 to predict mortality, the model had an accuracy in the medical group of 85% (95%CI: 84. 44 to 85. 83) and Sens 89. 78%, Spec 85. 11%, PPV 4. 97% and NPV 99. 9%. In the surgical group the accuracy was 81. 83% (95%CI: 80. 79 to 82. 84) and Sens 66. 67%, Spec 81. 85%, PPV 0. 40% and NPV 99. 96%.
Conclusion
The performance of the EWS model predicting mortality was different among patients with diabetes admitted for medical vs. surgical treatment. The overall accuracy of the model is statistically better in the medical group with Sens and Spec above 85%; while in the surgical group the Sens is quite low at 66%. The NPV in both groups is clinically relevant at more than 99%, but the PPV is extremely low. The difference among these subpopulations should be validated with other EWS and should be considered when using the predictions of these models in medical decision making. Our results should be interpreted cautiously, given they are from a single institution with a fairly low prevalence of adverse events including hospital mortality.

Weight stigma in pediatric type 1 diabetes: evaluating patient level factors and diabetes related outcomes

Supraja Rengan[1], Rachel Dunn[1], Justin Ma[1] & Sanjukta Basak[1]
[1]BC Children's Hopital, University of British Columbia, Pediatrics, Division of Endocrinology & Metabolism, Vancouver, Canada

Background
Weight stigma is defined as discrimination based on weight and body size and is well-documented among adults and children. Individuals who experience weight stigma are at risk of adverse physical and mental health outcomes. To our knowledge, there are no studies evaluating weight stigma in the pediatric Type 1 diabetes (T1D) population despite weight often being reviewed and discussed in diabetes clinic follow-ups.
Objective
Our study aimed to evaluate the prevalence of weight stigma in our pediatric □OBJT1D population and to identify any patient level factors associated with higher prevalence of weight stigma. We also aimed to determine if weight stigma is associated with poorer diabetes related health outcomes and increased diabetes distress.
Methods
A cross-sectional study was conducted among pediatric patients at BC Children's Hospital. Participants completed questionnaires that included experienced weight stigma (EWS), weight bias internalization scale (WBIS), weight self-stigma questionnaire (WSSQ), modified brief illness perception questionnaire (BIPQ) and diabetes distress scale (DDS). Data was extracted from the BC pediatric diabetes registry and chart review to gather patient level data and outcomes. Descriptive statistics and logistic regression analysis were used to analyze the data.
Results
There were a total of □OBJ□95 participants with a response rate of 30. 6%. The prevalence of experienced weight stigma was found to be 19. 4%, of which 20% identified family members to be the leading source of stigma. Of the participants endorsing weight stigma, 28. 5% scored high for weight self stigma, and 57. 1% scored high for internalized weight stigma. Female sex was found to be associated with weight stigma(P-value <0.05). Participants experiencing weight stigma had higher diabetes distress ($p<0.001$), and presented a non-significant trend towards increased residential instability (OR 1. 46, 95%CI 0. 98-2. 17), and higher A1c (OR 1. 34, 95%CI 0. 98-1. 84).
Discussion
In our institution, we identified 1 in 5 youth living with T1D experience weight stigma. Factors associated with weight stigma are female sex with a trend towards residential instability and higher A1c. As families and peers are key contributors to stigma, these findings underscore the importance of adopting a sensitive approach to discussions about weight in pediatric diabetes clinic. Given the complex interplay of obesity, weight stigma and diabetes management, this remains an important area research for developing interventions in clinical care.

Introduction
Diabetes mellitus (DM) is a metabolic disorder characterized by hyperglycemia and oxidative stress.
Objective
This study aimed to evaluate oxidative stress by assessing lipid peroxidation through the thiobarbituric acid reaction with malondialdehyde (MDA) and the plasma antioxidant capacity (FRAP) in patients with type 1 and type 2 DM. Correlations with other biomarkers were examined.
Methods
Serum samples were collected from 67 individuals, categorized into three groups: type 1 DM ($n=21$), type 2 DM ($n=32$), and non-DM controls ($n=14$) matched for age, sex, and body mass index (BMI), defined according to the 2022 American Diabetes Association guidelines. The MDA index was determined photometrically by measuring lipid peroxidation at 530 nm. Plasma FRAP levels were assessed based on the reduction of the Fe^{3+}-TPTZ complex to Fe^{2+}-TPTZ, measured at 593 nm. Statistical analysis was conducted using SPSS statistical software, version 26.
Results
The study included 67 participants: non-DM ($n=14$, 20. 9%), type 1 DM ($n=21$, 31. 3%), and type 2 DM ($n=32$, 47. 8%). The median age (min-max) in years was 41 (21–44) for non-DM, 47 (19–64) for type 1 DM patients and 43. 50 (21–66) for type 2 DM patients. Median BMI (min-max) in kg/m^2 was significantly higher in type 2 DM: 26 (21. 50–31. 60) compared to non-DM: 23. 50 (21. 30–26. 00), $p<0.001$ and type 1 DM: 25. 1 (17. 70–32. 70), $P=0.001$. The glycated hemoglobin (HbA1c) levels were significantly higher in patients with DM (Type 1: 7. 20%, 6. 30–11. 40; Type 2: 9. 70%, 5. 40–14. 00) compared to non-diabetics (5. 20%, 4. 90–5. 50, $p<0.001$). Triglycerides levels were significantly elevated in type 2 DM (89. 00 mg/dL, 72. 00–106. 00) compared to non-DM (61. 00 mg/dL, 56. 00–231. 00, $p<0.001$). No significant differences were observed in total cholesterol, HDL, LDL, uric acid, C-reactive protein (CRP), ferric reducing ability of plasma (FRAP), or thiobarbituric acid (TBA)/malondialdehyde (MDA) levels. Correlation analysis revealed significant associations between FRAP and triglycerides in type 1 DM ($r=0.600$, $P=0.011$) and between CRP and FRAP in type 2 DM ($r=0.380$, $P=0.042$).
Conclusion
Significant correlations between FRAP and triglycerides in type 1 DM and between CRP and FRAP in type 2 DM highlight the role of oxidative stress, lipid metabolism, and inflammation in diabetes progression. Monitoring oxidative stress markers alongside metabolic parameters may enhance our understanding of diabetes-related complications, aiding in targeted interventions.

Efficacy of frequency rhythmic electrical modulated system (FREMS) in the treatment of diabetic neuropathy: a systematic review and meta-analysis of randomized controlled trials

Alireza Azarboo[1], Parisa Fallahtafti[1], Negar Zareshahi[1], Amin Javidan[1], Amirhossein Ghaseminejad-Raeini[1] & Mahboobeh Hemmatabadi[2]
[1]School of Medicine, Tehran University of Medical Sciences, Tehran, Iran; [2]Department of Endocrinology, Vali-Asr Hospital, Endocrinology, and Metabolism Research Center, Imam Khomeini Complex Hospital, Tehran University of Medical Sciences, Tehran, Iran

Background
Painful diabetic peripheral neuropathy (DPN) is a debilitating complication of diabetes with limited therapeutic options. Frequency Rhythmic Electrical Modulation System (FREMS), a non-invasive electrotherapy, has shown potential in managing the symptoms. We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs) on FREMS for symptomatic DPN.
Methods
Databases, including PubMed, Scopus, and Embase, were searched until October 2024. Studies involving adults with DPN comparing FREMS with placebo were included. Data on Visual Analog Scale (VAS) scores and nerve conduction were extracted. Standardized mean differences (SMDs) with 95% confidence intervals (CIs) were pooled using random-effects models. Risk of bias was assessed using RoB 2. Heterogeneity was quantified via I^2 statistics, with sensitivity analyses and publication bias evaluation.
Results
Five RCTs (302 participants) were included. FREMS significantly reduced daytime VAS pain scores post-treatment (SMD -0. 56, 95% CI -0. 82 to -0. 29, $I^2=4\%$) and at follow-up (SMD -0. 47, 95% CI -0. 73 to -0. 21, $I^2=0\%$). Nighttime VAS pain scores also improved post-treatment (SMD -0. 54, 95% CI -0. 80 to -0. 27, $I^2=44\%$) and at follow-up (SMD -0. 38, 95% CI -0. 65 to -0. 12, $I^2=1\%$). FREMS improved motor nerve conduction but showed no effect on sensory conduction or microvascular blood flow.

Conclusion
FREMS is effective in reducing DPN pain with sustained benefits and a favorable safety profile. Future research should focus on standardizing treatment protocols and exploring long-term outcomes to integrate FREMS into clinical practice effectively.

Introduction
Children and adolescents with type 1 diabetes (T1D) have an increased risk to develop other autoimmune diseases. Autoimmune gastritis (AIG) is the third most frequent autoimmune comorbidity in T1D adults, while few data are available for children.
Objectives
Single-center, cross-sectional, observational study aimed to evaluate the prevalence of serum anti-parietal cell antibodies (APCA) and its related clinical alterations in children and adolescents with T1D.
Methods
Data on APCA assay [positive (+) or negative (-)], autoantibodies against β-cells at T1D onset (IAA, GAD, ICA) and other organ-specific autoantibodies, AIG-related symptoms (dyspepsia, abdominal pain and early postprandial satiety), anaemia, and mean corpuscular volume (MCV) alterations were recorded (last annual routine outpatients visit). In confirmed APCA(+) subjects, additional laboratory tests [iron, vitamin B12, chromogranin A, gastrin-17, and intrinsic factor autoantibodies (IFAs)] and gastrointestinal endoscopy (GE) were performed.
Results
146 patients with T1D were recruited [54. 1% males, 70% Caucasian, mean age 14. 5±3. 55 yrs, T1D duration 8. 36±4. 01 yrs, A1c 60±15 mmol/l]. Eight out of 146 subjects were APCA(+) (prevalence 5. 5%). APCA(+) subjects, compared to APCA(-) ones, had a higher prevalence of AIG symptoms ($P < 0.001$), thyroid autoimmunity ($P = 0.002$), and combination of IAA+GAD autoantibodies at T1D onset ($P < 0.001$) (Table). They also had a trend towards a higher prevalence of anaemia ($P = 0.054$). In APCA(+) subjects we found anaemia (25%), microcytosis (25%), iron deficiency (37. 5%), vitamin B12 deficiency (57. 1%), high levels of gastrin-17 (28. 6%) and chromogranin A (42. 9%). None was positive for IFAs. Lastly, 6 out of 8 APCA(+) patients underwent GE: 2 subjects showed endoscopic features of AIG (thinned and oedematous areas of the gastric antrum and corpus mucosa). Histological examination identified signs of chronic gastric mucosal inflammation in all patients (4 mild and non-specific alterations, indicating early stages of AIG; 1 marked alterations in glandular structure; 1 advanced AIG and discrete mucosal atrophy).
Conclusions
The prevalence of APCA(+) we found in our youths with T1D was 5. 5%, consistent with findings from few available previous studies. In contrast, we didn't found a higher prevalence in females. Our data suggest the usefulness of a regular screening for AIG, mainly in patients with thyroid autoimmunity, IAA+GAD at T1D onset, and AIG symptoms. The early is the diagnosis, the early is the treatment of its related symptoms and deficiencies.

Seasonal trends, clinical characteristics, and glycemic control in type 1 diabetes mellitus: a descriptive study from two private tertiary hospitals in nairobi, Kenya

Menbere Kahssay[1, 2], Rosebella Ondiek[1], Renson Mukhwana[3] & Thomas Ngwiri[3]

[1]Aga Khan University Hospital Nairobi, Department of Pediatrics and Child health, Nairobi, Kenya; [2]Aga Khan University Hospital Nairobi, Department of Pediatrics and Child health, Pediatric Endocrinology, Nairobi, Kenya; [3]Gertrude's Children Hospital, Nairobi Kenya, Department of Pediatrics and Child health, Nairobi, Kenya

Introduction
Type 1 diabetes mellitus (T1DM) is a chronic autoimmune disorder leading to insulin deficiency. Lifelong use of insulin and optimal glycemic control (HbA1c < 7. 5%) is essential for preventing long-term complications and ensuring a good quality of life. Globally, variations in T1DM incidence, seasonal trends, clinical features, and glycemic control have been reported, largely influenced by ethnic, socioeconomic, and healthcare disparities. However, there is a paucity of comprehensive studies investigating these parameters among newly diagnosed T1DM patients in sub-Saharan Africa. Understanding these factors is crucial for identifying potential environmental triggers, optimizing treatment protocols, and improving patient care tailored to regional contexts.
Objective
To describe the seasonal trends, clinical characteristics, and glycemic control of T1DM patients at two private tertiary level hospitals in Nairobi, Kenya, from 2013 to 2023.
Methods
A retrospective descriptive study was conducted at Aga Khan University Hospital, and Gertrude's Children Hospital Nairobi, involving 109 paediatric T1DM patients. Sample size was determined using Daniel's formula. Clinical data, including age at diagnosis, diabetes duration, Diabetic ketoacidosis (DKA) at presentation, month of diagnosis, HbA1c levels, and insulin regimen, were analyzed using SPSS-25. Descriptive statistics summarized categorical and continuous variables.
Results
Among 109 patients analysed, 52. 3% were male, the mean age at diagnosis was 8. 67 years (SD = 4. 28), the peak age group being 5-12 years A seasonal trend was observed, with peak diagnosis during the cool dry season (June–September, 34. 3%) and short rainy season (October–December, 26%). DKA was observed in 55% of cases at the time of diagnosis. Basal-bolus therapy was the predominant insulin regimen (84. 4%). The mean HbA1c was 9. 49% (SD = 2. 3), with values ranging from 6. 4% to 15. 37% with mean diabetes duration of 6. 49 years (SD= 3. 6). Private insurance (54. 3%) and self-pay (33. 3%) were the main payment methods.
Conclusion
This study identified a distinct seasonal pattern in paediatric T1DM diagnosis with peaks in the cool dry season (June–September) and short rainy season (October–December), suggesting potential environmental or infectious triggers. Notably, 52% of patients presented with DKA at diagnosis - significantly lower than the estimated 80% DKA prevalence in Africa. This indicates better awareness and healthcare access in our urban setting. However, despite earlier diagnosis and with relatively short disease duration (6. 4 years) - glycemic control remains poor (mean HbA1c 9. 49%) underscoring the need for enhanced diabetes management strategies, including use of diabetes technology such as continuous glucose monitoring and insulin pumps.

JOINT2622

Exploring the early symptoms of depression in children, adolescent and young adults: a review with public patient involvement

Archana Nepal[1] & Binaya Bhattarai[2]

[1]Patan Academy of health sciences, Pediatrics, Lalitpur, Nepal; [2]HAMS Hospital, Metro hospital, Endocrinology, kathmandu, Nepal

Background
Type 1 diabetes (T1D) is a chronic condition that significantly impacts both physical and mental health. Depression is prevalent among children, adolescents, and young adults with T1D but often remains underdiagnosed. Identifying early symptoms of depression in this population is crucial for timely intervention and improved disease management.
Objective
This study explores early markers of depression in children, adolescents, and young adults with T1D through a comprehensive literature review and public patient involvement (PPI).
Methods
A two-phase approach was employed. The first phase involved a systematic literature review (2000–2024) focusing on depression prevalence, symptoms, and screening tools in T1D. The second phase incorporated PPI through focus group discussions (FGDs) with patients, guardians, and clinicians to identify and rank early depressive symptoms. The findings were then compared with established depression and diabetes distress screening tools.
Results
Depression prevalence in children and adolescents with T1D varied from 6. 3% to 46. 3%. Commonly used screening tools, such as the Children's Depression Inventory (CDI), Center for Epidemiological Studies Depression Scale (CES-D), and Patient Health Questionnaire-9 (PHQ-9), effectively captured general depressive symptoms but lacked diabetes-specific emotional burdens. Diabetes distress tools, such as the Problem Areas in Diabetes (PAID) scale and Diabetes Distress Scale (DDS), identified unique stressors but did not comprehensively screen for depression. FGDs highlighted early depression markers, including sadness, social withdrawal, academic decline, diabetes-related distress, and feelings of unfairness about having diabetes.
Conclusion
Early depressive symptoms in children and young adults with T1D encompass both general and diabetes-specific features. Current depression screening tools may not fully capture these nuances. Developing an integrated screening approach that incorporates diabetes-specific distress along with depression screening tools could improve early identification and intervention.
Keywords: Type 1 diabetes, depression, diabetes distress, early symptoms, children, adolescents, screening tools

A rare metabolic puzzle: the case of an infant with hadh mutation

Maria Karsas[1]
[1]University of Pretoria, Paediatric Endocrinology, Pretoria, South Africa

Background
Recurrent hypoglycemia in infants can result from a variety of causes, complicating the diagnostic process. The episodic nature of symptoms and the need for timely metabolic and genetic testing make the workup particularly challenging. Early and accurate identification of the underlying cause is essential to prevent neurological damage and guide appropriate management.
Clinical presentation
A 2 month old female presented with a history of seizures from 17 days of life. At the age of 2 months it was noticed that her seizures were secondary to hypoglycaemia. She was born at term with a birth weight of 2. 73kg. She has no positive family history. Of note, she has 3 siblings, 1 of which demised at the age of 9 months due to unknown causes but was noted to be malnourished.
Results and discussion
Biochemistry revealed a hypoglycaemia (glucose 2. 2 mmol/l) with an inappropriately normal insulin of 5. 9m IU/l and normal c-peptide of 3. 2μg/l. Her serum growth hormone however at the time was 2. 8μg/l (reference: 0. 12-7. 79 μg/l) and she had a serum cortisol of only 118nmol/l, indicating the presence of hypocortisolism and possibly even growth hormone deficiency. Her CT Brain was normal and the Ga-68 Dotatate whole body PET/CT showed no avid disease. Genetic testing revealed a mutation in the hydroxyacyl-CoA dehydrogenase (HADH) gene, a key enzyme in fatty acid oxidation and insulin regulation. Thus, a genetic diagnosis of autosomal recessive congenital hyperinsulinism, subtype HADH was made. There is no know association in the literature with a HADH mutation presenting with a combination of hyperinsulinism and hypercortisolism or hypopituitarism. She responded however to treatment with diazoxide and oral hydrocortisone and is currently growing well without any hypoglycaemic events.
Conclusion
This case highlights the critical role of HADH in energy metabolism and the challenges of diagnosing and managing rare metabolic conditions in infancy.

Morphofunctional assessment in type 1 diabetes mellitus: usefulness of muscle ultrasound in the evaluation of body composition and its relationship with metabolic variables

María Teresa Zarco Martín[1, 2], María Del carmen andreo-lopez[1, 3], Victoria Contreras Bolivar[1 3 4] & María Luisa Fernández Soto[4 3 5]
[1]Unidad de Endocrinología y Nutrición, Hospital Universitario San Cecilio., Granada, Spain; [2]Fundación para la Investigación Biosanitaria de Andalucía Oriental (FIBAO), Granada, Spain; [3]Instituto de Investigación Biosanitaria de Granada (Ibs. Granada), Granada, Spain; [4]CIBER Fragilidad y Envejecimiento Saludable (CIBERFES), Instituto de Salud Carlos III, Madrid, Spain; [5]Departamento de Medicina. Universidad de Granada, Granada, Spain

Introduction
Sarcopenia has been proposed as a complication of diabetes. However, there are few body composition studies in type 1 diabetes mellitus (T1DM). Thus, the use of ultrasound as a portable and emerging clinical tool could be useful for the early diagnosis of sarcopenia. Our objectives were to describe ultrasound parameters of body composition in people with T1DM and to determine if there are associations with metabolic variables.
Material and Methods
Cross-sectional study in people with T1DM. Demographic (age, sex), analytical (glycosylated hemoglobin: HbA1c) and clinical variables (total insulin dose (DTI), muscle strength measured with Jamar dynamometer in kilograms (kg) - cut-off point: <p10 of Spanish population-, quadriceps rectus femoris muscle mass and abdominal subcutaneous fat adipose mass (superficial adipose tissue - TASu- and total adipose tissue-TAT-) with ultrasound -Sonosite S-Nerve®) were collected. Statistical analysis was performed with IBM SPSS v. 25.
Results
Fifteen patients with T1DM were evaluated (53% female, mean age 35 $\pm$ 12 years, BMI 22. 8 $\pm$ 3. 3kg/m2 and mean HbA1c 9. 2$\pm$2. 3). Low muscle strength was detected in 28%. The mean rectus femoris quadriceps muscle thickness or Y-axis was 1. 5$\pm$0. 3 and its mean area, 5. 6$\pm$2. 1. Mean adipose tissue (TAT) was 1. 2$\pm$0. 8, mainly dependent on superficial adipose tissue (TASu), with mean 0. 6$\pm$0. 4. The Y-axis correlated positively with muscle strength ($r = 0.5$, $P = 0.04$) and negatively with metabolic control in T1DM ($r = 0.6$, $P = 0.03$). Worse metabolic control (higher HbA1c) correlated positively with DTI ($r = 0.4$, $P < 0.001$), TASu($r = 0.7$, $P < 0.001$) and TAT($r = 0.7$, $P < 0.001$).
Conclusions
In this preliminary study, metabolic control correlated with ultrasound measurements of muscle mass and abdominal adipose tissue. Therefore, the assessment of morphofunctional status seems to be useful and could propose new therapeutic strategies in T1DM.

Pancreatic steatosis in newly diagnosed type 2 diabetes: relationships with glycemic control and exocrine function

Tahsin Taner Karaevren[1], Refika Yorulmaz Kaya[2], Mahinur Cerit[3], Halit Şendur[3], Burak Kalafat[3], Gizem Yaz Aydın[4], Özlem Gülbahar[4], Mehmet Yalçın[2], Ayhan Karakoç[2], Müjde Aktürk[2], Füsun Baloş Törüner[2], Alev Eroğlu Altınova[2], Taha Çetin[5] & Ethem Cerit[2]
[1]Gazi University, Faculty of Medicine, Department of Internal Medicine, Ankara, Türkiye; [2]Gazi University, Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Türkiye; [3]Gazi University, Faculty of Medicine, Department of Radiology, Ankara, Türkiye; [4]Gazi University, Faculty of Medicine, Department of Biochemistry, Ankara, Türkiye; [5]Gazi University, Faculty of Medicine, Department of Nephrology, Ankara, Türkiye

Background
Pancreatic steatosis (PS) is characterized by abnormal fat accumulation in pancreatic tissue and is often associated with obesity, metabolic syndrome, and type 2 diabetes mellitus (T2DM). While its pathophysiology and impact on pancreatic functions have been explored, the interplay between PS, glycemic control, and exocrine dysfunction in T2DM remains inadequately defined.
Objective
To evaluate the presence of pancreatic steatosis, the factors affecting it, and its relationship with endocrine and exocrine pancreatic functions in newly diagnosed T2DM patients.

Methods
A total of 126 individuals were included in the study, comprising 63 newly diagnosed T2DM patients and 63 healthy controls matched for age, sex, body mass index and body fat distribution. Body composition, biochemical parameters (glucose, insülin, C-peptide, HbA1c), fecal elastase levels, and pancreatic/hepatic steatosis grades (evaluated using ultrasonography) were assessed.
Results
Newly diagnosed T2DM patients exhibited significantly higher hepatic steatosis grades ($P = 0.018$) and lower fecal elastase levels ($P < 0.001$) compared to controls. Pancreatic exocrine insufficiency was more prevalent in the T2DM group ($P < 0, 001$). A positive correlation was observed between pancreatic steatosis grade, hepatic steatosis grade, and hepatic fat fraction. HbA1c levels demonstrated a nonlinear (inverse U-shaped) relationship with pancreatic steatosis, peaking at 9. 8% and declining thereafter, while showing a continuous negative relationship with fecal elastase levels. HbA1c predicted low fecal elastase (<200 μg/g) with a cutoff value of 7. 4%. Patients with HbA1c levels $>$ 9. 8% exhibited reduced pancreatic steatosis alongside persistent exocrine insufficiency.
Conclusions
Pancreatic steatosis is closely associated with hepatic steatosis, glycemic control, and pancreatic exocrine dysfunction in newly diagnosed T2DM patients. Fecal elastase, with an HbA1c cutoff value of 7. 4%, serves as a practical marker for detecting pancreatic exocrine insufficiency. The interplay between pancreatic steatosis, glycemic control, and exocrine dysfunction highlights the need for comprehensive metabolic assessments in this population.
Key words
Exocrine pancreatic insufficiency, fecal elastase, HbA1c, hepatic fat fraction, hepatic steatosis, pancreatic steatosis

Neonatal diabetes: clinical characteristics, genetic analysis and long-term follow-up from a single-center experience
Abdurrahman Güney[1], Hande Turan[1], Hasan Karakas[1], Ilayda Altun[1], Gökçe Velioğlu Haşlak[1], Mert Uçar[1], Elvan Bayramoğlu[1] & Olcay Evliyaoglu[1]
[1]Istanbul University-Cerrahpasa Cerrahpaşa Faculty of Medicine, Istanbul, Türkiye

Introduction
Neonatal diabetes mellitus (NDM) is a rare monogenic form of diabetes that presets within the first six months of life, and is classified as either transient (TNDM) or permanent (PNDM). This study aims to describe the clinical characteristics, genetic findings, treatment strategies, and long-term follow-up of 11 NDM patients based on a single-center experience.
Methods
This study involved 11 patients with NDM diagnosed, treated, and followed between 2013 and 2025 years. Clinical, biochemical, and genetic data were evaluated retrospectively. Genetic analysis was performed in all patients.
Results
Among 11 patients (7 male) from 9 unrelated families, TNDM and PNDM were diagnosed in 1 and 10 patients. Sixty-four percent were born to consanguineous parents. Genetic mutations were identified in 64%, the most common mutation was in the PTF1A distal enhancer ($n = 6$)), one patient had KCNJ11 mutation. Fifty-four percent were born prematurely, and 90. 9% were small for gestational age. The median age at diagnosis was 1 day, All patients received insulin replacement therapy. *Glibenclamide was initiated in the patient with the KCNJ11 mutation*. In PNDM patients, the median insulin dose was 0. 55 U/kg/day initially and 0. 58 U/kg/day at last follow-up, with no significant difference. Six patients received insulin via insulin pumps. Median HbA1c at last control was 7. 5% and there was no difference in HbA1c levels compared to conventional insulin treatment. Patients with PTF1A mutations diabetes was associated with pancreas agenesis, thus they required pancreatic enzyme replacement. Pancreas agenesis was not associated with other abnormalites. One patient whose genetic analysis is pending has also exocrine pancreas insufficiency whose pancreas could not be visualized. All males exhibited catch-up growth, surpassing -2 SDS; whereas two females under two years remained below -2 SDS. These females with height below -2 SDS also had low weight. Except for the deceased KCNJ11-positive patient, all males achieved weight above -2 SDS at last follow-up.
Conclusion
NDM is a rare disorder with variable genotypes and clinical phenotypes. PTF1A mutation was the most common genetic cause in our cohort, particularly relevant in populations with high consanguinity rates. Genetic testing is crucial for identifying conditions such as pancreatic agenesis and initiating timely treatment, as well as guiding appropriate treatments such as sulfonylurea therapy in KCNJ11 mutations.

JOINT1492
Comparative analysis of ventricular repolarization in patients with type 1 diabetes vs. control and patients using insulin pump vs. multiple daily injections
Ekin Yiğit Köroğlu[1], Ayşe İrem Demirtola Mammadli[2], Caglar Keskin[1], Ahmet Kursat Soyer[1], Didem Ozdemir[3], Oya Topaloglu[3], Reyhan Ersoy[3] & Bekir Cakir[3]
[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism Diseases, Ankara, Türkiye; [2]Ankara Bilkent City Hospital, Cardiology, Ankara, Türkiye; [3]Ankara Yıldırım Beyazıt University Faculty of Medicine, Endocrinology and Metabolism Diseases, Ankara, Türkiye

Objective
The frequency of cardiovascular mortality is increased in type-1 diabetes mellitus(T1DM). Both hyperglycemia and hypoglycemia increase the risk of cardiac complications. This study aimed to use the ECG parameters of ventricular repolarisation times to assess the risk of arrhythmogenesis in patients with T1DM.
Methods
Age, sex, age at diagnosis of T1DM, duration of T1DM, insulin-pump use status, duration of insulin-pump use, biological and diabetic age at insulin pump insertion, continuous glucose monitoring(CGM) status, carbohydrate counting status, diet compliance status, history of technical problems with insulin-pump, total insulin doses, presence of hypertension, history of diabetic foot, hyperlipidemia, stroke, coronary heart disease, symptomatic hypoglycemia at least once a week, diabetic foot, peripheral vascular disease, hospitalization for hypoglycemia, presence of diabetic neuropathy, presence and type of diabetic retinopathy, diabetic nephropathy status, hemoglobin A1c(HbA1c) value, creatinine, microalbuminuria status, and spot urine microalbumin/creatinine ratio levels were recorded. Electrocardiographic(standard 12-lead ECG) parameters, parameters corresponding to ventricular repolarisation times, and used as indicators of arrhythmogenesis were collected. These were P-wave, QRS-wave, T-wave, PR-interval, QT, QTmax, QTmin, QTc, QTcmax, QTcmin, QT-dispersion, QTc-dispersion, Tp-e, JTc, Tp-e/QT, Tp-e/QTc, index of cardio-electrophysiological-balance(iCEB). Obtained parameters were evaluated between patients with T1DM and the control group. In addition, the patient group was divided according to the method of insulin therapy used(basal-bolus insulin therapy vs insulin-pump) and compared within themselves.
Results
125 patients with T1DM and 50 controls were included in the study. 62 patients were on basal-bolus insulin therapy, and 63 were on insulin pump therapy. Patients who used insulin pumps had lower HbA1c than those who did not(8.45 ± 1.60 vs 9.62 ± 2.01, $P = 0.001$). The incidence of symptomatic hypoglycaemia was lower in the insulin pump group, but the history of hospitalisation due to hypoglycaemia was similar in both treatment groups. P-wave, QT, QTmax, QTmin, QTc, QTcmax, QTcmin, Tp-e, and JTc were longer in T1DM patients(p values $=0.024$, 0. 012, 0. 007, 0. 001, <0.001, <0.001, 0. 001, 0. 001, and 0. 004, respectively). QRS duration was significantly shorter, and JTc, iCEB, and iCEBc were significantly longer in insulin pump patients(p values $=0.045$, 0. 031, 0. 019, and 0. 005, respectively).
Conclusion
In conclusion, patients with T1DM have prolonged ventricular repolarisation time and may be predisposed to arrhythmias. This study also suggests that insulin pump therapy may provide better glycemic control and less hypoglycemia. However, when assessing the effect of this condition on the risk of arrhythmia, it is essential to consider the patient's medical history and to remember that the risk of arrhythmia may persist despite improvements in the course of the disease.

JOINT2186
Investigation of the relationship between alexisomia and treatment adherence in diabetic obese individuals: a pilot study
Özge Baş Aksu[1], M Hakan Aksu[2], Özgür Demir[1] & Rıfat Emral[1]
[1]Ankara University, Department of Endocrinology and Metabolism, Ankara, Türkiye; [2]Gazi University, Department of Psychiatry, Ankara, Türkiye

Objective
Alexisomia is defined as the difficulty in recognizing and expressing bodily sensations and emotions. The Alexisomia Scale evaluates individuals through three sub-dimensions: DIB, difficulty in describing bodily emotions; LHM, lack of health management based on bodily emotions; OA, over adaptation. In chronic diseases like diabetes mellitus(DM), the inability to recognize and respond to bodily sensations may negatively impact treatment adherence. Our study aimed to investigate the relationship between alexisomia and treatment adherence in diabetic obese individuals and evaluate the effects of GLP-1 receptor agonist therapy on alexisomia, depression, anxiety, and stress.
Methods
This cross-sectional study included diabetic obese individuals. Adult patients diagnosed with type 2 DM and a body mass index (BMI) of $\geq$30 kg/m^2 were included, while those with active psychiatric disorders and undergoing related treatment were excluded. Anthropometric, demographic, and clinical characteristics, as well as laboratory data and ongoing treatments for at least three months, were recorded. Internal awareness of the participants was assessed using the Alexisomia Scale, while depression, anxiety, and stress levels were evaluated with the Depression, Anxiety, and Stress Scale (DASS). Treatment adherence was assessed using the 8-item Morisky Medication Adherence Scale (MMAS-8).
Results
The study included 38 patients (mean age 60. 2 $\pm$ 11. 06 years, 60. 5% female), with a median BMI of 32. 1 kg/m^2 (range: 30. 0–52. 8). Fifty percent of the patients used insulin, and 39. 5% were receiving GLP-1 receptor agonist therapy. When diabetic obese patients were examined in terms of alexisomia, alexisomia subgroups, depression, anxiety, stress, and treatment adherence, a statistically significant relationship was found between alexisomia and treatment adherence (P = 0. 043, r = 0. 330). Specifically, a significant relationship was observed between DIB and treatment adherence (P = 0. 017, r = 0. 385). Patients were also compared in terms of alexisomia, depression, anxiety, stress, and treatment adherence based on GLP-1 RA usage, but no statistically significant differences were found between the groups (P = 0. 740, P = 0. 464, P = 0. 532, P = 0. 717, P = 0. 532, respectively).
Discussion and Conclusion
Our study found that patients experiencing difficulty in identifying and perceiving their bodily sensations had lower treatment adherence. Screening for these characteristics in patients may contribute to strategies aimed at improving treatment adherence. While GLP-1 receptor agonists are effective therapies for type 2 diabetes, our findings suggest that GLP-1 RA therapy does not significantly impact alexisomia, depression, anxiety, or stress levels. Due to the limited sample size, these findings should be confirmed in larger-scale studies.

Clinical characteristics, risk factors, and outcomes of DKA in type 1 diabetes: a comparative study of continuous subcutaneous insulin infusion (CSII) vs multiple daily injections (MDI)

Angelica Sharma[1], Canay Onder[2], Azamat Kojanazarov[3], Nazarova Bakhora[4], Salixoba Zebo[4], Manbir Duggal[2], Madhulika Kotra[5], Hafsa Promi[2], Anu Abraham[2], Shamanth Soghal[2], Anmol Bagga[2], Nevil Philip[2], Susan Browne[6], Sophie Haughton[7], Lucy Bomphrey[8], Punith Kempegowda[2] & Team DEKODE[1, 2]
[1]Norfolk and Norwich NHS Foundation Trust, Norwich, United Kingdom; [2]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [3]Republican Specialized Scientific and Practical Medical Center of Endocrinology named after academician Y. Kh. Turakulov, Anaesthesiology and Intensive Care, Tashkent, Uzbekistan; [4]Centre of Endocrinology, Tashkent, Uzbekistan; [5]M. S. Ramaiah Medical University, Bengaluru, India; [6]Wirral University Teaching Hospital NHS Foundation Trust, Birkenhead, United Kingdom; [7]Sheffield Teaching Hospital NHS Foundation Trust, Sheffield, United Kingdom; [8]Warsall Manor Hospital, Warsall, United Kingdom

Background
Diabetic ketoacidosis (DKA) is a severe complication of type 1 diabetes (T1D) that requires prompt intervention to avoid life-threatening outcomes. Continuous subcutaneous insulin infusion (CSII) has been shown to improve glycaemic control and reduce hypoglycaemic episodes compared to multiple daily injections (MDI). However, the impact of insulin delivery method on DKA risk remains unclear, particularly with concerns over CSII device malfunction.
Objective
This study compared the frequency of DKA admissions, precipitating factors, clinical features, and outcomes in adults with T1D using CSII vs MDI to identify any differential impact of insulin delivery methods on DKA risk and outcomes.
Methods
A retrospective analysis of DKA admissions from January 2020 to July 2023 within the Digital Evaluation of Ketosis and Other Diabetes-related Emergencies (DEKODE) cohort was conducted. Participants were grouped into two cohorts: CSII users (cases) and MDI users (controls). Propensity score matching was applied with a 1:5 matching ratio. Key outcomes assessed included precipitating factors, biochemical markers, hypoglycaemic events, DKA duration, length of hospital stay, and mortality.
Results
Among the 1, 594 DKA episodes reviewed, 6. 3% (n = 100) occurred in CSII users. CSII users were younger (mean age 35. 7 years vs. 39. 6 years for MDI, P=0. 028) and had a higher proportion of females (59% vs. 45. 4% for MDI, P=0. 011). Suboptimal compliance was the most common precipitant in both groups, followed by intercurrent illness, with CSII malfunction being a notable cause in the CSII cohort. After matching, there were no significant differences in age, gender, ethnicity, or BMI across the groups. CSII users presented with higher admission ketone levels (6. 1 vs. 5. 6 mmol/l, P = 0. 043) and potassium levels (5. 2 vs. 5. 0 mmol/l, P = 0. 036) compared to MDI users. In addition, CSII users had fewer hypoglycaemic events during DKA management (7% vs. 17. 2%, P = 0. 015). DKA duration (13. 9 hours vs. 17. 9 hours in MDI, P = 0. 005) and length of hospital stay (2. 9 vs. 5. 5 days, P = 0. 0003) were significantly shorter in the CSII group. No deaths occurred in the CSII group.
Conclusions
Although CSII offers benefits in glycaemic control and reduced hypoglycaemia, DKA remains a significant risk, with 1 in 16 episodes occurring in CSII users. Despite shorter DKA duration and hospital stay, CSII users require careful monitoring to prevent and manage DKA effectively. Importantly, 18% of DKA cases in CSII users were linked to device malfunction, emphasising the need for improved education on device maintenance and troubleshooting to minimise this risk.

Association of arterial stiffness with mineral metabolism in type 2 diabetes patients with chronic kidney disease

Nodira Alikhanova[1], Charos Musakhanova[1], Nozimakhon Nazarova[1] & Lola Abboskhujayeva[1]
[1]Republican specialized scientific and practical medical center of endocrinology named after academician Y. Kh. Turakulov, Tashkent, Uzbekistan

Background and Aims
Type 2 diabetes mellitus (T2DM) is a major cause of chronic kidney disease (CKD), affecting 30–40% of diabetic patients. CKD progression increases the risk of cardiovascular disease (CVD), with arterial stiffness playing a crucial role in CVD pathogenesis. Pulse wave velocity (PWV) is a reliable marker of arterial stiffness. This study aims to assess the relationship between arterial stiffness (measured by PWV) and mineral metabolism parameters in T2DM patients with CKD.
Materials and Methods
This cross-sectional study included 105 adult patients with T2DM and CKD, classified into five -stages per KDIGO 2012 guidelines: CKD 1 n = 24, CKD 2 n = 21, CKD 3 n = 25, CKD 4 n = 15, CKD 5 n = 20. Arterial stiffness was assessed using PWV measured at the carotid-femoral level with the SphygmoCor XCEL system. Serum calcium, phosphorus, alkaline phosphatase, vitamin D, parathyroid hormone (PTH), calcitriol, and fibroblast growth factor 23 (FGF-23) levels were analyzed. Statistical analysis was conducted using the Spearman correlation coefficient, with P-values $<$0. 05 considered significant.
Results
The mean age of participants was 60. 3$\pm$8. 1 years, with 58. 1% female. The duration of illness with T2DM was 12. 87$\pm$7. 34 years. PWV increased with CKD progression, from 9. 06$\pm$2. 20 m/s in CKD stage 1 to 10. 75$\pm$2. 34 m/s in stage 5 (P = 0. 004). FGF-23 levels showed a strong positive correlation with PWV (r = 0. 618, P $<$ 0. 001). No significant correlation was found between PWV and serum calcium (r = -0. 098, P = 0. 409), phosphorus (r = 0. 162, P = 0. 169), vitamin D (r = 0. 005, P = 0. 962), or PTH (r = 0. 062, P = 0. 696).
Conclusion
Arterial stiffness, as indicated by PWV, increases with CKD severity in T2DM patients and is strongly correlated with FGF-23 levels. These findings highlight the potential role of FGF-23 as a biomarker for vascular complications in CKD. Further research is needed to elucidate the mechanisms linking FGF-23 and arterial stiffness.

Functional analysis of RFX2 gene as a candidate gene for monogenic diabetes

Ingrida Stankute[1], Ugne Meskauskaite[1], Valerie Schwitzgebel[2, 3] & Rasa Verkauskiene[1]

[1]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Pediatric Endocrine and Diabetes Unit, Department of Child and Adolescent, University Hospital of Geneva, Diabetes Center, Faculty of Medicine, University of Geneva, Geneva, Switzerland; [3]Diabetes Center, Faculty of Medicine, University of Geneva, Geneva, Switzerland

Introduction

Monogenic diabetes (MD) makes up up to 5% of diabetes cases, with over 40 genes confirmed to cause it, though many remain unidentified. A Lithuanian-Swiss study identified a novel variant in the *RFX2* gene, suggesting its potential role in diabetes. The study aimed to explore how *RFX2* gene knockdown impacts insulin production and its clinical implications in a patient with this variant.

Methods

A novel c. 1894G > A (p. Ala632Thr) variant in the *RFX2* gene was confirmed by PCR and Sanger sequencing. Functional analysis was performed by knocking down the gene in INS-1 832/13 cells, and insulin production was assessed using ELISA after glucose stimulation at 0 mM, 2. 5 mM, and 15 mM concentrations. Statistical analysis was conducted using IBM SPSS software 23. 0, and data are presented as median (min. -max. values).

Results

A 9-year-old boy diagnosed with diabetes and treated for type 1 diabetes was later found to have a novel c. 1894G > A (p. Ala632Thr) variant in the *RFX2* gene at age 16. Autoantibodies for glutamic acid decarboxylase and tyrosine phosphatase-like protein were negative, though insulin autoantibodies were at the cut-off range for positivity, considering the ongoing insulin treatment, patient was suspected to have genetic diabetes. Co-segregation analysis showed no family members with diabetes signs or the same variant, prompting functional analysis of *RFX2* in cell culture. Insulin production of *siRFX2* cells vs. wild-type cells after stimulation with glucose (2. 5 mM) was lower, 1. 5 $\times$ 10^{-5} (1. 4 $\times$ 10^{-5} – 1. 7 $\times$ 10^{-5}) vs. 1. 6 $\times$ 10^{-5} (1. 3 $\times$ 10^{-5} – 1. 8 $\times$ 10^{-5}), respectively, $P = 0.049$. Stimulation with 15 mM glucose concentration triggered the same insulin production from both, wild-type and knocked-down cells. Insulin secretion in *siRFX2* cell after using different glucose solutions, showed higher response with higher glucose concentration, 0 nM glucose - 0. 5 $\times$ 10^{-5} (0. 4 $\times$ 10^{-5} – 0. 8 $\times$ 10^{-5}); 2. 5 mM glucose –1. 5 $\times$ 10^{-5} (1. 4 $\times$ 10^{-5} – 1. 7 $\times$ 10^{-5}), 15 mM glucose - 6. 6 $\times$ 10^{-5} (6. 1 $\times$ 10^{-5} – 7. 6 $\times$ 10^{-5}), respectively, $P < 0.001$.

Conclusion

This experiment investigated the effect of *RFX2* gene knockdown on insulin production *In vitro*. While the findings did not confirm *RFX2* as a causative gene for monogenic diabetes, they suggested an altered glucose threshold in mutant cells, with impaired insulin production at low glucose and normal secretion at high glucose concentrations. This highlights the complexity of diabetes classification and underscores the need for further research into its etiology and pathogenesis.

Three case studies of congenital hyperinsulinism - variants and clinical outcomes

Johannes Boy[1], Matthias Begemann[2], Saeed El Ahmadieh[1] & Angeliki Pappa[1]

[1]University Hospital Aachen, Pediatric Endocrinology and Diabetes, Aachen, Germany; [2]University Hospital Aachen, Human Genetics, Aachen, Germany

Introduction

Congenital hyperinsulinism (CHI) is the most common cause of persistent hypoglycemia in neonates and encompasses a heterogeneous group of genetic, syndromic, and reversible causes. Timely and targeted diagnostics and therapy are crucial to prevent developmental damage and fatal outcomes. Genetic diagnostics are of particular importance, especially in Diazoxide-resistant cases, as they provide insight into further treatment steps and prognosis.

Methods

We present the cases of two neonates and one infant with different genetic causes of CHI (1-HFN4A, 2-, 3-ABCC8). The clinical course during the neonatal period, diagnosis, acute therapy, further diagnostic and therapeutic steps, and follow-up are described. Differences between medication-sensitive, diffuse, and focal forms are discussed.

Results

1. A female full-term infant who was large for gestational age (39 weeks gestation, 4670g) with postnatal hypoglycemia. Despite a carbohydrate-enriched diet, euglycemia could not be achieved. Diagnosis of CHI was confirmed through blood sampling during hypoglycemia, successful therapy with Diazoxide. HFN4A variant was identified. 2. A female pre-term infant who was large for gestational age (35 weeks gestation, 3330g) with postnatal and persistent hypoglycemia under carbohydrate diet. CHI was confirmed. Diazoxide therapy was ineffective, Octreotide provided insufficient response. A heterozygous compound ABCC8 mutation was found. Surgical intervention revealed a diffuse form histologically and 50% pancreas resection. Post-surgery, hyperinsulinism persisted. A therapy trial with lanreotide is planned. 3. A male full-term infant who was large for gestational age (40 weeks gestation, 4280g) with postnatal euglycemia, developing generalized seizures at 7 months due to hypoglycemia. Fewer hypoglycemic events under Diazoxide and carbohydrate diet. Paternal ABCC8 mutation was detected. PET-CT showed no focal abnormality, and a Diazoxide withdrawal trial has not yet resulted in severe hypoglycemia.

Conclusion

Persistent hypoglycemia in the neonatal period and infancy requires prompt and sequential diagnostics and therapy. Rapid genetic testing can help narrow down differential diagnoses. Until genetic results are available, a Diazoxide trial is recommended. In focal forms of CHI, PET-CT and surgery are often beneficial, whereas in diffuse forms, partial pancreatectomy rarely achieves euglycemia. Effective collaboration between neonatology, pediatric endocrinology, and human genetics is crucial for timely diagnosis and treatment.

Multi-center investigation of pediatric diabetes in China

Bingyan Cao[1], Chunxiu Gong[2] & Guoshuang Feng[3]

[1]Children's Hospital Affiliated to Capital Institute of Pediatrics, Department of Endocrinology, Beijing, China; [2]Beijing Children's Hospital, Capital Medical University, Big Data Center, Beijing, China; [3]Beijing Children's Hospital, Capital Medical University, Department of Endocrinology, Genetics and Metabolism, Beijing, China

Objective

To investigate the characteristics and trends of diabetes mellitus in Chinese children and compare type 1 and type 2 diabetes mellitus.

Methods

The first pages of medical records of 13322 newly diagnosed children with diabetes aged 1 to 18 from children's medical centers in 30 provinces were collected from 2016 to 2022. The study analyzed the epidemiology, complications, and disease burden of childhood diabetes.

Results

A total of 13, 322 hospitalized children were analyzed, including 6, 477 males (48. 62%) and 6, 845 females (51. 38%). Of these, 11, 965 were diagnosed with T1DM and 1, 357 with T2DM. The mean age for T1DM patients was 8. 23 $\pm$ 3. 97 years, with a male-to-female ratio of 0. 91:1. For T2DM patients, the mean age was 12. 64 $\pm$ 2. 06 years, and the ratio was 1. 35:1. T1DM most commonly occurred in children aged 5 to 14, while T2DM was prevalent in those aged 10 to 14. The peak incidence seasons for T1DM were July, August, and January, with August being the peak for T2DM. From 2016 to 2022, the proportion of hospitalized children with diabetes rose from 1. 40‰ to 2. 42‰, with T2DM hospitalizations growing significantly faster than T1DM (19. 14% vs 8. 68%). The rate of diabetic ketoacidosis (DKA) was higher in T1DM than T2DM (39. 92% vs. 11. 94%, $P < 0.01$). Conversely, conditions such as hyperlipidemia, fatty liver, hyperuricemia, hypertension, metabolic syndrome, and obesity were significantly more prevalent among T2DM patients. However, cerebral edema rate did not significantly differ between T1DM and T2DM. The analysis indicated that T2DM, ketoacidosis, hyperuricemia, and length of hospital stay significantly increase costs.

Conclusion

The incidence of both T1DM and T2DM in Chinese children is rising, with a more pronounced increase in T2DM. Significant differences exist between the two types regarding age, gender distribution, complication rates, and hospitalization costs.

Therapeutic education in children and adolescents with type 1 diabetes mellitus; systematic review

Despoina Rizikou[1], Afroditi Tsalkitzi[2], Chrysoula Tsiou[2], Maria Meletiadou[3], Antonia Kalogianni[2] & Eugenia Vlachou[2]
[1]University of West Attica, General Hospital Of Piraeus "Tzaneio", Nursing, Athens, Greece; [2]University of West Attica, Nursing, Athens, Greece; [3]General Hospital of Piraeus "Tzaneio", Cardiac Intensive Care Unit, Athens, Greece

Introduction
The therapeutic education of Type 1 Diabetes Mellitus (T1DM) in children and adolescents is an ongoing process and an integral part of its successful management. Therapeutic education programs, taking into account the unique characteristics and developmental needs of each child/adolescent, aim to empower and promote autonomy, enabling them to effectively take over self – management of their disease which contributes to improving their quality of life and preventing complications.
Purpose
The purpose of this systematic review was to evaluate the impact of therapeutic education in children and adolescents with T1DM on self- management of their disease.
Method
International bibliography was reviewed using electronic database such as PubMed, Cochrane Library and Scopus. Keywords such as "Therapeutic education", "Type 1 diabetes mellitus", "children", "adolescents, "self-management", "glycemic control", "educational programs" in combination with Boolean operators (AND, OR) were used in English language to search for studies conducted during 2014 - 2024.
Results
A total of 23 studies were reviewed and evaluated based on predefined quality and relevance criteria. 19 of these studies demonstrated an improvement in the glycemic control of children and adolescents with T1DM, although 9 of them did not show a statistically significant reduction in glycated hemoglobin (HbA1c). Additionally, 6 studies showed better adherence to treatment after attending a therapeutic educational program, with 2 of them emphasizing an increase in diabetes-related knowledge. Specifically, combined educational approaches incorporating psychoeducational interventions appeared to improve T1DM self-management. Moreover, 10 studies reported that using digital tools such as Continuous Glucose Monitoring (CGM) can also strengthen the adherence to treatment. Benefits on quality of life were recorded in 8 studies, but in 4 of them, these benefits were not maintained on the long term. Furthermore, according to 4 studies, parental participation in therapeutic programs improved family relationships and children's confidence in managing the disease. Finally, 5 studies highlighted the contribution of specialized diabetes interdisciplinary team, integral members of which are nurses, in the overall improvement of T1DM management.
Conclusion
Therapeutic education is a key factor in the effective management of T1DM in children and adolescents. Its impact is further enhanced through personalized support, family involvement, and the integration of new technologies. Specialized diabetes nurses play a crucial role as primary health providers of education and support for children and their families. Further studies are needed to delve into therapeutic education in children and adolescents as a cornerstone of monitoring their glycemic control.

Hamman's syndrome as a rare complication of diabetic ketoacidosis in a newly diagnosed pediatric patient with type 1 diabetes mellitus

Danai Barlampa[1], Maria Dolianiti[1], Ioannis Anargyros Vasilakis[1], Michaela Nikolaou[1], Ioanna Farakla[1] & Christina Kanaka Gantenbein[1]
[1]Division of Endocrinology, Diabetes and Metabolism 'Aghia Sophia' Children's Hospital ENDO-ERN center for Rare Paediatric Endocrine Diseases, First Department of Pediatrics Medical School, National and Kapodistrian University of Athens, "Aghia Sophia" Children's Hospital, Athens, Greece, Athens, Greece

Hamman's syndrome, an uncommon complication of diabetic ketoacidosis (DKA), is characterized by spontaneous subcutaneous emphysema and pneumomediastinum. The pathophysiology of Hamman's syndrome in the context of DKA is multifactorial, with increased intra-alveolar pressure due to Kussmaul respiration and recurrent vomiting being key contributors to alveolar rupture. This case report describes an 11-year-old female of Indian origin, newly diagnosed with type 1 diabetes mellitus (T1DM), presenting with severe DKA. Upon admission, the patient had a blood pH of 7. 11, bicarbonate levels of 5. 4 mmol/l, a partial pressure of carbon dioxide (pCO2) of 16. 5 mmHg and Glu: 405mg/dl. Her vital signs were the following: Blood pressure: 133/89mmHg, heart rate: 144bmp, respiratory rate: 50/min, temperature: 36, 7°C. Clinical symptoms included a 7-day history of polydipsia, polyuria, and weight loss (3 kg), along with acute onset of chest pain and shortness of breath for 1 hour prior to presentation. On examination, the patient demonstrated Kussmaul breathing and tachycardia. Initial management with intravenous fluids and *insulin infusion* was initiated at a local general hospital. Following stabilization, she was transferred to a tertiary pediatric center for further evaluation and care. Routine physical examination at the tertiary center revealed *bilateral neck crepitus* and a mediastinal crunch on auscultation, suggestive of Hamman's syndrome. The diagnosis was confirmed with imaging, including chest X-ray and computed tomography (CT). During her hospital stay, the patient underwent continuous pediatric, cardiological, pulmonological, and endocrinological evaluations to ensure comprehensive management of both her acute condition and underlying comorbidities. Successful treatment of DKA led to complete resolution of her symptoms, and she was discharged with a structured follow-up plan. This case underscores the importance of recognizing Hamman's syndrome as a potential complication of DKA in pediatric patients. Early identification and differentiation from more severe conditions, such as Boerhaave's syndrome, are critical for ensuring optimal outcomes. Increased awareness and understanding of this rare syndrome can aid in prompt diagnosis and effective management, thereby improving patient care.

Introduction
The transition of young adults with type 1 diabetes mellitus (T1DM) is challenging for the young person, their families and health care providers. They must assume higher levels of autonomy and often neglect their healthcare. For a more successful change of care, structured transition programs are necessary. Our aims are to characterize T1DM patients who went from pediatric to adult care in the last 2 years, evaluate their glycemic control over time, and the occurrence of acute complications.
Methods
The transition model adopted in our center consists of a multidisciplinary team that includes nurses, the pediatric endocrinologist, and the adult endocrinology team. Data regarding demographic characteristics, time since diagnosis, glycemic control, and complications was collected from electronic clinical files. Glycemic control was evaluated using HbA1c, glucose management indicator (GMI), coefficient of variation (CV), time in range (TIR) and time below range (TBR), at 6 months intervals.
Results
25 patients with T1DM had transition appointments in the last 2 years, 40% female, median age at diagnosis 11 years and at transition 19 years. Median time since diagnosis at transition of 8 years. All had continuous subcutaneous insulin infusion (CSII), 80% had continuous glucose monitoring. 76% are currently enrolled in higher education. No patient was lost to follow-up, and all are still with CSII, 24% changed to automated insulin delivery (AID) systems. There was 1 hospitalization for ketoacidosis (around 12 months after transition), with no previous serious acute complications. There was a statistically significant worsening of HbA1c ($P < 0.001$), GMI ($P = 0.001$) and TIR ($P < 0.001$) 6 months after transition. GMI values improved 18 months after transition ($P = 0.027$).
Discussion
Our center's transition model for T1DM patients has been successful, with no losses to follow-up. Only one showed a serious acute complication. Glycemic control worsened initially after transition, with a subsequent improvement after

	6 months before transition	At transition	6 months after transition	12 months after transition	18 months after transition	24 months after transition
N	25	25	24	15	12	5
HbA1c	7. 3%	7. 5%	8. 1%	9. 2%	7. 4%	7. 2%
GMI	7. 2%	7. 5%	8. 1%	8%	7. 6%	7%
CV	40. 9%	40. 9%	39. 6%	39. 4%	37. 3%	34. 2%
TAR	38. 7%	46. 1%	47. 8%	48. 5%	39. 1%	28. 4%
TIR	55%	48. 8%	47. 2%	45. 4%	54. 8%	68. 6%
TBR	6. 2%	5. 5%	4. 9%	3. 9%	3. 3%	3%

18 months, that seems to extend into the 24-month mark, which might reflect their increasing autonomy in self-care, reinforcing the need for therapeutic re-education aimed at young adults.

Correlation between inflammation, metabolic syndrom and visceral fat in young type 1 diabetes patients

Samir Mkaouer[1], Zeineb Rekaya[1], Meriem Yazidi[1], Elyes Kamoun[1], Nadia Khessairi[1], Ibtissem Oueslati[1], Fatma Chaker[1] & Melika Chihaoui[1]
[1]Chu La Rabta, Endocrinology Department, Tunis, Tunisia

Introduction
Insulin resistance (IR), feature of type 2 diabetes, is an inflammatory state that promotes atherosclerosis and increases cardiovascular mortality. IR is often underrecognized in young adults with type 1 diabetes (T1D). The aims of this study were to determine the prevalence of IR in young T1D and evalue the inflammatory status of T1D with IR.
Methods
We conducted a cross-sectional study including 68 T1D. The study subjects were young adults, aged between 18 and 45 years. Each patient underwent a physical examination (anthropometric parameters and blood pressure), a fasting biological sample collection for the measurement of HbA1c, lipid parameters and C reactive protein (CRP), an evaluation of body composition by DXA Scan which measured the the visceral fat mass (VFM). Proportion of visceral fat (PVF) was calculated using the formula: PVF = (VFM/weight)*100 High visceral fat levels (HVF) was defined by a PVF >1, 1 in men and >0, 7 in women. MS was diagnosed according to the International Federation of Diabetes (IDF) criteria.
Results
The study population consisted of 29 men (42. 6%) and 39 women (57. 4%). The mean age was 29. 4±7. 23 years. The median duration of diabetes was 11 years (4. 2–17. 0), with a range from 1 to 29 years. MS was observed in 14 patients (20. 6%). HVF was present in 15 patients (23, 4%). CRP levels were higher in T1D patients with MS (2. 6 mg/l [1. 85–5. 5]) compared to those without MS (1. 6 mg/l [1–3. 8]), with a *P*-value of 0. 068. CRP levels were Significantly higher in T1D patients with MS (3, 85 mg/l [1, 92-6, 77]) compared to those without MS (1, 45 [1, 00-3, 02]) with a *P*-value of 0, 006.
Conclusion
