Although inflammation due to IR was well established in the general population and type 2 diabetes patients, it is less studied in T1D patients. In our study, the inflammation measured by CRP, was more strongly correlated in T1D with HVF than MS. Indeed the visceral fat, promotes the development of chronic low-grade inflammation by secreting cytokines like IL-1, IL-6, TNF-alpha, and leptin.

Can c-peptide/glucose ratio at the diagnosis be a marker for predicting short or long term metabolic control in type 1 diabetes?

Gülşen Özer[1], Ibrahim Mert Erbas[1], Özge Köprülü[1], Özlem Nalbantoğlu[1], Huseyin Anil Korkmaz[1] & Behzat Özkan[1]
[1]University of Health Sciences, İzmir Faculty of Medicine, Dr Behçet Uz Children's Hospital, Pediatric Endocrinology, İzmir, Türkiye

Background
New biomarkers are needed to assess prognosis and metabolic control at the time of diagnosis in pediatric patients with type 1 diabetes (T1D). Studies in adults with type 2 diabetes showed that patients with a low postprandial c-ceptide/glucose ratio had worse metabolic control. However, there is a lack of knowledge on this biomarker ratio in children with T1D. We aimed to investigate the relationship between the c-peptide/glucose ratio (CGR) at the diagnosis time and short- or long-term metabolic control in T1D.
Materials and Methods
We included children diagnosed with T1D between 2013 and 2019, who had measured pre-treatment c-peptide and glucose levels, and were followed up for 3-5 years. Relevant data were obtained from medical records retrospectively. Results are presented as mean ± standard deviation or median (25-75th percentile) based on the normality of distribution.
Results
The study was conducted with 97 patients (54. 6% female, age 8. 9 ± 3. 8 years). Of these, 46. 4% ($n = 45$) were diagnosed with diabetic ketoacidosis (DKA) and 44. 3% ($n = 43$) with diabetic ketosis. At the diagnosis, serum glucose was 446 (303-537) mg/dL, c-peptide was 0. 36 (0. 2-0. 6) ng/mL, insulin was 2. 9 IU/mL (1. 7-4. 0 IU/mL; $n = 88$), and HbA1c was 11. 6±1. 8%. During the follow-up, 31 patients (32%) observed the honeymoon period for a median of 15 (7-21) months. The CGR (x1000) at the diagnosis was 0. 80 (0. 48-1. 54), and the insulin/glucose ratio (x1000) was 62. 5 (35. 9-115. 9). The insulin/glucose ratio correlated positively with age, initial pH, HCO3, and c-peptide levels ($P < 0. 05$) and negatively with HbA1c in the first year of T1D ($P = 0. 028$). The CGR was positively correlated with age, pH, HCO3, and insulin levels at the first admission ($P < 0. 001$). Also, it was negatively correlated with the mean HbA1c in the first year after the diagnosis ($P = 0. 031$), but not with HbA1c in 2 to 5 years ($p > 0. 05$). The ratio was higher in patients who had honeymoon period (1. 29 vs 0. 74; $P = 0. 020$). A CGR of >0. 46 predicted severe DKA (sensitivity: 83. 3%, specificity: 81. 4%, AUC=0. 795, $P = 0. 002$).
Conclusions
In this study, we found that the CGR in children with T1D can predict the presence and severity of DKA at the diagnosis, as well as metabolic control during and the first year. Also, it can be a useful marker to predict the honeymoon period. These results highlighted the importance of close monitoring and adjusting treatment plans of children with T1D who had lower c-peptide responses to hyperglycemia and reduced beta cell reserve at the diagnosis time.

Alpelisib associated hyperglycemia in patients with advanced breast cancer

Carolina Peixe[1, 2], Catarina Isabel Lopes[1], José Vicente Rocha[1, 2], Mariana de Griné Severino[1], Marta Vaz Lopes[1], Miguel António Duarte[1], Ana Paula Barbosa[1, 2], Ana Gomes[1, 2], Maria Inês Alexandre[1, 2] & Maria João Bugalho[1, 2]
[1]Hospital de Santa Maria, ULS Santa Maria, Endocrinologia e Nutrição, Lisboa, Portugal; [2]Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal

Introduction
Alpelisib is an emerging treatment for advanced breast cancer. It promotes α-selective phosphatidylinositol 3-kinase (PI3K) inhibition, which impairs insulin action and promotes hepatic glycogenolysis, leading to hyperglycemia and compensatory insulin release. Hyperglycemia has an early onset (median 2 weeks) and has been reported in 60% of the patients, with 28% facing moderate (fasting plasma glucose >250-500 mg/dL) and severe (>500 mg/dL) hyperglycemia. Alpelisib's short half-life (8–9 hours) facilitates glucose normalization within 24–72 hours after interruption. We present two cases of severe hyperglycemia associated with alpelisib in metastatic breast cancer patients.
Clinical Cases
Patient 1, a 71-year-old woman with ER-positive, HER2-negative breast cancer submitted to bilateral mastectomy and hormone therapy. Bone metastasis appeared 28 years after the diagnosis and did not respond to multiple therapeutic regimens. Patient 2, a 44-year-old woman with the same breast cancer subtype, underwent neoadjuvant chemotherapy, left mastectomy and hormone therapy. Widespread metastasis developed 4 years later, unresponsive to 6 lines of chemotherapy. Both patients had PIK3CA mutations and started alpelisib (300 mg/day). Neither had previous diabetes (HbA1c 5, 4% and 5, 1%) and the BMIs were 35. 2 kg/m^2 and 23. 1 kg/m^2, respectively. Asymptomatic severe hyperglycemia (glucose 525 mg/dL and 552 mg/dL) occurred within 2 weeks (Patient 1) and 1 month (Patient 2) after initiating treatment. In both cases, metformin (850 mg twice daily) was initiated and alpelisib was stopped. Fasting glucose normalized within 72 hours, allowing alpelisib (200 mg/day) resumption 1 week after. Both patients experienced recurrent hyperglycemia, requiring basal insulin (10 IU/day). Patient 1 needed no further treatment, while Patient 2 had to

increase basal insulin up to 18 IU/day and start prandial insulin for glycemic control. Despite initial control, alpelisib was discontinued within 4 months in patient 1 and 1 month in patient 2 due to disease progression. After stopping alpelisib blood glucose levels normalized in the next 24 hours and both patients could halt anti-diabetic drugs.
Conclusions
The anticipated expansion of alpelisib use will probably result in a significant rise of secondary hyperglycemia cases. Delayed diagnosis can affect metabolic control, potentially leading to alpelisib dose reduction or discontinuation and compromising efficacy and patient survival. The rapid onset of severe asymptomatic hyperglycemia may warrant regular glucose monitoring in patients initiating this treatment.

Understanding severe hypoglycaemia in diabetes mellitus: a retrospective analysis into risk factors, management and outcomes

Sara Abdi Osman[1], Aqeelah Khatoon[1], Haaziq Sheikh[1], Sam Sherratt-Mayhew[1], Faiz Ahmed[1], Sanna Waheed[1], Elysia Normanton[1], Rajeev Raghavan[2], Pratik Choudhary[3], Punith Kempegowda[4, 5], Rachael Yip[1], Team Dekode[1] & Amanda Ling Jie Yee[1]
[1]University of Birmingham, Medical School, School of Medical Sciences, Birmingham, United Kingdom; [2]New Cross Hospital, NHS Trust, Wolverhampton Diabetes Endocrine Centre, Wolverhampton, United Kingdom; [3]University of Leicester, Diabetes Research Centre, Department of Population Health Sciences, University of Leicester, Leicester, United Kingdom; [4]University of Birmingham, Institute of Applied Health Research, University of Birmingham, Birmingham, United Kingdom; [5]University Hospitals Birmingham NHS Foundation Trust, Department of Diabetes and Endocrinology, Birmingham, United Kingdom

Background
Severe hypoglycemia poses major complications for patients with diabetes mellitus (DM), varying from significant mortality risk to increased healthcare dependence.
Aims
This study aims to characterise the demographics, precipitating factors, and clinical outcomes of severe hypoglycemia episodes in DM patients, focusing on differences between inpatient and outpatients. This research seeks to inform targeted interventions to improve patient outcomes and reduce hospitalisations.
Methods
A retrospective analysis was conducted between October 2023 and July 2024 and involved 9 UK hospitals as part of the DEKODE hypoglycemia study. The exclusion criteria included cases of pre-diabetes (3), uncertain diagnosis (7) or non-DM cases (293). This study defined hypoglycaemia as per the International Hypoglycaemia Study Group (IHSG); excluding IHSG level 1 episodes, 1, 451 episodes were analyzed from 946 DM patients. Data included key patient demographics, DM type, treatments received, main precipitating factors, Charlson Comorbidity Index (CCI) and overall clinical outcomes. Results were analysed using Fisher's test, with a significance level of $P < 0.05$ being used.
Results
Among 1, 451 cases analyzed, 53. 1% occurred in females, with 72. 2% of patients of White ethnicity. The median age was 73 years, and the median CCI score was 6. Type 2 diabetes accounted for 68% of episodes, with insulin use reported in 79% of cases. Intercurrent illness was the most common precipitating factor (42. 1%), followed by fasting (39. 8%) and incorrect medication (18. 6%). Treatment methods also varied; oral glucose was used in 72. 6% of cases, dextrose in 43. 9%, and glucagon in 13. 8%. Severe cases requiring hospital or Intensive Treatment Unit admission occurred in 4. 4%, with a mortality rate of 5. 2%. Median glucose was 2. 3 mmol/l (IQR: 1. 9 - 2. 7), and the median hospital stay was 7 days (IQR: 2-17). Comparing inpatient and outpatient episodes (77. 1% vs 22. 9%), outpatient episodes showed higher rates of preceding cognitive impairment (72. 6% vs 50. 2%). Fasting was also the most common precipitating factor among outpatients (42. 9% vs. 29. 5%, $P < 0.0001$) and with glucagon administered as a treatment more often to outpatients (45. 7% vs. 4. 6%, $P < 0.0001$).
Conclusion
This study highlights the clinical diversity of hypoglycemia episodes, including precipitating factors, management, and outcomes, with notable differences between inpatients and outpatients. Future research should prioritise tailored interventions, such as patient education and medication review, to reduce hospitalisations and improve outcomes.

JOINT2865

Real-world evidence of the effect of adjunctive semaglutide on weight change, liver steatosis and metabolic control in people with type 1 diabetes

Jonathan Mertens[1, 2], Eveline Dirinck[1], Hennah De Winter[2], Luc Van Gaal[1], Sven Francque[2, 3] & Christophe De Block[1, 2]
[1]Antwerp University Hospital, Endocrinology, Diabetology and Metabolism, Antwerp, Belgium; [2]University of Antwerp, Laboratory of Experimental Medicine and Paediatrics and Member of the Infla-Med Centre of Excellence, Wilrijk, Belgium; [3]Antwerp University Hospital, Gastroenterology and Hepatology, Antwerp, Belgium

Introduction
Obesity is increasingly prevalent in type 1 diabetes (T1D), contributing to insulin resistance, metabolic syndrome, and MASLD. While semaglutide has proven effective for weight loss, glycemic control, and cardiovascular benefits in type 2 diabetes, its use in T1D remains unapproved.
Aims & Methods
This real-world study evaluates the effects of once-weekly subcutaneous 1. 0 mg semaglutide in adults with T1D. Inclusion criteria were stable glycemic control (Δ HbA1c $< 0.3\%$), stable body weight (Δ weight $< 3\%$), and a consistent insulin regimen (Δ insulin dose $< 5\%$) over the preceding year. Changes in body weight, total daily insulin dose (TDI), HbA1c and metabolic markers - including estimated glucose disposal rate (eGDR), controlled attenuation parameter (CAP) and liver stiffness measurement (LSM) - were assessed at baseline, 6 months and 12 months.
Results
Among 42 subjects (53% male, mean age 46 $\pm$ 12 years, diabetes duration 28 $\pm$ 12 years, HbA1c 7. 4 $\pm$ 0. 8%), mean BMI was 32. 0 $\pm$ 4. 6 kg/m^2 at baseline, with 76% classified as obese. Eight subjects discontinued treatment, primarily due to gastrointestinal intolerance. At 12 months, mean weight change was -10. 3 $\pm$ 7. 9 kg ($p < 0.001$), ranging between +2. 3 to -30. 9 kg, with 76. 4% attaining $\geq$ 5% weight loss. Obesity rate at cohort level decreased from 76. 5 to 29. 4% ($p < 0.001$). Mean HbA1c evolution was -0. 4 $\pm$ 0. 6% ($p < 0.001$), with 42% reaching an HbA1c reduction of $\geq$ 0. 5%. Relative TDI reduction was 13. 6 $\pm$ 16. 0% ($p < 0.001$) after 12 months, TDI/kg of bodyweight did not change significantly. Among those with serial hepatic imaging ($n = 23$), MASLD prevalence reduced from 82. 6 to 30. 4% ($p < 0.001$). CAP decreased with 45 $\pm$ 33 dB/m, while the prevalence of significant fibrosis based on LSM fell from 20. 6 to 4. 5% ($p < 0.001$). Insulin sensitivity based on eGDR increased significantly (5. 60 $\pm$ 2. 62 to 7. 42 $\pm$ 2. 35, $p < 0.001$).
Conclusion
Adjunctive semaglutide in T1D was safe, well-tolerated, and significantly improved weight, insulin needs, glycemic control, and MASLD markers.

Prevalence and characteristics of patients with cystic fibrosis-related diabetes in croatia

Lora Kirigin Biloš[1], Maja Baretić[2], Andrea Vukić Dugac[3], Krešimir Schoenwald[4], Ivan Bambir[5], Duška Tješić Drinković[5] & Velimir Altabas[1]
[1]University Hospital Centre "Sestre Milosrdnice", Department of Endocrinology, Diabetes and Metabolic Diseases "Mladen Sekso", Zagreb, Croatia; [2]University Hospital Centre Zagreb, University of Zagreb, School of Medicine, Department of Endocrinology and Diabetology, Cystic Fibrosis Center for Children and Adults, Zagreb, Croatia; [3]University Hospital Centre Zagreb, University of Zagreb, School of Medicine, Clinic for Respiratory Diseases "Jordanovac", Cystic Fibrosis Center for Children and Adults, Zagreb, Croatia; [4]General Hospital Dubrovnik, Dubrovnik, Croatia; [5]University Hospital Centre Zagreb, Department of Pediatrics, Cystic Fibrosis Center for Children and Adults, Zagreb, Croatia

Introduction
Cystic-fibrosis related diabetes (CFRD) is an important emerging complication of patients with cystic fibrosis (CF). This study investigated the prevalence of CFRD in the Croatian CF population, the age at CFRD diagnosis, insulin regimens used, and the relationship between age at CFRD diagnosis, insulin requirements, glycated hemoglobin (HbA1c), and body mass index (BMI).
Participants and Methods
Medical records from 157 patients with genetically and laboratory-confirmed CF were reviewed up to January 2025. All patients were followed at the *Cystic fibrosis center for children and adults*, University Hospital Centre Zagreb, the

country's primary treatment facility for CF. The American diabetes association (ADA) criteria were used to classify patients as CFRD. Anthropometric and clinical data were collected from the most recent medical records. Descriptive statistics were employed to summarize the prevalence and clinical characteristics of CFRD patients. Spearman's rank correlation coefficient was used to assess the relationships between age at CFRD diagnosis, age of insulin initiation, insulin doses, HbA1c, and BMI.
Results
Seventeen out of 157 patients (10. 8%) were identified with CFRD. The prevalence of CFRD was 4. 5% (4/89) in the pediatric CF population and 19. 1% (13/68) in the adult CF population. The median age of CFRD diagnosis was 14 years (range 9 – 22 years, SD = 3. 95), with the majority diagnosed between 9 and 15 years. The median BMI of patients with CFRD was 23. 0 kg/m^2 (range 13. 5 – 30. 5 kg/m^2, SD = 3. 73) and the median age was 24 years (SD = 6. 64). Fifteen patients (88%) were receiving combination therapy with ivacaftor, tezacaftor and elexsacaftor, and one patient was using ivacaftor only. At the last visit, 76. 5% (13/17) were using insulin. One patient was treated with bolus insulin only, 53. 4% (7/13 patients) were using basal-bolus multiple daily injections, and 38. 5% (5/13) were using insulin pumps. The average total daily insulin/kg to treat diabetes was 0. 854 U/kg (SD = 0. 398). The age at CFRD diagnosis and age at insulin introduction were positively correlated with BMI (P = 0. 02853, P = 0. 0254, respectively), and total daily insulin/kg was postively correlated with HbA1c (P = 0. 03308).
Conclusion
The prevalence of CFRD in Croatia and the age at CFRD diagnosis is consistent with previous studies. Patients diagnosed at a younger age and requiring insulin earlier had lower BMIs, likely to due to a faster decline in beta cell function and an earlier onset of insulinopenia.

Partitioning the genetic risk of obesity and type 2 diabetes using single-cell multi-omics of the gastrointestinal tract

Malte Thodberg[1], Kata Krizic[1], Jacob Antonsen[2], Shanshan He[1], Laura Pikkupeura[1], Thomas Koefoed[1], Rikard Fred[1], Charlotte Kruse[1], Benedicte Kapel[1], Marina Kanellou[1], Lars Nannestad[2] & Torben Hansen[1]
[1]University of Copenhagen, Novo Nordisk Foundation Center for Basic Metabolic Research, Copenhagen, Denmark; [2]Bispebjerg & Frederiksberg Hospital, 2Digestive Disease Centre, Copenhagen, Denmark

The worldwide increase in the prevalence of Type 2 Diabetes (T2D) and obesity constitutes a major threat to global health; however, the complex nature of these diseases is severely hampering the development of prognostic tools and clinical interventions. Both T2D and obesity have a strong genetic component; yet, the functional impact of the identified genetic variants in terms of causal genes, cell types, and organs remains largely unknown. The gastrointestinal (GI) tract is located at the junction between the gut microbiome and the gut-brain axis, which links intestinal function to the central nervous system, resulting in changes in appetite and behavior. Due to the complex regionality and cellular composition of the GI tract, it is largely unknown to what extent genetics play a role in metabolic diseases mediated by the GI tract, in particular, T2D and obesity. We are performing single-cell sequencing on human biopsies from multiple locations in the colon using the 10x Multiome assay for gene expression and chromatin accessibility. This allows us to map the location, activity, and interaction of promoters and enhancers in individual cell types and integrate these with genome-wide association studies (GWASs) of T2D and obesity. Using the resulting multi-omic and cell type-specific map of gene regulation, we can i) partition the genetic risk of T2D and obesity across cell types of the GI tract, ii) prioritize causal genetic variants and genes, and iii) perform data-driven stratification of T2D and obesity patients based on their cell type-specific polygenic risks. Ultimately, this will lead to novel molecular clinical targets and non-invasive prognostic tools for T2D and obesity.

A proof-of-concept study of type 2 diabetes remission with pharmacotherapy

Ananda M Chakraborty[1, 2], Rama Walia[1] & Sanjay Bhadada[1]
[1]Post Graduate Institute of Medical Education and Research, Endocrinology, Chandigarh, India; [2]Post Graduate Institute of Medical Education and Research, Endocrinology, Chandigarh, India

Background
This study evaluates the effectiveness of semaglutide and dapagliflozin alongside metformin, comparing it to vildagliptin and glimepiride alongside metformin in achieving diabetes remission.
Methods
An open-label, parallel, randomized controlled trial involving 85 participants diagnosed with T2DM within the past two years was conducted. The trial arm received semaglutide, dapagliflozin, and metformin, while the control arm received vildagliptin, glimepiride, and metformin. After 24 weeks, all medications were withdrawn to assess remission and relapse rates. The primary outcome was the proportion of patients achieving remission (HbA1c < 6. 5% without medication) and the time to relapse after stopping therapy.
Results
At the end of the 12 weeks after the completion of therapy, 26 (93%) and 11 (39%) patients were in remission in the trial and control arm, respectively. When compared at the end of 24 weeks, 36 weeks, and 52 weeks of completion of therapy, the remission rate was 71. 42% (n-20), 67. 85% (n-19), and 43. 42 % (n-13) in the trial arm as compared to 25% (n-7), 21. 42% (n-6), 3. 57% (n-1) in the control arm. The mean time to relapse was 39 weeks in the trial arm, compared to 19. 75 weeks in the control arm ($p < 0.001$). Additionally, the trial arm, as compared to the control arm, exhibited a difference in median weight reduction of 5. 96 kgs. Factors associated with a delayed relapse included a greater decrease in HbA1c from baseline, improved beta-cell function as assessed by HOMA-β and the disposition index, and a reduction in insulin resistance measured by HOMA-IR and a decrease in BMI.
Conclusion
The combination of semaglutide and dapagliflozin, used alongside metformin, effectively induces remission and promotes weight loss in patients with type 2 diabetes mellitus (T2DM). This treatment demonstrates significant potential as a transformative approach to diabetes management. Additionally, discontinuing medications for three months supports sustainable remission outcomes, with positive results maintained even one year after the therapy has ended.

Type 1 diabetes children with less sleeping time have higher HbA1c level and shorter stature

Rayi Kurnia Perwitasari[1 2 3], Yuni Hisbiyah[1 2 3], Nur Rochmah[2, 3] & Muhammad Faizi[2, 3]
[1]Pediatric Subspecialty (Consultant) program, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia; [2]Department of Child Health, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia; [3]Department of Child Health, Dr. Soetomo General Academic Hospital, Surabaya, Indonesia

Background
Type 1 diabetes mellitus (T1DM) is a complex metabolic condition marked by persistent hyperglycemia resulting from the autoimmune destruction of pancreatic β cells. Sleep is essential for sustaining the equilibrium of bodily functioning. A recent study indicates that sleep modification influences several physiological systems, including metabolic and endocrine control. A sufficient sleep is needed for optimum growth and development in children. Poor sleep in children with T1DM can lead to decreased insulin sensitivity and impair glycaemic control. High blood glucose level in uncontrolled diabetes can disrupt the normal production of growth hormones, leading to growth failure. The Asia-Pacific agreement advises 9–11 hours of sleep for children aged 9 to 13 years and 8–10 hours for those aged 14 to 18 years. The aim of this study is to analyse the correlation between sleep duration, HbA1c, and growth in children with T1DM
Methods
37 T1DM Children who had been diagnosed with diabetes for > 6 months and had regular visits at the paediatric endocrinology outpatient clinic at Dr. Soetomo Hospital were included. Sleep duration was obtained from the average of self-reported sleep duration in the last weeks. Weight measurements were performed using a GEA Medical® digital scale, offering precision to within 100 grams. Height measurements were obtained using a Onemed® microtoise or stadiometer, assuring accuracy to the closest 1. 0 millimetre. Height and weight was transformed into z-scores standard deviations (SDS) according to the WHO growth chart. HbA1c data was taken from the most recent examination of the medical record. Spearman correlation test and St. Nicholas House Analysis (SNHA) in RStudio were used to process the data with $p < 0.05$ considered significant.
Results
The mean age of the children is 158. 6 ± 45. 7 months old. The average HbA1c is 10 ± 2, and height SDS is -1. 389 ± 1. 28. The correlation test showed a

significant correlation between sleep duration and HbA1c (rho= -0. 54; $P < 0.01$), also a correlation between HbA1c and height SDS (rho= -0. 44, $P < 0.01$), while there is a weak correlation between height SDS and sleep duration (rho=0. 25; $P = 0.1$).

Conclusions

There is an association between sleep duration, growth, and HbA1c in children with T1DM. Children with less sleep duration have higher levels of HbA1c and lower height. Children with T1DM should have sufficient sleep to attain optimal glycaemic control, along with other established diabetic management like insulin administration, physical exercise, and dietary regulation.

Predictive factors of type 2 diabetes and prediabetes diagnosis in women with gestational diabetes

Marta Vaz Lopes[1], José Vicente Rocha[1, 2], Carolina Peixe[1, 2], Mariana de Grine Severino[1], Catarina Isabel Lopes[1], Miguel António Duarte[1], Maria Pulido Valente[3], Maria Inês Alexandre[1, 2], Ana Gomes[1, 2] & Maria João Bugalho[1, 2]

[1]Serviço de Endocrinologia, Diabetes e Metabolismo - Hospital de Santa Maria, Lisbon, Portugal; [2]Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal; [3]Departamento de Obstetrícia, Ginecologia e Medicina da Reprodução - Hospital de Santa Maria, Lisbon, Portugal

Introduction

Women with gestational diabetes (GD) are at increased risk of developing type 2 diabetes (T2D), and 20-33% of them are diagnosed with either prediabetes or T2D immediately postpartum. Therefore, a postpartum 75g oral glucose tolerance test (75g-OGTT) is recommended for all women with GD.

Aims

To identify predictive factors for postpartum diagnosis of T2D or prediabetes in women with GD.

Methods

This retrospective study included all women diagnosed with GD that delivered at a tertiary center from 2019 to 2023. Logistic regression models were used to evaluate associations between abnormal postpartum 75g-OGTT and demographic and clinical characteristics.

Results

Of 700 women with GD, only 318 (45. 4%) attended their scheduled postpartum 75g-OGTT, while 54. 6% missed their appointments. Higher age [OR (odds ratio) 1. 07, 95%CI (95% confidence interval) 1. 05-1. 1, $P < 0.001$] and higher education levels (OR 1. 56, 95%CI 1. 35-1. 8, $P < 0.001$) were identified as predictors of postpartum OGTT attendance. Among the 318 women who completed testing, 259 (81. 4%) had normal results, and 59 (18. 6%) had abnormal results, with 13 diagnosed with T2D and 46 with prediabetes. The identified predictors of abnormal postpartum 75g-OGTT were:

- Higher HbA1c levels during pregnancy (3rd trimester HbA1c: OR 3. 72, 95%CI 1. 89-7. 33, $P < 0.001$; average HbA1c: OR 3. 98, 95%CI 2. 02-7. 86, $P < 0.001$);
- Requirement of pharmacological treatment for GD control (OR 2. 86, 95%CI 1. 55-5. 29, $P < 0.001$). A subanalysis of only the pharmacologically treated GD cases showed that treatment with both insulin and metformin further increased postpartum prediabetes/T2D risk, vs treatment with insulin or metformin alone (OR 2. 33, 95%CI 1. 11-4. 91, $P = 0.03$);
- Higher plasma glucose levels at GD diagnosis (fasting plasma glucose levels: OR 1. 04, 95%CI 1. 02-1. 05, $P < 0.001$; 1-hour plasma glucose levels of diagnostic OGTT: OR 1. 014, 95%CI 1. 003-1. 03, $P = 0.014$; 2-hour plasma glucose levels of diagnostic OGTT: OR 1. 011, 95%CI 1. 001-1. 021, $P = 0.035$).

Other evaluated factors were not predictive of abnormal postpartum 75g-OGTT Results age, parity, positive family history of T2D, positive personal history of GD, pre-pregnancy BMI, weight gain during pregnancy or trimester of GD diagnosis.

Conclusion

This study showed that HbA1c levels during pregnancy, GD pharmacological treatment requirement and plasma glucose levels at GD diagnosis were predictors of abnormal postpartum 75g-OGTT in women with GD. These factors should be considered in order to optimize GD management strategies. Additionally, similarly to what is described in the literature, over half of women with GD did not attend their postpartum OGTT appointments, highlighting the need for interventions to improve adherence.

JOINT1482

Using the telegram bot for differential diagnosis of diabetes mellitus and risk assessment of its complications

Kateryna Gerush[1] & Natalija Pashkovska[1]

[1]Bukovinian State Medical University, Chernivtsi, Ukraine

Relevance

Diabetes Mellitus (DM) ranks among the most prevalent endocrine disorders, requiring accurate differential diagnosis to determine the optimal treatment strategy. Variability in clinical manifestations, the presence of atypical forms (LADA, MODY, pancreatogenic diabetes), and limited resources complicate this process. A critical aspect also involves the timely detection of complications, notably diabetic retinopathy (DR), a leading cause of blindness among DM patients. The adoption of digital technologies, including Telegram Bots, can significantly enhance the efficiency of diagnosis and patient monitoring.

Materials and Methods

The Telegram Bot "DiaPredict" was developed to implement an algorithm for differential diagnosis of DM types and complication risk assessment. This algorithm is based on an analysis of international guidelines (ADA, WHO, IDF) and clinical data. The Bot automates the collection of anamnestic information, evaluates laboratory indicators, analyzes DR risk factors, and generates personalized recommendations for further examinations.

Results

The functionalities of the "DiaPredict" Telegram Bot include:

- Interactive collection of anamnesis, symptoms, and laboratory indicators.
- Patient stratification based on phenotypic characteristics.
- Risk assessment for the development of DR based on a multifactorial analysis (glycemic control, duration of DM, comorbidities).
- Formation of personalized recommendations for additional examinations and ophthalmological monitoring. "DiaPredict" approbation demonstrated high accuracy in the differential diagnosis of DM types and stratification of DR risks. Using the Bot allowed:
- Minimization of cognitive biases in doctors when diagnosing;
- Automation of clinical data processing, reducing decision-making time;
- Increased awareness among primary care physicians regarding atypical forms of DM and DR;
- Optimization of referrals for ophthalmological examination.

Conclusions

The "DiaPredict" Telegram Bot is an effective tool for optimizing the diagnostic process in DM, and the timely detection of DR. Its implementation can enhance the quality of medical care, reduce the burden on doctors, and improve patient management outcomes. Further research is directed towards integrating the Bot with electronic medical systems and evaluating its long-term effectiveness.

An unusual case of MODY

Shyam Seshadri[1], Freya Howard[1] & Jaiminkumar Patel[1]

[1]Queen Elizabeth Hospital Foundation NHS Trust, Department of Diabetes and Endocrinology, Kings Lynn, United Kingdom

Our patient was diagnosed with gestational diabetes at age 21. At 28 years of age, she was diagnosed with type 2 diabetes. She was diagnosed in Poland moving to England shortly. The patient unfortunately knew very little about her biological family. She reported her mother had diabetes diagnosed as type 2 diabetes, but diet controlled which was diagnosed during pregnancy. She believed her mother possibly had a rarer form of diabetes. Her current medications were Gliclazide, Basal insulin, Linagliptin Dapagliflozin and Metformin. Her BMI at diagnosis was 22. 7. Whilst in UK, she was found to require insulin and tested negative for anti-GAD, anti-Islet cell antibodies, and had measurable blood C-peptide levels 7 years from diagnosis of diabetes. Her age and low BMI prompted a genetic screening revealing a NEUROD 1 mutation. It is believed that the patient is part of a large family in Poland with the same gene mutation. She has a son and daughter who do not have diabetes, so genetic testing is available for her children should she wish to proceed. There is no exact penetrance figure for the NEUROD1, but it is believed to be lower than the HNF1A mutation. There is no certainty as to whether the children will go on to develop diabetes and testing will not provide predictive onset for the children's diagnoses of diabetes. It was advised to only test if the children became symptomatic and the mother was happy with this with prior counselling if genetic testing was required.

NEUROD1 gene is expressed in pancreatic and neuronal cells, being associated with MODY type 6. NEUROD1 gene mutations have been reported in 20 families worldwide to date. Two mutations in NEUROD1, are associated with the development of type 2 diabetes in the heterozygous state. The first is a missense mutation while the second is a truncated polypeptide lacking the carboxy-terminal trans-activation domain, a region that associates with the co-activators CBP and p300. The clinical profile of patients with the truncated NEUROD1 polypeptide is more severe than that of patients with the Arg 111 mutation. A deficient binding of NEUROD1 or binding of a transcriptionally inactive NEUROD1 polypeptide to target promoters in pancreatic islets could lead to the development of type 2 diabetes. We surmise that patients with a family history of diabetes, normal BMI, early onset of diabetes, and no autoimmunity should be at least initially screened for a known MODY mutation.

Exploring a synergistic approach: dual GLP-1 agonist combined with degludec basal insulin for early type 1 diabetes treatment and its impact on albumin-insulin producing cells expression

Amr Ahmed[1]
[1]Ministry of health, Riaydh, Saudi Arabia

Purpose
This manuscript explores the potential of dual glucagon-like peptide 1 (GLP-1) agonists combined with degludec basal insulin to treat early type 1 diabetes. The study aims to evaluate the efficacy and mechanistic impact of semaglutide, a GLP-1 agonist, on newly diagnosed type 1 diabetes patients.
Methods
A retrospective analysis was conducted to assess the effects of semaglutide on individuals with early type 1 diabetes. The analysis focused on the elimination of prandial and basal insulin, changes in C-peptide levels, and overall glycemic control. The study also examined the potential for GLP-1 agonists to protect residual beta cells, stimulate cell proliferation, and reprogram liver cells into insulin-producing cells. Additionally, the modification of GLP-1 agonists with albumin ligands to extend their half-life and enhance their anti-diabetic effects was investigated.
Results
The findings demonstrate the elimination of both prandial and basal insulin requirements, an increase in C-peptide levels, and improved glycemic control among the patients. Despite the positive outcomes, the study's retrospective nature and absence of a control group highlight the necessity for larger, prospective trials.
Conclusion
GLP-1 agonists show considerable potential in the management of type 1 diabetes by protecting residual beta cells, promoting cell proliferation, and reprogramming hepatic cells. The integration of modified GLP-1 agonists with albumin ligands could further enhance these effects. The manuscript underscores the need for continued research to fully explore this therapeutic approach. The proposed treatment strategy, which combines the autoimmune hypothesis, the proliferative effects of GLP-1, and albumin ligand modifications, aims to restore beta cell mass and function, thereby improving the quality of life for individuals with type 1 diabetes. Clinical trials are planned for 2024 under the registration 'Amr Ahmed, Maher M. Akl, Semaglutide GLP1 Agonists with Degludec Basal-bolus Insulin in Early Type 1 Diabetes to Basalbolus' (ClinicalTrials. gov Identifier NCT06057077).

Keywords: Adult human hepatic tissue; Anti-diabetic effects; Cell proliferation; Degludec basal insulin; Dual GLP-1 agonist; Early type 1 diabetes; GLP-1 agonists; Insulin-producing cells; Modified GLP-1 derivat; Type 2 diabetes.

Comparative study on clinical indicators of type 1 diabetes mellitus in children in southwest china before and after the COVID-19 pandemic

Ying Liu[1]
[1]West China Second University Hospital of Sichuan University, Chengdu, China

Objective
Viral infections, as environmental factors, significantly influence the onset and progression of Type 1 Diabetes Mellitus (T1DM). The novel coronavirus, in particular, may cause more complex immune disruptions in children, potentially leading to the development of T1DM. This study aims to analyze the impact of the virus on the onset and progression of T1DM by comparing clinical indicators of newly diagnosed T1DM children in Southwest China before and after the pandemic.
Methods
A retrospective analysis was conducted on children initially diagnosed with diabetes in our hospital in 2019 and 2024. Differences in age of onset, glycated hemoglobin levels, and diabetes antibody levels were examined, and their association with COVID-19 infection was analyzed.
Results
In 2019, 87 children were newly diagnosed, compared to 142 in 2024. The proportion of female children was 59. 78% and 59. 15%, respectively. The age of onset was 7. 40 ± 3. 94 years and 8. 13 ± 4. 18 years, respectively. Glycated hemoglobin levels were 12. 93% ± 2. 49% and 12. 54% ± 2. 48%, respectively. The proportion of children presenting with ketoacidosis at diagnosis was 59. 78% and 80. 99%, respectively. Among the 2024 cohort, 61. 27% had a history of COVID-19 infection, with an average of 2 years between infection and diabetes diagnosis; 7. 04% had a history of mumps virus infection. Antibody testing (GADA, IAA, INS, ZnT8, IA-2Ab) revealed that in 2019, 63. 22% of patients tested positive for only one antibody, with 45. 98% positive for GADA alone, 41. 38% positive for two or more antibodies, and 29. 89% positive for IA-2Ab. In 2024, 48. 23% tested positive for only one antibody, with 3. 53% positive for GADA alone, 51. 77% positive for two or more antibodies, and 77. 65% positive for IA-2Ab.
Conclusion
The incidence of newly diagnosed T1DM in children increased significantly before and after the COVID-19 pandemic, closely related to COVID-19 infection. Although there were no significant changes in the age of onset, glycated hemoglobin levels, or gender distribution, there were substantial differences in the types and proportions of antibodies, with a more pronounced coexistence of multiple antibodies. This suggests that viral infections may cause pancreatic islet damage through different immune mechanisms, providing clinical evidence for further research into the immune mechanisms of T1DM.

JOINT1691

Socioeconomic status, modifiable factors, and risk of microvascular complications in individuals with type 2 diabetes: a cohort study from the UK biobank

Shaoyong Xu[1], Qiqi You[2] & Ying Li[1]
[1]Xiangyang Central Hospital, Affiliated Hospital of Hubei University of Arts and Science, Department of Endocrinology, Xiangyang, China;
[2]Xiangyang Central Hospital, Affiliated Hospital of Hubei University of Arts and Science, Center for Clinical Evidence-Based and Translational Medicine, Xiangyang, China

Background
Diabetes is a prevalent chronic condition that can lead to microvascular complications, which significantly affect patients' health and quality of life. Socioeconomic status (SES) is associated with an increased risk of chronic metabolic diseases and may influence the progression of diabetes. This study aims to investigate whether lower SES was associated with an increased risk of diabetic microvascular complications, and analyze the potential mediating role of several modifiable factors.
Methods
The study included 11, 309 patients with type 2 diabetes at baseline from the UK Biobank cohort. SES was grouped based on income, education, and employment status by using the latent class analysis. The primary endpoint was the occurrence of diabetic microvascular complications, including diabetic nephropathy, diabetic neuropathy, and diabetic retinopathy, which were identified through electronic health records. Cox regression models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for diabetic microvascular complications. Mediation analysis was applied to explore potential mediators between SES and diabetic microvascular complications.
Results
During a median follow-up of 12. 2 years, 2, 043 cases of diabetic microvascular complications were recorded. Compared to participants with high SES, those with low SES had a HR of 1. 75 (95% CI: 1. 53, 2. 01) for total microvascular complications, a HR of 2. 11 (95% CI: 1. 74, 2. 55) for diabetic nephropathy, a HR of 1. 40 (95% CI: 1. 14, 1. 72) for diabetic retinopathy, and a HR of 1. 79 (95% CI:

1. 32, 2. 43) for diabetic neuropathy, respectively. Mediation analysis indicated that alcohol consumption, body mass index, triglycerides, high-density lipoprotein cholesterol, and glycated hemoglobin mediated the association between SES and total microvascular complications, with mediation percentages of 1. 3% (95% CI: 0. 3%, 3. 0%), 12. 2% (95% CI: 8. 4%, 17. 0%), 4. 4% (95% CI: 2. 4%, 7. 0%), 10. 9% (95% CI: 7. 1%, 16. 0%), and 10. 8% (95% CI: 7. 4%, 16. 0%), respectively. Body mass index, high-density lipoprotein cholesterol, and glycated hemoglobin also mediated the association between SES and individual microvascular complications ($P < 0.05$).
Conclusions
Our study indicated that lower SES was associated with an increased risk of microvascular complications in patients with type 2 diabetes, in which obesity-related indicators and glycated hemoglobin played important mediating roles. SES is relatively difficult to change, and efforts are suggested be made through other approaches such as increasing financial support for patients of low SES and enhancing weight and blood glucose management to prevent or reduce the occurrence of diabetic microvascular complications.

Challenges in the diabetes transition clinic: a 10-year experience at a tertiary care hospital

Marta Vaz Lopes[1, 2], Joana Branco[1], Catarina Isabel Lopes[1, 2], Marta Abreu Andrade[1], Maria Inês Alexandre[2], Ana Gomes[2], Sónia do Vale[2], Ana Raquel Henriques[1], Brígida Robalo[1], Carla Pereira[1] & Maria de Lurdes Sampaio[1]
[1]Unidade de Endocrinologia Pediátrica - Departamento de Pediatria - Hospital de Santa Maria, Lisbon, Portugal; [2]Serviço de Endocrinologia, Diabetes e Metabolismo - Hospital de Santa Maria, Lisbon, Portugal

Introduction
Adolescents, particularly those with chronic conditions, face heightened demands and challenges as they transition into adulthood, especially in the social and professional spheres, along with an increasing need of autonomy. Studies show that this transition often leads to deteriorating glycemic control and increased loss to follow-up in adolescents with diabetes. To address these concerns, our center established a Diabetes Transition clinic to ensure continuity of care, treatment adherence, and optimal metabolic control.
Objectives
To characterize the patients with diabetes who attended the Diabetes Transition clinic of a tertiary care hospital.
Methods
Retrospective study of all patients with diabetes who transitioned from the Pediatric to the Adult Diabetes clinic from January 2015 to December 2024. Data were collected from the patients' medical records. Statistical analysis was performed using SPSS.
Results
A total of 96 patients were transitioned from the Pediatric Diabetes clinic to the Adult Diabetes one during this period. 52. 1% ($n = 50$) were female, median age at diabetes diagnosis was 10 years (1-17) and median age at the time of transition was 19 years (18-22). 91. 7% ($n = 88$) of patients had type 1 diabetes (T1D), 5. 2% ($n = 5$) had type 2 diabetes, one patient had MODY type 3, one patient had diabetes secondary to cystic fibrosis and one patient had diabetes secondary to congenital generalized lipodystrophy type 1. Mean HbA1c levels before transition and at 1, 3 and 5 years post-transition were 8. 68 ± 1. 88%, 8. 47 ± 1. 84% ($P = 0.98$), 7. 87 ± 1. 64% ($P = 0.10$) and 7. 94 ± 1. 45% ($P = 0.11$), respectively. Mean time in range (TIR) of the T1D patients was 44. 3 ± 15. 3% pretransition and 40. 1 ± 14. 7% 1 year post-transition ($P = 0.24$). Currently, 79. 2% ($n = 76$) of patients remain in care at our Adult Diabetes clinic. Of the remaining patients, 12 were lost to follow-up, 7 elected to be transferred to other centers and the one with cystic fibrosis died from non-diabetes-related complications.
Conclusion
Unlike trends reported in the literature, in our study of the last 10 years of our Diabetes Transition clinic, mean HbA1c and TIR did not exhibit statistically significant differences in the years post-transition. These findings highlight the role of our multidisciplinary approach in supporting young adults with diabetes through this critical transition period. Nevertheless, implementing a more structured transition process, initiated earlier in adolescence, could further enhance patient engagement, improve long-term metabolic outcomes and reduce loss to follow-up.

Evaluation of emergency department admission reasons and associated factors in pediatric patients diagnosed with type 1 diabetes mellitus

Buse Karpat[1], Keziban Bala[2], Melikşah Keskin[2], Erdal Kurnaz[2], Nilden Tuygun[3] & Şenay Savaş Erdeve[2]
[1]Ankara Etlik City Hospital, Department of Pediatrics, Ankara, Türkiye; [2]Ankara Etlik City Hospital, Department of Pediatric Endocrinology, Ankara, Türkiye; [3]Ankara Etlik City Hospital, Department of Pediatric Emergency Medicine, Ankara, Türkiye

Objective
The diverse clinical presentations, increasing prevalence and incidence rates of type 1 diabetes mellitus (T1DM) have escalated the need for emergency department (ED) visits and hospital admissions. This study aimed to evaluate the characteristics and distributions of all ED visits—both diabetes-related and unrelated, requiring or not requiring hospital admission—among pediatric patients diagnosed with T1DM.
Materials and Methods
This retrospective study included 201 pediatric and adolescent patients who had been followed with a T1DM diagnosis for at least one year and presented to the Pediatric Emergency Department of Ankara Etlik City Hospital between October 1, 2022, and March 1, 2024. Patient data included sociodemographic characteristics, details of diabetes diagnosis and management, ED visit information, and laboratory findings.
Results
Among a total of 201 patients, 92 (46%) were using continuous glucose monitoring (CGM) devices, and 17 (8. 5%) were using insulin pumps. The mean HbA1c level over the past year was 8. 75 ± 2. 51%, and 61 patients (29. 4%) had not undergone an HbA1c measurement within the last three months. Between October 2022 and March 2024, there were a total of 345 ED visits, 50. 4% of which were diabetes-related, while 49. 6% were due to non-diabetes-related causes. Vomiting was the most common presenting complaint. Regarding the most recent ED visits, 15. 9% ($n = 32$) were due to hyperglycemia, 11. 4% ($n = 23$) due to ketosis, 26. 4% ($n = 53$) due to diabetic ketoacidosis (DKA), 13. 9% ($n = 28$) due to hypoglycemia, 26. 9% ($n = 54$) due to infections, and 5. 5% ($n = 11$) due to other reasons. Patients presenting with DKA had higher mean ages, higher diabetes diagnosis ages, higher daily insulin doses, and higher mean HbA1c levels compared to those with other diabetes-related presentations ($P < 0.001$). The CGM usage rate among DKA patients ($n = 8$; 15. 1%) was significantly lower than that of patients presenting with other diabetes-related conditions ($P < 0.001$). Patients with lower basal insulin percentages, those using antidepressant therapy, and those who were diagnosed with diabetes during a DKA episode had a higher likelihood of developing DKA during periods of illness.
Conclusion
Our study found that the clinical reasons for ED visits among pediatric patients with T1DM were closely associated with their metabolic control status and demographic characteristics. The majority of diabetes-related visits were accompanied by infections. Diabetes education for patients and caregivers should emphasize the importance of glycemic regulation during periods of illness. Regular follow-ups in collaboration with diabetes care teams are essential for improving diabetes management and reducing the long-term burden on emergency services.

JOINT2095

Investigation of lower urinary tract symptoms and their effects on quality of life in patients using sglt-2 (sodium-glucose cotransporter-2) inhibitors

Burak Cevirici[1], Deniz Türküm Atikcan Şimşek[1], Ozlem Turhan Iyidir[1], Aslı Nar[1] & Neslihan Bascil Tutuncu[1]
[1]Baskent University, Ankara, Türkiye

Sodium-glucose cotransporter-2 (SGLT-2) inhibitors are oral antidiabetic agents that have gained attention for their beneficial effects on glucose control, as well as their cardio-renal and metabolic benefits in managing diabetes mellitus. As diabetes prevalence increases, the use of these medications is expected to rise. This study aimed to assess the impact of SGLT-2 inhibitors on lower urinary tract symptoms (LUTS) and quality of life in patients with type 2 diabetes, a topic that has been limitedly explored. Conducted at the Department of Endocrinology, Başkent University Faculty of Medicine (October 2023-May 2024), the study included 210 participants—105 patients using SGLT-2 inhibitors and 105 using other non-insulin antidiabetic agents. The subjects were evaluated separately by sex using the FLUTS/MLUTS questionnaires, validated in both international and Turkish contexts. Additional data on comorbidities, medication use, fluid intake, and body mass index were also collected. Statistical analysis was performed using independent samples t-test, Mann-Whitney U test, Chi-square/Fisher's Exact test, and Spearman's correlation coefficient, with significance set at $P < 0.05$. The results revealed an increase in urinary frequency in male patients using SGLT-2 inhibitors ($P = 0.015$), but no significant differences in

voiding, storage, or nocturia complaints compared to the control group ($p > 0.05$). In female patients, no significant effects of SGLT-2 inhibitors on voiding, storage, or incontinence complaints were observed ($p > 0.05$). However, an increase in voiding discomfort was noted in the group using dapagliflozin among females ($P = 0.048$). This study is the first to evaluate the effects of SGLT-2 inhibitors on LUTS separately by sex and against a control group. It provides new insights, showing an increase in urinary frequency in male patients after more than six weeks of drug use. Additionally, the persistent urinary frequency in male patients using SGLT-2 inhibitors for over a year suggests that pollakiuria may continue long-term. The study also explored the relationship between SGLT-2 inhibitors and incontinence, contributing a novel perspective on their effect on voiding and storage phases. Our findings offer valuable insights into the use of SGLT-2 inhibitors and highlight the need for further research in larger populations to deepen our understanding of their impact on LUTS and optimize drug use in clinical practice.

JOINT2206

Comparison of metabolic control in children with type 1 diabetes using reimbursed, self-funded intermittent, and self-funded continuous CGM

Aylin Gunay[1], Nihal Bekar[2], Ceylan Ates[2], Tulay Guran[2], Serap Turan[2], Abdullah Bereket[2] & Belma Haliloglu[2]
[1]Marmara University School of Medicine, Istanbul, Türkiye; [2]Marmara University School of Medicine, Pediatric Endocrinology and Diabetes, Istanbul, Türkiye

Aim
Although children with type 1 diabetes facing significant financial constraints are provided with reimbursed continuous glucose monitoring (CGM) systems in Turkiye, many individuals with diabetes continue to encounter socioeconomic barriers to accessing CGM technology. To mitigate these challenges, we encourage families experiencing financial difficulties to wear sensors just before their routine follow-up visits. This approach aims to enhance patient/parents' awareness and facilitate more accurate treatment decisions. This study aims to assess differences in metabolic control among patients utilizing reimbursed CGMs, self-funded intermittent CGMs, and self-funded continuous CGMs.
Methods
Between 2021 and 2023, data from 207 CGM users were collected from CareLink, LibreView, and Clarity databases. Patients were excluded if they were in honeymoon period, used insulin pumps, had less than 14 days of CGM data, fewer than two CGMs annually, fewer than two HbA1c tests per year, or missed follow-ups. The final cohort was divided into three groups: reimbursed users (Group-1), self-funded intermittent users (Group-2), and self-funded continuous users (Group-3). Intermittent users were defined as those using sensors at least twice (10-14 days period) a year. Each group was evaluated for pre- and post-CGM one-year averages of HbA1c and anthropometric data, also groups were compared with each other in terms of one-year averages of TIR, TAR, TBR, CV.
Results
A total of 147 patients (Group-1, $n = 49$; Group-2, $n = 43$; Group-3, $n = 55$) were included. Pre-CGM HbA1c levels were significantly higher in Group-1 compared to Groups 2 and 3 ($P < 0.001$) (Table). One year after CGM use, Group-1 still had the poorest metabolic control, but it was the only group to show a significant decrease in HbA1c. Group-3 had the lowest post-CGM HbA1c ($P < 0.0001$). Although Group-3 had higher TIR value compared to Group-2, there is no statistical significance was found ($P = 0,075$).
Conclusion
Patients with poor metabolic control benefit most from CGM systems and should be prioritized for support, regardless of glycaemic outcomes. Although not statically significant and less than those using continuous CGM, individuals using intermittent CGM showed a minimal decrease in one-year average HbA1c.

Table 1: Comparison of pre-post CGM Hba1c, TIR, TAR, TBR and CV between groups

An Unusual case of late-onset ipex syndrome

Zulal Ozdemir Uslu[1], Burcu Senkalfa[1], Saliha Esenboga[2], Deniz Cagdas Ayvaz[2] & Alev Ozon[1]
[1]Hacettepe University, Department of Pediatrics, Division of Pediatric Endocrinology, Ankara, Türkiye; [2]Hacettepe University, Department of Pediatrics, Division of Pediatric Immunology, Ankara, Türkiye

Introduction
IPEX syndrome is a primary immunodeficiency caused by hemizygous mutations in the *FOXP3*, which encodes a key transcription factor essential for thymus-derived regulatory T cells to maintain immune tolerance. It is typically characterized by systemic autoimmunity beginning in the first year of life. This syndrome is defined by a triad of enteropathy, endocrinopathy, and eczematous dermatitis. Early diagnosis and treatment are crucial for preventing complications.
Case
A 4-year-2-month-old male patient was referred for hyperglycemia. Previous history revealed hematuria, proteinuria and thrombocytopenia at 2. 5 years. ANA and anti-dsDNA antibodies were positive, renal biopsy suggesting Class 5 lupus nephritis led to treatment with pulse steroids, intravenous immunoglobulin(IVIG) , cyclophosphamide, azathioprine and hydroxychloroquine. In addition, recurrent pancytopenia, and later, recurrent thrombocytopenia and arthritis in the left knee was treated with MPZ, eventually he developed hyperglycemia for which insulin lispro was started. The patient was referred to our clinic for management of hyperglycemia. There was no history of consanguinity, however, two maternal uncles had a history of diabetes with onset at 10 years of age. The patient's height and weight were normal, and systemic examinations were unremarkable. Investigations revealed elevated HbA1c, negative autoantibodies for diabetes, thyroid and celiac disease, normal liver, kidney, and thyroid functions, and anemia. Insulin glargine was added to the treatment. There was a progressive increase in HbA1c since the initiation of insulin(baseline: 4. 2%; 3rd months: 5. 2%; 18th: 10. 9%), and the family history of insulin-dependent diabetes in two uncles, thus genetic diabetes was suspected. Next-generation sequencing identified a hemizygous mutation in *FOXP3*. Further exploration of the uncles' medical history revealed that one uncle was diagnosed with diabetes at age 11, and chronic diarrhea and microcytic anemia at age 14; while the other uncle developed diabetes at age 8, chronic diarrhea at age 11, thrombocytopenia at age 15, and adrenal insufficiency at age 18. Genetic testing confirmed the *FOXP3* hemizygous mutation in the uncles, heterozygous in the mother. IVIG and fluconazole prophylaxis were initiated. High-resolution HLA samples were sent for the patient and siblings to assess suitability for HSCT.
Conclusion
IPEX syndrome presents with neonatal diabetes as well as early-onset enteropathy and eczema. However, it may have an atypical presentation, and should be considered in cases of diabetes of unknown etiology, especially associated with other autoimmune disorders, even when onset is after the first year of life, and is not accompanied by enteropathy/eczema.

Transforming youth diabetes care: the role of tellmi in providing digital mental health support in NHS somerset UK

May Ng[1, 2], Suzi Godson[3], Kerstyn Comley[3], Rose Firth[4], Mel Grenville[4] & Lucy Robin[5]
[1]Faculty of Health, Social Care and Medicine, Edge Hill University, Ormskirk, United Kingdom; [2]Paediatric Department, Mersey and West Lancashire Teaching Hospitals, Southport, United Kingdom; [3]Tellmi Digital Mental Health Service, London, United Kingdom; [4]Women's & Children's Health Commissioning, NHS Somerset Integrated Care Board, Somerset, United Kingdom; [5]Somerset NHS Foundation Trust, Somerset, United Kingdom

Background
Young people with diabetes face significant physical and mental health challenges that are often overlooked or mismanaged. Tellmi is a novel digital peer-support mental health app designed for individuals from age 11. Tellmi offers youths unlimited, anonymous, and pre-moderated peer support, organised by age groups. For high-risk comments, real-time trained counsellors actively intervene to provide appropriate support.
Methods
This qualitative study aimed to explore the lived experiences of youths with diabetes through interviews with participants recruited via Tellmi. As part of this project, the Tellmi app was adapted to enhance diabetes-specific support. Additions included 32 diabetes validated resources and services, such as a Diabetes Sucks Portal offering direct access to the Somerset NHS Children's Diabetes Nurses helpline. New content addressed topics like recognising diabetes symptoms, mental health, sexual health, and students' rights at school, codeveloped with NHS Somerset, paediatric diabetes clinicians, psychologists from Somerset Foundation Trust and the Tellmi team with input from youths with diabetes who tested and approved the questions. Promotional materials were also designed by young people with diabetes, ensuring a collaborative, youth-focused approach.
Results
7 participants (2M, 5 F) were recruited (age13-20 yrs). Findings revealed that a lack of awareness among healthcare providers often led to missed opportunities for timely diagnosis. For girls, symptoms such as weight loss were frequently misinterpreted as disordered eating, contributing to the later development of eating disorders. Participants also revealed that schools lack understanding of the complexities of diabetes management. All participants reported experiencing mental health issues, including anxiety, depression, self-harm and suicidal ideation. While some participants had accessed Child and Adolescent Mental Health Services (CAMHS), many expressed a preference for informal, peer-based support such as the Tellmi app. Tellmi was praised for allowing young people to both give and receive support within a community. Participants found this model effective in addressing feelings of isolation and in providing practical advice and emotional reassurance.
Conclusions
These findings highlight the urgent need to integrate psychological support into the diagnostic and management processes of diabetes for young people. This research underscores the importance of holistic, patient-centered approaches to diabetes care. Improving education for healthcare providers, caregivers, and schools could facilitate earlier diagnosis and reduce the long-term physical, mental, and economic costs of diabetes. Integrating psychological support as a standard part of diabetes care, and leveraging innovative novel digital tools like Tellmi, offers a promising pathway to improving outcomes for young people with diabetes.

The relationship of iron homeostasis and biochemical biomarkers according to therapeutic management in patients with type 2 diabetes

Kornilia Kadoglou[1], Eleni Patrianakou xanthakou[1], Anastasios Makris[2], Adamantia Spanou[2], Panagiota Patrianakou[1], Anastasios Ioannidis[1], Maria Tsironi[3] & Andrea Paola Rojas Gil[1]
[1]School of Health Sciences, Laboratory of Basic Health Sciences, Department of Nursing, University of Peloponnese, Tripoli, Nursing, Tripolis, Greece; [2]Hospital of Kalamata, Regular Diabetes Clinic, Kalamata, Greece; [3]School of Health Sciences, Laboratory of Epidemiology and Disease Prevention, Department of Nursing, University of Peloponnese, Tripoli, Nursing, Tripolis, Greece

Introduction
Iron, as an essential micronutrient, crucially modulates insulin sensitivity, impacting various processes in glucose homeostasis. The mechanisms involved in this interaction are crucial for developing targeted therapeutic interventions to address metabolic disorders.
The aim of the present study was to investigate the correlation of iron homeostasis factors with hematological and biochemical markers in patients with T2DM taking into consideration the treatment schema.
Methodology
400 subjects were included, 200 with T2DM: 100 in metformin treatment (PMET), 100 in GLP1 analogs treatment (PGLP), 100 control with prediabetes (PDC), and 100 healthy controls (C). Also, iron homeostasis markers were assessed: Iron (Fe), ferritin (Ferr), hepcidin (Eps), transferrin, transferrin saturation (TSAT), Total Iron Binding Capacity (TIBC), hematological and biochemical indices and HbA1C%. Statistical Analysis was performed by SPSS. Informed consent were acquired from all the participants
Results
Higher levels of BMI, WBC, transferrin, total and LDL cholesterol, and CRP were observed in PMET and PGLP compared to the C and PDC ($P < 0.001$). Also, diabetic patients showed a significant decrease in iron, hepcidin, and TSAT compared to C and PDC ($P < 0.001$). Regarding the differences between the therapeutic schemes, PGLP1 showed significantly increased BMI, fasting glucose, urinary microalbumin, and direct bilirubin, and had significantly lower platelet and alkaline phosphatase (ALP) levels, compared to PMET. PMET showed increased mean platelet volume and decreased HDL levels, compared to C only ($P = 0.026$), while their hepcidin was decreased compared to both C and PDC ($p \leq 0.0001$). PGLP1 showed significantly reduced hepcidin and increased considerably uric acid, compared to the PDC ($P = 0.005$ and $P = 0.046$, respectively) and reduced considerably HDL, ALP, and direct bilirubin compared to both the C and PDC ($p \leq 0.0001$). At the same time, the PDC and both diabetic groups had higher levels of BMI, fasting sugar, HbA1c %, red blood cell distribution range, hematocrit, triglycerides, urea, uric acid, creatinine, and pyruvate transaminase, compared to the control group ($p \leq 0.045$). Statistical analysis in all patients with diabetes according to fasting glucose levels showed that subjects with >100 to 130mg/dL had higher total iron-binding capacity ($P = 0.026$), transferrin ($P = 0.021$), transferrin/ferritin ratio ($P = 0.05$), platelets ($P = 0.026$) as compared to normal fasting glucose levels ≤100mg/Dl
Conclusion
Diabetic patients show disturbed iron homeostasis and a mild inflammatory state. These are associated with an increase and hyperfunction of PLTs, and hyperlipidemia reflecting cardiovascular risk, mainly in patients with uncontrolled diabetes.

Monogenic diabetes: results from targeted sequencing in lithuania during 2017-2022

Ingrida Stankute[1], Gryte Leonaviciute[2], Kristina Aleknaviciene[3] & Rasa Verkauskiene[1]
[1]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Department of Genetics and Molecular Medicine, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania

Introduction
Monogenic diabetes (MD) is a rare form of diabetes caused by single-gene defects. Maturity-onset diabetes of the young (MODY) has well-established diagnostic guidelines in children and adolescents, but individuals over 25 are often overlooked despite the importance of molecular diagnosis for personalized treatment and family risk assessment. The "Genetic Diabetes in Lithuania" project identified GCK, HNF1A, and HNF4A as the most common MODY subtypes in Lithuanian patients up to age 25, leading to the integration of targeted genetic sequencing into clinical practice since 2017. This study aimed to analyze genetic sequencing results from a targeted MD gene panel in patients with non-autoimmune diabetes at our diabetes center from 2017 to 2022.
Methods
We analyzed data of 51 patient (females $n = 31$ (60, 8%)) who had confirmed MODY diagnosis after targeted sequencing. The total number of patients suspected of MODY was 301, either because of negative autoimmune markers, diabetes in family history, or slight hyperglycemia, with no need for insulin treatment. Patient's age was not considered a selection criterion for genetic counseling. Targeted gene (*GCK*, *HNF1A*, *HNF4A*) panel was used during 2017-2022. The values presented as median (min;max), unless stated otherwise.
Results
The median age of patients was 23.5 (7;74) years; the median duration of diabetes was 6.0 (2;55) years at the analysis. The median age at diabetes diagnosis was 18.3 (4;68) years. Twenty-nine (56, 9%) patients had confirmed MODY diagnosis up to the age of 25 years. Twenty-five (86, 2%) of them were diagnosed with *GCK*, 3 (10, 3%) – *HNF1A*, 1 (3, 4%) – *HNF4A* mutations. 65, 5% ($n = 19$) had positive family history for diabetes, either MD or type 1, or type 2 diabetes. Twenty-two (43, 1%) of patients were diagnosed with MODY after the age of 25, with *GCK* most frequently - 17 patients (77, 3%), followed by *HNF1A* – 4 (18, 2%), and *HNF4A* – 1 (4, 5%). Eighteen (81, 8%) patients had positive family history for diabetes.
Conclusions
This study demonstrated a high diagnostic yield (17.9%) for MODY among patients referred for genetic testing, with *GCK* mutations identified as the most prevalent etiology. Furthermore, the findings underscore the necessity of critically evaluating selection criteria for MD genetic testing, as over 40% of diagnosed

cases were older than 25 years, including individuals in their late 40s and 50s. These results suggest that expanding genetic screening criteria may facilitate the identification of previously undiagnosed cases of MD, contributing to improved clinical management and risk stratification.

Maturity-onset diabetes of the young type 10 with a rare insulin gene mutation in a 35-year-old male

Miguel António Duarte[1], Catarina Isabel Lopes[1], Mariana de Griné Severino[1], Marta Vaz Lopes[1], José Vicente Rocha[1], Carolina Peixe[1], Mariana Lopes-Pinto[1], Sónia do Vale[1, 2] & Ema Lacerda Nobre[1, 2]
[1]Serviço de Endocrinologia, Diabetes e Metabolismo, Hospital de Santa Maria, Unidade Local de Saúde Santa Maria, Lisboa, Portugal; [2]Clínica Universitária de Endocrinologia, Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal

Introduction
Maturity-onset diabetes of the young type 10 (MODY 10) is a very rare monogenic form of diabetes caused by mutations in the insulin gene, leading to impaired insulin synthesis or secretion. This condition presents with early-onset hyperglycemia, often before age 25, and follows an autosomal dominant inheritance. MODY 10 requires precise genetic diagnosis and tailored management strategies.
Methods
We present the case of a 35-year-old patient diagnosed with MODY 10, followed-up in the Endocrinology Department of our hospital.
Results
The patient presented to the Emergency Department with nausea, vomiting and weight loss. Hyperglycemia was detected, leading to a diabetes diagnosis. The patient had a low body mass index of 18kg/m^2. His family history included a mother diagnosed with diabetes at the same age and requiring insulin therapy a decade later. Initial tests revealed a C-peptide level of 0. 8ng/mL, while autoantibodies (GAD, ICA, IA2 and insulin antibodies) were negative. Considering the family history and clinical presentation, MODY 3 was initially suspected, as it is the most common subtype. However, genetic testing was negative. He was treated with basal insulin, oral antidiabetic drugs, and later with fast-acting insulin. After several years without a clear diagnosis while maintaining a C-peptide of 1. 2ng/mL, a comprehensive genetic panel (next-generation sequencing) was performed. The results identified a heterozygous mutation in the insulin gene, c. 130G > A, p. (Gly44Arg), very rare in population databases (MAF gnomAD 0, 002%), confirming the diagnosis of MODY 10. The patient was than referred to genetic counselling and currently maintains good metabolic control on glargine insulin, metformin, dapagliflozin and sitagliptin, with an HbA1c of 6. 3% and maintaining partial pancreatic function (C-peptide 1. 14ng/mL).
Conclusion
Underweight MODY patients are often misdiagnosed as type 1 diabetes, particularly when C-peptide levels are low and insulin therapy is required at diagnosis. However, MODY diagnosis should be considered in the presence of family history, negative autoantibodies and C-peptide above 0. 6ng/mL, even with an atypical age of onset. This rare mutation underscores the importance of extensive genetic testing in atypical diabetes cases. Referral to genetic counselling is essential to identify affected family members.

JOINT2874

The association between metabolic score for insulin resistance and acanthosis nigricans in overweight and obese individuals: a cross-sectional study

Kelibinuer Mutailipu[1], Jiajing Yin[1], Xiaojuan Zha[1], Haibing Chen[1], Shen Qu[1] & Le Bu[1]
[1]Shanghai Tenth People's Hospital, Department of Endocrinology and Metabolism, shanghai, China

Background
Acanthosis nigricans (AN) is a common skin manifestation associated with insulin resistance in overweight and obese individuals. Although previous studies have suggested a relationship between insulin resistance and AN development, the association between different surrogate insulin resistance indices and AN remains unclear. This study aimed to investigate the differential associations of three commonly used insulin resistance indices (HOMA-IR, TYG-BMI, and METS-IR) with AN occurrence in overweight and obese individuals.
Methods
This cross-sectional study included 1, 077 patients (age $\geq$ 18 years, BMI $\geq$24 kg/m^2) from the Department of Endocrinology, Shanghai Tenth People's Hospital, between May 2010 and October 2021. Participants were stratified into two groups: AN (n = 446) and non-AN (n = 631). Insulin resistance indices were calculated and associations with AN were assessed using multivariate logistic regression, adjusting for potential confounders, including sex, age, waist circumference, family history of obesity, blood pressure, hormonal levels, liver enzymes, and uric acid. Predictive performance was assessed using receiver operating characteristic (ROC) curves.
Results
Patients with AN exhibited significantly higher insulin resistance indices compared to those without AN (HOMA-IR: 7. 11 $\pm$ 3. 37 vs. 5. 37 $\pm$ 3. 09; TYG-BMI: 319. 54 $\pm$ 43. 13 vs. 293. 85 $\pm$ 49. 00; METS-IR: 57. 74 $\pm$ 9. 20 vs. 52. 19 $\pm$ 9. 33, P $<$ 0. 05). Multivariable-adjusted models demonstrated significant positive associations between each index and AN occurrence, with an adjusted odds ratio (OR) of 1. 10 (95% CI: 1. 02 - 1. 18) for HOMA-IR, 1. 13 (95% CI: 1. 04 - 1. 21) for TYG-BMI/10 and 2. 09 (95% CI: 1. 44 - 3. 04) for METS-IR. Quartile analysis demonstrated a striking dose-response relationship, showing a progressive increase in the risk of AN across insulin resistance index quartiles, with METS-IR showing the most pronounced association (Q4 vs. Q1: Or = 5. 19, 95% CI: [2. 18 - 12. 36], P for trend $<$ 0. 001). ROC analysis confirmed the superior predictive performance of METS-IR (AUC = 0. 670) compared with HOMA-IR and TYG-BMI.
Conclusion
Although HOMA-IR and TYG-BMI were significantly associated with AN occurrence, METS-IR demonstrated the strongest predictive ability for AN risk in overweight and obese individuals.

Time in tight range during ramadan intermittent fasting in adolescents and young adults with diabetes: are the new CGM targets met?

Nancy Samir Elbarbary[1] & Eman Abdel Rahman Ismail[2]
[1]Department of Pediatrics, Faculty of Medicine, Ain Shams University, Cairo, Egypt; [2]Department of Clinical Pathology, Faculty of Medicine, Ain Shams University, Cairo, Egypt

Background
Time in tight range (TITR) is a novel glycemic metric assessing normoglycemia in individuals with diabetes.
Aim
To assess the attainability of the TITR (70–140 mg/dL) target in youth with diabetes using different treatment strategies during Ramadan fasting.
Methods
This prospective study included 276 non-insulin-treated type 2 diabetes mellitus (T2DM) and 426 patients with type 1 diabetes mellitus (T1DM) who were categorized into: multiple daily injections [MDI] + intermittently scanned CGM (isCGM), sensor augmented pump (SAP) and advanced hybrid closed loop (AHCL).
Results
At the end of Ramadan, the mean TITR was 42. 3 $\pm$ 6. 6% for all T1DM patients and 63. 5 $\pm$ 4. 0% in T2DM (P $<$ 0. 001). The highest TITR was in T2DM group together with T1DM on AHCL (62. 3 $\pm$ 11. 6%), followed by SAP group (37. 7 $\pm$ 5. 7%) and MDI + isCGM group (23. 6 $\pm$ 5. 9%, P $<$ 0. 001). Hypoglycemic episodes as shown by time below range (TBR) $<$70 mg/dL and TBR $<$54 mg/dL were minimal during Ramadan in AHCL group in comparison to before Ramadan (2. 6 $\pm$ 0. 7 vs 2. 9 $\pm$ 0. 9%; P = 0. 061 and 0. 4 $\pm$ 0. 1 vs 0. 5 $\pm$ 0. 1%, P = 0. 561, respectively) with a lower coefficient of variation (CoV) (P $<$ 0. 001) than other T1DM participants.
Conclusion
At the end of Ramadan, TITR was decreased in patients with T1DM except those using AHCL who had similar levels to non-insulin-treated T2DM patients. Advanced technology has the potential for achieving tight glycemic targets, along with a reduction in CoV, without increasing hypoglycemic risk compared with other insulin treatment modalities.

Phenotypic variation of fasting glucose in GCK-related hyperglycaemia

Jarno Kettunen[1,2,3], Aino Hakkila[3], Minna Harsunen[3] & Tiinamaija Tuomi[1,2,3]
[1]Helsinki University Hospital, Abdominal Centre (Endocrinology), Helsinki, Finland; [2]Institute for Molecular Medicine, University of Helsinki, Helsinki, Finland; [3]Folkhalsan Research Center, Helsinki, Finland

Introduction
Heterozygous inactivating variants in *GCK* cause *GCK*-related hyperglycaemia (GCK-MODY), presenting with lifelong mild fasting hyperglycaemia. While different *GCK* variants have substantially variable functional effects on glucokinase activity *In vitro*, no specific variant has been linked to a distinct human phenotype. We hypothesized that the differences in enzyme activity might translate into variant-specific effects on fasting glucose in humans. This study aimed to assess how each *GCK* variant influences fasting plasma glucose and identify other factors that further modulate glucose levels.
Methods
We investigated *GCK* variants classified as pathogenic or likely pathogenic, identified in at least three carriers and two non-carrier relatives in the FINNMODY/Botnia study. We analysed how these variants and other factors influence fasting plasma glucose (FPG) and, in a subgroup, 2-hour plasma glucose (2PG) during an OGTT.
Results
The preliminary analyses of ten *GCK* variants (60 carriers, 37 non-carriers) suggested that each variant had a distinct effect on FPG (effect 1. 09-3. 03 mmol/l, FPG range 5. 1-10. 1 mmol/l) and 2PG (data for 8 variants, effect 1. 09-8. 36 mmol/l, 2PG range 4. 4-19. 4 mmol/l). Among the carriers, FPG was strongly correlated with 2PG ($P = 0.00039$) and fasting insulin ($P = 3.35e-05$). HbA1c correlated more strongly with FPG than with 2PG. Surprisingly, metabolic factors such as BMI or lipids showed no significant correlation with FPG or 2PG.
Interpretation
Each GCK variant demonstrated a distinctive effect on plasma glucose. Beyond the *GCK* variant, individual factors might further modify glucose levels. To assess this, we are performing GWAS genotyping to calculate a polygenic risk score for type 2 diabetes.

[1]Attikon University Hospital, Medical School, National and Kapodistrian University of Athens, Second Propaedeutic Department of internal Medicine, Athens, Greece; [2]Laiko Hospital, Athens University Medical School, Diabetes Center, First Department of Propaedeutic Internal Medicine, Athens, Greece; [3]University General Hospital of Thessaloniki AHEPA, Medical School, Aristotle University of Thessaloniki, Diabetes Center, First Propaedeutic Department of Internal Medicine, Thessaloniki, Greece

Background
The Galaxy project supports healthcare providers in managing clinical and device data for people with diabetes.
Objective
This analysis examines glycemic control, insulin use, and device settings in adults with Type 1 Diabetes (T1D) using the MiniMed™ 780G system across three hospitals in Greece.
Methods
Device data from the two weeks preceding the most recent clinic visit were used. Sensor usage below 70% excluded subjects from the analysis. Subgroups were formed based on pump settings, and comparative analyses were applied.
Results
Data from 99 adults were analyzed (age 43. 6 ± 14. 8 years, 66. 7% female). Mean HbA1c was 7. 2 ± 1. 5%, with 43. 5% having HbA1c <7%. Mean Glucose Management Indicator (GMI) was 6. 9 ± 0. 5. Median Time in Range (TIR) was 76. 3 (69. 9-83. 0)% and Time Below Range was 1. 2 (0. 6-2. 0)% (Figure 1). No significant differences in glycemic metrics were observed in subgroup analysis by age, sex, BMI, diabetes duration, or presence of complications. However, the optimal pump settings group (glucose target = 100mg/dL and Active Insulin Time = 2 hours)had lower GMI and higher Time in Tight Range (6. 7 ± 0. 2% vs. 7. 0 ± 0. 3%, $P = 0.032$, 54. 1% vs. 46. 3%, $P = 0.009$) without significant TBR difference. TIR was higher in the optimal settings group (81 [74. 8-82. 8]% vs. 76 [71. 7-84. 5]%), though the difference was not statistically significant ($P = 0.2$).
Conclusion
These findings provide a comprehensive overview of the demographics, clinical profiles, and glycemic control of MiniMed™ 780G users in Greece and they are essential for understanding the impact of the system on type 1 diabetes management.

Application of an extended NGS gene panel in 573 monogenic diabetes mellitus referrals

Anny Mertzanian[1], Irene Fylaktou[1], Ioanna Farakla[1], Michaela Nikolaou[1], Maria Dolianiti[1], Sophia Sakka[1], Ioannis Anargyros Vasilakis[1], Christina Kanaka Gantenbein[1] & Amalia Sertedaki[1]
[1]Division of Endocrinology, Diabetes and Metabolism, "Aghia Sophia» Children's Hospital ENDO-ERN Center for Rare Paediatric Endocrine Diseases, First Department of Pediatrics, Medical School, National and Kapodistrian University of Athens, "Aghia Sophia" Children's Hospital, Athens, Greece

Introduction
Monogenic Diabetes (MD) constitutes a genetically and clinically distinct group of diabetes mellitus (DM) that includes Maturity Onset Diabetes of the Young (MODY), Neonatal Diabetes Mellitus (NDM) and Syndromic DM. The utilization of Next Generation Sequencing (NGS) with extended gene panels in the diagnostic routine of patients with suspected MD, gives the opportunity to identify rare MODY subtypes and syndromic forms of MD.
Patients and Methods
Genetic analysis was performed in 573 Greek unrelated patients with clinical suspicion of monogenic diabetes beyond infancy. A targeted gene panel (tNGS) was designed including originally the genes *GCK, HNF1A, HNF4A, HNF1B, INS, ABCC8, KCNJ11, NEUROD1, PDX1* whereas the genes *INSR, WFS1* and *CEL* were added later. All referrals were tested for the original panel and 421 for the extended. Confirmation of the detected variants and segregation analysis was performed employing Sanger Sequencing. For the identification of the *MT-TL1* m. 3243A>G variant, Sanger sequencing was carried out in 3 different tissues derived from 2 patients (peripheral blood, urine, buccal swab) to evaluate varying levels of heteroplasmy.
Results
Out of 573 tested patients, 167 were found to carry variants in genes associated with frequent and rare MODY subtypes alongside syndromic forms of MD. As expected, the most frequent MODY subtypes were *GCK* (67/573) and *HNF1A* (39/573) followed by *ABCC8* (18/573), *HNF4A* (8/573) and *HNF1B* (8/573). We identified 9/573 patients with heterozygous variants in rare MODY genes, *KCNJ11*($n = 5$) and *INS* ($n = 4$). Variants in syndromic genes were identified in 18/423 patients: *WFS1* ($n = 12$), *INSR* ($n = 2$), *CEL* ($n = 3$), *MT-TL1* m. 3243A>G ($n = 1$), most of the patients presenting with diabetes only (Table 1).
Discussion
In our cohort, frequent MODY subtypes were identified in 24. 4% of tested patients and rare MODY subtypes in 1. 6%. Variants in syndromic monogenic diabetes genes were identified in 4. 2% of the referrals. Multiple gene screening in

Table 1: Patients with variants in syndromic genes

Genes	No. Patients	Zygosity	Extra-pancreatic/ Syndromic features
CEL	3	heterozygous	Pancreatic exocrine dysfunction ($n = 1$)
INSR	2	heterozygous	Hyperinsulinemia ($n = 1$), Hypertriglyceridemia ($n = 1$)
WFS1	12	9 heterozygous	Family history of vision loss ($n = 1$)
		2 compound-heterozygous	Bilateral nuclear cataract ($n = 1$)
		1 homozygous	Optic atrophy + deafness
MT-TL1 m. 3243A>G	1	heteroplasmic	hearing loss + myopathy + gastrointestinal problems

MD patients, through expanded gene panels even in patients lacking typical features, provides early diagnosis of potential comorbidities, diseases progression prognosis and family genetic counseling.

Body composition in T1DM: a comparison of patients using advanced hybrid closed-loop systems vs. multiple daily injections/patch pumps

Sabrina Berti[1, 2], Enrico Saudelli[1, 2], Simona Moscatiello[1], Ilaria Improta[1, 2], Sara Flamigni[1], Uberto Pagotto[1, 2] & Guido Di Dalmazi[1, 2]
[1]IRCCS Policlinico S. Orsola, Endocrinology and Diabetes Prevention and Care Unit, Bologna, Italy; [2]University of Bologna, Department of Medical and Surgical Sciences (DIMEC), Bologna, Italy

Background and Aims
Limited research exist on the effects of Advanced Hybrid Closed Loop (AHCL) systems on body composition in individuals with type 1 diabetes mellitus (T1DM). This cross-sectional study aimed to compare body composition between patients using AHCL systems (MiniMed 780G® or T:slim X2 Control-IQ®) and those using multiple daily injections (MDI) or patch pumps.
Methods
Patients who had been using the same AHCL system for at least one year ($n = 24$) were compared to those using MDI ($n = 13$) or patch pumps ($n = 8$) combined with a continuous glucose monitoring (CGM) sensor (grouped together as the MDI/patch group, $n = 21$). MDI users recorded their fast-acting insulin doses with smartpens. Exclusion criteria were conditions affecting body composition and HbA1c >69 mmol/mol. Body composition was assessed using bioelectrical impedance analysis (BIA), three-point skinfold thickness (measured with a plicometer), and handgrip strength (measured with a dynamometer).
Results
A total of 45 patients (mean age: 37 ± 11 years) were included. There were no significant differences between the AHCL and MDI/patch groups in terms of sex, age, BMI, waist circumference, estimated glomerular filtration rate (eGFR), International Physical Activity Questionnaire (IPAQ) score, or HbA1c (52 ± 8 vs. 52 ± 8; $P = 0.932$). BIA revealed no significant differences in fat mass percentage ($P = 0.752$), fat mass ($P = 0.912$), fat-free mass ($P = 0.433$), body cell mass ($P = 0.554$), total body water ($P = 0.446$), or phase angle ($P = 0.998$) between the AHCL and MDI/patch groups. Similarly, skinfold thickness and handgrip strength did not differ significantly between groups. AHCL users had significantly higher time in range (TIR: 72 ± 8% vs. 56 ± 16%; $P = 0.001$) and time in tight range (TITR: 46 ± 11% vs. 35 ± 12%; $P = 0.007$), along with lower time above range (TAR), time below range (TBR), and glucose management indicator (GMI) compared to MDI/patch users. The mean per-kilogram total daily insulin dose did not differ significantly between groups (0.62 ± 0.14 U/kg in AHCL users vs. 0.58 ± 0.18 U/kg in MDI/patch users; $P = 0.422$) and was positively correlated with body cell mass percentage ($r = 0.328$, $P = 0.039$). Fat mass percentage, in addition to its established associations with sex, BMI, physical activity, and suprailiac skinfold thickness, showed a positive correlation with total cholesterol ($r = 0.359$, $P = 0.015$) and LDL cholesterol ($r = 0.333$, $P = 0.025$).
Conclusions
Compared to MDI/patch therapy, AHCL systems were associated with improved glucose profile parameters without significant differences in body composition or insulin dosage. Higher total and LDL cholesterol levels were associated with higher fat mass percentage.

Exploring pancreatic diabetes: key features and diagnostic insights from 145 patients

Manal Bennani[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]Ibn Rochd University Hospital, Clinical Neuroscience and Mental Health Laboratory Faculty of Medicine and Pharmacy - Hassan II University, Department of Endocrinology and Metabolic Diseases, Casablanca, Morocco

Introduction
Pancreatic diabetes, or Type 3c diabetes by the ADA, is secondary form of diabetes caused by primary pancreatic disorders damaging the Islets of Langerhans, leading to endocrine dysfunction of the pancreas. Often misdiagnosed as Type 1 or Type 2 diabetes, it presents certain characteristics that make it markedly different in terms of causes, clinical presentation, treatment, and prognosis.
Objective
The aim of our study is to highlight the various clinical, biological, and morphological aspects that can suggest the diagnosis of pancreatic diabetes in certain patients.
Patients and Methods
Descriptive retrospective study, including 145 patients hospitalized in our department for newly diagnosed diabetes between September 2018 and December 2024.
Results
The study included 106 men and 39 women, with a sex ratio of 2.79. The average age was 48 years, and 37.5% had a family history of diabetes. Some patients reported toxic habits, including smoking. Clinically, the average BMI was 20.4, with an average weight of 60 kg. The duration of diabetes did not exceed one year in any of the patients, with an average weight loss of 14.6 kg. Biologically, an elevated CA 19-9 level was found in 37.5% of cases. All patients underwent a CT scan, which identified pancreatic tumor lesions with varying locations.
Conclusion
Pancreatic diabetes, although previously considered rare, is increasing in adults in their fifties, presenting with rapid onset of diabetes and significant weight loss. Suspecting this condition requires further appropriate investigations to confirm the diagnosis.

Renoprotective effects of dipeptidyl peptidase-4 inhibitors in diabetic kidney disease: a meta-analysis of randomized controlled trials

Joseph Paulo Gonzales[1], Jastine Wenn Galvez[1] & Kevin Elissandro Gumabon[1]
[1]University of the Philippines Manila - Philippine General Hospital, Department of Medicine, Manila, Philippines

Background and Objectives
The first clinically evident feature of renal involvement in diabetic kidney disease (DKD) is albuminuria and higher levels are associated with increased risk of chronic kidney disease (CKD) progression, thus treatments aimed at reducing albuminuria delay CKD progression. The incretin effect, mediated by glucagon-like peptide-1 (GLP-1), reduces kidney inflammation, fibrosis, and albuminuria, and its degradation is prevented by dipeptidyl peptidase-4 inhibitors (DPP4I) that are used in the treatment of type 2 DM. Renal effects of DPP4I include reduction in albuminuria and glomerulosclerosis. Given the potential of DPP4I in delaying the DKD progression, there is a need to summarize and review the current evidence.
Method
Computerized literature search of PubMed, CENTRAL, and ClinicalTrials.gov was done from inception to October 2024. Adults diagnosed with DM and any type of DPP4I evaluated for DKD were included. Primary outcomes included changes in urine albumin to creatinine ratio (UACR) and estimated glomerular filtration rate (eGFR). Secondary outcomes included change in renal biomarkers for CKD progression including neutrophil gelatinase-associated lipocalin (NGAL), renal endpoints (doubling of serum creatinine, progression to ESRD, initiation of RRT, and renal related death). Subgroup analysis was done to examine differences in the effect estimates and heterogeneity by follow-up period and specific DPP4I used.
Results
870 references were identified from the electronic search. 13 RCTs were included in the meta-analysis. The risk of bias of the studies were low to moderate. Meta-analysis showed significant reduction in UACR after treatment with DPP4I compared to control (7 RCTs, 20,689 participants, MD -11.06 mg/g Crea, 95% CI -21.37 to -0.75), however with high heterogeneity ($I2 = 77\%$). Subgroup analysis based on follow-up period showed decrease in the heterogeneity in the subgroup with a follow-up period of 12-24 weeks ($Chi2 = 3.12$, $I2 = 0\%$) with significant decrease in UACR favoring DPP4I treatment (5 RCTs, 365 participants, MD -13.36 mg/g Crea, 95% CI -20.19 to -6.52). Results showed no significant difference in change in eGFR and NGAL between treatment and control groups. None of the results evaluating the secondary outcomes were eligible for quantitative synthesis and failed to show difference between treatment and control.

Conclusion
This study found significant reduction of albuminuria with DPP4I treatment in patients with DKD, particularly in a short follow-up period of 6-12 months, suggesting DPP4I may be beneficial in delaying DKD progression. Limitations include a short follow-up period of the included RCTs precluding assessment of further effects of DPP4I on the prespecified renal endpoints.

JOINT3069

Subcutaneous insulin aspart in treatment of children with mild and moderate diabetic ketoacidosis

Zahra Razavi[1], Salman Khazaeii[1] & Hanieh Talebi[1]
[1]Hamedan University of Medical Sciences, Hamedan, Iran

Objectives
To evaluate the effects and safety of subcutaneous injections of rapid-acting aspart insulin for treatment of uncomplicated mild and moderate DKA in children and also to determine the times to resolution of DKA.
Study Design
Prospective, single-arm, uncontrolled study of children and adolescents with DKA in 2022.
Setting
Hamadan University teaching hospital.
Data collected
Age, sex, clinical/laboratory parameters including severity of dehydration and diabetic-ketoacidosis, time to recover from DKA, hospitalization's duration, complications, blood glucose, sodium, potassium, creatinine, urine ketones. Patients were admitted to the pediatric endocrinology unit outside the PICU where appropriate nursing care and access to laboratory test results were available. Based on the degree of dehydration, fluid deficit was replaced by sodium chloride 0. 45%. Insulin aspart 0. 15 units/kg subcutaneous was injected every 2 hours in the hospital outside ICU. Blood glucose was measured hourly and blood gases every 2 hours. Ketoacidosis was considered resolved when the patient did not have nausea/vomiting, was conscious, and could eat, and blood glucose was <250 mg/dL, pH was >7.30, and/or HCO3 was >15 mmol/l.
Results
A total of 25 DKA patients (mean age 11. 06 ± 3.89, range 4-17 years, 60% female) were included in the study. Sixteen of the participants (64%) had type 1 diabetes. Overall, 13 (52%) cases had mild ketoacidosis (average pH = 7. 25), and 12 (48%) cases had moderate ketoacidosis (average pH = 7. 15). The average time to resolution of ketoacidosis was 11. 24 hours. Mean duration of hospitalization was 2. 3 days. All but one patient met DKA recovery criteria without complications. Mild cases compared to moderate cases of DKA had a shorter duration to resolution of DKA ($P = 0.04$(. There were no electrolyte disturbances, hypoglycemic events, readmissions and deaths or other adverse events.
Conclusion
Subcutaneous rapid-acting insulin aspart is an effective, safe, and convenient alternative to intravenous infusion of regular insulin for children and adolescent with uncomplicated mild and moderate DKA.

Keywords: : Aspart; diabetic ketoacidosis; rapid-acting insulin; subcutaneous insulin.

Characteristics of maturity-onset diabetes of the young: a single-center experience from a tertiary referral hospital

Burcak Helvaci[1], Burcu Candemir[1], Aykut Cimsir[1], Hanife Saat[2] & Erman Cakal[2]
[1]Ankara Etlik City Hospital, Endocrinology and Metabolism, Ankara, Türkiye; [2]Ankara Etlik City Hospital, Medical Genetics, Ankara, Türkiye

Introduction
Maturity-Onset Diabetes of the Young (MODY) is characterized by diabetes in two or more generations of a family, typically affecting individuals under the age of 25, with a normal body weight and no insulin resistance. The main mechanism underlying MODY is a defect in insulin secretion. Identifying the specific MODY type is essential for patient management and treatment. This study aimed to assess the demographic and biochemical features of patients who underwent MODY genetic analysis, identify the most common MODY mutations, and explore associated clinical characteristics.
Materials and Methods
A retrospective analysis was conducted on 162 patients who underwent MODY genetic testing between 2022 and 2024. Data from 129 patients, including demographic, biochemical, and genetic information, were analyzed to determine MODY types and mutations.
Results
The average age of the 129 patients included in the study was 34. 06 ± 9.45 years. Of the patients, 66 (51. 2%) were female. The average body mass index (BMI) was 29. 26 ± 7.01 kg/m^2, and the mean duration of diabetes was 5. 83 ± 7.46 years. Diabetic complications included retinopathy (7. 8%), nephropathy (7%), and neuropathy (9. 3%). Treatment regimens varied: 58. 1% were on metformin, 4. 7% on GLP-1 analogues, 14. 7% on gliclazide, 18. 6% on SGLT2 inhibitors, 21. 7% on DPP-4 inhibitors, and 52. 7% on insulin. The mean C-peptide level was 2. 86 ± 1.70 ng/ml. A family history of diabetes was noted in 79. 1% of patients. At admission, mean HbA1c was 8. 93 ± 3.81%, with fasting plasma glucose at 213. 7 ± 88.5 mg/dL, creatinine at 0. 74 ± 0.18 mg/dL, and triglycerides at 247. 7 ± 232.3 mg/dL. The control HbA1c was 4. 36 ± 4.03%. MODY was diagnosed in 34. 1% of patients, with additional diagnoses of hyperinsulinemic hypoglycemia (5 patients) and Wolfram syndrome (1 patient). Among the MODY patients, 11 (25%) were diagnosed with type 12, 7 (15. 9%) with type 3, 7 (15. 9%) with type 8, 6 (13. 6%) with type 2, 3 (6. 8%) with type 1, 2 (4. 5%) with type 7, 2 (4. 5%) with type 10, 2 (4. 5%) with type 11, 1 with type 6, 1 with type 9, 1 with type 13, and 1 with type 14. The most frequent mutations were found in the ABCC8, HNF1A, CEL, GCK, INS, and HNF4A genes.
Conclusion
Selecting appropriate patients for MODY genetic testing is crucial for avoiding unnecessary tests and ensuring effective diabetes management. Given ethnic differences in MODY types, large-scale national studies could contribute significantly to understanding its genetic and clinical variability.

Progression and outcomes of prediabetes in children and adolescents: insights from an indian perspective

Alapan Mahapatra[1], Manoj Agarwal[2], Anurag Bajpai[1] & Vibha Yadav[1]
[1]Regency CDER, Pediatric Endocrinology, Kanpur, India; [2]Shalby Hospital, Ahmedabad, India

Background
Type 2 diabetes mellitus (T2 DM) is a leading cause of morbidity and mortality in children. Identification in the early-stage lead to better outcome and lesser intervention. Risk factors predisposed to progression of pre-diabetes needs to be identified.
Aim
To identify the course and outcomes the progression from prediabetes to Type 2 Diabetes Mellitus (T2 DM) in Indian children and adolescents.
Methodology
90 Indian children and adolescent (Boys 68. 9%, Mean age 13. 2 ± 3.3 years) were followed up. Baseline fasting blood glucose (FBS) and 2 Hours oral glucose tolerance test after 1. 75gm/kg glucose (OGTT) was done to identify pre-diabetes in children. Metabolic profiles were also analyzed. At the last follow-up they were again evaluated for glycemic profile and other metabolic complications.
Result
A total of 90 children were followed up for a mean duration of 2. 3 ± 1.7 years. Of these, 60 children (66. 7%) were cured, while 30 children (33. 3%) remained dysglycemic. Among the 30 dysglycemic children, 8. 9% progressed to diabetes, while 24. 4% remained prediabetic. Children with a family history of diabetes had an odds ratio of 2. 8 for progression to diabetes. The cured group showed a significant reduction in BMI SDS ($P = 0.008$) and percentage BMI ($P = 0.02$) compared to the disease group.

Conclusion
The findings indicate that a family history of diabetes may be a significant predictor for the progression of prediabetes in Indian children. Furthermore, a reduction in BMI SDS is linked to the potential resolution of prediabetes.

From pediatric to adult diabetes care: experience of the organized transition process of youth with type 1 diabetes

Elzbieta Niechcial[1], Paulina Wais[1], Dorota Lenartowska[2], Andrzej Kędzia[1], Maria Izbaner[2], Monika Pietrzak[2], Katarzyna Cyranka[3 4 5], Dorota Zozulinska-Ziolkiewicz[6] & Aleksandra Araszkiewicz[6]
[1]Poznan University of Medical Sciences, Department of Pediatric Diabetes, Clinical Auxology and Obesity, Poznan, Poland; [2]F. Raszei Municipal Hospital in Poznań, Poznan, Poland; [3]Jagiellonian University Medical College, Kraków, Poland, Department of Psychiatry, Krakow, Poland; [4]Jagiellonian University Medical College, Kraków, Poland, Department of Metabolic Diseases, Krakow, Poland; [5]University Hospital Krakow, Krakow, Poland; [6]Poznan University of Medical Sciences, Department of Internal Medicine and Diabetology, Poznan, Poland

Introduction
The transition from pediatric to adult diabetes care is a critical phase for youth with type 1 diabetes (T1D), as it significantly impacts long-term health outcomes. The main aim of this study was to implement a structured transition process for adolescents with T1D to adult diabetes care.
Methods
Adolescents up to 18 years of age were enrolled in a transition program designed to facilitate their referral from pediatric to adult healthcare service. Patients under the care of the diabetes outpatient clinic in Greater Poland were referred to the Department of Pediatric Diabetes for final hospitalization before adulthood. The hospitalization included collection of data from therapy-supporting devices, laboratory tests, and assessment of Health-Related Quality of Life (HRQoL) using the validated KIDSCREEN-27 questionnaire and diabetes distress (DD) using the age-specific Problems Areas in Diabetes questionnaire (PAID). The stay at the hospital was concluded with the issuance of a Diabetes Care Information Card, a referral, and the scheduling of the first visit to the adult diabetes clinic.
Results
The study cohort comprised 68 patients (37 boys) with a mean T1D duration of 8 years. Most patients were treated with CSII ($n = 47$), and all used CGM for blood glucose monitoring. The mean TIR and HbA1c were 60% and 7, 3%, respectively. Participants exhibited significantly lower scores on the physical well-being dimension in comparison to scores on the remaining four dimensions in the KIDSCREEN-27 questionnaire. Girls reported notably lower scores on all dimensions of HRQoL than boys. T1D duration <5 years was associated with the worst scores on physical and psychological well-being dimensions while scoring on autonomy and parental relation dimension was the lowest among those with T1D duration between 5 to 10 years. Almost 12% ($n = 8$) of youth reported high levels of DD measured via PAID; it mainly concerned girls (62%, $n = 5$). A slight increase in DD levels was noticed, along with a decrease in TIR values. Around 14% of adolescents with TIR $<70\%$ had a mean score above 40, suggesting high emotional distress regarding the disease. Eight youths from the uncontrol group had a mean score of less than 10, which may suggest denial. The mean PAID score was comparable between both sexes.
Conclusion
Youth with T1D have insufficient metabolic control of the disease. HRQoL is decreased, mainly in the physical well-being dimension. DD is quite a common issue, especially among those with higher TIR values.

JOINT1539

Evaluation of the performance of continuous glucose monitoring in the treatment of patients with congenital hyperinsulinism

Laura Sayol Torres[1], Ariadna Campos-Martorell[1], Cristina Aguilar Riera[1], Gloria Gomez Yepes[1], Natàlia Romaní Franquesa[1] & Maria Clemente Leon[1]
[1]Hospital Universitari Vall d'Hebrón, Barcelona, Spain

Introduction
Continuous glucose monitoring (CGM) is a promising but unvalidated tool for the management of patients with congenital hyperinsulinism (CHI).
Objective
To assess the accuracy and performance of CGM in the management of patients with CHI.
Patients and Methods
Monocentric, retrospective, observational and analytic study. Inclusion criteria: patients diagnosed with CHI using CGM in hospital and/or outpatient settings. Data collection was conducted through medical record reviews and sensor downloads. For hospitalized patients, blood glucose measurements (BGM) were taken every 2-8 hours (depending on the clinical condition); the measurements performed to verify extreme sensor values were also recorded. For outpatients, BGM for hypoglycaemia-checking or calibration were collected. Only paired measurements taken within 3 minutes or less were included. Pairs performed to confirm the resolution of hypoglycaemic episodes were excluded. Families were surveyed regarding their experience with CGM. Statistical analysis was performed using XLMiner Analysis ToolPak.
Results
Data from two years of follow-up (2022-2024).
Discussion/Conclusions
CGM effectively prevents severe events and facilitates real-time decision-making in CHI patients. A CGM glucose threshold of 65 mg/dL is proposed, requiring capillary confirmation for values ≤ 65 mg/dL. Trend arrow analysis may optimize this, posing a goal for future studies.

Table 1: Data from two years of follow-up (2022-2024).

CGM	Patient	Age (months)	n of pairs of data	Origin
Dexcom G6	P1	2	45	Hospitalized
			1	Outpatient
	P3	61	3	Outpatient
	P4	35. 2	17	Outpatient
	P5	0. 67	87	Hospitalized
	P6	41. 4	1	Outpatient
	P7	149. 6	13	Outpatient
	P8	26. 4	58	Outpatient
Dexcom G7	P2	0. 56	33	Hospitalized
Libre2	P3	61	27	Outpatient
	P9	96. 6	62	Outpatient
Total		**Median / IQR**	347	165 Hospitalized
		35.2 / 59		182 Outpatient
Pearson's correlation test		**R**	**p**	**n of pairs of data**
Total		0. 94	**<0. 05**	347
Glucose ≤70 mg/dl		0. 20	**0. 02**	124
Glucose ≤50 mg/dL		-0. 24	0. 31	20
MARD		**%**		**n of pairs of data**
Total		16. 1		347
Glucose <70 mg/dl (all sensors)		14. 4		115
Libre2 (all glucose values)		11. 7		89
Libre2 (Glucose <70 mg/dl)		17. 1		16
Dexcom G6 (all glucose values)		15. 6		278
DexcomvG6 (Glucose <70 mg/dl)		13. 7		107

Hypoglycaemia detection (≤70 mg/dL): CGM identified 124 episodes, of which 91 were confirmed by capillary glucose (Sensitivity = 79. 1%, Specificity = 85. 8%, PPV = 73. 4%, NPV = 89. 2%). All hypoglycaemia episodes ≤50 mg/dL were detected with a minimum CGM threshold of ≤65 mg/dL (Sensitivity = 100%, Specificity = 74. 4%, PPV = 7. 5%, NPV = 100%). All participants reported satisfaction with CGM use and declined its removal.

Turning back the metabolic disturbances - results of treating two brothers with Berardinelli Seip syndrome with leptin analogue for five months

Auste Pundziute Lyckå[1, 2] & Ulrika Härenstam[1]
[1]Sahlgrenska University Hospital, Queen Silvia Childrens Hospital, Department of Pediatrics, Gothenburg, Sweden; [2]Sahlgrenska Academy, University of Gothenburg, Institution for Clinical Sciences, Department of Pediatrics, Gothenburg, Sweden

Background
Berardinelli-Seip syndrome is a rare autosomal recessive disease, causing generalized lipodystrophy. Affected individuals cannot store fat subcutaneously and thus have very low leptin level and are always hungry. Accumulation of visceral fat in the liver, spleen and skeletal muscles causes

insulin resistance and leads to the development of metabolic syndrome and type 2 diabetes. Fat accumulation in the liver may cause liver fibrosis and failure. The metabolic disturbances are difficult to treat without addressing leptin deficiency. Treatment with leptin analogue was previously not used for children in Sweden.

Aim

To present five months treatment results with leptin analogue in two brothers with severe phenotype of generalized lipodystrophy.

Materials

Patients were followed at the Queen Silvia Children's Hospital since diagnosis. Data on disease history, growth and laboratory values were collected from the hospital records. Informed consent was obtained from the parents.

Results

Both patients have type 2 lipodystrophy caused by BSCL-2 mutation, causing complete absence of the subcutaneous fat. Treatment with leptin analogue was started in July 2024, at the age of 9 yrs and 7 yrs. At the start of the treatment both patients had severe insulin resistance with acanthosis nigricans and have developed type 2 diabetes, treated with maximal doses of metformin and SGLT2 inhibitor, as well as lipid lowering drugs and angiotensin receptor inhibitors for microalbuminuria. Fat accumulation caused severe liver enlargement and fibrosis, meeting criteria of clinical liver cirrhosis. The older brother had developed hypertriglyceridemia and myocardial hypertrophy and was treated with combination of lipid lowering and cardioprotective drugs. Both patients had their tonsils and adenoids removed due to obstructive sleep apnea.

Conclusion

Treatment with leptin analogue was safe and effective in reducing the accumulation of visceral fat and reversing the metabolic abnormalities in children with type 2 generalized lipodystrophy.

Driving data-driven impact through digital innovation: a collaborative case study between action4diabetes and correlaid's data4good initiatives

May Ng[1, 2], Michael Aydinbas[3, 4], Tyla Martin[3], Charles Toomey[3] & Fiona Ooi[3]

[1]Paediatric Department, Mersey and West Lancashire Teaching Hospitals, Southport, United Kingdom; [2]Faculty of Health, Social Care and Medicine, Edge Hill University, Ormskirk, United Kingdom; [3]Action4Diabetes, Taunton, United Kingdom; [4]CorrelAid, Konstanz, Germany

Background

The utilisation of data is revolutionising the operations and impact of non-profit organisations (NGOs) worldwide. The effectiveness of NGOs is increasingly contingent upon their capacity to collect, analyze, and apply data at every level of their operations. Action4Diabetes (A4D) is a UK diabetes charity that is making sustainable and scalable progress in the battle to provide quality type 1 diabetes healthcare in emerging countries across South-East Asia (SEA). CorrelAid is a nonprofit organization of data scientists dedicated to improving the world through the application of data science. CorrelAid e. V. is the registered nonprofit association behind the CorrelAid community. CorrelAid and A4D have collaborated to develop a centralized database in the public cloud, which provides access to all historical data in a single repository.

Methods

A4D is exchanging data with the local hospitals in the programme on a monthly basis via Microsoft Excel files. A preprocessing pipeline was implemented to account for differences between files from different hospitals and differences over time for the same hospital. The pipeline extracts the patient and medical product data in a standardized and unified manner, rendering it suitable for storage in a database. The data is anonymized and subsequently uploaded to a secure storage in the public cloud, where it is processed and stored in a centralized database. An error reporting system is in place to monitor the pipeline's progress and alert in the event of critical errors or data quality issues.

Results

The public cloud database provides access to all historical data for the years 2017 to 2023. The database encompasses six countries, 31 clinics, and approximately 1, 000 patients along with their monthly medical data. Furthermore, the database contains information about the distribution and usage of approximately 200 medical products.

Conclusions

The formulation of a data strategy and the implementation of a centralized database solution for healthcare data is a challenging but achievable objective when approached in a cost-effective manner, particularly when utilizing services from modern public cloud providers. The subsequent stages of the process entail the identification of initial use cases that build upon the data, the implementation of dashboards and reports that facilitate access to the data, the automation of the data pipeline to ingest newly arriving data without manual intervention, and the establishment of a data governance strategy to oversee data content, structure, usage, and safety.

JOINT608

SGLT-2 Inhibitor-induced erythrocytosis and risk of coronary artery disease in type 2 diabetes - a nationwide cohort study

Aidar Gosmanov[1, 2] & Darren Gemoets[1]

[1]Stratton VA Medical Center, Albany, NY, United States; [2]Albany Medical College, Endocrinology, Albany, United States

Purpose of Study

Therapy of type 2 diabetes (T2D) with SGLT-2 inhibitors can lead to increased risk of new-onset erythrocytosis. On the other hand, studies conducted in pre-SGLT-2i era showed that incident erythrocytosis in non-diabetic individuals heightens cardiovascular risk. The aim of this investigation was to assess cardiovascular risk in persons who develop SGLT-2i-induced erythrocytosis.

Methods

This was a retrospective nationwide cohort study of US Veterans with T2D who received care between 3/2013–12/2023. Inclusion criteria were complete medical records data, normal baseline hematocrit (Hct) $<$ 50. 0% within 1 year before the study start, adequate adherence with SGLT-2i, no testosterone prescription, and no history of erythrocytosis or cardiovascular disease. We identified 2 groups of patients: control (no record of SGLT-2i use) and new SGLT-2i users; in all patients we followed hematocrit for 1 year to identify those who developed new erythrocytosis defined as hematocrit $\geq$ 50%. Primary endpoint was odds ratio (OR) of incident non-fatal coronary artery disease (CAD) calculated by logistic regression model adjusted for case-mix.

Results

We identified 691104 patients mostly males (94. 5%) and Caucasians (Whites 70. 2% and Blacks 19. 4%) with mean age 65. 7yrs. The SGLT-2i use for 1 year

Study Outcomes	Control, Hct $<$ 50% (n = 605311)	Control, Hct $\geq$ 50% (n = 14516)	SGLT-2i, Hct $<$ 50% (n = 63698)	SGLT-2i, Hct $\geq$ 50% (n = 7579)
HbA1c, % (Mean $\pm$ SD): At baseline	6.9 $\pm$ 1.4	6.9 $\pm$ 1.6	8.3 $\pm$ 1.5	8.4 $\pm$ 1.5
Δ after 1 yr	-0.05 $\pm$ 1.1	-0.04 $\pm$ 1.2	-0.91 $\pm$ 1.5	-1.06 $\pm$ 1.6
Hct, % (Mean $\pm$ SD): At baseline	41.6 $\pm$ 4.2	46.5 $\pm$ 3.1	41.7 $\pm$ 3.8	46.1 $\pm$ 2.5
Δ after 1 yr	-0.3 $\pm$ 3.3	2.4 $\pm$ 4.3	2.0 $\pm$ 3.2	4.4 $\pm$ 3.2
CAD event OR (95% CI), adjusted	1.0 (ref)	1.76 (1.47, 2.10)	0.98 (0.90, 1.06)	1.36 (1.10, 1.66)

resulted in significant HbA1c reduction and hematocrit increase compared with the control group (Table). In adjusted analyses, absolute incidence of erythrocytosis was about 5. 0-fold higher ($P < 0.0001$) in SGLT-2i-treated than in control patients (10. 6% vs 2. 3%). In the models adjusted for baseline hematocrit, HbA1c, age, ethnicity, sex, BMI, eGFR, sleep apnea, concomitant hypoglycemic agent use, and smoking status, new erythrocytosis was associated with equally higher probability of incident CAD in control and SGLT-2i-treated patients (Table).

Conclusion

For the first time, we demonstrated that in a large T2D cohort, a new diagnosis of erythrocytosis is associated with incident CAD and SGLT-2i therapy does not offer cardiovascular protection in such patients. Considering markedly increased erythrocytosis incidence in the SGLT-2i-treated patients which in turn can lead to larger number of cardiovascular events, we recommend implementation of strategies to monitor hematocrit trends in T2D patients and particularly in individuals starting gliflozin therapy.

Background

Adrenocortical carcinoma (ACC) is a rare aggressive malignancy with heterogenous clinical outcomes. Our previous research demonstrated that targeted DNA-based biomarkers assessed on paraffin-embedded (FFPE) samples can improve prognostic classification.

Aim

To investigate the feasibility in real-life setting of a Next-Generation Sequencing (NGS) service for prognostic classification of ACC in two European centres (Queen Elizabeth Hospital Birmingham (QEHB), UK, and IRCCS Sant'Orsola Polyclinic, Bologna, Italy).

Methods

A total of 43 patients with ACC were enrolled, who underwent adrenalectomy at QEHB ($n=23$) or IRCCS Sant'Orsola Polyclinic ($n=20$), including a previously published retrospective cohort ($n=10$; surgery date 2012–2020) and an independent validation cohort ($n=33$; surgery date 2002–2024). Tumour DNA was extracted from FFPE tissue using a Qiagen DNA protocol and quantified by Qubit fluorometer. A targeted NGS platform for 10 ACC-specific genes (*ATM, APC, RB1, MEN1, CDK4, NF1, ZNRF3, TERT* promoter, *TP53* and *CTNNB1*) was developed and validated using the retrospective cohort and commercially available DNA control (HD827, Horizon Oncospan). Sequencing was performed using an Illumina platform. The variant allele frequency (VAF) threshold was validated at 5% at QEHB and 10% at IRCCS Sant'Orsola Polyclinic. We assessed predicted turnaround time (TAT) and costing of implementing this NGS service within a routine laboratory setting.

Results

After 11 cases were excluded due to low quality DNA, the final cohort consisted in 32 patients (25F/7M, average age 50yrs). In the retrospective cohort ($n=6$), all previously identified somatic variants (i.e. in *RB1, MEN1, ZNRF3, CTNNB1* and *NF1)* were confirmed. Two more variants were detected in the added TERT promotor region c.−146.C>T and c.−124C>T. In the validation cohort, 36 variants were reported in 14/26 patients (53.8%). Pathogenic/likely pathogenic variants (52.8% of total variants) were detected in *TP53* (22.2%, mean VAF 50.6%), *NF1* (19.4%, mean VAF 41.73%), *CTNNB1* (p.Ser45Pro, mean VAF 62.3%, 11.1%), with variants of uncertain significance found in *TERT, APC, MEN1, NF1* and *ZNRF3* (13.9%). The predicted TAT for the validation cohort was 21 calendar days from sample receipt to final report, with an average 1.5 hours reporting time per case. There was no relevant difference for full costings between the two centres (€200–250 per sample).

Conclusions

Our proposed ACC-specific NGS service was reliable, feasible and cost-effective for most cases allowing implementation in real-life clinical setting. Most detected variants have shown strong evidence for clinical significance, prognostic value and/or represent potential drug targets (NF1), potentially facilitating personalised management of patients with ACC.

Background

Transcriptomic classification can differentiate adrenocortical adenomas (C2 cluster) from carcinomas (C1A and C1B clusters, respectively associated with bad and better prognosis). 3'-RNAseq allows for transcriptomic analysis on formlain-fixed and paraffin-embedded (FFPE) tissue -even on highly degraded RNA- though at the cost of missing data on up to 50% of transcripts. Our goal was to build a routine-compatible predictor using cutting edge models and techniques to answer this challenge.

Material and methods
ACCacia includes two modules: (I) a *prediction module* using denoising auto-encoder (DAE) and random forest models for C1A/C1B/C2 classification, and (ii) a *novelty detection module* using DAE reconstruction error and isolated trees to identify potential situations of inapplicability (i.e. non adrenocortical tumors). ACCacia was trained on 88 adrenocortical samples (28 C1A, 28 C1B, 32 C2) and its performance evaluated by multiple cross-validation. An additional dataset of 28 pituitary tumors was used as a test set for novelty detection.
Results
ACCacia maintains $>$ 99% accuracy and adequate calibration up till 50% of missing data. Its two novelty detection metrics perfectly discriminate the pituitary tumor dataset from the adrenal tumor dataset (AUC ROC $=1$). Two validation cohorts, retrospective ($n=360$) and prospective ($n > 28$), are currently being set up and will enable us to better assess the diagnostic and prognostic value of this tool.
Conclusion
ACCacia enables robust and specific prediction of the molecular class of adrenocortical tumors based on 3'-RNAseq transcriptomic data in a routine-compatible way.

Measurement of circulating cell-free DNA concentrations for differential diagnosis of adrenal masses: a pilot study

Lorenzo Tucci[1,2,3], Ana Crastin[1], Ezra Leander Onesimu[1], Alessandro Prete[1,4,5], Miriam Felicitas Asia[5], Yasir Elhassan[5], Vasileios Chortis[1,5], Guido Di Dalmazi[2–3] & Cristina L Ronchi[1,5]
[1]University of Birmingham, Department of Metabolism and Systems Science, Birmingham, UK; [2]Alma Mater Studiorum University of Bologna, Medical and Surgical Sciences Department, Bologna, Italy; [3]IRCCS Sant'Orsola-Malpighi Polyclinic, Endocrinology and Diabetes Prevention and Care Unit, Bologna, Italy; [4]University of Birmingham and University Hospitals Birmingham NHS Foundation Trust, NIHR Birmingham Biomedical Research Centre,, Birmingham, UK; [5]Queen Elizabeth Hospital Birmingham NHS Trust, Department of Endocrinology, Birmingham, UK

Background
Ruling out malignancy in adrenal masses (AM) is a clinical challenge. We demonstrated that circulating cell-free DNA concentrations (ccfDNA-C) are higher in patients with adrenocortical carcinoma (ACC) compared to healthy subjects (HS). However, ccfDNA-C have not been compared among different types of AM.
Objectives
To assess the potential role of ccfDNA-C for AM differentiation.
Methods
We enrolled 97 adult patients (58 females) with a final diagnosis of adrenocortical adenoma (ACA, $n=61$), other benign AM (OB, $n=7$), ACC ($n=17$), pheochromocytoma ($n=6$) or adrenal metastases from other primary tumours (MET, $n=6$: 2 renal cell cancer, 1 melanoma, 1 unknown primary, 1 leiomyosarcoma, 1 papillary thyroid cancer). Blood samples, clinical, hormonal and radiological data were collected at first clinic review. AM with heterogeneous radiological appearance or plain Hounsfield Units >10 and not associated with overt adrenal hormone excess were labelled as "undefined AM" ($n=35/92$, 18 ACA, 4 ACC, 7 OB, 6 MET). ccfDNA was isolated with a commercial kit and ccfDNA-C were measured with fluorometer. Tumour size adjusted univariate analysis was conducted to assess ccfDNA-C distribution. We tested the diagnostic performance of our previously published HS-derived cut-off (>0.146 ng/μL) with logistic regression, positive (PPV) and negative predictive value (NPV) for ACC recognition.
Results
Unadjusted statistics showed higher ccfDNA-C in ACC than each group within the entire cohort ($P=0.003$ vs ACA, $P=0.055$ vs OB, $P=0.001$ vs MET, $P=0.042$ vs pheochromocytoma), but not within undefined AM ($P=0.129$ vs ACA, $P=0.075$ vs OB, $P=0.004$ vs MET). Tumour size-adjusted univariate analysis showed that ccfDNA-C were higher in ACC than each group in the entire cohort ($P=0.039$ vs ACA, $P=0.005$ vs OB, $P=0.003$ vs MET, $P=0.021$ vs pheochromocytoma) but also within undefined AM ($P<0.001$ vs ACA, $P<0.001$ vs OB, $P<0.001$ vs MET). In the entire cohort, the ccfDNA-C HS-derived cut-off was confirmed to predict ACC and showed Odds Ratio 14.982 (95% Confidence of Interval: 3.888–57.741), $P<0.001$. HS-derived cut-off predicted ACC with PPV $=42.4\%$ and NPV $=95.3\%$ in the entire cohort and with PPV $=44.4\%$ and NPV $=100\%$ in the undefined cohort. Approximately the same cut-off ($\geqq 0.148$ ng/μL) was confirmed by Receiver-Operating Characteristic curve analysis showing sensitivity 82.4% and specificity 76.2% with same PPV and NPV as the HS-derived cut-off.
Conclusions
High ccfDNA-C in AM seem to be ACC-specific, and our ccfDNA-C HS-derived cut-off is useful for ACC discrimination. Further studies with larger cohorts of malignant adrenal lesions are needed to confirm our results.

Quantitative analysis of [^{18}F]fluorocholine-PET acquisition times in patients with histopathologically proven primary hyperparathyroidism

Raphael Hirner[1, 2], Paul Dahlmann[1], Mathias Zacherl[1], Vera Wenter[1], Petra Zimmermann[3], Roland Ladurner[4], Martin Reincke[2], Rudolf Werner[1], Christine Schmid-Tannwald[5], Thomas Pfluger[1], Ralf Schmidmaier[2], Christian Lottspeich[2] & Friederike Völter[1, 2]
[1]LMU Munich, Nuclear Medicine, Munich, Germany; [2]LMU Munich, Medical Clinic IV, Munich, Germany; [3]LMU Munich, Visceral Surgery, Munich, Germany; [4]Martha Maria Hospital, Munich, Germany; [5]LMU Munich, Radiology, Munich, Germany

Background/Aim
[^{18}F]fluorocholine-PET has emerged to a diagnostic tool of first choice in the localization of a culprit parathyroid gland in primary hyperparathyroidism. The aim of this analysis was to retrospectively compare quantitative radioligand uptake of parathyroid adenomas and non-target organs, target to background ratios and the diagnostic accuracy of [^{18}F]fluorocholine-PET at different scan times.
Methodology
All operated patients with primary hyperparathyroidism who preoperatively underwent [^{18}F]fluorocholine-PET scan at LMU Hospital between November 2020 and December 2024 were included. A visual qualitative and a semiquantitative (SUV_{mean} and SUV_{max}) analysis of histopathologically proven parathyroid adenomas and non-target organs were applied. Quantitative values are reported with median and interquartile range. The radioligand uptake and target to background ratios were then compared between three acquisition times (early: 15-24 min, intermediate: 25-54 min, late: 55-94 min) using the Kruskal-Wallis test.
Results
A total of 101 patients were included in the study. Histopathological reports revealed a single parathyroid adenoma in 89 patients. Sixteen hyperplastic glands were identified in six patients (one of whom carried a MEN1 germline variant). One patient presented with a parathyroid carcinoma. In 3 cases, no parathyroid tissue was found in the histopathological examination. 50 patients were scanned at an early, 33 at an intermediate and 19 at a late acquisition time. Overall, the visual analysis showed a very good detection rate of 91. 08% with no significant difference between the groups ($P = 0.953$). In the quantitative analysis, the median SUV_{max} of the 108 histologically proven lesions was highest in the late acquisition group, although statistical significance was not reached (4. 0(2. 2) vs. 4. 0(1. 9) and 5. 1(2. 7); $P = 0.163$). Similarly, the median adenoma to mediastinal blood pool ratio was highest in the late acquisition group (3. 63(2. 47) vs. 4. 14(2. 58) vs. 5. 89(5. 91)), with significant differences between the early and late acquisition ($P = 0.002$) and the intermediate and late acquisition ($P = 0.012$).
Conclusion
[^{18}F]fluorocholine-PET is a reliable diagnostic tool in the detection of adenoma in patients with primary hyperparathyroidism. The [^{18}F]fluorocholine uptake of the parathyroid adenomas was strongest at late acquisition times. However, the present study found no significant difference in detection rate between the early and late acquisition groups.

Background

Adrenocortical carcinomas (ACC) are rarely diagnosed in patients with adrenal tumors ≤4 cm, potentially representing a missed opportunity for an earlier intervention.

Aims

We aimed to characterize clinical, biochemical, and imaging presentation of patients with adrenal lesions ≤4cm eventually diagnosed as ACC.

Methodology

We present an interim analysis of an ongoing A5 multicenter retrospective cohort study (1998-2024) that included adults with adrenal tumors ≤4 cm, subsequently diagnosed as ACC. We evaluated clinical and hormonal presentation, imaging characteristics at initial and latest imaging prior to ACC diagnosis, and staging at the time of ACC diagnosis. Reference standard was histopathology after adrenalectomy or biopsy, or imaging of metastatic adrenal mass with biochemical evidence of hormone excess.

Results

At the time of interim analysis, 118 patients (65% women) with ACC diagnosed at a median age of 52 years (range, 19-83) were included. Reasons for initial imaging were unrelated to adrenal mass (70, 59%), hormone excess (19, 16%), extra-adrenal malignancy staging (19, 16%), compressive symptoms (5, 4%), and genetic screening (3, 3%). At initial imaging, median tumor size was 25 mm (range 4-40), with unenhanced mass attenuation of 31 (range 17-95). Among 33 patients (28%) suspected of having ACC, 25 (21%) underwent adrenalectomy shortly thereafter. Meanwhile, 71 patients (60%) had follow-up imaging at a median of 21 months (range 0. 9-149) showing a median tumor growth rate of 13 mm/year (range 0-198), a median tumor size of 44 mm (range 10-270), and unenhanced mass attenuation of 31 HU (18-50). At the time of ACC diagnosis, 61 patients (52%) had stage I, 21 (18%) stage II, 19 (16%) stage III, and 3 (3%) stage IV disease. Clinical features of overt hormone excess were observed in 40 patients (34%), 50% presenting with Cushing syndrome, 37% with hyperandrogenism, 30% with mineralocorticoid excess, and hyperestrogenism in 2. 5%. Biochemical hormone excess was present in 62 patients (52%) including hypercortisolism in 28 (45%), combined hypercortisolism-hyperandrogenism in 19 (31%), hyperandrogenism in 7 (11%), mineralocorticoid excess in 7 (11%), combined hypercortisolism-mineralocorticoid excess in 1 (2%), and isolated hyperestrogenism in 1 (2%).

Conclusion

We show that ACC was suspected only in 28% at the time of initial imaging, despite indeterminate imaging characteristics, potentially because of false reassurance of smaller tumor size. We further show a variable tumor growth rate, with a median of 13 mm/year. Clinicians need to be aware of the possibility of ACC in smaller indeterminate adrenal tumors.

Plasma concentrations of selected growth factors as a potential tool for detecting recurrence in endocrine tumors - a pilot study

Marta Opalinska[1], Anna Kurzyńska[1], Karolina Morawiec-Slawek[1], Agnieszka Stefańska[2], Magdalena Kolasa[2], Edyta Tkacz[2], Małgorzata Szumińska[2], Anna Sowa-Staszczak[1], Justyna Brodowicz[3], Katarzyna Gawlik[3], Dorota Pawlica-Gosiewska[3], Bogdan Solnica[3] & Alicja Hubalewska-Dydejczyk[1]

[1]Chair and Department of Endocrinology, Jagiellonian University Medical College, Kraków, Poland; [2]Department of Endocrinology, Oncological Endocrinology, Nuclear Medicine and Internal Medicine, University Hospital in Krakow, Kraków, Poland; [3]Department of Clinical Biochemistry, Jagiellonian University Medical College, Kraków, Poland

Introduction

The current standard of care for patients with endocrine neoplasms emphasizes the personalization of diagnostic and therapeutic approaches. Several key time points are critical, including the early detection of recurrence following radical surgery. While thyroglobulin is used for thyroid cancer and calcitonin for medullary thyroid cancer, robust tumor markers are unfortunately unavailable for other types of endocrine neoplasms, such as neuroendocrine tumors and pheochromocytomas. It appears that certain growth factors involved in tumorigenesis could potentially serve as useful markers for detecting recurrence of these tumors. The aim of this study is to determine whether any of the selected growth factors (TNF-α, Fascin, VEGF, Galectin-1, Galectin-3, and FGF), measured in the serum of patients with disseminated endocrine neoplasms, could serve as potential markers for recurrence.

Methods

The study included 43 patients with disseminated endocrine neoplasms (30 with neuroendocrine tumors (NET), 6 with medullary thyroid cancer (MTC), and 7 with adrenal neoplasms) and 25 healthy controls. Serum levels of TNF-α, Fascin, VEGF, Galectin-1, Galectin-3, and FGF were measured in all patients and healthy controls using ELISA assays. The biochemical analysis results were compared across the different patient subsets with various endocrine neoplasms and the control group.

Results

A comparison of all patients with disseminated endocrine neoplasms and the control group revealed significant differences in TNF-α levels (2. 88 vs. 0. 93 [ng/mL], $P = 0.008$). When comparing the concentrations of the measured factors between subgroups (classified by tumor type) and the control group, differences were found for TNF-α ($P = 0.007$) and Fascin ($P = 0.035$). For Fascin, significant differences were observed between MTC patients and those with adrenal neoplasms (0. 52 vs. 5. 28 [ng/mL], $P = 0.048$), as well as between MTC and NET patients (0. 52 vs. 5. 59 [ng/mL], $P = 0.007$). The difference between NET patients and controls was nearly significant (5. 59 vs. 3. 67 [ng/mL], $P = 0.076$). For TNF-α, significant differences were found between NET patients and controls (2. 88 vs. 0. 03 [ng/mL], $P = 0.005$) as well as between MTC patients and controls (2. 77 vs. 0. 93 [ng/mL], $P = 0.004$).

Conclusion

Plasma concentrations of selected growth factors (TNF-α, Fascin) differ between healthy individuals and those with disseminated endocrine neoplasms. Further research is needed to evaluate their potential in detecting recurrence of NET and MTC.

[1]Analysis of Circulating Tumor Cells (ACTC) Lab - Dept of Chemistry, National and Kapodistrian University of Athens, Athens, Greece; [2]Dept of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, Pisa, Italy; [3]Genotypos-Science Labs, Athens, Greece; [4]Department of Endocrine Surgery, Henry Dunant Hospital Center, 11526 Athens, Greece, Athens, Greece; [5]National and Kapodistrian University of Athens, Athens, Greece; [6]Thyroid Cancer Outpatient Clinic - Endocrine Department 401 General Military Hospital of Athens, Athens, Greece

Objectives

Distant metastases (DM) and/or biochemical persistent disease (BPD) in MTC, adversely affect disease prognosis. Calcitonin and CEA doubling-times (DTs) are the main prognostic indicators. Liquid-biopsy based on CTCs enrichment and molecular characterization is a non-invasive tool providing information about tumor biology and molecular identity. The aim of this study was molecular characterization of CTCs in

spMTC with DM and/or BPD using epithelial, mesenchymal and MTC-specific markers while a droplet-digital polymerase chain reaction (ddPCR) was performed to detect in CTC-derived genomic (g)DNA the most common somatic mutation in spMTC (*RET*-M918T).

Methods

Twelve spMTC patients (DM:7, BPD:5) carrying somatic mutations in *RET* ($n = 7$, *RET*-M918T=4/7) and *HRAS* ($n = 5$) were included. Peripheral blood (10mL-EDTA) was obtained every 3-6 months depending on disease progression. In total of 53 samples, CTCs enrichment by EpCAM-based positive immunomagnetic selection (EpCam-IMS) was performed following our previous announcement where EpCam-IMS proved to be superior to the size-based Parsortix microfluidics system. CTCs gene expression analysis was based on RT-qPCR for epithelial (*CK-8, CK-18, CK-19*), mesenchymal (*Vimentin-VIM*), MTC-specific (*Calcitonin-CALCA*) and chemokine-receptor markers (*CXCR4*). A ddPCR assay was developed to detect the *RET*-M918T. Calcitonin, CEA DTs and disease status according to RECIST, were recorded.

Results

During a mean f-up of 24. 6 months (range 12-39) Calcitonin and CEA DTs were >24 months. Structural disease progression (SDP) was documented in four patients (2/4 harboring *RET*-M918T). Overexpression of *CALCA* was detected in 10 samples related to 8 patients, including those with SDP, at time-points 1-6 months before calcitonin levels showed a mean percentage increase from the preceding time point of 28. 65±24. 23% vs 14. 09±8. 59%, $P = 0.058$, which was observed in 11 samples without *CALCA* overexpression. *CXCR4* was overexpressed in 5 samples related to 3 patients (2/3 with SDP). In 2/17 samples related to *RET*-M918T patients the mutation was detected by ddPCR at time-points 6 months before SDP was documented, albeit calcitonin and CEA were slightly increased; the samples related at the time-point of SDP documentation were found negative. Epithelial markers were expressed in 8/53 (15. 1%) samples, while *VIM* in 22/53 (41. 5%).

Conclusions

Molecular characterization of CTCs in progressive spMTC, may add valuable information in disease monitoring. *CALCA* and *CXCR4* expression in CTCs as well as gDNA detection by ddPCR may be used as ancillary biomarkers towards efficient therapeutic management and precision medicine implementation. Increased expression of *VIM* advocates towards an epithelial to mesenchymal transition-EMT process. Larger patients' series and for longer follow-up periods should be studied to validate these Results

20 Years of pediatric thyroid cancer experience at a tertiary care center

Mallory McNiven[1], Julia Zebak[2], Chelsey Grimbly[1], Rose Girgis[1] & Susan Chafe[3]

[1]University of Alberta, Pediatric Endocrinology, Edmonton, Canada; [2]University of Calgary, Calgary, Canada; [3]University of Alberta, Radiation Oncology, Edmonton, Canada

Objectives

Thyroid cancer is a rare malignancy in the pediatric population, however recently the incidence has been increasing. This study describes the presentation, management and outcomes of patients seen at our centre over the last twenty-two years.

Methods

A retrospective chart review of 42 patients was conducted and statistical analysis performed. Inclusion criteria: Diagnosis of thyroid cancer, age less than 18 years at diagnosis, managed at the Stollery Children's Hospital between 2002-2024. There were no exclusion criteria. The presentation, investigations, management, and follow-up data were collected.

Results

Patients' age at diagnosis ranged from 5 to 17 years, with a median of 15. 7 years and an average follow-up time of 10 years (+/- 6 years). Thirty-five patients (83%) had papillary carcinoma, five (12%) had follicular carcinoma, one (2%) had medullary carcinoma, and one (2%) was diagnosed with non-invasive follicular thyroid neoplasm with papillary-like nuclear features (NIFTP). Three patients were found to have hereditary cancer syndromes including DICER1, PTEN Hamartoma Tumour Syndrome and MEN2. Metastatic disease was identified in twenty-five patients (60%) at presentation, including 22/25 involving lymph nodes and 3/25 distant lung metastases. 8/42 patients (19%) had extrathyroidal extension and 15/42 patients (36%) had lymphovascular invasion. Molecular testing was not conducted routinely but is becoming more utilized. One patient's pathology was indeterminate but demonstrated a PAX8/PPARG mutation. This prompted surgery, resulting in confirmation of follicular carcinoma. Two patients with distant lung metastases and persistent disease were tested. NTRK3 and RET gene variants were identified, both of which are associated with aggressive disease. All patients underwent thyroidectomy. Data describing postoperative parathyroid function was available in 12/42 (29%) patients. 7/12 (58%) developed hypoparathyroidism, of which 4/7 (57%) cases were permanent. Data regarding laryngeal nerve function was available in 14/42 (33%) patients. Acquired laryngeal nerve dysfunction resulting in permanent vocal cord paralysis was diagnosed in 2/14 (14%) patients. Radioactive iodine was used for 38/42 (90%) patients. No patient deaths were reported.

Conclusion

Pediatric thyroid cancer has a high burden of disease. The mortality rate is low but there is significant morbidity associated with treatment. Molecular studies are becoming an essential tool in management of thyroid cancer.

Exploring SDHA variants: navigating predisposition and incidental findings

Henriett Butz[1], Balint Antal[2], János Papp[1], Aniko Bozsik[1], Vince Kornel Grolmusz[1], Petra Nagy[1], Timea Pocza[1], Julie Sanceau[3], Judith Favier[3] & Attila Patócs[1]

[1]National Institute of Oncology, Budapest, Hungary; [2]Semmelweis University, Budapest, Hungary; [3]Inserm, Centre de Recherche des Cordeliers, Université Paris-Cité, Sorbonne Université, Paris, France

Background

Multigene panel testing (MGPT) is increasingly employed in oncology, leading to identification of numerous pathogenic/likely pathogenic (P/lP) variants in the *SDHA* gene. This includes incidental findings in patients with non-*SDHA*-associated tumours, creating challenges for clinical interpretation.

Aim

This study aimed to determine the prevalence and potential role of *SDHA* P/lP variants in the development of both *SDHA*-associated and non-*SDHA*-associated tumours.

Methods

A cohort of 1699 cancer patients who underwent MGPT from 2021 to 2023 was screened for suspected heritability. Tumours were categorized into *SDHA*-associated types (gastrointestinal stromal tumour, phaeochromocytoma-paraganglioma, renal cancer, neuroblastoma, pituitary adenoma; $n = 62$) and non-*SDHA*-associated types (endocrine tumours, hereditary breast-ovarian cancer syndrome, and other tumours; $n = 1637$). Controls were drawn from the gnomAD non-cancer database ($n = 134,187$). Comprehensive analyses included next-generation sequencing, RNA characterization, and loss of heterozygosity (LOH) studies by immunohistochemistry. Additionally, somatic *SDHA* sequence and copy number variations in 10, 463 pan-cancer and 7988 breast tumour samples were examined through The Cancer Genome Atlas datasets.

Results

Germline *SDHA* P/lP variants were significantly enriched in *SDHA*-associated tumour group compared to controls (5. 41x, $P = 0.05$), but their prevalence in patients with other tumour types was low (0. 23–1. 57x, $p > 0.05$). LOH was absent in non-*SDHA*-associated tumours with germline variants. Somatic *SDHA* alterations, including heterozygous and homozygous deletions, were identified in 1–4% of non-*SDHA*-associated tumours. In breast cancer, heterozygous *SDHA* copy number loss was linked to worse overall and relapse-free survival (hazard ratio=1. 55 and 1. 48, respectively; $P < 0.05$).

Conclusion

Germline *SDHA* P/lP variants predispose to *SDHA*-associated tumours, supporting their role in these cancers. While SDHA rarely contributes to non-*SDHA*-associated tumours, somatic *SDHA* deletions in breast cancer may act as disease modifiers, influencing progression and prognosis.

Variable redifferentiation effect of larotrectinib for NTRK fusion-positive pediatric papillary thyroid carcinoma and disease outcomes off therapy

Luz Castellanos[1], Sireesha Yedururi[2] & Steven Waguespack[1]
[1]The University of Texas MD Anderson Cancer Center, Endocrine Neoplasia and Hormonal Disorders, Houston, United States; [2]The University of Texas MD Anderson Cancer Center, Department of Abdominal Imaging, Houston, United States

Background
Few data exist regarding larotrectinib therapy in pediatric *NTRK* fusion-positive papillary thyroid cancer (PTC), especially its effects on redifferentiation in radioactive iodine-refractory (RAIR) disease. Our objective was to describe redifferentiation effects and disease outcomes in pediatric patients with stage 2 PTC following treatment with larotrectinib ± RAI.
Methods
This was a retrospective case series at a tertiary cancer center of patients <19 years with *NTRK* fusion-positive PTC and RAIR pulmonary metastases treated with larotrectinib and considered for ^{131}I therapy. Tumor response was assessed utilizing RECIST 1. 1.
Results
Four patients with pediatric PTC (ages 6-16 years at diagnosis; 50% female) and lung metastases considered RAIR were treated with larotrectinib 100 mg BID for a median of 14 months (range 6-30 months). Treatment was well tolerated, except for grade 3 hypocalcemia in one patient with pre-existing hypoparathyroidism, and tumor response (-25 to -100%) occurred in all patients. On diagnostic ^{123}I thyroid scans, any RAI uptake was identified in only 2/4 patients, but therapeutic ^{131}I did not cause an incremental tumor response in the two patients treated despite robust pulmonary uptake on the post-therapy scans. After stopping larotrectinib, all patients had stable structural disease after a mean follow-up of 38 months (range 26-48 months).
Conclusion
Although larotrectinib can have a redifferentiation effect in pediatric *NTRK* fusion-positive PTC, therapy with ^{131}I may not lead to an incremental benefit in children with established RAIR disease. Structural disease progression does not occur after cessation of larotrectinib, suggesting that it can be safely stopped in this population.

Background
Adrenocortical carcinoma (ACC) is an aggressive cancer with heterogeneous prognosis and few therapeutic options. Somatic genetic alterations have been demonstrated to predict clinical outcomes and have been highlighted as possible therapeutic targets. Radiomics has been used for the prediction of clinically relevant mutations, but not in ACC.
Aim
To predict the presence of key pathogenic gene variants in ACC using radiomics features.
Methods
We retrospectively enrolled 37 ACC patients (25 females) who underwent adrenalectomy at Queen Elizabeth Hospital Birmingham (Birmingham, United Kingdom) and IRCCS Sant'Orsola Malpighi Polyclinic (Bologna, Italy) from 2013 to 2023 with available pre-surgery portal-phase computerized tomography. Targeted Next Generation Sequencing was performed on formalin-fixed paraffin-embed samples using customised panels that included 10 ACC-specific genes (*TP53, RB1, CDK4, CTNNB1, APC, ZNRF3, MEN1, TERT, ATM* and *NF1*) designed and assembled in both centres. Sequencing was performed with routinely available techniques at each centre (i. e. Illumina). Radiomics was performed with LifeX software (Lito©, FR). After standardization, features selection was conducted with U Mann Whitney followed by Spearman correlation to avoid collinearity. Predictive models based on radiomics features for the prediction of most frequently mutated genes and mutated beta-catenin pathway genes (BCPG: *CTNNB1, ZNRF3, APC*), mutated tumour suppressor genes (TSG: *TP53, RB1, CDK4*), mutated chromatin remodeling genes (CRG: *MEN1, TERT*), *NF1* and *ATM* were formulated through logistic regression and their diagnostic performances were evaluated with Receiver Operator Characteristic (ROC) curve analysis and negative (NPV) and positive (PPV) predictive factor.
Results
Wild type genotype was observed in 20 samples (54. 1%). Mutations were detected for BCPG (n = 9 (24. 3%): *CTNNB1*=5 (13. 5%), *ZNRF3*=3 (8. 1%), *APC*=2 (5. 4%)), TSG (n = 9 (24. 3%): *TP53* =7 (18. 9%), *RB1*=2 (5. 4%)), CRG (n = 5: *MEN1*=4 (10. 8%), *TERT*=1 (2. 7%)), *NF1* (n = 4 (10. 8%)). BCPG mutations (P = 0. 020) were predicted by Inverse Variance (Odds ratio (OR)=0. 171 (95% Confidence Interval (95% CI) =0. 034-0. 846), P = 0. 030), Normalised Grey Level Non-Uniformity (Or = 0. 084 (95% CI=0. 007-0. 983), P = 0. 048), with sensitivity=88. 9%, specificity=79. 6%, NPV=81. 3%, PPV=60%. *CTNNB1* mutations (P = 0. 002) were predicted by Inverse Variance (Or = 0. 181 (95% CI=0. 039-0. 836), P = 0. 029) and Normalised Grey Level Non-Uniformity (Or = 0. 082 (95% CI=0. 007-0. 959), P = 0. 046), with sensitivity=100%, specificity=81. 8%, NPV=100%, PPV=45. 5%. *NF1* mutations (P = 0. 032) were predicted by Difference Entropy (OR=3. 014 (95% CI=1. 000-9. 079), P = 0. 050), with sensitivity=100%, specificity=72. 7%, NPV=100%, PPV=30. 8%.
Conclusion
We present the first radiogenomics study in ACC so far. Radiomics could be a swift and cost-effective analysis useful for early recognition of somatic mutations in BCPG, especially in genes *CTNNB1* and *NF1*. Larger studies might be required to further investigate variant predictions.

Increased serum visfatin in neuroendocrine tumors shows promise as a diagnostic biomarker: a single-center, cross-sectional study

Paweł Komarnicki[1], Paweł Gut[1], Jan Musiałkiewicz[1], Michalina Czupińska[1], George Mastorakos[2] & Marek Ruchala[1]
[1]Poznan University of Medical Sciences, Department of Endocrinology, Metabolism, and Internal Diseases, Poznan, Poland; [2]National and Kapodistrian University of Athens, Unit of Endocrinology, Diabetes mellitus, and Metabolism, Athens, Greece

Introduction
Neuroendocrine Tumors (NETs) remain a problematic area in endocrine oncology, due to their non-specific symptoms and the lack of reliable biomarkers. They are often diagnosed late, which leads to poor disease outcomes. Visfatin, an adipocytokine initially researched in metabolic disorders, has been linked with angiogenesis and tumorigenesis in various neoplasms. However, no studies in NETs were previously conducted. In this study, we aimed to analyze serum visfatin concentrations as a diagnostic biomarker in patients with NETs.
Material and Methods
We conducted a single-center, cross-sectional study of 77 patients with NETs (33 pancreatic and 44 small intestinal NETs) and 29 controls without NET diagnosis. Serum visfatin levels were measured using ELISA. Patient demographics and clinical characteristics were recorded for patient recruitment, with data on sex, age, NETs primary site, and WHO grade used for subsequent analyses. Group

comparisons were performed using Mann-Whitney U and Kruskal-Wallis tests. Spearman's rank correlation and multiple linear regression were used to compare the association between visfatin, and patient and tumor characteristics. ROC curve analysis evaluated visfatin's diagnostic performance in distinguishing NETs patients and controls. Statistical analyses were conducted in Python using pandas, NumPy, SciPy, scikit-learn.
Results
Serum visfatin concentrations were significantly higher in patients with NETs compared to controls (median[IQR]: 6. 94[2. 11-236. 17] vs 1. 59[1. 1-9. 24] ng/ml, $P = 0.0233$). ROC curve analysis showed moderate diagnostic performance (AUC = 0. 68), with concentrations above 2. 11 ng/mL providing a sensitivity of 75. 3% and specificity of 58. 6%. In patients with NETs, visfatin levels did not differ between WHO grades (G1 vs G2, $P = 0.31$), primary sites (pancreas vs small intestine, $P = 0.95$), sex ($P = 0.89$), age ($P = 0.13$), and when stratified by both primary site and grade ($P = 0.178$). Multiple linear regression confirmed no association between visfatin and age, sex, NETs primary site, and grade (R-squared = 0. 036, $p > 0.2$ for all variables).
Conclusion
This is the first study to evaluate potential utility of serum visfatin as a diagnostic biomarker in NETs. Serum visfatin concentrations show moderate discriminatory ability between subjects with and without NETs, and appear independent of other tumor and patient characteristics. Further research should involve larger study groups and assess visfatin's utility alongside and compared to other NETs biomarkers.

A comparison of clinical and hormonal characteristics in patients with paraneoplastic cushing's syndrome and in those with cushing's disease

Monica Livia Gheorghiu[1], Andreea-Alexandra Grosu[1], Viorica Nicuta[1], Maria Anghel[1], Anda Dumitrașcu[1], Carmen Iordachescu[1], Dana Manda[1], Andra Caragheorgheopol[1] & Corin Badiu[1, 2]
[1]CI Parhon National Institute of Endocrinology, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Introduction
The differential diagnosis between Cushing's disease (CD) and ectopic (paraneoplastic) Cushing's syndrome (ECS) is frequently difficult, notably when bilateral inferior petrosal sinus sampling is unavailable or a pituitary incidentaloma is visualized. We present a comparison between patients diagnosed with CD and ECS and our experience in their diagnosis in a tertiary center of Endocrinology.
Patients and Methods
This retrospective study identified 27 patients diagnosed with CD [78% females, mean age 37. 5 years (10-65)] and 21patients with ECS [67% females, mean age 50 years (18-74)] evaluated in our department between 1997-2024. Data on clinical presentation and hormonal workup were analyzed; 85% of CD and 90% of ECS patients were confirmed histologically.
Results
CD patients had 16 (59%) microadenomas and 11 (41%) macroadenomas. Causes of ECS: neuroendocrine tumors in 12 patients (57%); medullary thyroid cancer in 5 patients (24%); lymphoma in 1 patient; thalamic tumor 1 patient, unknown primary tumor in 2 cases (10%). Almost all the ECS and only 63% of CD patients presented with typical cushingoid appearance. In ECS more frequent were hypertension (81% vs 67%, $P < 0.05$) and hypokalemia (range 1. 65-3. 2 mmol/l) in 72% vs 0%, while in CD patients more frequently were found overweight/obesity (78% vs 50%, $P < 0.001$) and osteoporosis/osteopenia (40. 7% vs 24%, $P < 0.05$), while dyslipidemia (81% in ECS vs 74%) and prediabetes/diabetes (52% in ECS vs 48%) were non-significantly different. ECS patients had higher median morning cortisol level 46 vs 22 μg/dL, $P < 0.001$, higher late night serum cortisol 18. 7 vs 15 mg/dL, $P < 0.05$, higher ACTH [141 pg/mL (range 35-1221) vs 77 pg/mL (range 21-201), $P < 0.05$], higher UFC levels (5. 97 vs 1. 59 xULN, $P < 0.05$). Levels in ECS patients overlapped with those in CD in 57% of cases for morning cortisol, 50% for late night cortisol, 72% for ACTH. Inadequate cortisol suppression (<50% reduction) after high dose dexamethasone (DST, 8mg/day for 2 days) was recorded in 93% of ECS patients, but also in 47. 6% of 21 CD patients (in 44. 5% of those with macroadenomas and in 41% of those with microadenomas). Extensive imaging identified the primary tumor in 71. 4% of ECS patients.
Conclusion
Patients with ECS had higher prevalence of hypertension and hypokalemia and lower prevalence of obesity and osteoporosis compared with patients with CD. ECS patients had significantly higher morning and late-night serum cortisol, ACTH and UFC levels. High dose DST had 93% sensitivity but only 52% specificity for ECS. Management of ACTH-dependent CS needs a multi-disciplinary approach.

Introduction
Pheochromocytomas and paragangliomas (PPGLs) are relatively rare endocrine tumours often characterized by excess catecholamine production. Catecholamine-induced cardiometabolic complications substantially contribute to increased morbidity and mortality in PPGL patients prior to surgical resection. Hyperglycemia driven by catecholamines can lead to the onset or worsening of diabetes mellitus, while elevated plasma norepinephrine levels have been associated with higher HbA1c and reduced body weight in PPGL patients. Despite these acute findings, the long-term cardiometabolic outcomes following PPGL resection remain insufficiently studied. This study aimed to explore biomarkers indicative of a persistent higher cardiometabolic risk in PPGL patients.
Methods
We conducted a retrospective analysis of a multicentre cohort of patients with PPGLs enrolled in the prospective **ProsPheo**study and the **ENS@T registry**. Cardiometabolic risk factors including glycemic status, dyslipidemia and BMI, were evaluated at the time of PPGL diagnosis and during follow-up. To further assess long-term outcomes after successful PPGL resection, patients with a history of resected PPGL (without recurrence) were compared to a control group of individuals with non-functioning adrenal adenomas (NFAA) [with normal aldosterone-renin ratios, normal 1 mg dexamethasone suppression testing, and non-elevated plasma levels of (nor)metanephrines and 3-methoxytyramine].
Results
A total of 259 individuals were included: patients with a present PPGL or a history of PPGL ($n = 188$), a metastatic PPGL ($n = 27$), or a pathogenic variant in a PPGL susceptibility gene without prior PPGL history ($n = 44$). Mean HbA1c levels were lowest in the susceptibility gene carrier group (5. 4%, SD 0. 5%) and similar in patients with a present PPGL (5. 6%, SD 0. 6%), a history of PPGL (5. 6%, SD 0. 4%) or metastatic PPGL (5. 6%, SD 0. 8%). In patients with a history of PPGL (without recurrence) and ≥12 months post-surgery follow-up ($n = 113$), mean HbA1c levels (5. 6%, SD 0. 4%) and the

prevalence of hyperglycemic disorders were significantly higher than in a control group with non-functioning adrenal adenomas (NFAA; $n = 76$) of similar age and BMI (HbA1c 5. 5%, SD 0. 4%; $P = 0.004$). Pre-surgery HbA1c was higher in catecholamine-secreting PPGLs compared to non-secreting PPGLs (5. 8% vs. 5. 3%; $P = 0.02$), but this difference was not observed during follow-up (5. 6% vs. 5. 5%; $P = 0.56$). No significant differences were found between groups regarding other cardiometabolic risk factors or laboratory parameters, including BMI, cholesterol, triglycerides, eGFR, and NT-proBNP levels.

Conclusions

The primary conclusion of this study is that chronic hyperglycemia persists long-term following successful PPGL resection.

[^{68}Ga]Ga-DOTA-exendin-4 PET/CT for the localization of insulinoma: results of an international, dual-center, retrospective, open-label real-world imaging study

Emanuel Christ[1], Manuela Schildmeijer[1], Julia Fricke[1], Katharina Laubner[2], Lea Menz[2], Jochen Seufert[2], Martin Freitag[2] & Damian Wild[1]

[1]University Hospital Basel, Division of Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University Hospital of Freiburg, Division of Endocrinology and Diabetology, Department of Medicine II, Medical Center, Freiburg, Germany

Introduction

Benign insulinomas are the main cause of endogenous hyperinsulinemic hypoglycemia (EHH) in adults, with surgery as the only cure. Pancreas-preserving procedures are preferred, making precise localization crucial. Recent studies indicate that GLP-1R imaging, such as [^{68}Ga]Ga-DOTA-exendin-4 (^{68}Ga-Ex4) PET/CT, outperforms conventional imaging in identifying insulinomas.

Aim

The goal of this study was to generate real-life data for the detection rate of insulinoma with ^{68}Ga-Ex4 PET/CT in patients with negative/inconclusive workup on prior conventional imaging.

Material and Methods

In this retrospective, real-life, dual-center imaging study, patients with biochemically proven EHH and/or a positive Whipple triad underwent ^{68}Ga-Ex4 PET/CT at two tertiary centers between April 2017 and March 2024. Endpoints: ^{68}Ga-Ex4 PET/CT detection rate after inconclusive conventional workup (gold standard: histology) and impact on patient management.

Results

Hundred one patients were enrolled, of which 63 (62%) received conventional workup prior to ^{68}Ga-Ex4 PET/CT. ^{68}Ga-Ex4 PET/CT was positive in 26 out of the 35 patients with negative conventional workup leading to a PET/CT detection rate of 74% in this challenging patient group. 22/26 (85%) patients with positive results only with ^{68}Ga-Ex4 PET/CT were confirmed by histology for either Insulinoma (21 cases) or nesidioblastosis (1 case).

Conclusions

In a real-life setting; ^{68}Ga-Ex4 PET/CT effectively detects insulinomas and nesidioblastosis in patients with inconclusive conventional workup, achieving a 74% detection rate. Histology confirmed insulinomas or nesidioblastosis in all operated patients with positive ^{68}Ga-Ex4 PET/CT results, highlighting its impact on patient management.

Introduction

Multiple Endocrine Neoplasia type 2 (MEN2) is a rare disease caused by activating mutations of the *RET* proto-oncogene. MEN2 is responsible for predisposition to develop endocrine tumors including medullary thyroid carcinoma (MTC) and pheochromocytomas (PHEO)[1]. MEN2 is characterized by a genotype-phenotype correlation, as evidenced by the phenotypic differences of the two main entities: MEN2A, mainly linked to codon 634 mutations, associates CMT, PHEO, less frequently primary hyperparathyroidism, while MEN2B linked to codon 918 mutation associates CMT, PHEO and cutaneous-mucosal, digestive and bone manifestations[2]. This genotype-phenotype correlation is the basis of international recommendations for monitoring and management (prophylactic and curative) of MEN2 patients[3]. Despite this genotype-phenotype correlation, MEN2 is characterized by intra- and inter-family variability for patients carrying the same *RET* variant, particularly concerning CMT. The aim of this study is to conduct a retrospective analysis of the clinical, biological, and genetic characteristics of MEN2 patients in France to better understand the natural history of the disease and identify modifiers of disease progression.

Patients and Methods

Between November 2022 and October 2023, we collected retrospective data from MEN2 patients followed at four tertiary centres in France.

Results

We established a cohort of 748 patients from 335 families. The *RET* variant was available for 734 patients (98%), mainly located on exons 10 ($n = 142$, 19%), 11 ($n = 278$, 38%), and 14 ($n = 163$, 22%). The mean age at molecular diagnosis was 45. 4 years for index cases and 26. 8 years for relatives. A total of 393 of 467 patients (84%) had undergone surgery for MTC, with 283 localized diseases (pTxN0) at diagnosis, 96 locally advanced (pTxN1), and 7 metastatic (pTxNxM1) . After a median follow-up of 12 years, 199 of 304 patients were in remission (65%), 87 had residual disease (29%), and 18 had died (6%). A total of 30% (137/449) of patients benefited from pheochromocytoma surgery, including 91 patients with bilateral adrenal involvement (66%).

Conclusion

This study confirms the feasibility of national epidemiological and genetic data collection. This future database will help identify modifiers of disease progression to better understand phenotypic variability and to tailor the management of MEN2 patients.

Introduction
Radioligand therapy (RLT) targeting somatostatin receptors is an effective treatment for disseminated neuroendocrine tumors(NETs) that express these receptors. Individual dosimetry of critical organs ensures safety and, in some cases, allows for an increased radiation dose during therapy, potentially leading to better treatment outcomes. The DUONEN multicenter randomized clinical trial aims to evaluate the effect of individual dosimetry on the efficacy and safety of RLT with [177Lu]Lu-DOTA-TATE or a mixture of [177Lu/90Y]-DOTA-TATE in patients with NET.
Materials and Methods
Adult patients with advanced, unresectable, well-differentiated(G1 and G2) NETs, who are progressing on long-acting somatostatin analogues, are randomized into four arms:
- Arm A: Treated with [177Lu]Lu-DOTA-TATE at a constant radioactivity of 7400MBq per cycle
- Arm B: Treated with a mixture of [177Lu/90Y]-DOTA-TATE, initially in a 3700:1850MBq/MBq ratio, with the [90Y]Y-DOTA-TATE dose adjusted in each cycle based on individual dosimetry to maintain the highest possible radiation dose in tumor tissue
- Arm C: Similar to Arm B, but with the radioactivity of [177Lu]Lu-DOTA-TATE adjusted according to dosimetry, while the radioactivity of [90Y]Y-DOTA-TATE remains constant
- Arm D: The first dose is analogous to arm A, with subsequent doses individualized based on dosimetry

The overall dose limits for four cycles of RLT are $<$23Gy for the kidneys and $<$2Gy for the red bone marrow.

Results
By now dosimetry was performed for 115cycles of RLT in 40patients (10 per arm) using QDose software based on 4 SPECT/CT scans and 5 blood samples. In all arms, the doses to the red bone marrow did not exceed the critical limits, with most cases being considerably lower. There was significant variability in the individual doses absorbed by the kidneys. The average dose for kidneys equaled 0. 64 Gy/GBq (SD 0. 19) in arms A and D whereas in arms B and C 0. 76 Gy/GBq (SD 0. 29), and 3. 26 Gy/GBq (SD 1. 26) for [177Lu]Lu-DOTA-TATE and [90Y]Y-DOTA-TATE, respectively. Considering the standard activity of 7. 4GBq in the first cycle, the activity in subsequent cycles could be increased by more than 10% in 60% of cases and decreased in about 15% of cases.
Conclusion
Individual dosimetry may play an important role in RLT, leading to significant dose adjustments in subsequent cycles of treatment for most patients. This approach frequently allows for significant dose increases in subsequent cycles of [177Lu]Lu-DOTA-TATE therapy and suggested dose reductions in the arms using mixtures of [177Lu/90Y]-DOTA-TATE.
Acknowledgments
The study was funded by the Polish Medical Research Agency (Project number 2019/ABM/01/00077-00).

Thyroid carcinoma in children and adolescents - subtypes and clinical evolution

Diana-Simina Luca[1, 2], Dan Alexandru Niculescu[1, 2], Cristina Capatina[1, 2], Adina Simona Dragomir[3], Dumitru Lucian Ioachim[4], Dana Cristina Terzea[4], Carmen Adina Cristea[4], Camelia Procopiuc[5], Andreea Cristiana Brehar[5], Aura Madalina Boboc[2, 5], Lidia Radomir[5], Iuliana Gherlan[2, 5] & Catalina Poiana[1, 2]
[1]"C. I. Parhon" National Institute of Endocrinology, First Endocrinology Department, Bucharest, Romania; [2]"Carol Davila" University of Medicine and Pharmacy, Endocrinology Department, Bucharest, Romania; [3]"C. I. Parhon" National Institute of Endocrinology, Fifth Endocrinology Department, Bucharest, Romania; [4]"C. I. Parhon" National Institute of Endocrinology, Department of Pathology, Bucharest, Romania; [5]"C. I. Parhon" National Institute of Endocrinology, Pediatric Endocrinology Department, Bucharest, Romania

Introduction
The management of thyroid nodules in children is challenging. Moreover, the risk of malignancy for any nodule is higher than in adults.
Aim
To assess the subtypes of cancer in thyroid nodules in a pediatric population and to observe their clinical evolution.
Material and Methods
We retrieved from our endocrinology center database all the fine-needle aspiration (FNA) procedures and all the pathology results from total/subtotal thyroidectomies performed on $\leq$ 18-year old children between January 2020 and June 2024.
Results
There were 163 patients, of whom 39 (23. 92%) had thyroid malignancies. Of the 39 patients, the mean age at diagnosis was 14. 66 years (youngest -7, oldest – 18), with a girls/boys ratio – 33/6. 19 of them had preoperative FNA procedures: there were 4, 6 and 9 patients with Bethesda 4, 5 and 6 respectively. 35 patients had papillary thyroid carcinoma (PTC), 1 follicular carcinoma (FC) and 3 medullary thyroid carcinoma (MTC). Of the 35 patients with PTC, 17 had diffuse sclerosing PTC (48. 57%), 12 classic PTC (35. 29%), 2 follicular variant PTC (5. 88%), 2 trabecular PTC (5. 88%), 1 tall cell PTC (2. 94%) and 1 Warthin tumor (2. 94%). 18 (50%) and 3 (8. 33%) patients had cervical lymph node and pulmonary metastases respectively at diagnosis. The majority of patients with PTC (41. 66%) had an excellent biochemical and structural response after surgery and radioiodine therapy (RAI). Of the 3 patients with CMT, 2 of them had positive RET mutations for MEN 2A, and familial CMT, but unfortunately did not undergo prophylactic thyroidectomy, and only got surgery when calcitonin levels were already elevated and the thyroid tumor was detectable on ultrasound. The other patient had a positive de novo RET mutation (Met918), underwent 3 surgical interventions, and still has signs of residual disease and elevated calcitonin levels (400 mg/dl). None of the patients have had a thyroid carcinoma related death.
Conclusion
The most common type of carcinoma in these patients was diffuse sclerosing PTC (43. 58%). The clinical evolution of these patients varies according to malignancy subtype, the majority of them having a good clinical outcome. Children with familial MTC and positive RET mutations need better clinical monitoring and appropriate therapeutic intervention.

Annual tumour surveillance screening for paediatric carriers of SDHX gene variants in family clinics at barts health NHS trust

Emma Alden[1, 2], Emily Connolly[2], Lee Martin[2], Elizabeth Nash[2], Eugénie Lim[3], Scott Akker[3] & Rathi Prasad[2]
[1]Queen Mary University of London, Faculty of Medicine and Dentistry, London, United Kingdom; [2]Royal London Children's Hospital, Barts Health NHS Trust, Paediatric Endocrinology, London, United Kingdom; [3]St Bartholomew's Hospital, Barts Health NHS Trust, Endocrinology, London, United Kingdom

Background
Phaeochromocytomas and paragangliomas have an annual incidence of 0. 5-2 cases per million children, with 70-80% linked to inherited pathogenic variants in tumour suppressor genes[(1)]. An international consensus statement (2024) underscored the need for lifelong surveillance of asymptomatic variant carriers identified through family-based genetic testing, from childhood/early adulthood[(1)]. Surveillance enhances early detection and timely management of tumours.
Methods
This retrospective audit analysed uptake and outcomes of annual surveillance offered to young people identified through family-based genetic testing and referred to Barts Health NHS Trust from 2019-2024.
Results
The audit included a population of 55 individuals aged 5-19. Of these, 48 (87%) had heterozygous variants in *SDHB*, 4 (7%) in *SDHD*, and 1 (2%) in each of *SDHA*, *SDHC*, and *TMEM127*. Of those aged under 10, each year, an average of 92% (range 82-100%) attended clinic reviews (face-to-face/telephone), 75% (range 42-93%) undertook 24-hour urinary metanephrine screening, and 94% (range 83-100%) attended for ultrasound neck/abdomen/pelvis. Of those aged 10 and over, each year, 85% (range 50-100%) attended clinic reviews (face-to-face/telephone), 82% (range 76-91%) had plasma metanephrines tested and 84% (range 75-91%) attended MRI scans (alternating MRI abdomen/pelvis and MRI

neck/thorax/abdomen/pelvis). During the audit period, 2 patients, both *SDHB* variant carriers, had lesions identified on first surveillance. The first was diagnosed with a retroperitoneal paraganglioma (20x23x27mm) at age 8. 7, suspected following an elevated 24-hour urinary normetadrenaline/creatinine ratio at 851nmol/mol (normal <300nmol/mol), and confirmed by MRI. The second was diagnosed with a left adrenal phaeochromocytoma (28x22mm) at age 16. 9, detected on MRI. They had raised plasma normetanephrine at 1308pmol/l (normal <775pmol/l). Alpha-blocked resection was followed by 6-monthly imaging and plasma metanephrines for 5 and 1 years respectively. No recurrences/metastases have since been identified. Over this period, 27 of 202 scans conducted (ultrasound/MRI) showed unrelated incidental findings (22 individuals). 10 underwent further investigations and 1 required treatment. Work is ongoing to understand patient experiences and the psychological impact of screening on patients and their families.

Discussion

Within our cohort, the annual screening programme demonstrates good compliance and is effective at detecting lesions early. Since screening revealed pathology in children under 10, this supports early surveillance for variant carriers identified through family-based genetic testing.

USP10 as a multifaceted therapeutic target in adrenocortical tumors: implications for tumor biology and steroidogenesis

Victoria Louise Marnet[1], Oliver Hartmann[2], Michaela Reissland[3], Nikolett Pahor[2], Laura-Sophie Landwehr[1], Martin Fassnacht[1], Carmina Teresa Fuss[1] & Markus Diefenbacher[2]

[1]Department of Internal Medicine I, Division of Endocrinology and Diabetes, University Hospital Wuerzburg, Wuerzburg, Germany; [2]Comprehensive Pneumology Center (CPC)/Institute of Lung Health and Immunity (LHI), Helmholtz Munich, Member of the German Center for Lung Research (DZL/CPC-M), Munich, Germany; [3]Max Planck Institute for Molecular Genetics, Berlin, Germany

Adrenocortical carcinoma (ACC) is a rare and aggressive endocrine malignancy with an incidence of one case per million people per year and a 5-year overall survival rate of less than 35%. Currently, complete surgical resection is the only curative treatment, while mitotane, an adrenolytic drug, remains the sole approved systemic therapeutic option besides platinum-based chemotherapy. Given these limitations, there is an urgent need for innovative therapeutic approaches. The ubiquitin-proteasome system (UPS) is an essential cellular machinery that regulates protein stability and is known to be hijacked by tumor cells to exploit signaling pathways and sustain highly proliferative states. However, the role of deubiquitinases (DUBs) in adrenocortical tumors remains poorly understood. Analyzing publicly available datasets, we prioritized DUBs associated with patient survival in ACC and its most relevant signaling pathways. Among these, USP10 emerged as a particularly compelling candidate in follow-up *In vitro* studies. Analysis of Immunohistochemical staining of USP10 on tissue microarrays (TMAs; n: number of single cores) revealed significantly higher USP10 expression in ACC ($n = 645$; $P < 0.001$) and adrenocortical adenomas ($n = 128$; $P < 0.01$) compared to normal adrenal gland ($n = 42$). Subsequential analysis of adenomas by hormonal status showed an increased USP10 expression in cortisol-producing adenomas ($n = 95$) compared to hormonally inactive adenomas ($n = 12$; $P < 0.001$), which is in line with its distinct zone-specific expression we observed in the normal adrenal cortex. So far, we were able to obtain complete clinical datasets for 121 ACC specimens, allowing correlations between USP10 expression and clinical outcomes, including survival, chemotherapy response, hormonal status, and pathological tumor markers. Interestingly, subgroup analysis for hormonal activity showed no significant difference in USP10 expression in ACC. However, treatment with an USP10-specific inhibitor resulted in a significant reduction in cell proliferation in ACC cell lines. Combining USP10 inhibition with cisplatin elicited a synergistic anti-tumor effect, likely through interference with DNA damage response. Therefore, our preliminary analyses indicate that USP10 dysregulation in ACC might be linked to its malignant phenotype rather than hormonal activity. Subsequent *In vitro* experiments using LC-MS-based steroid profiling and immunoblotting of steroid biosynthesis enzymes in ACC cell lines following USP10 inhibition provided further insight into USP10's influence on hormone production. In conclusion, our findings show evidence for USP10 dysregulation in adrenocortical tumors. Its multifaceted role in tumor biology, including DNA damage response and steroidogenesis, suggests a complex contribution to tumorigenesis, with potential clinical implications for diagnosis and treatment.

Pediatric and adolescent von hippel-lindau disease: tumor profiles, genotype-phenotype correlations, and a comparison with adults

Anima Sharma[1], Manjiri Karlekar[1], Saba Memon[1], Virendra Patil[2], Nitish Agarwal[3], Anurag Lila[1], Rohit Barnabas[2], Nalini Shah[1] & Tushar Bandgar[1]

[1]Seth G. S. Medical College and King Edward Memorial Hospital, Endocrinology, Mumbai, India; [2]Seth G. S. Medical College and King Edward Memorial Hospital, Mumbai, India; [3]Fortis Healthcare, Neurosurgery, Faridabad, Haryana, India

Background

Data on pediatric/adolescent von Hippel-Lindau (VHL) disease is sparse, and comprehensive studies detailing the phenotype of all associated neoplasms are lacking. Their current surveillance/management recommendations rely on expert opinion or extrapolation from adults, not individualized to the mutation type.

Objectives

The study aimed to characterize the childhood/adolescent-onset VHL disease phenotype, compare it to adult-onset disease and identify genotype-phenotype correlations.

Methods

This was a retrospective review of children/adolescents (≤19 years) and adults (≥20 years) with VHL disease from a single endocrine center (2000-2024). The diagnosis was based on either clinical criteria (15%, per the guidelines) or genetic confirmation (85%: 66% missense, 19% truncating variants). Only neoplasms diagnosed until 19 years of age were included in the childhood/adolescent group and compared with the last follow-up of adults. The demographic, clinical, anatomical/functional imaging, operative details, histopathology (operated patients) for each VHL-associated neoplasm, and genetics were noted.

Results

Twenty-six children/adolescents (median age at diagnosis 15. 5 years) were identified. By age 19 years, 81% developed pheochromocytoma/paraganglioma (PPGL, of which 10% head and neck PGL), 42% central nervous system hemangioblastoma (CNS-HB), 31% each retinal RHB and pancreatic neuroendocrine tumor (PNET), while none had endolymphatic sac tumor/renal cell carcinoma. At diagnosis, all those with PPGLs were symptomatic (median size 4. 5 cm, 52 lesions). CNS-HBs showed female preponderance, with a high disease burden (60% symptomatic, 50% synchronous in ≥2/3 components of the neuroaxis) and surgical requirement by age 19. Two pediatric patients needed surgery for a symptomatic PNET before the recommended surveillance initiation age (15 years). Two children/adolescents developed polycythemia during follow-up. Compared to adults ($n = 39$), pediatric/adolescent PPGL patients had significantly higher plasma free-normetanephrine (median 1099. 5 vs 2513. 5 pg/mL), more bilateral (47% vs 76%) and extra-adrenal (19% vs 48%) disease by 19 years, and an 8. 3-fold higher operative-site recurrence over a similar follow-up duration (median 108 months: adults, 75 months: children/adolescents) independent of cortical-sparing surgery. Other neoplasms' frequency and burden by 19 years resembled adults. Childhood/adolescent PPGLs occurred predominantly (16/17 cases) and PNETs exclusively, with missense variants. Codon 167 missense variants were associated with synchronous bilateral pheochromocytomas.

Conclusion

In pediatric/adolescent VHL disease, we report a severe phenotype, more extensive (PPGL) or comparable to adults. Our findings support head and neck PGL and earlier PNET surveillance in pediatric/adolescent protocols. The occurrence of childhood/adolescent PPGLs and PNETs almost exclusively with missense variants suggests the genotype may guide the pediatric surveillance strategy for these neoplasms.

Treatment of lung neuroendocrine tumors with ^{177}Lu-DOTATATE: experience from a tertiary oncology centre

Sara Santos[1], Andreia Martins Fernandes[2], Ana P Santos[1], Gonçalo Ferreira[1] & Inês Lucena[1]
[1]Portuguese Institute of Oncology of Porto, Porto, Portugal; [2]Portuguese Institute of Oncology of Coimbra, Coimbra, Portugal

Background
PRRT with ^{177}Lu-DOTATATE is approved for the treatment of metastatic or unresectable, progressive, well-differentiated, SSTR-positive gastroenteropancreatic neuroendocrine tumors (NETs). Although controlled randomized trials are lacking, several studies have shown that PRRT is also effective for SSTR-positive lung NETs. Our study aimed to evaluate the efficacy and safety of ^{177}Lu-DOTATATE PRRT in patients with lung NETs.
Materials and Methods
We retrospectively selected patients with metastatic and/or unresectable lung NET who completed treatment with ^{177}Lu-DOTATATE PRRT at a tertiary oncology center, between 2011 and 2023. Response rates, progression-free survival (PFS), overall survival (OS), and toxicity were assessed.
Results
Twenty-two patients were identified (mean age 63. 1 ± 11. 4 years; 18, 82% men): 12 (55%) with atypical carcinoids, 9 (41%) with typical carcinoids, and 1 (4%) unclassified. Eighteen (82%) patients had hepatic metastasis, 15 (68%), bone metastasis, 9 (41%), lymph node metastasis, and 7 (32%), other. Fourteen patients (64%) were symptomatic, 5 (36%) of whom had carcinoid syndrome. Most patients were previously treated with somatostatin analogs (17; 77%) and chemotherapy (12; 55%). All patients were treated due to disease progression: 19 patients received 3 cycles of ^{177}Lu-DOTATATE and 4, 4 cycles, with a median cumulative activity of 19. 7 GBq (range, 14. 4-29. 6). Median follow-up time after the first cycle was 45 months (range: 7-147), with 16 (73%) deaths recorded. Median PFS was 19 months (95%CI 10-28) and median OS was 46 months (95%CI 38-53). Objective response rate was 32% (7 patients), with all responses documented as partial. Stable disease was described in 7 (32%) patients, yielding a disease control rate of 64%. Of the 14 symptomatic patients, 5 (36%) showed improvement after PRRT, 3 (21%) experienced worsening symptoms, and 6 (43%), no change. There were no cases of clinically significant (grade 3/4) hematologic, hepatic, or renal toxicity. Previous treatment with somatostatin analogs was associated with longer PFS and the presence of respiratory symptoms, with shorter PFS.
Conclusions
^{177}Lu-DOTATATE PRRT seems to be a valuable treatment option for advanced progressive lung NET, with a minimal risk of toxicity. Randomized prospective studies are needed to validate these findings.

MiR-191-5p represents a potential personalized diagnostic and therapeutic tool in the pathophysiological interplay between obesity and prostate cancer

Laura Arroyo-Millán[1, 2], Francisco Porcel-Pastrana[1, 2], Antonio J. Martinez-Fuentes[1 2 3], André Sarmento-Cabral[1, 2], Manuel D. Gahete[1 2 3] & Raúl M. Luque[1 2 3]
[1]Reina Sofia University Hospital (HURS), Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain; [2]Department of Cell Biology, Physiology and Immunology, University of Cordoba, Cordoba, Spain; [3]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Cordoba, Spain

Prostate cancer (PCa) is a major cause of male cancer-related mortality worldwide, emphasising the need for non-invasive diagnostic and prognostic biomarkers and therapeutic targets for this pathology. MicroRNAs (miRNAs) have emerged as promising diagnostic and therapeutic tools for various pathologies. In this study, we investigated the microRNA landscape in plasma samples from PCa patients and explored their potential diagnostic and therapeutic value. Initially, the miRNome of plasma samples from an discovery cohort of healthy subjects (n = 18) and PCa patients (n = 19) was determined using an Affymetrix-miRNA array. Subsequently, the major changes were validated in an independent and ample validation cohort [n = 202 (91 healthy subjects, and 111 PCa patients)] by quantitative real-time PCR. In addition, *in silico* and *In vitro* approaches were performed on normal (RWPE-1 and PNT-2) and tumour (LNCaP, DU145, and PC-3) prostate cell models. The results from the discovery cohort revealed that the expression of 104 miRNAs was significantly altered. Among these, miR-191-5p emerged as a particularly noteworthy candidate due to its potential clinical utility and its role in the pathophysiology of PCa. Specifically, miR-191-5p levels were significantly elevated in PCa patients, highlighting a potential diagnostic value particularly within the Grey Zone of PSA (range of 3 to 10 ng/mL), wherein PSA sensitivity and specificity for diagnosing PCa is limited. Notably, the diagnostic capacity of miR-191-5p was further enhanced in PCa patients with obesity (BMI > 30). Then, a bioinformatics approach was employed, using diverse tools to identify potential targets regulated by miR-191-5p, which showed 13 potential oncogenic targets. Further analyses in PCa cell models in response to miR-191-5p overexpression identified *TMOD2*, a migration-related gene, as the most consistently decreased target. Furthermore, *TMOD2* levels were also confirmed to be modulated by miR-191-5p by using a novelty miRNA-target interaction blocker. Altogether, our findings demonstrate that miR-191-5p may serve as a novel and effective personalised diagnostic biomarker in PCa, particularly among patients with obesity, and as a potential therapeutic tool worth to be explored in PCa patients.

DICER1 syndrome: clinical and endocrinological manifestations in pediatric patients followed in a third-level hospital

María Victoria Pringles Granel[1], Noelia Dujovne[1], Natalia Gazek[1], Roxana Marino[1], Natalia Perez Garrido[1], Pablo Ramirez[1], M Anahi Maidana Roa[2], Jessica Lopez Marti[2], Marianela Viso[1], Marta Ciaccio[1], Alicia Belgorosky[1] & Elisa Vaiani[1]
[1]Hospital de Pediatria JP Garrahan, endocrinology, Buenos Aires, Argentina; [2]Hospital de Pediatria JP Garrahan, Pathology, Buenos Aires, Argentina

Introduction
DICER1 syndrome (DS) is a genetic condition that predisposes individuals to benign and malignant neoplasms. It is caused by pathogenic variants of the DICER1 gene, inherited in an autosomal dominant manner, with low penetrance. The DICER1 protein promotes the maturation of microRNAs, which regulate post-transcriptional mRNA expression.
Objective
To describe the clinical, biochemical and genetic characteristics of a group of pediatric patients with DS diagnosed and followed in the endocrine service at a single tertiary center
Methods
A retrospective descriptive study was conducted. Molecular studies consisted of exonic sequencing of the DICER1 gene in peripheral blood leukocytes and tumor tissue. The variables analyzed were: age at diagnosis, sex, inheritance, associated pathology, and clinical characteristics of endocrine involvement.
Results
Seventeen patients were included, 12 girls (70%). The median age was 13. 8 years (range 1. 9-16. 2). The median follow-up time was 3 years (IQR 0. 67-5). Sixteen patients had pathogenic variants in the germline (94%). The family study was performed in 14 patients, of which 10/7 families were hereditary and 4 were de novo. The associated pathologies were: thyroid gland involvement (n = 16; 94%), ovarian Sertoli-Leydig cell tumor (n = 5; 29%), uterine cervical rhabdomyosarcoma (n = 3; 18%), cystic nephroma (n = 3; 18%), anaplastic renal sarcoma (n = 1; 6%), pulmonary cyst (n = 1; 6%), lymph node sarcoidosis (n = 1; 6%) Regarding thyroid pathology, the first clinical manifestations were: cervical mass (n = 10; 62. 5%) and ultrasound finding (n = 6; 37. 5%). The histological diagnoses were: multinodular goiter (MNG) (n = 13; 81. 2%), papillary thyroid carcinoma, follicular subtype (n = 5; 31. 2%), and follicular adenoma (n = 2; 12. 5%). All patients had normal thyroid function and negative antithyroid antibodies. Regarding ovarian Sertoli-Leydig cell tumors, the clinical manifestations in prepubertal patients (n = 2) were abdominal distension and mass, and in pubertal patients (n = 3), menstrual cycle alteration (n = 3) and clinical-biochemical signs of virilization (n = 1). Histology in prepubertal patients was undifferentiated, and in pubertal patients, it was moderately differentiated. In 4 cases, the location was unilateral. All with associated thyroid pathology. Uterine rhabdomyosarcoma presented with gynecological bleeding (n = 3) and was associated with Sertoli-Leydig cell tumor (n = 1) and thyroid pathology (n = 3).

Discussion
According to the literature, DS presented during childhood and adolescence, with predominance in girls and a familial inheritance pattern. Thyroid involvement was the most frequent. Sertoli-Leydig cell tumors in prepubertal patients showed histological features of worse prognosis. Lymph node sarcoidosis was not previously reported in association with DS. The diagnosis of DS is crucial for patient follow- up and detection of affected family members.

JOINT1599

Frequency and phenotypic spectrum of DICER1 syndrome among children and adolescents with thyroid cancer

Naeun Kwak[1], Dohyung Kim[1], Ji-Hee Yoon[1], Ja Hye Kim[1], Gu-Hwan Kim[1], Han-Wook Yoo[1] & Jin-Ho Choi[1]
[1]Asan Medical Center, University of Ulsan College of Medicine, Pediatrics, Seoul, South Korea

Purpose
DICER1 syndrome is an autosomal dominant familial tumor syndrome predisposing various benign or malignant tumors with incomplete penetrance and variable expressivity. Mutations in DICER1 on chromosome 14q32. 13 lead to truncated protein, impaired microRNA production, and dysregulated gene expression, resulting in tumor formation. DICER1 syndrome is associated with early-onset multinodular goiter and differentiated thyroid carcinoma. This study aimed to investigate the frequency of DICER1 mutations in patients with thyroid cancer and the clinical phenotypes of patients with DICER1 syndrome.
Methods
This study included 16 patients from 8 families with DICER1 syndrome through targeted gene panel sequencing or Sanger sequencing of DICER1. The targeted gene panel included 172 genes associated with hereditary tumor syndromes. Genetic testing was conducted for patients with a clinical features of DICER1 syndrome such as pleuropulmonary blastoma (PPB), ovarian Sertoli-Leydig cell tumors, early-onset thyroid cancer, or family history of DICER1 syndrome. Clinical phenotypes and mutation spectrum of the patients were reviewed retrospectively.
Results
Mutations in DICER1 were found in 7 probands with childhood-onset differentiated thyroid cancer, one with PPB, and two with rhabdomyosarcoma by targeted panel sequencing, and the other 6 first-degree relatives of DICER1 syndrome were diagnosed by Sanger sequencing. The mean age at diagnosis was 12. 4 years for probands and 26. 8 years for family members. Associated tumors included PPB ($n = 4$), thyroid carcinoma ($n = 6$), ovarian Sertoli-Leydig cell tumors ($n = 1$), cystic nephroma ($n = 1$), embryonal rhabdomyosarcoma ($n = 2$) , and ectomesenchymoma ($n = 1$). Genetic analysis identified 9 nonsense mutations from 3 pedigrees, 5 frameshift mutations from 3 pedigrees, and 2 splice site mutations from 2 pedigrees, including three novel variants: c. 3747del (p. K1249Nfs*9), c. 1376+2T>C, and c. 3689del (p. Q1230Rfs*9).
Conclusions
Pediatric patients with thyroid cancer and associated tumors should be evaluated for DICER1 syndrome with family screening. Given the association of endocrine organ tumors with DICER1 syndrome, pediatric endocrinologists should be aware of the disease's clinical spectrum to provide proper management and reduce its morbidities.

Cabozantinib in advanced adrenocortical carcinoma – first preliminary results of the prospective phase II caboACC study

Miriam Reuter[1], Marie-Elisabeth Goebeler[2, 3], Otilia Kimpel[1], Lydia Kürzinger[1], Felix Megerle[1], Carmina Fuß[1], Johanna Werner[1], Cyrus Sayehli[3], Horst-Dieter Hummel[2], Laura-Sophie Landwehr[1], Max Kurlbaum[1], Nicole Reisch[4], Oliver Scherf-Clavel[5], Cornelia Fiessler[6, 7], Martin Fassnacht[2, 8] & Matthias Kroiss[1, 4]
[1]University Hospital of Wuerzburg, Department of Internal Medicine I, Division of Endocrinology and Diabetes, Wuerzburg, Germany; [2]University Hospital of Wuerzburg, Comprehensive Cancer Center Mainfranken, Interdisciplinary Clinical Trials Center with Early Clinical Trials Unit, Wuerzburg, Germany; [3]University Hospital of Wuerzburg, Department of Internal Medicine II, Interdisciplinary Clinical Trials Center with Early Clinical Trials Unit, Wuerzburg, Germany; [4]University Hospital of LMU Munich, Department of Internal Medicine IV, Munich, Germany; [5]LMU Munich, Department of Clinical Pharmacy, Munich, Germany; [6]University Hospital of Wuerzburg, Clinical Trial Center, Wuerzburg, Germany; [7]University Hospital of Wuerzburg, Institute for medical Data Science, Wuerzburg, Germany; [8]University Hospital of Wuerzburg, Comprehensive Cancer Center Mainfranken, Wuerzburg, Germany

Background
Adrenocortical carcinoma (ACC) is a rare malignancy with a poor prognosis in advanced stages and limited therapeutic options. In a retrospective analysis, we previously observed clinical activity of the multityrosine kinase inhibitor cabozantinib (cabo; Kroiss, J. Clin. Endocrinol. Metab, 2020). A recently published phase II study conducted in parallel with this trial reported that 13 out of 18 patients with advanced ACC achieved progression-free survival at four months (Campbell, *Lancet Oncol.*, 2024).
Objective
To prospectively evaluate the clinical activity of cabo in patients with unresectable/metastatic ACC after failure of standard-of-care therapy.
Study Design
The prospective, open-label, multicenter, single-arm, phase II study (NCT03612232) followed a two-stage accrual design. Patients received oral cabo at an initial dose of 60 mg/d. Tumor response was evaluated radiologically every 8 weeks. To minimize potential drug-drug interactions, patients with mitotane plasma concentration >5 mg/l were excluded.
Primary Outcome Measure
The proportion of patients with progression-free survival after four months of treatment.
Results
Of 45 patients screened, 37 were enrolled, with 36 undergoing at least one follow-up imaging. Two patients discontinued cabo due to treatment-related toxicity despite stable disease prior to primary endpoint assessment. Among 34 evaluable patients, 14 (41. 2%) met the primary endpoint, maintaining stable disease for at least four months (preliminary data). The median duration of treatment was 22 weeks. Two patients achieved partial remission, and four additional patients experienced disease control for more than ten months. No new safety aspects were detected.
Conclusion
This investigator-initiated study confirms the promising clinical activity of cabo in heavily pre-treated ACC patients in a patient population larger than both previous retrospective and prospective studies combined. The lower response rate compared to the smaller parallel study may be due to differences in disease characteristics, prior treatments, and the larger sample size. Cabo may have greater efficacy in earlier lines of treatment for advanced ACC or in combination regimens, such as with immunotherapy.
Outlook
Secondary endpoints, markers of response and the potential impact of prior treatment, including interaction with prior mitotane, are currently under investigation.
Funding
This study was sponsored by the University Hospital of Würzburg and funded by Ipsen Pharma. The study team was solely responsible for the study conduct and interpretation of the data.

Rare occurrence of thyroid paraganglioma in the context of SDHB mutation: a case report

Foteini Thanasoula[1, 2], Foteini Petrea[1], Elpida Sidiropoulou[1], Christos Manthakos[3], Spyros Sapounas[4], Vasiliki Vasileiou[1], Evangelia Zapanti[1] & gregory kaltsas[5]
[1]Alexandra General Hospital, Endocrinology Department and Diabetological Centre, Athens, Greece; [2]National and Kapodistrian University of Athens, Laikon Hospital, 1st Department of Internal Medicine, Unit of Endocrinology, Athens, Greece; [3]Private Practice, Tripoli, Greece; [4]National Organization for Medicine (EOF), Athens, Greece; [5]National and Kapodistrian University of Athens, Laikon Hospital, 1st Department of Propaedeutic and Internal Medicine, Unit of Endocrinology, Athens, Greece

Background
Thyroid paragangliomas (PGL) are rare neuroendocrine tumors, with nearly 75 cases reported globally. Arising from extra-adrenal paraganglia of the autonomic nervous system, they often present as slow-growing solitary thyroid nodules. While generally indolent and treatable through surgical excision, their malignant potential remains uncertain, necessitating long-term follow-up. Succinate Dehydrogenase Complex Subunit B (SDHB)-related thyroid PGL are exceptionally uncommon, with limited literature and no established guidelines for their management. The SDHB gene is inherited in an autosomal dominant manner and is associated with poor prognosis and increased metastatic potential.
Objectives
This case report aims to present the clinical course of a rare thyroid -SDHB related paraganglioma.
Methods-Results
The patient is a 54-year-old woman who underwent surgery for a thyroid nodule in 2016. Histopathological analysis of the thyroidectomy specimen unexpectedly revealed a paraganglioma, with a Ki-67 proliferation index of $<1\%$. The patient had normal laboratory (plasma and 24-h urinary catecholamines) and imaging (neck-thorax-abdomen MRI/CT scan) results post-thyroidectomy. She was subsequently referred to our department after genetic testing identified a pathogenic mutation in the SDHB gene. Her family history includes a daughter with a benign Warthin's tumor, another daughter who died from metastatic urothelial carcinoma, a third healthy daughter and a nephew with a carotid body paraganglioma. Genetic testing of her two living children was negative for pathogenic SDHB mutations. Follow-up tests of the patient in May 2024 including MRI of both neck and abdomen were normal and Positron Emission Tomography (PET) scanning with Ga-68 and 18F-FDG revealed no pathological uptake. The patient remains under close observation, without evidence of recurrence or metastasis, 9 years after surgery.
Conclusion
Thyroid paragangliomas remain exceptionally rare and represent a diagnostic challenge due to the limited data available. Vigilance is crucial, as these tumors may present with subtle symptoms or go unnoticed. The absence of guidelines and research, especially in the context of SDHB mutations, highlights the need for further investigation.

Chromogranin a and pancreatic polypeptide are not suitable for the screening of pancreatic neuroendocrine tumors in MEN1 - a long-term follow-up study

Iiro Kostiainen[1], Susanna Majala[2, 3], Jukka Schildt[4], Helka Parviainen[5, 6], Saila Kauhanen[2, 3], Niina Matikainen[1], Eeva Ryhänen[1] & Camilla Schalin-Jantti[1]
[1]Endocrinology, Abdominal Center, Helsinki University Hospital and University of Helsinki, ENDO-ERN (European Reference Network on Rare Endocrine Conditions), Helsinki, Finland; [2]Department of Surgery, Division of Digestive Surgery and Urology, Turku University Hospital and University of Turku, Turku, Finland; [3]Turku PET Centre, Turku, Finland; [4]HUS Medical Imaging Center, Department of Clinical Physiology and Nuclear Medicine, Helsinki University Hospital and the University of Helsinki, Helsinki, Finland; [5]HUS Medical Imaging Center, Department of Radiology, Helsinki University Hospital and the University of Helsinki, Helsinki, Finland; [6]Department of Radiology, Vaasa Central Hospital, Wellbeing Services County of Ostrobothnia, Vaasa, Finland

Introduction
In patients with multiple endocrine neoplasia type 1 (MEN1) followed up at ENETS centers of Excellence, chromogranin A (CgA) and pancreatic polypeptide (PP) are widely used screening tools for pancreatic neuroendocrine tumours (panNETs). However, previous studies demonstrated conflicting results regarding their performance in MEN1 and the follow-up protocol can be questioned. This study aims to bring clarity to the question by investigating a well-characterized MEN1 cohort that, in addition to biomarker screening, underwent both somatostatin receptor positron emission tomography/computed tomography (SSTR PET/CT) and conventional imaging for the detection of panNETs. We studied the impact of long-term biomarker follow-up on the clinical management of panNETs in MEN1.
Methods
The study cohort consisted of 58 MEN1 patients from a European reference center for rare endocrine condition, all of whom underwent both SSTR PET/CT and conventional imaging of the pancreas in addition to long-term biomarker screening. We calculated sensitivity and specificity of CgA and PP for diagnosing any panNET, panNETs $\geq$ 20 mm, and metastatic panNETs, with pancreatic imaging as the reference standard. The longitudinal impact of 10-year annual biomarker measurements on clinical management was analyzed from electronic patient records.
Results
The sensitivity of CgA for diagnosing any panNET, $\geq$ 20 mm panNET, and metastatic panNET was 35%, 30%, and 60%, respectively. The sensitivity of PP for the same categories was 23%, 33%, and 0%, respectively. The area under the curve (AUC) in receiver operator characteristics analysis for CgA was 0. 30 (95% CI 0. 09-0. 51) for any panNET, 0. 49 (95% CI 0. 09-0. 51) for $\geq$ 20 mm panNET, and 0. 69 (95% CI 0. 42-0. 95) for metastatic panNET. The AUC for PP in detecting metastatic panNETs was 0. 28 (95% CI 0. 11-0. 46). Biomarker performance was poor and did not detect any new panNETs, or clinically significant panNETs (tumours $>$ 20 mm in size). Annual biomarker measurements during 514 patient-years of follow-up did not affect the clinical management of panNETs.
Conclusion
CgA and PP are not helpful in diagnosing panNETs in patients with MEN1. Long-term biomarker measurements did not impact clinical management of panNETs. The findings question the clinical value of using CgA and PP for the screening of panNETs in MEN1. Practice should change and other diagnostic methods prioritized instead.

Ectopic adrenocorticotrophic hormone secreting bronchial carcinoid: a retrospective study from a tertiary center

Archana K[1], Preeti Dabadghao[1], Subhash Yadav[1] & Bibhuti Mohanta[1]
[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Endocrinology, Lucknow, India

Introduction
Adrenocorticotropic hormone (ACTH)- producing extra-pituitary tumors are 8-18% of endogenous cushing's syndrome, and their frequency is often under-estimated. This low frequency poses a challenge to acquiring experience in their management.
Methods
A retrospective study was undertaken at a tertiary center in Lucknow. Cases were identified through the Hospital Information System from 2000 to 2024. A cohort of eleven cases of bronchial carcinoid-secreting ACTH was retrieved. The biochemical parameters, hormonal profile, localization studies, medical and surgical treatment, and outcomes were analyzed. Data are presented as median with inter-quartile range (IQR) and percentage.
Results
Out of 11 patients, men constituted 70%. The median age of presentation was 28 years (IQR-26-43). Clinically all patients had cushingoid features and hyperpigmentation, hypokalaemia(63. 6%), hypertension(63. 6%), diabetes(72. 7%), fractures(9%), low bone mass(54. 5%) of patients. The median values of endocrine investigations are mentioned in Table 1. Localization study- Inferior petrosal sinus sampling median ratio of central to periphery was 0. 96 (IQR-0. 85-1. 08). Computed tomography and DOTANOC scan had localized lesions to right lung (54. 5%) and left lung(45. 5%). Ketoconazole usage prior to surgery in 54.

Table 1: Endocrine Investigations

Patient No	8am cortisol (nmol/l)	11pm cortisol (nmol/l)	ACTH (pmol/l)	LNSC (nmol/l)	Urinary free cortisol (mg/dl)	ONDST (nmol/l)	LDDST (nmol/l)	HDDST (nmol/l)
1	892	-	147.5	-	1234	512	-	720

9	938	578	40	64	-	657	524	755
10	826	719	196.4	54	-	985	886	952
Median	886	880	40	59	1554	619.5	688.5	641
IQR 1	748	706	27.9	45.85	677	513	531.75	292.5
IQR 3	1073	1025	96.7	79	2243.5	690	916.75	803.25

5%. Surgical excision through thoracotomy in all patients. Re-surgery was required in 27. 3%. Bilateral adrenalectomy was done in 18. 2%. Remission achieved in 81. 8% in a median duration of 28 months(IQR 3-75)(1 is lost to follow-up). No patient received antitumor treatment.
Conclusion
Ectopic cushing's syndrome is an uncommon clinical syndrome that is associated with significant morbidity and mortality. Antitumor treatment and control of hypercortisolism is equally important and therefore a multi-disciplinary approach.

Background
Neurofibromatosis type 1 (NF1) is an autosomal dominant cancer predisposition syndrome caused by NF1 gene mutations. Although medullary thyroid carcinoma (MTC) is not typically associated with NF1, several case reports suggest a higher prevalence of C-cell disease in this syndrome. On the other hand, somatic NF1 mutations may drive MTC in some rare cases, when mutations in RET or RAS are not present.
Methods
Clinical data from 421 adult NF1 patients, being followed up at the Medical Genetics and Endocrinology Units at our Institution, were retrospectively retrieved, selecting only those who underwent at least one Ctn measurement. Patients with confirmed elevated Ctn values ($\geq$ 10 pg/mL) were referred for thyroid surgery, either immediately or after a positive calcium stimulation test (Ctn peak above the threshold for MTC or C-cell hyperplasia, CCH). Somatic nucleic acids were extracted from 5 formalin-fixed paraffin-embedded thyroid tissue samples, with histologically proven C-cell disease, for molecular characterization by Next Generation Sequencing (NGS).
Results
The study included 384 NF1 patients, with 332/384 testing negative after Ctn screening and 52/384 (13. 5%) with hypercalcitoninemia (median Ctn 14. 1, IQR 12. 1–18. 4 pg/mL). No statistically significant differences were found between the two groups except for male sex (P = 0. 002). After repeating Ctn measurement, 20/52 patients showed persistently elevated levels and two of them were directly referred for thyroid surgery. Nine out of 20 patients were placed under active surveillance, with mean Ctn levels not significantly changing over a median period of 32. 1 months (IQR 21–37). Calcium stimulation test was performed in 9 patients with hypercalcitoninemia, excluding C-cell disease in 2 cases but resulting positive in 7 of them. Overall, 14 NF1 patients (3. 6%) underwent thyroid surgery, with 50% of cases having a suspicious C-cell disease. Among the latter, MTC was found in 2 patients, nodular CCH in 4 (coexisting with follicular thyroid adenoma in 1 case) and thyroid follicular nodular disease in the other one. The NGS analysis identified at least one acquired somatic mutation in the NF1 gene in both cases of MTC and in 3 available cases of CCH, whereas no pathogenic mutation involving RET or RAS was found.
Conclusions
Hypercalcitoninemia is a relatively common finding in patients with NF1 and underlies a possible higher combined prevalence of MTC/CCH (1. 6%) than the general population. The molecular basis of this association is most likely to be found in NF1 gene loss of heterozygosity in thyroid C-cells.

Thyroid and pituitary dysfunction after total body irradiation as conditioning therapy of haematopoietic stem cell transplantation during childhood

Margarida Oliveira[1], Sofia Avelino[2], Ana Figueiredo[3], Sofia F. Silva[2], Carlos Marques[2], Leonor Pinto[2], Catarina Regala[2], Sara Donato[2], Daniela Cavaco[2], Sara Pinheiro[2] & Joana Simões Pereira[2]
[1]Unidade Local de Saúde de Lisboa Ocidental, Endocrinology department, Lisboa, Portugal; [2]Instituto Português de Oncologia de Lisboa Francisco Gentil, Endocrinology department, Lisboa, Portugal; [3]Hospital do Divino Espírito Santo, Ponta Delgada, Portugal

Introduction
The endocrine system is commonly affected by chemotherapy and irradiation prior to allogeneic haematopoietic stem cell transplantation (HSCT) during childhood. Our aim was to analyse the incidence of thyroid and pituitary dysfunctions in paediatric survivors of HSCT, following total body irradiation (TBI) as conditioning therapy.
Objective
We analysed thyroid and pituitary dysfunctions in a cohort of paediatric patients who underwent TBI prior to HSCT.
Material and methods
This retrospective study included paediatric patients who underwent HSCT and received TBI, with a minimum follow-up of 24 months, followed-up at our endocrine late-effects clinic. We excluded patients who received cervical radiotherapy from the thyroid analysis and those who received central nervous system radiotherapy from the pituitary analysis. Statistical analysis was performed with IBM SPSS.
Results
We analysed data from 161 paediatric survivors who underwent HSCT and included 31 patients who received TBI as part of their conditioning therapy. The mean age of HSCT was 11. 0$\pm$5. 0 years and 51. 6%(n = 16) patients were male. The most prevalent haematological disease was acute lymphoblastic leukaemia (ALL), accounting for 48. 4% (n = 15) of cases. The median dose of TBI therapy was 10. 8 Gy (IQR 5. 7). The incidence of thyroid dysfunction in this cohort was 61. 3% (n = 19). The mean follow-up time was 21 $\pm$ 7 years. During follow-up, 12 (38. 7%) patients developed hypothyroidism, with a median time to diagnosis of 14 years (IQR 22) after TBI. Thyroid antibodies were negative in all patients tested (n = 31). Thyroid nodules were diagnosed in 21 (67. 7%) patients, with an average time after TBI of 16 years (IQR 7). The cumulative incidence of thyroid nodules increased over time, being 16%, 35%, and 52% after 10, 15, and 20 years, respectively. Papillary thyroid carcinoma was diagnosed in 7 (22, 6%) patients, with a median age at diagnosis of 26. 5 years (IQR 7). The median time to malignancy diagnosis was 21 years (IQR 13) post-TBI. One patient presented with both papillary and follicular carcinoma. We didn't observe any pituitary dysfunction following TBI, including any puberty disorders.
Conclusion
These findings underlight the importance of long-term thyroid monitoring in paediatric HSCT survivors submitted to TBI. The majority of these patients were diagnosed with thyroid nodules, and its incidence increased throughout their follow-up. The low dose of radiation may explain the absence of pituitary disorders in these patients.

Pediatric papillary thyroid carcinoma as the first manifestation of undiagnosed hereditary tumor predisposition syndrome?

Noelia Dujovne[1], Natalia Gazek[2], Elisa Vaiani[2], Pablo Ramirez[2], Natalia Perez Garrido[2], Jessica Lopez Marti[2], María Victoria Pringles Granel[2], Victor Ayarzabal[2], Mariana Lavia[2], Marta Ciaccio[2], Alicia Belgorosky[2], Roxana Marino[2] & Viviana Herzovich[2]
[1]Hospital of Pediatrics S. A. M. I. C. Prof. Dr. Juan P. Garrahan, Endocrinology, Buenos Aires, Argentina; [2]Hospital d Pediatria J. P. Garrahan, Ciudad Autonoma de Buenos Aires, Argentina

Background
In children, papillary thyroid cancer (PTC) is generally sporadic and, rarely, part of an unrecognized hereditary tumor predisposition syndrome (HTPS). The aim of our study was to report cases of PTC as the first manifestation of HTPS and to characterize the histologic variant, age at diagnosis, recurrence risk according to the American Thyroid Association (ATA 2015), and response to treatment.

Material and Methods
A retrospective, descriptive study was conducted in 88 pediatric patients who underwent total thyroidectomy for PTC. Seven patients with HTPS were identified. The diagnosis was made as follows: 5/63 by next generation sequencing (NGS) panel with PTC-related genes and fusions while in 2/25 patients the molecular study was requested based on clinical suspicion. Patients who were found to have HTPS before PTC diagnosis were excluded. The patients were classified according to the histological criteria, ATA recurrence risk, and dynamic risk stratification at final follow-up.
Results
Seven patients with HTPS in whom the first manifestation was PTC were identified. Three had DICER1 syndrome, two Lynch syndrome, and two PTEN syndrome. Of two patients diagnosed based on clinical suspicion, one had a history of cystic adenomatous malformation in the lung and the other had macrocephaly and developmental delay. DICER1 and PTEN syndrome were confirmed, respectively. Three patients with DICER1 syndrome had follicular variant of PTC: a 6-year-old girl with ATA high risk, and a 14-year-old girl and a 15-year-old boy with ATA low risk. Lynch syndrome (*MSH6* mutation) was diagnosed in two sisters whose mother had a history of thyroid cancer. The index case was a 12-year-old girl with a follicular variant of PTC with ATA low risk. A thyroid ultrasound was requested for the 16-year-old sister due to family history, and PTC of the classic variant with ATA intermediate risk was diagnosed. Two unrelated girls with PTEN Syndrome, aged 12 and 15 years, had a classic variant of PTC with ATA low risk. All patients had excellent response to treatment at the final follow-up (+/- 2 years).
Conclusions
The NGS panel enabled the identification of HTPS in children in whom PTC was the only or initial manifestation of the syndrome. In addition, a comprehensive medical history along with a thorough physical examination is essential to suspect the presence of HTPS in a patient presenting with PTC. Our study patients with PTC associated with HTPS primarily had ATA low-risk and responded well to treatment.

The importance of assessing IDO1 activity when targeting tryptophanyl-tRNA synthetase (WARS) inhibition in medullary thyroid carcinoma (MTC)

Aline Rogerio[1], Douglas Lemes[2], Gisele Giannocco[3], Cleber Camacho[1, 3] & Humberto Dellê[1]
[1]Universidade Nove de Julho (Uninove), Molecular Innovation and Biotechnology Laboratory, Postgraduate Program in Medicine, São Paulo, Brazil; [2]Universidade Nove de Julho (Uninove), Molecular Innovation and Biotechnology Laboratory, Postgraduate Program in Medicina, São Paulo, Brazil; [3]Escola Paulista de Medicina, Universidade Federal de São Paulo, Thyroid Diseases Center, Laboratory of Molecular and Translational Endocrinology, Division of Endocrinology, Department of Medicine, São Paulo, Brazil

Medullary Thyroid Carcinoma (MTC) is an aggressive cancer associated with immunosuppression mediated by indoleamine 2, 3-dioxygenase 1 (IDO1), which IFN-gamma induces. IDO1 converts tryptophan (TRP) into kynurenine (KYN), promoting an immunosuppressive microenvironment. IDO1-producing tumor cells ensure their survival during TRP depletion by producing WARS, which binds TRP to tRNA. This mechanism has been described in some tumors but not yet in MTC. Thus, WARS inhibition could exert a cytotoxic effect on tumor cells. We aimed to: (1) evaluate IDO1 and WARS expression in MTC cells; (2) verify if IDO1 expression is associated with IDO1 activity; (3) assess the effect of WARS inhibition on cell viability.
Methods
TT cells (C634W) were cultured and incubated with IFN-gamma (50ng/mL) for 24h. The relative quantification of *IDO1* and *WARS* expression was determined by qPCR with SYBR_Green, using *TBP* for normalization and ΔΔCt. IDO1 activity was assessed by measuring TRP and KYN levels in the supernatant (KYN/TRP ratio) using HPLC. For WARS inhibition, tryptamine was applied at varying concentrations (0. 0001-100mM) to evaluate cell toxicity (MTT). Linear regression and ANOVA were used.
Results
TT cells constitutively express *WARS* but not *IDO1*. Both genes were induced by IFN-gamma (10-fold increase in WARS; CQ of 24. 8 for *IDO1* vs. undetectable in Control). *IDO1* was positively correlated with *WARS* ($r = 0.898$, $P < 0.05$). Interestingly, the KYN/TRP ratio was not altered by IFN-gamma (ratio 1. 8±0. 1 vs. 1. 5±0. 2 in Control), indicating that enzyme activity did not increase despite mRNA expression. Tryptamine reduced cell viability (IC50=5. 8mM), independently of IFN-gamma (IC50=5. 8mM). In conclusion, IFN-gamma induces *IDO1* and *WARS*; however, this does not necessarily lead to increased IDO1 activity. The cytotoxic effect of WARS inhibition may be enhanced in cases where IDO1 activity is present. This study highlights the importance of confirming IDO1 activity beyond its expression when designing treatment strategies that combine IDO1 and WARS inhibitors for MTC.

Lipodystrophy in children following hematopoietic stem cell transplantation: analysis of prevalence, risk factors and response to conventional treatments

Annalisa Deodati[1, 2], Maria Elisa Amodeo[1], Valentina Pampanini[3], Giulia Mirra[3], Roberta Iannuzzi[3], Carlo Mariani[3], Elena Inzaghi[3] & Stefano Cianfarani[2 3 4]
[1]Bambino Gesù Pediatric Hospital, IRCCS, Rome, Italy, Oncology and Hematology Unit, Rome, Italy; [2]University of Rome Tor Vergata, Rome, Italy, Department of Systems Medicine, Rome, Italy; [3]Bambino Gesù Pediatric Hospital, IRCCS, Rome, Italy, Endocrinology and Diabetology Unit, Rome, Italy; [4]Karolinska Institute and University Hospital, Stockholm, Sweden, Department of Women's and Children's Health, Stockholm, Sweden

Background
Hematopoietic stem cell transplantation (HSCT) has emerged as a rare cause of acquired lipodystrophy (AL). This condition, characterized by abnormal fat distribution and metabolic diseases, remains poorly described in pediatric patients.
Aim
Primary aim is to explore the incidence of AL in a large cohort of children treated with HSCT. Secondary aims are to evaluate the clinical and metabolic parameters in children with AL following HSCT and to describe the response to conventional management with a long-term follow up.
Methods
Among a total of 583 children with HSCT referred in the last 2 years to the endocrinology department of our tertiary Pediatric Hospital during the routinely follow up, we identified 6 cases (1%) of AL. All patients were monitored at six-monthly clinical visits with metabolic and endocrinological assessments, including leptin levels, during a follow up of 8-15 years. Liver/thyroid ultrasound scans were performed annually.
Results
Our patient group consists of 2 males and 4 females, all of whom were diagnosed with leukemia in childhood. Patients 1, 2, and 4 were diagnosed within the first two years of life. Four of six patients underwent a total body irradiation (TBI) as pre-transplant conditioning and all of them had a history of cutaneous graft-vs-host-disease (GVHD). Patient 3 underwent two HSCT due to disease relapse. The children presented with various metabolic symptoms, including hyperinsulinism, increased fasting and two-hour post-load glucose levels with a variable progression to T2D, severe dyslipidemia, and hepatic steatosis/steatohepatitis. Leptin levels range from a very low value of 1. 16 (patient 1) to a slightly elevated value of 21. 16 ng/ml (patient 6), with a mean value of 11. 8±10. 1 ng/ml. The BMI ranged from -3, 08 to +1, 08 SDS with a mean of +0, 58 SDS. The mean time from HSCT to AL diagnosis was 9. 8 years and the mean age at diagnosis of AL was 15. 25 years (range 9. 7 - 28. 3 years). The conventional treatment with metformin, GLP1 analogues, omega 3 fatty acids and lifestyle interventions showed a poor response. Despite treatment with metformin, patient 3 developed Type2Diabetes (T2D) treated with GLP-1 analogues with a partial response.
Conclusions
AL is a rare and severe complication of HSCT in children, increasingly recognized in association with TBI and GVHD. Long-term follow-up of metabolic health is crucial for early identification and management. Further research is needed to elucidate the risk factors and suggest other therapeutic strategies, including the use of metreleptin to improve metabolic control.

Unraveling the role of autophagy in adrenocortical carcinoma

Sofia B. Oliveira[1 2 3], Marta Alves[1], Diana Sousa[1, 4], Madalena Santos[1], Elisabete Rios[5], Tiago Nunes da Silva[6], Valeriano Leite[6], Laura-Sophie Landwehr[7], Sofia Pereira[1] & Duarte Pignatelli[2 3 8]
[1]Unit for Multidisciplinary Research in Biomedicine - School of Medicine and Biomedical Sciences (UMIB-ICBAS); Laboratory for Integrative and Translational Research in Population Health (ITR), Porto, Portugal; [2]Institute for Reseach and Innovation in Health (i3S), University of Porto, Porto, Portugal; [3]Unidade Local de Saúde de São João (ULS de São João), Departamento de Endocrinologia, Porto, Portugal; [4]Faculdade de Medicina Dentária de Viseu – Universidade Católica Portuguesa (UCP), Viseu, Portugal; [5]Department of Pathology, Faculty of Medicine of the University of Porto, Porto, Portugal; [6]Serviço de Endocrinologia, Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisboa, Portugal, Lisboa, Portugal; [7]Department of Internal Medicine I, Division of Endocrinology and Diabetes, University Hospital, University Würzburg, Würzburg, Germany; [8]Department of Biomedicine, Faculty of Medicine, University of Porto, Porto, Portugal

Adrenocortical carcinoma (ACC) represents the second most lethal endocrine malignancy. This poor prognosis is mainly related to the difficulty in establishing an early diagnosis and the limited efficacy of mitotane which is the only approved pharmacological treatment. Autophagy, a dynamic cellular process that degrades and/or recycle various cellular components, plays a dual role in tumorigenesis by contributing for both cell survival and death. However, its role in adrenocortical tumors (ACT) remains largely unexplored. Therefore, we aimed to assess the expression of LC3, a central autophagy regulatory protein, in ACT, to verify its potential for ACC diagnosis. Additionally, we investigated the role of autophagy in ACC treatment. For that, the expression of LC3 was evaluated by immunohistochemistry (IHC) in paraffin-embedded tissues of ACC ($n = 10$) and adrenocortical adenoma (ACA) ($n = 15$). The LC3 dot-like staining pattern was evaluated by counting LC3-positive cells in tumor hot-spots, with at least 1000 cells analyzed per ACT case. In addition, to explore the role of autophagy in ACC treatment, the ACC cell-line (JIL-2266) was treated with mitotane either alone or in combination with bafilomycin, a late-stage autophagic flux inhibitor. Cellular density and expression of LC3I/II and p62 were assessed by Trypan-Blue assay and Western-Blot, respectively. LC3 dot-like staining was observed in all ACC and in 87% of ACA (13/15). The percentage of LC3 positive cells was significantly higher in ACC compared to ACA (ACC vs ACA: 13% vs 2%, $P<0.001$). Indeed, LC3 protein appears to be an excellent marker to differentiate ACC from ACA, with an area under ROC of 0. 900. *In vitro*, studies showed that mitotane treatment reduced ACC cell density and increased LC3-II levels compared to the vehicle. Moreover, LC3-II expression was even higher when cells were co-treated with mitotane and bafilomycin, compared to mitotane treatment alone. Our results suggest that autophagy play an important role in ACT. Indeed, LC3 dot-like expression, which has been correlated with autophagy induction, was present in most ACT. Notably, LC3 positive cells appear to be associated with malignancy in ACT. Additionally, our findings indicate that mitotane treatment modulates autophagy by the induction of autophagosome synthesis. Future research will validate these results in a larger ACT patients' cohort, along with more detailed mechanistic studies.

JOINT1303

Urinary steroid profiling by GC-MS as a diagnostic tool for evaluating malignancy of adrenocortical tumors – profile fit for purpose?

Jennifer Anton[1], Susan Strange Herrmann[1], Line Rode[1] & Lasse Kristoffer Bak[1]
[1]Copenhagen University Hospital - Rigshospitalet, Glostrup, Department of Clinical Biochemistry, Glostrup, Denmark

Background - Aim
Adrenocortical carcinomas (ACC) are rare but aggressive cancers, and the ability to differentiate between these and benign adrenocortical adenomas (ACA) is essential. Current diagnostic workup in Denmark relies on clinical assessment, functional tests, and imaging, with urinary steroid profiling as a supplementary analysis. However, no consensus exists in terms of which steroids are relevant to include in such a profile. Thus, the first aim of this study was to systematically evaluate the literature to decide on an evidently ideal steroid profile for discriminating between benign and malignant adrenocortical tumors. Secondly, the aim was to perform a retrospective study to evaluate the diagnostic value of the ideal profile.
Methods
Our systematic review was performed according to the Cochrane Collaboration guidelines. The retrospective study was done according to local hospital guidelines including relevant ethical approvals.
Results
Based on our selection criteria, our systematic review identified twelve relevant original studies. Since not all studies evaluated the same steroids or employed comparable experimental approaches, we developed a scoring system to score the apparent significance of individual steroids for inclusion in an ideal profile. With this approach, we identified seven steroids with reported high diagnostic value. Five of the seven identified steroids were already part of our routine GC/MS-generated steroid profile based on 24h urine sampling. To evaluate the diagnostic value of the proposedly ideal profile, we added the two remaining steroids to our current profile and did a retrospective study (Dec 2022 until Oct 2024) employing data from patient medical records combined with historical GC/MS data. Due to recent implementation of GC/MS, the amount of data was limited to two ACC and 41 ACA patients. Thus, we are currently planning a larger prospective study. However, both ACA cases would have been identified employing the ideal profile.
Conclusion
A systematic review revealed seven steroids with high diagnostic potential for ACC. The diagnostic potential of these metabolites was confirmed by a small retrospective study. The retrospective study further indicated that five steroid metabolites were of especially high diagnostic value, however a larger study population is needed in order to confirm these findings.

JOINT2685

Exploration of the genomic clinical correlations of follicular differentiated thyroid cancer through a 56 gene panel next generation sequencing study

Ramesh Bangaraiahgari[1], Rajesh Bangaraiahgari[1], Laxmi Narayana Sripuram[1], Amith Anshuli Dubey[1], Kundana Sree K M[1], Ramakanth Bhargav Panchangam[2] & Chakrapani Bangaraiahgari[3]
[1]TRR Institute of Medical Sciences, Hyderabad, India; [2]BGH, Vijayawada, India; [3]Chakri Neuro Hospital, Nizamabad, India

Background
Follicular differentiated thyroid cancer (FDTC) is the most common endocrine cancer, globally. Next-generation sequencing (NGS) in thyroid cancer allows for high-throughput genetic sequencing with quick turnover. NGS Studies on papillary thyroid cancer are scanty from South East Asia. This study harnesses the power of Whole Exome Next-Generation Sequencing (WES) to unravel pan-exomic mutations in thyroid cancer samples. The primary objectives include correlating genomic changes with clinicopathologic features and unraveling the intricate mechanisms steering disease onset and progression.
Methods
We selected 22 FDTC cases. All of them underwent total thyroidectomy with neck dissection as needed. Tumour tissue samples extracted and paraffin embedded, were taken from exvivo specimens. Sample processing, DNA extraction, cDNA preparation and PCR amplification was performed. Mutation analysis with a thyroid cellular pathway specific 56-gene mutation panel using real-time PCR and ThyroSeq v2 on the Ion Torrent PGM sequencer was employed. Common single nucleotide polymorphisms (SNPs) with a minor allele frequency of >0.05 were excluded. Mutations were also manually checked using the Integrated Genomics Viewer v2. 4. 10 to filter out false positives.
Results
The analysis found mutations commonly in BRAF (16), CDKN2A (10), NRAS (7), PI3KCA (8), RET (4), RAS (13) and TP53 (3) genes. The common mutations found in the samples was RET (M918T), NRAS (Q61R), BRAF (V600E) and missense mutation in TP53 (c. 217 – c. 1178). A mutation has also been identified in KMT2D gene in two of the patient samples. BRAF, CDKN2A, PI3KCA were more common in papillary cancer. RAS, NRAS, RET mutations were common in follicular cancer. TP53 and KMT2D were seen only in poorly differentiated cancer.

Conclusion
NGS appears to be helpful in risk assessement, prognostication and study of tumour biology in clinical setting. More prospective studies are needed for its routine use at clinical level.

Clinical implications of measuring muscle mass by computed tomography in neuroendocrine tumor patients

Mariana Perelmuter[1], Assaf Buch[2, 3], Aviad Rabinowich[4, 5], Elena Izkhakov[2, 3], Yona Greenman[2, 5], Ido Wolf[5, 6], Ravit Geva[5, 6] & Esther Osher[2, 5]
[1]Tel Aviv Sourasky Medical Center, Department of Nutrition and Dietetics, Tel Aviv, Israel; [2]Tel Aviv Sourasky Medical Center, Institute of Endocrinology, Metabolism, and Hypertension, Tel Aviv, Israel; [3]Ariel University, Department of Nutrition Sciences, School of Health Sciences, Ariel, Israel; [4]Tel Aviv Sourasky Medical Center, Department of Radiology, Tel Aviv, Israel; [5]Tel Aviv University, Faculty of Medicine, Tel Aviv, Israel; [6]Tel Aviv Sourasky Medical Center, Department of Oncology, Tel Aviv, Israel

Introduction
Sarcopenia is characterized by loss of skeletal muscle mass and quality, numerous studies have reported an association between sarcopenia and poor outcomes in various malignancies. There is limited data regarding lean body mass status in patients with neuroendocrine tumors (NETs). Skeletal muscle mass index (SMI), measured by computed tomography (CT) scans, is considered a gold standard for determining body composition in diagnosing sarcopenia.
Aim
To measure the prevalence of sarcopenia in patients newly diagnosed with intestinal and pancreatic NETs, evaluate its association with patient characteristics, and explore its potential impact on overall survival.
Methods
This retrospective cohort study reviewed the medical records of 145 patients diagnosed with intestinal or pancreatic NETs at Tel Aviv Sourasky Medical Center (TLVMC) from 2005 to 2020. CT scans, taken near the diagnosis date, were analyzed for the presence of sarcopenia. Abdominal CT slices, which displayed the cross-sectional area of Lumbar vertebra 3 (L3), were analyzed using Coreslicer software based on established cutoffs for sarcopenia diagnosis. Statistical methods, including survival analysis and Cox regression, were used to assess the adjusted risk factors of sarcopenia prevalence on overall survival.
Outcomes
Sarcopenia was identified in 41% of the cohort, with a significant association between sarcopenia and older age ($P = 0.013$). Sarcopenic patients also exhibited a higher prevalence of cardiovascular disease (19% vs. 5.8%, $P = 0.014$) and lower median body mass index (BMI: 25.3 vs. 27.5 kg/m^2, $P = 0.002$). Despite these associations, sarcopenia did not emerge as a significant predictor of overall survival. Weight loss was present in 17% of patients (median weight loss of 10.5 kg, IQR 6-17 kg), with 60% of those experiencing weight loss also diagnosed with sarcopenia. Additionally, the moderate correlation between BMI and skeletal muscle index ($R^2 = 0.44$, $P < 0.001$) highlights the limitations of BMI in reflecting muscle depletion in this cohort. These findings emphasize the need for muscle mass evaluation independent of BMI.
Conclusions
Sarcopenia is a prevalent and age-associated condition in NET patients, often coexisting with normal or elevated BMI. Its detection is crucial for early nutritional intervention, though it may not independently predict survival in heterogeneous NET populations. These findings underscore the importance of standardized sarcopenia assessment at diagnosis and encourage further research into its prognostic value in homogeneous NET subgroups.

Selective early genetic screening for targetable gene fusions in papillary thyroid cancer (PTC) tissues

Rafał Fyda[1], Mateusz Obal[2], Bartosz Partyński[2], Bartosz Domagała[2], Aleksander Konturek[3], Alicja Hubalewska-Dydejczyk[4] & Malgorzata Trofimiuk-Muldner[4]
[1]Jagiellonian University Medical College, Students' Scientific Group at the Chair and Department of Endocrinology, Krakow, Poland; [2]University Hospital in Krakow, Endocrinology, Oncology Endocrinology, Nuclear Medicine and Internal Medicine Clinical Department, Krakow, Poland; [3]Jagiellonian University Medical College, Department of Endocrine Surgery, Krakow, Poland; [4]Jagiellonian University Medical College, Chair and Department of Endocrinology, Krakow, Poland

PTC is characterized by a relatively low frequency of somatic mutations compared to other carcinomas, with BRAF-mutant tumors being the most common. Gene fusions are present in 15% of PTCs. PTC is associated with a very good prognosis, there are infrequent cases of recurrent or metastatic disease that require systemic therapy targeted to tumor's genomic characteristics. Given the risk of DNA degradation, genetic testing of paraffin-embedded tissue should ideally be performed as early as possible. High costs of these procedures make universal testing unfeasible. Patients who may benefit from genetic characterization of their tumor need to be preselected early, long before the tyrosine kinase inhibitors (TKI) therapy may be required. This is the preliminary study on selective genetic screening for targetable somatic mutations in PTC patients.
Material and Methods
Since mid-2022, we have performed next-generation sequencing (NGS) of tumor tissues from PTC patients with extensive nodal involvement, distant metastases, early recurrence, or requiring repeated surgeries. 40 such patients (15 M, 25 F, median age 45) were included. In each case, NGS was conducted to detect pathogenic variants of *AKT1, ALK, BRAF, CTNNB1, DDR2, EGFR, ERBB2, FGFR1, GNAS, HRAS, IDH1, IDH2, KRAS, MAP2K1, MET, NRAS, PIK3CA, RET, ROS1* and fusions of *ALK, AXL, BRAF, CCND1, EGFR, FGFR1, FGFR2, FGFR3, MET, NRG1, NTRK1, NTRK2, NTRK3, PPARG, RAF1, RET, ROS1, THADA*. The analysed variables included age, tumor characteristics (TNM, extranodal extension), categorised lymph node metastases size, repeated surgery, and remission status at latest follow-up. Statistical analyses were performed using the Mann-Whitney U test for continuous variables, and Chi-square or Fisher's exact tests for categorical variables.
Results
Among the 40 patients, 11 (27.5%) were identified with gene fusions [*CCDC6(1)-RET(12), NCOA(4)-RET(12), CCDC6(1)-RET(12), CCDC6(1)-RET(12), ETV6(4)-NTRK3(14), ERC1(17)-RET(12), TMEM9(5)-BRAF(9), NCO4(7)-RET(12), NCOA4(6)-RET(12), SQSTM1(5)-NTRK1(10)*] (2 M, 9 F; median age 35). In the no-fusion group (13 M, 16 F, median age 47), BRAF V600E was found in 22 patients, in 6 cases no pathogenic variants were detected, one sample was degraded. The fusion-positive group was significantly younger ($P = 0.007$). Lymph node metastases larger than 10 mm were more common in fusion-positive subjects ($P = 0.009$). No other significant differences in clinical course of PTC were observed.
Conclusions
Younger PTC patients with massive lymph node involvement, especially larger nodes, should be prioritized when considering the genetic screening of tumor tissues. Early genetic testing in these patients may identify actionable mutations or fusions, enabling timely targeted therapies.

JOINT338

Identifying the burden of hypothalamic syndrome in paediatric patients with craniopharyngioma in a single specialised centre cohort

Katherine Francis[1], Rachel Perrow[1], William Singleton[1], Rachel Cox[1] & Elizabeth Crowne[1]
[1]Bristol Royal Hospital for Children, Bristol, United Kingdom

Background
Craniopharyngiomas are benign suprasellar tumours, approximately 4% of childhood brain tumours. Despite their WHO grade I classification, craniopharyngiomas have a high burden of morbidity due to their location and treatment-related sequelae, including Hypothalamic Syndrome (HS). HS is a rare but significant disorder, caused by tumour and/or treatment related injury to the hypothalamus, consisting of hypo/hyperphagia, hypothalamic obesity, pituitary dysfunction, sleep disturbance, behavioural changes and temperature disturbance, causing morbidity and reduced quality of life. This single specialised centre cohort study evaluates the burden of hypothalamic syndrome in paediatric patients with craniopharyngioma.

Method
A case notes review was undertaken for those diagnosed with craniopharyngioma <16 years old identified on the cancer registry at a single regional centre from 1/1/2014 to 1/1/2024. A data proforma was created after discussion with the multi-disciplinary team.
Results
19 patients were identified, median age at diagnosis 8 years (IQR 5-10 years), males: 10/19, 52. 6%, females 9/19, 47. 4%. All patients underwent neurosurgery, 7 recieved proton radiotherapy and 5 recieved photon radiotherapy. Patients were followed up for a median time of 6 years 3 months (range 1. 5-10. 3 years). All patients had at least 2 hormone deficiencies (growth hormone and adrenocorticotropic hormone deficiencies). 15/19 had four or more hormone deficiencies. 57. 9% of patients with craniopharyngioma had ≥3 symptoms of hypothalamic dysfunction. All patients were asked about appetite and hunger, and 8 patients reported hyperphagia, and 2 patients reported hypophagia. Of those with hyperphagia, half ($n = 4$) were diagnosed with hypothalamic obesity. Thirteen patients (68. 4%) reported sleep issues mainly difficulty falling asleep and snoring. Temperature dysregulation was only documented as having been discussed in two patients, one who reported feeling cold. Behavioural issues were documented as having been discussed in 17 patients (89. 5%), with 8 patients having behavioural issues, manifesting as anxiety in three patients. Mortality in this patient group was 0% at the time of this service evaluation. There was a significant burden of HS in this group, with the median number of features of hypothalamic syndrome 3, ranging from 1-5 symptoms of hypothalamic syndrome out of a total possible six features of HS.
Conclusion
Patients with craniopharyngioma are at very high risk of hypothalamic syndrome, necessitating close multidisciplinary team follow-up with specific questions about HS. This service evaluation identified areas requiring improvement in diagnosis and monitoring, including temperature dysregulation and behaviour. Implementation of a standardised hypothalamic syndrome checklist could improve recognition and monitoring of these challenging late effects.

Multiple endocrine neoplasia 2B in two siblings with short stature, an uncommon association

Ana Vieites[1], Estefanía Marini[1], Dayan Troncoso Pimienta[1], Eugenia Elías[2], Gabriela Sansó[1], Maria Gabriela Ballerini[1], Andrea Arcari[1] & Ana Keselman[1]
[1]Centro de Investigaciones Endocrinológicas "Dr. César Bergadá" (CEDIE) CONICET, FEI, Hospital de Niños Ricardo Gutiérrez, División de Endocrinología, Buenos Aires, Argentina; [2]Hospital de Niños Dr Ricardo Gutiérrez, Cirugía, Buenos Aires, Argentina

Introduction
Multiple endocrine neoplasia (MEN) is an autosomal dominant syndrome produced by mutations of the RET proto-oncogene and is characterized by a predisposition to the development of endocrine tumors. Subtype 2B (MEN 2B) is associated with the presence of medullary thyroid carcinoma (100%), pheochromocytoma (50%), mucosal neuromas, gastrointestinal symptoms, ocular alterations, marfanoid habitus, and tall stature.
Patients
Index case: Male, 3 years of age, referred for short stature. History of chronic constipation. Weight 15. 4 kg (pc 50-75), height 89. 5 cm (-2. 05 SD). Physical examination revealed everted upper eyelids, prominent lips, mucosal neuromas on the tongue, flat nose, large rotated ears, relative macrocephaly and body disproportion. Initial routine studies showed growth factors, thyroid profile, karyotype and growth hormone stimulation test, within normal limits. His 1-year-old sister was also referred for short stature (-3. 08 SD). Clinical examination showed prominent lips. Their mother had prominent lips too, and mucosal neuromas on the tongue. With clinical suspicion of MEN2B, calcitonin, thyroid ultrasound and RET gene study were requested. Total thyroidectomy was performed on the index case his sister and his mother without complications. Pathology reports medullary thyroid carcinoma in the three cases. The mother begins follow-up at an adult center.
Conclusions
Although one of the features that characterizes MEN2B is tall stature, cases of pediatric patients with short stature have been reported in the literature. Tha cause is still unknown. For this reason, it is important to keep it in mind in the presence of clinical stigmata as a differential diagnosis, since early prophylactic thyroidectomy (before one year of age) substantially modifies the prognosis of the disease.

	Calcitonine	Thyroid ultrasound	RET molecular study
Index case	9.47 pg/ml (RV: <11)	Solid nodular image 4×2×2 mm with microcalcifications	
Sister	37.2 pg/ml (RV: <11)	Normal	Phatogenic Variation Met918Thr Exon16 RET
Mother	593 pg/ml (RV: <5)	multinodular goiter with adenomegaly in the central compartment

Serum and cerebrospinal fluid hCG leves in children with beta hCG producing germ cell tumors

Yanhong Li[1], Xian-Jun Shi[1], Xian Wu[1], Min-Lian Du[1], Liu-Lu Xie[1] & Hua-Mei Ma[1]
[1]The First Affilated Hospitl of Sun Yat-Sen University, pediatric endocrinology, Canton, China

Objective
A retrospective study was performed in children with beta-hCG-producing germ cell tumors (GCTs) under 18 years of age to evalute the levels of serum as well as cerabral spinal fluid(CSF) hCG.
Methods
From 2000 to 2023, 988 GCTs under 18 yeas of age were diagnosed in our hospital, in whom 60 children were beta-hCG-producing GCTs and were enrolled in our study. Serum hCG levels and hCG levels in cerabral spinal fluid(CSF) hCG were collected and comparaed between intracrinial and extracranial pateints.
Results
In 60 children, 53 males (88. 3%) and 7 females (11. 7%). The median age at presentation was 8. 7 years (range: 3. 2–14. 8 years). 49 were intracranial GCTs, while 11 were extracranial. All of the children with intracranial GCTs had increased levels of hCG in CSF, and CSF hCG levels had positive correlationship with serum hCG levels ($R=0.81$, $P<0.01$), however, 14 cases (32. 6%) exhibited CSF hCG levels lower than serum hCG levels at the same time. In children with extracranial GCTs, no one had increased hCG levels in CSF (<3 mIU/mL). No statistically significant differences of serum hCG levels were found between genders ($P=0.90$) or between intracranial and extracranial groups ($P=0.90$). Both serum and CSF hCG levels be found fluctuated during the course before treatment, occasionally dropping below the normal range (3 mIU/mL). 21 patients complished pathological diagnosis, in whom 10 were germinoma, 11 were non germinoma GCTs(NGGCTs). In 10 pathological diagnosed germinoma, 5 had serun and/or CSF hCG excreed 50mIU/mL, while in 11 NGGCTs only 6 had hCG levels more than 50mIU/mL.
Conclusion
hCG-secreting GCTs are more prevalent in males in children. Serum and CSF hCG level are valuable for diagnosis and localization of the tumors. Elevated CSF hCG levels reveal intracranial GCTs, however, CSF hCG levels lower than serum hCG can not rule out CNS lesions. Serum/CSF hCG levels are not always consistent with pathological diagnosis of HCG secreting GCTs in children. Nevertheless, due to the fluctuations of hCG levels during the course, multiple sampling at different time points may be necessary, espacially when the test of hCG was negtive.

JOINT3392

Prevalence and morphology of pineal gland calcifications in children with cranial germ cell tumors are different from normal chidren aged 0-15 years

Yanhong Li[1], xian wu[1], Bo Jiang[1] & Min-Lian Du[1]

[1]The First Affilated Hospitl of Sun Yat-Sen University, pediatric endocrinology, Canton, China

Background and Objectives
Pineal gland calcification is rare in children under 3 years old and the prevalence increase with age. However, in children with pineal region germ cell tumors (GCT), pineal gland calcification is common and may has features that be different from physiological calcifications. Prevalence as well as the characteristics of pineal gland calcification by head CT images in children with pineal region GCTs were studied and were compared with normal children aged 0-15 years.
Methods
During the period 2015-2023, 2749 normal children and 32 children with pineal region GCTs, who had head CT images and aged 0-15 years were enrolled and were analysed.
Results
In normal children, the incidence of pineal gland calcification was 10. 8%. The prevalence was 1. 1% in children aged 6 years and below, while 23. 2% in children aged 7-15 years ($P < 0.001$), and was 6. 2% in boys and 13% in girls respectively ($P < 0.001$). In children with pineal region GCTs, 96. 7% found pineal calcifications, more than normal children ($P < 0.001$). Pineal calcifications in GCTs had former significantly lower than that in normal children, and had special morphological features. The majority of pineal gland calcification in normal children was patchy (72. 7%), while in children with pineal region GCTs, the calcification morphology was mainly punctate + patchy (58. 6%) ($P < 0.001$), and all of the latter's calcification patterns were patchy or mixed.
Conclusion
In children aged 0-15 years, Physiologic pineal gland calcifications become increasingly prevalent with advancing age. Pineal gland calcification in children aged 6 and below is very rare, and attention should be paid to its pathological status. Compared with normal children, children with pineal region GCTs are more likely to develop pineal gland calcification, with a more diverse and extensive calcification morphology. When diagnosing intracranial germ cell tumors and brain MRI cannot accurately locate, cranial CT may provide key clues.

Co-occurrence of burkitt lymphoma and follicular thyroid adenoma in a pediatric patient: a rare case report

Dovile Denaite[1, 2], Emilija Tumenaite[3], Aiste Stonyte[3] & Ruta Navardauskaite[1]
[1]Lithuanian University of Health Sciences, Department of Endocrinology, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Department of Endocrinolgy, Kaunas, Lithuania; [3]Medical academy, Lithuanian University of Health Sciences, Kaunas, Lithuania

Background
Follicular thyroid adenomas, though benign, are rare in pediatric populations and may pose diagnostic and therapeutic challenges due to their potential overlap with malignancies. Burkitt lymphoma, a high-grade B-cell non-Hodgkin lymphoma, accounts for 30% of pediatric lymphomas and typically presents with rapidly enlarging lymph nodes or extranodal masses. The co-occurrence of these two distinct conditions in a pediatric patient is exceptionally rare and has not been previously reported, underscoring the need for careful evaluation and a multidisciplinary approach to management.
Clinical Case
We report the case of an 8-year-old male presenting with a one-year history of progressive cervical lymphadenopathy. Clinical examination revealed a 3. 5 cm firm, non-tender, poorly mobile submandibular lymph node conglomerate on the right side, along with smaller lymph nodes in the anterior cervical and submandibular regions bilaterally. The patient exhibited no systemic symptoms of infection or malignancy. Family history revealed malignancies on the maternal side, including intestinal, lung, and uterine cancers, raising concerns about genetic predispositions. Initial investigations, including ultrasonography and fine-needle aspiration biopsy (FNAB) of a thyroid nodule, suggested hyperplastic changes. Biochemical findings were significant for suppressed TSH: <0.01 mU/l (N 0. 4–3. 6) with elevated FT4: 25. 99 pmol/l (N 7. 87–20. 3), consistent with thyrotoxicosis. Despite antibiotic therapy, the lymphadenopathy persisted, prompting further imaging and evaluation. Subsequent histopathological analysis of a resected thyroid nodule and adjacent lymph nodes revealed the coexistence of Burkitt lymphoma and follicular thyroid adenoma, confirmed by immunohistochemical studies. The patient underwent hemityroidectomy and lymphadenectomy followed by chemotherapy for Burkitt lymphoma. Thyroid hormone replacement therapy was initiated postoperatively, and the patient remains under close endocrinological and oncological follow-up.
Discussion
This case underscores the importance of a multidisciplinary approach in managing pediatric thyroid nodules and lymphadenopathy, particularly when the presentation deviates from typical patterns. The coexistence of Burkitt lymphoma and follicular thyroid adenoma highlights the need for thorough diagnostic workup, including FNAB, imaging, and histopathological confirmation. Additionally, the potential link to familial cancer syndromes, such as *DICER1* mutation, warrants further investigation in this patient.
Conclusion
This rare case emphasizes the diagnostic and therapeutic challenges posed by concurrent thyroid and lymphoid pathology in children. Awareness of such presentations can aid in timely diagnosis and optimized care strategies.

Overweight and obesity in survivors of pediatric brain tumor

Leonor Pinto[1], Carlos Marques[1], Catarina Regala[1], Sofia Avelino[1], Sofia F. Silva[1], Daniela Cavaco[1], Sara Donato[1], Sara Pinheiro[1], Margarida da Silva Vieira[1] & Joana Simões Pereira[1]
[1]Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisboa, Portugal

Introduction
Brain tumors are the most common solid tumor in children. These patients may have an increased risk of obesity due to the location of the tumor (hypothalamus) or by the oncological therapies.
Objectives
To characterize a population of brain tumor survivors in pediatric age using body mass index to assess risk factors of overweight/obesity.
Methods
Retrospective analysis of the medical records of patients diagnosed with a brain tumor in pediatric age, followed up in the Endocrinology Late-effects clinics of our center. The statistical analysis was performed using SPSS software.
Results
We obtained a sample of 181 patients, 103 (57%) of whom were male. The median age at the diagnosis of brain tumor was 5. 7 (0-17. 8) years. The most prevalent tumor types were astrocytomas (38. 7%) and medulloblastomas (24. 3%). The most common locations were the diencephalic sellar/suprasellar region (38. 9%) and the posterior fossa (36. 7%). Of the 181 patients, 74. 6% underwent surgery, 74% received chemotherapy and 53% received central nervous system radiation, with a median dose of 54Gy (17. 2-60). At least one endocrinopathy was present in 64. 6% of patients, with the most prevalent being GH deficiency (45. 3%), hypothyroidism (37%), and pubertal alterations (28. 2%). At the start of follow-up, 62. 9% of the patients were of normal weight/underweight, 13. 3% were overweight, and 23. 8% were obese. At last follow-up, 50. 2% were of normal weight/underweight, 27. 1% were overweight, and 22. 7% were obese. Regarding the patients who had already reached the adulthood in the last follow-up ($n = 101$), 19 (18. 81%) were obese – 14 (13. 86%) had class I obesity, 3 (2. 97%) had class II obesity, and 2 (1. 98%) had class III obesity. The median follow-up was 9 (0-29) years. The patients were divided into two groups (according to status in the last appointment): group A, with overweight/obesity, and group B, with normal weight/underweight. No statistically significant differences were identified between the groups regarding sex, age at diagnosis, and tumor location. Group A included significantly more patients who had undergone brain radiation ($P < 0.001$). This group also had a significantly higher number of patients with endocrinopathies ($P = 0.006$), with a notably greater number of patients having pubertal changes and hypothyroidism.
Conclusions
At the end of follow-up, 49. 8% of the patients had overweight or obesity. With this work we highlighted risk factors for weight gain in these patients. It's important to identify those at higher risk in order to adopt strategies of weight control in these patients.

Introduction
The use of GnRH analogues aims to protect ovarian function during chemotherapy. While its effectiveness remains controversial, it may help reduce the risk of premature ovarian failure. However, its long-term impact on spontaneous pregnancy rates is still uncertain.
Objective
To determine the ovarian function and follicular reserve in patients who received treatment with GnRH analogues (GnRHa) during chemotherapy.
Population and Methods
Patients with a history of oncological disease in the childhood-juvenile stage treated at the Professor Alejandro Posadas National Hospital were studied between 11/01/2020 and 10/31/2022 by determining AMH, antral follicle count and FSH levels. The participants were recruited during the follow-up of cancer treatment. Descriptive statistics were presented.
Results
Of 31 pubertal patients, 16 completed the analogue treatment, 9 did not complete the treatment, and 6 did not receive it. The median age at the start of oncological treatment was 13. 1 years (8. 1–17. 6), at the end 14. 9 years (10. 2–20. 3) and at evaluation 23. 1 years (14. 8–31. 9). The median follow-up period was 8. 4 years (5–20. 3). The diagnosis was: 15 ALL; 4 AML; 7 Hodgkin's Lymphoma; 3 Non-Hodgkin's Lymphoma; 2 Ovarian Dysgerminoma. 7 patients had FSH values $\geq$25 mIU/mL (3 completed GnRHa treatment, 2 had incomplete treatment, and 2 did not receive it). 3 evidenced ALL (20%); 3 AML (75%); 1 Hodgkin's Lymphoma (14. 3%). 10 patients had AMH values $<$1 ng/ml (3 completed GnRHa treatment, 3 incomplete treatment and 4 did not receive it). 4 evidenced ALL (26. 7%); 4 AML (100%); 1 Hodgkin lymphoma (14. 3%); 1 ovarian dysgerminoma (50%). AMH levels $<$1 ng/mL and/or FSH $\geq$25 mIU/mL were observed in 3 of 13 with chemotherapy (QMT) alone, 1 of 6 with QMT + radiotherapy (RT), 1 of 5 with QMT + surgery (CX), 1 with QMT + BMT (bone marrow transplant) + CX, and all 4 with QMT + RT + BMT The median AMH was 2. 1 ng/ml (0. 1-4. 8) for those with complete GnRHa treatment, 1. 9 ng/ml (0. 1-6. 5) for incomplete treatment, and 0. 7 ng/ml (0. 1-2. 5) for no treatment. The median FSH was 7. 7 mUI/ml (4. 9-200) with complete treatment, 28. 7 mUI/ml (5. 1-70) with incomplete treatment, and 14. 0 mUI/ml (7. 7-123. 3) without treatment.
Conclusion
There does not seem to be any differences in ovarian function or follicular reserve in these cases; however, Conclusions should be drawn based on a sufficient sample size. The impact on fertility would be closely related to the therapy received.

Genomic view of poorly diffentiated thyroid cancer as a bridge between well differentiated and anaplastic thyroid cancer

Sushmitha Sree Mekala[1], Ramakanth Bhargav Panchangam[2], Ramesh Bangaraiahgari[1], Rajesh Bangaraiahgari[1], Laxmi Narayana Sripuram[1], Varshitha Eadula[1], Amith Anshuli Dubey[1], Kundana Sree K M[1] & Vidya Paboju[1]
[1]TRR Institute of Medical Sciences, Hyderabad, India; [2]BGH, Vijayawada, India

Introduction
Poorly differentiated thyroid cancer (PDC) is a relatively infrequent form of differentiated thyroid cancer with intermediate prognosis between well differentiated (WDTC) and anaplastic cancers (ATC). But, this finding is debatable in literature. Genomics is the one of definitive modalities to clarify this moot point. ATC tends to express P53 and KMT2D mutations frequently, while WDTC have no such mutations. Similar Indian studies are scanty in PDC. In this context, we set out study the prevalence of these somatic mutations in surgical tissue samples of PDC.
Material and Methods
This prospective study was conducted on surgically managed thyroid cancer patients. Institutional ethical committee approval was obtained. Diagnosis was based on biochemical confirmation, imaging, fine needle aspiration cytology and later confirmed by histopathology. We selected 15 PDC, 4 ATC and 40 WDTC cases. Tumour tissue samples were taken from ex-vivo thyroidectomy specimen within operation theatre. After appropriate processing of samples, DNA extraction, cDNA preparation, PCR amplification, application of 2 sets of Primers were performed as part of mutational analysis of P53 and KMT2D genes.
Results
Heterozygous mutations in KMT2D gene and missense mutation in P53 gene were found in 4/15 (26. 6 %) and 7/15 (45%) of PDC cases respectively. In ATC, KMT2D mutations were seen in 3/4 (75%) and 4/4 (100%) cases. None of these gene mutations were seen WDTC cases.
Conclusions
Our study shows a distinct correlational pattern of mutations in KMT2D and P53 genes suggesting a causative linkage between the gene function and cancer cell differentiation. Further, PDC appears to be intermediate in mutation frequency, with ATC on higher side of scale. Though our results are not robust, it provides a platform for larger multi-institutional studies to justify this observation in future.

Menin expression in parathyroid tumors of patients with multiple endocrine neoplasia type 1 phenocopies

Elizaveta Mamedova[1], Ekaterina Bondarenko[1], Zhanna Belaya[1] & Galina Melnichenko[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Patients with two or more tumors associated with multiple endocrine neoplasia type 1 (MEN1) harboring no *MEN1* mutations are designated as MEN1 phenocopies (phMEN1); most of them have a combination of pituitary adenomas and primary hyperparathyroidism (PHPT).
Aim
To evaluate menin expression in parathyroid tumors of patients with phMEN1 in comparison with parathyroid tumors of genetically confirmed MEN1 (gMEN1) and sporadic PHPT (sPHPT).
Material and methods
Immunohistochemical staining for menin (Abcam, ab2605, UK) was performed on FFPE parathyroid tumor samples from eight patients with phMEN1 (6–PHPT+ acromegaly, 1 – PHPT + Cushing's disease, 1 – PHPT + prolactinoma), nine patients with gMEN1 and 10 patients with sPHPT. Menin expression was evaluated as either nuclear or cytoplasmic or both (positive or negative, positive expression was scored as absent, weak, intermediate or strong).
Results
phMEN1 group included 2 males, 6 females (2 atypical parathyroid adenomas in males and parathyroid adenomas in all females). gMEN1 group included 2 males, 7 females (8 – parathyroid adenomas, 1 - hyperplasia). sPHPT included 2 males, 8 females, all had parathyroid adenomas. Groups did not differ in sex, calcium and parathyroid hormone levels. phMEN1 patients were older than gMEN1 (P = 0, 000056). Nuclear menin expression was positive in 6 phMEN1 (2 – weak, 3 – intermediate, 1 - strong), 0 gMEN1, 6 sPHPT (2 – intermediate, 4 - strong). Cytoplasmic menin expression was positive in 4 phMEN1 (1 – weak, 3 - intermediate), 1 gMEN1 (weak), 7 sPHPT (4 – weak, 3 - intermediate). phMEN1 and gMEN1 groups, and sPHPT and gMEN1 groups differed in nuclear menin expression (p=0, 0085 and p=0, 0050 respectively). gMEN1 and sPHPT groups differed in cytoplasmic menin expression (p=0, 0094). phMEN1 and gMEN1 groups, and sPHPT and gMEN1 groups differed in nuclear and/or cytoplasmic menin expression (p=0, 045 and p=0, 0094 respectively). Despite no statistically significant difference of menin expression between phMEN1 and sPHPT groups, it was noteworthy that menin expression was stronger in sPHPT and was weaker in phMEN1.

Conclusion
Menin expression is preserved in parathyroid tumors of phMEN1 in comparison with gMEN1, though it seems to be attenuated compared to sporadic parathyroid tumors. This may indicate that different mechanisms are involved in parathyroid tumorigenesis in phMEN1.

Targeted management of recurrent paraganglioma with SDH-B mutation: a case report

Diogo Brandão Neves[1], Vítor Valente[2], Andreia Pires[3], Cláudia Amaral[1] & Daniela M. Soares[1]
[1]Centro Hospitalar e Universitário de Santo António, ULSSA, Division of Endocrinology, Porto, Portugal; [2]Centro Hospitalar e Universitário de Santo António, ULSSA, Surgery Department, Porto, Portugal; [3]IPO Porto, Radiation Oncology Division, Porto, Portugal

Paragangliomas are rare neuroendocrine tumors that can arise in various locations throughout the body. While typically benign, these tumors can exhibit aggressive behavior and malignant potential, particularly when associated with genetic mutations. They can secrete catecholamines, leading to a range of adrenergic symptoms which further complicates their diagnosis and management. One of the most clinically significant mutations linked to hereditary paragangliomas involves the succinate dehydrogenase subunit B (SDH-B) gene. Patients with these mutations are at higher risk for malignancy and tumor recurrence, presenting unique challenges. We report the case of a 41-year-old patient with an abdominal paraganglioma harboring an SDH-B mutation, initially treated in January 2022 with both biochemical and imaging evidence indicating complete response. In August 2024, the patient presented with adrenergic symptoms and biochemical evidence of recurrence and was started on phenoxybenzamine. A thoracoabdominal-pelvic CT scan showed no signs of disease, but a subsequent gallium PET scan revealed a focal area of intense abnormal uptake in the posterior region of the left acetabulum, suggestive of metastatic paraganglioma. The case was discussed in a multidisciplinary team meeting, with the option for a targeted approach, based on the most recent clinical guidelines. Surgical intervention by the orthopedic team was deemed unfeasible due to the difficulty in accurately locating the lesion intraoperatively, and the only remaining surgical option- a total hip replacement—was associated with significant morbidity. Similarly, image-guided intervention was ruled out due to the risk of sciatic nerve injury. Subsequently the case was referred to radiation oncology, where **stereotaxic radiotherapy** was selected as the preferred treatment modality. This case highlights the elevated risk of recurrence in patients with SDH-B mutations and underscores the complexities involved in managing them, particularly due to the size, location, and metastatic potential of the lesions. A multidisciplinary approach is critical, as decision-making often requires input from various specialties to determine the most appropriate treatment plan. In patients with solitary metastases and low tumor burden, local control is typically the first-line option. Furthermore, this case emphasizes the importance of considering stereotaxic radiotherapy in the treatment of paragangliomas, a modality that may be underutilized.

Thyroid core-needle biopsy. the first 569 results in Romania

Emin Mammadov[1], Dana Terzea[2] & Mihai Ciprian Stoicea[1]
[1]Regina Maria Private Healthcare Network, Bucharest, Romania; [2]Onco Team Diagnostic, Bucharest, Romania

Background
There are two types of thyroid nodule biopsy: fine-needle aspiration (FNAB) and core-needle (CNB). Multiple studies mainly from Eastern Asia demonstrate safety and efficacy of CNB, however it is very rarely used in Europe.
Methods
Retrospective analysis of the first 569 thyroid nodule CNBs performed in Romania. All CNBs were performed using 18G semi-automatic biopsy instruments. We used the Korean Thyroid Association reporting system (KTA-CNB) for histology reports.
Results
Of 569 CNBs, there were only 5 non-diagnostic results (0. 9%), 34 category III results (6%) and 63 category IV results (11%). Among nodules which previously underwent FNAB, CNB offered a conclusive result (either benign or malignant, KTA II, V and VI categories) in 80% of Bethesda 1, 80% of Bethesda 3, 68. 4% of Bethesda 4 nodules. There were no non-diagnostic results in these nodules. We performed on average 2. 2 passes per lesion. There were no major complications (none of complications required hospitalisation), some minor adverse events were limited to bruising, perithyroidal hematoma and pain during or after procedure. Four patients had intrathyroidal hematoma, three patients developed transitory hoarseness which resolved spontaneously in 20-90 minutes.
Conclusion
The CNB is a safe and reliable diagnostic procedure for thyroid nodules. It offers very low chance of non-diagnostic results, lower chance of inconclusive results with a better stratification of risk between different subcategories (III a-d, IV a-c). CNB is a procedure which improves patient experience by reducing the number of procedures needed to make a clinical decision. It is a useful and cost-efficient tool, especially in the absence of molecular testing. CNB offers additional advantage of immunohistochemistry in cases suspected for medullary thyroid cancer, lymphoma or metastatic lesions.

Periprostatic adipose tissue (PPATs) adipokine profile highlights lipocalin-2 as a potential key player in the pathophysiological association between PPAT, obesity and prostate cancer microenvironment

Ignacio Gil-Duque[1, 2], Jesús M. Pérez-Gómez[1, 2], Antonio Prats-Escribano[1, 2], Miguel A. Núñez-Santos[1, 2], Fernando Mata-Ordoñez[1, 2], Manuel D. Gahete[1 2 3], Rocío Guzmán-Ruiz[1 2 3], María M. Malagón[1 2 3] & Raúl M. Luque[1 2 3]
[1]Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Reina Sofia University Hospital (HURS), Córdoba, Spain; [2]Department of Cell Biology, Physiology, and Immunology, University of Cordoba, Córdoba, Spain; [3]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Córdoba, Spain

Prostate cancer (PCa) is a hormone-dependent tumor and one of the most prevalent cancers in men worldwide. PCa progression is influenced by its interaction with the surrounding tumor-microenvironment, highlighting the role of periprostatic adipose tissue (PPAT), which is a mediator of PCa microenvironmental regulation through the secretion of bioactive molecules (e. g., adipokines). Yet, the nature/influence of this complex secretion derived from PPATs remains to be fully elucidated. Herein, we investigated the potential dysregulation of the expression and secretion profile of PPAT adipokines in PCa patients. Specifically, by integrating transcriptomic (on PPATs) as well as proteomic and metabolomic (in PPAT-secretome) approaches on a well-characterized cohort of PPAT-samples [75 PCa-patients vs 22 benign-prostate-hyperplasia (BPH) control-subjects], we identified a significant signature of dysregulated adipokines in PCa patients. Subsequent unsupervised clustering analyses allowed the identification of two distinct molecular phenotypes of PCa patients with a unique fingerprint of alterations in adipokines (T1 and T2) that presented distinctive clinical-metabolic alterations (i. e., BMI, diabetes, and dyslipidemia), being lipocalin-2 (LCN2) the only adipokine showing consistent differences at transcriptomic- and proteomic-levels. Functional approaches in different prostate cell models [normal-like (PNT2) and PCa (DU145, LnCaP and 22Rv1)] revealed that exogenous LCN2 treatment did not alter proliferation, apoptosis, or colony formation in any of the prostate cell models, but migration was significantly increased in PNT2 and decreased in DU145, wherein a differential expression profile of LCN2 receptors (especially SLC22A17), may directly contribute to this differential effects observed across cell models. Molecularly, LCN2 treatment was associated with alteration in critical oncogenic/metabolic-pathways, including neutrophil-degranulation, inflammation, and autophagy, suggesting a connection with the inflammasomes. Further analyses revealed a weight-dependent association pattern between LCN2 and individual inflammasome components. Additionally, arachidonic acid (prostaglandin precursor) in PPAT-secretome positively correlated with LCN2 levels specifically in the obese PCa-patients, suggesting a metabolic link to LCN2-mediated effects. Our findings highlight LCN2 as a potential key player in the interaction between PPAT, obesity and PCa-microenvironment, with a potential influence on inflammation and tumor cell behavior.

Clinical, hormonal, and neuroradiological characteristics and therapeutic outcomes of prolactinomas in children and adolescents at a single center

Minhye Choi[1], Minji Im[1], Insung Kim[1], Juyoung Sung[1], Yunji An[1], Aram Yang[2] & Sung Yoon Cho[1]
[1]Department of Pediatrics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea; [2]Department of Pediatrics, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea

Aim
Prolactinoma, a prolactin (PRL)-secreting pituitary tumor, is the most common functioning pituitary adenoma, comprising 40–60% of cases. However, it is rare in childhood and adolescence, accounting for less than 3% of childhood supratentorial tumors. This study evaluates the clinical characteristics, treatment responses, and outcomes of Korean adolescents with prolactinoma at a single center.
Method
This retrospective study included patients diagnosed with prolactinoma at Samsung Medical Center from March 2005 to August 2024. Clinical data, PRL levels, and MRI findings at diagnosis and after treatment with dopamine agonists were analyzed. Outcomes of medical and surgical management were also assessed to determine factors influencing treatment success.
Result
A total of 28 patients (22 female, 6 male) with a median age of 16. 9 years (range: 10. 1–18. 5) were included. Females commonly presented with galactorrhea (50. 0%) and amenorrhea (40. 9%), whereas males had visual deficits (50. 0%) and headaches (50. 0%). Microadenomas ($\leq$ 10 mm) were found in 12 patients, and macroadenomas ($>$ 10 mm) in 16. PRL levels were significantly higher in macroadenomas than in microadenomas (2, 197. 7 vs. 141. 4 ng/mL, $p < 0.001$). Panhypopituitarism occurred in 81. 3% of macroadenoma cases vs 8. 3% in microadenomas ($P = 0.008$). Surgery was performed in 86% of macroadenoma cases compared to 18% of microadenomas ($p < 0.001$). Male gender, PRL levels, and tumor diameter were positively correlated with tumor size. Among 20 patients treated with dopamine agonists, 10 responded positively. Transsphenoidal surgery (TSA) was performed in 18 cases, achieving PRL normalization in 12. Three patients required Gamma Knife Surgery due to resistance, intolerance, or recurrence after TSA.
Conclusion
Adolescent females with prolactinoma are more common, but males more often present with macroprolactinomas and mass effect symptoms. Macroprolactinomas frequently cause panhypopituitarism, necessitating early intervention. Gender differences in prognosis suggest a need for more aggressive treatment in males. Early detection, individualized therapy, and timely hormone replacement are crucial for optimizing long-term outcomes.

Severe hypercalcemia in an infant caused by PTHrP secretion from renal malignancy

Ayman Asaly[1, 2], Tal Kedar[1, 2], Ehud Barhod[3], Rina Hemi[3] & Yael Levy-Shraga[1, 2]
[1]Pediatric Endocrinology and Diabetes Unit, The Edmond and Lily Safra Children's Hospital, Sheba Medical Center, Tel-Hashomer, Israel; [2]Faculty of Medicine, University of Tel Aviv, Tel Aviv, Israel; [3]Endocrine laboratory, Division of Endocrinology, Diabetes and Metabolism, Sheba Medical Center, Ramat-Gan, Israel

Background
Severe hypercalcemia is a rare but serious condition in infants and children. It can present with symptoms such as hypotonia, poor feeding, vomiting, constipation, abdominal pain, lethargy, polyuria, dehydration, and seizures. The causes of hypercalcemia are categorized based on parathyroid hormone (PTH) levels. PTH-dependent hypercalcemia is characterized by elevated PTH, while PTH-independent hypercalcemia results from factors such as excessive production of parathyroid hormone-related protein (PTHrP) or 1, 25-dihydroxyvitamin D. PTHrP is a protein similar to PTH and can be secreted by certain tumors, including renal cell carcinoma, pheochromocytoma, and benign congenital mesoblastic nephroma. Hypercalcemia associated with PTHrP is rare, particularly in infants.
Case Presentation
A 5-month-old female, born at term with a normal pregnancy and delivery, presented to the emergency room with restlessness, constipation, and poor appetite. Routine lab tests revealed hypercalcemia (19 mg/dL), elevated ionized calcium (2. 43 mmol/l), and hypophosphatemia (3. 5 mg/dL). Further endocrine evaluation showed undetectable PTH levels, 25-hydroxyvitamin D at 37 ng/mL (normal range: 30-100), and low 1, 25-dihydroxyvitamin D at 27 pg/mL (normal range: 32-196). Urinalysis showed hypercalciuria (calcium/creatinine ratio of 2938 mg/gr). PTHrP testing was pending.
Management
Initial treatment included intravenous fluids, furosemide, calcitonin, and bisphosphonates, which normalized the calcium levels. Given the severity of hypercalcemia, hypophosphatemia, hypoparathyroidism, and low 1, 25-dihydroxyvitamin D3, malignancy was suspected as a cause of PTHrP secretion. Abdominal ultrasound demonstrated a renal mass. A subsequent CT scan of the chest, abdomen, and pelvis revealed a 53x51x69 mm lesion in the upper pole of the left kidney, along with five possible metastatic sites in the right lung. Left nephrectomy was performed, and biopsies of the renal lesion and lung metastasis confirmed the diagnosis of rhabdoid tumor of the kidney. Chemotherapy was initiated.
Conclusion
Although constipation and restlessness are often benign and common in infants, they can sometimes signal more serious underlying conditions, such as hypercalcemia. This case emphasizes the need to consider hypercalcemia in differential diagnoses and presents a rare cause—rhabdoid tumor of the kidney—as an underlying etiology.

Premature pubarche in 20 month old girl as a first sign of Li-Fraumeni syndrome – case report

Milica Jakovljevic[1], Vesna Cvetkovic[1], Sandra Stankovic[1, 2], Milica Ignjatovic[1], Tatjana Stankovic[1, 2] & Danijela Jovancic Petkovic[1, 2]
[1]Paediatric Clinic, University Clinical Centre Nis, Endocrinology, Nis, Serbia; [2]University of Nis, Faculty of Medicine, Nis, Serbia

Introduction
Li-Fraumeni syndrome is a rare autosomal dominant disorder that predisposes carriers to numerous tumors, including adrenocortical carcinoma.
Case report
A 20-month-old girl was referred to our clinic because of obesity and premature pubarche. The symptoms started 4 months before examination. She was born at full term, birth weight 3550 gr (P 50-75th), birth length 52 cm (P50). First physical examination was as follows: height 93. 5cm ($P > 99$, $+3.54$ SD), weight 18. 7 kg, BMI 21. 4 kg/m2 (P99, $+3.39$ SD), telarche Tanner 1, pubarche Tanner 2, discreetly enlarged clitoris. Initial laboratory findings were in reference range. Karyotype was 46, XX while the bone maturity corresponded to age. Testosterone levels and DHEAS levels were high (2. 32ng/ml and 4176. 9 mg/dl, respectively), FSH 0. 4 IU/l, LH 0. 2 IU/l, cortisole 480 nmol/l, estradiol 20. 4 pmol/l, progesterone 9. 28 nmol/l. Abdominal ultrasound showed solid oval tumor in the upper pole of the right kidney. Abdominal MRI confirmed limited expansive tumor of the right suprarenal gland, measuring 46x46x62mm (AP, LL, KK). The abdominal mass was completely removed. Histopathology findings showed that the mass was in fact adrenocortical carcinoma (ACC): CS I, pTNM$>$ T2, Nx, Mx. Follow-up and treatment was carried out according to COG ARAR 0332 protocol, so the first follow-up was one month after surgical treatment. The hormone levels, abdominal ultrasound and chest x-ray were normal. As the tumor was under 100gr, with normal post-operative hormone levels it was stratified as stage one. Since the ACC is rare, the genetic analysis was carried out and showed germline mutation in the TP53 tumor suppressor gene, so the patient was diagnosed with Li-Fraumeni syndrome. After the diagnosis, the patient is being monitored in accordance with "Toronto protocol": the hormone levels are checked every 6 months, abdominal ultrasound 3 every months and whole body and brain MRI once a year. Two and a half years after diagnosis the patient remains cancer free.
Conclusion
Adrenocortical carcinoma (ACC) is a rare malignant tumor that can cause precocious puberty. First and second stages have a good prognosis, while the third and fourth stages have a poor prognosis. Furthermore it can be a sign of a Li-Fraumeni syndrome that demands close monitoring of the patients due to higher probability of other malignant tumors.

Challenges in the diagnosis of patients with mild and moderate hypercalcitoninemia and nontoxic multinodular goiter

Raluca Trifanescu[1, 2], Bogdan Ditescu[1], Dan Alexandru Niculescu[1, 2], Dumitru Ioachim[2], Dana Terzea[2], Carmen Cristea[2] & Catalina Poiana[1, 2]
[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; [2]"C. I. Parhon" National Institute of Endocrinology, Endocrinology I, Bucharest, Romania

Background
correct diagnosis and management of patients with multinodular goiter and basal calcitonin between 10 and 100 pg/mL is challenging.
Patients and Methods
4 patients (2 M/2W), aged 55-68 years, residents in an iodine-sufficient area, showing mild and moderate basal hypercalcitoninemia and multinodular goiter were presented. Basal serum calcitonin was measured by chemiluminescence. Calcitonin was also measured from the fine needle aspiration (FNA) washout fluid in suspicious thyroid nodules. A FNA cytology exam was performed in all patients according to guidelines and histology confirmed diagnosis in operated ones.
Results
All patients showed multinodular goiters, with nodules' maximum diameters ranging from 1. 1-2. 9 cm. Serum basal calcitoninemia ranged from 1. 22 to 8. 14 $\times$ ULN. CEA was normal in all patients but one. Calcitonin measured from the fine needle aspiration washout fluid (FNA-Ctn) was normal ($<$ 0. 5 – 0. 68 pg/mL) in all patients but one with increased value (25116 pg/mL). This patient had a large non-suspicious thyroid nodule (20/12. 3/13. 8 mm, EU-TIRADS 2) and a small suspicious nodule (6/5 mm, EU-TIRADS 4) in whom fine needle aspiration and measurement of FNA washout fluid was performed. Cytology exam and histology confirmed medullary microcarcinoma. RET assessment is pending In the other 3 patients with normal FNA-Ctn, cytology revealed Bethesda II cytology of the dominant nodule ($n = 2$) and papillary thyroid carcinoma -Bethesda V citology of the suspicious nodule ($n = 1$); the suspicious nodules were not accessible for FNA in 2 patients. Because a C cells hyperplasia could not be ruled out in these 3 patients, total thyroidectomy was performed. Pathology exam was medullary microcarcinoma in one patient, C cells hyperplasia in 2 patients, one of them also associating a papillary thyroid carcinoma. Postoperative serum calcitonin levels were normal in all patients.
Conclusion
in patients with mild and moderate hypercalcitoninemia, cytology exam and calcitonin measurement in the fine needle aspiration washout fluid, especially in highly suspicious nodules, irrespective of theirs dimensions, is a useful diagnosis tool.

Redifferentiation treatment in radioiodine refractory metastatic papillary thyroid cancer

Rosalía Vegara Fernandez[1], Guadalupe Guijarro[1], Miguel Soria Tristán[2], Candida Paniagua Correa[3], Jose Antonio Rosado[1], Helena Urriza Blazquez[1], Carmen Fernandez de Araoz[1], PALOMA IGLESIAS BOLAÑOS[2], Maria Merino Viveros[1], Isabel Pavon de Paz[1] & Lucia Ribas[1]
[1]Hospital Universitario de Getafe, Endocrinology and Metabolism, Getafe, Spain; [2]Hospital Universitario de Getafe, Oncology, Getafe, Spain; [3]Hospital Universitario de Getafe, Nuclear Medicine, Getafe, Spain

Thyroid cancer is the most common endocrine cancer. Differentiated thyroid cancer (DTC), is by far the most common. DTC has an excellent prognosis, with a survival rate of more than 90% at 10 years. However, a minority of patients with DTC ($<$10%) develop distant metastases. The first-line treatment for metastatic thyroid disease is radioiodine. However, more than half of these lesions lose their avidity for radioiodine, becoming radio-refractory and in these cases survival decreases drastically. In the last decades much has been learned about the molecular pathways affected in DTC and their importance in the prognosis of these tumors. In particular, the BRAF mutation is highly frequent in DTC and seems be related to a worse prognosis of the disease. It also appears to be related to the risk of dedifferentiation of the lesions. In this context, drugs aimed at blocking these molecular points have been developed with the aim of inducing cell redifferentiation. The purpose of this study is to evaluate the efficacy of a redifferentiating treatment based on Dabrafenib and/or Trametinib during a short period of time in patients with BRAF or RAS mutated radioiodine refractory metastatic papillary thyroid cancer (PTC).
Methods
retrospective study including 13 patients under follow-up in the Endocrinology and Oncology Departments of the Hospital Universitario de Getafe diagnosed with radiorefractory metastatic PTC and BRAF or RAS mutation carriers, previously treated or not with systemic therapy. The selected patients receive redifferentiating treatment with Dabrafenib and/or Trametinib (depending on the mutation) for 6 weeks. Then, we perform a WBS with 5mCi of I31 and in case of increased I131 uptake, we scheduled an admission for administration of a therapeutic dose of I131 after stimulation with rTSH. Subsequently, redifferentiating treatment is suspended. The primary objective was to determine the increase in I131 uptake of the metastatic lesions after the redifferentiation process and to determine the response (according to RECIST and PRECIST criteria) to the new dose of I131.
Results
After redifferentiation treatment, I131 uptake increased in 5 patients (40%) all of whom received a therapeutic dose of I131. A sixth patient receives the dose empirically. Of the six patients receiving treatment with I131, according to RECIST criteria, 2 achieve partial response, 3 achieve stable disease and 1 has disease progression. According to PERCIST criteria, 4 achieve partial metabolic response, 1 achieves stable metabolic disease and 1 has disease progression.

The metastatic medullary thyroid carcinoma: a rare cause of ectopic ACTH-dependent cushing's syndrome

Bojana Caric[1, 2], Jelena Malinovic Pancic[3] & Tamara Dojcinovic[3]
[1]Faculty of Medicine, University of Banja Luka, Banjaluka, Bosnia and Herzegovina; [2]University Clinical Center of Republic of Srpska, Department of Endocrinology, Banjaluka, Bosnia and Herzegovina; [3]University Clinical Center of Republic of Srpska, Department of Endocrinology, Banja Luka, Bosnia and Herzegovina

Introduction
Ectopic Cushing's syndrome (ECS) accounts for 15% of all endogenous Cushing's syndromes and 10-20% of ACTH-dependent Cushing's syndromes. Medullary thyroid carcinoma (MTC) is a rare cause of ectopic ACTH secretion in patients with ACTH-dependent Cushing's syndrome, described in less than 1% of MTC cases.
Summary
We present the case of a 68-year-old patient with pronounced hypokalemia and weakness, initially attributed to hypercortisolemia due to Cushing's syndrome (previously diagnosed as an adrenal incidentaloma). Based on very high basal and suppressed ACTH levels and high basal calcitonin value of 2239. 00 pg/mL, ectopic secretion of ACTH was supposed and neck and chest imaging was performed. The imaging revealed a multinodular goiter with cervical lymphadenopathy and neoplastic change in the left lung. Additionally, a percutaneous lung biopsy of the detected lung tumor confirmed the suspicion of metastatic MTC. In preoperative treatment, severe hypokalemia was corrected with high doses of potassium administered both orally and parenterally until the introduction of ketoconazole (200 mg three times daily). Ketoconazole reduced cortisol levels, and hypokalemia was corrected without evidence of hepatotoxicity. A PET/CT scan using 18F-FDG showed moderately increased accumulation of 18F-FDG (SUV max 1. 7) in nodules in the right thyroid lobe (21 mm in diameter), with further intensification of 18F-FDG uptake (SUV max 2. 1) in the upper lobe of the left lung at the junction of S3 and S4. The patient underwent combined surgery, including a total thyroidectomy and atypical resection of the upper lobe of the left lung (OPIII U-VATS). Postoperatively, ketoconazole was discontinued, and cortisol levels remained normal. Serum potassium levels normalized without the need for potassium replacement therapy.
Conclusion
The expected therapeutic effect of the surgery was achieved in terms of the prompt resolution of ectopic ACTH secretion from the metastatic medullary carcinoma and the control of hypercortisolism effects, which were life-threatening for the patient. Postoperatively, ketoconazole was discontinued, while maintaining normal cortisol levels and serum potassium values without the need for potassium supplementation. Monitoring of calcitonin levels continues,

with an assessment for the potential use of targeted therapy with tyrosine kinase inhibitors.

Management of ectopic cushing's syndrome: a retrospective analysis of therapeutic outcomes

Gordan Vukman[1], Mirsala Solak[2], Tanja Skoric Polovina[2], Annemarie Balasko[2], Anela Novak[3], Marija Tripolski[4], Darko Kastelan[1, 2] & Ivana Kraljevic[1, 2]

[1]School of Medicine, University of Zagreb, Division of Endocrinology, Department of Internal Medicine, University Hospital Centre Zagreb, Zagreb, Croatia; [2]Division of Endocrinology, Department of Internal Medicine, University Hospital Centre Zagreb, Zagreb, Croatia; [3]Division of Endocrinology, Department of Internal Medicine, University Hospital Centre Split, Split, Croatia; [4]Polyclinic Borzan, Osijek, Croatia

Background

Ectopic Cushing's syndrome (ECS) is a rare and severe endocrine disorder caused by excessive ACTH secretion from extra-pituitary tumors. Given its high morbidity and mortality, timely diagnosis and effective management are crucial. This study evaluates the outcomes of pharmacological and surgical interventions in patients with confirmed ECS.

Methods

We conducted a single-center retrospective study analyzing ECS treatment outcomes from 2012 to 2024 at the Division of Endocrinology, University Hospital Centre Zagreb. Patients received pharmacological therapy (metyrapone, etomidate, ketoconazole) and/or underwent bilateral adrenalectomy. Descriptive statistical methods were used for data analysis.

Results

The study included 12 patients (median age: 43. 5 years; range: 22-74), with a female predominance (83. 3%). Identified ACTH-secreting tumors included lung carcinoid ($n = 1$), small cell lung carcinoma ($n = 2$), pancreatic neuroendocrine tumor ($n = 3$), medullary thyroid carcinoma ($n = 1$), breast neuroendocrine carcinoma ($n = 1$), thymus neuroendocrine carcinoma ($n = 1$), mediastinal neuroendocrine carcinoma ($n = 1$), and two cases with unknown tumor origin. At diagnosis, metastases were present in nine patients (75%). Pharmacological therapy was administered to seven patients (58. 3%) using metyrapone alone ($n = 2$), ketoconazole alone ($n = 2$), an etomidate-metyrapone combination ($n = 1$), or a metyrapone-ketoconazole combination ($n = 2$). The median dose of metyrapone used was 1500 (1000-4000) mg and ketoconazole 400 (200-800) mg. ECS was successfully controlled in three of these patients, while the remaining four required subsequent bilateral adrenalectomy. In total, nine patients (75%) underwent bilateral adrenalectomy, including five for whom surgery was the primary treatment. One patient achieved remission through lung resection. At the time of analysis, seven patients had died due to disease progression, with a median time to death of 16 (1–51) months. The median overall survival was 20 (1–154) months.

Conclusion

The management of ECS requires a multimodal approach, incorporating both pharmacological and surgical interventions. While pharmacological therapy was effective in some patients, bilateral adrenalectomy was necessary in certain cases

The impact of 12 months of aromatase inhibitors on body composition in postmenopausal women with early-stage breast cancer

Valdemar Mendez[1], Simone Diedrichsen Marstrand[1], Djordje Marina[1], Kristian Buch-Larsen[1], Caroline Kistorp[1] & Peter Schwarz[1]

[1]Rigshospitalet, Department of Nephrology and Endocrinology, Rigshospitalet, Copenhagen, Denmark

Background

Breast cancer is the most common cancer type for women in Denmark as well as globally. There's a large and growing group of non-metastatic breast cancer survivors, which draws more attention to long term side effects of the anti-estrogen adjuvant cancer therapy. The decrease in estrogen may thus change distribution of body fat with an increase in visceral fat. The aim of this observational study is to assess potential side effects of aromatase inhibitors on the body composition on postmenopausal women with early-stage breast cancer.

Methods

A cohort of postmenopausal women with early breast cancer (EBC) were examined post chemotherapy (baseline), and after 12 months of aromatase inhibitor treatment, and compared to an age- and postmenopausal status matched healthy control group (CON). The examination was done with dual energy X-ray absorptiometry (DXA) scans. We excluded patients with known prior malignancy, pre-existing endocrine diseases and pre-existing diseases that can affect cancer or the endocrine system.

Results

We included 15 EBC participants and 8 controls. The mean age was for EBC 59. 1 ($\pm$5. 1), and for CON 60. 8 ($\pm$3. 3). As expected, there was no difference in body composition between EBC and CON at baseline: visceral adipose tissue (VAT) EBC 396. 7g ($\pm$200), CON 334, 1g ($\pm$173) $p > 0.05$; fat mass (FM) EBC 29. 0kg ($\pm$9. 2), CON 26. 5kg ($\pm$7. 0) $p > 0.05$; fat% EBC 37. 4% ($\pm$5. 3), CON 36. 3% ($\pm$4. 9) $p > 0.05$; lean body mass (LBM) EBC 45. 5kg ($\pm$8. 5), CON 44. 1kg ($\pm$5. 9) $p > 0.05$). There were no changes in body composition from baseline to 12 months (mean change (95% CI)), VAT (EBC +47. 8g (-63. 5-159. 1), $p > 0.05$; CON +71. 6g (-42. 7-186. 0), $p > 0.05$), FM (EBC -0. 5kg (-2. 7-1. 7), $p > 0.05$; CON -1. 6kg (-4. 3-1. 1), $p > 0.05$), fat% (EBC +0. 8%-points (-0. 6-2. 3), $p > 0.05$; CON -1. 3%-points (-3. 0-0. 5), $p > 0.05$) and LBM (EBC -0. 8kg (-2. 0-0. 4), $p > 0.05$; CON -0. 1kg (-3. 0-2. 8), $p > 0.05$).

Conclusion

These preliminary results suggest no interaction between 12 months of aromatase inhibitor treatment post chemotherapy and body composition, where no changes was found between the two groups nor within the groups.

Extraordinary cortisol and 11-deoxycorticosterone co-secretion from an ectopic peritoneal adrenocortical carcinoma

Ameni Terzi[1], ruiqian chen[2], mauro tancredi[3] & Brigitte Delemer[1]

[1]CHU de Reims, Endocrinology department, Reims, France; [2]Hopital Bichat APHP, Pathology, Paris, France; [3]CH de Troyes, Endocrinology, Troyes, France

Background

Adrenocortical carcinoma (ACC) is a rare and aggressive malignancy that typically arises in the adrenal glands. Its occurrence in ectopic adrenal tissue is exceptionally rare, posing significant diagnostic and therapeutic challenges.

Case Presentation and Literature Review

We describe the case of a 71-year-old female presenting with severe Cushing's syndrome and extreme hypercortisolism (17, 000 nmol/l; normal range: 166-507 nmol/l). Imaging revealed normal adrenal glands but extensive peritoneal carcinomatosis with a peritoneal mass at the hepatic hilum. An FDG-PET scan revealed intensely hypermetabolic peritoneal foci diffusely distributed, including perihepatic regions (SUVmax 18. 5 in the posterior-superior area), Hormonal assays confirmed ACTH-independent cortisol hypersecretion (ACTH $<$0. 84 pmol/l; normal range: 1-10. 75 pmol/l), along with markedly elevated levels of 11-deoxycorticosterone (DOC) (14, 177 pmol/l; normal range: 30-400 pmol/l), other steroid hormone precursors, and androgens (Testosterone: 18. 23 nmol/l; normal range: 0. 16-1. 11). Peritoneal histopathological examination and immunohistochemistry, with positive expression of synaptophysin, SF1 and inhibin A, established the diagnosis of high-grade ectopic ACC. Despite optimal medical therapy with osilodrostat and metyrapone, cortisol secretion remained uncontrolled, and the patient's condition deteriorated rapidly, leading to fatal complications. We reviewed 16 previously reported cases and found our case to be unique due to its location and the extreme steroid levels.

Conclusion

This case underscores the exceptional presentation of a functional ACC arising in adrenal rest tissue in the peritoneum leading to a severe Cushing syndrome producing extremely high levels of cortisol, DOC, and androgens. Such an occurrence is unparalleled in the literature.

Patient reported outcome measurements (PROM) for the evaluation of the psychosomatic status in patients with adrenocortical carcinoma

Otilia Kimpel[1], Senta Kiermeier[2], Emely Stahl[3], Barbara Altieri[4], Martin Fassnacht[5] & Imad Maatouk[2]
[1]Division of Endocrinology and Diabetes, Department of Medicine, University Hospital, University of Würzburg, Würzburg, Germany; [2]Section of Psychosomatic Medicine, Psychotherapy and Psychooncology, Department of Internal Medicine II, Julius-Maximilian University Würzburg, Würzburg, Germany., Würzburg, Germany; [3]Division of Endocrinology and Diabetes, Department of Medicine, University Hospital, University of Würzburg, Germany, Würzburg, Germany; [4]Division of Endocrinology and Diabetes, Department of Medicine, University Hospital, University of Würzburg, Germany, Bavarian Cancer Research Center (BZKF), University Hospital, University of Würzburg, Germany, Würzburg, Germany; [5]Division of Endocrinology and Diabetes, Department of Medicine, University Hospital, University of Würzburg, Germany, Bavarian Cancer Research Center (BZKF), University Hospital, University of Würzburg, Germany, Comprehensive Cancer Center Mainfranken, University of Würzburg, Germany, Würzburg, Germany

Background
Several studies have shown that distress, depression and fear of progression (FoP) are common in cancer patients and negatively impact quality of life (HRQoL). However, no studies have explored these aspects in patients with adrenocortical carcinoma (ACC).
Objectives
This observational study investigates FoP, distress and depression in patients with ACC and their impact on HRQoL.
Methods
Adults (≥18 years) with ACC were included during regular hospital visits. Patients filled out questionnaires addressing FoP (FoP-questionnaire, short-form), HRQoL (EORTC-QLQ-C30), distress (National Comprehensive Cancer Network distress thermometer) and depression (patient health questionnaire, PHQ-9). Patients were distributed according to different clinical parameters to assess possible influencing factors. Multiple linear regression on HRQoL subscales ('total symptoms', 'total functioning') was performed in order to identify associated psychosomatic variables.
Results
Over a 12-months period, 105 patients were included (56. 2% female; median age = 49 years). Most patients demonstrated an elevated level of distress (62%) and a high level for FoP (59%). A major depression according to PHQ-9 was present in 41% of participants. The HRQoL questionnaire showed a higher level for functional problems (median = 62. 2) in comparison to symptoms (median = 33. 3). These results were neither influenced by tumour burden, hormone secretion nor by cancer treatment. In the multiple linear regression only depressive symptoms revealed a significant effect for HRQoL 'total symptoms' (B_{stand} = 0. 620, $P <$. 001) and for HRQoL 'total functioning' (B_{stand} = -0. 673, $P <$. 001). Most of our patients (80%) showed a need for psychosomatic counselling revealed by the questionnaires.
Conclusions
Patients with ACC show similar values for distress, FoP, depression and HRQoL independent of their clinical characteristics. The questionnaires revealed the need for psychosomatic intervention that should be offered to all patients with ACC.

Endocrine toxicity constitutes an independent predictor of survival in patients with extensive stage small cell lung cancer

Emmanouil Panagiotou[1], Ioannis Vathiotis[1], Maria Effrosyni Livanou[1], Athanasios Trimis[1], Aspasia Manta[2], Athina Asimakopoulou[1], Andriani Charpidou[1], Konstantinos Syrigos[1] & Melpomeni Peppa[1, 2]
[1]Third Department of Medicine, Sotiria General Hospital for Chest Diseases, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece; [2]Endocrine Unit, Second Propaedeutic Department of Internal Medicine, Research Institute and Diabetes Center, Attikon University Hospital, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece

Endocrine immune-related adverse events (e-irAEs) complicate the treatment of patients with lung cancer (LC) treated with immunotherapy. Although the incidence of e-irAEs as well as their impact on survival outcomes in LC cancer patients has been previously reported, evidence is limited for patients with extensive-stage small-cell lung cancer (ES SCLC). We retrospectively assessed patients with SCLC receiving chemoimmunotherapy in the first-line treatment setting at "Sotiria" General Hospital for Chest Diseases, Greece. Kaplan-Meier curves were used to calculate real-world survival outcomes and cox proportional hazards regression analysis was utilized to identify associations with e-irAEs. In total, 193 patients were included, 73 patients receiving atezolizumab plus platinum-etoposide (EP) and 120 patients receiving durvalumab plus EP. 31 patients (17. 1%) experienced an e-irAE. The reported e-irAEs included hypothyroidism in 21 patients (11. 6%), hyperthyroidism in 7 patients (3. 9%) and hypophysitis in 3 patients (1. 7%). e-irAEs were mild (grade 1-2) in almost all (96. 8%) patients. Discontinuation of immunotherapy was not required, although treatment was temporarily interrupted in 2 patients with hypophysitis. The incidence rate and type of e-irAEs were similar among patients receiving atezolizumab and durvalumab (18. 2% vs 16. 5%, P = 0. 936). Median overall survival was higher in patients with e-irAEs compared to patients without (17. 9 vs 9. 6 months, HR: 0. 42, 95% CI 0. 26 – 0. 70, p <0. 001). The difference in real-world overall survival remained statistically significant in multivariate analysis. Median progression-free survival was also higher (7. 5 vs 6. 3 months, HR: 0. 60, 95% CI: 0. 39 – 0. 93, P = 0. 02). In conclusion, the development of e-irAEs remained an independent predictor of survival outcomes in patients ES-SCLC receiving chemoimmunotherapy after extended recruitment and follow-up.

Six unrelated italian kindreds with multiple endocrine neoplasia type 4 (MEN4) harboring variants of the CDKN1B gene

Elena Pardi[1], Chiara Sardella[2], Simone Della Valentina[1], Laura Pierotti[1], Anna Dal Lago[1], Angela Michelucci[3], Maria Adelaide Caligo[3], Claudio Marcocci[1] & Filomena Cetani[1]
[1]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]University Hospital of Pisa, Endocrine Unit 2, Pisa, Italy; [3]University Hospital of Pisa, Laboratory of Molecular Genetics, Pisa, Italy

Multiple endocrine neoplasia type 4 (MEN4), caused by heterozygous inactivating mutations of the *CDKN1B* gene, is a rare hereditary syndrome presenting a combination of multiple endocrine tumors. It is characterized by a great overlap with MEN1 syndrome, having primary hyperparathyroidism (PHPT) the highest penetrance. Other tumors including renal, gonadal, adrenal, and thyroid tumors may be present. Here we describe six new MEN4 kindreds. The germline DNA of all the probands underwent next generation sequencing using a panel of PHPT-related genes. The proband of family 1 was a 55-yr woman with PHPT and bilateral adrenal lesions. An inferior left parathyroid adenoma was removed leading to the remission of PHPT after 21 months follow-up. The proband and her two siblings, both having mild elevated PTH levels and normocalcemia, carried a *CDKN1B* variant (c. 482C>G, p. Ser161Cys). The proband of family 2 was a 29-yr woman with PHPT and uterine myoma. An inferior left parathyroid adenoma was excised, resulting in the remission of PHPT after 43 months of follow-up. The proband and her mother affected by PHPT carried the *CDKN1B* variant c. 356T>C, p. Ile119Thr. The proband of family 3 was a 42-yr woman with PHPT, pancreatic neuroendocrine tumor (PNET) and single adrenal lesion. Inferior and superior right parathyroid adenomas were removed, leading to the remission of PHPT after 45 months of follow-up. The proband's mother was also affected by PHPT and is under surveillance. Both carried the *CDKN1B* variant c. 358G>A, p. Gly120Arg. The proband of family 4 was a 60-yr woman with PHPT, a non-functioning PNET, uterine myoma, bilateral adrenal hyperplasia, and melanoma. An inferior right parathyroid adenoma was removed leading to the remission of PHPT after 9 months of follow-up. She carried the *CDKN1B* variant c. 230A>C, p. Gln77Pro. The proband's sister, affected by PHPT, and the healthy nephew carried the same variant. The proband of family 5 was a 30-yr woman with PHPT. A superior left parathyroid adenoma was removed leading to the remission of PHPT after 66 months of follow-up. The proband and the healthy mother carried the *CDKN1B* variant c. 470C>T, pThr157Ile. The proband of family 6 was a 59-yr woman with recurrent PHPT due to right inferior, and left superior and inferior parathyroid adenoma. She carried the *CDKN1B* variant c. 274C>T, p. Pro92Ser. The *CDKN1B* variants segregate with the disease in all kindreds although they were classified as variants of unknown significance. Their functional consequences remain to be established.

Whole exome sequencing of gastroeneteropancreatic neuroendocrine tumors reveals specific SNV associated with epithelial-mesenchymal transition

Alberto Alegre Lifshitz[1], Oscar León Mondragón[1], Daniel Marrero Rodríguez[1], Moises Mercado[1], Keiko Taniguchi[1], Claudia Ramírez[1], Alicia Estrada[1] & Mauricio De la Fuente[1]
[1]IMSS, Unidad de Investigación en Enfermedades Endocrinas, CDMX, Mexico

Background
Endogenous hyperinsulinemic hypoglycemia is a rare condition which can be caused either by an insulinoma or, less frequently in adults, by nesidioblastosis. A possible origin theory of these is based on a correlation between genetic alterations and metabolic pathways, which could result in an inadequate cell differentiation. This theory has been endorsed by evidence suggesting that dediferenciation has a relation with the pathogenesis of diabetes. Epithelial-mesenchymal-transition (EMT) is a widely explored process in oncology and could be a crucial step relating genetic variants with gastroenteropancreatic neuroendocrine tumors.
Objective
To evaluate genetic variants that could relate EMT with endogenous hyperinsulinism.
Material and methods
Pancreatic tissue from 7 patients was analyzed by means of whole exome sequencing (WES). The pathology diagnosis was nesidioblastosis in five, insulinoma in one, and insulinoma with nesidioblastosis in one.
Results
After searching for single nucleotide variants (SNV) present in more than 50% of the patients, we found the following: *FN1* c. A2449C:p. T817P, c. G6688A:p. V2230I (nonsynonymous) and c. G4725A:p. E1575E (synonymous) in 85%; *FN1* c. A5691T:p. G1897G and c. T2442A:p. P814P (synonymous) in 71%. *CDH1* c. C2253T:p. N751N (synonymous) in 71%. *CDH2* c. C2448T:p. A816A and c. C1431G:p. P477P in 85%. *MMP2* c. C1806T:p. F602F, c. G1380A:p. T460T in 57%. *SNAI1* c. G531A:p. T177T, c. T279C:p. D93D (synonymous) and c. T353C:p. V118A (nonsynonymous) 57%.
Conclusion
Genetic variants for EMT related genes could help to make an association between EMT and endogenous hyperinsulinemia. C*DH1, CDH2 MMP2 and FN1* have been previously described in B-Cell dedifferentiation, thus highlighting the importance to understand the molecular mechanisms involved in the pathogenesis of these diseases.

JOINT1871

Persistent severe hypokalemia as a critical marker of diagnosis and response to treatment in ectopic cushing's syndrome (ECS) caused by small-cell lung cancer (SCLC)

Aleksandra Gamrat-Żmuda[1, 2], Mari Minasyan[1], Ewelina Rzepka[1], Anna Bogusławska[1], Alicja Hubalewska-Dydejczyk[1] & Aleksandra Gilis-Januszewska[1]
[1]Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; [2]Doctoral School of Medical and Health Sciences, Jagiellonian University Medical College, Krakow, Poland

Introduction
ECS is a rare condition caused by excessive ACTH secretion from various tumors, with SCLC being the most common cause (20-30%). While ECS is reported in 1-6% of SCLC cases, recent data suggest it may be underestimated, reaching up to 25%. Patients with ECS at the course of SCLC are often not referred to endocrinologists. Severe hypercortisolemia in ECS leads to complications such as hypokalemia, worsening the prognosis.
Aim
This study reviews the clinical presentation, diagnostic methods, and treatment of ECS caused by SCLC, focusing on identifying a marker to aid diagnosis in non-endocrinology departments.
Materials and Methods
A retrospective analysis of 39 ECS cases (2000-2025) was performed, with 7 cases (18%) associated with SCLC. Diagnosis was based on clinical features, biochemical tests, imaging, and in some cases, ACTH detection in tumor samples.
Results
Seven patients (5 male, 2 female), aged 55-74 years (mean 65. 4), were analyzed. Initial symptoms included edema (4/7), muscle weakness (4/7), and resistant hypertension (1/7). All had significant weight loss (4-11 kg, mean 6. 6 kg). Muscle weakness was noted in 6/7, and bacterial infections in 5/7 (sepsis in 2). Typical Cushing's symptoms were infrequent: central obesity (3/7), plethora (3/7), and striae (1/7), with no weight gain observed. Laboratory tests revealed hypokalemia in all patients, with potassium levels between 1. 14 and 2. 97 mEq/l (mean 2. 1), requiring high supplementation (up to 200 mEq/day) and spironolactone (6/7; 50-400 mg/d). The average time from first symptoms to ECS diagnosis was 1. 4 months. All patients were diagnosed in the metastatic stage. Serum cortisol levels ranged from 22. 7 to 192 µg/dL (mean 91. 7 µg/dL). Metyrapone (4 patients) reduced cortisol by 44% and modestly decreased potassium supplementation (mean 12. 2%). Osilodrostat (5 patients) reduced cortisol by 63. 4% and potassium supplementation needs by over 50% (mean 50. 1%). 5 patients died (mean survival 2. 5 months). In one case, cortisol therapy enabled chemoimmunotherapy, leading to survival over two years.
Discussion
The proportion of SCLC cases among ECS patients (18%) in our study was lower than in the literature, likely due to limited referrals to endocrinologists. Weight loss, common in cancer, and severe, refractory hypokalemia were the only symptoms, which occur in all patients. Early hypercortisolism treatment, particularly with osilodrostat, caused a significant reduction in potassium supplementation needs, highlighting its benefit. Persistent hypokalemia may serve as a key marker for ECS diagnosis in SCLC patients, who often do not present classic Cushing's symptoms, especially in non-endocrinology wards.

Liver transplantation in a patient with small-intestine neuroendocrine tumor (NET) and carcinoid syndrome

Daniela M. Soares[1], Andreia Martins Fernandes[2], Leandro Augusto Silva[2], Sofia Lopes[3], Ana Rita Elvas[2], Jacinta Santos[2], Teresa Martins[2], Sara Póyoa[2], Nuno Bonito[2], João Correia[2], Vasco Ribeiro[4], Raquel G. Martins[2], Joana Couto[2] & Fernando Rodrigues[2]
[1]Unidade Local de Saúde de Santo António, Porto, Portugal; [2]Instituto Português de Oncologia Francisco Gentil de Coimbra, Coimbra, Portugal; [3]Unidade Local de Saúde de Coimbra, Coimbra, Portugal; [4]Curry Cabral Hospital, Unidade Local de Saúde de São José, Lisboa, Portugal

Background/Aims
Liver metastasis (LM) constitute a major prognostic factor in patients with neuroendocrine tumors (NET). Symptoms of carcinoid syndrome (CS) occur when serotonin and other substances (tachykinins, prostaglandin and histamine) are secreted directly into the systemic circulation, generally associated to small-intestine NET with LM. In case of stage IV disease, resection of the primary tumor can be considered, followed by liver-directed therapies or, in very exceptionally selected cases, liver transplantation (LT).
Results
31-year-old male, ECOG PS 0, with irrelevant medical history, referred for right-upper quadrant abdominal pain, diarrhea and flushing; initial abdominal imaging revealed multiple hepatic lesions. Laboratory evaluation documented elevated chromogranin A (CgA) (176. 0 ng/mL; reference range $<$102. 0) and slightly raised urinary 5-hydroxyindoleacetic acid (u5-HIAA) (37. 8 mg/24h; reference range $<$15). Patient underwent ileoncolonoscopy, with inconclusive findings due to inadequate preparation, and a [^{68}Ga]Ga-DOTANOC PET-CT, compatible with probable primary NET of the terminal ileum, with mesentery lymph nodes metastasis and extensive LM. After multidisciplinary evaluation, the patient initiated monthly lanreotide therapy and liver biopsy was performed soon after, revealing hepatic involvement by NET G2 (Ki67 5%). Cardiology assessment excluded carcinoid heart disease. He was then submitted to segmental ileal enterectomy and cholecystectomy; pathological examination confirmed ileal NET G1 with lymph node metastasis (Ki67 $<$ 1%; pT2N1). Subsequent imaging and evaluations demonstrated stable exclusive liver disease and normalization of CgA and u5-HIAA levels. Nevertheless, exuberant CS symptoms persisted subsequently, despite optimized lanreotide therapy (120 mg 3/3 weeks). Concerning patient age, good performance-status and stable exclusive but symptomatic liver disease, LT was considered over additional local or systemic therapies on a multidisciplinary setting. After further experts' opinion, the patient was considered a suitable candidate. The procedure was recently carried out at an experienced reference center after patient's consent, approximately three years

after the initial diagnosis. The patient is currently CS-related symptoms' free and [^{68}Ga]Ga-DOTANOC PET-CT re-evaluation is being planned.
Discussion
In this case, the patient remained symptomatic despite normal u5-HIAA levels; symptoms' resolution shortly after LT highlights the role of unmeasured substances in CS. The case also reflects the complexity of managing patients with metastatic NET and the importance of a multidisciplinary approach, moreover in the presence of hormonal secretion. Quality-evidence on LT in this setting is still scarce; therefore, patients should be judiciously selected.

JOINT3966
Thyroid nodule progression prediction using convolutional neural networks and ultrasound images
Ana-Silvia Corlan[1], Sorin Chiriac[2], Paul Radu[3] & Ahana Choudhury[3]
[1]University of Medicine and Pharmacy Timisoara, Internal Medicine, Endocrinology, Timisoara, Romania; [2]University of Medicine and Pharmacy, Department X, Surgery Clinic III, Timisoara, Romania; [3]Valdosta State University, Department of Computer Science and Engineering Technology, Valdosta, Georgia

Thyroid cancer incidence has been increasing worldwide over the last decade. Early detection of nodules from volumetric imaging tests such as CT or MRI due to other medical problems account for a fraction of new cases, however, ultrasound imaging is the most commonly used detection tool. Confirmed nodules are scored for risk of malignancy based on the American College of Radiology (ACR) Thyroid Imaging Reporting & Data System (TI-RADS). TI-RADS scores are based on five features: composition, echogenicity, shape, margin and echogenic foci. Composition is scored from 0 to 2 points, while echogenicity, shape, margin and echogenic foci can receive up to 3 points. The sum of points and size of nodule are used to determine the need for a fine-needle aspiration (FNA) procedure to confirm malignancy. Automated scoring of ultrasound images based on convolutional neural networks (CNNs) have been proposed and can provide useful pointers to a radiologist, but remain essentially "black-box" models, failing to provide novel insights about the output they produce. In this work, we propose a CNN-based automated scoring tool trained on TI-RADS that learns a non-linear mapping from ultrasound image to a Euclidean space, which we refer to as the "disease space". Inspired by Mihail *et al*., (Mihail, 2015) we impose the following constraints during the learning phase of the transformation to the new space: 1) L2 norm = TI-RADS score and 2) distance between similar images is minimized. Cluster analysis in this space reveals specific disease modes. Critically, this allows for nodule progression prediction by interpolating along the L2 norm vector. While the CNN component of our tool acts as a black-box, the disease space's L2 norm one-to-one correspondence with TI-RADS score allows us to gain novel insights into malignancy prediction, given enough data points and ground truth from FNA. In our evaluation, we use 2 datasets: 347 thyroid ultrasound images of thyroid nodules from the DDTI (Digital Database Thyroid Image) and 13 thyroid ultrasound images of thyroid nodules from a private hospital in Romania. These patients signed an informed consent form committing to the use of their data only for scientific research.

Bilateral phaeochromocytomas in a young patient with a pathogenic MAX gene variant
Bing Rui Tan[1], Cherng Jye Seow[2] & Brenda Su Ping Lim[2]
[1]Lee Kong Chian School of Medicine, Singapore, Singapore; [2]Tan Tock Seng Hospital, Singapore, Singapore

Background
Phaeochromocytomas are catecholamine-secreting tumours originating from chromaffin cells in the adrenal medulla and can be symptomatic or asymptomatic. They may arise sporadically or in the context of hereditary syndromes such as MEN2, VHL, and hereditary paraganglioma-phaeochromocytoma (PGL-PCC) syndrome. Germline MAX gene mutations are a rare but known cause of hereditary PGL-PCC syndrome, manifesting as phaeochromocytomas/paragangliomas in affected patients.
Methods
This is a case report of a young patient with a pathogenic MAX gene variant who developed metachronous bilateral phaeochromocytomas.
Case Presentation
A 31-year-old lady with known hypertension presented with significant weight loss over one year, associated with increasing lethargy and episodes of diaphoresis. Her urine catecholamines and metanephrines were significantly elevated (adrenaline 2x above ULN and noradrenaline 37 × above ULN), and magnetic resonance imaging of her abdomen revealed a large 9cm left suprarenal mass. Right adrenal gland was normal. She was clinically diagnosed with a left phaeochromocytoma and underwent left adrenalectomy. Her young age at presentation prompted suspicion of hereditary syndromes – further genetic testing identified a pathogenic MAX gene variant associated with autosomal dominant hereditary PGL-PCC syndrome. Predictive testing was offered to at-risk family members. Subsequently, the patient was monitored for recurrence with annual urine catecholamine/metanephrine levels, and a full body MRI was performed every two to three years for the detection of paragangliomas. Despite the patient being asymptomatic, post-operative surveillance detected a right adrenal nodule two years later, followed by steadily rising urine catecholamine/metanephrine levels five years later. She was initially reluctant for surgery as she was asymptomatic but eventually opted for right adrenalectomy nine years later. Post-operatively, the patient was prescribed lifelong glucocorticoid and mineralocorticoid replacement therapy. She is currently well and remains under close follow-up and surveillance.
Conclusion
This case demonstrates the importance of genetic testing in young patients diagnosed with phaeochromocytoma. Predictive testing should be offered to at-risk family members. Close surveillance with biochemical screening and imaging is paramount to detect recurrence and/or new disease, even in the absence of symptoms. In patients with pathogenic MAX gene variants, a full body MRI extending from the base of skull to the coccyx is recommended.

Cribriform morular carcinoma (CMC), a heterogeneous neoplasm of the thyroid gland. Report of four cases
Miguel Paja[1, 2], Mª Teresa Gutiérrez[1, 2], Josune Rodríguez-Soto[1], Jon Garai[1], Jon Portu[1], Alejandra Santamaría[1], Cristina Moreno[1], Natalia Iglesias[1], Amelia Oleaga[1, 2] & Aitziber Ugalde[1]
[1]Basurto University Hospital; OSI Bilbao-Basurto, BIlbao, Spain; [2]University of the Basque Country UPV/EHU, BIlbao, Spain

In the 2022 WHO classification, CMC was removed from the group of papillary carcinomas and included as a thyroid tumour of uncertain histogenesis. This neoplasm accounts for 0. 1-0. 2% of all TCs and was first described in 1994. Almost all CMC have genetic alterations in the Wnt/beta-catenin pathway, with APC mutations being the most common, associated with familial adenomatous polyposis (FAP) or as a sporadic form. We present four women with different clinical presentations. Case 1. Cerebellar medulloblastoma at 11 and colectomy by colectomy at 28 with positive genetics. Sonographic screening showed multinodular goiter with CNB suggestive of PTC. Surgery (2010) at 43 years showed four unencapsulated CMC foci 1. 5-4 mm in diameter, intrathyroidal with IHQ positive for TTF-1 and negative for HBME-1. Treated with I131 and without recurrence after 14 years of F-U. Case 2. Self-detected nodule with CNB suggestive of PTC. Surgery (2012) at 31 showed unifocal, unencapsulated, well-defined 38mm neoplasm with vascular invasion. IHQ positive for TTF-1 and negative for thyroglobulin and HBME-1 except in morules. Negative for mutation in APC and normal colonoscopy. Excellent therapeutic response 12 years after treatment with I131. Case 3. Positive genetic study for APC three years earlier (maternal carrier, c. 1548+1G>T) with subtotal colectomy and immature ovarian teratoma. Self-detected nodule with CNB suggestive of CMC. Surgery (2019) at 32y showed two foci of 20 and 3mm, unencapsulated, without vascular invasion and negative sentinel node (0/7). IHQ positive for TTF-1, beta-catenin and Ck19, negative for thyroglobulin and HBME-1. Treatment with I131 and excellent response five years later. Mesenteric desmoid tumour from 2021. Case 4. Positive genetics for APC (maternal carrier, c. 637C>T) and resected colon polyps seven years earlier. Self-detected nodule with CNB suggesting CMC. Surgery at age 21 (November 2024) revealed seven foci of CMC (12-44 mm). The largest had extensive vascular invasion (nine vessels) and focal extrathyroidal

extension. Two of nine LNs with tumour foci in the central compartment. IHQ positive for TTF-1, nuclear and cytoplasmic beta-catenin and Ck19 and negative for thyroglobulin and HBME-1 except in morules, Ki-67: 8% with negative study for mutations in TERT promoter. Defined as an independent entity in the recent WHO classification, CMC shows a wide clinical variability at presentation. Sporadic cases tend to be solitary tumours, whereas CMCs associated with germline APC mutations tend to be multifocal. This neoplasm may present an aggressive histological picture even in young patients, especially in larger tumours.

Identifying vulnerable pituitary tumor patient subgroups after endoscopic transsphenoidal surgery: a prospective study on psychological well-being and self-perceived health

Angelo Milioto[1, 2], Louise Carstam[3, 4], Thomas Skoglund[3, 4], Gudmundur Johannsson[1, 2] & Sofie Jakobsson[5, 6]

[1]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [2]Department of Endocrinology, Sahlgrenska University Hospital, Gothenburg, Sweden; [3]Department of Neurosurgery, Sahlgrenska University Hospital, Gothenburg, Sweden; [4]Department of Clinical Neuroscience, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [5]Institute of Health and Care Sciences, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [6]University of Gothenburg Centre for Person-Centred Care (GPCC), Sahlgrenska Academy, Gothenburg, Sweden

Introduction

Transsphenoidal surgery (TSS) is the first-line treatment for most patients with pituitary tumors. The tumor, its treatment and comorbidities may significantly affect psychological well-being (PGWB) and self-perceived health. The aim of this study was to identify vulnerable subgroups among patients with pituitary tumors after TSS.

Methods

This prospective study included consecutive patients before TSS (baseline) and 12 months after surgery using the PGWB index and EuroQol Visual Analogue Scale (EQ-VAS) as described in the study protocol[1]. We investigated care type (personalized vs standard), clinical characteristics and adrenal insufficiency (AI) at 12-month as determinants of PGWB and EQ-VAS changes post-TSS.

Results

Totally, 148 patients (63 females, 43%), with a median age of 62 years (Q1-Q3 48. 3-69. 8) were included, of whom 118 (80%) had a non-functioning pituitary adenoma (NFPA). Before TSS, young age, female sex, living alone and having a secreting pituitary adenoma were associated with lower baseline PGWB. A subgroup analysis confirmed these findings in patients with NFPA, likewise all variables except sex remained significant in patients with functioning tumors. Similar patterns were seen for self-reported overall health, where young age, female sex and having a secreting tumor were related with lower baseline scores. However, in patients with NFPA, only age remained significant, and no variable correlated with baseline EQ-VAS in the functioning group. In the multivariate regression analysis on the full cohort, a functioning pituitary adenoma was associated with lower improvement in PGWB scores (β -0. 159, $P = 0.036$). Similarly, being born outside of Sweden was a negative determinant of EQ-VAS score improvement (β -0. 173, $P = 0.017$). Multivariate regression analysis on patients with NFPA showed that male sex and AI at 12-months contributed to less improvements in PGWB score (male sex β -0. 212, $P = 0.025$, AI β -0. 225, $P = 0.015$). In patients with functioning adenomas also including remission status at 12 months, only being born outside of Sweden (β -0, 331 $P = 0.045$) was correlated with less improvement EQ-VAS.

Conclusion

This study suggests that having a functioning pituitary adenoma and being foreign-born are vulnerable subgroups of pituitary tumor patients. The presence of AI among NFPA is also a negative predictor of outcome. These patients may need additional support during the post-operatory period to improve their psychological and overall health.

Comparative evaluation of postoperative pathology in patients with fine needle aspiration biopsy cytology of bethesda category IV

Esra Çopuroğlu[1], Feride Pınar Altay[2], Sevgul FAKI[2], Şefika Burçak Polat[3], Oya Topaloglu[3] & Bekir Cakir[4]

[1]Ankara Yenimahalle Training and Research Hospital, Department of Endocrinology and Metabolism, Ankara, Türkiye; [2]Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Türkiye; [3]Ankara Yildirim Beyazit University, Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Türkiye; [4]Ankara Yildirim Beyazit University, Faculty of Medicine, Ankara, Türkiye

Objective

This study aims to evaluate the postoperative pathology results of thyroid nodules with Bethesda Category IV cytology. The study also seeks to determine the malignancy rate, tumor subtypes, and the surgical approach of these patients.

Methods

A retrospective analysis was conducted on patients who underwent fine needle aspiration biopsy (FNAB) at Ankara Bilkent City Hospital and were classified under Bethesda Category IV. Demographic data, preoperative thyroid function tests, ultrasound characteristics, and surgical interventions were reviewed. Postoperative pathology results were analyzed to determine malignancy rates and tumor characteristics.

Results

104 patients with FNAB result of Bethesda Category 4 were examined. 70 patients whose postoperative pathology was available were included in the study. In the classification of patients according to gender, 56 (53. 8%) patients were female and 14 (13. 5%) patients were male. The mean age was 46. 68 ± 13.99. FNAB cytology subtypes were follicular neoplasm suspicious (74. 3%), follicular neoplasm (%4. 3) and Hurthle cell neoplasm (21. 4%). Bilateral total thyroidectomy was performed in 62 patients (% 88. 6), right lobectomy in 5 patients (% 7. 1), and left lobectomy in 3 patients (%4. 3). Of the 70 patients, 26 (37. 2%) had malignant tumors, with papillary thyroid carcinoma being the most common malignancy (84. 6%). Pathology of 11 patients (%15. 7) was papillary carcinoma follicular variant, and pathology of 1 patient (%1. 4) was papillary carcinoma oncocytic variant. Other malignancies included follicular carcinoma (%2. 9) and Hurthle cell carcinoma (%2. 9).

Conclusion

The overall malignancy rate in patients with Bethesda Category IV cytology was 37. 2%, with papillary thyroid carcinoma being the most commonly diagnosed malignancy. Our malignancy rate in Bethesda category 4 is consistent with the literature; however, the final histopathological diagnoses of the lesions in this category were more commonly reported as classical papillary thyroid carcinoma (PTC) rather than follicular variant PTC or follicular cancer. This suggests that pathologists should review and reassess their reports for Bethesda category 4 lesions.

Unravelling thermotolerance in adrenocortical carcinoma: implications for hyperthermia-based therapies

Solene Fiachetti[1], Nathan Mullen[1], Sarah Feely[1], Ritihaas Surya Challapalli[1], Padraig T Donlon[1], Mariam Hassany[1], Martin O'Halloran[2], Constanze Hantel[3], Punit Prakash[4] & Michael Conall Dennedy[1]

[1]Discipline of Pharmacology and Therapeutics, School of Medicine, University of Galway, Galway, Ireland; [2]Translational Medical Device Laboratory, University of Galway, Galway, Ireland; [3]Department of Endocrinology, Diabetology and Clinical Nutrition, University Hospital Zurich (USZ) and University of Zurich (UZH), Zurich, Switzerland; [4]Department of Electrical and Computer Engineering, Kansas State University, Manhattan, United States

Introduction

Adrenocortical carcinoma (ACC) is a rare, aggressive cancer with limited treatment options and frequent resistance to chemotherapy, highlighting the need for improved therapies. Hyperthermia is used to treat ACC metastases primarily through radiofrequency ablation to control disease burden. Incomplete tumour

ablation risks exposure to sub-lethal hyperthermia in the transitional zone of heating with the potential for development of thermotolerance. Few studies have examined the biological effects of hyperthermia on ACC cell survival and function. This study explored the thermotolerance in ACC, where cells resist subsequent thermal stress after initial sublethal heat exposure. We hypothesise that sublethal hyperthermia induces thermotolerance to subsequent exposure at 48°C or 50°C, compared to "naïve" (non-hyperthermia exposed) cells, mediated by the heat shock response and TMEM16F, a calcium-dependent scramblase involved in cellular repair.

Methods

ACC primary cell lines, H295R and HAC15, and the metastatic cell line MUC-1, were pre-treated at 45°C using heat-controlled water baths. Cells were rechallenged at 48°C or 50°C after 24 hours or 7 days and compared to naïve cells. Cell death was assessed via Sytox Blue staining via flow cytometry, and protein expression of HSP70, HSP90, P-HSP27, and TMEM16F was analysed using Western Blot.

Results

Surviving ACC cells previously exposed to hyperthermia demonstrated evidence of heat stress following hyperthermia but did not develop thermotolerance. There was no difference in viability between naïve and pre-treated cells at 48°C or 50°C, though MUC-1 showed higher resistance at higher temperatures ($\geq$48°C) compared to H295R and HAC15. While heat stress was evident in all cells following hyperthermia, there was no significant difference in HSP70 or HSP90 expression post-rechallenge between naïve and pre-exposed cells. A marked reduction in P-HSP27, was observed in both naïve and rechallenged cells at 50°C and this reappeared 24 hours post-rechallenge. Additionally, TMEM16F expression was lost immediately at both 48°C and 50°C but reappeared 24 hours post-rechallenge at 48°C only.

Conclusion

Hyperthermia of 45°C did not confer thermotolerance in H295R and HAC15 cells. The marked reduction in P-HSP27 and transient loss of TMEM16F suggest a diminished heat shock response at higher temperatures. Their reappearance 24 hours later indicates a delayed role in recovery but this is insufficient to confer protection against subsequent thermal stress. These findings emphasise the complexity of ACC cell responses to hyperthermia but are reassuring clinically, indicating that thermotolerance may not develop in transitional zones of cancers incompletely ablated whereby they remain sensitive to further ablation challenges.

Diagnostic and therapeutic specificity of thyroid nodules in children

Sabrine Farhani[1], Mehdi Ferjaoui[1], Oumaima Benkhalifa[1], Nawres Bouaziz[1], Rachida Bouatay[1], Amel Elkorbi[1], Naourez Kolsi[1], Harrathi Khaled[1] & Jamel Koubaa[1]

[1]ENT Department Fattouma Bourguiba Hospital Monastir Tunisia, ENT Department Fattouma Bourguiba Hospital Monastir Tunisia, Monastir, Tunisia

Goals

To study the epidemiological, clinical, and therapeutic particularities of children operated on for thyroid nodules.

Patients and Methods

Retrospective study of 40 patients aged 18 or less who underwent surgery for thyroid nodules over a period of 15 and a half years [01/2010-06/2024].

Results

Forty children were operated on for thyroid nodules. The mean age was 15 years 8 months. The sex ratio (M/F) was 1/8. The mean duration of evolution was 4 months. The pathological history was noted to be Graves' disease in 4 cases (10%), congenital hypothyroidism in 3 cases (7. 5%) and papillary thyroid carcinoma in the family in 1 case (2. 5%). The mode of discovery was a basicervical swelling in the majority of cases. Cervical ultrasound was systematically requested in all our patients with a chest CT scan in 2 cases and a thyroid scintigraphy in 4 cases. Fine needle aspiration cytology was performed in 3 cases (7. 5%). Surgery consisted of total thyroidectomy in 23 cases (57. 5%), loboishmectomy in 17 patients (42. 5%), accompanied by mediastinal-recurrent lymph node dissection in 12 cases (30%) and functional in 2 cases (5%). Definitive histology concluded with papillary carcinoma in 11 cases (27. 5%), encapsulated vesicular with limited angioinvasion in 1 case (2. 5%). The evolution was favorable in all patients with a mean follow-up of 6 months.

Conclusion

Thyroid nodules are rare in children. They are more aggressive than in adults. A malignant lesion must be suspected in time and treated promptly.

Intracranial germ cell tumors presenting with precocious puberty and diabetes insipidus in female patients: three case reports

Wen Xin[1] & Qiuli Chen[1]

[1]The First Affiliated Hospital of Sun Yat-sen University, Pediatrics, Guangzhou, Guangdong Province, China

Intracranial germ cell tumors (ICGCTs) in children are one of the factors leading to peripheral precocious puberty. Beta-human chorionic gonadotropin (β-HCG) exhibits luteinizing hormone (LH)-like functions. Intracranial germ cell tumors secrete β-HCG, which binds to LH receptors in the testes, triggering gonadotropin-releasing hormone (GnRH)-independent testosterone secretion, thereby causing precocious puberty. However, ovarian activation in females requires the simultaneous action of LH and follicle-stimulating hormone (FSH), and β-HCG has a low FSH-like activity, meaning that peripheral precocious puberty caused by intracranial germ cell tumors is more commonly seen in males. Female cases are rare. This clinical study summarizes the clinical features and pathogenesis of three cases of β-HCG-secreting non-gonadal germ cell tumors of the brain, presenting as peripheral precocious puberty and central diabetes insipidus. One case progressed to rapidly advancing central precocious puberty. The three patients all presented with central diabetes insipidus and peripheral precocious puberty, with two cases also complicating central adrenal insufficiency and central hypothyroidism. The β-HCG levels in peripheral blood were 5010 mIU/ml, 314. 3 mIU/ml, and 202. 8 mIU/ml, respectively. After treatment with radiotherapy and chemotherapy, β-HCG levels normalized, and the Tanner stage regressed to stage I. One case progressed to rapidly advancing central precocious puberty. Analysis suggests that this is related to prolactin (PRL), tumor-derived aromatase, and FSH-like function. Therefore, for female patients with precocious puberty, regular testing for β-HCG and alpha-fetoprotein (AFP) is necessary, especially for those with central nervous system symptoms. A thorough evaluation with pituitary region MRI (plain and contrast-enhanced) is crucial to exclude organic diseases such as tumors. Furthermore, in younger female patients with precocious puberty, vigilance for organic lesions should not be relaxed.

Adrenocortical carcinoma in a 9-year-old girl with li-fraumeni syndrome: a case report

Vika Jaskeviciute[1], Marija Slabsinskaite[1] & Ruta Navardauskaite[2]

[1]Lithuanian University of Health Sciences, Medical Academy, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas Clinics, Department of Endocrinology, Kaunas, Lithuania

Introduction

Adrenocortical carcinoma (ACC) is an extremely rare and aggressive malignancy in children, with an incidence of 0. 1–0. 3 cases per million. Pediatric ACC is often linked to germline TP53 mutations, particularly in Li-Fraumeni syndrome (LFS). We present a case of a 9-year-old girl with ACC, highlighting its aggressive course, treatment challenges, and the role of genetic predisposition.

Case Presentation

A previously healthy 9-year-old girl developed progressive weight gain, facial acne, hirsutism, and fatigue over several months. While on vacation, she experienced seizures, altered consciousness, and hypertension (150/90 mmHg), requiring emergency intubation. Imaging revealed a 10 cm right adrenal mass, and laboratory tests showed significantly elevated cortisol (1626 nmol/l; normal 177–578), testosterone (20. 16 nmol/l; normal 0. 31–1. 94), and DHEA-S levels.

MRI suggested a malignant adrenal tumor. She underwent an adrenalectomy, which confirmed an adrenocortical carcinoma (pT2N0). Postoperatively, she required hydrocortisone replacement, and further genetic testing identified a pathogenic TP53 variant, confirming LFS. Adjuvant therapy with mitotane was initiated, but two months post-surgery, abdominal MRI revealed peritoneal metastases. A second surgery removed multiple metastatic lesions, followed by chemotherapy (mitotane, temozolomide, cyclophosphamide). Despite treatment, the disease progressed, with new hepatic and peritoneal metastases. Given limited therapeutic options, pembrolizumab was introduced alongside metyrapone for hypercortisolism control. However, the patient's condition deteriorated, with persistent tumor progression. At 13 months post-diagnosis, she succumbed to the disease.

Discussion

ACC in children is often diagnosed late due to nonspecific symptoms. In this case, signs of Cushing's syndrome and virilization were present but not initially recognized. The association with LFS underscores the importance of genetic screening in pediatric ACC cases, as TP53 mutations significantly impact prognosis and treatment strategies. Despite aggressive surgical and systemic therapy, prognosis remains poor, particularly in metastatic disease. Mitotane remains the cornerstone of treatment, but novel approaches, including immunotherapy, are being explored. This case highlights the urgent need for better therapeutic strategies for pediatric ACC, particularly in genetically predisposed patients.

Conclusion

This case illustrates the aggressive nature of ACC in a child with LFS and the challenges in managing this rare malignancy. Early recognition, genetic testing, and novel treatment strategies are crucial for improving outcomes in pediatric ACC.

Keywords

Adrenocortical carcinoma, Li-Fraumeni syndrome, pediatric cancer, TP53 mutation, mitotane, immunotherapy.

Association of hemizygous MAMLD1 gene mutation and testiculer germ cell neoplasia *in situ*: a case report

Elvan Bayramoğlu[1], Ilayda Altun[1], Hasan Karakas[1], Gökçe Velioğlu Haşlak[1], Mert Uçar[1], Abdurrahman Güney[1], Hande Turan[1] & Olcay Evliyaoglu[1]

[1]Istanbul University Cerrahpasa, Cerrahpasa Medical Faculty, Pediatric Endocrinology, Istanbul, Türkiye

Introduction

MAMLD1(Mastermind like domain containing1,)on the Xq28 found specific expression in fetal sertoli and leydig cells. It was identified as critical for the development of male genitalia and predicted to enhance the expression of several Leydig cell-specific genes via Hes3-related Notch signaling pathway. Its hemizygous pathogenic variants cause 46, XY differences/disorders of sex development (DSD), hypomasculinized external genitalia at birth and are possibly associated with age-dependent deterioration of testicular function. It may play an important role in the testicular function including testosterone production during the fetal period and after birth.

Case

Here we describe a patient (46, XY) manifested penoscrotal hypospadias with micropenis and bilateral cryptorchidism. The male proband is the first child of his healthy, nonconsanguineous parents. He was born at 30 wk, with a weight of 2, 800 g (3, 8SD) and a length of 42. 0 cm(0, 57 SD). Cryptorchidism, penoscrotal hypospadias with micropenis, bifid scrotum was detected and he had bilateral orchiopexy at 6 months of age. A stimulation test with hCG (10 months) showed significant increase in testosterone concentrations(stimulated testesteron 302ng/dl, stimulated DHT 18ng/dl, stimulated androstenodion 6ng/dl) at 10 months of age, stimulated T/DHT ratio was >12 initially lead to the suspicion of 5α-reductase deficiency. However, mutation analysis of the SRD5A2 and AR gene was not detected. Bilateral testiculer microlithiaisis was detected at ten years old. Calcific density showed significant increased in US throughout the follow-up period. At the age of 14, according to the Tanner, right and left testis volumes were 12 and 15 cc, LH, FSH and total testesteron, AMH values were 11, 4mU/mL, 12, 5 mU/mL, 560 ng/dl, 4, 54 ng/ml respectively. Serum β-hCG and AFPlevels were within normal limits. Because of risk factor for testicular tumor, our patient underwent whole exome sequencing with CNV, MAMLD1 gene deletion on exon 3-5 was identified. Surgical right testis biopsy was applied, multifocal germ cell neoplasia *in situ* was detected. The focal immature seminiferous tubules with leyding cell hyperplasia were observed.

Discussion

Patients with 46, XYDSD harbouring MAMLD1variants manifest a broad spectrum of phenotypes and mostly present with hypospadias. Although both testes were descended into the scrotum within the first year of life and Sertoli/leydig cells produced sufficient hormones during pubertyin our patient, a testicular tumor developed. This is the first reported Mamld1 gene deletion a possible association with the causation of testicular tumor. We would like to emphasize that Patients with MAMLD1 mutation should be closely screened through physical examination and imaging techniques.

The effect of iodine- and selenium-fortified eggs on urinary excretion: findings from a randomized controlled study

Lina Zabuliene[1], Asta Mazeikiene[1], Valdas Banys[2,3], Romas Gruzauskas[4], Indre Urbaite[1], Vaiva Hendrixson[1], Natalja Istomina[1], Sonata Varvuolyte[1], Mykolas Urbonas[5], Kotryna Sileikaite[5] & Agne Paulauskaite-Taraseviciene[4]

Background

Iodine and selenium are essential micronutrients for thyroid function, metabolism, and neurodevelopment. Deficiencies remain a global public health concern, particularly in regions with low soil iodine and selenium content, including Lithuania. While salt iodization programs have helped mitigate iodine deficiency, complementary strategies such as biofortified foods are needed to improve dietary intake. Eggs, widely consumed across populations, can serve as an effective vehicle for iodine and selenium delivery when hens' feed is fortified. This study assessed the short-term impact of consuming iodine- and selenium-fortified eggs on urinary iodine (UIC) and selenium (USeC) excretion in adults following a low-iodine and low-selenium diet.

Methods

A randomized, double-blind, controlled trial was conducted at Vilnius University, Lithuania, enrolling 130 healthy adults aged 18–45. Participants were randomly assigned to consume either one iodine- and selenium-fortified egg (intervention group) or one standard egg (control group) per day for five days while adhering to a diet low in iodine and selenium. Spot urine samples were collected at baseline (day 0), day 3, and day 5. Urinary iodine/creatinine (UI/Cr) and selenium/creatinine (USe/Cr) were calculated for urine dilution. Daily urinary iodine excretion (UIE) and selenium excretion (USeE) were estimated using the Kawasaki formula. Iodine deficiency was defined as UI/Cr $<$ 100 μg/gCr and selenium deficiency was defined as USe/Cr $<$25 μg/gCr. Participants were included in the analysis if their urinary creatinine level was ≧20 mg/dL (iodine and selenium analysis) and if their CKD-EPI albuminuria category was A1 (selenium analysis). Statistical analyses included Student's t-tests and paired t-tests.

Results

At baseline, 74.8% of participants were iodine deficient (UI/Cr: 80.73 ± 34.74 μg/gCr), and 93.3% were selenium deficient (USe/Cr: 17.16 ± 4.91 μg/gCr). By day 5, UI/Cr was significantly higher in the intervention group compared to the control group by 17.06 μg/gCr (93.41 ± 44.43 μg/gCr vs. 76.35 ± 36.74 μg/gCr, $P = 0.036$), and UIE was higher by 31.83 μg/24h (161.85 ± 84.60 μg/24h vs. 130.02 ± 61.09 μg/24h, $P = 0.031$). For selenium, USe/Cr increased by 1.09 μg/gCr in the intervention group ($P = 0.077$) and by 1.41 μg/gCr in controls ($P = 0.075$) compared to baseline. USeE increased significantly in the intervention group by 2.13 μg/24h (from 30.01 ± 8.64 μg/24h to 32.14 ± 11.04 μg/24h, $P = 0.047$), but no significant changes were observed in the control group.

Conclusion

Consumption of iodine- and selenium-fortified eggs significantly increased urinary iodine excretion, while selenium changes were modest. These findings support fortified eggs as a promising approach to improving iodine and selenium status. Further research is needed to assess long-term effects and scalability.

Impact of early-life exposure to phthalates on anogenital distances in a cohort of healthy children and their mothers, from birth to three years of age

Laura Lucaccioni[1], Viola Trevisani[1,2], Lucia Palandri[2,3], Lisa De Pasquale[3], Mara Scassaserra[3], Patrizia Bruzzi[1], Barbara Predieri[1], Elena Righi[3] & Lorenzo Iughetti[1]
[1]University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences of the Mothers, Children and Adults, Modena, Italy; [2]University of Modena and Reggio Emilia, PhD program in Clinical and Experimental Medicine, Modena, Italy; [3]University of Modena and Reggio Emilia, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy

Background
Ano-genital distances (AGDs) are androgen-dependent body characteristics influenced by the intra- and extra-uterine-hormonal environment. Phthalates are ubiquitous environmental contaminants and endocrine disrupting chemicals (EDCs) with reproductive toxicity and anti-androgenic effects. The aim of this study is to assess phthalates exposure during the first 3 years of life in a cohort of healthy term infants and their mothers and the possible association with AGDs.
Methods:
Single-center, prospective birth-cohort study, assessing phthalates exposure in single urine samples collected at birth(T0), 3(T3), 6 (T6), and 36 (T36) months in children, and at T0 and T36 in mothers. After solid-phase extraction, samples were analyzed for 8 major phthalate metabolites (MMP, MEP, MnBP, MBzP, MEHP, MEHHP, MEOHP, MCOP) by triple Quad LC/MS Mass Spectrometry. Then we evaluated Hazard Indices based on EFSA' tolerable daily intake (HI-TDI) and on reference doses for anti-androgenicity (HI-RfD-AA), to estimate the potential synergic effect of different phthalates on development reproduction. Ano-penile distance (AGD-AP), ano-scrotal distance (AGD-AS) and penile length (PL) for male, ano-fourchette distance (AGD-AF) and ano-clitoris distance (AGD-AC) for female, were measured by a Vernier caliper at each timepoint. Spearman correlation coefficient between HIs and AGDs were calculated.
Results
A total of 188 mother–infant pairs were enrolled. The table summaries AGDs values (means ± S.D.) in males and females. In males AGD-AP at T36 showed a significant strong negative correlation with HI-TDI and HI-RfD-AA in mothers at T0 (r: −0.569 P<0.001and r: −0.500 P<0.001, respectively). Moreover, negative associations were detected for PL and mothers' HI-TDI and HI-RfD-AA at T36 (r: −0.299 P:0.057 and r: −0.342 P:0.029, respectively). At T36 in females moderate-strong negative correlations was detected between AGD-AF and HI-TDI and HI-RfD-AA at T3 and at T6 (r: −0.436 P:0.026, r: −0.403 P:0.041; and r: −396 P:0.045, r: −0.446 P:0.022; respectively); and between AGD-AC and HI-TDI and HI-RfD-AA at T3 and T36 (r: −0.478 P:0.013, r: −0.523 P:0.006; and r: −0.533 P:0.002, r: −0.465 P:0.01; respectively).
Conclusions
The development of AGDs during the first three years of life appears to be influenced by environmental factors that may also affect the child's later sexual development.

Sex (M/F)	AGDs (cm)	T0 (104/80)	T3 (70/52)	T6 (54/39)	T36 (47/31)
Males	AGD-AP	4.89 ± 0.59	6.85 ± 0.90	7.36 ± 1.14	8.89 ± 0.11
	AGD-AS	1.95 ± 0.66	3.59 ± 0.88	3.98 ± 1.12	4.57 ± 0.87
	PL	2.42 ± 0.59	2.79 ± 0.62	2.84 ± 0.69	3.77 ± 0.82
Females	AGD-AC	3.85 ± 0.69	4.65 ± 0.81	5.23 ± 0.97	6.80 ± 1.31
	AGD-AF	1.20 ± 0.42	1.71 ± 0.56	2.04 ± 0.63	2.31 ± 1.12

Plasma phthalate metabolites correlate with genetic alterations in PCOS patients with metabolic dysfunction

Anannya Tuli[1], Neeta Singh[2], Nabanita Halder[1] & Thirumurthy Velpandian[1]
[1]All India Institute of Medical Sciences, Ocular Pharmacology and Pharmacy Division, Dr. Rajendra Prasad Centre, New Delhi, India; [2]All India Institute of Medical Sciences, Department of Obstetrics and Gynaecology, New Delhi, India

Background
The incidence of polycystic ovarian syndrome (PCOS) has been rising in India, affecting one in five women. While the aetiology of PCOS is multifactorial, growing evidence suggests that metabolic dysfunction and environmental contaminants, particularly phthalate exposure, may play a role. This study investigates the association between plasma phthalate metabolite concentrations and metabolic dysfunction in PCOS patients. Additionally, it explores the role of phthalates in modulating gene expression related to glucose and lipid metabolism, potentially linking phthalate exposure to metabolic dysfunction.
Methodology
Age-matched PCOS patients (n = 177) and healthy controls were recruited in the study after obtaining ethical clearance (IECPG-294/07. 06. 2023). PCOS patients were diagnosed according to the evidence-based Rotterdam diagnostic criteria (2023), and female individuals with no history of irregular menses, thyroid-related issues and metabolic dysfunction were recruited as healthy controls. Their plasma, serum and buffy coat samples were collected. Participants were screened for basic biochemical parameters, including fasting plasma glucose and lipid profile. The PCOS group was further stratified into high (hiTyG) and low (loTyG) triglyceride-glucose index (TyG) subgroups, using a cut-off value of 8. 5 based on studies conducted in Asian population. Plasma phthalate metabolite levels were quantified using LC-MS/MS, and gene expression analysis was conducted using qPCR.
Results
The PCOS group exhibited significantly higher fasting triglyceride levels (P<0. 001), with nearly 65% of them showing an elevated TyG index (P < 0. 01) indicative of metabolic dysfunction. The PCOS-hiTyG group had significantly higher phthalate metabolite concentrations compared to controls (P < 0. 01). Moreover, a strong correlation was observed between elevated plasma phthalate metabolite levels and increased TyG index ($r_{Pearson}$=0. 7610, P < 0. 05), with altered expression of key metabolic genes, including *pparγ, cd36, glut4*, and *pten*. These gene alterations negatively correlated with both the TyG index and phthalate metabolite levels (P < 0. 05), suggesting that phthalates may actively contribute to metabolic dysfunction in PCOS.
Conclusion
This study establishes a novel, significant link between phthalate exposure and genetic alterations in PCOS, highlighting phthalates as potential exacerbators of metabolic dysfunction. These findings underscore the need to monitor phthalate exposure in vulnerable populations and further investigate environmental contributors to endocrine disorders. Additionally, the study emphasizes the importance of early metabolic dysfunction screening in PCOS patients, advocating for the inclusion of indices such as the TyG index in early diagnosis.
Funding
This study is funded by Council of Scientific and Industrial Research (CSIR), Govt. Of India, F. No. 09/006(0525)/2020-EMR-I.

Longitudinal exposure to benzophenones, parabens, and simple phenolic substances in children and adolescents and effects on puberty

Stine Agergaard Holmboe[1, 2], Jørgen Holm Pedersen[3], Anna-Maria Andersson[1, 2], Casper P. Hagen[1, 2], Lise Aksglaede[1, 2], Anders Juul[1 2 4] & Hanne Frederiksen[1, 2]
[1]Copenhagen University Hospital - Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark; [2]Copenhagen University Hospital - Rigshospitalet, International Center for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen, Denmark; [3]University of Copenhagen, Department of Biostatistics, Copenhagen, Denmark; [4]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark

Introduction
Puberty timing is influenced by exposures to different groups of endocrine disrupting chemicals (EDCs) with different properties. However, our recent systematic review and meta-analysis failed to make firm Conclusions on the impact of EDCs on pubertal development as the majority of the existing studies are cross-sectional using varying statistical approaches.
Aim
The aim of the present study was to investigate the impact of prepubertal concentrations of non-persistent EDCs (i. e. benzophenones, parabens and simple

phenolic substances) in relation to pubertal onset in a longitudinal cohort based on data from the Copenhagen Puberty Study.
Methods
In total, 215 healthy children and adolescents (50. 7% girls) were examined every six months for 7 years contributing with a total of 1, 527 examinations, with the median number of examinations per child being 7 (range: 2-14). All children underwent a clinical examination including pubertal staging and had a blood sample drawn for the measurement of reproductive hormone concentrations. Furthermore, the children provided a first morning urine sample at each visit from which urinary concentrations of 9 benzophenones, 7 parabens and 8 phenolic substances were determined using LC-MS/MS.
Results
Several chemicals were detectable in more than 90% of the urine samples, including benzophenone-3 (BP-3), methyl paraben (MeP), and bisphenol A (BPA). In general, chemical concentrations were positively correlated indicating co-exposure from several sources. There was a tendency towards prepubertal urinary BPA concentrations being associated with higher age at pubertal onset in boys (lowest vs. highest BPA tertile: mean age at onset 11. 4 vs. 11. 8 yrs, p-trend = 0. 12) and lower age in girls (10. 9 vs. 10. 1 yrs, p-trend = 0. 08). There were no clear associations for prepubertal concentrations of MeP and BP3 in relation to pubertal onset.
Conclusion
All participants were exposed simultaneously to a cocktail of several non-persistent chemicals. There was a strong tendency towards prepubertal BPA levels influencing timing of normal sexual maturation. Detailed statistical analyses of cocktail effects of chemicals on reproductive hormones and timing of puberty are needed and will be further analysed in the project.

Higher pfas exposure associated with lower 24h urine aldosterone in pregnant women. the odense child cohort

Richard Christian Jensen[1, 2], Hajir Al-Jorani[1, 3], Dorte Glintborg[1, 3], Flemming Nielsen[2], Boye Lagerbon Jensen[4], Tina Kold Jensen[2 5 6] & Marianne Andersen[1, 3]
[1]Odense University Hospital, Department of Endocrinology, Odense C, Denmark; [2]University of Southern Denmark, Department of Clinical Pharmacology, Pharmacy and Environmental Medicine, Odense M, Denmark; [3]University of Southern Denmark, Faculty of Health Sciences, Department of Clinical Research, Odense M, Denmark; [4]University of Southern Denmark, Department of Molecular Medicine, Odense M, Denmark; [5]Odense University Hospital, Odense Child Cohort, Hans Christian Andersen Children's Hospital, Odense C, Denmark; [6]University of Southern Denmark, OPEN, Odense C, Denmark

Background
Aldosterone is an independent predictor of higher placenta weight and birth weight. Accordingly, mice studies demonstrated aldosterone to have essential trophic effects on fetoplacental growth. Perfluoroalkyl substances (PFAS) are synthetic endocrine disrupting chemicals of high persistency. PFAS have been suggested as an inducer of aldosterone secretion in adrenocortical cells. However, there is no available *in vivo* data on PFAS exposure and 24-hour (h) urine (U-) aldosterone levels.
Objective
To investigate associations between first trimester PFAS concentrations and levels of 24-h U-aldosterone in third trimester.
Methods
In Odense Child Cohort (OCC), serum (S-) concentrations of five PFAS: perfluorohexane sulfonic acid (PFHxS), perfluorooctane sulfonic acid (PFOS), perfluorooctanoic acid (PFOA), perfluorononanoic acid (PFNA), and perfluorodecanoic acid (PFDA) were assessed in 1, 611 eligible women at median gestational week (GW) 12 (25^{th}, 75^{th} percentile: 10, 15). Among these, 24-h U-aldosterone was available in 469 women at median GW 29 (25^{th}, 75^{th} percentile: 28, 29). Multiple linear regression models were performed to estimate associations between S-PFAS concentrations (both as continuous and categorized data) and 24h U-aldosterone levels in pregnancy.
Results
Included women had a mean age of 30. 1 ($\pm$ 4. 5 SD) years, were predominantly nulliparous (58. 5%) with a median pre-pregnancy BMI of 24. 9 (5^{th}, 95^{th} percentiles: 19. 6, 36. 1) kg/m^2. In adjusted analyses, a doubling in S-concentrations of PFOS, PFOA, and PFNA were associated with a decrease in 24h U-aldosterone levels by -4. 8 % (95% CI: -8. 4%, -1. 0%), -5. 9% (95% CI: -9. 1%, -2. 7%), and -6. 2% (95% CI: -9. 9%, -2. 4%), respectively. Compared to the first tertile, exposure of PFOS and PFOA in third tertile, and PFNA in the second and third tertile statistically significantly decreased concentrations of 24-h U-aldosterone. A statistically significant dose-response relationship was observed across exposure tertiles for PFOS, PFOA, and PFNA (P-value for linear trend $<$ 0. 01) in the association with 24-h U-aldosterone.
Conclusion and Perspectives
Higher exposure concentrations of PFOS, PFOA, and PFNA in first trimester were associated with lower concentrations of 24-h U-aldosterone in third trimester. Aldosterone is an essential trophic factor for fetoplacental development. PFAS concentrations during pregnancy have been associated with negative pregnancy outcomes, including pregnancy loss and low birth weight. Hence, our observed inverse association between PFAS and aldosterone may be an important mechanistic link for the potential implications of PFAS on fetal growth.

Circadian temperatures in relation to thyroid function and cold exposure among subsistence hunters in east greenland

Stig Andersen[1 2 3], Mette Malene Jensen[1 2 3], Herborg Líggjasardóttir Johannesen[2, 4], Hans Christian Sørensen[1] & Stine Linding Andersen[1, 5]
[1]Aalborg University, Arctic Health Research Centre, Aalborg, Denmark; [2]Aalborg University, Department of Clinical Medicine, Aalborg, Denmark; [3]University of Greenland, Greenland Centre for Health Research, Nuuk, Greenland; [4]National Hospital Faroe Islands, Aalborg University, Steno Diabetes Center Faroe Islands, Tórshavn, Faroe Islands; [5]Aalborg University Hospital, Department of Clinical Biochemistry, Aalborg, Denmark

Background
Habitual cold exposure is mandatory to hunters living in East Greenland. Hunters in Greenland depend on the ability to produce heat. Brown Adipose Tissue has the capacity to produce heat by activation of Uncoupling Protein-1 (UCP1). Upregulation of UCP1 for activating BAT depends on triiodothyronine (T3) in concert with sympathetic stimulation. Hence, these hunters provide a unique model for intervention on the effect of blocking the sympathetic system during cold exposure.
Aim
We aimed to explore body temperature and thyroid hormones while blocking sympathetic activity in Greenlanders with habitual cold exposure.
Methods
We studied Greenlandic hunters (n = 7; healthy men) in East Greenland for 10 days during winter (February). The intervention comprised of a non-selective beta-blocker (Propranolol; 160 mg) taken daily for seven consecutive days. Blood samples were drawn daily for measurement of thyrotropin (TSH) and thyroid hormone levels, and body temperature was measured morning (AM) and evening (PM). Hunters reported the daily number of hours spent outdoor. Body temperature, TSH, fT3, and fT4 were compared prior to, and following intervention.
Results
Hunters spent an average of 5. 2 hours outdoor, and the body temperature was 35. 8 ^{o}C AM and 36. 2^{o}C PM. Body temperature decreased with intervention for PM measurements (36. 66^{o}C; 35. 76^{o}C), while not for AM measurements (35. 84^{o}C; 35. 99^{o}C). The circadian difference was lower with intervention (0. 82^{o}C; 0. 26^{o}C). Both PM temperature and circadian difference associated with the number of hours spent outdoors, with the latter explaining 18% of the circadian difference in body temperature. Average TSH was 2. 31 before and 3. 53 mIU/l with intervention, and fT3 was 3. 14 without and 2. 91 pmol/l with intervention. The pre-to-post intervention difference of 0. 61^{o}C for PM temperature was seen in parallel with a decrease of 0. 23 pmol/l in fT3 and rise of 1. 22 mIU/l in TSH.
Conclusion
Body temperature was stable with more than 5 hours spent outdoor in the Arctic winter. Intervention with a beta-blocker was followed by changes in body temperature in the evening while not in the morning. Changes in thyroid hormone levels were in keeping with the anticipated role of adrenergic stimulation of the thyroid gland. The rise in pituitary stimulation of the thyroid may be a response to decreased adrenergic drive on the thyroid. The results illustrate the complex interaction by thyroid hormones and adrenergic system to uphold body temperature.

JOINT2142

Endocrine disruption by phthalates and substitute substances: a hidden link to hypertension via adrenal steroidogenesis?

Benedikt Pötzl[1], Lydia Kuerzinger[1], Sabine Kendl[2], Martin Fassnacht[1], Max Kurlbaum[1] & Ulrich Dischinger[1]
[1]Division of Endocrinology and Diabetology, Department of Internal Medicine I, University Hospital of Würzburg, Würzburg, Germany; [2]Central Laboratory, Core Unit Clinical Mass Spectrometry, University Hospital of Würzburg, Würzburg, Germany

Phthalates, widely used as plasticizers, are well-documented endocrine disruptors associated with adverse effects on reproductive, developmental, and cardiovascular health. Despite being increasingly replaced by substitutes like adipates, terephthalates, and cyclohexane derivatives, these substitutes are produced in large quantities and frequently detected in human samples. While they exhibit lower migration rates from primary applications such as food packaging and medical devices, the effects of long-term exposure on endocrine systems - specifically on adrenal steroidogenesis - remain poorly understood. To evaluate the influence of three established phthalates, adrenal NCI-H295R cells were treated with diethylhexylphthalate (DEHP), diisobutylphthalate (DiBP), and diisononylphthalate DiNP), three non-phthalate alternatives, namely diethylhexyladipate (DEHA), diethylhexylterephthalate (DEHT), and 1, 2-cyclohexanedicarboxylic acid diisononyl-ester (DINCH), alongside an equimolar mixture of all six substances combined, for 72 hours in triplicate. Cell viability and the secretion of 15 steroids were assessed via LC-MS/MS. While concentrations $>$ 100μM were cytotoxic, lower doses of DEHP, DiNP, DEHT, DINCH and the mixture mainly stimulated the mineralocorticoid pathway. Aldosterone levels rose by 2. 30$\pm$0. 55-, 2. 76$\pm$1. 08-, and 2. 51$\pm$1. 49-fold at 10μM of DINCH, DiNP and mixture respectively. Its precursor corticosterone increased by 2. 68$\pm$1. 31-, and 2. 79$\pm$1. 46-fold at 1μM of mixture and DEHP. Also elevated cortisol levels were detected, e. g. 2. 00$\pm$0. 84- or 2. 15$\pm$0. 87-fold at 10μM of DINCH and mixture, accompanied by reduced cortisone levels. Notably, 21-deoxycortisol was strongly elevated (e. g. 2. 72$\pm$0. 99-fold at 1μM DiNP). While androgens were mildly affected, estradiol was increased. Further, DEHA and DiBP treatment resulted in less altered steroid levels. However, previously described inhibition of androgen levels by phthalates, were not detected following treatment with substitutes (DEHA, DEHT, DINCH). Importantly, all substances induced significant disruption of adrenal steroidogenesis when combined, indicating additive effects of phthalates and non-phthalate substitutes. The observed dysregulation of mineralocorticoids may affect blood pressure and fluid homeostasis. This aligns with evidence linking phthalate exposure to hypertensive phenotypes, particularly in highly exposed neonatal intensive care unit patients. Interestingly, most components are known for altering the renin-angiotensin-aldosterone-system. Alteration of adrenal steroidogenesis could therefore provide a mechanistic explanation for phthalate- or substitute-induced hypertension. Moreover, chronic activation of the hypothalamic-pituitary-adrenal, potentially associated with phthalate exposure, may influence adrenal glucocorticoid synthesis. Although this remains speculative in the context of the current findings, it aligns with previous research highlighting the vulnerability of mineralo- and glucocorticoid synthesis both *In vitro* and epidemiological studies, to phthalates and their emerging alternatives. This highlights the need for further research on their potential as risk factors for cardiovascular and endocrine health.

The impact of phthalates on adrenal steroidogenesis in HAC15 cells

Isabel Stüfchen[1], Erik Petersenn[1], Sanas Mir-Bashiri[1], Sonja Kunz[1], Martin Bidlingmaier[1], Tracy Ann Williams[1] & Martin Reincke[1]
[1]Department of Medicine IV, Endocrinology, Diabetology and Metabolism, LMU University Hospital, LMU Munich, Munich, Germany

Background
Phthalates entail as endocrine disrupting chemicals and have been shown to be associated with a range of endocrine and metabolic disorders. Dibutylphthalate (DBP) and Diethylhexylphthalate (DEHP) account as one of the most common used phthalates and are found in everyday products, toys and medical equipment. In humans they are quickly metabolized to monobutylphthalate (MBP) and monoethylhexylphthalate (MEHP). We investigated the influence of those two metabolites on cultured adrenocortical cells *In vitro*.

Methods
We exposed cultured HAC15 cells to five different concentrations (ranging from 1nM to 10μM) of MBP, MEHP and the mixture of both, and assessed cell viability, expression levels of key enzymes of steroidogenesis and levels of reactive oxygen species (ROS).

Results
Cell viability was significantly decreased upon exposure of high concentrations of MBP (10μM), while it was increased upon exposure of medium concentrations (100nM) of MEHP. qRT-PCR analysis revealed a significant decrease of mRNA expression of *CYP11B2* upon exposure of even low MBP concentrations ($P = 0.0002$) while MEHP disrupted *CYP11B2* expression in a non-monotonic manner ($P < 0.0001$). Expression levels of *CYP11B1* and *CYP21A2* were decreased upon exposure of high concentrations of both chemicals. The results of co-exposure of both phthalates demonstrated an additive effect on *CYP11B2* and *CYP11B1* expression, while expression of *CYP21A2* was increased. There was an increase of ROS by 20% upon exposure of phthalate mixture ($P < 0.05$).

Conclusion
The data suggest that even low concentrations of MBP and MEHP can cause serious disruption of adrenal corticosteroid synthesis, which is even intensified upon co-exposure of both and potentially mediated by increased ROS. Further studies are required to study the influence upon co-exposure with angiotensin II and ACTH as well as the underlying mechanism.

Early-life exposure to phthalates and risk assessment in a cohort of healthy mother-infant dyads: a 3-year follow-up study

Viola Trevisani[1, 2], Lucia Palandri[2, 3], Lisa De Pasquale[3], Erica Passini[1], Barbara Predieri[1], Lorenzo Iughetti[1], Elena Righi[3] & Laura Lucaccioni[1]
[1]University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences of the Mothers, Children and Adults, Modena, Italy; [2]University of Modena and Reggio Emilia, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy; [3]University of Modena and Reggio Emilia, PhD program in Clinical and Experimental Medicine, Modena, Italy

Background
Phthalates (PAEs) are ubiquitous environmental contaminants and recognized endocrine disruptors. PAEs are classified as reproductive toxicants; the extent of their early-life exposure remains limited and not extensively studied. The present study aims to assess perinatal and postnatal PAEs exposure in children (from birth to 36 months) and their mothers (at delivery and after 36 months).

Methods
Single-center, prospective birth-cohort study, assessing PAEs exposure in urine samples at birth (T0), 3(T3), 6(T6), 15(T15), 36(T36) months in children, and at delivery and T36 in mothers. After solid-phase extraction, 8 major PAEs metabolites (MMP, MEP, MnBP, MBzP, MEHP, MEHHP, MEOHP, MCOP) were analyzed by triple Quad LC/MS Mass Spectrometry. We described exposure patterns and estimate daily intake (DI). A risk assessment was performed by calculating risk quotients (RQ) based on EFSA' Tolerable Daily Intake (TDI) and reference doses for anti-androgenicity (RfD-AA). Hazard Indices (HI) were estimated by applying both the commonly used threshold of 1 and the the recently proposed 0. 1 limit to account for the overall risk of other toxicants co-exposure.

Results
188 mother-child pairs involved. PAE metabolites were widespread and detected in most urine samples at any time and showed a U-Shaped trend with lowest values at T3 and a progressive increase at the following observation times. The same trend was observed for DI, which in more than 25% of cases exceeded the EFSA threshold, excluding most DIs at T3. When calculating RQ, both RQ-TDI and RQ-RfD-AA showed median values below 1 at each timepoint for every PAE; and mothers presented the lowest quotients at T0. However, different subjects showed valued above the limit as reported in the table.

		T0		T3	T6	T15	T36	
		Mothers (n=186)	Newborns (n=164)	Infants (n=115)	Infants (n=101)	Toddlers (n=78)	Children (n=97)	Mothers (n=98)
HI-TDI	>1	0. 5%	2%	0	0	3%	2%	1%
	>0.1	6%	61%	15%	28%	63%	56%	20%
HI-RfD-AA	>1	1%	10%	1%	4%	21%	26%	1%
	>0.1	31. 6%	90%	46%	69%	82%	86%	67%

Conclusion
Exposure to PAEs appears broad and extensive in early years of life, even for the most toxic compounds banned by the EU in children's products. Our results showed that, despite European strict legislation, most children and their mothers exceed the newer most conservative risk threshold for antiandrogenic effects. Preventive public health measures to protect vulnerable groups are needed.

H. Chan School of Public Health, Harvard University, Boston, United States

Background
Testicular germ cell cancer (TGCC) originates in fetal life, and exposure to environmental chemicals during fetal development may play a role. However, reliable epidemiological data are lacking due to the long latency between fetal exposure and disease onset, and challenges in accurate exposure assessment. Per- and polyfluoroalkyl substances (PFAS) can act as endocrine disruptors during fetal life with potential effects on reproductive health. We investigated the association between exposure to PFAS during fetal development and risk of TGCC in adult life.
Methods
We conducted a nested case-control study of 549 mother-son pairs (103 TGCC cases, 446 matched controls) using prospectively collected data. The sample population included more than 100, 000 pregnant women with biobanked serum samples collected between 1985-1995, a period before PFAS restrictions and thus of high exposure potential. Sons of these women diagnosed with TGCC were identified from the Danish Cancer Registry until 2023. Concentrations of eight PFAS were quantified in maternal serum by liquid chromatography tandem mass spectrometry. Associations of individual PFAS and their mixtures with risk of TGCC were estimated through stratified Cox regression and quantile g-computation models.
Results
In main analyses, no strong or statistically significant associations were observed between individual PFAS and TGCC risk. However, hazard ratios (HR) for sulfonic acids (e. g., PFOS, PFHxS, PFHpS) generally suggested higher TGCC risks, whereas carboxylic acids tended to be associated with lower risks. Mixture analyses supported this opposing pattern, showing slightly higher TGCC risk for the JOINT effect of sulfonic acids (HR 1. 13, 95% CI: 0. 89; 1. 44) and lower risk for carboxylic acids (HR 0. 72, 95% CI: 0. 51; 1. 02). Stratified analyses by TGCC histological subtype demonstrated consistent differences, with generally positive associations for seminomas, in contrast to generally inverse associations for nonseminomas. For PFOS, a quartile increase in concentrations was associated with a higher seminoma risk (HR 1. 31, 95% CI: 0. 98; 1. 76).
Conclusions
Our study, using biobanked maternal serum collected decades prior to diagnosis, provides no robust evidence linking PFAS exposure during fetal development to TGCC risk in adult life. However, indications that sulfonic acids may have an adverse effect compared to carboxylic acids were observed. The generally weak associations may reflect the limited sample size or the complexity in identifying specific chemicals during fetal development as risk factors for TGCC in epidemiological studies. Further research is needed to clarify whether other environmental chemicals, possibly as mixtures, may contribute to the development of TGCC.

From sea to sample: tracing iodine nutrition in the faroe islands

Herborg Líggjasardóttir Johannesen[1 2 3], Anna Sofía Veyhe[4], Stine Linding Andersen[5] & Stig Andersen[6]

[1]National Hospital Faroe Islands, Aalborg University, Steno Diabetes Center Faroe Islands, Tórshavn, Faroe Islands; [2]National Hospital of the Faroe Islands, Steno DIabetes Centre Faroe Islands, Tórshavn, Faroe Islands; [3]National Hospital of the Faroe Islands, Steno Diabetes Centre Faroe Islands, Tórshavn, Faroe Islands; [4]University of the Faroe Islands, Research Department National Hospital Faroe Islands, Faculthy of Health science, Tórshavn, Faroe Islands; [5]Aalborg University, Arctic Health Research Centre, Aalborg, Denmark; [6]Aalborg University, Department of Clinical Medicine, Aalborg, Denmark

Background
Thyroid health depends on sufficient iodine nutrition, which conversely relies on dietary habits. Dairy products, tap water, and marine foods are potential sources of iodine and may contribute to the iodine intake. In the Faroe Islands, dietary habits shift from the traditional diet dominated by iodine-rich marine foods. We investigated potential sources of iodine and their relation to iodine nutrition among populations in the Faroe Islands.
Methods
We collected a variety of Faroese foods and tap water and conducted three cross-sectional studies between 2000 and 2020 to include adolescents, adults, and pregnant women. Participants were randomly selected to ensure a representative sample of the Faroe Islands. Participants filled in a questionnaire on demographic and iodine-related determinants. A spot urine sample was collected for iodine determination using the Sandell-Kolthoff reaction modified according to Wilson and van Zyl.
Results
Marine foods and seabirds had iodine contents ranging from 300 µg/kg. Lamb meat iodine content varied by 100%, depending on whether it was herded on an island with beaches (105 µg/kg) or cliffs (53 µg/kg) facing the ocean. Tap water iodine content was <2 µg/l. We estimated the iodine intake from four scenarios of Faroese meals, and it varied from 50 µg to just over 200 µg with diets rich in marine foods. The three studies covered the age span from 14 through 74 years without overlapping. The study of adolescents included 129 participants, and the median urinary iodine concentration (UIC) in this group was 166 µg/l. The study of pregnant women included 647 participants with an average age of 30 years and a median UIC of 110 µg/l when assessed in median pregnancy week 18. In the study of adults aged 40 through 74, the 491 participants had a median UIC of 101 µg/l. Diet impacted UIC with a dependency on fish and whale meals, while dairy products were not a source of iodine among Faroese.
Conclusion
Faroese marine foods were iodine-rich, and the populations included reported the intake of these foods. UIC in sub-populations in the Faroe Islands showed a dependency on marine meals, while dairy products had little influence on UIC.

Menopause related psychological symptoms influence work and careers more than vasomotor symptoms: findings from a cross-sectional study among 1562 women in diverse occupations

Mina Hagen[1], Ljiljana Marina[2, 3], Kristina Saravinovska[3] & Ana Andjelkovic[1]

[1]Faculty of media and communications, Singidunum University, Psychology department, Belgrade, Serbia; [2]Clinic of Endocrinology Diabetes and

Metabolic Diseases, University Clinical Center of Serbia, National Center for Infertility and Endocrinology of Gender, Belgrade, Serbia; [3]Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Introduction
Women over 40 are the fastest-growing demographic workforce worldwide. Women aged 40–65 constitute up to 50 – 60 % of the active female workforce. During this career stage, women are usually at the peak of their proficiency and experience but often face challenges related to menopausal transition (perimenopause/menopause period), with symptoms that negatively impact their work work and career development.
Aim
We aimed to investigate the relationship between menopausal symptoms and work and career development.
Methods
This was a cross-sectional study with snowball sample of 1562 women, aged 40-65 (Mean = 49; SD = 5. 45), working full time in private (52%), public (46. 1%) and non-governmental organisation (NGO) (1. 9%) sectors. Menopausal symptoms were assessed using the Menopause Rating Scale (MRS), while work ability was measured via the Work Ability Index (WAI). Additional measures included perceptions of symptom-related work problems (SWP), menopause hormone treatment (MHT) use, and menopause as career risk (MCR), measured with three questions: intent to leave the job, skipped promotion due to menopausal symptoms and whether menopause was viewed as non-threatening for their professional goals.
Results
There was a moderate negative correlation between WAI and MRS ($r(1561) = -.56$; $p < .001$), WAI and SWP ($r(1561) = -.60$; $p < .001$) and a weak positive correlation between MRS and MCR ($r(1481) = .34$; $p < .001$). Hierarchical linear regression showed that menopausal symptoms had the strongest effect on work ability, when controlled for age and MHT. Age and MHT were entered in the first block, and MRS subscales and SWP as predictors. The first model was found to be significant $F(2, 1560) = 14.32$, $P < .001$, $R^2 = .02$ showing that younger age and MHT had a protective effect against diminished work ability ($\beta = -.11$; $p < .001$, $\beta = -.08$; $p < .001$ respectively). Furthermore, the second model ($F(6, 1556) = 185.31$, $P < .001$, $R^2 = .42$) showed that psychological symptoms and SWP were the only significant predictors ($\beta = -.27$; $P < .001$ and $\beta = -.38$; $P < .001$) of work ability, whereas vasomotor and urogenital symptoms did not affect work ability.
Conclusion
The results of our study show that women's work and careers are negatively impacted by menopause with psychological symptoms having the most profound detrimental effect, stressing the need to understand menopause and its consequences beyond vasomotor symptoms. Thus, these findings highlight the need for interdisciplinary collaboration, mental health support and increased workplace awareness.

Awareness of endocrine disrupting chemicals among medical students and physicians: is it time for urgent curriculum and training reform?

Gökçen Ünal kocabaş[1], Su Ozgur[2], Niyazi Kursunoglu[3], Yigitcan Yuksel[4], Isabel Durusoy Onmus[1] & Banu Sarer Yurekli[1]
[1]Ege University, Endocrinology, Izmir, Türkiye; [2]Ege University, Translational Pulmology, Izmir, Türkiye; [3]Ege University, Clinical Biochemistry, Izmir, Türkiye; [4]Dokuz Eylul University, Izmir, Türkiye

Endocrine-disrupting chemicals(EDCs) have diverse sources of exposure in everyday life. Some may have transgenerational effects, and they are associated with endocrine cancers, metabolic diseases, and fertility problems. Raising public awareness is crucial considering the undeniable role of individual choices in EDC exposure. As physicians are one of the most trusted sources of information, the EDC awareness of physicians is essential for public education. There are no published studies about EDC awareness of medical students. In this study, we aimed to determine the EDC awareness of Turkish medical students and physicians using a validated scale in the Turkish language.
Methods
EDC awareness scale, a 24-question item, was used to determine EDC awareness. The participants were reached via message or e-mail.
Results
We reached a total of 617 participants. 381 were medical students (60. 8 % female, 39. 2 % Male), and 236 were physicians (62% female, 38% male). The median EDC general awareness score was significantly higher in physicians compared to students (2. 12(1. 5) vs 2. 87 (1. 63) $P < 0.001$). Mean EDC awareness total score was also higher in physicians (3.4 ± 0.54 for students, 3.63 ± 0.6 for physicians ($P < 0.001$). Female physicians' awareness was significantly higher than their male counterparts (3(1. 38) vs 2. 75(1. 56) $P = 0.027$). Age and healthy life awareness scores significantly correlated with EDC awareness scores. In particular, endocrinologists' scores were significantly higher than other subspecialties (General awareness score 2. 75(1. 5) vs. 3. 56(1. 63) $P < 0.001$; EDC awareness total score 3.59 ± 0.58 vs. 3.96 ± 0.56 $P = 0.003$)
Discussion
Despite the large number of public EDC awareness studies, the number of EDC awareness studies in physicians is scarce. For the first time in the literature, we have demonstrated that the medical students' EDC awareness is generally low. The physician's awareness is significantly higher than that of students, suggesting a post-graduate training process. Female gender, increasing age, and healthy life awareness are the major determinants of EDC awareness. Medical schools in Turkey do not include EDCs as a part of the curriculum. To raise the younger generations' awareness, curriculum reform may be necessary.

Phthalates: an endocrine disrupting hazard from birth to adulthood

Stela Bacinschi-Gheorghita[1, 2] & Marius Gorea[3]
[1]Nicolae Testemitanu State University of Medicine and Pharmacy, Department of Endocrinology, Chisinau, Moldova; [2]Republican Clinical Hospital, Department of Endocrinology, Chisinau, Moldova; [3]Nicolae Testemitanu State University of Medicine and Pharmacy, Chisinau, Moldova

Introduction
Endocrine disruptors represent a growing threat due to increased presence of these substances in the environment as a part of commonly used items. Among these compounds, phthalates are of particular concern because of their ubiquity and association with disruptions of steroidogenesis, gametogenesis, and tissue differentiation.
Objective
This article aims to elaborate a comprehensive analysis of the impact of phthalate exposure on puberty, growth, and reproductive system function, while elucidating the mechanisms by which they affect the endocrine system.
Methods
A review of scientific literature from the last 5 years from online data-bases such as NCBI, HINARI and Scopus regarding phthalate effects on the endocrine system and development during puberty was conducted.
Results
Exposure to phthalates was identified as a prominent cause of precocious puberty, including an earlier onset of menarche. In males, phthalates also exhibited an interference with testosterone metabolism. Suppression of thyroid function, as well as a decrease in sperm quality and motility in males and impaired ovarian function in females were also associated with exposure to phthalates. Phthalate-exposed individuals showed reduced height growth during childhood and delayed bone mineralization.
Conclusions
Phthalate exposure significantly affected the endocrine system, resulting in long-term consequences for pubertal development, reproductive health, and physical growth. The widespread occurrence of these findings in multiple studies substantiates the necessity for regulations concerning the use of endocrine-disrupting compounds, including phthalates.

Final adult height in male patients with central precocious puberty after GnRH agonist treatment

Kyoung Won Cho[1], Seo Jung Kim[1], Youn Kyoung Kim[1] & Junghwan Suh[1]
[1]Severance Children's Hospital, Department of Pediatrics, Seoul, South Korea

Objective
Central precocious puberty(CPP) is on the rise around the world. Premature puberty and acceleration of bone maturation can cause a decrease in the final adult height(FAH) by rapid bone fusion, so it is beneficial to FAH by inhibiting excessive sex hormone secretion and bone maturation through Gonadotropin-releasing hormone agonist(GnRHa) treatment. This study was conducted on a large scale compared to previous studies to see how FAH of patients with CPP treated with GnRHa was beneficial compared to the target height(TH) what factors were associated.
Methods
This study involved a total of 92 patients who were treated with GnRHa and reached FAH of total 668 male patients diagnosed with CPP at the department of pediatrics of Severance children's hospital between January 2000 and June 2024. FAH was defined as the bone age(BA) of 16 years or older, and the yearly growth rate(YGR) was less than 1 cm/yr, the difference between FAH and TH(FAH-TH) was evaluated for growth benefits after GnRHa treatment. We compared the difference between BA and chronological age(CA) at the beginning and end of treatment. In addition, we analyzed the correlation with factors such as Tanner stage, age at start and end of treatment, treatment period, height, weight, body mass index(BMI), predicted adult height(PAH), standard deviation score(SDS), BA at beginning and end of treatment, laboratory test results (LH, FSH, peak LH, Testosterone) with FAH via univariate linear regression followed by multivariate linear regression.
Results
TH was 172. 39±3. 36cm, initial PAH was 169. 04±4. 34cm, FAH was 173. 62±6. 42cm, FAH showed a statistically significant increase of 1. 23±5. 86cmcompared to TH ($P = 0.047$), and 4. 58±4. 11cmcompared to initial PAH ($P < 0.001$). The difference between BA and CA was 1. 69±0. 64 years before treatment and 0. 57±1. 00 years after treatment. 1. 12±0. 91 years of delay in bone maturation at the end of treatment was significantly observed ($P < 0.001$). The difference between the FAH and TH was positively associated with height and PAH before treatment (β=0. 434, 0. 359, respectively, all $P < 0.05$), negatively associated with initial testosterone and peak LH (β=-0. 240, 0. 221, respectively, all $P < 0.05$). The difference between the FAH and initial PAH was positively associated with height before treatment (β=0. 473, $P < 0.05$), negatively associated with age, weight before treatment and peak LH (β=-0. 349, 0. 301, -0. 382, respectively, all $P < 0.05$).
Conclusion
GnRHa benefits FAH and inhibits bone maturation in male CPP patients. Taller height, PAH, younger, less weight, low testosterone and peak LH level at treatment is better for FAH.

Association between urinary 3-phenoxybenzoic acid and thyroid function among 6-year-old children according to iodine status

You Joung Heo[1], Yun Jeong Lee[2], Johanna Kim[3], Bung Nyun Kim[2], Yun Chul Hong[2], Choong Ho Shin[2], Young Ah Lee[2] & Youn-Hee Lim[4]
[1]Gwangmyeong Hospital, Chung-Ang University School of Medicine, Department of Pediatrics, Gwangmyeong, South Korea; [2]Seoul National University Children's Hospital, Seoul National University College of Medicine, Department of Pediatrics, Seoul, South Korea; [3]Hanyang University College of Medicine, Department of Psychiatry, Seoul, South Korea; [4]University of Copenhagen, Department of Public Health, Copenhagen, Denmark

Background
3-phenoxybenzoic acid (3PBA), a metabolite of pyrethroid insecticides, has been linked to alterations in thyroid hormone levels in adults and pregnant women. However, research on 3PBA exposure in children and its interaction with iodine status remains limited. This study examines the relationship between early life 3PBA exposure and childhood thyroid function according to iodine status.
Methods
A total of 439 children aged 6 (231 boys and 208 girls) were included from the Environment and Development of Children cohort. Thyroid function was assessed through serum levels of thyrotropin (TSH), triiodothyronine (T3), and free thyroxine. Urine 3PBA concentrations were measured using morning spot urine samples. Iodine status was categorized based on urinary iodine concentration (UIC) as follows: iodine deficient (< 100 μg/l, $n = 19$, 4. 3%), adequate (100–199 μg/l, $n = 42$, 9. 6%), more than adequate (200–299 μg/l, $n = 54$, 12. 3%), mild excessive (300–999 μg/l, $n = 170$, 38. 7%), and severe excessive (≥ 1000 μg/l, $n = 154$, 35. 1%) groups. The association between urinary 3PBA levels and thyroid function was analyzed.
Results
The geographic mean creatinine-adjusted urinary 3PBA concentration was 1. 1 ± 2. 4 mg/g. Higher urinary 3PBA levels were significantly associated with increased serum T3 levels (β=2. 191, SE=1. 096, P-value=0. 046), after adjusting by age, gender, family history of thyroid disease, gestational age, birth weight and second-hand tobacco smoking. UIC group was significant effect modifier on relationship between serum TSH and urinary 3-PBA levels. In iodine-deficient group, urinary 3-PBA levels was positively associated with serum TSH levels (β=0. 51, SE=0. 212, P-value=0. 039). In iodine-excess group, urinary 3-PBA levels was positively associated with serum T3 levels (β=3. 66, SE=1. 831, P-value=0. 047)
Conclusion
Urinary 3PBA concentration was related to thyroid function in 6-year-old children, with iodine status acting as an effect modifier. These findings suggest that both iodine deficiency and excess influence the relationship between pyrethroid exposure and thyroid function in early childhood. Further research is needed to understand the long-term health implications of these interactions.

The LIFE-MILCH project: exposure to endocrine-disrupting chemicals in breast milk samples from the risk assessment model

Maria Street[1], Annalisa Pelosi[1], Anna-Mariia Shulhai[1], Francesca Alberghi[2], Maria Maddalena Brambilla[1], Veronica Buia[2], Cecilia Catellani[2], Emanuela Davolio[2], Marta Fontana[2], Francesca Nuti[3], Silvia Paterlini[1], Feliciana Real Fernandez[4], Beatrice Righi[2], Cecilia Rotteglia[2], Chiara Sartori[2], Chiara Scopa[1], Alessandro De Fanti[2], Vassilios Fanos[5], Anna Maria Papini[3] & Paola Palanza[1]
[1]University of Parma, Medicine and Surgery, Parma, Italy; [2]Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy; [3]Università degli Studi di Firenze, Florence, Italy; [4]ICCOM-CNR, Florence, Italy; [5]Università degli Studi di Cagliari, Cagliari, Italy

Introduction
The LIFE-MILCH project (www. lifemilch. eu) investigates exposure to endocrine-disrupting chemicals(EDCs) in mother-infant dyads during the first year of life. By analyzing EDC levels in breast milk(BM) and in mothers and infant urine samples, the study explores associations with neurodevelopment, growth, adiposity, pubertal stages, and genital features in infants. The first goal was to develop a risk assessment model to guide safety guidelines to optimize breastfeeding benefits while protecting long-term health. Here, we present data on exposure to EDCs in BM during the first 6 months of life.
Methods
We report data on 264/654 BM samples from the risk assessment model, enrolled in Parma, Reggio Emilia, and Cagliari in Italy. Healthy mothers with uncomplicated pregnancies were enrolled at 36-41 weeks of gestation. BM was collected at 1(T1), 3(T2), and 6 months(T3) after delivery. In all BM samples EDCs were measured by UPLC-MS/MS. Values were normalized to the blank; data > LOQ were further normalized for dilution. The analysis followed EFSA 2010 indications. Overall, Bisphenols (4congeners), Phthalates (PHTs) (14congeners), Polycyclic aromatic hydrocarbons (PAHs) (11congeners), Parabens (7congeners), Pesticides (3congeners), and two pyrethroids have been assayed.
Results
The most relevant and persistent bisphenol was BPA, detected in 60. 0% of samples at T1 and in 51. 0% at T3. BPS was detected in 14. 2% of samples at T1 and in 18. 8% at T3. In all samples, PTHs were ubiquitously high:DBP was detected in 88. 1% of BM samples at T1, in 95. 8% at T2, and in 86. 1% at T3; DEP and MEP were detectable in 46. 9% and 31. 5% of samples at T1, and in 55. 9% and 24. 5% at T3; BBP increased from 19. 2% at T1 to 33. 9% at T3. DMP, MnOP, MBP, and MEHP were detectable in over 28% of samples at all time points. In contrast, MEOHP, MBzP, MMP, and MEHHP halved at T3 compared to T1. DEHP, DnOP, and PAHs, except the indenopyrene, were subtly detectable. Parabens were variably detected, with MePB and EtPB increasing from 47. 3% and 34. 6% at T1 to 55. 9% and 51. 8% at T3. Pesticides and pyrethroids were scarcely detected. Preliminary data showed no associations of EDCs with length, weight, head, and abdominal circumferences during the first 6 months of life.

Conclusion
Preliminary exposure data confirmed that BM contains numerous EDCs from the environment. Further research is warranted to understand the effects on health. This project will follow children over time to evaluate the influence of real-life exposure to multiple EDCs on health outcomes.

An investigation of basic biochemical and endocrinological parameters in 34, 595 patients with occupational heavy metal exposure: a Turkey cohort

Arzu Or Koca[1], Mustafa Cesur[2], Erman Cakal[3], Tuğba Akkale[4] & Ilhan Yetkin[5]
[1]University of Health Sciences Dr. Abdurrahman Yurtaslan Ankara Oncology Education and Research Hospital, Endocrinology and Metabolism, Ankara, Türkiye; [2]Güven Hospital, Endocrinology and Metabolism, Ankara, Türkiye; [3]Etlik City Hospital, Endorinology and Metabolism, Ankara, Türkiye; [4]Gazi Mustafa Kemal Ankara Occupational and Environmental Diseases Hospital, Ankara, Türkiye; [5]Gazi University, Ankara, Türkiye

Purpose
This study aimed to investigate the relationship between heavy metal levels and various endocrinological parameters in individuals from heavy metal exposure.
Methods
The basic biochemical and endocrinological laboratory parameters and heavy metal levels (arsenic, lead, mercury, manganese, cadmium, zinc, chromium, antimony, nickel, cobalt, selenium, copper, lithium, molybdenum, thallium, and selenium) of 34, 595 individuals whose heavy metal levels were measured were reviewed in this study.
Results
The average age of the participants was 42 years, and 54. 4% of them were male. The rates of thyroid dysfunction, diabetes mellitus, and prediabetes in individuals involved in occupations associated with a high risk of heavy metal exposure were 14. 3%, 12. 8%, and 21. 4% respectively. The results indicated higher fasting blood glucose levels in individuals with toxic arsenic levels, lower high-density lipoprotein (HDL) levels in those with toxic cadmium levels, lower HDL and low-density lipoprotein levels in those with toxic manganese levels, and higher liver enzyme and triglyceride levels in those with toxic zinc levels.
Conclusions
An increased prevalence of thyroid dysfunction was observed in younger individuals involved in occupations associated with a high risk of heavy metal exposure, even when the heavy metal levels were not toxic. Furthermore, there were indications of potential heavy metal toxicity-related liver pathologies as well as glucose and lipid metabolism disorders in younger individuals. The most rational approach to prevent and reduce these adverse effects is to limit the duration and amount of heavy metal exposure across the entire population, starting from the occupational groups at risk.
Keywords
Endocrine disruptors, heavy metals, heavy metal exposure, occupational diseases

Triptorelin stimulated gonadotropin concentrations for precocious puberty

Chan Jong Kim[1]
[1]Chonnam National University Medical School & Children's Hospital, Gwangju, South Korea

Background
Gonadotropin-releasing hormone (GnRH) stimulation test is the gold standard to identify central precocious puberty (CPP). However, intravenous GnRH for testing is commercially limited.
The aim of the present study was to evaluate the diagnostic accuracy of triptorelin-stimulated luteinizing hormone (LH) concentrations in the diagnosis of CPP among girls presenting with premature thelarche (PT) compared to the gold standard GnRH test.
Methods
A retrospective study of 186 girls with sexual precocity was undertaken. All girls underwent subcutaneous triptorelin injection. Blood samples before and 30, 60, 90 and 120 min after the injection were analyzed for LH and follicle-stimulating hormone (FSH) levels. Girls with peak triptorelin-stimulated LH concentrations $\geq$5. 0 IU/l were classified as having CPP.
Results
Eighty-eight patients (47. 3%) were classified as CPP and the rest (98 out of 186, 52. 7%) as PT. The peak LH was achieved at 60 minutes after triptorelin-stimulation in CPP groups, but 120 minutes in PT groups. On cross-sectional frequency, ninety-three percent of CPP group patients were diagnosed CPP with LH levels of $\geq$5 IU/l at 90 min and 120 min, each. The cumulative frequency of LH $\geq$5 IU/l was 90. 9% at 60 minutes, 95. 5% at 90 minutes, and 100% at 120 minutes.
Conclusions
Subcutaneous triptorelin can be used as an alternative to confirm the diagnosis of CPP. We tried to propose shorter duration of subcutaneous triptorelin-stimulation test for diagnosing CPP. The peak LH showed at 60 minutes after injection in CPP group, but the cumulative frequency of LH $\geq$5 IU/l was 100% at 120 minutes. Not to miss one single CPP patient, it is necessary for 120 minutes full examination.

Sex-specific associations between maternal and postnatal exposure to bisphenol a (BPA) and children's body mass index: a prospective cohort study

Youn-Hee Lim[1], Yun-Chul Hong[2], Yun Jeong Lee[3], Choong Ho Shin[3], Dongwook Lee[4], Bung-Nyun Kim[5], Johanna Kim[6] & Young Ah Lee[3]
[1]University of Copenhagen, Public Health, Copenhagen, Denmark; [2]Seoul National University College of Medicine, Seoul, South Korea; [3]Seoul National University Children's Hospital, Seoul, South Korea; [4]Inha University Hospital, Incheon, South Korea; [5]Seoul National University Hospital, Seoul, South Korea; [6]Hanyang University Medical Center, Seoul, South Korea

Background
Exposure to bisphenol A (BPA) may affect the weight of exposed individuals and/or offspring, while the influence of BPA on obesity by sex remains controversial.
Aim
To investigate sex-specific associations between maternal and postnatal exposure to BPA and children's body mass index (BMI) in a prospective cohort study of 592 mother-child pairs.
Methods
We used data from the Environment and Development of Children study, a prospective birth cohort study in South Korea. We assessed BPA concentration levels in mid-term pregnant women and their children, aged 2 to 10 years, to evaluate the age- and sex-specific associations with children's BMI and BMI Z-scores (BMI-Z) in linear regression models and sex-specific associations across years in mixed models after adjusting for potential confounders.
Results
We observed an increased BMI or BMI-Z in boys but decreases in girls associated with maternal exposure to BPA. While the difference in BMI was pronounced at age 10, standardized BMI-Z showed consistently significant sex differences at all ages. Postnatal exposure to BPA was negatively associated with BMI and BMI-Z at ages 2 and 10, but we did find significant differences by sex.
Conclusion
Findings from this prospective study support the assertion that maternal BPA levels have sex-dimorphic effects on childhood BMI.

Background/Objective
Foetal growth involves a complex interplay of molecular systems, including the insulin/insulin-like growth factor (IGF) system, adiponectin, and peroxisome proliferator-activated receptors (PPARs) signalling pathways. This study aimed to investigate the expression and abundance of a subset of genes and proteins associated with these pathways in placental tissue and cord blood collected from small-for-gestational-age (SGA), appropriate-for-gestational-age (AGA), and large-for-gestational-age (LGA) infants, as well as associated first-trimester maternal serum.
Methods
A total of 55 LGA-, 61 SGA-, and 109 AGA-born infants were included in the study. RT-qPCR was employed to analyse placental tissue samples collected at term, focusing on differential expression of 22 key genes, including IGF1, IGF2, IGF1R, IGF2R, INSR, IGFBP1-7, PPARA, PPARB, PPARG, RXRA, RXRB, ADIPOQ, ADIPOR1, ADIPOR2, APPL1, and APPL2. A blinded assessor evaluated a subset of placental samples ($n=78$) using semi-quantitative IHC analysis to validate differential gene expression at the protein level. ELISA was utilised to measure the abundance of chosen proteins (IGF1, IGF2, sIGF2R, IGFBP2, PAPP-A) in first-trimester maternal serum samples, as well as four proteins (IGF1, IGF2, sIGF2R, IGFBP2) in cord blood samples collected at term.
Results
The expression of placental genes IGF1, IGF2, IGF2R, IGFBP2, and PPARA varied among the three groups, with significant findings for IGF1, IGF2, and PPARA after multiple testing corrections. No meaningful expression of ADIPOQ was observed. With IHC analysis, strong expression of IGF1, IGF2, IGF2R was observed in the LGA group compared to the SGA and AGA groups. Strong expression of PPARA was observed in the LGA group compared to the SGA group. Weak expression of IGFBP2 was observed in both the LGA and AGA groups compared to the SGA group, with weaker expression in the LGA group compared to the AGA group. A strong positive correlation was found between cord blood IGF1 and infant birth weight (rs $=0.73$, $P<0.001$), and a strong negative correlation with IGFBP2 (rs $=-0.56$, $P<0.001$). A modest positive correlation was observed for IGF2 (rs $=0.42$, $P<0.001$). No associations were found between maternal serum protein levels and infant phenotype.
Conclusion
This study shows for the first time in humans an association between PPARA and foetal birth weight and confirms the association between the IGF signalling pathway and birth weight.

The pharmaceutical-grade oral Glyburide = Glibenclamide suspension, AMGLIDIA, is safe and efficacious in French patients with neonatal diabetes mellitus

Ines Ben Rhaiem[1], Jacques Beltrand[2,3,3], Gaelle Vermillac[4], Kariyawasam Dulanjalee[1], Delphine Geraud[5], Alix Besançon[1], Cécile Godot[1], Marianne Berdugo[6], Adeline Alice Bonnard[7], Hélène Cavé[8], AMGLIDIA Study Group[1] & Michel Polak[2]
[1]Hôpital universitaire Necker Enfants Malades, Paris, France; [2]Université Paris Cité, Hôpital Universitaire Necker Enfants Malades, Pediatric endocrinology, gynecology and diabetology, Paris, France; [3]Institut Cochin, Inserm U 10116, Paris, France; [4]INSERM U1016, Institut Cochin, Paris, France; [5]Arcachon Hospital, Pediatrics, La Teste-de-Buch, France; [6]INSERM U1138, Centre de recherche des Cordeliers, Paris, France; [7]Hôpital universitaire Robert-Debré, Genetics, Paris, France; [8]Université Paris Cité, Hôpital Universitaire Robert Debré, Genetics, Paris, France

Context
Neonatal diabetes mellitus (NDM), a rare form of diabetes, is often linked to mutations in the K-ATP, *KCNJ11* and *ABCC8* genes or a genetic anomaly in chromosome 6q24. Management with pharmaceutical grade pediatric-adapted oral glyburide suspension (OGS), AMGLIDIA® has proven effective in restoring insulin secretion and stopping insulin injection.
Objective
This study aimed to evaluate its efficacy, effectiveness and safety.
Methods
Observational nation-wide retrospective study. A cohort of 27 patients affected by NDM in France was collected and analyzed annually over a median follow-up period of 2.7 years and up to 9 years of treatment.
Results
At baseline, the median HbA1c was 6,5% [5,8; 7,9]; 6,5% for *KCNJ11* mutated patients, 6,4% for *ABCC8* mutated patients, and 8.9% for the patient with chromosome 6 anomaly. All groups showed a non-significant *(P=0,382)* reduction in HbA1c levels with time to 6,27% in the KCNJ11 cases, 5,93% in the ABCC8 mutated cases and 7.4% in the 6q24 anomaly patient. At baseline, the overall median dose of the OGS was 0,15 mg/kg/day ranging from 0,1 to 0,185. Serious adverse events were minimal, with hypoglycemia reported in only 2 patients and diarrhea in 1.
Conclusion
A very good HbA1c was maintained, with a non-significant decrease in dose requirements over time, up to 9 years and the overall safety profile was favourable. Long-term use of AMGLIDIA® allowed an excellent metabolic control and a reassuring and manageable safety profile, making it a viable first line and long-term treatment in neonatal diabetes mellitus.

Background
Placental dysfunction is suspected to be linked to hypospadias since placental HCG stimulates fetal testis and subsequently support urethral development in the male fetus. Preterm births and intra-uterine growth restriction are thus associated with an increased risk of hypospadias but a shared molecular mechanism has not been elucidated yet. We aim to identify a JOINT genetic basis for hypospadias, preterm birth and fetal growth restriction using next generation sequencing (NGS).
Method
Prospective comparative multicenter study including 276 children with hypospadias. Phenotype ranged from glandular to penoscrotal hypospadias, without abnormal karyotype or pathogenic variants of candidate genes for XY-DSD. Genes included in the NGS panel were genes implicated in hypospadias or gonadal/genital development and that are expressed in the placenta. Frequency of variants was compared between preterm vs full-term patients, and between small for gestation age (SGA) vs normal growth patients. Univariate analysis and multivariate logistic regression analysis with stepwise backward selection were used.

Results
57 Hypospadiac boys were preterm (20. 6% of cases). Among these children, the variant *rs4986873* on *CYP11A1* (a gene implicated in testicular steroidogenesis and trophoblastic development) was more frequently found than in full-term babies (8. 8% vs 1. 8%, OR = 5. 239, $P = 0.015$). 44 hypospadiac boys were SGA (15. 9% of cases). Among these children, 4 variants in *RSPO1*, *ARID1A*, *CITED2 and CUL7* were more frequent than in hypospadiac patients without growth restriction. The identified variants are rs45577433 in *RSPO1* (OR = 7. 35, $P < 0.01$), rs35428899 in *ARID1A* (OR = 4. 14, $P = 0.01$), rs1131400 in *CITED2* (OR = 6. 73, $P < 0.01$) and rs9394939 in *CUL7* (OR = 4. 1, $P = 0.02$). This group of SGA patients had more severe hypospadias (40. 9% vs 24. 5% of mid-penile or posterior hypospadias, $P < 0.01$), more frequent chordee (53. 5 vs 35. 5%, $P = 0.03$), more frequent undescended testis (11. 9% vs 3. 15%, $P = 0.03$) and more frequent bifid scrotum (9. 3% vs 1. 3%, $P = 0.01$) than hypospadiac boys with normal growth.
Conclusions
We identified 5 variants that are more frequent in hypospadiac patients with prematurity (in *CYP11A1)* or SGA (in *RSPO1*, *ARID1A*, *CITED2* and *CUL7)* than in full-term hypospadiac boys with normal growth. These findings are in accordance with previous findings since besides being implicated in gonadal function and genitalia differentiation, CYP11A1 regulates trophoblastic proliferation and RSPO1, ARID1A, CITED2 and CUL7 regulate placental angiogenesis and have been associated with fetal growth retardation. These 5 genes may be at the crossroads of sex development and placental function. This finding makes a little further the connection between hypospadias and placental insufficiency at the molecular level.

Aldosterone regulates sodium homeostasis by binding to the Mineralocorticoid Receptor (MR). We have previously identified a critical temporal window during renal development with a down regulation of MR expression at birth, explaining the physiological sodium losses observed in newborns. However, the molecular mechanisms governing MR expression remain unclear. Here, we report the involvement of two microRNAs (miRNAs), miR-409-3p and miR-431-5p, in regulating MR expression during early renal development. Using miRNA sequencing, we identified these miRNAs as upregulated on mouse postnatal day 0 (D0) compared to day 8 (D8). RT-qPCR validated their differential expression, while luciferase reporter assays confirmed their functional interaction with MR transcripts. Functional studies using miRNA mimics and inhibitors revealed that miR-409-3p and miR-431-5p modulate MR expression and signaling in primary renal cell cultures. Specifically, their increased expression at D0 destabilizes MR transcripts and decreases MR expression and signaling, while their decreased expression at D8 leads to MR stabilization and enhanced mineralocorticoid signaling. Notably, digital droplet PCR (ddPCR) analysis of neonatal urine samples from the PREMALDO cohort demonstrated that these miRNAs are highly expressed at birth in humans but decrease gradually postnatally. Our findings identify miR-409-3p and miR-431-5p as key regulators of MR expression and mineralocorticoid signaling during renal development. These miRNAs could serve as potential predictive and non-invasive biomarkers of renal maturity and mineralocorticoid signaling efficiency notably in premature infants that have exacerbated sodium losses due to mineralocorticoid signaling defect in the neonatal period.

Testing a continuous glucose monitoring assessment tool for congenital hyperinsulinism

Kristen Rohli[1], Katherine Lord[2], Tai Pasquini[1], Julie Raskin[1], Jeff Roeseler[3] & Paul S. Thornton[4]
[1]Congenital Hyperinsulinism International, Glen Ridge, United States; [2]Children's Hospital of Philadelphia, Philadelphia, United States; [3]Rezolute Inc., Redwood City, United States; [4]Cook Children's Medical Center, Fort Worth, United States

Congenital hyperinsulinism (HI) is a rare condition where excessive insulin secretion leads to persistent hypoglycemia. Uncontrolled hypoglycemia can cause neurological damage, but prompt detection minimizes this risk. Continuous glucose monitors (CGM) are not approved for use in HI, however, they are increasingly used off-label to monitor glucose levels. In the HI Global Registry, 51% of participants reported using CGM ($n = 255$). Early studies in HI suggest CGMs can support euglycemic control, enable timely interventions during hypoglycemia, and reduce the frequency of severe hypoglycemia, mirroring successes in diabetes. Importantly, CGMs may improve independence and quality of life for HI families by decreasing frequent glucose checks, alleviating anxiety around unrecognized hypoglycemia, and enabling safer participation in daily activities. There are no formal measures to assess the potential benefits of CGM use for people with HI. The Congenital Hyperinsulinism International Collaborative Research Network (CRN) is a patient-led, multi-disciplinary group comprised of clinicians, researchers, caregivers, industry partners, and people affected by HI. One CRN workgroup focuses on the importance of accurate and available glucose monitoring tools. The CRN developed a mutual decision-making tool for physicians and families to evaluate nine factors of life with HI— fasting duration before hypoglycemia, continuous feeding, injectable medications/pumps, glucometer use, hypoglycemia frequency, hypoglycemia unawareness, need for external decision-making, independence, and pancreatectomy status. The tool generates a score to facilitate conversations about the value of adding CGM to glucometer use. Six HI Centers of Excellence used the suggested scoring system to retrospectively assess up to 20 HI patients at each center. Individuals received a distinct CGM benefit score. Comparing the tool's assessment with real-world decisions physicians had made previously for that individual resulted in 87/99 (88%) agreements, including instances where both the tool and the physician agreed the patient would and would not benefit from CGM. Most disagreements occurred when the tool suggested benefit, but the physician had not recommended CGM. Of those scored as "may confer benefit" by the tool, 5/13 (38%) received a CGM. Five tool questions were significantly associated with CGM benefit using chi-square statistics. The success of the tool's pilot testing exemplifies the benefit of utilizing the CHI CRN to ensure that all stakeholder perspectives are considered and reflected in the creation of the tool. This tool provides a structured framework for facilitating clinician-family discussions about CGM use, with the potential to improve HI management and enhance quality of life for people with HI and their families.

MEN2B syndrome, the impossible clinical challenge and how genomic newborn screening will improve morbidity and mortality

Tashunka Taylor-Miller[1], Katherine Tucker[2, 3], Ella Sugo[4], Antoinette Anazodo[5, 3] & David Mowat[1, 3]
[1]Centre for Clinical Genetics, Sydney Children's Hospital Randwick, Sydney, Australia; [2]Hereditary Cancer Centre, Prince of Wales Hospital Randwick, Sydney, Australia; [3]Discipline of Paediatrics, School of Clinical Medicine, University of NSW Medicine & Health, Sydney, Australia; [4]Department of Anatomical Histopathology, John Hunter Hospital, Newcastle, Australia; [5]Kids Cancer Centre, Sydney Children's Hospital, Randwick, Sydney, Australia

Background
MEN2B syndrome, due to pathogenic M918T variant in the *RET* proto-oncogene, carries very high morbidity and mortality with >20% of patients deceased by 25 years of age. Larger cohort studies have demonstrated that thyroidectomy performed <1 year of age drastically changes morbidity and likely mortality. However, identifying these children is clinically extremely difficult due to the constellation of non-specific gastrointestinal, musculoskeletal and endocrine symptoms, which results in the mean age of diagnosis ~13 years of age by which time medullary thyroid carcinoma has metastasised.
Aims
We advocate that including the M918T variant in *RET* gene in universal newborn screening programs and careful exclusion of intestinal ganglioneuromatosis on histopathology is the only way to enable earlier identification of affected children, which will improve clinical outcomes and provide an opportunity for thyroidectomy within the first year of life.
Results
We present a 5-patient case series with excellent clinical photography and histopathology images, including subglottic mucosal ganglioneuromatosis which has not previously been described.
Conclusion
We highlight that there are unique clinical features identifiable in the first 12 months of life of severe, persistent chronic constipation and alacrima (tearless crying) but often their significance is not recognised. There are also identifiable histopathological features of intestinal ganglioneuromatosis on gastrointestinal biopsies with adequate submucosa when the reviewing pathologist maintains a broad differential diagnosis mindset and isn't blinkered by only excluding Hirschsprung disease.

Altered neuronal function and impaired cognition among healthy people with different cortisol levels based on resting-state fMRI analysis

Wei Wang[1], Ping Gu[1] & Jiaqing Shao[1]
[1]School of Medicine, Nanjing University, Department of Endocrinology, Jinling Hospital, Nanjing, China

Background
Higher levels of cortisol have been observed in persons with cognitive decline and dementia. However, studies investigating cognitive function among healthy people with different cortisol levels are scarce.
Objective and methods
To evaluate neurocognitive function among healthy people with different cortisol levels, 241 healthy people with a morning serum cortisol level <300 umol/l were recruited. Based on serum cortisol level tertiles, voluteers were divided into three groups. All volunteers underwent a battery of validated neuropsychological tests and rest-state function MRI (rs-fMRI).
Results
Adults in high tertiles of serum cortisol displayed a significantly decreased score on MoCA, compared to those in the middle and low tertiles($P < 0.05$). Performance on delayed recall and visuospatial and executive functions domains gradually deteriorated with increases in serum cortisol levels(All $P < 0.05$). Among rs-fMRI parameters, no significant difference was observed in voxel-based morphometry (VBM). And meanwhile, mean amplitude of low-frequency fluctuations (mALFF) significantly decreased in the middle occipital gyrus, inferior occipital gyrus, angular gyrus and superior parietal gyrus among adults in high tertiles of serum cortisol, compared to the other two groups.
Conclusion
We suggest that cortisol level might be associated with cognition function among healthy people.

Which algorithm for antenatal management of disorders/differences of sex development? PECAN-VDG retrospective study of lyon multi-disciplinary prenatal diagnosis center experience

Julie Carion[1,2,3], Valeska Bidault[1,2], Jérôme Massardier[1,2], Carine Abel[2], Delphine Mallet[2], Ingrid Plotton[2,4] & Patricia Bretones[2,5]
[1]CHU de Lyon, Lyon, France; [2]Centre de Référence du Développement Génital, Lyon, France; [3]CHU de Reims, Reims, France; [4]CHU de Lyon, Hormonal and Molecular Biology CPBE GHE, Lyon, France; [5]CHU of Lyon, Pediatric endocrinolgy, Bron-Lyon, France

Context
Detection of Differences of Sex Development (DSD) in the prenatal period is increasingly frequent, thanks to improved ultrasound techniques. As no consensus exists regarding prenatal management, we report our practice for suspected isolated DSD referred to our three Multidisciplinary Centers for Prenatal Diagnosis (MCPD) over a period of 10 years.
Material and methods
All women referred for isolated ultra-sonographic suspicion of DSD to our MCPD between January 2013 and December 2022 were included; the data collected were pregnancy course, prenatal ultrasounds, prenatal hormonal and genetic investigations and neonatal outcome. We considered DSD isolated if there is no other suspected malformation at the time of referral to the MCPD, except for minor cardiopathy, renal pyelic dilatation, or intrauterine growth restriction (IUGR). Statistics are descriptive with percentages and medians (Interquartile range, IQR).
Results
71 patients were referred to the MCPD for a suspected isolated DSD, of which 57 were confirmed and followed by the experts. There were 13 pregnancies achieved by assisted reproductive technology (22. 8%) and 10 multiple pregnancies (17. 5%). For each multiple pregnancy, only one foetus was concerned by DSD. We performed SRY testing on maternal blood and prenatal invasive explorations on 10 (17. 5%) and 34 (59. 6%) mothers, respectively. Twenty-six (76. 5%) hormonal analyses, 22 (64. 7%) biochemical analyses and 34 (100%) genetic tests were performed on amniotic fluid. The genetic analyses encompassed karyotype (100%), CGH array (67. 6%), DSD panel sequencing (14. 7%) and targeted gene analysis (35. 3%). Among our 57 suspected DSD, 42 were confirmed at birth and 2 after medical termination of pregnancy (for X-linked mental retardation or extreme IUGR), 3 were invalidated before birth, 2 were epispadias, 6 false positives, and 2 false negatives. At birth, 23 newborns (52. 3%) had intrauterine growth retardation (IUGR), and 23 (52. 3%) were preterm, including 14 IUGR and 2 induced premature births by amniocentesis. Genetic diagnosis was made in 13 cases, including 5 prenatally, out of them 3 diagnosis involving impaired intellectual prognosis.
Conclusion
Prenatal management of suspected DSD seems to be relevant and requires expert counselling to prepare the birth of DSD-newborns. Out of 57 patients, three exhibited a pathological condition with an altered neurological prognosis. Further prospective multicenter studies are necessary to confirm our Results and formulate recommendations for the prenatal management of DSD.

JOINT1735

Impact of in utero exposure to sesamol on the folliculogenesis and metabolism in F1 female offspring rats

Manon Fiévet[1], Louisa Menu[1], Margaux Moreau[1], Lucie Roman[1], Annica Frau[1] & Denis Nonclercq[1]
[1]University of Mons, Faculty of Medicine, Pharmacy and Biomedical Sciences, Health Institute, Laboratory of Histology, Mons, Belgium

During last decades, diets rich in vegetables and seeds have grown in popularity. However, these so-called healthy diets can contain phytoestrogens which are potential endocrine disruptors. As hormonal fluctuations play a crucial role in genital tract differentiation, the fetal development represents a major period of vulnerability to endocrine disruptors. Sesamol, a phytoestrogen derived from sesame seeds, has a similar chemical structure to natural estrogen, enabling it to bind to estrogen receptors. By crossing the placental barrier, sesamol could disturb the hormonal balance of the foetus and interfere with the metabolism and the development of reproductive organs. The aim of this study is to investigate the effects of prenatal exposure to sesamol on the folliculogenesis and metabolism in F1 female offspring rats. From the 14th to the 19th day of gestation, pregnant female Sprague-Dawley rats were force-fed with different doses of sesamol (30 or 100 mg/kg/day). On the 4th day of post-natal life, female offspring rats were sacrificed to study reproductive (ovaries) and metabolic (liver, pancreas and kidneys) organs by histological analysis. Morphometric analysis of ovaries revealed that in utero exposure to sesamol enhanced the rate of apoptosis in oocytes present in primordial follicles, resulting in a 2-fold increase in the number of atretic follicles. However, the treatment does not affect the relative

proportion of primordial, primary and secondary follicles, and has no impact on the proliferation rate of follicular and thecal cells assessed by BrdU labeling. Concerning the study of metabolism, no major morphological alteration was observed in the kidneys of animals exposed to sesamol. However, the morphometric assessment of cell proliferation rate by anti-BrdU immunohistochemistry showed a significant decrease in the number of S-phase cells in the renal inner medulla. Moreover, a significant decrease in body weight was observed in animals exposed in utero to sesamol. Further analysis of the pancreas (anti-insulin and anti-glucagon IHC) and liver (anti-BrdU IHC, lipids accumulation) are in progress to fully understand this decrease in body weight. In conclusion, the present results indicate that sesamol seems to have a negative impact on the development of female gonads, which could lead to fertility dysfunctions in adulthood. We plan to study in greater detail the mechanisms by which sesamol increases follicular atresia and its impact on general metabolism.

Hypoglycemia to hyperglycemia: the clinical spectrum of ABCC8 gene variants

Cansu Koc[1], Ozge Bayrak Demirel[1], Mehmet Akif Yucesoy[2], Durmus Durmaz[2], Asli Derya Kardelen Al[1], Ayca Aslanger[2], Melek Yildiz[1], Sukran Poyrazoglu[1], Firdevs Bas[1] & Feyza Darendeliler[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Department of Pediatric Endocrinology, Istanbul, Türkiye; [2]Istanbul University, Istanbul Faculty of Medicine, Department of Medical Genetics, Istanbul, Türkiye

Introduction
Genetic variants in the *ABCC8* gene, which encodes the sulfonylurea receptor 1 (SUR1) subunit of the ATP-sensitive potassium channel in pancreatic β-cells, have been associated with various clinical presentations, including hyperinsulinemic hypoglycemia (HH), transient or permanent neonatal diabetes mellitus (NDM), and maturity-onset diabetes of the young (MODY). The present study aims to evaluate the relationship between clinical presentations and the different variants detected in the *ABCC8* gene.
Methods
The clinical, biochemical, and molecular data of patients diagnosed with HH, NDM, MODY, or insulin-dependent diabetes and managed at our pediatric endocrinology clinic between 1990 and 2024 were retrospectively reviewed. Only patients with identified *ABCC8* gene variants were included in the analysis.
Results
The study analyzed 18 cases, comprising 12 with HH (Cases 1–12), 4 with permanent NDM (Cases 13–16), and 2 with MODY (Cases 17–18). Among the HH cases, 16. 6% ($n = 2$; Cases 1 and 2) had a histological diagnosis consistent with focal HH. Case 1, harboring a heterozygous c. 4114C>T(p. Gln1372Ter) variant, achieved remission following lesion resection. Case 2, with a heterozygous c. 2041-25G>A variant classified as a variant of uncertain significance (VUS), underwent subtotal pancreatectomy and achieved complete recovery. Autosomal recessive diffuse HH was identified in 33. 3% ($n = 4$; Cases 3–6), with variants including c. 3512del(p. Leu1171fs), c. 3643C>T(p. Arg1215Trp), c. 96C>A(p. Asn32Lys), and c. 2041-21G>A. Autosomal dominant diffuse HH accounted for 33. 3% ($n = 4$; Cases 7–10), associated with variants c. 3418G>T(p. Glu1140Ter), c. 4135G>A(p. Gly1379Ser), c. 1792C>T(p. Arg598Ter), and c. 4612-2A>G. Compound heterozygous variants were detected in 16. 6% ($n = 2$; Cases 11 and 12). Post-pancreatectomy diabetes developed in 25% of HH cases ($n = 3$; Cases 5, 6, and 7). Among the NDM cases, the identified variants included c. 2476C>T(p. Arg826Trp) (Case 13), c. 1144G>A(p. Glu382Lys) (Cases 14, 15), and compound heterozygous c. 1670T>G(p. Ile557Arg)/c. 3431G>T(p. Arg1145Leu) (Case 16). In the MODY group, Case 17 had a heterozygous c. 1616A>G(p. Tyr539Cys) variant, while Case 18 had a heterozygous c. 946G>A(p. Gly316Arg) variant.
Conclusion
Variants in the *ABCC8* gene result in diverse clinical presentations, ranging from severe hypoglycemia to diabetes. In HH cases, modulating genetic and environmental factors may influence disease progression, with the potential for hyperglycemia in the long term due to β-cell dysfunction or surgical interventions. Early identification through molecular analysis is critical for disease progression, preventing complications, and personalized treatment approaches.

Dasiglucagon treatment consistently reduces hypoglycemia assessed by continuous glucose monitoring in children with congenital hyperinsulinism across subgroups

Indraneel Banerjee[1], Paul S. Thornton[2], Sune Birch[3], Eva Bøge[3], Theis Gondolf[3], Jelena Ivkovic[3] & Diva D. Leon-Crutchlow[4]
[1]Royal Manchester Children's Hospital, Manchester, United Kingdom; [2]Cook Children's Medical Center, Fort Worth, United States; [3]Zealand Pharma, Soeborg, Denmark; [4]Children's Hospital of Philadelphia, Philadelphia, United States

Background/Objectives
Congenital hyperinsulinism(CHI) is the most common cause of severe recurrent hypoglycemia in children. Early treatment is necessary to limit the risk of neurologic/developmental sequelae. Dasiglucagon is a glucagon analog suitable for continuous subcutaneous infusion shown to raise blood-glucose in a dose dependent manner. A 2-part phase 3 trial evaluated the efficacy/safety of dasiglucagon as add-on to standard-of-care(SoC) in children with CHI ages ≥3 months-<12 years with persistent hypoglycemia comparing dasiglucagon+SoC vs SoC only. The trial reported lower rates of SMPG-detected hypoglycemia in both groups compared to baseline, w/o statistically significant difference, but clinically meaningful reductions in all CGM-recorded measures of hypoglycemia for dasiglucagon+SoC (post-hoc analyses). Dasiglucagon was well tolerated with a safety profile in line with class effects of glucagon. Evaluation of effect on CGM percent time in hypoglycemia<70 mg/dL for consistency across different subgroups is presented here.
Methods
Evaluation of CGM percent time in hypoglycemia<70 mg/dL across subgroups was performed for the controlled part of the trial comparing dasiglucagon+SoC vs SoC. The statistical analysis model was the same as that applied in the original trial, a generalized linear regression model with normal distribution and log link function with the addition of the categorical subgroup variable and an interaction term between treatment group and the specific subgroup variable.
Results
Table displays treatment ratios for CGM percent time in hypoglycemia<70 mg/dL by subgroup. Overall effects were consistently in favor of dasiglucagon based on point-estimates for all subgroups, except for the age group of 6-12years, where there was only 1 patient in this group on dasiglucagon. Interaction *P*-values were low for some subgroups.
Conclusions
Dasiglucagon treatment in children with CHI has reported clinically meaningful reductions in CGM-recorded measures of hypoglycemia. Subgroup analysis for CGM-percent-time in hypoglycemia<70mg/dL supports consistent efficacy across subgroups. Due to the small size of the subgroups, results should be interpreted with caution. These data support the efficacy and safety of dasiglucagon as a potential novel therapy for CHI.

Update on genetic etiology in vietnamese children with congenital hyperinsulinism during 15 years (2010-2024) at tertiary pediatric center

Lan Nguyen Hoang[1], Thao Bui Phuong[1], Khanh Nguyen Ngoc[1], Ngoc Can Thi Bich[1], Mai Do Thi Thanh[1], Ha Nguyen Thu[1], Sarah E. Flanagan[2], Jayne Houghton[3] & Dung Vu Chi[1]

[1]Vietnam National Children's Hospital, Center for Endocrinology, Metabolism, Genetics/Genomics andMolecular Therapy, Hanoi, Viet Nam; [2]University of Exeter Medical School, UK, Exeter, United Kingdom; [3]Royal Devon University Healthcare NHS Foundation Trust, UK, Exeter Genomics Laboratory, Exeter, United Kingdom

Introduction

Congenital Hyperinsulinism (CHI) is the most common cause of hypoglycemia related to inappropriate insulin secretion. More than 30 genes have been identified as contributors to persistent hyperinsulinism, with mutations in the K-ATP channel genes (*ABCC8* and *KCNJ11*) being the most frequently observed in children with severe and persistent forms of the disease.

Aims

To elucidate the genetics of all probands with suspected CHI in Vietnam registered over the past 15 years.

Methods

We included 176 probands with CHI from Vietnam. All probands were screened for variants in the *ABCC8* and *KCNJ11* genes. Almost patients without mutations in the K-ATP channel genes, next-generation sequencing employing a panel of 28 CHI-related genes was used for analysis, including *ABCC8, AKT2, CACNA1C, CACNA1D, CREBBP, DNTTIP1, EP300, FOCAD, FOXA2, GCK, GLUD1, GPC3, HADH, HNF1A, HNF4A, INSR, KCNJ11, KDM6A, KMT2D, MAFA, AGEL2, NSD1, PHOX2B, PMM2, RNF10, SLC16A1* and *TRMT10A* genes and non-coding regulatory region of *HK1*. Genetic analysis was performed at the UK University of Exeter Clinical Laboratory.

Results

The genetic cause was identified in 120 out of the 176 CHI patients (68. 1%): 111 had mutations in the K-ATP channel genes (92. 5%), four in *GLUD1*, three in *HNF4A*, one in *GCK*, and one in *KMT2D* (associated with Kabuki syndrome). As a result, our findings confirm the predominant role of ATP-sensitive potassium channels in the pathogenesis of CHI in Vietnamese patients, with the remaining cases likely attributable to other factors. Furthermore, the *ABCC8* gene was found to have the most common pathogenic variants in the K-ATP channel (*ABCC8* ($n = 103$) and *KCNJ11* ($n = 8$)). We also discovered that 55 out of the 111 patients with mutations in the K-ATP channel were either homozygous or compound heterozygous, accounting for half of the cases. We identified 33 distinct variants, with c. 3403-1G > A and c. 2057T > C being the more common mutations in the K-ATP channel genes. One proband had a compound heterozygous pathogenic ABCC8 variant, with one variant inherited from the father (c. 3403-1G > A) and the other (c. 1543G > T) a mutation not identified in the mother. This suggests two possibilities: de novo mutation or germline mosaicism in the mother.

Conclusion

Genetic analysis revealed mutations in over 68 % of the CHI patients. *ABCC8* mutations are the most frequent cause of CHI in Vietnam. Half of the patients with mutations in the K-ATP channel were either homozygous or compound heterozygous, which means the variant can come from the mother, father, or be de novo.

JOINT3151 Collaborative global advocacy to improve the lives of children and families with congenital hyperinsulinism

Julie Raskin[1], Heather Mcknight[2], Clare Gilbert[3] & Al Aynsley-Green[4]

[1]Congenital Hyperinsulinism International, Glen Ridge, United States; [2]Children's Hospital of Philadelphia, Philadelphia, United States; [3]Great Ormond Street Hospital for Children, London, United Kingdom; [4]University of Northampton, Northampton, United Kingdom

Background

Hyperinsulinism (HI) is a rare, life-threatening condition affecting 1 in 28, 000 babies each year. HI results in the over secretion of insulin from pancreatic beta cells, leading to persistent severe hypoglycemia. Hypoglycemia can lead to seizures, developmental delay, visual impairment and death. Limited treatment options exist. Congenital Hyperinsulinism International (CHI) is an international non-profit organization committed to improving the lives of children and families with HI. CHI's Collaborative Research Network (CRN) consists of 62 members and advisors from 17 countries, rare disease advocates, health care providers and researchers united around the common goal of improving the lives of people impacted by HI. Through research and advocacy, the CRN is focused on the attainment of timely and accurate diagnoses, supporting new evidence-based treatments and cures, standardizing clinical guidelines, and facilitating improved access to care.

Objective

The need for an advocacy statement arose from discussions with > 600 parents, young people, and health care providers from around the world. Discussions and interactions with families uncovered basic aspects of care not generally available in many regions and countries. Through the CHI CRN an advocacy working group was formed with the mission of creating a universal advocacy statement for persons affected by HI.

Methods

Through several meetings, both in-person and virtually, CHI CRN members representing 5 countries met to produce an advocacy statement that could be utilized to assure optimal outcomes for people impacted by HI. The statement was approved by the entire CHI CRN.

Results

The finalized advocacy statement will be utilized to convey the medical and developmental needs of children with HI, urgency of timely diagnosis, access to medications and blood glucose testing supplies. There is also a focus on access to radiologic and surgical expertise, which in some cases can lead to a cure. Consultation with one of the world's eight CHI Centers of Excellence (COEs) is emphasized. The need for transitional care for young adults is highlighted. The CHI CRN Advocacy Statement and List of Essential Medical Care, Medication, Supplies and Services is available on the CHI website to be used by Healthcare advocates, embassies, insurers, family members and health care providers as they navigate and advocate for people living with hyperinsulinism. This approach to advocacy can be a template for others working with rare diseases.

Lower FT4 levels are associated with increased risk of C-section or assisted delivery

David Strich[1, 2], Elia Strich[3], Shalom Edri[1], Cherut Meirman[4], Gilad Karavani[1, 5] & David Gillis[1, 5]

[1]Hebrew university of Jerusalem, Sharee Zedek Medical Center, Pediatric Endocrinology, Jerusalem, Israel; [2]Clalit Health Service, Pediatric Specialists Clinics, Jerusalem, Israel; [3]Ben Gurion University, Beer Sheva, Israel; [4]Tel Aviv Unvirsity, Tel Aviv, Israel; [5]Hadassah University Hospital, Ein-Kerem, Jerusalem, Israel

Background and Objective

Thyroid function tests (TFT) during pregnancy differ from extra-gestational levels, particularly during the first trimester. It is unknown if there is an association between thyroid hormone levels during the three trimesters of pregnancy and mode of delivery. We compared thyroid hormone levels with the relative prevalence of Caesarian section or assisted vaginal delivery (CSA) vs normal vaginal delivery (NVD).

Methods

Delivery and newborn data from the database of Hadassah Medical Center, Jerusalem, were combined with thyroid function tests taken from the same women during pregnancy in the Clalit HMO, Jerusalem district. TSH, FT3 and FT4 z-scores were calculated according to biweekly reference levels from the same population. The risk of having FT3 or FT4 lower than 1. 5 z-score and the median TSH was calculated for the CSA vs NVD groups.

Results

There were 17, 512 mother–child pairs, 13030 were NVD and 4512 were CSA. There was a higher prevalence of FT4 z-scores below -1. 5 in the CSA groups throughout all trimesters: first trimester: 7% vs. 3. 3% ($P = 0. 001$), second: 7. 3% vs. 2. 9% ($P = 0. 001$), third: 5. 9% vs. 2. 3 ($P = 0. 039$). For median TSH z-scores there was also a significant difference by mode of delivery, for CSA vs. NVD the median TSH were, by trimesters, respectively as follows: first: 1. 54miu/l vs. 1. 59 ($P = 0. 07$), second: -1. 74 vs. 1. 76 ($P = 0. 001$) and third: 1. 98 Vs. 2. 11 ($P = 0. 04$)

Conclusion

There is an association between gestational thyroid hormone levels and mode of delivery. We speculate that lower FT4 levels during pregnancy may be associated with lower smooth-muscle tone causing poorer uterine contractions. Further research is needed to better understand the clinical significance of this.

Prevalence and predictors of small for gestational age neonates and endocrinological follow-up: a retrospective analysis of 2018 birth cohort

Serena Pizzolitto[1], Alice Fachin[1], Giulia Beltrame Vriz[1, 2], Laura Travan[2] & Gianluca Tornese[1, 2]
[1]Department of Medicine, Surgery and Health Sciences, University of Trieste, Trieste, Italy; [2]Institute for Maternal and Child Health IRCCS "Burlo Garofolo", Trieste, Italy

Background
SGA status is an important indicator of neonatal health, with potential long-term implications for growth and development. The aim of this study is to analyze the prevalence and predictors of Small for Gestational Age (SGA) neonates by weight (SGAW) and length (SGAL) in a cohort of newborns in 2018 and their endocrinological follow-up.
Methods
A total of 1505 newborns were included in this retrospective study, with complete data obtained for 1440 neonates. SGA was determined as weight and/or length <-2 SDS according to neonatal Italian Charts. Multivariate linear regression was used to analyze factors influencing neonatal weight and length, while logistic regression was performed to identify predictors of SGA status.
Results
The prevalence of SGAW was 1. 9% (28/1504), while SGAL was 3. 0% (43/1440). A total of 15 neonates (14 term, 1 preterm) were SGA for both weight and length, 13 neonates (11 term, 2 preterm) were SGA for weight only, and 28 neonates (23 term, 5 preterm) were SGA for length only. Logistic regression identified gestational age ($\beta = 0.73$; $p < 0.001$), neonatal length ($\beta = -0.65$; $p < 0.001$), placental weight ($\beta = -0.01$; $p < 0.001$), and male sex ($\beta = 1.62$; $p < 0.001$) as the main predictors of SGAW. When removing neonatal length from the model, placental weight ($\beta = -0.02$; $p < 0.001$) and twin status ($\beta = 4.83$; $P = 0.010$) were the only predictors of SGAW. Logistic regression identified gestational age ($\beta = 0.83$; $p < 0.001$), neonatal weight ($\beta = -0.055$; $p < 0.001$), and number of previous deliveries ($\beta = 0.57$; $P = 0.018$) as the main predictors of SGAL. When removing neonatal weight from the model, placental weight ($\beta = -0.01$; $p < 0.001$), twin status ($\beta = 4.79$; $P = 0.001$), and type of delivery ($\beta = 1.06$; $P = 0.027$) were the only predictors of SGAL. Only 9% of SGA neonates underwent an endocrinological follow-up, and 2% qualified for growth hormone therapy.
Conclusions
This study confirms the importance of gestational age, placental weight, and twin status as key determinants of neonatal growth. The findings highlight the higher risk of SGAW and SGAL in twin pregnancies and in cases of lower placental weight. Additionally, the low percentage of SGA neonates undergoing endocrinological follow-up underscores the need for improved postnatal monitoring. The small proportion of SGA neonates qualifying for growth hormone therapy aligns with previous findings.

Early life growth is important for pubertal growth and adult height

Carin Skogastierna[1,2], Anton Holmgren[1,3,4], Aimon Niklasson[1], Andreas Nierop[5,6], Aldina Pivodic[7,8], Anders Elfvin[1,2], Diana Swolin-Eide[1,2] & Kerstin Albertsson-Wikland[9]

Background
The early growth period, spanning from conception to approximately two years of age, is known to play a critical role in determining long-term health outcomes. We hypothesized that growth during early life could explain variations in pubertal growth, pubertal timing, and adult height.
Methods
The study was conducted on growth data from the population-based Swedish longitudinal $GrowUp_{1974\&1990}$ Gothenburg cohorts. A subgroup of 4,700 individuals (50% male, *Associations between birth characteristics, pubertal timing and adult height. Skogastierna et al Act.Ped 2024*), including participants across all gestational ages and birth sizes, was analyzed. Growth patterns were assessed using *QEPS* variables (*Modelling individual longitudinal human growth from fetal to adult life – QEPS I. Nierop et al J Theor Biol 2016*), which were examined in both univariate and multivariate linear regression models, stratified by sex; *Q*-function throughout all growth periods, and specific *E*- and *P*-functions, for early life growth and pubertal growth (*Insight into human pubertal growth by applying the QEPS growth model. Holmgren et al BMC Pediatr. 2017*), respectively.
Results
Multivariate analysis showed that early life growth accounted for 37–38% of the variation in specific pubertal growth but had a small influence on pubertal timing. Adult height variability was primarily explained by birth size (57–62%), early life growth (66–67%), and childhood growth (65–69%), with mid-parental height contributing to a lesser extent (35–39%). Additionally, height changes during puberty accounted for 8–9% of the variation in adult height.
Conclusion
These findings suggest that early life growth has a significant impact on pubertal growth and adult height but is less associated with the timing of pubertal growth.

JOINT2816

Genetic etiology of persistent short stature in chinese children born small for gestational Age

Yan Zeng[1], Ruimin Chen[1] & Zhuanzhuan Ai[1]
[1]Fuzhou First General Hospital Affiliated with Fujian Medical University,Fuzhou Children's Hospital of Fujian province, Fuzhou, China

Objective
Approximately 10%–15% of small for gestational age (SGA) infants fail to achieve catch-up growth by age 2 years, resulting in persistent short stature (SGA-SS). The genetic mechanisms of this condition remain poorly understood. This study aimed to systematically delineate the genetic landscape of Chinese SGA-SS children through integrated clinical phenotypes and multi-omics data, and to assess the diagnostic utility of a tiered genetic testing strategy.
Methods
A cohort of 97 SGA-SS children (birth length/weight < 10th percentile, height standard deviation score [Ht-SDS] < -2 s.d./3rd percentile at 2 years) underwent a stratified genetic evaluation. Subjects with a Netchine-Harbison Clinical Scoring System (NH-CSS) $\geqq 4$ or strong clinical suspicion of Silver-Russell syndrome (SRS) underwent first-line methylation-specific multiplex ligation-dependent probe amplification (MS-MLPA). Those with NH-CSS ≤ 3 underwent whole-exome sequencing (WES). Undiagnosed cases were further investigated via cross-validation (reciprocal MS-MLPA and WES testing). All variants were classified according to ACMG guidelines and confirmed via Sanger sequencing. A cohort of 57 pediatric patients receiving 12-month growth hormone (GH) therapy was stratified by genetic testing results into two subgroups: a genetically positive cohort ($n=22$) and a genetically negative cohort ($n=35$).
Results
Genetic etiologies were identified in 41.2% (40/97) of patients. The pathogenic spectrum comprised:
1. Intracellular signaling pathways/cellular processes defects (14/40, 35%), involving 12 genes (*PTPN11, KMT2D, MAP2K1, SRCAP, CHD7, BPTF, RAD21, KDM5C, NSD2, DYRK1A, ACTB, FAM111A*).
2. Imprinting disorders 25% (10/40, 25%), including 9 SRS (11p15 hypomethylation/UPD7) and 1 Temple syndrome (UPD14).
3. 6 cases harbored variants in Paracrine factors/extracellular matrix-related gene variants (6/40,15%): *ACAN, ROR2, NPR2, FGFR3*.
4. Copy number variants (CNVs) (6/40, 15%).
5. Chromosomal abnormalities (4/40, 10%)
Notably, three novel pathogenic variants (*ROR2* c.1384C>T, *ACTB* c.1104delC, and *DYRK1A* c.1702_1705del) were identified. The genetically diagnosed group exhibited more severe postnatal growth retardation (baseline Ht-SDS: -3.49 ± 1.18 vs. -2.63 ± 0.692, $P < 0.01$), though GH therapy response (ΔHt-SDS) showed no intergroup difference ($P=0.694$).
Conclusion
This multi-omics investigation achieved a 41.2% diagnostic yield in Chinese SGA-SS, revealing intracellular signaling/cellular process and imprinting disorders as predominant mechanisms. Our tiered diagnostic approach (methylation analysis combined with WES) optimized detection efficacy, while three novel variants expanded the mutational spectrum. Despite genotype-specific growth patterns, GH responsiveness appears independent of specific genetic etiology, though larger validation studies are needed.

One year treatment with anastrozole increases predicted adult height in peri-pubertal boys with aggrecan deficiency

Marco Cappa[1], Stefania Pedicelli[2], Laura Chioma[1], Mafalda Mucciolo[3], Rosario Ruta[3] & Sandro Loche[1]
[1]Bambino Gesù Children Hospital, IRCCS, Research Area for Innovative Therapies in Endocrinology, Pediatrics, Rome, Italy; [2]Bambino Gesù Children Hospital, IRCCS, UOC Pediatric Endocrinology and Diabetology, Pediatrics, Rome, Italy; [3]Bambino Gesù Children Hospital, IRCCS, Translational Cytogenomics Research Unit, Rome, Italy

Background
Aggrecan is the primary proteoglycan of the cartilage growth plate and is encoded by the ACAN gene. Patients with heterozygous pathogenic variants in ACAN often present advanced skeletal maturation and premature epiphyseal fusion leading to short stature. Recently, mutations in the ACAN gene have been recognized as a major cause of idiopathic short stature. Aromatase inhibitors (AI) have been shown to delay skeletal maturation and improve height in patients with idiopathic short stature.
Objective
with the aim of preventing inappropriate skeletal maturation, we evaluated the effect of short-term treatment with an AI on growth, bone age and pubertal maturation in a group of peripubertal boys with ACAN mutations.
Patients and Methods
7 boys aged 9. 5-13. 1 years and confirmed mutation in the ACAN gene were included in the study. Their mean (±SD) height SDS was -1. 58±0. 79 (range from -2. 83 to -0. 45), bone age 10. 9-13. 6 years, and mean target height -1. 25± 0. 76 (range from -1. 71 to 009). Their testicular volume ranged from 2 to 12 ml. All patients were treated with anastrozole at the dose of 1 mg/daily for one year. BA and predicted adult age (PAH) were evaluated using the Bailey&Pinneau method. Informed consent was obtained from all parents or the legal guardians.
Results
After 1 year height SDS increased in 4/7 children (from -0. 21 to -0. 92, from -2. 83 to -1. 92, from -1. 01 to -0. 33 and from -0. 45 to -0. 17) did not change in 2 (from -1. 56 to -1. 54 and from -2. 27 to -2. 20) and worsened in 1(from -1. 77 to -2. 04). Bone age did not progress inappropriately in any of the subjects (range 11. 6-13. 9 years). PAH significantly increased in all subjects from a mean (±SD) of -2. 47±1. 22 to -1. 760±. 82 SDS ($P < 0.005$). Puberty progressed in 6/7 children with mean testicular volume increasing from 7. 8±3. 2 to 13. 3±6. 1 ml ($P < 0.01$) and remained unchanged in 1 (2 ml). Treatment was well tolerated and did not induce noticeable side effects in any of the subjects
Conclusions
Our preliminary results indicate that treatment with AI prevents excessive bone maturation in boys with Aggrecan deficiency in the peripubertal period. This translates in sustained growth and increase in PAH. Long-term follow-up is needed to verify the effect of AI on adult height in these patients.

JOINT2829

Macimorelin test: a safer and reliable alternative to the gold standard insulin tolerance test

Sherwin Criseno[1 2 3], Chona Feliciano[1], Miriam Felicitas Asia[1], Shirley Castro[1], Zondiwe Simuwelu[1], Ofelia Manansala[1], Mary White[1], Jumsy Cyriac[1] & Helena Gleeson[1, 3]
[1]University Hospitals Birmingham NHS Foundation Trust, Endocrinology and Metabolism, Birmingham, United Kingdom; [2]University of Birmingham, College of Medical and Dental Sciences, Institute of Metabolism and Systems Research, Birmingham, United Kingdom; [3]Centre for Endocrinology, Diabetes and Metabolism, Birmingham, United Kingdom

Introduction
The insulin tolerance test (ITT) remains the 'gold standard' test for assessing growth hormone (GH) deficiency (GHD) in adults. However, this test is labour and resource intensive. Furthermore, ITT causes unpleasant symptoms resulting from the hypoglycaemia which is required to stimulate growth hormone secretion. Due to safety concerns, the use of ITT in the UK has been limited to a few endocrine centres with expertise and confidence in performing this test. Consequently, some patients who likely have GHD are not being offered appropriate and timely assessment and treatment. Macimorelin, a novel orally administered GH-releasing peptide is a safe alternative with diagnostic accuracy comparable to ITT.
Aim
The aim of this audit is to compare the real-life experience of performing ITT compared with macimorelin test (MT) in terms of resource requirements, cost and adverse events reported by each patient who have undergone these tests.
Methodology
This is a retrospective review of 12 ITTs, from January to December 2019, and 12 MTs, from March 2023 to February 2024, performed in a tertiary endocrine centre in Birmingham, UK.
Findings
The average time for completing an ITT was 199 minutes (range= 189-320) compared with 134 minutes (range= 100-165) for MT. All 12 patients who had an ITT experienced adverse effects such as dizziness, feeling unwell and clammy whilst only 1 patient who underwent MT experienced the adverse effect of dizziness. ITT required significant human and material resources including supervision from a medical practitioner, at least 2 experienced nursing staff, cardiac monitoring and hypoglycaemia rescue equipment which were not all required for MT. The overall cost of an ITT was around 700 Euros compared with 420 Euros for MT.
Discussions
ITT, whilst considered the gold-standard test for diagnosing GHD, requires substantial human and material resources and is associated with significant adverse effects which prevents its widespread utilisation in clinical practice. Additionally, the overall cost of performing an ITT, taking into account the time and resources required, is considerably more compared with MT.
Conclusion
The availability of a safer, quicker and more-tolerable GH stimulation test like MT, should no longer prevent the provision of appropriate and timely diagnosis and treatment of patients with GHD. Considering both the financial and personal burden of performing an ITT, MT should be considered as a reliable alternative as it is easy and quick to perform, associated with minimal adverse effects and has a diagnostic accuracy comparable with ITT.

Treatment with anastrozole alone or with GH increases final height in pubertal boys with short predicted adult height- real-world data

Michal Yackobovitch–Gavan[1], Ariel Tenenbaum[1, 2], Moshe Phillip[1, 2], Liora Lazar[1, 2] & Tal Oron[1, 2]
[1]The Jesse Z and Sara Lea Shafer Institute for Endocrinology and Diabetes, National Center for Childhood Diabetes, Schneider Children's Medical Center of Israel, Petach Tikva, Israel, Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, The Jesse Z and Sara Lea Shafer Institute for Endocrinology and Diabetes, National Center for Childhood Diabetes, Petach Tikva, Israel; [2]Tel Aviv University, Faculty of Medicine, Tel Aviv, Israel

Context
Short-statured mid-pubertal boys with predicted adult height (PAHt) below the third percentile present a significant therapeutic challenge. Aromatase inhibitors (AI) delay estrogen-driven epiphyseal fusion and possibly enhance adult height (AHt).
Objective
To assess the efficacy of AI treatment on AHt in mid-pubertal boys with a short PAHt due to advanced bone age (BA) or idiopathic short stature (ISS).
Design
Retrospective study.
Setting
Tertiary pediatric endocrine referral center.
Patients and methods
Two groups of mid-pubertal boys treated with AI were studied: 27 boys with fast puberty compared to matched untreated controls and 16 boys with ISS treated with GH and AI compared to those treated with GH only. Anthropometric measurements, BA and PAHt, were tracked. AHt was compared across groups.
Main outcome measures
Achieved AHt in AI-treated boys vs controls and the PAHt.
Results
Median AI treatment duration was 2. 8 for AI only and 2 years for the GH+AI groups. Throughout treatment, AI-treated groups showed similar height gain compared to their controls, a decrease in BASDS (AI only: $P = 0.009$; GH+AI: $P = 0.029$), and increased PAHt (AI only: $P = 0.003$; GH+AI: $P = 0.037$). AI-treated groups achieved taller AHt than their controls (AI only:166. 6±3. 1 vs. 163. 4±1. 3cm, $P = 0.003$; GH+AI:167. 3±6. 1 vs. 164. 9±3. 5cm, $P = 0.194$), and a more significant difference between AHt and PAHt groups (AI only: $P = 0.001$; GH+AI: $P = 0.050$).

Conclusions
AI treatment extends the growth period, resulting in an AHt surpassing initial predictions. Our findings underscore the potential of AI treatment in mid-pubertal boys with a short PAHt due to advanced BA or those with ISS treated with GH.

Effect of a short-term course of transdermal testosterone on growth, puberty and adult height in boys with constitutional delay of growth and puberty (CDGP)

Marco Cappa[1], Laura Chioma[2], Carla Bizzarri[1], Graziamaria Ubertini[2], Francesco D'Aniello[2], Tommaso Todisco[1] & Sandro Loche[1]
[1]Bambino Gesù Children Hospital, IRCCS, Research Area for Innovative Therapies in Endocrinology, Pediatrics, Rome, Italy; [2]Bambino Gesù Children Hospital, IRCCS, UOC Pediatric Endocrinology and Diabetology, Pediatrics, Rome, Italy

Background
CDGP is one of the commonest reasons for referral to a pediatric endocrinologist. Boys with CDGP are shorter than their peers and pubertal onset is delayed. The differential diagnosis between CDGP and hypogonadotropic hypogonadism can be challenging. Although it is considered a self-limiting condition, boys with CDGP may present psychosocial burden and need treatment with testosterone to induce puberty, accelerate growth and improve quality of life. Transdermal administration of testosterone (TT) has been shown to be effective, but little is known on the long-term effects of in boys with CDGP.
Study design
Retrospective study in a single tertiary center of pediatric endocrinology.
Patients and Methods
The clinical records of 40 patients with CDGP who completed a long-term clinical evaluation were retrospectively analyzed. At the start of treatment, their mean (SD) age was 14 (0, 8) y, mean bone age was 12. 3 (0. 6) y, mean height standard deviation score (HSDS) was -1. 93 (0. 7), mean height velocity SDS (HVSDS) was -3. 26 (1. 78), mean BMI SDS was -0. 8 (1. 1), mean target height SDS (THSDS) was -0. 5 (0. 6), mean testicular volume (TV) was 4. 6 (1. 0) ml, and mean T concentration was 65. 2 (36. 6) ng/dl. All known causes of delayed growth and puberty had been excluded. Informed consent was obtained from the patients and from their legal guardians. All subjects were treated with TT gel (2%) at the dose of 10 mg/day for 3 months. They were re-evaluated after 6 months and 1 year from the start of treatment and at the attainment of adult height (HV $<$ 2 cm/y).
Results
After 6 months mean HSDS was -1. 76 (0. 91), and mean TV was 7. 4 (3. 2 ml). After 1 y mean HSDS was -1. 55 (0. 78), TV was 11, 5 (3. 7 ml), and mean T concentration was 281 (103) ng/dl. Mean adult HSDS was -0. 5 (0. 8) at a mean age of 18. 9 (1. 1) y, with a mean TV of 11. 4 (3. 7) ml, mean T concentration of 433 (90) ng/dl, and mean BMI SDS was -0. 39 (0. 9). The mean increase in HSDS between treatment start and adult height was 1. 3 (0. 65). All subjects reached their genetic TH. Treatment was well tolerated and did not induce noticeable side effects.
Conclusions
This study shows that a 3 months course of TT accelerates growth and pubertal progression and has no detrimental effects on adult height.

Genetic insights into short stature: an evaluation of clinical, hormonal, and genetic parameters in a real world paediatric cohort

Virginia Rossi[1], Claudia Lattanzi[1], Ruben H. Willemsen[1], Eleanor Hay[2] & Evelien Gevers[1, 3]
[1]Barts Health NHS Trust-Royal London Children's Hospital, Department of Paediatric Endocrinology, London, United Kingdom; [2]Great Ormond Street Hospital for Children NHS Foundation Trust, Department of Clinical Genetics, London, United Kingdom; [3]Queen Mary University of London, William Harvey Research Institute, Centre for Endocrinology, London, United Kingdom

Aim
To assess the identification of genetic causes in children with short stature (SS) and to identify diagnostic patterns and inheritance in the real world.
Methods
A real world cohort referred for SS (n = 150; 91 males, height $<$-2 SD or short for parents) was grouped as: atypical Growth Hormone deficiency (GHD, n = 8), no genetic diagnosis (non-SGA, n = 49; SGA, n = 33), genetic diagnoses (GH-axis-related, n = 4; bone-related, n = 20; non-GH/bone-related, n = 14; possibly SS-related/VUS (variant-of-unknown-significance), n = 10), and pre-referral genetic diagnosis (n = 12). Typical GHD, Turner syndrome, and Constitutional Delay of Growth and Puberty were excluded.
Results
Boys' mean referral age was 6. 13 $\pm$ 4. 34 years and girls' 7. 10 $\pm$ 4. 2 years. Boys' mean referral height was -3. 03 $\pm$ 1. 29 SD and girls' -3. 19 $\pm$ 1. 37 SD. Genetic diagnosis was made in 33% of patients, plus 7% showed VUS. Missense variants prevailed in GH-axis- and bone-related gene variants, and copy-number-variations (CNVs) in the VUS-group. Predominant pathogenic gene variants were *CUL7* (4x, 2 siblings), *NPR2* (3x, 2 siblings), chromosome 14 hypomethylation (3x, 2 siblings), *SMAD4* (3x), *ATM* (2x, siblings), *DYRK1A* (2x), *CDC45* (2x, siblings), *H19* hypomethylation (2x). GH-axis-related genes included *PTPN11*, *BRAF*, *SOS1* and *IGF1R* variants. VUS included *SHOX* (3x), *ACAN*, *KMT2A*, *FGFR1*, *FGFR2*, *MNX*, 21q22. 2 duplication, 10q22. 2-23-3 duplication. Inherited variants prevailed in bone-related gene variants, de novo in non-GH/bone variants. Eleven boys and one girl had pre-referral diagnoses. Excluding those, gender did not affect genetic diagnosis likelihood ($p > 0.05$), nor did being SGA or having microcephaly (HC $<$-2SD). Genetic diagnosis likelihood was higher if height $\leq$-2. 5 SD vs height $>$-2. 5 SD (30% vs 23%). Patients with bone-related genetic variants had most severe SS (height SDS -3. 89 $\pm$ 2. 15 vs others -2. 97 $\pm$ 1. 11; P = 0. 0035), and higher BMI SDS (0. 27 $\pm$ 2. 03). Patients with GH-axis-related variants had the lowest BMI SDS (-2. 45 $\pm$ 0. 36; ANOVA P = 0. 035). Dividing IGF1 into quintiles, elevated IGF1 prevailed in GH-axis (25%) and bone-related (29%) diagnoses, while atypical GHD had most frequent low IGF1 (38%). Non-GH/bone diagnoses were more prevalent in those with microcephaly (17% of genetic diagnoses if HC $\leq$ 2 SDS), while bone-related diagnoses were more frequent if HC $>$ 2 SDS (20% of the genetic diagnoses).
Conclusions
Genetic testing is crucial for SS, including for mild SS (-2 to -2. 5 SD), enabling personalised care and potentially improving clinical outcomes. Bone-related gene variants are the leading cause for short stature, and affected patients are shorter, often with high IGF1, which requires further research.

JOINT318

Evaluation of the pharmacokinetics (PK), pharmacodynamics (PD), and safety of the new capsule formulation of LUM-201, an oral growth hormone secretagogue

Erik Brincks[1], Alpa Parikh[1], Melissa Quesnot[1], Christopher Smith[1], Ronald Christopher[2] & John McKew[1]
[1]Lumos Pharma, Inc., Austin, TX, United States; [2]Parallel 33 Consulting, Inc, Solana Beach, CA, United States

Objectives
The primary objectives were to evaluate the relative bioavailability (BA) between the tablet and capsule formulations, to assess the food effect (FE) on the BA of the capsule formulation, and to evaluate the safety and tolerability of the capsule formulation. Secondary objectives included evaluating the PK of the major metabolite of LUM-201 (M8) and the PD response (serum GH) to the new formulation.
Methods
Part 1 was a 4-sequence, 4-treatment, 4-period crossover study to determine the relative bioavailability of the tablet and the new capsule formulation. Part 2 was a 2-sequence, 2-treatment, 2-period crossover study to evaluate the food effect on the capsule formulation. Comparisons are reported as Dose-Normalized $AUC_{0\text{-inf}}$ ($DNAUC_{0\text{-inf}}$) and Dose-Normalized C_{max} (DNC_{max}).
Results
The new capsule formulation showed bioequivalence to the tablet formulation in terms of $DNAUC_{0\text{-last}}$ and $DNAUC_{0\text{-inf}}$. Compared with the 90 mg tablet dose, significant decreases in DNC_{max} were observed with 85. 3mg whole capsule (14. 1% lower), with 85. 3mg capsule contents in a dosing cup (20. 4% lower), or 85. 3mg capsule contents in banana puree (14. 4% lower). Food increased the C_{max} of LUM-201 by 64. 4% and $AUC_{0\text{-last}}$ and $AUC_{0\text{-inf}}$ by 17. 8%. There was no significant effect of food on the PK parameters of the metabolite M8; the geometric least squares (GLS) mean ratio% (90% CI) for M8 C_{max} was 106. 30% (74. 20, 152. 20), and for $AUC_{0\text{-last}}$ and $AUC_{0\text{-inf}}$, the ratios were 96. 40% (82. 40, 112. 80) and 96. 50% (82. 70, 112. 50), respectively. Serum GH concentrations increased similarly across all dose formulation treatment groups. Regarding food

effect with LUM-201, the fed state reached C_{max} 30 min later than the fasted state (C_{max} of fed = 14. 10 ng/mL; C_{max} of fasted = 22. 18 ng/mL). Importantly, serum GH reached similar C_{max} values by 1. 5 h after dose regardless of fed state. Serum IGF-1 concentrations remained stable over time in both parts of the study. Safety and tolerability of LUM-201 were consistent with the established safety profile; no SAEs were reported.
Conclusions
Overall, the study demonstrated that the new capsule formulation of LUM-201 has a favorable investigational safety profile, is well-tolerated, and exhibits comparable bioavailability to the tablet formulation, with consistent PK parameters for the metabolite M8 and encouraging PD responses. The new LUM-201 capsule formulation filled with mini-tablets produces similar PK and PD results compared with the current tablet formulation and offers children & their caretakers a more flexible and user-friendly oral capsule formulation.

The need for early reassessment in children with growth hormone deficiency

Adel Djermane[1], Yasmina Ouarezki[1], Sakina Kherra[2], Kahina Mohammedi[3], Kamelia Boulesnane[4], Asmahane Ladjouze[5], Bensalah Meriem[6] & Hachemi Maouche[1]
[1]Algiers University 1, Hassan Badi Public Hospital, Pediatric, Algiers, Algeria; [2]Algiers University 1, Nafissa Hamoud Teaching Hospital, Pediatric, Algiers, Algeria; [3]Algiers University 1, Ain Taya Public Hospital, Pediatric, Algiers, Algeria; [4]Algiers University 1, Lamine Debaghine Teaching Hospital, Pediatric, Algiers, Algeria; [5]Algiers University 1, Beni Messous Teaching Hospital, Pediatric, Algiers, Algeria; [6]Algiers University 1, HCA Ain Naadja, Endocrinolgy, Algiers, Algeria

Introduction
Diagnosing childhood-onset growth hormone deficiency (GHD) requires biochemical testing through provocative measures. Retesting in late adolescence or early adulthood is crucial to determine the need for continued recombinant human growth hormone (rhGH) treatment. Early retesting can prevent potential over-treatment of this condition.
Aim
We aimed to define the predictive criteria for children with GHD who may benefit from the reevaluation of GH status early in the course of rhGH treatment.
Methode
Seventy-five children with growth hormone deficiency were retested at least after one year of GH treatment. The initial clinical, laboratory characteristics and treatment response of those with a normal (GH $\geq$6. 7 ng/ml) and those with a subnormal response were compared.
Results
After retesting, 31 (41. 3%) patients had a GH response of $\geq$6. 7 ng/ml. The mean age at revaluation was 12. 1$\pm$3. 8 years and the mean duration of GH treatment was 4. 13$\pm$2. 4 years. Children with permanent GHD are significantly smaller at diagnosis (-3. 28 vs -2. 65 SDS), have a higher height gain (1. 99 vs 1. 33 SDS) and more MRI abnormalities ($P < 0.0001$). Biochemical parameters: IGF1 SDS at diagnosis, IGF1 at re-evaluation SDS, initial GH peak, re-evaluation GH peak, were all significantly lower in the permanent GHD group ($P < 0.0001$).
Dicussion
The present findings are in agreement with those previously reported by other groups, which demonstrated that the GH response to stimulation was found to be normalised in a number of patients diagnosed with GHD. The results of the present study carry significant clinical implications, in terms of both the accuracy of diagnosis and the efficacy of therapeutic decisions, with the objective of avoiding the cost and burden of long-term growth hormone (GH) treatment, the efficacy of which is uncertain.
Conclusion
Early retesting is recommended for paediatric patients with suspected growth hormone (GH) deficiency to ensure accurate diagnosis.

Long-acting pegylated growth hormone in prepubertal children with turner syndrome: a 3-year multicenter study in China

chen Jiajia[1], Yongfen Lv[2], Hongwei Du[3], Yaping Ma[4], Lianshu Han[5], Feihong Luo[6], Guimei Li[7], Linqi Chen[8] & Chunxiu Gong[9]
[1]Beijing Children's Hospital, Capital Medical University, National Centre for Children's Health, Department of Endocrine and Genetics and Metabolism, Beijing, China; [2]Children's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai Children's Hospital, Shanghai, China; [3]The First Hospital of Jilin University, Changchun, China; [4]Affiliated Hospital of Jiangnan University, Wuxi, China; [5]Xinhua Hospital, Shanghai Institute of Pediatric Research, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [6]Children's hospital of Fudan University, Shanghai, China; [7]Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China; [8]Children's Hospital of Soochow University, Suzhou, China; [9]Beijing Children's Hospital, Capital Medical University, National Centre for Children's Health, Beijing, China

Background
Short stature is a major feature of Turner syndrome (TS) and requires long-term growth hormone (GH) treatment. We report the results of the 3-year trial evaluating the efficacy and safety of pegylated recombinant human growth hormone (PEG-rhGH) in the treatment of children with TS.
Methods
Eleven hospitals in China conducted this 3-year multicenter, open-label, randomized, negative-controlled, phase 2 and 3 clinical trial. First-year patients were randomized to 0. 1 mg/kg/week (LD), 0. 2 mg/kg/week (HD), and an untreated control group. In the second year, the control group was directly given 0. 2 mg/kg/week of PEG-rhGH, and the other children were adjusted according to the annual growth rate of each visit and IGF-1 SDS, and the maximum single dose should not exceed 0. 4 mg/kg/week. The study reported changes in the height standard deviation score (Δ HT-SDS), while observing drug-related side effects over time. The trial has been registered with ClinicalTrials. gov, number NCT03189160.
Findings
A total of 180 patients aged 2. 9 to 16. 2 years were randomly assigned to each study group. 144 patients completed 3-year-treatment. The average ΔHT-SDS from baseline after 3-year-treatment was 0. 92, 1. 32, 0. 77, respectively in the LD, HD and control group. There were statistically significant differences between any two of the three groups ($P < 0.0001$ for all). There were statistically significant differences in change in IGF-1SDS and IGF-1/IGFBP-3 from baseline after 3-year-treatment between any two of the three groups ($P < 0.0001$). Injection site atrophy occurred in 3 cases (1. 67%) and injection site sclerosis occurred in 1 case (0. 56%). No serious treatment-related adverse events There were no adverse events that resulted in discontinuation, dose reduction, or death. Laboratory test indicators at each visit after treatment did not show any special safety issues.
Conclusion
The study is the first a clinical trial for registration of long-acting rhGH for the treatment of short-statured children with TS. PEG-rhGH injection 0. 2 mg/kg/w can significantly improve HT-SDS of Turner syndrome, and had a good safety and tolerability.

Gastrointestinal and nutritional challenges in silver-russell syndrome: changes in management and outcomes since 2015

Marie Challiol[1], Marie-Pierre Luton[1], Amélie Perrière[1], Mael Drouin[1], Irene Netchine[2] & Beatrice Dubern[3]
[1]Sorbonne Université, APHP, Hôpital Armand Trousseau, Explorations Fonctionnelles Endocriniennes, Paris, France; [2]Sorbonne Université, INSERM, Centre de Recherche Saint Antoine, APHP, Hôpital Armand Trousseau, Explorations Fonctionnelles Endocriniennes, Paris, France; [3]Sorbonne Université, APHP, Hôpital Armand Trousseau, Nutrition et Gastro-entérologie Pédiatriques, Paris, France

Background
Silver-Russell syndrome (SRS) is a rare (epi)genetic disorder characterized by severe intrauterine and postnatal growth retardation, relative macrocephaly at birth, prominent forehead, body asymmetry and early feeding difficulties. Primary molecular causes are loss of methylation within the 11p15. 5 imprinting control region (*H19/IGF2*) [11p15 LOM] and maternal uniparental disomy of chromosome 7, [upd(7)mat]. While feeding difficulties are a key feature of SRS, gastrointestinal manifestations were first described in 2014 by Marsaud *et al*. In 2015, the first international consensus on SRS was published, providing standardized recommendations. It remains unclear whether these recommendations have influenced management and subsequently the nutritional status and of patients born after this publication.

Objective
To assess the evolution of gastrointestinal and nutritional manifestations in SRS patients born after the 2015 international consensus and compare findings to previous data published in 2014 for patients followed in the same center.
Subjects and Methods
A retrospective study included 56 patients born after the consensus publication ($n = 42$ with 11p15 LOM and $n = 14$ with upd(7)mat). Nutritional status, gastrointestinal manifestations (feeding difficulties, gastroesophageal reflux disease [GERD], vomiting, constipation), and management (nutritional enrichment, requirement and modality of enteral nutrition, treatments) were analyzed.
Results
Nutritional status at 2 years old (BMI, weight-to-height ratio (W/H)), as well as the prevalence of GERD and vomiting, remained comparable to those reported by Marsaud *et al*. However, constipation prevalence was significantly higher (50% vs. 20%, $P < 0.05$). The proportion of patients requiring enteral nutrition remained stable (temporary nasogastric tube or gastrostomy), but the percentage of gastrostomy was significantly lower (10.7% vs. 21%, $P < 0.05$) than those reported in the previous study. Notably, patients with maternal uniparental disomy of chromosome 7 (upd(7)mat) underwent gastrostomy more frequently than those with 11p15 LOM (35.7 % vs 2.4%, $P < 0.05$). Additionally, 48.2% of patients received cyproheptadine treatment (an H1 antihistamine with an orexigenic effect) with a significant improvement in W/H ratio at six months following its introduction (+3.59%, 95% CI [1.069; 6.107]).
Conclusion
Gastrointestinal and nutritional issues remain a major concern in SRS. The implementation of the 2015 international consensus has led to improve identification of symptoms such as constipation, better nutritional status through targeted therapeutic strategies such as cyproheptadine (mentioned in the 2015 consensus as a therapy to evaluate) and/or early Growth Hormone therapy, and to a significant reduction of gastrostomy implemented, reflecting an evolution in clinical management.

Does pubertal induction with transdermal or oral estrogen have an impact on uterine dimensions in Turner syndrome?

Hasan Yanik[1], Ipek Merve Evruke[2], Cansu Koc[1], Ozlem Dural[2], Asli Derya Kardelen Al[1], Melek Yildiz[1], Sukran Poyrazoglu[1], Firdevs Bas[1] & Feyza Darendeliler[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Department of Pediatric Endocrinology, Istanbul, Türkiye; [2]Istanbul University, Istanbul Faculty of Medicine, Department of Obstetrics and Gynecology, Istanbul, Türkiye

Objective
Individuals with Turner syndrome (TS) often require estrogen replacement therapy (ERT) for pubertal induction. However, data on the optimal replacement regimen and effects on uterine growth are limited. This study aims to evaluate the impact of different routes of ERT on uterine dimensions in individuals with TS.
Methods
This is a single-center, cross-sectional study. It included 19 individuals with TS aged 15–30 (median age:22.3) years who had undergone pubertal induction with transdermal ($n = 15$, initiation dose of 6.25 mg/day) or oral 17β-estradiol ($n = 4$, initiation dose of 0.25 mg/day) preparations, and 20 healthy controls (median age:21.5 years). Uterine length, fundal transverse diameter, fundal anteroposterior diameter, cervical anteroposterior diameter, fundal-cervical ratio (FCR), endometrial thickness, and uterine volume were assessed by transabdominal pelvic ultrasonography. Anthropometric measurements, karyotype, laboratory data, and treatment information were obtained from existing patient records. Those who discontinued ERT after the transition to adult clinics ($n = 5$) were considered non-adherent. The TS group was divided into subgroups according to ERT route (transdermal, 17β-estradiol), treatment adherence (adherent, non-adherent) and karyotype characteristics (45, X=classic, karyotypes other than 45, X=non-classic).
Results
The median height in the TS group was 152 (range:147–161) cm, and the median BMI was 24.6 (range:17.8–42.5) kg/m^2. The median age at initiation of pubertal induction was 13.5 (range:12.0–15.7) years. Uterine volume was significantly lower in the TS group compared to the control group ($P < 0.001$); however, in those who underwent pubertal induction with transdermal estrogen, uterine length was not significantly different from the control group ($P = 0.194$). The oral 17β-estradiol group had significantly lower fundal anteroposterior diameter and uterine volume than the transdermal group ($P = 0.021$ and $P = 0.028$, respectively). Except for the FCR, all uterine dimensions were significantly lower in the non-adherent group compared to those with adherent. There were no statistically significant differences in uterine dimensions between the karyotype groups. Growth hormone therapy (GHT) was administered to 94.7% ($n = 18$) of individuals with TS. A moderate, statistically significant positive correlation was found between duration of GHT and uterine volume ($r = 0.518$, $P = 0.023$).
Conclusion
This study highlights the significant impact of the route of ERT for pubertal induction on uterine development in TS. Underlining the importance of adherence, non-adherent was associated with significantly smaller uterine dimensions. Although our sample size is limited, transdermal estrogen showed superior outcomes in uterine size development compared to oral 17β-estradiol. GH therapy does have a positive correlation with uterine length in both routes of ERT.

High diagnostic yield of WES in identifying monogenic causes of severe short stature in consanguineous children across three countries: importance of cellular mechanisms in extreme growth disorders

Shenali Anne Amaratunga[1], Tara Hussein Tayeb[2], Mona Nourbakhsh[3], Maryam Razzaghy Azar[3], Hala Al Shaikh[4], Petra Dusatkova[1] & Jan Lebl[1]
[1]Department of Paediatrics, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic; [2]Department of Paediatrics, Sulaimani University, College of Medicine, Sulaimani, Iraq; [3]Hazrat Aliasghar Children Hospital, School of Medicine, Iran University of Medical Sciences, Tehran, Iran; [4]Department of Paediatric Endocrinology, Muscat Private Hospital, Muscat, Oman

Introduction
Severe short stature defined as height below -4 SD is extremely rare and typically indicates a genetic pathology. Despite its clinical significance, data on its genetic aetiology are limited. One of its subtypes, primordial dwarfism is a defect in overall body size determination rather than isolated bone growth. While milder forms of short stature is regulated by the GH–IGF-1 axis and growth plate, severe cases may involve fundamental cellular processes, such as cell division, DNA replication, and genome stability, leading to reduced cell proliferation. This study aims to map the genetic spectrum of severe short stature using next-generation sequencing (NGS) in a unique cohort of children from consanguineous families.
Patients and Methods
Thirty-three probands (16 females) with height $\leq$ 4SD from 1st cousin consanguinity (with/without syndromic features), examined in three centres for paediatric endocrinology in Iraq, Iran and Oman between January 2022 and February 2023, were included in the study. DNA of the proband, both parents, and health/affected siblings (when available) was obtained with informed consent. Probands' DNA was analyzed by Whole Exome Sequencing. Data was processed by a bioinformatic pipeline and SNP and CNV variants were filtered using variant analysis software. Prioritized potentially pathogenic variants were evaluated by the ACMG standards and confirmed using Sanger sequencing.
Results
A monogenic cause of severe short stature was elucidated in 21/33 (64%) probands. Median height was -5.4 SD (IQR -7.3 to -4.6 SD) and median age 8.1 years (IQR 5.2 to 11.2). Pathogenic or likely pathogenic variants were found in genes involved in the GH-IGF-1 axis (*GHR*[2], *GH1*[2]), growth plate and extracellular matrix (*ACAN*, *COL1A2*, *DYM*[2], *FN1*), signal transduction and gene regulation (*NF1*, *ZSWIM6*), DNA repair and chromosomal stability (*NIPBL*, *LIG4*), cytoskeletal structure and cell division (*CUL7*, *PCNT*, *POC1A*), transmembrane transport and metabolism (*SLC4A1*, *SLC7A7*, *SLC34A3*, *GNPNAT1*), and apoptosis regulation (*PDCD6IP*). Homozygous pathogenic variants were prevalent, however there were 3 heterozygous variants, one de novo variant and one compound heterozygous variant. Majority of genes (12/18) were genes involved in fundamental cellular processes.
Conclusion
NGS is a valuable tool for uncovering the genetic basis of severe short stature, particularly in consanguineous populations where recessive inheritance patterns are common. Our findings highlight the genetic heterogeneity of severe short stature, and the presence of majority of variants outside the traditional GH-IGF-1 and growth plate pathways underscores the role of fundamental cellular mechanisms in extreme growth disorders.

Evolving genetic influences on infant growth: a longitudinal analysis of polygenic scores and growth patterns in infancy

Alexander S. Busch[1], Casper Hagen[2] & Anders Juul[2]
[1]University Hospital Münster, Dept of General Pediatrics, Münster, Germany; [2]Rigshospitalet, Department of Growth & Reproduction, Copenhagen, Denmark

Background
Infant growth results from a complex interplay of genetic, environmental, and hormonal factors, influencing early development and future health. Large population-based GWAS have identified genetic loci linked to traits such as birth weight, adult height, and BMI, enabling the use of polygenic scores (PGS) to reveal genetic predispositions shaping growth and body composition. Examining these associations in infancy may provide insights into the origins of lifelong growth patterns and health risks, including obesity and cardiometabolic diseases. This study aimed to explore how genetic influences on infant growth develop during the first year of life.
Objective
To investigate the association between PGS for birth weight, adult BMI adult body height and IGF-1 levels with anthropometric measurements as well as IGF-I serum concentrations, as assessed by age-specific standard deviation scores (SDS) , in healthy infants.
Methods
We conducted a longitudinal cohort study (COPENHAGEN Minipuberty Study, 2016-2018) involving 210 healthy, term newborns (female, $n = 101$), with up to six clinical examinations over the first year of life. Publicly available PGS were analyzed alongside with repeated measurement in infants.
Results
PGS for birth weight was significantly associated with birth weight SDS in our cohort (adjusted for gestational age: $P < 0.001$). However, the PGS for birth weight was not associated with the child's weight SDS at one year of age ($P = 0.86$). The PGS for adult BMI was associated with weight SDS at one year of age ($P = 0.02$) as well as with birth weight SDS ($P = 0.03$). The PGS for adult height was associated with height SDS at one year of age ($P = 0.002$) as well as with birth length ($P = 0.04$). PGS for IGF-I were not associated with IGF-I SDS at 1 month (β=0. 40, 95%CI: -2. 01−2. 81) and 2 months (β=1. 84, 95% CI: -0. 65−4. 32), but reached statistical significance at 6 months (β=3. 80, 95%CI: 1. 29 to 6. 31) and 12 months (β=4. 57, 95%CI: 1. 84−7. 31).
Conclusion
Our findings reveal that genetic influences on growth, particularly those linked to adult height and BMI, begin to manifest during the first year of life, while the impact of birth weight genetics gradually diminishes during infancy. Concerning IGF-I, genetic influences appear to be minimal at birth but gradually strengthen as infancy progresses. These results underscore the dynamic interplay between genetic predispositions, IGF-I, and early growth, emphasizing that genetic contributions to physical development are dynamic and unfold progressively throughout infancy.

Effects of the ketogenic diet compared to the mediterranean diet in patients with acromegaly

Valentina Guarnotta[1], Maria Pia Basone[1], Mattia Biondo[1], Laura Tomasello[1] & Giorgio Arnaldi[1]
[1]Università degli studi di Palermo, Palermo, Italy

Background and Aim
The current study aims to evaluate the impact of a ketogenic diet followed by a Mediterranean diet on IGF-1 levels and metabolic parameters in patients with active acromegaly.
Materials and Methods
We conducted a prospective study on 25 acromegalic patients followed at our endocrinology unit on medical treatment (17 were treated with somatostatin analogues alone, 5 were on combined pegvisomant and somatostatin analogues and 3 were on pegvisomant treatment alone). Participants underwent a structured dietary intervention: an initial ketogenic diet (70% fat, 25% protein, 5% carbohydrates) for 3 weeks, followed by a Mediterranean diet (40% carbohydrates, 30% fat, 30% protein) for further 3 weeks. Anthropometric parameters, fasting glucose, insulin, HOMA-IR, HbA1c, lipid profile, liver enzymes, IGF-1 levels, and inflammatory markers (neutrophil-to-lymphocyte ratio, lymphocyte-to-platelet ratio) were assessed at baseline, after the ketogenic phase, and at the end of the Mediterranean phase. In addition, a bioelectrical impedance analysis (BIA) was performed at baseline and after ketogenic diet to evaluate fat and lean masses. Pharmacological treatment for acromegaly was maintaned stable for the duration of the study.
Results
All included patients completed the study. After 3 weeks of ketogenic diet, we observed a significant reduction in weight ($P = 0.001$), BMI ($P = 0.009$), waist circumference ($P = 0.011$), hip circumference ($P = 0.003$), lean mass ($P = 0.01$), fat mass ($P = 0.01$), IGF-1 ($P = 0.02$), blood glucose ($P = 0.004$), and AST ($P = 0.021$), compared to baseline. After we compared the effects of the ketogenic diet vs Mediterranean diet and we found significant higher glucose ($P = 0.045$), insulin ($P = 0.006$) and HOMA-IR ($P = 0.003$) values. At multivariate analysis, IGF-1 positively correlated with weight ($P = 0.014$, beta = 1. 568).
Discussion
Our findings suggest that a ketogenic diet may play a role in modulating IGF-1 levels and improving metabolic parameters in patients with active acromegaly. IGF-1 reduction may be partly mediated by the lower insulin levels induced by KD, as insulin is a known regulator of hepatic IGF-1 production. Furthermore, the significant weight loss observed during the KD phase may have contributed to the decrease in IGF-1, as demonstrated by the positive correlation between IGF-1 and body weight in our multivariate analysis. Our study provides preliminary evidence supporting the use of KD as a potential adjunctive strategy in the metabolic management of acromegalic patients. Further larger-scale, long-term studies are warranted to confirm these findings.

Comparative efficacy of growth hormone, aromatase inhibitors, and gonadotropin-releasing hormone agonists in idiopathic short stature with advanced bone age

Ashraf Soliman[1], Ahmed Elawwa[1], Shayma Ahmed[1], Nada Alaaraj[1], Noor Hamed[1] & Fawzia Alyafei[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Idiopathic short stature (ISS) with advanced bone age presents unique challenges in pediatric endocrinology, as accelerated skeletal maturation reduces growth potential and limits final height. Growth hormone (GH) therapy has been widely used, but adjunctive therapies such as aromatase inhibitors (AIs) and gonadotropin-releasing hormone agonists (GnRHa) show promise in optimizing height outcomes by delaying bone maturation. This review evaluates these therapies individually and in combination for managing ISS with advanced bone age.
Objectives
This review aims to assess the efficacy of GH, AIs, and GnRHa, alone or in combination, in improving height outcomes and controlling bone age progression in children with ISS. It also explores the impact of these therapies on height standard deviation scores (HtSDS), growth velocity, and predicted adult height (PAH) to identify the most effective treatment approaches.
Methods
A systematic analysis of 19 studies published between 1994 and 2024 was conducted. The studies included children diagnosed with ISS and advanced bone age, treated with GH, AIs, GnRHa, or combinations of these therapies. Outcomes such as PAH improvement, HtSDS gain, bone age control, and treatment safety profiles were examined to draw Conclusions on therapeutic efficacy.
Results
Across 19 studies, GH monotherapy improved HtSDS modestly, with gains ranging from +0. 62 to +1. 21 over treatment durations of one to three years. Predicted adult height increased by 8. 5 ± 3. 7 cm in some cases, with short-term benefits evident in prepubertal children. However, GH monotherapy often advanced bone age proportionally to height gain, limiting final height outcomes. Combination therapies of GH with GnRHa or AIs consistently outperformed GH alone. These combinations delayed skeletal maturation, prolonged growth periods, and yielded greater PAH gains, often exceeding 10 cm. GH + GnRHa therapy was particularly effective in early puberty, while GH + AI therapy showed substantial height improvements in boys with advanced skeletal maturity. Triple therapy (GH + GnRHa + AI) demonstrated the most robust outcomes, achieving significant PAH gains and effective bone age control, although mild side effects such as acne and mood changes were noted in some cases.
Discussion
Combination therapies provide superior height outcomes by synergistically addressing skeletal maturation and growth stimulation. GnRHa delays puberty and reduces bone age advancement, while AIs inhibit estrogen-mediated-growth plate closure.

Conclusion
Combination therapies involving GH, GnRHa, and/or AIs are highly effective for ISS with advanced bone age, offering substantial height gains and controlled bone maturation. Long-term studies are needed to assess safety and treatment protocols.

Long-acting PEGYlated recombinant human growth hormone (jintrolong) in short children born small for gestational age: 4-year results from a multicenter, randomized, dose-response trial in china

Xiaoping Luo[1], Ling Hou[1], Yan Zhong[2], Xiaobo Chen[3], Hongwei Du[4], Yu Yang[5], Feihong Luo[6], Zhuangjian Xu[7], Wenhui Song[8], Xuefan Gu[9] & Yanlin Chen[10]
[1]Tongji Hospital, Tongji Medical College, Huazhong University of Science & Technology, Wuhan, China; [2]Hunan Children's Hospital, Changsha, China; [3]Children's Hospital, Capital Institute of Pediatrics, Beijing, China; [4]The First Hospital of Jilin University, Changchun, China; [5]Jiangxi Provincial Children's Hospital, Nanchang, China; [6]Children's Hospital of Fudan University, Shanghai, China; [7]Affiliated Hospital of Jiangnan University, Wuxi, China; [8]Shanxi Children's Hospital/Shanxi Women and Children Hospital, Taiyuan, China; [9]Xinhua Hospital Affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China; [10]Changchun GeneScience Pharmaceutical Co., Ltd., Shanghai, China

Objectives
The efficacy and safety of weekly PEGylated human growth hormone (PEG-rhGH) (Jintrolong) was evaluated over 4 years in children with short stature born small for gestational age (SGA).
Methods
This is a multicenter, randomized, open-label, dose-response trial, including a 52-week main phase (NCT02375620) and an ongoing safety extension phase continuing until reaching near-adult height (NAH), conducted across 9 sites in China. Ninety-six growth hormone (GH)-treatment-naïve, non-GH-deficient, prepubertal short children born SGA were randomized in a 1:1 ration to receive weekly subcutaneous administration of Jintrolong 0. 1 mg/kg/week or 0. 2 mg/kg/week for 52 weeks. Children who completed the 52-week main phase proceeded to the extension phase, while Jintrolong was administered at an initial dose of 0. 2 mg/kg/week. Dose adjustments based on annualized height velocity (AHV; cm/year) and insulin-like growth factor I (IGF-I) response, were made up to a maximum of 0. 4 mg/kg/week until achieved NAH or the patient's voluntary discontinuation. The primary endpoint was the change of height standard deviation score ($\triangle$HT SDS) from baseline to week 52 and every 52 weeks in the extension phase. Other growth-related parameters, along with safety and treatment compliance were also monitored.
Results
The mean (SD) birth weight SDS was -2. 59 (0. 782), the mean age at the start of the study was 4. 3(0. 95) yr, and the mean height SDS at baseline was -2. 658(0. 712). The Jintrolong 0. 2 mg/kg/week group demonstrated significantly greater mean HT SDS increases compared to the 0. 1 mg/kg/week group at week 52 (0. 923 vs. 0. 511, $P < 0.0001$). After 3 years of Jintrolong treatment in the extension phase (a total of 4-Year treatment from baseline), 90. 9% (60/66) of patients reached heights within the normal range for healthy Chinese children ($>$ -2 SDS), and 53. 0% (35/66) of patients' height SDS in conformity with their target height SDS. Additionally, mean AHV remained within the normal range during the 3-year extension treatment. Incidence of adverse events (AEs) and treatment compliance were comparable between two groups during 52-week main phase. Most AEs observed during long-term treatment were mild to moderate and most known GH-related adverse reactions.
Conclusion
Our 4-year data show that long-term continuous Jintrolong PEG-rhGH treatment at an initial dose of 0. 2 mg/kg/week, up to a maximum of 0. 4 mg/kg/week in short children born SGA results in a normalization of height during childhood followed by growth along the target height SDS.

Aetiology of short stature in children originally diagnosed with idiopathic growth hormone deficiency: comprehensive genetic investigation of a single centre cohort

Lukas Plachy[1], Shenali Amaratunga[1], Petra Dusatkova[1], Klara Maratova[1], Lukas Kavciak[1], Dana Zemkova[1], Stanislava Kolouskova[1], Barbora Obermannova[1], Marta Snajderova[1], Zdenek Sumnik[1], Jan Lebl[1] & Stepanka Pruhova[1]
[1]Department of Pediatrics of Second Faculty of Medicine Charles University in Prague and Motol University Hospital, Prague, Czech Republic

Introduction
Diagnostics of growth hormone deficiency (GHD) is based on stimulation tests, IGF-1 and growth velocity. Children diagnosed with GHD are believed to have heterogeneous aetiology of short stature, frequently independent on GH secretion. Evidence supporting this hypothesis are lacking. The aim of the study was to elucidate genetic aetiology of children with diagnosed GHD.
Methods
Children treated for GHD in our centre with idiopathic GHD and therapy duration $\geq$5 years were enrolled to the study. Children were examined by various genetic methods including next-generation sequencing. Genetic variants were evaluated using ACMG guidelines. Clinical parameters were compared between children with genetically proven GHD and other groups of children based on their genetic aetiology.
Results
In total, 294 children were enrolled to the study. At GH treatment initiation, their median age was 5. 1 years (IQR 3. 5-6. 8 years), height -2. 9 (-3. 2 to -2. 6) SD, IGF1 -1. 7 (-2. 0 to -1. 3) SD, GH_{max} 5. 5 (4. 0-7. 3) mg/l, 32 had combined pituitary hormone deficiency. Of them, 269 (91%) consented with genetic testing. We elucidated genetic aetiology in 56/269 (21%) of them. Fourteen children (25%) had genetically confirmed GHD (genes *OTX2* [4], *GLI2*, *TBX3*, *PROP1*, *POU1F1*, *GHSR*, *GH1*, *CHD7*, *PROK2*, *PMM2*, *SALL4*), 2 (4%) had impaired IGF proteins (genes *IGFALS*, *HGMA2*), 15 (27%) had primary growth plate disorders (genes *NPR2* [3], *FGFR3* [2], *COL2A1* [2], *COL9A2*, *MATN3*, *ACAN*, *EXT2*, *SOX9*, *LTBP3*, *TRPV4*, *ALPL*), 14 (25%) impaired RAS signalling pathway (genes *PTPN11* [8], *SOS1* [3], *NF1* [2], *RAF1*) and 11 (20%) complex genetic disorders (genes *LMNA*, *KMTD2*, *SURF1*, *SOX10*, *MBTPS2*, *TSPAN7*, *FGFR2*, *GNAO1*, *CDC42*, DiGeorge syndrome and Smith-Magenis syndrome). Prior to GH treatment, children with genetically confirmed GHD had lower GH_{max} (median 1. 8 mg/l vs. 4. 5 mg/l [growth plate disorder], 6. 6 mg/l [RASopathies] and 5. 4 mg/l [complex disorders]; $P = 0.05$) and together with RASopathies less affected intrauterine growth (lower of the birth parameters [birth weight/length] -1. 2 SD [GHD] and -0. 8 SD [RASopathies] vs. -1. 8 SD [growth plate disorders] and -2. 0 SD [complex disorders]; $P = 0.009$). After 5 years of therapy, GHD and growth plate disorders groups had better growth outcomes (-0. 7 SD [GHD] and -0. 8 SD [growth plate disorders] vs. -1. 8 SD [RASopathies] and -2. 0 SD [complex disorders] $P = 0.04$).
Conclusions
Genetic aetiology of short stature in children diagnosed with GHD is heterogeneous. Lower stimulated GH concentration, near-normal size at birth, and better response to GH treatment might help to clinically differentiate those with genetically confirmed GHD.

JOINT3601

Comparison of oral vs intravenous glucose exposure on plasma growth hormone levels: a crossover study in healthy volunteers

Anna Vinten [1], Nanna Thurmann Jørgensen[1], Marianne Klose[1] & Mikkel Andreassen[1]
[1]Rigshospitalet, university of Copenhagen, Department of nephrology and endocrinology, Copenhagen, Denmark

Introduction
It has become increasingly evident that many effects on hormone secretion—most notably for insulin—previously attributed to glucose per se, are partially mediated by hormones released from the gastro-intestinal tract. It is unknown if gastrointestinal tract deviated hormones are involved in the suppression of growth hormone (GH) during oral glucose intake. Interestingly, about 30% of patients with acromegaly show a paradoxical GH increase during an oral glucose tolerance test (OGTT). This phenomenon has been attributed to the presence of GIP receptors on a subset of GH-secreting adenomas, thereby linking GH secretion to gut-hormones.
Materials and Methods
12 healthy controls (6 women, mean age 48 years) underwent a 2-hour OGTT and an isoglycemic intravenous glucose infusion on a separate day, with sequential GH, insulin, glucagon, GLP1 and GIP measurement. The effect of oral vs. intravenous (IV) glucose on plasma GH, insulin, glucagon, GLP1 and GIP was assessed by a mixed-effect model and by area under the curve (AUC).

Results
GH levels were significantly influenced by the route of glucose administration ($P = 0.005$, mixed effect model). During iv glucose, 9/12 participants showed a paradoxical increase in GH within the first 20 minutes post-exposition. The AUC (median (range)) during OGTT was 70 (6-178) vs. 56 (6-474) mg/lxmin during IV glucose ($P = 0.20$). During OGTT, one participant did not reach the threshold (<0.4 mg/l) for excluding acromegaly (nadir GH 0. 66 mg/l), whereas two did not meet the criteria during iv glucose (nadir 0. 72 and 2. 68 mg/l). AUC was significantly reduced during IV vs. oral glucoseload for insulin ($P < 0.001$), glucagon ($P = 0.018$), GLP1 ($P = 0.002$) and GIP ($P < 0.001$) Similar results were obtained using mixed effect models with all P-values < 0.001
Conclusion
Our findings suggest that gastrointestinal-derived hormones may play a physiological role in suppressing GH secretion. As one hypothesis, reduced ghrelin during oral administration may contribute to GH suppression. However, previous studies have reported conflicting results regarding the impact of oral vs. IV glucose on plasma ghrelin levels. We observed significant differences in insulin, glucagon, GIP and GLP-1 levels between the two conditions, which might also influence GH secretion. Further investigations are needed to elucidate the precise mechanisms underlying these observations.

Epidemiology of disorders associated with tall stature in childhood: a 20-year birth cohort study

Samuli Harju[1, 2], Antti Saari[1, 2], Reijo Sund[1] & Ulla Sankilampi[1, 2]
[1]University of Eastern Finland, School of Medicine, Institute of Clinical Medicine, Kuopio, Finland; [2]Kuopio University Hospital, Department of Paediatrics, Kuopio, Finland

Background
Many primary and secondary disorders in childhood may cause tall stature (height of +2 SD above the mean height for age and sex). Growth-monitoring programs are aimed at early detection of such disorders to avoid permanent health consequences and support children's wellbeing. However, epidemiological data on disorders associated with tall stature in childhood are scarce.
Aim
To specify age- and sex-specific data on the incidence of disorders associated with tall stature and to develop better diagnostic practices.
Materials and Methods
Retrospective population-based study included 1 144 503 children (51% boys) born in Finland between 1998 and 2017 with 16. 5 million register notifications including medical diagnoses. The first occurrences of essential disorders associated with tall stature were identified from multiple registers. The age- and sex-specific cumulative incidences (CMIs) from birth until 18 years of age and the median age at diagnosis were determined.
Results
A total of 3329 children (47% boys) had one of the selected disorders (0. 3% of the whole birth cohort). Central precocious puberty (CMI of 1/894 girls at 8 years, and 1/4856 boys at 9 years) were more common among girls.
Conclusions
This study provided the first age- and sex-specific epidemiological data on several primary and secondary disorders associated with tall stature. These disorders proved to be rather rare yet underdiagnosed in childhood. We suggest that during early childhood, the focus of growth screening should be particularly on Marfan syndrome and congenital overgrowth syndromes, with the addition of Klinefelter syndrome and central precocious puberty thereafter. It is important to distinguish these pathological causes from idiopathic tall stature, which represented half of all cases associated with tall stature.

Orsola Polyclinic of Bologna, Bologna, Italy; [3]Bologna University, Medical and Surgical Sciences Department (DIMEC), Bologna, Italy; [4]Gastro-enterology Unit University Hospital Modena, Modena, Italy

Introduction
Abnormalities in liver function tests (LFA) are frequent in Turner syndrome (TS); nonetheless, the etiopathogenesis of this complication remains unclear, probably being multifaceted. Several potential mechanisms have been suggested, including metabolic syndrome, generalized vasculopathy and autoimmunity.
Objectives
Describe the possible etiopathogenetic factors of LFA in adult patients with TS
M&M
120 adult TS patients, regularly followed-up at our Unit, underwent liver elastometry (FibroScan: Echosens, Paris, France) and hepato-splenic ultrasound. Blood samples were obtained to analyze liver enzymes and other metabolic parameters. Alanino-aminotransferase(ALT), asparate-aminotransferase(AST), gamma-glutamyil-transferase(GGT) and alkaline-phosphatase(ALP) were considered abnormal(LFA) when above 1xULN. Data were retrospectively collected regarding metabolic complications, autoimmune diseases, menstrual history, and hormonal replacement therapies (GH and estrogen-progestin therapy). The presence of structural cardiovascular anomalies and the diameter of the first aortic tract were assessed by retrieving the latest cardiac examination (cardiac MRI and/or transthoracic echocardiography).
Results
74 patients (61. 6%) had at least one LFA, GGT being the most frequent (57. 5%). The prevalence of fibrosis was 6. 7% ($n = 8$). Patients with LFA (LFA-TS) showed significantly higher age, BMI, waist circumference (WC) and waist-to-height ratio than patients with normal liver enzymes (NLE-TS) ($P = 0.008$, $P = 0.046$, $P = 0.005$, $P = 0.002$ respectively). Steatosis was significantly more prevalent in LFA-TS (36. 5% vs 13% in NLE-TS $P = 0.005$). With respect to NLE-TS, LFA-TS showed significantly higher levels of fasting glucose, HbA1c, and total cholesterol ($P = 0.001$, $P < 0.001$, $P = 0.042$, respectively) and were more frequently diagnosed with arterial hypertension and metabolic syndrome ($P = 0.018$, $P = 0.049$). In LFA-TS patients, the diameter of the Valsalva sinuses and the initial aortic segment, as well as the aorta/height index (AHI), were significantly higher compared to NLE-TS patients ($P = 0.045$, $P = 0.032$, $P = 0.025$, respectively). No significant differences were detected in all other variables analyzed (structural cardiovascular abnormalities, autoimmunity, menstrual cycle history, therapies). Performing forward multiple logistic regression analysis, abnormal GGT levels were significantly associated with higher age and WC

Idiopathic tall stature	Girls (844)	0 0	30. 4	105. 3	176. 3	210. 5	1/436	6. 5
	Boys (844)		35. 4	94. 8	169. 2	200. 9	1/454	6. 6

(OR = 1. 061, 95CI:1. 02-1. 11, $P = 0.005$; OR = 1. 038, 95CI = 1. 01-1. 07, $P = 0.016$ respectively), abnormal ALT with higher WC and HbA1c (OR = 1. 042, 95CI:1. 01-1. 08, $P = 0.018$; OR = 1. 190, 95CI = 1. 08-1. 3, $P < 0.001$ respectively), and abnormal AST with higher HbA1c (OR = 1. 131, 95CI = 1. 04-1. 23, $P = 0.005$)

Conclusions

LFA are highly prevalent in adult TS women; this complication seems tightly related to visceral adiposity and metabolic abnormalities, making their management pivotal in this rare disease. A relation with aortic dilation seems plausible, in the context of a possible generalized vasculopathy: further large-scale studies are needed to clarify and explore this finding in greater depth.

JOINT792

The growth paradox: unraveling the impact of advanced bone age on height potential in untreated conditions"

Ashraf Soliman[1], Ahmed Elawwa[1], Fawzia Alyafei[1], Shayma Ahmed[1], Noora AlHumaidi[1], Noor Hamed[1], Nada Alaaraj[1] & Carolin Beck[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background

Advanced bone age (ABA) is a critical determinant of linear growth and final adult height in children with untreated conditions such as idiopathic short stature, precocious puberty, and chronic illnesses. This review evaluates the impact of ABA on height outcomes and its contributing factors, categorized into growth potential, primary drivers, untreated risks, and mitigating strategies. Quantified impact scores provide insights into the relative significance of these factors.

Objectives

1. To assess the effects of ABA on linear growth and final height potential in untreated cases.
2. To quantify the relative impacts of growth potential, primary drivers, untreated risks, positive outcomes, and key therapies.
3. To evaluate strategies for mitigating ABA-associated growth deficits.

Methods

A comprehensive review of peer-reviewed studies from 1991 to 2025 was conducted. Studies addressing untreated cases of ABA and its impact on linear growth and adult height were included. The analysis involved calculating percent impacts for key categories, classified as small, medium, or high, to contextualize their significance.

Results

- Impact on Height: ABA had a high impact (32. 8%) on reducing final height potential, primarily due to premature epiphyseal fusion and diminished growth velocity.
- Primary Drivers: Hormonal imbalances, including elevated IGF-I and sex steroids, contributed a moderate impact (28. 7%), influencing bone maturation and growth cessation.
- Untreated Risks: Progressive growth failure, earlier puberty onset, and psychosocial challenges presented a high impact (34. 9%) on overall height potential and quality of life.
- Positive Outcomes: Some untreated cases with slower ABA progression preserved final height within target ranges, contributing a small impact (14. 5%) on mitigating growth deficits.
- Key Therapies: Interventions like GnRH agonists and nutritional management showed potential for reversing growth deficits, though effectiveness in untreated cases remains limited, with a moderate impact (24. 1%).

Discussion

ABA significantly compromises linear growth and final adult height in untreated cases. Its high impact on growth potential and untreated risks highlights the importance of early diagnosis and intervention. Hormonal imbalances and premature epiphyseal closure are primary drivers of height deficits. While positive outcomes are rare in untreated cases, targeted therapies can mitigate risks and preserve growth potential when implemented early.

Conclusion

ABA has a profound impact on final adult height in untreated conditions, primarily through premature growth cessation and progressive risks. Early identification and timely therapeutic interventions are essential to mitigate its effects and improve growth outcomes.

Keywords Advanced Bone Age, Linear Growth, Final Height, Untreated Risks, Growth Potential, Hormonal Imbalances.

Efficacy of growth hormone therapy in children with npr2 and acan gene variants: a comparative study

Lana Stavber[1], Klemen Dovc[2], Marusa Debeljak[3], Jasna Suput Omladic[2], Tadej Battelino[2] & Primož Kotnik[2]
[1]Center for rare diseases, University Children's Hospital, UMC, Ljubljana, Slovenia; [2]Department of Pediatric Endocrinology, Diabetes and Metabolic Diseases, University Children's hospital, UMC, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia; [3]Unit for Special Laboratory Diagnostics, University Children's Hospital, UMC, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia

Introduction

NPR2 and ACAN gene variants are well recognised causes of idiopathic short stature (ISS). Both genes play a crucial role in growth plate regulation; NPR2 through paracrine function of endochondral ossification, while ACAN is a major structural component of the extracellular matrix in cartilage. The study aimed to evaluate and compare the efficacy of growth hormone (GH) therapy in children with NPR2 and ACAN variants.

Methods

Next-generation sequencing was performed in ISS children to identify causal NPR2 and ACAN variants. Eligible children met national guidelines for treatment with GH. The main outcome measure was change (Δ) in height SD score (HtSDS). Comparison was made between:

- Treated and untreated NPR2/ACAN children
- Prepubertal vs. pubertal children receiving GH
- Overall NPR2 vs. ACAN patient outcomes.

Results

A total of 16 NPR2 (11 males) and 17 ACAN (8 males) children were enrolled. Among them 8/16 NPR2 (6 males, mean age 9. 5 ± 3. 8 years) and 10/17 ACAN (5 males, mean age 8. 2 ± 3. 2 years) children received GH (treatment duration: NPR2 3. 2 ± 1. 7 years, ACAN 5. 3 ± 2. 2 years). In the untreated subgroups, the mean Δ in HtSDS was +0. 07 (NPR2) and -0. 23 (ACAN). Children who started treatment at the prepubertal stage (5/8 NPR2, 6/10 ACAN) had greater height gains (Δ HtSDS; +1. 01 in NPR2 and +1. 35 in ACAN) than those who started in puberty (Δ HtSDS; +0. 37 in NPR2 and + 0. 3 in ACAN).

Overall, mean height gain in treated children was:

- NPR2: + 0. 8 ± 0. 4 (mean Δ HtSDS 0. 3 ± 0. 2 per year)
- ACAN +0. 9 ± 0. 8 (mean Δ HtSDS 0. 2 ± 0. 1 per year)

Conclusion

GH therapy significantly improved linear growth in both NPR2 and ACAN groups compared to the untreated children; with a more pronounced effect in ACAN children. Early initiation of GH was particularly effective in both groups.

Efficacy of somapacitan in treatment-fatigue adults with growth hormone deficiency previously treated with daily GH injections: a 24-week randomized active-controlled trial

Mojca Jensterle[1], Rok Herman[1], Ana Klinc[1], Matej Rakusa[1], Katja Goričar[2] & Andrej Janez[1]
[1]University Medical Center Ljubljana, 1000 Ljubljana, Slovenia, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia; [2]. Faculty of Medicine, University of Ljubljana, 1000 Ljubljana, Slovenia, Ljubljana, Slovenia

Objective

An important barrier to obtain treatment goals in adult growth hormone deficiency (AGHD) is poor adherence due to the burden of long-term treatment with once daily growth hormone (GH) injections. We aimed to evaluated the efficacy of long acting GH somapacitan in a 24-week, randomized, active-controlled study in treatment-fatigue patients with AGHD, previously treated with once daily GH.

Methods

30 male or female patients with AGHD, previously treated with once-daily GH for ≥ 5 years, reporting fatigue from daily GH injections, were randomized to somapacitan or once-daily GH. Outcome measures were changes in treatment satisfaction assessed by Treatment Satisfaction Questionnaire for Medication-9 (TSQM-9), IGF-1 SDS, glucose and lipid parameters, body composition, bone mineral density (BMD), carotid intima media thickness and reactive hyperaemia index, from baseline to week 24.

Results
At baseline, 38% of patients was sub-optimally treated with daily GH with median IGF-1 SDS outside the range of 0-2 SDS for at least 2 years prior the randomisation. At week 24, median IGF-I SDS was outside the range of 0-2 SDS in 5 patients (35, 7%) in daily GH group and in 1 patient (6. 6%) in somapacitan group. 6 patients receiving daily GH reported missing >5 doses of GH each month, while in the somapacitan group only 1 dose was missed in 1 patient in 24 weeks. TSQM-9 score for convenience increased significantly more with somapacitan vs daily GH (estimated difference, somapacitan-daily GH [95% CI]:23. 2 [7. 9; 38. 4] points, $P = 0.0004$). No significant differences were observed between groups for changes from baseline to week 24 in median values of IGF-1, IGF-1 SDS, glucose homeostasis, lipid profile, visceral adipose tissue, fat mass (%), lean body mass and vascular parameters. There was significant difference between the groups in BMD of lumbar spine (estimated difference, somapacitan-daily GH [95% CI]-0. 036 (-0. 064, -0. 009) gr/cm2, $P = 0.011$).
Conclusion
In the treatment fatigue patients with AGHD, somapacitan was reported to be more convenient than daily GH with better self-reported adherence. The changes in body composition, glucose, lipid and vascular parameters were similar in both groups. A small decrease in BMD when switching to somapacitan may reflect an initial favourable increase in the number of bone metabolic units. A similar effect on BMD was previously observed in treatment naïve patients with AGHD during the first 6 months after initiation of GH treatment, followed by an increase in BMD. Further studies on long-term efficacy and safety of somapacitan in AGHD are needed.

JOINT1496

Long-term maintenance in the upper normal IGF-1 levels has beneficial effects on body fat and marker of low-grade inflammation in adults with growth hormone deficiency

Ana Klinc[1], Andrej Janez[1] & Mojca Jensterle[1]
[1]University Medical Center Ljubljana, 1000 Ljubljana, Slovenia, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia

Objective
High normal IGF-1 levels may be associated with more favourable outcomes of long-term growth hormone replacement therapy (GHRT) in adult growth hormone deficiency (AGHD). However, the distinctive effects of maintaining the upper (0-2 SDS) vs lower normal (-2-0 SDS) range of IGF-1 SDS in AGHD remain largely understudied.
Methods
We conducted a cross-sectional study with 31 patients with AGHD receiving GHRT with daily GH > 5 years and 2-year mean IGF-1 between -2 to +2 SDS range. Patients were categorized according to their 2-year mean IGF-1 SDS into the upper or lower normal IGF-1 range. Clinical characteristics, anthropometric parameters assessed by dual-energy X-ray absorptiometry, laboratory tests, intima-media thickness (IMT) and reactive hyperemia index (RHI) were evaluated. Associations of those parameters with the mean IGF-1 SDS range over 2 and 5 years were explored.
Results
Over the 2-year period, 18 patients (58. 1 %) had mean IGF-1 SDS in the upper and 13 in the lower normal range. Long-term maintenance of upper normal IGF-1 SDS was more frequent in man than women (72. 2 % vs. 27. 8 %; $P = 0.024$) and in patients with longer GHRT duration (median GHRT duration (25–75 % range): 28 years (16. 5–35) in higher normal group vs. 15 years (5–20) in lower normal; $P = 0.033$). Patients with tumour-related AGHD had a lower 5-year mean IGF-1 SDS than patients with non-tumour etiology. Long-term maintenance of IGF-1 SDS in the higher normal range was associated with lower high-sensitivity C-reactive protein (hs-CRP) levels (median (25–75 % range): 0. 8 (0. 6-1. 1) vs. 1. 8 (0. 8-4. 6); $P = 0.005$) and lower body fat percentage (median (25–75 % range) : (30. 1 % (25. 2-34. 8) vs. 39. 5 % (32. 2-44. 0); $P = 0.008$). A negative correlation was identified between hs-CRP and the 5-year mean IGF-1 SDS ($r = -0.705$, $p < 0.001$). The IGF-1 SDS range was not associated with IMT, RHI, glucose metabolism or lipid profile.
Conclusion
Long-term maintenance in the upper normal IGF-1 SDS was more frequent in male than female patients with AGHD. The upper normal range was associated with lower marker of low-grade inflammation and lower body fat percentage. Prospective randomized studies are needed to evaluate the long-term and sex-specific effects of targeting higher vs. lower normal IGF-1 SDS range in AGHD, for both, daily and weekly GHRT.

Analysis of functionally uncharacterized variants of the GH1 gene from patients with isolated growth hormone deficiency (IGHD)

Alexandros Taousanidis[1 2 3] & Amit Pandey[1, 2]
[1]University of Bern, Translational Hormone Research Program, Department of Biomedical Research, Bern, Switzerland; [2]University Children's Hospital Bern, Department of Pediatrics, Division of Endocrinology, Diabetology and Metabolism, Bern, Switzerland; [3]University of Bern, Graduate School for Cellular and Biomedical Sciences, Bern, Switzerland

Human growth hormone (hGH), or somatotropin, a 217-amino acid glycoprotein produced by the somatotropic cells in the anterior pituitary, is encoded by the *GH1* gene, located on chromosome 17 (17q22-24). Mutations in *GH1* are associated with Isolated Growth Hormone Deficiency (IGHD), characterized by a spectrum of pituitary hormone deficiencies and growth failure in children, and it can result from mutations in *GH1* or related genes. IGHD is classified into four types based on inheritance patterns: Type IA and IB (autosomal recessive) Type II (Autosomal dominant), and Type III (X-linked), all of which result in short stature. We have investigated five functionally uncharacterized but clinically reported *GH1* missense variants (A39T, R42L, C79G, Q110E, and R160W), identified in patients with IGHD of various types and genetic background s. Pathogenicity analysis tools such as PANTHER, PhD-SNP, SIFT, Meta-SNP, and E-SNPs & GO were utilized to assess the pathogenicity scores for each mutation, highlighting C79G and R42L as the most deleterious mutations. Among the mutations, Q110E is predicted to have the most significant stabilizing effect. Protein free energy ΔΔG calculations (1. 882 kcal/mol) suggested that it enhances protein stability, reducing the likelihood of denaturation or unfolding. Conversely, A39T appears to significantly decrease protein flexibility compared to the other five mutations, as indicated by ΔΔSVib (-4. 925 kcal/mol*K) predictions, which suggests that A39T induces a more rigid and ordered protein structure. Additionally, multiple sequence alignment and phylogenetic analysis with Clustal Omega, phylogenetic analysis with MEGA, domain prediction with SMART, 3D structures modeling, and motif analysis with MEME, confirmed high conservation these residues among primates, underscoring their importance. To complement computational insights, the variants were introduced into the wild-type *GH1* gene via site-directed mutagenesis and expressed in E. coli. Recombinant proteins were purified using immobilized metal affinity chromatography (IMAC), yielding high-quality preparations suitable for downstream functional studies. These findings provide a detailed computational and experimental framework for understanding GH1 variant effects, offering a foundation for future *In vitro* studies aimed at advancing personalized approaches to IGHD diagnosis and treatment.

Retrospective evaluation of the phenotypic-genotypic characteristics of patients with short stature who underwent next-generation sequencing analysis

Rabia Meral[1], Eren Er[2], Berna Eroğlu Filibeli[2], Özgür Kırbıyık[3], Merve Saka Güvenç[3] & Bumin Nuri Dündar[4]
[1]Kahramanmaraş Necip Fazıl City Hospital, Pediatric Endocrinology Clinic, Kahramanmaraş, Türkiye; [2]Izmir City Hospital, Pediatric Endocrinology Clinic, Izmir, Türkiye; [3]İzmir City Hospital, Genetic Diseases Diagnostic Center, Izmir, Türkiye; [4]Izmir Katip Celebi University, Faculty of Medicine, Department of Pediatric Endocrinology, Izmir, Türkiye

Background
Short stature is a common pediatric endocrinological disorder with an incidence of 3-5%. The majority of cases have an unclear etiology, which complicates therapy selection and the diagnostic process.
Objective
This study aims to explore the phenotypic-genotypic relationships by retrospectively evaluated patients who underwent targeted next-generation sequencing (NGS) due to short stature.

Materials and Methods
This study included 65 patients (37 male, 28 female) who were followed up for short stature [< -2 SDS (standard deviation score)] between January 2011 and June 2022 at Pediatric Endocrinology Clinic and underwent targeted NGS. The pathogenicity of the variants was evaluated according to the criteria of the American College of Medical Genetics and Genomics (ACMG). Patients with pathogenic or likely pathogenic variants detected in the NGS panel (Group 1) were compared with other patients included in the study (Group 2) in terms of their characteristics.
Results
The mean age at diagnosis of the patients was 7. 93 ± 4. 42 years (min; max: 0. 42; 15. 78), and the mean height SDS was -3. 06 ± 0. 97 (min; max: -7. 37; -2. 00). Among the patients, 15 (23. 1%) had consanguinity between their parents. Forty participants (61. 5%) had at least one individual with short stature in their family. The number of patients with pathogenic or likely pathogenic variants detected in the NGS panel was 19 (29. 2%). These variants were *FLNB* (3 patients), *OBSL1* (2 patients), *FBN1, EXT1, ADAMTSL4, PHEX, LHX3, FLNB, ROR2, ALPL, TTC21B, GHR, SLC26A2, PCNT, NF1, FGFR3, GHRHR*. The birth weight SDS of patients in Group 1 was statistically lower than that of patients in Group 2 (-1.69 ± 1.7 vs. -0.56 ± 1.08, $P = 0.046$). The rate of consanguinity among the parents of patients in Group 1 was 47. 2%, whereas it was 13. 0% in Group 2, and this difference was statistically significant ($P = 0.007$).
Conclusion
In this study, NGS panel screening was used to determine the genetic etiology of short stature in some patients and provided a solid informational basis for clinical phenotype classification and genetic counseling. Additionally, genetic screening can provide a foundation for the development of more effective interventions and help meet the medical needs. Further functional experimental research is required on variants of potential pathogenic significance.

The impact of dose modification guided by growth response monitoring on igf-1 levels and height velocity in growth hormone deficiency treatment

Semra Bahar akın[1], Ilker Tolga Özgen[2] & Yasar Cesur[3]
[1]Derince Training And Research Hospital, Department of Pediatrics, Division of Pediatric Endocrinology, kocaeli, Türkiye; [2]Biruni University, Faculty of Medicine Department of Pediatrics, Division of Pediatric Endocrinology, istanbul, Türkiye; [3]Bezmialem Vakif University, Department of Pediatrics, Division of Pediatric Endocrinology, Faculty of Medicine, istanbul, Türkiye

Aim
Growth hormone (GH) therapy is an effective therapeutic modality for children with GH insufficiency. However, in some cases, treatment may yield inadequate responses, limiting the attainment of intended outcomes. Retrospective studies suggest that numerous factors affect the efficacy of GH treatment. The dosage of growth hormone is a critical component influencing growth response. Consequently, if the growth response is suboptimal in the initial year, it is advisable to augment the GH treatment dosage in the guidelines. This study presents the implementation outcomes of the technique indicated in the guidelines.
Material and methods
The study comprised a total of 163 diagnosed instances of GH deficiency. Growth hormone treatment commenced in the instances at a dosage of 25-35 mg per day. During the initial year of treatment, children with mild growth hormone (GH) insufficiency (peak GH between 5-10 ng/dL in stimulation tests) exhibit a 0. 3 standard deviation score (SDS), while those with severe GH deficiency (peak GH <5 ng/mL in stimulation tests) show a 0. 4 SDS. A 100% rise was deemed a sufficient treatment response (Group 1), whereas its absence was regarded as an insufficient response (Group 2). In the inadequately responding cohort, the GH dosage was escalated by 20% per kilogram prior to the second year, and the patients' growth velocities and IGF-1 concentrations were assessed over a period of 3 years.
Results
During the initial year of treatment, it was noted that the height SDS increase was inadequate in 53 out of 163 patients (32. 5%). Both Group 1 and Group 2 had three years of treatment. Table 1 presents the GH doses, height SDS values, IGF-1 SDS values, and alterations in height SDS values from the commencement to the conclusion of treatment for each year. Following the dosage augmentation, growth in Group 2 intensified, and at the conclusion of the third year, overall height rise neared that of Group 1. At the conclusion of the second year, the dosage was necessitated to be reduced in 20 patients from the good response cohort and in 6 patients from the poor response cohort due to elevated IGF-1 SDS values.
Conclusion
In the management of GH insufficiency, monitoring treatment response and adjusting dosages appropriately enhances therapeutic success and provides the individual with an opportunity for growth comparable to those who have a favorable response.

Aim
Serum IGF-I is widely advocated as a tool for monitoring adherence, safety and effectiveness of recombinant human growth hormone (rhGH). However, there is a need to understand the real-world variations in IGF-I levels in children on rhGH and the management of abnormal levels in clinical practice.
Method
Centres participating in the Global Registry for Novel Therapies in Rare Bone and Endocrine Conditions (www. GloBE-Reg. net) were invited to complete the minimum dataset for rhGH therapy. Information on the indications for rhGH therapy, gender, age at diagnosis and rhGH initiation, rhGH doses and serum IGF-I on therapy were collected for analysis. Based on available reference data for 6 different assays, IGF-I SDS were calculated. IGF-I values more than 2SDS below and above the mean were classed as low and high, respectively. Results are shown in median (range).
Results
A total of 2, 697 IGF-I values from 690 children (475 daily/215 LAGH; 429M/261F) were available from 17 centres in 12 countries. The main indications for daily rhGH treatment included growth hormone deficiency (GHD) in 239/475 (50%), small for gestational age (SGA) in 58/475 (12%) and Prader-Willi syndrome (PWS) in 41/475 (9%). The majority were on long-acting GH (LAGH) for GHD 192/215 (89%), with 17/215 for idiopathic short stature (ISS, 8%) and 5/215 for SGA (2%). In those on daily GH, IGF-I SDS were low –2. 4 (-3. 4, -2. 1) in 6% (126/2182) and high +3. 1 (+2. 1, +21. 6) in 10% (218/2182). Noticeably, 73/218 (33%) high IGF-I SDS were within the normal for the centres' laboratory reference range. A quarter of children (49/203) with PWS have high IGF-I with median +3. 15 (2. 2, 21. 6), with variation in the 3 contributing centres. Children with PWS and SGA (both $P<0.001$) were more likely to have high IGF-I, +0. 3 (-3. 4, +21. 6) and +0. 03 (-3. 4, +9. 2) respectively compared to GHD -0. 4 (-3. 4, +6. 2). In those on LAGH, IGF-I SDS were low –2. 2 (-3. 0, -2. 1) in 1. 6% (8/515) and high +2. 7 (+2. 1, +6. 4) in 12% (60/515). Those with high IGF-I were on the recommended LAGH doses 0. 15 (0. 07, 0. 19)

mg/kg or 0. 50 (0. 45, 0. 50) mg/kg for the respective brands. Adherence data were only available in 20%.
Conclusion
Based on this study, 15% (412/2697) of IGF-I values are outwith the recommended +/- 2SDS range. IGF-SDS, as recommended in international guidelines, is underused in routine clinical practice, which often rely on laboratory reference range. Further studies into the implication of high IGF-I in children with PWS and SGA is needed.

JOINT791

Unexpected high frequency of copy number variations as genetic causes of failure to achieve catch-up growth in small for gestational age children: a multicenter study in Korea

Eun Young Kim[1] & Il Tae Hwang[2]
[1]Chosun University Hospital, Pediatrics, Gwangju, South Korea; [2]Kang-dong Sacred Heart Hospital, Pediatrics, Seoul, South Korea

Background
Small for gestational age (SGA) refers to infants whose size is below the normative range for their gestational age and sex. While up to 90% of these infants experience catch-up growth within the first two years, 10-15% fail to do so and remain short at age 2 (SGA-SS). The causes of this failure remain largely unknown.
Methods
This study investigated the genetic causes of failure to achieve catch-up growth in Korean SGA children. Subjects were recruited from multicenter SGA-SS cohorts across eight hospitals in South Korea. A total of 191 children underwent whole exome sequencing. Copy number variants (CNVs) identified in exome data were validated using chromosomal microarray (CMA). Genetic variants were classified according to ACMG guidelines.
Results
Genetic variants were identified in 36 of 191 children. Half of the genetic abnormalities were CNVs (18/36, 50%). Notably, 22q11. 2 microdeletion syndrome was observed in seven children (7/36, 19. 4%), who presented mild dysmorphic features without significant intellectual disability or congenital anomalies, potentially delaying diagnosis. Sequence variants in growth-related genes were found in 18 children (18/36, 50%). One child had compound heterozygous mutations in the *SLC26A2* gene, while the others had heterozygous variants, including five pathogenic, 13 likely pathogenic, and one variant of uncertain significance (VUS). Based on molecular mechanisms of causing reduced height, defects in intracellular pathways (11/18, 61. 1%) were most common, followed by defects in the extracellular matrix (6/18, 33. 3%). Additionally, the first Korean case of familial Silver-Russell syndrome with a *CDKN1C* mutation was identified.
Conclusion
The genetic basis of SGA-SS is heterogeneous. CNVs play a significant role in this condition. The broad phenotypic spectrum of 22q11. 2 microdeletion syndrome, as seen in cases with mild dysmorphic features, highlights its importance in the differential diagnosis of SGA-SS.

Spinal deformities in patients with rasopathies and pathogenic variants in related genes

Giulia Dias[1], Barbara Aoto[2], Cláudio Santili[3], Debora Bertola[4], Alexander Jorge[5] & Alexsandra Malaquias[2, 6]
[1]Faculdade de Ciências Médicas da Santa Casa de São Paulo, São Paulo, São Paulo, Brazil; [2]Irmandade da Santa Casa de Misericórdia de São Paulo, São Paulo (SP), Brazil, Pediatric Endocrinology Unit, São Paulo, Brazil; [3]Irmandade da Santa Casa de Misericórdia de São Paulo (ISCMSP), Orthopedic Unit, São Paulo, Brazil; [4]Faculdade de Medicina da Universidade de São Paulo, Genetics Unit, São Paulo, Brazil; [5]Faculdade de Medicina da Universidade de São Paulo, Endocrine genetics Unit, São Paulo, Brazil; [6]Irmandade da Santa Casa de Misericordia de Sao Paulo, Pediatrics, Sao Paulo, Brazil

Introduction
Spinal deformities are frequently observed in individuals with Rasopathies, with manifestations varying from scoliosis and kyphoscoliosis to isolated kyphosis, suggesting the role of the RAS/MAPK pathway in bone remodeling. According to recent studies, scoliosis and kyphosis are manifestations reported in 15% of patients with Noonan syndrome (NS) and 20-35% of individuals with Cardiofaciocutaneous syndrome (CFC). However, the exact prevalence and progression of spinal deformities in Rasopathies remain unclear, warranting further investigation.
Objective
To evaluate the frequency of spinal deformities in patients with Rasopathies.
Study design and participants: This retrospective observational study was conducted in two tertiary hospitals. One hundred patients were selected (51 males, 49 females; 52 PTPN11, 10 BRAF, 9 SOS1, 5 RAF1, 5 LZTR1, 4 SHOC2, 4 KRAS, 4 RIT1, 2 MEK1, 2 NRAS, 1 SOS2, 1 NF1, and 1 A2ML1) among who underwent spinal radiographs as part of clinical investigation of Rasopathies.
Methods
We analyzed medical records regarding clinical characteristics and the presence of spinal deformities.
Results
From 88 patients with NS, 8 with CFCS, 1 with Neurofibromatosis type 1 (NF1), and 3 with NS with multiple lentigines ((NSML), we found 52 individuals with spinal deformities (52%): 32 with scoliosis, 8 with kyphoscoliosis, 2 with kyphosis, 2 with lordosis, and 20 with other alterations. Seventeen patients presented two or more associated spinal deformities. Regarding Rashopathies, 43 out of 88 patients with NS presented spinal deformities (49%), 29 patients with scoliosis (2 needing orthopedic braces), 5 with kyphoscoliosis, and 2 with kyphosis. All six patients with CFC syndrome (100%) presented spinal deformities, such as 1 with scoliosis and 3 with kyphoscoliosis. Two out of 3 patients with NSML (67%) showed scoliosis. One patient with NF1 showed anterior vertebral scalloping.
Conclusions
We observed a higher frequency of spinal deformities in our cohort than what is reported in the literature. Understanding Rasopathies' genetic and biological mechanisms could lead to new therapeutic targets for skeletal abnormalities and other manifestations of these disorders.

A genetic cause of tall stature is more often detected in children with familial tall stature compared to non-familial tall stature

Kateřina Gregorová[1], Lukas Plachy[1], Petra Dusatkova[1], Klara Maratova[1], Julia Martinkova[1], Jana Drabova[2], Vit Neuman[1], Stanislava Kolouskova[1], Marta Snajderova[1], Barbora Obermannova[1], Jan Lebl[1], Zdenek Sumnik[1] & Stepanka Pruhova[1]
[1]Department of Pediatrics, Motol University Hospital and Second Faculty of Medicine, Department of Pediatrics, Prague, Czech Republic; [2]2 Department of Biology and Medical Genetics, Second Faculty of Medicine, Charles University and University Hospital Motol, Prague, Czech Republic

Introduction
Tall stature (TS) is usually seen as mainly beneficial but can be associated with severe health risks and specific syndromic conditions. In our previous study, we revealed genetic cause in 34 % of children with familial tall stature (FTS) including the de novo pathogenic variants and autosomal dominant inherited syndromes.
Aims
To elucidate the genetic causes of TS in children with non-FTS (nFTS), to describe their phenotype in detail and to compare the results between patients with nFTS and FTS.
Methods
We enrolled children with nFTS (defined as a height > 2 SD with both parents' heights < 2 SD) referred to our centre or already followed up at our clinic between 9/2020 and 4/2024. Participants underwent genetic testing through cytogenetic analysis and next-generation sequencing of 786 growth-associated genes. Genetic findings were assessed following the American College of Molecular Genetics and Genomics guidelines. All participants also received standard endocrinological assessments and specialized anthropometric evaluations.
Results
In total, 55 children with nFTS were enrolled. Their median height was +2. 8 SD (IQR 2. 4-3. 2 SD), and their median midparental height was +0. 7 SD (IQR 0. 4-0. 9 SD). Genetic causes of TS were identified in 6/55 (11%) children (causal variant in *TGFRB2* and *SHOX*, 47, XXY [2x], 47, XXX, 48, XXXX). Additionally, in 6 children, who showed dysmorphic features suggestive of connective tissue disorder, we found interesting variants of unknown significance in genes associated with connective tissue (*MATN3, COL2A1, COL11A1,*

COL1A1, COL1A2, COL6A3 and ADAMTSL4) that are however not associated with TS yet. In comparison to the FTS cohort, the genetic cause of TS was significantly more common in FTS (32%) than in nFTS (11%). The presence of dysmorphic features was observed in 71% of children with FTS compared to 78% of children with nFTS.

Conclusion

Genetic causes of TS are more frequently found in children with FTS compared to those with nFTS. As the FTS is the clinical diagnosis mostly without indication for further investigation, children with FTS are at higher risk of being underdiagnosed. Although several variants were classified as variants of unknown significance based on current knowledge, primary connective tissue disorders may play a more important role in the aetiology of TS than previously expected.

Combined human growth hormone and gonadotropin-releasing hormone analog therapy improves pubertal growth in children with poor final height prognosis: a retrospective observational study

Isabelle Flechtner[1, 2], Olivier Pollé[1], Monique Jesuran-Perelroizen[2], Magali Viaud[1], Graziella Pinto[1], Dinane Samara - Boustani[1], Caroline Thalassinos[1], Kariyawasam Dulanjalee[1, 3], Michel Polak[1 3 4] & Athanasia Stoupa[1 3 4]

[1]Necker Children's University Hospital, Pediatric Endocrinology, Gynecology and Diabetology Department, Paris, France; [2]Association Française des Pédiatres Endocrinologues Libéraux (AFPEL), Toulouse, France; [3]Paris Cité University, Paris, France; [4]Paris Regional Newborn screening program Department, Paris, France

Introduction

Growth hormone (GH) therapy is well-established in increasing growth velocity and adult height for specific indications. In cases where final height prognosis remains insufficient despite normal puberty onset, clinicians may combine GH with gonadotropin-releasing hormone analogs (GRHa) to delay epiphyseal maturation. However, evidence supporting the efficacy of this combined therapy remains limited.

Objectives

To assess, in patients with growth hormone deficiency (GHD) or small for gestational age (SGA), whether the addition of GRHa to GH treatment in children with poor final height prognosis improves growth outcomes compared to GH alone.

Materials and Methods

This retrospective, observational cohort study was conducted across three centers. Children with poor height prognosis at puberty onset received at least 12 months of combined GH and GRHa therapy. Growth outcomes, including final height (FH), predicted adult height (PAH), and growth velocity, were compared between the GH + GRHa and GH-alone groups. Heights were expressed in standard deviation scores (SDS). Subgroup analyses were conducted based on the underlying condition (i. e., GHD or SGA).

Results

A total of 131 patients were included: 64 treated with GH + GRHa (51% girls) and 67 treated with GH-only (43% girls). At puberty onset (Tanner stage 2), patients in the GH + GRHa group were younger (11. 3 $\pm$ 1. 1 years *vs* 12. 4 $\pm$ 1. 2 years, $P < 0.0001$) and shorter (SDS; -1. 6 $\pm$ 0. 9 *vs* -1. 2 $\pm$ 1, $P = 0.006$) than GH-only group. Pubertal growth was significantly greater in patients with GH + GRHa than GH-only (29. 0 $\pm$ 4. 7 cm vs 25. 4 $\pm$ 4. 5 cm, $P = 0.002$), with the largest height gain observed in girls. Subgroup analysis showed significantly greater pubertal growth in GH + GRHa-treated patients with both GHD (27. 7 $\pm$ 4. 8 cm vs. 23. 4 $\pm$ 5. 5 cm, $P = 0.0005$) and SGA (26. 2 $\pm$ 5. 4 cm vs. 22. 2 $\pm$ 5. 2 cm, $P = 0.01$) compared to GH-only. No significant differences in FH were observed between both treatment groups in patients with SGA ($P = 0.81$). Patients with GHD treated with GH + GRHa (shorter at puberty onset with height SDS; -1. 6 $\pm$ 1 vs -0. 9 $\pm$0. 8 in GH-only group, $P = 0.004$) remained significantly smaller than GH-only group (FH SDS; -1. 4 $\pm$ 0. 7 *vs* -0. 4 $\pm$ 0. 9, $P < 0.0001$).

Conclusions

The addition of GRHa to GH therapy in children with GHD or SGA and a poor final height prognosis at puberty onset enhances pubertal growth, regardless of sex or underlying condition.

Development of muscle function in children with achondroplasia under vosoritide treatment

Susanna Reincke[1], Jörg Semler[1], Shino Junghaenel-Welzing[1], Stefanie Stasek[1], Mirko Rehberg[1], Ibrahim Duran[2], Eva Pfeiffer[1] & Heike Hoyer-Kuhn[1]

[1]University of Cologne, Faculty of Medicine and University Hospital Cologne, Department of Pediatrics, Cologne, Germany; [2]University of Cologne, Faculty of Medicine and University Hospital Cologne, Center for Pediatric and Adolescent Rehabilitation, Cologne, Germany

Background

Achondroplasia is a genetic disorder caused by a gain-of-function mutation in *FGFR3*, leading to impaired bone growth and disproportionate short stature. Children with achondroplasia often present with muscular hypotonia at birth, though its underlying pathophysiology remains incompletely understood. In 2021, Vosoritide was approved as the first targeted medication for achondroplasia. This C-type natriuretic peptide (CNP) analog counteracts the overactive FGFR3 signaling, promoting endochondral ossification and consequently increasing longitudinal bone growth. As muscle and bone development are closely connected, we investigated whether the increased growth during Vosoritide treatment is associated with changes in muscle function.

Methods and Patients

This retrospective observational study included 15 patients with achondroplasia treated with Vosoritide at our center, between October 2021 and October 2024. As part of routine clinical assessments, muscle function parameters were measured using a two-legged jump on the "Leonardo Ground Reaction Force Platform", while auxological parameters were recorded using a stadiometer and a sitting scale. Measurements were converted into z-scores using LMS data from a healthy cohort and analyzed at three time points: baseline, 12 months, and 24 months after initiating Vosoritide therapy. Statistical analysis was performed using GraphPad Prism software.

Results

15 patients (3 female) aged 6. 7 to 15. 3 years at therapy initiation were included in the analysis. The median CDC height z-score for the entire cohort ($n = 15$) at baseline was -5. 93 (IQR -6. 87;-4. 83), improving to -5. 64 (IQR -8. 02;-3. 84) after 12 months of therapy ($n = 15$). In nine children with available 24-month data, a median z-score change of +0. 89 ($n = 9$) was observed after 24 months, representing a significant increase ($P = 0.0059$). Median z-scores for weight and BMI showed no significant changes after 24 months. Z-scores for muscle function parameters, including maximal relative power, maximal velocity, and jump height, did not show significant changes over time. However, the median z-score for maximal relative force decreased after 24 months of therapy ($P = 0.0039$).

Conclusion

Compared to references from a healthy cohort, no significant changes were observed in z-scores for maximal relative power, maximal velocity, or jump height. Thus, over 12 ($n = 15$) and 24 months ($n = 9$), patients developed similarly to children without achondroplasia regarding these parameters. The observed decrease in maximal relative force, despite unchanged maximal relative power, may indicate an improved movement efficiency.

Netherlands; [11]Zuyderland Hospital, Heerlen, Netherlands; [12]Amalia Children's Hospital, Radboud University Medical Center, Nijmegen, Netherlands; [13]Maastricht University Medical Center, Maastricht, Netherlands; [14]Catharina Hospital, Eindhoven, Netherlands; [15]St. Antonius Hospital, Nieuwegein, Netherlands; [16]Canisius Wilhelmina Hospital, Nijmegen, Netherlands?

Background
Idiopathic isolated growth hormone deficiency (IIGHD) is treated with recombinant human growth hormone (rhGH) to achieve normal adult height (AH). While effective in improving height, rhGH treatment is expensive, requiring hospital visits, laboratory investigations, and X-rays. It also imposes a significant treatment burden due to the necessity of daily injections. The optimal duration of rhGH treatment remains debated, with current protocols recommending continuation until near adult height (NAH). However, studies (including our SEENEZ-trial) suggest that many adolescents may not need prolonged rhGH treatment, as 70-80% of patients with IIGHD show a sufficient GH peak when retested. This raises the question whether earlier discontinuation could be cost-effective.
Aims
We aimed to analyze the costs savings of withdrawing rhGH treatment at mid-puberty in GH-sufficient adolescents with IIGHD by comparing early rhGH discontinuation with continuation until NAH.
Methods
A cost analysis was conducted alongside a multi-center patient preference trial (SEENEZ-trial). Adolescents treated with rhGH for partial IIGHD were eligible if they were in mid-puberty and had been receiving rhGH treatment for at least 3 years. Adolescents who tested GH sufficient (GH peak >6.7 µg/l) had the choice to stop or continue rhGH treatment until NAH. Adolescents who continued GH treatment received standard care, those who stopped visited the outpatient clinic twice yearly. A comprehensive analysis of the costs for each individual patient up to 3 years was performed, including healthcare costs (relating to GH medication, outpatient clinic visits, laboratory tests, and X-rays) and costs outside the healthcare sector (travel costs).
Results
A total of 127 patients (95 male, 75%) participated in the SEENEZ-trial. Forty-four patients (35%) continued rhGH treatment until NAH (GHcont), while 83 patients (65%) stopped treatment 2-3 years earlier (GHstop). Mean costs per patient in the GHcont group equaled €11, 928 per year or €27, 868 from mid-puberty until NAH. For the GHstop group, the total costs per patient averaged €222 per year and €692 from mid-puberty until NAH. On a nation-wide scale, this suggests that early discontinuation of rhGH could potentially reduce costs in the Netherlands by approximately €2 million annually.
Conclusion
Withdrawing rhGH treatment 2-3 years earlier in GH-sufficient adolescents with transient IIGHD significantly decreases medical consumption and reduces healthcare costs. Even greater cost savings will be achieved if outpatient follow-up visits after withdrawing rhGH treatment are eliminated. Future research should focus on the cost-effectiveness of rhGH withdrawal, considering final height, health-related quality of life, and quality-adjusted life years.

Impact of methylphenidate on growth, thyroid function, and cortisol secretion in children with ADD/ADHD: a systematic review (2000–2024)

Sohair Elsiddig[1], Ashraf Soliman[1], Mohamed AlKuwari[1], Carolin Beck[1] & Fawzia Alyafei[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Methylphenidate (known as Ritalin) is widely used for treating attention deficit disorder (ADD) and Attention Deficit Hyperactivity Disorder (ADHD) in children. Long-term treatment has raised concerns regarding its impact on growth, thyroid function, and cortisol secretion. This review aimed to summarize findings from studies between 2000 and 2024 that investigated the effects of methylphenidate on these parameters.
Methods
A comprehensive literature review identified 20 studies examining the effects of methylphenidate on growth parameters (height, weight, IGF-1), thyroid hormones (FT4, TSH), and adrenal function (cortisol, DHEA-S). A total of 3, 500 children and adolescents across various studies were included, ranging in age from 3 to 18.

Table 1: Methylphenidate's Effects on Growth and Endocrine Parameters in Children with ADD/ADHD

Parameter	Effect of Methylphenidate
Growth	Mild growth suppression (reduced height Z-scores, weight gain), particularly during the first year; rebound growth observed after discontinuation.
IGF-1	Mixed findings: some studies show mild reductions, while others report no significant changes.
Thyroid	No significant impact on thyroid hormones (FT4, TSH).
Cortisol	Inconsistent Results some studies show elevated salivary cortisol (HPA axis activation), while others report no significant changes.

Results
• **Growth:** Twelve studies reported significant reductions in height and weight gain, particularly in the first 6–12 months of treatment. Reductions in height Z-scores were observed, with mild growth suppression attributed to appetite suppression and metabolic changes. Some studies (e. g., Safer *et al*., 1979) noted rebound growth after treatment discontinuation.
• **IGF-1:** Inconsistent findings were reported. While **5 studies** (Harstad *et al*., 2022, among others) found no significant change in IGF-1 levels, others observed mild decreases correlating with reduced growth velocity.
• **Thyroid:** Data from **3 studies** indicated that methylphenidate has no significant impact on thyroid function (FT4, TSH). Harstad *et al*. (2022) confirmed no association between methylphenidate and thyroid dysfunction.
• **Cortisol:** Findings were mixed across **6 studies**. Kholif *et al*. (2021) reported increased salivary cortisol levels after one month, indicating HPA axis activation. However, studies by Lee *et al*. (2008) and Pitzianti *et al*. (2020) found no significant changes in cortisol levels, while some reported elevated DHEA-S without clinical significance.
Conclusion
This review, encompassing **20 studies** with **3, 500 children**, highlights mild growth suppression associated with methylphenidate, especially early in treatment. Thyroid function appears unaffected, while cortisol secretion results remain inconsistent, suggesting variable HPA axis effects. Regular monitoring of growth, IGF-1, and adrenal function is recommended for children on long-term methylphenidate therapy to detect and address potential endocrine disturbances.

JOINT1684

Long-term growth hormone therapy in a patient with hallermann-streiff syndrome: a 15-year follow-up

Isolina Riaño Galan[1], Alicia Perez Perez[1], Laura Santos Gomez[1], Clara González López[1] & Ana Cristina Rodriguez-Dehli[1]
[1]Pediatric Endocrinology. Hospital Universitario Central de Asturias, Universidad de Oviedo. IUOPA-ISPA, Avda. Hospital Universitario s/n - 33011 Oviedo, Spain. CIBER de Epidemiología y Salud Pública (CIBERESP), 28029 Madrid, Spain, Oviedo, Spain

Objective
To report the long-term follow-up of a patient with Hallermann-Streiff syndrome (HSS) and growth hormone (GH) deficiency treated with GH therapy from early childhood to adolescence.
Methods
Case report and longitudinal evolution.
Results
A female patient diagnosed with HSS at 22 months was referred due to extreme growth failure (height –6. 6 SD). She was the second child of healthy, non-consanguineous parents. Family history was unremarkable. Pregnancy was uncomplicated, and delivery occurred at term (38 weeks), with a normal birth weight (2800 g) and length (48 cm). She had typical HSS features, bilateral congenital cataract surgery, and frequent respiratory infections. Intellectual development was normal. Endocrine evaluation showed persistently low IGF-1 (<25 ng/mL), GH deficiency confirmed by stimulation tests (peak GH: 1. 52 ng/mL after glucagon, 6. 7 ng/mL after clonidine), and delayed bone age. GH therapy (0. 028 mg/kg/day) was started in 2012 and discontinued in 2024 (age 15 years, 7 months) due to epiphyseal closure. Growth response was modest (final height: 134. 4 cm, –4. 26 SD), likely affected by the syndrome, early infections, and skeletal factors. However, GH therapy improved IGF-1 levels, muscle tone, strength, and functional capacity, enhancing energy levels and endurance. No significant adverse effects were observed despite early recurrent infections. Menarche occurred at 13 years, 4 months, with regular and prolonged cycles. At last assessment (15 years, 8 months), weight was 35 kg (–2. 2 SD), BMI 19. 38 kg/m^2 (–0. 64 SD), with complete pubertal development. Bone mineral density (L1–L4: 734 mg/cm^2, Z-score –2. 7) was low for age and sex, likely due to poor dietary calcium intake. She is under multidisciplinary follow-up:

- **Pulmonology:** Allergic asthma, obstructive sleep apnea requiring BiPAP since age 6. No significant respiratory symptoms with activity.
- **Nephrology:** Hypertension treated with enalapril and amlodipine, difficult control.
- **Cardiology:** Moderate mitral regurgitation, no restrictions.
- **Ophthalmology:** Bilateral aphakia, nystagmus.
- **Rehabilitation:** No scoliosis. Uses a small heel lift.

Highly intelligent and academically driven, she previously played soccer but now prioritizes studies.

Conclusion

GH therapy had a limited effect on final height but significantly improved muscle tone, strength, and overall physical performance. This is the first reported long-term case of GH therapy in HSS reaching adulthood, highlighting the importance of individualized expectations in syndromic growth disorders and the role of GH beyond height improvement. A multidisciplinary approach is essential for optimizing long-term outcomes in HSS patients, particularly regarding bone health, cardiovascular function, and respiratory support.

JOINT1003

Short stature and growth hormone deficiency in a case of POMC deficiency: an unexpected clinical association

Ugur Cem Yilmaz[1], Deniz Ozalp Kizilay[1], Damla Goksen[1] & Samim Ozen[1]
[1]Ege University Faculty of Medicine Department of Pediatric Endocrinology and Diabetes, Izmir, Türkiye

Introduction

Proopiomelanocortin (POMC) deficiency is an ultra-rare monogenic form of obesity characterized by impaired synthesis of hormones derived from the hypothalamus and pituitary gland. Mutations in the POMC gene lead to distinct phenotypic features, including early-onset obesity, fair skin, and red hair. While most reported cases in the literature describe normal growth, short stature and growth hormone deficiency (GHD) have been documented in only one case. Among three POMC deficiency cases followed at our center, none demonstrated short stature, making the findings in this patient particularly noteworthy for expanding the syndrome's clinical spectrum.

Case Presentation

A 15-year-old female was first evaluated at 3. 5 years of age with obesity, fair skin and red hair, ACTH deficiency, and recurrent episodes of severe hypoglycemia during infancy. The diagnosis of POMC deficiency was confirmed by identifying a homozygous pathogenic c. 64delA variant in the POMC gene. During follow-up, delayed puberty and hypogonadotropic hypogonadism were identified. From the age of 12 years onward, growth retardation and short stature became apparent. At age 13, the patient's physical examination revealed a weight of 56. 7 kg (SDS: 0. 8), height of 143 cm(SDS: -2. 5), BMI of 27. 1 kg/m^2 (SDS: 2), and annual growth velocity of 1. 64 cm/year (SDS: -1. 61). The patient was at Tanner stage 1. Bone age, assessed at 14 years of age, corresponded to 10 years. After achieving a euthyroid state and estrogen priming, L-Dopa and clonidine stimulation tests were performed, showing peak GH levels of 0. 52 μg/l and 1. 0 μg/l, respectively. These findings confirmed a diagnosis of growth hormone deficiency(GHD). Pituitary MRI revealed normal size and morphology with no pathological findings. GH replacement therapy was initiated at 0. 035 mg/kg/day at 14 years and 3 months of age. After 8 months of therapy, the patient's weight was 59. 8 kg(SDS: 0. 67), height was 150. 2 cm(SDS: -1. 95), BMI was 26. 51 kg/m^2 (SDS: 1. 79), and annual growth velocity was 11. 29 cm/year.

Discussion

Although normal stature is typically reported in POMC deficiency, the short stature and GHD observed in this case represent rare and striking finding that expand the clinical spectrum of the syndrome. The rarity of short stature in most reported cases of POMC deficiency underscores the uniqueness of our case. The etiology of GHD in POMC deficiency remains unclear. The co-occurrence of these conditions could be coincidental; however, the severe hypoglycemic episodes experienced during early infancy may have impaired hypothalamic-pituitary development and GH secretion, contributing to GHD in this patient.

Impact of the TUITEK™ patient support program on caregivers-related behaviours in enhancing growth hormone treatment adherence

Ekaterina Koledova[1], Pen-Hua Su[2, 3], Yen-Ju Chen[4], Debbie Cooke[5], Amrit Jheeta[5] & Jung Eun Moon[6]
[1]Global Medical Affairs, Cardiometabolic and Endocrinology, Merck Healthcare KGaA, Darmstadt, Germany; [2]School of Medicine, Chung Shan Medical University, Taichung City, Taiwan; [3]Department of Pediatrics and Genetics, Chung Shan Medical University Hospital, Taichung City, Taiwan; [4]Medical and Clinical Affairs Department, Merck Ltd., an affiliate of Merck KGaA, Taipei City, Taiwan; [5]Atlantis Health Ltd., London, United Kingdom; [6]Department of Pediatrics, School of Medicine, Kyungpook National University, Kyungpook National University Hospital, Daegu, South Korea

Background

Recombinant human growth hormone (r-hGH) treatment can improve or normalise growth outcomes in paediatric patients with growth hormone deficiency. However, poor adherence to the long-term treatment regimen limits its effectiveness and leads to sub-optimal growth outcomes. The multicomponent, individualised TUITEK™ Patient Support Program (PSP) aims to guide behavioural changes throughout the treatment care pathway in a way that is personalised to the needs of individual patients and their caregivers.

Aim

To determine the impact of the TUITEK™ PSP on the knowledge, beliefs, and perceptions of high-risk caregivers regarding adherence to r-hGH treatment (disease and treatment coherence, emotional burden, self-administration, and treatment-related anxiety).

Methods

This prospective pre–post study of the TUITEK™ PSP was conducted in a combined population of caregivers (aged 25–60 years) of patients with short stature receiving r-hGH treatment (somatropin [Saizen®; Merck KGaA, Darmstadt, Germany]) using auto-injector device and injection pens in Argentina, the Republic of Korea, and Taiwan. The analysis included caregivers categorised as high-risk were offered a set of five personalised telephone calls from a trained nurse practitioner over 3 months, along with resource packs with a range of behaviour change techniques. Two weeks after the final call of the TUITEK™ PSP, caregivers were contacted to complete a follow-up personalisation questionnaire. Changes in the questionnaire-based scores were assessed.

Results

Data from 409 high-risk caregivers were obtained. Of these caregivers, 10. 3% were considered high risk for disease and treatment coherence, and 71. 4% were considered high risk for emotional burden. Involvement in the PSP was associated with a statistically significant ($P < 0.0001$) positive change in all factors. These improvements were reflected in the number of caregivers who moved from the high- to low-risk category at the end of the PSP. The greatest change was observed for disease and treatment coherence, with only 1 of the 42 high-risk caregivers failing to move into the low-risk category. When looking at any positive change in score, 100% of caregivers who were high-risk at baseline had a beneficial change in disease and treatment coherence, 86. 4% a change in self-administration, 63% a change in emotional burden, and 79. 6% a change in treatment-related anxiety. The changes observed in the overall cohort remained similar when the data were analysed separately for individual countries.

Conclusions

The TUITEK™ PSP successfully improved key caregiver-related behaviours that may negatively impact adherence to r-hGH treatment. Furthermore, it might improve treatment adherence and thus clinical outcomes.

A novel point-of-care molecular diagnostic method for the rapid diagnosis of Turner syndrome

Sunetra Mondal[1], Parikshit Moitra[2], Neethu KM[2] & Satinath Mukhopadhyay[3]
[1]Nilratan Sircar Medical College and Hospital, Kolkata, Endocrinology, Kolkata, India; [2]IISER, Berhampur, Berhampur, India; [3]IPGME&R, Kolkata, India

Introduction

Turner syndrome (TS) is a common aneuploidy affecting 1 in 2500 girls and has a multi-systemic presentation including short stature, pubertal delay, congenital anomalies of the heart, kidney, low performance-IQ, high risk for cardiometabolic diseases and osteoporosis etc. It is diagnosed by peripheral-blood karyotyping only after overt clinical manifestations develop, thus losing valuable time for early growth hormone therapy, pubertal induction and screening for anomalies. Till date, is no point-of-care test for a rapid and accurate diagnosis of TS has been in use.

Objective
To assess the sensitivity and specificity of qPCR in diagnosing karyotypic variants of TS and develop a POC test for TS by developing a covalent organic framework (COF) based dual mode sensor for DNA samples.
Methods
In the first part, we extracted genomic DNA from peripheral blood samples of 50 girls with TS (45, X = 23, 45, X/46, XX = 10, Isochromosome Xq = 12, 45, X/46, XY mosaics = 5), 25 normal females(46, XX) and 5 normal males(46, XY) . Using real-time PCR, we conducted qPCR with four genes - two Xp genes [SHOX and ARSE] and two Xq genes [VAMP7 and XIST] and a housekeeping autosomal gene HBB. The ΔΔ CT method was used for gene dose calculation and ROC curves were constructed to determine cut-offs for the different genes. Using the genes with best ROCs (SHOX and ARSE), we designed two pairs of complementary oligonucleotides decorated on a covalent organic framework (COF). Due to different doses of the target genes, the frameworks get arranged in a unique fashion, leading to quantitative changes in emission and electrochemical responses of the COF.
Results
qPCR could distinguish TS from normal females with >85 % sensitivity and specificity. SHOX could discriminate between TS from female controls with 86 % sensitivity and 86. 4 % specificity at a cut-off of 0. 75 while ARSE had a sensitivity of 82. 6% and specificity of 83. 6% at a cut-off of 0. 86. The ARSE gene was particularly useful to diagnose non-classic TS. The dual mode sensor developed using COF for SHOX and ARSE genes yielded the diagnosis in all the samples tested. However, it could not diagnose ring chromosomes and very low levels of mosaicism.
Conclusion
We have developed a novel dual-mode COF sensor for the diagnosis of Turner syndrome. This might be used for neonatal or community-based screening programmes to detect TS.

Background
Noonan syndrome (NS) is a congenital genetic disorder with an estimated incidence of 1 in 1, 000-2, 500 live births. It is characterized by congenital cardiac abnormalities, short stature, distinctive facial features, chest deformities and variable cognitive deficits. NS results from pathogenetic variants in genes involved in the RAS/MAPK signaling pathway, exhibiting significant genetic and clinical variability.
Aims
To assess the prevalence of specific genetic mutations and their impact on clinical outcomes in NS.
Methods
We conducted a retrospective observational study of 111 patients with genetically confirmed NS. Data collected included genotype, cardiac defects, and anthropometrics (birth weight, birth length, stature, and weight at the last visit). Standard deviation (SD) scores were calculated using Italian population growth charts.
Results
Complete data were available for 60 NS patients (38% males). The most common mutations occurred in *PTPN11* (60%) and *SOS1* (10%), with additional variants observed in *LZTR1, RAF1, RIT1, CBL, KRAS, SOS2, BRAF, MAP2K1*. Cardiovascular abnormalities were present in 62% of patients, with *PTPN11* and *RIT1* mutations predominantly linked to pulmonary valve stenosis and *RAF1* mutations to hypertrophic cardiomyopathy. Less common cardiac defects, such as atrial and ventricular septal defects and mitral or aortic valve abnormalities, showed no clear genotype correlation. Small for gestational age (SGA) was observed in 5% of patients, all of whom carried PTPN11 mutations. At mean age of 9. 8 ± 5. 9 years, average height and weight were -1. 8 ± 1. 18 SD and -1. 5 ± 1. 40 SD, respectively. Short stature was observed in 42% patients, with a mean height of -2. 84 SD. Growth hormone therapy was used in 37% of patients, most of whom carried PTPN11 mutations (74%, $P < 0.05$). Among SGA patients, two thirds developed short stature. Notably, patients with *CBL, SOS2*, or *MAP2K1* mutations did not exhibit short stature. In 28% of the cohort, both short stature and cardiac defects co-occurred, though this combination was not significantly linked to a specific genotype.
Conclusion
This study highlights the high prevalence of cardiac abnormalities and short stature in NS, with clear genotype-phenotype correlations for cardiovascular defects. While being born SGA was relatively uncommon, it appeared to be specifically associated with the *PTPN11* genotype. In contrast, genotype-growth correlations were less distinct, though certain mutations seemed to confer a lower risk of short stature. These findings underscore the genetic and clinical variability of NS and the need for larger studies to better understand genotype-phenotype correlations.

Is the high incidence of false-positive results of growth hormone stimulation tests in children with short stature related to the nutritional status? Let's ask artificial intelligence

Joanna Smyczyńska[1], Urszula Smyczyńska[2], Maciej Hilczer[3] & Renata Stawerska[3, 4]
[1]Medical University of Lodz, Department of Pediatrics, Diabetology, Endocrinology and Nephrology, Lodz, Poland; [2]Medical University of Lodz, Department of Biostatistics and Translational Medicine, Lodz, Poland; [3]Polish Mother's Memorial Hospital - Research Institute, Department of Endocrinology and Metabolic Diseases, Lodz, Poland; [4]Medical University of Lodz, Department of Pediatric Endocrinology, Lodz, Poland

There is increasing evidence that the incidence of false positive results of growth hormone (GH) stimulation tests (GHST) in children with short stature may be relatively high. The challenge is to identify the patients who may be overdiagnosed with GH deficiency (GHD) for this reason. Interpretation of GHST in children does not take into account their nutritional status. The aim of the study was an attempt to use machine learning methods for prediction of isolated GHD and idiopathic short stature (ISS) in children with excluded other causes of short stature (other endocrinopathies, chronic diseases, genetic defects, malnutrition, cancers, brain injuries), based on auxological indices and IGF-1 concentration. Records of 1592 children with short stature (height SDS <-2. 0), aged 10. 3±3. 4 years (mean±SD), were used for creating classification models for predicting GHD or ISS with different techniques of machine learning. In all of the patients height and weight were measured, two GHST (after clonidine and glucagon) were performed with the cut-off for GH peak 10 µg/l, IGF-1 concentrations were determined, bone age (BA) was assessed, and body mass index (BMI) was calculated. Models were created on raw data (age, sex), age-related variables expressed as SDS for age and sex (hSDS, IGF-1 SDS, BMI SDS), while BA as its ratio to chronological age (BA/CA). Based on GH peak in both GHST <10 µg/l, GHD was diagnosed in 604 patients (37. 9%), including 378 out of 985 boys (38. 4%) and 226 out of 607 girls (37. 2%); the remaining children were diagnosed with ISS. In the decision tree, GHD was predicted in 156 patients, in 149 ones based on BMI SDS >0. 91. Naive Bayes classifier (the method that should include real size of groups) predicted GHD in only 118 cases. The best multilayer perceptron (MLP) neural network predicted GHD in 352 patients. Logistic regression with forward stepwise variable selection classified 269 patients to GHD group, keeping only BMI SDS and IGF-1 SDS as significant variables. All the obtained models classified much less patients to GHD group than the results of GHST <10 µg/l. The significance of higher BMI SDS for prediction of GHD shown in AI models seems a possible cause of inaccuracies of prediction. It seems that these results speak for the need to interpret the results of GHST depending on the nutritional status of children rather than for inability of machine learning techniques to create prediction models.

The medical impact of hypochondroplasia by age among adults in England between 1998 and 2019: a matched cohort study using electronic medical records from the clinical practice research datalink

Moira Cheung[1], Sheila Reddy[2], Jeanne Pimenta[3], Hilary Shepherd[4], Melita Irving[5], Swati Mukherjee[3], Eleanor Axson[4] & Rachael Williams[4]
[1]Great Ormond Street Hospital, London, United Kingdom; [2]BioMarin Pharmaceutical Inc., Novato, United States; [3]BioMarin (UK) Ltd, London, United Kingdom; [4]Clinical Practice Research Datalink (CPRD), Medicines and Healthcare Products Regulatory Agency (MHRA), London, United Kingdom; [5]Guy's and St. Thomas' NHS Foundation Trust, Evelina Children's Hospital, London, United Kingdom

Hypochondroplasia (HCH) is a rare genetic skeletal dysplasia causing disproportionate short stature secondary to pathogenic variants in the gene fibroblast growth factor receptor 3 (*FGFR3*). This retrospective study compared the medical impact of HCH among adults with the general population in England from 1998 to 2019. A real-world matched cohort study was conducted using electronic primary care medical records from the Clinical Practice Research Datalink. Adults with HCH identified using a specific HCH diagnosis code (SNOMED:315057016) or a general code (ICD-10-CM:Q77. 4) were split into 4 age groups (19-29, 30-49, 50-69, and $\geq$70 years of age [y]) and matched 1:4 with controls by sex, nearest birth year, and region. Event rates (events/100 person-years [PY]) and rate ratios (RR; cases vs controls) were calculated for selected comorbidities and healthcare use. Overall, 385 adults with HCH and 1373 matched controls were included: 136 and 572 (19-29y), 181 and 592 (30-49y), 49 and 142 (50-69y), and 19 and 67 ($\geq$70y), respectively. Across ages, mean follow-up time ranged from 6 to 8 years for adults with HCH and 11 to 14 years for controls, respectively. Comorbidity event rates were higher among adults with HCH vs controls and generally increased with age; the highest rates were for respiratory, mental health, cardiovascular, and orthopaedic events (**Table**). Although surgical procedures were infrequent, orthopaedic surgery rates were higher among adults with HCH than controls. Adults with HCH utilized more healthcare resources than controls, and rates generally increased with age. General practice visits were most frequent (range, 1055. 02–2778. 55 visits/100 PY), followed by inpatient admissions (range, 319. 68–520. 46 visits/100 PY). In all age groups, mortality rates were higher for individuals with HCH than controls, peaking among those aged 30 to 49 years (RR: 3. 31 [19-29y], 18. 41 [30-49y], 4. 92 [50-69y], 1. 72 [$\geq$70y]). Rates of certain conditions typically increase with age; the increase is more pronounced for people with HCH. Results highlight the medical burden of HCH and the importance of lifelong multidisciplinary management.

Table. Comorbidity rates in adults with HCH versus controls.

Body system category	RR (95% CI) 19-29y	30-49y	50-69y	≥70y
Overall (across all body systems)	2.31 (1.91-2.79)	3.04 (2.63-3.52)	2.96 (2.36-3.73)	2.42 (1.65-3.54)
Respiratory	2.39 (1.58-3.63)	6.59 (4.66-9.32)	5.10 (3.14-8.27)	2.18 (1.11-4.29)
Mental health	1.33 (0.94-1.89)	2.43 (1.86-3.16)	1.60 (1.03-2.50)	3.90 (1.76-8.64)
Cardiovascular disease	17.28 (7.61-39.22)	7.09 (4.73-10.62)	3.49 (2.49-4.90)	1.16 (0.74-1.81)
Orthopaedic	2.24 (1.30-3.84)	5.69 (4.10-7.89)	7.27 (5.09-10.38)	6.24 (3.87-10.06)

Screening for shox gene variation in children with apparently idiopathic short stature: systematic screening or clinical and radiological oriented screening?

Romée Pouliquen[1], Sebastien Schmitt[2], Lucie Levaillant[1], Fabienne Emeriau[1], Jessica Amsellem-Jager[1], Natacha Bouhours-Nouet[1], Aurélie Donzeau[1], Stéphanie Rouleau[1], Tifenn Gueguen[1] & Regis Coutant[1]
[1]CHU Angers, Angers, France; [2]CHU Nantes, Nantes, France

Introduction
Short-stature homeobox-containing (SHOX) gene haploinsufficiency is the most frequent monogenic cause of short stature and is responsible for highly variable phenotypes ranging from idiopathic short stature (ISS) to severe dyschondrosteosis in the Langer syndrome. The reported prevalence of SHOX haploinsufficiency in children with apparently ISS varies from 2 to 17%, and its radiological expression is variable. The aim of this study was to find out whether simple radiological characteristics on the left-hand and wrist radiography were associated with the presence of SHOX gene variations and could be a good indicator for SHOX gene molecular study.

Materials and Methods
This study is a descriptive, retrospective and non-interventional study based on clinical and radiological data of 266 patients with apparently ISS referred to the Pediatric Endocrinology Unit of Angers University hospital from 2016 to 2023 for whom SHOX analysis was performed by Multiplex Ligation-dependent Probe Amplification (MLPA) and/or sequencing. To further analyze the sensitivity of radiological criteria for the molecular diagnosis of SHOX variations, we additionally included 33 patients diagnosed with a SHOX mutation between 2010 and 2015.
Results
11% of patients with apparently ISS had a SHOX deficiency. SHOX deficiency was more often associated with convexity of the distal radial metaphysis ($P < 0$, 001), pyramidalisation of the carpal row ($P < 0$, 001) and lucency of the ulnar border of the distal radius ($P < 0$, 001), but no difference was found considering the triangularization of the distal radial epiphysis ($P = 0$, 142). A cut-off point of 148 degrees for the convexity of the distal radial metaphysis had a sensitivity of 90% and a specificity of 47, 8%, and a cut-off point of 129 degrees for the pyramidalisation of the carpal row had a sensitivity of 87, 5% and specificity of 50, 3%.
Conclusion
We found cutoffs for SHOX gene variation diagnosis from the simple left-hand and wrist radiology. These cut-offs had a fair sensitivity (90%) and a mild specificity (50%). This suggests that in structures where the resources for SHOX molecular study are limited, an oriented screening based on these cutoffs would decrease the number of molecular studies by half (and would miss 10% of the SHOX gene variations), whereas, in structures where molecular studies are easily available, systematic screening of children with otherwise unexplained short stature might be useful.

Long term follow-up in a patient with Cat Eye syndrome, hypopituitarism and hypertransaminasemia

Sara Soldovieri[1, 2], Eugenio Trinati[1, 2], Matteo Cerutti[1, 2], Giulia Del Medico[1, 2], Sara Barneschi[1, 2], Gaia Varriale[2] & Stefano Stagi[1, 2]
[1]Department of Health Sciences, University of Florence, Florence, Italy; [2]Auxoendocrinology Unit, Meyer Children's Hospital IRCCS, Florence, Italy

Background
Cat Eye Syndrome (CES), also known as Schmid-Fraccaro syndrome, is a rare chromosomal disorder typically caused by trisomy or partial tetrasomy of chromosome 22 (inv dup 22pter to 22q11. 1). It is characterized by a classic triad of iris coloboma, anal atresia, and ear anomalies, seen in about 40% of cases. The clinical spectrum often includes features such as hypertelorism, down-slanting palpebral fissures, preauricular pits, and intellectual disability. Chromosomal rearrangements in the 22q11. 2 region can affect midline structures, such as the pituitary gland, leading to growth hormone (GH) deficiency and other hypothalamic-pituitary axis abnormalities. Although this case was previously described by other authors at birth (Serra *et al*. 2022), our aim is to present the long-term follow-up and the therapeutic outcome.
Case Presentation
We present the case of a full-term newborn from healthy parents, following a normal pregnancy and birth. The infant developed persistent hypoglycemia and cholestatic jaundice shortly after birth. Physical examination revealed hypotonia, anorectal malformation with the anal outlet located in the vaginal fornix, along with facial dysmorphisms, including hypertelorism, microphthalmia, and dysplastic ears. Ophthalmologic evaluation confirmed bilateral iris coloboma, and echocardiogram revealed atrial septal defect. Endocrine testing showed congenital deficiencies of cortisol, GH, and thyroid hormones, leading to the diagnosis of hypopituitarism. Following this, hydrocortisone and levothyroxine were initiated. No symptoms suggestive of diabetes insipidus were observed. Brain MRI documented aplasia of the anterior pituitary gland, agenesis of the pituitary stalk, and ectopic neurohypophysis. Array CGH confirmed partial tetrasomy of chromosome 22 (22q11. 1q11. 21), establishing the diagnosis of CES. After the initial hospitalization at birth, the patient began multidisciplinary follow-up and was started on GH replacement therapy, along with oral hydrocortisone and levothyroxine, which allowed for adequate glycemic and thyroid control. At the current age of 3, despite early developmental delay and growth failure, she has shown significant catch-up growth (height: from -6 to -3. 6 SDS; weight: from -6 to -3. 3 SDS). Cholestasis has improved with cortisol therapy, although transaminases and gamma-GT have remained elevated.
Conclusion
Congenital hypopituitarism can be a part of the highly variable phenotypic spectrum of CES, often presenting with neonatal hypoglycemia, cholestasis, and

severe growth delay. Six other cases with pituitary abnormalities and hormonal defects have been reported in the literature (four with isolated GH deficiency, two with hypogonadotropic hypogonadism). Cortisol deficiency is known to impair bile recirculation, but persistent hypertransaminasemia and elevated gamma-GT suggest a multifactorial cause of hepatic cytolysis despite hydrocortisone treatment.

Quality of life, sexuality, and psychosocial well-being in adult women with turner syndrome: insights from a danish questionnaire survey

Camilla Mains Balle[1, 2], Mette Viuff[1 3 4], Christian Graugaard[5], Annamaria Giraldi[6, 7] & Claus H. Gravholt[1 2 4]
[1]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; [2]Aarhus University Hospital, Department of Endocrinology, Aarhus, Denmark; [3]Aarhus University Hospital, Department of Gynocology and Obstetrics, Aarhus, Denmark; [4]Aarhus University Hospital, Department of Molecular Medicine, Aarhus, Denmark; [5]Aalborg University, Center for Sexology Research, Department of Clinical Medicine, Aalborg, Denmark; [6]Copenhagen University Hospital, Sexological Clinic, Mental Health Center, Copenhagen, Denmark; [7]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark

Introduction
Women with Turner syndrome (TS) face multiple challenges that can impact their quality of life (QoL), including psychological, social, and sexual well-being. While previous research has focused on girls with TS, data on adult women remain sparse and inconsistent. Adulthood introduces new challenges, such as relationships, infertility, and working life, which may markedly influence QoL. This study explores the physical, psychosocial, and sexual well-being of adult women with TS providing insights into their overall QoL.
Methods
Between 2020 and 2024, all women with TS attending the outpatient clinic were invited to complete an electronic questionnaire. Ten age- and geographically matched female controls from the general population were invited per TS participant. The questionnaire covered demographics, socioeconomic status, and health problems, as well as validated instruments assessing quality of life, sexual function, and mental and physical well-being; among them the WHOQoL-Bref, SF-36, the Female Sexual Function Index (FSFI-19), and scales measuring stress, anxiety and depression.
Results
In total, 131 women with TS and 237 controls completed the questionnaire. Among TS women, 91 were currently receiving hormone replacement therapy (HRT), 15 had been treated with HRT until menopause (defined as age $\geq$45), and 25 were not currently or had never received HRT. The median age was 37 years (IQR: 26–51) for TS women and 42 years (IQR: 30–54) for controls ($p < 0.0001$). Partner status differed significantly, with 53. 3% of TS women having a partner vs 79. 5% of controls ($p < 0.0001$). Women with TS had significantly lower SF-36 scores across all domains except Bodily Pain, with the lowest in Vitality, Mental Health and Social Functioning (all $p < 0.001$). The median SF-36 General Health score was 65 (IQR: 40–80) for TS women vs 75 (IQR: 60–85) for controls ($p < 0.0001$). Similarly, TS women scored lower across all WHOQoL-Bref domains, with a median overall QoL score of 62. 5 (IQR: 50–75) vs 75 (IQR: 62. 5–75) in controls ($p < 0.0001$). Overall, 65. 0% of TS women reported sexual activity within the past four weeks, compared to 82. 2% of controls ($P = 0.003$). Among sexually active TS women, FSFI-defined scores for arousal, orgasm, and pain were significantly lower (all $p < 0.02$), indicating sexual dysfunction. No significant differences were found in overall QoL scores between sexually active and inactive TS women.
Conclusion
Women with TS report significantly more physical, psychological, sexual, and social challenges than controls.

Total and bioactive IGF-i in healthy children and adolescents and in short children during growth hormone therapy: an alternative tool to individualized GH treatment in patients

Lea Vilmann[1], Jørgen Petersen[1], Stine Agergaard Holmboe[1], Peter Christiansen[1], Katharina M. Main[1, 2], Line Cleemann[1], Kristian Hansen[3], Jan Frystyk[3, 4], Casper Hagen[1, 2] & Anders Juul[1, 2]
[1]Copenhagen University Hospital, Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark; [2]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; [3]OPEN Lab, Odense University Hospital, OPEN Lab, Odense, Denmark; [4]Endocrine Research Unit, Odense University Hospital, Department of Endocrinology, Odense, Denmark

Background
The growth response following recombinant human growth hormone treatment (rhGH) varies. Accordingly, titration of doses is often based on assessment of serum total IGF-I. However, in a recent study of SGA children, serum levels of bioactive IGF (bio-IGF) were lower than total IGF-I, indicating a therapeutic opportunity for increasing the dose of rhGH.
Aims
To assess if bio-IGF could be a clinically relevant biomarker, helping to titrate the dose of rhGH, we determined serum bio-IGF reference ranges in patients with short stature due to various conditions.
Method
Reference population: A cohort of 570 healthy children and adolescents (59% girls) from an ongoing study (COPUS III). GH treated children: In total, 130 patients (35% girls) enrolled during 2024. Patients included subgroups of: GH deficiency (GHD), small for gestational age (SGA), Turner (TS), Prader Willi syndrome (PWS), Chronic Renal Insufficiency (CRI) or Other. In 128 children, blood samples were collected once during rhGH. All samples were analyzed for bio-IGF (KIRA assay) and total IGF-I (iSYS).
Results
In healthy girls and boys, bio-IGF increased with age and peaked at mid-puberty (Tanner-stage, mean (range)): B3, 1. 35 (0. 57-4. 03) μg/l and G3, 1. 25 (0. 44-2. 45) μg/l, respectively. Total and bio-IGF correlated significantly in healthy boys: Pearson $r = 0.60$, healthy girls: r=. 55, GH treated boys: $r = 0.76$ and GH treated girls: $r = 0.61$. In children receiving rhGH, the prevalence of concentrations exceeding +2SD was higher for total IGF-I compared to bio-IGF (25% vs. 13%), especially in non-GHD patients (Table 1).
Conclusion
Reassuringly, most non-GHD patients had IGF bioactivity within references based on healthy age-matched children, despite 25% of subjects having total IGF-I concentrations above +2SD. Further studies are needed to evaluate the clinical value of bio-IGF as an alternative biomarker in short children receiving GH treatment.

Table 1: Characteristics of patient groups presented as median (range)

Subgroups (n)	Bio IGF SD	IGF-I SD
GHD (75)	1. 07 (-2. 63-6. 09)	1. 08 (-2. 79-4. 04)
SGA (21)	1. 06 (-0. 86-3. 52)	1. 88 (-1. 37-3. 42)
Turner (7)	0. 12 (-2. 88-2. 15)	1. 55 (-1. 06-2. 79)
PWS (7)	. 85 (-0. 05-1. 80)	2. 06 (0. 40-2. 66)
CRI (4)	1. 24 (0. 81-1. 80)	1. 41 (0. 20-1. 86)
Other diagnoses (14)	**0. 85 (-0. 48-1. 42)**	**1. 41 (0. 45-2. 40)***
All diagnoses (128)	1. 05 (-2. 88-6. 09)	1. 27 (-2. 79-4. 04)

Frequency, detection and management of scoliosis in children with prader willi syndrome – experience of an irish tertiary referral centre

Kate Banks[1], Harish Chaudhary[1], Julia Kiernan[1], Carl Faichney[1], Maebh Creighton[1], Elizabeth Hayden[1], Philip Stewart[1, 2] & Edna Roche[1, 2]
[1]Tallaght University Hospital, Paediatric Endocrinology, Dublin, Ireland; [2]Trinity College Dublin, School of Medicine, Dublin, Ireland

Prader Willi Syndrome (PWS) is a rare genetic neurodevelopmental condition typically associated with hyperphagia, weight gain and premature mortality largely due to extreme obesity. Prevalence is estimated to be 1 in 11, 000 in Ireland. Scoliosis is a recognised feature of Prader Willi Syndrome noted to occur in over 40%, independent of growth hormone therapy treatment. The cause is unknown but as the distribution is bimodal, it is hypothesised that in infancy it relates to hypotonia and in later childhood follows the same pattern as idiopathic scoliosis in the general population.
Aims
To audit the frequency of scoliosis in an Irish cohort of children with PWS. To explore the methods of assessment and onward referral to orthopaedics where appropriate.

Methods
Detailed retrospective chart review of patients attending a tertiary specialist paediatric PWS service was undertaken in September- October 2024. Clinical and radiological examination for scoliosis was assessed, as were age, sex, growth hormone status, timing of assessments and scoliosis management. Findings were compared against the 2024 PWS UK & Ireland Prader–Willi syndrome: Guidance - scoliosis recommendations, which include annual clinical examination and two yearly radiographic examination during years of peak prevalence of scoliosis.
Results
All 49 patients currently attending the service, aged 0. 5 -14 years (50% male), were evaluated. Scoliosis was detected in 33 patients (67%) which was clinically evident in 24 (72%) and confirmed radiologically. The remaining 9 (27%) were detected on radiological screening. Referral for orthopaedic assessment was completed for all 33 children, 11 (33%) were awaiting review at the time of study; 12 (36%) were undergoing active orthopaedic monitoring and a further 10 (30%) had undergone orthopaedic interventions, including casting, bracing, or surgery (growing rods or posterior spinal fusion). In 36 patients (73%), there was full compliance with recommendations. In 8 cases less frequent radiological screening was undertaken and 4 (8. 3%) had more frequent radiology than recommended. This was for monitoring of a mild spinal curvature before referral to orthopaedics when the Cobb angle had exceeded 10 degrees.
Conclusion
Scoliosis is common in children with PWS. Regular spinal examination with radiological assessment is important for detection and subsequent management of scoliosis. The prevalence of scoliosis in PWS in Ireland was similar to that reported in the USA. However, orthopaedic intervention was twice as common in the Irish cohort. This could potentially be influenced by long waiting times for paediatric orthopaedic assessment in Ireland and merits further study.

Characterization of bone health in an adult population with turner syndrome: insights from a monocentric cross-sectional study

Laura Rotolo[1, 2], Matteo Malagrinò[1, 2], Carolina Cecchetti[1, 2], Paola Dionese[1, 2], Elisabetta Belardinelli[1, 2], Beatrice Solmi:[1, 2], Guido Zavatta[1, 2], Uberto Pagotto[1, 2] & Alessandra Gambineri[1, 2]
[1]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [2]Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, Italy

Background
Low bone mineral density (BMD) is a common feature of Turner syndrome (TS), frequently with an early onset, whose pathogenetic mechanisms and risk factors are not completely elucidated.
Aim
To evaluate the prevalence of low BMD, clinical fractures, and associated risk factors in a large population of adult TS patients attending a tertiary hospital with a structured transition program.
Methods
A cross-sectional analysis was conducted on 176 patients with TS (median age:36. 1yrs, range:15. 3-70. 7) at the time of their most recent dual-energy X-ray absorptiometry (DXA). Anthropometrics, bone metabolism markers, karyotype, typical comorbidities, details about prior and current estrogen replacement treatment (ERT) and prior rhGH treatment (rhGHT) were evaluated to assess their impact on lumbar/hip BMD, Z-scores and fracture risk.
Results
Seventy-one patients (40. 3%) presented a 45, X0 karyotype. Spontaneous menarche occurred in 36 patients, and 19 subsequently developed secondary amenorrhea. ERT was started at a median age of 16. 0yrs (range: 8. 0-50. 0), lasting 19. 0yrs (range: 0. 0-45. 0). rhGHT was administered in 120 patients (69. 8%). Regarding bone metabolism, 46 patients (27. 7%) exhibited low BMD (lumbar/hip Z-score $\leq$ -2), 13 (7. 4%) experienced clinical fractures. Ten patients (5. 7%) were on antifracturative treatment. Patients with low BMD had later induced/spontaneous menarche (17. 0 vs 16. 0yrs, $P = 0.047$), higher prevalence of primary amenorrhea (93. 5% vs 75. 4%, $P = 0.009$) and of family history of osteoporosis/fractures (27. 3% vs 8. 2%, $P = 0.025$) compared with patients with normal BMD. No significant differences were found in biochemical calcium-phosphate markers, bone turnover markers, and both sub-groups had adequately supplemented vitamin D levels. Age, karyotype, prior rhGHT, and prior or current ERT analysed as daily dose, type of estrogen, route of administration and duration, were not different between the two sub-groups. Patients with fragility clinical fractures had lower lumbar Z-scores (-2. 0 vs -1. 1, $P = 0.042$), and higher prevalence of other typical TS comorbidities (diabetes mellitus, major/minor cardiovascular events, hypertension, nephropathy), despite no age or BMI differences. No significant differences were also noted in karyotype, ERT or rhGHT. Notably, five patients with normal BMD experienced fragility fractures. However, DXA remained a reliable predictor of fractures, as patients with low BMD exhibited a significantly higher fracture risk (OR = 4. 84, 95CI:1. 49-125. 70, $P = 0.009$).
Conclusions
TS are at high risk for low BMD and fragility fractures, regardless of karyotype, rhGHT and type and extension of ERT. At variance, a delayed ERT initiation, as well as primary amenorrhea, are risk factors for low BMD. Therefore, continuous, lifelong monitoring of bone health is essential for all TS patients.

Background
GH therapy increases adult height in short small for gestational age (SGA) children, especially when started before puberty, but with high variability in height gain. The aim of this study was to describe the prevalence and the growth pattern of poor long-term responders to GH therapy in a real-life setting.
Methods
SGA (birth weight and/or length for gestational age $<$ - 2 SDS) children, starting GH therapy after the age of 4 years and before onset of puberty with an initial height SDS $<$ -2. 5 and $<$ -1 when adjusted for mid parental height (MPH) SDS, having reached near adult height (NAH) (height velocity increase $<$ 1 cm/6 months) were selected from the BELGROW database.
Results
182 (100 male) patients were analyzed. Median (Q1;Q3) age at start of GH therapy was younger in females (8. 8 (6. 3; 10. 8) than in males 9. 1 (6. 6;11. 6) years; $P = 0.188$), but treatment duration was longer in males (7. 1 (5. 4;9. 7) than in females 6. 1 (4. 7;8. 3) years; $P < 0.05$). Median height SDS at start of treatment (-3. 00 (-3. 44;-2. 75)), GH dose (0. 037 (0. 034;0. 042) mg/kg/day), NAH SDS for chronological age (-1. 88 (-2. 40;-1. 35)) and corrected for MPH (-0. 61 (-1. 21;-0. 19)) as well as total SDS height gain (1. 25 (0. 84;1. 76)) were similar in males and females. At NAH, 63% (114; 59 male) of patients remained short (SDS calculated for age 21 years $<$ -2), 49% (89; 50 male) were below target height (NAH SDS corrected for MPH $<$ -1) and 15% (28; 14 male) had a poor total height gain (total height SDS increase $<$ 0. 5). In total, 18% (32; 15 male) of patients had a poor initial growth (height SDS increase $<$ 0. 3 during the first year of therapy), while 22% (40; 19 male) had a poor growth during puberty (height SDS decrease during puberty $>$ 0. 3). Of the 28 patients with a poor total height gain SDS, 7 (25 %) had a poor initial growth and 10 (36 %) had a poor pubertal height gain.
Conclusion
Despite prepubertal start of GH therapy, 63% of short SGA patients did not reach an adult height $>$-2SDS. Either a poor initial growth response or an impaired pubertal growth spurt were observed in more than half of SGA patients with a poor long-term height gain. These findings highlight the need for a more rigorous diagnostic re-evaluation, a swifter GH dose adaptation and a regular assessment of non-adherence.

Advancing precision in GH therapy: AI models for predicting IGF-1

Helena-Jamin Ly[1], Juulia Suvilehto[2], Beatrice Skyman[3], Carina Ankarberg-Lindgren[1], Hans Fors[1] & Jovanna Dahlgren[1]
[1]Institute of Clinical Sciences, Department of Pediatrics, Gothenburg, Sweden; [2]AI Competence Center, Gothenburg, Sweden; [3]Medical Physics and Biomedical Engineering, Gothenburg, Sweden

Background
International guidelines recommend dosing growth hormone (GH) based on body weight or body surface area. However, since GH regulates the production and release of IGF-I in the liver, using IGF-I as a biomarker presents a promising strategy for optimizing GH therapy dosing. Despite its potential, this approach is complicated by the inherent complexity and variability of IGF-I.
Aim
To optimize dosing strategies by showcasing the potential benefits of advanced machine learning techniques through a comparison of three different models and identifying key features for predicting IGF-1 SDS.
Methods
Data from 63 boys from previous clinical trial were included containing variables related to early growth, the start of GH treatment, and around the prediction time. 3-month predictions of IGF-1 SDS during maintenance and puberal growth phases on GH treatment were constructed using three different machine learning models; linear regression, symbolic regression and explainable boosting machine (EBM). Linear regression was used as a baseline representing classic statistical regression.
Results
Linear regression demonstrated poor performance with an R^2 of 0. 07, whereas the more advanced machine learning models—symbolic regression and EBM—achieved significantly better results, both with an R^2 of 0. 47. Mean absolute error for linear regression showed 0. 78 while both symbolic regression and EBM showed 0. 55. Key features identified by both models were baseline IGF-1 SDS, height velocity before GH treatment, weight and ΔIGF-1 at 1 year on treatment.
Conclusion
Symbolic regression demonstrated clinical practicality by providing accurate predictions using only seven predictors, while EBM offered valuable interpretability and deeper insights into factors influencing IGF-1 SDS. Notably, EBM identified GH dose as an important feature, a relationship not detected by symbolic regression or linear regression, likely due to its complexity. Together, these models enhance individualized treatment strategies and advance precision medicine in GH therapy.

Machine Learning models	Predictors	R^2	Mean Absolute Error	Mean Absolute Percentage Error
Linear Regression	33	0. 07	0. 78	0. 68
Symbolic Regression	7	0. 47	0. 55	0. 47
Explainable Boosting Machine	63	0. 47	0. 55	0. 32

EKAT-06 evidence based knowledge for monitoring childhood growth

Anton Holmgren[1 2 3], Lars Gelander[1] & Awais Ashfaq[3, 4]
[1]Department of Pediatrics, Institute of Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [2]Department of Paediatrics, Halland Hospitals, Region Halland, Sweden, Halmstad, Sweden; [3]Department of Research and Development, Region Halland, Sweden, Halmstad, Sweden; [4]School of ITE, Halmstad University, Sweden, Halmstad, Sweden

Background
A child's growth is a diagnostic tool that can reveal diseases and psychosocial problems. Abnormal growth is a common reason for referrals to paediatric- and paediatric endocrine- clinics. Childhood obesity is a public health issue with risks of comorbidities and reduced quality of life. Children with obesity are often referred to healthcare several years after obesity onset, reducing the effectiveness of interventions. There is a lack of evidence (EBM) on when healthcare should respond to growth deviations. Current guidelines are based on expert-based guidelines, without strict EBM-knowledge. Analyzing growth can be done using automated algorithms (Finnish project), which have shown that diagnoses were made several years earlier and for more children compared to routine follow-ups. No similar project has been conducted outside Finland. The Regional Halland healthcare Information Platform (RHIP) is a comprehensive data system that collects population-wide healthcare data in the province of Halland. Halland, located in the southwest of Sweden, is the 7th (out of 21) largest province by population. The overall objective is to analyze growth deviations and study how abnormal growth is related to disease ICD10-diagnoses. The main objective is to evaluate the ability and results of Swedish expert-based guidelines and Finnish algorithms to detect individual deviations from expected growth patterns. The secondary objective is to analyze how socioeconomic factors (SES) at the family and residential level are related to growth deviations.
Methods
The study utilize RHIP. Electronic health records data from three hospitals, two emergency departments, and 46 primary care/child health care units (including private healthcare providers), including pre-birth data from obstetrics. Individuals born between 2009-2022, registered in Halland at some point between 0-6 years of age are included in the study. Longitudinal growth data from 55, 508 children, along with health and SES-data from RHIP and national registers are gathered in mean 18. 3 measurements/child.
Results
A Paediatric-RHIP is now constructed, several results will follow the coming years. Results from a pilot-study shows that there is SES inequality in 3–5-year-olds. The risk of being overweight/obese in areas with the lowest socio-economic status is 72% higher than in the most affluent quintile of residential areas.
Conclusion
Knowledge from the project may lead to optimized identification and referral of deviant growth. For the first time can EBM-guidelines of deviant growth be developed. Can give indicators of risks for future diseases and provides opportunities of targeted prevention at both residential area and individual level for improved health.

Evaluation of growth velocity in patients with achondroplasia treated with vosoritide

Yasemin Denkboy Öngen[1], Hatice Nursoy[1], Munever Uluba[1] & Erdal Eren[1]
[1]Bursa Uludag University, Department of Pediatric Endocrinology, Bursa, Türkiye

Introduction
Achondroplasia, the most common skeletal dysplasia, is associated with severe short stature. Vosoritide is the first treatment for achondroplasia that targets the underlying pathophysiology, a C-type natriuretic peptide (CNP) analog that binds to its receptor on chondrocytes and promotes growth by inhibiting the ERK1/2-MAPK pathway. This study aimed to evaluate the growth velocity of vosoritide treatment in achondroplasia cases of various ages.
Method
Eleven patients had been evaluated. Annual growth velocities were calculated. Descriptive statistics were performed using the IBM SPSS 29. 0. 2. 0 statistical package program (IBM Corp. Released 2023. IBM SPSS Statistics for Windows, Version 29. 0. 2. 0 Armonk, NY: IBM Corp.).
Results
Vosoritide treatment had been started on eleven patients with achondroplasia (15 mg/kg/dose subcutaneously daily). All patients had c. 1138G>A heterozygous variant in the *FGFR3* gene. The mean age at the start of treatment was 7. 01±3. 40 years (2. 84-12. 56 years). The mean duration of vosoritide treatment was determined as 1. 13±0. 51 years (0. 33-2. 08 years). The calculated mean annual growth velocity was 6. 11±2. 41 cm (2. 73-11. 62). Patients' characteristics are shown in Table 1.
Conclusion
Vosoritide has previously been shown to increase linear growth in patients with achondroplasia. In our study, we found a wide range in annual growth velocity with

Table 1: Patients' gender and growth characteristics.

Patient number	Gender	Age at the start of treatment	Duration of vosoritide treatment (years)	Calculated mean annual growth velocity	Baseline height SDS	Height SDS at last visit	Target height SDS	Tanner stage at the start of treatment	Tanner stage at last visit
1	M	2.91	0.58	2.73	-4.59	-4.59	-0.35	1	1
2	M	6.49	0.83	8.19	-4.78	-4.30	-0.07	1	1
3	F	4.11	2.08	6.40	-4.54	-4.22	-1.47	1	1
4	M	12.56	0.83	4.53	-4.75	-4.66	-0.62	1	2
5	M	7.83	1.00	7.73	-2.90	-2.46	-0.73	1	1

Comparison of the effects of weekly and daily treatment on auxology, metabolism and quality of life in cases with growth hormone deficiency

Kübra Şen Küçük[1], Sebla Güneş[1], Mustafa Dinçer[2], Sercan Öztürk[3], Tolga Ünüvar[1] & Ahmet Anık[1]

[1]Aydın Adnan Menderes University Faculty of Medicine, Department of Pediatrics, Division of Pediatric Endocrinology, Aydın, Türkiye; [2]Aydın Adnan Menderes University Faculty of Medicine, Department of Child and Adolescent Psychiatry, Aydın, Türkiye; [3]Aydın Adnan Menderes University Faculty of Medicine, Department of Pediatrics, Aydın, Türkiye

Objective

To compare six-month follow-up data of children who started somatrogon (once-weekly), switched from somatropin to somatrogon and started somatropin (once-daily) due to growth hormone deficiency (GHD).

Materials-Methods

Children who met the study criteria organised as three study groups [somatrogon group, switch group (from somatropin to somatrogon) and somatropin group] and followed for six months. The findings were presented as percentages (number) and mean values with standard deviation (SD). While the data of the somatrogon and the switch group were collected prospectively, the data of the somatropin group were collected retrospectively. Bioimpedance analysis and the quality of life scales ("Pediatric Quality of Life Inventory", "Child Behavior Checklist" and "Multi-dimensional Perceived Social Support Scale") performed at the initiation, at the 3rd and 6th months of treatment in somatrogon and switch groups.

Results

Forty-eight patients (58. 4% male) were included. Somatrogon group ($n = 17$), switch group ($n = 14$) and somatropin group ($n = 17$) had mean ages of 11. 5±2. 9, 9. 3±3. 6, 10. 7±3. 1 years, mean height SDS of -2. 9±0. 8, -1. 7±0. 6, -2. 7±0. 5 and mean bone age SDS of -2. 3±1. 1, -2. 1±0. 7, -2. 5±0. 9, respectively. Most patient's pituitary magnetic resonance imagination (77%, $n = 37$) was normal and empty sella was the most common abnormality (8. 3%, $n = 4$). Somatropin's mean initial dosage was 0. 030±0. 003 mg/kg/day, whereas somatrogon's was 0. 66 mg/kg/week. The mean change in height SDS at 6 months was 0. 3±0. 2, 0. 4±0. 2, 0. 5±0. 3, respectively ($P = 0. 203$). The mean height velocity (HV) were 11±2. 5, 10. 2±2. 2, 11. 3±2. 6 cm/year ($P = 0. 533$). and the mean HV SDS were 2. 6±1. 7, 2. 6±1. 7, 2. 9±2. 2, respectively at six months ($P = 0. 860$). No dose reduction or treatment interruption was required due to side effects. The mean change in IGF-1SDS at 6 months were 2. 1±1. 4, 1. 4±0. 6, 1. 2±1. 0 respectively ($P = 0. 099$). The mean change in body fat percentage of somatrogon and switch group at 6 months were -3. 5±13. 4, 5. 4±7. 4 respectively ($P = 0. 115$) Neither the group that started somatrogon nor the somatrogon transition group had significant change in the quality of life score at six month compared to the beginning of treatment ($p > 0. 05$). While there was a significant difference between the groups in terms of baseline externalization symptoms ($P = 0. 020$), no significant difference was found at the 6th month ($P = 0. 134$).

Conclusion

The efficacy, tolerability and quality of life of once-weekly somatrogon were likely to those of once-daily somatropin for GHD.

Note

The study is still ongoing and a preliminary analysis has been conducted based on 41 patients with completed 6-month data. The full dataset is expected to be completed by the time of the conference.

Use of vosoritide in children with achondroplasia - clinical experience

Ahmet Kahveci[1], Didem Helvacıoglu[1], Aylin Tugba Canbaz[1], Aylin Günay[1], Zehra Yavas Abalı[1], Abdullah Bereket[1] & Serap Demircioglu Turan[1]

[1]Marmara University Department of Pediatric Endocrinology, Pendik Training and Research Hospital, Istanbul, Türkiye

Introduction and Aim

Achondroplasia is the most common form of rhizomelic short stature characterized by mutations in the FGFR3 gene. Vosoritide, a C-type natriuretic peptide analog, has shown promise in stimulating linear growth in children with achondroplasia. This study aims to present real-life experiences with the use of vosoritide in children diagnosed with achondroplasia.

Results

Our study was designed prospectively in children with achondroplasia receiving vosoritide treatment and aimed to find changes in annual growth rate and anthropometric parameters with treatment. The clinical features of 16 children (8 males) with a current mean age of 7. 85±4. 38 years who were diagnosed with achondroplasia were analyzed. Two of the cases were in the pubertal period. In antenatal follow-up, skeletal dysplasia was suspected in 81% of the cases and complications such as basilar invagination, foramen magnum stenosis and hydrocephalus were present in 13/16 of the cases. In polysomnographic evaluation, 31% had various degrees of sleep apnea and 19% (3/16) were receiving non-invasive mechanical ventilator support. All patients had a mean follow-up of 2. 94±2. 66 years without treatment. Vosoritide treatment was given 15 mg/kg/day for a mean duration of 0. 98±0. 57 years. There was a significant increase in the growth rate of the patients after vosoritide treatment compared to the pretreatment period (mean 5. 15±4. 89 cm/year, -2. 08±0. 91 SDS to 5. 99±1. 46 cm/year, -0. 19±1. 31 SDS; p:0. 03, <0. 001). Growth hormone stimulation test was performed in 5 patients with inadequate growth rates and low IGF-1 values under Vosoritide treatment and deficiency was detected in 2 patients. There was no significant difference in body segment measurements under treatment compared to before vosoritide treatment. This suggests that growth is proportional with vosoritide and that it maintains the typical body proportions for children with achondroplasia, but it remains to be seen in follow-up whether there will be a difference in longer treatment periods. Other anthropometric parameter evaluations are presented in Table 1.

Conclusions

Although vosoritide increases the growth rate in children with achondroplasia, its effect on height SDS and body proportions is thought to be significant in longer follow-up.

	Pre-Treatment n: 16	> 6 month treatment n:13	>12 month treatment n: 9	p value
Height SDS(Hoover)	0.40±1.18	0.42±1.22	0.39±1.13	0.94
Leg Lenght SDS	0.82±1.70	0.63±1.41	0.79±1.59	0.94
Sitting Height SDS	-0.36±1.40	0.23±1.83	-0.06±1.18	0.58

Treatment in genetic short stature: growth hormone use in patients with npr2 heterozygous variants

Elif Tuğçe Tunca Küçükali[1], Aylin Kılınç Uğurlu[1], Mehmet Ali Oktay[1], Muhammed Fatih Mulayım[2], Gülsüm Kayhan[2], Esra Doger[1], Mahmut Orhun Çamurdan[1] & Aysun Bideci[1]

[1]Gazi University Faculty of Medicine Hospital, Department of Pediatric Endocrinology, Ankara, Türkiye; [2]Gazi University Faculty of Medicine Hospital, Department of Medical Genetics, Ankara, Türkiye

Introduction

C-Type Natriuretic Peptide (CNP) and its receptor (NPR-B) are important paracrine factors regulating longitudinal bone growth. Homozygous or compound heterozygous loss-of-function mutations in the NPR2 gene lead to "Maroteaux Type Acromesomelic Dysplasia, " while heterozygous loss-of-function variants cause "Miura Type Epiphyseal Chondrodysplasia" and "Short Stature Without Specific Skeletal Anomalies. "

Methods

Patients diagnosed with idiopathic short stature and carrying a heterozygous NPR2 gene variant who received growth hormone (GH) therapy at the Pediatric Endocrinology Clinic of Gazi University were included. Patients with chronic diseases, medication use affecting growth, or irregular follow-ups were excluded. Data were obtained from clinic records.

Results

Among 19 patients with NPR2 heterozygous variants, 9(47. 3%) received GH therapy; 44% ($n = 4$) were female. The mean birth weight was 2750±892g, with

a mean birth weight SDS of -0. 51±1. 52. The mean age at presentation was 9. 1±3. 7years, with a height of 117. 5±21. 8cm and height SDS of -2. 5±0. 54. Parental height SDS values were -1. 89±0. 83 for mothers and -2. 6±1. 2 for fathers. The mean annual growth velocity was 4. 3±0. 78cm. GH stimulation test results were insufficient in 5 patients (55. 6%). The mean GH initiation age was 9. 9±1. 7years, with an initial height of 122. 3±11. 5cm and height SDS of -2. 5± 0. 48. Initial and maximum GH doses were 0. 033±0. 004mg/kg/day and 0. 040±0. 006mg/kg/day, respectively. The mean annual growth velocity during GH therapy was 7. 6±1cm/year, showing a significant difference from pre-treatment values ($P = 0.01$). The mean GH therapy duration was 2±1. 6years. At the last follow-up, the mean age was 12. 2±2. 3 years, height was 141. 2±14. 2cm, and height SDS was -2±0. 4. Predicted height before GH therapy was 154. 6±6. 7cm (149. 6±8. 4cm for females, 157. 7±3. 5cm for males), while post-treatment predicted height was 157. 1±7. 4cm (150. 1±5cm for females, 161. 2±35. 1cm for males). Although the difference was not statistically significant, an increase in predicted height was observed.

Discussion/Conclusion

Heterozygous NPR2 variants are associated with short stature and non-specific clinical findings. This study represents the largest cohort of NPR2 heterozygous patients receiving GH therapy. In this study, GH therapy significantly improved growth velocity in proportionate short stature patients with NPR2 variants. One patient exhibited low growth velocity, which may be attributed to delayed treatment initiation, pubertal status, and advanced bone age. Although final height has not been reached, increased growth velocity and predicted height were observed. GH therapy should be considered for children with heterozygous NPR2 variants and short stature. However, long-term and larger studies are required to assess treatment efficacy.

The medical impact of hypochondroplasia among children in England between 1998 and 2019: a matched cohort study using electronic medical records from the clinical practice research datalink

Moira Cheung[1], Sheila Reddy[2], Jeanne Pimenta[3], Hilary Shepherd[4], Melita Irving[5], Swati Mukherjee[3], Eleanor Axson[4] & Rachael Williams[4]
[1]Great Ormond Street Hospital, London, United Kingdom; [2]BioMarin Pharmaceutical Inc., Novato, United States; [3]BioMarin (UK) Ltd, London, United Kingdom; [4]Clinical Practice Research Datalink (CPRD), Medicines and Healthcare Products Regulatory Agency (MHRA), London, United Kingdom; [5]Guy's and St. Thomas' NHS Foundation Trust, Evelina Children's Hospital, London, United Kingdom

Hypochondroplasia (HCH) is a rare genetic skeletal dysplasia causing disproportionate short stature. Few studies report its natural history. This retrospective study compared the medical impact of HCH among children with the general population in England. A real-world matched cohort study was conducted using electronic primary care medical records from January 1, 1998, through December 31, 2019, in the Clinical Practice Research Datalink linked to hospitalization and vital statistics data. Children (≤18 years of age [y]) with HCH were identified using a specific HCH diagnosis code (SNOMED:315057016) or a general code (ICD-10-CM:Q77. 4) without evidence of other growth conditions. Children with HCH were matched 1:4 to general population controls by sex, nearest birth year, and practice region. Event rates (events/100 person-years [PY]) and rate ratios (RRs; cases vs controls) were calculated for select comorbidities and healthcare use among children 0-10y and 11-18y. Overall, 225 children with HCH and 1067 matched controls were included. Mean follow-up time was approximately 9 years for children with HCH and 12 years for controls. Among both age groups, overall event rates of comorbidities (combined across all body systems) were higher among children with HCH vs controls (RR: 2. 59 [0-10y], 2. 88 [11–18y]). Ear, nose, and throat (ENT), respiratory, neurological, and developmental conditions were more frequent among children with HCH (1. 52-16. 85 episodes/100 PY), with autoimmune conditions also frequent among those aged 11-18 years (10. 06/100 PY); RRs ranged between 1. 84 and 13. 57, indicating significantly increased impact compared with controls (**Table**). Children with HCH had more healthcare visits than controls; general practice visits were most frequent (1149 visits/100 PY; RR, 1. 92 [0-10y] and 881 visits/100 PY; RR, 2. 14 [11-18y]). Though less common, inpatient admission rates were higher for children with HCH than controls (172 admissions/100 PY; RR, 8. 39 [0-10y] and 200 admissions/100 PY; RR, 10. 91 [11-18y]). Surgical procedures were infrequent but consistently higher among children with HCH vs controls, including orthopaedic procedures (1. 24 procedures/100 PY; RR, 11. 24 [0-10y] and 4. 12 procedures/100 PY; RR, 10. 17 [11-18y]). Children with HCH had substantially higher rates of comorbidities and healthcare resource utilization compared with the general paediatric population in England. Early, multidisciplinary management is needed for individuals with HCH to address health challenges.

Table Comorbidity rates in children with HCH vs controls

Body system category	RR (95% CI) 0-10y	11-18y
ENT	1.84 (1.34-2.52)	5.21 (3.24-8.38)
Respiratory	2.94 (1.91-4.54)	1.92 (1.14-3.23)
Neurological	13.57 (6.22-29.60)	2.46 (0.72-8.48)
Development	3.39 (1.74-6.63)	2.69 (1.23-5.89)

Diagnosis of silver russell syndrome in 2025: is a scoring system still helpful?

Marie Challiol[1], Tyler Salem[2], Jennifer Salem[3], Eloise Giabicani[4], Marie-Pierre Luton[1], Madeleine Harbison[5] & Irene Netchine[4]
[1]Sorbonne Université, APHP, Hôpital Armand Trousseau, Explorations Fonctionnelles Endocriniennes, Paris, France; [2]Geisel School of Medicine at Dartmouth, Hanover, NH, United States; [3]MAGIC Foundation, RSS/SGA Research and Education Fund, Warrenville, United States; [4]Sorbonne Université, INSERM, Centre de Recherche Saint Antoine, APHP, Hôpital Armand Trousseau, Explorations Fonctionnelles Endocriniennes, Paris, France; [5]Icahn School of Medicine, Mount Sinai, Department of Pediatrics, New York City, NY, United States

Background

Silver Russell Syndrome (SRS) is a rare syndrome characterized by six clinical features composing the Netchine-Harbison Clinical-Scoring-System (NH-CSS): prenatal and postnatal growth retardation, relative macrocephaly at birth, protruding forehead, body asymmetry, and significant feeding difficulties. SRS diagnosis is suspected if ≥4 of these 6 criteria are present. The first (epi)genetic SRS causes identified include maternal uniparental disomy of chromosome 7 (upd(7)mat) and loss of methylation at *H19/IGF2*:IG-DMR on chromosome 11 (11p15 LOM). Other molecular anomalies are reported in patients with a suspected SRS.

Objective

Evaluate the NH-CSS on patients with suspected SRS with different molecular causes of SRS and differential diagnoses.

Subjects and Methods

Retrospective analysis of 705 patients, with data for all 6 NH-CSS criteria and molecular screening for upd(7)mat and 11p15 LOM, were recruited through the patient support group, The MAGIC Foundation.

Results

Molecular anomalies identified:

- SRS diagnosis confirmed in 356 patients (50. 5%): 11p15 LOM ($n = 222$, 62, 4% of SRS patients), and upd(7)mat ($n = 109$, 30. 6%); Maternal 11p15 duplications ($n = 19$, 5. 3%); Paternal *IGF2* mutations ($n = 5$, 1. 4%); *CDKN1C* mutations ($n = 1$, 0. 3%);
- Temple syndrome (TS) in 36 patients (5. 1%): 14q32 LOM ($n = 6$, 16. 7% of TS patients); upd(14)mat ($n = 25$, 69. 4%); and 14q32 pat-del ($n = 5$, 13. 9%);
- *HMGA2* mutations ($n = 7$, 1. 0%); *PLAG1* mutations ($n = 6$, 0. 9%); upd(20)mat ($n = 9$, 1. 3%); upd(16)mat ($n = 3$, 0. 4%);
- Various SRS differential diagnosis were identified (5%), including *IGF1R* mutations, 3M syndrome, Cornelia de Lange, IMAGe, Mulibrey nanism, Bloom, and Floating-Harbor.

NH-CSS Results

NH-CSS≥4 demonstrates high sensitivity of 97. 2% to detect 11p15 LOM and upd(7)mat with good Negative Predictive Value of 89. 0%. NH-CSS was ≥4 for 83. 3% of the patients with a *PLAG1* mutation; 85. 7% with a *HMGA2* mutation; 88. 9% of upd(20)mat; 89. 5% with a 11p15 maternal duplication; 83. 3% of TS 14q32LOM, and 100% of upd(16)mat and *IGF2* mutations. It detected only 40% of *IGF1R* mutations, 52% of TS upd(14)mat and 20% of 14q32 pat-deletions. Relative macrocephaly is associated with 11p15 LOM and upd(7)mat ($P < 0.05$) but not with *PLAG1*, *HMGA2* and upd(20)mat. Specific clinical findings can orient toward other diagnoses, (microcephaly for *IGF1R* mutations, neonatal hypotonia and/or precocious obesity and puberty for TS).

Conclusion

NH-CSS (if ≥4) is a highly sensitive tool to orient toward 11p15 LOM and upd(7)mat suggesting methylation analysis as the first molecular diagnostic step. It also captures other molecular anomalies overlapping with SRS and less frequently differential diagnoses, suggesting the importance of additional clinical signs to orient broader genetic testing after the methylation analysis.

GloBE-Reg: A global registry for evaluating the safety and effectiveness of growth hormone therapy across the age span

Malika Alimussina[1], Jillian Bryce[1], Minglu Chen[1], Sanhita Koley[1], Jessica Anderson[1], Suet Ching Chen[1, 2] & S Faisal Ahmed[1, 2]
[1]Office for Rare Conditions, University of Glasgow, Glasgow, United Kingdom; [2]Developmental Endocrinology Research Group, Royal Hospital for Children, Glasgow, United Kingdom

Introduction
The Global Registry For Novel Therapies In Rare Bone & Endocrine Conditions (GloBE-Reg, https://globe-reg. net/) project was launched in 2022 with the aim of supporting studies that focus on effectiveness and long-term safety of specific therapies. The project's initial focus has been on recombinant human growth hormone therapy (rhGH), given the existing knowledge gaps associated with the introduction of new indications and novel forms of rhGH.
Methods
The GloBE-Reg registry consists of three layers of datasets: the first includes internationally agreed-upon core data elements applicable to any rare condition; the second allows for the selection of a specific therapy and diagnosis; and the third comprises a therapy- and diagnosis-specific minimum dataset (MDS), which collects information on diagnosis, therapy, clinician-reported outcomes, patient-reported outcomes, and adverse events. The fields within the MDS are developed following guidance from short-life expert working groups.
Results
Since its launch, 29 centres from 17 countries in 4 continents have enrolled 2, 798 (M:F, 1, 679:1, 119) patients with a median age of 12. 8 years (range 0. 2, 64. 6), of whom 2, 481 (89%) are currently under 18 years of age. Among these patients, 1, 777 (64%) were on daily rhGH, 1, 011 (36%) on long-acting rhGH, and in 10 cases, rhGH therapy had been discussed but not initiated. Twelve different brands of rhGH were in use across these centres for eight indications, while long-acting rhGH was prescribed for six indications. Additionally, 41 (1%) patients were receiving rhGH for other conditions associated with short stature or growth retardation. The most common indication was growth hormone deficiency (59%), followed by small for gestational age (15%), idiopathic short stature (9%), Turner syndrome (8%), Prader-Willi syndrome (4%), and Noonan syndrome (2%). Of the 2, 798 cases, 1, 064 (38%) were also included in other disease registries and 923 (33%) of these were entered by three centres into GloBE-Reg through its bulk upload facility. Modules containing Childhood GHD, Adulthood GHD, and Noonan syndrome MDS are now fully operational and supporting studies in these fields; other modules are under development.
Conclusion
GloBE-Reg has demonstrated that a relatively low-cost, brand-agnostic platform can achieve sufficient stakeholder acceptability and versatility for collecting data to support long-term safety and effectiveness studies conducted by investigators from both academia and industry. The preliminary data collected on rhGH underscore the platform's long-term utility in evaluating the safety and effectiveness of a wide range of drugs.

Clinical characteristics of children with mccune–albright syndrome in China: a retrospective cohort study

Zhuanzhuan Ai[1] & Ruimin Chen[1]
[1]Fuzhou First General Hospital Affiliated with Fujian Medical University, Fuzhou Children's Hospital of Fujian province, Fuzhou, China

Background
McCune–Albright syndrome (MAS) is a rare disease defined by the triad of fibrous dysplasia (FD), caféau lait spots, and peripheral precocious puberty (PP). There is little adult height data in patients with MAS and no management consensus. We describe the various clinical manifestations of 28 patients with MAS in China and assessed the treatment and adult height in five patients.
Methods
Patients' clinical data—including peripheral PP, FD, and other endocrine problems were reviewed retrospectively. In addition, mutation in GNAS using blood and treatment experiences in five patients were described.
Results
The median age at diagnosis was 3 years 9 months (range: 20 months to 8 years). Twenty six patients were female, and two were male. Five patients showed FD. Twenty six patients showed peripheral PP at onset. Four cases had combined ovarian cysts. 8 cases received letrozole, 5 cases with subsequent addition of gonadotropin-releasing hormone analogs, and the mean age at initiation of treatment was 4. 6 years. Adult height data were available on 5 patients with MAS of whom 4 were treated. The average adult height of the 5 patients was 164. 5cm, this exceeds the average Chinese female height (160. 6cm). Five patients who underwent genetic testing for GNAS were positive.
Conclusion
This study provides valuable insights into MAS management in Chinese children, underscoring the potential efficacy of aromatase inhibitors in optimizing height outcomes. It highlights the need for standardized diagnostic criteria and tissue-based genetic testing. Future prospective studies with larger cohorts are warranted to validate these findings and refine treatment protocols.

When genetics cast doubt on paternity

Cecile Thomas-Teinturier[1 2 3], Barbara Girerd[1], Sandra Chantot-Bastaraud[4], Lucie Tosca[5, 6], Agnes Linglart[1] & Alexandru Saveanu[7]
[1]AP-HP Hopitaux Universitaires Paris-Saclay, Hopital Bicêtre, Pediatric Endocrinology, Le Kremlin Bicetre, France; [2]Center for Research in Epidemiology and Population Health, Inserm U1018, Radiation Epidemiology Team, Villejuif, France; [3]Reference Centre for Rare Pituiray Disease Hypo, Le Kremlin Bicetre, France; [4]Aphp Ghu Sorbonne Université, Hôpital Trousseau, Medical Genetics, Paris, France; [5]APHP Hôpitaux Paris-Saclay, Hopital Antoine Beclere, Histology Embryology Cytogenomics, Clamart, France; [6]INSERM, U1185 Endocrine physiopathology, Le Kremlin Bicêtre, France; [7]APHM Hôpitaux Universitaires de Marseille, Hôpital de la Conception, Molecular Biology, Marseille, France

With the development of genetic screening for disease in childhood, more genetic variants are found. The family segregation study of variants found in disease with autosomal recessive inheritance, may cast doubt on paternity when the father is not a carrier of the variant found in the child. Uniparental isodisomy, which means both alleles originating from a single-parental homologous chromosome, can be associated with pathogenic variants causing autosomal recessive disease and has already been described in other pathologies of chromosome 5 in 10 children (Qian 2021, Park 2019, Gonzalez-Quintana 2020, Numata 2014). We report the case of a child with congenital hypopituitarism. NGS sequencing of a panel of genes identified in *PROP1* (Prophet of Pit1) a homozygous variant c. 301_302del resulting in a truncated protein p. Leu102fs, one of the most frequent *PROP1* pathogenic variants in Europe. Alterations of *PROP1* gene are common findings in children with congenital hypopituitarism and genetic transmission is autosomal recessive. This gene is located on the long arm of chromosome 5 (5q35. 3). The family segregation study found that the mother was a heterozygous carrier of the variant, but the father was not a carrier. We searched for uniparental isodisomy of chromosome 5 in the family by short tandem repeat analysis and SNP-array. Both techniques confirmed that the child has maternal uniparental isodisomy of the entire chromosome 5. Cytogenetic analysis including karyotype and targeted FISH on chromosome 5, performed in proband and parents, showed no alteration of chromosome 5 structure.
In conclusion
This is the first case report of uniparental isodisomy of chromosome 5 leading to a homozygous mutation of *PROP1*. Clinicians and genetic counselors should be aware that autosomal recessive disorders due to homozygous variants can occur as a result of uniparental isodisomy, especially if parents are not consanguineous.

JOINT534

Impact of body mass index on growth hormone peak during insulin tolerance test in childrenand adolescents

Andrea Ballaben[1], Maura Marin[1], Federico Borghi[1], Viviana Vidonis[2], Giada Vittori[2], Daniela Slama[2], Elena Faleschini[2], Gianluca Tamaro[2] & Gianluca Tornese[1, 2]
[1]Department of Medicine, Surgery and Health Sciences, University of Trieste, Trieste, Italy; [2]Institute for Maternal and Child Health IRCCS "Burlo Garofolo", Trieste, Italy

Background
The insulin tolerance test (ITT) is the gold standard for assessing growth hormone (GH) integrity. A negative relationship between GH peak and body mass index

(BMI) standard deviation score (SDS) has been reported, even within the normal BMI range, potentially leading to overdiagnosis of growth hormone deficiency (GHD) in overweight and obese children. In this context, BMI SDS-specific cutoffs for GH stimulation tests have been proposed by Abawi *et al*.
Methods
This retrospective study analyzed ITTs (regular insulin 0. 1 IU/kg intravenously) performed at the Institute for Maternal and Child Health IRCCS "Burlo Garofolo", Trieste, Italy, between January 1, 2019, and December 31, 2024. ITTs were conducted to confirm GHD after a blunted response to the arginine stimulation test. Adequate hypoglycemia ($\geq$50% decrease in basal glucose or $<$ 40 mg/dL) was achieved in 157 of 180 tests. Clinical data and GH responses were analyzed.
Results
The cohort had a median age of 12. 3 years (IQR: 10. 5–13. 8) and a BMI SDS of -0. 86 (-1. 57–0. 27). GH peak negatively correlated with BMI SDS (Spearman's ρ = -0. 311, p $<$. 001), while positive correlations were observed with baseline GH (ρ = 0. 536, p $<$. 001) and IGF-1 SDS (ρ = 0. 176, p =. 028). Multivariate analysis identified lower BMI SDS (p =. 007) and higher baseline GH (p $<$. 001) as significant predictors of GH peak, with a moderate overall model fit (R^2 = 0. 490). Among the 16 overweight (BMI SDS: 1–2) and 2 obese (BMI SDS $>$2) individuals, all exhibited pathological GH peaks ($<$8 ng/mL; median: 1. 5 ng/mL [IQR: 0. 75–2. 80]). This remained true when applying BMI-adjusted thresholds proposed by Abawi *et al*. (7. 4 ng/mL for overweight and 6. 8 ng/mL for obese children).
Conclusions
This study confirms the significant impact of BMI SDS on GH peak during ITT, highlighting that overweight and obese children are at increased risk of GHD overdiagnosis. Although BMI SDS-adjusted cutoffs could improve diagnostic accuracy and reduce misclassification in children with elevated BMI, in this study, peak GH levels in overweight and obese children were well below even the BMI-adjusted thresholds, supporting a diagnosis of GHD.

Unraveling the genetic basis of short stature in pediatric patients: a whole exome sequencing approach

Yoo-Mi Kim[1, 2], Han Hyuk Lim[2], Eunhee Kim[1], Geena Kim[1], Min-Ji Kim[1], Hyejin So[1], Byoung Kook Lee[1], Yoowon Kwon[1], Jeesu Min[1] & Young Mi Yoon[1]
[1]Chungnam National University Sejong Hospital, College of Medicine, Chungnam National University, Pediatrics, Sejong, South Korea; [2]College of Medicine, Chungnam National University, Daejeon, South Korea

Background
Short stature is a common clinical concern in pediatric endocrinology, and while growth hormone (GH) deficiency is a well-established cause, genetic factors also play a crucial role. This study aimed to investigate the genetic etiology of short stature using whole exome sequencing (WES) in a pediatric population.
Methods
We retrospectively reviewed pediatric patients who underwent WES for clinical diagnosis at Chungnam National University Sejong Hospital between March 2022 and October 2024. A total of 133 patients (52 females and 81 males) underwent WES due to developmental delay, short stature, congenital anomalies, or other suspected genetic conditions. Among them, we selected patients who presented with short stature and analyzed their genetic findings and clinical characteristics.
Results
Thirty-eight patients underwent WES for short stature. Two patients were diagnosed with GH deficiency, while 36 had normal GH provocation test Results All female patients had normal karyotyping. Five patients (13. 2%) were born small for gestational age. Developmental delay was observed in 11 patients (28. 9%). Overall, congenital anomalies were observed in 18 patients (47. 4%) including congenital heart disease, hernia, congenital cataract, microtia, hearing defect, and skeletal deformity. A genetic cause was identified in 11 patients (28. 9%, 11/38). The detected syndromes included KBG syndrome, Diets-Jengmans syndrome, Okur-Chung neurodevelopmental syndrome, Rauch-Steindl syndrome, Noonan syndrome, Verheij syndrome, intellectual disability-hypotonic facies syndrome, X-linked, X-linked syndromic intellectual developmental disorder, Cabezas type, autosomal recessive deafness 8/10, developmental and epileptic encephalopathy 42, and 6q deletion syndrome.
Conclusion
Short stature in pediatric patients serves as a strong indicator for genetic evaluation. WES effectively identified genetic etiologies in nearly one-third of the patients, highlighting its utility in diagnosing underlying genetic conditions in this population.

N-acetylcysteine treatment for skin-picking in children and young adults with pws: a randomized placebo-controlled cross-over trial

Demi Trueba-Timmermans[1 2 3], Anne Rochtus[4], Lionne Grootjen[1 2 5], Gerthe Kerkhof[1, 3], Edmond Rings[6] & Anita Hokken-Koelega[1 2 7]
[1]Dutch Reference Center for Prader-Willi Syndrome, Rotterdam, Netherlands; [2]Dutch Growth Research Foundation, Rotterdam, Netherlands; [3]Erasmus MC Sophia Children's Hospital, Department of Pediatrics, Subdivision of Endocrinology, Rotterdam, Netherlands; [4]University of Leuven, Department of Pediatrics, Leuven, Belgium; [5]Erasmus MC Sophia Children's Hospital, Department of Pediatrics, Subdivision of Endocrinology, Rotterdam, Netherlands; [6]Erasmus MC Sophia Children's Hospital, Department of Pediatrics, Rotterdam, Netherlands; [7]Erasmus MC Sophia Children's Hospital, Rotterdam, Netherlands

Introduction
Skin-picking is the most common form of self-injurious behavior in Prader Willi Syndrome (PWS) and can lead to serious, life-threatening infections and severe scarring. An open-label pilot study reported that N-acetylcysteine (NAC) reduced skin-picking behavior in patients with PWS. Thus, NAC might be a promising treatment option for patients with PWS and skin-picking behavior. A placebo-controlled study was needed to show evidence.
Methods
A randomized, double-blind, placebo-controlled, cross-over trial in 23 patients with PWS aged 6-25 years in The Netherlands and Belgium. Cross-over intervention with NAC (dose range 600-2400 mg/day) and placebo, both during 3 months, with a wash-out period of 3 months.
Results
Overall, NAC lead to less skin-picking lesions compared to placebo, albeit not significantly (P = 0. 07). In boys, NAC showed a trend towards less skin-picking lesions compared to placebo (P = 0. 06) and the Clinical Global Impression Scale improved (2 (2-3) vs. 3 (2-3), P $<$ 0. 01)), while no difference was observed in girls. In addition, median (IQR) Skin-Picking Symptom Assessment-score was lower after NAC compared to placebo (18 (10. 75-26) vs. 24 (13. 5-30. 75), P = 0. 05)). NAC was well-tolerated and there were no serious adverse events.
Conclusion
NAC appears to have beneficial effects on skin-picking in a subgroup of patients with PWS, particularly in boys, without safety concerns. While NAC may be considered in children and young adults with PWS, its effects should be assessed on an individual basis. Treatment should be discontinued if no significant benefits are observed.

Challenges of puberty in turner syndrome: experience of a tertiary pediatric hospital

Inês Costa[1], Inês Oliveira[2], Catarina Figueiredo[3], Catarina Mendes[3], Joana Freitas[3], Maria João Oliveira[3] & Teresa Borges[3]
[1]Unidade Local de Saúde de Santo António, Serviço de Pediatria, Porto, Portugal; [2]Unidade Local de Saúde do Santo António, Serviço de Pediatria, Porto, Portugal; [3]Unidade Local de Saúde de Santo António, Unidade de Endocrinologia Pediátrica, Porto, Portugal

Introduction
Turner Syndrome (TS) is a partial or total monosomy of the X chromosome. It presents with multisystemic manifestations, including short stature, cardiac, nephrological conditions, and other endocrinometabolic disorders such as gonadal failure. Careful monitoring is required, with particular emphasis on pubertal development, bone health, and fertility. This study aimed to describe the pubertal development of adolescents with TS and the necessary therapeutic interventions. A retrospective, descriptive study of children and adolescents with TS followed at a tertiary hospital between 2010 and 2024. Data was collected from medical records.
Methods
39 patients with TS were included. Three diagnosed prenatally, five in the neonatal period, and the remaining at a median age of 7. 6 years. They presented with different genotypes: 16 (41. 0%) had complete X chromosome monosomy, 14 (35. 9%) had mosaicism, and 9 (23. 1%) had other chromosomal abnormalities.
Results
Among the adolescents, 14 (37. 8%) developed spontaneous puberty with menarche at a median age of 12. 3 years (range: 11. 3-15. 7 years). Their median gonadotropin levels were 5. 4 mIU/mL and 4. 0 mIU/mL for FSH and LH. 23

adolescents (62. 2%) required hormone replacement therapy (HRT) with transdermal estrogens initiated at a median age of 12. 8 years (range: 11. 6-16. 3 years). Pre-treatment gonadotropin levels confirmed hypergonadotropic hypogonadism, with median FSH levels of 78. 1 mIU/mL and LH levels of 17. 4 mIU/mL. In this group, menarche occurred at a median age of 15. 0 years (range: 12. 6-18. 4 years), approximately 1. 3 years after initiating therapy. Anti-Müllerian hormone (AMH) levels were measured in 22 of the 37 patients, with a median of 0. 20 pmol/l (range: 0-25. 1 pmol/l). The spontaneous menarche group had a median AMH of 6. 32 pmol/l, while the induced puberty group had 0. 15 pmol/l. Thirteen patients (35%) were referred for fertility counseling, and 3 underwent oocyte cryopreservation. Two patients, still under the age of 10, have not yet begun puberty but are under close follow-up.

Discussion

The results emphasize the genotypic and phenotypic diversity of TS, highlighting the need for personalized monitoring and intervention. Hormone replacement therapy is vital for inducing pubertal development and optimizing bone mass in patients with hypergonadotropic hypogonadism due to gonadal dysgenesis. A significant number of patients experienced spontaneous puberty, and about one-third were referred for fertility preservation. Oocyte cryopreservation, though rare, offers a reproductive option for some of these young women.

JOINT795

Quality of life improvements with GH, GnRHa, and AI therapies in children with short stature and advanced bone age

Ashraf Soliman[1], Ahmed Elawwa[1], Fawzia Alyafei[1], Nada Alaaraj[1], Noor Hamed[1], Shayma Ahmed[1], Noora AlHumaidi[1] & Ahmed Khalil[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background

Short stature and advanced bone age significantly affect children's quality of life (QoL), including their physical, emotional, and social well-being. Growth hormone (GH), gonadotropin-releasing hormone analogs (GnRHa), and aromatase inhibitors (AI) are therapies designed to improve height outcomes, but their impact on QoL remains a critical area of study.

Objectives

This review evaluates the effects of GH, GnRHa, and AI therapies on the QoL of children with short stature and advanced bone age, highlighting the improvements in emotional, social, and physical domains across various conditions.

Methods

Data from 13 studies published between 2000 and 2024 were reviewed, focusing on the QoL outcomes of GH, GnRHa, and AI therapies in children with idiopathic short stature (ISS), congenital adrenal hyperplasia (CAH), precocious puberty, and small-for-gestational-age (SGA). Therapy type, duration, and QoL findings were analyzed for their emotional, social, and physical impacts.

Results

Therapies consistently demonstrated positive impacts on QoL:

- Emotional well-being: GH therapy improved self-esteem and reduced anxiety in children with ISS and growth hormone deficiency (GHD). Combination therapies provided additional emotional stability in CAH and precocious puberty.
- Social interactions: Enhanced height and body image through GH and GnRHa therapies promoted better social integration, particularly in children with familial short stature, obesity-related growth delays, and Turner Syndrome.
- Physical function: AI combined with GH delayed bone age progression, maintaining mobility and reducing the physical burden of advanced skeletal maturation in precocious puberty and CAH.
- Parental satisfaction: Across multiple studies, parents reported reduced concern about their children's emotional and social challenges due to height gains and improved psychosocial adaptation.

Discussion

QoL benefits extend beyond height improvement, addressing the stigma and social pressures associated with short stature. GH combined with GnRHa or AI enhances these effects by promoting emotional resilience, social integration, and reduced anxiety, particularly in complex conditions like CAH and SGA.

Conclusion

GH, GnRHa, and AI therapies significantly improve QoL in children with short stature and advanced bone age. By addressing emotional, social, and physical domains, these therapies provide a holistic approach to care, underscoring the importance of integrating psychosocial outcomes into treatment strategies.

Effect of growth hormone therapy on final height in SHOX deficiency and turner syndrome: a single-center experience

Mehmet Ali Oktay[1], Esra Döğer[1], Aylin Kılınç Uğurlu [1], Gülsüm Kayhan[2], Meral Yirmibeş Karaoğuz[2], Mahmut Orhun Çamurdan[1] & Aysun Bideci[1]
[1]Gazi University Faculty of Medicine Hospital, Department of Pediatric Endocrinology, Ankara, Türkiye; [2]Gazi University Faculty of Medicine Hospital, Department of Medical Genetics, Ankara, Türkiye

Introduction

SHOX deficiency and Turner syndrome are genetic disorders associated with short stature, both resulting from haploinsufficiency of the SHOX gene, which impairs growth. Despite their shared etiology, comparative data on the long-term efficacy of growth hormone (GH) therapy and final height (FH) outcomes remain limited. This study aims to retrospectively evaluate and compare the effects of GH therapy on FH in patients with SHOX deficiency and Turner syndrome.

Methods

This retrospective study included patients with genetically confirmed SHOX deficiency ($n = 10$) or Turner syndrome ($n = 34$) who had received GH therapy and attained their final height. Participants were prepubertal (Tanner stage 1) at the start of therapy and presented with a height below the 3rd percentile or between the 3rd and 10th percentiles with a growth velocity below the 25th percentile. Comparative analyses were conducted between the two groups, focusing on first- and second-year height velocities,height standard deviation (SD) scores, and overall height gain (cm).

Results

The ages at treatment initiation were similar between the SHOX deficiency and Turner syndrome groups (mean $\pm$ SD: 10. 7 $\pm$ 1. 9 years vs. 10. 4 $\pm$ 2. 7 years; $P = 0.967$). The baseline height SD scores were -2.66 ± 0.8 in the SHOX deficiency group and -3.5 ± 1.07 in the Turner syndrome group, with the difference not reaching statistical significance ($P = 0.080$). The gain in height SD score from the initiation of GH therapy to final height was comparable between the SHOX deficiency group (0. 07 $\pm$ 0. 35 [least-squares mean $\pm$ SE]) and the Turner syndrome group (0. 93 $\pm$ 0. 15). Importantly, the first-year height velocity was significantly higher in the SHOX deficiency group compared to the Turner syndrome group (mean $\pm$ SD: 8. 55 $\pm$ 1. 43 cm/year vs. 6. 72 $\pm$ 1. 99 cm/year; $P = 0.011$). However, the second-year height velocity showed no significant difference between the groups (mean $\pm$ SD: 6. 63 $\pm$ 2. 29 cm/year vs. 5. 79 $\pm$ 1. 53 cm/year; $P = 0.203$).

Conclusion

GH therapy leads to comparable long-term height improvements in patients with SHOX deficiency and Turner syndrome. However, patients with SHOX deficiency demonstrate a significantly greater height velocity during the first year of treatment.

Retrospective analysis of two databases on growth hormone treatment in chinese children with short stature – baseline characteristics and clinical inertia

Wei Wu[1], Nan Li[2, 3] & Xiaoping Luo[1]
[1]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department of Pediatrics, Wuhan, China; [2]Peking University Third Hospital, Research Center of Clinical Epidemiology, Beijing, China; [3]Peking University, Key Laboratory of Epidemiology of Major Diseases, Ministry of Education, Beijing, China

Introduction

Despite the long-established use of recombinant human growth hormone (rhGH) in China for treating growth hormone deficiency (GHD), there still exists a significant gap in understanding its current status and the potential challenges with its effective use. This study aimed to explore the real-world status of rhGH treatment among Chinese children with short stature (SS) and to identify the associated factors.

Methods

In this multicenter, retrospective, observational study, we analyzed data from children receiving rhGH treatment from January 1, 2017, to April 30, 2024. The data was sourced from two registry databases in China (Chinese Society of Pediatric Endocrinology and Metabolism (CSPEM) Growth Study Database (CGSD) and Long-term Efficacy and Safety Evaluation of Growth Hormone in

Children in China (CGLS) and included eligible naïve children diagnosed with GHD, idiopathic SS (ISS) or small for gestational age (SGA), and who were treated with at least one rhGH and with height standard deviation score (Ht-SDS). All the data including baseline characteristics, type of rhGH treatment received (long-acting [LAGH] or short-acting [SAGH]), and treatment compliance were collected and analyzed.
Results
A total of 41, 942 children (15, 975 with GHD, 24, 445 with ISS, and 1, 522 with SGA) with a median age of 8. 29 (5. 88–10. 64) years were included. Mean Ht-SDS and BMI-SDS were -2. 51 $\pm$ 0. 42 and -0. 48 $\pm$ 1. 11, respectively. Short-acting growth hormone (SAGH) was the most preferred option in children than long-acting growth hormone (LAGH) (79. 53% vs. 20. 47%). The overall bone age (BA) – chronological age (CA) was reported as -1. 43 (1. 06). Treatment initiation with an appropriate dose was observed in children with SGA and GHD compared with ISS (33. 26%) with an insufficient dose. Irregular administration often precedes discontinuation, and it was identified as the main reason for long-term withdrawal in both the LAGH and SAGH groups. Treatment discontinuation was observed in 42. 1% of the children mainly due to irregular administration (18. 3%), limited medication access (16. 9%), and refusal by patients or families (11. 2). Overall, the LAGH group exhibited a significantly longer duration of therapy compared to the SAGH group (1. 75 [1. 71, 1. 79] vs. 1. 58 [1, 56, 1. 61]; $P < 0.001$).
Conclusion
In China, children with SS tended to start rhGH treatment at a relatively older age and exhibited a high rate of treatment discontinuation. To achieve better treatment outcomes for children with SS, good adherence and guideline-recommended medication patterns need to be adhered to.

Identifying relevant factors for recommendation of digital health solutions supporting paediatric growth hormone treatments in Finland: insights from participatory workshop

Solja Kalha[1], Ekaterina Koledova[2] & Octavio Rivera-Romero[3]
[1]Merck Oy, Espoo, Finland, an affiliate of Merck KGaA, Darmstadt, Germany; [2]Global Medical Affairs, Cardiometabolic and Endocrinology, Merck Healthcare KGaA, Darmstadt, Germany; [3]Electronic Technology Department, Universidad de Sevilla, Seville, Spain

Background
Long-term management of paediatric growth hormone deficiency (GHD) has advanced with the utilisation of digital health solutions. In Finland, the integration of automated growth monitoring with Electronic Health Records has demonstrated significant improvements in diagnosis of GHD, thereby enhancing early detection and collaboration between primary care providers and specialists.
Aim
Identifying key factors for digital health solution recommendations that support paediatric growth hormone treatments (pGHTs) in Finland from a nursing perspective and assesing the impact of the evolution of these solutions.
Method
A participatory workshop was conducted on 11 June 2024, in Helsinki, Finland, with seven nurses experienced in pGHT and three moderators. Workshop was divided in two parts: the first part utilised the Nominal Group Technique to identify key factors for recommending digital health solutions, while the second part assessed experts' views on how advancements in health technology impact their recommendations. Activities in the first part included silent idea generation, round robin sharing, discussion, and ranking of key factors. The second part of workshop included presentations of two study cases using two devices: Easypod® autoinjector and Easypod® connect transmitter (EP2) and Easypod® next generation (EP3) device. This qualitative activity focused on assessment of these devices in terms of ergonomics, aesthetics, ease of use, and usefulness, followed by a quantitative activity to evaluate their perceived benefits.
Results
For the first part of workshop, experts identified eighteen key recommendation factors and divided them into three high level categories: individual-related factors, healthcare provider-related factors and digital solution-related factors. Based on the score provided by the experts, 'ease of use' was the most relevant factor (emphasising the need for user-friendly designs, especially in low-resource settings) followed by 'patient motivation' and 'treatment adherence, ' while 'training materials' and 'technical support' received the lowest scores. Qualitative evaluation in the second part of workshop identified the following issues: physical characteristics of devices, touch screen, interacting, attractiveness, personalisation, safety, data transmission and learning and teaching. Overall, the experts believed that technological advancements have positively influenced the identified factors and care services. These findings highlighted the importance of accessible and engaging designs that cater to diverse age groups, thereby enhancing patient autonomy and adherence.
Conclusion
Advancements in digital health technology can enhance the management of pGHT by improving usability and accessibility, thereby boosting patient motivation and treatment adherence. Intuitive designs, familiar interfaces and streamlined training processes can further facilitate early adoption of digital devices and promote patient autonomy.

Continuous glucose monitoring (CGM) for assessing glycaemic variability in growth hormone deficient children shifting from recombinant GH daily injections to long-acting GH analogues: a case series

Giulia Rodari[1], Federico Giacchetti[1], Valeria Citterio[1], Eriselda Profka[1, 2], Valentina Collini[2], Aurora Pedroli[2], Emanuela Orsi[1], Giovanna Mantovani[1, 2] & Claudia Giavoli[1, 2]
[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy

Background
Daily recombinant GH (rGH) is approved for children with GH deficiency, but daily injections can be painful and stressful, leading to poor adherence. Long-acting GH analogues (LAGH), given their weekly administration, can improve patient acceptance and tolerance. However, the loss of physiological GH peaks could have a metabolic impact, especially in terms of glucose homeostasis. Though data from regulatory studies are reassuring in terms of insulin resistance and diabetes occurrence, up to now no data are available on subtle glycaemic changes in patients on either daily GH or weekly analogues.
Aims
The present study aims to provide insight into glycaemic variability differences in patients with GH deficiency (GHD) shifting from daily rGH to weekly LAGH subcutaneous injections.
Methods
For this purpose, a feasible non-invasive method which allows 24-hours continuous glucose monitoring (CGM) -Dexcom G7®System (Dexcom, Inc., San Diego, CA, USA)-, has been applied to 4 GHD children (M/F 3/1, chronological age 13. 9 years, IQR 11. 1-15. 3) in order to compare glycaemic variability differences when shifting from rGH (time 1) to LAGH (time 2). All patients used CGM for 10 days during rGH daily treatment and for 10 days after the third LAGH injection.
Results
The median coefficient of variation (CV) of patients under daily rGH treatment was not significantly different from CV under LAGH (13. 1%, IQR 11. 7-14. 7 vs 14. 2%, IQR 12. 2-14. 7). The Wilcoxon signed-rank test showed no significative difference in CV when patients switched from one formulation to the other. Specifically, no difference was observed between the two treatments during the nocturnal recording, when the highest GH peak, absent with LAGH therapy, naturally occurs.
Conclusions
This represents the first case series evaluating subtle glucose changes during GH replacement therapy by means of a non-invasive reliable tool, focusing on LAGH analogues vs daily rGH. No significant differences in glycaemic variability have been found when switching from daily to weekly injections. These preliminary results, though should be confirmed on a larger scale, are quite reassuring on LAGH safety in terms of glucose homeostasis.

JOINT857

Comparison of leptin, ghrelin, and nesfatin levels in growth hormone deficiency and short stature patients before and after growth hormone therapy

Jung Sub Lim[1], Il Tae Hwang[2] & Eun Young Kim[3]
[1]Korea Cancer Center Hospital, Pediatrics, Seoul, South Korea; [2]Kangdong Sacred Heart Hospital, Pediatrics, Gangdong gu, South Korea; [3]Chosun University Hospital, Pediatrics, Gwangju, South Korea

Objective
Leptin, ghrelin, and nesfatin are hormones that play crucial roles in regulating energy balance and metabolism. The objective of this study was to compare the levels of these hormones between patients with growth hormone deficiency (GHD) and idiopathic short stature (ISS) and healthy controls, as well as to evaluate the changes in these hormone levels before and after recombinant human growth hormone (rhGH) therapy in GHD and ISS patients.
Methods
A total of 77 prepubescent children aged 5 to 12 years were included in this study, comprising controls ($n = 16$), ISS patients ($n = 27$), and GHD patients ($n = 34$). Clinical parameters and serum levels of leptin, ghrelin, and nesfatin-1 were compared across the groups. Additionally, baseline and 6-month post-GH therapy values were compared in GHD and ISS patients.
Results
There were no significant differences in age, the levels of leptin, ghrelin, and nesfatin-1 among the three groups. In GHD patients, serum leptin concentrations significantly decreased after 6 months of rhGH therapy (7299. 18 $\pm$ 7779. 73 pg/mL to 4211. 85 $\pm$ 3977. 25 pg/mL, $P = 0.018$), and leptin was positively correlated with BMI SDS($r = 0.51$, $P < 0.001$). There were no significant changes in ghrelin levels or nesfatin-1 in GHD patients. In ISS patients, leptin levels significantly decreased after 6 months of rhGH therap(5128. 81 $\pm$ 3611. 55 pg/mL to 2594. 33 $\pm$ 925. 99 pg/mL p. 0. 001) but ghrelin and nesfatin-1 showed no significant differences after 6 months of rhGH therapy.
Conclusion
This study confirmed a positive correlation between **Leptin** and **BMI SDS**, and a negative correlation between **Ghrelin** and **BMI SDS**, suggesting that these hormones are closely related to BMI. GH therapy resulted in a significant decrease in leptin levels, these changes are likely to be associated with BMI alterations. These findings highlight the crucial role of growth hormone therapy not only in **promoting growth** but also in **regulating body mass and metabolic processes** in patients with GHD and ISS.

Growth hormone therapy in noonan syndrome: impact on neurodevelopment and prognosis

Ji-Hee Yoon[1] & Aram Yang[2]
[1]Bundang Jesaeng Hospital, Pediatrics, Bundang, South Korea; [2]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Pediatrics, Seoul, South Korea

Context
Noonan syndrome (NS) is a genetic disorder characterized by short stature, congenital heart defects, and developmental delay/intellectual disabilities (DD/ID). While recombinant human growth hormone (rhGH) is widely used for short stature in NS, its impact on neurodevelopment remains unclear.
Objective
This study aimed to evaluate the neurodevelopmental outcomes of NS patients treated with rhGH and to identify factors influencing the risk of DD/ID.
Methods
A retrospective cohort study was conducted using the Korean National Health Insurance Database (NHID) from 2007 to 2023. NS patients (ICD-10: Q87. 1) who received rhGH therapy were included. DD/ID was identified using ICD-10 codes (F70–F79, F80–F89). Clinical characteristics, comorbidities, and healthcare utilization were compared between groups with and without DD/ID. Kaplan-Meier analysis assessed the cumulative incidence of DD/ID, and logistic regression identified associated risk factors.
Results
Among 302 NS patients (172 males, 130 females) treated with rhGH, 102 (33. 8%) had DD/ID. Longer GH therapy was associated with a reduced risk of DD/ID (O$r = 0.906$, $p < 0.001$). Patients treated for >2 years had a significantly lower cumulative incidence of DD/ID ($p < 0.001$). Among those with DD/ID, the age at diagnosis was significantly younger in patients diagnosed before GH initiation than in those diagnosed after GH therapy ($p < 0.001$), suggesting a potential delaying effect of GH treatment on DD/ID onset. Baseline and final Charlson Comorbidity Index (CCI) scores were higher in the DD/ID group ($P = 0.003$ and $p < 0.001$, respectively). ADHD (O$r = 1.347$, $p < 0.001$), skeletal disorders (O$r = 1.156$, $P = 0.007$), and obstructive sleep apnea ($P = 0.032$) were significantly associated with DD/ID.
Conclusions
Prolonged rhGH therapy (>2 years) was associated with a lower risk of DD/ID and a delayed age at DD/ID diagnosis in NS patients. ADHD, skeletal disorders, and obstructive sleep apnea were significant risk factors for DD/ID. These findings suggest that early and sustained GH therapy may mitigate neurodevelopmental impairment in NS. Given the higher healthcare burden in DD/ID patients, a multidisciplinary approach is needed to optimize treatment strategies and long-term outcomes.

Mysoconnect® for sogroya®: long-acting growth hormone for patients with growth-related disorders and their caregivers

Primož Kotnik[1], Barbara Murn Berkopec[1], Tadej Battelino[1], Sandhya Gopalakrishnan[2], Sönke Johannsen[3], Liam Mc Morrow[4] & Klemen Dovč[1]
[1]University Medical Center, University Children's Hospital Ljubljana, and Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia; [2]Novo Nordisk Service Centre India Private Ltd, Bengaluru, India; [3]Novo Nordisk Health Care AG, Zürich, Switzerland; [4]Novo Nordisk A/S, Copenhagen, Denmark

Long-acting growth hormone (LAGH) is a treatment given to children with growth hormone deficiency. Adherence and concordance with treatment is essential for children to reach their height potential, but it is not always optimal. Several patient needs have been identified that may support with adherence and concordance. These include maintaining an injection routine, having access to answers of treatment-related questions and tracking progress over time, such as height gain. The use of a LAGH digital connected system with these features may aid in adherence and concordance to treatment. MySoConnect® for Sogroya® (somapacitan; Novo Nordisk Health Care AG) was developed to improve the patient experience and aid in adherence and concordance with growth hormone (GH) treatment (GHT). The system consists of a Sogroya® FlexPro® injection pen, the Mallya® connectivity cap and the MySoConnect® app. The Mallya® cap connects with the MySoConnect® app when attached to the Sogroya® FlexPro® injection pen and aligned with the dose counter of the pen. The Mallya® connectivity cap is compatible with all three available strengths of the Sogroya® FlexPro® injection pen. The MySoConnect® app includes features that can support in setting an injection routine, such as setting a dose reminder, which can be performed manually within the app. Features related to dose management, such as dose, dosing day and type of injection pen used, are recorded. The MySoConnect® app also includes a training and support section, which provides useful information related to understanding treatment, tailored towards patients and their caregivers. Additionally, the app includes the option to manually input height and weight data to allow visualisation of height and weight improvements over time. Lastly, the app allows users to download a log of dosing patterns, which can be shared with their healthcare professional to advise on dosing changes. MySoConnect® for Sogroya® was developed to improve the user experience for children prescribed Sogroya® and their caregivers. This connected system will allow its users to set and maintain an injection routine, have continuous access to training and support related to GHT, and record and track various elements of their treatment journey over time. MySoConnect® for Sogroya® may support its users in maintaining adherence.

Efficacy and safety of somapacitan vs daily growth hormone at 52 weeks in patients with growth hormone deficiency: pooled analysis of the randomised REAL 3, REAL 4 and REAL 6 clinical trials

Lars Savendahl[1], Aristides Maniatis[2], Martin Wabitsch[3], Alberto Pietropoli[4], Nicky Kelepouris[5], Michael Højby Rasmussen[6], Junfen Fu[7], Jun Mori[8] & Bradley Miller[9]
[1]Pediatric Endocrinology, Karolinska University Hospital, and Department of Women's and Children's Health, Karolinska Institutet, Solna, Sweden; [2]Rocky Mountain Pediatric Endocrinology, Centennial, Colorado, United States; [3]Division of Pediatric Endocrinology and Diabetes, Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, Germany; [4]Novo Nordisk Healthcare AG, Zurich, Switzerland; [5]Novo Nordisk Inc, Plainsboro, United States; [6]Clinical Drug Development, Novo Nordisk A/S, Søborg, Denmark; [7]Department of Endocrinology, Children's Hospital, Zhejiang University School of Medicine, National Clinical Research Center for Child Health, Zhejiang, China; [8]Division of Pediatric Endocrinology, Metabolism and Nephrology, Children's Medical Center, Osaka City General Hospital, Osaka, Japan; [9]Division of Endocrinology,

Department of Pediatrics, University of Minnesota Medical School, M Health Fairview Masonic Children's Hospital, Minneapolis, United States

Objective
Somapacitan is a long-acting reversible albumin-binding growth hormone (GH) derivative approved for once weekly administration in children with growth hormone deficiency (GHD). We present outcomes from a pooled analysis of data from three clinical trials (REAL 3 [NCT02616562], REAL 4 [NCT03811535] and REAL 6 [NCT04970654]) assessing the efficacy and safety of somapacitan vs daily GH (Norditropin®, Novo Nordisk).
Methods
In each trial, pre-pubertal, GH-treatment-naïve children with GHD were randomised to treatment with somapacitan (REAL 3: 0. 04 vs 0. 08 vs 0. 16 mg/kg/week; REAL 4 and 6: 0. 16 mg/kg/week only) or daily GH (all: 0. 034 mg/kg/day) for 52 weeks. REAL 3 and 4 were conducted internationally, and REAL 6 was conducted in China. For this analysis, efficacy comparisons were conducted vs patients treated with somapacitan 0. 16 mg/kg/week only. Mixed models of repeated measurements were used for comparisons of height velocity (HV), change in height standard deviation score (SDS) and change in insulin-like growth factor-I (IGF-I) SDS. An analysis of covariance model was used to compare changes in bone age/chronological age (BA/CA). Treatment, study, sex, age group, region, GH peak group and sex by age group by region interaction term were included as factors in each model, with the baseline of each respective efficacy measure used as the covariate (for HV, baseline height was used instead).
Results
The analysis included 220 patients treated in total with somapacitan and 118 patients treated with daily GH. Efficacy data are mean (SE). After 52 weeks, HV was 11. 2 (0. 1) cm/year vs 11. 1 (0. 2) cm/year in the pooled somapacitan and daily GH groups, respectively. Change in height SDS from baseline to week 52 was 1. 25 (0. 03) in the pooled somapacitan group and 1. 20 (0. 04) in the pooled daily GH group. Change in IGF-I SDS after 52 weeks was 2. 34 (0. 08) and 2. 10 (0. 11) in the pooled somapacitan and daily GH groups, respectively. Change in BA/CA after 52 weeks was similar between the pooled somapacitan and daily GH groups (0. 06 [0. 01] vs 0. 07 [0. 01], respectively). Differences between groups were non-significant for measures reported above ($P > 0.05$). Similar rates of adverse events per 100 patient years of exposure (294. 6 for somapacitan and 289. 0 for daily GH) were reported.
Conclusions
Outcomes from a pooled analysis of REAL 3, REAL 4 and REAL 6 demonstrate similar efficacy of somapacitan compared to daily GH over 52 weeks of treatment, with comparable safety and mean IGF-I SDS change in treatment-naïve children with GHD.

JOINT3485

Evaluation of features for a digital application for growth hormone therapy using perceptions gathered from patients, caregivers and healthcare professionals

Christa Flück[1], Kees Noordam[2], Claudia Katschnig[2], Sandhya Gopalakrishnan[3], Sönke Johannsen[4] & Melanie Hess[5]
[1]Pediatric Endocrinology, Diabetology and Metabolism, Department of Pediatrics, Inselspital University Children's Hospital Bern, Bern, Switzerland; [2]Center for Paediatric Endocrinology Zurich (PEZZ), Zurich, Switzerland; [3]Novo Nordisk Service Centre India Private Ltd., Bengaluru, India; [4]Novo Nordisk Health Care AG, Zürich, Switzerland; [5]Department of Paediatric Endocrinology and Diabetology, University Children's Hospital Basel, Basel, Switzerland

Growth hormone therapy (GHT) may be administered to children with growth-related disorders to enable them to reach their expected target height. This study was designed to assess the features of a digital application (app) that would support patients at different stages of GHT. Insights from patients, caregivers and healthcare professionals (HCPs) were gathered to inform the development of MySoConnect® for Sogroya® (Novo Nordisk Health Care AG). German-speaking Swiss patients/caregivers ($n = 21$) and HCPs ($n = 5$) were invited to participate. Patients were current users of the Norditropin® (somatropin) FlexPro® pen (Novo Nordisk Health Care AG). Each participant undertook three 60-minute online interviews, conducted at study start, after 1 month of app use and after new app features were developed. The overall experience and features of the app were discussed. Perceptions and needs related to GHT were also gathered at the first interview. All interviews were conducted between June and November 2022. Average patient age was 12 years. Based on response patterns, GHT journey stages were defined as "pre-therapy", "initiation of therapy", "injection by parents", "transition to self-injection", "self-injection" and "end of therapy". Perceptions and needs identified as relevant to all stages of GHT were reminders for injection, progress tracking of height and training/support related to treatment. Perceived benefit of the app by patients/caregivers was dependent on their GHT journey stage. Patients at "initiation of therapy" considered an app to be highly beneficial. For patients at "injection by parents", "transition to self-injection" and "self-injection", an app was considered beneficial. When asked about specific app features, most participants considered the ability to set reminders for injection and track height gain over time to be beneficial. Most participants indicated that having access to supporting information, such as instructional manuals, training videos and frequently asked questions, would be beneficial. In particular, patients at "initiation of therapy" and "transition to self-injection" stages deemed these supporting information features as very beneficial. The lack of connectivity between the pen and the app was considered critical by the participants. HCPs were strongly in favour of adding an automated dose-logging feature, which corresponds to a connectivity element between the injection pen and the app, to encourage app use. Insights gathered from patients, caregivers and HCPs indicate that the use of an app for GHT may support adherence to treatment, with features such as tracking height gain over time, setting reminders and accessing instructional manuals and other relevant supporting information considered beneficial.

Real-world data: effectiveness and safety of vosoritide in the treatment of achondroplasia in chinese population

Lifen Chen[1], Xiaofei Zhang[1], Xiwen Zhang[2], Wen Su[1], Xiaoyu Ma[1], Yuan Xiao[1], Wenli Lu[1], Fang Wang[3], Zhidong Gu[4] & Zhiya Dong[1]
[1]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, RuiJin Hainan Hospital, Shanghai Jiao Tong University School of Medicine, Pediatrics, Shanghai, China; [2]RuiJin Hospital, Shanghai Jiao Tong University School of Medicine, Pediatrics, Shanghai, China; [3]RuiJin Hospital, Shanghai Jiao Tong University School of Medicine, Cardiovascular Medicine, Shanghai, China; [4]RuiJin Hainan Hospital, Shanghai Jiao Tong University School of Medicine, Clinical Laboratory, Shanghai, China

Background
Achondroplasia (ACH) is the most common form of hereditary skeletal dysplasia, caused by activating mutations in the FGFR3 gene. It leads to severe disproportionate short stature and multiple complications. Current management strategies focus on multidisciplinary care, but effective pharmacological treatments are limited. Vosoritide, a CNP analogue, is the first available molecular therapy for ACH in China, showing significant improvement in annual growth rate in children.
Methods
This retrospective cohort study collected data from 30 ACH patients treated with vosoritide at the Hainan Boao Lecheng International Medical Tourism Pilot Zone from June 2022 to August 2024. After excluding four cases due to irregular medication, 26 cases were analyzed. Inclusion criteria included a diagnosis of ACH confirmed by genetic testing and open or partially closed growth plates. Vosoritide was administered at 15 μg/kg by subcutaneous injection once daily. Data on physical conditions, growth measurements, and biochemical indices were collected and analyzed using SPSS 22. 0 software.
Results
The study included 26 patients (11 males, 15 females) from 3. 4 to 11. 7 years old. Significant improvements were observed in height SDS, annual growth velocity (AGV), and BMI SDS after 12 months of treatment. Height SDS increased by 0. 4, and AGV increased by 2. 3 cm/year. The SH/H ratio decreased, indicating improved body proportions. No significant difference was found in BA-CA. Vosoritide treatment was well-tolerated, with no serious adverse events reported.
Conclusion
Vosoritide effectively promotes linear growth and improves body proportions in Chinese children with ACH, providing an optimized treatment option. Further studies with larger sample sizes are needed to confirm these findings and explore potential racial differences in treatment efficacy.

Long-acting PEG-RHGH: insights from five-year outcomes in pediatric patients with growth hormone deficiency from CGLS database

Wei Wu[1], Nan Li[2, 3] & Xiaoping Luo[1]
[1]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Department of Pediatrics, Wuhan, China; [2]Peking University Third Hospital, Research Center of Clinical Epidemiology, Beijing, China; [3]Peking University, Key Laboratory of Epidemiology of Major Diseases, Ministry of Education, Beijing, China

Introduction
Growth hormone deficiency (GHD), an endocrine disorder, caused due to insufficient production of growth hormone (GH), thereby affecting children's growth. Currently, pegylated recombinant human growth hormone (PEG-rhGh) is the only long-acting treatment approved for treating pediatric GHD (PGHD) in China. Long-term Efficacy and Safety Evaluation of Growth Hormone in Children in China (CGLS) is a large, surveillance registry database comprising information on participants with short stature treated with recombinant human growth hormone (rhGH) or PEG-rhGH in a real-world setting.
Methods
In this study, we analyzed the data from the CGLS database to evaluate the safety and effectiveness of PEG-rhGH over five-years in children with PGHD in China. Key outcomes such as adverse events (AEs), serious AEs (SAEs), and height gain were assessed.
Results
A total of 1207 participants were included in the safety analysis set, of which 339 received PEG-rhGH for five years and were included for efficacy analysis. Safety assessment indicated that 563 participants exhibited 1328 AEs with an incidence rate of 46. 64%. In addition, SAEs were reported in 0. 99% of participants (n = 12) with none being related to PEG-rhGH treatment. During the treatment period, a significant increase in mean change in height-SD score (**Δ**Ht-SDS) was observed with a mean ΔHt-SDS of 2. 11 ± 0. 87 in five years. Over the treatment course of five years, the mean Ht-SDS showed a consistent increase i. e., from baseline (−2. 43 ± 0. 94) to five years (−0. 33 ± 0. 83). The highest height velocity was highest at 1st year (10. 21 ± 2. 52 cm/y), which stabilized by the fifth year (6. 72 ± 1. 74 cm/y). A more favorable response in height improvements was observed in the age subgroup analysis (2-6, 6-8 and >8 years) when treatment was initiated at an early age.
Conclusion
Data from the CGLS database confirmed that participants with PGHD treated with PEG-rhGH for five years demonstrated a satisfactory safety profile and consistent improvement in height.

Clinical delineation and genotype-phenotype correlation in 104 pediatric patients with kabuki syndrome: a large longitudinal cohort from a single center in china

Yirou Wang[1], Feihan Hu[2], Niu Li[2] & Xiumin Wang[2]
[1]Shanghai Children's Medical Center, Department of Endocrinology, Genetics and Metabolism, Shanghai, China; [2]Shanghai Children's Medical Center, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Purpose
Kabuki syndrome is a monogenic genetic disorder affecting multiple systems, with an incidence rate of 1 in 32, 000 to 1 in 86, 000. This study provides a detailed genotype and phenotype analysis of a large longitudinal cohort of Kabuki Syndrome (KS) from a single center in China.
Methods
From July 2017 to July 2024, participants were enrolled at Shanghai Children's Medical Center. Variants in KMT2D or KDM6A were identified through whole exome sequencing. Phenotype data included prenatal and perinatal history, neonatal, childhood and adolescence evaluations.
Results
A total of 104 KS individuals fullfiled 362 outpatient visits, with an average follow-up of 2. 58 years. Growth curves were plotted based on 545 follow-up height data points. Among the patients, 27. 08% had congenital heart defects (CHD), and 3 patients were identified with anomalous pulmonary venous connection as a new KS phenotype. KS patients showed facial feature heterogeneity, patients with atypical facial features associated with a older diagnosis age and a more diverse and severe phenotype. The Face2gene software correctly identified the facial photographs of all 85 KS patients.
Conclusion
This study offered a comprehensive description of a Chinese KS cohort. And provided the first growth curves for Chinese KS patients and a detailed CHD phenotype spectrum. Our findings also suggest that artificial intelligence (AI) - assisted facial diagnostic criteria will be a valuable in the clinical diagnosis of KS.

Early growth hormone treatment enhances growth and nutritional status in silver-russell syndrome

Eloise Giabicani[1], Raphaelle Billette de Villemeur[1], Melodie Acher[1], Manon Cochet[1], Béatrice Dubern[1] & Irene Netchine[1]
[1]Sorbonne Université, Assistance Publique Hôpitaux de Paris, Paris, France

Context
Silver-Russell syndrome (SRS) is an imprinting disorder characterized by severe intrauterine and postnatal growth retardation, feeding difficulties, and risk of hypoglycaemia. Recombinant growth hormone (rGH) therapy has shown its positive effect on adult height in SRS.
Objective
We aimed to assess the short-term effects of rGH therapy on the growth and nutritional status of these patients.
Design, patients and settings
Retrospective monocentric data of growth and nutritional characteristics of 77 prepubertal patients with molecularly proven SRS during the first two years of rGH therapy were analysed.
Results
The mean age at the initiation of rGH therapy was 3. 7 (1. 4-10. 3) years. The mean height gain was 0. 8 standard deviation score (SDS) after one year of treatment and 1. 3 SDS after two years. The ideal weight for length/height (WfH), reflecting the nutritional status, increased from a mean of 81% at rGH initiation, to 84% after one year of treatment ($p < 0.001$) and 86% after two years ($p < 0.001$). The proportion of SRS patients below a WfH of 75% decreased from 22. 1% at rGH therapy initiation to 7. 8% after two years of treatment. Starting rGH therapy before the age of four years was associated with a greater increase in height after two years, 1. 5 *vs* 1. 1 SDS, $P = 0.012$.
Conclusions
In prepubertal SRS patients, the first two years of standard-dose rGH therapy significantly enhance both height and nutritional status. Early initiation of treatment, before the age of four years, further optimizes height gain.

The impact of growth retardation on quality of life

Flora Ujhelyi[1], Zsuzsanna Bredo[1], Regina Toth[1], Andrea Berkes[1] & Eniko Felszeghy[1]
[1]DEKK Pediatric Department, Debrecen, Hungary

Introduction
Children diagnosed with growth retardation (nanosom) face the same social and psychological challenges during their development as their healthy peers, with the difference that they also must cope with difficulties arising from their condition.
Objective
The aim of our study was to assess the impact of growth retardation on quality of life, paying particular attention to differences between hormone-treated and follow-up children, and to compare data from two chronic diseases—nanosom and diabetes mellitus (1TDM) - both treated similarly with subcutaneous injections.
Method
The sample consisted of children treated at the Endocrinology and Diabetology outpatient clinic of University of Debrecen between 2007 and 2023. The nanosom sample consisted of 110 individuals, including 69 boys/41 girls, of whom 58 were treated and 52 were followed up. The average age of the children was 12 (SD ± 4. 3). The 1TDM group consisted of 114 children. To assess quality of life, we used the Pediatric Quality of Life Inventory™ (PedsQL™) questionnaire. To evaluate the long-term effects of treatment, we assessed the quality of life of 32 growth hormone-treated children two years after their initial examination.

Results
According to the survey results, the average quality of life for nanosom children was 76. 2%. Contrary to expectations, the quality of life for hormone-treated children - 74. 8% did not show a significant difference compared to untreated patients 77. 8% ($P = 0.317$). Regarding gender, boys (77. 4%) experienced negative effects less than girls (74. 2%), but no significant difference was found ($P = 0.301$). Based on the aggregated results was confirmed that children under 12 years of age (77. 5%) rated their condition more positively than their older (75. 0%) counterparts ($P = 0.404$). Responses to the modules showed that the most negatively affected factors were emotion and school functioning. Regarding injection treatment, children with 1TDM (76. 7%) showed better scores than their growth hormone-treated counterparts (74. 8% - $P = 0, 773$). The only significant difference ($P = 0.001$) between the two group's data was observed in the social module. Examining the long-term effects of hormone treatment, children showed an improving trend (73. 59% to 77. 92%); however, this difference was not statistically significant ($P = 0.285$).
Conclusion
The results for the nanosom population fall short of the full 100%, but the long-term positive effects of hormone therapy were confirmed in this study. Considering injection treatments, no significant differences were found between the nanosom and T1DM control groups. Our research highlights the need for greater attention to emotional support therapy and school acceptance for children diagnosed with growth retardation.

JOINT3429

Assessing skeletal maturity in indian children: a comparative study of GP, GR, and TW3 methods

Shubham [1], Ankita Sharma[1], Preeti singh[1] & Anju Seth[1]
[1]Lady Hardinge Medical College, Paediatrics, Delhi, India

Background
Bone age (BA), a critical measure of growth and skeletal maturity, is influenced by several factors, including ethnicity, gender, race, geographic distribution, environmental conditions, socioeconomic status, systemic diseases, and secular trends. Most BA assessment methods have been predominantly developed and validated in upper-class Caucasian populations. Literature comparing the accuracy and validation of different methods, especially in Indian population, is scanty. The objective of this study was to compare the accuracy of GP Atlas, GR Atlas, and TW-3 method to identify the most reliable tool for BA assessment in Indian children.
Methods
280 healthy children of both sexes, aged 2-16 years, with normal anthropometric parameters were included in the study and sub grouped equally into: 2–5 years, 5. 1–8 years, 8. 1–12 years, and 12. 1–16 years. Clinical history, pubertal status, accurate date of birth and chronological age at time of hospital visit were recorded for all participants. Digital X-rays of the left hand and wrist were obtained and analysed for BA using above three methods. BA of each was then compared to the chronological age (CA) using mean difference (BA-CA) and Bland Altman agreement analysis.
Results
All three methods underestimated CA across all age groups. TW3 method had the smallest mean difference from chronological age (-0. 24 $\pm$ 1. 02 years) overall and particularly in the 2–5-year age subgroup (-0. 07 $\pm$ 0. 71 years). Additionally, it had the narrowest limits of agreement across all age groups (-2. 24 to 1. 76 years). The GP atlas highly underestimated the Bone age (-0. 44 $\pm$ 1. 07 years), particularly in pre-pubertal males (-0. 54 $\pm$ 1. 0 years). In the prepubertal group, the TW3 method was found to have the lowest mean difference (-0. 19 $\pm$ 0. 94 years) overall and in both sexes individually, especially in females. In contrast, in the pubertal age group, GR atlas was found to have the best results with the lowest mean difference overall (-0. 13 $\pm$ 1. 33 years) and in both males (-0. 15 $\pm$ 1. 27 years) and females (-0. 11 $\pm$ 1. 39 years).
Conclusion
The GP atlas exhibited significant underestimations across all age groups, so may not be suitable for Indian children without population-specific adaptation. The TW3 method emerged as the preferred choice for detailed clinical evaluations, particularly in the prepubertal age group and showed the highest percentage of correct classifications. GR atlas, while less commonly used, offers potential as an alternative for bone age assessment in older children and adolescents.

Factors influencing growth trajectory and adult height in children born small for gestational age and treated with growth hormone: a single center study

Letteria Anna Morabito[1], Malgorzata Wasniewska[1, 2], Cecilia Lugarà[2], Domenico Corica[1, 2], Giovanni Luppino[2], Roberto Coco[2], Tiziana Abbate[2] & Tommaso Aversa[1, 2]
[1]Pediatric Unit, Gaetano Martino University Hospital of Messina, Messina, Italy; [2]Department of Human Pathology in Adulthood and Childhood "Gaetano Barresi", University of Messina, Messina, Italy

Background
treatment with growth hormone (GH) has been approved by many countries for short children born small for gestational age (SGA) with no postnatal growth recovery. To date, optimization of the efficacy of GH treatment has not been achieved in SGA patients.
Aim
to investigate the impact of GH therapy on growth trajectory (GT) and adult height (AH) in children born SGA and to identify factors influencing the efficacy of GH therapy in terms of height gain (HG).
Methods
the study population consisted of 38 SGA children (20 M, 18 F) length without postnatal growth recovery and treated with GH for at least 5 years (mean age at GH start: 7. 65$\pm$ 3. 26 years; mean height (H): -3. 05$\pm$0. 55 SDS) and followed in our Center between 2010 and 2023. Clinical and anthropometric data [age, bone age, H (SDS), weight (SDS), BMI (SDS), SG and delta H -target height (H-TH)] at the start (T0), during GH treatment [at 1 (T1) and 2 years (T2) of therapy, during puberty onset (P0), first (P1) and second year (P2) of puberty] and at the reaching of AH were collected.
Results
HG increased during the first years of GH treatment (mean H at T1 and T2 were -2. 47$\pm$0. 55 SD and -2. 07$\pm$0. 57 SDS respectively). H at P0 was -1. 89$\pm$0. 76 SDS, at P1 it was -1. 61$\pm$0. 84 SDS and at P2 it was -1. 50$\pm$0. 78 SD. HG resulted greater in males (1. 21$\pm$0. 96 SDS) than females (0. 53$\pm$0. 49 SD; $P < 0.005$). Mean total HG (THG) was 0. 95$\pm$0. 87 SDS. Delta H-TH reduced from the start of therapy until the first two years of puberty: H-TH was -1. 63$\pm$0. 74 SDS at T0, -1. 03$\pm$0. 77 SDS at T1, -0. 66$\pm$0. 87 SDS at T2, -0. 10$\pm$1. 07 SDS at P1, and -0. 01$\pm$1. 13 SDS at P2. However, AH resulted reduced (-2. 11$\pm$0. 88 SDS), although within the TH range in 83% of patients. Only 3 patients had an AH below the lower limit of TH. AH was higher in males than females (-1. 70$\pm$0. 85 SDS vs -2. 77 $\pm$ 0. 39 SDS; $P < 0.005$). HG during T1, H at T0 and at P0 did not significantly influence AH.
Conclusions
GH treatment improves GT in SGA children. AH results within TH limits in the majority of patients, even in cases with delayed start of therapy. Sex and timing of GH initiation can influence AH in SGA children. Early selection of SGA patients for GH therapy could further improve their GT.

Childhood-onset growth hormone deficiency: transition from pediatric to adult endocrine care in the Netherlands

Judith Renes[1, 2], Anita Hokken-Koelega[1, 3] & Dutch Growth Hormone Advisory Board
[1]Dutch Growth Research Foundation, Rotterdam, Netherlands; [2]Albert Schweitzer Hospital, Department of Pediatrics, Dordrecht, Netherlands; [3]Erasmus University Medical Center - Sophia Children's Hospital, Rotterdam, Netherlands

Background
Childhood-onset growth hormone deficiency (CO-GHD) can vary in cause and severity. Managing the transition of patients with CO-GHD into adulthood can be challenging with regard to reconfirming GHD (when and how) and continuing GH treatment (dosing) as well as determining transition readiness.
Objective
A survey was performed amongst all accredited pediatric endocrinologists in The Netherlands aiming to gather valuable insights into current practices regarding the transition of care for adolescents with CO-GHD.
Results
The survey was completed by 33 respondents (67%). Of them, 58% works in a university hospital and 42% in a general hospital. All participants indicated to stop GH in adolescents with idiopathic isolated GHD and reconfirm the diagnosis.

In case of pathogenic gene variants causing isolated GHD, the majority would stop (65%). Also, in tumor-related GHD (even after high dose radiation (>40 Gy)) and adolescents with midline abnormalities, the majority would stop GH and retest (68% and 79%, respectively). However, in case of ≥2 additional pituitary hormone deficiencies 65% indicated they would continue GH. If indicated, GHD is reconfirmed using serum IGF-I levels and/or GH provocation tests. Forty-four percent of the participants indicated that an IGF-I level >0 SDS excluded adult GHD. The most frequently performed GH provocation test was the GHRH-arginine test, but since GHRH is no longer available, most use either arginine or clonidine provocation test (65%) and 14% use the insulin tolerance test. In case of persistent GHD, GH dosages vary widely, from 0. 3 mg/day (39%) to restarting with 0. 7 mg/m^2/day and slowly lowering the dose (18%) or GH titration aiming at IGF-I levels being -1 to +1 SDS (43%). Transition readiness is assessed in consultation with the patient (83%), with the majority indicating that there are no clear guidelines and/or programs used (80%). Most patients are transferred to adult endocrine care at 18 years of age (93%), either using a referral letter (59%) or during a single JOINT consultation (35%).

Conclusion

There are considerable differences in local policies with regard to confirming persistent GHD and GH dosing after adult height attainment. Furthermore, the transition of care to adult services is not uniformly organized. It is important to also evaluate the consequences of different approaches in terms of e. g. body composition and bone development and develop a national guideline.

Effects of growth hormone (GH) and sex steroid therapy on brain structure and pituitary function in turner syndrome (TS)

Ashraf Soliman[1], Muna Sharaf[2], Nada Alaaraj[1], Fawzia Alyafei[1], Shayma Ahmed[1] & Noor Hamed[1]
[1]Hamad Medical Corporation, Doha, Qatar; [2]Palestine Diabetic Institue, West Bank, Palestine

Background

Turner Syndrome (TS) is characterized by complete or partial loss of one X chromosome, leading to a range of physical, cognitive, and neurodevelopmental abnormalities. Therapeutic interventions such as GH and sex steroid therapy have shown promise in addressing these deficits, but their effects on brain structure and pituitary function remain under scrutiny.

Objectives

To investigate the effects of GH and sex steroid therapy on brain structure, pituitary function, and associated clinical outcomes in individuals with TS.

Methods

This review synthesizes findings from studies involving TS patients, comparing brain structure, pituitary function, and clinical outcomes with healthy controls (HC). Data include sample sizes ranging from 9 to 65 individuals, with a focus on neuroimaging, hormonal levels, and cognitive performance metrics.

Detailed Results:

• Brain Structure: TS individuals exhibit smaller hippocampus, caudate, thalamic nuclei, and parieto-occipital brain volumes compared to HC (Murphy *et al*., 1993). GH and sex steroid therapies influence these metrics, with estrogen deficiency linked to reduced gray and white matter development (Li *et al*., 2019). Enhanced basal ganglia and cerebellar growth during adolescence was observed with combined therapies (O'Donoghue *et al*., 2019).

• Pituitary Function: GH therapy increases adrenal steroid responsiveness (Balducci *et al*., 1998), reduces fat mass, and improves lean body mass (Gravholt *et al*., 2002). GH-IGF axis irregularities in TS can be normalized with sex hormone replacement (Gravholt *et al*., 1997).

• Cognitive Outcomes: Oxandrolone, a common adjunct with GH, improves working memory but GH alone does not significantly affect cognitive performance [(Ross *et al*., 1997)](https://consensus. app; (Ross *et al*., 2003).

Discussion

GH and sex steroid therapies have significant impacts on TS-associated deficits. GH improves growth and body composition, while sex steroids address estrogen deficiency, critical for neurodevelopment. The findings underscore the importance of therapy timing and individualized approaches to maximize outcomes. Limitations include small sample sizes and heterogeneity in therapy protocols across studies.

Conclusion

GH and sex steroid therapies positively impact brain structure and pituitary function in TS, with combination therapy yielding the most substantial benefits. Tailored interventions and rigorous monitoring are essential to optimize clinical and neurodevelopmental outcomes in TS patients.

Growth hormone therapy in children with congenital acyanotic heart disease and short stature: balancing growth and cardiac health

Ashraf Soliman[1], Anas Abdulkayoum[1], Nada Alaaraj[1], Noor Hamed[1], Sohair Elsiddig[1] & Fawzia Alyafei[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background

Children with congenital acyanotic heart disease (CAHD), including atrial septal defect (ASD) and ventricular septal defect (VSD), frequently experience growth failure due to energy deficits, malnutrition, and altered hemodynamics. Growth hormone (GH) therapy is a potential treatment for short stature in this population; however, its effects on cardiac function warrant careful evaluation.

Objectives

To assess the real impact of GH therapy on growth velocity and cardiac function in children with CAHD and short stature, focusing on benefits and risks to inform safe and effective treatment practices.

Methods

A systematic review of 20 studies published between 2000 and 2025 was conducted, involving 2, 300 children with CAHD and short stature. Real impacts on growth outcomes (height velocity and z-scores), cardiac stability, and adverse events were calculated based on pooled study data.

Results

• Growth Outcomes: GH therapy improved height velocity by an average of 39. 1%, demonstrating significant benefits for growth failure in this population.

• Cardiac Stability: Cardiac function remained stable in 86. 6% of cases, with no significant deterioration in ejection fraction or ventricular dimensions reported.

• Mild Cardiac Changes: Transient mild cardiac changes, such as slight increases in left ventricular mass, were observed in 13. 4% of cases but did not impact overall heart function.

• Metabolic Risks: Mild metabolic side effects, including fluid retention and insulin resistance, occurred in 10. 2% of cases and were manageable with routine monitoring.

Discussion

GH therapy significantly benefits growth outcomes in children with CAHD while maintaining an acceptable safety profile. The findings underscore that cardiac changes are mostly mild and transient, particularly when therapy is monitored appropriately. Improved growth outcomes contribute to better overall health and quality of life in this population. Coordination between pediatric cardiologists and endocrinologists is crucial to optimize treatment outcomes.

Conclusion

GH therapy is a safe and effective intervention for short stature in children with CAHD when administered with careful cardiac monitoring. Its significant growth benefits and manageable risks make it a valuable option for addressing growth deficits in this vulnerable population.

Growth Hormone Therapy in Children with CAHD

Aspect	Key Findings	Number of Studies	Number of Patients
Growth Velocity Improvement	39. 1% improvement in height velocity	20	2300
Cardiac Stability	86. 6% cases with stable cardiac function	18	2100
Mild Cardiac Changes	13. 4% cases with mild cardiac changes	12	1500
Metabolic Side Effects	10. 2% cases with mild metabolic side effects	10	1300

JOINT2365

Should the initial dose of long-acting growth hormone therapy somatrogon for pediatric growth hormone deficiency be standard for each child?

Eren Er[1], Benay Turan[1], Gülümay Vural Topaktaş[1], Emrullah Arslan[1], Gülçin Arslan[1] & Bumin Nuri Dündar[2]
[1]Izmir City Hospital, Pediatric Endocrinology Clinic, Izmir, Türkiye; [2]Izmir Katip Celebi University, Faculty of Medicine, Department of Pediatric Endocrinology, Izmir, Türkiye

Background

The Long-Acting Growth Hormone (LAGH) therapy, Somatrogon, has been available in Turkey since October 2023 for children with growth hormone deficiency (GHD). LAGH demonstrates equal efficacy compared with daily GH,

with the added advantage of reduced injection frequency. Although clinical studies have highlighted the efficacy and safety of Somatrogon, the standard initial dose for each child may present difficulties in dose titration.
Objective
The aim of this study was to evaluate dose titrations based on insulin-like growth factor 1 (IGF-1) levels in children initiated on Somatrogon therapy for pediatric growth hormone deficiency (PGHD)
Methods
A single-center, retrospective study was conducted including children initiated on Somatrogon therapy with a diagnosis of PGHD between April 1, 2024, and October 31, 2024. A total of 56 children with GHD (37 males), mean age 12. 42 ± 2. 88 years were commenced on LAGH therapy (initial dose 0. 66 mg/kg/week). 20 patients were GH naïve, and 36 were switched from daily GH to LAGH. Auxology, pubertal stage, laboratory findings including IGF-1 levels (measured 96th hours post-weekly injection) were obtained retrospectively from medical records.
Results
The mean duration of Somatrogon therapy was 0. 46 ± 0. 13 years. Dose reduction was achieved in 55. 5% of individuals due to high IGF-1 SDS, and this rate was similar to patients who were GH naïve and switched from daily GH to LAGH. Dose reductions were made in 33. 3% of 21 prepubertal individuals, 76. 9% of 13 with pubertal stage Tanner 2, 50% of 16 with Tanner 3, and 100% of individuals with Tanner 4/5 (6 patients). Children with Tanner stage 4/5 had a mean dose of 0. 51 ± 0. 02 mg/kg/week and a mean dose reduction of 22. 47 ± 3. 51 %. Children were divided into 4 groups according to their peak growth hormone response to stimulation tests. Dose reduction was made in 56. 5% of those with hormone levels between 7 and 10 ng/mL, 54. 4% of those with levels between 5 and 7 ng/mL, 41. 7% of those with levels between 3 and 5 ng/mL, and 80% of those with levels < 3 ng/mL (severe GHD). The children with severe GHD had a mean dose of 0. 56 ± 0. 08 mg/kg/week and a mean dose reduction of 14. 54 ± 12. 33 %.
Conclusion
Somatrogon may be a suitable option in PGHD patients, but the recommended initial dose of 0. 66 mg/kg/week may need to be individualized, particularly in children with severe GHD and in Tanner stage 4/5 of puberty. Careful monitoring and dose adjustment based on IGF-1 levels are necessary to maintain safety and efficacy.

Design of a phase 2, randomized, controlled, multicentre study of vosoritide treatment in children with idiopathic short stature

Ming Sheng[1], Ron Rosenfeld[2], Bradley Miller[3], Lawrence Silverman[4], Alice Huntsman Labed[1], Ian Sabir[1] & Andrew Dauber[5]
[1]BioMarin (UK) Ltd, London, United Kingdom; [2]Department of Pediatrics, Oregon Health & Science University, Portland, United States; [3]Division of Endocrinology, Department of Pediatrics, University of Minnesota Medical School, Minneapolis, United States; [4]Division of Pediatric Endocrinology, Goryeb Children's Hospital, Atlantic Health System, Morristown, United States; [5]Children's National Hospital, Washington DC, United States

Idiopathic short stature (ISS) is diagnosed in individuals with height 2 to 2. 25 standard deviations below age- and sex-matched populations with no other defined aetiology. Evidence suggests that C-type natriuretic peptide is a master regulator of growth. Its analogue vosoritide is an approved targeted therapy for achondroplasia, a condition in which fibroblast growth factor receptor 3 (FGFR3) overactivity causes impaired endochondral ossification and growth. Preliminary experience from an ongoing phase 1/2 proof-of-concept study (NCT04219007) supports that vosoritide may offer benefits in a broad spectrum of short-stature conditions beyond achondroplasia, including children with short stature attributed to variants in natriuretic peptide receptor 2 (*NPR2*) and aggrecan (*ACAN*). Study 111-210 (NCT06382155) is a phase 2, randomized, controlled, multicentre study designed to compare efficacy and safety over a range of vosoritide doses vs placebo (short-term) and human growth hormone (hGH; long-term) in children with ISS. Study 111-210 aims to recruit approximately 100 prepubertal children with ISS aged ≥3 to <10 years (females) or <11 years (males) with a height Z-score less than or equal to −2. 25 from US Centers for Disease Control and Prevention average-stature references. Participants must also be naïve to growth-promoting agents. Baseline annualized growth velocity (AGV) will be established prospectively during a 6-month pretreatment growth-assessment phase. Participants will then be randomized 1:1:1:1:1 to 7. 5, 15. 0, or 22. 5 µg/kg/day vosoritide, 0. 24 mg/kg/week (starting dose) of daily hGH (US only), or placebo in the dose-finding phase of the study. Participants and investigator/study-site personnel will be blinded to vosoritide and placebo. Participants will complete a minimum of 6 months of blinded treatment (maximum 6 months of placebo), followed by open-label treatment with the selected therapeutic dose of vosoritide until they reach near-final adult height in the long-term phase. Participants randomized to hGH will receive open-label hGH for a minimum of 4 years, after which they may transition to open-label vosoritide at the therapeutic dose, if desired. The objectives of the dose-finding phase are to evaluate the safety and efficacy of 3 doses of vosoritide compared with placebo as measured by change from baseline in AGV after 6 months of treatment. The objectives of the long-term phase are to evaluate the safety and efficacy of the therapeutic dose of vosoritide vs hGH on height and height Z-score after long-term treatment.

JOINT315

Phase 3 pivotal trial design of daily oral LUM-201's efficacy and safety in treatment-naïve children with growth hormone deficiency (GHD) in randomized, double-blind, placebo-controlled study

Aleksandra Bruchey[1], Christopher Smith[1], John McKew[1], Michael Thorner[1, 2] & Pisit (Duke) Pitukcheewanont[1]
[1]Lumos Pharma, Inc., Austin, TX, United States; [2]Emeritus University of Virginia, Endocrinology, Charlottesville, United States

Objectives
The primary objective of the OraGrowtH Phase 3 study is to evaluate the efficacy of daily oral LUM-201 (1. 6 mg/kg) in improving growth velocity over 12 months in prepubertal children with GHD. LUM-201, an oral growth hormone secretagogue (GHS), acts on the GHS receptor 1a in the pituitary and hypothalamus to stimulate GH release. Clinical evidence suggests that LUM-201 increases GH pulse amplitude, resulting in increased insulin-like growth factor 1 (IGF-1) and growth. The FDA has acknowledged that, due to LUM-201's unique mechanism of action, its efficacy can be compared to placebo or injectable GH, which delivers GH concentrations about five times greater than physiological levels. 1. 6 mg/kg/day dose was selected based on prior pediatric studies. This study seeks to clinically validate the predictive enrichment marker (PEM) classification, which identifies patients who respond to LUM-201, by assessing changes in growth velocity, IGF-1 SDS, and height SDS over 12 months.
Methods
The OraGrowtH Phase 3 Trial, (global, multicenter, 12-month, randomized, double-blind, placebo-controlled) will enroll treatment-naïve, prepubertal children with GHD who test positive for PEM at screening. A positive PEM result is defined as a baseline IGF-1 concentration > 30. 0 ng/mL and a peak serum GH concentration ≥ 5. 0 ng/mL following a single dose of LUM-201. 150 subjects will be randomized in a 2:1 ratio to receive either daily LUM-201 or placebo (identical capsules) for 12 months. Subjects will attend clinic visits every three months until Month 12. At 12 months subjects will be eligible for an extension trial receiving LUM-201 for up to three years. During the trial, measurements such as height, body weight, and vital signs will be tracked. Safety assessments will include laboratory tests, ECGs, and pharmacokinetic and pharmacodynamic data. Bone age will be evaluated with standard X-rays at screening and Month 12 visits. Adverse events and the use of concomitant medications will be monitored and documented at each visit.
Results
The detailed study design will be presented at the meeting.
Conclusions
LUM-201 represents a novel investigational treatment option for patients with GHD. By stimulating endogenous GH release via the GH-releasing hormone pathway and reducing somatostatin activity, LUM-201 preserves the physiological feedback loop, distinguishing it from exogenous GH injections. The OraGrowtH Phase 3 trial aims to further evaluate LUM-201's efficacy and safety as an oral treatment for GHD.

JOINT187

Changes in body composition, ghrelin, adipokines, and FGF23 in growth hormone deficient children during rhGH therapy

Alina-Daniela Belceanu[1], Cristina Preda[1] & Stefana Bilha[1]
[1]University of Medicine and Pharmacy "GR. T. POPA", Iasi, Romania

Introduction
Growth hormone (GH) therapy not only accelerates growth but also improves body composition of children with GH deficiency (GHD) by modulating lipid and

carbohydrate metabolism. This effect is potentially mediated through adipokines secreted by adipose tissue and ghrelin. Additionally, maintaining proper phosphate balance is crucial for linear growth. Fibroblast growth factor 23 (FGF23), a key regulator of phosphorus levels in the blood, may contribute to the increased renal phosphorus reabsorption observed during recombinant human GH (rhGH) therapy. This study explored the effects of one year of rhGH therapy on body composition, adipokines, acylated/unacylated ghrelin (AG/UAG), and FGF23 in children with GHD.
Materials and Methods
This prospective observational study of 42 prepubertal, non-obese children with GHD undergoing their first year of rhGH replacement therapy. Changes in body composition, adipokine levels, AG/UAG, and FGF23 were evaluated at baseline and compared to results after 6 and 12 months of treatment.
Results
The participants, with an average age of 9. 2 ± 2. 6 years, experienced significant growth acceleration. Over the 12-month period, total body fat decreased markedly, the lipid profile improved, and bone mineral density (BMD) showed a significant increase. Leptin and UAG levels dropped substantially, while adiponectin and AG concentrations increased. Plasma cFGF23 and IGF1 levels rose significantly, correlating with higher serum phosphate levels. However, FGF23 concentration changes did not affect BMD. The observed correlation between FGF23, IGF1, and height SDS suggests a potential role of FGF23 in linear growth. Regression analysis indicated that rhGH therapy influenced leptin and adiponectin levels independently of lean or fat mass but had no direct impact on ghrelin.
Conclusions
GH replacement therapy improves body composition and modifies adipokine profiles in GHD children. It also directly affects leptin and adiponectin levels regardless of body composition. Additionally, GHD children show increased serum phosphate levels, which appear linked to an upregulation of FGF23 rather than suppression, challenging the conventional understanding of FGF23's phosphaturic role. Further studies are necessary to uncover the molecular pathways through which the GH/IGF1 axis regulates adipokine secretion and alters FGF23 plasma levels.
Keywords GH deficiency, adipokines, ghrelin, IGF1, body composition, FGF23.

Big data as a strategy in the development of population auxological studies

Ignacio Diez-Lopez[1], Sandra Maeso Mendez[1], Ioar Casado Tellechea[2], Jose A Lozano[2] & Aritz Pérez[2]
[1]Department of Pediatrics. UPV-EHU. UD of Vitoria. Child and adolescent endocrinology. OSI Araba. BioAraba., Vitoria, Spain; [2]Center for Applied Mathematics BCAM, Bilbao, Spain

Introduction
To date, knowledge of population dynamics and its repercussions on health required complex, long and expensive field studies. Big data tools are nowadays postulated as a tool of first magnitude for weighted population changes observed in real time if reliable sources of collection and adequate mathematical and computer tools for their assessment are available.
Main objective
Carry out a methodological approach to the use of big data applications to prepare auxological growth tables in our population with high statistical power, as a first step to infer the measurement for the entire CCAA. Assess how our population is in the auxological variables with respect to the current Orbegozo 2011 standards and Spanish growth studies 2010.
Material and methods
Data collected from episodes of computerized medical records, studying the variables sex, age, weight, height, place of residence (PC, health center, neighborhood) of our population between 01/01/2020-03/31/2020 (avoiding effect pandemic) To calculate the curves and percentile tables we have used the Cole-Green LMS algorithm with penalized likelihood, implemented in the RefCurv 0. 4. 2 (2020) software, which allows managing large amounts of data. The hyperparameters have been selected using the BIC (Bayesian information criterion). To calculate population deviations from the reference, being above 1. 5 standard deviations from the mean according to age has been taken as a reference.
Results
66, 975 computerized episodes of children under 16 years of age and a total of 1, 205, 000 variables studied are collected. Although data is available, individuals $>16^{a}$ are excluded due to low N. The graphs of our population are represented with respect to the standards, observing that there are differences with Orbegozo 2011 and Spain 2010. We present the data and percentages of overweight/obesity by age and sex. There are significant differences of more overweight in the entire sample of men and women in our population than the usual standards. Big data technology surpasses classic population studies in power and is an innovative tool compared to auxological studies (limited in N) carried out to date. The development of these new strategies in auxology will allow us to know almost in real time the epidemiological situation of the population in different variables, being able to infer health actions in a more effective way.

Non-evidence-based and off-label growth therapies - observations from consultations and practice patterns

Ilja Dubinski[1, 2], Kees Noordam[1, 3] & Urs Eiholzer[1]
[1]Pediatric Endocrinology Center Zurich (PEZZ), Zurich, Switzerland; [2]Department of Pediatrics, Dr. von Hauner Children's Hospital, University Hospital, LMU Munich, Munich, Germany; [3]Department of Paediatrics, Radboud University Medical Centre, Nijmegen, Netherlands

Introduction
Growth assessments do not always lead to established diagnoses and respective therapeutic options. This can cause considerable stress for patients and families. Some ask for alternative (or additional) non-evidence-based or off-label methods (e. g. growth hormone) for growth stimulation. However, the possibility of such off-label treatment has led to a change in the way the diagnosis of 'short stature' has been approached in recent years. A trend from 'growth medicine' to 'growth engineering' is currently being observed. There is no reliable data on the frequency and content of such enquiries.
Methods
An anonymous international online survey was conducted with paediatric endocrinologists from the Young European Society for Paediatric Endocrinology ("YES-Group"). The response rate was 47. 8 % (total 65 participants). The relevance of this topic from the perspective of paediatric endocrinologists was surveyed. In addition, the frequency/thematic content of corresponding enquiries and the attitudes of colleagues were surveyed. Specific prescription frequencies of off-label use treatments with growth hormone (GH), aromatase inhibitors (AI) /Gonadotropin-Releasing-Hormone (GnRH) analogues or both were queried separately.
Results
In 44. 6 % of cases, non-evidence-based methods were requested in every fifth to second consultation by patients or parents. 96. 9 % of colleagues considered the topic to be relevant. Most clarify the ineffectiveness (76. 9%) or potential risks (47. 7%). Most people asked about 'special diets/optimisation of nutrition' and 'food supplements', among other methods. 29. 3% prescribed off-label GH, 50. 8 % refused (for AI 15. 4 % and 33. 9 % respectively/for GH plus AI or GnRH analogues 19. 9 % and 33. 9 % respectively).
Conclusion
Non-evidence-based and off-label methods for growth stimulation play a significant role in patient counselling. A proactive approach in counselling for non-evidence-based methods could prevent disappointments or even risks. The off-label use of GH or GH plus AI/GnRH is frequent and the subject of ongoing societal, ethical and medical discourse.

Table 1: Which types of non-evidence-based methods have your patients or parents inquired about this year? Select all that apply (n = 65, multiple choice, below 5 % not shown).

Non-evidence based method	Ratio of requests
Food supplements	75.0%
Special diets/optimisation of nutrition	59.4%
Off-label use of Growth Hormone	40.6%
Sports (e. g. swimming)	35.9%
Medical drugs (other than GH and/or AI)	34.4%
Physiotherapy (e. g. stretching exercises) /physical thrp./manual thrp.	26.6%
Herbal remedies/phytotherapy	26.6%
Sleep regulation	25.0%
Zinc	18.8%
Arginine suppelment	17.2%
Strength/weight training	14.1%
Homeopathy	7.8%
Stress reduction	7.8%
Aromatase inhibitors	6.3%

Dysregulation of RNA-Exosome machinery component EXOSC4 in MASLD-HCC progression

María Isabel Pozo-Relaño[1,2,3], Víctor J Fernández-Ramírez[1,2,3], Samanta Lozano-de la Haba[1,2,3], Manuel Rodriguez-Perálvarez[1,4,5], Raúl M Luque[1,2,3], Juan Luis López-Cánovas[1,2,3] & Manuel D Gahete[1,2,3]
[1]Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Córdoba, España, Córdoba, Spain; [2]Departamento de Biología Celular, Fisiología e Inmunología, Universidad de Córdoba, Córdoba, España, Córdoba, Spain; [3]Hospital Universitario Reina Sofía, Córdoba, España, 4CIBER Patofisiología de la Obesidad y Nutrición (CIBERobn), Córdoba, España, Córdoba, Spain; [4]Departamento de Hepatología y Trasplante Hepático, Hospital Universitario Reina Sofía, Córdoba, España, Córdoba, Spain; [5]CIBER Enfermedades Hepáticas y Digestivas (CIBERehd), Córdoba, España, Córdoba, Spain

Metabolic-associated steatotic liver disease (MASLD) is a leading cause of chronic liver disease and can progress to hepatocellular carcinoma (HCC). Understanding the molecular mechanisms underlying MASLD progression to HCC is essential for developing effective therapeutic strategies. Previous studies have suggested that RNA processing and metabolic machinery, including the RNA-Exosome complex, may play a pivotal role in MASLD-HCC progression. However, the specific role and contributions of the RNA-Exosome complex in HCC development remain poorly understood. The aim of this study was to characterize the dysregulation and putative role of the RNA-exosome machinery, specifically the component EXOSC4, in MASLD-HCC progression to identify new diagnostic/prognostic biomarkers and/or potential therapeutic targets. Bioinformatic approaches were implemented to analyze the dysregulation of the RNA-exosome machinery and to characterize, in silico, the expression of EXOSC4 at mRNA/protein levels in MASLD, MASLD-related HCC, Metabolic Dysfunction-Associated Steatohepatitis (MASH), HCC and control (normal or adjacent tissue) samples in 16 cohorts (2 retrospective and 14 in silico). Correlations between EXOSC4 expression and clinical parameters relevant to MASLD-HCC progression were evaluated. Pathway enrichment analyses were performed to identify associated cellular and molecular processes. Finally, the role of EXOSC4 was characterized in vitro (proliferation, migration, clonogenic and tumorosphere formation assays) by modulating its expression (silencing and overexpression) in two liver-derived cell lines (Hep3B and SNU-387) and in vivo through a preclinical model of Hep3B-induced xenograft tumors. These analyses revealed that the RNA-exosome machinery is dysregulated in MASLD and HCC. Specifically, the EXOSC4 component was consistently overexpressed in the cohorts studied, wherein high EXOSC4 expression was associated with clinical parameters of malignancy, such as poor survival, increased invasion and recurrence capacity. Consistently, high EXOSC4 expression was associated with the enrichment of oncogenic pathways, such as cell cycle regulation or DNA repair. Consistent with these results, in vitro assays demonstrated that EXOSC4 silencing reduced classical parameters tumor aggressiveness, while EXOSC4 overexpression increased malignancy. Furthermore, in vivo studies confirmed the pro-tumorigenic potential of EXOSC4 by inducing tumor growth in murine models. In conclusion, our results reveal a critical role of the RNA-Exosome machinery, particularly the EXOSC4 component in MASLD-CHC progression. These results suggest that EXOSC4 may serve as a potential biomarker and/or therapeutic target for this pathology.

Setmelanotide in the Management of Pediatric Obesity Due to Genetic Disorders: Clinical Response and Quality of Life Assessment

Mercedes Rivera Cuello[1], Fuensanta Guerrero del Cueto[1] & Isabel Leiva-Gea[1]
[1]Hospital Regional Universitario, Málaga, Spain

Background
Setmelanotide, a melanocortin-4 receptor (MC4R) agonist, has been approved for treating obesity caused by genetic disorders affecting the leptin-melanocortin pathway. This single-center case series evaluates six pediatric patients who began treatment between March and December 2024.
Methods
Baseline assessments included anthropometric measurements, laboratory tests, and adapted questionnaires for ages below and above 12 years. The questionnaires included hunger symptoms and impact of hyperphagia from patient and caregiver perspectives. Two patients with Bardet-Biedl Syndrome (BBS) had completed six months of follow-up at the time of submission, allowing comparisons between baseline and six-month evaluations.
Results
The study included six children (two males, four females) aged 5 to 15 years. At baseline, the median BMI-for-age z-score was +3.25 (range: 2.84–5.8), and the median body fat percentage was 35.43% (range: 24.5–42.5%). Genetic diagnoses included four patients with BBS (one compound heterozygosity for BBS1 and one for BBS2, heterozygosity for BBS4 and BBS19, and homozygosity for BBS9), one patient with a homozygous pro-opiomelanocortin (POMC) deficiency, and another with compound heterozygosity for leptin receptor (LEPR) deficiency. 50% of the patients had prediabetes, and 50% had hypertriglyceridemia at baseline. Hunger scores for patients <12 years ranged from 9–13 out of 15, while older patients scored between 5–10 out of 12. The hyperphagia impact scores ranged from 13–21 out of 24 in younger patients and 10–21 out of 24 in older ones. The highest-rated symptom was "persistent hunger after eating," and hyperphagia most affected "leisure and free time" and "relationships with family and friends." Family members reported the greatest impact on "mood and emotions" and "relationships". After six months, two BBS patients showed improvements in anthropometric and quality-of-life measures. A 6-year-old patient's hunger score decreased from 9 to 8, hyperphagia impact from 13 to 9, family impact from 11 to 8, and BMI reduced by -2.02 kg/m^2. A 13-year-old patient's hunger score dropped from 6 to 4, hyperphagia impact from 10 to 7, family impact from 15 to 14, and BMI decreased by -5.11 kg/m^2.
Conclusions
Preliminary results suggest setmelanotide improves BMI, hunger scores, and hyperphagia's impact on patients and families. Further analysis when the follow-up for the other patients has been completed will provide more insight into the consistency and magnitude of these changes. While results are promising, ongoing evaluation may help assess the durability of setmelanotide's effects and its long-term impact on obesity management and quality of life.

Adverse waist-for-height ratio trajectories in childhood are associated with cardiometabolic and cardiovascular risk by age 10

David Horner[1], Bo Chawes[1], Klaus Bønnelykke[1], Jakob Stokholm[1], Morten Rasmussen[1] & Rebecca Kofod Vinding[1]
[1]COPSAC clinical research unit, Copenhagen, Denmark

Introduction
Waist-for-height ratio reflects central adiposity, a key predictor of cardiometabolic health. This study examines how adverse waist-for-height trajectories in childhood are associated with increased cardiometabolic and cardiovascular risk by age 10.
Methods
Analysis was conducted within the COPSAC2010 cohort, comprising 700 mother-child pairs with detailed phenotyping across 14 visits. We used latent class analysis to identify child waist-for-height ratio trajectories from 1 week to 10 years. Cardiometabolic risk (CMR) was derived from composite z-scores of HDL, triglycerides, glucose, blood pressure (height-adjusted), and HOMA-IR, while cardiovascular disease (CVD) risk was calculated using NMR blood metabolomics and Cox models from the UK Biobank. Scores were z-scored within the cohort for interpretation. Models were adjusted for demographics, lifestyle factors, physical activity, sleep, diet, and relevant clinical measures.
Results
We identified three distinct waist-for-height ratio trajectories from 1 week to 10 years: a stable "Reference group" (66%), a "Rising-then-falling" group (18%), and a "Slow-rising" group (15%). Compared to the reference group, the "Slow-rising" group (15%) had significantly higher CMR ($\alpha = 0.79$, $P < 0.0001$) and CVD scores ($\alpha = 0.53$, $P < 0.0001$), reflecting worse cardiometabolic risk. This group also showed elevated levels of C-peptide ($\alpha = 106$, $P < 0.0001$), HOMA-IR ($\alpha = 0.15$, $P < 0.0001$), GlycA ($\alpha = 0.04$, $P < 0.0001$), and hs-CRP ($\alpha = 0.60$, $P < 0.0001$), alongside lower HDL ($\alpha = -0.17$, $P < 0.001$). Compared to the reference group, the "Rising-then-falling" group (18%) had significantly lower HbA1c levels ($\alpha = -0.90$, $P = 0.003$) and slightly higher ApoB levels ($\alpha = 0.03$, $P = 0.032$). Adjusting for waist-for-height ratio cross-sectionally at 10 years explained most of the variance in risk, rendering previous associations for the "Slow-rising" group nonsignificant, however findings for the "Rising-then-falling" remained significant.
Conclusion
Childhood waist-for-height ratio trajectories are strongly linked to cardiometabolic and cardiovascular risk by age 10. These findings emphasise the need for early monitoring and intervention to address central adiposity patterns and reduce the risk of long-term adverse health outcomes.

Efficacy of treatment with combination dapagliflozin and metformin vs metformin alone in overweight and obese women with polycystic ovary syndrome: a randomized controlled trial

Vishal Agarwal[1], Sambit Das[1], Arun Choudhury[1], Dayanidhi Meher[1], Devadarshini Sahoo[1], Sandeep Sahu[1], Subhadra Priyadarshini[2], Binod Prusty[1], Bijay Das[1], Amogh Chappalagavi[1] & Sheenam Gupta[1]
[1]Kalinga Institute of Medical Sciences, Endocrinology, Bhubaneshwar, India; [2]Kalinga Institute of Medical Sciences, Research and development, Bhubaneshwar, India

Background
Polycystic ovary syndrome (PCOS) is a common endocrine disorder characterized by insulin resistance and hyperandrogenemia, particularly in overweight and obese women. Dapagliflozin and other sodium-glucose cotransporter-2 (SGLT2) inhibitors may offer additional benefits to metformin, which is commonly used to improve metabolic parameters in patients with PCOS. This study compares the efficacy of metformin alone vs dapagliflozin plus metformin in reducing hyperandrogenism and insulin resistance in overweight and obese women with PCOS.
Methods
Sixty-four overweight or obese non-diabetic women between 18 and 40 years old diagnosed with polycystic ovary syndrome (PCOS) as per Rotterdam criteria were enrolled. Patients were randomly allocated to receive either a combination of dapaglifozin plus metformin (DAPA + MET) or metformin (MET) alone treatment. The DAPA + MET group received dapagliflozin 10 mg once daily plus metformin 1000 mg twice daily, while the MET group received metformin 1000 mg twice daily for six months. Changes in hormonal profile, anthropometric parameters, glucose and lipid homeostasis, and adverse events (AEs) were evaluated.
Results
At baseline, both groups had similar demographic, clinical and metabolic characteristics. Over 24 weeks, both groups showed significant reductions in body mass index (BMI), fasting insulin, fasting plasma glucose (FPG), homeostatic model assessment for insulin resistance (HOMA-IR), and androgenic markers like free androgen index (FAI) and serum testosterone levels ($p < 0.05$ within groups). The DAPA + MET group demonstrated greater reductions in BMI (-1. 62 vs. -0. 42 kg/m^2), fasting insulin (-1. 38 vs. -0. 74), HOMA-IR (-0. 51 vs. -0. 31), serum testosterone (-0. 12 vs. -0. 06), and FAI (-1. 21 vs. -0. 62) compared to metformin alone. However, the differences between groups were not statistically significant. Changes in lipid profiles were also comparable between groups. Adverse events such as urinary tract infections (UTI) and vaginal irritation were reported more frequently in the DAPA + MET group ($P = 0.043$).
Conclusion
Both DAPA + MET and MET were effective in improving insulin resistance, hyperandrogenemia, and metabolic parameters in overweight and obese women with PCOS. While the combination therapy demonstrated greater improvements in weight loss and insulin sensitivity, the differences were not statistically significant. However, the increased incidence of UTIs and vaginal irritation should be considered when prescribing dapagliflozin in this population. Further long-term studies with larger sample sizes are needed to confirm the potential added benefits of dapagliflozin in managing PCOS.

Enzymatic approach to neonatal hyperbilirubinemia

Kiumars Pirkalani[1, 2]
[1]Mehr Medical Group, Internal Medicine, Tehran, Iran; [2]Mehr Medical Group, Internal Medicien, Tehran, Iran

Background
The ultra -old problem of neonatal hyperbilirubinemia has been solved by complex settings of exchange transfusion and phototherapy and beside time/cost and ward consuming issues; treatment is not optimum. Till now it has not been clarified whether low grade hyperbilirubinemia is harmful or beneficial regarding the antioxidant nature of unconjugated bilirubin. Besides Albumin binding, transportation to the liver, uptake, conjugation and secretion into bile has not been fully investigated for therapeutic intervention. Conjugation within the circulation omits these steps and will be faster than natural absorption, conjugation and release. We proposed that peripheral conjugation with a canine glucose transferase short cut all these steps without the need for the energy rich uridyl-glucuronic-transferase which is relatively deficient in neonates in premature babies.
Methods
After successful preclinical study, two enzymes i. e. human glucuronic transferase and canine glucose transferase were used at in 12 patients in three clinical phases. Type I Crigler Najjar models were not available so moribund neonates with life expectancy of less than three months were used for toxicity studies.
Results
The human enzyme was unable to conjugate bilirubin in human serum because of the lack of uridyl-diphosphate. Addition of uridyl-diphosphate completed the task within minutes. Conjugation with glucose under canine glucose transferase was easy, without the need for uridyl-diphosphate and resulted in water soluble monoconjugates. The reaction was completed within seconds without complex needed agents or by products *In vitro*. *In vitro* studies of hundreds of blood samples were extremely successful with glucose transferase. The details are out of the scope of this presentation. A single injection caused a reduction of harmless Bilirubin of 8mg/dl down to zero in a timely curve in 12 human neonates.
Conclusion
Treatment of neonatal hyperbilirubinemia with canine glucose transferase at picogram concentrations is safe and can be accomplished as treatment and prophylaxis.

Growth trajectories of height and body composition in pre-pubertal and early pubertal stages across obesity transition groups: a longitudinal study

Seo Jung Kim[1], Youn Kyoung Kim[1], Kyoung Won Cho[1] & Junghwan Suh[1]
[1]Severance Children's Hospital, Department of Pediatrics, Seoul, South Korea

Background
Childhood obesity, particularly its transitions between normal weight and obesity, remains poorly understood regarding its impact on growth and body composition during pre-pubertal and early pubertal stages. Investigating these dynamics is crucial for dispelling misconceptions about obesity's relationship with height and guiding effective early interventions.
Objective
To longitudinally analyze changes in body measurements and compositions during the pre-pubertal and early pubertal stages, comparing groups with differing obesity transitions.
Methods
Anthropometric and body composition data were collected at ages 7 and 12 from 5, 353 children categorized into four groups: obese (obese at both ages; $n = 215$), obese-to-normal (obese at age 7, non-obese at age 12; $n = 134$), normal-to-obese (non-obese at age 7, obese at age 12; $n = 373$), and control (non-obese at both ages; $n = 4,631$). Measurements included height, weight, body fat mass (BFM), skeletal muscle mass (SMM), body mass index (BMI), body fat mass index (BFMI), skeletal muscle mass index (SMMI), and waist-to-hip ratio (WHR). Growth differences were analyzed using a Difference-in-Difference (DID) estimator.
Results
The obese group exhibited significantly higher weight, BFM, SMM, BMI, BFMI, and SMMI at both ages compared to the control group. When comparing growth trajectories, the obese group showed greater increases in weight, BFM, SMM, BMI, BFMI, and WHR, but not height, relative to the obese-to-normal and control groups. Similarly, the normal-to-obese group displayed increased body composition metrics, excluding height, compared to controls.
Conclusions
Children remaining obese during pre-puberty and early puberty exhibit greater increases in body composition metrics, excluding height, compared to those transitioning to normal weight or remaining non-obese.

Introduction
Clinical features of nonsyndromic monogenic obesity are predominantly derived from case-based publications due to rarity of the condition. Here, we aimed to establish the frequency of specific ethiologies among a nationwide cohort of monogenic obesity and describe clinical features and associated manifestations of each specific etiologies.
Methods
Cross-sectional data were collected from 22 paediatric endocrinology centers across Turkiye, including patients with biallelic LP/P variants in *LEP, LEPR, POMC, PCSK1, MC4R, SIM1, ADCY3, CEP19* and monoallelic LP/P variants in *MC4R*. Clinical data and anthropometric measurements prior to specific treatment were analyzed. Statistical analyses were performed for groups with ≥ 5 cases.
Results
A total of 113 patients (49% female) were evaluated. The most common mutations were monoallelic *MC4R*($n = 41$) and biallelic *LEPR*($n = 38$), followed by *POMC*($n = 10$), biallelic *MC4R*($n = 10$), *LEP*($n = 5$), *PCSK1*($n = 3$), *CEP19*($n = 3$), *ADYC3*($n = 2$), and *SIM1*($n = 1$) mutations (Table). Significant differences were identified in weight-SDS, BMI-SDS, bone age-SDS, and HOMA-IR values ($P = 0.008$, <0.0001, 0.0075, and 0.02 respectively) among different ethiologies. *LEP* mutations were associated with the highest BMI-SDS, while *LEPR* and biallelic *MC4R* cases had the worst metaboilic profile. Advanced bone age-SDS was observed in *LEPR* and monoallelic *MC4R* cases. The age of obesity-onset was predominantly <1 year in biallelic *LEP, LEPR, MC4R, ADCY3, CEP19* and *SIM1* mutations and 1-5 years in *POMC* and *PCSK1* mutations. Endocrine dysfunctions were common in *LEPR, POMC* and *PCSK1* cases. Psychiatric disorders and intellectual disability were observed in 11.5% and 8.3% of patients, respectively.
Conclusion
This paediatric cohort details the clinical characteristics of non-syndromic monogenic obesity and demonstrates that LEPR mutations are as common as monoallelic MC4R mutations in Turkiye. LEPR and biallelic MC4R mutations had the worst metabolic profile. LEPR and monoallelic MC4R cases exhibited significantly advanced bone age-SDS without increased height-SDS.

Introduction
The EOSS-P (Edmonton Obesity Staging System for Pediatrics) is a comprehensive tool that defines obesity severity beyond traditional

anthropometric measures (weight or body mass index). It assesses obesity burden across four domains: metabolic, mechanical, mental health, and milieu. We previously demonstrated that EOSS-P scores at 8-10 years were associated with adverse cardiometabolic health outcomes at 15-17 years. Given strong evidence between living with excess weight and poorer mental health outcomes, we aimed to study associations between EOSS-P staging at 8-10 years and mental health outcomes at 15-17 years.
Methods
Data were obtained from the QUALITY cohort, a prospective study of Quebec children with a parental history of obesity. This analysis focused on the children with obesity at ages 8-10 and 15-17 years ($n = 72$). EOSS-P was staged at 8-10 years, ranging from Stage 0 (no abnormalities across domains) to Stage 3 (significant impairment across domains). Participants reported on mental health symptoms at 15-17 years old using two validated questionnaires, the Composite International Diagnostic Interview for anxiety (CIDI-A) and for depression (CIDI-D). We estimated the associations between the EOSS-P stage at 8-10 years and mental health at 15-17 years using multivariable linear regression models adjusted for age and sex. Multiple imputation and inverse probability of censoring weighting addressed missing data and selection bias due to loss to follow-up, respectively. We log-transformed CIDI-A and expressed results in sympercents.
Results
At 8-10 yrs, 0. 6% of the sample belonged to EOSS-P Stage 0, 33. 0% to Stage 1, 40. 0% to Stage 2, and 26. 0% to Stage 3. Compared to Stage 1, belonging to Stage 2 at 8-10 years was associated with an increase in CIDI-D of 2. 39 points [CI: -0. 65; 5. 32] but no meaningful association with CIDI-A at 15-17 years. Belonging to Stage 3 at 8-10 years was associated with an increase in CIDI-D of 2. 04 points [CI: -1. 97; 5. 87] and a 17. 92% [CI: -24. 20%; 79. 33%] increase in CIDI-A at 15-17 years compared to belonging to Stage 1.
Conclusion
A higher EOSS-P stage at age 8-10 years showed a trend towards less favourable mental health at age 15-17 years, independent of baseline mental health staging within the EOSS-P. Notably, although modest, the increase in depressive and anxiety symptoms in late adolescence suggests a potentially clinically meaningful association, despite the small sample size. Results need to be confirmed in a larger sample.

Benefits of ambulatory blood pressure monitoring over office blood pressure in children and adolescents with severe obesity: findings from the bern obesity in childhood and adolescence biorepository

Alexander Koch[1, 2], Hyntie Cui[1], Sibylle Tschumi[3], Giacomo Simonetti[4, 5], Markus Juonala[6, 7], Matthias Kopp[8], Marco Janner[1] & Christoph Saner[1, 9]
[1]Inselspital, Bern University Hospital, University of Bern, Division of Paediatric Endocrinology, Diabetology and Metabolism, Department of Paediatrics, Bern, Switzerland; [2]University of Bern, Graduate School for Health Sciences, Bern, Switzerland; [3]Inselspital, Bern University Hospital, University of Bern, Division of Paediatric Nephrology, Department of Paediatrics, Bern, Switzerland; [4]Ospedale San Giovanni, Ente Ospedaliero Cantonale, Pediatric Institute of Southern Switzerland, Bellinzona, Switzerland; [5]Università della Svizzera Italiana, Faculty of Biomedical Sciences, Lugano, Switzerland; [6]Turku University Hospital, Division of Medicine, Turku, Finland; [7]University of Turku, Department of Medicine, Turku, Finland; [8]Inselspital, Bern University Hospital, University of Bern, Division of Paediatric Respiratory Medicine and Allergology, Department of Paediatrics, Bern, Switzerland; [9]The Royal Children's Hospital, Murdoch Children's Research Institute, Parkville, Victoria, Australia

Background
Prevalence of hypertension (HTN) among children and adolescents with severe obesity is up to five times higher compared to their normal-weight peers. Youth hypertension is a strong predictor of cardiovascular (CV) morbidity and premature mortality. Ambulatory blood pressure monitoring (ABPM) has proven superior to office blood pressure (oBP) for diagnosis and CV risk prediction in adults. Growing evidence supports its use in the paediatric population. However, data on ABPM in children and adolescents with severe obesity and associations with measures of mass and body composition remain sparse.
Methods
Data on anthropometry (percent of the 95th body mass index percentile according to CDC [%BMIp95], waist-to-height ratio [WHtR], impedance-related percent of body fat [%BF] and muscle mass [%MM]) as predictors, and on oBP and 24-hour ABPM as outcomes (normal BP, ambulatory HTN, white coat HTN [WCH] and masked HTN [MH], non-dipping) according to ESH guidelines were drawn from the Bern Obesity in Childhood and Adolescence Biorepository. Descriptive statistics and adjusted logistic regression analyses were applied.
Results
A total of 351 individuals, 52. 4% males, had a mean (SD) age of 12. 2 (2. 6) years and a %BMIp95 of 124 (17. 9). WHtR ($n = 316$) was 0. 58 (0. 06), %BF and %MM ($n = 241$) was 41. 9% (6. 4) and 31. 7% (3. 7), respectively. Based on oBP measurements ($n = 302$), 8% had Grade 1 HTN, 9% had Grade 2 HTN. Based on ABPM ($n = 351$), 15% had ambulatory HTN and 44% were non-dippers. In 302 participants with oBP and ABPM, ABPM detected WCH in 36 of 52 individuals with abnormal oBP, and MH in 28 of 251 individuals with normal oBP, overall disproving 21% of oBP findings. An increase in 1-unit %BMIp95 and 0. 01-unit WHtR was associated with ambulatory HTN (OR 1. 02 [1. 01-1. 04] and 1. 07 [1. 01-1. 13], respectively). An increase in 1-unit %BF was associated with non-dipping (1. 05 [1. 01-1. 10]), whereas a 1-unit increase in %MM was protective from non-dipping (0. 91 [0. 84-0. 98]).
Conclusion
Our results provide evidence for the benefits of ABPM in children and adolescents with severe obesity for discriminating BP subtypes and for risk stratification, and we show that body composition measures provide distinct information on blood pressure outcomes.

Background
Rare variants in melanocortin-4 receptor (MC4R) pathway genes may impair MC4R signalling, leading to hyperphagia and early-onset, severe obesity. In a Phase 3, open-label trial, the MC4R agonist setmelanotide reduced weight and hunger in patients aged 2 to 5 years with proopiomelanocortin (POMC) deficiency, leptin receptor (LEPR) deficiency, or Bardet-Biedl syndrome (BBS) at 1 year (primary time point). Here, we report sustained improvements in weight outcomes at 18 months of setmelanotide.
Methods
The VENTURE trial (NCT04966741) evaluated 52 weeks of setmelanotide treatment in patients aged 2 to 5 years with hyperphagia and obesity due to biallelic *POMC* or *LEPR* variants or genetically confirmed BBS. This analysis assessed body mass index (BMI), BMI z-score, and percent of the BMI 95th percentile (%BMI95) from baseline to Month 18 of a long-term extension study.
Results
Eight patients (POMC/lEPR, $n = 5$; BBS, $n = 3$) completed 18 months of setmelanotide. All patients had severe obesity at baseline (BMI z-score range, 2. 4 to 7. 3) and had clinically meaningful reductions in weight at Month 18. The mean

percent change from baseline in BMI was −21. 5% at Month 12, −22. 3% at Month 15, and −23. 3% at Month 18. The mean change from baseline in BMI z-score was −1. 9 at Month 12, −2. 0 at Month 15, and −2. 1 at Month 18. The mean change from baseline in %BMI95 in percentage points was −37. 0 at Month 12, −38. 5 at Month 15, and −41. 3 at Month 18. Skin hyperpigmentation (87. 5%; all treatment related) and nasopharyngitis (62. 5%; all not treatment related) were the most common reported adverse events.

Conclusion

In the first trial of setmelanotide in patients 2 to 5 years of age, robust reductions in age-appropriate weight measures were seen in all patients at 18 months of treatment, with no new safety concerns. No approved therapies for patients 2 to 5 years old with obesity in the studied populations currently exist, despite the need for early intervention with targeted therapy in these patients.

JOINT1016

Exosomal miRNA profile and its association with insulin resistance in obese children and NAFLD patients

Il Tae Hwang[1], Eun Young Kim[2] & Jung Sub Lim[3]
[1]Kangdong Sacred Heart Hospital, Pediatrics, Gangdong gu, South Korea; [2]Chosun University Hospital, Pediatrics, Gwangju, South Korea; [3]Korea Cancer Center Hospital, Pediatrics, Seoul, South Korea

Objective

Recent studies suggest that microRNAs (miRNAs) may serve as novel biomarkers for predicting insulin resistance-related conditions, such as obesity, metabolic syndrome, and non-alcoholic fatty liver disease (NAFLD), in both adults and children. This study aimed to compare serum exosomal miRNA levels among obese children, children with NAFLD, and healthy controls in a Korean pediatric population. Additionally, the study sought to analyze the association between these miRNAs and markers of insulin resistance.

Methods

A total of 30 prepubertal children were included in this study, with 10 children in each group: obesity ($n = 10$), NAFLD ($n = 10$), and healthy controls ($n = 10$). Each group consisted of 5 males and 5 females. Serum exosomal miRNA was analyzed using next-generation sequencing (NGS). Statistical analyses were performed to compare miRNA expression levels between the groups and to assess correlations with clinical parameters and insulin resistance markers, including the triglyceride-glucose index (TyG), TyG index adjusted for ALT (TyG_ALT), and homeostatic model assessment of insulin resistance (HOMA-IR).

Results

All participants were prepubertal, with average ages of 8. 7 years in the NAFLD group, 8. 6 years in the obesity group, and 8. 3 years in the control group, with no significant age differences between the groups. MicroRNAs 34a-5p, 122-5p, 885-5p, and 885-3p were found to be significantly upregulated in the NAFLD group compared to both the obesity and control groups. These miRNAs were positively correlated with AST and uric acid levels. Additionally, miRNAs 122-5p, 885-5p, and 885-3p showed positive correlations with ALT and the TyG_ALT index. In contrast, miRNAs 570-3p and 32-3p were downregulated in the NAFLD group compared to both the obesity and control groups and negatively correlated with AST, ALT, and the TyG_ALT index.

Conclusion

Specific miRNAs, particularly 34a-5p, 122-5p, 885-5p, 885-3p, 570-3p, and 32-3p, exhibit differential expression in children with NAFLD compared to obese and healthy controls. These miRNAs are closely associated with liver function and insulin resistance markers, highlighting their potential as biomarkers for NAFLD and related metabolic disturbances in pediatric patients.

Hepatic triglyceride export in acromegaly and the effects of treatment - a preliminary study

Clemens Baumgartner[1], Matthaeus Metz[1], Marianna Beghini[1], Lorenz Pfleger[1], Anna Tosin[1], Oliver Koldyka[1], Hannes Beiglboeck[1], Paul Fellinger[1], Greisa Vila[1], Anton Luger[1], Alexandra Kautzky-Willer[1], Angelika Freudenthaler[1], Sabina Baumgartner-Parzer[1], Herbert Stangl[2], Martin Krssak[1, 3], Thomas Scherer[1], Michael Krebs[1] & Peter Wolf[1]
[1]Medical University of Vienna, Internal Medicine III, Vienna, Austria; [2]Medical University of Vienna, Institute of Medical Chemistry, Center for Pathobiochemistry and Genetics, Vienna, Austria; [3]Medical University of Vienna, High-Field MR Centre, Department of Biomedical Imaging and Image-Guided Therapy, Vienna, Austria

Overview

High growth hormone (GH) concentrations are associated with low intrahepatic lipids (IHL). Lately, our study group reported a GH mediated stimulation of hepatic triglyceride (TG) export in healthy males as possible antisteatotic mechanism. However, the impact of long-term GH excess in acromegaly on hepatic TG export is yet unknown.

Methods

For this preliminary analysis, GH/IGF-I axis activity and hepatic TG secretion were investigated in 8 patients with active acromegaly (4 female, median 52 [IQR: 44-55] years, BMI 28. 1 [26. 5-31. 9] kg/m2). Hepatic TG secretion was assessed via an intralipid infusion protocol and IHL were measured using magnetic resonance spectroscopy. In 5 Patients, measurements were repeated after successful treatment. Data before treatment were compared to an unmatched group of 9 male volunteers (23 [22-27] years, BMI 21. 2 [20. 2-25] kg/m2) with low IHL.

Results

IHL content was comparable between patients with acromegaly and controls (1. 2 [1. 1-1. 4] vs. 0. 9 [0. 8-1. 4] %, $P = 0. 556$). Hepatic TG secretion was not increased in active acromegaly (patients vs controls: 577 [483-738] vs 436 [401-785] mg/h, $P = 0. 336$). Successful treatment of acromegaly did not significantly reduce hepatic TG secretion (577 [483-738] vs 475 [393-634] mg/h, $P = 0. 242$). Data for IHL was present for 6 patients before and 3 patients after treatment initiation (1. 2 [1. 1-1. 4] vs. 0. 9 [0. 7-1. 3] %).

Conclusion

According to this preliminary analysis, low IHL in acromegaly is not associated with a substantial increase in hepatic TG secretion. These findings are in contrary to previous investigations of healthy individuals during short-term GH/IGF-I axis modulation. Further studies will need to clarify possible adaptations in hepatic lipid metabolism after long-term GH excess.

Phase II study to assess the efficacy and safety of pasireotide in patients with post-bariatric hypoglycaemia: PASIPHY study design

Andreea Ciudin[1], Tracey McLaughlin[2], Jan Tack[3], Tricia Tan[4], Antonio Jose Torres[5], Andrea Piacentini[6], Wence Agbotounou[7], Arnd Mueller[7] & Mary Elizabeth Patti[8]
[1]Vall d'Hebron University Hospital, Barcelona, Spain; [2]Stanford University School of Medicine, Stanford, United States; [3]University of Leuven, Leuven, Belgium; [4]Imperial College London, London, United Kingdom; [5]Hospital Clinic San Carlos, Universidad Complutense de Madrid and IdISSC, Madrid, Spain; [6]Recordati SpA, Milan, Italy; [7]Recordati AG, Basel, Switzerland; [8]Joslin Diabetes Center and Harvard Medical School, Boston, United States

Introduction

Post-bariatric hypoglycaemia (PBH) complicates up to 38% and 12% of gastric bypass and vertical sleeve gastrectomy surgeries, respectively. PBH, characterised by postprandial hyperinsulinaemic hypoglycaemic episodes in association with neuroglycopenic symptoms, is caused by rapid gastric emptying and excessive secretion of glucagon-like peptide 1 (GLP-1) and insulin. There are no approved medical therapies; affected patients suffer extreme disability. Pasireotide, a somatostatin receptor ligand, binds with high affinity to somatostatin receptor subtype 5, inhibiting GLP-1 and insulin secretion and slowing gastric emptying. PASIPHY, a Phase II dose-finding study (NCT05928390), will assess pasireotide efficacy and safety in patients with PBH.

Methods
~72 patients with PBH (age ≥18 years; bariatric surgery ≥6 months prior) will enrol across ~25 sites (Europe/USA). The study comprises a ≤3-week (W) screening, a 4W run-in and a 12W randomised, double-blind, placebo-controlled treatment period. Patients with ≥4 postprandial hypoglycaemic events (self-monitored blood glucose [SMBG] <54 mg/dL [<3. 0 mmol/l], a neuroglycopenia event or a level 3 hypoglycaemic event) during the run-in period are randomly allocated to subcutaneous pasireotide at doses of 50, 100 or 200 μg 3 times a day (tid) or matching placebo (3:1 ratio). All patients initiate treatment with 50 μg pasireotide; dose increases occur on days 5 (to 100 μg) and 9 (to 200 μg). Those completing the 12W core phase can choose to receive pasireotide during a 36W open-label extension. All patients will start the extension on pasireotide 50 μg tid; dose can be adjusted for safety/efficacy reasons (up to 200 μg). The primary endpoint is change in blood glucose levels measured by peak:nadir glucose area under the curve during the mixed-meal tolerance test (MMTT) from baseline to W12 of treatment. Core-phase secondary endpoints (assessed at W4, W8 and W12, unless otherwise specified) include: change from baseline in rate of level 2 hypoglycaemic events; change from baseline in rate of level 3 hypoglycaemic events; duration of level 2 hypoglycaemic events; change from baseline in frequency of rescue therapy use; change from baseline to W12 in insulin, glucagon and GLP-1 secretion during MMTT; change from baseline to W12 in health-related quality of life; and incidence of adverse events throughout the study. These endpoints and others will be assessed throughout the extension.
Conclusion
PASIPHY will provide valuable data on pasireotide efficacy and safety, ascertain which dose has the best benefit:risk ratio, and determine whether it is a viable treatment option for patients with PBH.

Empagliflozin: sex-specific effects on mitochondrial function and cellular redox-balance in HFPEF and MASLD

Niklas Geiger[1, 2], Alexander Nickel[2], Michael Kohlhaas[2], Palina Zytner[1, 2], Simon Kloock[1], Michael Matz[1, 2], Mia Külzer[2], Jessica Ulrich[3], Vasco Sequiera[2], Martin Fassnacht[1], Andreas Geier[4], Christioph Maack[2] & Ulrich Dischinger[1, 2]
[1]University Hospital Würzburg, Department of Endocrinology and Diabetes, Würzburg, Germany; [2]University Hospital Würzburg, Comprehensive Heart Failure Center, Würzburg, Germany; [3]University of Würzburg, Pharmacology and Toxicology, Würzburg, Germany; [4]University Hospital Würzburg, Department of Hepatology, Würzburg, Germany

Background
Empagliflozin, a sodium-glucose co-transporter 2 (SGLT-2) inhibitor, has shown beneficial effects in obesity-related conditions such as heart failure with preserved ejection fraction (HFpEF) and metabolic dysfunction-associated steatotic liver disease (MASLD). However, the precise cellular mechanisms behind these effects are not fully understood, and there is limited knowledge about gender-specific differences in responsiveness to empagliflozin.
Methods
Male and female wistar rats were fed either standard chow **(CO)** or a high-fat/fructose **(HFD)** diet combined with L-NAME for 8 weeks to induce obesity and associated comorbidities like HFpEF and MASLD. Following this regimen, the rats received either empagliflozin **(EMPA)** or saline **(HFD)** for additional 8 weeks, with ad libitum access to either HFD or a low-fat/high-fructose diet. Echocardiography (ECG) was conducted at the end of treatment. Histological assessment for H. E., OilRed and CD3 was performed in hepatic tissue. Isolated cardiomyocytes were evaluated for mitochondrial redox state, while isolated cardiac and hepatic mitochondria were subjected to high-resolution respirometry to assess oxygen consumption (with pyruvate/malate, fatty acids, and succinate as substrates) and redox state with an Oroboros Oxygraph-2k.
Results
In the ECG analysis, the male HFD group exhibited a significantly reduced E/A-ratio with preserved ejection fraction (EF), indicating diastolic dysfunction and an HFpEF phenotype when compared to CO. Cardiac mitochondrial respiration in HFD was significantly lower than in CO but was fully restored by EMPA. EMPA treatment significantly increased the E/A-ratio, in line with a significantly restored mitochondrial redox balance. In female HFD rats, echocardiography similarly showed a significantly reduced E/A-ratio, consistent with diastolic impairment and preserved ejection fraction. Here, EMPA restored the E/A-ratio and mitochondrial respiration was significantly higher compared to HFD. Hepatic histological assessment in the male HFD group indicated increased lipid storage and inflammation with non-significant EMPA-effects. Regarding mitochondrial respiration, the male HFD group exhibited significantly higher respiration rates compared to CO. Mitochondrial O_2 consumption was significantly lower with EMPA compared to HFD in males with stronger effects in females.
Conclusions
Empagliflozin has distinct sex-specific effects in a diet-induced model of HFpEF and MASLD. It enhances cardiac and hepatic mitochondrial function in males while yielding different outcomes in females. Males experience a stronger impact from empagliflozin on cardiac mitochondrial respiration, while stronger effects on hepatic mitochondrial respiration could be detected in females. These findings underscore the importance of incorporating sex-based analyses in HFpEF and MASLD research, as responses to empagliflozin may vary significantly between sexes, potentially influencing treatment strategies.

Diagnostic performance of triglyceride-glucose-based indices for identifying metabolic syndrome in paediatric populations

Valeria Calcaterra[1, 2], Virginia Rossi[1], Lucia Labati[3, 4], Erika Cordaro[1, 2], Laura Schneider[1], Alice Colombo[1], Massimiliano Turzi[1], Valentina Fabiano[1, 5] & Gianvincenzo Zuccotti[1, 5]
[1]Buzzi Children's Hospital, Department of Paediatrics, Milan, Italy; [2]University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy; [3]Buzzi Children's Hospital, Department of Biomedical and Clinical Sciences, Milan, Italy; [4]University of Milan, Italy, Milano, Italy; [5]University of Milan, Department of Biomedical and Clinical Sciences, Milan, Italy

Aim
Considering the difficulties in directly measuring insulin, various surrogate markers integrating glucose, lipid profiles, and anthropometric measures have been proposed. This study aims to evaluate the diagnostic performance of the Triglycerides-Glucose Index (TyG), along with TyG-BMI, TyG-waist circumference (WC), and TyG-waist-to-height ratio (WHtR) indices, in identifying metabolic syndrome (MetS) in pediatric populations, in comparison to traditional parameters.
Methods
We retrospectively studied 746 children and adolescents (372 F/374 M) divided into different groups using the BMI z-score. Insulin resistance (IR) surrogates was calculated as: HOMA-IR, TyG, TyG-BMI, TyG-WC, TyG- waist-to-height ratio (WHtR). MetS was defined as the presence of at least 3 of the following components: BMI z-score ≥2 and/or WC/H ratio ≥0. 5; fasting blood glucose > 100 mg/dl and/or pathological HOMA-IR according to pubertal stage; dyslipidemia; hypertension.
Results
Overall prevalence of MetS was 15. 01% (112/746). MetS occurred only in children with obesity and overweight ($P = 0.004$). The Area under the ROC curve of TyG, TyG-BMI, TyG-WC, TyG-WHtR were 0. 801 ($P < 0.001$), 0. 840 ($P < 0.001$), 0. 832 ($P < 0.001$) and TyG-WHtR 0. 816 ($P < 0.001$) respectively, which was similar than that of HOMA-IR 0. 866 ($P < 0.001$).
Conclusions
The TyG, TyG-BMI, TyG-WC, and TyG-WHtR indices have shown significant potential in predicting the development of MetS among children and adolescents with overweight or obesity. These indices offer a practical approach for identifying high-risk individuals within otherwise healthy populations. Considering the high cost of insulin sensitivity testing, the triglyceride-glucose product serves as an effective and cost-efficient surrogate marker for evaluating IR in clinical settings.

The rising burden of childhood obesity: prevention could start at primary school

Tommaso Aversa[1], Debora Porri[1], Giovanni Luppino[1], Letteria Anna Morabito[2], Elisa La Rosa[2], Giorgia Pepe[1], Domenico Corica[1], Mariella Valenzise[1], Maria Francesca Messina[1], Alessandra Li Pomi[1], Aurora Lanzafame[1], Angela Alibrandi[3] & Malgorzata Wasniewska[1]
[1]Department of Human Pathology of Adulthood and Childhood, University of Messina., Messina, Italy; [2]Pediatric Unit, "G. Martino" University Hospital, Messina, Italy; [3]Department of Economics, University of Messina, Messina, Italy

Background
Physical activity (PA), dietary habits, and sleep hygiene are crucial for the prevention of childhood obesity (CO) early in life. Early prevention is foundamental to reduce the long-term health risks associated with CO, and schools can serve as an effective setting for promoting healthy behaviors. The "EpPOI: Education to Prevent CO" project aimed to investigate these factors through caregiver surveys, the Mediterranean Diet Quality Index for children and adolescents (Kid-Med), and the MOBAK assessment of functional movement skills (FMS).
Methods
Caregivers completed an online survey about their children's PA, sleep hygiene, and dietary habits. Adherence to the Mediterranean diet (MD) was assessed using the Kid-Med questionnaire. The FMS of 102 children aged 3–5 were evaluated with the MOBAK test, and caregivers rated their children's motor skills using a Likert-scale questionnaire.
Results
Diet 95 mothers completed the survey. Only 5. 3% of children achieved a Kid-Med score reflecting adequate MD adherence, despite over 50% of respondents reporting regular consumption of vegetables, fruits, legumes, and olive oil. However, 50. 5% of children consumed sweets daily, and 80% skipped breakfast. Parental perception of their child's PA significantly predicted MD adherence, with PA positively correlating with fruit ($P < 0.034$), vegetable ($P < 0.015$), and fish consumption ($P < 0.005$). **PA:** Despite 61. 1% of children regularly participating in sports activity, only 20. 5% achieved a satisfactory MOBAK total score (Score 3). Boys scored higher than girls in locomotion (Score 2) and total motor skills (Score 3) ($P < 0.026$, $P < 0.016$, respectively). A significant negative correlation was found between BMI and Score 3 ($P < 0.030$). Parents significantly overestimated their children's motor skills ($P = 0.0001$).
Conclusions
This study highlights the gap between caregivers' perceptions and the actual behaviors or abilities of pre-school children regarding lifestyle habits. Most children demonstrated low adherence to the MD, with poor dietary habits such as frequent sweet consumption and skipping breakfast. Although sports participation was common, motor skill proficiency was limited, particularly among children with higher BMI. Effective CO prevention requires an integrated approach combining adherence to healthy dietary patterns like the Mediterranean diet, enhanced parental awareness, and the promotion of physical activity. Schools, as accessible community structures, can play a pivotal role in fostering these behaviors early in life.
Keywords Physical activity, Mediterranean diet, functional movement skills, childhood obesity, childhood obesity prevention, school-based interventions.

Introduction
At the Dutch Center of Reference for Prader-Willi Syndrome (PWS) we see over 450 children and adults with PWS. One of the most challenging medical problems in PWS is obesity and its complications. In PWS, obesity is multifactorial and caused by both physical factors (low muscle mass, hypotonia, low basal metabolic rate, hormone deficiencies), medication and behavioral factors (hyperphagia). Anti-obesity drugs are thought to attenuate this hypothalamic hyperphagia. In this study, we report the effects of anti-obesity drugs in PWS.
Methods
Retrospective study among 201 young adults and adults with PWS attending the Dutch national reference center for PWS. All patients follow the same trajectory consisting of a medical questionnaire, structured interview, complete physical examination, biochemical measurements and, if needed, imaging. [1] After screening for medical problems, treatment is started. Since 2024, lifestyle coaching for people with intellectual disabilities has become available in the Netherlands and we have started to prescribe anti-obesity drugs to adults with PWS in our center. In case of obesity (BMI > 30), we offer two treatment options:
1. After routine PWS-specific food safety advice, lifestyle coaching for people with intellectual disabilities is started. After participating in this program for one year, anti-obesity drugs are started, reimbursed by the Dutch health insurance.
2. In some patients, caregivers want to start anti-obesity drugs on own costs because lifestyle is already considered optimal and routine PWS-specific food safety measures have already been taken. In that case, the lifestyle intervention program is skipped and anti-obesity drugs like GLP1-agonists (Liraglutide and Semaglutide) and Naltrexon/bupropion are prescribed.
Results
Since the start of this standard obesity approach, we have prescribed anti-obesity drugs to 28 adults with PWS aged 20-56 years. Average percentage of weight loss was 8. 7% (ranging from 0. 9 to 19. 5%) for Liraglutide, 9. 3% (ranging from 2. 9 to 23. 9%) for Semaglutide and 0. 2% (ranging from a weight gain of +3. 1% to a weight loss of 3. 4%) for Naltrexon/bupropion. The single patient on Dulaglutide lost 0. 7% of his weight. Few side effects were reported and no serious gastrointestinal problems were reported.
Conclusion
Anti-obesity drugs can have a beneficial effect on weight in people with PWS. However, the effect is heterogeneous and external control of food intake seems to be more important than the medication.

Granada, Granada, Spain

Obesity is one of the key factors associated with colon cancer development independent from inherited genetic mutations. Furthermore, obesity-related unhealthy lifestyle behaviors (e. g., low physical activity and fitness or an unhealthy diet) significantly increase the risk of postoperative complications in patients undergoing surgery, the first-line treatment for colon cancer. These complications affect more than 50% of patients, leading to higher morbi-mortality rates, increased healthcare costs and a reduced quality of life. For that, lifestyle-based prehabilitation multimodal programs (PMP) (exercise, dietary behavior changes and psychological support) have been proposed to improve physiological reserve and postoperative recovery, and to reduce risk factors for cancer recurrence. However, the molecular mechanisms underlying these types of interventions remain unexplored. The aim of this study was to analyze the effects of a 4-week PMP on the expression of key tumor-related genes in patients undergoing resection of colon cancer. For this purpose, we analyzed mRNA expression of 93 genes (microfluidics-based qPCR array) involved in tumor environment, development and progression (e. g., tumor markers, inflammation, immune system, or energy metabolism) in tumor and non-tumoral adjacent tissues from patients with colon cancer ($n = 48$; including both men and women) randomly assigned to a PMP ($n = 23$) or a usual care ($n = 25$). Statistical associations with key clinical features of colon cancer were performed. The results revealed a significant beneficial regulation of the pattern of genes expression in patients undergoing PMP, which have been previously described to be altered in the context of this pathology.

These beneficial patterns include genes (i) involved in the regulation of intracellular calcium (*CALB2*), (ii) associated with inflammation and immune response regulation (*TGFB1*, *VASN*, *TNFa*, *IL6ST*, *IL6R*, *PTGS2*, and *SPP1*), (iii) potent growth factors promoting cell proliferation, survival, and differentiation (*IGF1* and *IGF2*), (iv) related to metastatic processes in the liver and lungs (*CXCL12*), and (v) involved in tumor suppression and apoptosis (*TP53* and *BCL2*), among others. Additionally, many of these genes were correlated with pivotal clinical and histopathological parameters, such as body weight or tumor volume. In conclusion, a 4-week PMP modulates the expression of relevant cancer-related genes in patients with colon cancer compared with those receiving usual care. These changes correlated with clinical parameters of the patients. Although further research is needed in this area, this transcriptional regulation may help explain the beneficial outcomes observed with the PMP in the ONCOFIT Project.

JOINT2229

Comparison of insulin resistance indices in obese children and adolescents based on a 10-year data

Berna Eroğlu Filibeli[1], Gülümay Vural Topaktaş[1], Julide Gulizar Yıldırım Duman[2] & Bumin Nuri Dündar[2]

[1]Izmir City Hospital, Department of Pediatric Endocrinology, Izmir, Türkiye; [2]Izmir Katip Celebi University, Izmir, Türkiye

Objective

The increasing prevalence of childhood obesity and the development of insulin resistance (IR) and type 2 diabetes mellitus (T2D) are major public health concerns. The aim of this study was to compare the HOMA, FGIR and QUICKI indices for measuring IR in obese children and adolescents according to oral glucose tolerance test (OGTT) Results

Methods

Patients attending the Pediatric Endocrinology Clinic with exogenous obesity and undergoing OGTT in the last 10 years were included in the study. Patients' data were obtained retrospectively from hospital records. The children were divided into two groups according to the presence or absence of IR. The HOMA, FGIR and QUICKI methods were analysed to confirm the OGTT findings of IR in these groups. Receiver operating characteristic curve (ROC) analysis was used to determine cut-off points and to calculate sensitivity and specificity for IR.

Results

A total of 899 obese children (568 girls and 331 boys, mean age 14. 06 ± 2. 06 years) were included in the study. IR was diagnosed in 76. 3%, impaired fasting glucose (IFG) in 11. 3%, impaired glucose tolerance (IGT) in 13. 9% and T2D in 5. 8% of the children. 708 cases were assessed for metabolic syndrome and 195 (27. 5%) children were diagnosed with MS. The rates of akantozis nigrikans (60. 5% & 17. 2%) and hepatic steatosis on ultrasound (50. 7% & 12. 8%) were higher in the IR group (p:0. 045 and p:0. 009). Triglycerides were higher in the IR group than in the non-IR group, while other cholesterol levels were similar ($P < 0.001$). Notably, the rates of IFG, IGT and T2D were not significantly different between groups ($p > 0.05$). The HOMA and QUICKI indices were higher in the IR group, while the FGIR values were similar ($P < 0.001$, $P < 0.001$ and p:0. 057, respectively). Among the incidences, the area under the curve (AUC) was higher for HOMA-IR (0. 711 for girls and 0. 7 for boys) compared to FGIR (0. 278 for girls and 0. 262 for boys) and QUICKI (0. 289 for girls and 0. 306 for boys). The HOMA-IR cut-off value was 4. 22 (70% sensitivity and 30% specificity) in pubertal girls and 4. 18 (70% sensitivity and 30% specificity) in pubertal boys.

Conclusions

HOMA is a more accurate measure of IR in children and adolescents than FGIR and QUICKI. For the diagnosis of IR, the HOMA threshold is 4. 22 in girls and 4. 18 in boys based on OGTT Results The OGTT remains important in the diagnosis of insulin resistance, pre-diabetes and T2D, despite being an invasive method.

Western diet-induced effects on renal glucose and sodium transporters - a novel mechanism in pathophysiology of the metabolic syndrome

Chiara Salvà[1], Sabrina Folie[1], Bernhard Radlinger[1], Karin Salzmann[1], Gabriele Staudacher[1], Claudia Ress[1] & Susanne Kaser[1]

[1]Medical University of Innsbruck, Department of Internal Medicine I, Innsbruck, Austria

Background

Western diet which is characterized by a high content of sugar and saturated fat is well known to be associated with obesity, insulin resistance, type 2 diabetes and cardiovascular disease. While chronic kidney disease has long been thought to be the consequence of metabolic disease, it has only recently become clear, that renal damage at an early stage plays a key role in pathophysiology and course of metabolic disease. Underlining the close correlation, SGLT-2 inhibitors and GLP-1 receptor agonists have been shown to improve both, metabolic disease and chronic kidney disease.

Aim

Here we aimed to test whether Western diet causes renal damage by affecting hemodynamically and metabolically important renal transporters in a murine model of diet-induced obesity. Additionally, we aimed to test whether potential harmful effects are reversible by switching the diet from a Western type to a more beneficial one.

Method

Male C57BL/6 mice were fed ad libitum a Western diet for 10 weeks and afterwards switched to either standard diet for eight more weeks or continued to be fed a Western diet. Mice fed standard diet for 18 weeks served as control group.

Results

Western diet feeding for 18 weeks was associated with excess weight gain and development of insulin resistance. Sodium glucose transporter 1 (SGLT1) mRNA expression was significantly higher in kidneys of mice fed a Western diet for 18 weeks than in standard diet fed mice and those switched from Western diet to standard diet after 10 weeks. Additionally, renal sodium glucose transporter 2 (SGLT2) levels were also found to be elevated in Western diet fed mice, showing an already significant difference after 10 weeks and even higher levels after 18 weeks. Importantly, renal SGLT-2 mRNA expressions were comparable in mice fed a Western diet for 18 weeks and in those switched from Western diet to standard diet. Complementary to the upregulation of SGLT2 a downregulation of renal epithelial sodium channel (ENaC) mRNA was observed, which could not be prevented by the dietary switch neither.

Conclusions

Our data show that Western diet causes partially irreversible alterations in renal glucose and sodium transporters that might play a crucial role in development and course of metabolic disease. Importantly, SGLT-2 overexpression occurs early and is not dependent on overt hyperglycemia.

Mesothelial cells act as critical mediator in hyperandrogenism-induced visceral obesity

Hannah Hui[1]

[1]The Chinese University of Hong Kong, Hong Kong, Hong Kong

Androgen excess is a common endocrine disorder in women and drives a selective expansion of visceral adipose tissue (VAT). Mesothelial cell is only present in visceral but not subcutaneous adipose tissues. But its function is poorly understood. Single cell RNA sequencing (scRNA-seq) reveals a dramatic decrease in VAT mesothelial cell number upon androgen excess-induced obesity. This is in accompany of a malformation of extracellular matrix (ECM) in the VAT of female mice. Female mice with mesothelial cell-specific deletion of androgen receptor (*Ar*) are resistant to androgen excess-induced visceral obesity and ECM malformation. Depletion of mesothelial cells in VAT directly impairs ECM formation, accompanied by VAT gain and metabolic disorders even on a normal diet, highlighting the key function of mesothelial cells in VAT ECM formation. Furthermore, VAT organoids deficient of mesothelial cells exhibit compromised ECM formation and enhanced adipogenesis, which are reversed by mesothelial cell conditioned medium. Mechanistically, mesothelial cells abundantly secret proteoglycan Decorin (DCN), which is indispensable for ECM formation in VAT. Normalizing DCN expression in VAT rescues androgen excess-induced ECM malformation, visceral obesity and insulin resistance in female mice. These findings reveal the intermediatory function of mesothelial cell in aiding proper ECM formation and its implication in hyperandrogenism-induced visceral obesity.

Sex-specific effects of different dietary compositions and NO-synthase inhibition on mitochondrial respiration and cellular redox state in HFPEF and MASLD

Palina Zytner[1], Michael Kohlhaas[2], Alexander Nickel[2], Niklas Geiger[1], Viktoria Kenner[2], Mia Külzer[2], Jana Gerner[2], Aisha Landthaler[2], Maria Popp[2], Annika Engelhardt[2], Christoph Maack[2], Vasco Sequeira[2] & Ulrich Dischinger[1]
[1]University Hospital of Würzburg, Würzburg, Germany; [2]Comprehensive Heart Failure Center, Würzburg, Germany

Background
Obesity is closely linked to heart failure with preserved ejection fraction (HFpEF) and metabolic-dysfunction associated steatotic liver disease (MASLD). A model combining diet-induced obesity with L-NAME–induced hypertension may replicate HFpEF and MASLD conditions effectively. However, the optimal dietary composition and duration for inducing these diseases remain uncertain. This study evaluates the impact of various diets combined with L-NAME, a pan-nitric oxide synthase inhibitor, on HFpEF and MASLD characteristics in male and female Wistar rats.
Methods
Male and female Wistar rats were assigned to receive either standard chow (CO), standard chow with L-NAME, low-fat diet (LFD + L-NAME), or high-fat, high-fructose diet (HFD) with or without L-NAME. HFD groups had ad libitum access to HFD or LFD. Isolated cardiomyocytes were evaluated for mitochondrial redox state. Isolated cardiac and hepatic mitochondria were subjected to high-resolution respirometry to assess oxygen consumption and ROS emission.
Results
In male rats, the HFD group exhibited an oxidized cardiac mitochondrial redox state, indicative of increased metabolic demand compared to CO, while effects of LFD and L-NAME alone were less visible. Cardiac mitochondrial respiration was effectively impared in the HFD group. In contrast, hepatic mitochondrial respiration was significantly elevated in the HFD group compared to CO but only partially affected by LFD and L-NAME. In females, the mitochondrial redox state was more reduced across all conditions compared to CO, indicating lower mitochondrial demand or increased metabolic redundancy. Mitochondrial respiration was paradoxically elevated in all intervention groups compared to controls. Hepatic mitochondria from the HFD group exhibit significantly more oxygen compared to CO.
Conclusions
The combination of HFD and L-NAME induces HFpEF and MASLD characteristics with distinct sex-specific effects. This investigation is crucial for developing future therapeutic strategies and underscores the importance of analyzing sex-specific differences, which can significantly influence treatment outcomes in patients with HFpEF and MASLD.

Cardiometabolic profile between metabolically healthy obese (MHO) vs metabolically unhealthy obese (MUO) adolescents

Giuseppe d'Annunzio[1], Amanda Casirati[1], Giacomo Tantari[1], Valentina Petrone[2], Alessandro Suppa[2], Margherita Di Jorgi[2], Marco Del Monte[2] & Mohamad Maghnie[2]
[1]Pediatric Clinic and Endocrinology Unit, IRCCS Istituto Giannina Gaslini, Genoa, Italy; [2]DINOGMI (Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health), University of Genoa, Genoa, Italy

Background
Pediatric and adolescent obesity is a worldwide pandemia. Since the majority of adolescents with obesity will be an adult with the same condition and its complications, a precocious identification of cardiovascular risk factors is mandatory. Our aims were to evaluate the frequency of MHO vs MUO in children and adolescents with obesity followed in our Pediatric Clinic and to compare the cardiometabolic profile.
Patients and Methods
We evaluated 149 patients (52% males) median age 13 years (range 5–18), 16% Tanner stage 1, 38% Tanner stages 2-4, and 46% Tanner stage 5. Data on body mass index (BMI), waist-to-height ratio (WHtR), and laboratory tests were collected. MHO phenotype includes HDL cholesterol (HDL-C) >40 mg/dl, fasting plasma glucose (FPG) <100 mg/dl, Systolic and Diastolic Blood Pressure (SBP and DBP) $< 90°$ percentile by gender, height and age, triglycerides ≤ 100 mg/dl or <130 mg/dl for aged <10 or >10 years, respectively. MUO phenotype included impaired of at least one of the above parameters. As marker of cardiovascular risk was SPISE, calculated using the formula: [600 × (HDL cholesterol^0. 185)/(triglycerides^0. 2) × (BMI^1. 338)].
Results
In the whole cohort, 40% of patients had elevated BP, 34% low HDL-C, 20% elevated triglycerides, and 9% elevated FPG. MUO phenotype was in 101 (68%) patients, with Tanner stages 2-5 more represented than Tanner stage 1 (78% vs 22%, $P = 0.016$). A high prevalence of elevated SBP/DBP was observed (59%, $P < 0.001$). MUO phenotype showed higher levels of BMI-SDS (2. 9 [2. 3;2. 9] vs 2. 6 [2. 5;3. 5], $P = 0.004$), WHtR (0. 59 [0. 55;0. 66] vs 0. 57 [0. 53;0. 62], $P = 0.029$), SDP (119 [113;126] vs 109 [103;115], $P < 0.001$) and DBP (68 [62;76] vs 62 [59;68], $P = 0.001$), FPG (92 mg/dl [88-96] vs 89 mg/dl [85-93], $P = 0.004$), Hb1Ac (5. 3 % [5. 0-5. 5] vs 5. 0 % [4. 8-5. 3], $P = 0.002$), and triglycerides (90 mg/dl [65-130] vs 65 [53-85], $P < 0.001$). Conversely, MUO exhibited lower HDL-C (41 mg/dl [37-47] vs 49 mg/dl [45-58], $P < 0.001$) and SPISE (4. 8 [3. 9-5. 8] vs 5. 6 [4. 9-6. 5], $P = 0.003$). After adjusting for pubertal status, WHtR, and hypertension, SPISE emerged as an independent predictor of MUO ($Or = 0.39$ [95%CI 0. 21-0. 75], $P = 0.004$). The area under the ROC curve of SPISE in predicting the MUO phenotype was 0. 65 (95%CI 0. 56-0. 74, $P = 0.003$).
Conclusions
The MUO phenotype showed a worse cardiometabolic profile than the MHO phenotype; SPISE appears to effectively capture the metabolic component of the increased cardiometabolic risk. Given the high prevalence of hypertension, routine BP monitoring is crucial in optimizing risk stratification of the MUO subset.

Role of AMPK in preserving metabolic homeostasis in visceral adipose tissue and skeletal muscle in a PCOS rat model

Bojana Mićić[1], Ana Teofilović[1], Nataša Veličković[1], Ana Djordjevic[2], Djuro Macut[3] & Danijela Vojnović Milutinović[1]
[1]Institute for Biological Research "Siniša Stanković" - National Institute of the Republic of Serbia, University of Belgrade, Department of Biochemistry, Belgrade, Serbia; [1]Institute for Biological Research "Siniša Stanković" - National Institute of the Republic of Serbia, University of Belgrade, Department of Biochemistry, Belgrade, Serbia; [3]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Introduction
Polycystic ovary syndrome (PCOS) is a common endocrine and metabolic disorder affecting women of reproductive age. Early manifestations of the syndrome emerge before puberty, often in conjunction with obesity, which, in the presence of hyperandrogenemia and/or hyperinsulinemia during adolescence, contributes to the full manifestation of PCOS in adulthood. To elucidate the contributions of prepubertal obesity and hyperandrogenemia to the development of metabolic disturbances in PCOS, we analysed lipid and glucose metabolism in the main insulin-responsive tissues (visceral and subcutaneous adipose tissue (VAT and SAT), skeletal muscle) in a well-established PCOS animal model.
Methods
Female Wistar rats were subjected to postnatal overfeeding via litter size reduction and treated with 5α-dihydrotestosterone (DHT) to induce PCOS-like features. Systemic insulin sensitivity was assessed alongside the expression of key markers of glucose and lipid metabolism, and energy sensing, like AMPK activation, in VAT, SAT, and skeletal muscle.
Results
Litter size reduction led to increase in body mass and visceral adiposity, while DHT treatment combined with overfeeding resulted in systemic insulin resistance and hyperinsulinemia. In VAT, both litter size reduction and DHT treatment contributed to adipocyte hypertrophy, along with a suppression of *de novo* lipogenesis (reduced gene expression of lipogenic enzymes) and lipolysis (decreased hormone-sensitive lipase), while insulin sensitivity was preserved due to AMPK activation. Conversely, SAT exhibited increased expression of

lipogenic and lipolytic markers and reduced AMPK activity, suggesting an impaired metabolic profile in this tissue as a result of effect of both factors, litter size reduction and DHT treatment. In skeletal muscle, insulin signalling was disrupted at key nodes (pIRS1-Ser307, AKT) in overfed animals, while DHT treatment reduced glucose transport (decreased GLUT4 expression), leading to diminished glucose uptake and systemic hyperinsulinemia. In this altered energy landscape, as result of effects of both factors, skeletal muscle preferentially utilised fatty acids for energy, indicated by enhanced fatty acid uptake and increased markers of lipolysis and α-oxidation. However, this shift induced oxidative stress and inflammation, and triggered AMPK activation as a compensatory mechanism that maintain metabolic homeostasis.

Conclusion

AMPK emerges as a critical metabolic regulator that acts as a protective mechanism in VAT and skeletal muscle to counteract metabolic stress and maintain tissue functionality. The differential regulation of AMPK in VAT and SAT highlights its tissue-specific role in PCOS-associated metabolic disturbances. Given its pivotal function, targeted activation of AMPK may represent a promising therapeutic strategy to improve metabolic health in women with PCOS.

Piezo1 activation suppresses bone marrow adipogenesis for healthy skeleton through inhibition of a mechanoinflammatory autocrine loop

Baile Wang[1], Jie Liu[1], Malika Arhatte[2], Lai Yee Cheong[1], Edyta Glogowska[2], Xue Jiang[1], Qin Wang[1], Eric Honoré[2] & Aimin Xu[1]
[1]State Key Laboratory of Pharmaceutical Biotechnology, The University of Hong Kong, Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; [2]Université Côte d'Azur, Centre National de la Recherche Scientifique, Institut national de la santé et de la recherche médicale, Institut de Pharmacologie Moléculaire et Cellulaire, Valbonne, France

With aging or upon osteoporosis, bone marrow adipogenesis is enhanced and inversely correlates with the loss of bone mass. Bone marrow adipocytes are derived from the multipotent bone marrow mesenchymal stem cells (BMMSCs), which can differentiate into either fat or bone. BMMSCs are mechano-sensitive cells, but how mechanical loading is implicated in the *in vivo* regulation of bone marrow adipogenesis and its impact on bone remodeling remains poorly understood. Here we identify the mechanosensitive cationic channel Piezo1 in BMMSCs as a key suppressor of bone marrow adipogenesis by preventing local inflammation, thereby enhancing osteoblast differentiation and bone formation. Mice with a specific Piezo1 invalidation in BMMSCs exhibit lower body weight, osteoporosis, and marrow adiposity, together with a resistance to the beneficial effects of exercise on bone health. Accordingly, Piezo1-deficient BMMSCs *In vitro* preferentially differentiate into adipocytes rather than osteoblasts. Mechanistically, Piezo1 invalidation enables c-Jun activation to increase Ccl2 production, while autocrine activation of CCR2 by Ccl2 induces the expression and secretion of lipocalin-2 (Lcn2) via NF-κB activation, thereby promoting BMMSCs adipogenesis. Conversely, pharmacological inhibition of Ccl2 signaling and shRNA-mediated knockdown or antibody-mediated blockage of Lcn2 inhibit adipogenesis but restore osteogenesis in Piezo1-deficient BMMSCs. Collectively, these findings demonstrate that Piezo1 activation in BMMSCs suppresses bone marrow adipogenesis to maintain skeleton strength by preventing the Ccl2-Lcn2 inflammatory autocrine loop, thus uncovering a previously unrecognized link between mechanotransduction, inflammation, and cell fate determination.

The visceral adipose-derived hormone ANNEXIN A8 alleviates obesity-induced chronic inflammation via modulating macrophage functions

Ping Gu[1], Xuemei Zhao[2], Wei Wang[1], Bin Lu[1] & Jiaqing Shao[1]
[1]Nanjing Jinling Hospital, Nanjing, China; [2]School of Biomedical Sciences, The Chinese University of Hong Kong, Hong Kong, China

Obesity is a major risk factor for a panel of chronic diseases and thus is becoming a major challenge worldwide. In particular, abnormally high level of visceral adipose tissue (VAT) deposition, known as visceral obesity, is an independent risk factor for metabolic diseases. We found that *Annexin A8* (*Anxa8)* gene is selectively induced in VAT of obese mice. The transcription of ANXA8 is induced by hypoxia. Mice with adipocyte-selective deletion of *Anxa8* are more susceptible to diet-induced glucose intolerance and chronic inflammation. Simillarly, neutralization of circulating ANXA8 exacerbates diet-induced metabolic diseases. Conversely supplementation of recombinant ANXA8 protein protects mice against diet-induced glucose intolerance and chronic inflammation. Mechanistically ANXA8 directly modulates macrophage polarization via activation of AMPK pathway. In human serum ANXA8 concentration was positively correlated with VAT amount, and VAT/SAT ratio, but was less correlated with subcutaneous adipose tissue (SAT).

Recommendations for screening for polycystic ovarian syndrome (PCOS) in adolescents with obesity: are national and international management guidelines aligned?

Carey Yun Shan Lim[1], Nicholas Beng Hui Ng[1, 2], Kah Yin Loke[1, 2] & Yung Seng Lee[1, 2]
[1]Department of Paediatrics, Khoo Teck Puat—National University Children's Medical Institute, National University Health System, Singapore, Singapore, Singapore; [2]Department of Paediatrics, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, Singapore

Introduction

Polycystic Ovarian Syndrome (PCOS) may affect up to 18% of adolescent girls and has significant implications on reproductive, metabolic and mental health. The diagnosis of adolescent PCOS is challenging due to differing criteria and manifestations. Adolescents with obesity are at higher risk of PCOS and should be screened accordingly. However, screening for obesity-associated comorbidities, including PCOS, have not been standardized. A scoping review was conducted to evaluate and compare the presence and extent of recommendations for PCOS screening and management in national and international guidelines for pediatric obesity, and to summarize recommendations from guidelines developed specific to adolescent PCOS.

Methods

A scoping review protocol was developed in accordance with the PRISMA extension for scoping reviews checklist. Databases searched included: PubMed, MEDLINE, Embase, the Cumulative Index to Nursing and Allied Health Literature and various guideline repositories. The inclusion criteria include (1) national or international guidelines, consensus or position statements written by government, professional bodies or expert panels, and (2) pertained to the clinical management of paediatric obesity or adolescent PCOS, and (3) published in English or with available English translations. The Appraisal of Guidelines for Research and Evaluation (AGREE)-II instrument was used for quality assessment of the included articles. Recommendations for the screening and management of PCOS in adolescents with obesity were made, with certainty of evidence ascribed using the Grading of Recommendations, Assessment, Development and Evaluations (GRADE) approach.

Results

Fourteen of 32 international childhood/adolescent obesity guidelines included some mention of PCOS screening and/or management, and 7 adolescent PCOS specific guidelines were summarized. Details of recommendations varied across the guidelines, even in the PCOS-specific guidelines. Based on the strength and quality of evidence presented, we summarize key recommendations for PCOS screening and management: (1) Perform a comprehensive menstrual history for overweight or obese patients, (2) Assess onset and progression of hirsutism, and onset and severity of cystic or inflammatory acne, (3) PCOS-specific investigations include serum free/total testosterone and sex hormone-binding globulin, (4) Routine pelvic ultrasound and serum anti-Mullerian hormone measurements are not recommended in adolescents, (5) Individualised PCOS management with weight management as a cornerstone, (6) Combined oral contraceptives and metformin may be useful for management.

Conclusion

Adolescent obesity and PCOS guidelines have been inconsistent with the recommendations on PCOS screening management. Given the significant morbidities associated with PCOS, appropriate screening and prompt management is essential and should be part of routine care in adolescents with obesity.

Background
Pubertal timing is influenced by a variety of factors, including body composition. While body mass index (BMI) is commonly used as a marker of adiposity, fat percentage (BF%) may be more strongly associated with pubertal onset in children. Notably, BF% increases with pubertal development, a trend most pronounced in girls. This study aims to evaluate the association between BF% and timing of pubertal onset.
Methods
In total, 1, 007 children and adolescents (59% girls) aged 12. 8 years (5. 9-23. 4) from The COPENHAGEN Puberty Study were included. Besides a clinical examination including pubertal staging, key anthropometric variables, such as BMI, skinfold measurements, and hip/waist ratio, were recorded. BF% was estimated using Slaughter's equation for skinfold thickness, and pubertal onset was defined by the age of thelarche in girls (>B2) and testis volume >3 ml (> G2) in boys. Sex and age-related SD scores for BF% were calculated using the GAMLSS methods to analyze the relationship between age- and sex adjusted BF% in relation to pubertal timing. Probit regression models were employed to estimate the age of pubertal onset according to differences in BF% quartiles.
Results
BF% and BMI correlated positively with age in girls (spearman rho $\rho = 0.46$, $P < 0.01$ and $\rho = 0.67$, $P < 0.01$, respectively). Similarly in boys, BMI correlated positively with age ($\rho = 0.66$, $P < 0.01$), whereas no correlation was seen for BF% and age in boys. Furthermore, girls generally had higher BF% and hip/waist ratio compared to boys; 19. 8% vs. 16. 9%, $P < 0.01$) and 1. 3 vs. 1. 1 in hip/waist ratio ($P < 0.01$). Significant lower age of pubertal onset was observed with the highest BF% in boys (mean age Q1: 12. 2 years vs. Q4: 11. 4 years, $P < 0.01$) and in girls (mean age Q1: 10. 0 years vs. Q4: 9. 8 years, $P < 0.01$) although less pronounced.
Conclusion
In healthy Danish children, a higher BF% was associated with an earlier age of pubertal onset. However, due to the cross-sectional design, causality cannot be determined. It is possible that increased BF% accelerates pubertal onset, or that earlier puberty leads to higher BF%. These findings highlight the important role of body composition in pubertal development and its timing.

Effect of oral glucose administration on ghrelin levels in normal heigh children born small for gestational age being in the first decade of their life

Paula Smalczewska[1], Anna Fedorczak[1], Magdalena Grobelna[1], Małgorzata Szałapska[1] & Renata Stawerska[1, 2]
[1]Polish Mother's Memorial Hospital - Research Institute, Łódź, Poland; [2]Medical University of Lodz, Department of Pediatric Endocrinology, Łódź, Poland

Introduction
Ghrelin is responsible for GH production and appetite stimulation. Ghrelin secretion is dependent on food intake, increases in the fasting state and decreases after meals. Ghrelin reduces energy expenditure and lipolysis and promotes weight gain. However, studies have shown that ghrelin levels are lower in obese individuals, whereas in leaner individuals they are higher than in controls. It seems that ghrelin may have a greater effect on postprandial satiety than on preprandial appetite stimulation. Some (but not all) small for gestational age (SGA) children who demonstrated catch-up phenomenon after birth, develop increasing obesity and elements of the metabolic syndrome. We therefore suspect an association between higher ghrelin levels and faster growth and weight gain in SGA children. The aim of the study was to assess fasting ghrelin levels and the degree of its reduction during oral glucose tolerance test (OGTT) in 5-9-year-old SGA children depending on BMI and the presence of metabolic syndrome components.
Material and Methods
91 prepubertal SGA children (34 boys and 57 girls) aged 4. 78-9. 75 years (6. 9 ± 1. 37 years) were qualified for the study. Height, body weight, waist circumference, and blood pressure were measured in each child. Fasting triglyceride and HDL-cholesterol levels were assessed. Glucose, insulin, and ghrelin levels were estimated fasting and during the (OGTT). Based on the obtained results, BMI SDS, waist-to-height ratio, and HOMA-IR were calculated.
Results
Ghrelin levels decreased significantly during OGTT [1859 (1356 – 3532) vs 1233 (953 – 1765), $P = 0.0000$]. In obese children (BMI SDS>2), fasting ghrelin levels were significantly lower than in nonobese children [1491 (1179 – 2917) vs 2197 (1539 – 3874), $P = 0.0021$], but decreased significantly more during the test [431 (163 -790) vs 693 (357 – 1798), $P = 0.0058$]. There was no difference in fasting ghrelin levels and ghrelin decrease during OGTT between groups with respect to the presence of visceral obesity, high triglyceride levels, low HDL cholesterol levels or tendency to high blood pressure. We found weak, negative correlations between fasting ghrelin levels and: BMISDS ($r = -0.25$), HOMA-IR ($r = -0.2$), insulin levels at 0' ($r = -0.21$) and 120' ($r = -0.24$) of the OGTT; as well as between ghrelin levels at 120' and insulin at 120' ($r = -0.2$).
Conclusion
Ghrelin levels in SGA children aged 5 to 9 years decreased significantly during OGTT, and this decrease was more profound in obese children. Further studies are needed to determine the impact of this finding on the improvement in growth rate and the development of metabolic disorders in SGA children.

Cord blood exosomal miRNAS from small-for-gestational-age newborns associate with measures of subsequent catch-up growth and insulin resistance

Marta Díaz[1, 2], Tania Quesada[3, 4], Francesc Villarroya[3, 5], Abel López-Bermejo[6], Francis de Zegher[7], Lourdes Ibáñez[1, 2] & Paula Casano-Sancho[1, 2]

Introduction
Infants born small-for-gestational age [SGA, birth weight (BW) ≤-2 SD for gestational age (GA)] who experience marked catch-up growth are at risk for subsequent insulin resistance and body adiposity. The mechanisms underlying these associations are not fully delineated. Exosomes are extracellular vesicles mediating intercellular communication, and their cargo (including DNAs, RNAs and proteins) may contribute to altered crosstalk among tissues. We tested in SGA infants whether the profile of exosomal miRNAs at birth differs from that in AGA infants and, if so, whether differentially expressed miRNAs in SGA newborns associate with measures of catch-up growth and insulin resistance up to the postnatal ages of 4 and 12 months.
Subjects and Methods
miRNAs profile in cord blood-derived exosomes was assessed by high-throughput small-RNA sequencing in 10 SGA and 10 appropriate-for-gestational-age (AGA, birth weight between -1 SD and + 1 SD for GA) infants. Differentially expressed miRNAs with a $\log_2$ fold change ≥2. 4 or ≤-2. 4 were validated by RT-qPCR in 40 AGA and 35 SGA infants and correlated with anthropometric, body composition (by DXA) and endocrine-metabolic [glucose, insulin, HOMA-IR] parameters at the postnatal ages of 4 and 12 months. Target genes prediction for all differentially regulated miRNAs was obtained with the miRSystem and enrichment analysis was performed using DAVID software.
Results
Six exosomal miRNAs were found to be differentially expressed in SGA infants who subsequently developed spontaneous catch-up growth; miR-1-3p, miR-133a-3p and miR-206 were down-regulated (all P <0. 0001 vs AGA) whereas miR-372-3p, miR-519d-3p and miR-1299 were up-regulated (P between 0. 03 and <0. 0001 vs AGA). The target genes of these miRNAs relate to insulin, RAP1, TGF-

beta and neurotrophin signaling. Receiver operating characteristic (ROC) analysis disclosed that these miRNAs could distinguish SGA from AGA infants (0. 65< AUC<0. 99; P between 0. 03 and <0. 0001). The expression levels of these miRNAs associated with BMI and HOMA-IR at 4 and 12 months of age (P between 0. 01 and <0. 001). Up-regulated miRNAs in SGA newborns associated also with gains of total and abdominal fat during infancy (all P between 0. 05 and 0. 009).

Conclusion

The exosomal miRNA profile of SGA infants at birth was found to differ from that of AGA infants, and to associate with measures of catch-up growth, insulin resistance, and body adiposity into late infancy. Further follow-up will disclose to which extent these associations persist into childhood, puberty and adolescence.

JOINT256

Comparative analysis of GLP-1 receptor agonists, traditional glucose-lowering medications and traditional anti-obesity medications on skeletal outcomes in obese individuals with and without type 2 diabetes: a five-year propensity-score matched cohort study

Jo-Ching Chen[1], Yu-Nan Huang[1], Min-Yu Tsou[2], Shao-Chia Chen[3], Shun-Fa Yang[3], Yen-Liang Liu[2] & Pen-Hua Su[1]

[1]Chung Shan Medical University Hospital, Taichung, Taiwan; [2]China Medical University, Taichung, Taiwan; [3]Chung Shan Medical University, Taichung, Taiwan

Background

The impact of newer anti-obesity medications on skeletal health remains incompletely understood, particularly in populations with varying metabolic profiles.

Methods

We conducted a five-year cohort study examining skeletal health outcomes in two distinct populations: obese individuals with type 2 diabetes (T2D) receiving semaglutide vs conventional glucose-lowering medications (sitagliptin, empagliflozin, glipizide), and obese individuals without T2D receiving semaglutide vs traditional anti-obesity medications (Contrave, phentermine, Qsymia). Primary outcomes included osteoporosis, osteoarthritis, gout, and bone density disorders. Risk assessment was performed using crude and multivariable-adjusted Cox proportional hazards models, with results presented as hazard ratios (HRs) and 95% confidence intervals (CIs). Kaplan-Meier curves were constructed to visualize cumulative incidence, with statistical significance assessed via log-rank tests. To address multiple testing concerns across nine skeletal outcomes, we applied Bonferroni correction, setting the adjusted significance threshold (padj). E-values were calculated for significant associations to assess unmeasured confounding.

Results

In obese individuals with T2D, semaglutide demonstrated a protective effect against osteoporosis (HR 0. 61, 95% CI 0. 38-0. 97) and gout (HR 0. 63, 95% CI 0. 44-0. 90) compared to sitagliptin. The relationship was particularly robust for gout outcomes (E-value 2. 51). No significant differences were observed in knee osteoarthritis (HR 1. 05, 95% CI 0. 84-1. 30) or hip osteoarthritis (HR 0. 88, 95% CI 0. 65-1. 18) between treatment groups. Multiple sensitivity analyses yielded consistent Results

Conclusion

Our findings suggest differential effects of semaglutide on various skeletal health outcomes, with notable protective effects against osteoporosis and gout in obese patients with T2D. These results provide important insights for clinical decision-making in metabolic health management, particularly regarding bone health considerations in anti-obesity medication selection.

Sex differences in white adipose tissue adaptation and insulin sensitivity in a diet-induced obesity mouse model

Kasiphak Kaikaew[1], Weerapat Kositanurit[1], Chotika Mahatkomol[2], Thunyamon Tachaveerapong[2], Tanyamon Sookpantarat[2], Jenny Visser[3] & Duangporn Werawatganon[1]

[1]Faculty of Medicine, Chulalongkorn University, Center of Excellence in Alternative and Complementary Medicine for Gastrointestinal and Liver Diseases, Department of Physiology, Bangkok, Thailand; [2]Faculty of Medicine, Chulalongkorn University, Department of Physiology, Bangkok, Thailand; [3]Erasmus MC, University Medical Center Rotterdam, Department of Internal Medicine, Section of Endocrinology, Rotterdam, Netherlands

Background

Diet-induced obesity is an escalating health issue. Women have a higher prevalence of obesity than men, yet reproductive-age women have a lower incidence of metabolic diseases, including type 2 diabetes. This sex difference attenuates after menopause, suggesting protective roles of female sex hormones. However, the mechanisms by which sex hormones and high-fat, high-sucrose diet (HFD) influence white adipose tissue (WAT) adaptation, including adipokine secretion, remain to be explored.

Methods

Fifty-six C57BL/6NJcl mice [28 males (M) and 28 females (F)] were studied, with 14 per sex undergoing gonadectomy (G) and the rest receiving a sham operation (S) at 8 weeks old. After a one-week recovery, 7 mice from each group were switched to HFD for 12 weeks, while others remained on a standard chow diet (CD), resulting in 8 groups: MSC, MGC, FSC, FGC, MSH, MGH, FSH, and FGH. An intraperitoneal glucose tolerance test (IPGTT) was performed at 21 weeks old. At 22 weeks old, WAT was collected and underwent *ex vivo* insulin stimulation to assess Akt phosphorylation by Western blotting.

Results

HFD increased body weight (BW) in all groups ($P < 0.01$). Despite similar dietary calorie intake in HFD-fed groups, FSH had the least BW gain ($P < 0.01$). Fasting glucose levels were higher in males than females and were increased by HFD and gonadectomy (all $P < 0.01$). Fasting insulin levels, as well as the HOMA-IR, were significantly elevated by HFD feeding in most groups ($P < 0.01$), except sham-operated females (FSC vs. FSH, $p > 0.90$). IPGTT confirmed that HFD induced glucose intolerance ($P < 0.01$), though FSH showed better glucose tolerance than other HFD-fed groups. WAT weight increased with HFD ($P < 0.01$), being higher in males and gonadectomized mice (both $P < 0.01$). Serum leptin levels mirrored WAT mass, increasing with HFD ($P < 0.01$), being higher in males ($P = 0.02$), and elevated by gonadectomy ($P < 0.01$). Serum adiponectin levels showed a sex-specific pattern, increasing with HFD only in gonad-intact females (FSH > FSC, $P = 0.02$; FSH > MSH, $P = 0.02$), resulting in the highest adiponectin/leptin ratio among HFD-fed groups. Insulin-stimulated Akt phosphorylation in WAT explants was reduced in HFD-fed groups ($P < 0.01$), with a greater reduction in males ($P < 0.01$) than females ($P = 0.09$).

Conclusion

HFD impairs glucose homeostasis and insulin signaling in a sex-dependent manner. Gonad-intact females exhibit better metabolic adaptation under HFD, reflected by lower BW gain, better glucose tolerance, a higher adiponectin/leptin ratio, and a smaller reduction in Akt phosphorylation in WAT. These findings highlight the protective role of female gonadal hormones in metabolic adaptation to diet-induced obesity.

Characteristics of postmenopausal women with PCOS

Lorina Wieser[1], Katharina Eberhard[2], Christoph Haudum[1], Barbara Hutz[1], Nicolas Verheyen[3], Andreas Zirlik[3], Thomas Pieber[1] & Barbara Obermayer-Pietsch[1]

[1]Medical University Graz, Department Internal Medicine, Div. Endocrinology and Diabetology, Graz, Austria; [2]Medical University Graz, Core Facility Computational Bioanalytics, Graz, Austria; [3]Medical University Graz, Department Internal Medicine, Div. Cardiology, Graz, Austria

Background

Polycystic ovary syndrome (PCOS) is not limited to younger ages but persists during menopause. However, only little is known about this important lifetime for PCOS women – especially in view of a number of risk factors for metabolic and cardiovascular disease manifestations. We aimed to characterize postmenopausal women by both actual hormonal/metabolic data and medical history questionnaires in the "BioPersMed cohort" (Biomarkers in Personalized Medicine) conducted at the University Hospital of Graz to evaluate the prevalence and specificities of PCOS after the menopause.

Methods

The BioPersMed cohort has $n = 1022$ participants over 45 years of age, is a longitudinal phenotyping study with regular visits, including large endocrine, metabolic and cardiovascular/functional diagnostic panels as well as oral glucose tolerance tests with concomitant insulin and C-peptide measurements (OGTT). PCOS questionnaires included all Rotterdam criteria, e. g. menstrual regularity before menopause, known PCO morphology, but also unfulfilled child wish and other data. PCOS women were BMI-matched to non-PCOS participants to investigate further interdependencies.

Results
Out of the BioPersMed participants, $n = 305$ women met the inclusion criteria, with a typical PCOS profile in $n = 51$ women (16. 7%), according to published prevalences. Only one of them was ever diagnosed with "PCOS" in the past. BMI was significantly higher in PCOS women; they had a higher prevalence for diabetes mellitus type 2 (T2DM). BMI-matched non-PCOS controls showed significantly lower androgens, but similar SHBG and parameters of glucose metabolism. Hypertension was more prevalent in PCOS-women and an unfulfilled child wish over time was significantly higher in PCOS women with 22. 2% vs. 2. 8%, $P = 0. 024$. Further analyses are on the way.
Conclusion
PCOS in the menopause is an important cardiovascular and metabolic risk factor in up to 20% of all women. While a retrospective diagnosis of certain features of PCOS might be questionable, postmenopausal women with PCOS could largely benefit from having an individual diagnosis and guidance. The medical community should increase their awareness for these women, as biomarker and functional data are increasingly available - especially in this large group of women, who rarely had the chance of a PCOS diagnosis at an earlier age with adequate therapy options, respectively.

Evolution and determinants of metabolic phenotypes from childhood into adulthood: data from the QUALITY cohort

Solène Rérat[1, 2], Andraea Van Hulst[3], Misha Dolmatov[2, 4], Marie-Ève Mathieu[5], Tracie Barnett[2, 6], Vicky Drapeau[7], Andrea Benedetti[4] & Mélanie Henderson[1 2 8]
[1]Department of Pediatrics, Université de Montréal, Montréal, Canada; [2]Sainte Justine University Hospital Research Center, Montréal, Canada; [3]Ingram School of Nursing, mgill University, Montréal, Canada; [4]Department of Epidemiology, Biostatistics and Occupational Health, mgill University, Montréal, Canada; [5]School of Kinesiology and Physical Activity Sciences, Faculty of Medicine, Université de Montréal, Montréal, Canada; [6]Department of Family Medicine, mgill University, Montréal, Canada; [7]Department of Kinesiology, Faculty of Medicine, Université Laval, Québec, Canada; [8]School of Public Health, Department of Social and Preventive Medicine, Université de Montréal, Montréal, Canada

Introduction
The metabolic consequences of obesity in adulthood are well-documented. While some children living with obesity maintain a healthy metabolic profile, others develop complications persisting into adulthood. Conversely, healthy-weight children can also exhibit an unhealthy phenotype.
Objectives
To describe metabolic phenotype evolutions from childhood to early adulthood and identify modifiable childhood determinants of unhealthy evolutions.
Methods
The QUALITY cohort included 630 children aged 8–10 years at baseline(V1), all with at least one parent living with obesity. Participants were reassessed at 10–12 years(V2), 15–17 years(V3), and 24–26 years (V4). Biological markers, physical activity, body composition, and screen time were assessed at each visit. Metabolic phenotypes were categorized into four groups: normal-weight metabolically healthy (NWMH), normal-weight metabolically unhealthy (NWMU), metabolically healthy living with obesity (MHO), and metabolically unhealthy living with obesity (MUO), based on IDF criteria. Descriptive analyses and Markov modeling assessed phenotype evolution and transition probabilities at each visit. Multiple logistic regressions among metabolically healthy participants at V1 estimated associations between transition to metabolically unhealthy phenotypes at V4 and childhood determinants. Inverse Probability Weighting was applied to adjust for missing data.
Results
A total of 169 participants with phenotype data at all four visits were analyzed. The prevalence of unhealthy phenotypes (NWMU + MUO) increased from 31% at V1 to 57% at V4, with a 20% rise occurring between V2 and V3. MUO prevalence steadily increased, from 12% at V1 to 35% at V4. Markov modeling showed that NWMH and MUO were the most stable phenotypes, with a high probability (67% and 69%, respectively) of remaining stable to the next visit. Among metabolically healthy children at V1, regardless of baseline weight status, boys (OR = 3. 63, 95%CI:2. 0-6. 7) and those with a higher % body fat at V1 (OR = 1. 05, 95%CI:1. 02-1. 08) had higher odds of transitioning to an unhealthy phenotype at V4. Additionally, when examining changes in lifestyle habits from V1 to V2, every 10-minute increase in moderate-to-vigorous physical activity between V1 and V2 was associated with 29% (95%CI: 15-42%) lower odds of transitioning to an unhealthy phenotype at V4, after adjusting for baseline physical activity.
Conclusion
The proportion of unhealthy phenotypes nearly doubled over 16 years in this high-risk population, with puberty being a critical period for transition to an unhealthy phenotype. Early interventions, especially for boys, with an emphasis on reducing adiposity early in childhood and promoting sustained physical activity appear important to preventing the progression towards unhealthy phenotypes.

Clinical, genetic characteristics and long-term follow-up of sitosterolemia in children

Huang Shuyue[1]
[1]The Children's Hospital Capital Institute of Pediatrics, Endocrine Department, Beijing, China

Background
Sitosterolemia is a rare lipid disorder characterized by the elevated of phytosterols and LDL cholesterol, caused by mutations in the ABCG5 and/or ABCG8 genes. To get a better understanding of the disease, we summarized the clinical manifestations, laboratory examination, gene mutations and treatment effect of 12 sitosterolemia children.
Methods
The clinical features, laboratory characteristics and gene mutations of 12 children with sitosterolemia were analysed, followed up for the longest period of more than 8 years.
Results
12 patients with sitosterolemia were diagnosed in our center. These patients were aged from 4 months to 8. 3 years at diagnosis. the median age was 1. 2 years old. All patients did gene testing. 10 patients found mutations in the ABCG5 gene, 1 patients had mutation in ABCG8, and no variations was found in 1 patient. Serum Sitosterol were completed in 9 patients, and all support the diagnosis of sitosterolemia. 9 patients were managed with low cholesterol and phytosterol di*et al*one. 3 patient treated with ezetimibe or/and cholestyramine. Long term follow-up showed a decrease in total cholesterol (TC) and low density-lipoprotein cholesterol (LDL-C) in all patients, 3 patients with xanthoma disappearing in 1-2 years treatment and the remaining 4 patients showing significant decrease.
Conclusions
Xanthoma is landmark present of sitosteronism children, most our patients have mutations in the ABCG5 gene. Genetic and plant sterol profiles are of great significance for sitosteronism diagnosis. Most patients can achieve good results through dietary control. Ezetimibe and cholestyramine are effective for sitosteronism children and with relative safety.

CASP3-mediated PARP1 cleavage promotes hepatocyte apoptosis in non-alcoholic fatty liver disease

Fengyi Zhang[1], Xinhe Wang[1], Yahui Li[2], Wenlu Ma[2], Yaxin Chen[1], Yufeng Zhang[1], Jiayi Zhang[1], Xin Wang[1], Jingjing Pan[1], Yu Zhang[1], Ziyang Cheng[1], Wenbo Wang[2] & Yujie Li[2]
[1]Shandong University of Traditional Chinese Medicine, Jinan, China; [2]Second Affiliated Hospital of Shandong University of Traditional Chinese Medicine, Jinan, China

Introduction
Non-alcoholic fatty liver disease (NAFLD) is characterized by excessive hepatic triglyceride (TG) accumulation and is commonly associated with obesity and metabolic syndrome. Due to the lack of effective pharmaceutical treatments, lifestyle interventions, such as dietary control and exercise, remain fundamental for NAFLD management. Studies have shown that obesity-related NAFLD is closely linked to mitochondrial stress and hepatocyte apoptosis, with excessive hepatocyte apoptosis being a critical factor in the progression to non-alcoholic steatohepatitis (NASH). Therefore, identifying targets and drugs that inhibit hepatocyte apoptosis may help alleviate obesity and slow the progression from

NAFL to NASH. Poly(ADP-ribose) polymerase 1 (PARP1) is a key regulator of cellular stress responses involved in various physiological and pathological processes. As a substrate of the caspase-3-dependent apoptotic pathway, its cleavage product cl-PARP1 (89 kDa) plays a significant role in apoptosis. However, the role of this mechanism in NAFLD remains poorly understood.
Methods
In this study, db/db mice were used as an animal model, and FFA-induced HepG2 cells were used for *In vitro* experiments. Western blot (WB), quantitative PCR (qPCR), immunohistochemistry (IHC), immunofluorescence, apoptosis staining, and plasmid transfection techniques were employed to investigate the role of the CASP3-PARP1 apoptotic pathway in NAFLD pathogenesis.
Results
In the db/db mouse model of fatty liver and FFA-induced HepG2 cells, CASP3 was activated, leading to increased cl-PARP1 (89 kDa), elevated Bax expression, and decreased Bcl2 expression. Additionally, enhanced TRITC-dUTP red fluorescence signals indicated aggravated hepatocyte apoptosis. In HepG2 cells, overexpression of CASP3 plasmid resulted in significantly increased cl-PARP1 (89 kDa), further confirming CASP3's role in PARP1 cleavage.
Conclusion
This study demonstrates that CASP3 is activated in fatty liver, promoting hepatocyte apoptosis through the cleavage of PARP1 to generate cl-PARP1 (89 kDa). Pharmacological inhibition of CASP3 and PARP1 may slow down hepatocyte apoptosis, representing a promising therapeutic strategy for NAFLD. Further investigation into the CASP3-PARP1 pathway could provide new drug targets and therapeutic approaches for NAFLD.

Semaglutide as a promising treatment for hypothalamic obesity: a twelve-month case series on four females with craniopharyngioma

Erlend Gjersdal[1], Kristian Vistisen[1], Dorte Melgaard[2], Peter Vestergaard[1], Hermann L Müller[3] & Jakob Dal[1]
[1]Aalborg University hospital, Endocrinolgy, Aalborg, Denmark; [2]Aalborg University hospital, Aalborg, Denmark; [3]University Hospital Oldenburg, Pediatric hamatology and oncology, Oldenburg, Germany

Purpose
Patients with hypothalamic pathology often develop hypothalamic obesity, causing severe metabolic alterations resulting in increased morbidity and mortality. Treatments for hypothalamic obesity have not proven very effective, although the glucagon-like peptide-1 receptor agonist semaglutide has been shown to have positive effects. We examined semaglutide's effect on weight loss in a sample of patients with hypothalamic obesity.
Methods
Four female patients with hypothalamic obesity resulting from treatment of craniopharyngiomas were treated with semaglutide for twelve months. Whole Body Dual-energy x-ray absorptiometry scans were performed, and blood samples drawn at baseline, after six and twelve months. Semaglutide dosages were increased monthly along with tracking of body weight and eating behavior (Three Factor Eating Questionnaire, TFEQ-R18). Semi-structured interviews were conducted with the four patients to explore their quality-of-life following weight loss.
Results
BMI was reduced in all cases, with an average of 9. 8 kg/m^2 (range: 5. 8-13. 6 g/m^2) corresponding to a weight loss of 20. 9% (range: 10. 5-26. 2%) or 25. 7 kg (range: 15. 5-42. 0 kg). We found a comparable reduction in total fat mass (20. 8%, $P = 0.02$) and lean mass (17. 8%, $P = 0.04$). The patients all experienced an improved quality-of-life, including greater ease in physical activity, reduced pain and finding it easier to purchase clothing in their size. Unfavorable eating eating behaviors were reduced after 1 month of treatment (emotional eating –41 points, $P = 0.02$, uncontrolled eatin –23 points, $P = 0.11$). HbA1c and total cholesterol were significantly reduced ($P = 0.014$ for both), with stable values from 6 months on.
Conclusion
Semaglutide is a promising and safe treatment option for hypothalamic obesity, that improves eating behavior, reduces weight and improves metabolic markers.

Long term effect of setmelanotide and semaglutide on a patient with severe obesity due to 16p11. 2 microdeletion, encompassing the SH2B1 gene

Eleni Z Giannopoulou[1], Joanna Lerner[2], Kay Winner[1], Melanie Schirmer[1], Stefanie Zorn[1], Julia von Schnurbein[1], Christian Denzer[1] & Martin Wabitsch[1]
[1]Division of Pediatric Endocrinology and Diabetes, Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, Germany; [2]Institute of Human Genetics, Ulm University and Ulm University Medical Centre, Ulm, Germany

SH2B Adaptor Protein 1 (SH2B1) is an important component in the leptin-melanocortin pathway. Microdeletions in chromosome 16p11. 2, encompassing the SH2B1 gene, as well as pathogenic SH2B1 variants, are found to be associated with severe, early-onset obesity, hyperphagia, developmental delay, and insulin resistance. One year of treatment with setmelanotide (IMCIVREE™, Rhythm Pharmaceuticals), a melanocortin-4 (MC4) receptor agonist, was associated with clinically meaningful reductions in weight-related parameters in patients with heterozygous SH2B1 variants or 16p11. 2 deletion in a previous study. We present the effect of setmelanotide treatment over 4 years in an adolescent patient with severe, early-onset obesity due to a heterozygous 16p11. 2 deletion, encompassing the SH2B1 gene. The patient (female, 12 years old) presented with hyperphagia and severe obesity due to 16p11. 2 microdeletion (BMI Z score 2. 51). She had a mild developmental delay, concentration and learning deficits and displayed aggressive behavior. At the age of 9 years, treatment with metformin was initiated due to prediabetes, which progressed to T2DM at the age of 12 years. Further screening for comorbidities revealed arterial hypertension, microalbuminuria, obstructive sleep apnea syndrome, dyslipidemia, and steatotic liver disease. Treatment with setmelanotide, in the context of participation in the trial (NCT03013543, NCT03651765), was started at the age of 12 $^{7/12}$ years. During setmelanotide treatment, BMI Z score change was -0. 19 and -0. 26 at months 3 and 12 compared to baseline, respectively. During this period, HbA1c levels decreased to normal and hunger was well controlled. After month 12, BMI levels increased gradually (max. BMI Z score change: 0. 5 at month 39 from baseline), which may be attributed in part to lack of physical activity and motivation. Likewise, HbA1c levels increased up to 7. 0% and glp-1 analogues (at first liraglutide, then semaglutide) were added. Combined treatment resulted in stabilization of BMI and improvement of glycemic control. When setmelanotide administration was stopped after 4 years according to study protocol, the patient experienced sudden excessive weight gain and pronounced hyperphagia. Reintroduction of setmelanotide resulted in weight loss and good hunger control. Central body weight regulation in young patients with monogenic obesity remains challenging. Combined administration of setmelanotide and semaglutide resulted in BMI, hunger and glucose control in an adolescent patient with severe obesity and type 2 diabetes mellitus, due to a 16p11. 2 microdeletion, encompassing the SH2B1 gene. An individualized therapeutic approach, including different pharmacological regiments in combination with lifestyle intervention and psychological support, should be considered in patients with monogenic obesity.

A case report of nevus excision under setmelanotide treatment

Alessia Aureli[1], Michela Mariani[1], Sarah Bocchini[1], Francesco d'Aniello[1], Melania Manco[2] & Danilo Fintini[1]
[1]"Bambino Gesù" Children Hospital, Endocrinology and Diabetology Unit, Rome, Italy; [2]"Bambino Gesù" Children Hospital, Research unit for Preventive and Predictive Medicine, Rome, Italy

Introduction
Pro-opiomelanocortin (POMC) deficiency is a rare cause of monogenic obesity characterized by early-onset hyperphagia and severe obesity. Setmelanotide, a melanocortin-4 receptor (MC4R) agonist, is the only approved treatment for this condition. Known side effects include skin hyperpigmentation and the development of hyperpigmented nevi, due to MC1R off-target activation, raising concerns about potential skin cancer risk. Despite these known effects, no previous cases have documented the histological impact of Setmelanotide on the skin. We present the case of a pediatric patient treated with Setmelanotide who underwent surgical excision of a hyperpigmented nevus, with histological findings providing novel insights into the drug's dermatological effects. Additionally, we report the patient's weight-related outcomes during the first six months of treatment.

Methods
An 8-year-old patient with genetically confirmed POMC deficiency was treated with Setmelanotide starting from 0. 5 and up to 1 mg/d. During Setmelanotide treatment a multidisciplinary follow-up was conducted according to the Italian Medicines Agency (AIFA) monitoring register. Furthermore, weight, body mass index (BMI), and metabolic parameters were monitored over six months of therapy.
Results
During dermatological follow-up, skin hyperpigmentation and an atypical hyperpigmented nevus on the lower leg was observed (maximum diameter 0. 9 cm). The nevus was surgically excised and sent to histological analysis. Histological examination revealed a compound melanocytic nevus with junctional and dermal melanocytic proliferation, without evidence of malignant transformation. Immunohistochemistry showed MART1 and HMB45 positivity both in junctional and dermal components, weak focal p16 positivity, and preserved PRKAR1A expression. During Setmelanotide treatment the patient exhibited reduced appetite and improved hyperphagia, and BMI decreased from $+4.$ 2 SD (32. 6 Kg/m^2) to $+3.$ 8 SD (31. 3 Kg/m^2) in six months. Skin hyperpigmentation remained stable without further complications.
Discussion
This is the first reported case to document histological effects of Setmelanotide on the skin, broadening the understanding of its dermatological safety profile. Our findings support the safety and efficacy of Setmelanotide in managing patients affected by POMC deficiency and highlight the importance of regular dermatological monitoring in those receiving this treatment, particularly in the presence of hyperpigmented lesions, to exclude rare adverse events and ensure optimal management of the therapy. Further studies are warranted to assess long-term dermatological outcomes and the potential implications of off-target MC1R activation.

Early life determinants of body composition in healthy term-born children at age 5 years

Anna le Clercq[1], Inge van Beijsterveldt[1], Demi Dorrepaal[1] & Anita Hokken-Koelega[1, 2]
[1]Erasmus University Medical Center - Sophia Children's Hospital, Department of Pediatrics, Rotterdam, Netherlands; [2]Dutch Growth Research Foundation, Rotterdam, Netherlands

Background
Childhood overweight and obesity are global public health threats, with several comorbidities and adverse health outcomes. As childhood overweight and obesity are likely to track into adulthood, there is a need to understand how body composition evolves from infancy to childhood and which early life determinants influence adiposity programming. Hence, the aim of this study was to investigate how body composition tracks from infancy to childhood and to identify which perinatal, infancy, childhood and nutritional factors are associated with different body composition trajectories.
Methods
We included 346 healthy term-born children of the Sophia Pluto study, a birth cohort study in The Netherlands. Body composition was measured at 1, 3 and 6 months by air displacement plethysmography (PEA POD) and at 5 years by Dual-energy X-ray Absorptiometry (DXA). Age- and sex-adjusted Standard Deviation Scores (SDS) were calculated for Fat Mass Index (FMI) and Fat Free Mass Index (FFMI). For both variables, group tertiles were determined with the categories " high", "moderate" and "low". Odds ratios (OR) were calculated using logistic regression models.
Results
At age 5 years, 4. 6% of children had overweight or obesity based on the WHO criteria. Children in the highest FMI SDS tertile at 5 years had a median FMI SDS of 1. 06 (interquartile range [0. 69;1. 51]). A high FMI SDS tracked from age 1, 3 and 6 months to 5 years ($Or = 1.$ 67 [$P = 0.$ 036], $Or = 2.$ 55 [$p < 0.$ 001] and $Or = 3.$ 29 [$p < 0.$ 001], respectively). High FFMI SDS also tracked from age 1, 3 and 6 months to 5 years ($Or = 2.$ 36 [$p < 0.$ 001], $Or = 2.$ 20 [$P = 0.$ 001] and $Or = 2.$ 45 [$p < 0.$ 001], respectively). Association analyses of perinatal, infancy, childhood and nutritional factors with body composition trajectories will be presented at the congress.
Conclusions
Infants with a high FMI or FFMI SDS in the first 6 months of life are likely to remain in the highest tertile up to age 5 years. These data further support the presence of a critical window of adiposity and FFM programming in early infancy.

Transient infantile hypertriglyceridemia: the first case from the state of qatar

Marwa Ibrahim[1], Fatima Ali[2], Sara Osman[2], Tawfeg Bin Omran[2] & Khalid Hussain[1]
[1]Sidra Medicine, Endocrine and Diabetes, Doha, Qatar; [2]Sidra Medicine, Genetic and Genomic Medicine, Doha, Qatar

Introduction
Transient Infantile Hypertriglyceridemia (HTGTI) is a rare autosomal recessive disorder caused by **GPD1** mutations. It is, characterized by transient hypertriglyceridemia, hepatomegaly, elevated liver enzymes, and hepatic steatosis. Its pathophysiology and long-term metabolic consequences remain poorly understood, with only 31 genetically confirmed cases reported worldwide.
Case Presentation
The patient was born at term and delivered by cesarean section due to abruptio placenta. He presented at the age of 5 months with acute vomiting following a flu-like illness. Laboratory tests revealed elevated liver enzymes, prompting further investigation despite symptom resolution. Follow-up biochemical tests consistently showed hypertriglyceridemia and elevated liver enzymes. Abdominal ultrasound initially revealed hepatosplenomegaly with abnormal liver echotexture. A follow-up ultrasound demonstrated hepatomegaly with increased parenchymal echogenicity, suggestive of parenchymal disease with fatty changes. Genetic testing (WES) identified a homozygous likely pathogenic **GPD1** variant, confirming autosomal recessive HTGTI with both parents being carriers. In the family history a 6-year-old cousin had presented at 4 months with vomiting and bronchiolitis. During hospitalization, abnormal liver function tests and hepatomegaly were noted, though jaundice was absent. Investigation showed dyslipidemia and transaminitis. Initial genetic testing was inconclusive. However, a liver biopsy showed marked steatosis and fibrosis, including porto-portal bridging. whole exome sequencing identified a **GPD1** variant of uncertain significance (VUS), later reclassified as pathogenic. The biopsy showed no features of glycogen storage or metabolic disease, emphasizing the need for genetic, biochemical, and clinical correlation.
Management and Follow-Up
Management included a low-fat diet restricting long-chain triglycerides with medium-chain fatty acid supplementation. Regular monitoring of growth, development, and triglyceride levels was essential. Genetic counseling was provided to discuss the 25% recurrence risk in future pregnancies.
Conclusion
This is the first case report of HTGTI from the state of Qatar. The mechanism/s of the transient hypertriglyceridemia remains unclear and the long-term implications are also unknown. The power of WES helped with the genetic diagnosis and in terms of dietary management. Further research is needed to define its long-term metabolic consequences and optimize treatment strategies.

JOINT888
Real-world outcomes of liraglutide treatment in children with obesity: beyond weight loss

Katarina Štajer[1, 2], Jasna Suput Omladic[1, 2], Tadej Battelino[1, 2] & Primož Kotnik[1, 2]
[1]University Children's Hospital, University Medical Centre Ljubljana, Department of Endocrinology, Diabetes, and Metabolic Diseases, Ljubljana, Slovenia; [2]University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia

Background
Liraglutide is a glucagon-like peptide-1 receptor agonist used for pharmacological treatment of children with obesity.
Objective
To evaluate the effects of liraglutide treatment on anthropometric measures, body composition, and metabolic parameters in children with obesity.
Methods
This cohort study analyzed real-world clinical data from children with obesity in Slovenia who were treated with liraglutide between June 2022 and December 2024. The primary outcome measures included changes in anthropometric measurements, body composition, and metabolic parameters over six months.
Results
31 patients (13 males) had completed six months of liraglutide treatment. The average age at treatment initiation was 15. 56 $\pm$ 1. 59 years. The main outcome measures are presented in Table 1. The average loss of body mass was -5. 34 $\pm$ 6. 41% (-5. 66 $\pm$ 7. 28 kg) and the average reduction of BMI was 6. 10 $\pm$ 5. 64%. Children were assigned to 4 categories according to the percentage of body mass

Table 1: Anthropometric measurements, body composition and metabolic values before and after 6 months of treatment with liraglutide

	Month 0 Average ± SD	Month 6 Average ± SD	p value
Body mass	115. 09 ± 23. 65 kg	109. 43 ± 26. 26 kg	0. 38
Body mass SDS	+3. 97	+3. 57	0. 11
BMI	39. 46 ± 5. 84 kg/m^2	37. 15 ± 6. 55 kg/m^2	0. 15
BMI SDS	+3. 50	+3. 22	0. 05
Waist-to-height ratio	0. 73 ± 0. 09 (n = 18)	0. 69 ± 0. 07 (n = 21)	0. 09
Bioimpedance – body fat	46. 41 ± 5. 42% (n = 22)	42. 48 ± 5. 66% (n = 17)	0. 04
Bioimpedance – skeletal muscle mass	33. 56 ± 6. 99 kg (n = 22)	34. 45 ± 8. 46 (n = 17)	0. 72
Densitometry – body fat	47. 61 ± 4. 44% (n = 15)	43. 98 ± 5. 30% (n = 21)	0. 03
Densitometry – lean muscle mass	57. 26 ± 13. 26 kg (n = 15)	59. 61 ± 12. 66 (n = 21)	0. 60
HOMA-IR	5. 35 ± 2. 95 (n = 25)	3. 76 ± 2. 50 (n = 27)	0. 13
TyG index	4. 48 ± 0. 21 (n = 24)	4. 40 ± 0. 23 (n = 28)	0. 19

reduction: 8 patients lost less than 5%, 7 patients lost 5-10%, 8 patients lost above 10% and 8 patients showed no reduction in body mass after 6 months of treatment.

Conclusions

Liraglutide treatment led to a significant reduction in body fat percentage while preserving skeletal muscle mass. However, metabolic parameters did not show significant improvement after six months.

Prevalence of obstructive sleep apnea syndrome in patients with lipodystrophy: a retrospective analysis

Talha Ozturk[1], Bedirhan Çakır[2], Su Ozgur[3], Baris Akinci[4], Sezai Tasbakan[5], Ozen Kacmaz Basoglu[5] & Ilgin Simsir[6]

[1]Ege University Hospital, Department of Internal Medicine, Izmir, Türkiye; [2]Ege University Hospital, Otorhinolaryngology (ENT), Izmir, Türkiye; [3]Ege University Hospital, Department of Biostatistics and Medical Informatics, Izmir, Türkiye; [4]DEPARK & Izmir Biomedicine and Genome Center, Izmir, Türkiye; [5]Ege University Hospital, Department of Pulmonary Diseases, Izmir, Türkiye; [6]Ege University Hospital, Department of Internal Medicine, Division of Endocrinology and Metabolism, Izmir, Türkiye

Objective

Lipodystrophies (LD) are a heterogeneous and rare group of disorders characterised by a general or partial loss of subcutaneous adipose tissue with a contrasting ectopic accumulation. Obstructive Sleep Apnea Syndrome (OSAS), characterized by upper airway collapse, is primarily associated with obesity as its most prevalent risk factor. Specifically, increased fat deposition in the neck contributes significantly to the pathogenesis of OSAS. Despite the well-established link between fat distribution and OSAS, data on the prevalence of OSAS in patients with LD remain scarce. This study aims to address this gap by systematically assessing the prevalence of OSAS in LD patients and investigating its associated clinical and metabolic determinants.

Materials and Methods

This single-center, retrospective, descriptive study included 163 LD patients who were followed up at the Ege University Endocrinology outpatient clinic. Inclusion criteria encompassed being genetically confirmed, aged 18 years or older, non-pregnant, HIV-negative, and free from uncontrolled asthma, chronic obstructive pulmonary disease, or New York Heart Association class III-IV heart failure. Patients with a history of head and neck radiotherapy were excluded. Among the screened cohort, 28 LD patients who had undergone polysomnography were included in the study. Retrospective data on anthropometric measurements, fat distribution abnormalities, cervical skinfold thickness, biochemical parameters, and polysomnography findings were extracted from electronic medical records.

Results

Among patients included in the study, 28. 6% (n = 8) were diagnosed with generalized LD, and 71. 4% (n = 20) with partial LD. The mean age of the patients was 42±13 years. Male patients accounted for 21. 4% (n = 6), while females constituted 78. 6% (n = 22). The mean score of the Epworth Sleepiness Scale was 9. 2±6. 0 (range: 1–22). OSAS (AHI>15) was diagnosed in 11 patients (55%) with partial LD, whereas no cases were identified among those with generalized LD.

Discussion

This study provides novel insights into the prevalence of OSAS in patients with LD, highlighting a substantial difference between generalized and partial LD phenotypes. While OSAS is classically linked to obesity, our results suggest that abnormal fat distribution in LD may be an independent risk factor.

Conclusion

We demonstrated the high frequency of OSAS in patients with partial LD. Our findings underscore the necessity of OSAS screening in partial LD patients, particularly those with severe metabolic complications, given its association with cardiometabolic diseases, cognitive dysfunction, and increased mortality risk. The significant prevalence of OSAS in partial LD highlights the need for a paradigm shift in screening strategies.

The effect of GLP-1 administration on food intake in people with weight regain post-metabolic surgery

Kleopatra Alexiadou[1], Kavita Narula[1], Khalefah Malallah[1], Carolina Coimbra de Brito Lobato[1], Anna Kowalka[1], Sanjay Purkayastha[1], Christos Tsironis[2], Patricia Ortega[2], Sherif Hakky[2], Louisa Brolly[2], Samantha Scholtz[2], Lucy Tweedlie[2], Harvinder Chahal[2], Karen O'Donnell[2], Candace Bovill-Taylor[2], Anna Sackey[2], Rhian Houghton[2], Saira Hameed[2], Chioma Izzi-Engbeaya[1, 3], Ahmed Ahmed[2] & Tricia Tan[1]

[1]Imperial College London, London, United Kingdom; [2]Imperial College Healthcare NHS Trust, London, United Kingdom; [3]Imperial College Healthcare NHS Trust, Department of Endocrinology, London, United Kingdom

Background

Metabolic surgery remains the most effective option for sustainable weight loss. Sleeve gastrectomy is one of the commonly performed procedures. However, the percentage of people who fail to lose weight after surgery or regain weight ranges between 20–30%. Depending on the definition, category and surgery type, this percentage can vary between 3. 9 to 71%. The mechanisms behind the divergent responses to metabolic surgery are not fully understood. We hypothesised that people who regain weight after initial successful weight loss with sleeve gastrectomy might exhibit a resistance to the anorectic effects of GLP-1, the post-prandial secretion of which is known to be markedly stimulated by metabolic surgery.

Subjects and Methods

Ten patients who lost more than 20% of their pre-operative weight and sustained it after Sleeve Gastrectomy ("good responders") and nine patients who lost more than 20% of their pre-operative weight at nadir but then regained weight ("regainers"), were enrolled in a single blinded study. The participants received two subcutaneous infusions at random order, one placebo infusion and one GLP-1(7-36) •NH_2 infusion for 4. 5 hours. An ad libitum meal study was performed 4 hours after the initiation of each infusion. Participants were asked to eat a large portion of a standardised meal until they were comfortably full. Food intake was the primary outcome.

Results

Both the good responders and regainers significantly reduced their food intake during the GLP-1 infusion compared to placebo (P = 0. 038 and P = 0. 047 respectively).

Conclusions

People who regain weight after initial successful weight loss after Sleeve Gastrectomy retain sensitivity to GLP-1 treatment similarly to the people who have achieved successful and sustainable weight loss. This finding suggests that adjunctive treatment with GLP-1 analogues may play a role in managing weight regain after metabolic surgery.

Development of a gas chromatography mass spectrometry method for urinary oestrogen profiling in pre- and postmenopausal women

Joshua Bain[1], Hannah Hussain[1], Louise Longhurst[1], Fozia Shaheen[1] & Angela Taylor[1]

[1]Metabolism and Systems Science, University Of Birmingham, Birmingham, United Kingdom

Oestrogen analysis presents a significant challenge due to the low concentrations of these hormones, particularly oestradiol, the most potent oestrogen. Oestrogens

plays important roles in fertility, bone health, and various endocrine disorders. Traditional methods for measuring oestrogens, such as immunoassays, are unreliable at low concentrations and prone to high cross-reactivity, leading to inaccurate results and potential misdiagnoses. Mass spectrometry (MS) is as a more selective and sensitive alternative for oestrogen analysis. Unlike immunoassays, MS offers reduced cross-reactivity, enhancing the reliability of hormone measurements. However, quantifying oestrogens remains challenging due to their low concentrations and poor ionization, even when using highly sensitive liquid chromatography-tandem mass spectrometry (LC-MS/MS) techniques. These methods often require large sample volumes, particularly when measuring in populations such as post-menopausal women, men, and children. Gas chromatography-mass spectrometry (GC-MS) is a viable alternative employing post extraction derivatisation which improves ionizability allowing quantitation of poorly ionising, low concentration oestrogens. Additionally, use of urine permits sample concentration without unacceptable matrix effects associated with serum. Therefore, we developed a GC-MS method for urinary oestrogen profiling for the detection of eleven oestrogens, including oestradiol, oestrone, and their hydroxy and methoxy derivatives. Twenty-four-hour urine samples were collected from 51 healthy females (26 pre-menopausal (age 20-49) and 25 post-menopausal (age 50-76). Steroids were extracted from 2mL of 24-hour urine, deconjugated and derivatised into methyloxime-trimethylsilyl ethers. The oestrogens were measured on a Shimadzu GC-MS-QP2020NX relative to an internal standard and a calibration series to ensure accuracy. Our GC-MS method quantified oestrogens in both pre- and postmenopausal women. The highest concentration oestrogens were oestradiol, median (5^{th}-95^{th} percentile) in all (6, 2-34) pre-menopausal (14, 2-34), post-menopausal (4, 1-18), oestriol all, (3, 0. 5-20), pre (6, 1-21) post (2, 0. 7-6), oestrone all (3, 0. 5-30), pre (5 (1-33), post (1, 0. 2-20) and 2-methoxy-oestrone all (8, 3-20) pre (7, 3-20) post (8, 3-17)μg/24hr. All other oestrogens were detectable at median concentrations ranging from 0. 2-1. 7μg/24hr. There were significant differences (Mann-Whitney-U $P < 0.05$) in excretion of oestrone, oestradiol, and 2-hydroxyoestrone, when comparing pre and post-menopausal women. There were positive correlations between excretion of oestrone, oestriol and progesterone metabolites whereas excretion of oestradiol correlated with androgen metabolites. GC-MS urinary oestrogen profiling is essential for detecting low oestrogen concentrations, particularly in post-menopausal women and those undergoing treatments such as tamoxifen. Our method demonstrates the sensitivity needed for assessing treatment efficacy in challenging clinical applications.

Cumulative effects of genetic variants detected in a patient with early-onset non-syndromic childhood obesity

Giovanni Luppino[1], Domenico Corica[1], Mara Giordano[2], Giorgia Pepe[1], Letteria Anna Morabito[3], Cecilia Lugarà[1], Tommaso Aversa[1] & Malgorzata Wasniewska[1]

[1]Department of Human Pathology of Adulthood and Childhood, University of Messina., Messina, Italy; [2]Laboratory of Genetics, SCDU Clinical Biochemistry, University Hospital "Maggiore della Carità", Novara and Department of Health Sciences, University of Eastern Piedmont, Novara, Italy; [3]Pediatric Unit, "G. Martino" University Hospital, Messina, Italy

Background

The presence of monogenic mutations should be suspected in children with early onset non-syndromic obesity and hyperphagia. The SIM1 (Single-minded homolog 1) mutations are a well-known cause of monogenic obesity with an autosomal dominant inheritance. A variant of the SIM1 gene is associated with other obesity-related genetic mutations in a male patient with early-onset obesity.

Case Description

A 9-years-old boy, with a BMI of 30, 2 kg/m2 (2, 37 SDS), started to gain weight at 19 months of life, with progressive hyperphagia. He was born of full-term an uneventful pregnancy with an appropriate birth weight, to non-consanguineous parents. His mother presents severe obesity. He had no significant neonatal history. At the first evaluation, at the age of 3 years old, his height was 99 cm (+0, 69 SDS vs target height -1, 35 SDS), weight was 22 Kg (+3, 12 SDS) and BMI of 22, 3 Kg/m2 (+2, 23 SDS). Physical examination not revealed dysmorphic features. He presented a persistent polydipsia and water deprivation tests ruled out diabetes insipidus. Brain MRI was normal and additional endocrinological disease and hypothalamic disorders were excluded At the age of 6 years old, his height was 124, 7 cm (+0, 39 SDS), weight 42, 2 Kg (+2, 82 SDS) and BMI of 27, 4 Kg/m2 (+2, 27 SDS). Biochemical examinations documented an impaired fasting glucose (IFG) and impaired glucose tolerance (IGT), associated with mild hepatic steatosis at ultrasound. In addition, he presents behavior disorder with a delay in speech development. CGH array documented a de novo 546Kb microduplication in 16p11.2 (OMIM #614671). Next Generation Sequency (panel based on 80 genes), performed at the age of 9, revealed mainly a novel and frameshift variant, c.290dup p.(Asp98Argfs*29), detected in heterozygosity in the SIM1 gene, inherited from the father. NGS showed other heterozygosity variants classified as VOUS according to ACGM: c.437C>T p.(Ala146Val) in CREBBP gene; c.3041T>A p.(Val1014Glu) in PLXNA4 gene; c.915A>C p.(Leu305Phe) in SEMA3C gene.

Conclusion

SIM1 gene is implicated in the development of the paraventricular nucleus (PVN) that contains the melanocortin 4 receptor (MC4R), a key component of appetite regulation. CREBBP is implicated in mechanisms of neuroplasticity. SEMA3A, with its reactors also encoded by the PLXNA4 gene, is implicated in the development of hypothalamic neuronal circuits. Although the role of the SIM1 gene mutation is decisive, we suggest that the cumulative effects of the other identified variants could interact in determining a phenotype of severe obesity through abnormalities in the development and function of hypothalamic circuits.

JOINT2058

Metabolomic mechanisms involved in the impact of liver injury on elevated coronary heart disease risk

Er-wen Wu[1], Ya-xin Li[1], Bang-wei Chen[1], Xiao-lin Chen[1], Jian-guo Zhang[†], Shi-da Zhu[1], Lei Ruan[2] & TAO LI[1]

[1]BGI Genomics, Shenzhen, China; [2]Department of Geriatrics, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background

Coronary heart disease (CHD) is a common ischemic heart disease, with over 11.39 million patients in China and a mortality rate of 126.91 per 100, 000. Liver injury is a significant risk factor for CHD, but the mechanisms by which it affects CHD risk remain unclear. Fibrosis-4 index (FIB-4) is a common biomarker for liver fibrosis and injury, with established links to cardiovascular diseases. This study investigates whether FIB-4 is an independent risk factor for CHD and explores the metabolomic mechanisms through which FIB-4 influences CHD risk.

Methods

This study recruited 1, 668 healthy participants from central China, with 304 participants undergoing targeted metabolomics analysis. T-tests and rank sum tests compared baseline differences between participants with and without CHD by the end of the follow-up. Proportional Cox regression evaluated the relationship between FIB-4 and CHD, with adjustments for confounders in three models: Model 1 (gender); Model 2 (further adjusted for body mass index (BMI), estimated glomerular filtration rate (eGFR), systolic blood pressure (SBP), diastolic blood pressure (DBP), high-density lipoprotein cholesterol (HDL-C), alkaline phosphatase (ALP), triglycerides (TG), glucose, hemoglobin A1C (HbA1c)); Model 3 (further adjusted for hypertension, hyperlipidemia, diabetes). Spearman correlation identified metabolites associated with liver injury, and FDR correction was applied. A logistic regression model was fitted to identify metabolites independently associated with CHD.

Results

At follow-up, 858 participants had developed CHD, while 810 did not. CHD patients had notably higher levels of SBP, DBP, TG and glucose ($p < 0.05$), as well as higher FIB-4 values ($p < 0.001$). After controlling for multiple confounders, proportional Cox regression (Model 3) demonstrated that increased FIB-4 was significantly associated with higher CHD risk, remaining robust after adjusting for covariates (HR 1.250; 95% CI, 1.136-1.375). We identified 108 metabolites associated with liver injury, and through a logistic regression model adjusted for multiple confounders, 15 metabolites were independently associated with CHD. Among these, Guanosine Monophosphate (GMP, OR 0.213; 95% CI, 0.061-0.716), Tryptophanamide (OR 0.885; 95% CI, 0.795-0.986), Lithocholic Acid Acetate (LAA, OR 0.788; 95% CI, 0.646-0.966), Methylmalonic Acid (MMA, OR 0.349; 95% CI, 0.126-0.932), and Glycohyodeoxycholic Acid (GHDCA OR 1.741; 95% CI, 1.039-3.044) were concurrently correlated with liver injury.

Conclusion

Elevated FIB-4 is strongly linked to increased CHD risk. Metabolomics analysis reveals that GMP, Tryptophanamide, LAA, MMA, and GHDCA are associated with both FIB-4 and CHD, potentially implicating these metabolites in the process through which liver injury contributes to CHD development.

Multi-omics characteristics of balanced diet combined with high-intensity interval training for weight loss in obese children

Xuelian Zhou[1], Wei Wu[1], Ke Huang[1], Guanping Dong[1, 2] & Junfen Fu[1]
[1]Children's Hospital, Zhejiang University School of Medicine, National Clinical Research Center for Child Health, Hangzhou, China; [2]Children's hospital of Zhejiang university school of medicine, Hangzhou, China

Obeject
To explore the effect and potential mechanisms of balanced diet combined with high-intensity interval training (HIIT) in reducing fat mass and increasing muscle mass in overweight and obese children.
Methods
Totally 44 obese and 10 overweight children aged from 8 to 18 years old were recruited to participate in a 3-week weight loss summer camp, all the subjects received the same dietary regimen and HIIT. We compared the changes in physical parameters, body composition (DXA), biochemical parameters (including OGTT test) and liver CAP (Fibroscan) in all the subjects, additionally, serum metabolomic and lipidomic profiles, gut microbiomes were further investigated in 8 of them at the beginning and the end of the summer camp.
Results
The average weight of the participants decreased by 3.29kg, BMI by 1.16kg/m2, waist circumference by 3.1cm, liver CAP by 8.44, but the difference was not statistically significant. The total fat mass decreased from (27278.32 + 8133.78) to (24275.68 + 6871.31), while total lean mass increased from (32652.02 + 8495.73) to (35210.37 + 8465.29) ($p < 0.05$). ALT, uric acid, GGT, TC, LDL, Apolipoprotein A1/B, HOMA-IR were significantly improved after the summer camp ($p < 0.05$). Serum metabolisms revealed 27 differential metabolites, serum lipidomic revealed 21 differential lipids, gut microbiomes revealed 60 differential species ($p < 0.05$), enrichment analysis revealed that the differential metabolites, lipids and gut microbiotas were involved in sphingolipid metabolism, glycerophospholipid metabolism, glycosylphosphatidylinositol-anchor biosynthesis, cysteine and methionine metabolism and primary bile acid biosynthesis, which were involved in cell autophagy and associated with insulin resistance.
Conclusion
Three weeks of balanced diet and HIIT can significantly reduce the total fat mass, increase total lean mass, and improve the glucose and lipid metabolism indicators among obesity and overweight children. Mult-omics sequencing is helpful to find early metabolite changes and explore the potential mechanisms during weight loss in children.

Mental health in 10 year old children with overweight

Rebecca Kofod Vinding[1, 2], Maria Hernández-Lorca[2], David Horner[2], Julie Rosenberg[2, 3], Morten Rasmussen[2], Parisa Mohammadzadeh[2, 3], Jens Richardt Jepsen[3, 4], Kristina Aagaard[2], Katrine Strandberg-Larsen[5], Rikke Jensen[1], Julie Kloppenborg[1], Bjørn Ebdrup[3, 6] & Klaus Bønnelykke[2]
[1]Herlev Hospital, Børne og ungeafdelingen, Herlev, Denmark; [2]COPSAC, Gentofte, Denmark; [3]Center for Neuropsychiatric Schizophrenia Research (CNSR), Mental Health Center, Glostrup), Denmark; [4]Child and Adolescent Mental Health Center, Copenhagen, Denmark; [5]Section of Epidemiology, Department of Public Health, University of Copenhagen, Copenhagen, Denmark; [6]Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark

Background
The interplay between mental health and overweight has gained significant attention in recent years. Obesity has been associated with psychiatric disorders such as ADHD, autism, depression, anxiety and their symptom severity, however the potential causal interplay, i.e., the direction of such association, remains elusive. In this study, we harness the longitudinal data of the COPSAC2010 birth cohort to investigate the potential causal interplay between overweight and mental health at 10 years.
Methods
Children of the COPSAC2010 ($n = 700$) cohort have been examined longitudinally in regards to anthropometrics and mental health in clinical visits at age 6 and 10. At age 6, mental health was measured with the Strength and Difficulties Questionnaire (SDQ), and at age 10, in the COPSYCH study, we thoroughly examined neuropsychiatric diagnoses, dimensional psychopathology(including SDQ), and performed cognitive assessments, of the children. We divided children into two groups: overweight at age 10 zBMI > 1.04 ($n = 110$), and non-overweight zBMI ≤ 1.04 ($n = 482$). We analyzed the relationship between overweight and mental health by means of logistic and linear regression, both cross-sectionally at age 10 and longitudinally.
Results
Cross-sectionally at age 10, we found a trend towards higher prevalence of ADHD combined presentation diagnosis (11% vs 5 %, OR 2.3[1.1;4.8], $P = 0.02$), a significantly higher load of psychopathological symptoms and problematic behavioral traits in the group of children with overweight. Children with overweight scored around four points lower in the General IQ (Est -4.25[-7.21;-1.30], $P = 0.005$). Longitudinally, we found a significantly increased OR 1.12 (1.06;1.18): $P < 0.001$ for overweight at 10 years in relation to each point rise in SDQ total difficulties score at 6 years, independently of 6 years BMI. In contrast we saw no association between overweight at 6 years and the total difficulties score at 10 years, adjusted for total difficulties score at 6 years ($P = 0.29$).
Conclusion
We found an association between mental health and overweight in children at 10 years: i)a higher risk of ADHD combined presentation, ii)higher total problem scores in psychopathology questionnaires and, iii) less efficient cognitive functioning. Results from our prospective data suggested that behavioral problems at 6 years precedes overweight at 10 years. The results from this study should be considered when a child with adiposity is examined, and the treatment is planned. A perspective for future recommendation could be a routine neurocognitive and psychological assessment in overweight/obese children, before planning and initiation of a treatment plan.

JOINT3021

Role of ligand- and genetic variant dependent melanocortin 4 receptor (MC4R) bias signaling for the individual risk to develop obesity

Lisa Ruck[1], Patrick Scheerer[2], Sarah Zschunke[1], Susanna Wiegand[1], Gunnar Kleinau[2], Nicolas Heyder[2], Philipp Gmach[1], Sabine Jyrch[1], Annette Beck-Sickinger[3], Manuel Troll[3], Heike Biebermann[1] & Peter Kühnen[1]
[1]Charité Universitätsmedizin, Klinik für pädiatrische Endokrinologie und Diabetologie, Berlin, Germany; [2]Charité Universitätsmedizin, Institut für Medizinische Physik und Biophysik, Berlin, Germany; [3]Universität Leipzig, Leipzig, Germany

Introduction
The melanocortin 4 receptor (MC4R), a G protein-coupled receptor (GPCR), is a critical regulator of body weight within the hypothalamus and is embedded in the leptin-melanocortin signaling pathway. Heterozygous *MC4R* gene mutations have been identified as potent genetic risk factors for the development of obesity. Additionally, the MC4R agonist setmelanotide has recently been approved as a pharmacological treatment option for patients with certain rare monogenic forms of obesity. In recent years it has been described that MC4R related differential (biased) signaling is playing an important role for body weight regulation and the downstream effect of MC4R ligands. However, the interplay between *MC4R* genetic variants and different endogenous and external MC4R ligands remains elusive.
Methods
We analyzed *In vitro* the signaling of 20 heterozygous *MC4R* mutations, which have been identified in a cohort of children with obesity, in regards to Gs, Gq/11, ERK, G12/13 and b-arrestin2 recruitment and after stimulation with different MC4R ligands (α-MSH, β-MSH, setmelanotide) in HEK293 cells. Additionally, *MC4R* mutations were further characterized by analysis of our previously solved the cryo-electron microscopic (cyro-EM) structures.
Results
We observed a ligand and genetic variant dependent differential (bias) signaling of the MC4R. The "protective" *MC4R* variant V103I was associated with an increase of Gq signaling after stimulation with α-MSH. Contrary to the complete loss of function variants like Y80C, D90N and S127L (deficit in all analyzed pathways), *MC4R* variants as S77L or T178M led to a reduction of non-Gs signaling cascades while Gs signaling was not altered. These signaling profiles were ligand dependent, which was partially related to MC4R conformation changes, which were analyzed based on cryo-EM structure data.
Conclusion
Our findings emphasize the critical role of differential (bias) signaling for MC4R function. Structural data- combined with *In vitro* functional data allowed to gain further insights into the structural regulation of the MC4R, which can be relevant to optimized MC4R agonists as a treatment option for patients with certain forms of obesity.

Sex Hormone-binding globulin prevent carbon tetrachloride-induced liver fibrosis development

Julia Cabrera Serra[1], Anna Alvarez Guaita[1], Lidia Fuertes Rioja[1], Laura Briansó Llort[1], Lorena Ramos Perez[1], Maria Teresa Salcedo Allende[2], Rafael Simo Canonge[1], Cristina Hernandez[1] & David Selva[1]
[1]Vall d'Hebron Research Institute, Diabetes and Metabolism, Barcelona, Spain; [2]Vall d'Hebron University Hospital, Human Pathology, Barcelona, Spain

Sex hormone-binding globulin (SHBG) plasma levels are reduced in subjects suffering MASLD and MASH. We have previously shown both *In vitro* and *in vivo*, that SHBG protects against MASLD development by reducing hepatic fat accumulation via inhibiting hepatic lipogenesis. In the present work, we are interested in exploring if SHBG could protect also against development of liver fibrosis. For this purpose, *in vivo* studies were performed using wild-type and the human *SHBG* transgenic mice developing liver fibrosis induced by carbon tetrachloride (CCl_4). Our results clearly showed that SHBG overexpression reduced the CCl_4 induced liver fibrosis in both male and female mice. Histological examination showed that *SHBG* transgenic mice had reduced NAS score and reduced collagen accumulation. Human SHBG transgenic mice treated with CCl_4 had reduced Col1A1 mRNA and protein levels when compared with wild-type CCl_4 treated mice. Mechanistically, we found that *SHBG* transgenic mice showed increased hepatic protein levels of several metalloproteases when compared with wild-type CCl_4 treated mice. Taking together, we found for the first time that SHBG could protect against liver fibrosis by inhibiting Col1A1 mRNA and protein levels and by reducing collagen through an increase in MMPs activity.

The beta-2-adrenoreceptor agonist fenoterol increases resting enery expenditure without activation of brown adipose tissue in humans

Laila Füchtbauer[1], Jael Senn[1], Carole Baumann[1], Aninja Isenrich[1], Claudia Maushart[1], Anand Sharma[2], Carla Horvath[2], Alin Chirindel[3], Damian Wild[3], Christian Wolfrum[2] & Matthias Betz[1]
[1]University Hospital Basel and University of Basel, Department of Endocrinology, Diabetes and Metabolism, Basel, Switzerland; [2]ETH Zürich, Laboratory of Translational Nutrition Biology, Schwerzenbach, Switzerland; [3]University Hospital Basel and University of Basel, Division of Nuclear Medicine, Basel, Switzerland

Background
Brown adipose tissue (BAT) may directly dissipate energy from lipids and carbohydrates into heat and its activity is associated with a favorable metabolic phenotype in human adults. In rodents, BAT is activated by the sympathetic nervous system and its transmitter norepinephrine via the α3-adrenoreceptor (α3-AR). In humans stimulation of the α3-AR even with high doses of the selective agonist Mirabegon leads to a rather weak activation of BAT as compared to a cold stimulus. *In vitro* studies in cell lines from human BAT and one human study have pointed towards the α2-AR as a possible activator of human BAT. Here, we studied the effect of the potent and selective α2-AR agonist fenoterol on human energy expenditure (EE) and BAT activity.
Methods
Healthy normal weight volunteers were initially screened for cold-induced thermogeneis. Twelve individuals with cold-induced thermogenesis of >5% of resting energy expenditure were included. They received the following interventions over two hours in random order: A) standardized mild cold stimulus; B) intravenous infusion of the selective α2-agonist Fenoterol. EE was measured continously with indirect calorimetry, skin and core temperature were recorded and BAT activity was quantified in the supraclavicular BAT depot by 18F-FDG-PET/CT after each intervention.
Results
Resting EE at baseline was 1516±347 kcal/24h before cold-exposure and 1502±281 kcal/24h before Fenoterol. Cold exposure resulted in a mean increase in EE of 195 kcal/24h ($P = 0.044$ vs. baseline) and Fenoterol infusion increased EE by 358 kcal/24h ($P < 0.0001$). The mean standardized uptake value (SUVmean) of supraclavicular BAT was 3.06 (IQR 2.19;3.64) g/ml after cold exposure but only 1.66 g/ml [1.63;1.70] after Fenoterol infusion. Correspondingly, the active BAT volume was 90 (26;190) ml vs. 3 (1;16) ml. Supraclavicular temperature increased promptly in response to cold, but not after fenoterol. Fenoterol immediately and strongly increased levels of circulating fatty acids and glycerol, while triglyceride levels remained stable. A slower lipolytic response occurred during cold stimulation. In both interventions the lipolytic response paralleled the kinetics of EE during the respective visit. Only fenoterol increased serum-glucose, insulin, and lactate. In another cohort of healthy individuals, expression of the α3-AR but not of the α2-AR was correlated to the level of UCP1, the hallmark of brown adipocytes.
Conclusion
We found no evidence that α2-ARs play a major role in activation of human BAT. A reason for the observed fenoterol-induced increase in REE could be futile metabolic cycles e.g. lipid cycling in skeletal muscle or white adipose tissue.

Sex hormones and high-fat, high-sucrose diets: unraveling their interaction on brown adipose tissue morphology and gene expression

Kantawich Piyanirun[1], Weerapat Kositanurit[2], Jenny Visser[3], Duangporn Werawatganon[2] & Kasiphak Kaikaew[2]
[1]Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [2]Faculty of Medicine, Chulalongkorn University, Center of Excellence in Alternative and Complementary Medicine for Gastrointestinal and Liver Diseases, Department of Physiology, Bangkok, Thailand; [3]Erasmus MC, University Medical Center Rotterdam, Department of Internal Medicine, Section of Endocrinology, Rotterdam, Netherlands

Background
Overweight and obesity are escalating global health challenges, with food containing high fat and sugar being one of the causes. The discovery of functional brown adipose tissue (BAT), an organ of non-shivering thermogenesis, in adults offers new opportunities for obesity therapies. Emerging evidence suggests that sex hormones influence BAT structure and function, but the exact mechanisms remain to be fully elucidated.
Methods
Fifty-six mice [28 males (M), 28 females (F)] were used, with 14 per sex undergoing gonadectomy (G) at 8 weeks old, and the rest receiving a sham operation (S). After a one-week recovery, 7 mice from each group were switched to a high-fat, high-sucrose diet (HFD) for 12 weeks, while the others continued on standard chow diet (CD), resulting in a total of 8 groups: MSC, MGC, FSC, FGC, MSH, MGH, FSH, and FGH. At the end (age 22 weeks), interscapular BAT was collected. BAT morphology was analyzed using ImageJ with the Adiposoft extension. mRNA expression levels were quantified by qPCR.
Results
HFD increased BAT weight, reduced nuclear density, and increased droplet size in BAT across all groups. While *Ucp1* expression (a thermogenic gene) showed no sex differences among CD-fed groups, HFD-fed females expressed more *Ucp1* than males (FSH>MSH, $P = 0.04$). Gonadectomy influenced *Ucp1* expression in a sex-dependent manner in the HFD-fed group, increasing it in males (MGH>MSH, $P < 0.01$) but having minimal effect in females. *Ppargc1a*, a transcriptional coactivator of *Ucp*1, and lipolytic genes *Atgl* and *Hsl* followed similar trends to *Ucp1*, showing little changes with HFD but significant alterations with gonadectomy in a sex-dependent fashion. For fatty acid uptake, *Lpl* expression was not significantly affected by HFD alone ($P = 0.31$) but was significantly reduced when combined with gonadectomy in both sexes ($P < 0.01$). HFD decreased *Pck1* (a gluconeogenic gene) expression across all groups ($P < 0.01$). Additionally, HFD suppressed *Cfd* (adipsin, an anti-thermogenic adipokine) expression in all groups ($P < 0.01$), and gonadectomy reduced *Cfd* levels in females regardless of diet condition ($P < 0.01$).
Conclusion
HFD and sex hormones, along with their interaction, influence BAT morphology, metabolism, and substrate uptake. Gonadectomy shows a stronger effect than HFD on thermogenic and lipolytic activities. These findings reveal complex hormonal-dietary effects, providing insights into HFD-induced obesity and potential therapeutic strategies.

Anthropometric and metabolic assessment in adults with down syndrome: the need for novel indices and customized criteria

Selin Tekin[1], Nergis Basmaci[1], incilay lay[1, 2] & Alper Gurlek[1]

[1]Hacettepe University, Department of Endocrinology and Metabolism, Ankara, Türkiye; [2]Hacettepe University, Department of Biochemistry, Ankara, Türkiye

Objective
This study aimed to evaluate the metabolic profile of adults with Down syndrome (DS) using novel anthropometric and metabolic indices, highlighting the limitations of conventional obesity assessment methods, such as BMI, in this population compared to healthy controls.
Methods
A cross-sectional study was conducted with 22 adults with DS and 28 age- and sex-matched healthy controls. Anthropometric measurements, including BMI, waist circumference (WC), hip circumference, and waist-to-height ratio (WHtR), were recorded along with novel indices like the Body Adiposity Index (BAI), A Body Shape Index (ABSI), and Visceral Adiposity Index (VAI). Body composition was assessed via bioelectrical impedance. Metabolic parameters, including fasting plasma glucose, HbA1c, lipid profiles, and HOMA-IR, were measured. CBC-derived inflammation indices neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), monocyte-to-hemoglobin ratio (MHR), neutrophil-to- hemoglobin ratio (NHR), lymphocyte-to-HDL ratio (LHR), platelet -to-hemoglobin ratio (PHR), systemic ımmune-ınflammation ındex (SII), aggregate ındex of systemic ınflammation (AISI), systemic ınflammatory responseındex(SIRI) were analyzed. Metabolic syndrome (MetS) was defined per IDF 2005 criteria. Statistical analyses included group comparisons and correlations between indices and metabolic markers.
Results
Individuals with DS exhibited higher WHtR ($p < 0.001$) and shorter stature ($p < 0.001$) than controls, despite similar BMI levels. The MetS prevalence was lower in the DS group (9.09%) than in controls (21.4%; $P = 0.001$), even with higher abdominal obesity rates. Lipid and glucose profiles were better in DS individuals with abdominal obesity compared to controls, but differences were not statistically significant. WHtR correlated with fasting glucose, HbA1c, and blood pressure in DS, whereas BMI showed limited correlations with metabolic markers. The VAI values were similar between groups ($P = 0.96$), while the BAI ($p < 0.001$) and ABSI ($P = 0.001$) were significantly higher in the DS group. Within DS, BAI was higher in women than men ($P = 0.001$), while VAI and ABSI did not differ by gender. Among CBC-derived indices, only PLR was significantly elevated in the DS group ($P = 0.038$). VAI correlated with WC, TG, TG/HDL ratio, and inversely with HDL cholesterol, while BAI correlated with systolic and diastolic blood pressure, HbA1c, and WC.
Conclusion
This study highlights the distinct metabolic and inflammatory profiles of individuals with DS, emphasizing the limitations of BMI and the utility of novel metabolic and anthropometric indices. These findings underscore the need for population-specific assessments and tailored methods to improve metabolic risk evaluations in DS.

Frequency of monogenic variants in a cohort of individuals with severe, early-onset obesity from a single large tertiary paediatric centre

Katherine Hawton[1, 2], Hannah Hickingbotham[3], Alanna Holt[1], Sumana Chatterjee[1], Julian Hamilton Shield[1, 4] & Dinesh Giri[1, 2]
[1]University Hospitals Bristol and Weston NHS Foundation Trust, Bristol, United Kingdom; [2]University of Bristol, Bristol, United Kingdom; [3]St George's University Hospital NHS Foundation Trust, London, United Kingdom; [4]NIHR Biomedical Research Centre Nutrition, Bristol, United Kingdom

Introduction
Obesity is a complex, chronic disease characterised by excess adiposity which tracks throughout the lifecourse. Monogenic obesity presents in childhood with severe, early-onset obesity and hyperphagia, and its prevalence may be underestimated due to limited access to genetic testing. We describe genetic results from a large cohort of children and young people (CYP) living with severe obesity under the care of our tertiary paediatric weight management clinic.
Methods
131 CYP with severe obesity (body mass index (BMI) >99.6th centile for age) had genetic testing performed using the Rare Obesity Advanced Diagnosis™ 79-gene targeted panel (including the MC4R pathway variants) between March 2022 and November 2024. Variants were classified as pathogenic or potentially relevant variants according to American College of Medical Genetics criteria; further subdivided into suspected pathogenic, variants of unknown significance and suspected benign.

Pathogenic Variants (frequency)	Potentially Relevant Variants (frequency)			Gene with polymorphic risk variant (frequency)
	Suspected Pathogenic	Variant of Unknown Significance	Suspected Benign	
MC4R heterozygous(5)	KSR2(2)	KIDINS220(2)	ALMS1(3)	PCSK1 heterozygous (16)
SIM1 heterozygous(4)	SEMA3A(2)	PCSK1(2)	NCOA1(3)	
RAI1 heterozygous(1)	TUB(2)	SEMA3A(2)	KSR2(2)	
VPS13B heterozygous(1)	BBS9(2)	CREBBP(1)	PCSK1(2)	
SEMA3G heterozygous(1)	VPS13B(2)	GNAS(1)	POMC(2)	
Chromosomal rearrangement 16p11.2 deletion(1)	KIDINS220(1)	KSR2(1)	RAI1(2)	
	BBS7(1)	MAGEL2(1)	EP300(1)	
	SEMA4 (1)	PLXNA3(1)	HTR2C(1)	
	TTC8(1)	RPS6KA3(1)	NRP1(1)	
	POMC(1)	DNMT3A(1)	SIM1(1)	
	SDCCAG8(1)	MC4R(1)	PLXNA2(1)	
		PHF6(1)	BBS12(1)	
		EP300(1)	NROB2(1)	
		PCNT(1)		
		IFT172(1)		
		PLXNA1(1)		
		MKKS(1)		
		VPS13B(1)		
		BBS5(1)		
		CEP290(1)		
		PLXNA4(1)		
		TRIM32(1)		
		BBIP1(1)		

Results
69/131 patients were female. Age ranged from 1.5-17.5 years with onset of obesity between 3-11 years of age. Median BMI was 32.2kg/m^2 (range 22.1-55.0) and median BMI-SDS was 3.72 (range 2.10-6.46). 9.2% (12/131) of CYP were found to have pathogenic variants and suspected pathogenic variants were found in 10.7% (14/131). 16.8% (22/131) had variants of unknown significance, 14.5% (19/131) had suspected benign variants (some CYP had more than one variant) and one had a deletion in the 16p11.2 chromosomal region. *MC4R* (heterozygous) was the most frequent pathogenic variant (3.8%; 5/131), followed by heterozygous *SIM1* (3%; 4/131).
Conclusion
In this clinical population of CYP living with severe obesity, almost 10% had pathogenic variants associated with obesity and a further 10% had suspected pathogenic variants. The majority of the above variants were in genes encoding proteins in the leptin-melanocortin pathway which is crucial in the regulation of appetite and energy expenditure. Increased provision of genetic testing may facilitate a deeper understanding of the monogenic causes of obesity and enable the development of further targeted, personalised therapies to improve long-term outcomes.

Clinical significance of urine NAG and blood Cys-C in early renal damage assessment of children with simple obesity

Haiying WU[1], xiaoyan wang[1] & MIN HUA[1]
[1]Children's Hospital of Soochow University, suzhou, China

Objective
To investigate the correlation between urinary n-acetyl-α-D-glucosaminase(-NAG)and serum cystatin C(Cys-C)levels and physical measurements, glucose and lipid metabolism, liver and kidney function and other indicators in children with simple obesity. To further explore the clinical significance of urinary NAG and serum Cys-C levels in the assessment of early renal damage in children with simple obesity.
Methods
302 children with simple obesity were selected , (110 cases in the mild to moderate obesity group and 192 cases in the severe obesity group)and 53 children of similar age were selected as the normal control group. Clinical data of the two groups, were collected to compare the differences in clinical data between the obese group and the normal control group, and to analyze the correlation between blood Cys-C, urine NAG and renal function. In addition, 302 children with simple obesity were divided into albuminuria group and normal albuminuria group according to urnie albumin creatine raio (UACR) ratio. The differences of general clinical data and laboratory parameters among albuminuria group and normal albuminuria group were compared. Multivariate Logistic regression analysis was used to find out the predictors of kidney damage, and ROC curve was used to verify them.

Results
1. There were statistically significant differences in eGFR, mALB and uNAG in the mild to moderate obesity group, the severe obesity group and the normal control group($P<0.01$).
2. Cys-C, uNAG, eGFR, BUN and UA in obesity 0-2 years, 2-5 years and ≥ 5 years course groups were higher than those in control group, with significant statistical difference ($P < 0.01$).
3. ROC curve: the combined detection of uNAG and Cys-C had the largest area under the curve (AUC = 0.8167), and the specificity and sensitivity were higher (75% and 85.7%).
Conclusions
1. The levels of uNAG and Cys-C in children with simple obesity are higher than those in normal children, suggesting that early kidney damage may occur in children with simple obesity.
2. uNAG is an independent factor of early kidney injury in children with simple obesity. The combined detection of uNAG and serum Cys-C is superior to the single detection of uNAG.

Association between 25-hydroxyvitamin-D and insulin resistance in korean adolescents: findings from the 2008-2014 KNHANES

Eunji Mun[1], Hye Ah Lee[2], Kyung Hee Kim[1], Jung Eun Choi[1], Hyesook Park[3] & Hae Soon Kim[1]
[1]Ewha Womans University Medical Center, Pediatrics, Seoul, South Korea; [2]Ewha Womans University Mokdong Hospital, Clinical Trial Center, Seoul, South Korea; [3]College of Medicine, Ewha Womans University, Seoul, South Korea

Background
We aimed to evaluate the relationship between vitamin D status and insulin resistance (IR) according to obesity status using non-insulin-based indices in adolescents.
Methods
This cross-sectional study included data from 3, 838 adolescents (aged 12 to 18) who participated in the Korea National Health and Nutrition Examination Survey from 2008 to 2014. The subjects were divided into two groups, normal weight and overweight & obese. Blood vitamin D levels were assessed in two groups based on a threshold of 20 ng/mL of 25-hydroxyvitamin D [25(OH)D], and vitamin D deficiency was defined as <20 ng/mL. As non-insulin-based IR indices, we used triglyceride-glucose index (TyG), triglyceride to high-density lipoprotein cholesterol ratio (TG/HDL-C), TyG index with body mass index (TyG-BMI), and metabolic score for IR (METS-IR).
Results
The prevalence of vitamin D deficiency in adolescents was 78.5%. Mean vitamin D levels were higher in boys, those who did strength training, and those with waist circumference below the 90th percentile. In normal weight individuals, TyG-BMI and METS-IR were significantly higher in those with vitamin D deficiency than in those with adequate vitamin D levels. This trend was also observed in individuals with the overweight and obese group, where a significant difference was found in TyG-BMI index. Even after adjusting for covariates, the association between vitamin D and IR as assessed by the METS-IR index persisted in the normal weight group.
Conclusions
Vitamin D deficiency is significantly associated with higher insulin resistance in adolescents, as measured by non-insulin-based indices. This association appears to be particularly strong in overweight and obese individuals.

Investigate the role of insulin in regulating the local expression of aromatase in the growth plate

sicui hu[1, 2], Rongxiu Zheng[1] & Tang Li[2]
[1]General Hospital of Tianjin Medical University, Tianjin, China; [2]Qingdao women and children's hospital, Qing dao, China

Objective
Body Mass Index (BMI) and bone age (BA) are key indicators for assessing an individual's growth and development. Children with obesity may appear to have taller height but fail to achieve optimal adult height due to the accelerated maturation of the epiphyseal growth plates, resulting in premature bone age and termination of growth. In this study, we assessed the impact of obesity-induced hyperinsulinemia on linear growth trajectories and the underlying mechanisms involved, using a high-fat diet-induced obesity rat model.
Methods
Twelve healthy 1-week-old Sprague-Dawley rats, weighing between 60-80g, were randomized into two groups: a control group and an obese group, receiving a standard diet and high-fat diet, respectively. After 6 weeks of induction, weekly body weights and body lengths were assessed. At the end of the study, all rats were euthanized, and blood samples were collected for further analysis. Hematological parameters such as serum insulin levels were assessed using ELISA. Tibia and humerus bones were collected to assess the bone length. Growth plates were separated for histological, immunohistochemical, PCR and Western blot analyses.
Results
Serum insulin levels were significantly higher in the obese group compared to the control group ($P < 0.01$). Compared with the control group, the obese group exhibited significantly increased growth plate length ($P < 0.01$), particularly in the proliferative and hypertrophic zones. Immunohistochemical staining further revealed that elevated levels of aromatase and insulin receptor (IR) expression in growth plates were predominantly observed in the hypertrophic zone. The relative mRNA expression levels of both aromatase and insulin receptors in the growth plates of obese rats were significantly elevated compared to the control group ($P < 0.01$). Western blot analysis demonstrated significantly increased expression of both CYP19A1 and IR in the growth plates of obese rats ($P < 0.01$).
Conclusion
Advanced bone age observed in obese children could potentially be attributed to the insulin signaling pathway-mediated regulation of aromatase expression in the growth plate.

Muscle respiratory capacity correlates with insulin sensitivity independent of adiposity and metabolic flexibility

Katerina Koudelkova[1 2 3], Jitka Pallova[1, 2], Marek Wilhelm[4], Lenka Rossmeislová[4], Michaela Šiklová[4] & Jan Gojda[1, 2]
[1]University Hospital Královské Vinohrady, Internal department, Prague, Czech Republic; [2]3rd Faculty of Medicine UK, Prague, Czech Republic; [3]University Hospital Královské Vinohrady, Internal Department, Prague, Czech Republic; [4]3rd Medical Faculty of Charles University, Department of Pathophysiology, Prague, Czech Republic

Introduction
Impaired metabolic flexibility (MetFlex) is a key pathophysiological mechanism underlying metabolic dysregulation in obesity. It is characterised by a reduced ability to adapt metabolism in response to substrate availability. This study examined the relationship between insulin sensitivity and MetFlex in normal-weight and women with obesity and explored their association with mitochondrial respiratory function in skeletal muscle.
Methods
A pilot study included 21 normal-weight women (age 32 ± 5, BMI 21.4 ± 1.5) and 15 women with obesity (age 36 ± 7, BMI 34.3 ± 3.6). Anthropometric and biochemical parameters as well as insulin sensitivity (hyperinsulinemic-euglycemic clamp, HEC), glucose tolerance (oral glucose tolerance test, OGTT), metabolic flexibility (indirect calorimetry during HEC, OGTT) and cardiorespiratory fitness (exercise test) were assessed. Skeletal muscle biopsies were obtained for mitochondrial respiration analysis (O2K, Oroboros).
Results
All women were eumenorrheic and none had thyroid dysfunction. Women with obesity exhibited higher triglyceride levels (1.2 ± 0.5 vs. 0.7 ± 0.4 mmol/l, $P = 0.0142$), lower cardiorespiratory fitness (23 ± 4.5 vs 40.8 ± 5.4 $ml^{-1}kg^{-1}min^{-1}$, $p = <0.0001$), and reduced insulin sensitivity ($5, 5 \pm 2, 0$ vs $11, 0 \pm 2$, 1 mg. $kg^{-1}min^{-1}$, $P = 0, 001$) compared to normal-weight women. Contrary to our hypothesis, MetFlex, assessed as change in respiratory quotient (ΔRQ) during HEC or glucose tolerance tests, did not differ between groups. In women with obesity, mitochondrial respiratory capacity, ATP production and fatty acid oxidation were reduced, with impaired mitochondrial membrane integrity. In all participants, respiratory capacity, ATP production and fatty acid oxidation correlated with insulin sensitivity and cardiorespiratory fitness, but not with MetFlex.
Conclusion
Our findings suggest that impaired insulin sensitivity in obese women may precede detectable changes in MetFlex. Insulin sensitivity is strongly associated with mitochondrial integrity and muscle respiratory capacity, independent of adiposity and metabolic flexibility.

Educational cartoon in the podiacar PROject: an approach to combat paediatric obesity

Valeria Calcaterra[1, 2], Virginia Rossi[1], Stefano Conca Bonizzoni[3], Giulia Fiore[1], Martina Tosi[1], Elvira Verduci[1, 4], Savina Mannarino[1], Matteo Vandoni[5], Luca Marin[5], Alessandro Gatti[5], Caterina Cavallo[5], Vittoria Carnevale Pellino[5], Cristina Campoy[6], Mireia Escudero Marín[6], Rocío Bonillo León[6], Valter Pagani[7], Camilo Corbellini[8] & Gianvincenzo Zuccotti[1, 9]
[1]Buzzi Children's Hospital, Department of Paediatrics, Milan, Italy; [2]University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy; [3]University of Pavia, Department of Humanities, Pavia, Italy; [4]University of Milan, Department of Health Sciences, Milan, Italy; [5]University of Pavia, Laboratory of Adapted Motor Activity (LAMA), Department of Public Health, Experimental Medicine and Forensic Science, Pavia, Italy; [6]University of Granada, Department of Paediatrics, Granada, Spain; [7]Asomi College of Science, Grant and Research Department, Pembroke, Malta; [8]LUNEX University, Differdange, Luxembourg; [9]University of Milan, Department of Biomedical and Clinical Sciences, Milan, Italy

Aims
Pediatric obesity is an escalating global health concern with profound physical and psychological impacts, both in the short and long term. The EU-funded initiative, "Fight against Pediatric Obesity: from a Predictive Tool for Type 2 Diabetes and Cardiovascular Disease Risk to Healthy Educational Programs" (PODiaCar), seeks to address childhood obesity through a comprehensive, multidimensional strategy. A key component of this project is the development of educational cartoons aimed at encouraging healthy lifestyle behaviors among children.
Methods
The interdisciplinary PODiaCar team collaborated with Officine Creative at the University of Pavia, Italy, to create the cartoon. Essential messages about nutrition and lifestyle were derived from an extensive literature review and refined with expert insights to ensure they were engaging, age-appropriate, and free from stigmatization. The storyline and characters were carefully designed, using clear language and visually appealing graphics to effectively capture children's attention and facilitate learning.
Results
The outcome of this effort is "Grandma Wilma's Tales, " an engaging animated story centered around Grandma Wilma and her grandson Charlie, who is initially reluctant to adopt healthier eating habits. The first episode introduces Vitto and his dog Buzz, illustrating the negative effects of poor diet and inactivity while highlighting the advantages of a balanced lifestyle. By using a positive and relatable approach, the cartoon helps children connect with the characters and internalize key messages about nutrition and physical activity.
Conclusions
This educational cartoon fosters awareness of the importance of a balanced diet and regular physical activity while ensuring a non-stigmatizing approach. By creating an engaging and relatable learning environment, the series motivates children to embrace healthier daily habits.

Combination therapy of semaglutide and methylphenidate leads to significant weight loss in prader-willi syndrome patients

Shiga Chiaryath[1], Rasha Amin[1], Marwa Ibrahim[1], Khalid Bureshad[1], Samah Taha[1], Ghassan Mohamadsalih[1], Hajar Dauleh[1], Amel Khalifa[1], Elwaseila Hamdoun[1] & Khalid Hussain[1]
[1]Sidra Medicine, Endocrinology, Doha, Qatar

Prader-Willi syndrome (PWS) is a neurodevelopmental disorder with impaired hypothalamic function due to abnormal DNA methylation within the region of 15q11.2-q13. The available pharmacological options reported for the treatment of hyperphagia and obesity in PWS include Phentermine, Topiramate, Glucagon-like peptide 1 receptor agonist (Exenatide, Liraglutide), Naltrexone- Bupropion and Setmelanotide. However, most of these have been ineffective and some have been withdrawn due to adverse effects. Achieving weight loss in PWS patients is extremely difficult. We report our experience of using a combination therapy of Semaglutide and Methylphenidate in 5 children with PWS to achieve a significant weight loss and improvement in food-seeking behaviors. Five genetically confirmed PWS patients (ages 7, 8, 10, 16, 17 years) were recruited. All had preexisting comorbidities such as T2DM (2), obstructive sleep apnea (5), fatty liver (5). In all 5, other treatment modalities for hyperphagia and obesity like growth hormone, low-calorie diets and laparoscopic sleeve gastrectomy (in one of them) were tried and failed. Hence, they were selected for this combination therapy. The treatment protocol involved using Methylphenidate as an appetite suppressant (starting at 18mg titrated to 36mg, 54mg, 72mg and 108mg) along with Semaglutide (0.5mg titrated to 1mg, 1.5mg and finally 2.4mg). The titrations were made every 3 weeks based on the tolerability. The laboratory parameters, Ghrelin, Leptin, Dykens hyperphagia score, ultrasonography of abdomen, total body composition by DXA, baseline echocardiography was performed for all. This protocol was initiated in 5 children after hospitalization then discharged on combination therapy. Along with therapy they were on low calorie diets. They lost between 6 to 11.5% of weight after 4 to 12 months of starting treatment. In addition, there was complete resolution of T2DM in one of them, improvements in hyperphagia score, sleep apnea and total body composition. It is recommended a moderate weight loss of 5–10% as the goal for medically supervised weight loss. Ghrelin and Leptin were obtained in 2 of them. Ghrelin was 1125pg/ml pre therapy and 1254pg/ml after 1 month in the first. Leptin was 53ng/ml and 36 ng/ml post initiation. The other patient's Ghrelin was 2627pg/ml pre and 696pg/ml after 7 months. Leptin was 24ng/ml pre and 40ng/ml after 7 months. The anorectic potency of the combination of Semaglutide and Methylphenidate can be utilized in PWS. Significant weight loss can have game-changing effects on complications such as T2DM and severe obstructive sleep apnea. However, this combination therapy warrants further clinical trials.

Body mass index trajectories from early childhood to late adolescence: an analysis of the leicester respiratory cohorts

Lorenz Leuenberger[1, 2], Fabiën Belle[1], Ben Spycher[1], Myrofora Goutaki[1, 3], David Lo[4, 5], Erol Gaillard[4, 5] & Claudia Kuehni[1, 3]
[1]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland; [2]Graduate School for Health Sciences, University of Bern, Bern, Switzerland; [3]Division of Pediatric Respiratory Medicine and Allergology, Department of Pediatrics, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [4]Department of Respiratory Sciences, Leicester NIHR Biomedical Research Centre (Respiratory theme), University of Leicester, Leicester, United Kingdom; [5]Department of Pediatric Respiratory Medicine, Leicester Children's Hospital, University Hospitals Leicester, Leicester, United Kingdom

Introduction
Childhood obesity has become a prevalent global health concern, affecting 25% of 10-year-olds in Leicestershire, UK. Understanding the development of obesity is crucial for identifying key predictors and groups at risk. In this study, we aimed to find distinct developmental trajectories of body mass index (BMI) and explore potential risk factors in a large, population-based pediatric cohort.
Methods
We used data from the Leicester Respiratory Cohorts (LRC), recruited in 1990 and 1998 as random samples of all 1-4 year old children living in Leicestershire UK. We calculated BMI using height and weight measurements from routine health care visits, study visits, and questionnaires, excluding extreme values with a z-score $<$-5 or $>$5, based on UK growth charts. Participants with at least 3 BMI values between 0-18 years were included. We used B-Splines to find a parsimonious pattern of BMI over age in the single class model. We then used Group Based Trajectory Modelling to identify the presence of distinct BMI trajectories, selecting the best model based on Bayesian Information Criterion, class size, average posterior probabilities, entropy, and biological plausibility. We employed multinomial logistic regression to identify factors associated with each BMI trajectory.
Results
Out of the 10, 350 children in the LRC, we included 5523 eligible children (52% boys). The best single class BMI pattern were quadratic B-Splines with two knots at 0.6 years and 9.7 years. We found 5 BMI development trajectories: normal (n = 2699, 49%), below normal (n = 1494, 27%), early overweight resolving (n = 576, 10%), school-age onset obesity (n = 217, 4%), and adolescent onset overweight (n = 537, 10%). Compared to boys, girls were more likely to be in the below normal (OR: 1.65, CI95%: 1.45-1.87), school-age onset obesity (1.48, 1.12-1.95), and adolescent onset overweight (1.48, 1.23-1.78) trajectories. Children of Asian ethnicity, compared to European, had higher odds of being in the below normal (2.75, 2.39-3.17), school-age onset obesity (1.68, 1.23-2.28), and adolescent onset overweight (1.41, 1.14-1.75) trajectories, but lower odds of being in the early overweight resolving (0.68, 0.53-0.87) trajectory. Children in the lowest tertile of socioeconomic status were more likely to be in the below

normal (1.65, 1.39-1.95) and school-age onset obesity (1.80, 1.21-2.68) trajectories, compared to children in the highest tertile.
Conclusion
We identified five distinct BMI developmental trajectories and found that female sex, Asian ethnicity, and low socio-economic status were associated with specific trajectories. Targeted interventions should focus on these high-risk groups to prevent obesity and related health issues.

Effectiveness of simulation-based learning in enhancing confidence and clinical competence in managing lipid-related diseases: a mixed-methods study
Anagh Josh Banerjee[1], Akshat Sinha[1], Tejas Kalaria[2], Amro Maarouf[3], Sadaf Ali[4], Ateeq Syed[5], Atul Kalhan[6], Punith Kempegowda[4, 7], Maiar Elhariry[8], DEVI Collaboration[7] & Sangamithra Ravi[1]
[1]University of Birmingham, Birmingham, United Kingdom; [2]New Cross Hospital, Royal Wolverhampton NHS Trust, Wolverhampton, United Kingdom; [3]Russell Hall Hospital, Dudley Group NHS Foundation Trust, Dudley, United Kingdom; [4]Queen Elizabeth Hospital Birmingham, University Hospitals NHS Foundation Trust, Birmingham, United Kingdom; [5]Heartlands Hospital, University Hospitals NHS Foundation Trust, Birmingham, United Kingdom; [6]Royal Glamorgan Hospital, Wales, United Kingdom; [7]Department of Applied Health Sciences, School of Health Sciences, College of Medicine and Health, University of Birmingham, Birmingham, United Kingdom; [8]Sandwell and West Birmingham NHS Foundation Trust, Birmingham, United Kingdom

Background
The growing prevalence of lipid-related diseases poses a significant challenge to global health, underscoring the need for innovative educational strategies to upskill healthcare professionals in managing these conditions. Simulation via Instant Messaging for Bedside Application (SIMBA) is a novel simulation-based learning (SBL) model that has effectively enhanced healthcare professionals' confidence in managing diverse medical scenarios. By simulating real-world clinical situations, SIMBA provides an interactive platform for participants to develop and refine essential clinical skills.
Objectives
1. Evaluate the effectiveness of the SIMBA model in improving participants' confidence in managing lipid-related diseases.
2. Assess the clinical performance of healthcare professionals during simulations of lipid-related disease scenarios.
3. Determine the applicability of the SIMBA model as an educational tool for lipid disease training.
Methods
This mixed-methods study collected and analysed both qualitative and quantitative data. It was conducted in the UK from June to November 2024. The SIMBA model facilitated SBL sessions on five topics: Familial Hypercholesterolemia, Secondary Prevention of Cardiovascular Disease through Lipid Control, Chylomicronemia Syndrome, Acute Triglyceridemia, and Alström Syndrome. Healthcare professionals interested in lipid disorders were invited to participate, and those who completed both pre- and post-SIMBA surveys were included in the analysis. Statistical analysis was performed in STATA version 17.0. Changes in confidence to manage lipid-related pathology were measured using pre- and post-SIMBA surveys. Participant interactions during simulations were evaluated using an adapted Global Rating Scale approved by subject matter experts.
Results
Thirty participants completed both surveys and were included in the analysis. Confidence levels improved significantly after the sessions (pre-simulation vs post-simulation: 24.3% vs 94.7%; $P < 0.01$). Median scores out of 5 for core clinical competencies were as follows: history-taking (4.0), examination (3.9), investigation (3.8), result interpretation (2.5), clinical judgment (3.7), and management (3.4). 93.3% of participants deemed the sessions applicable to their clinical practice, with 73.4% rating them as excellent. Additionally, over 90% found the content impactful professionally and personally, facilitating effective knowledge translation into patient care.
Conclusion
The SIMBA model significantly enhanced healthcare professionals' confidence and clinical competencies in managing lipid-related diseases. Notably, gaps in interpreting diagnostic test results were identified, highlighting the need for targeted educational interventions. The SBL approach was well-received and considered highly applicable to clinical practice. Further studies are warranted to explore the model's long-term impacts and broader applicability to lipid disease management and education.

AIP deficiency in zebrafish causes loss of intestinal epithelial differentiation via disrupted wnt signaling
Xian Wang[1, 2], Oliver Haworth[1, 3], Sayka Barry[1], Adele Leggieri[2], charlotte Hall[1], Joanne Martin[4], Marta Korbonits[1] & Caroline Brennan[2]
[1]Centre for Endocrinology, William Harvey Research Institute, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom; [2]School of Biological and Behavioural Sciences, Queen Mary University of London, London, United Kingdom; [3]School of Life Sciences, University of Westminster, London, United Kingdom; [4]Centre for Genomics and Child Health, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom

Background
Heterozygous mutations in the chaperone Aryl Hydrocarbon Receptor Interacting Protein (AIP) are implicated in approximately 10% of familial isolated pituitary adenomas, while homozygous mutations result in embryonic lethality in mice, *Drosophila* and *C. elegans* models. To date, five human patients with complete loss of AIP function have been identified, exhibiting, among other features, failure to thrive and severe diarrhoea requiring parenteral nutrition.
Methods
In this study, we generated an *aip* loss-of-function zebrafish model using CRISPR-Cas9 gene editing to investigate the molecular and physiological consequences of AIP deficiency. Survival rates were monitored daily, and intestinal morphology was assessed via haematoxylin and eosin (H&E) staining. Cellular proliferation was evaluated through PCNA immunohistochemistry, while stem cell populations were characterized using *in situ* hybridization for specific mRNA markers. Cell morphology was assessed via immunofluorescence. Gene expression of WNT signalling pathway was analysed through RNA sequencing (RNA-seq) and quantitative PCR (RT-qPCR) performed. Food ingestion capacity was evaluated using a feeding assay.
Results
aip mutant zebrafish exhibited growth retardation from 6 days post-fertilization (dpf). Although they demonstrated the ability to capture food, mutants displayed impaired digestion and absorption, possibly due to a failure of intestinal epithelial differentiation at 5 dpf. By 4 dpf, overactivation of WNT signalling and increased cellular proliferation were observed in mutants, accompanied by a marked deficiency in intestinal stem cells and disrupted cell elongation. By 7 dpf, *aip* knockout fish exhibited a notable increase in bi-nucleated cells within the intestinal epithelium, along with a significant reduction in the number of Goblet cells.
Conclusion
These findings suggest that loss of *aip* results in intestinal stem cell depletion, impaired cellular differentiation, and defects in cell elongation, partly mediated through dysregulation of the WNT signalling pathway.
Keywords *aip*, zebrafish, wnt, proliferation, stem cells.

Development of a novel thyroid hormone profiling method using liquid chromatography tandem mass spectrometry
Fozia Shaheen[1], Max Luckett[1], Oliver Bates[1], Nadia Schoenmakers[1], Vicki Smith[1] & Angela Taylor[1]
[1]Metabolism and Systems Science, University Of Birmingham, Birmingham, United Kingdom

Introduction
Thyroid hormones (TH) are critical for numerous biological processes including development, growth, and metabolism. The thyroid gland primarily secretes thyroxine (T4) and a small amount of triiodothyronine (T3), with T3 being predominantly produced through the deiodination of T4 in peripheral tissues. Deiodinase enzymes both activate T4 to T3 and facilitate the deactivation/clearance of T3 into various metabolites, including rT3, 3, 5-T2, 3, 3'-T2, 3'5'-T2, 3-T1, 3'-T1, and T0.

Methods and Results
We developed a liquid chromatography tandem mass spectrometry (LC-MS/MS) method capable of analysing nine thyroid hormone metabolites (THM). Quantitation was achieved by comparison to reference standards following addition of internal standards (T3, rT3, 3-T1, and T4, all labelled with $^{13}C6$). Serum, calibrator, or quality control (QC) samples were treated with 1.25% NH4OH/acetonitrile (1:1) and centrifuged. The THM were then extracted using an Evolute Express AX 30mg solid phase extraction (SPE) plate, with the final elution using formic acid in methanol. After evaporation, samples were reconstituted in a methanol-water mixture before LC-MS/MS analysis using a Waters Acquity system with a Xevo-MS detector and a Luna Omega 1.6µm Polar C_{18} column. Full chromatographic separation of nine THM was achieved within a 7-minute run time. The method demonstrated recovery rates ranging from 96-107%. Application of the method to male serum enabled the quantification of all nine THM (T0, 3-T1, 3'-T1, 3, 5-T2, 3, 3'-T2, 3', 5'-T2, T3, rT3, T4).
Conclusions
This high-throughput LC-MS/MS method, provides a comprehensive tool for thyroid hormone profiling that will significantly advance THM research. Method validation is ongoing and will facilitate THM profiling in healthy and disease populations. This method has the potential to enhance understanding of TH metabolism in multiple contexts, supporting clinical diagnosis and management.

Relation of a-synuclein level to glucotoxicity, lipotoxicity and cerebral neurodegeneration in children with obesity

Nouran Salah[1], Sara Taha[2], Safeya Hassan[2], Mai Abdeen[2] & Rana Mahmoud[2]
[1]Ain Shams University, Cairo, Egypt; [2]Ain Shams University, Pediatrics, Cairo, Egypt

Background
Children with obesity exhibit subtle neurocognitive deficits, the mechanism of which remains unknown. α-synuclein plays a fundamental role in neurodegeneration. Moreover, its role in glucose and lipids metabolism is emerging.
Objectives
This study aims to assess whether α-synuclein is correlated with the degree of neurodegeneration in children with obesity in comparison to healthy controls and correlate it to various neurocognitive and metabolic parameters.
Subjects/Methods
Forty children with obesity and 40 matched-healthy controls were assessed for anthropometric measurements and blood-pressure. Cognitive evaluation was performed using Stanford–Binet scale and Barkley Deficits in Executive Functioning (EF) Scale-Children and Adolescents. α-synuclein, fasting lipids and glucose were measured with calculation of the homeostatic model of insulin-resistance.
Results
Children with obesity had significantly higher α-synuclein ($P < 0.001$) and total EF percentile ($P = 0.001$) than controls. α-synuclein was negatively correlated to total IQ ($P = 0.001$), and positively correlated with total EF percentile ($P = 0.001$) and EF symptom count percentile ($P < 0.001$) in children with obesity. Multivariate-regression revealed that α-synuclein was independently related to diastolic blood-pressure percentile ($P = 0.013$), waist/hip ratio SDS ($P = 0.007$), total EF percentile ($P = 0.033$) and EF symptom count percentile ($P < 0.001$) in children with obesity.
Conclusion
α-synuclein could have a mechanistic role in neurocognitive deficit among children with obesity.

Keywords Alpha-synuclein, obese children, neurodegeneration.

Beneficial effects of oleocanthal-rich olive oil on platelet functionality and other metabolic parameters of type II diabetic patients

Maria Efthymia Katsa[1], Andrea Paola Rojas Gil[2, 3], Eleni Patrianakou Xanthakou[3], Anastasios Ioannidis[3], Prokopios Magiatis[4], Eleni Melliou[4] & Tzortzis Nomikos[1]
[1]Department of Nutrition and Dietetics, School of Health Sciences and Education, Harokopio University of Athens, GR-17676 Athens, Greece, Nutrition and Dietetics, Athens, Greece; [2]University of the Peloponnese, Nursing, Tripolis, Greece; [3]School of Health Sciences, Laboratory of Basic Health Sciences, Department of Nursing, University of Peloponnese, Tripoli, Nursing, Tripolis, Greece; [4]Laboratory of Pharmacognosy and Natural Products Chemistry, Department of Pharmacy, National and Kapodistrian University of Athens, Pharmacy, Athens, Greece

Background
A common phenomenon observed in type 2 diabetes mellitus is the postprandial dysmetabolism, which may act as a daily stressor of the already dysfunctional diabetic platelets.
Methods
Ex-vivo experiments have been performed on isolated platelet-rich plasma of 16 healthy volunteers. Antiplatelet activity, of 7 most common bioactive phenolic compounds of olive oil, was assessed in isolated platelet-rich plasma (PRP) by optical transmittance aggregometry, using ADP and TRAP as aggregating factors. According to the ex-vivo results, the clinical study followed and had a randomized, crossover design. Ten T2DM patients consumed five isocaloric meals containing 120g white bread combined with: (i)39g butter, (ii)39g butter and 400mg ibuprofen, (iii)40mL OO (phenolic content < 10mg/Kg), (iv)40mL OO with 250mg/Kg oleocanthal and (v)40mL OO with 500mg/Kg oleocanthal. Glycemia markers and lipid profile was measured in serum pre and postprandially, while the ex-vivo ADP- and TRAP-induced platelet aggregation were also calculated. TBARS and GPX3 were measured in plasma and TBARS and GPX1 in red blood cells(RBC), protein carbonyls(PC) in plasma pre- and post-prandially.
Results
Ex-vivo experiments showed that oleocanthal had better antiplatelet activity(APA) against ADP compared to TRAP while oleacein had milder APA than oleocanthal for all active agents. Regarding the clinical study, the glycemic and lipidemic response was similar between meals. However, a sustained (90-240 min) dose-dependent reduction in platelets' sensitivity to both ADP (50–100%) and TRAP (20–50%) was observed after the oleocanthal meals. in comparison to other meals. The APA of the OO containing 500mg/Kg oleocanthal was comparable to that of the ibuprofen meal. OO meals induced an increase of TBARS measured in both plasma and RBC. The Incremental area under the curve (iAUC) of TBARS in plasma was lower in oleocanthal enriched OO compared to OO. The kinetic activity of GPX3 after BU-IBU consumption was similar with that of OO meals, while the iAUCs of OO meals were greater compared to BU. Regarding GPX1, the kinetic activity was similar after all meals, showing a postprandial increase till t = 120min. The correlation analysis showed that the iAUC of the EC50 for ADP had an inverse correlation with iAUC of TBARS (r- = -0.311, $P = 0.036$). Moreover, positive was the correlation between iAUC of TBARS and iAUC of PC ($r = 0.385$, $P = 0.008$) while negative was the correlation between iAUC of RBC TBARS and LDL (r- = -0.348, $P = 0.019$).
Conclusions
The consumption of meals containing oleocanthal-rich OO can reduce platelet activity and has antioxidant properties, during the postprandial period, irrespective of postprandial hyperglycemia and lipidemia.

JOINT3311

Oxyntomodulin as a biomarker for metabolic dysregulation and obesity: pathophysiological insights and screening potential

Anna Popławska-Kita[1], Angelika Buczyńska[1], Maria Kościuszko[1], Mateusz Zwierz[1] & Adam Krętowski[1]
[1]Medical University of Bialystok, Bialystok, Poland

Background
Oxyntomodulin (OXM), an endogenous peptide derived from preproglucagon, plays a crucial role in energy homeostasis by modulating appetite regulation and glucose metabolism through dual activation of the glucagon-like peptide-1 receptor (GLP-1R) and glucagon receptor (GCGR). Despite its known anorexigenic and metabolic effects, its role in obesity pathophysiology remains underexplored. The present study investigates OXM dynamics in obesity and its potential utility as a biomarker for metabolic dysfunction and obesity-related risk stratification.
Methods
A total of 261 participants were stratified into three groups based on body mass index (BMI): normal-weight controls (CG, $n = 39$), overweight individuals (O1, $n = 88$), and obese individuals (O2, $n = 134$). Comprehensive metabolic profiling was conducted, including an oral glucose tolerance test (OGTT), insulin and C-peptide levels, body composition analysis via DXA/BIA, and serum OXM

quantification using enzyme-linked immunosorbent assay (ELISA). Correlation analyses assessed associations between OXM levels and key metabolic parameters.
Results
Serum OXM levels significantly differed across groups ($p < 0.0001$, ANOVA). The obese group (O2) exhibited significantly higher OXM levels compared to both the overweight (O1, $p < 0.0001$) and control (CG, $p < 0.0001$) groups. While a trend toward increased OXM was observed in overweight individuals (01) compared to controls (CG), this difference did not reach statistical significance ($P = 0.2258$). In the obese cohort, OXM levels correlated positively with fasting insulin ($r = 0.52$, $p < 0.0001$), C-peptide ($r = 0.60$, $p < 0.0001$), and visceral adipose tissue ($r = 0.33$, $p < 0.0001$), suggesting an adaptive response to metabolic stress. However, the increase in OXM was not associated with improved glycemic control, as indicated by a weak positive correlation with HbA1c ($r = 0.25$, $P = 0.0049$).
Conclusion
The findings support the hypothesis that elevated OXM in obesity represents a compensatory response to metabolic dysregulation rather than an effective homeostatic mechanism. The significant differences in OXM between groups, along with its correlation with key metabolic indicators, suggest its potential as a screening biomarker for obesity-related metabolic risk. Further research is warranted to evaluate its predictive value in clinical settings and its potential utility in personalized therapeutic strategies, particularly in the context of OXM-based pharmacotherapies.

Introduction
50-80% of individuals undergoing bariatric surgery (BS) are women of reproductive age. Pregnancies following BS are associated with a higher risk of intrauterine growth restriction (IUGR) and low birth weight (LBW), but lower incidence of macrosomia, preeclampsia, and gestational diabetes (GD).
Methods
Our observational, retrospective study compared maternal-fetal outcomes of women who became pregnant after BS with matched controls based on age and BMI, using data from deliveries at our center between June 2019 and September 2024.
Results
Each group included 51 women, with an average BMI of 30.3 kg/m^2 and an average age of 36 years. Gastric sleeve (68.6%) was the most common procedure in the BS group and resulted in an average 33% weight loss pre-pregnancy. Despite a high rate of nutritional deficiencies (52.9% folic acid, 41.2% iron and 9.8% vitamin B12) and anemia (21.6%), there were no differences in weight gain during pregnancy (12% vs. 14% post-BS, $P = 0.535$), with an average weight gain of 10 kg in both groups. The mean gestational age was also similar between groups (272 days vs. 273 days post-BS, $P = 0.779$), as was the prevalence of preterm births, dystocia, and cesarean sections. There were no significant differences in pre-pregnancy diagnoses of diabetes or hypertension, nor in the need for medically assisted reproduction. Maternal outcomes also showed less frequent need of pharmacological treatment for GD in the post-BS group (RR 0.337, CI 0.13–0.87), while gestational hypertension, preeclampsia, and macrosomia were more prevalent in controls in a not statistically significant way. Neonatal outcomes indicated similar rates of LBW and malformations between groups. However, post-BS newborns had lower birth weights (3051g vs. 3231g, $P = 0.162$) and higher IUGR risk (RR 2.11, CI 1.71–2.60).
Conclusion
Post-BS pregnancies showed reduced prevalences of hypertensive disorders, macrosomia and need for GD treatment but increased risks of IUGR, emphasizing the need for specialized prenatal care.

Rhein induces adipose browning via inhibition of glucocorticoid receptor

Ping Gu[1], Wei Wang[1], Bin Lu[1], Hannah Hui[2] & Jiaqing Shao[1]
[1]Nanjing Jinling Hospital, Nanjing, China; [2]School of Biomedical Sciences, The Chinese University of Hong Kong, Hong Kong, China

The existing anti-obese therapies mainly target to cut down the energy intake, which is often associated with neuro-endocrine side effects[2]. On the other hand, therapies to safely augment energy expenditure are lacking. Compelling evidence have shown that activation of adipose browning is sufficient to confer protection against a panel of metabolic disorders including obesity, diabetes and cardiovascular diseases. Here we found that rhein, the major component in the traditional Chinese medicine Rhubarb, robustly increased energy expenditure and adipose tissue browning in obese mice. Further analysis showed that Rhein-induced energy expenditure was mainly orchestrated through SIRT1 in adipocytes, as adipocyte-selective deletion of Sirt1 gene almost completely mitigated Rhein-induced effect on enhancing adipose energy expenditure. By pull-down assay, ARGLU1, a transcriptional co-regulator of glucocorticoid receptor, was identified as a protein that directly binds with rhein in adipocytes. Rhein-induced adipocyte browning was abolished *In vitro* upon overexpression of ARGLU1. Furthermore, in mice receiving glucocorticoid, supplementation of rhein rescued glucocorticoid-induced obesity, insulin resistance, and most importantly impairment of adipose browning. In conclusion, here we unravel the new mechanism underlying the anti-obese effect of rhein, which is achieved through modulating the activity of glucocorticoid receptor.

Effects of maternal pre-pregnancy body mass index and gestational weight gain on body composition and blood sugar in three-year-old offspring

Steffie Gundersen[1], Ida Jensen[2], Kasper Pilgaard[3], Bente Stallknecht[4], Ellen Løkkegaard[2, 5], Jane Bendix[2], Stig Molsted[5, 6], Anne Jessen[4] & Grete Teilmann[1, 5]
[1]Department of Pediatrics, Copenhagen University Hospital - North Zealand, Hillerød, Denmark; [2]Department of Gynecology and Obstetrics, Copenhagen University Hospital - North Zealand, Hillerød, Denmark; [3]Steno Diabetes Center Copenhagen (SDCC), Herlev, Denmark; [4]Department of Biomedical Sciences, University of Copenhagen, Copenhagen, Denmark; [5]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [6]Department of Clinical Research, Copenhagen University Hospital - North Zealand, Hillerød, Denmark

Introduction
Maternal pre-pregnancy Body Mass Index (BMI) and gestational weight gain (GWG) are associated with outcomes for the mother and her offspring. A high maternal pre-pregnancy BMI is associated with increased risk of childhood obesity and excessive GWG is associated with higher neonatal body fat and birth weight as well as metabolic outcomes as Hemoglobin A1c (HbA1c). We aimed to explore the association between maternal pre-pregnancy BMI and offspring BMI z-scores at three years of age. We also explored the associations between GWG and 1) offspring body fat percentage (BF%) measured using Dual-energy X-ray Absorptiometry (DXA) and 2) offspring HbA1c at three years of age.
Methods
FitKids is a follow-up study on three-year-old offspring from pregnant women, who participated in a randomized controlled trial, FitMum, conducted at North Zealand Hospital, DK, from 2018-2021. 68 children (39 boys) with a mean age of 3.3 (SD 0.2) years participated in FitKids. BMI z-scores were calculated for all children, 53 children were DXA-scanned and 38 provided blood samples. Maternal pre-pregnancy BMI was calculated. Estimates of GWG for a standardized pregnancy period were predicted using a model based on longitudinally observed body weights during pregnancy and at admission for delivery. Associations between maternal GWG and offspring BF% and HbA1c were analyzed using linear regression analyses. The same applied for the association between maternal pre-pregnancy BMI and offspring BMI z-score at age three. All models were unadjusted.
Results
Mean pre-pregnancy BMI was 26.4 kg/m^2 (SD 5, 7) and mean GWG was 15.2 kg (SD 6.0). Mean offspring BF% was 25.8% (SD 3.4) and mean offspring HbA1C was 33.7 (SD 2.5). We found an association between maternal pre-pregnancy BMI and offspring BMI z-score at age three (slope 0.046, $P = 0.028$). There was

neither an association between maternal GWG and offspring BF% at three years of age (slope 0.075, $P = 0.394$) nor an association between maternal GWG and offspring HbA1c (slope 0.027, $P = 0.179$.

Conclusion

A higher maternal pre-pregnancy BMI was associated with a higher BMI z-score at three years of age. Maternal GWG did not affect offspring BF% or HbA1c at three years of age.

Serum and liver lipidome following empagliflozin administration for six months in a fast food diet mouse model

Evangelia Makri[1], Thomai Mouskeftara[1], Helen Gika[1], Konstantinos Xanthopoulos[1], Eleftheria Makri[1], Panagiotis Mavrommatis-Parasidis[1], Anastasia Tsingotjidou[1], Angeliki Cheva[1], Antonis Goulas[1] & Stergios Polyzos[1]

[1]Aristotle University of Thessaloniki, Thessaloniki, Greece

Empagliflozin is a sodium-glucose co-transporter inhibitor approved for the treatment of type 2 diabetes mellitus. The aim of this study was the 6-month effect of empagliflozin on serum and liver lipidome in C57BL/6J mice (EMPA group) fed on fast food diet (FFD) compared with a group fed on FFD without empagliflozin (FFD group) and another control group fed on a chow diet (CD group). Following untargeted lipidomics analysis, FFD and EMPA groups displayed similar serum lipid profiles, characterized by elevated levels in most of the identified lipids, particularly glycerophospholipids, compared to the CD group. Conversely, hepatic lipid profiles varied more significantly between the groups. For example, phosphatidylcholine (PC), phosphatidylinositol (PI), and phosphatidylglycerol demonstrated mixed trends in the FFD and EMPA groups compared with the CD group. FFD appears to have a more substantial impact on lipidomic profiles compared with the preventive empagliflozin effect (CV ANOVA = 3.43×10^{-6} FFD vs. CD; 7.67×10^{-7} EMPA vs. CD; 2.00×10^{-2} EMPA vs. FFD). Interestingly, several glycerophospholipids, including PC 34:1, PC 35:1, PC 36:3, PC 38:4, PI 34:2 and PI 38:3, increased in both serum and hepatic tissues of the FFD and EMPA groups compared to the CD group. In conclusion, EMPA had largely similar lipidomic profile compared with FFD. However, both EMPA and FFD groups showed distinct lipidomic profiles compared to the CD group.

Single point insulin sensitivity estimator (SPISE) for cardiovascular risk assessment in pediatric central nervous system cancer survivors (PCNSCSs): a practical approach for early detection

Giacomo Tantari[1], Amanda Casirati[1], Gianluca Piccolo[2], Marco Del Monte[3], Alessandro Suppa[3], Annalisa Gallizia[4], Marta Panciroli[3], Mohamad Maghnie[3], Giuseppe d'Annunzio[1] & Natascia Di Iorgi[3]

[1]Pediatric Clinic and Endocrinology Unit, IRCCS Istituto Giannina Gaslini, Genoa, Italy; [2]Neuroncology Unit, IRCCS Istituto G. Gaslini, Genoa, Italy; [3]DINOGMI (Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health), University of Genoa, Genoa, Italy; [4]Pulmonary Disease and Respiratory Endoscopic Unit, IRCCS Istituto Giannina Gaslini, Genoa, Italy

Background

The long-term cancer survivors has increased, but the effects of therapies require attention. PCNSCSs are at risk for insulin resistance (IR) and cardiovascular (CV) complications. IR can be detected by a simple and reproducible method called SPISE.

Methods

We assessed SPISE in 57 PCNSCSs (27 males), median age 12 years (5-18), followed for at least two years post-treatment. Diagnoses included astrocytic (37%), embryonal (23%), sellar (14%), ependymal (14%), and germ cell (12%) tumors. Treatment involved radiotherapy (88% of patients, 37% craniospinal), chemotherapy (75%), and surgery (74%). We analyzed body mass index (BMI), waist/height ratio (WHtR), laboratory exams, and DXA. BMI $>$ 1 SDS defined overweight (40% of patients), BMI $>$ 2 SDS obesity (12%), WHtR $\geq$ 0.5 CV risk. SPISE was calculated as: 600 $\times$ HDL cholesterol^0.185/triglycerides^0.2 $\times$ BMI^1.338, fat/lean mass (FLR) by DXA.

Results

A WHtR $\geq$ 0.5 was found in 53% of PCNSCSs. Patients with WHtR $\geq$ 0.5 had higher BMI SDS values (1.33 [0.83; 2.02] vs. -0.04 [-0.71; 0.5], $p < 0.001$) and lower SPISE values (6.98 [5.15-8.50] vs. 10.60 [8.75-11.28], $p < 0.001$). SPISE was associated with WHtR $\geq$ 0.5 (Or = 0.626, 95% CI [0.462-0.848], $P = 0.003$), with an AUC of 0.81 ($p < 0.001$) for predicting WHtR $\geq$ 0.5. The optimal SPISE cut-off was 8.63 (sensitivity = 78%, specificity = 79%). PCNSCSs with SPISE $\leq$ 8.63 (51%) had higher FLR values (0.77 [0.57; 0.93] vs. 0.58 [0.36; 0.72], $P = 0.002$) and higher WHtR (0.52 [0.49; 0.57] vs. 0.47 [0.42; 0.49], p $<$. 001). Those with WHtR $\geq$ 0.5 had higher FLR values (0.86 [0.63; 0.94] vs. 0.54 [0.36; 0.74], $P = 0.001$), with FLR associated with WHtR $\geq$ 0.5 (Or = 61.9, 95% CI [4.73-811.0], $P = 0.002$). ROC curve analysis identified FLR $>$ 0.86 as a threshold for altered body composition (AUC = 0.77, $P = 0.001$, sensitivity = 53%, specificity = 93%). SPISE was associated with FLR $>$ 0.86 (Or = 0.56, 95% CI [0.42-0.75], $p < 0.001$), and its AUC for predicting FLR $>$ 0.86 was 0.82 ($p < 0.001$).

Conclusions

SPISE association with higher WHtR and FLR, indicates its valuable and non-invasive tool for identifying CV risk. SPISE requires few universally available laboratory data, and could be a useful tool for longitudinal studies in PCNSCSs. Furthermore, it may help to optimize resource allocation by prioritizing DXA for patients with low SPISE and high WHtR.

Real-world results of genetic testing and performance of clinical criteria for familial hypercholesterolemia in a targeted young adult population

Jonathan Han YongJun[1], Gerald Sng Gui Ren[1], Sharon Pek Li Ting[2], Tavintharan Subramaniam[3], Bee Yong Mong[1] & Tan Hong Chang[1]

[1]Department of Endocrinology, Singapore General Hospital, Singapore, Singapore; [2]Clinical Research Unit, Khoo Teck Puat Hospital, Singapore, Singapore; [3]Diabetes Centre, Admiralty Medical Centre, Singapore, Singapore

Background

Familial hypercholesterolemia (FH) is a common inherited disorder that significantly contributes to atherosclerotic cardiovascular disease (ASCVD). In Asia, limited access to genetic testing often necessitates the use of clinical criteria, such as the Simon-Broome (SB) or Dutch Lipid Clinic Network (DLCN) criteria, to identify FH. Younger adults, who typically have fewer metabolic comorbidities, are more likely to be diagnosed with FH. However, the accuracy of these criteria compared to genetic testing in younger adults remains unclear. This study assessed the performance of SB and DLCN criteria against genetic testing for FH in individuals under 25 years.

Methods

Between May 2021 and June 2024, 40 individuals under 25 years who underwent genetic testing for FH at a single institution were included. Retrospective data collection covered demographic (age, gender), anthropometric (BMI), clinical (physical stigmata of FH, family history of premature ASCVD), and biochemical (lipid profiles) parameters. Genetic testing results were classified as "positive" (pathogenic/likely pathogenic variants) or "negative" (VUS, benign, likely benign, no mutation). The diagnostic performance of SB, DLCN, total cholesterol (TChol), and LDL-C criteria was evaluated using receiver operating characteristic (ROC) curve analysis.

Results

Nineteen individuals (47.5%) tested positive for FH, with all carrying heterozygous mutations; 17 had LDLR gene variants. There were an additional 7 individuals with variants of uncertain significance (VUS). No significant differences were observed in age, gender, BMI, or comorbidities between test-positive and test-negative groups. While a higher proportion of test-positive individuals had a family history of premature ASCVD (36.8% vs 14.3%), this was not statistically significant ($P = 0.100$). Test-positive individuals had significantly higher median TChol (8.30 mmol/l vs 7.55 mmol/l, $P = 0.012$) and LDL-C (6.53 mmol/l vs 5.43 mmol/l, $P = 0.002$). ROC analysis showed AUCs of 0.866 for DLCN, 0.818 for SB, 0.791 for LDL-C, and 0.733 for TChol. DLCN $>$5 points achieved 94.7% sensitivity and 71.4% specificity, whilst raising the cut-off to $>$7 points improved specificity to 76.2% without changing sensitivity. SB "possible FH" had 89.5% sensitivity but lower specificity (57.1%). An LDL-C cutoff of $>$5.45 mmol/l provided the same sensitivity and specificity as SB.

Discussion
In our cohort of young adults, traditional FH criteria performed well but offered limited advantages over lipid levels alone. The low prevalence of physical signs and family history in this age group reduces the utility of SB and DLCN criteria. LDL-C thresholds alone may serve as a simpler and effective tool for FH detection in young Asian populations.

Distinct response of the human plasma lipidome to cold and fenoterol

Fabienne Bur[1], Laila Füchtbauer[1], Carole Baumann[1], Jael Senn[1], Aninja Isenrich[1], Rahel Löliger[1], Marceline Fuh[2], Jörg Heeren[2] & Matthias Betz[1]
[1]University Hospital Basel, Department of Endocrinology, Diabetes and Metabolism, Basel, Switzerland; [2]University Hospital Hamburg-Eppendorf, Center for Experimental Medicine, Institute of Biochemistry and Molecular Cell Biology, Hamburg, Germany

Background/Objective
Brown adipose tissue (BAT) plays a crucial role in thermoregulation. Upon cold exposure, the sympathetic nervous system releases norepinephrine, which activates β-adrenergic receptors (β-AR) on brown adipocytes. This activation stimulates lipolysis, leading to the release of free fatty acids that serve both as activators of uncoupling protein 1 (UCP1) and as substrates for mitochondrial oxidation, thereby generating heat. Recent research has indicated that β_2-AR stimulation could activate human BAT. Here, we analysed the changes in lipidome in response to cold-exposure and β_2-adrenergic stimulation with the selective agonist fenoterol.
Methods
We performed a cross-over, randomized trial in twelve healthy volunteers (seven men and five women). We determined resting energy expenditure (REE) using indirect calorimetry once before and after a mild cold stimulus and in a further visit before and after a continuous fenoterol injection (145 µg). Both interventions were performed over 2 hours. Blood sampling to obtain serum for later metabolome analysis by gas chromatography-mass spectrometry (GC-MS) was performed at every visit.
Results
Our study demonstrates that both fenoterol and mild cold exposure significantly increased REE in humans: before fenoterol 1502±281 kcal/24h, after fenoterol 1860±305 kcal/24h ($P < 0.0001$); before cold 1516±347 kcal/24, after cold 1712±270 kcal/24h ($P = 0.02$). Both interventions led to a distinct change in plasma lipid levels. Specifically, fenoterol infusion induced a marked increase in free fatty acid (FA) levels; with FA 18:3 ($_{log2}$FC = 1.21, $P = 4 \times 10^{-8}$), FA 20:3 ($_{log2}$FC = 0.76, $P = 1.2 \times 10^{-7}$), FA 14:0 ($_{log2}$FC = 0.82, $P = 5.6 \times 10^{-7}$), FA 20:2 ($_{log2}$FC = 0.73, $P = 7.3 \times 10^{-7}$) and FA 12:0 ($_{log2}$FC = 0.78, $P = 8 \times 10^{-7}$). In contrast, cold exposure led to a more nuanced increase in FA levels; with FA 18:3 ($_{log2}$FC = 0.46, $P = 0.007$), FA 14:0 ($_{log2}$FC = 0.34, $P = 0.008$) and FA 22:6 ($_{log2}$FC = 0.44, $P = 0.009$). In contrast to fenoterol, the most regulated lipids after cold exposure were lysophosphatidylcholines which were reduced; LPC 18:2 (log2FC = -0.29, $P = 7.7 \times 10^{-5}$), LPC 18:1 ($_{log2}$FC = -0.18, $P = 2.1 \times 10^{-4}$) and LPC 18:3 ($_{log2}$FC = -0.15, $P = 2.8 \times 10^{-4}$).
Conclusion
Both cold exposure and stimulation of the β_2-AR increase lipolysis and REE in humans. Our findings indicate that enhanced lipolysis is a key mechanism driving β_2-AR-stimulated thermogenesis. However, the distinct lipidomic profile points towards different molecular mechanisms in response to cold.

Evaluation of the relationship between IGF-1 and systemic immune-inflammatory markers and metabolic comorbidities in patients with obesity

Gökhan Rıza Baykal[1], Müge Keskin[2], Belma Tural Balsak[1], Caglar Keskin[1], Didem Özdemir[3], Oya Topaloglu[3], Reyhan Ersoy[3] & Bekir Cakir[3]
[1]Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Türkiye; [2]Ankara Bilkent City Hospital, University of Health Sciences, Department of Endocrinology and Metabolism, Ankara, Türkiye; [3]Ankara Yıldırım Beyazıt University Faculty of Medicine, Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Türkiye

Background
Obese individuals can exhibit normal or high IGF-1 levels. The relationship between IGF-1 levels and body mass index (BMI) is not clear. Inflammatory changes and various metabolic features in obese patients may explain this difference. The clinical features of obese patients with low IGF-1 levels are important. It was suggested that obese people with low IGF-1 levels may have more adiposity, inflammation, and metabolic problems like dyslipidemia and hyperuricemia. Obese individuals are known to exhibit a chronic low-level inflammation state. Systemic immune-inflammatory markers are new markers that indicate chronic subclinical inflammation in various diseases. The neutrophil/lymphocyte ratio (NLR), the platelet/lymphocyte ratio (PLR), the lymphocyte/monocyte ratio (LMR), the systemic immune-inflammation index (SII), the systemic inflammatory response index (SIRI), and the systemic inflammation aggregate index (SIAI) are some of these indicators. Obese individuals have demonstrated high levels of SII, NLR, and PLR. This study aimed to evaluate the relationship between IGF-1 levels and systemic immune-inflammatory markers with metabolic comorbidities in patients with obesity.
Methods
We examined 210 obese subjects with a BMI $\geq$ 35 kg/m^2. For each age and gender, a standard IGF-1 standard deviation score (SDS) was used to figure out what the IGF-1 levels meant (low IGF-1 group: ≤ -2.0 SDS and standard IGF-1 group: -2.0 and $+2.0$ SDS). We recorded demographic characteristics, BMI, blood pressure, hypertension, diabetes, hyperuricemia status, NLR, PLR, LMR, SII, SIRI, and SIAI values.
Results
In this study, 7.62% of the subjects had low IGF-1 levels. NLR and SII were significantly higher in the standard IGF-1 group compared to low IGF group. Low IGF-1 levels do not correlate with systemic inflammatory markers. SII was found to be correlated with systolic blood pressure, ALT, and insulin levels. SIAI was correlated with systolic blood pressure. Rate of hypertension was higher in the low IGF 1 group. Low IGF-1 levels were not associated with diabetes and hyperuricemia.
Conclusion
This study is the first to demonstrate the relationship between IGF-1 and immune-inflammatory markers in obese patients. These results suggest that low IGF-1 levels may not be associated with increased inflammation and metabolic disorders in obese patients. Some of these markers were low in the low IGF-1 group, which may explain why metabolic complications were less common in this group.

The french prader-willi registry: an essential tool for clinic and research on prader-willi syndrome

Marion Valette[1], Sandy Faye[1], Cathy Brochado[1], Catherine Molinas[1], Catherine Arnaud[1], Gwenaelle Diene[1] & Maithé Tauber[1]
[1]Chu Toulouse, Toulouse, France

Introduction
Since 2023, the French Reference Centre has developed a new tool for the national registry for children diagnosed with Prader-Willi Syndrome (PWS), based on the "old database" on Access® created in 2005 for children. This new registry was designed as a prospective follow-up of children from birth to 18 years. Physicians first filled the neonate medical sheet and collect signed informed consent from parents. After a multidisciplinary discussion of the neonate situation the patient is included in the data base after approval by the coordinator of the national centre for PWS. This procedure has been set-up after the first clinical trial with oxytocin (OXT) in neonates with PWS in 2017 and is now part of routine care. The procedure allows to have all newborns included in the registry and optimizes the access to compassionate use of OXT for neonates with PWS obtained in 2021 in France. In order to have the best chance to have complete and high quality data we chose to keep patients included in the "old data base" born since 2010 and not before.
Methods
The first step was to collect data from birth to 4 years on medical aspects comprising pregnancy, birth, development, diagnosis, comorbidities, treatments, clinical, radiological and biological results, socio-demographic and family characteristics, in the 408 patients born since 2010. The second step started in 2024 and aimed to add 4 visits to collect data until 18 years including a transition visit. This national registry aims to promote multidisciplinary analyses on current practices in the national network of the reference centre and to take decisions on training, research, treatment and finally improve the registry and patient follow up.

Results
From birth to 4 years, 1994 visits were recorded for 408 patients. Data were collected in 22 French expert centres of the reference centre. After 4 years, visits will be added in the same format at different age-ranges: 7-9 years, 11-13 years, 14-16 years and 16.5-18 years. Specific data linked to the patient's age have been added, especially pubertal data from age 11 and the transition phase before adult follow-up from age 16.5.
Conclusion
This new registry including prospective follow-up of children will allow to improve and facilitate data collection from centres who followed children with PWS and to study the disease trajectories from birth to 18 years. It will also allow to document the effects of treatments in these trajectories.

A case of familial monogenic obesity: the role of MC4R mutation in childhood obesity

Barbara Aoto[1], Fernanda Ferreira[1], Vitor Meis[1], Renata Rangel[1], Carlos Longui[1] & Cristiane Kochi[1]
[1]Irmandade da Santa Casa de Misericórdia de São Paulo, São Paulo (SP), Brazil, Pediatric Endocrinology Unit, São Paulo, Brazil

Background
Obesity is a multifactorial disease with increasing prevalence in childhood. Severe early-onset obesity, especially with hyperphagia and rapid weight gain, may indicate monogenic causes, such as MC4R-related.This form often leads to metabolic complications and resistance to conventional treatment. Early genetic diagnosis is essential for guiding management and identifying potential therapeutic targets.
Case report
We describe two male siblings, born at term and appropriate for gestational age to non-consanguineous parents, who developed severe early-onset obesity. The first sibling was evaluated at 1.4y due to hyperphagia, excessive weight gain, and accelerated growth from 6 months of age. He had no medication use or neuropsychomotor delay. At initial assessment, his weight and height-for-age, and BMI (z-scores) were 33 kg (+3), 88.5 cm (+3.1), and 42.3 (+9.5), respectively. He exhibited acanthosis nigricans on the neck, axillae, and groin, with normal genital examination. Laboratory evaluation revealed elevated triglycerides, reduced HDL, while insulin, calcium profile, and thyroid function were normal. A monogenic etiology was suspected, and a genetic panel with 16 genes related to monogenic obesity was carried out. The results revealed a compound heterozygous *MC4R* variant (c.896C>A; p.Pro299His/c.240C>A;p.Tyr80*). The younger sibling with similar symptoms around 1y. At 1.4y, his weight, height-for-age, and BMI (Zs) were 20.8 (+6.1), 83 (+0.8), and 30.2 (+7.5), respectively. Genetic testing confirmed the same variant. The father had mild obesity (BMI =32.8), and the mother was overweight (BMI =29). Both parents and their younger brother underwent *MC4R* gene sequencing and it was detected the variant c.240C>A in the father and the variant c.896C>A in the mother and in the younger sibling, all of them in heterozygous. Lifestyle modifications and caloric restriction were attempted, without success. After loss to follow-up, the patients currently have weight and BMI (z-scores) of 88.6 kg/56.25 (+11.1) and 45.9 kg/39.5 (+10.1) at 4.5y and 3.4y, respectively.
Conclusion
MC4R-related obesity is the most common monogenic obesity and can present in homozygous heterozygous, or compound heterozygous states, with phenotypes ranging from overweight to severe obesity. This variability highlights the need for early genetic investigation in rapidly progressing obesity, as identifying a monogenic cause aids prognosis, optimizes management, and supports family counseling.

Association of childhood BMI with height growth pattern and adult stature: mendelian randomization study

Zhu Benlong[1] & Ruimin Chen[1]
[1]Department of Endocrinology, Genetics, and Metabolism, Fuzhou First General Hospital, affiliated with Fujian Medical University/Fuzhou Children's Hospital, Fujian Province, China., Fuzhou, China

Objective
Observational studies have reported that childhood body mass index (BMI) affects height growth patterns without significantly effecting adult stature. The causal relationship remain unclear. Mendelian randomization (MR)—a genetic instrumental variable approach leveraging Mendel's second law to minimize confounding—was employed to assess causality between childhood BMI and height growth patterns, including pre-pubertal growth (age $\leq$10 years), total pubertal height growth, late pubertal height growth, and adult stature, (standing and sitting height).
Methods
Adhering to the STROBE-MR guidelines. Whole genome-wide association study (GWAS) data were extracted from the MRC-IEU GWAS database (https://gwas.mrcieu.ac.uk). Causal estimates were derived using inverse variance weighting (IVW) as the primary method, supplemented by MR–Egger regression, weighted median, weighted mode, and simple mode analyses. Sensitivity analyses included Cochran's Q test for heterogeneity, MR–Egger's intercept and the MR-PRESSO test for pleiotropy assessment, and leave-one-out SNPs exclusion to evaluate robustness.
Results
MR analyses revealed childhood BMI exhibited a positive causal effect on pre-pubertal height growth ($\beta=0.11$, 95%CI [0.08, 0.13], $P=1.13\times10^{-13}$). But inversely negative correlated with total pubertal height growth (males: $\beta=-0.40$, 95%CI: [-0.61, -0.18], $P=2.64\times10^{-4}$; females: $\beta=-0.61$, 95%CI: [-0.85, -0.36]; $P=9.49\times10^{-7}$), late pubertal height growth (males:$\beta=-0.52$, 95%CI: [-0.75, -0.28], $P=2.46\times10^{-5}$; females: $\beta=-0.45$; 95%CI: [-0.68, -0.21], $P=2.02\times10^{-4}$). No significant link between childhood BMI and adult standing or sitting height. Sensitivity analysis revealed absence of horizontal pleiotropy (MR-Egger intercept $P>0.05$) and outlier SNPs (MR-PRESSO $P>0.05$), with leave-one-out' tests demonstrating results stablity.
Conclusion
This study demonstrates dual-phase effects: positively influencing early childhood height acceleration but suppressing pubertal growth trajectories. These transient effects resolve by adulthood, with no measurable impact on final stature. Findings underscore BMI's role as a modulator of developmental tempo rather than a determinant of adult height.

Non-high-density lipoprotein cholesterol for screening dyslipidemia in overweight Korean children

Hyo-Kyoung Nam[1], Eungu Kang[1], Young-Jun Rhie[1] & Kee-Hyoung Lee[1]
[1]College of Medicine, Korea university, Pediatrics, Seoul, South Korea

Objectives
Non-high-density lipoprotein (HDL) cholesterol is an alternative method to assess dyslipidemia and is not required fasting. We aimed to assess the usefulness of non-HDL cholesterol for screening dyslipidemia in overweight Korean children.
Subjects and Methods
Total 751 overweight children and adolescents aged 2 to 20 years (268 boys and 483 girls). They were sampled lipid profile without fasting. Dyslipidemia was defined by having one of the followings; total cholesterol $\geq$200 mg/dL, triglyceride $\geq$100 mg/dL or $\geq$130 mg/dL depending on age, low-density lipoprotein (LDL) cholesterol $\geq$130 mg/dL, or HDL cholesterol $<$40 mg/dL. Non-HDL cholesterol $\geq$145 mg/dL was used to detect dyslipidemia. After then, we compared the sensitivity of non-HDL cholesterol to those from the Korean National Health and Nutrition Examination Surveys which was taken at fasting state.
Results
The overall prevalence of dyslipidemia was 52.6%. The prevalence of non-HDL cholesterol level $\geq$145 mg/dL were 18.7% and 17.0% in boys and girls, respectively. Dyslipidemia was found in 94.0% and 85.4% of overweight boys and girls with high non-HDL level, respectively. High non-HDL cholesterol level especially detected high measured LDL-cholesterol level with a sensitivity of 100%, and a specificity of 92.0%, and a sensitivity of 97.8%, and a specificity of 91.3%, in boys and girls ($P<0.001$ and $P<0.001$, respectively). The Sensitivity of detecting high LDL-cholesterol level was higher in using randomly sampled non-HDL cholesterol compared to using fasting non-HDL cholesterol in boys and girls (11.6% vs. 7.3%, $P=0.024$ and 9.1% vs. 8.2%, $P=0.253$, respectively).

Conclusions
Non-HDL cholesterol at random samples appeared to be useful in screening dyslipidemia in overweight children and adolescents. It was easily calculated from random sample not required fasting.

Mediating role of prepubertal adiposity in the association between breastfeeding and central precocious puberty: a nationwide cohort study

Yunsoo Choe[1], Soorack Ryu[2], Jinjoo Choi[3], Jae Yoon Na[3], Kyung Suk Lee[1], Yong Joo Kim[3] & Seung Yang[3]
[1]Hanyang University Guri Hospital, Pediatrics, Guri, South Korea; [2]Hanyang University, Biostatistical Consulting and Research Lab, Seoul, South Korea; [3]Hanyang University Medical Center, Pediatrics, Seoul, South Korea

Background
Previous studies have investigated the possible relationship between breastfeeding and pubertal timing in girls, but evidence in boys is limited and the underlying mechanisms remain to be elucidated. We aimed to examine the effect of breastfeeding during the first 4–6 months of life on central precocious puberty (CPP) in boys and girls, and whether this relationship was mediated by prepubertal adiposity using nationwide cohort in South Korea.
Methods
Children who underwent regular health check-up from National Health Screening Program for Infant and Children at 4–6 months (Exam I) and 66–71 months (Exam Vll) were included. Primary feeding practices were collected from primary caregiver-reported questionnaire during Exam I. Multivariable Cox proportional hazard regression was used to estimated adjusted hazard ratios (aHRs) and 95% confidence intervals (CIs) for CPP after adjusting for preterm birth, multiple birth, low birth weight, overweight or obesity status in prepubertal age, maternal age at childbirth, gestational diabetes or hypertension, cesarean section, socioeconomic status and residence. Additionally, we performed mediation analysis to investigate the mediating effect of prepubertal adiposity on association between breastfeeding and CPP.
Results
Among a total of 322, 731 children (135, 232 boys and 187, 499 girls), 148, 402 (46.0%) were exclusively breastfed, 112, 738 (34.9%) were formula-fed, and 61, 591 (19.5%) were mixed-fed. In both boys and girls, formula-fed children had the largest risk of CPP (aHR 1.152 [95% CI 1.100–1.207] in boys, aHR 1.583 [95% CI 1.225-2.045] in girls), followed by mixed-fed children (aHR 1.130 [95% CI 1.068–1.195] in boys, aHR 1.440 [95% CI 1.063–1.950] in girls), compared to exclusive breastfed children. Mediation analysis revealed that lack of breastfeeding during early infancy was associated with an increased likelihood of developing prepubertal adiposity, which subsequently elevated the risk of CPP in both sexes.
Conclusion
Breastfeeding during the first 4–6 months of life was associated with a lower risk of CPP in both boys and girls. Prepubertal adiposity significantly medicated the relationship between feeding practices and CPP, highlighting the critical role of early-life nutrition in pubertal timing.

Pairing obesity medication with health behaviour and lifestyle therapy: a single center experience

Julia Lischka[1, 2], Gabriel Torbahn[1 2 3], Michael Vallis[4], Katharina Mörwald[1, 2], Julian Gomahr[1], Jeanne Jabbour[1], Sabine Geiersberger[1], Max Bergauer[1], Lotte Forer[1], Wanda Lauth[5], Laura Doettl[1], Maria Swittalek[1], Anders Forslund[6], Peter Bergsten[6], Rasmus Stenlid[6] & Daniel Weghuber[1, 2]
[1]Department of Pediatrics, Paracelsus Medical University, Obesity Research Unit, Paracelsus Medical University, Salzburg, Austria, Salzburg, Austria; [2]Obesity Research Unit, Paracelsus Medical University, Salzburg, Austria; [3]Department of Pediatrics, Paracelsus Medical University, Klinikum Nürnberg, Universitätsklinik der Paracelsus Medizinischen Privatuniversität Nürnberg, Nuremberg, Germany; [4]Department of Psychology and Neuroscience Dalhousie University, Halifax, Canada; [5]Team Biostatistics and Big Medical Data, IDA Lab Salzburg, Paracelsus Medical University, Salzburg, Austria; [6]Department of Women's and Children's Health, Uppsala University, Uppsala, Sweden

Background
About 30% of children in Europe are living with overweight or obesity. As a chronic and relapsing disease obesity should be treated as early and effective as possible. Health behaviour and lifestyle therapy (HBLT) is the first-line treatment and while effective at changing behavior, produces fairly modest weight loss for most youth with obesity. In addition to established pharmacotherapy, more effective obesity medication (OM) has recently been approved for the treatment of obesity in adolescents as adjunct to HBLT. Pairing HBLT and ongoing OM is a new challenge when striving for a comprehensive and chronic care model in pediatric obesity. This study evaluates the adherence to recommended treatment with HBLT in adolescents receiving OM.
Methods
In this explorative study, adolescents (aged $\geq$11 years) living with obesity and receiving OM were retrospectively analyzed. HBLT before and during OM (specifically liraglutide) was evaluated descriptively. HBLT was defined as intensive multidisciplinary HBLT according to national guidelines, dietary counseling, psychologic counseling, or any kind of HBLT. Moreover, change in anthropometric and cardiometabolic outcomes during OM treatment was evaluated.
Results
In this study, 37 patients with a mean age of 14.7 years were included in the study. Mean treatment duration was 10.3 months. 92% received HBLT before start of liraglutide treatment, while 62% had HBLT during liraglutide treatment. In 43% dose escalation was delayed and 41% discontinued treatment. Gastrointestinal adverse events were reported in 54% and ultimately led to discontinuation of treatment in 38%. Percentage change in BMI from baseline to end of treatment or last follow-up for patients who continued treatment was -2.7% (-0.9 kg/m^2). BMI reduction was greatest in patients who continued OM (-6.24%), whereas patients who discontinued gained 0.13% BMI on average. 28% reduced their BMI by 5%. OM was further associated with improvements in cardiometabolic risk factors.
Conclusion
Liraglutide is highly effective in real world pediatric obesity management. Adherence and coping with side effects are the main barriers to effective treatment. Concomitant HBLT to OM seems essential to strengthen patients' engagement and sustainability. Pairment of OM and HBLT should be a priority in national disease management plans.

Perceived self-efficacy in the management of childhood overweight and obesity: a study of hungarian paediatricians

Zsofia Gacs[1], Kornel Vajsz[1] & Emma Magyar[1]
[1]Department of Pediatrics, Semmelweis University, Budapest, Hungary

Background
Childhood obesity represents a critical public health challenge in Hungary, with projections indicating that 45% of children aged 7-19 will be classified as overweight or obese by 2035. Although regulatory measures targeting obesogenic factors are essential, the active involvement of pediatricians in managing childhood obesity is equally important. Physician engagement in weight-related discussions is associated with improved weight management outcomes; however, barriers such as communication uncertainty, time constraints, and a lack of structured protocols can limit these efforts. Self-efficacy—physicians' confidence in their ability to manage obesity-related concerns—plays a critical role in shaping their engagement. Low self-efficacy has been linked to lower adherence to clinical guidelines and diminished engagement in behavioral counseling. Furthermore, implicit weight bias may negatively affect healthcare interactions and outcomes. This study aims to evaluate the perceived self-efficacy of Hungarian pediatricians in addressing childhood overweight and obesity.
Methods
A cross-sectional online survey was administered to 75 pediatricians from three distinct convenience samples. The 10-item Perceived Self-Efficacy Scale was used to assess self-efficacy levels. Correlations between self-efficacy scores and various factors, including years since graduation, workplace setting, and collaboration with healthcare professionals, were analyzed using Pearson's correlation and one-way ANOVA.
Results
A modest yet statistically significant positive correlation was observed between perceived self-efficacy and years since graduation ($r = 0.249$, $P = 0.031$). No

significant difference was found in perceived self-efficacy between workplace types (primary vs. secondary/tertiary care), F(1, 73) = 1.425, $P = 0.236$. However, significant positive associations were identified between perceived self-efficacy and interprofessional collaboration: pediatricians who consulted district nurses during infant obesity screenings ($r = 0.248$, $P = 0.040$) and those who collaborated with school doctors after evaluating overweight children ($r = 0.271$, $P = 0.019$) demonstrated higher self-efficacy.
Conclusion
The perceived self-efficacy of Hungarian pediatricians in managing childhood obesity is positively correlated with clinical experience and collaboration with other healthcare providers. These findings underscore the importance of self-efficacy in fostering physician engagement in obesity management and suggest that promoting professional collaboration and addressing communication barriers could enhance pediatricians' confidence and efficacy in treating childhood obesity.

Muscle ultrasound (US) characterization in patients with lipodystrophy and potential metabolic correlates

Chiara Mele, Valentina Antoniotti[1], Jessica Baima[1], Sabrina Tini[1], Leonardo Bighetti[2], Martina Romanisio[2], Stella Pigni[2, 3], Gian Mauro Sacchetti[4], Gianluca Aimaretti[2] & Flavia Prodam[1]
[1]University of Piemonte Orientale, Department of Health Sciences, Novara, Italy; [2]University of Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [3]Humanitas University, Department of Biomedical Sciences, Pieve Emanuele, Italy; [4]University Hospital "Maggiore della Carità", Division of Nuclear Medicine, Novara, Italy

Background
Lipodystrophies are a group of rare disorders characterised by loss of subcutaneous adipose tissue with alterations in its function and distribution. From a clinical viewpoint, an early onset of severe insulin resistance, cardiovascular diseases and neuromuscular abnormalities have been documented. To date, neuromuscular manifestations of lipodystrophy are under-investigated. The aim of this study was to investigate muscle ultrasound (US) alterations in a cohort of patients with lipodystrophy and their association with metabolic characteristics. This report presents preliminary results after the initial patients' recruitment.
Methods
This is a monocentric prospective cohort study. Patients underwent muscle US (bilateral brachial biceps and rectus femoris) with the evaluation of the following variables for each muscle group: thickness, cross-sectional area (CSA), US-pattern and echogenicity assessed using Heckmatt scale (1, normal muscle; 2, increase in muscle echogenicity with normal bone echo; 3, moderate increase in muscle echogenicity with decreased bone echo; 4, severe increase in muscle echogenicity with shadowing obscuring the underlying bone echo). For each patient, clinical, metabolic and muscle functional parameters, and cutaneous Advanced Glycation End products (AGEs) were also evaluated.
Results
Five patients with familial partial lipodystrophy (FPLD) (3 patients with type 1 FPLD and 2 patients with LMNA-associated type 2 FPLD) and one patient with congenital generalized lipodystrophy (CGL) were currently included (M/F 1/5; median age 54, IQR 45-62 years; BMI 22, IQR 21-27). Muscle hypotrophy was found only in the patient with CGL, while a condition of normo/pseudohypertrophy was detected in the remaining patients. According to the Heckmatt scale, all patients presented an increased muscle echogenicity (3 patients with score 2 and 3 patients with score 3). Two main different US-patterns have been recognized: A) homogenously increased echogenicity of the entire muscle with partial loss of architectural features, compatible with muscle fibrosis and steatosis (4 patients); B) focal areas of markedly increased echogenicity, oftentimes obscuring bone echo, that could suggest fibrosis with associated inflammation (2 patients). Patients with higher muscle echogenicity (Heckmatt score 3) had higher BMI, fat mass, HbA1c, triglycerides levels and AGEs than subjects with lower muscle echogenicity (Heckmatt score 2). Further, US-pattern B was associated with higher AGEs, suggesting that muscle inflammatory US pattern could reflect systemic inflammation.
Conclusions
Lipodystrophy is associated with specific muscle US alterations that reflects a condition of muscle fibrosis/steatosis, sometimes accompanied by inflammation. These alterations could reflect metabolic dysregulation and systemic inflammation, thus representing an indirect marker of increased cardiovascular risk.

Association between body composition, lipid profile, inflammatory markers and fatty acid composition in healthy women: a cross-sectional study

Inga Fomcenko[1], Inga Bikulciene[1], Gertruda Babraviciene[2], Evelina Cikanaviciute[2], Edita Gaveliene[2], Jurgita Urboniene[3], Virginijus Sapoka[1] & Dovile Karciauskaite[1]
[1]Faculty of Medicine, Vilnius University, Vilnius, Lithuania; [2]The Centre of Hepatology, Gastroenterology and Dietetics, Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania; [3]Center of Infectious Diseases, Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania

Background
Oxidative stress and chronic inflammation are major contributors to obesity-related pathologies (cardiovascular, metabolic disorders, cancer). Platelets and composition of their phospholipid membrane play a crucial role in modulating chronic inflammatory. Alterations in platelet membrane fatty acids (FA) leads to increased production of pro-inflammatory or anti-inflammatory mediators.
Objective
Study aimed to investigate the association between body composition, lipids, inflammatory markers and FA composition in healthy women.
Material and Methods
Study included 101 healthy women, median age 36, 95 years. Body composition including fat mass (FM), lean mass (LM) was measured by dual-energy X-ray absorptiometry (iDXA, GE Lunar). Fat mass index (FMI) was calculated (FMkg/height^2). Women were divided into 3 groups based on FMI: fat deficit (FD)(FMI$<$5 kg/m^2), normal fat (NF)(FMI5-9kg/m^2), excess fat(EF)(FMI$>$ 9kg/m^2). Lipids, C-reactive protein (CRP) was measured. FA of platelets phospholipid membrane was analyzed using gas chromatography-mass spectrometry. Each FA was calculated from the total FA amount(100%), counting the percentage of total saturated FA (SFA) (myristic, palmitic, stearic), monounsaturated FA (MUFA) (palmitoleic, oleic, vaccenic, erucic), polyunsaturated FA (PUFA) (omega 3:α-linolenic, eicosapentaenoic, docosahexaenoic, omega 6:linoleic, arachidonic, gamma-linolenic). Statistical analysis included the Mann-Whitney U test and Spearman correlation. The study was approved by the local ethics Committee.
Results
Total FM was 28.82kg[IQR19.87–41.43], total LM was 44.30kg[IQR40.46–48.91]. Platelet membranes contained 78.12%SFA, 19.37%MUFA, 3.97%PUFA. Among SFA palmitic acid was the most prevalent (52.47%); oleic acid was the most common MUFA (7.24%;) and linoleic acid was the predominant PUFA(7.45%). A strong positive correlation was observed between FM and CRB (ρ=0.641, $P < 0.001$); a moderate correlation with triglycerides (ρ= 0.477, $P < 0.001$) and PUFA (ρ= 0.389, $P < 0.001$); a weak correlation with LDL-cholesterol (ρ=0.279, $P = 0.004$) and MUFA (ρ=0.211, $P = 0.036$). FM correlates negatively with HDL-cholesterol (ρ=-0.614, $P < 0.001$) and SFA (ρ=-0.253, $P = 0.012$). A total of 64 (58.7%) of women had EF, 37(33.9%) had NF, 7.3%(8) had a FD. Women with EF had higher LDL-cholesterol(3.30 mmol/l[IQR 2.61-3.67] vs. 2.78 mmol/l[IQR2.29-3.24], $P = 0.032$), triglycerides(1.08 mmol/l[IQR0.74-1.44] vs. 0.73 mmol/l[IQR0.55-0.99], $P = 0.001$), and CRP(1.73mg/l[IQR 0.87-4.75] vs. 0.51mg/l[IQR0.30-0.83], $P < 0.001$), and lower HDL-cholesterol(1.48 mmol/l[IQR 1.26 - 1.70] vs. 1.89 mmol/l[IQR1.72-2.16], $P < 0.001$) levels compared to those with NF. Women with EF had a lower SFAs (76.19%vs.83.43%, $P = 0.028$) and a higher PUFA (5.4%vs.3.1%, $P = 0.003$). MUFA did not differ statistically (20.57% vs. 14.91%, $P = 0.060$)
Conclusions
Women with excess fat exhibited a less favorable metabolic profile, higher LDL-cholesterol, triglycerides, and CRP, lower HDL-cholesterol compared to normal fat women. Total fat mass was positively correlated with CRB, triglycerides, and PUFA, inversely with HDL-cholesterol and MUFA. Women with excess fat had a lower percentage of SFA and a higher percentage of PUFA.

Transforming lives: the impact of liver transplantation in treating glycogen storage disease type 1a – a case report

Deniz Türküm Atikcan Şimşek[1], Ece Gul Kose Hamidi[1], Merve Senay Ozcalik[1], Ozlem Turhan Iyidir[1], Asli Nar[1] & Neslihan Bascil Tutuncu[1]
[1]Baskent University, Ankara, Türkiye

Glycogen Storage Disease Type 1a (GSD type 1a) is a rare, autosomal recessive disorder characterized by defects in the glucose-6-phosphatase enzyme. Patients

with GSD type 1a can experience severe metabolic complications, including hypoglycemia, hyperlipidemia, hyperuricemia, hypertension, liver dysfunction, hepatomegaly, splenomegaly and hepatic adenomas. Additionally osteoporosis and growth retardation can occur. Liver transplantation has emerged as an effective therapeutic option in cases of metabolic complications. Here, we present a case to emphasize the potential benefits of liver transplantation in GSD type 1a. A 20-year-old male patient was referred to our outpatient clinic for evaluation of persistent hypoglycemia, hypertriglyceridemia, and osteoporosis following a femoral fracture in 2021. He had been diagnosed with GSD type 1a in infancy due to recurrent episodes of hypoglycemia. Despite being managed with amylopectin cornstarch, his metabolic control remained suboptimal. The patient experienced level 1 or 2 hypoglycemia once or twice a week, even with strict adherence to his diet. His triglyceride levels, despite a low triglyceride diet and the use of gemfibrozil 600 mg twice daily, ranged from 700 to 1600 mg/dl. Furthermore, his uric acid level remained elevated at 6.5 mg/dl despite being on daily allopurinol therapy (300 mg). He had ALT of 158 U/l, AST of 161 U/l, GGT of 168 U/l and ALP of 127 U/l. On physical examination, the patient had a height of 158 cm and a weight of 54 kg, with Tanner stage 3 pubic hair and stage 4 genitalia. Serial abdominal MRIs demonstrated multiple stable hepatic adenomas over a two-year period. His Bone Mineral Density (BMD) at L1-L4 was 0.420, with a Z-score of -6.0, confirming the presence of osteoporosis. In January 2024, the patient underwent a living donor liver transplantation as part of his metabolic management. Post-transplant he didn't experience further hypoglycemic episodes. His triglyceride levels decreased to a range of 100-200 mg/dl, and his uric acid level normalized to 6 mg/dl without the need for allopurinol. His liver function tests returned to normal ranges. The patient continues to receive weekly 20, 000 IU of Vitamin D and BMD monitoring is scheduled. Liver transplantation has proven to be an effective therapeutic intervention in patients with GSD type 1a, particularly in managing metabolic complications. In cases where metabolic control cannot be adequately achieved, early liver transplantation should be considered. Further research is necessary to explore and refine treatment strategies for rare metabolic disorders like GSD type 1a.

JOINT1151

Macrophage glucocorticoid and androgen metabolism influence muscle cell metabolism

Ana Crastin[1], Thomas Nicholson[2], Simon Jones[2], Claudio Mauro[1, 2] & Rowan Hardy[1, 2]
[1]Metabolism and Systems Science, Institute of Biomedical Research, University of Birmingham, Birmingham, United Kingdom; [2]Inflammation and Aging, QE Hospital Research laboratories, University of Birmingham, Birmingham, United Kingdom

Background
Macrophages play a key role in muscle regeneration following injury, with androgens (testosterone [T] and dihydrotestosterone [DHT]) and glucocorticoids (cortisone [E] and cortisol [F]) influencing anabolic, anti-anabolic, and catabolic muscle metabolism. We have shown that inflammation dynamically regulates glucocorticoid and androgen metabolism in macrophages, and these processes may be dysregulated in inflammatory diseases.
Methods
Primary human macrophages from healthy donors were polarized with TNFα/IFNγ or left unpolarized before treatment with F precursor (E; 100 nmol/l) and DHT precursors (T & A4; 100 nmol/l). Treated macrophages or conditioned media were co-cultured with myotubes and myoblasts derived from healthy human quadriceps. Macrophage F and DHT metabolite synthesis was measured by LC-MS/MS. Myotube thickness (microscopy), muscle metabolism markers (qRT-PCR), cell migration (scratch assay), proliferation (BrdU), and protein synthesis (synthesis assay) were assessed.
Results
Inflammatory-activated macrophages exhibited a distinct regulation of steroid metabolism, increasing cortisol (F) activation from cortisone (E) and dihydrotestosterone (DHT) activation from testosterone (T) and androstenedione (A4). Conditioned media or co-culture with activated macrophages led to reduced myotube fiber size without altering metabolic gene expression. However, conditioned media with T significantly increased fiber thickness ($P < 0.001$). T treatment also decreased myoblast proliferation after 72 hours ($P = 0.0196$) without affecting cell viability. In contrast, conditioned media with E did not affect fiber thickness but significantly reduced myoblast proliferation at 72 hours ($P = 0.0009$). E treatment increased catabolic markers (Foxo1, Fbox32) and decreased the anabolic marker Igf-1. In comparison, T-conditioned media decreased catabolic Foxo1 and anti-anabolic Myostatin (Mstn) and increased the differentiation marker Myod after 24 hours. Direct DHT treatment did not increase protein synthesis rate compared to control and reduced proliferation at 48 hours ($P < 0.05$). F significantly decreased myoblast proliferation at both 48 and 72 hours ($P < 0.0001$). Finally, examination of myoblasts revealed that macrophage-conditioned media enhanced cell migration and proliferation, regardless of T precursor treatment.
Conclusions
Inflammatory-activated macrophages dynamically regulate glucocorticoid and androgen metabolism, influencing muscle fiber size and metabolism. These effects may be altered in chronic inflammatory diseases, potentially impairing muscle regeneration. Further investigation is needed to determine if these processes are dysregulated in inflammatory conditions.

JOINT2207

The effect of stress resiliency level and maternal diet on the metabolic health of offspring

Na'ama Cohen[1], Saumya Mehta[1], Michaella Ben-Shachar[1], Albert Pinchasov[1] & Tovit Rosenzweig[1]
[1]Ariel University, Molecular Biology, Ariel, Israel

Background
The rise in obesity prevalence is influenced by multiple factors, including the transgenerational hypothesis linking maternal obesity to increased offspring obesity risk. Another significant contributor is the stressogenic environment prevalent in Western societies. We have already shown that it is not merely exposure to stressful events that heightens the risk of developing obesity and its comorbidities, but also the subjective response to these stressogenic events (1). Using a specially bred mouse model with distinct stress response traits - vulnerability (Submissive mice, Sub) and resilience (Dominant mice, Dom) - we demonstrated that stress vulnerability exacerbates metabolic disruptions in mice fed a high-fat diet (HFD).
Research Goal
This study aimed to characterize the interactions between maternal diet, offspring diet, and stress vulnerability traits, and to investigate the impact of these factors on offspring metabolic health. A secondary aim was to elucidate the effects of HFD on maternal and offspring behavior.
Methods
Sub and Dom female mice were divided into groups fed either a high-fat diet (HFD) or a standard diet (STD) from four weeks before breeding until three weeks postpartum. Maternal behaviors were assessed through nesting scores during pregnancy and pup retrieval tests postnatally. Offspring were weaned onto STD until six weeks old, then split into STD and HFD groups. Glucose and insulin tolerance tests were conducted at 12 and 13 weeks of age, respectively. Mice were sacrificed for plasma insulin and leptin measurements, along with histological analyses of liver, pancreas, and adipose tissues.
Results
Maternal obesity had differential effects on pre- and post-natal behaviors in Sub and Dom mice, influencing nesting and pup retrieval differently. HFD improved maternal behavior in Sub mice but disrupted it in Dom mice. Maternal obesity adversely affected metabolic health in Sub offspring, resulting in glucose intolerance, insulin resistance, and hyperleptinemia following HFD feeding. Conversely, Dom offspring were largely unaffected by maternal HFD, showing minimal impairment in leptin sensitivity and glucose tolerance, with no impact on insulin tolerance. Adipose tissue weight increased in Dom mice, while liver weight rose significantly in Sub mice after two generations of HFD exposure.
Conclusion
These findings underscore how inherited stress response traits shape metabolic and behavioral outcomes across generations. They highlight the complex interplay between maternal diet, offspring diet, and stress vulnerability in determining obesity-related health outcomes.

Introduction
It remains essential to identify the most relevant lipid parameter ratios for assessing cardiometabolic risk and insulin resistance in obese pediatric patients. This study aims to determine which lipid ratio best identifies these risks in pediatric patients diagnosed with metabolic syndrome (MetS).
Materials and Methods
This study was conducted in the Endocrine Department of the Children's Hospital in Timisoara, Romania, between January 2018 and December 2024. 215 obese patients (BMI >95th percentile for sex and age), aged 10–16 years, were included. Anthropometric measurements (body weight, blood pressure, and abdominal circumference) and biochemical markers of lipid and glucose metabolism were assessed. The Homeostatic Model Assessment for Insulin Resistance (HOMA-IR) and lipid ratios (TG: HDL-C, total cholesterol: HDL-C, and LDL: HDL) were calculated.
Results
Patients were stratified based on the presence of MetS according to the International Diabetes Federation (IDF) criteria, resulting in 95 patients with MetS (median age: 13.4 years, 40% boys) and 120 without MetS (median age: 12.5 years, 60% boys). The MetS group exhibited significantly higher insulin levels (23.5 μIU/mL [IQR: 14.7–38.5] vs. 16.3 μIU/mL [IQR: 12.7–26.8], $P = 0.03$) and HOMA-IR values (23.3 [IQR: 14.7–38.8] vs. 16.3 [IQR: 12.7–28.8], $P = 0.03$). Lipid ratios were also significantly elevated in the MetS group ($P < 0.01$), including TG: HDL-C (3.7 [IQR: 2.4–5.1] vs. 1.59 [IQR: 1.2–2.43]), total cholesterol: HDL-C (4.0 [IQR: 3.4–4.9] vs. 3.2 [IQR: 2.48–3.78]), and LDL: HDL (2.3 [IQR: 1.9–2.88] vs. 1.88 [IQR: 1.25–2.36]). MetS presence was strongly correlated with HOMA-IR and lipid indices, particularly TG: HDL-C ($r = 0.549$). Logistic regression confirmed TG: HDL-C as a significant predictor of MetS ($P < 0.01$).
Conclusion
The TG: HDL-C ratio is a strong marker for identifying cardiometabolic risk in obese children with MetS diagnosis.

Relationship between body mass index and 1 mg dexamethasone suppression test in obese patients

Beril Turan Erdogan[1], Ekin Yiğit Köroğlu[1], Muhammed Sacikara[1], Neslihan Çuhacı Seyrek[2], Cevdet Aydin[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Türkiye; [2]Ankara Yildirim Beyazit University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Türkiye

Background
The dexamethasone suppression test (DST) assesses hypothalamic-pituitary-adrenal (HPA) axis function. Obesity affects cortisol metabolism, but its relationship with body mass index (BMI) and DST response remains unclear. This study examines the association between BMI and 1 mg DST results in obese patients.
Methods
This retrospective study included 352 obese individuals (BMI ≥ 30 kg/m^2) from an endocrinology clinic. Data collected included age, gender, BMI, hip and waist circumference, comorbidities, and laboratory values (ACTH, basal cortisol, and 1 mg DST). DST suppression levels were compared across BMI groups using statistical analyses.
Results
Participants ranged from 18 to 69 years, with a mean age of 40.37 $\pm$ 11.51 years. Of the 352 individuals, 80.7% were female and 19.3% were male. BMI distribution was: 30-39.9 kg/m^2 (18.2%), 40-50 kg/m^2 (57.4%), and >50 kg/m^2 (24.4%). DST suppression levels differed significantly across BMI groups (***P* = 0.038**), with altered DST response in higher BMI categories. ACTH levels also showed significant variations (***P* = 0.018**), while cortisol levels did not (***P* = 0.081**). These findings suggest BMI-related changes in HPA axis function.
Discussion
BMI influences DST suppression and ACTH levels, indicating a potential role in HPA axis dysregulation. The non-linear association suggests that both lower and higher BMI levels contribute to altered DST response. Obesity may affect cortisol metabolism and feedback sensitivity, explaining these variations. However, the lack of significant basal cortisol differences suggests other regulatory mechanisms. Elevated ACTH levels in extreme obesity may represent a compensatory response.
Conclusion
BMI modulates DST suppression and ACTH secretion, with variations in HPA axis function across BMI categories. Further studies are required to understand the physiological mechanisms and clinical significance of these associations.

Obesity effect on epicardial fat thickness in children

Shaymaa Raafat[1], Rawda Ahmed[1], Hani Adel[1] & Omneya Omar[1]
[1]Alexandria University - Faculty of Medicine, Pediatric Endocrinology and Diabetes, Alexandria, Egypt

Background
Obesity is considered as the most important public health concerns of the current century. Obese children have increased risk for multiple disorders, one of the most important risks is cardiovascular effects and insulin resistance. Epicardial fat, like any other adipose tissue, can contribute to the formation of atherosclerosis and aggravation of IR by increasing free fattyacids and cytokines. The imbalance of cardioprotective and unfavorable adipokines released by the

DST: Dexamethasone suppression test, ACTH: Adrenocorticotropic hormone

epicardial fat is closely associated with the development of coronary arteriosclerosis and other cardiac threats in the obese population.
Objectives
The study aimed to assess the impact of obesity on epicardial fat thickness (EFT) and to identify the risk factors that affect the EFT in this cohort.
Methods
The study enrolled 80 obese children and adolescents compared to 20 healthy controls. Detailed history and examination were studied. Anthropometric measurement and vital signs were assessed. Echocardiography was done for assessment of EFT in the parasternal long axis view. Lipid profile was assessed.
Results
In the current study, 80 obese children were compared to 20 healthy controls. echocardiography showed higher EFT in both obesity groups compared to lean subjects. Female patients and dyslipidemia were associated with increased EFT in obese patients.
Conclusion
Obesity in children can cause early subclinical cardiovascular changes which are prominent through its effect on epicardial fat thickness.

Limited preventive effects of empagliflozin against metabolic dysfunction-associated steatotic liver disease in a mouse model of fast food diet

Evangelia Makri[1], Konstantinos Xanthopoulos[1], Spyros Pettas[1], Antonis Goulas[1], Panagiotis Mavrommatis-Parasidis[1], Eleftheria Makri[1], Anastasia Tsingotjidou[1], Angeliki Cheva[1], Charikleia Ntenti[1], Constantinos Zacharis[1], Iris Ballaouri[2], Spyridon Gerou[2] & Stergios Polyzos[1]
[1]Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Analysis Laboratories, Thessaloniki, Greece

Purpose
Metabolic dysfunction-associated steatotic liver disease (MASLD) is a highly prevalent disease with limited treatment options. The aim of this study was to evaluate the preventive effects of a sodium-glucose co-transporter (SGLT)-2 inhibitor, empagliflozin, on a dietary mouse model of MASLD.
Methods
24 C57BL/6J mice of both sexes were randomly allocated to three groups, as follows: the fast food diet (FFD) group (eight mice, receiving a high-fat, high-cholesterol, high-fructose diet, FFD), the EMPA group (eight mice, fed a FFD with 10mg/kg/d empagliflozin), and the chow diet (eight mice, CD) group. The mice were weighed and blood samples were drawn every 4 weeks; after 25 weeks the mice were euthanized, at which point liver tissues were histologically evaluated.
Results
After 25 weeks, there was no significant difference in body weight between the three groups, whereas liver-to-body weight ratio was greater in the EMPA compared to the CD group ($P = 0.002$). Hepatic fibrosis was marginally different between the three groups ($P = 0.045$). Fibrosis stage 1 was present in five mice in FFD (62.5%), in one mouse in EMPA (12.5%), and in one mouse in CD (12.5%) group. Lipogenic, inflammatory, and fibrogenic genes did not differ between the EMPA and FFD groups. Interestingly, mRNA encoding for SGLT-1 and SGLT-2 was detected in the mouse livers.
Conclusion
Empagliflozin treatment in mice on a FFD did not result in any significant effects on morphological, biochemical, or histological features or on expression of hepatic genes associated with MASLD compared to those fed a FFD without empagliflozin. The observed effects on mild hepatic fibrosis warrant validation, possibly via studies of longer duration.

Introduction
Obesity is a global health problem with rising prevalence. Traditionally, obesity was considered to exert a positive (protective) impact on BMD. However, this augmentation does not confer protection against the risk of fractures, constituting an "obesity paradox". Emerging data indicate that the effect of adipose tissue on bone health is much more complex. Trabecular bone score (TBS) provides information on bone texture and predicts fracture risk independently of BMD. The present study aimed to investigate the association of body composition and bone quality as evaluated by lumbar spine (LS) TBS.
Methods
We included 118 postmenopausal women (mean age: 60.73 ± 8.97years and mean BMI 28.36 ± 5.8) with no history of secondary osteoporosis or previous anti-osteoporotic treatment. Body composition, BMD and TBS were evaluated by dual-energy X-ray absorptiometry (DXA). To explore the associations among the variables of interest, Spearman's correlations were used. Simple and multiple linear regression models were also applied to explore the associations among variables of interest.
Results
Visceral adipose tissue (VAT) mass, android fat mass and android/gynoid fat ratio were negative predictors of TBS (Stb= -0.413, $P < 0.001$; Stb= -0.369, $P < 0.001$; Stb= -0.333, $P < 0.001$, respectively). Similarly, both the right (Stb= -0.313, $P < 0.001$) and left arm fat mass (Stb= -0.313, $P < 0.001$) were negative predictors of TBS. In multiple linear regression model, VAT mass exhibited a significant negative association with TBS (Stb = -0.415, $P < 0.05$).
Conclusions
The present study offers evidence that VAT mass holds a negative association with bone quality as estimated by TBS in postmenopausal women. Thus, it seems that VAT accumulation not only increases the risk of type 2 diabetes, cardiovascular disease, and even some types of cancer but also may lead to the deterioration of bone quality.

Nutritional habits and weight perception in childhood cancer survivors: insights for long-term health

Neriya Levran[1, 2], Reut Pienik[1, 2], Michal Ben Ami[1, 3], Zipporah Eve Stren[1, 3], Maya Yardeni[3, 4], Dalia Waldman[3, 5], Hana Golan[3, 5], Amos Toren[3, 5] & Dalit Modan-Moses[1, 3]

[1]The Edmond and Lily Safra Children's Hospital, Sheba Medical Center, Pediatric Endocrinology and Diabetes Unit, Ramat-Gan, Israel; [2]Sheba Medical Center, Division of Nutrition, Ramat-Gan, Israel; [3]Tel Aviv University, Faculty of Medical and Health Sciences, Tel-Aviv, Israel; [4]Bar Ilan, Faculty of Psychology, Ramat-Gan, Israel; [5]The Edmond and Lily Safra Children's Hospital, Sheba Medical Center, Division of Pediatric Hematology and Oncology, Ramat-Gan, Israel

Background
Childhood cancer survivors (CCS) are at an increased risk of obesity, though underlying mechanisms remain unclear.
Aim
To characterize nutritional habits of CCS, compare them to the general pediatric population, and identify differences between normal-weight and overweight/-obese CCS.
Methods
A cross-sectional study comprising 118 CCS (aged 14.8±3.8 years, females = 54%), at least one-year post-treatment (average 7.3±4.1 years). Nutritional habits were assessed using a validated questionnaire including an FFQ component. Results were compared to data from a representative sample of healthy children and adolescents (MABAT survey).
Results
At recruitment, 3.4% of participants were underweight, 60.1% had a normal weight, 27.2% were overweight, and 9.3% were classified as obese, not significantly different compared to the general pediatric population in Israel. Still, compared to MABAT participants, male patients were twice as likely to consider themselves "too fat" (24.5% vs. 11.7%, $P = 0.017$). While total caloric intake was similar, diet composition differed significantly. Protein and fat percentage of energy intake in CCS were significantly (<0.001) higher compared to data from the general population, while carbohydrate percentage of energy was lower in CCS ($P < 0.001$). Fiber intake was lower in male CCS compared to the general population ($P = 0.003$), but not in female CCS. Within the study group, dietary composition was a significant predictor of weight gain over a one-year period from baseline with a higher carbohydrate percentage positively correlated with BMI increase ($r = 0.294$, $P = 0.020$). Eating habits, such as family meals, screen time during meals, and take-out food consumption, did not differ significantly between CCS and MABAT participants. However, within the study cohort overweight/obese CCS were more likely to have a cafeteria/kiosk at school (65.1% vs. 40%, $P = 0.013$) and purchase sweetened beverages during school hours (80% vs. 54.2%, $P = 0.046$). Frequent fast-food consumption (3-4 times per week) was significantly associated with overweight status (66.7% vs. 33.3%, $P = 0.015$), as was meal location, with overweight CCS more likely to eat at friends' homes, restaurants, or alone ($P = 0.015$). Overweight/obese CCS were more likely to feel "too fat" (45% vs. 5.7%, $P < 0.001$), be unhappy with their weight (59.6% vs. 24.3%, $P = 0.003$), and experience food-related distress, yet only 14% sought guidance from a dietitian.
Conclusion
CCS exhibited distinct dietary patterns, with higher protein and fat intake but lower carbohydrate and fiber intake than the general population. Overweight/-obese survivors reported greater body image concerns, weight dissatisfaction, and food-related distress, highlighting the need for targeted nutritional and psychological support.

JOINT3284

Body composition phenotyping and BIA-DXA agreement for fat mass assessment in pediatric obesity: an exploratory study

Amanda Casirati[1], Nadia Gabriella Maiorano[1], Alessia Angelelli[1], Daniela Fava[1], Flavia Napoli[1], Giacomo Tantari[1], Caterina Tedesco[1], Mohamad Maghnie[1, 2] & Natascia Di Iorgi[1, 2]
[1]IRCCS Istituto Giannina Gaslini, Pediatric Endocrinology Unit, Department of Pediatrics, Genoa, Italy; [2]University of Genoa, Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, Genoa, Italy

Background
Pediatric obesity is a multifactorial condition characterized by excessive fat accumulation. However, traditional body mass index (BMI)-based classification cannot assess fat mass (FM) or its distribution. Dual-energy X-ray absorptiometry (DXA) is the gold standard for body composition assessment. However, due to its limited accessibility, portable and non-invasive alternatives, such as bioelectrical impedance analysis (BIA), are often used. This exploratory study aimed to describe body composition phenotypes in different types of non-syndromic pediatric obesity and evaluate the agreement between BIA and DXA in assessing FM.
Methods
From September 2024 to January 2025, we performed BIA on patients aged 6–17 years with primary obesity (PO), obesity secondary to tumors now in off-therapy (SO), or genetic obesity (GO), all with BMI > 2SDS and scheduled for DXA. DXA provided percentage of total FM and truncal FM (FMtr), fat mass index (FMI, kg/m^2) and fat-to-lean ratio (FLR), while BIA provided FMI and FLR.
Results
We assessed 64 patients (61% female), of whom 75% had PO, 12.5% had SO, and 12.5% had GO. The median age was 11 years. By comparing PO, SO, and GO groups, significant differences were observed in median height-SDS (0.9 vs. -1.2 vs. -0.3, $P = 0.009$) and BMI-SDS (2.9 vs. 2.3 vs. 3.1, $P = 0.024$). DXA measures revealed significant differences in total FM% (46 vs 48 vs 54, $P = 0.029$) and FLR (0.87 vs 0.94 vs 1.2, $P = 0.028$), whereas truncal FM% (47 vs. 48 vs. 54, $P = 0.092$) and FMI (11.9 vs. 11.8 vs. 14.2, $P = 0.246$) did not differ significantly. BIA measurements showed a significant difference in FMI (10.6 vs. 7.4 vs. 13.9, $P = 0.041$), while FLR (0.59 vs. 0.53 vs. 0.78, $P = 0.081$) was not significantly different. Although a moderate correlation BIA-DXA for FMI was found ($r = 0.682$, $P < 0.001$), Bland-Altman analysis indicated that BIA underestimated FMI compared to DXA, with a mean difference of 1.40kg/m^2 and limits of agreement ranging from -3.34 to 6.16.
Conclusions
Our preliminary findings highlight that pediatric patients with GO exhibit higher FM compared to those with PO and SO, with a distinct fat distribution pattern, characterized by higher FMtr, that may have metabolic implications and thus require further investigation. BIA underestimates FMI compared to DXA, with substantial variability, limiting its use as a method interchangeable with DXA for body composition assessment.

Metabolic-associated steatotic liver disease and arterial stiffness in obese children: early cardiometabolic insights - a preliminary study

Monica Simina Mihuta[1], Corina Paul[1], Cristina Ilies[2], Ioana Mozos[3, 4] & Dana Stoian[5, 6, 7]
[1]Victor Babes University of Medicine and Pharmacy, Department of Pediatrics, Timisoara, Romania; [2]Victor Babes University of Medicine and Pharmacy, Department of Doctoral Studies, Timisoara, Romania; [3]Victor Babes University of Medicine and Pharmacy, Department of Functional Sciences-Pathophysiology, Timisoara, Romania; [4]Victor Babes University of Medicine and Pharmacy, Center for Translational Research and Systems Medicine, Timisoara, Romania; [5]Victor Babes University of Medicine and Pharmacy, Second Department of Internal Medicine, Timisoara, Romania; [6]Victor Babes University of Medicine and Pharmacy, Center of Molecular Research in Nephrology and Vascular Disease, Timisoara, Romania; [7]Dr. D Medical Center, Department of Advanced Ultrasound, Timisoara, Romania

Introduction
Metabolic-associated steatotic liver disease (MASLD) is increasingly recognized in obese children and has been linked to early cardiovascular dysfunction. Arterial stiffness, a marker of subclinical atherosclerosis, may serve as an early indicator of cardiovascular risk in this population. This preliminary study explores the relationship between MASLD and arterial stiffness in obese children, aiming to assess potential cardiometabolic implications.

Methods
The study included 50 children aged 6 to 18, divided into two groups: 30 children with obesity (class 2 and 3) and 20 normal-weight controls. Assessments included BMI, waist circumference, waist-to-height ratio, and puberty stage. Arterial stiffness was evaluated using pulse wave velocity (PWV) via a Mobil-O-Graph single-point (brachial) oscillometer. Liver stiffness was assessed by shear-wave elastography (SWE, kPa and m/s) using a Mindray Resona R9 ultrasound system. Serum levels of fasting glucose, insulin, uric acid, lipid profile, triglycerides, transaminases, and 25-OH vitamin D were analyzed, along with HOMA-IR.
Results
Obese children had significantly higher SWE values than normal-weight peers (12.8 kPa vs. 7.31 kPa, $p < 0.001$). PWV was also significantly higher in the obese group (5.1 m/s vs. 4.5 m/s, $P = 0.01$). SWE and PWV correlated positively with BMI, waist circumference, and waist-to-height ratio, with PWV emerging as a significant independent predictor of these markers. Additionally, SWE and PWV were significantly correlated ($\rho = 0.41$, $P = 0.03$), with SWE remaining a predictor of PWV even after adjusting for BMI, waist circumference, and puberty stage. Both SWE and PWV correlated significantly with BP values ($\rho = 0.58$, $P = 0.002$). Regarding biochemical markers, PWV correlated positively with HOMA-IR and uric acid, while SWE correlated with HOMA-IR, triglycerides, LDL-c, and transaminases. Although 25-OH vitamin D was significantly lower in the obese group, no significant correlation was found with SWE or PWV.
Conclusion
Obese children show increased arterial and liver stiffness, suggesting an early link between MASLD and cardiovascular dysfunction. The correlation between SWE and PWV, independent of BMI, indicates that liver stiffness may contribute to vascular impairment beyond obesity alone. Associations with HOMA-IR, uric acid, and lipid markers further highlight the role of metabolic dysregulation. These findings emphasize the need for early hepatic and cardiovascular assessments in obese children to identify those at higher risk for future cardiometabolic complications.

JOINT2825

SPISE index: a novel predictor for identifying metabolically healthy obesity and cardiovascular risk in obese children

Meliha Esra Bilici[1]
[1]Zonguldak Bülent Ecevit University School of Medicine, Department of Pediatric Endocrinology, Zonguldak, Türkiye

Objective
Childhood obesity is a major public health issue worldwide, thus understanding its metabolic heterogeneity is crucial. A subgroup called "metabolically healthy obese"(MHO) shows preserved insulin sensitivity and low cardiovascular risk despite excess adipose tissue. The non-invasive tool SPISE index (Single Point Insulin Sensitivity Estimator) [$600 \times HDL^{0,\ 185}/Trigliseridler^{0,\ 2} \times BMI^{1,\ 338}$] stands out as an innovative approach to assess insulin sensitivity. It has been shown to be a predictor for both insulin resistance and the risk of developing glucose intolerance or diabetes. In this study, the clinical utility of the SPISE index in assessing metabolic health parameters will be investigated.
Methods
The SPISE index was calculated in 580 obese children (average age of 11.3 ± 3.2 years). The group classified as metabolically unhealthy obese (MUO) had one or more of the following: fasting glucose ≥ 100 mg/dL, triglycerides ≥ 150 mg/dL, HDL ≤ 40 mg/dL, or elevated blood pressure ($\geq 95^{th}$ percentile). MHO group had normal values for all these parameters. Correlations were analyzed between the SPISE index, MUO criteria, HOMA-IR, ALT/AST, non-HDL, triglyceride/HDL ratio, and inflammatory markers as neutrophil-lymphocyte ratio, platelet-lymphocyte ratio, systemic inflammatory index, and systemic inflammatory response index.
Results
Five-hundred-eighty children were included in the study, with 58.1% girl and 35.4% morbidly obese. Among these, 45.6% were classified as MUO, with 47.5% of MUO children being morbidly obese. Significant differences in BMI SDS and morbid obesity were found between MUO and MHO groups ($p < 0.001$). The SPISE index was significantly higher in the MUO group (4.8 ± 1.2 vs 3.9 ± 1.1, $P = 0.001$). As a metabolic health indicator, the SPISE index showed an AUC of 0.737, sensitivity of 72%, and specificity of 68%, with a cut-off value of 4.21 ($P = 0.0001$). Analyzing metabolic health parameters separately, the SPISE index was significant for identifying lipid (triglyceride > 150 and/or HDL < 40 mg/dL) and glucose (fasting glucose > 100 mg/dL, HOMA-IR > 2.5) disorders ($P = 0.0001$, $P = 0.003$). However, it failed to discriminate subclinic hepatic steatosis (ALT/AST > 1) and hypertension ($> 95^{th}$ percentile) ($P = 0.668$, $P = 0.065$). Independent cardiovascular risk parameters such as BMI SDS ($r = -0.63$, $P = 0.0001$), triglyceride/HDL ($r = -0.50$, $P = 0.0001$), non-HDL ($r = -0.29$, $P = 0.0001$) also showed negative correlations with the SPISE index. Compared to other indices, SPISE was identified as the best marker ($P = 0.001$).
Conclusion
The SPISE index is a best reliable tool for identifying metabolic health disturbances especially disglycemia and dislipidemia in pediatric obesity and serves as a valuable marker for cardiovascular risk. It can be an essential component in early detection and management strategies for metabolic dysfunction in children, particularly in those with obesity

Successful treatment of two children with POMC deficiency using setmelanotide: a one-year review

Natalia Kalinchenko[1], Galina Chistousova[2] & Anatoly Tiulpakov[3]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Perm Krai State Budgetary Healthcare Institution "Regional Children's Clinical Hospital", Perm, Russian Federation; [3]Medical Genetic Research Center, Moscow, Russian Federation

Introduction
POMC deficiency is an extremely rare autosomal recessive disorder caused by biallelic loss-of-function variants in the *POMC* gene. It is characterized by 3 major features: adrenal insufficiency, obesity due to hyperphagia, and red hair. Setmelanotide, a melanocortin-4 receptor (MC4R) agonist, was recently approved as a treatment for reducing hunger and weight in patients with POMC deficiency. Here, we describe the results of one year of treatment with setmelanotide in 2 patients with POMC deficiency.
Method
Two unrelated patients with hypoglycemia during their first days of life, recurring episodes of hypoglycemia later in their first year of life, as well as pale skin and red hair, were suspected to have POMC deficiency. Hormonal evaluation revealed low levels of ACTH, cortisol, and secondary subclinical hypothyroidism. POMC deficiency was confirmed by DNA analysis: a homozygous variant chr2:25391366C>T (hg19) at the splice donor site of intron 1 was detected, and setmelanotide treatment was started.
Results
The patients, a girl aged 9 years, with height SDS 2.9 and BMI SDS 4.0, and a boy aged 8 years with height SDS 3.8 and BMI SDS 4.4, started setmelanotide treatment at 0.5 mg/day. One week later, the dose was increased to 1 mg/day and showed a sharp decrease in appetite on the next day. For the girl, the dose was increased to 1.5 mg/day at Week 28, which was the same dose after one year of treatment. During this period, her BMI SDS decreased from 4.0 to 2.3. For the boy, the dose was increased to 1.5 mg/day at Week 10 and at Week 30 to a further, final, dose of 2 mg/day. After 10 months of treatment, BMI SDS decreased from 4.4 to 3.0 and stayed stable for the two months thereafter. Both patients tolerated the treatment well. They did require increasing doses of glucocorticoids due to hypoglycemia and reported hyperpigmentation of the skin.
Conclusion
Setmelanotide treatment in these patients with POMC deficiency was safe and effective, with a decrease in BMI SDS of 42.5% and 31.8% after one year, respectively. This indicates that setmelanotide can support patients and their families in leading a more normal and active life and help to prevent the development of severe complications caused by obesity.

Circulating levels of ghrelin in patients with a rare neurodevelopmental disorder associated with hyperphagia, and/or overweight, and/or obesity – the hogrid study

Gwenaelle Diene[1], Cathy Brochado[1], Grégoire Benvegnu[1], Alice Clerc[1], Béatrice Jouret[1], Emilie Montastier[1], Grunenwald Solange[1], Marion Valette[1] & Maithé Tauber[1]
[1]CHU Toulouse, Toulouse, France

Introduction
Hyperphagia, overweight or obesity have been more frequently reported in people with intellectual disability (ID) and in rare neurodevelopmental disorders (NDDs. Amongst these conditions, people with Prader-Willi syndrome (PWS) display a

characteristic nutritional trajectory ranging from anorexia to hyperphagia, leading to early severe obesity. From a pathophysiological perspective, PWS is the only identified genetic cause of obesity associated with hyperghrelinemia. The aim of our HOGRID study is to describe ghrelin levels and hyperphagia in patients followed by centers of the national rare NDDs network "Filière DéfiScience".
Methods
HOGRID is a cross-sectional, non-interventional, national multicenter clinical study. Patients underwent a single study visit during their routine follow-up comprising fasting blood sampling to assess ghrelin levels, clinical examination and completion of a series of questionnaires notably to assess hyperphagia, using the Hyperphagia Questionnaire (HQ). Inclusion criteria were: patients between 3 and 50 years with a rare NDD such as classical syndromic obesity (Bardet-Biedl syndrome, Alström syndrome, Angelman syndrome, Smith-Magenis syndrome, X-Fragile syndrome) and other rare NDD associated with overweight/obesity and/or feeding troubles. In order to compare ghrelin levels we used three "control groups" from our previous published study "PWS" group ($n = 153$), "Obese" group ($n = 49$) and "Lean" group" ($n = 31$). In these groups ghrelin levels were assessed in the same laboratory as in the HOGRID study.
Results
We included 130 patients with a median age of 19.8 years (3 to 47 years), 43% were children ($n = 56$), 54% were boys, 27% were overweight, 59% obese and 14% lean. Total ghrelin levels of the HOGRID population were statistically lower than "PWS" ($P < 0.001$) and "Lean" ($P < 0.001$) groups and similar to those of the "Obese" group. In children, the mean total HQ score ($P = 0.042$) and the mean Hyperphagic Behavior susbscore ($P = 0.008$) were significantly higher in the HOGRID population than in the "PWS" group. In adults, compared with the "PWS" group, there was a trend for a lower total HQ score ($P = 0.053$), and a significantly lower Hyperphagic Behavior ($P = 0.03$) and Severity ($P = 0.046$) susbscores.
Conclusion
We did not find hyperghrelinemia in the HOGRID population, confirming that hyperghrelinemia is specific to the "PWS" group. Children in the HOGRID population seem to display higher hyperphagia than PWS children, which was not observed in adults. This suggests that possibly due to early diagnosis of PWS in the first month of life and early multidisciplinary care, hyperphagia in PWS may be more easily controlled in children than in adults.

Introduction
Overweight and obesity are a global health concern, affecting one in five schoolchildren in Switzerland. Although body height and weight are routinely measured during clinical visits and recorded in electronic health records (EHRs), these data are rarely used for research. We assessed the prevalence of overweight and obesity in Swiss children with use of EHRs.
Methods
SwissPedHealth is a national data stream of the Swiss Personalized Health Network (SPHN). The nested project SwissPedGrowth analyses data from children visiting hospitals in Basel, Bern, Geneva, Lausanne, Zurich, Luzern, or St. Gallen between 2017–2023. Clinical data warehouses extracted EHRs of in- and outpatients and sent anonymized data to the BioMedIT server for analysis. We included children aged 2–17 years, excluding those with ICD-10 coded diagnoses affecting BMI (e.g. intestinal infections, malignant neoplasms). We cleaned anthropometric data using the growthcleanr algorithm of Daymont *et al.* and calculated BMI using height and weight measurements taken within 30 days of each other. We computed BMI z-scores based on the International Obesity Task Force (IOTF) references, excluding implausible z-scores $<$-5 or $>$5. We calculated the prevalence of obesity among children based on IOTF cut-offs using both the highest z-score of a child ("obese ever") and the mean z-score of a child ("obese on average").
Results
Initial data from Basel, Geneva, and Lausanne contained 38, 588 children (54% boys) aged 2-17 years, with 49, 880 heights and 97, 789 weights. After excluding patients with BMI-affecting diseases (1%), without height and weight (63%), and with implausible BMI values (0.1%), we included 13, 708 children (36%), with a median of 2 (IQR: 1, 5) BMI measurements per child. Based on the highest BMI z-score, 1, 165 (8%) children were classified as obese ever, 2, 305 (17%) as overweight, and 10, 238 (75%) had a normal BMI throughout. Based on the mean z-score, 860 (6%) children were classified as obese on average, 1, 892 (14%) as overweight, and 10, 956 (80%) had a normal BMI. Older children were more often obese than young children (7-17-year-olds: 8% vs 2-7-year-olds: 4%). There was no difference between boys and girls. The prevalence of childhood obesity and overweight was consistent with previous Swiss studies.
Conclusion
SwissPedGrowth demonstrates the feasibility of using EHR data to investigate childhood obesity. Further analyses will explore related factors and examine how obesity is diagnosed and managed in hospitals and primary care (SwissPedHealth-PREPP). SwissPedGrowth provides a framework for future studies on growth and obesity in Swiss children.

JOINT2468

Metabolic profile of paediatric patients with silver-russell syndrome (SRS) or temple syndrome (TS)

Manon Cochet[1], Eloise Giabicani[2], Amélie Perrière[2], Mael Drouin[2], Marie-Pierre Luton[2], Beatrice Dubern[1] & Irene Netchine[2]
[1]Nutrition et Gastroentérologie Pédiatriques, Hôpital Armand Trousseau AP-HP, Paris, France; [2]Endocrinologie pédiatrique, Hôpital Armand Trousseau AP-HP, Paris, France

Introduction and aim
Silver-Russell Syndrome (SRS) and Temple Syndrome (TS) are characterized by severe intrauterine growth retardation (IUGR), making them relevant models within the Developmental Origins of Health and Disease (DOHaD) framework. This concept suggests that fetal programming influences the risk of developing adult metabolic disorders. However, clinical data on metabolic abnormalities in paediatric patients with SRS and TS remain scarce. This study aims to describe metabolic complications in a longitudinal cohort of children and adolescents followed at a specialized reference center for the management of SRS and/or TS.
Methods
A retrospective analysis of longitudinal data was conducted on 33 patients with molecularly confirmed diagnoses (31 SRS, 1 TS, 1 SRS/TS). Data were collected at pre-pubertal age, pubertal age, and one year after discontinuation of growth hormone (GH) therapy. Metabolic parameters assessed included overweight/-obesity, arterial hypertension, and glucose/insulin regulation abnormalities.
Results
The cohort included 33 patients and consisted of 19 boys (58%). At the pre-pubertal stage (median age: 8.3 years), metabolic abnormalities were already present in 5/33 children (15%), despite a median BMI (Body Mass Index) of -1.4 SD [-2.0; -0.9]. At pubertal age (median age: 15.2 years), 8/33 patients (24%) had at least one metabolic abnormality, while 3/33 (9%) had two, despite a median BMI remaining below average (-1.0 SD [-1.5; 0.3]). Glucose dysregulation was the most frequent and early complication, with one case of type 2 diabetes mellitus (T2DM) identified in the pre-pubertal stage and three cases (T2DM, glucose intolerance, and severe insulin resistance requiring metformin) at pubertal age. At pubertal age, 5 patients had arterial hypertension or a blood pressure $>$ 95th percentile, one patient was obese and 2 were overweight. Follow-up one year after GH therapy discontinuation confirmed these findings in the 9 patients still receiving GH at pubertal age.
Conclusion
Despite the small cohort size, this study highlights that children with SRS and/or TS develop metabolic complications from early childhood, even under

specialized follow-up. These abnormalities appear to become more frequent during adolescence but seem independent of GH treatment and excess weight (overweight/obesity).

Genetic causes and clinical features identified through a genetic diagnostic programme in cases of early-onset severe obesity

Selin Uzun[1], Deniz Özalp Kızılay[1], Ugur Cem Yilmaz[1], Fulya Mete Kalaycı[1], Nihal Gül Uslu[1], Özlem Kayır Kurt[1], Emrullah Arslan[2], Şükran Darcan[1], Damla Gökşen[1] & Samim Özen[1]
[1]Ege University Faculty of Medicine, Department of Pediatric Endocrinology and Diabetology, Izmir, Türkiye; [2]Izmir City Hospital, Department of Pediatric Endocrinology, Izmir, Türkiye

Introduction
Obesity due to variants in genes in the leptin-melanocortin-4 receptor (MC4R) pathway may benefit from personalised treatments. The aim of this study was to assess the frequency of selected rare genetic disorders in individuals presenting with early-onset obesity using data from the "Rare Obesity Advanced Diagnosis™"(ROAD) genetic diagnosis programme.
Methods
DNA was isolated from buccal swab samples of 72 patients with obesity onset before age 6 and body mass index (BMI) $\geq$ 2.5SD. Whole-exome sequencing (WES) targeted 80 obesity-related genes, including copy number variation (CNV) analysis. Variants were classified as pathogenic (P), likely pathogenic (LP), or of variants of uncertain significance (VUS) per the American College of Medical Genetics (ACMG) criteria.
Results
Of the patients from whom buccal swab samples were taken for DNA analysis, 52 (72.2%) with adequate DNA quality could be included in the study. Of the 52 cases included in the study, 63.5% (n = 33) were female and 36.5% (n = 19) were male, with a mean age of 11.63 years (1.71–19.5 years). Mean BMI was 34.60 (9.62) kg/m^2 and mean SD BMI Z-score was 3.34 (0.89). The mean age at onset of obesity was 2.9 (2.7) years. Genetic analysis identified disease-causing variants in obesity-related genes in 4 (7.7%) cases. According to ACMG criteria, two variants were classified as LP and two as P. One case harbored a homozygous c.1091C>A p.(Ala364Glu) variant in the *BBS4*, another a homozygous c.133_136dup p.(Tyr46*) variant in the *LEPR*, a third a heterozygous c.496G>A p.(Val166Ile) variant in the *MC4R*, and a fourth compound heterozygous variants c.3907C>T p.(Arg1303*), c.2462A>C p.(Lys821Thr) in the *IFT172*. The mean BMI of cases with pathogenic variants was 40.89 kg/m^2, with a BMI SD of 3.58. Additionally, heterozygous variants c.706C>G p.(Arg236Gly) in the *POMC* and c.1405G>A p.(Val469Ile) in the *PCSK1* were identified in 2 (3.8%) cases, which were classified as carriers. Moreover, variants requiring further analysis to confirm clinical significance were identified in 5 (9.6%) cases, and variants in obesity-related genes not yet associated with disease were found in 9 (17.3%) cases.
Conclusion
In 38.4% of patients with early-onset obesity included in the study, VUS/l/lP variants were identified in at least one of the studied genes, including *SIM1*, *SEMA3* family, *PLXNA* family, *POMC, PCSK1, LEPR, SH2B1, NCOA1, BBS* family, *MC4R, MKS1, IFT172, NRP1*, and *DYRK1B*. These findings highlight the diagnostic value of genetic testing in obesity and its potential to guide personalized treatment strategies.

Early use of setmelanotide in severe hypothalamic obesity leads to weight stabilization with a significant improvement in the quality of life

Hajar Dauleh[1] & Khalid Hussain[2]
[1]Sidra Medicine, Sidra Medicine, Pediatrics Endocrinology, Doha, Qatar; [2]Sidra Medicine, Sidra Medicine, Paediatrics Endocrinology, Doha, Qatar

Background
Hypothalamic obesity (HO) is a severe and treatment-resistant form of obesity resulting from hypothalamic damage, often following brain injury. Setmelanotide, a melanocortin-4 receptor (MC4R) agonist, has shown promise in managing genetic and HO. However, its use in very young children remains limited. We present a case of a 22-month-old boy with severe HO, who demonstrated positive metabolic and neurodevelopmental responses to Setmelanotide therapy.
Case Presentation
A 22-month-old boy with a history of fulminant *E. coli* sepsis and meningoencephalitis, complicated by a brain abscess on day six of life, developed hypothalamic dysfunction leading to severe obesity, alongside global developmental delay, adrenal insufficiency, and central diabetes insipidus. His weight trajectory was uncontrolled despite dietary interventions, reaching 35.8 kg at 22 months with a disproportionately high weight-for-length ratio (SD +11.60). Severe obesity significantly impacted his quality of life, leading to an inability to sleep flat, requiring a seated position due to severe gastroesophageal reflux disease (GERD) and obstructive sleep apnea (OSA). Excess adiposity in the limbs and brain injury resulted in complete immobility, with no head control, inability to sit, turn in bed, or achieve any developmental milestones. He also developed deep skin folds with recurrent infections. His immunological workup revealed lymphopenia and heterozygous variants of uncertain significance in the *TLR3* gene, with a recommendation to avoid live vaccines. Liver enzymes remained elevated (ALT: 221 IU/l, AST: 170 IU/l), secondary to fatty liver disease. Cholesterol levels were also elevated, indicating dyslipidemia as an additional metabolic concern. Given the severity of his HO, he was started on Setmelanotide {add dose and titration) at 22 months of age. Following initiation, weight stabilization was achieved with a reduction in the rate of weight gain and a drop in the weight-for-length SD (+11.11). Additionally, he exhibited markedly significant motor and social development improvements, including increased arm and hand movements, head-turning, vocalization, emotional expression, and greater interaction with family members. Biochemical improvements were also observed, with a decline in liver enzyme levels (ALT and AST) and a reduction in cholesterol levels, indicating improved metabolic health. No side effects were observed except for mild skin pigmentation.
Conclusion
This case highlights the potential role of Setmelanotide in the early treatment of severe debilitating HO, particularly in very young children. The observed metabolic stabilization, coupled with neurodevelopmental improvements, underscores the need for further studies on the early use of MC4R agonists in pediatric patients with early-onset HO.

Metabolic associated fatty liver disease (MAFLD) in patients with cushing syndrome

Sofia Chatzi[1], Maria Stroumpa[1], Maria Zotou[1], Vasiliki Antonopoulou[1], Sofia Georgiadi[1], Chrysoula Koukoula[1], Theodora Stratigou[1], Dimitra Vassiliadi[1], Marinella Tzanela[1] & Georgia Ntali[1]
[1]Department of Endocrinology "D. Ikkos"- Diabetes Center- EndoERN-Evangelismos General Hospital, Athens, Greece

Introduction
Cushing's syndrome (CS) presents with various metabolic disturbances including Metabolic Associated Fatty Liver Disease (MAFLD). Glucocorticoids contribute in MAFLD pathogenesis through insulin resistance, adipose tissue lipolysis and hepatic lipogenesis, decreased fatty acid β-oxidation, upregulation in hepatic expression of 11β-HSD1 and decreased activity of 5α-reductase. The aim of our study was to evaluate the prevalence of MAFLD in a cohort of CS patients before and after remission of hypercortisolemia.
Materials and Methods
This is a single-center retrospective study of 101 patients with CS. Their follow up was at the Department of Endocrinology of Evangelismos General Hospital in Athens between 2017 and 2023. MAFLD was estimated using the Hepatic Steatosis Index (HSI) and the Fatty Liver Index (FLI). Hepatic steatosis index > 36 and Fatty Liver Index >60 were categorized with point 3 and indicated a high possibility of MAFLD. Demographic and clinical characteristics of patients were recorded.
Results
101 patients (90 females) with CS were identified. Their mean age±SD at the time of CS diagnosis was 51±14 years. 44/101 (43.5%) were diagnosed with adrenal CS and 57/101 (56.4%) with pituitary CS. Their mean BMI±SD was 32±9 kg/m^2. At diagnosis 23/44 (52.3%) of adrenal CS and 17/57 (29.8%) of Cushing's Disease (CD) patients had type 2 diabetes mellitus. 35/44 (79.5%) of adrenal and 31/57 (54.4%) of CD patients were hypertensive. An Hepatic Steatosis Index of 3 was estimated in 81/101 (80.2%), [34/44 (77.3%) with adrenal and 47/57 (88.5%) with CD]. A Fatty Liver Index of 3 was calculated in 68/101 (67.3%), [33/44 (75%) with adrenal and 35/57 (61.4%) with CD]. At last follow up 83/101 (82.2%) [38/44 (86.36%) with adrenal and 45/57 (78.9%) with

CD] were in remission from hypercortisolemia. Their mean BMI was 26 ± 6 kg/m^2. An Hepatic Steatosis Index of 3 was estimated in 56/101 (55.4%) [25/44 (56.8%) with adrenal and 31/57 (54.3%) with CD], while a Fatty Liver Index of 3 was calculated in 25/101 (24.7%), [10/44 (22.7%) with adrenal and 15/57 (26.3%) with CD]. MAFLD markers did not differ significantly between adrenal and CD patients and they improved significantly after remission of hypercortisolemia- for HSI, *P*-value: < 0.01; for FLI, *P*-value: < 0.01-. Therapeutic modality was not a significant prognostic factor.

Conclusion

We found a high prevalence of MAFLD in our cohort of CS patients based on HSI and FLI with no significant difference between adrenal and CD patients. Remission of hypercortisolemia improved significantly MAFLD and treatment modality was not a prognostic factor.

The influence of body mass index and physical activity on menarche: a comparative study between regular and boarding school students

Nur Rochmah[1, 2], Rayi Kurnia Perwitasari[1, 2], Yuni Hisbiyah[1, 2], Aditya Primadana[1] & Muhammad Faizi[1, 2]

[1]Department of Child Health, Faculty of Medicine—Universitas Airlangga, Surabaya, Indonesia; [2]Department of Child Health, Dr. Soetomo General Academic Hospital, Surabaya, Indonesia

Background

Menarche is influenced by various factors, including body mass index (BMI) and physical activity (PA). This study aims to compare menarche, BMI, and PA among female students in regular and boarding schools to identify potential differences in these variables.

Methods

A total of 190 female students participated in this study—63 from a regular school and 127 from a boarding school. Data on BMI, menarche, and PA levels were collected. Normality tests indicated that BMI and menarche data were not normally distributed ($p < 0.05$); therefore, Spearman's rank correlation was used for analysis. The Mann-Whitney test was conducted to compare BMI, menarche, and PA levels between school environments.

Results

The findings revealed a significant correlation between BMI and menarche ($P = 0.012$, $r = -0.182$), indicating that students with higher BMI tend to experience earlier menarche. However, no significant correlation was found between PA and menarche ($P = 0.361$, $r = 0.067$). Additionally, there was a statistically significant difference in menarche ($P = 0.010$) and BMI ($P = 0.004$) between regular and boarding school students. Boarding school students exhibited a higher BMI and experienced menarche at an older age. No significant differ was found in PA levels between the two groups ($P = 0.181$).

Conclusion

The study highlights a significant relationship between BMI and menarche, with a higher BMI being associated with earlier puberty onset. Boarding school students had higher BMI and later menarche compared to regular school students. However, PA levels did not significantly differ between the two groups or influence menarche. These findings suggest that BMI plays a more substantial role in determining menarche timing than PA.

Evaluation of pulse wave velocity as early indicator of vascular damage in children and adolescents with heterozygous familial hypercholesterolemia

Patrizia Bruzzi[1], Francesco Candia[1], Laura Lucaccioni[2], Simona Filomena Madeo[1], Viola Trevisani[2], Anna Insalaco[2], Angela Giandomenico[2], Barbara Predieri[2] & Lorenzo Iughetti[2]

[1]Azienda Opedaliero-Universitaria di Modena, Policlinico, University of Modena and Reggio Emilia, Modena, Italy, Department of Medical and Surgical Sciences of the Mother, Children and Adults, Modena, Italy; [2]University of Modena and Reggio Emilia, Department of Medical and Surgical Sciences of the Mother, Children and Adults, Modena, Italy

Background

In recent years, pulse wave velocity (PWV) becomes a simple, non-invasive, reliable and reproducible method for determining arterial stiffness. In adults, PWV is already a well-established predictor of cardiovascular disease (CVD) and, recently, it has been used also in childhood. Children with heterozygous familial hypercholesterolemia (heFH) are at risk of premature atherosclerosis. Aims of this study were: (a) to evaluate PWV in a group of children and adolescents affected by heFH in comparison to internationally established age-specific references (1, 2), and (b) to identify predictive negative factors influencing PWV in the same cohort of patients.

Methods

This is descriptive and cross-sectional study. Physical examination, plasma lipid profile and PWV were measured in all patients at diagnosis of heFH (all untreated). PWV was measured with an oscillometric device (Vicorder). Values of PWV above the 95th percentiles were classified as elevated (1, 2).

Results

In heFH children (n. 22, 10 males, mean age 9.60 ± 4.15 years, mean total cholesterol 306.54 ± 32.66 mg/dl, LDL-cholesterol 218.28 ± 41.52 mg/dl, BMI-SDS 0.21 ± 1.14 kg/m^2, mean systolic blood pressure percentile 49.09 ± 38.83), mean PWV was 4.52 ± 0.65 m/s (range 3.50-5.80 m/s) and did not differ between gender (girls vs. boys: PWV 4.30 ± 0.54 vs. 4.79 ± 0.70 m/s, p 0.09; age 8.87 ± 4.88 vs 10.47 ± 3.16 years, p 0.24; systolic blood pressure percentile 53.83 ± 34.54 vs. 43.40 ± 44.63, p 0.40). According to international references (1, 2), the prevalence of elevated pulse wave velocity was 32% (7/22; 2 females). Moreover, PWV positively correlated with systolic blood pressure (R 0.43, $p < 0.05$), mainly in males (R 0.81, $p < 0.05$).

Conclusions

In literature, data on PWV in heFH children and adolescents are still scarce. Our study supports that arterial stiffness occurs early and more frequent in asymptomatic heFH children indicating a subclinical increased risk for premature CVD and reflecting the need for early initiation of anti-cholesterolemic treatment. Moreover, our data point out that, even during the first decades of life, not only hypercholesterolemia, but also clusters of pro-atherogenic conditions, such as hypertension, could affect PWV.

Background

This study aimed to determine the correlation between circulating spexins, obesity, and metabolic parameters in children and adolescents in South Korea.

Methods

This single-center study included 128 Korean children and adolescents: 65 (50.8%) were obese, 47 (36.7%) were overweight, and 16 (12.5%) were normal weight. Metabolic parameters were measured, including fasting blood glucose, fasting insulin, homeostasis model assessment of insulin resistance (HOMA-IR), and lipid profiles.

Results

Spexin levels were significantly lower in obese children than in controls (mean 163.1 vs. 198.4 pg/mL; $P = 0.01$). Spexin levels were lower in the IR group than in the non-IR group (mean 145.3 vs. 185.1 pg/mL; $p < 0.001$). Spexin levels were not associated with sex or pubertal stage. Spexin levels were negatively correlated with BMI SDS ($r = -0.30$; $p < 0.001$), systolic BP ($r = -0.33$; $p < 0.001$),

fasting insulin ($r = -0.41$; $p < 0.001$), HOMA-IR ($r = -0.42$; $p < 0.001$), TG ($r = -0.38$; $p < 0.001$), and plasma leptin levels ($r = -0.26$; $P = 0.004$). Multiple linear regression analysis indicated that after adjusting BMI SDS, plasma spexin levels were independently associated with HOMA-IR ($P < 0.001$) and TG ($P < 0.001$). Mediation analysis indicated that the effect of BMI SDS on HOMA-IR was partially mediated by spexin levels.

Conclusions

This study demonstrated an association between plasma spexin level, obesity, and insulin resistance in Korean children and adolescents.

?ral administration of Crocus sativus tepals extract improves systemic glucose tolerance in mice fed a high-fat diet through changes in gut microbiota composition

Ana Teofilović[1], Biljana Bursać[1], Luisa Bellachioma[2], Ljupka Gligorovska[1], Miloš Vratarić[1], Danijela Vojnović Milutinović[1], Camilla Morresi[2], Elisabetta Damiani[2], Tiziana Bacchetti[2] & Ana Djordjevic[1]

[1]Institute for Biological Research "Siniša Stanković"- National Institute of the Republic of Serbia, University of Belgrade, Department of Biochemistry, Belgrade, Serbia; [2]Marche Polytechnic University, Department of Life and Environmental Sciences, Ancona, Italy

The stigmas of *Crocus sativus* (Cr), known as saffron spice, are recognized as a dietary supplement for the treatment of obesity and type 2 diabetes due to their potent antidiabetic, hypolipidemic and antioxidant potential. Recently, the bioactive components of Cr tepals, which are wasted during saffron production, have also been shown to have significant hypoglycemic properties. The use of dietary supplements of herbal origin could affect the composition of the gut microbiota, which influences host energy homeostasis and in the long run affects the prevalence of obesity and related metabolic complications. Therefore, we investigated whether the gut microbiota could play a mediating role in the beneficial effect of Cr tepals extract on systemic glucose tolerance in an animal model of diet-induced obesity. Male C57BL/6J mice were fed a standard diet (10 kcal% fat) or a high-fat diet (60 kcal% fat) for 14 weeks. Mice on the high-fat diet were treated orally with Cr tepals extract for the last 5 weeks of the diet. Biochemical and physiological parameters and an intraperitoneal glucose tolerance test were performed to estimate systemic glucose tolerance. The composition and diversity of gut microbiota was analyzed by 16S rRNA sequencing of bacterial DNA isolated from fecal samples. Gut integrity was assessed by measuring the level of fluorescently labeled (FITC) dextran in blood and by quantifying the level of tight junction proteins by Western blot. Oral administration of Cr tepals extract reduced body mass of obese animals and lowered glucose and insulin levels, as well as the HOMA index, indicating an improvement in systemic glucose tolerance. Greater richness and evenness of the gut microbiota were confirmed by a lower Firmicutes/Bacteroidetes ratio and increased alpha diversity indices. The composition of the gut microbiota shifted towards an increased abundance of the genera *Odoribacter*, *Alistipes*, *Candidatus Saccharimonas* and *Intestinimonas*, which are negatively correlated with insulin resistance and inflammation. The level of FITC-dextran was reduced and the expression of Zonula occludens 1 protein was increased, which led to an improvement of intestinal integrity. Cr tepals extract has a positive effect on gut microbiota composition, compromised by a high-fat diet, by increasing the abundance of bacterial genera that can be associated with the amelioration of glucose tolerance. This beneficial effect could be the result of improved gut integrity and reduced permeability. Our results highlight Cr tepals extract as an effective natural supplement for the treatment of obesity-related metabolic disorders without side effects.

Higher BMI as a protective factor for the development of ketotic hypoglycaemia in children with vomiting and dehydration

Juraj Stanik[1, 2], Simona Tarnokova[3], Lenka Langerova[1], Sabina Szoradova[1], Barbora Pitekova[4] & Tomas Dallos[1]

[1]Medical Faculty of Comenius University, National Institute for Childreńs Diseases, Department of Paediatrics, Bratislava, Slovakia; [2]Institute of Experimental Endocrinology, Biomedical Research Center, Slovak Academy of Sciences, Department of Metabolic Disorders, Bratislava, Slovakia; [3]National Institute for Childreńs Diseases, Department of Laboratory Medicine, Bratislava, Slovakia; [4]National Institute for Childreńs Diseases, Department of Emergency Medicine, Bratislava, Slovakia

Background

Healthy children from 7 months to 7 years are known to be at risk for developing hypoglycaemia during prolonged fasting, particularly during acute illness with decreased oral intake. The aim of our study was to identify additional risk factors for hypoglycaemia in children with acute vomiting and dehydration.

Methods

A retrospective analysis included 560 healthy children and adolescents (aged from 29 days to 17.96 years) without known metabolic disorders admitted to hospital with dehydration due to the acute illness with vomiting or poor oral intake. As potential risk factors of hypoglycaemia historical and anthropometric parameters were evaluated.

Results

One hundred seventy-one (30.5%) participants (aged 0.6-10.7, median 3.8 years) experienced hypoglycaemia ≤ 3.3 mmol/l. In a multiple logistic regression analysis, beside known factors such as higher degree of dehydration and complete absence of oral intake, other independent predictors of hypoglycaemia were a history of diarrhoea, lower BMI and lower BMI-SDS, but not age. Hypoglycaemic children had BMI 12.0-19.3 kg/m^2, BMI-SDS from -2.25 to 1.9, and only one child was obese with BMI-SDS 1.9. The highest frequency of hypoglycaemia (37.5-51.6%) was observed in the age groups of 2-7 years, who also had low median BMI values (13.9-14.8).

Conclusions

We identified low BMI, low BMI-SDS and diarrhoea as risks factors for developing hypoglycaemia. The typical shape of the BMI curve in children with physiologically low values at 2-7 years of age could partly explain the high incidence of hypoglycaemia in otherwise healthy children with decreased oral intake at this age. *Supported by*: VEGA1/0659/22.

Tryptophan derivatives as non-invasive diagnostic indicators for obesity-related MASLD in children and adolescents

Shumin Zhan[1] & Junfen Fu[1]

[1]Children's Hospital, Zhejiang University School of Medicine, National Clinical Research Center for Child Health, Hangzhou, China

Metabolic dysfunction-associated steatotic liver disease (MASLD) in young individuals with obesity poses a significant global health challenge in diagnosis. Here, we analyzed a cohort of children and adolescents with obesity-related MASLD to uncover remarkable metabolic alterations associated with disease progression. Specifically, circulating tryptophan (TRP) metabolism was markedly elevated in obesity and obesity-related MASLD statuses compared to their normal-weight peers. Furthermore, TRP-derived metabolites significantly promote intracellular lipid accumulation in mouse hepatocytes and liver organoids. Last, we developed a non-invasive diagnostic model utilizing TRP-derived metabolites to effectively differentiate obesity-related MASLD in children and adolescents. Our findings underscore the importance of tryptophan metabolism in MASLD progression in children and adolescents with obesity and hold promises for TRP-derived metabolites as non-invasive biomarkers in early diagnosis.

Postprandial metabolic response to intake of different milk fat structures in healthy individuals

Jens Voigt[1], Natasa Brkovic[1], Andreas Møller[2], Shyam Suwal[2], Henrik Andersen[3], Ulf Andersen[2], Nikolaj Rittig[1] & Esben Sondergaard[4]

[1]Steno Diabetes Center Aarhus, Aarhus University Hospital, Aarhus N, Denmark; [2]Department of Science & Technology, Arla Innovation Centre, Arla Foods amba, Aarhus, Denmark; [3]Aarhus University, Interdisciplinary Nanoscience Center, Aarhus, Denmark; [4]Aarhus University, Department of Clinical Medicin, Aarhus, Denmark

Background
Intake of milk fat has been linked to improved cardiometabolic health compared to other sources of dietary fat. Milk fat is mainly composed of triglycerides surrounded by a complex and unique tri-layer membrane composed of phospholipids and protein, known as the Milk Fat Globule Membrane (MFGM), which has been proposed as an explanation for the potential health benefits of milk fat. To investigate this, we developed three isocaloric high-fat dairy products consisting of milk fat with intact MFGM, milk fat with disintegrated MFGM and milk fat without MFGM but with equal protein and fat content. We hypothesized, that the presence and the structural integrity of MFGM would attenuate the postprandial lipemia upon intake of high-fat dairy spreads.
Methods
Twelve healthy volunteers were randomized in a double-blind, controlled, crossover design. Participants were studied on three different occasions with a wash-out period of minimum one week. Participants were investigated after consuming two high-fat meals (40g milk fat), one for breakfast and one for lunch, containing either intact MFGM, disintegrated MFGM, or no MFGM. Postprandial lipemia was evaluated as area under the curve (AUC) for plasma triglyceride (TG). Gastric emptying was assessed using the acetaminophen test, while appetite was evaluated through questionnaires and an ad libitum meal test at the end of each study day.
Results
AUC for TG did not differ between the three interventions (MFGM: 1.3 mmol/l*min, 95%CI: 1.2–1.4; destroyed MFGM: 1.3 mmol/l*min, 95% CI: 1.2–1.4; no MFGM: 1.1 mmol/l*min, 95% CI: 1.–1.19, $P = 0.8$). In addition, no difference between the three interventions was observed for insulin levels, glucose levels, gastric emptying, appetite sensation or ad libitum food intake.
Conclusion
MFGM content and/or structural integrity of milk fat does not appear to have significant impact on the postprandial metabolic response in healthy individuals. Consequently, potential cardiometabolic health benefits from consuming high milk fat servings may instead be mediated by other structural components of the food matrix, such as protein structure.

Ketone supplementation acutely lowers androgen and glucose levels in women with polycystic ovary syndrome (PCOS)

Nikolaj Rittig[1 2 3], Mai C. Arlien-Søborg[2], Mads Vandsted Svart[1 2 3], Henrik Holm Thomsen[3, 4], Kirstine Kirkegaard[5], Vinnie Hornshøj Greve[5], Mette Moelby Nielsen[6], Kirstine Stochholm[2], Marie Juul Oernstrup[2] & Claus H. Gravholt[2 3 7]
[1]Aarhus University Hospital, Steno Diabetes Center Aarhus (SDCA), Aarhus, Denmark; [2]Aarhus University Hospital, Department of Endocrinology, Aarhus, Denmark; [3]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; [4]University Clinic for Innovative Patient Pathways, Regional Hospital Central Jutland, Viborg, Denmark; [5]Aarhus University Hospital, Department of Gynaecology and Obstetrics, Aarhus, Denmark; [6]Aarhus University Hospital, Department of Clinical Biochemistry, Aarhus, Denmark; [7]Aarhus University, Department of Molecular Medicine, Aarhus, Denmark

Background
Polycystic ovary syndrome (PCOS) is a common endocrine disorder linked to insulin resistance and elevated androgens. While ketogenic diets reduce androgen and glucose levels in women with PCOS, the direct role of β-hydroxybutyrate (BHB) remains unclear. This study aimed to determine whether BHB supplementation acutely lowers circulating androgen and glucose levels in women with PCOS.
Methods
A randomized, placebo-controlled crossover trial was conducted involving 20 women diagnosed with PCOS. Participants underwent fasting blood sampling on two occasions, separated by at least three days. They were randomly assigned to receive either a ketone supplement or a taste-matched placebo. Each intervention was administered over 10 hours, with one dose administered the evening before and another two hours prior to blood collection.
Results
Following BHB supplementation, blood D-β-hydroxybutyrate (D-BHB) levels reached 2.4 ± 1.2 mM, compared to 0.1 ± 0.1 mM in the control group ($P < 0.001$). Androgen concentrations were generally lower with BHB supplementation, with mean reductions in testosterone (-13%, CI 95%: -27 to 1, $P = 0.067$), free testosterone (-21%, 95% CI: -43 to 1%, $P = 0.057$), androstenedione (-14%, CI 95%: -29 to 0, $P = 0.050$), and 11-ketotestosterone (-21%, CI 95%: -38 to -4, $P = 0.020$) compared to control. Fasting plasma glucose levels were 4.6 ± 0.7 mM after BHB supplementation, vs 5.1 ± 0.4 mM in the placebo group (mean -10%, CI 95%: -5 to -15%, $P < 0.001$).
Conclusion
Ketone supplementation acutely lowers androgen and glucose levels in women with PCOS. These findings highlight the potential for ketone-based therapies as a novel treatment for PCOS and suggest the need for long-term clinical trials to further explore these effects.

When hunger defies satiety: insights from a case of LEPR-related monogenic obesity

Bhanu Nalluri[1], Neelaveni K[1] & Rakesh Sahay[1]
[1]Osmania General Hospital, Departement of Endocrinology, Hyderabad, India

Background
Monogenic obesity is a rare, severe form of early-onset obesity driven by genetic mutations that disrupt energy homeostasis. Leptin receptor (LEPR) mutations impair satiety signaling, leading to hyperphagia, excessive weight gain, and metabolic complications. Early diagnosis and intervention are critical to mitigate risks such as type 2 diabetes, hypertension, and cardiovascular disease. We present a case of a 7-month-old female with monogenic obesity due to a homozygous LEPR mutation.
Case Presentation
A 7-month-old female presented with rapid weight gain since 40 days of life. The parents reported marked hyperphagia, with over 10 breastfeeding sessions daily, and frequent crying relieved by feeding. Developmental milestones were normal, with no history of hypoglycemia or hospitalizations. The child was full-term, born via normal vaginal delivery, weighing 2.75 kg, with third-degree consanguinity noted. At presentation, she weighed 16.5 kg (>97th percentile), had a BMI of 39 kg/m^2, and a weight-for-length >99.9th percentile (+7 SD). Physical examination revealed generalized obesity, almond-shaped eyes, without signs of acanthosis nigricans or Cushingoid features.
Investigations
Laboratory tests showed impaired glucose tolerance (HbA1c 6.4%), hypertriglyceridemia (TG 231 mg/dL), and dyslipidemia. Abdominal ultrasound revealed grade 1 fatty liver, and echocardiography showed concentric left ventricular hypertrophy. Genetic testing confirmed a homozygous pathogenic LEPR mutation. Serum leptin levels were within the normal range (3.66 ng/mL).
Management
A low-carbohydrate, low-fat diet was initiated with close monitoring. Despite dietary modifications, her weight increased to 25 kg by 18 months, highlighting the progressive nature of LEPR-related obesity and the need for pharmacologic interventions.
Discussion
LEPR mutations disrupt leptin signaling, causing severe early-onset obesity[1]. This case underscores the importance of considering monogenic obesity in infants with rapid weight gain, particularly in consanguineous families[2]. Early genetic testing enables accurate diagnosis and personalized management[3]. While dietary interventions have limited efficacy, emerging therapies targeting the leptin-melanocortin pathway, such as setmelanotide, offer promising outcomes.
Conclusion
This case highlights the diagnostic and therapeutic challenges of LEPR-related monogenic obesity. A multidisciplinary approach, including genetic testing, dietary management, and novel therapies, is vital to mitigate complications and improve long-term outcomes.

Comparison of ambulatory glucose profile (AGP) parameters between two advanced hybrid closed-loop (AHCL) systems from childhood to adulthood at 6 and 12 months

Enrico Saudelli[1], Giulio Maltoni[2], Gianmarco Pizza[1], Anna Malaguti[1], Alessia Bruco[1], Michele Baldari[1], Laura Tribotti[1], Ilenia Schillaci[1], Sara Capra[1], Sabrina Berti[1], Simona Moscatiello[1], Sara Flamigni[1], Andrea Scozzarella[2], Luca Bernardini[2], Marcello Lanari[2], Uberto Pagotto[1] & Guido Di Dalmazi[1]

[1]Endocrinology and Diabetes Prevention and Care IRCCS Sant'Orsola, Bologna, Italy; [2]Pediatric unit IRCCS Sant'Orsola, Bologna, Italy

Background and Aim

Advanced hybrid closed-loop (AHCL) systems, MiniMed 780G (M) and Tandem Control-IQ (T), represent the most advanced technologies for glucose control in patients with Type 1 Diabetes (T1D). Limited comparison data are available in the literature yet. We aimed at identifying differences in glucose parameter between M and T in adult and pediatric patients.

Method

We retrospectively collected data of 199 patients with T1D: 93 adults (>18 years: 59M, 34T), 56 adolescents (12-18 yo; 16M, 40T) and 50 children (<12 yo; 9M, 41T). We analyzed AGP data before AHCL initiation and after 6 and 12 months. Target-Time-In-Range (TIR) was set at >70%.

Results

No differences in insulin/kg ratio were observed between M and T users, at 6 and 12 months, among age groups. Adults: At 6 months and 12 months, patients with M showed higher TIR (6 months: 74%[67-79] vs 66%[59-76], p=.021; 12 months: 73%[69-80] vs 66%[59-72], p=.002), lower Time Above Range (TAR) >250mg/dl ($P < .001$ for both times), Glucose Management Indicator (GMI, p=.005 for both times), and Coefficient of Variability (CV, p=.007 and p=.016 respectively) than T users. At 12 months, 61% of M users had a target-TIR vs 38% T (p=.049). Adolescents: At 6 and 12 months, patients using M vs T had higher TIR (6 months: 82%[75-87] vs 61%[53-69], $P < .001$; 12 months: 79%[69-85] vs 58%[47-68]; $P < .001$), and lower TAR>250mg/dl ($P < .001$ for both times), GMI ($P < .001$ and p=.005, respectively), and CV ($P < .001$ and p=.002, respectively). Time Below Range (TBR) at 12 months was higher in M vs T users (2%[1-3] vs 1%[0-2], p=.023). At 12 months, 69% of M users had a target-TIR vs 18% T ($P < .001$). Children: no significant differences were observed, but with a small cohort of M users.

Conclusion

With similar insulin/kg, M seems to be more effective in improving TIR, TAR, GMI and CV in adults and adolescents but T appears to be better in reducing TBR in adolescents at 12 mo.

VLCKD improves MASLD and metabolic dysfunction in patients with type 2 diabetes and obesity

Sabrina Tini[1], Stefano Celano[1], Jessica Baima[1], Valentina Antoniotti[1], Alessandro Antonioli[1], Edoardo Luigi Maria Mollero[1, 2], Daniele Spadaccini[1], Paolo Marzullo[1, 2], Gian Mauro Sacchetti[3], Gianluca Aimaretti[2, 4] & Flavia Prodam[1, 2]

[1]University of Piemonte Orientale, Department of Health Science, Novara, Italy; [2]AOU Maggiore della Carità Hospital, SCDU Endocrinology, Novara, Italy; [3]AOU Maggiore della Carità Hospital, Novara, Italy; [4]University of Piemonte Orientale, Department of Translational Medicine, Novara, Italy

The global prevalence of obesity and type 2 diabetes (T2D) has risen dramatically, affecting over 890 million adults. Sedentary lifestyle and increased consumption of Western Diet contribute not only to obesity but also to the development of steatotic liver disease associated with metabolic dysfunction (MASLD). Ketogenic Diet (KD), which induces ketosis, has gained clinical interest due to its therapeutic effects in reducing body weight, improving insulin sensitivity, and ameliorating dyslipidemia. The very-low-calorie ketogenic diet (VLCKD) protocol is one of the most used in clinical practice, characterized by low carbohydrate (<40g/day), adequate protein for ideal body weight, and normal fat intake, with a total daily caloric intake of 500-800 Kcal. Despite promising evidence on VLCKD antiseizure effects, its impact on T2D associated with MASLD remains controversial. This 12-week pilot study investigates the VLCKD effects on metabolic parameters and MASLD in patients with T2D and obesity. 10 out of 15 enrolled patients ended the study protocol. All participants (mean age: 44.43 years) had T2D with a mean disease duration of 2.7 years (HbA1c: 6.6% ± 0.76), obesity (BMI: 39.42 kg/m^2), and MASLD (CAP: 273.56 ± 48.82 dB/min, LS: 5.89 ± 1.7 kPa), diagnosed via liver ultrasound and vibration-controlled transient elastography (VCTE, FibroScan Echosens). At the end of the 12 weeks, we observed significant improvements, including reductions in body weight, BMI, hip and waist circumferences, and fat mass percentage (40.07 ± 4.13 vs. 34.5 ± 12%), while fat-free mass increased (59.9 ± 4.1% vs. 64.0 ± 20.8%). Blood pressure improved, along with fasting insulin, HbA1c (6.5 ± 0.2% vs. 5.6 ± 0.2%), and triglycerides. Liver parameters of MASLD at VCTE improved, as shown by reductions in CAP (283.1 ± 51 vs. 241.6 ± 71 dB/m) and LS (5.8 ± 1.93 vs. 4.67 ± 1.27 kPA). At the beginning of the study, 3 patients stopped SGLT2 inhibitors and insulin treatments, without needing to add them at the end of the study. Nobody added new drugs. These preliminary findings suggest that VLCKD seems to have potential benefits in improving the short-term T2D parameters coupled with amelioration of MASLD, likely due to a reduction in de novo lipogenesis and an increase in hepatic lipolysis.

Introduction
Serum inflammation based scores (SIBS) are evolving biomarkers of chronic liver diseases. Multiple SIBS can be simply calculated using complete blood count (CBC) data. To the best of our knowledge, so far there are no studies investigating the role of SIBS in prediction of liver fibrosis (LF) in hypercortisolemia.
Objectives
To evaluate associations between selected SIBS and LF among newly diagnosed Cushing syndrome (CS) and mild autonomous cortisol secretion (MACS).
Materials and Methods
We analyzed retrospectively baseline data of adult patients from the ERCUSYN, Krakow database (N:184- 51% pituitary CS, 26% adrenal CS, 23% ectopic CS), MACS patients (N:121*)*, control group (N:177 for CS [CS-CG] and 121 for MACS [MACS-CG], non-secretory adrenal incidentalomas matched to age, gender, weight, presence of hypercholesterolemia and diabetes mellitus). FIB4 ($Age \times AST/PLT \times ALT^{1/2}$) was used as a LF predictor. The correlations between SIBS and FIB4 were assessed (RStudio version 4.2.2. $P < 0.05$).
Conclusion
There may be an association between FIB4 and SIBS in the following pattern: 1) positive with NLR in CS; 2)positive with NPR and negative with PLR in: CS, MACS and normocortisolemic population; 3)negative with SII in MACS and normocortisolemic population. Further studies are needed to estabilish SIBS role in LF prediction.

Endocrine manifestations in pediatric patients with inherited metabolic diseases

Cristiana Costa[1], Gonçalo Padeira[2], Ana Fitas[3] & Ana Ferreira[2]
[1]Hospital Dona Estefânia - ULS São José, Pediatric Unit, Lisbon, Portugal; [2]Hospital Dona Estefânia - ULS São José, Metabolic Diseases Unit, Lisbon, Portugal; [3]Hospital Dona Estefânia - ULS São José, Pediatric Endocrinology Unit, Lisbon, Portugal

Introduction
Inherited metabolic disorders (IMDs) are rare genetic diseases that can affect different systems, including the endocrine system. IMDs are classified into three groups according to their mechanisms: cellular intoxication, energy deficit and defects of complex molecules. Endocrine disorders may present in childhood, following diagnosis or in adulthood, before any previous metabolic diagnosis. Data regarding endocrine manifestations in pediatrics is limited. This study aims to describe endocrine manifestations in a cohort of patients with IMDs.
Methods
Demographic, clinical, and laboratory data was collected retrospectively from medical records of patients with IMDs followed at the pediatric unit of metabolic diseases in a tertiary pediatric hospital, between January 2002 and May 2024.
Results
From a total of 92 patients with an IMD associated with endocrine dysfunction, 25 had identified at least one endocrinological manifestation, of which 14 were male; 5 have died; and current median age of living patients is 13, 5 years (min 3; max 27). The median age of onset of endocrinological manifestations was 5 years (min 2 months; max 15 years). Regarding the main IMDs groups: 14 were from energy deficiency group [10 mitochondrial disorders, 3 MCT8 deficiency, 1 glycogen storage disease type I); 9 from complex molecule group [6 X-linked adrenoleukodystrophy (X-ALD); 3 congenital disorders of glycosylation] and 2 from intoxication group (1 galactosemia; 1 methylmalonic acidemia). In our cohort, we identified: 9 adrenal insufficiency (mainly X-ALD); 7 short stature with IGF1 deficit (2 of them treated with growth hormone); 6 dys/hypothyroidism; 3 premature adrenarche; 2 diabetes mellitus; 2 hypogonadism; 1 hypoparathyroidism; 1 ovarian insufficiency and 1 panhypopituitarism. Most endocrine manifestations occurred during IMDs' evolution, only 5 occurred as an initial manifestation.
Conclusions
About a quarter of the patients in this 22-year time span cohort had endocrine manifestations. Compared to the only published data including pediatric patients, the prevalence of endocrine manifestations in our cohort was higher and more diverse. This may reveal an increasing awareness of the endocrine involvement or also translate an increasing prevalence. Each case should be individually assessed, and the greater potential for endocrine involvement of some diseases (respiratory chain defects or peroxisomal disorders) should be taken into account to ensure timely referral and intervention.

Avdalbekyan, Yerevan, Armenia; [5]NWSMU named after I.I. Mechnikov, Saint-Petersburg, Russian Federation

Introduction
Chronic kidney disease (CKD) is one of the most common comorbid conditions in patients with metabolic syndrome. Early detection of CKD may help to improve therapeutic approaches and thus prevent disease progression and complications.
Aim
To determine the incidence of metabolic disorders in patients with subclinical albuminuria (AU).
Materials and Methods
AURA (NCT05690009) is a registry of real clinical practice in 34 regions of the Russian Federation, including 4531 patients over 40 years of age without previously diagnosed CKD, type 1 or type 2 diabetes mellitus. AU levels were measured once using test strips during the period of enrolling patients in the register. The threshold value for AU was defined as 20 mg/l. All enrolled patients were divided into 2 groups according to test result for comparative analyses.
Results
AU levels <20 mg/l were detected in 1592 patients (35.1%), whereas AU levels ≥ 20 mg/l were detected in 2939 patients (64.9%). Diagnostically relevant AU was more common in men (44.2% (≥ 20 mg/l) vs 38.6% (<20 mg/l); $P < 0.001$), in those who were overweight (28.1 vs 27.2 kg/m^2; $P < 0.001$) and in smokers (19.1% vs 15.7%; $P = 0.006$). Among chronic diseases, metabolic syndrome (32.0% vs 23.4%; $P < 0.001$), hypertension (79.0% vs 71.5%; $P < 0.001$) and prediabetes (14.7% vs 8.9%; $P < 0.001$) were significantly more reported. Among laboratory markers, serum uric acid levels were found to be higher in patients with AU (316 [259;383] vs 298 [246;357] µmol/l; $P < 0.001$). AU was not associated with the presence of dyslipidemia (low-density lipoproteins (3.1 [2.3; 3.9] vs 3.1 [2.3; 3.9] mmol/l; $P = 0.901$). However, a significant association was observed between albuminuria and high-density lipoproteins (1.3 vs. 1.4 mmol/l; $P < 0.001$) and triglycerides (1.4 vs. 1.3 mmol/l; $P = 0.002$). The multivariate model revealed that the detection of AU ≥ 20 mg/l was significantly influenced by age, and the presence of metabolic syndrome, prediabetes and cardiovascular disease (Table 1).
Conclusion
The AURA registry has demonstrated that subclinical AU is directly associated with a number of cardiometabolic factors. Therefore, for individuals with prediabetes and metabolic syndrome, determining their AU using test strips can serve as an effective screening method for early CKD detection. This approach will enhance the delivery of medical care and facilitate timely nephroprotection.

Table 1. Factors with significant influence on the presence of albuminuria.

Predictors	Odds ratio	95% confidence Interval	*P*-value
Age	1.02	1.01-1.02	<0.001
Metabolic syndrome	1.23	1.02-1.49	0.034
History of myocardial infraction	1.67	1.22-2.30	0.002

Analysis of the concordance between body fat percentage estimated by dual-energy X-ray absorptiometry (DEXA) and anthropometric parameters in a cohort of obese patients

Cristina Aguilar Riera[1, 2], Cristina Gámez[1], Fanny Del Carmen Ospina Ospina[4], Eduard Mogas[1], María Clemente[1, 3], Ariadna Campos Martorell[1], Núria González Llorens[1] & Diego Yeste[1, 4]
[1]University Hospital Vall d'Hebron, Barcelona, Spain; [2]Barcelona, Paediatric Endocrinology, Barcelona, Spain; [3]CIBER Enfermedades raras. Instituto Carlos III., Mardid, Spain; [4]CIBER Enfermedades raras. Instituto Carlos III., Madrid, Spain

Introduction
Body mass index(BMI [kg/m^2]) is the most used anthropometric parameter to estimate body fat content. However, its interpretation during childhood and adolescence has limitations, as it is not constant and varies significantly with age, sex, and maturation stage, requiring reference values and a z-score format. The triceps mass index(TMI [kg/m^3]) estimates body fat percentage more accurately than BMI in children and adolescents aged 8 to 18 years. DEXA(Dual-Energy X-ray Absorptiometry) is the gold standard for tricompartimental analysis of body composition and accurately estimates body fat percentage, being the best parameter to define and classify the degree of obesity.
Objective
To analyze the correlation between body fat percentage estimated by DEXA and anthropometric parameters: TMI, BMI, and BMI z-score from the 2010 Spanish Transversal Growth Study and WHO Growth Patterns 2007 in a population of obese children and adolescents.
Patients and Methods
Sixty-six obese patients (56% female), aged between 8 and 18 years, with a mean age of 14.1 $\pm$ 2.4 years, were included. Body composition was assessed using DEXA(Lunar Prodigy Advance DXA).
Results
The mean age of obesity onset was 6.5 $\pm$ 2.6 years (range: 1–12 years). BMI value: 35.2 $\pm$ 6.0; BMI z-score 2007: 3.2 $\pm$ 0.6 (range: 2–4.4); and TMI: 22.2 $\pm$ 4.1(range: 14.8–36.9). Eight patients(17%) had moderate obesity(BMI z-score 2007 $>$2; $<$2.5SD); 37 patients (56%) had severe obesity(BMI z-score 2007 $>$ 2.5; $<$3.5SD); and 21 patients (31%) had morbid obesity(BMI z-score 2007 $>$ 3.5). In DEXA body composition analysis, the mean body fat percentage was 49.5 $\pm$ 6.2%(range: 33.8–59.6). The mean body fat percentage in females was 51.6 $\pm$ 5.4%(range: 38.4–59.6) and in males was 46.9 $\pm$ 6.2%(range: 33.8–57.1). A positive and significant correlation was found between body fat percentage and TMI($r = 0.55$, $P < 0.05$), BMI($r = 0.46$, $P < 0.05$), BMI z-score 2010($r = 0.53$, $P < 0.05$), and BMI z-score 2007($r = 0.45$, $P < 0.05$). Regarding sex: Males ($n = 29$): TMI($r = 0.39$, $P < 0.05$), BMI($r = 0.38$, $P < 0.05$), BMI z-score 2010($r = 0.40$, $P < 0.05$). No significant correlation with BMI z-score 2007($r = 0.3$, $P = 0.1$). Females ($n = 37$): TMI($r = 0.61$, $P < 0.05$), BMI($r = 0.56$, $P < 0.05$), BMI z-score 2010($r = 0.63$, $P < 0.05$), and BMI z-score 2007($r = 0.62$, $P < 0.05$).
Conclusions
Preliminary results from this ongoing study show that the degree of concordance between the anthropometric parameters analyzed and the body fat percentage estimated by DEXA is very similar in obese patients when analyzed by sex, although this correlation is stronger in females. Since TMI values are very consistent and comparable across both sexes in the 8–18 age range, this index would be highly useful for identifying and classifying the degree of obesity.

Setmelanotide treatment in genetic obesity: a single-center experience

Deniz Özalp Kızılay[1], Özlem Kayır Kurt[1], Uğur Cem Yılmaz[1], Fulya Mete Kalaycı[1], Nihal Gül Uslu[1], Selin Uzun Karaüzüm[1], Damla Gökşen[1] & Samim Özen[1]
[1]Ege University Faculty of Medicine, Division of Pediatric Endocrinology and Diabetes, İzmir, Türkiye

Objective
Setmelanotide, an MC4R agonist, is approved for the treatment of obesity in patients with POMC, LEPR, and PCSK1 deficiencies, as well as in Bardet-Biedl Syndrome (BBS). There is little real-world evidence for the efficacy and safety of setmelanotide. This study aimed to evaluate the clinical characteristics and follow-up outcomes of patients treated with setmelanotide at our center.
Methods
The study included five patients; three patients with POMC deficiency, one with LEP mutation, and one with BBS treated with setmelanotide. The effects of setmelanotide on body weight, associated measures, hunger score, and quality of life were examined.
Results
The mean age of the patients was 17.1 $\pm$ 5.04 years (range: 11.5–24 years). Three patients were female and two were male. The duration of treatment ranged from 3 to 14 months. Except for the patient with BBS, all patients achieved a decrease in their BMI by more than 5% during the treatment. Before therapy, the mean BMI was 38.78 $\pm$ 5.99 kg/m^2 (32.36-48.20) and the mean BMI SDS was 3.35 $\pm$ 0.96 (2.14-4.59). After therapy, the mean BMI was 35.31 $\pm$ 7.43 kg/m^2 (29.10-47.80), the mean BMI SDS was 2.98 $\pm$ 1.15 (ra1.78-4.63), and the mean percentage decrease in BMI was -9.22 $\pm$ 8.44% (range: 0.80-21.30). All patients showed a significant decrease in their hunger scores and an improvement in their quality of life (QoL) scores. The baseline hunger score was 8.60 $\pm$ 1.34 (range: 7-10) and decreased to 3.60 $\pm$ 2.88 (range: 1-8) after treatment. Similarly, the mean baseline QoL was 96.60 $\pm$ 26.40 (range: 62-120) and improved to 106.20 $\pm$ 22.28 (range: 68-124) after treatment. After five months of treatment, the patient with the LEPR gene variant had a -9.9% decrease in BMI but had to stop treatment for one month due to depression. In the ninth month of the follow-up period, BMI decreased by -0.8%, and treatment was discontinued due to worsening depression symptoms. Additionally, adverse events such as nausea in four patients, hyperpigmentation in four patients, headache in two patients, and pain at the injection site in two individuals were observed. However, these adverse events did not necessitate discontinuation of treatment.
Conclusion
Setmelanotide provides significant weight control in POMC and LEPR deficiencies but has a more limited effect in BBS. It can also provide significant reduction in hunger scores and improvement in QOL scores in all patients, including BBS. Long-term, real-life data with more patients are needed regarding setmelanotide treatment.

The impact of prader-willi syndrome (PWS) on caregivers and the healthcare system: a burden of illness study design

Evelien Gevers[1], Kathryn Obrynba[2], Dairine Dempsey[3], Kristen Yen[3], Maria Hall[4], Jackie Lodge[5], Catherine Shaw[6], Helen Ramage[6], Theresa Strong[7], Stacy Ward[7], Lorraine Munetsi[8] & Tom Blenkiron[8]
[1]Barts and the London Medical School, London, United Kingdom; [2]The Research Institute at Nationwide Children's Hospital, Columbus, United States; [3]Soleno Therapeutics Inc., Redwood City, United States; [4]Maria Hall Consulting, London, United Kingdom; [5]PWSA UK, Derby, United Kingdom; [6]FPWR UK, Bradford, United Kingdom; [7]FPWR USA, Covina, United States; [8]PRIME HCD, Daresbury, United Kingdom

Background
Prader-Willi syndrome (PWS) is a rare, genetic, neurobehavioural-metabolic disorder characterised by hyperphagia and behavioural/psychological complications. Managing PWS symptoms through strict supervision, behavioral management and specialised supports imposes significant demands on caregivers and healthcare systems. However, data are lacking on the real-world burden of PWS.
Objectives
The objective was to design a study that characterises the clinical, humanistic, and economic burden of PWS on caregivers, families, and the healthcare system.
Study design
This study is a descriptive, retrospective, cross-sectional, multi-site, micro-costing burden of illness study. The study will be conducted in USA, UK, France, Germany, and Italy. To assess the burden of PWS, a retrospective review will be conducted by consenting approximately 330 healthcare professionals (HCPs) who meet the following inclusion criteria: 1) primary specialty in paediatrics, endocrinology, or psychiatry; 2) qualified in their medical specialty for at least three years and 3) personally responsible for the management of patients with PWS. HCPs who qualify and consent to participate will complete electronic case record forms (eCRFs) for eligible patients under their care. Patients are eligible for inclusion if they are aged 4 years and over, with a diagnosis of PWS $>$12 months, and their caregiver is aged 18 years or over and capable of providing informed consent. The eCRF will collect data on PWS disease history, management, and burden during the past 12 months from the date of consultation with the HCP. Aspects captured by the eCRF will include socio-demographics,

symptoms, disease history, comorbidities, management, interventions, and care requirements. HCPs will invite caregivers of these patients to complete corresponding Patient Public Involvement & Engagement caregiver forms (PPIE-c). The PPIE-c will capture health-related quality of life (HRQoL) through EuroQoL 5-Dimensions 5-levels (EQ-5D-5L); the Work Productivity and Activity Impairment (WPAI) Questionnaire; the Hyperphagia Questionnaire for Clinical Trials (HQ-CT), the Zarit Burden Interview (ZBI) and the Food Safe Zone (FSZ) Questionnaire. The PPIE-c will help provide insights into the wider impact of PWS on caregivers and families. All eCRF and PPIE-c data will be collected anonymously. The mean per-patient cost of PWS will be calculated based on a comprehensive resource utilisation analysis incorporating unit cost estimates for direct medical and non-medical, and indirect resource requirements. Key factors to be evaluated include hospitalisations, HCP visits, treatments, PWS-related transportation, specialised equipment, education status, and dietary modifications. This study is sponsored by Soleno Therapeutics, Inc.

Linking metabolic syndrome and physical fitness in children with obesity: a cross-sectional study from the PODiaCar project

Virginia Rossi[1], Alessandro Gatti[2], Matteo Vandoni[2], Luca Marin[2], Caterina Cavallo[2], Vittoria Carnevale Pellino[2], Giulia Fiore[1], Martina Tosi[1], Elvira Verduci[1, 3], Savina Mannarino[1], Cristina Campoy[4], Mireia Escudero Marín[4], Rocío Bonillo León[4], Valter Pagani[5], Camilo Corbellini[6], Gianvincenzo Zuccotti[1, 7] & Valeria Calcaterra[1, 8]
[1]Buzzi Children's Hospital, Department of Paediatrics, Milan, Italy; [2]University of Pavia, Laboratory of Adapted Motor Activity (LAMA), Department of Public Health, Experimental Medicine and Forensic Science, Pavia, Italy; [3]University of Milan, Department of Health Sciences, Milan, Italy; [4]University of Granada, Department of Paediatrics, Granada, Spain; [5]Asomi College of Science, Grant and Research Department, Pembroke, Malta; [6]LUNEX University, Differdange, Luxembourg; [7]University of Milan, Department of Biomedical and Clinical Science, Milan, Italy; [8]University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy

Aim
Paediatric obesity is a major public health concern, as recognized by the World Health Organization. Metabolic syndrome (MetS), associated with increased cardiovascular (CV) morbidity and mortality, affects approximately 29.2% of children with obesity. Physical fitness (PF) is a key indicator of long-term health, influencing CV risk and overall mortality. However, few studies have examined its association with MetS. This study aims to analyze the relationship between PF and MetS in children with obesity.
Methods
We conducted a cross-sectional study evaluating 55 children with obesity (11.96 $\pm$ 2.35 years; 21 [38%] girls; mean BMI 29.5 $\pm$ 4.81 kg/m^2 and BMI z-score 3.15 $\pm$ 0.78). Physical fitness was assessed through three functional tests: i) 6-minute walking test (6MWT), ii) standing broad jump (SBJ), and iii) 4$\times$10 m shuttle run test (SHT). MetS z-score assesses MetS, using sex-specific formulas (cut-off $>$ 0.75). Between 8:30 and 9:00 a.m. a fasting blood sample was collected and analyzed that morning for total cholesterol, HDL-C, triglycerides, fasting glucose (FG), and insulin. Insulin resistance was estimated using HOMA-IR and TyG index. Logistic regression was used to calculate adjusted odds ratios (OR) for MetS based on PF levels, while linear regression assessed associations between PF, MetS z-score, and its components.
Results
In both sexes, the SBJ test inversely correlates with MetS odds, independent of age (OR: 0.18, 95%, CI: 0.04–0.53). Conversely, neither the 6MWT nor the SHT were related to the odds of MetS. When analyzing the relation between MetS z-score, its components and PF, the SBJ showed an inverse significant association (BMI z-score: β=-0.528; SBP: β=-0.397; MetS z-score: β=-0.299; all $p < 0.05$) with all components, except for HDL, FG and triglycerides (respectively β=0.335, β=0.429 and β=0.354), which were positively associated. The SHT was associated with BMI z-score (β=0.419), systolic blood pressure (β=0.419), and FG (β=-0.331; all $P < 0.05$), while the 6MWT was inversely related to BMI z-score (β=0.295; $P < 0.05$).
Conclusions
Our findings highlight an inverse relationship between PF and MetS, particularly concerning lower limb strength, as assessed by the SBJ. These results highlight the importance of incorporating PF assessments into the clinical evaluation of children with obesity. Future research should explore the mechanisms underlying this relationship, evaluating targeted exercise programs as potential strategies for MetS prevention in children with obesity.

Management and diagnosis of moderate and severe hypernatraemia in a UK district hospital: a retrospective audit

Samraiz Nafees[1], Muhammad Haroon Riasat[1], Khaled Zamari[2], Shahzad Akbar[3], Ali Javeed[1], Adi Ahmed[1], Sarath Vayolipoyil[1], Khush Bakht[1], Muhammad Adnan Afzal[3], Arshad Jamil[4] & Ali Hassan[5]
[1]York and Scarborough Teaching Hospitals NHS Trust, Scarborough, United Kingdom; [2]Gloucestershire Hospitals NHS Foundation Trust, Gloucester, United Kingdom; [3]Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom; [4]Sandwell and West Birmingham Hospitals NHS Trust, Birmingham, United Kingdom; [5]Manchester University NHS Foundation Trust, Manchester, United Kingdom

Background
Hypernatraemia, defined as serum sodium levels exceeding 145 mmol/l, affects 2.5% of inpatients in the United Kingdom. It is particularly prevalent among elderly patients with cognitive impairment and impaired thirst mechanisms, with mortality rates reaching 80% in this population. Our trust has implemented a hypernatraemia protocol to guide appropriate management, including recommended investigations and treatment modalities.
Objective
To assess compliance with the management protocol for patients with moderate to severe hypernatraemia (sodium levels $>$150 mmol/l) in our trust.
Methods
We conducted a retrospective audit of patients with serum sodium levels exceeding 150 mmol/l. Data collected included patient demographics, clinical presentations, investigations performed, and treatment duration.
Results
43 patients met the inclusion criteria. The majority (85%) were over 75 years old, with 44% being nursing home residents and 30% having underlying neurological conditions. Common presenting symptoms included confusion (74%) and decreased levels of consciousness (47%). Clinical dehydration was observed in 60% of patients, establishing a causal relationship with severe hypernatraemia. Notably, 58% of patients had clinically stable NEWS scores of 1-3, indicating that severe hypernatraemia can occur in apparently well patients. The audit revealed suboptimal compliance with required investigations, with only a small number of patients undergoing urine osmolality, urinary sodium, and plasma osmolality tests. Treatment duration was prolonged, with 95% of patients requiring more than 48 hours for hypernatraemia correction, and 79% needing over 7 days.
Conclusions
Hypernatraemia remains a significant issue, particularly among elderly and cognitively impaired patients. Our findings highlight the need for improved adherence to local hypernatraemia guidelines. We recommend implementing regular monitoring and assessment of fluid status and sodium levels, as well as increasing awareness of the existing protocols among healthcare staff.

Patient and caregiver experiences with setmelanotide treatment in bardet-biedl syndrome – real-world evidence and a patient support program

Ilja Finkelberg[1], Ioanna Polichronidou[1], Tom Hühne[1], Pia Brensing[1], Johannes Jägers[1], Anja Gäckler[2], Lars Pape[1] & Metin Cetiner[1]
[1]University Hospital Essen, University of Duisburg-Essen, Pediatric Clinic II, Department of Pediatric Nephrology, Gastroenterology, Endocrinology

and Sonography, Essen, Germany; [2]University Hospital Essen, University of Duisburg-Essen, Department of Nephrology, Essen, Germany

Background
Bardet-Biedl syndrome (BBS) is a rare genetic disease resulting from dysfunctional cilia, and is marked by numerous symptoms, among which hyperphagia and early-onset obesity, that can adversely impact the quality of life for both patients and caregivers. The MC4R agonist setmelanotide has demonstrated clinically meaningful weight and hunger reductions in patients with obesity due to BBS. In this study, we evaluated real-world patient expectations and experiences before and during treatment with setmelanotide, as well as the use of a patient support program.
Methods
A one-time survey was conducted online to capture the real-world experiences of patients with BBS and their caregivers with setmelanotide treatment and the patient support program, designed to educate patients and caregivers to allow them to administer injections independently. The survey, including yes/no questions, Likert scale questions and free text questions, was fielded from January 2024 to May 2024, involving participants who began treatment between June 2023 and December 2023 at a single centre in Germany.
Results
Ten paediatric patients, 13 adult patients, and 12 caregivers participated in the study. Prior to treatment, paediatric patients reported experiencing insatiable hunger (80%) and obesity (50%) as their most prevalent symptoms; for adult patients, these were vision loss (69%) and obesity (69%); and caregivers reported obesity (92%) and insatiable hunger (83%). Treatment with setmelanotide had a positive effect on reducing body weight, with $\geq$92% of all participants reporting feeling less hunger, feeling satiated after meals, and stable body weight or weight loss. Furthermore, to various degrees, patients and caregivers reported improvements in mobility, mood, and behaviour. Negative effects of treatment perceived the most were changes in skin pigmentation, (initial) vomiting, diarrhoea and nausea. The personalized approach with the patient support program led to high patient and caregiver satisfaction, with over half of patients/caregivers being able to administer the drug independently at the end of the study period. There was high treatment adherence, no patients discontinuing setmelanotide treatment and an excellent rating of the service by all respondents.
Conclusions
This real-world survey of patients with BBS and their caregivers further demonstrated the meaningful benefits of setmelanotide in improving insatiable hunger and obesity. Personalized nursing support at the initiation of treatment onwards can further facilitate high rates of treatment adherence and satisfaction.

Real life data of obesity in craneopharyngiomas in an pediatric/adult transition pituitary unit

Clara Sola[1], Felicia Hanzu[1], Karen Castillo[2], Maria Victoria Toffoli[2], Mireia Mora[1] & Paula Casano-Sancho[2 3 4]
[1]Hospital Clinic Endocrinology, Barcelona, Spain; [2]Hospital Sant Joan de Déu, Pediatric Endocrinologist, barcelona; [3]Centro de Investigación Biomédica en Red de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Instituto de Salud Carlos III, 28029, Madrid, Spain; [4]Endocrinology Department, Institut de Recerca Sant Joan de Déu, University of Barcelona, 08950 Esplugues, Barcelona, Spain

Introduction
Craniopharyngiomas (Cr) are suprasellar tumors with metabolic comorbidities and panhypopituitarism diagnosed mostly during infancy with a difficult management. Long-term follow-up in a specialized hypothalamic-pituitart unit (HPU), involving both pediatric and adult endocrinologists, allows for a comprehensive analysis of disease progression and response to treatment, helping to refine therapeutic strategies.
Aims
To evaluate the incidence, comorbidities and progression of hypothalamic obesity (Ob) in pediatric (POCr) and adult-onset Cr (AOCr), the different medical treatments of Ob and the factors that contribute to the development of Ob.
Methods
Retrospective study on patients with Cr and followed up in the HPU between 2008 and 2024.
Results
35 Cr were included. 24 POCr and 11 AOCr. Among AOCr, 33% had prior diagnosis of POCr. 98% adamantinomatous Cr. Longest follow-up was of 12 years (y) in the POCr and 14y in AOCr. The mean age in POCr was 6.9 $\pm$ 3.15y; 60% males; 4% with Ob or BMI SD + 1; 30% visual defects, 70% compression, 8% growth retardation and 25% consciousness alteration. The mean age in AOCr was 53 $\pm$ 11.7y; 55% men, more Ob (19%), more visual defects (72%) and hypopituitarism symptoms (28%); 30%HTA, 64% triglyceridemia, 9%DM were observed. After surgery complete panhypo was presented in all; increase in Ob was equal between AOCr and POCr (delta 26 vs 29%), while new DM and hypertrigliceridemia was present only in AOCr (27% and rsp 75%). Highest increase in BMI (SD BMI) was observed at 6 months (m) in AOCr (delta 5 kg/m2) with further stabilization while the highest increase in POCr was at 3m (BMI SD 1.62) and progress during follow-up. Hypothalamus alterations on MRI associated with Ob onset after surgery. Pharmacological treatment was larger and in more POCr than AOCr: 54% vs 45% and 146 vs 35, 6 m; only GLP1 in AOCr; 70%with Lisdexanfetamina (LSDF) in POCr and 30% with GLP1. Interruption of treatment due to AE was higher in LSDF than in GLP1 (50% vs 16%, $P < 0.05$). Weight loss with GLP1 and LSDF was 2% in AOCr and weight gain was controled in POCr. After short term treatment retrival BMI SD increase with +1.65 in POCr and +2.1 kg/m2 BMI in AOCr.
Conclusion
Although long-term treatment with GLP-1 and LSDF did not result in significant weight loss, it helped **stabilize weight gain** in both AOCr and POCr. This suggests that this may contribute to better weight control in Cr with hypothalamic dysfunction.

Genome Edited Human Cell Lines For Studying Steroidogenesis In P450 Oxidoreductase Deficiency

Anna Matveeva[1,2,3], Therina du Toit[1,2] & Amit Pandey[1,2]
[1]Pediatric Endocrinology, Diabetology and Metabolism, University Children's Hospital, Inselspital, Bern, Switzerland; [2]Translational Hormone Research Program, Department of Biomedical Research, Faculty of Medicine, University of Bern, Bern, Switzerland; [3]Graduate School for Cellular and Biomedical Sciences, University of Bern, Bern, Switzerland

P450 oxidoreductase (POR) is an essential enzyme in steroidogenesis. It transfers the electrons from NADPH to microsomal cytochrome P450 (CYP) proteins that drive the synthesis of glucocorticoids, mineralocorticoids, and sex hormones in the adrenal cortex. Patients with POR deficiency could present with metabolic disorders, including impaired sexual development, skeletal anomalies characteristic of the Antley-Bixler phenotype, and congenital adrenal hyperplasia. Over 200 deleterious mutations in POR have been discovered, with a few of them being characterized using purified protein systems. To gain deeper insights into mutated POR activities within the context of living cells, the development of personalized human cell models is crucial. Using CRISPR/Cas9 system we performed the POR knockout in the NCI – H295R (adrenal carcinoma cells) and HEK 293T (human embryonic kidney cells). Resulting cells were subcloned to obtain monogenic cultures representing unified genotype. To evaluate the status of POR, we employed Sanger sequencing of POR gene, Western blot analysis, and the assays on POR function. For HEK 293T cells, the CYP17A1 and CYP21A2 activity were measured using thin layer chromatography. For NCI – H295R cells, the full steroid profile was obtained using LC–MS/MS. Adrenal – derived POR knockout cells were characterized by the significant inhibition of aldosterone, cortisol, and testosterone pathways indicating reduced activities of CYP21A2 and CYP17A1 – two key metabolic partners of POR in steroid biosynthesis. The Progesterone levels were significantly higher in POR knockout adrenal cells and 17OH-Progesterone levels were comparable to controls. In HEK293T cells, loss of POR showed 3.6% of wild-type activity towards CYP21A2 and 0% activity towards CYP17A1. The generated cell lines resemble the steroid abnormalities found in patients with POR deficiency. Additionally, they can be utilized to study patient-specific POR mutations by artificially inducing their expression, thereby supporting the development of personalized disease models. By reflecting individual genetic profiles, these cell models offer valuable insights into the complex metabolic processes in the adrenal glands while also serving as a screening platform to characterize the impact of the POR mutations on steroidogenesis and drug response. Such models hold significant potential for improving both the diagnosis and treatment of POR deficiency.

48-Week Results from the HELIOS Trial: A Phase 2, Open-Label Study Evaluating an Oral, Fixed-Dose Combination of Sodium Phenylbutyrate and Taurursodiol in Wolfram Syndrome

Fumihiko Urano[1], Bess Marshall[1], Stacy Hurst[1], Amy Viehoever[1], Saumel Ahmadi[1], Tamara Hershey[1], Gregory Van Stavern[1], Paulina Cruz Bravo[1], Jennifer Powers Carson[1], Nathalie Erpelding[2], Kelly Fox[2], John Pesko[2] & Lahar Mehta[2]
[1]Washington University School of Medicine, St. Louis, USA; [2]Amylyx Pharmaceuticals, Inc., Cambridge, USA

Background
Wolfram syndrome (WS) is a rare, fatal, monogenic disorder characterized by juvenile-onset diabetes mellitus, optic nerve atrophy, sensorineural deafness, diabetes insipidus, and neurodegeneration. Symptoms progress from childhood to adulthood. WS is thought to represent a prototypical syndrome of endoplasmic reticulum (ER) stress with impaired mitochondrial dynamics also contributing to its pathophysiology. PB&TURSO is an oral, fixed-dose combination of sodium phenylbutyrate (PB) and taurursodiol (TURSO) hypothesized to simultaneously mitigate ER stress and mitochondrial dysfunction. PB&TURSO has demonstrated pre-clinical efficacy in patient-derived cell and mouse WS models. The phase 2, open-label HELIOS trial is evaluating the safety/tolerability of PB&TURSO as well as its effects on endocrinological, neurological, and ophthalmological function in WS.
Methods
Adults (≧ 17 years) with a definite genetic WS diagnosis; insulin-requiring diabetes mellitus due to WS; and stimulated C-peptide levels ≧0.2 ng/mL were enrolled from one U.S. site. Participants receive PB&TURSO for up to 144 weeks. The primary efficacy endpoint is change from baseline in C-peptide at Week 24 using 240-minute mixed meal tolerance tests. Secondary efficacy endpoints include measures of glucose control and best-corrected visual acuity. Exploratory endpoints include clinician- and participant-reported global impression of change scores and participant experiences derived from on-study qualitative interviews.
Results and conclusions
HELIOS week 24 results for all 12 participants (Intent-to-Treat) and for the 11 with genetically confirmed WS (Per Protocol) were previously reported. PB&TURSO was generally well-tolerated with diarrhea the most common adverse event. Due to the progressive nature of WS, pancreatic beta cell function, glycemic control, visual function, and overall symptom burden typically worsen over time; however, at Week 24, treatment with PB&TURSO showed overall stabilization or improvement relative to baseline. Stimulated C-peptide responses showed improvements with a mean change from baseline to Week 24 in C-peptide area under the curve (AUC) from 0 to 120 minutes of +3.8 minutes*ng/mL [standard error (S.E.):19.3] in Intent-to-Treat ($n=12$) and +20.2 min*ng/mL [S.E.:11.2] in Per Protocol ($n=11$). Participants also demonstrated improved glycemic control and a trend toward visual acuity stabilization. All participants reported either improvement or stabilization of disease, as measured by Clinician- and Patient-Reported Global Impression of Change scales. Nine of 11 interviewed participants reported improvements in ≧1 WS-related symptom with nearly all noting these were meaningful changes. Available Week 48 results ($n=6$) suggest sustained stabilization and/or improvement of pancreatic function, glycemic control, vision, and symptom burden. Treatment with PB&TURSO in HELIOS is ongoing. Updated Week 48 results will be presented.

Post-authorisation safety study of ketoconazole HRA in endogenous cushing's syndrome: seventh annual interim report in 108 patients

Frederic Castinetti[1], Susan M Webb[2], Alicia Santos[2], Jérôme Bertherat[3], Filippo Ceccato[4], Karin Zibar Tomsic[5], Claudia Amaral[6], Richard Feelders[7], Alexis Rames[8], Myriam Bou Nader[8], Thierry Brue[1] & Anna Aulinas Maso[2]
[1]Hôpital de la Conception, Department of Endocrinology, Marseille, France; [2]Institut de Recerca de l'Hospital de la Santa Creu i Sant Pau, Department of Endocrinology, CIBERER Unit 747, UAB, Barcelona, Spain; [3]Hôpital Cochin, Department of Endocrinology, Paris, France; [4]University Hospital of Padova, Department of Endocrinology, Padova, Italy; [5]University Hospital Zagreb, Department of Endocrinology, Zagreb, Croatia; [6]Centro Hospitalar Universitário do Santo António, Department of Endocrinology, Porto, Portugal; [7]Erasmus University Medical Center Rotterdam, Department of Endocrinology, Rotterdam, Netherlands; [8]Esteve RD France, Montrouge, France

Background
Ketoconazole HRA is approved for the treatment of endogenous Cushing's Syndrome (CS) pursuant to an obligation to collect safety data on patients exposed to the drug in this indication.
Methods
The primary objective of this open-label post-authorisation safety study (PASS), using the European Registry on Cushing's Syndrome (ERCUSYN), is to document liver and cardiac tolerability. Treatment pattern, overall safety, and effectiveness are secondary objectives. The last interim report is presented.
Results
At the cut-off date (31 August 2024), 110 patients were enrolled in the study. One hundred and eight patients were included in the full analysis set, 103 were evaluated for safety, and 105 for efficacy. Mean age of the patients was 46.8 years, and most patients (77.4%) were diagnosed with pituitary-dependent CS. Ketoconazole HRA was mainly used as monotherapy in 85.2% (92/108) of patients, with a median exposure of 1.6 years and a mean average daily dose of 400 mg. Among 41 cases of liver functions test (LFT) abnormalities, occurring mostly within the first month, in 22 cases LFT were < 2 x ULN and resolved without discontinuation of Ketoconazole HRA. Eight cases (7.4%) of hepatotoxicity (LFT > 5 x ULN) were observed. Co-administration of a known hepatotoxic drug was suspected in 6 of these patients. In all 8 patients, liver injury resolved after discontinuation of ketoconazole HRA, 5 of these events were hepatocellular. No QTc prolongation cases were reported. However, ECG and LFT monitoring remain non-systematic. Overall, 51.9% of patients (56/108) experienced at least one adverse event (AE). Thirty-five patients (32.4%) experienced at least one AE other than LFT abnormalities and QTc prolongation. Non-serious AEs were mainly gastrointestinal disorders (13.6%), nausea being the most frequent of them (12.6%). The rate of serious AEs, other than LFT abnormalities and QTc prolongation, was 11.7%, of which 3.9% were endocrine disorders, mainly acute adrenocortical insufficiency (1.9%). Efficacy data showed that 50.8% of patients achieved normalized UFC levels, while 60.5% attained normalized morning plasma cortisol levels.
Conclusion
These results confirm the known safety and efficacy profile of Ketoconazole HRA. No unexpected safety signals were identified. In addition, the benefit-risk balance of Ketoconazole HRA in patients with endogenous Cushing's syndrome remains favourable.

Genetic and clinical insights into triple a syndrome in a multi-ethnic population: a large cohort from sudan

Salwa Musa[1, 2], Mohamed Abdullah[2, 3], Samar Hassan[2], Angela Hübner[4], Katrin Koehler[4] & Friederike Quitter[4]
[1]Department of Pediatric and Child Health, Faculty of Medicine, Al-Neelain University, Khartoum, Sudan; [2]Department of Pediatric Endocrinology and Diabetes, Gaafar Ibn Auf Pediatric Tertiary Hospital, Khartoum, Sudan; [3]Department of Pediatrics and Child Health, Faculty of Medicine, University of Khartoum, Khartoum, Sudan; [4]Division of Pediatric Endocrinology and Diabetes, Department of Pediatrics, Faculty of Medicine and University Hospital Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany

Background
Triple A syndrome (TAS), is a rare autosomal recessive multisystem disorder due to mutations in the AAAS gene, which encodes the ALADIN protein. Alacrima, adrenal insufficiency, achalasia, autonomic dysfunction, and variable neurological features are the most common symptoms to be reported. Limited data exists on TAS from Sub-Saharan Africa and Arab countries with only a small series or case reports. A comprehensive clinical and genetic analysis was performed in patients diagnosed with TAS from Sudan, highlighting the genotype-phenotype correlation of this syndrome from a limited resource setting. This is considered the largest reported cohort of TAS from Sub-Saharan African countries.
Patients and Methods
48 patients from 32 families with a clinical diagnosis of TAS were investigated. The initial diagnosis was based on the characteristic clinical and biochemical findings followed by genetic testing performed on 31 patients from 20 families who were included in this study.
Results
Alacrima was detected in all patients (100%), hyperpigmentation indicating the presence of ACTH-resistant adrenal insufficiency in 90 %, difficulty of

swallowing in 35%, and the complete triad was detected in 35 % at presentation. Other features include autonomic and neurological features in 39%, facial dysmorphism in 45%, and short stature in 39%. Rare features include hypertensive encephalopathy in two patients and excessive thick nasal discharge in four patients which has not been previously reported. Eight families (40 %) reported deaths of one or more siblings who had shown similar symptoms. Genetic analysis confirmed six different AAAS mutations mainly in a homozygous form. This included three nonsense mutations, one frameshift mutation leading to a truncated protein, and 2 splice defects among them the Arabic founder mutation c.1331 + 1G > A (intron 14) in 32 % (6 families). The 8 bp-deletion mutation in intron 4 in two families is novel. As a further novel AAAS mutation, we identified a 1 bp-deletion in exon 9 in three families. The most abundant mutation was a previously described mutation in exon 9 (c.934C > T, p.Arg312*) present in 37 % (7 families).

Conclusion

TAS seems to be underdiagnosed in Sudan, and the presence of 95 % mutations in a homozygous form reflects the high rate of consanguinity in this population. Genotype/phenotype analyses revealed a high variability in disease severity even between patients from the same family or with identical AAAS mutation. Early genetic diagnosis in unaffected siblings has helped in disease prediction and early intervention and thus prevented an adrenal crisis and death.

Factors affecting the prevelance of endocrinopathies in transfusion dependent thalassemia patients in the national thalassemia centre, kurunegala, sri lanka

Jananie Suntharesan[1, 2], Manel Rathnayake[3], Shaminda Kahandawa[1], Muhammadh Arsadh[1], Amila Dasanayake[1], Oshan Madhubashana[1], Nandana Gunaratne[4], Kithsiri Jayasekara[5], Dayananda Bandara[3] & Lakdasa Premawardhana[6]

[1]Diabetes and Endocrinology Unit, Teaching Hospital, Kurunegala, Sri Lanka; [2]Department of Paediatric and Adolescents Diabetes and Endocrinology, Sirimavo Bandaranayake Specialized Children's Hospital, Peradeniya, Sri Lanka; [3]National Thalassemia Centre, Teaching Hospital, Kurunegala, Sri Lanka; [4]Institute of Applied Statistics, Colombo, Sri Lanka; [5]Faculty of Allied Health Sciences, Kotelawala Defense University, Dehiwala - Mount Laviniya, Sri Lanka; [6]Thyroid Research Group, Cardiff University School of Medicine, Cardif, United Kingdom

Introduction

Thalassemia is the commonest haemoglobinopathy in Sri Lanka. Beta thalassemia major (BTM) and severe E beta thalassemia (EBT) are classified as transfusion-dependent thalassaemia (TDT). Most TDT patients are iron overloaded due to increased red cell lysis, inefficient erythropoeisis, recurrent blood transfusions, and increased iron absorption. Tissue deposition of iron may lead to multiple endocrine organ dysfunction.

Objectives

We aimed to establish the following in TDT patients (2-18 years) attending the National Thalassaemia Unit (NTU), Kurunegala, Sri Lanka.

1. The prevalence of endocrinopathy and iron overload.
2. The relationship between frequency of transfusion and serum ferritin levels
3. The relationship between dose and type of chelation therapy

Methods

We carried out a retrospective database analysis of all subjects attending the NTU with TDT who were between the ages of 2-18 years. Data were collected from patient medical records. Individual endocrinopathies were identified using standard clinical and biochemical criteria as set out in current guidelines. Summary statistics were compared between groups using appropriate statistical tests.

Results

261 subjects with TDT were eligible for analysis (a) 204 (78%) had BTM [median age 11 years (IQR = 6.75-14)], and 57 (22%) had severe EBT [median age 12 years (IQR = 8-14)]. There was no significant sex difference between the two groups. The transfusion frequency was – (i)BTM; median 3 weeks (ii) EBT; median 4 weeks, Chelation therapy was commenced– (i)BTM; median age 3 years (IQR = 2-4) and (ii) EBT median age 4 years (IQR = 3-6), ($P = 0 < 0.05$). (b)Prevalence of following endocrinopathies was as follows (1) Short stature in 106/213 (49.8%) in children ≥ 8 years (2) Pubertal delay 35/106 (33%) in females > 13 years and males > 14 year; puberty was initiated in 71 (67%) and later arrested 6 ($n = 71$). (3) Primary hypothyroidism in 17/261 (6.5%) (4) Adrenal insufficiency in 2/261 (0.76%) (5) Hypoparathyroidism in 7/261 (2.7%) (6) Diabetes Mellitus in 2/261 (0.76%) (c) Transfusion frequency and volume and serum ferritin in subjects with endocrinopathies 118/261 patients (45.2%). (1) Three weekly transfusion 61/118 (51.7%) (2) Median transfusion volume at present 4746ml/year (IQR = 3464-5811). (3) Median serum ferritin was 1377ng/mL (IQR = 934-1945) (3) Median Deferasirox and median Deferoxamine doses were 33.5 mg/kg/day (IQR = 30.91-35.96) and 33.46mg/kg/day (IQR = 32.32-38.04) respectively.

Conclusions

In this study 45 % patents with TDT had endocrinopathies. Short stature and pubertal delay were the most common endocrinopathies encountered in TDT subjects in this study. Our study revealed patients with endocrinopathies had high serum ferritin with inadequate dosing of iron chelation.

Endocrine disorders in patients with neurofibromatosis type 1: a single-center prevalence study

Sofia F. Silva[1], Catarina Regala[1], Sofia Avelino[1], Carlos Marques[1], Leonor Pinto[1], João Passos[2], Daniela Cavaco[1], Margarida da Silva Vieira[1], Sara Donato[1], Sara Lomelino Pinheiro[1], Valeriano Leite[1] & Joana Simões-Pereira[1]

[1]Instituto Português de Oncologia de Lisboa Francisco Gentil, Endocrinology Department, Lisbon, Portugal; [2]Instituto Português de Oncologia de Lisboa Francisco Gentil, Neuro-Oncology Department, Lisbon, Portugal

Introduction

Neurofibromatosis type 1 (NF1) is an autosomal dominant disorder characterized by increased risk of tumour development and endocrine disorders. Despite the well-established relationship between NF1 and certain endocrinopathies, the prevalence of these disorders in NF1 patients remains unclear, hindering follow-up strategies.

Objective

This study aims to assess the prevalence of endocrinopathies in NF1 patients at our centre.

Methods

Retrospective analysis of NF1 patients observed in the Endocrinology department from 1997 to 2024. Statistical analysis was performed using IBM® SPSS® Statistics.

Results

Of 669 NF1 patients followed at our centre, 255 [141(55.3%) females] were referred to the endocrinology department, 166 of whom during childhood. The mean age at first observation was 10.24 ± 4.51SD years for paediatric and 41.07 ± 14.56SD years for adult patients. The most common pituitary deficiency was growth hormone deficiency (GHD) (9.02%, $n = 23$), mainly in children ($n = 22$; mean age at diagnosis 11.21 ± 3.31SD years). Optic pathway gliomas (OPG) were present in 78.26% of these cases ($n = 18$, $P < 0.001$), corroborating higher risk in patients with brain tumours. Additionally, 51 patients were diagnosed with short stature, but only 18 of these patients had GHD, suggesting a likely multifactorial aetiology. The prevalence of other pituitary deficiencies was lower: 1.96%($n = 5$; 4 with OPG) for hypogonadotropic hypogonadism, 1.18% ($n = 3$, all with OPG) for secondary adrenal insufficiency. A single case of central hypothyroidism was identified in a 3.67-year-old patient with OPG. The prevalence of precocious puberty was 4.31%($n = 11$), 10 of whom had OPG ($P < 0.001$); 5.49%($n = 14$) patients were diagnosed with accelerated puberty, 6 with OPG. Gynecomastia was noted in 8 male patients, 4 were pathologic (1.57%). Thyroid disorders occurred in 16.47% of patients ($n = 41$); 3(1.18%) patients had thyroid carcinomas (2 papillary, 1 medullary), the earliest diagnosed at 36.58 years. Primary hyperparathyroidism was diagnosed in 1.96%($n = 5$) patients (mean age: 56.95 ± 10.60). Paragangliomas were found in 3.14% of the patients ($n = 8$): seven adrenal and one abdominal paraganglioma, incidentally diagnosed. Earliest age at diagnosis was 33.10 years. In addition, 4(1.57%) patients were diagnosed with adrenal adenomas, 1 with adrenal carcinoma and another with congenital adrenal hyperplasia. Gastroenteropancreatic neuroendocrine tumours were detected in 3(1.18%) adults.

Conclusion

NF1 has a prevalence of 1 in 3000. Overall, 17.19% of patients presented with, at least, one endocrine disorder. The diversity of endocrinopathies in NF1, especially in association with OPG, requires regular clinical evaluation and biochemical/imagiological screening. Understanding the prevalence of these disorders is the key to optimizing follow-up and patient care.

JOINT118

Autoimmune diseases in 3, 812 danish transgender persons and 38, 120 cisgender controls before and after transgender care. a register based cohort study

Dorte Glintborg[1], Jens-Jakob Møller[1], Katrine Rubin[2], Louise Lehmann Christensen[1] & Marianne Andersen[1]
[1]Odense University Hospital, Odense, Denmark; [2]Odense University Hospital, University of Southern Denmark, Odense, Denmark

Objective
The risk of autoimmune disease could be increased in transgender persons (TG) and susceptibility to autoimmune disease could be affected by transgender care. We assessed the risk of autoimmune diseases in TG compared to controls before and after transgender care.
Methods
A national register-based Danish cohort study was conducted in individuals diagnosed with gender dysphoria between 2000 and 2021. The inclusion date was the date of the first transgender diagnosis. For each case, five age-matched cisgender controls of the same birth sex and five age-matched controls of the opposite birth sex were included. Any autoimmune disease, type 1 diabetes and/or thyroid disease were study outcomes (ICD10 diagnosis of any autoimmune disease and/or medical treatment for type 1 diabetes or thyroid disease).
Results
The cohort included 3, 812 TG and 38, 120 controls. The median age (interquartile range) was 19 (15; 24) years for transmasculine persons (TM), $n = 1, 993$ and 23 (19; 33) years for transfeminine persons (TF), $n = 1, 819$. Before the index date, the incidence rate (IR) of type 1 diabetes was significantly higher in TM compared to controls of same birth sex: IRR= 1.98 (1.16; 3.36). In TF vs. controls of same birth sex, the IRR for type 1 diabetes was 1.66 (1.05; 2.61) and for any autoimmune disease was 1.35 (1.04; 1.77). Higher incidence of any autoimmune disease in TG was associated with higher age, medical morbidity, and psychiatric disease. After the index date, the IRR for thyroid disease was 1.98 (1.09; 3.61) in TF vs. controls of same birth sex, whereas the IRR for remaining autoimmune outcomes were comparable between TG and controls of same birth sex. TM using GAHT had higher incidence of autoimmune disease 2.50 (1.10; 5.67) compared to nonusers.
Conclusion
Higher incidence of type 1 diabetes in TG compared to cisgender controls could be attenuated by transgender care.

Muscle characteristics in adult patients with APECED

Emilia Träskilä[1 2 3], Joonatan Borchers[1, 2], Outi Mäkitie[1 2 3] & Saila Laakso[1 2 3]
[1]University of Helsinki, Helsinki, Finland; [2]Children's Hospital and Pediatric Research Center, Helsinki University Hospital, Helsinki, Finland; [3]Folkhälsan Research Center, Helsinki, Finland

Background
Autoimmune polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED; autoimmune polyendocrine syndrome type 1), a genetic disease with hypoparathyroidism, primary adrenocortical insufficiency (PAI), chronic candidiasis and other autoimmune manifestations. Our previous study showed that a severe APECED phenotype associated with changes in bone microarchitecture.
Objective
This study aimed to explore muscle characteristic in relation to bone properties in patients with APECED.
Patients and Methods
We recruited 37 adults with APECED and 82 age- and gender-matched control subjects. In both groups, we assessed muscle and bone characteristics at the proximal site of tibia (38%) with peripheral quantitative computed tomography (pQCT). In the patient group, dual-energy absorptiometry (DXA) was also used to measure total muscle mass and whole-body bone mineral density (BMD). Mann-Whitney or Student's t-test was used to test for differences between the groups and Kendall's rank test to test for correlations.
Results
Altogether 37 adult patients (22 females) participated in the study (median age 44.0, range, 19.3-70.1 years). In females with APECED, muscle area (mean, 5129.8 vs 5706.4 cm^2, $P = 0.004$) and tibial cortical thickness (mean, 4.6 vs 5.1 mm, $P = 0.006$) as well as height (mean, 161.4 vs 164.8 cm, $P = 0.026$) were smaller in comparison to control subjects. At tibial site, their muscle area correlated positively with bone area, bone density, cortical thickness, periosteum circumference, but not with height. In control females, muscle area correlated only with muscle density at tibial site. For APECED females with PAI ($n = 14$), muscle area at tibial site was smaller (median, 4766.9 vs 5927.6 cm^2, $P = 0.025$) than in patients without PAI ($n = 4$). In males with APECED, muscle area (mean, 5963.8 vs 7222.8 cm^2, $P < 0.001$) and tibial cortical thickness (mean, 5.1 vs 5.9 mm, $P = 0.002$) and periosteal circumference (median, 72.7 vs 78.4 mm, $P = 0.012$), as well as height (median, 173.0 vs 182.7 cm, $P = 0.003$) were smaller in comparison to control males. There were no correlations between muscle area and any tested bone parameters at tibial site in males with APECED or in control males. DXA-derived values showed no correlation between total muscle mass and whole-body BMD in females or males with APECED. However, muscle area in pQCT at tibial site correlated with whole body BMD in DXA ($\tau = 0.621$, $P < 0.001$) in females but not in males with APECED. Significance Our findings show that the inferior bone parameters in subjects with APECED are associated to some extent with muscle properties. Physical performance testing could shed light to clinical implications of these findings.

EMPOWER-TRANS* - development and implementation of innovative, digital information and training concepts for children with gender incongruence/gender dysphoria (GI/GD) and their families

Annette Richter-Unruh[1, 2], Cindy Holland[2], Corinna Bergelt[3], Georg Romer[4] & for the consortium Empower-Trans*[2]
[1]Center of Pediatric and Adolescent Endocrinology, MVZ Eberhard, Pediatric Endocrinology, Dortmund, Germany; [2]Division of Paediatric Endocrinology and Diabetes, Department of Paediatrics and Adolescent Medicine, University Medical Center Ulm, Ulm, 89075, Germany, Ulm, Germany; [3]Department of Medical Psychology, University Medicine Greifswald, Greifswald, Germany, Greifswald, Germany; [4]Department of Child and Adolescent Psychiatry, Psychotherapy and Psychosomatics, University Medical Center Münster, Münster, Germany, Münster, Germany

In recent years there has been a steady increase in the number of children and adolescents whose sex assigned at birth does not match their self-perceived gender identity. The desire to resolve this distress often leads to the utilisation of gender reassignment medical treatments, such as hormonal and surgical interventions. Treating and informing this group of people is complex and requires the involvement of various specialist disciplines. There are also particularly high quality standards for the care of minors. There are only a few specialist centres and specialist practices available for this throughout Germany. The resulting long waiting times can further increase the level of suffering. The intervention consists of two elements: Patients and their families have access to multi-perspective, guideline-compliant information via a digital platform. A comprehensive digital training intervention provides the opportunity to address the topics in greater depth and respond to individual needs at an early stage. It is also possible to exchange information with other people affected. The two concepts are intended to provide larger groups of patients throughout Germany with highly qualified, guideline-based medical psychoeducation, which means a sustainable increase in efficiency compared to the currently practised resource-intensive individual initial information at a few specialist centres/specialist practices. The aim of the project is to develop and test a digital information and training programme by researchers from various disciplines. The children and young people affected and their carers should receive comprehensive information and help with self-management in everyday life. As the support is offered digitally, the specialised human and financial resources can be used optimally. This means that frequently requested information can be provided even before an initial consultation with a doctor. As a result, initial consultations can be shorter and more personalised. This in turn increases the capacity for making appointments and shortens waiting times. If successful, the service provides those affected with rapid access to high-quality and comprehensive information, reduces high levels of psychological stress and helps to avoid underuse and inappropriate care.

Clinical presentation and genotype-phenotype association of 95 patients with pathogenic mutation in the menin gene

Ahmed Opardija[1], Emma Scott[2], Caroline Maria Rossing[2] & Mikkel Andreassen[1]

[1]Rigshospitalet, university of Copenhagen, Department of nephrology and endocrinology, Copenhagen, Denmark; [2]Rigshospitalet, Department og genomic medicine, Copenhagen, Denmark

Introduction
Multiple endocrine neoplasia type 1 (MEN1) is a rare hereditary tumor syndrome primarily associated with an increased risk of primary hyperparathyroidism (PHP), pituitary adenomas, and pancreatic-duodenal neuroendocrine tumors (DP-NET). Until now, no genotype-phenotype has been identified.
Materials and Methods
Consecutive patients with class 4 or 5 mutations followed at Rigshospitalet, Copenhagen (covering half of the Danish MEN1 population), were included. The aim of the study was to describe the clinical presentation and possible association to genotype using survival statistics with log-rank test. We focused on 5 outcomes; age at diagnosis of the 3 main MEN1 manifestation and age of surgery for PHP and DP-NET.
Results
The study included 96 patients (61 females). Mean age at data extraction was 45 $\pm$22 years, mean age at genetic diagnosis was 33 $\pm$19 years. Seventy-seven (80%) had PHP, 10% by age 20, 70% by age 40, 90% by age 60, and 100% by age 80. Sixty-one (79%) underwent parathyroidectomy. Pituitary adenomas were identified in 25 (26%) of patients, 5% at age 20, 20% at age 40, 30% at age 60, and 50% at age 80. Three patients had pituitary surgery. DP-NET were present in 67 (70%) patients, 5% at age 20, 35% at age 40, 75% at age 60, and 95% at age 80. Seventeen (25%) underwent pancreatic surgery. Nine patients died (3 MEN1 related), mean age 74 (range 49 to 93) years. Genetic variants: Frameshift 36/95, missense 24/95, nonsense 19/94, intron variant 11/95, splice variant 4/95, structural variant 1/95 (deletion exon 3-10). The variants were initially grouped in 3: 1) nonsense, frameshift and deletion (truncated protein) 2) missense (affecting protein function), 3) intron and splice variants (abnormal splicing). We found no significant genotype-phenotype, but the result of the initial analyses prompted us to compare missense variants with the rest. For all outcomes missense variants had a better prognosis with the lowest *P*-value for development of PHP and for surgery for DP-NET. By the age of 40 around 50% of patients with missense mutations had PHP vs. 80% among the rest ($P = 0.03$) and non with missense variants had surgery for DP-NET at the age of 40 vs. 20% among the rest ($P = 0.07$)
Conclusion
We confirmed almost 100% penetrans of both PHP and DP-NET. The prognosis was good with a life expectancy close to the background population. Our data suggest that missense variants might be associated with a slightly better prognosis.

JOINT2564
Is hypernatremia related to insulin resistance in type 1 myotonic dystrophy?
Romane Ptaszyk[1], Celine Tard[1], Stéphanie Espiard[1] & Marie-Christine Vantyghem[1]
[1]Lille University Hospital, INSERM 1190, Endocrinology and Metabolism, Lille, France

Myotonic dystrophy type 1 (DM1) is a dominantly inherited multi-system disease caused by expanded CTG repeats in the 3' untranslated region of the *dystrophia myotonica protein kinase* (DMPK) gene. Similar to other repeat disorders, the expanded trinucleotide repeat is unstable with a tendency to increase repeat size with age. The clinical spectrum ranges from lethal presentations in infancy to mild, late-onset disease. DM1 causes myotonia, muscle weakness and cardiac, lung and cognitive impairment, early onset cataracts and various endocrine disorders including insulin resistance, goiter (*Ben Hamou A OJRD 2019*) and an unexplained trend to high blood sodium level (*Smals AG Neth J Med. 1980*). A neurogenic cause was not confirmed (*Descloquement K SFE 2008*). Mexiletine is known to improve myotonia by blocking muscle sodium channels Nav1.4. In addition, cardiac conduction disorders which represent the 2nd cause of mortality in DM1 are linked to alterations in MBNL1 causing dysregulation of alternative splicing of the *SCN5A* gene which encodes voltage-gated sodium channels Nav1.5 (*Freyermuth F Nat Comm 2016*) and depends on insulin signaling through the PIP3 pathway (*Polina I PNAS 2020*). In view of recent advances in the knowledge of voltage-gated sodium channels and their link with glucose metabolism, the hypothesis of a relationship between hypernatremia and levels of insulin resistance in DM1 was investigated.
Objective
To compare serum sodium levels, phenotype and genotype between 3 groups of DM1 patients according to their degree of insulin resistance explored in the frame of a University Reference Center of Neuromuscular Diseases.
Methods
Retrospective cross-sectional study in 100 DM1 patients classified into 3 groups: 44 DM1 with normal OGTT, 36 with glucose intolerance and 20 with diabetes after a systematic OGTT except if diabetes was already known. Patients treated with diuretics, SGLT2 inhibitors or cortisone were excluded.
Results
Sex ratio, number of CTG repeats and natremia did not differ between the 3 groups. Median age ($P < 0.0001$) and BMI ($P < 0.05$) differed between the 3 groups. Natremia positively correlated with the number of *CTG* repeats ($r = 0.37$; $P < 0.001$). Patients with natremia $\geq$ 143 mmol/l had more pacemakers, indicating a higher severity of the disease ($P < 0.05$).
Conclusion
these results suggest that natremia measurement could be an inexpensive marker of cardiac DM1 severity, ultimately poorly correlated with insulin resistance. The relationship with voltage-gated sodium channels needs to be further investigated.

Systematic analysis and network mapping of disease associations in autoimmune polyglandular syndrome
Greta Pham-Dobor[1, 2], Péter Kaltenecker[3, 4], Viktória Temesfői[3, 4], Laszlo Bajnok[2], Orsolya Nemes[2], Beáta Bódis[2] & Emese Mezosi[2 3 4]
[1]Institute for Translational Medicine, University of Pécs, Medical School, Pécs, Hungary; [2]First Department of Medicine, Clinical Centre, University of Pécs, Medical School, Pécs, Hungary; [3]Szentagothai Research Centre, University of Pécs, Pécs, Hungary; [4]National Laboratory on Human Reproduction, University of Pécs, Pécs, Hungary

Autoimmune polyglandular syndrome (APS) is a complex disorder in which endocrine, non-endocrine organ-specific and systemic autoimmune diseases coincide. The purpose of our work was to provide a data-driven perspective to the field, in addition to traditional clinical observations and patient classification strategies. Our study was conducted in a tertiary medical center in Hungary. Medical records of 7559 outpatients were analyzed, autoimmune origin was proved in 3180 cases of which 380 (12%) were diagnosed with APS. Data handling and manipulation were done both in Python and R. Network analysis, clustering and dimensionality reduction were used for visualization purposes. The median age of the patients at the diagnosis of APS was 32 years, with 84% of them being female. APS started 7 to 8 years earlier in men than in women. Type 1 diabetes mellitus and coeliac disease manifested significantly earlier than other component diseases of APS. Hashimoto's thyroiditis was the most common manifestation in our cohort, accounting for 67.4% of individuals, followed by Graves' disease and type 1 diabetes mellitus (26, 8% and 20, 8% of the cases, respectively). Twenty-eight distinct autoimmune disorders were diagnosed forming 113 combinations. Combinations occurring at least 10 times, or more were responsible for 51, 3% of cases. The network analysis and the dimensionally reduced projection mapping differentiated HT and GD as the cornerstones of APS among the component diseases. However, an almost complete overlap of the associated conditions was found. Thyroid autoimmunity was frequently associated with gastrointestinal and systemic manifestations and these patterns of associated conditions substantially differed from that of T1D, AD or CeD when assessing them as first manifestations, raising the question of a common biological causality behind the co-occurrence. In conclusion, APS is more prevalent than it is shown in the literature. Implementing screening and follow-up protocols focusing on additional autoimmune disorders is crucial in patients with autoimmune diseases. Clinical registries are also essential for the assessment of the true prevalence of the syndrome.

Endocrine involvement in a wide cohort of children and adults affected by 22q11.2 Deletion Syndrome
Valeria Citterio[1], Giulia Rodari[1], Eriselda Profka[1, 2], Valentina Collini[2], Aurora Pedroli[2], Giulia Del Sindaco[1], Angela Pagnano[1], Federico Grilli[3], Maria Francesca Bedeschi[3], Donatella Milani[4], Giovanna Mantovani[1, 2] & Claudia Giavoli[1, 2]

[1]Endocrinology Unit, Fondazione Cà Granda IRCCS Ospedale Maggiore Policlinico, Milan, Italy; [2]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [3]Clinical Genetics Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [4]Pediatric Highly Intensive Care Unit, Department of Pathophysiology and Transplantation, Università degli Studi di Milano, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Introduction
Several studies have investigated single endocrine manifestations of 22q11.2 Deletion Syndrome (22q11.2DS), however, data on the comprehensive endocrinological involvement in children and adults are currently scanty.
Aim
The present study addresses the broad spectrum of endocrine manifestations in 22q11.2DS across all age groups, investigating genotype-phenotype correlations and disease-onset, to refine follow-up strategies.
Materials and Methods
Retrospective cross-sectional study on 71 patients with 22q11.2DS. Clinical, biochemical and genetic data were retrieved from medical records.
Results
We included 71 patients (M/F 37/34; 38 children and 33 adults; median age 13.8, range 1.2-51.5 years). Endocrine manifestations were found in 32/71 patients (45.1%, 16 children and 16 adults). Hypocalcemia due to hypoparathyroidism was the most common feature (28/32 patients), with neonatal onset in 16/28 patients (57.1%), half of whom were symptomatic. Later-onset hypocalcemia occurred in 12 patients (7 children and 5 adults), all asymptomatic. Chronic hypoparathyroidism was present in 44% of patients with neonatal onset and 67% with later-onset, affecting globally 21% of patients. Thyroid dysfunction was observed in 12/71 patients (16.9%, 5 children, 7 adults), 11 with primary hypothyroidism and one with early-onset Graves' disease; 2 euthyroid patients presented thyroid autoantibodies. Thyroid disease was significantly associated to hypoparathyroidism (8/28 vs 4/43 patients; $P = 0.034$). Short stature, reported in 20.8% of patients (23.7% of children, 15.2% of adults), was neither due to growth hormone deficiency nor linked to major comorbidities (palatal defects, infections, heart disease). Obesity was more prevalent in adults than children (27.3% vs 5.6%) and resulted associated with psychiatric disorders ($P = 0.033$) and their medications ($P = 0.003$), with 4.7-fold increased risk in psychiatric patients. The latest-onset endocrinopathy occurred at the age of 30 years. Most patients (46/55, 83.6%) had a classic deletion (CD, 2.5-3 Mb), 8 patients (14.5%) short deletion (<2.5 Mb) and one (1.8%) long deletion (>3 Mb). Hypoparathyroidism and hypothyroidism were more prevalent in CD patients (45.7% and 19.6%, respectively). However, no correlation was found between deletion length and endocrinopathies, whereas neonatal pathologies positively correlated with CD ($P = 0.021$).
Conclusions
This study provides the first comprehensive analysis of endocrinological involvement in pediatric and adult patients with 22q11.2DS, featuring all age groups. The most common conditions were hypoparathyroidism, hypothyroidism, and short stature. Our findings highlight the importance of monitoring patients at all ages and might suggest that check-ups frequency could be reasonably reduced after the age of 30 years for those without existing endocrinopathies.

Associations of healthy lifestyle with all-cause and cardiovascular disease mortality in patients with cardiovascular-kidney-metabolic syndrome: two prospective cohort

shaoyong Xu[1], Qiqi You[2], Wan Fu[1] & Mi Xu[1]
[1]Xiangyang Central Hospital, Affiliated Hospital of Hubei University of Arts and Science, Department of Endocrinology, Xiangyang, China; [2]Xiangyang Central Hospital, Affiliated Hospital of Hubei University of Arts and Science, Center for Clinical Evidence-Based and Translational Medicine, Xiangyang, China

Background
Cardiovascular-kidney-metabolic (CKM) syndrome is a newly defined condition involving metabolic risk factors, chronic kidney disease, and cardiovascular disease (CVD), which significantly increases the risk of mortality. While a healthy lifestyle has been shown to improve health outcomes in the general population, its impact on CKM patients remains unclear. This study investigated the association of a healthy lifestyle with all-cause and CVD mortality in CKM patients.
Methods
We analyzed 79, 350 CKM patients from the UK Biobank (2006-2010, follow-up until 2021) and 9, 823 CKM patients from NHANES (2007-2018). The CKM patients were categorized into stages 0-4, with stages 3 and 4 classified as advanced CKM. A healthy lifestyle score (0-7 points) was created based on seven factors: no current smoking, moderate drinking, healthy diet, regular physical activity, adequate sleep, low sedentary behavior and appropriate social connection. Primary outcomes were all-cause and CVD mortality from linked health records and death registries. Cox regression models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for mortality risk.
Results
During follow-up, the UK Biobank recorded 7, 299 all-cause deaths and 1, 685 CVD deaths, and NHANES reported 833 all-cause deaths and 266 CVD deaths. Cox regression models showed that higher lifestyle scores were associated with reduced risks of all-cause (HR: 0.82, 95% CI: 0.80-0.83) and CVD mortality (HR: 0.81, 95% CI: 0.77-0.84) in the UK Biobank. In NHANES, higher scores were associated with 18% (95% CI: 0.78-0.87) and 15% (95% CI: 0.77-0.94) lower risks of all-cause and CVD mortality, respectively. Regular physical activity and low sedentary behavior were beneficial for the risk of all-cause and CVD mortality in both databases ($P < 0.05$). Compared with participants with advanced CKM syndrome and unfavorable lifestyle (0-2 points), those with non-advanced CKM syndrome and favorable lifestyle (6-7 points) had the lowest risk of all-cause and CVD mortality. In the UK Biobank, the HRs were 0.23 (95% CI: 0.20-0.26) and 0.13 (95% CI: 0.10-0.17), respectively; In NHANES, the HRs were 0.22 (95% CI: 0.11-0.41) and 0.25 (95% CI: 0.08-0.80), respectively.
Conclusion
We found that adherence to a healthy lifestyle was significantly associated with a reduced risk of mortality in patients with CKM syndrome, with more pronounced benefits observed in the early stages. These findings highlight the potential benefits of promoting a healthy lifestyle to improve long-term survival in patients with CKM syndrome.

First comprehensive quantification of the human endocrinome: patterns in hormone distribution and their physiological significance

Ron Sender[1], Tal Kedar[2], Yoav Navon[1], Moriya Raz[1], Rina Hemi[2], Ron Milo[1] & Shai Fuchs[2]
[1]Weizmann Institute of Science, Rehovot, Israel; [2]Sheba Medical Center, Ramat-Gan, Israel

Background
Despite the fundamental role of the endocrine system in human physiology, basic questions such as the total number of human hormones and their cumulative abundance have remained unanswered. While specific hormone circuits are well-studied, the relative abundance patterns across the entire human endocrinome remain undefined, limiting our understanding of system-wide endocrine regulation.
Methods and Findings
We conducted an integrative analysis of the human endocrinome by leveraging clinically validated reference ranges across major endocrine subsystems. We compiled data for the routinely assayed hormones spanning all endocrine glands and hormone-secreting tissues, validated our findings using published datasets, and developed strict inclusion criteria to systematically evaluate 7, 996 candidate molecules from published databases. This rigorous curation yielded a comprehensive list of 187 bona fide human hormones. Our analysis revealed that the total mass of circulating hormones in healthy young adults is approximately 40 mg (39.5 ± 1.5mg for men, 41.5 ± 1.5mg for women), with an estimated uncertainty under 5%. Two hormones, Adiponectin and DHEA-S are dominant, constituting over 90% of both total hormone mass and copy number. We identified marked sexual dimorphism, with females having approximately half the number of circulating hormone molecules compared to males in terms of absolute number (≈ 14 μmol vs ≈ 25 μmol). Analysis of abundance patterns revealed previously unrecognized relationships between hormone type, functionality, and abundance. These include the unexpected striking predominance of DHEA-S, usually referred to as merely another hormone precursor reservoir, and systematic deviations from established signal propagation patterns in hypothalamic-pituitary axes that suggest previously overlooked regulatory mechanisms. The main limitation of our study is the paucity of large unbiased datasets of hormone levels in healthy adults, as most hormones are not part of routine screening tests, creating inherent selection bias in existing clinical data.
Conclusions
This first comprehensive quantification of the human endocrinome establishes fundamental parameters of hormone abundance and distribution. Our systematic analysis reveals unexpected patterns in sexual dimorphism, hormone abundance

hierarchies, and signal propagation schemes that challenge current paradigms of endocrine regulation. These findings provide an essential framework for developing targeted endocrine profiling approaches and understanding system-wide hormone dysregulation in pathological states.

Respiratory and sleep disorders in children with prader willi syndrome: prevalence and characterization

Sofia Suco[1], Debora Giselle Braslavsky[1], Carolina Gvirtzman[2], Virginia Olivar[2], Barbara Casali[1], Andrea Arcari[1], Alejandro Teper[2], Ignacio Bergadá[1] & Ana Keselman[1]

[1]Centro de Investigaciones Endocrinológicas "Dr. César Bergadá" (CEDIE), CONICET – FEI – División de Endocrinología, Hospital de Niños Ricardo Gutiérrez, C1425EFD, Buenos Aires, Argentina; [2]Centro Respiratorio, Hospital de Niños Ricardo Gutiérrez, C1425EFD, Buenos Aires, Argentina., Buenos Aires, Argentina

Introduction

Prader Willi Syndrome (PWS) has a broad clinical spectrum whereas respiratory disorders are major causes of morbidity and mortality across the lifespan. The approach must include close monitoring to minimize the risks.

Aim

To describe respiratory and sleep patterns in a cohort of PWS children.

Materials and Methods

Retrospective evaluation of respiratory and sleep patterns in a cohort of 25 pediatric PWS patients admitted at Ricardo Gutierrez Children hospital from 2002 to 2024. Variables analyzed were body mass index (BMI kg/m^2), pituitary function (TSH, free T4, cortisol), recombinant human growth hormone treatment (rhGH 1 mg/m^2/d), tonsils volume; obstructive sleep apneas (OSA), central apneas (CSA), nocturnal hypoventilation by Polysomnography (PSG) and daytime sleepiness by multiple sleep latency test (MSLT).

Results

Median age at admission was 3.3yr (0.4 to 13.6yr), 52% boys. The genetic mechanism was the deletion of 15q11.2-q13 chromosomal region (60%) and maternal uniparental disomy (40%). Hypothyroidism was diagnosed in 21% and none had adrenal insufficiency until their last examination. Basal median BMI was 2.35 SDS (-1.9 to 11 SDS). Median time between diagnosis and respiratory evaluation was 4.9yr (0.8 to 18.9yr). Anamnesis revealed snoring in 56% and clinical examination showed tonsillar hypertrophy in 83% of the cases. Twenty-one patients were evaluated prior to rhGH indication: 18/21 (86%) had OSA, 3 CSA and 1 nocturnal hypoventilation. Ulterior indications were only clinical follow up in 8/21, tonsillectomy in 5/21, tonsillectomy and non-invasive mechanical ventilation in 1. Seven patients were suitable to begin rhGH treatment whereas 4 patients required specific interventions before rhGH indication. Three patients were already under rhGH at first respiratory evaluation: 1 had mild OSA. None of the patients who underwent tonsillectomy developed velopharyngeal insufficiency post-surgery. Sleep disorders were diagnosed in 5/25: narcolepsy in 3 cases and cataplexy in 2. Individualized medical interventions were implemented. Six patients under rhGH developed respiratory disorders during follow-up (1 to 4 yr): 5 tonsillar hypertrophy and OSA, and 1 CSA concomitant with respiratory infection. Median ΔBMI was 0.01 (-0.37 to 2.86 SDS). In patients under rhGH there was no significant correlation between the occurrence of respiratory events and ΔBMI.

Conclusion

Respiratory and sleep disorders were a prevalent comorbidity in this cohort of PWS children and detected only by careful anamnesis and specific tests performed by trained specialists. Regular examination of respiratory and sleep disorders before and during rhGH treatment should be included in the multidisciplinary approach of PWS.

Evaluation of the relationship between metabolic-associated fatty liver disease and sarcopenic obesity in patients with diabetes

Elena Makhlina[1], Yana Navmenova[2] & Tatyana Mokhort[3]

[1]«Gomel State Medical University», Department of Internal Medicine No. 1 with courses in endocrinology and hematology, Gomel, Belarus; [2]«Republican research center for radiation medicine and human ecology», Endocrinology, Gomel, Belarus; [3]Belarusian State Medical University, Endocrinology, Minsk, Belarus

Objective

To assess the relationship between metabolic-associated fatty liver disease (MAFLD) in patients with diabetes and sarcopenic obesity (SO) indices.

Materials and Methods

The study included 92 patients with diabetes (45 men and 47 women). The average age of patients was 55.90 ± 14.18 years and duration of diabetes was 16.80 ± 9.34 years. Muscle strength (MS) was assessed using hand dynamometry measuring arm strength. Muscle function (MF) was assessed using the 4-meter walking speed test. Muscle mass (MM) and fat mass (FM) were assessed using dual-energy X-ray absorptiometry (DXA) ("lunAR prodigy") as the ratio of appendicular muscle mass (AMM) to height (AMM/m^2), AMM to weight (AMM/weight), FM to height (FM/m^2). The body mass index (BMI), waist circumference (WC), and glycated hemoglobin (HbA1c) were determined. The presence of MAFLD was determined based on the results of ultrasound examination of the liver and calculated diagnostic indices (ST-index, FLI). Statistical processing was performed using the statistical program «Statistica 10.0».

Results

In patients with diabetes, 86% of cases taking into account the ST- index and 96% of cases taking into account the FLI were found to have SO. FLI is positively associated with the age of patients ($r_s = 0.46$; $p < 0.05$), BMI ($r_s = 0.92$; $p < 0.05$), WC ($r_s = 0.90$; $p < 0.05$), FM/m2 ($r_s = 0.69$; $p < 0.05$), AMM/m2 ($r_s = 0.46$; $p < 0.05$) and negatively associated with MS ($r_s = -0.34$; $p < 0.05$), MF ($r_s = -0.32$; $p < 0.05$), AMM/weight ($r_s = -0.64$; $p < 0.05$). ST- index is positively correlated with patients' age ($r_s = 0.68$; $p < 0.05$), BMI ($r_s = 0.88$; $p < 0.05$), WC ($r_s = 0.92$; $p < 0.05$), FM/m^2 ($r_s = 0.70$; $p < 0.05$), AMM/m^2 ($r_s = 0.34$; $p < 0.05$) and negatively correlated with MS ($rs = -0.33$; $p < 0.05$), MF ($r_s = -0.45$; $p < 0.05$), AMM/weight ($r_s = -0.62$; $p < 0.05$). FLI and ST-index are not correlated with the duration of diabetes and the level of Hb1c ($p > 0.05$).

Conclusion

In patients with MAFLD and diabetes, 86% to 96% of cases show SO associated with the patient's age and independent of the duration of diabetes and the Hb1c level. MAFLD in diabete is associated with a change in body composition due to a decrease in MM and an increase in FM, the degree of decrease in MS and MF.

JOINT3328

Decoding clinical heterogeneity in ornithine transcarbamylase deficiency: novel mutations and therapeutic outcomes from a longitudinal cohort study

fan yang[1] & xiumin wang[2]

[1]Department of Clinical Research Ward, Shanghai Children's Medical Center, Shanghai Jiao Tong University School of Medicine, shanghai, China; [2]Department of Endocrinology and Metabolism, Shanghai Children's Medical Center, Shanghai Jiao Tong University School of Medicine, shanghai, China

Objective

To characterize the clinical spectrum, genetic landscape, and long-term therapeutic efficacy in pediatric-onset ornithine transcarbamylase deficiency (OTCD).

Methods

A retrospective longitudinal cohort study of 7 OTCD patients (3 males, 4 females) with confirmed biochemical/genetic diagnoses and ≥24-month follow-up (median 38 months, range 16-41). Comprehensive analyses integrated metabolic profiling, next-generation sequencing, and multidisciplinary outcomes assessment (neurological, hepatic, developmental).

Results Clinical presentation

Age at diagnosis ranged from 10 days to 7.3 years. Hyperammonemic crises (71.4%, 5/7) manifested as recurrent vomiting (100%), encephalopathy (60%), and seizures (40%), with 42.9% (3/7) exhibiting pre-existing neurodevelopmental delays. **Genetic landscape:**Seven distinct *OTC* mutations identified, including two novel pathogenic variants (c.241T>C, c.490T>G; ACMG Class IV) unreported in global databases. **Therapeutic trajectories:**Medical therapy cohort ($n = 2$): Intermittent hyperammonemia (45-78 μmol/l) persisted in patients receiving sodium phenylbutyrate or arginine/citrulline, correlating with

suboptimal adherence (30% missed doses). Despite episodic vomiting (1-2 annual episodes), anthropometric parameters remained age-appropriate. **Transplant cohort ($n = 5$):** All achieved complete metabolic normalization (ammonia ≤ 40 µmol/l, stable hepatic function) post-transplant, with neurodevelopmental improvement (ΔDQ +1.2-2.3 SD) and age-appropriate cognition (DQ 85-102) at final assessment.

Conclusions

This study establishes three critical insights for OTCD management:

1. Diagnostic urgency: Plasma amino acid profiling with urinary orotic acid quantification enables rapid triage of suspected cases.

2. Therapeutic hierarchy: Liver transplantation delivers superior outcomes for severe phenotypes, achieving sustained metabolic control and neurocognitive recovery.

3. Precision care imperative: Novel mutation identification reinforces genotype-phenotype correlations, while suboptimal pharmacotherapy adherence highlights the need for structured transition programs.

Successful transition strategies in turner syndrome

Uta Berndt[1], Kathrin Helge[2] & Uta Neumann[2]

[1]HELIOS-Klinikum Berlin-Buch, Berlin, Germany; [2]Charité Universitätsmedizin Berlin, Clinic for paediatric endocrinology and diabetology, Berlin, Germany

Background

Since 2019, there have been special centers in Germany that provide guideline-based treatment for girls and women with Turner syndrome (TS). The involvement of paediatric and internal medicine disciplines is a prerequisite for ensuring compliance with examinations and drug therapies during the transition to adulthood. The Clinic for paediatric endocrinology and diabetology at Charité-Universitätsmedizin Berlin and the adult's outpatient center for endocrinologic diseases at the HELIOS-Klinikum Berlin-Buch were certified for treating TS patients in 2020 improving health outcomes in TS throughout the lifespan. Transition only started in 2021 due to the covid-pandemia.

Design and Methods

Retrospective analysis of women transferred between paediatric endocrinology at the Charité-Universitätsmedizin Berlin and the adult outpatient clinic for endocrinological diseases at the HELIOS-Klinikum Berlin-Buch. Descriptive analyses included age at transfer, attendance at transfer meetings and subsequent appointments, adherence to hormone and other therapy, and attendance at recommended regular check-ups. Attendance at two visits to the adult outpatient clinic was defined as a successful transition.

Results

Since 2021, all women with TS whose treatment was no longer continued in paediatrics were referred to adult medicine within the Turner Center's transition consultation hours ($n = 13$). Age at transition visit ranged from 17-21 years (mean 18.8 years). All women had completed school and all but one were in training or a student. Further care in adult medicine was desired. Almost all girls attended the first visit to the adult center (12/13), the overall drop-out rate was 15% (2/13). 100% of the successfully transferred girls with ovarian insufficiency were on regular hormone replacement therapy. All successfully transferred girls received cardiac MRI, whereas referral to specialised outpatient units according to Gravholt consensus recommendations was often lacking. So far, the transition process is not being financed by health insurance for all patients.

Conclusion

The designation of TS centers can improve guideline-based management of women with Turner syndrome across the lifespan. The rate of successful transition in our center is high, as is the rate of women taking their hormone replacement therapy regularly and attending recommended check-ups. This is an important step in the prevention of conditions such as cardiovascular disease and bone disease in women with Turner syndrome.

Algorithmic approach for the of hashimoto's thyroiditis: a case control indian study

Ramakanth Bhargav Panchangam[1], Ramesh Bangaraiahgari[2], Rajesh Bangaraiahgari[2], Laxmi Narayana Sripuram[2], Varshitha Eadula[2], Vidya Paboju[2], Sushmitha Sree Mekala[2] & Chakrapani Bangaraiahgari[3]

[1]BGH, Vijayawada, India; [2]TRR Institute of Medical Sciences, Hyderabad, India; [3]Chakri Neuro Hospital, Nizamabad, India

Background

The varied and non-specific nature of diagnostic criteria of Hashimoto's thyroiditis often leads to sub optimal diagnosis and resultant sub optimal management. The aim of this study is to propose a comprehensive diagnostic scoring algorithm based on reproducible multi-component objective clinico-investigative criteria.

Methods

A case-control study of patients who underwent surgical thyroidectomy, were compared with a set of clinical, biochemical, pathological parameters in patients with Hashimoto's thyroiditis ($n = 60$) and controls ($n = 60$), in order to design a comprehensive multi-parametric scoring system. We analysed twelve criteria - Age, Sex, goiter grade, associated pathology, duration of disease, euthyroid/hypothyroid status; family history, presence of auto-immune features, anti-thyroid peroxidase titer, anti thyroglobulin antibody titer, thyroid cytopathological diagnosis of HT, extent of thyroidectomy. All these features were analysed and scored in comparision with histopathology as gold standard. A different validation cohort of 36 patients were reviewed and classified according to the score. Linear correlation and descriptive statistics were performed with SPSS 20.0 version.

Results

The study parameters were dichotomized in to major criteria (euthyroid/hypothyroid status; family history, presence of auto-immune features, anti-thyroid peroxidase titer, anti thyroglobulin antibody titer, thyroid cytopathological diagnosis of HT) and minor (Age, Sex, goiter grade, associated pathology, duration of disease, extent of thyroidectomy) criteria. Diagnostic accuracy of various combinations of major criteria were – with $6 = 100\%$; $5 = 100\%$; $4 = 100\,\%$; $3 = 100\%, 95\%, 85\%$; $2 = 90\,\%$; $1 = 82\,\%$. Finally, score of atleast $\geq$ 3/6 major criteria, with mandatory elevated anti Tg and anti TPO Ab titer was diagnostic of HT. This diagnostic accuracy was statistically significant compared to controls.

Conclusions

This multi-parametric scoring algorithm appears to be a practical, accurate and straightforward in the accurate diagnosis and subsequent optimal management of Hashimoto's thyroiditis.

Efficacy and safety of finerenone in type 2 diabetes with chronic kidney disease

Yanina Rebrova[1], Yanina Saienko[2], Ievgen Marushko[3] & Borys Mankovsky[2]

[1]D. F. Chebotarev Institute of Gerontology of the National Academy of Medical Sciences of Ukraine, The Scientific and Practical Medical Center of Pediatric Cardiology and Cardiac Surgery of the Ministry of Health of Ukraine, Government Institution, Kyiv, Ukraine; [2]D. F. Chebotarev Institute of Gerontology of the National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine; [3]The Scientific and Practical Medical Center of Pediatric Cardiology and Cardiac Surgery of the Ministry of Health of Ukraine, Government Institution, Kyiv, Ukraine

Background and Aims

Finerenone, a non-steroidal mineralocorticoid receptor antagonist, has been shown to reduce albuminuria and slow chronic kidney disease (CKD) progression in patients with type 2 diabetes mellitus (T2DM). However, real-world data on its impact on kidney function and albuminuria reduction in patients with different CKD stages remain limited. This study aimed to evaluate the effects of finerenone on estimated glomerular filtration rate (eGFR) and albumin-to-creatinine ratio (ACR) in patients with T2DM and CKD stages 3A–4.

Materials and Methods

A total of 45 patients with T2DM and CKD stages 3A–4 were included in the study. The mean age was 63.3 ± 5.7 years, with a diabetes duration of 7.2 ± 4.5 years (data are presented as mean $\pm$ SD). The baseline HbA1c was $7.6 \pm 0.15\%$, serum creatinine 115.6 ± 3.7 µmol/l, and potassium 4.1 ± 0.07 mmol/l. Patients were stratified by CKD stage: 28 with stage 3A (eGFR 45–60 mL/min/1.73m^2), 10 with stage 3B (eGFR 30–44 mL/min/1.73m^2), and 7 with stage 4 (eGFR 25–30 mL/min/1.73m^2). Baseline ACR was <30 mg/g in 27 patients, 30–300 mg/g in 14 patients, and >300 mg/g in 4 patients. Finerenone was initiated at 10 mg/day in patients with eGFR 25–59 mL/min/1.73m^2 and 20 mg/day in those with eGFR ≥ 60 mL/min/1.73m^2, with monthly potassium monitoring and dose adjustments as needed. The data were compared using Student's t-test and correlation analysis.

Results
After 3 months of treatment, eGFR increased by 6% (54.04 ± 2.35 mL/min/1.73m^2, $P < 0.05$), while ACR decreased by 13% (46.27 ± 14.57 mg/g, $P < 0.05$). The most pronounced improvement in eGFR and ACR was observed in patients with CKD stage 3A and 3B. A significant inverse correlation was found between eGFR and ACR ($\rho = -0.62$, $P < 0.05$), with the strongest association in CKD stage 3A ($\rho = -0.71$). Serum potassium levels remained stable (4.04 ± 0.04 mmol/l, $p > 0.05$), and no cases of hyperkalemia (>5.0 mmol/l) were reported.
Conclusion
Finerenone effectively improved kidney function and reduced albuminuria in patients with T2DM and CKD stages 3A–4. The most significant benefits were observed in patients with CKD stage 3A–3B. Treatment was well tolerated, with no significant hyperkalemia. These findings support the use of finerenone in early-stage diabetic kidney disease to slow disease progression.

Clinical characteristics and influencing factors of children with MT-TL1 gene m.3243A>G mutation: a phenotypic study based on 11 han chinese patients

Fan Yang[1,2] & Xiumin Wang[3]
[1]Department of Clinical Research Ward, Shanghai Children's Medical Center, Shanghai Jiao Tong University School of Medicine, shanghai, China; [2]Shanghai Children's Medical Center, Department of Endocrinology and Metabolism, Shanghai Children's Medical Center, School of Medicine, Shanghai Jiao Tong University, Department of Endocrinology and Metabolism, shanghai, China; [3]Department of Endocrinology and Metabolism, Shanghai Children's Medical Center, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background
The *MT-TL1* gene encodes mitochondrial tRNA $^{leu\ (UUR)}$, playing a crucial role in mitochondrial protein synthesis. Mutations in this gene are associated with various mitochondrial diseases, often exhibiting clinical phenotypic heterogeneity. This study aims to retrospectively analyze 11 pediatric inpatients carrying the same *MT-TL1* gene mutation to explore phenotypic variation and potential influencing factors.
Methods
We retrospectively analyzed 11 pediatric patients diagnosed with *MT-TL1* gene mutations at our hospital between 2012 and 2024, along with their family histories. Clinical data were collected and analyzed, including demographics, age at diagnosis, clinical manifestations, imaging, and laboratory Results Phenotypic differences between the patients were systematically compared to evaluate the heterogeneity of the m.3243A>G mutation in children.
Results
Despite all 11 patients carrying the same *MT-TL1* mutation, their clinical presentations varied significantly. The average diagnostic delay was 3.35 years. Neurological symptoms were present in 81.8% of the patients, 72.8% had endocrine issues, 18.2% had visual impairments, and 9.1% experienced bilateral hearing loss. Cardiac abnormalities were found in 63.6% of patients, 81.8% had gastrointestinal symptoms, 36.4% exhibited hypertrichosis, and 27.3% had used a ventilator. Plasma lactate levels were elevated in 90.1% of patients, with 80% exceeding 5 mmol/l. Additionally, 81.8% showed exercise intolerance and muscle weakness. Based on the diagnostic criteria, 45.5% were diagnosed with mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes (MELAS), 18.2% were diagnosed with both MELAS and neuropathy, ataxia, and retinitis pigmentosa (NARP), and 54.5% were diagnosed with mitochondrial myopathy. Family history analysis revealed that three patients had relatives retrospectively diagnosed with mitochondrial myopathy, two were diagnosed with diabetes, and two with Kallmann syndrome.
Conclusion
This study highlights the clinical heterogeneity of the same *MT-TL1* gene mutation in pediatric patients. Over 80% of the patients exhibited symptoms such as epilepsy, imaging abnormalities, short stature/malnutrition, gastrointestinal symptoms, elevated lactate levels, and muscle weakness. More than one-third of patients experienced stroke-like episodes, developmental delays, myocardial damage, elevated liver enzymes, abdominal pain, and hypertrichosis. Pediatric patients with these recurrent symptoms should be considered for m.3243A>G mutation screening.

The role of MRI and ferritin in assessing iron overload and endocrine dysfunction in thalassemia major: focus on pituitary MRI findings

Ashraf Soliman[1], Shayma Ahmed[1], Carolin Beck[2], Nada Alaaraj[1], Noor Hamed[1], Fawzia Alyafei[1], Abbas Noureldin[1] & Elsaid Bedair[1]
[1]Hamad Medical Corporation, Doha, Qatar; [2]Hamad Medical Coropration, Pediatric Endocrine and Diabetes, Doha, Qatar

Background
Thalassemia major, a transfusion-dependent disorder, is commonly associated with chronic iron overload, resulting in significant endocrine dysfunctions such as impaired growth and delayed puberty. While serum ferritin is widely used as a marker of iron burden, it lacks specificity in predicting organ-specific damage. Magnetic resonance imaging (MRI) provides a more detailed evaluation of iron deposition, particularly in the pituitary gland, liver, pancreas, and heart. Understanding these correlations is critical for early diagnosis and effective management.
Objective
To assess the relationship between ferritin levels, MRI findings, and endocrine dysfunction, with a specific focus on pituitary MRI changes in thalassemia major.
Methods
A systematic review of 20 studies published from 2000 to 2025 was conducted, encompassing over 2,000 patients. The analysis included data on MRI-detected iron overload in the pituitary, pancreas, liver, and heart and their correlations with endocrine dysfunction. Relative impacts of iron burden were calculated based on MRI findings and ferritin correlations.
Results
- Pituitary Findings: MRI revealed reduced pituitary volume, hypointense T2* signals (<20 ms), and structural abnormalities. These findings were associated with hypogonadotropic hypogonadism and growth hormone deficiency, contributing to delayed puberty and stunted growth. The relative impact of pituitary iron overload was 80%, with a moderate ferritin correlation (0.8).
- Pancreatic Findings: Low T2* values (<20 ms) correlated with diabetes mellitus and glucose intolerance. The relative impact was 50%, and ferritin showed a weak correlation (0.5), highlighting the superior predictive value of MRI for pancreatic iron.
- Liver Findings: Liver iron concentration (LIC >7 mg/g dry weight) moderately correlated with ferritin (0.7) and was linked to thyroid and adrenal dysfunction, with a relative impact of 70%.
- Cardiac Findings: Low T2* values (<20 ms) reflected iron overload associated with cardiomyopathy risk. Ferritin showed a weak correlation (0.4), with a relative impact of 40%.

Conclusion
MRI is crucial in detecting organ-specific iron overload and its association with endocrine dysfunctions. Pituitary MRI findings strongly correlate with hormonal abnormalities and growth retardation, emphasizing its diagnostic and prognostic value. Ferritin, while accessible, often underestimates localized iron burden. Combining MRI with ferritin measurements improves diagnostic accuracy and facilitates early, targeted interventions to manage endocrine complications effectively.
Keywords
Thalassemia major, MRI, iron overload, ferritin, endocrine dysfunction, growth retardation, pituitary abnormalities.

Endocrinology and Metabolism, Shanghai Tenth People's Hospital, School of Medicine, Tongji University, Shanghai, China; [9]Institute of Natural Sciences and School of Mathematical Sciences, Shanghai Jiao Tong University, Shanghai, China; [10]Shanghai AI Laboratory, Shanghai, China; [11]Department of General Practice, Shanghai Tenth People's Hospital, School of Medicine, Tongji University, Shanghai, China

Aim
To investigate the application of deep learning-based facial recognition methods to facilitate the diagnosis of PCOS by leveraging the distinctive phenotypic features associated with the condition.
Methods
A muti-center, cross-sectional study was conducted from three tertiary hospitals in China from June 2023 to August 2024. A total of 163 participants with polycystic ovary syndrome (PCOS) and 162 non-PCOS women were recruited. Images were captured from multiple angles and were supplemented with clinical and metabolic data, including body mass index (BMI), glycated hemoglobin (HbA1c), blood lipid profiles, and sex hormone levels. Three convolutional neural network architectures (VGG-Net, ResNet-50, Inception-ResNet-v2) and Gradient-weighted Class Activation Mapping (Grad-CAM) were employed to distinct discriminative features in patients with PCOS.
Results
The mean age in participant with PCOS was 26.56 years old and have a higher body mass index (BMI), reduced number of menstrual cycles per year, elevated total testosterone and worse glycolipid metabolism than those without PCOS. Inception-ResNet-v2 achieved the highest accuracy for PCOS diagnosis, at 82.1%, whereas ResNet-50 and VGG-16, with an accuracy of 78.57% and 73.21% respectively. Inception-ResNet-v2 (AUC = 0.886) demonstrates the best performance for PCOS diagnosis, with its curve furthest from the diagonal. Additionally, the study employed Grad-CAM to visualize the model's focus on specific facial regions, particularly the jawline, nose, and forehead, which are indicative of PCOS traits such as hirsutism and acne.
Conclusions
Our findings demonstrated facial morphologic features in patients with PCOS was distinct and Artificial intelligence (AI)-based PCOS detection could achieve satisfactory sensitivity for detecting the patients with PCOS, which suggested the feasibility and potential of AI-driven facial recognition as a non-invasive and efficient tool for PCOS screening.
Keywords
polycystic ovary syndrome, facial recognition, deep learning.

Telomere length in patients with type 2 diabetes: impact of chronic kidney disease

Yanina Rebrova[1], Yanina Saienko[2], Dmytro Krasnenkov[2], Ievgen Marushko[3], Veronika Korcheva[2] & Borys Mankovsky[2]
[1]D. F. Chebotarev Institute of Gerontology of the National Academy of Medical Sciences of Ukraine, The Scientific and Practical Medical Center of Pediatric Cardiology and Cardiac Surgery of the Ministry of Health of Ukraine, Government Institution, Kyiv, Ukraine; [2]D. F. Chebotarev Institute of Gerontology of the National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine; [3]The Scientific and Practical Medical Center of Pediatric Cardiology and Cardiac Surgery of the Ministry of Health of Ukraine, Government Institution, Kyiv, Ukraine

Background and Aims
Telomeres are nucleoprotein structures located at the ends of chromosomes, playing a crucial role in maintaining genomic stability. In most somatic cells, telomeres progressively shorten with each cell division, eventually leading to replicative senescence or apoptosis when critically short. Previous research has demonstrated that patients with type 2 diabetes mellitus (T2DM) exhibit an increased rate of telomere shortening. However, data on telomere length in patients with both T2DM and chronic kidney disease (CKD) remain limited. The aim of this study was to assess the association between telomere length and CKD in patients with T2DM.
Materials and Methods
We analyzed 105 subjects divided into three groups. The first group included 65 patients with T2DM and CKD (mean age: 70.9 ± 8.0 years; diabetes duration: 5.9 ± 2.5 years; HbA1c: 7.1 ± 1.7%; serum creatinine: 145.0 ± 87.0 µmol/l; estimated glomerular filtration rate (eGFR): 44.0 ± 11.0 mL/min/1.73m^2; albumin/creatinine ratio (ACR): 36.0 ± 74.0 mg/g). The second group included 25 patients with T2DM but without CKD (age: 53.2 ± 6.8 years; diabetes duration: 3.7 ± 2.2 years; HbA1c: 7.6 ± 2.2%; serum creatinine: 89.6 ± 14.9 µmol/l; eGFR: 81.3 ± 12.2 mL/min/1.73m^2; ACR: 18.0 ± 9.7 mg/g). The third group included 15 control subjects without T2DM or CKD (age: 50.3 ± 3.8 years; HbA1c: 5.45 ± 0.3%; serum creatinine: 100.7 ± 22.5 µmol/l; eGFR: 83.0 ± 22.8 mL/min/1.73m^2; ACR: 11.0 ± 4.4 mg/g). Telomere length was measured in whole blood using monochrome multiplex quantitative PCR by calculating the telomere-to-single-copy gene (T/S) ratio.
Results
Telomere length (T/S ratio) was significantly higher in both groups of patients with T2DM compared to controls (0.989 ± 0.767 in T2DM with CKD, 1.11 ± 0.789 in T2DM without CKD, 0.535 ± 0.341 in controls; $P < 0.05$). No significant difference was observed between T2DM patients with and without CKD. Additionally, no significant correlation was found between telomere length and eGFR or ACR in any group.
Conclusion
Telomere length was shorter in patients with T2DM compared to controls, but CKD did not further contribute to telomere attrition. The pathogenetic and prognostic significance of telomere shortening in T2DM warrants further investigation.

Prevalence, incidence and risk factors for dysnatremia in european community-dwelling older adults – a secondary analysis of the DO-HEALTH trial

Laura Potasso[1,2,3], Maud Wieczorek[4,5], Sophie Monnerat[1], Julia Beck[1,3], Endel Orav[6], Mirjam Christ-Crain[1,3] & Heike Bischoff-Ferrari[4,5]
[1]University Hospital of Basel, Basel, Switzerland; [2]Cantonal Hospital of Baselland, Baselland, Switzerland; [3]Department of Clinical Research, University of Basel, Basel, Switzerland; [4]Centre on Aging and Mobility, University of Zurich and Stadtspital Zurich Waid, Zurich, Switzerland; [5]Department of Aging Medicine and Aging Research, University of Zurich, Zurich, Switzerland; [6]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, United States

Background
Plasma sodium disorders (dysnatremia) are the most common electrolyte disorders in hospitalized patients. However, data on their prevalence and incidence in community-dwelling and generally healthy older adults are currently scarce. The aim of this study was to estimate the prevalence and incidence of dysnatremia among community-dwelling older adults from five European countries.
Material and Methods
We performed a secondary analysis of DO-HEALTH, a multicenter clinical trial including community-dwelling participants aged ≥70 years from Austria, France, Germany, Portugal, and Switzerland, without major health events in the five years prior to inclusion. The trial duration was three years with yearly in-person clinical visits and blood samples. Data about sodium were collected yearly. Dysnatremia was defined as sodium levels <135 mmol/l (hyponatremia) or >145 mmol/l (hypernatremia). Incidence rates (IR) and 95% confidence intervals over the study period were estimated using negative binomial regression models.
Results
Out of the 2157 DO-HEALTH participants, 2141 (99.3%) had available sodium at baseline. At baseline, the overall prevalence of any dysnatremia, hyponatremia and hypernatremia were 3.4%, 2.4%, and 1.0%, respectively. Participants with dysnatremia at baseline were more likely to be older, have a lower body mass index and use thiazide or thiazide-like drugs, compared to participants with normonatremia. Over the three years of follow-up, the overall IR of dysnatremia, hyponatremia and hypernatremia were 3.3 (2.7-3.9), 2.1 (1.6-2.7) and 1.2 (0.9-1.6) per 100 person-years, respectively. The use of five or more medications and the use of thiazide or thiazide-like drugs at baseline were significantly associated with higher incidence rates of any dysnatremia and higher incidence rates of hyponatremia over the follow-up. No difference in the incidence rates of any dysnatremia, hyponatremia and hypernatremia were observed by sex or age.
Conclusion
In a large sample of European generally healthy community-dwelling older adults, the prevalence of any dysnatremia was 3.4%. Over three years of follow-up, the overall incidence rate of any dysnatremia was 3.3 per 100 person-years, with higher rates among individuals using more than five medications and using thiazide or thiazide-like drugs. These findings suggest that careful monitoring of sodium levels may be relevant even in generally healthy older adults.

Endocrinopathies in turkish children with inborn errors of immunity: a single-center experience

Gonul Buyukyilmaz[1], Keziban Toksoy Adıguzel[2], Pınar Kocaay[1], Mehmet Boyraz[1] & Ayse Metin[1]
[1]Ankara Bilkent City Hospital, Ankara, Türkiye; [2]Dr. Burhan Nalbantoğlu State Hospital, Nicosia, Cyprus

Objective
Inborn errors of immunity (IEI) represent a heterogeneous group of genetic disorders. We aimed to investigate endocrine disorders in children with IEI.
Materials Methods
This study included 84 patients with IEI who were evaluated in the pediatric endocrinology clinic between September 2019 and September 2023.
Results
Our findings revealed that 15.6% of the 32 patients with 22q11.2 deletion syndrome had permanent hypoparathyroidism. Hypergonadotropic hypogonadism was identified in one of four female patients with ataxia-telangiectasia (AT) and in all four females with severe congenital neutropenia (SCN) due to *HAX1* deficiency. Autoimmune thyroiditis (AIT) was detected in four of the 15 patients with common variable immunodeficiency (CVID). Additionally, hypergonadotropic hypogonadism was observed in one of nine males with CVID. Among the CVID patients, one presented with AIT, type1 diabetes mellitus (T1DM), hypoparathyroidism, and primary adrenal insufficiency. Of the 307 patients followed for selective IgA deficiency (sIgAD), 26 also received care in pediatric endocrinology. Among the sIgAD cases 3.2% had AIT, and 4.5% had T1DM. A patient with a STAT1 gain-of-function (GOF) variant was diagnosed with T1DM, AIT, and growth hormone deficiency, while a patient with a novel STAT3-GOF variant developed neonatal DM.
Conclusion
Autoimmune thyroiditis and T1DM were the most prevalent endocrine disorders in IEI patients. Primary ovarian insufficiency in females with SCN and AT, and primary testicular failure in a male patient with CVID was detected. Combined endocrine disorder involving T1DM, AIT, hypoparathyroidism, and primary adrenal insufficiency was identified in a patient with CVID for the first time.

A case of atypical wolfram syndrome with late diagnosis and without diabetes inspidus component

Özgür Yılmaz[1], Osman Erinç[1], Melek Yildiz[2], Kashyap Patel[3], Şengül Aydın Yoldemir[1], Murat Akarsu[1] & Ömür Tabak[1]
[1]İstanbul Kanuni Sultan Süleyman Training and Research Hospital, Department of Internal Medicine, İstanbul, Türkiye; [2]Istanbul University Faculty of Medicine, Department of Pediatric Endocrinology, Istanbul, Türkiye; [3]University of Exeter, Institute of Biomedical and Clinical Science, Exeter, United Kingdom

Introduction
Wolfram syndrome is a rare autosomal recessive disorder that begins in childhood, characterized by symptoms such as type 1 diabetes, optic atrophy, hearing loss, and neurogenic bladder. In this case, a 22-year-old male patient with chronic renal failure, whose diabetes insipidus symptoms were masked, and whose diagnosis was delayed, is presented. The patient's diagnosis, with multisystem involvement, was confirmed through genetic analysis.
Case
A 22-year-old male patient, diagnosed with diabetes since the age of 3, neurogenic bladder, bilateral sensorineural hearing loss, and chronic kidney failure for 6 years, presented to the emergency department due to the depletion of his home catheter. Upon finding a blood glucose level of 420 mg/dl, he was referred to the internal medicine clinic with a preliminary diagnosis of hyperglycemia. On physical examination, syndromic findings such as growth and developmental delay, bilateral hallux valgus, optic atrophy, and hearing loss were observed. Given the multisystemic symptoms, early-onset diabetes, and syndromic features, the patient, who was not considered to have polyuria due to chronic kidney disease, was initially suspected to have Wolfram Syndrome (DIDMOAD). However, the diagnosis was excluded due to the absence of diabetes insipidus symptoms. Other syndromic diabetes diagnoses such as MODY, mitochondrial genetic disorders, and Mauriac syndrome were also considered, but genetic tests yielded results incompatible with these conditions. Finally, after consultation with the Diabetes Research Excellence Center at the University of Exeter, genetic analysis revealed a homozygous WFS1 gene mutation, confirming the diagnosis of Wolfram Syndrome.
Discussion
This case highlights the challenges encountered in diagnosing Wolfram Syndrome. Wolfram syndrome is a rare disorder that begins with diabetes at an early age and presents with multisystemic effects. Atypical clinical courses can complicate the diagnostic process, and thus the entire spectrum of the disease should be considered, rather than just the classic triad. The masking of diabetes insipidus symptoms due to chronic kidney failure was a significant factor that delayed the diagnosis. Accelerating the genetic testing process is crucial for early diagnosis and disease management. A systematic evaluation of a patient who had been undiagnosed for a long period, along with consultation from an international center, led to the correct diagnosis. Early diagnosis of Wolfram Syndrome is vital for managing its progressive complications. Therefore, it is recommended that patients with early-onset diabetes and multisystemic findings undergo detailed genetic analysis.

Coexistence of thyroid autoimmunity with adrenal disease: clinical implications and insights

Nurmukhammed Jumaniyazov[1] & Zulaykho Shamansurova[2]
[1]Central Asian University, Endocrinology, School of Medicine, Tashkent, Uzbekistan; [2]Institute of Biophysics and Biochemistry at the National University of Uzbekistan, Metabolomics, Tashkent, Uzbekistan

Introduction
Thyroid autoimmunity and adrenal disease are two of the most frequently observed endocrine disorders that often coexist in clinical practice. The interplay between these conditions is particularly evident in autoimmune polyglandular syndromes (APS). The coexistence of thyroid autoimmunity, most commonly Hashimoto's thyroiditis (HT) or Graves' disease (GD), where in first can be seen thyroid function declining and in second case thyroid function increased with toxicity. Whereas Addison's disease (AD) is associated with declining function of adrenal cortex. Coexisting thyroid and adrenal autoimmune disorders in most cases can produce significant diagnostic and therapeutic challenges.
Materials and Methods
Published data from the past two decades from sources such as MEDLINE, PubMed, Scopus, and Web of Science were systematically analyzed to evaluate the coexistence of GD or HT with AD in APS. Data were extracted on laboratory findings, blood pressure patterns, and clinical presentations.
Results
The frequency of coexistence of GD or HT with primary adrenal insufficiency (AD) in the context of APS is summarized as follows. GD is less commonly associated with AD compared to HT. The prevalence of GD in patients with AD is estimated to be around 5-10%. HT is more frequently observed in patients with AD. The prevalence of HT in patients with AD is approximately 40-50%. Conversely, adrenal insufficiency is found in about 2-5% of patients with established autoimmune thyroid disease, including HT. According to literature coexistence of GD and AD, as seen in APS. Interestingly, coexistence both thyroid autoimmune diseases like GD or HT and AD high level TRab/TSI detected in 50-70% cases, mostly stimulating type, the TPOab were registered in 50-70% cases, 21-Hydroxylase autoantibody were positive in 85-90% cases. Clinical parameters in combination of GD with AD showed higher blood pressure than only GD. Heart rate also were elevated in combination than seen in AD without GD. Blood ACTH level were elevated, blood pressure, heart rate, blood sugar levels were more lower than in AD.
Conclusion
Coexistence of HT and AD is marked by elevated TSH, low Free T4, positive TPOAb, and low cortisol with elevated ACTH. AD contributes to electrolyte imbalances and hypotension. In contrast, GD with AD presents suppressed TSH, elevated Free T4/Free T3, positive TRAb, and similar adrenal insufficiency findings. Tachycardia from GD and hypotension from AD complicated management. Early diagnosis and treatment of both thyroid and adrenal dysfunction are essential to prevent severe complications like adrenal crisis or myxedema coma.

Chronic hypoparathyroidism video-based CME series improved physician knowledge to prepare for an era of emerging therapies

S Christy Rohani-Montez[1], Rita Moreira da Silva[1], Karen Reid[1], Patty Keating[2], Michele Rayes[3], Aliya Khan[4], Maria Luisa Brandi[5], Suzanne Jan de Beur[6], Lynn Kohlmeier[7] & Dolores M. Shoback[8]
[1]Medscape Education Global, London, United Kingdom; [2]HypoPARAthyroidism Association, Aldie, VA, United States; [3]HypoPARAthyroidism Association, Frisco, TX, United States; [4]McMaster University, Hamilton ON, Canada; [5]University Vita-Salute San Raffaele, Milan, Italy; [6]University of Virginia School of Medicine, Charlottesville VA, United States; [7]HypoPARAthyroidism Association, Spokane Osteoporosis and Endocrinology, Spokane WA, United States; [8]Endocrine Research Unit, San Francisco Department of Veterans Affairs Medical Center, University of California, San Francisco, San Francisco, CA, United States

Background
Managing chronic hypoparathyroidism is challenging; but innovative therapies are shifting treatment paradigms from reliance on oral calcium and activated vitamin D analogs to restoring parathyroid hormone (PTH) receptor activation in critical tissues like the kidneys and bones. However, many endocrinologists and nephrologists lack familiarity with these approaches and in evaluating their efficacy. To address these gaps, we developed a series of continuing medical education (CME) activities, to improve physician knowledge across 4 learning needs:.
1. The burden of hypoparathyroidism.
2. Limitations of current therapies.
3. Mechanisms of emerging therapies.
4. Expectations for these emerging therapies.
Methods
Three online video/synchronized slide-based CME activities were launched in May, June, and October 2024—each featuring different expert endocrinologists and patients with hypoparathyroidism sharing their diagnosis/management experiences and recent clinical data.[1-3] The effects of each activity were assessed using a multi-question, repeated pairs, pre-assessment/post-assessment study design. We analyzed results across all 3 activities in Jan-2025, with questions grouped according to the 4 identified learning needs. Differences pre- and post-assessment were evaluated using McNemar's test.
Results
Confidence in understanding the burden of chronic hypoparathyroidism improved for 37% of endocrinologists and 35% of nephrologists, as did implementing best practice guidelines for 40% of endocrinologists and 36% of nephrologists. Significant improvements in knowledge were also observed, particularly regarding the burden of living with hypoparathyroidism. Baseline knowledge of the mechanisms and expectations of emerging therapies was limited, but notable gains were made (Table).
Conclusions
This study highlights the effectiveness of online CME in improving chronic hypoparathyroidism knowledge. Further education is needed, particularly on the mechanisms and applications of emerging PTH therapies, to enhance provider confidence and transform patient care.

Table 1: Correct Pre- and Post-Assessment Response Rates According to Learning Needs.

			Correct response rates			
Learning Need	**Specialists**	**n**	**Pre**	**Post**	**Δ**	***P* value**
Burden of hypoparathyroidism	Endocrinologists	281	60%	76%	16%	$P<.001$
	Nephrologists	133	59%	76%	17%	$P<.001$
Limitations of current therapies	Endocrinologists	420	81%	90%	9%	P = NS
	Nephrologists	183	68%	78%	10%	$P<.001$
Mechanisms of emerging therapies	Endocrinologists	341	22%	31%	9%	$P<.001$
	Nephrologists	124	21%	24%	3%	$P<.001$
Expectations of emerging therapies	Endocrinologists	178	9%	21%	12%	$P<.001$
	Nephrologists	89	12%	13%	1%	$P<.001$

Case-based rare disease CME significantly improves competence in diagnosing mct8 deficiency in pediatric/endocrinology practice

S Christy Rohani-Montez[1], Megan Breuer[1], Grace O'Malley[1], Margaux LeBerre[1], Davide Tonduti[2] & Andrew Bauer[3]
[1]Medscape Education Global, London, United Kingdom; [2]COALA (Center for Diagnosis and Treatment of Leukodystrophies), Unit of Pediatric Neurology, V. Buzzi Children's Hospital, University of Milan, Department of Biomedical and Clinical Sciences, Milan, Italy; [3]Children's Hospital of Philadelphia, Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States

Background
A diagnosis of MCT8 deficiency is easily missed in paediatric/endocrinology practice due to poor familiarity with this rare disease and failure to order or adequately interpret thyroid function tests for babies with hypotonia, missed motor milestones and/or other red flags. Thyroid hormone analysis is a key step in diagnosis but often missed. To increase the recognition and diagnosis of patients presenting with potential MCT8 deficiency, we developed a CME-accredited interactive online case-based educational activity featuring 2 cases for learners to diagnose.
Methods
Physicians worked through 2 cases, answering questions along the way with evidence-based feedback regarding correct responses.[1] The education effects were assessed using a 3-question, repeated pairs, pre-assessment/post-assessment study design. One question assessed confidence. Differences from pre- to post-assessment were evaluated using McNemar's test. The activity launched in February 2024 and data were collected through mid-January 2024.
Results
1,816 endocrinologists and paediatricians participated in the education, with 983 completing both cases and all pre- and post-assessment questions. Significant improvements were seen, with 22/62 (35%) endocrinologists having correct responses at baseline, improving to 48/62 (77%) post case completion ($P<.001$). The corresponding figures for paediatricians were 276/921 (30%) pre-assessment vs 792/921 (86%) at post-assessment ($P<.001$). In particular, significant improvements were observed in physicians' ability to differentiate MCT8 deficiency from a condition with a similar presentation and select the right diagnostic tests, as well as in their knowledge of the burden of MCT8 deficiency for patients and their families. After participating in the activity, 55% of endocrinologists and 60% of paediatricians had measurable improved confidence in their ability to diagnose MCT8 deficiency.
Conclusions
This study demonstrates the success of online, interactive case-based education in improving clinicians' competence in diagnosing MCT8 deficiency.

Multiple endocrine neoplasia type 4 (MEN4) syndrome due to rare pathogenic variant of CDK1B gene: a case report

Anna Matrejek[1], Ewa Płaczkiewicz-Jankowska[2], Anna Nogieć[3], Alicja Hubalewska-Dydejczyk[4] & Malgorzata Trofimiuk-Muldner[4]
[1]University Hospital in Krakow, Endocrinology, Oncology Endocrinology, Nuclear Medicine and Internal Medicine Clinical Department, Krakow, Poland; [2]Jagiellonian University Medical College, Chair of Epidemiology and Preventive Medicine, Krakow, Poland; [3]University Hospital in Krakow, Department of Hematology Diagnostics and Genetics, Krakow, Poland; [4]Jagiellonian University Medical College, Chair and Department of Endocrinology, Krakow, Poland

Introduction
MEN4 syndrome is a rare autosomal-dominant disorder characterised by the co-presence of multiple neuroendocrine tumors, mainly of pituitary and parathyroid origin, with fewer than 100 cases reported since the diagnosis was established in 2006.[1,2] The prevalence of genetically confirmed MEN4 resulting from likely pathogenic or pathogenic variants is 0.07% in patients with suspected MEN1.[2] The underlying molecular mechanism involves loss of function of the tumor suppressor protein p27 due to heterozygous mutation in the *CDKN1B* gene.[3] We present a case of a patient diagnosed with MEN4 syndrome resulting from a reported once across databases but never published in literature, pathogenic variant in the CDKN1B gene.
Case presentation
A 45-year-old female patient presented to the ward with suspected hypopituitarism. Symptoms on admission comprised amenorrhoea for a year, fatigue, dyssomnia, and arthralgia. She denied headaches, vision impairment, polydipsia, or polyuria. The patient's history included obesity, hypertension, and hepatic steatosis. The hormonal work-up confirmed anterior hypopituitarism with mild hyperprolactinemia. The pituitary MR visualized a pituitary tumor sized 24x22x25 mm. The patient was scheduled for trans-sphenoid surgical excision. The pathology result indicated pituitary neuroendocrine tumor, with a weak-positive immunostaining for LH and alpha-subunit and a Ki67 proliferative index of less than 1%. Furthermore, the patient was diagnosed with mild primary hyperparathyroidism. Both parathyroid scintigraphy and neck ultrasound failed to detect affected glands. A single nodule was found on the thyroid ultrasound and later confirmed as a BIII lesion on FNA biopsy. Given the suspicion of multiple endocrine neoplasia, genetic testing was performed. After ruling out MEN1 syndrome, Sanger sequencing confirmed the presence of a heterozygotic, pathogenic variant of *CDKN1B* gene – a deletion at coding DNA position 285, located in the first exon of the gene. Resultant frame-shift mutation leading to premature termination codon presence precipitates nonsense-mediated decay of the aberrant mRNA. The patient's family history was non-specific (parents or siblings are not available for testing, and the only child was negative on genetic screening). Computed tomography of the chest, abdomen and pelvis did not reveal any other pathological lesions so far. Since then, the patient has remained under active surveillance.

JOINT181
Coexistence of papillary and medullary thyroid carcinomas in a patient with MEN2A
Kristy Tian [1] & Lih Ming Loh[1]
[1]Singapore General Hospital, Endocrinology, Singapore, Singapore

Background
The rare coexistence of medullary thyroid carcinoma (MTC) and papillary thyroid carcinoma (PTC) in Multiple Endocrine Neoplasia type 2A (MEN2A) presents unique challenges in diagnosis and treatment.
Case Presentation
We report a 28-year-old Chinese female diagnosed with MEN2A, initially presenting with multifocal MTC on fine needle aspiration of right thyroid nodules. The patient underwent total thyroidectomy, tracheoesophageal groove clearance, and right neck dissection. Histopathological examination of the thyroidectomy specimen revealed dual pathology: multifocal MTC in both lobes and unifocal PTC at the isthmus. Regional lymph node involvement was significant, with most showing metastatic MTC, and three level 6 lymph nodes exhibiting metastatic PTC.
Discussion
MEN2A is an autosomal dominant hereditary syndrome characterized by MTC, pheochromocytoma, and primary hyperparathyroidism, resulting from germline mutations in the RET proto-oncogene. These mutations lead to tumorigenesis through gain-of-function alterations. Although MTC is nearly universal in MEN2A and typically multifocal and bilateral, the coexistence of MTC and PTC in the same thyroid gland is extremely rare. Such cases may present as a mixed tumor with dual differentiation or as a collision tumor. Recent studies suggest that RET point mutations may also induce oncogenic activity in thyroid follicular cells, potentially contributing to PTC development. Distinguishing between MTC and PTC is crucial for management as treatment strategies differ significantly. While the American Thyroid Association (ATA) guidelines recommend TSH suppression to reduce recurrence risk in PTC, this is ineffective for MTC due to the absence of TSH receptors on thyroid C cells. Consequently, patients with dual pathology require a tailored therapeutic strategy to optimize the management of both malignancies.
Conclusion
The coexistence of MTC and PTC in MEN2A underscores the need for comprehensive histopathological evaluation and genetic analysis to guide appropriate clinical management.

JOINT3312
A case report of mccune-albright syndrome with hepatic focal nodular hyperplasia and review of literature
Liulu Xie[1] & Yanhong Li[1]
[1]The First Affiliated Hospital, Sun Yat Sen University, Pediatric, Guangzhou, China

Objective
We report the first case of McCune-Albright syndrome (MAS) complicated with hepatic focal nodular hyperplasia (FNH) in China, summarize the clinical features and possible related factors of MAS complicated with hepatobiliary system complications, and review the literature.
Method
A retrospective analysis was conducted on the clinical data of a patient with McCune-Albright syndrome (MAS) complicated by hepatic focal nodular hyperplasia (FNH) who was admitted to the Department of Pediatrics, First Affiliated Hospital of Sun Yat-sen University on November 25, 2011, and the relevant literature was reviewed.
Result
The patient, a female now aged 17, was diagnosed with McCune-Albright syndrome (atypical, café-au-lait spots, peripheral precocious puberty) at our hospital at the age of 5 years and 3 months due to "breast development for 3 months, vaginal bleeding 4 times, and accelerated growth." Genetic testing revealed a GNAS gene mutation in the peripheral blood. She has been regularly followed up in our hospital for 12 years since then, during which her ovaries exhibited continuous hyperfunction that was difficult to control. She also had comorbidities of Cushing's syndrome, pituitary hyperfunction, and multifocal pituitary adenomas. In the 6th year of follow-up, liver function abnormalities appeared, and hepatic imaging suggested hepatic adenoma and focal nodular hyperplasia, which largest lesion measured approximately 91*77* 72 mm (volume 262.3 cm^3). The pathological examination confirmed focal nodular hyperplasia. Due to the family's wishes, no surgical intervention was performed, and close follow-up was conducted instead. During this period, the lesion progressively enlarged to 99*82* 81 mm (volume 341.9 cm^3), after which it tended to stabilize and began to decrease in size. After a follow-up period of 6 years to date, the lesion has reduced to 56*26* 26 mm (volume 19.7 cm^3). During this period, liver function fluctuated with the size of the lesion, and liver function is currently normal.
Discussion
This case is the first reported in China of McCune-Albright syndrome (MAS) complicated by hepatic focal nodular hyperplasia, and the characteristics of lesion progression are reported, aiming to enrich the clinical spectrum of MAS and raise clinical awareness and attention to hepatobiliary system involvement in MAS. It is proposed that a high mutation dose of the GNAS gene, a high disease burden, and frequent or continuous autonomous ovarian function activity may be risk factors for hepatobiliary system involvement in MAS.
Keywords
McCune-Albright syndrome, hepatic focal nodular hyperplasia.

Quality of XLH care in the nordics: perspectives of parents with children with XLH
Signe Beck-Nielsen[1], Cathrine Alsaker Heier[2], Tia Monteiro[3], Asa Mandahl[4], Leif Lindsten[4], Victoria Hayes[5], Leigh Mathieson[5] & Ola Nilsson[6]
[1]Aarhus University Hospital, Centre for Rare Diseases, Aarhus, Denmark; [2]Oslo University, Division of Pediatrics, Oslo, Norway; [3]Kalfos, Helsinki, Finland; [4]XLH Svenska patientföreningen, Skövde, Sweden; [5]Kyowa Kirin

International plc, Marlow, United Kingdom; [6]Karolinska Institutet and University Hospital, Division of Pediatric Endocrinology and Center of Molecular Medicine, Stockholm, Sweden

Introduction
X-linked hypophosphataemia (XLH) is a genetic orphan disease that causes growth impairments, rickets in children, and lifelong osteomalacia throughout the life span. A 2019 international survey showed <2% of adults received all aspects of best care as laid out in the recent Haffner *et al* recommendations, however data on children's real-world XLH care and lived experiences is lacking. This research aims to evaluate parent/caregiver satisfaction with XLH care in children and identify barriers to optimal care.
Methods
Double-blind, virtual, 1-hour interviews were conducted in local language in January 2024. Interviewees included 8 parents/caregivers from Sweden (4), Finland (2) Denmark (1) and Norway (1); and 1 healthcare provider (HCP) from Finland. Interviews covered four themes: experiences of XLH care, treatments, understanding the burden of XLH, and improving XLH care. Key words were used to identify concepts discussed and quantify the qualitative data.
Results
Recruitment proved challenging due to XLH's rarity and the limited number of specialist HCPs. While engagement through patient advocacy groups (PAGs) was successful in Sweden, uptake was lower in other countries. Among the parents/caregivers interviewed ($n = 8$), all reported their child received care from endocrinologists and dentists, but none had support from psychologists or social workers. While satisfaction with specialist care was high, 25% noted communication gaps with their general practitioner (GP). Burdens of XLH care included frequent administration of phosphate and alfacalcidol and organizing life around care; 63% found it challenging to plan logistics for care, with some facing travel times of up to 5 hours for treatments. Interviewees suggested several improvements that could reduce the burden of XLH on families, including the need for a coordinating XLH care provider (38%), increased knowledge and awareness of the condition among GPs and hospital care providers (38%), and better access to optimal treatments (75%).
Conclusion
These findings identify key areas for improving the care experience of children with XLH, particularly by enhancing access to coordinated care and mitigation of logistical and communication challenges. Increasing physician knowledge and alleviating frustrations related to treatments options could further help reduce the burden on families. Future research should prioritize close collaboration with patient groups to facilitate more effective recruitment and engagement.

Association between body mass index (BMI) and immune-related adverse events among cancer patients receiving immune checkpoint inhibitors: a single institution analysis

Martina Lagana[1], Calogera Spagnolo[1], Angela Alibrandi[1], Salvatore Cannavo[1], Mariacarmela Santarpia[1] & Rosaria Ruggeri[1]
[1]University of Messina, Department of Human Pathology of Adulthood and Childhood DETEV, Messina, Italy

Whether overweight/obesity has an impact on immune checkpoint inhibitor (ICIs) toxicity and efficacy is currently under debate. The present study was aimed at evaluating the occurrence of irAEs among cancer patients on ICI therapy according to baseline BMI and gender.
Patients and Methods
We performed a retrospective analysis of 130 patients (93 males and 37 females, male/female ratio 2.5:1; median age 67 years, range: 32-85) with different types of cancer treated with ICIs at a single center. The primary tumours were: non-small-cell lung carcinoma ($n = 72$, 55%), melanoma ($n = 30$, 23%), renal cell carcinoma ($n = 17$, 13%), and others ($n = 3$, 3%).
Results
At baseline evaluation, median BMI in the whole cohort was 22 (range 18,1-36,7), and median body weight 70,5 kg (range 47 – 117). According to WHO classification, 3 patients (2.3%) were defined as underweight, 83 patients (63,8%) as normal weight, 37 patients (28.5%) as overweight and 7 patients (5.41%) as obese. During follow-up, any irAEs occurred in 42 patients (32%; median age 69 years), with significant differences between sexes (28 males and 14 females, F to M ratio 2:1; $P = 0.007$). Among them, 41 (31.5% of the whole cohort) developed thyroid dysfunction (hypothyroidism and/or thyrotoxicosis) without difference by sex ($P = 0.578$), primary hypothyroidism being the most common irAEs (39 patients; 30% of the whole cohort). Twenty-nine patients developed also non-endocrine AEs [cutaneous ($n = 10$), gastro-intestinal ($n = 9$), pulmonary ($n = 2$) and rheumatic ($n = 8$)], and difference by sex was significant ($P = 0.009$). Development of AEs was associated with higher BMI: the prevalence of AEs was 59.5% in overweight/obese patients *vs* 40.5% in normal weight patients ($P < 0.001$). Patients who developed AEs had higher body weight (75,5 $\pm$ 12 kg *vs* 70.2 $\pm$ 11 kg, $P = 0.017$) and BMI (25 $\pm$ 3.5 kg/m^2 vs22.7 $\pm$ 3 kg/m^2, $P = 0.002$) than patients who did not, in both sexes. At uni- and multivariate regression analyses, BMI was confirmed as an independent predictor of risk for developing AEs ($P < 0.001$), with overweight/obese patients having a OR of 3.182 compared to normal weight/underweight patients. BMI $\geq$25 kg/m^2 and AEs occurrence were associated to a better ECOG performance status ($P = 0.012$, and $P = 0.013$, respectively), although no differences in PFS and OS emerged.
Conclusion
Occurrence of ICI-related toxicities was more frequent in overweight/obese patients compared to normal weight/underweight patients. A BMI $\geq$25 kg/m^2 was associated with increased risk for developing AEs in both sexes. No clear association between BMI and immunotherapy efficacy/prognosis was observed.

JOINT619

Different faces of polycystic ovary syndrome: contrasting clinical and biochemical profiles in adolescents and adults

Noor Hamed[1], Aml Sabt[2], Fawzia Alyafei[1], Shayma Ahmed[1], Nada Alaaraj[1] & Ashraf Soliman[1]
[1]Hamad Medical Corporation, Doha, Qatar; [2]Sidra Medicine, Doha, Qatar

Objective
To compare the clinical and biochemical presentation of polycystic ovary syndrome (PCOS) in adolescent girls and adult women, focusing on differences in prevalence, age of presentation, symptoms, biochemical data, imaging findings, treatment response, and outcomes.
Methods
This review synthesized data from 18 studies published between 1990 and 2024, involving approximately 1,200 patients. The findings highlight distinct variations in PCOS characteristics and management strategies across these age groups.
Results
Adolescent girls demonstrated a prevalence of 5%-10%, particularly higher in those with obesity, compared to 6%-20% in adult women. Adolescents typically presented during early to mid-puberty with symptoms such as menstrual irregularity, acne, and mild hirsutism, while androgenic alopecia and infertility were rare. Adults commonly presented in late adolescence or early adulthood with more severe hirsutism, infertility, and androgenic alopecia. Biochemically, adolescents had mild hyperandrogenemia, reduced sex hormone-binding globulin, and early signs of insulin resistance, with more severe markers seen in obese subgroups. Adults exhibited pronounced dyslipidemia, insulin resistance, and greater metabolic abnormalities. Imaging findings were inconsistent in adolescents, while adults consistently demonstrated larger ovarian volumes with polycystic morphology. Adolescents responded well to lifestyle modifications, with metformin improving insulin sensitivity and ovulation. In adults, oral contraceptives effectively managed hyperandrogenism and menstrual irregularity, with insulin-sensitizing agents enhancing fertility outcomes.
Discussion
The observed differences in PCOS presentation between adolescents and adults can be attributed to developmental and hormonal factors. In adolescents, the overlap of normal pubertal changes with PCOS symptoms complicates diagnosis, and obesity exacerbates insulin resistance and hyperandrogenism. Conversely, prolonged exposure to hyperandrogenemia and metabolic dysfunction in adults contributes to more severe manifestations, including infertility and endometrial complications. These differences highlight the need for age-specific diagnostic criteria and management strategies. Adolescents show greater plasticity in their metabolic and hormonal systems, making lifestyle interventions particularly effective. Early intervention reduces long-term risks such as type 2 diabetes and cardiovascular disease. Adults often require more aggressive pharmacological interventions to address chronic complications. Understanding these distinctions can guide tailored therapeutic approaches to improve patient outcomes at different life stages.

Recommendations
1. Early identification and intervention in adolescents can prevent long-term complications of PCOS.
2. Adults require advanced therapies to manage severe symptoms and fertility issues.
Conclusion
Recognizing the differences in PCOS presentation and management between adolescents and adults is essential for effective age-appropriate care, minimizing long-term health risks, and improving quality of life.

JOINT677

The role of pituitary MRI in assessing endocrine dysfunction and growth defects in thalassemia major

Mohamed Alkuwari[1], Ashraf Soliman[2], Shayma Ahmed[2], Noor Hamed[2], Nada Alaaraj[2], Fawzia Alyafei[2], Abbas Noureldin[2] & Elsaid Bedair[2]
[1]Hamad Medical Coropration, Pediatric Endocrine and Diabetes, Doha, Qatar; [2]Hamad Medical Corporation, Doha, Qatar

Background
Thalassemia is a chronic transfusion-dependent disorder often associated with iron overload. Excess iron deposition in the pituitary gland leads to endocrine dysfunctions such as growth hormone (GH) deficiency and hypogonadotropic hypogonadism, significantly impacting growth and pubertal development. Magnetic resonance imaging (MRI) has emerged as a critical tool for evaluating pituitary iron overload and its correlation with endocrine dysfunctions.
Objective
To assess the role of pituitary MRI in detecting iron overload and its association with endocrine abnormalities and growth defects in patients with thalassemia major.
Methods
A systematic review of 20 studies involving over 1,500 thalassemia major patients was conducted. MRI findings of pituitary iron overload, reduced T2* relaxation times, and structural abnormalities were correlated with endocrine dysfunctions such as GH and gonadotropin deficiencies. Growth and pubertal outcomes were also analyzed.
Results
1. MRI Findings:.
• Pituitary iron overload was a consistent finding, with reduced T2* relaxation times (<20 ms) correlating with increased serum ferritin levels and liver iron concentration (LIC).
• Structural abnormalities included reduced pituitary volume, hypoplastic glands, and abnormal shapes.
2. Endocrine Dysfunction:.
• Growth hormone deficiency (GH) was observed in studies such as Noetzli *et al.* (2012), with delayed height velocity and impaired catch-up growth.
• Hypogonadotropic hypogonadism was common, presenting as delayed or arrested puberty, particularly in studies by Wood *et al.* (2015) and Jain *et al.* (2021).
• Additional hormonal abnormalities included secondary hypothyroidism, adrenal insufficiency, and gonadotropin suppression.
3. Growth Implications:.
• Short stature, delayed puberty, and stunted skeletal growth were prominent in patients with significant pituitary iron deposition.
• Long-term MRI monitoring and chelation therapy adjustments, as shown by Agha *et al.* (2023), improved growth trajectories in some patients.
4. Clinical Utility of MRI:.
• Studies such as Kildemoes *et al.* (2023) emphasized the accuracy of T2* MRI in quantifying pituitary iron and guiding chelation therapy.
• MRI findings predicted the severity of endocrine dysfunctions and provided insights into individualized management plans.
Conclusion
Pituitary MRI plays a pivotal role in detecting iron overload and predicting endocrine dysfunctions in thalassemia major. By identifying structural and functional abnormalities, MRI guides timely interventions to mitigate growth and pubertal defects. Incorporating routine MRI assessments into patient management protocols can significantly improve long-term outcomes.
Keywords
Thalassemia major, pituitary MRI, iron overload, growth hormone deficiency, hypogonadotropic hypogonadism, T2* relaxation time, endocrine dysfunction.

JOINT674

Comparative analysis of MRI and ferriscan in thalassemia major and intermedia: implications for growth, puberty, and endocrine health"

Shayma Ahmed[1], Ashraf Soliman[1], Noor Hamed[1], Nada Alaaraj[1], Fawzia Alyafei[1], Abbas Noureldin[1] & Elsaid Bedair[1]
[1]Hamad Medical Corporation, Doha, Qatar

Background
Thalassemia Major (TM) and Thalassemia Intermedia (TI) are distinct forms of beta-thalassemia, characterized by differences in transfusion dependence and iron overload patterns. Non-invasive imaging techniques, including T2* MRI and FerriScan (R2 MRI), have advanced the management of iron burden. However, differences in their diagnostic efficacy and their implications on growth, puberty, and endocrine functions in TM and TI remain underexplored.
Objective
This study aims to evaluate the differences in MRI (T2*) and FerriScan findings between TM and TI and their correlation with growth retardation, delayed puberty, and endocrine dysfunction.
Methods
A review of studies comparing MRI and FerriScan findings in TM and TI was conducted. Key parameters analyzed include liver iron concentration (LIC), cardiac iron overload, and extramedullary manifestations. Findings were correlated with growth patterns, pubertal development, and endocrine outcomes, including hypogonadism and short stature.
Results
• **Liver Iron Concentration (LIC):** FerriScan was more sensitive in detecting LIC in both TM and TI, particularly at higher iron burdens. T2* MRI tended to underestimate LIC, especially in TM patients with severe iron overload. In TI, FerriScan provided superior detection of moderate LIC, highlighting differences in iron deposition patterns.
• **Cardiac Iron Overload:** T2* MRI identified higher myocardial iron deposition in TM than in TI, where cardiac involvement was less frequent but associated with high-output heart states.
• **Growth Retardation:** Chronic iron overload and anemia in TM led to significant growth delays. In TI, the lower frequency of transfusions and delayed recognition of iron overload further exacerbated growth impairment.
• **Pubertal Delays:** Hypogonadism and delayed puberty were prevalent in both conditions, with higher severity in TM due to heavier transfusion burdens and iron toxicity. In TI, unrecognized iron overload compounded endocrine dysfunction.
• **Endocrine Dysfunction:** Hypogonadotropic hypogonadism, diabetes, and hypothyroidism were frequently observed in TM patients with severe iron burden. In TI, iron-related endocrine dysfunction occurred but was often overlooked due to milder transfusion dependence.
Conclusion
FerriScan demonstrated greater accuracy in measuring LIC, particularly in TM patients with high iron burdens and TI patients with moderate overload. MRI findings, when combined with FerriScan, provide critical insights into iron-related complications, enabling better management of growth, puberty, and endocrine outcomes. Regular imaging-guided chelation improves growth and endocrine function, but the implementation remains suboptimal in TI compared to TM. This underscores the need for tailored iron monitoring strategies for both conditions.

An intricate case of postmenopausal hyperandrogenism: causes and consequences

Mihaela Florea[1], Elena-Diana Cozma[2], Andra Dorneanu[2], Teodora Nastasa[2] & Stefana Bilha[1,3]
[1]"Sf. Spiridon" Clinical Emergency Hospital Iasi, Endocrinology, Iasi, Romania; [2]"Sf. Spiridon" Clinical Emergency Hospital Iasi, Iasi, Romania; [3]"Grigore T. Popa" University of Medicine and Pharmacy, Endocrinology, Iasi, Romania

Introduction
New-onset moderate-severe post-menopausal hyperandrogenism is associated with significant metabolic disorders that increase the risk of cardiovascular disease and mortality, prompting early diagnosis and treatment.

Case Report
We present the case of a 58-year-old nulliparous woman, menopaused at 55 years, with medical history of autoimmune thyroiditis, mild hypothyroidism, and important cardiometabolic comorbidities (arterial hypertension, heart failure, coronary stent, poorly controlled type 2 diabetes mellitus requiring insulin treatment, hyperlipidemia), that was referred to the Endocrinology Department to evaluate slowly progressive androgenic alopecia and hirsutism developed over the last 8 years, exacerbated 3 years before presentation. Clinical examination revealed a BMI of 38 kg/m^2 with abdominal fat distribution, blood pressure of 160/100 mmHg, frontotemporal alopecia, increased terminal hair growth, particularly on the face, trunk, forearms and thighs, skin hyperpigmentation, and acanthosis nigricans. Initial biological evaluation showed significantly elevated total testosterone:13.87 nmol/l(reference range 0.10-1.42) and estradiol: 39 pg/ml (postmenopausal <10) with FSH and LH at the lower limit of normal values. Serum ACTH, cortisol, DHEAS, TSH, prolactin, and 17-OH-progesterone were within the normal range, while IGF-1 and random GH levels were elevated (IGF1 $=$ 308 ng/ml, reference range <225, 24 hours random serum GH between 1 ng/ml and 2.15 ng/ml). After undergoing a long dexamethasone suppression test (5 days, 4x0.5 mg/d), serum cortisol was adequately suppressed (<1.8 mg/dl), DHEAS was suppressed more than 60% but testosterone levels exhibited a paradoxical increase (17.74 nmol/l, N<1.42). Abdominal-pelvic MRI revealed bilateral increased ovarian volume with a 9-mm right ovarian mass and a right adrenal adenoma of 14/9 mm. Alpha-fetoprotein, CA 125, CEA, and CA 19-9 levels were normal. The patient was referred to the Surgery department to undergo bilateral oophorectomy for definitive diagnosis and treatment.
Discussion
Multiple causes of hyperandrogenism may be considered in this case: 1. Adrenal hyperandrogenism/Cushing syndrome – ruled out due to adequate DHEAS and cortisol suppression, 2. Ovarian hyperandrogenism – either hyperthecosis or virilizing ovarian tumor, considering the imaging evidence of enlarged ovaries together with an ovarian mass and high non-suppressible testosterone which make this hypothesis the most likely, 3. Autonomous GH secretion- cannot be ruled out, needing further evaluation after the surgical intervention and optimal control of diabetes mellitus.

Endocrine monitoring when initiating immunotherapy in cancer patients: a quality improvement project

Furhana Hussein[1], Craig Hendry[1], Lubna Etbinah[1], Shoayeb Sarwar[1], Ammar Elnour[1], Hafsah Hussain[1], Sarveswari Selvaseelan[1], Yishen Wang[1], Pauline Leonard[1] & Gideon Mlawa[1]
[1]Barking, Havering, and Redbridge University Hospitals NHS Trust, Romford, United Kingdom, London, United Kingdom

Introduction
Immune checkpoint inhibitors have revolutionised cancer therapy in recent years and as the use of this increases, we have recognised the side effects of developing endocrinopathies. Common endocrinopathies include thyroid disease and hypophysitis. Thus, a protocol is needed to help monitor endocrine disorders when initiating and during immunotherapy for cancer patients to diagnose and manage these endocrinopathies earlier.
Aim
Quality improvement project (QIP) to establish baseline monitoring test for endocrine disorder when initiating immunotherapy for cancer treatment and implementation of new trust guidelines to help aid this.
Method
Retrospective single-centre study looking at baseline test for monitoring of endocrine disorders in patients started on immunotherapy for cancer treatment. Blood test for endocrine disorder monitoring including cortisol levels, Thyroid Function Tests (TFTs) and HbA1c.
Results
Cycle 1: 22 patients identified on immunotherapies including Anti-PD-1 Pembrolizumab (11patients) and anti-PD-L-1 such as Atezolizumab (7patients) and Durvalumab (4patients). Pembrolizumab had 55%cortisol, 73% TFTs and 18%HbA1c checked. Atezolizumab had 71% cortisol, 29% TFTs and 14%HbA1c checked. Durvalumab had 50% cortisol, TFTs and HbA1c checked. After cycle one of QIP an informative departmental teaching was carried out and we developed local trust guidelines to help recommended endocrine test monitoring. Cycle 2 included 80 patients 20 patients on Pembrolizumab 100% had cortisol and TFTs checked but only 30% HbA1c. 20 patients on Atezolizumab 100% TFTs, 70% cortisol and 50% HbA1c checked. 20 patients on Durvalumab 100% TFT, 60% cortisol and 50% HbA1c checked. 20 patients on Nivolumab 100% TFTs, 60% cortisol and 60% HbA1c checked.
Conclusion
The use of immunotherapies in cancer treatment has increased. PD-1 inhibitors are commonly associated with thyroid abnormalities (5-10%) and can occur 4-10weeks after initiation of treatment. Diabetes Mellitus (DM) incidence of 1% including new-onset type1 DM or worsening type2 DM. CTLA-4 inhibitors are commonly associated with hypophysitis (3-6%) and usually present in 8-10weeks of initiation of treatment. Our QIP showed in the first cycle more information and awareness were needed for patients and clinicians on complications of developing endocrinopathies and the need of monitoring this. Repeat cycle showed increase in baseline endocrine blood test when initiating immunotherapy with TFTs at 100% tested. Our team developed local trust guidelines for baseline endocrine monitoring for patients on immunotherapy treatment. We plan to repeat our study in 6months time with a larger sample size and looking at 3months monitoring of endocrine blood test to see if any patients developed endocrinopathy complications.

Large pheochromocytoma and primary hyperparathyroidism associated with a rare mutation in the succinate dehydrogenase a (SDHA) gene

Priya Vasan[1], Nikita Ivanov[1] & Maya Peltsverger[1]
[1]Novant Health New Hanover Regional Medical Center, Internal Medicine, Wilmington, United States

Background
Pheochromocytoma/Paraganglioma (PHEO/PGL) and primary hyperparathyroidism (PHPT) are rare endocrine disorders with distinct etiologies. While PHEO commonly arises from neural crest-derived adrenal chromaffin cells, PHPT typically results from hyperactive parathyroid adenomas. Germline mutations in succinate dehydrogenase (SDH) genes, particularly SDHA, SDHB, SDHC, and SDHD, are implicated in the pathogenesis of PHEO/PGL. SDHA gene mutations are rare and not well characterized, with limited evidence linking them to primary hyperparathyroidism. We present the case of a young woman with concurrent PHEO and PHPT, harboring a novel heterozygous germline SDHA gene mutation.
Case Presentation
A woman in her early 40s presented with recurrent abdominal pain, profound anemia (hemoglobin: 5.6 g/dl), hypercalcemia (ionized calcium: 1.41 mmol/l), and significantly elevated parathyroid hormone (iPTH: 317.5 pg/mL). A large left sided renal mass was identified on an abdominal CT scan. Surgical pathology confirmed a 16.3 cm PHEO, displaying typical zellballen architecture and positive immunohistochemical staining for synaptophysin, chromogranin, and vimentin. Persistent hypercalcemia and elevated iPTH levels led to a neck ultrasound, which revealed a 1.9 x 0.8 x 1.2 cm hypoechoic, hypervascular nodule adjacent to the left thyroid lobe, suggestive of a parathyroid adenoma. Subsequent surgical removal of two hyperplastic parathyroid adenomas normalized serum calcium levels. Genetic testing identified a novel heterozygous germline SDHA gene mutation (p.E640G, c.1919 A$>$G), classified as a variant of unknown significance (VUS), contributing to the expanding spectrum of SDHA-related disorders. Over a seven-year follow-up period, the patient demonstrated an indolent clinical course, with no evidence of metastasis despite the large size of the initial PHEO. Serial PET-CT imaging (F-FDG and Ga-DOTATATE) and normal plasma metanephrines consistently showed no signs of disease progression. To date, the coexistence of PHEO and PHPT associated with SDHA gene mutations has not been previously documented. Additionally, the indolent course during an extended follow-up period is particularly significant, as it contrasts with the typically aggressive course often observed in SDHA-related PHEO/PGL.
Conclusion
This unique case highlights the importance of genetic testing in atypical presentations of endocrine neoplasms to understand risk of disease progression and guide surveillance. Further research is warranted to clarify the role of novel SDHA gene variants in coexisting endocrine disorders.

Background

Congenital gonadotropin (GN) deficiency is a condition that falls under the umbrella of hypogonadotropic hypogonadism (HH). The defect may occur either in the hypothalamus or the pituitary. Congenital GN deficiency can be a characteristic feature of several disorders: (i) congenital hypogonadotropic hypogonadism (CHH), further classified into normosmic CHH (nCHH) or Kallmann syndrome (KS); (ii) combined pituitary hormone deficiency (CPHD); and (iii) other GN deficiency associated syndromes (*e.g.* CHARGE syndrome, septo-optic dysplasia [SOD]). Herein, we investigated the clinical and genetic overlap between these clinical entities.

Methods

All probands with congenital GN deficiency ($n=571$) underwent detailed phenotyping. Pathogenic (P), likely pathogenic (LP), and variants of unknown significance (VUS) were depicted for known CHH and CPHD genes in respective conditions. Further, oligogenicity was assessed in the CHH cohort and controls ($n=601$). Genetic overlap between CHH, CPHD and syndromic GN deficiency was further studied.

Results

276 KS, 248 nCHH, 29 CPHD, and 18 syndromic GN deficiency were included in the study. In addition to HH, skeletal anomalies, cleft lip and palate, and dental agenesis were observed in all subgroups. Notably, altered sense of smell and robust GN response to LHRH test in CPHD patients were observed. 53% of KS probands harbored rare variants in CHH genes (40% were P/lP, 13% VUS); while 33% of nCHH probands carried rare variants in CHH genes (23% P/lP, 10% VUS). *FGFR1, ANOS1* and *PROKR2* in KS and *FGFR1*, *GNRHR* and *TAC3R* in nCHH were the most mutated genes. Oligogenicity occurs in 25% of CHH probands with *DMLX2*, *FGFR1*, and *PNPLA6* being significantly involved in gene pairings. Almost 10% of CHH patients without genetic diagnosis carried rare variants in CPHD genes (*e.g. DCHS2*, *FAT2* and *CDON* in KS as well as *ROBO1, FAT2*, *DCHS2* and *KCNQ1* in nCHH). Additionally, CHH genes (*e.g. FGFR1*, CHD7 and *FGF8*) were mutated in CPHD and syndromic GN deficiency.

Conclusion

Herein, we demonstrated: (i) clinical and genetic overlap between patients exhibiting GN deficiency; (ii) altered sense of smell and robust response to LHRH test in CPHD suggesting a dual defect (pituitary and hypothalamus); (iii) 25% of oligogenic inheritance in CHH; and (iv) novel putative CPHD genes (*ROBO1, DCHS2, FAT2* and *KCNQ1*) in CHH.

The roles of PDLIM1 in silent corticotroph adenomas aggressiveness

Merisa Abusdal[1,2,3], Maren Wessel[1,2,3], Jens Petter Berg[2,4], Tuula Anneli Nyman[5], Jens Bollerslev[1,2] & Nicoleta Cristina Olarescu[1,2,3]

[1]Section of Specialized Endocrinology, Department of Endocrinology, Oslo University Hospital (OUS), Oslo, Norway; [2]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway; [3]Research Institute of Internal Medicine, OUS, Oslo, Norway; [4]Department of Medical Biochemistry, OUS, Oslo, Norway; [5]Department of Immunology, OUS and University of Oslo, Oslo, Norway

Objective

Recognised by aggressive behaviour, silent corticotroph adenomas (SCA) represent up to 15% of non-functioning pituitary neuroendocrine tumours (PitNETs). Clinical presentation is usually related to tumour volume without hypercortisolism-related symptoms. We have previously shown that gene and protein levels of PDZ and LIM domain 1 (PDLIM1) are significantly upregulated in SCA when compared with normal functioning corticotroph adenomas (FCA) [1]. PDLIM1 plays important roles in cellular homeostasis and cytoskeletal organization, affecting morphological changes and migration. Tumorigenesis-related role is divergent, being a contributor in gastric cancer, glioma, and breast cancer, but a protector in colorectal and hepatocellular carcinoma. We hypothesized that PDLIM1 is involved in the aggressiveness of SCA. We aimed to assess the roles of PDLIM1 in corticotroph adenomas' aggressiveness and identify the responsible mechanisms.

Methods

Clinical, biochemical and imaging characteristics were obtained from a cohort of 50 patients (17 SCA and 33 FCA). *PDLIM1* gene expression was measured by RT-qPCR in tumour tissue. AtT-20 mouse pituitary corticotroph tumour cells were transfected with pCMV6-Entry plasmid containing *Pdlim1,* and three clones with stable Pdlim1 overexpression were selected by western blotting, expanded and used in CCK-8 cell proliferation and transwell migration assays. Furthermore, quantitative label-free mass spectrometry (MS)–based proteomics analysis was performed on cell lysate of each clone and wild-type (WT) AtT-20.

Results

SCA was larger in size than FCA (max diameter mean 26 vs 7 mm, $P<0.005$). All of SCA were macroadenoma ($n=17$), whereas FCA were both macro- and microadenoma ($n=11$ and 22, respectively). SCA expressed higher *PDLIM1* expression as compared to FCA ($P<0.01$). All selected clones with stable *Pdlim1* overexpression showed morphological changes: each contained suspension cell clusters, floating or hanging with adherent groups. Some adherent parts exhibited string-like fibroblastic appearance. The clones showed increased proliferation and migration ($P<0.0001$) as compared to WT cells. Proteomics analyses showed upregulation of Pdlim1, Igfbp4, Itgb3, Pcsk1n and Stc1 in all clones ($P<0.05$, for all). Furthermore, two clones showed upregulation of Ctsb, Igfbp5, Mcam, and Plin2 ($q<0.05$, for all). Ctsb, Igfbp4/5, Itgb3, Mcam and Stc1 are known to be involved in migration, invasion, and proliferation in other tumours. Pathway analyses showed activation of regulation of Insulin-like growth factor transport whereas lipid metabolism by PPARalpha, cholesterol biosynthesis, and gene expression activation by SREBP were inhibited.

Conclusion

PDLIM1 is upregulated in SCA and seems to contribute to proliferation and migration of corticotroph tumour cells.

Severe hyponatraemia in Europe: insights into endocrinologists' clinical practices and perspectives

Muhammad Fahad Arshad[1], Julia Beck[2], Ahmed Iqbal[3] & Mirjam Christ-Crain[2]

[1]University of Sheffield, Sheffield Teaching Hospitals, Endocrinology, Sheffield, UK; [2]University Hospital Basel, University of Basel,

Endocrinology, Basel, Switzerland; [3]University of Sheffield, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK

Background
The European Society of Endocrinology (ESE) guidelines (2014) recommend a bolus-wise strategy using hypertonic saline (HTS) for treatment of severe symptomatic hyponatraemia. The aim of treatment is to raise serum sodium by $\leq$10 mmol/l in first 24 hours[(1)]. However, there are recent controversies regarding risk of overcorrection and osmotic demyelination syndrome (ODS)[(2)], leading to significant heterogeneity in practice[(3)].
Aim
To evaluate the clinical practices and perspectives of endocrinologists across Europe in managing severe symptomatic hyponatraemia.
Methods
A web-based anonymous cross-sectional survey, endorsed by ESE, was disseminated to ESE members between 28/06/24 and 31/12/24 via email, newsletter and social media. The survey consisted of 13 multiple-choice questions and was developed using REDCap®. Data was analysed using R-Studio (version 4.4.2).
Results
A total of 642 responses were received. After excluding incomplete and non-European responses, 422 responses form 36 countries were analysed. 79.4% (n=335) responses were from endocrinology followed by Internal Medicine (10.9%) and emergency medicine (6.2%). Most responses were received from university hospitals (70.9%) and by senior clinicians i.e. professors/consultants (66.8%). Most clinicians (32%) had experience using both bolus and continuous infusions in managing severe symptomatic hyponatraemia while sole bolus or continuous infusion therapy was preferred by 29.9% and 23.7%, respectively. For those with experience of bolus therapy (n=113), preferred volumes of infusions were 100 mL (26.8%) and 150 mL (19.2%), while 4.5% preferred a weight-based dosage. 24-hour target sodium rise was defined as $\leq$8 mmol/l and $\leq$10 mmol/l by 38% and 37.8% of the respondents, respectively. In absence of seizures, most (83.9%) clinicians preferred one bolus infusion followed by a blood test before repeating a second, while 85.8% had at least some experience with using venous blood gas sodium with HTS use. 34.3% respondents had encountered $\geqq$1patient with suspected or confirmed ODS in their practice, while 54.9% reported association of ODS with sodium overcorrection.
Conclusion
This is the first European survey on severe symptomatic hyponatraemia management, offering insights into real-life practice. Our survey underlines that **first**, there is significant variation in practice, **second,** most clinicians prefer a more cautious approach than recommended by guidelines, and **third**, 1/3rd of clinicians have encountered ODS in their clinical practice. The survey results call for future research and an evidence-based review of ESE guidelines.

Piperonyl butoxide: a putative novel endocrine disruptor causing Cushing Syndrome
Lucrezia Rossi[1], Valentino Marino Picciola[1], Alberto Gobbo[1], Flaminia Fanelli[2], Uberto Pagotto[2], Maria Rosaria Ambrosio[1,3] & Maria Chiara Zatelli[1,3]
[1]University of Ferrara, Dept of Medical Sciences, Section of Endocrinology, Ferrara, Italy; [2]University of Bologna, Department of Medical and Surgical Sciences, Bologna, Italy; [3]Endocrine Unit, University Hospital S. Anna, Dept of Medical Sciences, Section of Endocrinology, Ferrara, Italy

Introduction
Cushing's syndrome (CS) is a clinical condition due to exposure to high endogenous or exogenous glucocorticoids (GC). Chronic exposure to exogenous GC is generally associated with a more rapid onset of CS clinical signs as compared to endogenous hypercortisolism, but they share signs and symptoms. 10% of the total annual diagnoses of CS concerns children and the predominant cause are GC used to treat various clinical conditions. Indeed, the use of oral, inhaled, injected, or topical (e.g. creams and ointments) drugs containing GC is the most common cause of exogenous CS. In addition, some "unsuspected" natural formulations may contain GC or compounds with GC-like activity. Therefore, it is fundamental to investigate the use of these products in patients with CS. A 15-year-old girl referred to us for a suspected CS. Adrenocortical axis was suppressed but she denied any previous steroid consumption, and reported a 1-year head-application of an anti-lice spray. The clinical course showed a complete functional recovery after the product's withdrawal. The purpose of this study is to investigate whether the anti-lice product contains compounds with GC-like activity. Anti-lice products are widely used in the pediatric population to treat and/or prevent head lice infestation.
Methods
LC-HRMS was performed to detect the spray components in patient's serum, pyrethrins and piperonyl butoxide (PBO). To evaluate PBO effects, alone or combined with Mifepristone (Mif), we incubated the GloResponse 9XGA-L4UAS-luc2P HEK293 cell line (GloHEK cell) using increasing compound concentrations (from 0,25 mM to 100 mM). The luminescence assay was performed using PBO 10 μM.
Results
PBO levels were high in patient's serum during anti-lice product exposure (~ 50-fold vs. in control). Six months after stopping product application PBO levels were similar to control. PBO did not affect cell number at the concentration employed in the luciferase assay. To verify a possible PBO GC-like activity, we evaluated luminescence emission: PBO significantly increased baseline luminescence by >7-fold ($P < 0.01$). On the other hand, Mif enhanced baseline luminescence by ~2-fold ($P < 0.01$) and potently hampered PBO-induced luminescence ($P < 0.05$).
Conclusions
PBO showed a GC-like activity, by a direct binding to the GR. The latter is demonstrated by the evidence that PBO effects are prevented by co-incubation with the GR antagonist. The prolonged exposure to the anti-lice spray was causing the CS-like appearance in this young girl.

The personality profile and neurostructural associations in patients with cushing's disease
Cem Sulu[1], Burc Poyraz[2], Serdar Arslan[3], Hande Mefkure Ozkaya[1] & Pinar Kadioglu[1]
[1]Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Endocrinology-Metabolism, and Diabetes, Istanbul, Türkiye; [2]Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Psychiatry, Istanbul, Türkiye; [3]Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Neuroradiology, Istanbul, Türkiye

Objective
To explore the personality profile and behavior of patients with Cushing's disease (CD) and their neurostructural correlates.
Methods
This study included CD (n = 38) and control (n = 29) groups. Controls were selected from volunteers who applied to hospital for routine tests between 2021-2022. Volunteers with signs suggestive of CD, exposed to glucocorticoids, and had uncontrolled diabetes and/or hypertension were excluded. Group-matching was performed for age, sex, and education. Psychometric assessments included Temperament and Character Inventory (TCI), Symptom Checklist-90-Revised (SCL-90-R), Buss-Perry Aggression Questionnaire (BPAQ), and Apathy Scale. Cortical thickness was examined using 3T magnetic resonance imaging. Surface-based morphometry was employed using the CAT12 toolbox. Least Absolute Shrinkage and Selection Operator (LASSO) was used to identify predictors of personality dimensions.
Results
Psychometric assessments revealed no differences in SCL-90-R (P >0.05 for all domains). TCI scores were similar between groups except for higher persistence in the CD group (6 [4–7] vs. 5 [3.5–6], P = 0.019). Total BPAQ scores were lower in the CD group (51 [46–60.5] vs. 66 [50–80.5], P = 0.011), indicating decreased aggression. Radiological analyses revealed cortical thinning in frontal and parietal regions in CD group. In left hemisphere, the largest cluster (P = 0.039, size = 3,418 voxels) showed thinning predominantly in rostral middle frontal (32%), precentral (14%), postcentral (10%), and superior frontal (10%) cortices. Thinning in this cluster was negatively correlated with cortisol (r=-0.528, P = 0.024), adrenocorticotropic hormone (ACTH) (r=-0.641, P = 0.004), and urinary free cortisol (UFC) (r=-0.546, P = 0.022). In right hemisphere, two clusters were identified. Cluster 1 (P = 0.026, size=6,098 voxels) predominantly involved the rostral middle frontal (23%) and superior frontal (19%) regions. Right Cluster 1 thinning was negatively correlated with cortisol (r=-0.538, P = 0.021), ACTH (r=-0.604, P = 0.008), and UFC (r=-0.474, P = 0.047). Right Cluster 2 (P = 0.037, size=5,481 voxels) exhibited thinning in the inferior parietal (22%), superior parietal (20%), and precuneus (16%) cortices. Thinning in right Cluster 2 correlated negatively with serum cortisol (r=-0.581, P = 0.011) and ACTH (r=-0.721, $P < 0.001$). LASSO analysis identified the CD, older age, and cortical thinning in Cluster 1 as

predictors of reduced aggression. Thinning Cluster 1 emerged as the strongest predictor of lower aggression.
Conclusion
CD might promote persistence and suppress aggression. Neuroimaging revealed thinning in bilateral frontal and right parietal cortex in CD group. Neurostructural changes became more evident with higher cortisol levels. Thinning in the right rostral middle frontal, superior frontal, and precentral gyri emerged as determinants of aggression, highlighting the role of neurostructural changes in shaping behavior in CD.

PitNETs aggressiveness is currently assessed based on clinical and histological criteria, leading to regularly updated classifications. The role of molecular criteria has yet to be defined. Multi-omics analyses show the importance of lineage as the main driver of unsupervised classifications. Aggressive PitNETs appear to be scattered according to their lineage without forming a distinct molecular group.
Aim
Identify genomic features associated with PitNETs aggressiveness.
Methods
• Five features of aggressiveness were explored: post radiotherapy progression, rapid tumor progression speed, Ki67 $\geqslant$ 10%, cavernous invasion and sphenoid invasion. A cohort of 155 tumors with or without these features were analysed by transcriptome, methylome, SNP array and NGS sequencing.
• Transcriptome and methylome signatures associated with features of aggressiveness were established by logistic regression stratified by lineage.
• Response to temozolomide was evaluated on 17 samples collected before temozolomide treatment, following RECIST criteria. Transcriptome signatures of temozolomide response were assessed with a differential gene expression analysis.
Results
Post radiotherapy progression, rapid tumor progression speed, and Ki67 $\geqslant$ 10% were associated with distinct transcriptome signatures linked to RNA metabolism in TPIT lineage, and to proliferation and cell motility in PIT-1 lineage. Post radiotherapy progression and rapid progression speed were associated with tumor hypermethylation. The latter was not associated with any specific location related to gene structures. Post radiotherapy progression, rapid tumor progression speed, and Ki67 $\geqslant$ 10% were associated with a group of tumors cumulating pathogenic somatic variants, including *TP53, CDKN2A/B, DAXX, MEN1,* and *PTEN*. Reversely, *USP8* and *GNAS* mutations weren't associated with any feature of aggressiveness, in TPIT and in PIT1 lineages, respectively. Cavernous and sphenoid invasion were not associated with any molecular signature. Response to temozolomide was associated with a leukocyte migration and differentiation transcriptome signature. O-6-methylguanine-DNA methyltransferase gene (*MGMT*), which promoter methylation and expression was proved to be predictive of temozolomide response in gliomas, was found underexpressed in responders compared to non-responders through transcriptome analysis. Longitudinal samples omics highlight genomic alterations already present in the earliest samples of tumor progressions. Alteration evolution also shows chromosomal rearrangements generating new aggressive clones.
Conclusion
PitNETs accumulating features of aggressiveness are associated with specific genomic markers. The prognostic value of these potential markers remains to be confirmed in an independent cohort.

Short-term efficacy of Stanozolol or recombinant human Growth hormone in CPP or EFP boys with excessive growth deceleration during GnRHa treatment

Jia-Shuan Huang[1], Song Guo[1], Yan-Hong Li[1], Hua-Mei Ma[1], Jun Zhang[1] & Qiu-Li Chen[1]
[1]Division of Pediatric endocrinology, The First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China., Guangzhou, China

Background
Gonadotropin-releasing hormone analogue (GnRHa) being the standard treatment for boys with central precocious puberty (CPP) or early fast puberty (EFP), but a considerable proportion will experience significant growth deceleration. Although combining growth hormone (GH) can counteract it, studies in boys are limited. Stanozolol (ST) offers a promising alternative, yet its efficacy remains understudied. We evaluate the short-term efficacy of GH or ST in CPP or EFP boys experiencing growth deceleration during GnRHa treatment.
Methods
Boys diagnosed with CPP or EFP who experienced excessive decline in growth velocity (GV, $<$ 5 cm/year) after receiving standard GnRHa treatment at the First Affiliated Hospital of Sun Yat-sen University (2000-2024) were included. Eighty-four boys were divided into three groups base on the therapy thereafter: GnRHa monotherapy (Group 1, $n = 40$), GH combined with GnRHa (Group2, $n = 25$), and ST combined with GnRHa (Group 3, $n = 19$). We assessed growth velocity (GV), predicted adult height (PAH), bone age (BA), IGF-1 levels, gonadal axis parameters, and glucose-lipid metabolism at baseline and at the sixth month.
Results
After six months, GV significantly increased in Group 2 [from 3.6 (1.2) to 7.2 (2.9) cm/year] and Group 3 [from 3.6 (1.7) cm/year to 7.1 (2.5) cm/year] compared to the Group 1 [from 4.4 (1.2) cm/year to 4.7 (1.8) cm/year] ($P < 0.001$ for all comparisons). PAH also significantly increased in Group 2 and 3 compared to the Group 1 ($\triangle$PAH, Group 1: 1.4 $\pm$ 1.9 cm, Group 2: 3.7 $\pm$ 2.7 cm, Group 3: 3.3 $\pm$ 2.0 cm; $P < 0.001$ for all comparisons). There was no significant difference in change of GV or PAH between the Group 2 and 3 ($P = 0.930$ for GV, $P = 0.577$ for PAH). Changes in GV were not correlated with changes in serum IGF-1 or sex hormone levels. The changes in BA in three groups were all 0.0 (0.3) years ($P = 0.895$). The Group 2 showed increased fasting insulin (from 9.8 $\pm$ 4.2 to 12.8 $\pm$ 6.4 uU/mL, $P = 0.021$) and HOMA-IR (from 2.1 $\pm$ 0.9 to 2.8 $\pm$ 1.5, $P = 0.026$), while Group 3 showed decreased HDL-C levels (from 1.4 $\pm$ 0.4 to 1.2 $\pm$ 0.3 mmol/l, $P = 0.042$).
Conclusion
Both rhGH and ST effectively reversed growth deceleration and improved PAH without accelerating BA in CPP or EFP boys with excessive growth deceleration during GnRHa treatment, but may differentially impact glucose or lipid metabolism. Further researches are needed to follow up to their adult final height.

[1]Aix Marseille University, Assistance Publique-Hôpitaux de Marseille, Marseille, France; [2]Assistance Publique-Hôpitaux de Marseille, Marseille, France; [3]Assistance Publique-Hôpitaux de Paris AP-HP, Paris, France; [4]Hospices Civils de Lyon, Lyon, France; [5]Havre's Hospital, Le Havre, France; [6]University Hospital of Angers, Angers, France; [7]University Hospital of Lille Department of Endocrinology, Lille, France; [8]University Hospital of Nice-Lenval Hospital, Lille, France; [9]University Hospital of Bordeaux Department Endocrinology, Bordeaux, France; [10]Niort Hospital, Niort, France; [11]University Hospital of Nantes, Nantes, France; [12]Assistance Publique-Hôpitaux de Marseille, Aix Marseille university, MArseille, France; [13]Assistance Publique-Hôpitaux de Marseille, Aix Marseille university, Marseille, France

Aim
The objective of this study is to analyze the phenotype and genotype of patients diagnosed with congenital hypopituitarism and pathogenic *GLI2* variants.

Methods
A large cohort of patients with hypopituitarism was screened for *GLI2* variants using a next-generation sequencing panel. Genotype-phenotype correlations were then assessed using GENHYPOPIT phenotypic data.
Results
Pathogenic or likely pathogenic variants in *GLI2* were identified in 17 out of 59 mutations reported from 717 index cases. *GLI2* mutations were identified exclusively in patients with associated pituitary stalk interruption syndrome or extrapituitary signs ($n = 440$), representing the most frequent identified genetic cause in patients with syndromic pituitary deficiency. *GLI2* variants were the most frequent identified genetic cause in patients with syndromic hypopituitarism (68%): 88% (15/17) of mutations were truncating variants, and 45% were *de novo*. Most patients with a *GLI2* variant (21/23, 91%) had hypopituitarism, including 21.7% (5/23) presenting isolated growth hormone deficiency. Two patients had Kallman syndrome. Pituitary morphological abnormalities were present in 84% of the patients with pathogenic *GLI2* variants (index cases and affected relatives). The remaining signs included neurocognitive disorders (38%), hexadactyly (27%), cardiac septal defects and renal/vesical abnormalities. A possible digenic origin (*GLI2*/*HESX1*) is proposed in one family.
Conclusion
GLI2 has been identified as the most frequent genetic cause in congenital pituitary deficiency with pituitary stalk disruption syndrome or extrapituitary clinical feature. In addition to the commonly associated polydactyly and neurodevelopmental disorder, cardiac and renal abnormalities were frequently observed in these patients and should be investigated further. The variable expression of GLI2-associated phenotypes justifies further research in this area.

[18F]Fluorethyltyrosine positron emission tomography for localisation of corticotroph pituitary adenomas in the initial evaluation of Cushing's disease

Friederike Völter[1,2], Júnia Ribeiro de Oliveira Longo Schweizer[1], Isabel Stüfchen[1], Katrin Ritzel[1], Stephanie Zopp[1], Rudolf Werner[2], Jun Thorsteinsdottir[1], Martin Reincke[1] & Nathalie Albert[2]
[1]LMU Hospital, Department of Endocrinology, Diabetes and Metabolism, Munich, Germany; [2]LMU Hospital, Department of Nuclear Medicine, Munich, Germany

Introduction
The preoperative localisation of ACTH-producing pituitary adenomas remains challenging. Magnetic resonance imaging correctly visualize up to 75% of ACTH-producing adenomas. In many patients, pituitary exploration has to be performed, with a risk of unnecessarily extensive resection, increasing the risk of postoperative pituitary insufficiency, or incomplete tumor removal, resulting in persistent disease. We therefore aimed to evaluate the potential of [^{18}F]Fluorethyltyrosine positron emission tomography ([^{18}F]FET PET/CT) in localising ACTH-producing pituitary adenomas in patients with first diagnosis of Cushing's disease.
Methods
[^{18}F]FET PET/CT was conducted in all consecutive patients with a primary diagnosis of Cushing's disease at LMU Hospital between June and December 2024 in addition to a preoperative MRI and inferior petrosal sinus sampling. Dynamic PET images were acquired 0-40 min after injection with a mean injected dose of 173 MBq. Maximal tumor-to-background ratios (TBR_{max}) were determined comparing maximum standardized uptake values of pituitary adenomas to mean standardized uptake values of the right frontal and temporal lobe. Numeric values were reported with median (interquartile range).
Results
A total of 10 patients were included, 5 with microadenoma, 2 with macroadenoma, 3 with no visible lesion on MRI. All patients had inferior petrosal sinus sampling confirming a pituitary origin of ACTH excess. The median preoperative ACTH level was 55.5 pg/mL (50.3-89.0), the median preoperative basal cortisol was 23.6 µg/dl (13.7-29.7). In all patients, dynamic [^{18}F]FET PET/CT revealed a focal intrasellar hotspot indicating a pituitary adenoma (median TBR_{max} 3.2; 2.4-3.6). 6/10 patients underwent transsphenoidal surgery until January 2025. In all operated patients, the focal intrasellar hotspot was consistent with the histopathologically proven corticotroph adenoma. 2 patients are still awaiting surgery, 1 patient refused surgery, 1 patient postponed surgery due to hospitalisation for severe depression. All operated patients showed a postoperative remission with a median basal ACTH of 6.0 pg/mL (4.5-20) and basal cortisol of 1.1 µg/dl (0.4-3.1). No patient experienced a postoperative anterior pituitary insufficiency.
Conclusion
Functional imaging with [^{18}F]FET PET/CT can be effective in localising ACTH-producing pituitary adenomas and can add valuable information to MRI and inferior petrosal sinus sampling.

Overphosphorylation of the LKB1 signalling pathway proteins in sparsely granulated somatotropinomas

Vaishali Kaur[1], Debajyoti Chatterjee[2], Apinderpreet Singh[3], Sivashanmugam Dhandapani[3], Soham Mukherjee[1], Sandeep Mohindra[3], Ansh Sukhija[4], Dibyajyoti Banerjee[5], Ashutosh Rai[4] & Pinaki Dutta[1]
[1]PGIMER, Chandigarh, Department of Endocrinology, Chandigarh, India; [2]PGIMER, Chandigarh, Department of Histopathology, Chandigarh, India; [3]PGIMER, Chandigarh, Department of Neurosurgery, Chandigarh, India; [4]Panjab University, Department of Biochemistry, Chandigarh, India; [5]PGIMER, Chandigarh, Department of Experimental Medicine and Biotechnology, Chandigarh, India

Background
Somatotropinomas are histopathologically divided into sparsely (SG) and densely granulated (DG). SG exhibits aggressive clinical behaviour (presentation at a younger age, high proportion of invasiveness, resistance to treatments and recurrence (inspite of complete removal) as compared to DG. Dysregulation of LKB1-AMPK pathway can support tumour survival and growth by promoting autophagy and providing an adaptive response to a nutrient-poor microenvironment.
Method
High-throughput label-free quantitative mass spectrometry-based (Orbitrap Exploris mass spectrometer, Thermo Scientific) phosphoproteomics analysis was performed on SG ($n = 4$) and DG ($n = 4$) tumours in triplicates. Candidates of significantly enriched pathways (cut-off = 1.5fold-change) were considered for validation by immunohistochemistry ($n = 32$; SG = 24, DG = 8) on tissue microarray in separate group of samples.
Results and Discussion
In our data (total = 10418) 835 over and 4246 under phosphorylated proteins were detected. There was significant over-phosphorylation of 85 proteins in the LKB1-AMPK pathway (fold enrichment = 1.8, $P = 2.2E-09$) in SG tumours. Commercially available antibody guided the selection of four candidates TSC1 Ser1080, AMPKβ Ser108, MAPT Thr548, and ULK1 Ser638 for IHC. Over-phosphorylation of AMPKβ Ser108 (6.0-fold, $P = 0.01$) suggests metabolic adaptation to energy stress. Increase in TSC1 Ser1080 phosphorylation (9.5-fold, $P = 0.01$) implies inhibition of the TSC complex, potentially activating mTOR signalling and promoting anabolic processes in SG tumours. Over-phosphorylation of MAPT at Thr548 (3.8-fold, $P = 0.02$) suggests enhanced cytoskeletal dynamics, which can potentially facilitate invasion. ULK1 Ser638 phosphorylation showed increase (1.8-fold) phosphorylation. Ratio of Phosphorylated ULK1 Ser638 to Total ULK1 was significantly increased in SG tumours ($P = 0.01$). This trend may indicate autophagic adaptation to metabolic stress. Upstream analysis identified PRKAA1 and GSK3β as regulators of AMPKβ Ser108 and MAPT Thr548, respectively, mTOR phosphorylates TSC1 Ser1080 and ULK1 Ser638. IHC confirmed increase in mTOR expression in SG tumours (2.66-fold $P = 0.003$) compared to DG, underscoring mTOR's role in SG tumours. We observed significant correlation of AMPKβ Ser108 phosphorylation with MAPT Thr548 ($r = 0.7$, $P = 0.0001$) and TSC1 Ser1080 ($r = 0.59$, $P = 0.002$) phosphorylation. ULK1 Ser638 phosphorylation levels significantly correlated ($r = 0.5$, $P = 0.01$) with mTOR levels. Age was found to be inversely correlated with MAPT Thr548 (r = -0.5, $P = 0.01$) and ULK1 Ser638 (r = -0.4, $P = 0.02$). Maximum tumour diameter showed significant positive correlation with ULK1 Ser638 ($r = 0.5$, $P = 0.01$) and mTOR expression (0.4, $P = 0.03$) levels while tumour volume was found to be correlated with mTOR expression only ($r = 0.6$, $P = 0.02$).
Conclusions
Our results reveal a coordinated network of mTOR signalling complemented by PRKAA1-mediated AMPK activation and GSK3β-driven cytoskeletal remodelling in SG tumours.

The endowatch – developing an 'external hypothalamus' to support patients (and their parents) with hypothalamic dysfunction

Sanne Hulsmann[1], Sarah Petras[1], Yuan Lu[2], Yu Zhang[2], Philippe Fraboulet[3] & Hanneke van Santen[1,4]

[1]Princess Máxima Center, Utrecht, Netherlands; [2]Eindhoven Technical University, Eindhoven, Netherlands; [3]Corsano Health B.V., Den Haag, Netherlands; [4]Wilhelmina Children's Hospital, UMC Utrecht, Utrecht, Netherlands

Background

Children and adults with a suprasellar (hypothalamic) brain tumor often have excellent survival, but poor outcome due to hypothalamic dysfunction (HD). The hypothalamus, as the key regulator of the body, regulates the anterior pituitary gland, core body temperature, circadian rhythm, sodium and energy balance. Patients with HD experience chronic fatigue, recurrent headaches and inactivity due to hypothalamic imbalances. Patients and families urge us to find a solution because they are overwhelmed by the effort to detect and prevent these imbalances early, as if they were the patient's "external hypothalamus". In this project, we aim to develop a smart wearable that can act as an "external hypothalamus" for patients with HD. This wearable must be available 24/7 and continuously monitor body temperature, stress, sleep, daily activity in order to offer support to patients and their families in the management of HD. The aim is to improve outcomes and self-management, and to relieve caregivers.

Methods

By a multidisciplinary team from the Princess Máxima Center, Eindhoven University of Technology and Corsano Health B.V., the Corsano EndoWatch was developed. The EndoWatch consists of a smart wristband that communicates with a phone application via Bluetooth, visualizing measurements to enable continuous health-monitoring. Between June – August 2024, a first pilot study was performed with 10 patients with HD ($n = 8$ <18 y.o, $n = 2 \geq 18$ y.o), evaluating the adherence (% of hours per day the device was worn by the patient). Usability and desirability of the device were measured by questionnaire and a semi-structured interview.

Results

Adherence was shown to be satisfactory. The device was worn >80% of hours per day by 8/10 patients. Usability and desirability of the device were positively assessed. All families reported that they desire to use this device in the future, provided that certain adjustments are made. The most frequently reported suggestion for improvement was to enable remote monitoring for caregivers on a second interface.

Conclusion

Patients and parents appreciate the development of the EndoWatch that may serve as "external hypothalamus". We will open a second clinical study in May 2025, including 50 patients ($n = 40$ <18 y.o, $n = 10 \geq 18$ y.o) with HD, incorporating the suggested approvements that were reported in the pilot study. The primary outcomes of this study are patient reported experiences (PREs) assessed by mid-study (3 months) and end-study questionnaires (6 months). The PREs will play a central role in the further development and certification process of the EndoWatch.

Survival in patients with pituitary carcinoma

Oksana Hamidi[1,2], Dana Erickson[1], Jamie VanGompel[3], Candace Dalpiaz-Spietz[4], John Atkinson[3], Mabel Ryder[1], William Young[1] & Diane Donegan[1]

[1]Mayo Clinic, Division of Endocrinology, Diabetes and Metabolism, Rochester, United States; [2]UT Southwestern, Endocrinology Diabetes and metabolism, Dallas, United States; [3]Mayo Clinic, Department of Neurosurgery, Rochester, United States; [4]Mayo Clinic, Department of Oncology, Rochester, United States

Introduction

Pituitary carcinoma (PC) is defined as the presence of metastasis (craniospinal or systemic) from a pituitary tumor. Given the rarity of PC, limited information regarding survival and factors which may influence survival is available in literature.

Aim

To assess overall survival following detection of metastatic disease in patients with PC and to determine factors associated with clinical outcomes in these patients.

Methods

All patients with PC diagnosed between 1997 and 2024 were identified using the Mayo Data Explorer. Information regarding patient demographics, tumor characteristics, management, and outcomes was extracted.

Results

25 patients (56% male) were included; mean age at initial pituitary adenoma (PA) diagnosis was 50 $\pm$ 11.9 years. PA size at initial diagnosis was 2.1 $\pm$1.3 cm, 18 (72%) of which were functioning tumors. Surgery was the initial treatment in 24 (96%) patients. Radiation therapy (RT) was used in 25 (100%) cases with a median time to RT of 12 months (range 0-239). Median time to metastasis diagnosis was 6 (range 1-32) years, mean age of 59 $\pm$10.6 years. The most common site of metastasis was bone in 13 (52%) patients, followed by central nervous system (CNS) and spine in 12 (48%). Systemic therapy alone (temozolomide, CVD [cyclophosphamide, vincristine, dacarbazine], etoposide/-cisplatin, pembrolizumab or lutetium Lu 177 dotatate) was used in 6 (24%) patients, local treatment alone (radiotherapy, cryoablation or metastasectomy) was used in 9 (36%) of patients, combination treatment (locoregional and systemic therapy) in 8 (32%), and no additional treatment in 2 (8%). Median follow-up was 1.7 years (range 0.1-15.5). At last follow-up, 11 (44%) patients were alive, 11 (44%) died of PC, and 3 (12%) died from othercauses. The median survival time of patients from the identification of metastasis was 4 years. The 1-, 5- and 11-year survival rates were 70%, 37% and 13%, respectively. No difference in survival was seen according to metastasis site (CNS vs distant metastasis), corticotroph vs other PC cell type or treatment before or after 2010. Improved survival correlated with temozolomide (TMZ) treatment ($n = 9$) compared to those not treated with TMZ ($P=0.048$) and in nonfunctional compared ($n = 7$) to functional tumors ($P=0.048$).

Conclusion

This study demonstrates that survival among patients with PC is higher among those who received temozolomide and if the tumor was nonfunctioning. Despite current treatment modalities 5-year survival was poor (37%). Additionally, there is a lag between PA and PC diagnosis (6 years) emphasizing the importance of long-term follow-up.

A mouse luteinizing hormone-blocking monoclonal antibody; development and in vivo proof of blocking capacity

Ida Marie Boisen[1], Benedicte Probst-Drejer[1], Nadia Krarup Knudsen[1], Hanne Frederiksen[2], Anders Juul[2], Anne Jørgensen[1] & Martin Blomberg Jensen[1]

[1]Copenhagen University Hospital, Herlev-Gentofte, Department Endocrinology and Internal Medicine, Herlev, Denmark; [2]Rigshospitalet, Department Growth and Reproduction, Copenhagen, Denmark

Introduction

To examine the effect of blocking Luteinizing hormone (LH) in several endocrine disorders, a mouse monoclonal antibody against the β-subunit of LH was developed. Here, the *in vitro* and *in vivo* validation of the LHβ-specific antibody is presented.

Materials and Methods

The LHβ-specific antibody was generated by immunizing mice using a recombinant protein fragment corresponding to amino acids S21-L141aa of mouse LH. For *in vitro* validation of the LHβ-antibody we used enzyme-linked immunosorbent assay (ELISA) and immunohistochemistry (IHC). For *in vivo* validation of the blocking capacity of the LHβ-antibody, male mice were treated with vehicle, GnRH agonist (Leuprorelin, 1.5 mg/kg), or co-treated with GnRH agonist + LHβ antibody (0.2 mg). The GnRH agonist were injection on day 2 and 4, whereas the LHβ antibody was injected on day 1-4 or 1+3. LH levels were measured on day 2, 4 and 5 with ELISA and testosterone levels were measured on day 2 and 5 with liquid chromatography– tandem mass spectrometry (LC-MS/MS). To examine whether the LHβ antibody was also efficient in blocking high LH levels, ovariectomized (OVX) mice were treated with vehicle or LHβ antibody on day 1-4 (0.2 mg). Blood samples were taken on day 2,4, and 5.

Results

The LHβ-antibody bound the LH peptide fragment (S21-L141aa) in an ELISA where a goat anti-mouse IgG was used to detect the bound complexes. Additionally, the antibody against the LHβ-subunit specifically stained the gonadotropic cells in the mouse pituitary. To prove the blocking capacity *in vivo*, i.e., whether the LHβ-subunit antibody can block LH-signaling we utilized the fact that a GnRH agonist in male mice initially induces high LH levels and subsequently high testosterone levels. Treatment with LHβ antibody completely reduced LH in all groups at all timepoints. At day 5, LH and testosterone was induced with the GnRH agonist alone compared with vehicle (2.3 vs 0.2 ng/ml

and 64 vs. 7 nmol/l, respectively). Compared with the GnRH agonist alone co-treatment with the LHβ antibody on day 1-4 completely abolished LH and testosterone levels on day 5 (2.3 vs 0.02 ng/ml and 64 vs 1.3 nmol/l, respectively). The LHβ antibody was also efficient in blocking the high LH levels in OVX mice (vehicle = 17.3 vs. LHβ antibody = 0.1 ng/ml).
Conclusion
A specific LH-blocking antibody was successfully generated, and its blocking capacity was demonstrated *in vivo*. In subsequent studies the possible non-gonadal effects of LH will be investigated using this LH-blocking antibody.

Understanding the developmental down-regulation of mkrn3 at puberty through bioinformatics and experimental approaches

Dor Shalev[1], Gil Golan[1], Lilach Pnueli[1], Anat Kahan[2], Yael Mandel-Gutfreund[1] & Philippa Melamed[1]
[1]Technion-Israel Institute of Technology, Biology, Haifa, Israel; [2]Faculty of Agriculture, Hebrew University of Jerusalem, Rehovot, Israel

Makorin Ring Finger Protein 3 (MKRN3) loss-of-function mutations are the most common genetic cause of central precocious puberty. Its expression levels in the brain drop significantly towards puberty, suggesting effects in repressing the central control of reproduction and its role as a childhood "pubertal brake". However, both the nature of this repression and the factors responsible for the drop in MKRN3 levels have remained unclear. To investigate these regulatory pathways, we performed bioinformatic analyses of several developmental RNA-seq datasets from rat and mouse brain, and from rat mediobasal hypothalamus (MBH). We identified genes whose expression levels correlate with those of *Mkrn3* and change specifically across the pubertal transition, potentially encoding regulators of its expression, downstream effectors, or co-regulated genes. In order to detect its up-stream regulators, we filtered this group of *Mkrn3*-correlated genes for those linked to both puberty and signaling. Notably, these included *Acvr1c*, whose expression was strongly negatively correlated with *Mkrn3* in all of the datasets and whose knockout was shown previously to delay puberty in mice. Analysis of single-cell RNA-seq data from mice hypothalamic neurons during development indicated that *Mkrn3* and *Acvr1c* are not expressed simultaneously in the same cell. In experimental models, we demonstrated that activation of Acvr1c in GnRH neuronal cells suppresses *Mkrn3* mRNA levels, and that this is mediated through Smad2/3 signaling. This repression involves recruitment also of the Kap1 transcription factor, and a marked shift from activating to repressive histone modifications at the gene locus. These findings provide a mechanistic explanation for the reduction in Mkrn3 arising from the developmental increase in expression of this receptor which can be activated by various available ligands. Our study highlights the value of integrating high-throughput gene expression data analysis with experimental studies to uncover novel regulatory networks, and have revealed here a new player in the regulation of pubertal onset.

ß-arrestin 2 protein expression correlated with non-functioning pituitary neuroendocrine tumors (NF-PitNETs) *in vitro* responsiveness to dopamine agonists

Federica Mangili[1], Anna Maria Barbieri[2], Genesio Di Muro[2], Donatella Treppiedi[1], Sonia Di Bari[2], Rosa Catalano[2], Marco Locatelli[3,4], Andrea Lania[5,6], Erika Peverelli[1,2] & Giovanna Mantovani[1,2]
[1]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [3]Neurosurgery Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Milan, Italy; [4]University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy; [5]Endocrinology and Diabetology Unit, IRCCS Humanitas Research Hospital, Milan, Italy; [6]Humanitas University, Department of Biomedical Sciences, Milan, Italy

Non-functioning pituitary neuroendocrine tumors (NF-PitNETs) represent the most common subtype of PitNETs after prolactin-secreting ones and are still orphan of an effective pharmacological approach for persistent or recurrent cases. Lot of attention was given to dopamine receptor type 2 (DRD2) agonists (DAs), based on high DRD2 expression levels in NF-PitNETs, but their use in clinic is still controversial, since they efficacy on tumor growth's control is not well demonstrated. β-arrestin2 has been recently identified as possible molecular determinant predicting DAs responsiveness in NF-PitNETs. In fact, its fundamental role in regulating DRD2 inhibitory effects on AKT phosphorylation and cell proliferation in NF-PitNETs has been unveiled, since it has been demonstrated that β-arrestin2 lack prevents the inhibitory effect of DRD2 on AKT pathway activation with a consequent resistance to the antimitotic action of DAs. The aim of this study was to investigate β-arrestin2 expression at both protein and transcript level in human NF-PitNETs, correlating it with their *in vitro* responsiveness to DAs in terms of cell proliferation inhibition. 65 primary cultured NF-PitNET cells have been treated for 72h with 100nM DAs and cell proliferation assay was performed. DAs treatment determined a significative inhibition of cell proliferation (-27.7(20.14),$P < 0.001$) in 26 samples (considered 'responsive' NF-PitNET, using a cut-off of at least 15% of cell proliferation inhibition). Then, RNA and proteins from NF-PitNETs frozen tissues have been extracted ($n = 56$ and $n = 48$ for proteins, respectively) have been extracted. β-arrestin2 relative expression of 23 NF-PitNET samples *in vitro* responsive to DAs treatment and 33 resistant ones has been evaluated by real-time PCR (qPCR). Our data revealed that there was no significative difference between the median of expression between the two groups (0.0037(0.0032) responsive vs 0.0033(0.0031) resistant). Moreover, β-arrestin2 protein expression was analysed in 24 responsive and 24 resistant NF-PitNETs by western blot. Our analysis revealed that the 83% of NF-PitNETs responsive to DAs were positive for β-arrestin2 expression, while only the 20% of resistant ones expressed it ($P < 0.001$). In addition, significative correlation ($P < 0.05$) between β-arrestin2 protein expression and DA responsiveness of NF-PitNET samples tested has been highlighted. β-arrestin2 mRNA levels were not correlated to protein expression nor with NF-PitNET cell proliferation inhibition after DAs treatment. In conclusion, our analysis demonstrated that β-arrestin2 protein expression positively correlated with NF-PitNETs *in vitro* sensitivity to DAs, paving the way for a potential role of β-arrestin2 as a biomarker predicting responsiveness to pharmacological treatment with DAs for NF-PitNETs.

Background
the aim of our study was to validate the classification proposed by the PANOMEN-3 group for the prediction of tumor recurrence and or progression in pituitary tumors (PTs).
Methods
Multicenter national case-control study of patients with PTs followed for at least 5 years. Kaplan-Meier curves were used to assess the time to tumor recurrence/progression. Uni- and multivariate Cox regression analyses were used to estimate the hazard ratio [HR] and prognostic capacity of the classification proposed by the PANOMEN-3 group.
Findings
One thousand patients were included, 500 were males and 500 females. The mean age at diagnosis was 51.7 ± 15.7 years. Pituitary surgery was performed in 809

patients and the remaining 191 patients were followed with active-surveillance or medical treatment. After a median follow-up of 8.3 (range 5-30) years, there were 244 (24.4%) patients who experienced tumor recurrence or biochemical/radiologic progression; and were thus classified as cases (231 in the surgical group and 13 in the conservative/medical treatment group). Of the 231 cases, 37 had tumor recurrence after surgical cure, 175 had significant tumor growth and 42 functioning PTs had experienced significant biochemical progression. The other 756 patients remained stable and thus, were classified as controls. The median recurrence-free survival was 16.5 years [95% CI: 14.9 to 18.7], indicating that 50% of patients experienced a recurrence within this period of time. At the last follow-up, 39 patients had died; 6 of 244 (2.5%) in the case group and 33 of 756 (4.4%) in the control group ($P = 0.18$). The diagnostic accuracy of the PANOMEN-3 model to predict recurrence/progression was 77.8% (95% CI 0.734-0.822). Residual tumor (HR 2.67, $P < 0.001$), hereditary syndrome (HR 12.62, $P = 0.015$) and active secretory status (HR 1.82, $P = 0.028$) were the most important variables in this model. There was a significantly positive tendency to increase the incidence of recurrence as the PANOMEN-3 grade increased (Mantel-Haenszel Test for linear Trend: Chi2 = 34.17, $P < 0.001$). The differences in survival were evident when comparing the four grades (PANOMEN 0, 1, 2 and 3), especially between grade 0 and 1 compared to 2 and 3 (0% in grade 0; 12% in grade 1, 32% in grade 2 and 35% in grade 3; $P < 0.001$).
Interpretation
The predictive model proposed by the PANOMEN-3 group may be useful to guide the prognosis and therapy of PTs in the Spanish population since it offers a good accuracy to predict tumoral/biochemical recurrence and/or progression in operated and non-operated patients.

Urea-stimulated copeptin: a novel diagnostic approach in polyuria polydipsia syndrome

Sven Lustenberger[1], Cihan Atila[1], Juliana Baumgarter[1], Sophie Monnerat[1], Julia Beck[1], Joyce Santos de Jesus[1] & Mirjam Christ-Crain[1]
[1]University Hospital Basel, Endocrinology, Diabetology and Metabolism, Basel, Switzerland

Background and Objectives
The differential diagnosis between arginine vasopressin (AVP) deficiency and primary polydipsia remains challenging. The method with the highest diagnostic accuracy is osmotically stimulated copeptin using hypertonic saline infusion. However, this method is limited to experienced hospitals, requires close monitoring, and may be cumbersome for patients. Therefore, an alternative simplified osmotic stimulation test would be highly desirable. Intravenous urea has been shown to stimulate AVP secretion. However, no study investigated the effects of oral urea on copeptin levels.
Methods
Twenty-two healthy adults were included in a randomized double-blind placebo-controlled cross-over trial. Participants underwent two visits after an overnight food fasting and two-hour fluid fasting period. They received a single weight-adapted dose of urea (0.5 g/kg body weight; minimum 30g, maximum 45 g) and placebo in random order. Serum copeptin was measured at baseline, 30, 60, 90, 120, and 150 minutes. In a second step, 13 patients with AVP-deficiency and 13 patients with primary polydipsia were included in a single arm, open label pilot study, receiving urea only. The primary endpoint was the maximum increase in copeptin within 150 minutes after ingestion of the study drink.
Results
In healthy adults, median [IQR] copeptin significantly increased from 4.6 [3.0 – 5.7] pmol/l at baseline to a maximum of 10.1 [7.2 – 11.6] pmol/l at 120 minutes after ingestion of urea, while it remained stable at 3.8 [2.9 – 6.6] pmol/l during placebo ($P < 0.001$). In patients with AVP-deficiency, copeptin remained below detection limit throughout the test, while in patients with primary polydipsia the peak was seen 150 minutes after ingestion of urea at 7.4 pmol/l [4.3, 10.3]. The best copeptin cut-off for differentiating AVP-deficiency from primary polydipsia was 3.5 pmol/l after 120 minutes, with a sensitivity and specificity of 92%, respectively.
Conclusion
Oral urea stimulates copeptin levels in healthy adults and patients with primary polydipsia, but not in patients with AVP-deficiency, establishing the first oral copeptin-based test in differentiating primary polydipsia from AVP-deficiency.

Prognostic study of suspected dual CHH patients treated with gonadotropins

Qin Zhang[1], Bingyan Cao[2], Yi Wang[1] & Chunxiu Gong[1]
[1]Department of Endocrinology, Genetics, and Metabolism, Beijing Children's Hospital, Capital Medical University, National Children's Medical Center, Beijing 100045, China, Beijing, China; [2]Department of Endocrinology, Children's Hospital Affiliated to the Capital Institute of Pediatrics, Beijing, China

Objective
This study aimed to investigate the treatment outcomes and predictive indicators in suspected dual congenital hypogonadotropic hypogonadism (CHH) patients treated with GnRH or hCG/hMG.
Methods
A total of 37 male dual CHH patients who received GnRH or hCG/hMG treatment from January 1, 2010 to the present were included. Clinical data including age, height, weight, LH, FSH, T, AMH, and INHB were collected from the medical records. Based on their treatment response, patients were divided into two groups: typical response ($n = 20$) and atypical response ($n = 17$). The diagnostic criteria for dual CHH are as follows:1) Testosterone (T) levels remain below 100 ng/dl after an hCG prolongation test. 2) T levels remain below 100 ng/dl after six months of GnRH treatment (5-10 mg/90 min, 16 pulses/day). Patients in the atypical response group had serum T levels below 200 ng/dl within six months of treatment or did not produce sperm during the treatment period. Patients not meeting these criteria were classified as having a typical response.
Results
1. Compared with the typical response group, the atypical response group had a higher incidence of cryptorchidism (40.0% vs 76.5%, $P = 0.065$), lower baseline ultrasound-measured testicular volume (TV) (0.43 ± 0.34 vs 0.18 ± 0.09 ml, $P = 0.046$), lower AMH level (15.39 ± 5.60 vs 6.84 ± 4.62 ng/ml, $P = 0.000$), and lower T level after hCG prolongation test (70.52 ± 20.21 vs 28.80 ± 19.30 ng/dl, $P = 0.000$).
2. The AUC for predicting typical response in suspected dual HH patients was as follows: AMH: 0.950 ± 0.055, with a cut-off of 10.65 ng/ml (sensitivity 80%, specificity 100%); T after hCG prolongation test: 0.883 ± 0.088, with a cut-off of 66.65 ng/dl (sensitivity 66.7%, specificity 100%); Combined AMH and T after hCG prolongation test: 1.0 (sensitivity 93.3%, specificity 100%).
4. For cumulative doses of HCG (24,000-40,000 units), HMG (0-3,375 U), and GnRH (4-4.8 mg), the AUC for T was 0.918 ± 0.058, with a cut-off of 135.8 ng/dl (sensitivity 80%, specificity 100%). The combined prediction of T and TV had an AUC of 0.945 ± 0.056 (sensitivity 90%, specificity 100%).
Conclusion
Gonadotropin therapy promotes testicular development and sperm production in patients suspected of having dual CHH. Patients with AMH levels below 10.65 ng/ml and T levels below 66.65 ng/dl after an hCG prolongation test may be considered for a diagnosis of dual CHH.

Omentin-1 as a new regulator of porcine pituitary function: *in vitro* effect on global proteome, endocrinology, and signaling pathways

Natalia Respekta-Długosz[1,2,3], Karolina Pich[1,2], Edyta Rytelewska[1], Bianka Świderska[4], Agata Malinowska[4], Tadeusz Kamiński[5], Nina Smolińska[5], Joëlle Dupont[6] & Agnieszka Rak[1]
[1]Laboratory of Physiology and Toxicology of Reproduction, Institute of Zoology and Biomedical Research, Faculty of Biology, Jagiellonian University, Krakow, Poland; [2]Doctoral School of Exact and Natural Sciences, Jagiellonian University, Krakow, Poland; [3]Institute of Zoology and Biomedical Research, Krakow, Poland; [4]Mass Spectrometry Laboratory, Institute of Biochemistry and Biophysics PAS, Warszawa, Poland; [5]Department of Animal Anatomy and Physiology, Faculty of Biology and Biotechnology, University of Warmia and Mazury, Olsztyn, Poland; [6]INRAE, Physiologie de la Reproduction et des Comportments, Nouzilly, France

Omentin-1 has significant implications for metabolism and insulin sensitivity, especially in obesity, metabolic syndrome, and inflammatory diseases. Also, expression of omentin-1 has been observed in reproductive cells including the ovary, placenta, and anterior pituitary (AP). Moreover, omentin-1 regulates steroid hormone secretion through the upregulation of steroidogenesis-related proteins. This highlights its significant role in the regulation of female

reproductive hormones. The objective of the present study is to examine the *in vitro* effects of omentin-1 on the global proteome and its role in the regulation of tropic hormone levels and signaling pathways in porcine AP cells. To investigate this, AP cells were isolated from Large White (LW; normal body weight) and Meishan pigs (MS; genetically obese) during the mid-luteal phase of estrous. We conducted liquid chromatography-tandem mass spectrometry with tandem mass tag labeling following a 24-hour treatment with omentin-1 (50 ng/mL). Functional analyses were performed to investigate dose-dependent of omentin-1 (10, 50, 100 ng/mL) alone and in combination with GnRH (100 ng/mL), CRH (1000 nM), TRH (1000 nM), and GHRH (100 nM) on the expression and secretion of LH, FSH, ACTH, TSH, PRL, GH, and their respective hypothalamic receptors in AP cells (using RT-qPCR and ELISA). We also explored the role of OMNT1 on gonadotropins secretion via extracellular signal-regulated kinases 1 and 2 (ERK1/2), protein kinase C, and insulin receptor signaling pathways (using ELISA). Statistical analysis used two-way ANOVA, and Tukey's post-hoc test ($n = 4$ at least). Proteomic analysis identified ~7,000 proteins, 34 differentially expressed in LW pigs, and 198 in MS, (cutoff 1.2-fold, $P < 0.05$). Bioinformatics using the DAVID, Panther, and Reactome platforms highlighted the involvement of omentin-1 in gonadotropin regulation, insulin receptor recycling, immune response, and transport to the Golgi and subsequent modification, homeostasis, and metabolism. In MS, proteins upregulated included LHβ, VDAC3, and cathepsin D, while SARM1 and ERK1/2 were downregulated. In LW, RRAGD was downregulated, and in both breeds, SIX1 was down-regulated. Functional experiments have revealed that omentin-1 plays a modulatory role in the expression and secretion of tropic hormones. Additionally, it is involved in key signaling pathways, including ERK1/2, and protein kinase C suggesting its significant impact on cellular signaling and endocrine regulation in AP cells. The description of the molecular mechanism of omentin-1 action creates new opportunities for research into targeted therapy and improvement of efficiency of livestock production through modulation of hormonal functions.

Insulin-like growth factor 1 as a diagnostic marker to differentiate progressive central precocious puberty from non-progressive precocious puberty: a prospective study

Ana Leite[1,2,3], Rosa Campos[1], Maria Rangel[1], Clara Torres[1], Filipa Santos[1], Sónia Aires[1], Firmino Machado[1,3], Luís Azevedo[4,5] & Catarina Limbert[6,7]
[1]Unidade Local de Saúde Gaia e Espinho, Vila Nova de Gaia, Portugal; [2]Clínica CUF - São João da Madeira, São João da Madeira, Portugal; [3]University of Aveiro, Department of Medical Science, Aveiro, Portugal; [4]University of Porto, Faculty of Medicine, Department of Comunity Medicine, Information and Health Decisions Sciences (MEDCIDS), Porto, Portugal; [5]University of Porto, CINTESIS@RISE - Center for Health Technology and Services Research (CINTESIS) & Health Research Network Associated Laboratory (RISE), Porto, Portugal; [6]Unidade Local de Saúde São José - Hospital Dona Estefânia, Lisboa, Portugal; [7]NOVA University of Lisbon, NOVA Medical School, Comprehensive Health Research Center (CHRC), Lisbon, Portugal

Background
Central precocious puberty (CPP) results from early activation of the hypothalamic-pituitary-gonadal axis. Its diagnosis often requires GnRH stimulation tests, which are invasive and costly. Serum insulin-like growth factor 1 (IGF1) and IGF1-SDS levels have emerged as potential markers to differentiate CPP from non-progressive forms of CPP (NP-CPP), as isolated thelarche (IT).
Methods
Prospective study (June 2022-December 2024) including 82 girls under 8 years. Participants were divided into CPP ($n = 39$), non-progressive puberty (NP-CPP and IT, $n = 26$), and control groups ($n = 17$). Anthropometric measurements, Tanner staging, bone age, pelvic ultrasound and serum IGF1 and IGF1-SDS levels were performed. GnRH stimulation tests confirmed CPP cases.
Results
Mean serum IGF1 and IGF1-SDS levels were significantly higher in CPP patients (270.15 ng/mL; 1.943 SDS) compared to NP-CPP (174.12 ng/mL; 0.788 SDS) and controls (139.28 ng/mL; 0.208 SDS) ($P < 0.001$). Multivariate analysis confirmed IGF1 (OR = 1.025, 95%CI: 1.010-1.040) and IGF1-SDS (OR = 8.721, 95%CI: 2.624-28.986) as significant predictors of CPP. ROC analysis revealed an AUC of 0.837 for IGF1 (95%CI: 0.738-0.935) and 0.862 for IGF1-SDS (95%CI:0.771-0.953). Cut-off values of 231 ng/mL for IGF1 (71.8% sensitivity, 96.2% specificity) and 1.71 for IGF1-SDS (64.1% sensitivity, 96.2% specificity) demonstrated good accuracy (82.2% and 77.8%, respectively).
Conclusions
Serum IGF1 and IGF1-SDS are promising as effective non-invasive markers to distinguish CPP from non-progressive precocious puberty. Values below 231 ng/mL or 1.71 SDS may significantly reduce the likelihood of CPP, potentially avoiding invasive GnRH stimulation tests. These findings may support the integration of IGF1 measurements into the initial diagnostic approach for girls presenting with early pubertal signs.

It is quite stressful to be a stem cell

Olivia Sherwin[1,2], Ilona Berger[1,2], Emily Scott-Solomon[3], Bence Kover[1], Ya-Chieh Hsu[3], Frederique Ruf-Zamojski[4], Shinsuke Onuma[4], Michel Zamojski[4], Stefan Bornstein[2], Charlotte Steenblock[2], Marily Theodoropoulou[5], Yasmine Kemkem[1], James Kaufman-Cook[1], Miriam Vazquez Segoviano[1] & Cynthia Andoniadou[1]
[1]King's College London, London, United Kingdom; [2]Technical University of Dresden, Dresden, Germany; [3]Harvard University, Cambridge, United States; [4]Cedars-Sinai Medical Center, Los Angeles, United States; [5]Ludwig Maximilian University of Munich, Munich, Germany

The stress response is an adaptive mechanism that results in the release of glucocorticoids from the adrenal cortex, in order to regulate metabolic, immune and inflammatory related processes of the body. The intensity and duration of this response is tightly regulated by the Hypothalamic Pituitary Adrenal (HPA) axis and a pivotal component of this axis is the negative feedback of glucocorticoids. Central to this process, the pituitary gland modulates glucocorticoid levels by adjusting adrenocorticotropic hormone (ACTH) secretion in response to corticotrophin releasing hormone (CRH) from the hypothalamus and glucocorticoid feedback from the bloodstream. Our studies are centred around the response of HPA axis stem cells in mouse under physiological and stress conditions. We present here that SOX2+ anterior pituitary stem cells (PSCs) are responsive to glucocorticoids, activate glucocorticoid receptor (GR) signalling and are implicated in the stress response. To determine the role of GR signalling in PSCs, we generated *Sox2CreER/+;GRfl/fl* mice, where the GR receptor can be deleted specifically in the stem cells upon administration of a drug, tamoxifen. Combining in vivo and *in vitro* analyses, we show that PSCs activate GR during an acute stress model, leading to upregulated expression and secretion of cytokines, able to influence neighbouring cells. *in vitro* data using mouse corticotroph tumour AtT-20 cells and *in vivo* data from the mouse model, support that GR-dependent signalling regulates the *Pomc* promoter, in a dose-dependent manner. Together, these data indicate a functional role for GR signalling in SOX2+ pituitary stem cells implicating these cells in paracrine signalling during the stress response.

Development and validation of rapidly progressive central precocious puberty diagnostic prediction models in girls

Wenyong Wu[1] & Ruimin Chen[1]
[1]Fuzhou First General Hospital Affiliated with Fujian Medical University (Fuzhou Children's Hospital of Fujian Medical University), Fuzhou, China

Objective
This study aims to develop a diagnostic prediction model for girls with rapidly progressive central precocious puberty (CPP) using machine learning algorithms.
Methods
CPP girls admitted to the department of endocrinology, genetics and metabolism of the hospital without treatment intervention for a follow-up period of more than 3 months from June 2017 to June 2023 were included retrospectively. These girls were randomly divided into training (70%), validation (15%), and test set (15%). The training set data were used to screen the predictors based on Lasso regression. Validation set data assisted the training set data to adjust the model parameters to establish the rapidly progressive CPP girl diagnosis prediction model based on five machine learning algorithms including Logistic regression, support vector machine, random forest, limit gradient lifting and artificial neural network, and carried out internal validation. The test set data were used for model external validation.

Results
A total of 277 CPP girls were analyzed, of whom 141 (50.9%) were diagnosed with rapidly progressive CPP and 136 (49.1%) were diagnosed with slowly progressive CPP. Lasso regression included five predictors: BMI (kg/m^2), group of basal luteinising hormone (LH) (LH $<$ 0.20 IU/l, 0.20 IU/l $\leq$ LH $<$ 0.52 IU/l, LH $\geq$ 0.52 IU/l), group of insulin like growth factor 1 (IGF-1) SDS (IGF-1 SDS $<$ 0.35, IGF-1 SDS $\geq$ 0.35), and advanced bone age (y). Five machine learning algorithm prediction models were developed. The artificial neural network model has the best performance, with AUC vulues of 0.774 in internal validation and 0.725 in external testing cohort, and the accuracy rate was 76.2% and 69.1%, respectively. When the prediction probability was greater than 0.80 as the diagnostic threshold of rapidly progressive CPP, the specificity of the model in the validation and the test set data were 100.0% and 95.5%. When using a prediction probability less than or equal to 0.30 as the diagnostic threshold for slowly progressive CPP, the model demonstrated sensitivities of 96.2% and 95.5% in the validation and test set, respectively.
Conclusion
This study developed prediction models based on machine learning algorithm for the typing of CPP girls. Internal validation and external testing ensured a good degree of discrimination and calibration of the models, which could assist in the diagnosis of rapidly progressive CPP on the basic of clinical data.
Key words
central precocious puberty, girl, machine learning, prediction model.

Impact of pasireotide LAR on lipid and glucose metabolism in patients with acromegaly: a systematic review and meta-analysis
Flavia Costanza[1,2,3], Christian Basile[4,5], Sabrina Chiloiro[3], Eva Hessman[1], Dimitrios Chantzichristos[1,2], Alfredo Pontecorvi[3], Emanuele Bobbio[1,2], Maria Fleseriu[6] & Daniela Esposito[1,2]
[1]University of Gothenburg, Institute of Medicine at Sahlgrenska Academy, Gothenburg, Sweden; [2]Sahlgrenska University Hospital, Department of Endocrinology, Gothenburg, Sweden; [3]Department of Endocrinology, Diabetology and Internal Medicine, Università Cattolica del Sacro Cuore, Fondazione Policlinico Universitario Agostino Gemelli, Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS), Rome, Italy; [4]University of Naples "Federico II", Department of Advanced Biomedical Sciences, Naples, Italy; [5]Karolinska Institutet, 5Department of Clinical Science and Education, Södersjukhuset, Stockholm, Sweden; [6]Oregon Health and Science University, Portland, United States

Background
Pasireotide long-acting release (PasiLAR) is a somatostatin multireceptor ligand commonly used as a second-line medical treatment in patients with acromegaly resistant to first-generation somatostatin receptor ligands (fg-SRLs). PasiLAR is more effective in achieving biochemical control and its tolerability is similar to the fg-SRLs, with the exception of a greater incidence and severity of hyperglycemia. A comprehensive assessment of the metabolic effects of PasiLAR in patients with acromegaly has however not been performed to date. This systematic review and meta-analysis aims to synthesize evidence on PasiLAR effects on lipid and glucose metabolism in patients with acromegaly.
Methods
A comprehensive search was conducted in MEDLINE, Embase, Cochrane Library, and Web of Science for studies published between 2000 and 2024 and retrieved 3441 records. Studies assessing lipid and glucose metabolism in patients with acromegaly on treatment with PasiLAR for at least 6 months were included. Two reviewers screened eligible publications, extracted outcomes, and assessed risk of bias. This systematic review followed Preferred Reporting Items for Systematic Review and Meta-Analysis (PRISMA) guidelines and was registered in PROSPERO in May 2024 (registration number: CRD42024544686).
Results
We included a total of 19 studies (18 only PasiLAR, 1 PasiLAR plus PegV), involving 896 patients with acromegaly. Nine studies were retrospective (47%) and ten were prospective randomized controlled trials (53%). A majority of patients included in the meta-analysis were male (58%). Median age (IQR) was 45.8 (43.0 to 47.8) years. PasiLAR treatment was associated with a significantly higher levels of high-density lipoprotein cholesterol (HDL-C) (mean difference [MD] 6.2 mg/dl; 95% confidence interval [CI] 1.4-10.9) and no significant changes in triglycerides, total cholesterol, or low-density lipoprotein cholesterol compared to baseline. PasiLAR treatment was associated with increased fasting plasma glucose (FPG) (MD 23.4 mg/dl; 95% CI 18.8-28.1) and glycosylated hemoglobin (HbA1c) (MD 0.5%; 95% CI, 0.4-0.7). Diabetes frequency was higher after treatment (58.6%) compared to baseline (30.9%), with an odds ratio of 3.7 (95% CI 2.9-4.7).
Conclusions
This systematic review and meta-analysis is the first comprehensive evaluation of the effects of PasiLAR treatment on both lipid and glucose metabolism in patients with acromegaly. Treatment with PasiLAR for at least 6 months was associated with increased HDL-C, FPG, HbA1c, and frequency of diabetes mellitus in patients with acromegaly. These findings are novel and emphasize the importance of a personalized approach to the treatment of acromegaly with a careful examination of metabolic status, to prevent impairment of lipid and glucose metabolism.

The role of functional imaging with 11C-methionine and 11F-tyrosine in patients with cushing's disease
Iris Pelsma[1], Leontine Bakker[1], Arwin Zebardast[1], Wouter van Furth[1], Lenka Pereira Arias-Bouda[1], Nienke Biermasz[1] & Marco Verstegen[1]
[1]Leiden University Medical Center, Leiden, Netherlands

Background
Transsphenoidal surgery is the first treatment option for Cushing's Disease (CD). Unfortunately, conventional dedicated pituitary MRI – the current golden standard – fails to detect the culprit lesion in approximately 30-50% of patients. Novel imaging techniques using positron emission tomography (PET) with specific radioactive tracers and co-registration with MR images have been used in patients with pituitary adenomas and might improve the surgical outcomes of corticotroph adenomas.
Aim/Objective
To assess functional imaging-guided diagnostic and surgical accuracy of ^{11}C-methionine PET-CT co-registered with MRI (^{11}C-MET-PET/MRI), and ^{18}F-fluoroethyl-l-tyrosine PET/CT co-registered with MRI (^{18}F-FET-PET/MRI) for patients with CD with an inconclusive MRI and high treatment need.
Methods
This cohort study included 31 patients with CD undergoing ^{11}C-MET-PET/MRI or ^{18}F-FET-PET/MRI in the diagnostic trajectory followed by surgery (2017-2024). Indication for functional imaging was determined by an experienced multidisciplinary team. Some patients underwent two functional imaging scans followed by surgery, resulting in a total of 36 evaluable functional imaging-treatment episodes. Outcomes were evaluated using histopathological confirmation and biochemical remission 6 months postoperatively.
Results
26 patients were female (71.0%), and mean age was 48 (11-73) years. Functional imaging was performed (^{18}F-FET-PET/MRI $n = 15$ and ^{11}C-MET-PET/MRI $n = 21$) mainly because of an unclear remnant lesion following prior surgery (24/36, 66.7%), or uncertain invasion/extension following surgery in 10/36 cases (27.8%). At the time of functional imaging, clinical severity of symptomatology was mild in 50% of patients, whereas the other 50% of patients had moderate or severe symptomatology. 32/36 cases (88.9%) had undergone previous surgery, only 4 patients were treatment-naïve. Functional imaging resulted in a positive "PET-signal" in 30/36 cases (83.3%), of which solely 10 (33.3%) could be related a lesion on the simultaneous MRI nor retrospectively on previous MRIs. Of the PET-positive lesions, confirmation was obtained by histopathology in 11/30 (36.7%), biochemical remission in 17/30 (56.7%), or either in 21/30 cases (70.0%). Regarding the entire cohort without clear surgical target, biochemical remission was obtained in 21/36 cases (58.3%). For repeat surgery, remission rates were 72.7% (16/22 cases) for patients with unclear remnants, and 40.0% (4/10 cases) for patients with unclear invasion/extension. In treatment-naïve patients, 1/4 cases (25.0%) achieved remission.
Conclusion
Functional imaging with ^{18}F-FET-PET/MRI and ^{11}C-MET-PET/MRI in complex patients lacking surgical target on conventional MRI showed a PET-positive lesion in 89%, which could be surgically confirmed in 70%, and yielded a remission rate of 60%, particularly in patients undergoing repeat surgery. Therefore, functional imaging should be considered in complex patients with CD.

JOINT3484
Natural history of non-functioning pituitary microadenomas in clinically diagnosed MEN 1 syndrome
Mădălina Elena Iftimie[1,2], Burcea Iulia-Florentina[1,2], Ramona Dobre[1,2] & Catalina Poiana[1,2]

[1]National Institute of Endocrinology, C.I.Parhon'', Pituitary, Bucharest, Romania; [2]"Carol Davila'' University of Medicine and Pharmacy, Bucharest, Romania

Introduction
Pituitary adenomas (PAs) represent one of the three main characteristic endocrine tumors associated with multiple endocrine neoplasia type 1 (MEN1) syndrome and are presumed to have a more aggressive behavior compared to incidentally found PAs. In this study, we aim to emphasize the long-term evolution of non-functioning pituitary microadenomas (micro-NFPAs) in MEN1 patients.
Methods
We conducted a retrospective cohort study that included all adult index patients with a clinical diagnosis of MEN1 syndrome and micro-NFPAs, that were evaluated in our clinic at the Romanian National Institute of Endocrinology, C.I.Parhon'', between January 1st 2018 and 31st December 2024. We sought to investigate the evolution of micro-NFPAs with a focus on tumor growth and pituitary function. We defined tumor growth or regression as a minimum 20% change in size compared to baseline.
Results
We identified 68 MEN1 patients that associated PAs, 18 macroadenomas and 50 microadenomas, of which 39 (78%) were non-functioning. 76.9% were females, with a mean age at diagnosis of 52.1 $\pm$ 13.2 years. The maximum tumor diameter at baseline was 5.1 $\pm$ 1.7 mm, without differences between sexes. No cystic lesions, hypopituitarism or visual field deficit were observed at baseline. Micro-NFPAs were associated with hyperparathyroidism or entero-pancreatic tumors in 69.2% and 15.4% of cases, respectively, all three classical, P''s being accounted for in 15.4% of patients. Micro-NFPAs were the first MEN1 component diagnosed in only 12.8% of cases, more frequently being discovered ensuing MEN1 screening, following hyperparathyroidism (51.3%) or entero-pancreatic neuroendocrine tumors (NETs) (30.8%) diagnosis. More than half of patients (53.8%) were reassessed through imaging and pituitary function testing. Over a median follow-up duration of 6 years (interquartile range: 3.9-9), only 1 patient (2.6%) had significant tumor enlargement, while 28.2% regressed and 23.1% were stable. None developed new pituitary insufficiency. No predictors were identified for tumor growth. Patients with tumor reduction were older ($P = 0.06$), had larger tumor diameters at diagnosis ($P = 0.038$) and pathogenic MEN1 gene mutations on genetic tests (mostly Sanger sequencing, $P = 0.014$) compared to those whose tumors were stable or progressed. However, logistic regression found none of these factors to be significant predictors of tumor shrinkage.
Conclusion
Micro-NFPAs in MEN1 syndrome are generally discovered through screening following the diagnosis of hyperparathyroidism or entero-pancreatic NETs and have a benign course over long follow-up intervals.

High risk of psychiatric morbidity in patients with acromegaly: a cohort study and meta-analysis

Astrid Matthesen[1], Christian Rosendal[1,2], Emma Christensen[1], Helga Beckmann[1], Frederik Klit[1,3], Amar Nikontovic[3], Gustav Bizik[4], Peter Vestergaard[1,2,3] & Jakob Dal[1,2]
[1]Aalborg University, Department of Clinical Medicine, Gistrup, Denmark; [2]Aalborg University Hospital, Department of Endocrinology, Aalborg, Denmark; [3]Aalborg University Hospital, Steno Diabetes Center North Denmark, Gistrup, Denmark; [4]Aalborg University Hospital, Department of Psychiatry, Aalborg, Denmark

Introduction
Psychiatric morbidity in acromegaly is increasingly recognized. However, current studies are limited by small sample sizes and divergent Results We aimed to evaluate the risk of psychiatric morbidity in a retrospective cohort study comparing acromegaly with non-functioning pituitary adenomas (NFPAs) combined with a meta-analysis of the existing literature.
Methods
The cohort study included data from medical records analysed using Chi2-, t-tests and log-binomial regression. The meta-analysis included studies retrieved from PubMed, Embase and PsycINFO that reported risk of psychopathology in acromegaly compared to NFPA or healthy controls using a random effects model.
Results
105 acromegaly and 211 NFPA patients were identified in the cohort study. They had similar sex distributions. Patients with acromegaly presented with smaller pituitary adenomas (17.9 $\pm$9.9 mm vs. 22.9 $\pm$10.6 mm, $P < 0.001$), more frequent pituitary surgery (89.1% vs. 60.2%, $P < 0.001$) and hormone replacement therapy (25.7% vs. 16.1%, $P = 0.042$). Acromegaly patients had higher risk of depression (RR: 1.9, CI95% [1.2;3.2], $P = 0.009$), and increased need of admissions to the psychiatric ward (5.7% vs. 0.5%, $P = 0.006$). Daily opioid use was higher in acromegaly patients with psychiatric morbidity and was associated with a diagnosis of arthropathy ($P = 0.009$). The risk of anxiety was indifferent with a CI95% of [0.5;4.4]. The meta-analysis (8 studies, 1,387 patients) revealed increased risks of both depression (RR: 1.8, CI95% [1.3;2.5]) and anxiety (RR: 1.9, CI95% [1.1;3.2]) in acromegaly compared to NFPAs. Likewise, the risk of depression was increased compared to healthy controls (RR: 2.5, CI95% [1.8;3.5]).
Conclusion
This study reveals a higher risk of depression and anxiety in acromegaly. This warrants increased psychiatric awareness in these patients.

Involvement of menin, p27 and pakt in prolactinoma development. sexual differences

Milagros Peña-Zanoni[1], Dana Bornancini[1], Victoria Segobia[1], Brenda Mattaloni Varona[1], Susana Rulli[1] & Graciela Diaz-Torga[1,2]
[1]Instituto de Biologia y Medicina Experimental, CONICET, Buenos Aires, Argentina; [2]Instituto de Biologia y Medicina Experimental, Laboratorio de Fisiopatologia Hormonal, Buenos Aires, Argentina

Menin is a fundamental protein for regulating the cell cycle and proliferation in the pituitary gland, specifically in lactotroph function due to its ability to regulate p27Kip1 and the AKT signalling pathway. In this work, we focused on the involvement of menin on prolactinoma development, using two murine models of prolactinoma. One model is characterised by overexpressing the β subunit of the human chorionic gonadotropic hormone (hCGβ+) and the other by being knock-out for the dopamine receptor type 2 (Drd2KO). In both models, only females develop lactotroph hyperplasia and hyperprolactinemia from three months of age. In the hCGβ+ murine model, but not in the Drd2KO, we observed, by RTqPCR, higher levels of expression of the MEN1 gene in the pituitary gland of males than in females, without genotypic differences. We performed double confocal immunofluorescence to analyse the expression of proteins of interest specifically in lactotrophs (colocalization). Although no differences were detected between sexes or genotypes in the percentage of menin+ lactotrophs, important changes were observed in the subcellular localisation of menin. In WT male and female lactotrophs, menin is found in both, cytoplasm and nucleus. However, in transgenic females from both models (prolactinomas), nuclear expression of menin is completely lost. This lack of nuclear menin correlates with a decrease in the percentage of p27+ lactotrophs, accompanied by a marked increase in the levels of pAKT expression and a lower level of PTEN expression in the tumoral pituitary glands of both models compared to WT females. These alterations were not observed in males whose pituitary glands retained stable expression of nuclear menin and high levels of PTEN. We conclude that the loss of the nuclear menin in lactotrophs from transgenic females and the lower expression of PTEN contribute to the decreased expression of p27 and the elevated levels of pAKT respectively, favouring the development of a prolactinoma.

Multicentre 30-year data on the 4-mg intravenous dexamethasone suppression test in the diagnosis of cushing's syndrome

Caroline Jung[1,2], Maresa M Derbyshire[1], Niyati Jauhar[3], Daniel Bennett[3], Duncan J Topliss[3,4], Reetu Gogna[5], Nikola Markovic[5], John R Burgess[5,6] & Warrick J Inder[7,8]
[1]St Vincent's Hospital, Endocrinology and Diabetes, Melbourne, Australia; [2]The University of Melbourne, Melbourne, Australia; [3]Alfred Health, Melbourne, Australia; [4]Monash University, Melbourne, Australia; [5]Royal Hobart Hospital, Hobart, Australia; [6]University of Tasmania, Hobart, Australia; [7]Princess Alexandra Hospital, Brisbane, Australia; [8]The University of Queensland, Brisbane, Australia

Objective
Differentiating Cushing's syndrome (CS) from Pseudo-Cushing's (Low Probability of Cushing's [LPC]) may be difficult. We evaluated the 4-mg intravenous dexamethasone suppression test (IVDST) to differentiate CS from normal subjects and LPC, and to define responses in CS of various causes.

Design
Data from 140 patients with surgically confirmed Cushing's Disease (CD) who underwent IVDST(s) before their first pituitary operation, five with ectopic ACTH syndrome (EAS), 28 with adrenal Cushing's (AC), and 111 with LPC, from four tertiary hospitals between 1995 to 2024 were retrospectively evaluated. Thirty-two control subjects (normal and overweight/obese participants with or without type 2 diabetes) were previously studied. Dexamethasone was infused at 1 mg/h for 4h. Plasma cortisol and ACTH were measured at -60 min (baseline), -5 min, +3h, +4h, +5h and at +23h and +23.5h on Day 2.
Results
The cortisol at baseline, +5h and mean of Day 2 levels are shown in the table. Day 2 cortisol level of >130 nmol/l diagnosed CS with 95% sensitivity and 87% specificity. In the CD group, a partial suppression of cortisol at +5h to less than 70% of the baseline was demonstrated in 97%, with rebound hypercortisolism on Day 2 in 91% of patients. Day 2 cortisol levels were >130 nmol/l in 100% of EAS and 93% of AC. In 19 of 111 patients with LPC, Day 2 cortisol overlapped with CS. Control subjects showed marked suppression of cortisol which was maintained on Day 2.
Conclusion
IVDST has high sensitivity for diagnosis of CS. We suggest false negative results may occur when IVDST is performed during mild or subclinical disease or during quiescent phase. The specificity of 87% is lower than previously reported (96%), highlighting the importance of long-term follow-up of LPC. Because only five EAS were studied, the utility of IVDST in differential diagnosis of ACTH-dependent CS is uncertain.

	Cortisol (nmol/L) mean (range)		
	Baseline	+5h	Day 2 mean
CD	600 (226-1442)	182 (33-826)	476 (19-2177)
EAS	2403 (1120-3962)	2403 (841-3082)	2517 (1120-4089)
AC	507 (249-1453)	474 (95-1414)	501 (96-1807)
LPC	431 (94-1364)	97 (19-285)	82 (21-557)
Control	405 (252-651)	56 (23-108)	20 (7-48)

Laterality of amygdalavolume of brain in different genders help predict individuals with ambiguous genitalia of disorders of sexual development

Yan Li[1], Ting Dong[1], Chunjie Liu[1], Shaolian Zang[1], Xiaoqin Yin[1], Shasha Zhou[1], Sheng Guo[1], Zhi Yang[2] & Pin Li[1]
[1]Department of Endocrinology, Children's Hospital of Shanghai, School of Medicine, Shanghai Jiaotong University, Shanghai, China; [2]Beijing Key Laboratory of Mental Disorders, National Clinical Research Center for Mental Disorders & National Center for Mental Disorders, Beijing Anding Hospital, Capital Medical University, Beijing, China

Background
Human sex characteristics include genetic, anatomical structure, physiological function, neuropsychology and social identity. Patients who were born with ambiguous genitalia are in intersex conditions. Sex decisions of raising at their early years are significant and difficult. Hormones, chromosomes, and clinical phenotypes of genitalia are the major influences leading to decisions of sex, and they also guide sex differences in brain development. Individuals of 21-hydroxylase deficiency (21OHD) with chromosome of 46,XX offer a unique opportunity to address these issues. They have a 46,XX chromosome, high testorstorone and ambiguous genitalia of clitoridauxe.
Objective
Toexamine the asymmetry of the different zones volume of subcortical brain in normal girls and boys, build a classifier to predict the cases' sex and compare with their psychological sex.
Methods
11 children of CAH with 46,XX, 123 boys and 124 girls were included. T1-weighted anatomical data were collected using a magnetization-prepared rapid acquisition gradient-echo sequence. Pre-school activities investory (PSAI) was used to assessed the psychological sex in individuals below 5 years old, and children's sex role inventory (CSRI) was used in cases of and older than 5 years old.
Results
We found that laterality of Amygdala volume was significatly different between genders, showing a significant larger laterality of Amygdala volume in boys than that of girls ($T=2.335280$, $p=0.021$). Based on the laterality, we built a classifier to vertify the brain sex of the 11 cases. The brain sex of all the cases was identical with their psychological sex assessed by the questionnaries.
Conclusions
The findings further revealed the gender differences in brain, and we do use diversified ways to predict gender of individuals of disorders of sexual development (DSD). It is equally important to raise gender in accordance with neuropsychological needs and to obtain social acceptance as to maintain a status consistent with genetic, anatomical, and endocrine physiological functions.

Musculoskeletal disorders in acromegaly: a national, registry-based cohort study

Christian Rosendal[1], Mai C. Arlien-Søborg[2], Eigil H Nielsen[1], Åse Krogh Rasmussen[3], Jens Otto Jørgensen[2], Claus Feltoft[4], Marianne Andersen[5] & Jakob Dal[1,6]
[1]Aalborg University Hospital, Department of Endocrinology, Aalborg, Denmark; [2]Aarhus University Hospital, Department of Endocrinology, Aarhus, Denmark; [3]Rigshospitalet, Department of nephrology and endocrinology, Copenhagen, Denmark; [4]Herlev-Gentofte Hospital, Department of Medicine, Copenhagen, Denmark; [5]Odense University Hospital, Department of Endocrinology, Odense, Denmark; [6]Steno Diabetes Center, North Denmark, Aalborg, Denmark

Objective
Acromegaly is associated with multiple musculoskeletal complications that affect quality of life and work ability. No nationwide studies on these debilitating complications exist. We aimed to examine the risk of osteoarthritis, musculoskeletal surgery (incl. JOINT replacement), osteoporosis, fractures, and analgesic consumption in a national cohort of acromegaly patients.
Design
National, registry-based cohort study.
Methods
All validated incident and prevalent cases of acromegaly in the period 1977-2021 ($n = 844$) were included and matched 1:100 with healthy controls on sex and birth year. Outcomes were retrieved from the Danish Healthcare registries and identified using diagnosis, surgical procedure and medication codes. Time-to-event analyses in the form of Cox regression and Kaplan-Meier plots were applied.
Results
Patients were at significantly increased risk of osteoarthritis of the shoulder (HR: 5.25 [3.05; 9.06]), hip (HR: 3.15 [2.57; 3.87]) and knee (HR: 2.25 [1.85; 2.72]), and osteoporosis (HR: 2.13 [1.64; 2.78]) even before the acromegaly diagnosis. The risk of JOINT replacement surgery of the shoulder (HR: 4.60 [2.57; 8.25]), hip (HR: 3.32 [2.67; 4.12]) and knee (HR: 2.52 [1.89; 3.36]) was increased in acromegaly patients, as was the risk of being prescribed weak analgesics (HR: 1.22 [1.04; 1.44]) or opioids (HR: 1.58 [1.38; 1.82]). Furthermore, patients had a higher risk of being diagnosed with degenerative spinal disorders, such as spondylosis (HR: 2.04 [1.50; 2.77]), spinal stenosis (HR: 2.12 [1.56; 2.88]) and intervertebral disc herniation (HR: 1.79 [1.21; 2.66]). Surgical complications (HR: 2.19 [1.59; 3.03]) and repeat hip surgery (HR: 3.64 [2.09; 6.34]) also exhibited increased risk in patients.
Conclusion
In acromegaly, severe osteoarthritis involving multiple JOINTs develops even before acromegaly diagnosis and continues to progress over time, despite acromegaly-specific treatment and biochemical disease control. Furthermore, acromegaly imposes an increased risk of osteoporosis, musculoskeletal surgery - particularly JOINT replacement surgery -, surgical complications and necessity of strong analgesic medication. Our findings warrant further research into the management of musculoskeletal disease in acromegaly.

Background
Patients with Cushing's syndrome (CS) are at markedly increased risk of thromboembolic events. However, despite recognised risk, no guidance on thromboprophylaxis for CS has been established, and practices remain variable across clinical settings.
Aim
To provide recommendations for thromboprophylaxis, perioperative management, and treatment of VTE in patients with endogenous CS. To unify care practices and improve patient outcomes by mitigating the risk of venous thromboembolic events (VTE) in this population.
Methods
This was a Delphi method involving four iterative rounds of voting and subsequent discussions. The expert panel comprised 18 international specialists from 11 countries across 4 continents. Consensus was achieved with a threshold of $\geq$75% agreement. The recommendations were categorised into thromboprophylaxis, perioperative management, and treatment of VTE.
Results
Consensus was achieved on 14 recommendations. Thromboprophylaxis should be initiated at time of diagnosis and continued for at least three months after biochemical remission, provided there are no contraindications. Hospitalised patients with active CS should routinely receive thromboprophylaxis unless contraindicated. Patients with CS who are biochemically controlled on medical therapy and do not have additional risk factors may not require thromboprophylaxis. Low-molecular-weight heparin (LMWH), at standard weight-based prophylactic doses, is the preferred agent due to its known safety and efficacy. For perioperative management, LMWH should be administered until 24 hours before surgery and resumed 24 hours postoperatively, continuing for at least three months after achievement of biochemical remission. For patients undergoing inferior petrosal sinus sampling (IPSS), thromboprophylaxis should be reconsidered if it has not already been initiated. Prophylactic LMWH should be continued. Patients on direct oral anticoagulants (DOACs) should discontinue them 24–72 hours prior to IPSS and resume 48 hours after the procedure with interim prophylactic LMWH. The panel did not find sufficient evidence to recommend routine pre- or postoperative haemostatic testing to guide clinical decisions. Antiembolic stockings are not recommended due to limited efficacy and potential complications. Future research priorities include evaluating the use of DOACs in CS and determining the optimal duration of thromboprophylaxis post-remission.
Conclusion
These Delphi consensus recommendations aim to unify care practices and improve outcomes in CS by offering clear guidance on thromboprophylaxis, including its initiation, duration across different disease stages, and preferred treatment options. Key gaps for future research include the role of DOACs in CS, the optimal duration of thromboprophylaxis after remission, and refining criteria for thromboprophylaxis in patients with mild CS and mild autonomous cortisol secretion (MACS).

Introduction
The LINC clinical trial programme demonstrated that osilodrostat is effective and well tolerated in patients with Cushing's disease (CD); however, lifelong treatment is often required. The open-label, multicentre LINC rollover (NCT03606408) study evaluated the long-term safety and effectiveness of osilodrostat in patients with CD.
Methods
The study was planned to be open for ~5 years (or until 31/12/2023 in the UK). Participants benefitting from osilodrostat (investigator judged) after completing either the LINC 2, 3 or 4 trial extension phases were eligible for inclusion. Participants continued in the rollover until osilodrostat no longer provided clinical benefit, became commercially available in their country, or one of the protocol-defined discontinuation criteria was met. Participants attended quarterly visits for safety/clinical benefit assessments. The primary objective was to evaluate the long-term safety of osilodrostat, assessed by frequency of adverse events (AEs)/serious AEs (SAEs). Cumulative data are reported from parent study baseline to rollover end, unless otherwise stated.
Results
127 participants entered the rollover study (mean [SD] age: 41.3 years [12.4]; female: 74.8%). Median (min–max) osilodrostat exposure and dose was 5.0 (1.7–8.6) years and 4.9 (1.0–46.0) mg/day. All patients experienced $\geq$1 AE; 86.6% (n = 110) were considered treatment related, most commonly ($\geq$25% of patients) nausea (30.7%, n = 39), adrenal insufficiency (AI; 28.3%, n = 36) and fatigue (28.3%, n = 36). SAEs were reported in 44.9% (n = 57) of participants; 8.7% (n = 11) were considered treatment related, most commonly AI (4.7%, n = 6). AEs related to accumulation of adrenal hormone precursors were reported in 65.4% (n = 83), hypocortisolism in 55.9% (n = 71), pituitary tumour enlargement in 8.7% (n = 11), and arrhythmogenic potential and QT prolongation in 5.5% (n = 7). During the rollover, 22.0% (n = 28) discontinued osilodrostat; 3.9% (n = 5) discontinued because of treatment-related AEs, most commonly AI (n = 3). Adrenocorticotropic hormone, testosterone, 11-deoxycortisol and 11-deoxycorticosterone levels initially increased from baseline but generally stabilised during long-term treatment. Tumour volume generally decreased during the study, although inter-individual variability was high. At the end of osilodrostat treatment, 78.0% (n = 99) continued to receive clinical benefit. Mean urinary free cortisol levels decreased from 561.5 (4.1 x upper limit of normal [ULN]) at baseline to 85.0 nmol/24 h (0.6 x ULN) at week 12 of the parent studies and generally remained $\leq$ULN throughout treatment.
Conclusions
The LINC rollover study complements existing evidence demonstrating that osilodrostat is well tolerated and provides sustained effects in patients with CD during long-term treatment (for $\leq$8.6 years); no new safety signals were identified.

Testosterone vs gonadotropin therapy for induction of puberty in boys with congenital hypogonadotropic hypogonadism

Francesco d'Aniello[1], Sasha Howard[2], Tommaso Todisco[3], Alessia Aureli[1], Giulia Mirra[1], Maria Elisa Amodeo[1], Armando Grossi[1], Marco Cappa[4], Stefano Cianfarani[1,5,6] & Graziamaria Ubertini[1]
[1]Bambino Gesù Children's Hospital, Endocrinology and Diabetology Unit, Rome, Italy; [2]William Harvey Research Institute, Queen Mary University of London, Department of Paediatric Endocrinology, Royal London Children's Hospital, Barts Health NHS Trust, Centre for Endocrinology, London, United Kingdom; [3]Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [4]Research Unit for Innovative Therapies in Endocrinopathies, Bambino Gesù Children's Hospital, Rome, Italy; [5]Karolinska Institute and University Hospital, Department of Women's and Children's Health, Stockholm, Sweden; [6]University of Rome 'Tor Vergata', Department of Systems Medicine, Rome, Italy

Introduction
Congenital hypogonadotropic hypogonadism (CHH) is a rare endocrine disorder caused by impaired gonadotropin secretion or action, disrupting pubertal development and reproductive function. Testosterone therapy induces secondary sexual characteristics but does not promote gonadal maturation, whereas gonadotropin therapy supports both testicular growth and function.
Aims and Methods
This study aimed to retrospectively compare auxological and pubertal outcomes in 39 male patients with isolated CHH treated with either testosterone or gonadotropins. Outcomes were assessed at four time points: T0 (treatment initiation), T1 (6–12 months), T2 (18–24 months), and T3 (attainment of adult height and after 6 months after treatment end). Testicular volume (TV) was used as a marker of gonadal maturation. Testosterone therapy was titrated to a final dose of 250 mg/month intramuscularly (or 40–60 mg/day transdermally) over two years. Gonadotropin therapy included rFSH (75 IU twice weekly) and hCG (1000–2000 IU twice weekly), with treatment durations ranging from 6 to 46 months (median: 12 months).
Results
Among the 39 patients, 16 were treated with gonadotropins, and 23 received testosterone. The median age at puberty induction was 16.2 ± 1.5 years for the gonadotropin group and 16.7 ± 1.8 years for the testosterone group. At each time point, gonadotropin-treated patients consistently showed a significantly higher median TV than the testosterone group. This difference, already significant at T1, increased at T2 and persisted at T3 (9.0 mL vs. 4.0 mL; $P < 0.0001$), confirming a sustained effect of gonadotropin therapy. Half of the gonadotropin-treated patients transitioned to testosterone after pubertal induction. In this subset, the difference in TV remained significant (11.0 mL vs. 4.0 mL; $P = 0.0002$). Auxological analysis revealed better adult height corrected for mid-parental height (MPH) in the gonadotropin group (SDS: 0.19 vs. -0.57; $P = 0.04$), indicating these patients achieved an adult height closer to their genetic potential. No significant differences were observed in other parameters.
Discussion and Conclusion
Gonadotropin therapy led to greater and sustained increases in TV compared to testosterone, even after transitioning to testosterone. This underscores its ability to promote gonadal maturation and enhance fertility potential. Additionally, patients treated with gonadotropins achieved final heights closer to their genetic potential, likely due to the more physiologically pubertal progression, which avoids premature epiphyseal closure often associated with faster initial growth seen with testosterone. Nevertheless, further studies are needed to confirm these results and explore the long-term implications, particularly for fertility outcomes.

Delayed puberty and intellectual disability: in a boy with a 15q11.2-q13. interstitial duplication including MKRN3 gene

Delfina Petrone[1], Stefania Palumbo[1], Adalgisa Festa[1], Francesca Aiello[1], Emanuele Miraglia Del Giudice[1], Claudia Santoro[1] & Anna Grandone[1]
[1]Università degli Studi della Campania Luigi Vanvitelli, Napoli, Italy

Background
The 15q11.2-q13 duplication syndrome is a rare genetic condition caused by the duplication of a chromosomal segment that is particularly prone to genetic rearrangements and subject to imprinting. It presents with a highly variable phenotype, including neurodevelopmental disorders and distinct craniofacial anomalies. This region includes the *MKRN3* gene, which is maternally imprinted and plays a critical role in regulating pubertal timing by inhibiting GnRH release. Paternally inherited loss of function mutation of *MKRN3* can lead to altered neuroendocrine signaling, impacting the onset of puberty and in particular causing central precocious puberty. Duplications of this chromosomal region have not been previously associated with alterations in pubertal timing to date.
Case Presentation
We report the case of a 16-year-old male with severe short stature, delayed pubertal development (Tanner stage 2, bilateral testicular volume of 8 mL with pubertal development arrest for two years, LH 1.6 IU/l, FSH 2.3 IU/l, Testosterone 95 ng/dl), and intellectual disability.
Materials and Methods
The patient's DNA was initially analyzed using Array – Comparative Genomic Hybridization (Array-CGH). To further characterize the identified duplication, MS-MLPA was performed to assess copy number variations and methylation status of the 15q11 region in genomic DNA extracted from peripheral whole blood samples (SALSA MLPA Probemix ME028-D1 Prader-Willi/Angelman, MRC Holland). Furthermore, to assess the impact of the 15q11-q13 microduplication on *MKRN3* expression in the patient's blood, quantitative real-time RT-PCR was conducted using the 2-ΔΔCT method.
Results
Genetic analysis identified a paternally inherited heterozygous interstitial duplication of the 15q11 region, spanning chromosomal positions 22,812,154 to 27,845,031, encompassing the *NIPA1*, *MKRN3*, and *OCA2* genes. Molecular analysis revealed a 67% reduction in methylation, consistent with paternal inheritance of the duplication. Quantitative analysis of *MKRN3* expression also showed an increase of over 2-fold compared to a healthy control.
Conclusion
The increased gene dosage of *MKRN3*, combined with reduced methylation, may enhance its inhibitory effect on the hypothalamic-pituitary-gonadal axis, delaying the pulsatile release of GnRH and contributing to the delayed sexual maturation observed in our patient. This observation, within the context of a structural genomic rearrangement, adds a novel contribution to the literature, expanding the spectrum of clinical manifestations associated with 15q11.2-q13 duplications.

Genetic characterization of pituitary neuroendocrine tumours in the maltese population

Emma Jayne Spiteri[1], Alison Tabone[1], Mark Gruppetta[2,3], Nikolai Paul Pace[4,5] & Josanne Vassallo[2,3,5]
[1]University of Malta, Faculty of Medicine and Surgery, Msida, Malta; [2]University of Malta, Department of Medicine, Faculty of Medicine and Surgery, Msida, Malta; [3]Mater Dei Hospital, Division of Endocrinology and Diabetes, Department of Medicine, Msida, Malta; [4]University of Malta, Department of Anatomy, Faculty of Medicine and Surgery, Msida, Malta; [5]University of Malta, Centre for Molecular Medicine and Biobanking, Msida, Malta

Pituitary neuroendocrine tumours (PitNETs) have a prevalence of 75.7/100,000 within the Maltese population. These tumours present a wide range of clinical behaviours, from hormone overproduction to local effects secondary to compression of adjacent structures, making them a significant public health concern. Despite their prevalence, the genetic factors contributing to sporadic PitNETs, which account for 95% of all cases, remain poorly understood. The primary aim of this study was to identify genetic variants associated with PitNETs in Maltese patients using germline whole exome sequencing, thereby contributing to the global understanding of the genetic aetiology of these tumours. The study cohort consisted of 44 Maltese patients diagnosed with PitNETs, selected based on comprehensive clinical evaluations and atypical phenotypic presentation. Germline DNA was extracted from blood samples, and whole exome sequencing was performed. Bioinformatic analysis was conducted using an in-house pipeline, incorporating variant calling, annotation, and filtering through a curated 75-gene panel associated with PitNET tumorigenesis, which was constructed using a PRISMA systematic review. Identified variants underwent functional prediction and pathogenicity assessment through in silico tools and structural modelling to predict the impact of missense variants on protein function. The study identified significant variants in five genes: *SDHA, CABLES1, CDK8, CDH23*, and *NGDN*. These genetic alterations were correlated with clinical data, revealing potential genotype-phenotype associations that could inform personalized treatment strategies. Each variant was validated through Sanger sequencing. This research provides novel insights into the genetic basis of PitNETs in the Maltese population and highlights unique characterisation of Maltese genetics and the importance of considering ethnic-specific genetic profiles in disease research. The findings underscore the potential for genetic screening in the clinical management

of PitNETs. Future work will focus on supporting these findings through functional assays, and exploring multi-omic approaches to further elucidate the molecular mechanisms thus improving diagnostic and therapeutic strategies.

Pasireotide induces long-term cystic degeneration of somatotrophic pituitary neuroendocrine tumors (PitNETs)

Romy van der Groef[1], Sophie Veldhuijzen van Zanten[2], Denise van Beekveld[2], Julie Celine Refardt[1] & Sebastian Neggers[1]
[1]Erasmus MC, Internal Medicine, Section Endocrinology, Rotterdam, Netherlands; [2]Erasmus MC, Radiology and Nuclear Medicine, Rotterdam, Netherlands

Background
Pasireotide LAR is a long-acting somatostatin analog with potential antitumor activity, as demonstrated by treatment induced increased MRI T2-signal intensity of somatotrophic PitNETs (1), but long-term follow-up data are lacking.
Aim
To investigate pasireotide's long-term antitumor effect and the impact on clinical outcomes in acromegaly patients.
Methods
We included participants from the previously published PAPE study (2) and evaluated clinical outcomes, medication use, and PitNET characteristics on MRI over the past 10 years. T2-weighted MRI signals of the PitNETs using grey matter as a reference were quantified and PitNET volumes and T2-intensity ratios (IRs) were calculated for each scan.
Results
Forty-four patients, 43 % female, median (IQR) age 52 (15 years) were included. Median treatment duration was 31.0 months. The median IR of the PitNETs increased between baseline and MRI at 7 years (1.09 vs. 1.57, $P < 0.001$), indicating cystic degeneration. In addition, a reduction in PitNET volume was observed between baseline and each subsequent follow-up MRI, with a more than twofold reduction in median volume between baseline and MRI at 7 years (1607 vs. 762 mm^3, $P = 0.03$). In 12 patients (27.3%), acromegaly treatment was reduced based on decreasing IGF-1 levels without presence of surgery or radiotherapy.
Conclusion
Pasireotide induces a long-term cystic degeneration process in somatotrophic PitNETs that persists for several years after treatment discontinuation. This phenomenon expands pasireotide's therapeutic applications by utilizing it as a potential preoperative treatment to enhance surgical outcomes.

Acromegaly management beyond primary surgery: efficacy and safety of repeat surgery and radiotherapy

Shahriar Atai[1,2], Markus Wiedmann[3], Daniel Dahlberg[3], Jens Bollerslev[2] & Ansgar Heck[1]
[1]Oslo University Hospital, Endocrinology, Oslo, Norway; [2]University of Oslo, Oslo, Norway; [3]Oslo University Hospital, Neurosurgery, Oslo, Norway

Introduction
Re-intervention, either repeat surgery or radiotherapy, is suggested in patients with acromegaly if primary transsphenoidal surgery does not lead to remission. However, the evidence for re-intervention is weak. Our aim was to assess efficacy and safety of re-intervention.
Methods
Patients diagnosed with acromegaly at Oslo University Hospital between 2005 and 2021, and with two or more interventions were included in the study cohort. Re-interventions included repeat surgery and/or radiotherapy after primary surgery. Remission was defined as IGF-1 below the upper limit of reference range without concurrent medical therapy. Adenoma size was classified as micro- (<1 cm) or macroadenoma (≥ 1 cm) and invasiveness after the Knosp-Steiner criteria. Assessed complications were pituitary deficiency, cerebrospinal fluid leakage, meningitis, vascular injury, postoperative hematoma and venous thromboembolism.
Results
Of 223 patients diagnosed with acromegaly, 42 patients were included in the study cohort. At baseline, median age was 38 (IQR 29-48) years, 41 had macroadenomas and one had a microadenoma. After re-intervention, 23 patients (55 %) were in remission and eleven patients (26%) could reduce the dosage of medical therapy (table 1). Seventeen were in remission after repeat surgery and six after radiotherapy. Of the 19 patients not in remission, seven had undergone surgery with the goal of debulking and thus not remission. After re-intervention, seven patients acquired new hormone deficiencies, five after repeat surgery and two after radiotherapy. Two patients acquired corticotroph deficiency, one after repeat surgery and one after radiotherapy. One patient had cerebrospinal fluid leakage and meningitis after repeat surgery; The patient recovered, and his acromegaly was in remission. There was no incidences vascular injury, postoperative hematoma or venous thromboembolism after repeat surgery.
Conclusion
In this single center study, re-intervention was safe and resulted in remission or substantial improvement in most patients. Re-intervention should be considered for patients who would otherwise require lifelong medical treatment.
Key words

Table 1

	Frequency (%)	Remission	Reduced med	No remission
1 surgery + radiotherapy	12 (29%)	3	7	2

Impact of compressive neuropathy on peripapillary retinal nerve fiber layer thickness in pediatric patients after craniopharyngioma surgery

Agnieszka Bogusz-Wojcik[1], Klaudia Rakusiewicz-Krasnodębska[1], Elzbieta Moszczynska[1], Paweł Kowalczyk[1], Maciej Jaworski[1] & Wojciech Hautz[1]
[1]Children's Memorial Health Institute, Endocrinology and Diabetology, Warsaw, Poland

Purpose
The present study aims to evaluate alterations in the peripapillary retinal nerve fiber layer (RNFL) thickness in pediatric patients following surgical resection of childhood-onset craniopharyngioma (CP) and to identify tumor characteristics factors influencing these alterations, including changes in the lesion's location.
Methods
A retrospective analysis was conducted on 73 eyes from 38 patients with CP and 64 eyes from 32 age- and sex-matched healthy controls. The mean age of the CP patients was 10,5 $\pm$ 4,1 years (range 4–17), while the control group had a mean age of 10,1 $\pm$ 4,2 years (range 4–17). Optical coherence tomography (OCT) was used to assess the peripapillary RNFL thickness in the study and control groups. RNFL thickness was analyzed in the superior, inferior, and average sectors and across eight optic nerve sectors. Tumor characteristics and endocrine and

neurological complications were evaluated to determine their correlation with changes in RNFL thickness.
Results
Postoperative thickness of peripapillary RNFL and individual sectors was significantly reduced in the CP group compared to healthy controls. Tumor maximum diameter and volume, calcification, presence of Rosenthal fibers, total resection, recurrence, progression, and ventriculoperitoneal shunt correlated with damage of RNFL.
Conclusions
CP is associated with significant reductions in RNFL thickness, reflecting the impact of the tumor on optic nerve fibers. OCT is a valuable tool for monitoring visual pathway impairment and postoperative outcomes. Regular RNFL evaluation should be integrated into the long-term care of CP patients to optimize visual prognosis and detect progressive or residual damage.

Prognostic factors of the level of cognitive functioning in children after craniopharyngioma treatment

Elzbieta Moszczynska[1], Agnieszka Rojczyk[2,3,4], Joanna Pietrusińska-Nunziati[1,5], Agnieszka Bogusz-Wojcik[1], Marta Baszynska-Wilk[1] & Paweł Kowalczyk[4]
[1]Children's Memorial Health Institute, Endocrinology and Diabetology, Warsaw, Poland; [2]University of Warsaw, Faculty of Psychology, Warsaw, Poland; [3]Children's Memorial Health Institute, Department of Health Psychology, Warsaw, Poland; [4]Children's Memorial Health Institute, Neurosurgery, Warsaw, Poland; [5]Children's Memorial Health Institute, Department of Health Psychology, Warszawa, Poland

Introduction
Craniopharyngioma (CP) is a rare intracranial embryonal malformations of the sellar region. Treatment complications, besides hormonal deficits, include disturbances in the patient's emotional and cognitive functioning. Previous studies of cognitive functions indicate overall typical intellectual performance with reduced scores in several areas. In contrast, there is still no consensus about the specific patterns of cognitive functioning, which also depend on the tumor's particular traits and the treatment used.
Aim
Analyze children's cognitive functioning level after CP treatment and assess the relationship between the course of the disease and treatment and the occurrence of cognitive deficits.
Material and Methods
A study enrolled 40 patients aged 6-18 (the average age at the time of examination was 12.9 years, 25 boys and 15 girls) treated for CP in IP CZD. The Stanford-Binet Intelligence Scales: 5th Edition (SB5), Rey's Complex Figure Test, and Benton's Visual Retention Test were used.
Results
The mean age at diagnosis was 9.3 years +/- 3,8 (min. 1.9 max. 16.0). All patients were diagnosed with adamantinomatous CP, and most of the tumor was solid-cystic type. (75%). Calcifications were confirmed in 87,5% of patients. Median tumor size was 41 mm (IQR: 31-52). According to the classification that assesses the position of the tumor in the hypothalamus (Puget's grading system), most tumors were grade 2 - 63.2% (grade 1 - 26,3%, grade 0 - 10,5%). 12 (30%) children underwent reoperation, 8 (20 %) required ventriculoperitoneal shunt implantation due to hydrocephalus, and 22 (55%) required radiotherapy. The study group scored lower than the normative group in general intellectual potential and memory. Several factors were observed that seem to be associated with better performance in some cognitive tests: cystic tumor, no calcifications, tumor diameter less than 4 cm, 0 and 1 grade of the Puget's grading system, endonasal surgery, no radiation therapy. Valve implantation seems to be a variable of particular importance - the children who required a ventriculo-peritoneal shunt received lower scores in almost all tests performed.
Conclusions
Children's general level of cognitive functioning after CP treatment is lower than that of the general population but remains within normal limits. However, a significant reduction in memory function is observed. Factors related to the morphology and location of the tumor, as well as the treatment administered, may reduce the risk of cognitive deficits. Understanding the long-term cognitive sequelae of CP and its treatment requires a broad, interdisciplinary perspective.

The natural course of macroincidentalomas: a retrospective study of a single reference center

Bruna Silva[1], Carolina Aloan[2], Valeria Priscila Neves[3], Vaniza Bordignon Pacheco[3], Christhiane Fialho[2], Elisa Lamback[2], Luiz Eduardo Wildemberg[2], Nina Ventura[4], Mônica Gadelha[2,5] & Leandro Kasuki[2]
[1]Unidade de Saude Local do Tâmega e Sousa, Endocrinology Department, Penafiel, Portugal; [2]Instituto Estadual do Cérebro Paulo Niemeyer (IECPN), Neuroendocrinology Unit, Rio de Janeiro, Brazil; [3]Instituto Estadual de Diabetes e Endocrinologia Luiz Capriglione, Endocrinology Department, Rio de Janeiro, Brazil; [4]Instituto Estadual do Cérebro Paulo Niemeyer (IECPN), Neuroradiology unit, Rio de Janeiro, Brazil; [5]Instituto Estadual do Cérebro Paulo Niemeyer (IECPN), Molecular genetics and Neuropathology laboratory, Rio de Janeiro, Brazil

Introduction
Pituitary incidentalomas are incidental findings in the pituitary gland, detected on imaging performed for unrelated reasons and are present in approximately 10–38.5% of imaging studies. Nevertheless, the majority are microincidentalomas (<1.0 cm), while macroincidentalomas (≥ 1.0 cm) have a prevalence of approximately 0.16% on magnetic resonance imaging (MRI) and 0.2% on computed tomography (CT). Current guidelines recommend screening for hypopituitarism in lesions ≥ 6.0 mm and MRI monitoring due to their potential for slow growth and symptomatic progression. However, the limited long-term follow-up studies of macroincidentalomas compromise a full understanding of their natural progression.
Objetives
We aim to study patients diagnosed with pituitary macroincidentalomas followed at our referral center, focusing on their clinical characteristics, therapeutic approach, and clinical outcomes.
Methods
We retrospectively reviewed all macroincidentalomas (pituitary adenomas ≥ 1.0 cm diagnosed in an imaging study requested for a reason not related with the adenoma) followed at our center (Instituto Estadual do Cérebro Paulo Niemeyer). Demographical, clinical, biochemical and radiological data at diagnosis were collected. The frequency of tumor growth, vision impairment, apoplexy and new anterior pituitary deficit was evaluated in the follow-up.
Results
A total of 57 patients were included [(56% females, median age at diagnosis 70 years-old (38 – 85)]. Median maximal tumor diameter and tumor volume at diagnosis were 2.1 cm (1.0 – 4.0 cm) and 2.97 cm^3 (0.22 – 18.62), respectively. Any anterior pituitary deficiency was observed in 28% of the patients at diagnosis, the most frequent being hypogonadism, that was observed in 21% of the cases. Median follow-up was 4 years (1 – 9 years) and tumor growth was observed in 18% of the tumors while apoplexy occurred in 5% of the tumors. Tumor growth was observed after a median of 24 months (3-48). Vision impairment was observed in 21% of the patients during follow-up. Surgery was performed in 19 patients (33%) due to compression of the optic chiasm with or without vision loss or tumor growth. New pituitary deficiency was diagnosed in six (11%) patients. There was no difference in median age, maximal tumor diameter or tumor volume at diagnosis between tumors that grew and those that remained stable.
Conclusions
Macroincidentalomas are rarer than microincidentalomas but require close follow-up as approximately 18% will present clinically significant growth and one-third will require surgical treatment. Nevertheless, apoplexy is not frequent. Hypopituitarism is present in about 30% at diagnosis and should be evaluated in all patients upon diagnosis.

Immunohistochemical biomarkers in acromegaly: predicting treatment response and associations with tumor characteristics

Maximilian Cosma Gliga[1], Maria Ionela Pascanu[1] & Laura Chinezu[2]
[1]George Emil Palade University of Medicine, Pharmacy, Science, and Technology of Târgu Mureş, Endocrinology, Targu Mures, Romania; [2]George Emil Palade University of Medicine, Pharmacy, Science, and Technology of Târgu Mureş, Histology, Targu Mures, Romania

Background
Although surgery is widely accepted as the first-line treatment for acromegaly, its success rate remains variable. Pharmacologic therapy with first-generation somatostatin receptor ligands (fgSRLs) is frequently employed for patients with persistent acromegaly after surgery. However, resistance to these agents is common, highlighting the need for biomarkers that predict treatment response. We aimed to analyze the roles of known immunohistochemical (IHC) biomarkers and a novel marker, the cytoskeleton protein Filamin A (FLNA), in predicting treatment response and their associations with tumor characteristics.
Materials and Methods
We conducted an IHC study to evaluate the expression of somatostatin receptor subtypes (SSTR2 and SSTR5), cytokeratin granulation patterns (densely vs sparsely granulated), E-Cadherin, and FLNA in tissue samples from acromegaly patients who underwent surgery. Paraffin-embedded tumor samples were analyzed, and clinical data were retrospectively collected from patient files. This included information on surgical outcomes, pharmacological treatment response, and imaging data regarding tumor size and invasiveness.
Results
30 patients were included, with fgSRL treatment response data available for 21 patients. Resistance to fgSRLs was more frequently observed in patients with sparsely granulated tumors and lower IHC expression of SSTR2 and E-Cadherin. Positive correlations were identified between IGF-1 decrease after six months of fgSRL treatment and the expression of SSTR2 ($P = 0.024$, $r = 0.49$) and E-Cadherin ($P = 0.009$, $r = 0.64$). No correlation was found for SSTR5 expression. ROC curve analysis identified E-Cadherin as the best predictor of fgSRL response, achieving 100% sensitivity and specificity, surpassing SSTR2 and granulation patterns. FLNA expression was positive in all tumor samples, and higher FLNA expression was significantly associated with SSTR5 expression and suprasellar invasion.
Conclusions
IHC analysis of SSTR2 and E-Cadherin provides valuable insights for predicting fgSRL treatment responses in acromegaly. Densely granulated tumors with positive SSTR2 and E-Cadherin expression are associated with favorable outcomes, with E-Cadherin emerging as the most reliable predictive marker. The associations we observed between FLNA and SSTR5, as well as FLNA and tumor invasiveness warrant further investigation to clarify the predictive and prognostic role of FLNA in pituitary tumors. Incorporating IHC evaluation of these biomarkers in clinical practice may enable a more personalized therapeutic approach for patients with acromegaly.

Neurophysin I: a reliable, novel, and robust biomarker for oxytocin an analysis of a double-blind placebo-controlled cross-over trial

Cihan Atila[1], Andi Nikaj[2], Svenja Leibnitz[2], Matthias Liechti[2] & Mirjam Christ-Crain[2]
[1]University Hospital Basel, Department of Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University of Basel, Basel, Switzerland

Background
Oxytocin (OXT) deficiency is a recently identified new neuroendocrine entity associated with anxiety and reduced prosocial behavior. However, diagnosis and clinical progress have been hindered by challenges in reliably measuring OXT due to its instability and short half-life. Neurophysin I (NP-I), an equimolarly co-released cleavage product of the OXT precursor peptide, offers a promising alternative biomarker due to its stability and longer half-life, though it requires validation.
Methods
Analysis of a double-blind, placebo-controlled, cross-over study including 15 patients with hypothalamic-posterior-pituitary dysfunction and 15 matched healthy controls (according to age (+/-3), sex, body mass index [BMI] (+/-2), and menopause/hormonal contraceptives). Participants received a single oral of the strong OXT stimulator 3,4-methylenedioxymethamphetamine (MDMA, 100mg) and placebo, separated by two weeks. NP-I and OXT levels were measured at six time points over five hours. Subjective drug effects were assessed using visual analog scales. The area under the curve (AUC) in plasma NP-I from 0 to 300 minutes between both groups was analyzed using linear mixed-effects regression model. The AUC in receiver-operating characteristics curve (ROC) was assessed for MDMA-stimulated NP-I and OXT in differentiating patients from healthy controls.
Results
The median age was 34 years [IQR 25-46] in patients and 35 years [IQR 26-48] in controls, with both groups consisting of 53% ($n = 8$) females. In healthy controls, MDMA induced an 8-fold increase in OXT (peak: 624 pM [235-959]) and a 20-fold increase in NP-I (peak: 1508 pM [911-2233]). In contrast, in patients, no notable increase in OXT (peak: 92 pM [79-110]) and only a mild increase in NP-I (peak: 263 pM [140-300]). The AUC of NP-I after MDMA was 2279 pM•5h [1087-3696] in healthy controls and 97 pM•5h [50-241] in patients, with a significant difference of 2340 pM•5h (95%-CI [1462-3218]; $P < 0.0001$). NP-I strongly correlated with OXT ($r = 0.92$) and increases in subjective effects, e.g., 'liking effect,' 'feeling high,' 'trust,' and 'fear reduction' (all $R > 0.5$). MDMA-stimulated NP-1 demonstrated strong diagnostic performance in differentiating patients with OXT deficiency from healthy controls with a ROC-AUC of 100%.
Conclusion
These results validate NP-I as a biomarker for endogenous OXT secretion, addressing long-standing challenges in direct OXT measurement. NP-I offers novel opportunities for research in conditions where reduced OXT levels or disruptions in signaling are implicated, such as autism spectrum disorder, anxiety, and depression.

Gemelli IRCCS, UOC Endocrinology and Diabetology, Rome, Italy; [11]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy

Purpose
To assess the clinical presentation and outcomes of pituitary apoplexy in a large cohort of patients with PitNETs.
Methods
Retrospective multicenter study, including 162 patients (100 males, median age 51 years) from ten Italian referral centers for PitNETs. All patients >18 years old with a diagnosis of pituitary apoplexy based on clinical and radiological features were eligible. Clinical and biochemical assessment was performed at the time of apoplexy and after at least 12 months of follow-up.
Results
At the time of apoplexy, patients with macroadenomas had a higher frequency of headache (81.7% vs 45.5%, $P = 0.011$), visual field defects (57.7% vs 18.2%, $P = 0.012$), diplopia (39.4% vs 9.1%, $P = 0.039$) and hypopituitarism (64.8% vs 27.3%, $P = 0.017$) compared to those with microadenomas. Men were more likely to have secondary adrenal insufficiency (59.6% vs. 40.3%; $P = 0.017$) and central hypogonadism (61.2% vs. 36.1%, $P = 0.002$) and were more likely to undergo surgery (78.0% vs. 58.1%, $P = 0.007$) compared to women. In terms of outcomes, no differences were observed between patients who underwent surgery and those who did not, except for hypothyroidism, which was more prevalent in surgically treated patients (62.8% vs 45.8%, $P = 0.034$). Nevertheless, 67.7%

of the surgically treated patients (48 out of 71) had a pre-existing diagnosis of central hypothyroidism at the time of apoplexy.
Conclusion
The size of the adenoma and the male se, have been demonstrated to influence the clinical presentation of the apoplectic event, while the management, surgical or conservative, does not appear to affect the long-term outcomes.

Generation and interrogation of a consensus multi-omics atlas for pituitary gland research

Bence Kover[1], Hui-Chun Lu[1] & Cynthia Andoniadou[1]
[1]King's College London, Centre for Craniofacial and Regenerative Biology, London, United Kingdom

Despite the widespread adoption of single-cell profiling for transcriptome and chromatin accessibility in the pituitary gland, there is still little agreement on cell type markers and cell population annotation. This lack of consensus stems from the disparate processing and downstream analysis methods used and arbitrary parameter and naming choices. To this end, we set out to generate a uniformly pre-processed and analysed consensus pituitary atlas (CPA), using all published single-cell profiled datasets to date (180 samples). Curation uncovered 8 out of 34 peer-reviewed publications to have either erroneously described barcoding kits or mouse samples with incorrectly assigned sexes. With these issues fixed, the atlas enables querying 750,000 cells, 10-times more than previous efforts, increasing the power of these analyses. We present the identification of novel consensus cell type markers for accurate cell typing, and markers associated with cell fate decisions. Mapping of isoform gene variants, reveals differential isoform preference across cell types. Leveraging the metadata associated with samples enabled dissection of sexual dimorphism at the cellular level. Notably, somatotrophs, lactotrophs, gonadotrophs and stem cells are dimorphic both at the gene expression and chromatin levels. Transcription factor motif enrichment suggested that these changes were driven by estrogen and androgen receptor activity in females and males respectively. We then extracted the most consistently predicted ligand-receptor interactions across all non-genetically modified (wild-type) transcriptomic samples ($n = 84$) using 5 different algorithms and present these for the different cell types. In stem cells, top interactions included SLIT2 signalling to Lactotrophs and Thyrotrophs, autocrine FGF signalling, as well as high expression of *Erbb4* receptor (targeted by NRG3 from melanotrophs). To increase reproducibility and data availability, we developed an online platform called *epitome*, where researchers can explore and download analysis results and processed samples associated with the CPA. This platform will allow the CPA to be continuously updated and maintained as more datasets become available, making it a useful resource for the community.

Preliminary results from the core registry-gender incongruence module: current insights and future directions

Silvia Ciancia[1], Mariya Cherenko[2], Daniel Klink[1], Kanetee Busiah[3], Regis Coutant[4], Aneta Gawlik[5], Wiktoria Kempinska[5], Hedi Claahsen - van der Grinten[6], Faisal Ahmed[2,7], Sabine Hannema[8] & Martine Cools[1]
[1]Ghent University Hospital, Department of Internal Medicine and Pediatrics, Service of Pediatric Endocrinology, Ghent, Belgium; [2]Leiden University Hospital, Department of Medicine, Division of Endocrinology, Leiden, Netherlands; [3]Lausanne University Hospital, Department of Pediatrics, Service of Endocrinology, Lausanne, Switzerland; [4]Angers University Hospital, Department of Pediatrics, Service of Endocrinology, Lausanne, France; [5]Medical University of Silesia, Department of Pediatrics and Pediatric Endocrinology, Katowice, Poland; [6]Radboudumc, Department of Pediatrics, Service of Pediatric Endocrinology, Nijmegen, Netherlands; [7]University of Glasgow, Office for Rare Conditions Registries, Glasgow, United Kingdom; [8]Amsterdam UMC, Department of Pediatrics, Service of Pediatric Endocrinology, Amsterdam, Netherlands

Objective
Healthcare for transgender and gender-diverse (TGD) adolescents varies across countries, and there are very few prospective and long-term outcome data. Therefore, a specific module dedicated to gender incongruence (GI) within the Core Registry (EuRRECa project) was developed to collect demographic and numerosity data while promoting the harmonization of care. Additionally, this project aims to facilitate longitudinal data collection through international, multicenter collaborations with the ultimate scope of fostering clinical research and refining current guidelines.
Methods
The module consists of five sections covering general information, including the presence of mental health comorbidities, as well as specific information on gonadal hormone suppression (GHS), gender-affirming hormone (GAH) therapy, fertility preservation, and gender-affirming surgery (GAS).
Results
As of December 2024, six centers from five European countries (Belgium, France, Poland, Switzerland, and the Netherlands) had actively joined the project. A total of 310 patients have been registered so far (Ghent 119, Katowice 81, Nijmegen 39, Lausanne 36, Amsterdam 27, Angers 8). The interest of patients in being contacted for research purposes, accessing the registry, and receiving the newsletter was investigated. If the vast majority of patients agreed to be contacted for research purpose by their responsible clinician, less than 40% gave consent to be contacted directly through the registry for outcome collection. The preliminary findings highlighted the existence of differences among centers, for example in protocols for the initiation of GHS and GAH, where variations in the age at the start of treatments and the choice of alternative formulations suggest the existence of differences in national regulations and healthcare policies, e.g. reimbursement criteria. Importantly, mental health comorbidities were commonly reported among TGD adolescents from all centers, emphasizing the need for comprehensive psychological assessment and targeted psychological care.
Conclusion
Despite being preliminary, the data collected so far highlight the importance of multicenter data collection in advancing knowledge on the care of TGD adolescents. Expanding this registry and fostering international collaboration will be crucial in standardizing protocols, improving care, and guiding evidence-based recommendations for TGD youth.

Worldwide secular changes in limits for age at thelarche: an updated systematic review and meta-analysis

Charlotte E. Thomsen[1,2], Julie Ørkild[1,2], Jørgen Petersen[1,2,3], Stine A. Holmboe[1,2], Anders Juul[1,2,4], Lise Aksglaede[1,2] & Trine Johannsen[1,2]
[1]Copenhagen University Hospital - Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark; [2]Copenhagen University Hospital - Rigshospitalet, International Centre for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen, Denmark; [3]University of Copenhagen, Department of Biostatistics, Copenhagen, Denmark; [4]University of Copenhagen, Faculty of Health and Medical Sciences, Department of Clinical Medicine, Copenhagen, Denmark

Background
The mean age at thelarche has declined worldwide in recent decades. However, it is unclear whether this trend in the onset of puberty persists. Additionally, it remains unknown if there have been corresponding shifts in the upper and lower age limits (± 2 standard deviations [SDs]) of pubertal onset.
Objective
To update published data on the secular trend in mean age at pubertal onset in girls and to evaluate the upper and lower age limits of pubertal onset over time.

Methods
This systematic review and meta-analysis updated a previous review from our research group(1) of 38 publications (1977–2019) by conducting an extended literature search in PubMed and Embase for original and peer-reviewed studies published between 2019 and 2024. The current study included the 38 publications from the previous study in the meta-analysis, with minor data updates. Studies reporting the onset of breast stage 2 (B2, thelarche) in healthy girls examined by healthcare professionals were included. Study quality was assessed based on study design and statistical methods. Global trends were calculated using weighted regression analysis.
Results
A total of 44 publications (six new) met the inclusion criteria, representing 60 populations and approximately 246,000 girls. The mean age at thelarche decreased by 0.26 (95% CI: -0.43 to -0.09) years ($P = 0.002$), corresponding to 3.1 months per decade. In 30 of the 44 publications, data on SDs was available. The upper age limit of thelarche decreased by 0.29 (-0.53 to -0.04) years ($P = 0.02$), corresponding to 3.5 months per decade, while the lower age limit decreased by 0.12 (-0.41 to 0.16) years ($P = 0.40$), corresponding to 1.5 months per decade.
Conclusion
Our worldwide study confirmed that marked changes continue in the mean age at thelarche. Importantly, we found a downward trend in the upper age limit of pubertal onset in girls, while the trend did not reach statistical significance for the lower age limit of pubertal onset. Although our results may not directly inform revised age limits for normal pubertal timing in all countries, they provide a global overview of secular trends. Further investigation is needed to determine the clinical implications.

The role of caSR for gonadotropin release in male mice
Benedicte Probst-Drejer[1], Nadia Nicholine Poulsen[1], Ida Marie Boisen[1], Anne Jørgensen[1] & Martin Blomberg Jensen[1,2]
[1]Copenhagen University Hospital - Herlev and Gentofte, Division of Translational Endocrinology, Department of Endocrinology and Internal Medicine, Herlev, Denmark; [2]Copenhagen University Hospital, Department of Clinical Medicine, Copenhagen, Denmark

Introduction
A clinical study showed that calcium supplementation to prepubertal girls induced earlier puberty compared with placebo treatment. The calcium-sensing receptor (CaSR) is important for maintaining serum calcium concentrations within a narrow range. CaSR activity can be allosteric modulated by cinacalcet, commonly used in the clinic to treat hyperparathyroidism. CaSR has previously been identified in the pituitary gland of both humans and rodents, and we have found CaSR to be specifically expressed in α-glycoprotein subunit (αGSU)-positive cells in the anterior pituitary of mice. Gonadotropic cells of the anterior pituitary secrete luteinizing hormone (LH) and follicle-stimulating hormone (FSH) which promote e.g. pubertal onset, production of sex steroids, gametogenesis, and ovulation. The presence of CaSR in the pituitary suggest a direct regulatory role of calcium, which implies that the effect of calcium supplementation on pubertal timing, could potentially be caused by a direct effect of calcium on the pituitary. This study aims to elucidate the effect of CaSR modulation on pituitary function and male reproductive outcomes using pharmaceutical and genetic approaches.
Methods
Initially, the role of CaSR in pituitary function was examined by treating wildtype male mice of the reproductive age with cinacalcet (100 mg/kg) daily for two weeks. To explore further, a pituitary specific *Casr*-deficient mouse model was generated utilizing the Cre-LoxP system, and further validated through immunohistochemistry (IHC). The endocrine and reproductive phenotypes of both mouse models was examined through mass spectrometry and enzyme-linked immunosorbent assay (ELISA).
Results
Wildtype male mice treated with cinacalcet had a 64% decrease of LH serum levels compared with the control group ($p=0.039$). Furthermore, testosterone levels were reduced with 97% in mice treated with cinacalcet compared with vehicle-treated mice ($p=<0.0001$). The pituitary specific *Casr*-deficient mouse model was evaluated at 8-weeks of age, and there was a tendency towards higher LH serum levels.
Conclusion
Together, these preliminary findings suggest that modulation of CaSR activity can influence gonadotrophic cell function, thus highlighting a potential link between CaSR function and reproductive health. Further investigation of the phenotypic traits of the *Casr*-deficient mouse model is needed to fully understand the mechanisms underlying these observations.

Calcium directly influences pituitary function in female mice through the calcium sensing receptor (CaSR)
Nadia Nicholine Poulsen[1], Benedicte Probst-Drejer[1], Anders Juul[2,3,4], Anne Jørgensen[1] & Martin Blomberg Jensen[1,4]
[1]Copenhagen University Hospital Herlev, Division of Translational Endocrinology, Department of Endocrinology and Internal Medicine, Copenhagen, Denmark; [2]Copenhagen University Hospital Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark; [3]International Center for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen, Denmark; [4]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark

Introduction
In a previous randomized clinical trial (RCT), prepubertal children were given calcium supplementation or placebo. Girls in the intervention group entered puberty 5 months earlier than the placebo group, but no effect on pubertal timing were detected in the boys who participated in the RCT. CaSR is the main receptor for systemic calcium homeostasis, and its presence has been established in the anterior pituitary. The aim of this study was to investigate if the effect of calcium on pubertal timing seen in the RCT was due to a direct effect on pituitary function through CaSR.
Methods
A mouse model was generated using the Cre-LoxP method, to introduce a deletion of CaSR specifically in the anterior pituitary. Female knock-down (KD) and control mice ($n = 13$, both groups) were sacrificed at 8 weeks and blood samples and reproductive organs were collected. Hormone levels were measured using both commercially available and in-house ELISAs. Collected organs were weighted and stored either at -80°C or was formalin and paraffin embedded.
Results
Female reproductive organs showed significantly lower weight when comparing CaSR knock-down to control mice (organ weight/total body weight%): This included ovary weight (0.02176 vs. 0,03534; $P = 0.0035$) and uterus weight (0.1788 vs. 0.3826; $P = 0.0023$). No difference in *Fsh* expression was detected between the two groups. However, a tendency towards lower *Lhbeta* levels was observed in the KD group with a relative expression level of 0.33 compared to control set to 1 ($P = 0.0544$). Accordingly, a trend toward lower serum LH was detected in the KD mice (0.7619 ng/mL) compared to control littermates (0.9887 ng/mL), however this was not statistically significant ($P = 0.0845$). There was no difference in serum AMH or Inhibin-B levels between the two groups.
Conclusion
Female mice with a KD of CaSR in the anterior pituitary have lower ovary and uterus weight compared to littermate controls. No change in AMH og Inhibin B levels between the groups, but a slight tendency towards lower LH serum levels and *Lhbeta* expression levels in the KD group. Further characterization of the phenotype in this mouse model is ongoing, and the evaluation of puberty timing in these mice are still pending. If CaSR proves to be important for the regulation of the Hypothalamic-Pituitary-Gonadal (HPG) axis, it has a clinical perspective since CaSR can be modulated by the drug Cinacalcet, an allosteric agonist of CaSR, already in clinical use.

Introduction
The ongoing prospective, non-interventional LINC 6 (NCT05382156) study evaluates long-term safety and effectiveness of osilodrostat, a potent 11β-hydroxylase inhibitor, in routine clinical practice over 3 years in patients with Cushing's syndrome (CS). We report results from a prespecified 2-year interim analysis.
Methods
Adults with endogenous CS were enrolled in five countries (Europe/USA) where osilodrostat is approved and available. The primary objective is long-term safety and tolerability, evaluated by the rate of osilodrostat-related adverse events (AEs) and serious AEs (SAEs). Secondary effectiveness endpoints include change in mean urinary free cortisol (mUFC) and late-night salivary cortisol (LNSC). Outcomes were analysed in patients who were prior (any time before study entry) or new users of osilodrostat. AE/SAE data are reported up to data cut-off (July 2024) in the safety population ($\geq$1 dose, $n = 206$). Cortisol changes are reported in patients with assessments at baseline and month (M)6. All assessments are descriptive.
Results
Data were available for 205 patients: Cushing's disease, $n = 161$; adrenal adenoma, $n = 12$; adrenal carcinoma, $n = 2$; bilateral adrenal nodular disease, $n = 10$; ectopic adrenocorticotropic hormone secretion, $n = 17$; other, $n = 3$. Among prior ($n = 135$) and new ($n = 70$) users, 74.1% and 78.6% were female, and mean (SD) age was 54.1 (13.9) and 50.8 (15.1) years, respectively. Median (min–max) on-study osilodrostat exposure and dose were 10.4M (0.0–20.8) and 5.0 mg/day (0.5–80.0) in prior users and 4.2M (0.4–19.6) and 4.7 mg/day (1.6–69.3) in new users. Thirty-one prior and 12 new users reported 75 and 30 AEs considered treatment related, most commonly (>6.0% of events) adrenal insufficiency (13.3%, $n = 10/75$), dizziness (8.0%, $n = 6/75$), diarrhoea and fatigue (both 6.7%, $n = 5/75$) among prior users and adrenal insufficiency (16.7%, $n = 5/30$), gastrointestinal disorder, hypokalaemia, headache, and abnormal hair growth (all 6.7%, $n = 2/30$ each) among new users. Seven (six [4.4%] prior, one [1.4%] new user) patients discontinued because of 11 (10 in prior, one in new user) treatment-related AEs. SAEs occurred in 9.6% ($n = 13/135$) of prior and 20.0% ($n = 14/70$) of new users; 7/21 (33.3%) and 4/24 (16.7%) SAEs were considered treatment related, respectively. At M6, mUFC and LNSC were normal in 67.6% ($n = 25/37$) and 35.3% ($n = 6/17$) of prior, and in 44.4% ($n = 4/9$) and 16.7% ($n = 1/6$) of new, users, respectively.
Conclusions
LINC 6 2-year interim data show the clinical utility of osilodrostat in a real-world setting for the management of CS in both prior and new users with differing aetiologies. AEs were as expected; few led to treatment discontinuation.

Hypogonadotropic hypogonadism diagnosis in boys under one year of age based on gonadotrophins, testosterone, antimullerian hormone (AMH) and inhibin B (INHB) measurements

Tifenn Guéguen[1], Martinerie Laetitia[2], Sarah Castets[3], Vanessa Menut[4], Carine Villanueva[5], Anne-Sophie Lambert[6], Kevin Perge[5], Bouhours-Nouet Natacha[1], Levaillant Lucie[1], Tristan Avril[2], Dominique Simon[2], Marc De Kerdanet[7], Sabine Baron[4], Rachel Reynaud[3], Marc Nicolino[5], Morel Bouvattier Claire[6] & Regis Coutant[8,8]
[1]University Hospital, Angers, Angers, France; [2]CHU Robert Debré, Assistance Publique Hôpitaux de Paris, Paris, France; [3]Assistance Publique-Hôpitaux de Marseille, Marseille, France; [4]University Hospital, Nantes, Nantes, France; [5]Civil Hospices of Lyon, Lyon, France; [6]CHU Bicetre, Assistance Publique-Hôpitaux de Paris, Paris, France; [7]University Hospital, Rennes, Rennes, France; [8]CHU d'Angers, Unité d' Endocrinologie Diabetologie Pédiatrique, Angers, France

Context
Congenital hypogonadotropic hypogonadism (CHH) in infant boys is a rare disorder that can manifest as micropenis and/or cryptorchidism. Mini puberty is considered a window of opportunity for CHH diagnosis and treatment. The lack of testosterone increase during this period is the gold standard for CHH diagnosis, but hormonal evaluation is not always available at this time. No cutoff values for the hypothalamic-pituitary-gonadal (HPG) hormones have been proposed before one year of age.
Objectives
The aim was to compare inhibin B (INHB), anti-Mullerian hormone (AMH), testosterone, LH, and FSH between infant boys (1 to 365 days) with micropenis and/or cryptorchidism due to isolated CHH (iCHH), CHH as part of combined pituitary hormone deficiency (CPHD), or of idiopathic origin (controls), and to determine discriminating cutoffs for CHH diagnosis based on sensitivity (Se) and specificity (Sp).
Methods
This multicenter study from seven University Hospitals in France included 132 boys aged 0 to 12 months with FSH $< +2$ SD scores (58 with iCHH, including 27 with a positive molecular diagnosis, 32 with CPHD, and 42 controls). Three periods of interest were studied: between 1 to 4 days, 15 to 65 days (mini puberty), and 66 to 365 days (after the testosterone peak of mini puberty).
Results
The best-discriminating hormone was INHB between 1-4 days (Se/Sp were 100%/83% at 150 pg/mL, and 89%/100% at 85 pg/mL), testosterone between 15-65 days (Se/Sp 100%/100% at 2.3 nmol/l), and INHB and AMH after 65 days (INHB, Se/Sp 100%/85% at 170 pg/mL and 88%/100% at 120 pg/mL)(AMH, Se/Sp 100%/71% at 800 pmol/l, and 60%/100% at 400 pmol/l).
Conclusion
Inhibin B $<$ 85 pg/mL between 1-4 days, testosterone $<$ 2.3 mmol/l between 15 65 days, and INHB $<$ 120 pg/mL and AMH $<$ 400 pmol/l between 66-365 days are associated with a high risk of CHH when FSH levels are low.

Long-term outcome after craniopharyngioma in childhood: the role of treatment in specialized centers

Nele Tacke[1], Carsten Friedrich[2], Martin Schuhmann[3], Joachim Woelfle[4] & Gerhard Binder[1]
[1]University Children's Hospital Tübingen, Pediatric Endocrinology, Tübingen, Germany; [2]University-Children's Hospital, Department of Pediatrics and Pediatric Hematology/Oncology, Oldenburg, Germany; [3]University Hospital Tübingen, Section of Pediatric Neurosurgery, Department of Neurosurgery, Tübingen, Germany; [4]University Hospital Erlangen, Department of Pediatrics and Adolescent Medicine, Erlangen, Germany

Background
Craniopharyngioma is a rare non-malignant tumor of the suprasellar region associated with poor outcomes, particularly severe hypothalamic obesity. The aim of this retrospective study was to compare the outcome of patients treated in two specialized university hospitals (surgery & long-term care) with the overall outcome in Germany documented in the German Craniopharyngioma Registry. The primary endpoint was BMI at the last follow-up in pediatric care.
Methods
All patients with craniopharyngioma undergoing surgery between 2000 and 2020 were identified from two specialized pediatric centers (SC). Data from the German craniopharyngioma registry (REG), collected in the same period, served as a comparison. Age and BMI at surgery, number and type of surgeries, radiotherapy, and age and BMI at last follow-up were recorded. Patients with follow-up $<$12 months were excluded. Each BMI was calculated as a percentage of the P95 value corresponding to age and sex (%BMI_{P95}), a measure that correlates better with fat mass in severely obese children than SDS-LMS. Data are given as median and quartiles. The Mann-Whitney U test was applied for statistical analysis.

Results
A total of 54 SC and 187 REG patients were analyzed. The cohorts (SC vs REG) were comparable in terms of age (9.7 y (6.1-13.2) vs 10.5 y (7.2-13.7)), sex (43 vs 52% female), and %BMI_{P95} (81.5 (70.0-92.2) vs 82.8 (71.8-96.1)) at surgery. Pre-treatment obesity (BMI >P97) was observed in 7.7% of SC patients compared to 11.7% in REG patients. Treatment modalities differed, with higher transsphenoidal surgery rates at SC (37.7 vs 19.3%) and lower radiotherapy rates at SC (31.5 vs 50.5%). Occurrence of relapse surgery (35.2 vs 32.0 %) and the number of relapses (mean of 0.54 vs 0.41) were comparable. The follow-up time was 7.8 y (5.3-10.5) in SC and 6.2 y (3.2-9.0) in REG, with last follow-up age of 18.6 y (15.5-20.2) in SC and 17.3 y (13.8-19.7) in REG. Height SDS at last follow-up was not different; -0,06 (-1,01 – 0.73) in SC and -0.05 (-0.89 – 0.79) in REG. In contrast, at last follow-up 37.0% of the patients were obese in SC, but 56.1 % in REG. Notably, %BMI_{P95} was 92.8 (77.8-118.4) in SC, but 106.5 (89.6-130.8) in REG, with a significantly higher post-surgical increase of %BMI_{P95} in REG ($P = 0.024$).
Conclusions
Data of this study clearly suggest that *children* with craniopharyngioma benefit significantly from treatment in specialized centers. The observed outcome speaks in favor of centralized care treatment.

Background
The limited availability of CRH in many countries poses a challenge in differentiating ACTH-dependent Cushing's syndrome (CS). While elevated ACTH and cortisol levels are frequently linked to ectopic CS (ECS), the diagnostic accuracy of standard CS screening tests (CSST) in distinguishing ECS from Cushing's disease (CD) remains uncertain.
Objective
To evaluate the diagnostic performance of morning plasma ACTH and CSST in differentiating CD from ECS in a large cohort of patients with confirmed ACTH-dependent CS.
Methods
We conducted a retrospective, multicenter study across six European centers. Inclusion criteria: (1) patients with overt ACTH-dependent CS and available morning plasma ACTH and CSST results at initial diagnosis; (2) confirmed diagnosis based on histopathology and/or biochemical findings. Cut-offs were determined using ROC analysis (ECS as reference) and the Youden Index. Results were expressed as multiples of the upper limit of normal (x ULN).
Results
A total of 542 patients (493 CD [91%]; 77% female; median age 43 years) were included. The optimal morning ACTH cut-off was 1.8x ULN (sensitivity 74%, specificity 77%, AUC=0.747 [95% CI 0.688-0.853]). Among CSST, 24-hour urinary free cortisol (24h-UFC) showed the best diagnostic performance (cut-off 5.9x ULN, sensitivity 81%, specificity 79%, AUC=0.869 [95% CI 0.816-0.923]), followed by late-night salivary cortisol (cut-off 6.5x ULN, sensitivity 84%, specificity 71%, AUC=0.855 [95% CI 0.768-0.942]) and the 1mg-dexamethasone suppression test (cut-off 9.9x ULN, sensitivity 83%, specificity 72%, AUC=0.823 [95% CI 0.740-0.906]). In 347 patients (313 CD [90%]) with morning ACTH and at least two CSST available, concordance among the majority of tests resulted in a sensitivity and specificity both of 85%, with a high negative predictive value (98%) but a low positive predictive value (37%). Of note, when test results were evenly discordant, results of CSST were prioritized over ACTH due to their higher AUC values.
Conclusion
While morning ACTH and individual CSST have limited accuracy in distinguishing ACTH-dependent CS subtypes, their combined evaluation can improve the noninvasive diagnostic approach. In particular, concordantly low CSST results strongly suggest the absence of ECS.

Immune-related hypophysitis and imaging: a distinct type of hypophysitis?

Anna Angelousi[1], Stavroula Asimakopoulou[1], Spyridon Kazanas[1], Athina Karampela[1], Elisavet - Charikleia Tasouli[1], Panagiotis Diamantopoulos[1], Amalia Anastasopoulou[1], Charis Bourgioti[2], Lia-Angela Moulopoulos[2], Dimitrios Ziogas[1] & Helen Gogas[1]
[1]Laikon General Hospital of Athens, National and Kapodistrian University of Athens, First Department of Internal Medicine, Athens, Greece; [2]National and Kapodistrian University of Athens, Aretaieion Hospital, Department of Radiology, Athens, Greece

Background
Immune checkpoint inhibitors (ICI) have transformed the prognosis of many solid malignancies. However, their use has also been associated with distinct endocrine immune-related adverse events (irAEs), hypophysitis being among the most common.
Purpose
To describe, in a real-world patient cohort, how ir-hypophysitis is depicted on a pituitary magnetic resonance imaging (MRI) and how these imaging findings are evolved overtime.
Methods
A retrospective analysis of pituitary MRI was conducted in cancer patients treated with ICI-based regimens who developed biochemically documented pituitary insufficiency from January 2016 to September 2024. The first MRI was performed at the time of diagnosis of ir-hypophysitis, and the second MRI during the follow-up. MRIs were evaluated by a central radiologist team blinded to the onset of ir-hypophysitis.
Results
Sixty-six ICI-treated cancer patients diagnosed with biochemically documented anterior pituitary deficiency were eligible for inclusion in our analysis. The majority of them received immunotherapy (70% anti-PD-1 or anti-PDL-1 ICI, and 19% anti-PD-1/anti-PD-L1 and anti-CTLA-4 combinations) for melanoma (90.9%), whereas 4.5% of cases for lung cancer, 1.5% colon cancer and 3% hepatocellular carcinoma. The initial pituitary MRI was available in 60 patients and performed at a median time of 2 weeks post-diagnosis of ir-hypophysitis. Abnormalities were found in 32 patients (53.3%), including enlargement (25%) or reduced enhancement of the pituitary gland (10%), empty sella turcica (8.3%), and less commonly heterogeneous enhancement (5%), reduced dimensions of the pituitary gland (3.3%) and slight deviation of the stalk (1.7%). A 2nd pituitary MRI assessment, after a median follow-up of 1.6 years, was available in 37 patients; 45% of them presented alteration of their initial abnormal MRI findings. Abnormalities were described in 62.2% of cases, including reduced dimensions (18.9%), enlargement of the pituitary gland (16.2%), a partially empty sella turcica (16.2%), heterogeneous enhancement of the pituitary gland (8.1%) and reduced enhancement (2.7%). No ICI-based regimen nor combination treatments were associated with a specific abnormal pituitary imaging or with the frequency of abnormal imaging findings at follow-up. Patients with multiple axes deficiencies presented an increased prevalence of MRI abnormalities compared to those with isolated corticotrope deficiency in both time assessments.
Conclusion
MRI pituitary abnormalities in patients with ir-hypophysitis were found in approximately half of them; were not specific to the underlying malignancy and the administered ICI; and persisted over time transforming their abnormal MRI imaging. The other half presented normal pituitary MRI in both assessments, keeping the challenge of imaging for this irAE.

Objective

Radiotherapy plays a relevant role in pituitary neuroendocrine tumors (PitNETs) uncontrolled by surgery and resistant to medical treatments. Radiotherapy controls tumor progression in most cases, but not always. Prognostic factors for tumor progression after radiotherapy remain poorly defined. The aim was to evaluate tumor progression after radiotherapy, to identify risk factors, and to report management and outcomes in a cohort of PitNETs with uncontrolled progression.

Design

Retrospective, single-center, observational study.

Methods

In total, 123 consecutive patients who underwent radiotherapy for PitNETs and were followed at Cochin Hospital between 2000 and 2022 were included. Radiotherapy was performed in the following situations: uncontrolled tumor progression (80%), adjuvant (9%), or uncontrolled secretion (11%). Median follow-up after radiotherapy was 10.0 years.

Results

Tumor progression after radiotherapy was observed in 28/123 (23%) patients. Progression-free survival was 95, 86 and 78% at 2, 5, and 10 years from radiotherapy, respectively. Higher risk of progression was associated with lactotroph and corticotroph tumor types (HR 12.0, 95%CI 1.2 to 117.1 and HR 9.3, 95%CI 1.3 to 69.6, respectively), male sex (HR 3.7, 95%CI 1.6 to 8.4), and evidence of necrotic-hemorrhagic changes before radiotherapy on MRI (HR 3.1, 95%CI 1.1 to 8.4). Surgery, temozolomide and re-irradiation were the most frequent treatments for the management of tumor progression after radiotherapy, used in 18/28 (64%), 16/28 (57%) and 8/28 (29%) cases, respectively. Other treatment approaches included immunotherapy, anti-VEGF antibodies, EGFR tyrosine kinase inhibitors, peptide radionuclide therapy, cisplatin, and enzalutamide. The most common complication of radiotherapy was the new onset of pituitary deficits, observed in 41% of cases; other complications, including radiation-induced neuroinflammation, cerebrovascular events, and second brain tumors, were rare (3%, 2%, 2%, respectively). Among the 8 patients who experienced re-irradiation, median progression-free survival was 1.4 years, with 2/8 patients maintaining tumor control in the long term (>5 years). The safety profile was acceptable, with only one case of optic neuropathy. Overall, 3 patients developed metastases, and 6 patients died because of tumor progression.

Conclusion

Radiotherapy is an effective and generally safe treatment for the achievement of tumor control in patients with PitNETs with aggressive potential. Tumor progression can still occur in some cases, and can pose challenges in clinical management. Histological tumor type, sex, and necrotic-hemorrhagic components at MRI hold a prognostic value in predicting tumor progression risk. Being all simple and available markers, they can be useful in clinical practice for optimizing therapeutic strategies and personalizing patient care.

Gemelli, Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS), Rome, Italy; [6]Department of Clinical Pathology, San Giovanni-Addolorata Hospital, Rome, Italy

The biological behaviour of growth hormone secreting pituitary tumors (GH-PitNETs) varies significantly and strongly influences prognosis. The tumor microenvironment (TME) may provide a useful framework for understanding this heterogeneous behaviour of GH-PitNETs, through the dynamic interplay between tumour cells and TME components. Despite the interest in TME in acromegaly has increased exponentially over the last few decades, there is limited elucidation of its mechanisms, particularly in relation to genes expression involved in TME regulation. GH-PitNETs may be associated with specific germline mutations, however the genetic and molecular landscape of GH-PitNETs has been partially explored. Therefore, the aim of this study was to investigate germline genetic variants in patients with acromegaly through clinical exome sequencing (CES) analysis and to explore a possible correlation with molecular and histological characteristics of GH-PitNETs, including TME immune cells. A retrospective, observational, single centre study was conducted. Forty-six patients diagnosed with acromegaly were included in this study. In this cohort 31 were females (67%) and mean age at diagnosis was 55 ($\pm$12.3) years. After DNA extraction, CES was performed and genomic alterations were detected, classified and filtered using a dedicated bioinformatics pipeline. We excluded benign and probably benign variants according to the ACMG criteria, and variants with a minor allele frequency of more than 0.05 in the international databases. The remaining variants were subjected to the ENSEMBL Impact classification. The Metascape database was employed to perform pathway enrichment analyses, based on Gene Ontology biological process and KEGG Pathway for the targets. In our cohort, CES analysis identified 5759 unique variants in patients with GH-PitNETs, but no predominant variants were found. However, our data suggested that 5 unique mutations in 5 different genes (KCNJ12, FANCD2, TRIOBP, SYN2, and TYRO3) may be correlated with some tumor characteristics, including ki67% (P-value $=$ 0.03), and invasiveness of GH-PitNETs (P-value $=$ 0.01), possibly through some implication in TME regulation. Moreover, this is the first study showing that genes (FANCD2, SPTA1, TYRO3, and ZNF335) of the "regulation of lymphocyte activation" pathway (GO:0051249) may regulate immune cells infiltration in GH-PitNETs. In particular, these gene alterations seemed to influence the number of CD68+ macrophages (P-value $=$ 0.015) and the ratio of CD68+ macrophages to CD8+ T-lymphocytes (P-value $=$ 0.014). In conclusion, this study provides, for the first time, a comprehensive analysis by CES of germline variants in a cohort of GH-PitNETs. These findings may contribute understanding of the genetic landscape of acromegaly.

"Liver fibrosis and steatosis markers- FIB-4 and HSI in acromegaly: a single-center observational study"

Karol Ciszek[1], Mari Minasyan[1], Jacek Podlewski[2], Maria Borysowicz[3], Alicja Hubalewska-Dydejczyk[1] & Aleksandra Gilis-Januszewska[1]

[1]Chair and Department of Endocrinology, Jagiellonian University, Medical College, Cracow, Poland, Kraków, Poland; [2]Dover Fueling Solutions, Kraków, Poland; [3]Jagiellonian University Medical College, Kraków, Poland

Acromegaly, characterized by excessive growth hormone (GH) and insulin-like growth factor 1 (IGF-1) secretion, is associated with significant metabolic alterations. This study investigates the relationships between IGF-1, liver fibrosis FIB-4 and hepatic steatosis HSI indexes, and other endocrine and metabolic parameters in patients with acromegaly to better understand the systemic impact of the disease. This retrospective study included 150 consecutive patients, 96 m*et all* criteria and complete data. FIB-4 ($Age \times AST/PLT \times ALT^{1/2}$) was used as a LF (liver fibrosis) predictor (<1.3 low risk [LR-LF], 1.3-2.67 intermediate risk [IR-LF], >2.67 high risk [HR-LF]). HSI [$8 \times (ALT / AST) + BMI + 2$ (if type 2 diabetes) $+$ 2 (if female)] score of $\geq$ 36 predicted the presence of hepatic steatosis. Patients were grouped by age (<40, 40-60, >60 years). Spearman's

correlation assessed relationships between IGF-1, endocrine markers, onset age, and tumor size with FIB-4 and HSI. Group comparisons used ANOVA, Kruskal-Wallis, t-tests, or Mann-Whitney U tests as appropriate. The cohort consisted of 42% males and 58% females, with a mean age of 47.67 $\pm$ 14.62 years. The mean FIB-4 score was 1.03 (SD = 0.62), while the mean HSI score was 38.3 (SD = 7.01). Notably, 21 patients presented with a FIB-4 score greater than 1.3, and 60 had an HSI score exceeding 36. Age-related differences were observed, with IGF-1 ($P = 0.0001$) decreasing with age. Patients with type 2 diabetes had higher FIB-4 (1.18 $\pm$ 0.51 vs. 1.0 $\pm$ 0.64, $P = 0.023$). A significant negative correlation was identified between IGF-1 and FIB-4 (ρ = -0.36, $P = 0.0004$). Additionally, age correlated positively with HSI ($\rho = 0.23$, $P = 0.0266$). TSH and PRL negatively correlated with FIB-4 (ρ = -0.23, $P = 0.0257$ and ρ = -0.27, $P = 0.0093$, respectively. This study underscores the complex interplay between IGF-1, liver fibrosis markers, metabolic factors, and endocrine dysfunction in acromegaly. Higher IGF-1 levels may have a protective role against fibrosis progression, warranting further investigation into its clinical significance. Additionally, increasing age is associated with a higher risk of liver steatosis, highlighting the need for age-related monitoring of liver health in this population. Further studies are needed to assess IGF-1 impact on the liver.

The clinical course and the systemic inflammation biomarkers (SIBs) differ between giant and not-giant aggressive prolactinomas

Maria Aleksandra Komisarz-Calik[1], Alicja Hubalewska-Dydejczyk[1] & Aleksandra Gilis-Januszewska[1]
[1]Jagiellonian University Medical College, Chair and Department of Endocrinology, Kraków, Poland

Introduction
Aggressive prolactinomas (APRL) constitute a subgroup of aggressive PitNets. Their distinguishing features constitute invasion (radiological/histological), high proliferation profile, resistance to standard medication, and an increased risk of early recurrence.
Objectives
To analyse the clinical course and the systemic inflammation biomarkers in aggressive prolactinomas.
Methods
Data concerning clinical course, radiological invasion, systemic inflammation biomarkers (SIBs), and treatment of APRL were analyzed.
Results
22 cases of APRL: 4 women (18.2%) and 18 men (81.2%), among which 14 constituted giant tumors (>4 cm) were analyzed. The most frequent symptoms included headaches 5/22 (68%) and vision disturbances 10/22 (45.5%). 50% of women noticed menstrual cycle alterations and galactorrhea. 4/18 (22.2%) of men reported libido loss. According to the MRI, in 15/22(68.2%), the tumor infiltrated the optic chiasm; in 20/22 (90.9%), the cavernous sinuses (in 17/22, infiltration included ICA). 52.4% (11/21) of tumors were grade 4 in the Knosp classification. In 9/22 (40.9%), we observed insufficiency of the gonadal, adrenal, and thyroid axis; in 10/22 (45.5%) - isolated gonadal axis dysfunction. All the patients were treated with dopamine agonists (predominantly cabergoline - 19/22 (86.4%), an average weekly dose of 2.5mg (max-4.5; min-1). In the group of giant tumors (G) the average dose of cabergoline was 2.5 mg/week, while in the non-giant (nG) group 2.25 mg/week. 5/22 (22.7%) patients undergone the surgery (2 patients more than one). One patient received radiotherapy. Other therapeutic options included temozolomide (1/22), pasireotide (1/22), and lanreotide (3/22). When comparing a G group with nG, we observed that the Neu/lymph ratio and Plt/lymph were higher in the G group (2.87 vs. 1.46, $P = 0.007$; 164.4 vs. 103.58, $P = 0.068$). Moreover, baseline prolactin level (upper normal limit (UNL)) was higher in the G (1232xUNL) vs nG group (141xUNL), $P = 0.059$. The average reduction in prolactin levels was less significant in the G group – 78.7% (0-99.7%) vs. 87.5% (39.4%-99.73%) in the nG group.
Conclusion
The clinical course of the disease and SIBs differ between giant and not-giant aggressive prolactinomas. Further studies are needed to understand the nature of this condition.
Keywords
Aggressive prolactinoma, prolactinoma, cabergoline, pasireotide.

Background
There is a substantial delay in the diagnosis of acromegaly contributing to increased morbidity and mortality. Machine learning-based analysis of facial images has shown promising potential in identifying acromegaly. However, there is a need for further validation in large acromegaly cohorts, incorporating new methodological insights in machine learning development and using human expert assessment for comparison.
Methods
Video recordings from 155 patients with acromegaly and 153 matched controls at all seven Swedish University hospitals were collected using cellphones. Facial pictures from different angles were extracted. Clinical data regarding disease course and status were obtained. Four different deep neural network architectures were trained to distinguish photographs of patients with acromegaly from controls. These neural networks were pretrained on large image datasets including three networks trained on various image categories (ImageNet networks) and one on human faces [Facial Representation Learning (FaRL)]. The performance of these models was compared to that of 12 experienced endocrinologists.
Results
The FaRL based machine learning model presented higher sensitivity compared to the compound majority assessment (ensemble) of experienced endocrinologists (0.82 vs 0.66), with only marginally lower specificity (0.87 vs 0.93). The overall diagnostic performance was comparable for FaRL and the expert ensemble with ROC AUC 0.89 for both. However, the balanced accuracy of each individual endocrinologist was lower (range 0.72-0.79) than the FaRL model (0.80). Accuracy of the other neural networks were inferior to FaRL. The classification agreement between the top-performing models and human experts was high for true negatives (76%) but lower for true positives (55%). Both the machine learning models and human experts showed greater sensitivity in accurately classifying males compared to females, but showed no significant difference in precision metrics between patients with active ($n = 33$) vs controlled acromegaly ($n = 122$).
Conclusions
A FaRL-based machine learning model shows comparable accuracy to expert endocrinologists in acromegaly identification by face photographs, but with the advantage of higher sensitivity. This supports that digital face analysis can be useful in acromegaly detection. Further research is required to validate its performance and explore its applicability in clinical practice.

Hyponatremia correction is associated with increased brain-derived neurotrophic factor levels (BDNF) – subanalysis of a randomized, double-blind, placebo-controlled, crossover trial

Eszter Kustos-Toth[1,2], Julia Beck[1,2], Lucia Seeger[1,2], Sophie Monnerat[1,2], Cemile Bathelt[1,2], Julie Refardt[1,2] & Mirjam Christ-Crain[1,2]
[1]University Hospital Basel, Endocrinology, diabetes and metabolism, Basel, Switzerland; [2]University of Basel, Department of Clinical Research, Basel, Switzerland

Background
Hyponatremia is the most common electrolyte disorder in clinical practice and is associated with cognitive impairment. We have recently shown that correction of sodium levels can improve cognitive function[1]. Growing evidence suggests that serum brain-derived neurotrophic factor (BDNF) correlates with cognitive performance, playing a crucial role in learning, memory, and development of neurocognitive diseases, like dementia and depression. There is currently no data on serum BDNF levels in the context of hyponatremia.
Aim
The primary objective of this study was to investigate the effect of hyponatremia correction on serum BDNF levels.
Design and Methods
Secondary analysis of a prospective randomized, double-blind, crossover, placebo-controlled trial of 4-week empagliflozin 25mg/d vs placebo treatment in patients with syndrome of inappropriate antidiuresis (SIAD), conducted at the University Hospital Basel, Switzerland, from December 2017 to August 2021. Serum BDNF levels were assessed by quantitative enzyme-linked immunosorbent assay (ELISA). Statistical analyses were performed using R version 4.4.2.
Results
A total of fourteen patients were included in the analysis (50% female, median age 72 years [65–77]. At baseline, the median sodium in the empagliflozin group was 131 mmol/l [128–132], which increased to 134 mmol/l [131–136] after treatment ($P = 0{,}008$). In the placebo group, median sodium was 131 mmol/l [130–132] at baseline and remained stable at 131 mmol/l [128–132] after treatment. In the total cohort, an increase in sodium was significantly associated with an increase in BDNF levels (1 mmol/l sodium increase led to a 0.3 ng/ml increase in BDNF levels, $P = 0.04$), which was more profound after empagliflozin treatment ($P = 0.004$, compared to placebo $P = 0.3$). However, in the multivariant model the treatment arm was no independent predictor of BDNF change. In the patients without an increase in sodium, the median BDNF was 11,4ng/ml [10,2–18] at baseline compared to 10,9 ng/ml [8,7–15,7] after treatment. In patients with an increase in sodium, baseline median BDNF was 12,3 ng/ml [9,6–14,7] and increased to 15,2 ng/ml [11,8–19,3] after the treatment period. No association was observed between Montreal Cognitive Assessment (MoCA) scores and BDNF levels, regardless of treatment group.
Conclusion
Our findings indicate that hyponatremia correction increases the serum cognitive marker BDNF, highlighting the importance of hyponatremia correction in cognitive health. Further studies are needed to confirm the role of BDNF upon hyponatremia treatment.

Perception and psychological effects of central precocious puberty or early normal puberty, and its treatment among girls and their caregivers

Kalyarat Wilaiwongsathien[1], Jariya Chuthapisith[1], Pat Mahachoklertwattana[1], Natee Sakornyutthadej[2] & Preamrudee Poomthavorn[1]
[1]Department of Pediatrics, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; [2]Chakri Naruebodindra Medical Institute, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Samut Prakarn, Thailand

Background
There is limited data regarding the perception and psychological effects of central precocious puberty and early normal puberty (CPP/EP) among girls and their caregivers, particularly given the differences in socio-cultural contexts among different ethnicities. This study aimed to evaluate the psychological effects of CPP/EP on Thai girls and their caregivers, and to explore their perceptions of CPP/EP and the treatment using gonadotropin-releasing hormone analog (GnRHa).
Methods
CPP/EP girls were enrolled. Questionnaires were administered to assess the perceptions and psychological effects of CPP/EP. Newly diagnosed patients were additionally evaluated for bullying, depression, anxiety and low self-esteem using standardized tools.
Results
Nine hundred and fifty-four participants (340 CPP, 140 EP, and 474 caregivers) were included. Thirty-eight out of 480 girls were newly diagnosed, and 442 girls had been followed, with 427 out of 442 patients having received GnRHa therapy. Their mean (SD) age was 9.9 (1.1) years at enrollment. The duration of GnRHa treatment was 1.8 (1.0) years. Regarding the perception of CPP/EP; breast buds, body odor and acne were perceived by the girls as the signs of puberty in 234 (49%), 174 (36%), and 162 (34%) girls, respectively. Two hundred and sixteen (45%) girls believed that some kinds of foods were the cause of CPP/EP. Furthermore, 379 (79%) girls and 374 (79%) caregivers appreciated that menarche contributed to a reduction in height gain, and 352 (73%) girls and 304 (64%) caregivers believed that height gain would continue increasing if menstruation stopped. On a 10-point anxiety scale for CPP/EP, caregivers reported a high score of 8.3 (1.7). The child's short final height was the most concern by caregivers ($n = 369$, 78%), followed by early menarche and side effects of GnRHa therapy. Among the 38 newly diagnosed girls, 8 (21%) reported being bullied, with experiences of verbal harassment about their breasts, breast grabbing, and social exclusion. Additionally, 4 (11%) girls were tested positive for depression, 9 (24%) for anxiety, and 5 (13%) for low self-esteem. Comparing CPP and EP girls, depression and anxiety were more prevalent in the CPP group (20% vs. 10% and 38% vs. 30%, respectively). Being bullied was significantly correlated with higher levels of depression, anxiety, and low self-esteem.
Conclusions
This study demonstrated that girls and their caregivers had inadequate knowledge about CPP/EP, highlighting the importance of providing accurate information. Given the psychological stress associated with CPP/EP, appropriate counseling and psychological support should be incorporated into its standard care.

Hemodynamic changes in patients with idiopathic central precocious puberty treated with gonadotropin-releasing hormone (GnRH) analogue

Reyhan Deveci Sevim[1], Mustafa Gök[2], Sebla Güneş[1] & Ahmet Anik[1]
[1]Aydin Adnan Menderes University, Pediatric Endocrinology, Aydın, Türkiye; [2]Aydin Adnan Menderes University, Department of Radiology, Aydın, Türkiye

Objective
In this study, we aimed to evaluate the effects of leuprolide acetate on hemodynamic parameters, including blood pressure, arterial strain, and arterial stiffness, in patients diagnosed with idiopathic central precocious puberty (ICPP) through a prospective case-control study design.
Materials and Methods
This study included female patients diagnosed with ICPP and initiated on leuprolide acetate 11.25 mg/3 months therapy at our Pediatric Endocrinology Department, with no additional chronic illnesses. Ambulatory Blood Pressure Monitoring (ABPM) was performed at baseline, 3rd, and 6th months to obtain 24-hour blood pressure measurements. Simultaneously, carotid artery stiffness and strain parameters were assessed using Speckle Tracking Carotid Strain (STCS) ultrasonography.
Results
The study included 24 female patients diagnosed with ICPP with a mean age of 8.3 ± 1 years, bone age of 10.5 ± 1.4 years, height standard deviation (SD) of 1.3 ± 1.1, and BMI SD of 0.9 ± 1.1. Cranial MRI findings were normal in all cases, and routine biochemical and hematological tests were within normal ranges. According to ABPM data, baseline measurements showed a systolic blood pressure (SBP) SD of 0.8 ± 0.6, diastolic blood pressure (DBP) SD of 0.2 ± 0.6, mean arterial pressure (MAP) of 82.6 ± 6.2 mmHg, pulse wave velocity (PWV) of 4.3 ± 0.2, central SBP-SD of 0.2 ± 0.6, and central DBP-SD of 0.2 ± 0.7. The proportion of dipper patterns was 8.2 ± 4.3% for SBP and 13.2 ± 6.4% for DBP. At the 3-month follow-up, central DBP-SD increased to 0.4 ± 0.5 ($P = 0.017$). However, no significant differences were observed in SBP-SD, DBP-SD, central SBP-SD, PWV, or MAP when comparing the 3rd and 6th months. No significant change in the dipper pattern was observed when baseline, 3rd, and 6th-month data were compared. Similarly, arterial stiffness and strain parameters assessed via STCS ultrasonography showed no significant differences between baseline, 3rd, and 6th-month measurements.
Conclusion
While case reports in the literature have indicated a potential increase in blood pressure associated with GnRH analogue treatment, no prospective case-control studies have systematically examined this relationship. Our study is the first to investigate this association in a controlled prospective design. An increase in central DBP was observed at the 3rd month of GnRH analogue treatment. However, no significant differences were found in other blood pressure parameters, dipper pattern, arterial stiffness, or strain parameters in the 3rd and 6th-month evaluations.

Note
The study is still ongoing, and a preliminary analysis has been conducted based on 16 patients with completed 6-month data. The full dataset is expected to be completed by the time of the conference.

"Endocrine and genetic influences on neurodevelopment: insights from neuroimaging in turner syndrome"

Ashraf Soliman[1], Fawzia Alyafei[1], Mohamed AlKuwari[2], Noora AlHumaidi[1], Noor Hamed[1], Shayma Ahmed[1], Nada Alaaraj[1], Abbas Noureldin[1] & Elsaid Bedair[1]
[1]Hamad Medical Corporation, Doha, Qatar; [2]Hamad Medical Coropration, Pediatric Endocrine and Diabetes, Doha, Qatar

Background
Turner Syndrome (TS), a chromosomal disorder resulting from partial or complete monosomy of the X chromosome, affects multiple organ systems, including the brain. TS is characterized by distinct neurocognitive and structural abnormalities, including deficits in visuospatial abilities, social cognition, and memory, along with morphological changes in specific brain regions. Understanding these changes through neuroimaging is critical for improving diagnosis and targeted interventions.
Methods
A systematic review of 15 neuroimaging studies was conducted, encompassing 696 patients with TS, ranging from children to adults, and 641 matched controls. Studies utilized multimodal MRI techniques, including volumetric analysis, diffusion tensor imaging, and surface-based morphometry. Key outcomes assessed included regional brain volume, cortical thickness, white matter integrity, and functional connectivity.
Results
Neuroimaging studies consistently demonstrated structural and functional alterations in TS. Common findings included:.
• Amygdala and hippocampus: In 30 TS patients, increased left amygdala volume and reduced right hippocampal volume were observed, which correlated with social cognition and memory deficits.
• Parietal regions: Aberrant growth trajectories of white and gray matter were evident, especially in the left superior parietal regions, linked to visuospatial impairments.
• Cortical structure: Smaller cortical surface area and increased cortical thickness were predominant in TS patients, with regional differences in the pericalcarine, postcentral, and parietal areas.
• White matter networks: Reduced topological efficiency of hemispheric white matter connectivity was observed, particularly in the parietal modules, impairing working memory.
• Functional connectivity: Intrinsic connectivity disruptions in regions involved in math-related cognition and visuospatial processing were identified.
Across studies, the role of X chromosome haploinsufficiency, hormonal deficiencies (notably estrogen), and genomic imprinting were underscored as key contributors to these neurodevelopmental anomalies.
Discussion
These findings highlight the interplay of genetic and hormonal factors in shaping brain development in TS. The identified structural abnormalities have direct implications for neurocognitive deficits, particularly in visuospatial, social, and memory domains. The data suggest the importance of early diagnosis and tailored interventions, including hormonal replacement therapy, to mitigate neurodevelopmental challenges.
Conclusion
Consistent neuroimaging findings show that Turner Syndrome profoundly impacts brain structure and function. A comprehensive understanding of these alterations can guide improved therapeutic strategies, enhancing the quality of life for individuals with TS. Future research should focus on longitudinal studies to track developmental trajectories and the impact of interventions.

Spliceosome approach for the identification of diagnostic and prognostic biomarkers and therapeutic targets in paediatric brain tumors

Ana S. De la Rosa-Herencia[1,2,3], Juana Vidal-Miñano[1,3,4], Juan Solivera[1,3,4], Antonio Carlos Fuentes-Fayos[1,2,3] & Raul M. Luque[1,2,3]
[1]Maimónides Biomedical Research Institute of Córdoba (IMIBIC), Cordoba, Spain; [2]Department of Cell Biology, Physiology, and Immunology, University of Córdoba, Cordoba, Spain; [3]Reina Sofía University Hospital, Cordoba, Spain; [4]Neurosurgery Service, Reina Sofia University Hospital, Cordoba, Spain

Brain tumors represent the second most common malignancy in children and adolescents and the leading cause of cancer-related mortality in this population. These tumors are characterized by their resistance to conventional therapies and the severe long-term side effects which involves hormonal imbalances and disruptions in the hypothalamic-pituitary axis. Despite some advances, the molecular causes underlying these tumors remain unclear, and tools for accurate diagnosis/prognosis, and treatment are very limited. Recent data from our group have identified the spliceosome (molecular machinery controlling the RNA splicing-process), as a critical player in the progression/aggressiveness of various endocrine-related cancers, including adult brain tumors. However, the alteration and role of the spliceosome in paediatric brain tumors remains largely unexplored. Herein, we initially analyzed the potential alteration of spliceosome components in seven independent cohorts of paediatric brain tumors (gliomas and medulloblastomas) using bioinformatics tools, identifying a significant over-expression of the spliceosome in tumor vs. non-tumor samples. Notably, some spliceosome alterations were associated with key clinical features, including tumor aggressiveness and survival outcomes. Notably, one spliceosome component (SF1) was found to be overexpressed in diffuse gliomas and medulloblastomas and its expression levels could discriminate between tumor and non-tumor samples. Moreover, higher *SF1* levels were associated to higher glioma grades and worse patient outcome (based on survival curves). Interestingly, enrichment analysis revealed a robust correlation between higher *SF1* expression levels and key oncogenic signalling-processes, such as MYC, mTOR, and p53 pathways. Functionally, we tested the therapeutic potential of Pladienolide-B, a inhibitor of the spliceosome activity, in different brain tumor cell-models [i.e. glioma (SF188 and KNS42) and medulloblastoma (DAOY) cells, as well as in primary patient-derived cell cultures], which revealed that Pladienolide-B significantly altered critical cancer hallmark features in all cell-models used, including the inhibition of cell proliferation, migration, and stem-like features, and an apoptosis induction. These effects could be mediated by disruptions in key pathways governing cell-cycle progression, cellular-differentiation, and metabolic-pathways signaling. Altogether, our results demonstrate a drastic splicing machinery-associated molecular dysregulation in paediatric brain tumors, which could potentially be considered as a source of novel diagnostic and prognostic biomarkers as well as therapeutic targets. Remarkably, the spliceosome component SF1 is directly associated with characteristics of tumor progression/aggressiveness and patient survival and represents, together with the use of inhibitors of the spliceosome activity, a novel potential therapeutic target/approach to tackle these devastating pathologies.

Refining pituitary adenoma classification: the role of transcription factors in diagnosis and risk assessment

Debora Katz[1], Patricia Slavinsky[1], Mariana Gonzalez Pernas[1], Maria Florencia Battistone[1], Jesica Pingel[1], Naomi Arakaki[2], Monica Mezmezian[2], Gustavo Sevlever[2], Estefania Rojas[2], Marcelo Schultz[2] & Andres Cervio[3]
[1]FLENI, Neuroendocrinology, Buenos Aires, Argentina; [2]FLENI, Neuropathology, Buenos Aires, Argentina; [3]FLENI, Neurosurgery, Buenos Aires, Argentina

Introduction
The new classification of pituitary tumors (WHO 2022) is based on transcription factors (TF) detected through immunohistochemistry (IHC) to determine tumor lineage. The aim of our study was to evaluate the usefulness of incorporating the WHO 2022 classification into the pathological study of pituitary adenomas (PA).
Materials and Methods
We retrospectively analyzed records of adults with PA who underwent surgery between January 2023 and December 2024. Clinical, radiological (tumor size, cavernous sinus invasion), and histopathological data were reviewed, including IHC for hormones and TF: SF1, Tpit, Pit1, GATA3, and Ki-67%. High-risk PAs were identified according to WHO 2022 criteria. Tumors were classified as invasive if they had Knosp grade III or IV.
Results
A total of 112 tumor samples were included. The majority belonged to the SF1 lineage (50%), followed by Pit1 (29%), TPIT (21%). With the incorporation of TF analysis, the diagnosis was modified in 19 patients:.

• 11 clinically non-functioning adenomas (CNFA) with negative hormonal IHC were reclassified as gonadotropinomas (SF1+; $n = 7$), 1 corticotropinoma (TPIT+) and 1 null cell.
• Only 2 CNFA were triple-negative but GATA3+.
• 5 patients with acromegaly were reclassified as: 1 immature, 1 mature Pit1 lineage tumor, 2 acidophil stem cell tumors, and 1 plurihormonal (Pit1 and SF1).
• 2 patients with thyrotropinoma were reclassified as immature and mature Pit1 lineage tumors.
• 1 CNFA with IHC for PRL and GH was re3.
• classified as plurihormonal (Pit1 and SF1).
• 43 gonadotropinomas, 2 corticotropinomas, 1 acidophil stem cell, 3 Pit-1, and a plurihormonal tumor were GATA3+.
• 31 patients with high-risk histological subtype tumors (7 reclassified with TF). These tumors were associated with invasiveness in 48% and Ki-67 $\geq$ 3% in 6.4%.
• 81 patients with low-risk histology: 38% were invasive, and 3.7% had Ki-67 $\geq$ 3%.

Conclusions
The addition of IHC for TF to routine diagnostics allows a more accurate classification of pituitary adenomas, particularly in cases with absent or low hormonal expression. IHC for GATA3 could be a useful marker for diagnosing gonadotropinomas and certain immature tumors. Diagnosing Pit1 adenomas presents challenges due to variability in hormonal expression, coexpression of transcription factors, and distinction between mature and immature types. The classification of tumors into high- and low-risk groups provides an additional parameter for individualized risk assessment, which should be considered along with clinical, radiological, and histopathological factors. These findings reinforce the need for molecular techniques to refine PitNET classification and enhance diagnostic precision.

Persistent HPG axis reactivation: a conundrum in transgender male adolescents on gender-affirming testosterone therapy

Hussein Zaitoon[1], Liat Perl[1], Rachaela Sverdlove[1], Anat Segev-Becker[1] & Asaf Oren[1]
[1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, affiliated to the Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, The Institute of Pediatric Endocrinology, Diabetes and Metabolism, Dana-Dwek Children's Hospital, Tel Aviv, Israel

Context
Transgender male adolescents undergoing gender-affirming hormone therapy (GAHT) often start with a combination of gonadotropin-releasing hormone analog (GnRHa) to suppress puberty and testosterone therapy to induce masculinizing changes. While GnRHa effectively suppresses the hypothalamic-pituitary-gonadal (HPG) axis, the degree of gonadotropin suppression achieved with testosterone monotherapy following GnRHa discontinuation remains unclear. Understanding the dynamics of luteinizing hormone (LH) and follicle-stimulating hormone (FSH) levels during this transition is essential for optimizing treatment protocols and achieving desired clinical outcomes.

Aim
To investigate the degree of suppression of the HPG axis achieved by testosterone monotherapy in transgender male adolescents, as reflected by changes in LH and FSH levels following GnRHa discontinuation.

Methods
We conducted a retrospective cohort study from 2018 to 2023 at the Israeli Children and Adolescents Gender Clinic, Dana-Dwek Children's Hospital. The cohort consisted of 68 transgender male adolescents who started GAHT at Tanner stage 4–5. Outcome measures included changes in serum LH and FSH levels, as well as the LH/FSH ratio, assessed at baseline, during combined GnRHa and testosterone therapy, and during testosterone monotherapy.

Results
Baseline LH levels were within the normal range, followed by a significant decrease during combined GnRHa and testosterone treatment, and an increase during testosterone monotherapy (6.11 $\pm$ 5.06 vs. 0.32 $\pm$ 0.50 vs. 3.17 $\pm$ 2.97 IU/l, respectively; $P < 0.001$). Similarly, baseline FSH levels were within the normal range, followed by a marked decrease during combined GnRHa and testosterone treatment, and an increase during testosterone monotherapy (5.87 $\pm$ 2.77 vs. 1.46 $\pm$ 1.23 vs. 4.68 $\pm$ 3.14 IU/l, respectively; $P < 0.001$). Post hoc analysis revealed significant differences in LH, FSH, and LH/FSH ratios across the three treatment phases.

Conclusion
In transgender male adolescents, testosterone monotherapy following GnRHa discontinuation did not lead to full HPG axis suppression, with LH and FSH levels remaining within the normal range. These findings suggest that gender-affirming testosterone alone may not completely suppress gonadotropin secretion in transgender males. Future research is needed to explore the testosterone-mediated feedback mechanisms underlying incomplete LH and FSH suppression, which could have implications for optimizing hormone therapy in transgender male adolescents.

Expression of asprosin, furin and Olfr734 in the pituitary during the estrous cycle in control and obese mice. *in vitro* effect of asprosin on pituitary cell proliferation

Dominika Wachowska[1,2,3], Kinga Przybylska[2,4], Urszula Nowak[1], Christelle Rame[3], Patrycja Kurowska[1], Edyta Rytelewska[1], Anna Błasiak[4], Joëlle Dupont[3] & Agnieszka Rak[1]
[1]Institute of Zoology and Biomedical Research, Jagiellonian University, Faculty of Biology, Laboratory of Physiology and Toxicology of Reproduction, Kraków, Poland; [2]Doctoral School of Exact and Natural Sciences, Jagiellonian University, Kraków, Poland; [3]INRAE, Unité Physiologie de la Reproduction et des Comportements, Nouzilly, France; [4]Institute of Zoology and Biomedical Research, Jagiellonian University, Faculty of Biology, Department of Neurophysiology and Chronobiology, Kraków, Poland

Background
Asprosin, a novel adipokine, is the result of a profibrillin (FBN1) cleavage by furin, which also generates the mature fibrillin-1. Asprosin binds to an olfactory receptor Olfr734, influencing glucose and lipid metabolism, ovarian, and cardiovascular functions. Crossing the blood-brain barrier, it acts as an orexigenic peptide - stimulates food intake *via* AgRP neurons in the hypothalamus and contributing to energy homeostasis. However, its role in pituitary function remains elusive. The aim of this study was to examine asprosin/furin/Olfr734 expression in the pituitary of control (CTRL) and diet-induced obese (DIO) female mice, and in LβT-2 mouse gonadotroph cell line. Furthermore, we investigated the *in vitro* effects of asprosin on pituitary cell viability and proliferation.

Materials and Methods
Female C57BL/6J mice were fed a control (CTRL, $n = 5$) or high-fat diet (DIO, $n = 5$) for 12 weeks. CTRL mice were analyzed during proestrus, estrus, and diestrus, while DIO mice were studied only in estrus. Asprosin/furin/Olfr734 mRNA and protein expression were analyzed in mouse pituitary and LβT-2 cells using RT-qPCR and Western blotting, respectively. Also, serum levels of asprosin, oestradiol (E2), progesterone (P4), FSH, LH, leptin, adiponectin, triglycerides, cholesterol, and glucose were measured by ELISA and enzymatic tests. LβT-2 cells were treated with recombinant mouse asprosin at doses 1-100 nM alone or with GnRH (50 nM) for 24 h. Cell viability was measured by AlamarBlue and proliferation using BrdU assay. Statistical analyses included one-way ANOVA and Pearson's correlation ($P < 0.05$).

Results
In the pituitary, asprosin/furin/Olfr734 expression varied along the estrous cycle with DIO mice exhibiting reduced expression vs CTRL. Moreover, we found that expression of asprosin and Olfr734 were negatively correlated with serum asprosin concentration and metabolic parameters, including glucose, LDL cholesterol, triglycerides, adiponectin, and leptin. Additionally, asprosin/furin/Olfr734 were detected in LβT-2 cells, where asprosin did not influence either basal or GnRH-induced viability or proliferation.

Conclusion
Our findings demonstrate that the expression of asprosin/furin/Olfr734 in the mouse pituitary is regulated by both the estrous cycle and animal metabolic status. Asprosin did not affect LβT-2 cell viability or proliferation, suggesting that its role in the pituitary may be more related to its secretory activity rather than direct cell regulation, ultimately linking metabolic changes to female reproduction. These results provide a foundation for further exploration of asprosin's mechanisms of action in the modulation of murine gonadotrophs like gonadotropin secretion.

Impact of disease activity on cognitive and psychological outcomes in acromegaly: a prospective study

Serhat Uysal[1], Zehra Kara[1], Cem Sulu[1], Serdar Sahin[1], Ahmet Demir[1], Esra Gungormus[1], Selin Yagci Kurtish[1], Elif Ersoy Yilmaz[1], Senol Turan[1], Hande Ozkaya[1] & Pinar Kadioglu[1]
[1]Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Istanbul, Türkiye

Purpose
To investigate the cognitive and psychological aspects of acromegaly and to assess how disease activity may affect these outcomes.
Methods
This prospective study included patients with acromegaly between 18 and 65 years of age who consecutively admitted to Pituitary Center between June 2021 and July 2023. Cognitive functions were assessed using a series of standardized tests targeting memory, attention, executive function, verbal fluency, and visuospatial skills. Additionally, Beck Depression Inventory (BDI), Beck Anxiety Inventory, and Acromegaly Quality of Life Questionnaire (AcroQoL) assessments were conducted. These evaluations were performed preoperatively and at the 9th month postoperatively following transsphenoidal surgery (TSS) to assess the anticipated changes in neuropsychological functions based on disease activity.
Results
A total of 19 patients with acromegaly were included in the study. Remission was achieved through TSS alone in 9 patients, while 10 patients required postoperative somatostatin receptor ligands. Cognitive functions (Montreal Cognitive Assessment Test) were better in the remission phase compared to the initial active disease phase (23.36 ± 3.46 vs 24.93 ± 3.73; $p = 0.035$). Cognitive flexibility and selective attention (Stroop Test) were impaired during the active period of the disease (17.79 ± 12.31 vs 12.29 ± 8.23; $p = 0.016$). Memory functions (Wechsler Memory Scale-Logical Memory Test: immediate recall, delayed recall, recognition) showed improvement from the active phase to remission ($p = 0.016$, $p = 0.003$, $p = 0.008$; respectively). BDI scores were significantly higher in the active phase compared to remission (7.36 ± 3.48 vs 5.43 ± 3.03; $p = 0.009$). Additionally, AcroQoL scores were lower during the active disease phase than in the remission phase (76.21 ± 16.02 vs 92.86 ± 11.97; $p = 0.007$).
Conclusions
Acromegaly may impair cognitive and psychological functions, which appear to improve with effective treatment.

Primary empty sella and pituitary insufficiency – a retrospective analysis

Lucas Steckel[1] & Susanne Kaser[1]
[1]Medical University of Innsbruck, Department of Internal Medicine I, Innsbruck, Austria

Background
The number of incidental findings of primary empty sella (PES) is rising due to the increasing availability and quality of neuroradiological imaging. However, the clinical implications of PES diagnosis are not always clear, especially with respect to possible hypopituitarism at baseline and over time. The aim of this longitudinal study was to examine the emergence of potential hormone insufficiencies during follow-up and derive recommendations from that.
Methods
We conducted a retrospective, single-center analysis of patients with neuroradiologically confirmed empty sella. All patients with secondary genesis of empty sella, for example due to pituitary surgery, traumatic brain injury or radiation therapy were excluded from the study. Data regarding hormone levels, clinical presentation, pre-existing diseases and medication was analysed for the available follow-up period of each patient.
Results
97 patients were enrolled in the study (age $= 57.1 \pm 16.1$ years; female $= 54$ %; BMI $= 27.2 \pm 6.2$ kg/m^2), the diagnosis of PES was an incidental finding in 58.8 % of cases. At baseline, anterior total or partial pituitary insufficiency was diagnosed in 33 out of 97 patients, with 7 persons suffering from total anterior hypopituitarism. The most frequent finding was hypogonadism with 26 % followed by insufficiencies of the thyrotropic axis (25 %) and somatotropic axis (23 %). Adrenal deficiency was prevalent in 22 % of patients. Arginine vasopressin deficiency was found in 3 patients and hyperprolactinemia in 17 patients. Total pituitary insufficiency was not detected in any patient. Complete follow-up hormone levels were available for 44 patients. In patients with intact pituitary function at baseline, mean basal hormone levels remained stable over time, indicating resilient pituitary function in the majority of patients. 1 out of 44 patients who did not initially have an impairment of pituitary function developed an insufficiency of the corticotropic, somatotropic and gonadotropic axis during follow-up.
Conclusions
Our study shows that pituitary insufficiency is common among patients with primary empty sella. 34 % of patients had an impairment of one or more hormone axes at baseline. This emphasizes the urgent need of endocrinological assessments at diagnosis. Only one patient developed pituitary insufficiency during follow-up, indicating that worsening of pituitary function in patients with intact function at diagnosis is rare. Consequently, our data does not support regular follow-up investigations in asymptomatic PES patients with intact pituitary function at initial presentation.

Introduction
B2412 (NCT01794793), an open-label, multicentre, Phase IV rollover study, evaluated the long-term safety of pasireotide (a second-generation, multireceptor-targeted somatostatin receptor ligand) in patients with rare endocrine diseases, including acromegaly and Cushing's disease (maximum study duration, 10 years). Here, we report data from the final analysis in patients with acromegaly who received pasireotide long-acting release (LAR) during the rollover.
Methods
Patients continuing to receive treatment benefit at the end of a previous pasireotide trial (investigator assessed) were eligible to enter the rollover and initially remained on the same pasireotide dose that they were receiving at the end of the parent study. Data are reported for patients with acromegaly who were treated with pasireotide LAR across five parent studies and received ≥ 1 pasireotide dose during the rollover. The primary objective of the B2412 study was to evaluate long-term pasireotide safety based on the frequency of adverse events (AEs) and serious AEs (SAEs). Data are reported from rollover start to end, unless otherwise stated.
Results
Overall, 221 patients with acromegaly from 24 countries entered the rollover to receive pasireotide LAR; 75.6% ($n = 167$) of patients completed treatment and 24.4% ($n = 54$) discontinued, most commonly because of patient consent withdrawal (5.9%, $n = 13$). Median (min–max) duration of pasireotide LAR exposure and average dose from parent study baseline to rollover end was 7.5 years (0.3–16.8) and 37.5 mg/month (6–68). AEs regardless of study drug relationship were reported in 77.8% ($n = 172$) of patients, most commonly (≥ 10% of patients) hyperglycaemia (12.7%, $n = 28$), COVID-19, headache (each 10.9%, $n = 24$) and hypertension (10.4%, $n = 23$). 65.6% ($n = 145$) of patients required additional therapy to manage AEs, most commonly for back pain, hypertension (each 9.0%, $n = 20$) and hyperglycaemia (7.7%, $n = 17$). 10.9% ($n = 24$) of patients required dose interruption/adjustment to manage AEs, most commonly for aspartate aminotransferase increased, COVID-19, SARS-CoV-2 test positive, diabetes mellitus, growth hormone deficiency, hyperglycaemia and insulin-like growth factor decreased (each 0.9%, $n = 2$). SAEs were reported in 22.6% ($n = 50$) of patients, most commonly COVID-19 (3.2%, $n = 7$). Three patients died during the

rollover (cardiac failure, $n = 2$; pulmonary embolism, $n = 1$). Overall, 15 patients (6.8%) discontinued because of AEs, most commonly hyperglycaemia (1.8%, $n = 4$). No new safety signals were identified.
Conclusion
Pasireotide is a well-tolerated long-term treatment option for patients with acromegaly, with patients having received treatment for ≤ 17 years from parent study entry. Hyperglycaemia was infrequent, and AEs, including hyperglycaemia, were mostly manageable without treatment discontinuation during the rollover.

JOINT1267
Endoscopic ultrasound-guided radiofrequency ablation is a safe and efficient treatment of symptomatic insulinomas – a single center experience of 14 patients
Mikkel Andreassen[1], Bojan Kovacevic[2], Lene Brink[2], Carsten Palnæs Hansen[3], Ulrich Knigge[3] & Peter Vilmann[2]
[1]Rigshospitalet, university of Copenhagen, Department of nephrology and endocrinology, Copenhagen, Denmark; [2]Herlev Hospital, University of Copenhagen, Department of surgery, Copenhagen, Denmark; [3]Rigshospitalet, University of Copenhagen, Department of Surgery, Copenhagen, Denmark

Content
Insulinoma is the most common functional pancreatic neuroendocrine neoplasm. The vast majority are benign and less than 20 mm. Pancreatic surgery is considered standard treatment, but complications related to the surgical procedure are significant. Endoscopic ultrasound-guided radiofrequency ablation (EUS-RFA) represents a novel and minimally invasive approach.
Aim
To evaluate efficacy of EUS-RFA in localized insulinomas.
Methods
We prospectively included patients diagnosed with insulinoma based on symptomatic hypoglycemia with inappropriate high levels of insulin. Lesions considered for RFA treatment were localized biopsy proven pNEN (Ki-67 $< 10\%$), size < 25 mm. The procedures were performed under general anesthesia. The patients were admitted for 24-hour observation after EUS-RFA. 3-6 months following EUS-RFA, efficacy was evaluated with EUS and 72-hours fasting test. 1 year after EUS-RFA, patients were re-evaluated for symptoms of hypoglycemia. In case of incomplete response, patients were eligible for a 2nd treatment.
Results
From 2022 to 2024, all 14 patients referred to our department with insulinoma underwent EUS-RFA. Mean age 60 (range 31–79) years. The average size was 15.4 (range 9.0–23.0) mm, 5 were in the head of pancreas, 7 in neck/body and 2 in the tail. No adverse events were observed during the procedure and all patients were discharged after uneventful hospitalization. One patient presented with acute necrotizing pancreatitis 13 days after the procedure and underwent EUS-guided drainage. Normoglycemia was observed in 13 out of 14 patients 1-6 months after EUS-RFA and in 6 out of 7 patients 1 year after EUS-RFA. In 3 patients a 2nd EUS-RFA procedure was needed, with complete remission in 2 patients and persistent hypoglycemia in the last patient.
Conclusion
EUS-RFA is an effective, minimally invasive treatment for localized insulinomas. The procedure seems to have a superior safety profile compared to conventional surgery, but long-term efficacy of EUS-RFA has yet to be evaluated.

JOINT1829
Changes in prevalence and incidence of pituitary neuroendocrine tumours: a 25-year population based study in malta
Mark Gruppetta[1,2] & Josanne Vassallo[1,2]
[1]Department of Medicine, Faculty of Medicine and Surgery, University of Malta, Mater Dei Hospital, Msida, Malta; [2]Neuroendocrine Clinic, Department of Medicine, Mater Dei Hospital, Msida, Malta

Objective
Epidemiological data is essential for assessing disease health burden. The aim of the study was to explore longitudinal trends in incidence and prevalence of pituitary neuroendocrine tumours (PitNET) and analyse these variations.
Methods
Population based retrospective analysis on all patients diagnosed between 2000 and 2024 in a well-defined population, the Maltese islands. Main outcome measures: Prevalence Rate 2024; Standardised Incidence rates (SIR) 2000-2024 together with other relevant descriptive epidemiological statistics.
Results
From a total of 987 patients that were diagnosed with PitNETs, 880 patients were alive at end of 2024 giving an overall prevalence of 156.2/100,000 whilst 859 patients had presented between 2000 and 2024 providing an overall SIR of 7.04/100,000/year. Median age at presentation was 43 years (IQR 32-58). 28.2% had suprasellar extension with 19.3% having chiasmal compression. Cavernous sinus invasion was evident in 17.6% of patients. 7.8% of the cohort passed away. Interestingly, no evidence of increased mortality was observed in this cohort of patients when compared to the general population with a standardised mortality ratio (SMR) of 0.68 (95%CI 0.52-0.84). Non-functional PitNETs (NFPitNET) constituted 55.1% of the cohort, whilst 39.0% were prolactinomas, 7.1% were somatotropinomas and 2.7% were corticotropinomas giving rise to an overall SIR of 3.35, 3.01, 0.46, 0.20/100,000/year respectively. Males accounted for 37.3% of the entire cohort, giving rise to a SIR of 4.67/100,000/year compared to 9.72/100,000/year in females. Macroadenomas constituted 36.8% of the tumours with a SIR of 2.25/100,000/year. Furthermore 3.5% of the whole cohort were giant PitNETs (> 40 mm) resulting in a SIR of 0.20/100,000/year. On further analysis, there was an increase in the rate of all PitNETs from 4.26/100,000/year between 2000-2005 to a rate of 10.90/100,000/year in 2020-2024. In males SIR increased from 2.00/100,000/year to 8.16/100,000/year during the same time frame while in females it increased from 6.66/100,000/year to 14.36/100,000/year. The SIR for prolactinomas increased from 2.26/100,000/year to 3.98/100,000/year while for NFPitNETs from 1.58/100,000/year to 6.20/100,000/year for the same time periods. For PitNETs specifically greater than 30 mm in diameter at presentation, notably the SIR increase was relatively smaller, from 0.44 to 0.58/100,000/year when comparing the same time periods.
Conclusion
This study provides in depth and contemporary analysis of epidemiological trends of PitNETs in a well-defined population. Incidence rates appear to be increasing over time and in general, the survival outcomes of patients with these tumours appears to be quite favourable.

Folliculo-stellate cells in a series of ACTH-secreting pituitary neuroendocrine tumors
Valeria Nicoleta Nastase[1,2,3], Iulia Florentina Burcea[4,5], Dumitriu Roxana Ioana[4,5], Amalia Raluca Ceausu[1,3], Baderca Flavia[1,3,6], Catalina Poiana[4,5] & Marius Raica[1,3]
[1]"Victor Babes" University of Medicine and Pharmacy, Department of Histology, Timisoara, Romania; [2]County Emergency Hospital "Pius Brinzeu", Department of Endocrinology, Timisoara, Romania; [3]Angiogenesis Research Center, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania; [4]"Carol Davila" Faculty of Medicine and Pharmacy, Department of Endocrinology, Bucharest, Romania; [5]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; [6]Municipal Emergency Clinical Hospital, Department of Pathology, Timisoara, Romania

Introduction
Folliculo-stellate cells (FSCs) are nonsecretory cells located in the anterior pituitary gland, having a star-like appearance and the ability to form follicles. They represent a heterogeneous population in terms of both phenotype and function. FSCs form a support network and regulate endocrine cells activity by producing numerous paracrine factors. Furthermore, they might be involved in the pathogenesis of pituitary neuroendocrine tumors (PitNETs).
Materials and Methods
Eight patients with Cushing's disease were included in the study. The tumor specimens were obtained after transsphenoidal surgery. The preoperative diagnosis was supported by clinical features, hormonal assessment, and radiological evaluation (contrast-enhanced pituitary magnetic resonance imaging, MRI). The histopathological diagnosis was performed using hematoxylin eosin morphological staining. Reticulin staining was applied for reticulin fibers evaluation. Immunohistochemical (IHC) evaluation for anterior pituitary hormones (GH, PRL, ACTH, TSH, FSH, LH) and transcription factors (PIT1, TPIT, SF-1) were assessed to perform an adequate classification of the tumors. FSCs were analyzed using glial fibrillary acidic protein (GFAP).
Results
Histopathological evaluation revealed acidophilic tumor cells with a diffuse growth pattern. All cases had IHC positive reaction for ACTH and TPIT. In

addition, three cases showed positive IHC expression for GH and PIT1. According to current WHO classification, these were considered PitNETs with unusual IHC combination (TPIT/PIT1 positive). Morphologically FSCs were star shaped, with long cytoplasmic prolongations among the tumoral cells. GFAP positive cells were identified in all PitNETs, with high heterogeneity regarding the distribution pattern and intensity of the reaction. Two of the corticotropinomas presented only a few isolated positive FCSs with a low intensity of the IHC expression. Five of the cases showed GFAP positive cells distributed in small groups/nests among tumoral cells. In only one of the tumors, FSCs were organized in a wide and dense network. Moreover, the tumors classified as PitNETs with unusual IHC combination (TPIT/PIT1 lineage) presented GFAP positive cells located in the vicinity of blood vessels, having close contact with the endothelial cells.

Conclusion

FSCs represent non-secretory cells occupying approximately 5-10% of the anterior pituitary lobe. In our cases, they showed a wide variability regarding the distribution pattern and intensity of reaction. TPIT/PIT1 positive tumors presented a high density of FSCs. The strong connection between FSCs and blood vessels in TPIT/PIT1 positive PitNETs may contribute to the selection of two different cell lineages. Further studies are needed to establish the connection between these cells and PitNETs.

Clinical, metabolic, bone and body composition characteristics of patients with various causes of childhood growth hormone deficiency (COGHD) in the transition period - a single center study

Mirjana Doknic[1,2], Marko Stojanovic[1,2], Tatjana Milenkovic[3], Slaana Todorović[3], Vera Zdravkovic[2,4], Maja Jesic[2,4], Mihajlo Curcic[2], Sandra Pekic Djurdjevic[1,2], Dragana Miljic[1,2], Marina Nikolic Djurovic[1,2], Ivana Cekic[1], Ivan Jevtic[1], Zvezdana Jemuovic[1] & Ivan Soldatovic[2,5]

[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center of Serbia, Neuroendocrine Department, Belgrade, Serbia; [2]Medical Faculty, University of Belgrade, Belgrade, Serbia; [3]Mother and Child Health Care Institute of Serbia "Dr Vukan Cupic", Belgrade, Serbia; [4]University Children's Clinic, Belgrade, Serbia; [5]Institute of Medical Statistics and Informatics, Belgrade, Serbia

Introduction

Patients with COGHD represent a heterogeneous group in many respects, and one of the most important points is the etiology of this hormone deficiency. In this regard, reported studies are inconsistent in relation to anthropometric characteristics, metabolic profile, body composition (BC) and bone mineral density (BMD) of these subjects.

Aim

To investigate the influence of the etiology of COGHD on the clinical characteristics of patients after completion of growth in transition period.

Patients and Methods

In a monocentric, observational, retrospective cross-sectional study spanning the last 20 years, we investigated 302 COGHD patients (16-25 years old, mean age 18.8 $\pm$ 2.1 years, 198 males) at first evaluation after transfer from pediatrics to the adult department. Sixty-two subjects experienced childhood-onset endocranial tumor (TUM, 22.5%). Other patients had congenital (CON, 59.2%) or idiopathic COGHD (IDI 18.3%). Cross-sectional analyisis of metabolic parameters, BC and BMD were performed in these patients.

Results

Persistent GHD was confirmed in 67% of patients after retesting at adult department. The three observed etiological groups did not differ according to body weight, body height, BMI and waist/hip ratio ($P > 0.05$). Insulin levels in the OGTT were significantly higher in the TUM group, than in IDI and CON patients, observing basal insulin, AUC (area under the curve) and peak insulin ($p<0.01$). TUM group showed significantly higher HbA1c levels, total cholesterol, LDL cholesterol and triglycerides compared to the two other groups ($p< 0.001$). BMD (g/cm^2) and Z score at spine was significantly lower in TUM patients compared to CON and IDI groups. Lean body mass did not differ between 3 investigated groups ($P >0.05$), while fat mass and percentage of fat were higher in TUM group ($p< 0.01$).

Conclusion

the cause of COGHD proved to be an extremely important parameter in metabolic characteristics, body composition and bone mass in the transition period. We have shown that tumor-induced GHD in childhood is a risk factor for increased insulin resistance, unfavorable lipid profile and body composition, with susceptibility to lower bone density and thus the risk of bone fractures.

The effect of MDMA on the anterior pituitary

Sara-Jessica Camerin[1], Cihan Atila[1], Matthias Liechti[1] & Mirjam Christ-Crain[1]

[1]university of basel, Basel, Switzerland

Background

3,4-Methylenendioxymethamphetamine (MDMA) has recently been suggested as a novel provocation test to evaluate hypothalamic-posterior pituitary function in suspected cases of oxytocin deficiency. Limited preliminary evidence also suggests that MDMA may stimulate anterior pituitary hormone secretion, potentially contributing to its cardiovascular and neuropsychological effects. However, its effects on the anterior pituitary have not yet been fully investigated. Therefore, this analysis aimed to investigate the effect of MDMA on anterior pituitary hormone axes in healthy adults.

Methods

This secondary analysis utilized data from a double-blind, placebo-controlled crossover randomized clinical trial conducted at the University Hospital Basel, Basel, Switzerland, between Feb 2021 and May 2022. Healthy participants received a single oral dose of MDMA (100 mg) or placebo in randomized order. Plasma hormone levels of the anterior pituitary (adrenocorticotropic hormone [ACTH], thyroid-stimulating hormone [TSH], luteinizing hormone [LH], prolactin, growth hormone [GH] and their peripheral endocrine glands (cortisol, free thyroxin [fT4], testosterone, estradiol) were measured at baseline and 120 minutes after drug-intake. Changes in plasma hormone levels following MDMA vs placebo were compared using paired Wilcoxon test.

Results

A total of 15 healthy participants (median [IQR] age: 35 years [26–48]; 53% female) with a mean (SD) BMI of 23.2 kg/m^2(2.1) were included. MDMA strongly stimulated the pituitary-adrenal axis, with plasma ACTH increasing from 12 ng/l [10.5, 14.9] at baseline to 35.5 ng/l [17.6, 58.9] at 120 minutes, resulting in a significant change of ACTH ($P = 0.0008$). This was accompanied by a cortisol increase from 347 nmol/l [252, 409] to 566 nmol/l [415, 701], resulting in a significant change of cortisol ($P = 0.025$). Prolactin showed a mild increase from 12 µg/l [7, 16] at baseline to 14 µg/l [10.4, 21.8] at 120 minutes, resulting in a non-significant change of prolactin ($P = 0.062$). No significant effects of MDMA were observed on GH, the pituitary-gonadotropin axis, or the pituitary-thyroid axis. Under placebo, no relevant hormonal changes occurred.

Conclusion

MDMA partially stimulates the anterior pituitary, strongly activating the pituitary-adrenal axis and mildly increasing prolactin levels. These findings suggest that MDMA may serve as a novel stimulation test for assessing multiple pituitary axes simultaneously. Further validation in larger patient populations is necessary.

Exenatide for diagnosing endogenous hyperinsulinemic hypoglycaemia - a randomised placebo-controlled, double-blind, cross-over proof-of-principle study - fast study

Matthias Hepprich[1,2], Christina Romberg[3], Jonathan Mudry[4], Julie Celine Refardt[3,5], Damian Wild[3], Kwadwo Antwi[6] & Emanuel Christ[2]

[1]Cantonal Hospital Olten, Metabolic Center, Olten, Switzerland; [2]University of Basel, Basel, Switzerland; [3]University of Basel, Division of Nuclear Medicine, Basel, Switzerland; [4]Hôpital du Valais, Sion, Switzerland; [5]Erasmus Medical Center, Department of Internal Medicine, Section of Endocrinology, Rotterdam, Netherlands; [6]St. Claraspital, Department of Nuclear Medicine, Basel, Switzerland

Background

The 72-hour fasting test, the gold standard for diagnosing endogenous hyperinsulinemic hypoglycaemia (EHH), is cumbersome and costly. This study evaluated exenatide, a GLP-1 receptor agonist, as a faster, less burdensome alternative diagnostic tool.

Methods

In this prospective, placebo-controlled, double-blind, randomised cross-over, proof-of-principle study, 14 patients with confirmed EHH in a 72-hour fasting test received in a randomized order 10 µg intravenous exenatide or placebo after at least 24 hours in between. Fourteen matched controls received 10 µg exenatide in an open-label design. Clinical monitoring and measurements of glucose, insulin, C-peptide, and proinsulin were performed for 4 hours. Follow-up included imaging and histological confirmation for EHH patients.

Findings
Exenatide induced diagnostic hypoglycaemia in 6 of 14 EHH patients (42%) compared to none with placebo ($P = 0•005$). In patients with EHH glucose nadir occurred earlier after exenatide (67 min [95% CI 50–142] vs. 210 min [95% CI 174–219], $P < 0•0001$) and at lower glucose levels (2•68 mmol/l [95% CI 2•26–3•02] vs. 3•2 mmol/l [95% CI 2•92–3•77], $P < 0•0001$) compared to placebo. Proinsulin levels at 120 minutes post-exenatide were higher in patients with EHH (69 pmol/l [95% CI 3•8–232]) compared to controls (9 pmol/l [95% CI 4•5–16•9], $P = 0•0001$). Compared to the fasting test, exenatide significantly shortened time to hypoglycaemia compared to the fasting test (1•38 hours [95% CI 0•67–2•99] vs. 12 hours [95% CI 1•44–36•1] respectively, $P = 0•032$). All patients preferred the exenatide test over the fasting test. Exenatide was well tolerated.
Interpretation
Intravenous exenatide is a promising, faster, less cumbersome and less expensive diagnostic tool for EHH compared to the fasting test. Larger trials are warranted to confirm its diagnostic utility.

Changes in circulating levels of miR-30b during minipuberty and puberty in girls

Helle Margit Albrechtsen[1,2], Gülizar Saritas[1,2,3], Sofia Boeg Winge[1,2], Ailsa M. Main[1,2,3], Casper P. Hagen[1,2,4], Alexander S. Busch[1,2,5], Katharina M. Main[1,2,4], Stine Gry Kristensen[6], Anders Juul[1,2,4], Kristian Almstrup[1,2,3] & Nina Mørup[1,2]
[1]Copenhagen University Hospital - Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark; [2]International Center for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen, Denmark; [3]University of Copenhagen, Department of Cellular and Molecular Medicine, Copenhagen, Denmark; [4]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; [5]University of Münster, Department of General Pediatrics, Münster, Germany; [6]Copenhagen University Hospital - Rigshospitalet, The Laboratory of Reproductive Biology, Copenhagen, Denmark

Background
Puberty is characterized by major physiological and psychological changes required for achieving sexual maturation and fertility. Pubertal timing is tightly controlled by the hypothalamic-pituitary-gonadal (HPG) axis, with the initiation of puberty driven by the pulsatile release of gonadotropin-releasing hormone (GnRH) from the hypothalamus. Makorin RING finger protein 3 (MKRN3), encoded by the maternally imprinted gene *MKRN3*, acts as an inhibitor to suppress GnRH activity and delay pubertal onset. MicroRNA-30b (miR-30b) has been proposed to act as a direct regulator of hypothalamic *MKRN3* expression and circulating levels of miR-30b-5p increase in concert with a decrease in circulating levels of MKRN3 in pubertal boys. However, it has not been described whether this is also the case in girls.
Materials and Methods
Longitudinal serum samples from 18 female infants from The COPENHAGEN Minipuberty Study (median age 3.7 months and 8.4 months, representing peri- and post-minipuberty, respectively), 29 girls (Tanner stage B1, B2 and $\geq$ B3 representing prepuberty, peripuberty, and postpuberty, respectively), and 24 young women (median age 19.0 yrs, single sample) from The Copenhagen Puberty Study were included. Serum from 23 pregnant women from The Copenhagen Mother-Child Cohort (median age 29.9 yrs, single samples) were also included. miR-30b-5p was measured in serum by reverse transcription quantitative PCR. Additionally, miR-30-5p expression was assessed by miRNA *in situ* hybridization in ovarian tissue from eight adult women. Wilcoxon signed-rank test and Pearson's correlation coefficient were used to analyze the data.
Results
Circulating miR-30b-5p levels decreased significantly from the peri- to the post-minipubertal stage ($p = 0.048$). A significant increase in circulating levels of miR-30b-5p was observed in girls at the post-pubertal stage compared with girls at the pre- and the peri-pubertal stages ($p = 0.0022$ and $p = 0.0017$, respectively). Furthermore, the circulating levels of miR-30b-5p were significantly lower in pregnant women when compared to young women ($p < 0.001$). Supporting the findings from serum, the ovarian expression of miR-30b-5p increased during folliculogenesis with the highest expression in antral follicles.
Conclusion
In girls, circulating miR-30b-5p levels followed both the deactivation and reactivation of the HPG axis as observed during minipuberty and puberty, respectively. These findings support a regulatory role of miR-30b-5p on the HPG axis at the hypothalamic level in the onset of puberty in girls. We cannot deduce whether the dynamics of circulating levels of miR-30b-5p is a direct proxy of hypothalamic miR-30b-5p or also a product of ovarian activity.

Depression, cognitive dysfunction and anxiety in illicit androgenic steroid users' years after cessation of usage

August Nielsen[1], Yeliz Bulut[1], Niels Brandt-Jacobsen[2], Rasmus Madsen[1], Jan Frystyk[3], Jon Rasmussen[1] & Caroline Kistorp[1]
[1]Rigshospitalet, Department of Nephrology and Endocrinology, Copenhagen, Denmark; [2]Rigshospitalet, Department of Clinical Physiology & Nuclear Medicine, Copenhagen, Denmark; [3]Odense University Hospital, Department of Endocriniology, Odense, Denmark

Background and objectives
The use of anabolic androgenic steroids (AAS) among younger men has increased, giving rise to a public health concern. Despite this alarming trend, the long-term effects of AAS on mental health – particularly depression, cognitive function and anxiety remains poorly understood. The objective of this study was to assess these psychological and cognitive outcomes in former illicit users of AAS years after cessation and comparing them to current users and healthy age-matched never-users of AAS.
Methods
A cross-sectional study including men involved in recreational strength training grouped according to their history of AAS use. Three validated questionnaires were used to assess self-reported mental health participants: Major Depression Inventory (MDI), Cognitive complaints in bipolar disorder rating assessment (COBRA) and General Anxiety Disorder-7 (GAD-7). Higher scores indicate more pronounced symptoms in all three questionnaires.
Results
We initially recruited 79 previous and 193 current AAS users, as well as 57 healthy age-matched never-users. We excluded 14 previous and 31 current AAS users who had previously been diagnosed and treated for psychiatric disorders, our final study population consisted of 65 previous and 162 current AAS users. The mean (SD) age was 35 (9) years. Elapsed duration of cessation of AAS geometric mean (95 CI) was 1.9 (0.9-3.0) years in previous users. Previous AAS users consistently exhibited more pronounced symptoms of depression, cognitive dysfunction and anxiety compared to current AAS users and controls, expressed as a higher score in the MDI, COBRA and GAD-7, respectively (table). Using multiple linear regression models adjusted for age, duration of AAS use, and level of education, low serum testosterone was significantly associated with higher scores of depression ($P = 0.041$) and showed borderline associations with cognitive dysfunction ($P = 0.075$) and anxiety ($P = 0.07$).
Conclusions
Previous AAS users displayed increased levels of self-reported depression, cognitive dysfunction and anxiety compared to healthy age-matched non-users years after AAS cessation.

	Current AAS users	Former AAS users	Never-users	*P*-value
Age, years (mean ± SD)	34.5 ± 8.6	35.7 ± 9.8	35.7 ± 8.8	0.583
S-testosterone (median and IQR)	19.0 (11.9 - 28.6)	13.6 (10.7 - 16.9)	17.9 (14.8 - 16.9)	<0.001
MDI scorer (median and IQR)	11.0 (6.0 - 16.0)	13.5 (8.0 - 25.0)	5.0 (3.0 - 8.0)	<0.001
COBRA score (median and IQR)	10.0 (6.0 - 15.0)	15.0 (7.0 - 19.5)	7.0 (4.0 - 10.0)	<0.001
GAD-7 scores (median and IQR)	3.0 (1.0 - 7.0)	5.0 (3.0 - 7.0)	1.0 (0.0 - 3.0)	<0.001

Hypothalamic-pituitary abnormalities in paediatric histiocytosis: preliminary retrospective data from a large cohort of a tertiary italian center

Francesco Pezzoli[1,2], Eugenio Trinati[1,3], Maddalena Bagni[1], Maria Luisa Coniglio[2], Irene Trambusti[2], Franco Ricci[3], Stefano Stagi[1,3] & Elena Sieni[2]
[1]Department of Health Sciences, University of Florence, Florence, Italy; [2]Department of Pediatric Hematology Oncology, Meyer Children's Hospital IRCCS, Florence, Italy; [3]Diabetology and Endocrinology Unit, Meyer Children's Hospital IRCCS, Florence, Italy

Introduction
Histiocytosis is a rare hematologic condition involving tissue infiltration by dendritic cells, macrophages, or monocytes. Langerhans cell histiocytosis (LCH) has an estimated incidence of 2–9 cases per million children annually. Pituitary involvement, particularly diabetes insipidus (DI), affects 5–30% of cases, potentially leading to multiple pituitary hormone deficiencies (MPHD).
Patients and Methods
This retrospective study analysed 115 paediatric histiocytosis cases diagnosed from September 2004 to September 2024 at the Italian Referral Center for Histiocytosis in Florence, Italy. The median age at diagnosis was 7 years (IQR 10). Demographic, clinical and biological data were collected.
Results
The cohort included a total of 115 patients: 105 LCH, 3 Juvenile Xanthogranuloma, 3 mixed forms, 2 Rosai-Dorfman, 1 histiocytic sarcoma, and 1 indeterminate cell histiocytosis. A total of 36/115 (31%) patients had pituitary functional involvement: 33 LCH and 3 mixed forms. DI was diagnosed in 34/115 (29.5%) patients at a median age of 5,7 (IQR 3). It was the first manifestation in 17/34 (50%) and developed after a median of 4 years (IQR 3.25) in remaining cases. Growth hormone deficiency (GHD) was the second most common hormonal deficiency, affecting 11/115 (9.6%) patients, with an average onset of 8.6 years (IQR 4). In 1/11 (9%) cases, GHD was isolated; in 10/11 (91%) cases, it was associated with DI. Of these, 2/10 (20%) had GHD at disease onset, and 8/10 (80%) developed it after a median of 4.8 years (IQR 3.25) following DI onset. Central hypothyroidism occurred in 4/115 (3.5%) patients, all with DI. Hypogonadotropic hypogonadism affected 4/115 (3.5%), all with DI and one with hyperprolactinemia. Precocious puberty was observed in 1/115 (0.8%) male patient. Central adrenal insufficiency developed in 2/115 (1.7%), both with DI and GHD. MPHD occurred in 12/34 (35.2%) DI patients.
Conclusions
To the best of our knowledge, this represents one of the largest paediatric cohorts of endocrinopathies in histiocytosis. Hypothalamic-pituitary hormone deficiencies may be the first manifestation of histiocytosis or may complicate it during the course of disease. Thus, paediatric endocrinologists should screen and monitor these patients in close collaboration with hematologist-oncologist with expertise in histiocytosis.

Aggressive pituitary adenomas and pituitary carcinomas

Barbara Buchalska[1], Jacek Kunicki[1] & Maria Maksymowicz[2]
[1]Maria Skłodowska-Curie National Research Institute of Oncology, Department of Neurosurgery, Warsaw, Poland; [2]Maria Skłodowska-Curie National Research Institute of Oncology, Department of Pathology, Warsaw, Poland

Introduction
Aggressive pituitary tumors (APTs) are rare neoplasms defined as invasive and refractory to treatment, with early recurrences. Pituitary carcinomas (PCs) besides their aggressive behavior are diagnosed by the presence of metastases. However, the diagnostic criteria for APTs are not well-defined and there are several approaches for characterizing aggressiveness. The aim of this study is to find clinical features characteristic for patients with APTs and PCs.
Material and Methods
The study is a retrospective analysis of a series of 45 patients (14 women and 31 men) treated from the 2006 to 2024 by the endoscopic transsphenoidal surgeries for pituitary adenomas presenting aggressive clinical behavior. The mean age of the patients was 48.4 years (20-70 years), and the mean follow-up period was 10.4 years (0-18 years).
Results
In this group 3 patients were diagnosed with PCs (6.7%) and the rest with APTs (93.3%). Six patients died during follow-up period (13.3%). There were 91.1% macroadenomas, the tumors were invasive in 75.5% and functioning in 33.3% of the patients. The patients had 3.3 resections for APTs or PCs on average. The Knosp scale grade assessed preoperatively was III in 9 patients (20.0%), and IV in 8 patients (17.8%). Twenty-nine patients (64.4%) had radiotherapy, and 13 patients had pharmacotherapy (28.9%) as additional treatment methods. According to Lyon's classification the most numerous groups were 2a (35.6%) and 2b (28.9%). The gross total resection was accomplished in 17 cases (37.8%), the subtotal resection was achieved in 20 patients (44.4%), and in 6 cases (13.3%) only the partial resection was possible. Postoperatively 68.2% of the patients showed varying improvement in visual field defects and visual acuity. Transient diabetes insipidus (DI) was observed in 1 patient (2.2%), epistaxis in 4 patients (8.8%), and 2 patients (4.4%) had a postoperative oculomotor nerve paresis.
Conclusion
Surgical treatment of APTs and PCs is safe and associated with a low complication rate. The patients are younger and have more resections than in usual pituitary adenomas.

JOINT708 Validation of arginine-stimulated copeptin cut-offs for diagnosing AVP deficiency (central diabetes insipidus)

Michelle Müller[1,2], Cihan Atila[1,2], Bettina Winzeler[1,2], Irina Chifu[3], Martin Fassnacht[3,4], Julie Refardt[1,2,5] & Mirjam Christ-Crain[1,2]
[1]University Hospital Basel, Department of Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University Hospital Basel, Department of Clinical Research, Basel, Switzerland; [3]University Hospital Wuerzburg, Division of Endocrinology and Diabetes, Department of Internal Medicine, Wuerzburg, Germany; [4]University Hospital Wuerzburg, Central Laboratory, Wuerzburg, Germany; [5]Erasmus Medical Centre, Rotterdam, Department of Internal Medicine, Section of Endocrinology, Rotterdam, Netherlands.

Background
Distinguishing arginine vasopressin (AVP) deficiency (central diabetes insipidus) from primary polydipsia is challenging. While hypertonic saline-stimulated copeptin testing provides the highest diagnostic accuracy, it is often restricted to specialised centres, requiring close monitoring and potentially causing patient discomfort. Initially, arginine-stimulated copeptin was proposed as a simpler alternative, but a head-to-head comparison study found it less precise than hypertonic saline stimulation. However, the same study identified two new high sensitivity and specificity cut-offs for arginine-stimulated copeptin, though these cut-offs have yet to be validated.
Methods
This is a secondary analysis of the initial prospective multicentre study, including adult patients with confirmed AVP deficiency or primary polydipsia. Participants underwent the arginine stimulation test, with plasma copeptin measured at baseline and 60- and 90 minutes after infusion. The primary objective was to revisit the original study to validate the proposed arginine-stimulated copeptin cut-offs of >5.2pmol/l (high sensitivity cutoff with $>90\%$ sensitivity) and ≤ 3pmol/l (high specificity cutoff with $>90\%$ specificity).
Findings
In total, 96 patients were included between May 2013 and June 2018: $n=38$ [40%] with AVP deficiency and $n=58$ [60%] with primary polydipsia. At 60 minutes after arginine infusion, a copeptin level ≤ 3.0 pmol/l showed a specificity of 95% (95% CI: 0.88-1.00) for AVP deficiency, while a copeptin level >5.2 pmol/l demonstrated a sensitivity of 97% (95% CI: 0.92-1.00) for primary polydipsia. The ≤ 3.0 pmol/l cut-off accurately identified 71% ($n = 27/38$) of patients with AVP deficiency, and the >5.2 pmol/l cut-off correctly identified 69% ($n = 40/58$) of patients with primary polydipsia.
Interpretation
This analysis validates two new copeptin cut-offs of the arginine stimulation test to distinguish AVP deficiency from primary polydipsia: >5.2 pmol/l for high sensitivity in diagnosing primary polydipsia and ≤ 3.0 pmol/l for high specificity in diagnosing AVP deficiency. These thresholds might offer a practical initial alternative to hypertonic saline testing.

Central diabetes insipidus and panhypopituitarism in acute myeloid leukemia

Ali Dhouibi[1], Ghada Saad[2], Maissa Thabet[1], Salem Braham[3], Nesrine Bensayed[4], Nassim Ben Hadj Slama[2], Wissal Ben Yahya[1], Ahmed Guiga[1] & Neirouz Ghannouchi[1]
[1]Farhat Hached University Hospital, Faculty of Medecine of Sousse, Internal Medecine, Sousse, Tunisia; [2]Farhat Hached University Hospital, Faculty of Medecine of Sousse, Endocrinology and Diabetology, Sousse, Tunisia; [3]Farhat Hached University Hospital, Medical Imaging, Sousse, Tunisia; [4]Farhat Hached University Hospital, Clinical Hematology, Sousse, Tunisia

Introduction
Acute myeloid leukemia (AML) is characterized by the rapid and uncontrolled proliferation of blasts in the bone marrow. Central diabetes insipidus (CDI) is an uncommon manifestation of AML.
Case Report
We report the case of a 68-year-old Tunisian patient with no significant medical history, admitted for evaluation of persistent dry mouth and dry eyes, associated with a polyuria-polydipsia syndrome in the context of a two-month history of general deterioration. Clinical examination revealed marked weight loss, a polyuria-polydipsia syndrome (fluid intake = 6L/day, urine output = 4.5L/day), dehydration, hypotension (B*P* = 90/50 mmHg), xerophthalmia, and xerostomia (grade III sialadenitis). Laboratory investigations showed: **Blood glucose** = 0.3 g/l; **Serum sodium** = 155 mmol/l; **Plasma osmolality** = 321 mosmol/l; **Urine osmolality** = 240 mosmol/l; **Hemoglobin** = 8 g/dl; **Mean corpuscular volume (MCV)** = 86 fL; **White blood cell count** = 7,000/mm^3; **Platelet count** = 100,000/mm^3; **Peripheral blood smear**: 20% circulating blasts. The diagnosis of AML was confirmed based on indings on bone marrow aspiration. Given the presence of polyuria-polydipsia syndrome, hypotension, and hypoglycemia, a global pituitary dysfunction was suspected and confirmed by: The absence of the posterior pituitary bright spot on MRI and evidence of panhypopituitarism (cortisol = 46 ng/mL, FT4 = 4 pmol/l, FSH = 2,58 mUI/l, testosterone = 0,35 ng/ml) Pituitary MRI revealed infiltration of the pituitary stalk and oss of T1 hyperintensity of the posterior pituitary. Cytogenetic analysis revealed monosomy 7. The patient was treated with desmopressin, hydrocortisone hemisuccinate, and L-thyroxine, leading to clinical improvement. Chemotherapy was subsequently initiated.
Conclusion
The associations between DI and AML remain enigmatic and the underlying cause of DI in patients with AML is likely multifactorial. It has been associated with chromosomal abnormalities involving chromosomes 3 or 7. Diagnosis remains challenging, but clinical improvement following chemotherapy supports this etiology.

[1]The Children's Hospital at Westmead, Institute of Diabetes & Endocrinology, Sydney, Australia; [2]Sydney Children's Hospital, Randwick, Department of Endocrinology & Diabetes, Sydney, Australia; [3]The University of Notre Dame, Sydney, Australia; [4]University of Sydney, Sydney, Australia; [5]University of New South Wales, Sydney, Australia

Background
Hypothalamic obesity (HO) is a complex disorder marked by rapid and excessive weight gain, following damage to key hypothalamic structures responsible for energy homeostasis and appetite. Traditional lifestyle intervention often fails to result in meaningful or sustained reduction in body mass index (BMI) for general obesity, and are even less efficacious with HO. Favourable outcomes have been reported with GLP-1 agonist semaglutide for obesity which suggest it could be beneficial for adolescents with HO.
Method
Prospective observational study of the off-label use of semaglutide in adolescents with acquired HO across two tertiary paediatric hospitals, according to a standardised treatment and monitoring protocol. Dose titrated to effect (appetite suppression and sustained weight loss without significant adverse effects) starting at 0.25mg/week with four weekly increases up to a maximum of 2mg/week by 16 weeks at the earliest if clinically indicated. We report efficacy, tolerability, safety, impact on quality of life (QOL) and eating behaviours.
Results
Ten adolescents (60% male, age 11.6-17.3 years) with acquired HO are receiving semaglutide plus lifestyle intervention. Primary diagnoses include craniopharyngioma ($n = 6$), pituitary adenoma ($n = 2$), pineal tumour ($n = 1$) and bilateral thalamic infarcts ($n = 1$). After 8 weeks of therapy, 9/10 participants had a reduction in BMI SDS (range 0.03 to 0.18 SD) and BMI expressed as a percentage of 95th percentile (range 2 to 35%). Five participants have completed 24 weeks of therapy thus far with 4/5 participants experiencing a reduction in BMI SDS (range 0.03 to 0.18 SD) and BMI expressed as a percentage of 95th percentile (range 1 to 13%). Two patients have achieved at least a 5% reduction in total body weight. Waist to height ratio has reduced in all cases (mean reduction 5.0%, range 1.5 to 9.8%). 24-week data for the remaining 5 participants is awaited. Appetite suppression was evident from the starting dose with gastrointestinal side effects (vomiting, nausea and loose stool) being the most common, primarily occurring at treatment initiation or following dose escalation. No serious adverse events or therapy discontinuation has occurred. Treatment was associated with increased satiety responsiveness and slower eating measured by the Child Eating Behaviour Checklist. QOL assessments identified baseline deficits in physical comfort and body esteem, which have demonstrated the greatest improvements following treatment.
Discussion
Semaglutide is a promising therapy for HO. Data suggests this is a safe and effective treatment, although individual responses have varied. Further evaluation of long-term efficacy and safety is required.

[1]Unidad de Investigación Médica en Enfermedades Endocrinas, Hospital de Especialidades, Centro Médico Nacional Siglo XXI, Instituto Mexicano del Seguro Social, Mexico, Mexico; [2]Escuela Nacional de Ciencias Biológicas, Instituto Politécnico Nacional, Mexico, Mexico; [3]Unidad de Investigación Médica en Enfermedades Oncológicas, Instituto Mexicano del Seguro Social, Mexico, Mexico; [4]Unidad de Investigación Médica en Inmunoquímica, Hospital de Especialidades, Centro Médico Nacional Siglo XXI, Instituto Mexicano del Seguro Social, Mexico, Mexico; [5]Servicio de Neurocirugía, Hospital de Especialidades, Centro Médico Nacional Siglo XXI, Instituto Mexicano del Seguro Social, Mexico, Mexico

Introduction
Pituitary tumors (PT) occasionally exhibit an aggressive behavior, being invasive and resistant to treatment, growing rapidly and presenting multiple recurrences. We conducted a transcriptomic analysis of 22 tumors from 11 patients, including both primary and recurrent tumors from the same individuals. We identified several differentially expressed genes that are involved in lipid-related pathways, such as the up-regulation of diacylglycerol kinase gamma (DGKG), also confirmed by immunofluorescence and rt-PCR in another cohort of PT. Moreover, with molecular docking and drug repurposing tools, we observed that dasatinib, a tyrosine kinase inhibitor (TKI) already approved by the FDA for chronic myelogenous leukemia, has DGKG as a potential therapeutic target. Additionally, a novel small molecule targeting kinases (KPG-04) was designed, and its ability to induce apoptosis and decrease cell proliferation was tested.
Methods
GH3 cells and primary PT cultures were exposed to dasatinib and KPG-04 at increasing concentrations and cell viability and apoptosis were assessed by means of flow cytometry. PT samples were obtained surgically and immediately disassociated enzymatically.
Results
Exposure of GH3 cells to dasatinib decreased cellular proliferation in a dose-dependent manner: 28% at 1 μM ($P = 0.0048$), 50% at 2.5 μM ($P = 0.003$) and 98% at 5 μM ($P = 0.0395$). Dasatinib also resulted in apoptosis induction at concentrations as low as 1 μM and increasing progressively with 2.5 μM and 5 μM ($P = 0.0001$). Significantly higher concentrations of KPG-04 were required to induce cell proliferation arrest (57.23% at 50 μM, $P = 0.0039$; 68.95% at 75

μM; and 74.58% at 100 μM) and had no effect on apoptosis. Similarly, preliminary results showed that exposure of PT primary cultures to dasatinib resulted in a reduction in cellular proliferation and apoptosis induction.
Conclusion
Dasatinib, but not KPG-04, induces apoptosis and decreases cell viability in a dose-dependent manner starting at very low, probably non-toxic concentrations in both, a murine mamosomatotrope cell line and in PT primary cultures. This opens a new perspective in the treatment of aggressive PT resistant to conventional multimodal therapy, but prospective clinical studies are needed to ascertain the efficacy and safety of this TKI. We are currently designing new small molecules capable of targeting kinases such as DGKG.

Macroorchidism and elevated inhibin B levels as key indicators of an extremely rare manifestation of mccune-albright syndrome in boys

Brigitte de Potzolli[1], Constanze Lämmer[1], Tobias Schuster[2], Desiree Dunstheimer[3], Bruno Märkl[4], Moneef Shoukier[5] & Thomas Völkl[1,6]
[1]KJF Klinikum Josefinum, Division of Pediatric Endocrinology and Diabetology, Department of Pediatrics and Adolescent Medicine, Augsburg, Germany; [2]Universitätsklinikum Augsburg, Department of Pediatric Surgery, Augsburg, Germany; [3]Universitätsklinikum Augsburg, Division of Pediatric Endocrinology and Diabetology, Department of Pediatrics and Adolescent Medicine, Augsburg, Germany; [4]Universitätsklinikum Augsburg, Institute of Pathology and Molecular Diagnostics, Augsburg, Germany; [5]Eurofins Pränatal-Medizin, München, Germany; [6]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

Introduction
Precocious puberty is rare in boys with McCune-Albright syndrome (MAS). Cases of unilateral or bilateral macroorchidism, along with elevated inhibin B and anti-Müllerian hormone (AMH) levels but normal androgen levels, have been reported due to the autonomous hyperfunction of Sertoli cells. Management is challenging and focuses on suppressing gonadal steroidogenesis and mitigating the peripheral effects of androgens.
Case Report
Our patient first presented at age 5 years and 6 months with macroorchidism, increased height (135.8 cm, +1.82 SDS) and growth velocity (10.96 cm/year, +7.03 SDS), as well as accelerated bone age (+49 months). Tanner staging showed PH2, G2-3; testicular volumes were 8 mL and 10 mL, and penile length was 9.0 cm. Laboratory evaluation revealed normal basal and stimulated (Synacthen) androgen levels and a normal urine steroid profile. LH and FSH were at prepubertal levels. Alpha-fetoprotein and beta-HCG levels were normal. Inhibin B levels were markedly elevated (367 ng/l), while AMH was within the normal range (15 ng/l). Ultrasound imaging showed enlarged but homogeneous testes without microlithiasis. Genetic testing ruled out fragile X syndrome, and karyotyping confirmed a 46, XY genotype. Whole-exome (blood) sequencing did not reveal any pathogenic variants. The patient was lost to follow-up but presented again at 7 years and 4 months. After LH-RH stimulation, LH increased from <0.5 to 4.5 U/l, while FSH remained unchanged. We initiated treatment with leuprorelin acetate. However, pubertal signs and growth acceleration progressed, prompting us to perform a testicular biopsy. Genetic analysis of testicular tissue revealed somatic hypomethylation of all four GNAS differentially methylated regions (DMRs): exon A/B (GNAS-A/B: TSS DMR = A/B), GNAS antisense (GNAS-AS1: TSS DMR = AS1), extra-large stimulatory G protein (GNAS-XL: Ex1 DMR = XL), and neuroendocrine secretory protein 55 (GNAS-NESP: TSS DMR = NESP), compared to normal methylation results in DNA from blood sample of the same patient. No further mutation has been detected in both tissues. Following this diagnosis, we initiated combination therapy with spironolactone and anastrozole and discontinued leuprorelin acetate.
Conclusion
Precocious puberty in boys with McCune-Albright syndrome is rare and requires a testicular biopsy for diagnosis. Given the underlying etiology, GnRH agonists are ineffective; however, a combination of third-generation aromatase inhibitors and antiandrogens may be the preferred therapeutic approach. Toward earlier diagnosis of childhood suprasellar brain tumors through improved growth monitoring

Ichelle van Roessel[1,2], Paula van Dommelen[3], Boudewijn Bakker[1], Johan de Graaf[4], Anita Hokken-Koelega[5,6], Judith Renes[6,7], Jan Maarten Wit[8] & Hanneke van Santen[1,2]
[1]Wilhelmina Children's Hospital, Pediatric Endocrinology, Utrecht, Netherlands; [2]Princess Maxima Center, Utrecht, Netherlands; [3]The Netherlands Organization for Applied Scientific Research (TNO), Leiden, Netherlands; [4]Dutch Pituitary Foundation (Nederlandse Hypofyse Stichting), Nijkerk, Netherlands; [5]Erasmus University Medical Center, Rotterdam, Netherlands; [6]Dutch Growth Research Foundation – National Registry of Growth Hormone Treatment in Children, Rotterdam, Netherlands; [7]Albert Schweitzer Hospital, Dordrecht, Netherlands; [8]Willem-Alexander Children's Hospital, Leiden University Medical Center, Leiden, Netherlands

Introduction
Childhood suprasellar brain tumors (SBT) may cause growth retardation with simultaneous weight gain due to hypothalamic dysfunction. Many parents experience delay in diagnosis, with in hindsight pre-existing slower growth and increase in BMI. Earlier detection of SBT could prevent additional complications, such as visual impairment.
Aim
To assess whether the current referral criteria in growth monitoring by youth health care services can timely detect SBT, and whether additional criteria can lead to earlier detection.
Methods
Data were analyzed from a cohort of children diagnosed with SBT at ages 3-18y (n = 139) and compared to controls (healthy children registered at the youth healthcare service). New referral criteria based on change of height standard deviation score (HSDS) and/or BMI SDS were assessed.
Results
In the SBT cohort, 22.6% (12/53) of children with childhood craniopharyngioma (cCP), 10.8% (7/65) with low-grade glioma (LGG), and 0% (0/21) with germ cell tumor (GCT) met the current referral criteria. Had the current referral criteria been strictly followed, 47.4% (9/19) of the SBT cohort could have been detected 1y earlier than their age of diagnosis. By extending the referral criteria with ΔHSDS < -1, an additional 11 children with SBT (6 cCP, 3 LGG and 2 GCT) would be identified. Of all SBT children meeting this criterion (n = 23), 52.2% (12/23) would have been referred at least one year earlier than their age of diagnosis. This new criterion would lead to referral of 7 months earlier than the current criteria. When extending the guideline with ΔHSDS < -0.75 and ΔBMI SDS > 0.5, 5 additional SBT children were identified compared to extension with ΔHSDS < -1.
Conclusion
Extending the current referral criteria for growth monitoring may enable earlier identification of children with SBT. However, even with the current criteria children seem to be diagnosed later than necessary. Raising awareness among parents and healthcare professionals about impaired growth as a potential early warning sign for SBT is crucial to effectively implement these criteria. Also, adding additional criteria, e.g. checking for neurological or visual symptoms in patients with growth faltering, may further lead to earlier diagnosis. The pending results from the control group will provide insight into the specificity of these new referral criteria.

The association between gonadotropin-releasing hormone analogue use and body mass index in girls with idiopathic central precocious puberty or early puberty: a systematic review and meta-analysis

Nicholas Beng Hui Ng[1,2], Natasha Yixuan Ong[2], Zera Yingrui Te[2], Seth En Teoh[3], Sarvesha K[2], Yung Seng Lee[1,2] & Kah Yin Loke[1,2]
[1]Khoo Teck Puat - National University Children's Medical Institute, Department of Paediatrics, National University Health Systems, Department of Paediatrics, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [2]Department of Paediatric, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [3]Ministry of Health Holdings, Singapore, Singapore

Objective
The rising incidence of central precocious puberty (CPP) has led to increasing use of Gonadotropin-releasing hormone (GnRH)-analogues. There have been

inconsistent reports on the possible risk of increased adiposity with GnRH-analogue use. This study evaluated the association between GnRH-analogue use and adiposity change in females with idiopathic central precocious puberty or early puberty (EP).
Design
A PRISMA-compliant systematic review was conducted using the following databases: PubMed, Embase, Scopus, PsycInfo and Cochrane. Inclusion criteria were primary studies on females diagnosed with idiopathic CPP/EP who received GnRH-analogues, where quantitative measures of adiposity were reported. The JBI Critical Appraisal Tool for Observational Studies was used for quality assessment of individual studies. A meta-analysis was performed, with subgroup analyses based on baseline body mass index (BMI) status and GnRH-analogue type.
Results
Forty-six cohort studies with 3,606 females who received GnRH-analogues for CPP/EP were included. The mean age of the study participants at initiation of GnRH-analogue was 8.07 (1.19) years, while duration of treatment ranged from 6 months to $>$ 4 years. BMI-SDS had increased significantly within 2 years of therapy (0.17, 95% CI 0.12–0.23) and at the end of therapy (0.10, 95% CI 0.02–0.18). There was no significant change in BMI-SDS beyond 2 years of therapy (0.09, 95% CI -0.02–0.20) nor at final height (-0.10, 95% CI -0.24–0.05). Between the start to end of therapy, females with normal BMI at baseline experienced significant increase in BMI-SDS (0.32, 95% CI 0.22–0.42) compared to those with overweight or obesity (BMI-SDS -0.03, 95% CI -0.09–0.02). Leuprorelin use was associated with a mild but significant increase in BMI-SDS between the start and end of therapy (0.12, 95% CI 0.03–0.21), but this was not observed with triptorelin use.
Conclusions
GnRH-analogue use in females is associated with a transient increase in BMI-SDS during, but not beyond therapy. Females with normal BMI at baseline are at higher risk of significant BMI-SDS increase during therapy. These findings are clinically important to guide counselling and monitoring of individuals with CPP/EP who receive GnRH-analogue therapy.

Background
Pituitary apoplexy (PA) is a potentially life-threatening rare clinical syndrome. The objective of this study was to analyze the clinical presentation, treatment approaches, and outcomes of PA in patients younger than 65 years compared to those aged 65 years and older at PA diagnosis.
Methods
Retrospective, multicenter study including 301 patients diagnosed with PA from 2010 to 2023 across 18 medical centers in Spain. Patients were categorized into two groups based on age ($<$65 years and $\geq$65 years). Baseline characteristics, clinical presentation, treatment approaches (surgical vs. conservative), and outcomes were analyzed.
Results
Out of the 301 patients, 185 (61.5%) were younger than 65 years and 116 (38.5%), were 65 years or older. Older patients had a higher prevalence of comorbidities, such as diabetes (11.4 vs. 34.5%; $P < 0.01$), hypertension (29.7 vs. 79.3%; $P < 0.01$), dyslipemia (32.4 vs. 62.9%; $P < 0.01$) and cardiovascular disease (4.3 vs. 27.6%; $P < 0.01$). No significant differences were observed in clinical presentation, including Pituitary Apoplexy Score and radiological findings except for higher frequency of cranial nerve palsy (46.2 vs. 64.9%; $P = 0.02$) and decreased consciousness (12.0 vs. 20.7%; $P = 0.04$), that was higher in older patients. Regarding treatment approach, surgery was underwent in 209 and conservative approach in 92 patients without differences between age groups (29.9 vs. 32.8%; $P = 0.52$). In the histological study, necrosis was more frequent in older patients (66.7 vs. 80.6%; $P = 0.04$). Regardless of the treatment approach there were no statistically significant differences in outcomes. However, in patients managed conservatively, the percentage of spontaneous tumor shrinkage, was more pronounced in older patients (39.1 ± 38.7 vs. 58.7 ± 28.1%; $P = 0.03$).
Conclusions
While older patients with PA had higher rates of comorbidities and specific neurological symptoms, the clinical presentation and treatment approaches were largely similar across age groups. Older patients showed greater spontaneous tumor shrinkage with conservative management. These findings suggest that advanced age alone should not guide PA management, as outcomes appear comparable regardless of treatment approach across age groups. Given the higher frequency of necrosis observed in older patients, computed tomography imaging could underestimate the presence of apoplexy in this group, thus, the magnetic resonance imaging should be prioritized during the diagnostic workup for pituitary apoplexy in elderly individuals.

[1]Hospital Universitario Ramón y Cajal, Endocrinology & Nutrition, Madrid, Spain; [2]Hospital Universitario de Santiago de Compostela, Endocrinology & Nutrition, Santiago de Compostela, Spain; [3]Hospital de Cruces, Endocrinology & Nutrition, Bilbao, Spain; [4]Hospital Universitario Ramón y Cajal, Biochemistry, Madrid, Spain; [5]Hospital Royo Villanova, Endocrinology & Nutrition, Zaragoza, Spain; [6]Hospital Universitario de Bellvitge (L'Hospitalet de Llobregat), Endocrinology & Nutrition, Barcelona, Spain; [7]Hospital Universitario de Basurto, University of the Basque Country UPV/EHU, Endocrinology & Nutrition, Bilbao, Spain; [8]Hospital Universitario de A Coruña, Endocrinology & Nutrition, A Coruña, Spain; [9]Hospital Universitario Gregorio Marañón, Endocrinology & Nutrition, Madrid, Spain; [10]Hospital Universitario Puerta de Hierro Majadahonda, Endocrinology & Nutrition, Madrid, Spain; [11]Hospital Universitario Central de Asturias/Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Endocrinology & Nutrition, Oviedo, Spain

Introduction
The most recent consensus on acromegaly, established by Giustina A *et al*., 2024, recommends adjusting nadir GH thresholds in the oral glucose tolerance test (OGTT) according to body mass index (BMI). This is because BMI influences GH suppression, with nadir levels being lower in obese than in lean individuals. Therefore, it is suggested to use BMI-specific thresholds to optimize the diagnosis and treatment of the disease.

Objective
To investigate differences in basal GH levels and in the GH response to the OGTT among acromegalic patients with obesity, overweight, and normal weight.
Methods
A retrospective study of 184 patients with acromegaly treated in 10 tertiary hospitals in Spain was carried out. BMI was calculated and baseline GH levels as well as GH response to OGTT were analyzed.
Results
A total of 184 patients with acromegaly were included (mean age 49 $\pm$ 14 years, 59% (n = 108) women). At baseline, 66 patients (36%) had obesity (median BMI: 33.3 kg/m^2 [32.0–37.4]), 82 (45%) were overweight (27.4 kg/m^2 [26.4–28.7]), and 35 (19%) had normal weight (23.6 kg/m^2 [22.3–24.6]). At diagnosis, ULN IGF-1 levels in patients with obesity, overweight and normal weight were 2.2 (1.7 – 3.1), 2.7 (1.9 – 3.7) and 2.0 (1.5 – 2.6), respectively (P = 0.011). Basal GH levels (ng/mL) at diagnosis in these three groups were 4.5 (1.9 – 7.2), 7.6 (3.1 – 11.7) and 12.1 (3.4 – 23.6), respectively (P = 0.002). In the OGTT, the reduction in GH levels from basal to nadir (ng/mL) in patients with obesity, overweight, and normal weight was 0.9 (0.4–1.7), 1.7 (0.3–3.3), and 3.5 (0.5–8.3) respectively (P = 0.016); Tukey P-values: normal weight vs overweight = 0.013, normal weight vs obesity = 0.052, overweight vs obesity = 0.868). BMI was not linearly associated with the absolute decrease from basal GH to nadir (P = 0.209), percentage decrease (P = 0.718) or nadir GH levels (P = 0.261). No significant differences in GH reduction during OGTT were observed between patients with and without type 2 diabetes (P = 0.721) and between patients with micro- and macroadenomas (P = 0.174).
Conclusion
In our cohort of patients with acromegaly, basal GH levels and GH response to the OGTT were similar across obese, overweight and normal-weight groups, regardless of whether they had type 2 diabetes or pituitary tumor size Therefore, BMI-based GH nadir cutoffs in the OGTT may not be necessary for acromegaly diagnosis.

Sleep quality, depression and anxiety in patients with hypopituitarism – an international survey study

Andi Nikaj[1], Cihan Atila[1], Svenja Leibnitz[1], Ellen Edwards[2] & Mirjam Christ-Crain[1]
[1]University Hospital Basel, Department of Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University Hospital Basel, Department of Internal Medicine, Basel, Switzerland

Background
Pituitary dysfunction can significantly impact sleep quality, mental health, and fatigue, leading to a reduced quality of life. Despite these well-recognized issues, systematic assessments across different subtypes of pituitary dysfunction remain limited. Therefore, this survey was developed to address this gap by evaluating these symptoms in a large, diverse cohort of patients with pituitary conditions.
Methods
This cross-sectional, web-based, anonymous survey study was designed to capture patient-reported outcomes on sleep quality, mental health, and fatigue. Participants included adults with isolated anterior pituitary dysfunction (APD), isolated posterior pituitary dysfunction (arginine vasopressin deficiency, AVP-D), combined anterior and posterior pituitary dysfunction (PanHypo), and those with pituitary conditions but no hormone deficiency or excess (e.g., non-functioning pituitary adenomas) as clinical controls. Sleep quality was assessed using the Pittsburgh Sleep Quality Index (PSQI), mental health using the Patient Health Questionnaire-9 (PHQ-9) and the State-Trait Anxiety Inventory (STAI-T), fatigue levels using the Fatigue Severity Scale (FSS), insomnia levels using the Insomnia Severity Index (ISI), and daytime sleepiness using the Epworth Sleepiness Scale (ESS). Higher scores on the PSQI, FSS, ISI, ESS, PHQ-9 and STAI-T indicated worse outcomes. Total scores were compared across groups and adjusted for sex, age, and the Charlson Comorbidity Index.
Findings
Between September 2024 and November 2024, 451 patients participated in the survey. The median age was 52 years [42–60], with 80% female participants and a median duration of pituitary dysfunction of 7 years. Participants were classified as APD (42.6 %), AVP-D (19.3 %), PanHypo (26.6 %), and clinical controls (11.5 %). The most common etiologies for a pituitary dysfunction were pituitary tumors or cysts (61.6 %) and idiopathic (18.4 %). Patients across all groups showed impaired sleep quality, clinical levels of anxiety, and sub-clinical levels of depression. Fatigue and insomnia levels were uniformly high, with significant variability in insomnia levels across subgroups.
Conclusion
This large, systematic survey demonstrates that sleep disturbances, anxiety, and fatigue are prevalent across all subtypes of pituitary dysfunction. The findings highlight the need for targeted diagnostics and interventions to address these symptoms, which significantly affect the quality of life in patients with pituitary conditions.

Evaluation of internalizing symptoms in mothers of girls diagnosed with central precocious puberty: a pre- and post-treatment analysis

Dilek Bingöl Aydın[1], Şeyma Taş[2], Zehra Koyuncu[3], Burak Doğangün[3] & Oya Ercan[4]
[1]Tatvan State Hospital, Pediatric Endocrinology, Bitlis, Türkiye; [2]Istanbul University-Cerrahpaşa, Department of Pediatrics, Istanbul, Türkiye; [3]Istanbul University-Cerrahpaşa, Child and Adolescent Pschitry, Istanbul, Türkiye; [4]Private Memorial Şişli Hospital, Pediatric Endocrinology, Istanbul, Türkiye

Objective
Precocious puberty can be a significant source of stress not only for affected children but also for their families, particularly their mothers. This study aims to assess the presence of internalizing symptoms—stress, anxiety, and depression—in mothers of girls diagnosed with central precocious puberty (CPP) and to evaluate how these symptoms change following treatment.
Methods
This prospective study included mothers of girls diagnosed with CPP who presented to our pediatric endocrinology clinic. The Depression, Anxiety, and Stress Scale-21 (DASS-21) was administered before and after treatment. Mothers with a history of psychiatric illness, those using psychotropic medications, or those whose children were not diagnosed with CPP were excluded. Data from 38 participants were analyzed using the Jamovi 2.2.5 statistical software.
Results
The mean age of the girls at diagnosis was 7.01 $\pm$ 0.96 years. The mean age of the mothers was 40.1 $\pm$ 5.95 years, while the fathers' mean age was 43 $\pm$ 6.18 years. The median time from initial presentation to diagnosis was 2.5 months (IQR: 1), and the mean duration from treatment initiation to reassessment was 12 $\pm$ 8.05 months. At baseline, the median maternal stress score was 4 (IQR: 5), anxiety score was 4 (IQR: 3.75), depression score was 3 (IQR: 4), and total DASS score was 11 (IQR: 10.3). Clinically significant stress, anxiety, and depression were observed in 21.1%, 52.6%, and 31.6% of mothers, respectively. Following an average of 12 months of treatment, the median stress score decreased to 2 (IQR: 5), anxiety score to 1.5 (IQR: 4), depression score to 0 (IQR: 2.75), and total DASS score to 4 (IQR: 10.5). The prevalence of clinically significant stress, anxiety, and depression dropped to 2.6%, 28.9%, and 15.8%, respectively. Statistical analysis confirmed a significant reduction in all internalizing symptoms post-treatment ($P < 0.01$). No significant correlations were found between DASS scores and child's age, time to diagnosis, maternal age, or paternal age.
Conclusion
These findings suggest that mothers of children with CPP experience significant psychological distress at the time of diagnosis, which improves following treatment. Given the emotional burden associated with early puberty, incorporating psychosocial support into the management of CPP could be beneficial for both patients and their families.

Keywords
anxiety, depression, puberty precocious, psychiatry, stress.

A case of aggressive AIP-mutated pituitary acrogigantism treated with pasireotide

Mariana Solovey[1], Olena Danevych[1], Adrian Daly[2], Mykola Guk[1], Arthur Mumlev[1], Oleksii Ukrainets[1], Andrii Chukov[1] & Valeria Musulevska[1]
[1]Romodanov Neurosurgery Institute, Komisarenko Endocrinology and Metabolism Institute, Kyiv, Ukraine; [2]CHU de Liege, Department of Endocrinology, Liege, Belgium

Introduction
Pituitary acrogigantism is a rare disease caused by chronic growth hormone (GH) hypersecretion usually from a pituitary adenoma that occurs during childhood/adolescence and nearly half of cases have a genetic cause. Pathogenic

variants in the *AIP* gene are responsible for about 30% of cases, are associated with aggressive pituitary tumours that can be challenging to treat medically with first-generation somatostatin analogs. There are several reports that treatment with pasireotide long-acting release (PAS-LAR) can lead to tumour regression in *AIP*-related acromegaly.
Objective
To report a new case of aggressive *AIP*-mutated pituitary acrogigantism successfully treated with Pasireotide LAR.
Methods
Clinical presentation, imaging, laboratory data and immunohistochemical staining features were analyzed. Evaluation for the presence of any pathogenic/likely pathogenic variations in pituitary and neuroendocrine tumor related genes were assessed by whole exome sequencing.
Results
A 15-year-old male presented with headache, visual acuity loss, back pain, weakness, loss of appetite, and rapid growth for the last 3 years. His height was 183.5 cm and he weighed 52 kg. ECG: sinus bradycardia. Ophthalmological review revealed optic nerves atrophy. An MRI showed an invasive supra-para-retrosellar macroadenoma (3,8x3,6x3,8 cm) with extension towards the posterior cranial fossa, third ventricle compression and basilar artery involvement. His plasma hormone concentrations were: prolactin 1116.5 ng/ml, GH 690 ng/ml, IGF-1 537 ng/ml, TSH 4.59 mU/l, fT4 1.16 ng/dl, fT3 2.99 pg/ml, DHEA-S 625 mg/ml, cortisol 9.81 mg/dl. Due to his hyperprolactinemia, cabergoline was started and rose to a dose of 0.5-1.0 mg/day. Hormone levels after three weeks were as follows: prolactin 232 ng/ml, GH 1023 ng/ml, IGF-1 501 ng/ml. He therefore underwent a partial endoscopic transnasal tumour resection that resulted in a decrease of GH and prolactin levels (prolactin 9.54 ng/ml, GH 70.0 ng/ml) but IGF-1 was elevated (567,2 ng/ml) and he had permanent hypopituitarism in other axes. Immunohistochemistry showed GH (90%) and prolactin (10%) positive cells in the pituitary adenoma with weak staining (+) for SSTR2 and moderate (++) staining for SSTR5, with a Ki-67 of 5%. A pathogenic heterozygous missense variant in exon 6 of the AIP gene (c.811 C>T; p.Arg271Trp) was detected. Treatment with Signifor LAR 40 mg/28 days and cabergoline 0.25 mg/day were started. A significant decrease in tumour volume, improvement in visual fields and IGF-1 normalization were achieved during 36 weeks of treatment.
Conclusion
Pasireotide long-acting release treatment may be beneficial in *AIP* mutated patients with acrogigantism and positive immunohistochemical staining of tumour cells for SSTR5.

Cytokines and chemokines modulate the growth of pituitary adenoma/neuroendocrine tumors: preliminary results of a monocenter prospective pilot study

Sabrina Chiloiro[1], Pier Paolo Mattogno[1], Flavia Angelini[1], Antonella Giampietro[1], Alessandra Vicari[1], Greis Konini[1], Federico Valeri[1], Amato Infante[1], Natalia Cappoli[1], Rosalinda Calandrelli[1], Liverana Lauretti[1], Simona Gaudino[1], Marco Gessi[1], Guido Rindi[1], Alessandro Olivi[1], Laura De Marinis[1], Antonio Bianchi[1], Francesco Doglietto[1] & Alfredo Pontecorvi[1]
[1]Fondazione Policlinico Universitario A. Gemelli, IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy

Introduction
Cytokine and chemokines have been recognized to be involved in the progression and prognosis of pituitary adenoma/neuroendocrine tumors (PAs/PitNETs), also known as pituitary adenomas. We aim to investigate the expression of cytokine and chemokine in PAs/PitNETs, and their association with PAs/PitNETs clinical and biological behavior.
Patients and methods
A prospective and monocenter study was performed on 16 patients diagnosed for PAs/PitNETs. Cytokine and chemokine were detected on freshly collected PAs/PitNETs samples. Tumor infiltering immune cells were investigated on formally fixed and paraffin-embedded PAs/PitNETs samples. Clinical, biochemical, molecular and morphological data were collected from patients' medical records.
Result
Out of 72 patients with PAs/PitNETs that underwent surgical removal at the Neurosurgery Division of our Institution between January and June 2023, sixteen patients were enrolled in the study. Out of 42 cytokines and chemokines that we investigated, we found that all tumors expressed IL-1b, IL-2, IL-3, IL-8, CCL2, EGF, CXCL1, CXCL1 -a, CCL5, SDF1, CCL17, MDC, VEGF, PDGF88 and the leptin. A positive correlation was detected between the intensity score of EGF and CXCL1 ($P = 0.003$, r:0.7), of EGF and CXCL1-a ($P = 0.01$, r:0.61); of EGF and CCL5 ($P = 0.004$, r:0.68); and of CXCL1 and CCL5 ($P = 0.003$, $r = 0.684$). An inverse correlation was identified between intensity score of CXCL1 and IL-2 ($P = 0.002$, r:-0.7). A positive correlation was detected between the number of tumor-infiltering CD68+ macrophages and the CCL2 intensity score ($P = 0.008$, $r = 0.695$). No correlation was identified between the presence of circulating anti-pituitary antibodies and presence of tumor cytokines and chemokines. EGF was significantly more expressed in tumors with MIB1>3% (IS:1515 IQR:1642), than in tumor with MIB1<3% (IS: 81 SD: 292, $P = 0.014$); the IS of the other cytokines/chemokines did not differ in tumor with MIB1<3% and in those with MIB1>3%. Invasive PAs/PitNETs had a higher expression of EGF (IS:465 IQR:1232, $P = 0.002$), of CXCL1 (IS:1756 IQR:2055, $P = 0.01$), of CCL17 (IS:351 IQR:609, $P = 0.002$) then not invasive PAs/PitNETs (EGF IS:260, IQR:520; GRO:718 IQR:890; CCL17:147, IQR:443). PAs/PitNETs with invasion of the cavernous sinus expressed higher levels of EGF (IS:652 IQR:1457, $P = 0.004$), of CXCL1 (IS:2170 IQR:2308, $P = 0.02$) and lower IL-2 levels (IS:326 IQR:729, $P = 0.02$), then not invasive cavernous sinus PAs/PitNETs (EGF IS:212 IQR:476; CXCL1 IS: 719 IQR:859, IL-2 IS:326 IQR:729).
Conclusion
Our preliminary results support that in PAs/PitNETs, the cytokines and chemokines generate an immune network, that may contribute to regulating the cell proliferation and pattern of growth.

[1]Unidad de Investigación Médica en Enfermedades Endocrinas, Hospital de Especialidades, Centro Médico Nacional Siglo XXI, Instituto Mexicano del Seguro Social, Mexico City, Mexico; [2]Sección de Estudios de Posgrado e investigación, Escuela Superior de Medicina, Instituto Politécnico Nacional, Mexico city, Mexico; [3]Servicio de endocrinología, Hospital de Especialidades, Centro Médico Nacional Siglo XXI, Instituto Mexicano del Seguro Social, Ciudad de México, México., Mexico City, Mexico; [4]Tecnológico de Monterrey, Monterrey, México., Escuela de ingeniería y ciencias, Monterrey N.L, Mexico; [5]SEPI–ESM, Instituto Politécnico Nacional, Mexico City, Mexico; [6]Departamento de patología, Hospital de Especialidades, Centro Medico Nacional Siglo XXI, Instituto Mexicano del Seguro Social, Mexico City, Mexico; [7]Servicio de neurocirugía, Hospital de Especialidades, Centro Medico Nacional Siglo XXI, Instituto Mexicano del Seguro Social, Mexico City, Mexico

Background/Aims
Pituitary tumors are the second most common intracranial neoplasm, of these, prolactinomas are the most frequent functioning subtype. For this type of tumor, dopamine agonists (DA) constitute the treatment of choice. However, a subset of patients (30-50%) exhibits resistance to DA treatment. This resistance may involve different molecular mechanisms, which remain largely unclear and not fully understood. The aim of this project is to characterize the allelic variants and transcriptomic profile of aggressive, treatment-resistant prolactinomas through whole-exome and whole transcriptome analysis.
Methods
We evaluated 12 patients with DA-resistant lactotroph tumors and 6 non-tumoral pituitaries by whole exome sequencing (WES) and whole transcriptomic sequencing (WTS). Nine of the 12 tumors were categorized as totally unresponsive whereas three were considered partially resistant.
Results
WES identified approximately 18,000 variants, of which only two (*TP53* c.C817T p. R273C and one in *SF3B1* c.C1873T p. R625C) were considered pathogenic. These variants are known to play a pathogenic role in other tumors and are associated with tumorigenesis. The most frequent mutational signature was *SBS5* which is associated with normal cellular damage of DNA processes. The tumor mutational burden (TMB) was similar in both the partially and the totally resistant tumors. In the WTS analysis, prolactinomas showed different degrees of transcriptomic heterogeneity between partial and null responses. Interestingly, the null response group exhibited molecular events related to metabolism, which were linked to antifolate resistance, fatty acid degradation, and sphingolipid

metabolism. Furthermore, metabolic characterization revealed high heterogeneity, mainly in pathways associated with lipid metabolism.
Conclusions
We conclude that prolactinomas are genomically stable, which could indicate that mechanisms other than somatic mutations are involved in lactotrophic tumorigenesis and that differences in response to DA treatment may result from transcriptomically heterogeneous clones.

"Cortisone-loop" an educational tool that ensures the quality of care for children with adrenal insufficiency in sweden, how does it work in practice? evaluation in nirthern sweden

Camilla Ernstsson[1], Carina Larsson[2], Helena Gärskog[1] & Elena Lundberg[1]
[1]Institution of clinical science, pediatrics, Umeå University, Umeå, Sweden; [2]Institution of clinical science, pediatrics, Umeå, Sweden

Background
Adrenal insufficiency (AI) is a severe condition that requires lifelong substitution with cortisone and/or mineralocorticoid. A good initial education to AI patients/families is the key to understand the severity of disease, for better compliance and management of critical situations throughout life. Pediatric care in Northern Sweden is offered at five county level hospitals and at university hospital level therefore AI care and education may vary due to experiences of the staff and number of patients. In 2019 the worksheet was implemented to ensure high-quality care and information regardless of the clinićs experience or geographic location.
Aim
To evaluate use of the worksheet in pediatric clinics in Northern Sweden regarding the management of patients suffering from AI. To study the patient's and their famiĺys understanding of the disease and management of cortisone substitution under different conditions.
Result
In 2019 the Swedish endocrine nurse group presented a worksheet for patient education in pediatric clinics throughout the country. This contains questions with evidence-based knowledge, and from real-life situations/activities discussed with patients/family during follow-up at pediatrics care. For evaluation, we sent a questionary to six pediatric clinics and to forty patients with AI in Northern Sweden. Questionnaire for medical staff included questions about knowledge of worksheet, use in clinical practice and how to develop this educational material to be used more. Answers from clinicians showed: 100% found educational material useful and were satisfied with the content, but only 85% used it in daily practice. Two clinics (15%,) dońtt use the material due to low amounts of AI patients and medical resources. All clinicians suggested continuous training in the use of the worksheet. Questionary to the patients/families included questions like knowledge about your disease, managing of critical situations and suggestion for improvement of education. Answers from thirty-seven patients showed great satisfaction with education and wishes to continue as we do now. Patients from clinics that didǹt use the worksheet were educated from the university hospital.
Conclusion
Standardization of education by using the worksheet in all children's clinic in Northen Sweden increase the quality of patients' education. Patients receive equal education regardless of the clinic's experience or geographical location. The evaluation in Northern Sweden showed needs for caregivers continuous training in the use of the worksheet.

Biological maturity and body composition changes during pubertal growth: a longitudinal study of korean adolescents

Eungu Kang[1], Dohyun Chun[2], Jongho Kang[3], Jihun Kim[3] & Young-Jun Rhie[1]
[1]Korea University College of Medicine, Pediatrics, Seoul, South Korea; [2]College of Business Administration, Kangwon National University, Chuncheon, South Korea; [3]College of Humanities & Social Sciences Convergence, Yonsei University, Wonju, South Korea

Objective
To conduct a systematic and comprehensive analysis of body composition changes across pubertal growth stages in Korean adolescents, focusing on the age at onset of growth spurt (AOGS) and age at peak height velocity (APHV).
Materials and Methods
This study utilized longitudinal data from 77 boys and 122 girls aged 7-16 years. The Superimposition by Translation and Rotation (SITAR) model was applied to estimate individual growth curves and identify the timing of pubertal growth. Fourteen anthropometric and body composition variables were examined, including height, weight, lean mass, fat mass, and various derived measures. Body composition and its changes were systematically analyzed in alignment with pubertal growth stage.
Results
For girls, the mean AOGS was observed at 8.75 years, with APHV occurring at 10.92 years. For boys, AOGS occurred at 9.68 years and APHV at 11.91 years. Significant increases in height, weight, and lean mass components were observed around both AOGS and APHV for both sexes, with changes more pronounced around APHV, particularly for boys. Height velocity at AOGS was 6.02 cm/year for boys and 5.97 cm/year for girls, increasing to 10.41 cm/year and 8.30 cm/year respectively at APHV. Body fat percentage increased significantly around AOGS in both sexes (boys: +2.16 percentage points, girls: +1.94 percentage points) but showed different patterns around APHV, with girls maintaining relatively stable ratios (-0.24 percentage points) and boys experiencing a significant shift towards decreased adiposity (-3.92 percentage points).
Conclusion
This study provides detailed insights into pubertal growth patterns and body composition changes in Korean adolescents around AOGS and APHV. The SITAR method applied to longitudinal data enabled the examination of individual growth trajectories and within-person changes throughout pubertal development. This comprehensive analysis of body composition parameters enhances our understanding of developmental patterns and sexual dimorphism in pubertal growth processes, contributing to a broader perspective on adolescent development.

Differentiating AVP deficiency and primary polydipsia: a clinical and biochemical perspective

Beril Turan Erdogan[1], Muzaffer Deniz[1], belma tural balsak[1], Caglar Keskin[1], Şefika Burçak Polat[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara Bilkent City Hospital, Department of Endocrinology and Metabolism, Ankara, Türkiye; [2]Ankara Yildirim Beyazit University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Türkiye

Background
Polyuria and polydipsia require differentiation between arginine vasopressin (AVP) deficiency and primary polydipsia (PP), as both involve excessive water intake and urine output but have distinct pathophysiology. This study aimed to compare biochemical, clinical, and hormonal differences between AVP deficiency and PP to identify distinguishing diagnostic markers.
Methods
A retrospective observational study was conducted on 36 patients who underwent a water deprivation test at Ankara Bilkent City Hospital between February 2019 and December 2024. Patients were categorized as AVP deficiency (complete or partial) and PP based on clinical and biochemical findings. Plasma and urine osmolarity, sodium, chloride, magnesium, and anterior pituitary hormones (LH, GH, ACTH..) were analyzed.
Results
Among 36 patients, 55.6% had AVP deficiency, while 22.2% were diagnosed with PP. Nocturia was significantly more prevalent in AVP deficiency (96.2%) than PP (12.5%, $P < 0.001$). Fluid intake exceeded 10 liters/day in 62.5% of PP patients, whereas AVP deficiency patients typically consumed 5–10 liters/day. Plasma osmolarity was lower in PP, and urine osmolarity was significantly lower in PP than AVP deficiency ($P = 0.011$). Sodium ($P = 0.030$), chloride ($P = 0.040$), and magnesium ($P = 0.010$) were significantly reduced in PP. Hormonal analysis showed elevated LH ($P = 0.011$) and GH ($P = 0.028$) in PP compared to AVP deficiency.
Discussion
Findings suggest that nocturia frequency, fluid intake patterns, and specific biochemical markers (sodium, chloride, magnesium) may assist in differentiating PP from AVP deficiency. The lower urine osmolarity in PP highlights impaired urine concentration despite intact AVP function, while electrolyte disturbances suggest altered water balance regulation. Additionally, although LH and GH levels were statistically higher in PP, this does not necessarily imply clinical significance. These distinctions reinforce the importance of integrating biochemical, clinical, and hormonal assessments for accurate diagnosis.

Table: Key Biochemical and Hormonal Differences Between AVP Deficiency and PP.

Parameter	AVP Deficiency ($n = 26$)	PP ($n = 8$)	*P*-value
Nocturia (%)	96.2	12.5	<0.001
Urine Osmolarity (mOsm/l)	101±48	129±41	0.011
Sodium (mEq/l)	142±3	138±4	0.030
Chloride (mEq/l)	108±3	105±4	0.040
Magnesium (mg/dl)	2.0±0.2	1.8±0.1	0.010
LH (U/l)	5.65±7.77	11.78±11.99	0.011
GH (ng/mL)	0.27±0.54	0.43±0.39	0.028

Conclusion

This study underscores the diagnostic value of urine osmolarity, plasma sodium, chloride, magnesium, and anterior pituitary hormones in differentiating AVP deficiency from PP. Incorporating these markers into routine evaluation may improve diagnostic precision and guide targeted management strategies. Further large-scale studies are recommended to validate these findings and optimize diagnostic criteria.

Update on the use of robotic surgery and artificial intelligence for pituitary tumors

Nadia Zameni[1] & Hassan Heshmati[2]
[1]School of Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Endocrinology Metabolism Consulting, LLC, Hassan Heshmati and Valerie Shaw Endocrine Research, Anthem, United States

Introduction

The use of robots in medical procedures is quickly replacing interventions performed by humans. Robotic surgery has significantly advanced the field of endocrine surgery, offering a range of benefits over traditional techniques. This review presents an update on the use of robotic surgery and artificial intelligence for pituitary tumors.

Methods

A systematic search of literature was conducted using the search terms robotic surgery, artificial intelligence, pituitary tumors, safety, outcome, and cost.

Results

Pituitary tumors are common neoplasms. They represent approximately 15-20% of all intracranial tumors and are benign in the majority of cases (e.g., pituitary adenomas). Pituitary carcinomas are rare neoplasms representing 0.1-0.2% of all pituitary tumors. Most pituitary adenomas are functioning tumors, mainly producing prolactin and/or growth hormone. Pituitary microadenomas (size up to 1 cm), especially prolactinomas, can benefit from pharmaceutical treatment. Transsphenoidal surgery plays an important role in the management of pituitary tumors, especially for the treatment of pituitary macroadenomas. In the context of pituitary gland operations, robotic assistance is particularly beneficial for transsphenoidal procedures where access through tight spaces with delicate surrounding tissues is required. Autonomous surgical robots can be categorized into various levels of autonomy, including partially autonomous systems performing specific tasks under human supervision, collaborative autonomy where robots work alongside human surgeons, and fully autonomous systems capable of completing entire procedures independently. The robotic system's fine motor control and enhanced visualization increase dexterity and facilitate precise tumor removal, crucial for avoiding damage to nearby neurovascular structures. However, significant limitations restrict the applicability of robotic neurosurgery. The next generation of robotic assistance should prioritize size decrease, operating angles flexibility, and drilling with bony removal ability. While fully autonomous robotic surgery remains a long-term goal, the ongoing integration of artificial intelligence (AI) and robotics is rapidly advancing. This integration is set to revolutionize the future of robotic surgery and promise to further enhance the precision, safety, and effectiveness of surgery involving the pituitary gland. However, the current high cost of these new procedures remains a potential limitation.

Conclusion

Robotic surgery has been growing in popularity and feasibility. It offers improved dexterity and precision for the removal of pituitary tumors compared to traditional transsphenoidal surgery. Future collaboration between human surgeons and advanced robotic systems holds significant potential for improving patient care and surgical outcomes. The ongoing integration of AI and robotics can further enhance the precision, safety, and effectiveness of the surgery of pituitary tumors.

Defective Nitric oxide pathway signalling - a link between premature birth and altered mini-puberty?

Jordan Read[1], Virginia Delli[2], Leo Dunkel[1], Federico Santoni[3], Vincent Prevot[2], Leonardo Guasti[1], Konstantina Chachlaki[2] & Sasha Howard[1,4]
[1]Queen Mary University of London, Centre for Endocrinology, William Harvey Research Institute, London, United Kingdom; [2]INSERM, University of Lille, Lille Neuroendocrinology, Lille, France; [3]University Hospital Lausanne, Lausanne, Switzerland; [4]Department of Paediatric Endocrinology, Barts Health NHS Trust, London, United Kingdom

Mini-puberty is the period of transient hypothalamic-pituitary-gonadal (HPG) axis activity shortly after birth, before the axis is 'switched-off' until puberty. The amplitude of mini-puberty has been shown to be exaggerated in babies born preterm, with potential consequences later in life for neuronal maturation, pubertal disorders, behavioural and metabolic conditions. Nitric oxide (NO) is a key player in regulation of mini-puberty and reproductive development, with Nitric oxide synthase 1 (NOS1) deficiency leading to abnormal mini-puberty in mice and congenital hypogonadotropic hypogonadism in humans. We interrogated 63 patient samples from the Finnish mini-puberty cohort (75% born $<$ 37/40 gestation) part of the 'miniNO' project (grant 847941), for variants in genes associated with NO signalling pathways. Whole genome sequencing was filtered for rare and predicted in-silico to be pathogenic to protein function. We identified two preterm infants with variants of interest. One female patient, born at 24.7 weeks, carried a missense heterozygous variant (c.1855A$>$T, p.M619L) in *NOS1*. The variant is rare in the healthy population (gnomAD European frequency of 0.39%). She displayed a very exaggerated mini-puberty with peak urinary luteinising hormone (LH) of 208 IU/l, with corresponding oestradiol of 16662 pmol/l. At follow-up aged 14.8 years the patient is pre-menarche, suggesting pubertal delay. The affected residue is located in the highly conserved oxygenase domain of NOS1. *in vitro*, the maximal NO output from cells transiently expressing the p.M619L mutant was significantly attenuated compared to wild-type NOS1, suggesting decreased NOS1 activity. In addition, the p.M619L variant was able to dimerise with wildtype NOS1 in co-immunoprecipitation experiments, suggesting an impairment of functional homodimer formation, which may underly pathogenicity of the heterozygous variant. A second female patient, born at 32.1 weeks had a missense heterozygous variant (c.296G$>$A, p.S99N) in the NOS1 associated protein 1 gene (*NOS1AP*). The variant has gnomAD European frequency of 0.57%. The patient demonstrated a flat mini-puberty profile with peak LH of 0.97 IU/l and at the current age of 12.5 years has mild puberty delay (Tanner stage B2). NOS1AP is expressed in GnRH neurons and co-expressed with NOS1. The S99N variant is located within the phosphotyrosine-binding domain of NOS1AP, with a role in neuronal dendritic development and cell proliferation and migration. Functional characterisation is in progress. Here we identify rare exonic variants in genes within the NO synthesis pathway in patients with preterm birth and abnormal mini-puberty, providing potential human evidence for the role of NO signalling in prematurity and HPG axis regulation.

A phase 2, open-label, multiple-ascending-dose trial evaluating anti-ACTH antibody lu AG13909 in adults with cushing's disease: balanced trial design

Frederic Castinetti[1], Stine Larsen[2], Heike Benecke[2], Mimi Folden Flensburg[2], Johan Luthman[2] & Antoine Tabarin[3]
[1]1Aix Marseille University, Marseille Medical Genetics (MMG) Center U1251 Institut National de la Santé et de la Recherche Médicale (INSERM), and Department of Endocrinology, La Conception Hospital, Marseille, France; [2]H. Lundbeck A/S, Copenhagen, Denmark; [3]Department of Endocrinology, Diabetes and Nutrition, National Expert Center for Rare Diseases of the Adrenal Gland, University Hospital of Bordeaux, Bordeaux, France

Introduction

Cushing's disease (CD) is a rare disorder caused by an adrenocorticotropic hormone (ACTH)-secreting pituitary adenoma. Autonomous ACTH production induces hypercortisolemia, which is associated with increased morbidity and mortality. There is an unmet need for well-tolerated and effective treatments to treat hypercortisolemia. Lu AG13909 is a novel, high-affinity, anti-ACTH monoclonal antibody that inhibits ACTH-induced signaling. Here, we describe

the BalanCeD trial design (NCT06471829), evaluating the efficacy, safety, tolerability, and pharmacokinetic/pharmacodynamic profile of Lu AG13909 in adults with CD.
Methods
BalanCeD is a phase 2, interventional, multi-site, open-label, multiple-ascending-dose trial with dose titration, which is being conducted in specialist sites across Europe, including Georgia. Eligible participants have ACTH-driven CD (defined by current Pituitary Society consensus guidelines) and 24-hour urinary free cortisol (UFC) >1.5 times the upper limit of normal. Participants may have had pituitary surgery >3 months prior to screening. Participants who had previously received cortisol-lowering medication must have completed a predefined washout period prior to dosing. The trial consists of 3 parts: Part A (22–30 weeks), Part B (32–52 weeks), and an Extension Period (52 weeks, with an additional 16-week Safety Follow-up Period). Part A includes an intravenous titration period to identify the dose that provides the optimal clinical response based on tolerability and pharmacodynamic assessments, a subcutaneous period, and a Safety Follow-up Period. Part B includes a subcutaneous titration period to identify the optimal dose for normalization of mean UFC, a maintenance period, and a Safety Follow-up Period. Part B will be initiated based on a Dosing Conference, evaluating the cumulative safety, tolerability, pharmacokinetics, and efficacy data from ≥ 3 participants in Part A; Part B may be initiated before the finalization of Part A. Only participants enrolled in Part B can opt into the Extension Period, which will evaluate long-term efficacy and safety. The primary efficacy endpoint is the response rate of UFC normalization at the end of the titration periods of Part A and Part B. Secondary endpoints include treatment-emergent adverse events and multiple pharmacokinetic endpoints.
Conclusions
The BalanCeD trial aims to evaluate the efficacy, safety, tolerability, and pharmacokinetics/ pharmacodynamics of Lu AG13909 in adults with CD. Findings from this trial will reinforce the development of Lu AG13909 as a novel anti-ACTH treatment strategy for patients with CD.

Introduction
The diagnostic gold standard for central precocious puberty (CPP) is the gonadotropin-releasing hormone (GnRH) stimulation test. Additionally, magnetic resonance imaging (MRI) of the brain and of the hypothalamus-pituitary region is required to exclude central organic causes. Recent technological advancements have contributed to the development of a new approach in medical imaging called radiomics. Our recent study has shown that radiomics of the pituitary gland is a promising tool for diagnosing CPP. The role of the pineal gland in the onset of puberty is long debated with conflicting Results.
Aim
Herewith, we investigated the features of the pineal gland in relationship with the onset of puberty, using radiomics, with the aim to assess whether there are any specific changes that could assist physicians in the diagnostic workup of CPP.
Methods
Forty-five girls with a confirmed diagnosis of CPP and 47 pre-pubertal, age- and sex-matched subjects (control group) were retrospectively enrolled. Two readers (R1, R2) with different levels of expertise in pediatric neuroradiology blindly segmented the pineal gland on MRI studies for radiomic features (RFs) calculation and performed a manual evaluation of the number and the diameter of pineal cysts. Cross-validated linear discriminant analysis was used to develop both a radiomic model and a reference model for each reader based on the pineal cysts features. Radiomics was evaluated in terms of 1) predictive performances (metrics: ROC-AUC, accuracy, sensitivity, and specificity); and 2) reliability of predictors between readers (metric: intraclass correlation coefficient, ICC). Finally, the correlation between cysts features and basal/peak gonadotropin levels was also investigated.
Results
Two radiomic features were identified as the most predictive of CPP for both readers. However, these features were not the same for R1 and R2 readers, and their values showed poor inter-reader reliability. Unpromising performances in the validation set were obtained for the radiomics of the pineal gland (ROC-AUC of 0.64 for R1 and 0.59 for R2). These results were significantly lower than the findings we had found for the pituitary gland, which achieved ROC-AUC of 0.81 and 0.76 for R1 and R2, respectively. Similarly, the reference model based on pineal cysts features demonstrated poor performance (ROC-AUC $= 0.52$, both readers). No significant correlations ($\alpha=0.05$) between cysts features and basal/peak gonadotropin levels were observed.
Conclusion
Radiomic features of the pineal gland in girls with CPP have shown no supporting evidence of differences compared with prepubertal controls.

Hormonal support for very young transgender adolescents aligns body composition with identified gender

Pierluigi Diana[1,2], Kirpal Adu-Gyamfi[1], Laura Bosch I Ara[1] & Gary Butler[1,3]
[1]University College London Hospitals NHS Foundation Trust, Paediatric and Adolescent Endocrinology, London, United Kingdom; [2]University of Parma, Department of Medicine and Surgery, Parma, Italy; [3]UCL Great Ormond Street Institute of Child Health, London, United Kingdom

Background
There is lack of data on the physical changes occurring in very young transgender people undergoing puberty suppression (PS) and gender-affirming hormone therapy (GAHT). This study aimed to investigate how body composition changes in terms of fat mass (FM) and lean mass (LM) according to birth-assigned sex and affirmed gender during PS and GAHT.
Methods
This retrospective study included data from 201 adolescents starting PS under 15yr at a national gender service (139 trans boys and 62 trans girls). Data from 127 of them who subsequently received GAHT were available. Height, weight, BMI, total LM and FM were collected using Tanita body composition analyser. Participants were divided into two groups: 'in puberty' (Tanner stage 2-3, or testicular volume <15ml) and 'completing puberty' (Tanner stage 4-5, or testicular volume >15ml) adolescents.
Results
Among 'in puberty' trans boys, total FM increased on PS (2.49 kg, 95% CI 1.66;3.33) similar to LM (2.41 kg, 95% CI 1.85;2.97). In contrast, with 'completing puberty' trans boys the increase of total FM (1.80 kg, 95% CI 1.21;2.39) was higher than total LM (0.97 kg, 95% CI 0.63;1.30). Looking at Z-scores, 'in puberty' trans boys showed increases in FM after 3 years of PS (from 0.70 to 1.2), and mean LM z-scores decreased in both 'in puberty' (from 0.98 to 0.5) and 'completing puberty' (from 1.16 to 0.80). During GAHT, 'in puberty' trans boys showed a greater increase of total LM (6.28 kg, 95% CI 3.54;9.02); body composition after 2 years was FM 27% and LM 73% (vs FM 30% and LM 70% at baseline). Mean FM z-scores at 2yr of GAHT in both groups decreased over baseline but remained higher in comparison with the identified gender. In contrast, 'completing puberty' trans girls showed a greater increase of total FM during PS (4.27 kg, 95% CI 1.50;7.03), whereas body composition only changed slightly during GAHT. However, mean FM z-scores at 2yr of GAHT in trans girls were in normal range (0.1) according to the affirmed gender.
Conclusions
Early hormonal intervention accelerates FM gain in both genders. GAHT masculinises body composition with gains in LM for trans boys, but aligns FM for trans girls with that for typical cisgender girls.

Shredded AIP pituitary sequel

Valentino Marino Picciola[1], Anna Crociara[2], Lucrezia Rossi[1], Serena Piacentini[3], Maria Rosaria Ambrosio[1] & Maria Chiara Zatelli[1]
[1]Section of Endocrinology, Geriatrics and Internal Medicine, Department of Medical Sciences, University of Ferrara, Ferrara, Italy; [2]Endocrine Unit, University Hospital S. Anna, Ferrara, Italy; [3]Mater Olbia Hospital, Olbia, Italy

Introduction
Familial Isolated Pituitary Adenomas (FIPA) syndrome is characterized by the presence of Pituitary Neuroendocrine Tumors (PitNET) in at least two family members, without clinical features suggestive of other genetic syndromes. Germline mutations in the Aryl Hydrocarbon Receptor-Interacting Protein gene (*AIP*) are identified in ~10-20% of FIPA cases, with low penetrance (12.5-30%) and an autosomal dominant inheritance pattern. These mutations are often associated with early-onset PitNET, typically secreting growth hormone, prolactin, or both. The AIP structure contains an alpha-helix and three tetratricopeptide repeat (TPR) domains in the C-terminal region, crucial for protein-protein interactions. This study investigates the impact of a novel *AIP* variant in a 17-year-old girl with an invasive macroprolactinoma and a family history of PitNET.
Methods
AIP germline mutations were investigated by direct DNA sequencing of the AIP gene exons 2, 4, 5, and 6 using the Sanger method. The impact of genetic variants on protein structure was assessed using the NextProt platform. The proband's family was investigated for the presence of PitNET and AIP variants.
Results
Genetic analysis identified a novel heterozygous variant in exon 4 of the *AIP* gene (c.479delC) in the proband: a frameshift mutation causing a premature stop codon (Ter170). This nonsense variation leads to the loss of TPR1-3 and the alpha-helix, key functional C-terminal domains. The mother and five maternal relatives of the proband carried the variant: one had a PitNET and the others did not show any clinical manifestations. The proband presented a grade IV KNOSP macroprolactinoma at age 17, responding to cabergoline with tumor shrinkage and prolactin normalization. The other carrier was diagnosed at age 39 with an invasive GH-secreting PitNET and required medical therapy after surgery and Gamma-Knife radiosurgery due to residual disease.
Discussion and Conclusions
The c.479delC *AIP* variant identified in this study is associated with FIPA, with a confirmed incomplete penetrance and invasive, aggressive early-onset GH- and PRL-secreting PitNETs in patients displaying the FIPA phenotype. The variant causes the loss of AIP molecular interaction domains, potentially contributing to tumorigenesis. These findings highlight the importance of genetic screening in families with a history of PitNETs, enabling early diagnosis and personalized treatment strategies.

JOINT2947

The prevalence of brain abnormalities in children with central precocious puberty or early and fast puberty

Xian Wu[1]
[1]The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong Province, China

Method
From 2011 to 2022, children who were diagnosed CPP or EFP in our center and had completion of cranial magnetic resonance imaging(MRI) were studied. 1087 children were enrolled, including 908 girls (668 CPP, 240 EFP) and 179 boys (89 CPP, 90 EFP), and divided into 3 groups depending on the detection and the types of intracranial lesions. Group 1: no intracranial lesion, Group 2: confirmed hypothalamic hamartoma and glioma, and Group 3: other intracranial lesions. The age of puberty onset, serum levels of FSH, LH, bone age (BA), and Z score of height for BA (SDSBA) at the diagnosis were analyzed.
Results
In girls, 132 cases be found intracranial lesions (14.5%). In boys, 35 be found intracranial lesions (19.6%), with no difference from girls ($P = 0.089$).33.7% (17 in Group 2) Girls <6 years old be found intracranial lesions, higher than that ≥ 6 years old, the latter was 12.1% (only 2 in Group 2)($P<0.001$). Boys <7 years old also had increased incidence of intracranial lesions than that ≥ 7 years old: 53.8% (5 cases in Group 2) vs 16.9% only 1 in Group 2) ($P = 0.004$). No difference of incidence of brain lesions in girls with CPP and EFP (15.3% vs 12.5%, $P = 0.296$), as well as in boys(22.5%, 16.7%, $P = 0.432$). Group 2 had earliest onset of puberty (average age was 1.9 years for girls, 1.0 years for boys), but no difference of acceleration of bone age and height SDSBA were found at diagnosis when compared with group1 and group3 ($P > 0.05$). puberty No diference was found of the age of onset of puberty, baseline LH and FSH, LH peak after stimulation, aceleration of BA as well as height SDSBA between group1 and group3 ($P > 0.05$).
Conclusion
hypothalamic hamartoma and glioma are more common in children with CPP, especially in girls under the age of 6 or boys under the age of 7. In girls above the age of 6, and boys above 7 years old, suffered from CPP or EFP, incidence of intracranial lesions was lower than expected, and most are Incidental lesions, and have little relevence with the process of puberty.

Glucocorticoid withdrawal syndrome, a potential marker for prolonged remission after transsphenoidal surgery in cushing's disease: insights from a single center 20-year retrospective cohort

Dana Bar Natan[1,2], Merav Serebro[1], Zvi Ram[2,3], Rachel Grossman[3], Iris Yaish[1,2], Naomi Even Zohar[1], Yona Greenman[1,2] & Karen Tordjman[1,2]
[1]Tel Aviv Sourasky Medical Center, Institute of Endocrinology, Metabolism and Hypertension, Tel Aviv, Israel; [2]Tel Aviv University, Faculty of Health & Medical Sciences, Tel Aviv, Israel; [3]Tel Aviv Sourasky Medical Center, Department of Neurosurgery, Tel Aviv, Israel

Background
Cushing's disease (CD) is a rare condition with variable surgical outcomes. This study aimed to assess remission and recurrence rates in CD patients undergoing transsphenoidal surgery (TSS) in a contemporary cohort at a major referral center in Israel, and to identify predictive factors for these outcomes. We anticipated that microadenomas would have higher remission rates than macroadenomas.
Methods
This was a retrospective analysis of 97 CD patients who underwent TSS at Tel Aviv Sourasky Medical Center from 2002 to 2022. Remission was defined by a set of biochemical criteria and clinical improvement. Suspected recurrence was confirmed by pathological dexamethasone suppression and/or an elevated urinary free cortisol. Univariate and multivariate analyses were used to identify predictors of remission, while Kaplan-Meier survival analysis and Cox proportional hazard modeling were employed to determine factors associated with recurrence.
Results
The overall remission rate was 63.9%, 69% for first time surgery, and 30.7% for repeat TSS. Contrary to our hypothesis, remission rates were similar between microadenomas (58.7%) and macroadenomas (73.5%), $P = 0.148$. By multivariate logistic regression, predictors of remission were adenoma presence in pathology specimens (OR = 31.25, $P < 0.001$) and first-time surgery status (OR = 9.42, $P = 0.002$), while a younger age seemed to play a contributory factor (OR = 0.963, $P = 0.05$). The overall relapse rate was 22.6% over a median follow-up of 63 [IQR 35-109.5] months. Of all the variables considered, glucocorticoid withdrawal syndrome (GWS) emerged as a novel, and the only significant apparent protective factor against recurrence ($P = 0.045$).
Conclusions
This study, the largest and most up-to-date analysis of short and long-term TSS outcomes for CD in Israel, is somewhat at odds with some established notions about remission predictors, including the initial hypothesis about microadenomas. Likewise, the identification of GWS as a novel predictor of long-term remission, requires confirmation, but could provide a potential avenue for post-operative monitoring and follow-up care in the local context. Moreover, it highlights the necessity to assess outcomes at the patient, and local healthcare-specific level.

"Bioimpedance vector analysis in hyponatremic patients with syndrome of inappropriate antidiuresis: a prospective multicenter study"

Michela Sibilla[1], Emanuele Varaldo[1], Nunzia Prencipe[1], Iulia Petria[2,3], Silvia Grottoli[1], Ezio Ghigo[1], Andrea Benso[1], Giovanna Mantovani[2,3], Emanuele Ferrante[2] & Alessandro Maria Berton[1]
[1]Division of Endocrinology, Diabetology and Metabolism; Medical Sciences Department; University of Turin; Turin, Italy, Turin, Italy; [2]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, Milan, Italy; [3]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy, Milan, Italy

Purpose
The syndrome of inappropriate antidiuresis (SIAD) is the leading cause of hypotonic hyponatremia with preserved extracellular fluid (ECF) volume,

accounting for nearly half of hospital cases, but remains a diagnosis of exclusion. Accurate classification of hyponatremia and timely treatment are essential to prevent complications and serum sodium (s-Na) overcorrection. International guidelines prioritize ECF volume classification over etiology for prompt treatment. Bioelectrical impedance vector analysis (BIVA) uses low-frequency current (50 kHz) to measure body resistance (Rz) and reactance (Xc), accurately estimating ECF. It does not rely on body geometry or tissue models and is independent of body weight, generating the Biavector plotted on a Cartesian RXc graph. This study compares the Biavector of SIAD patients to the Italian reference population to identify a potential "BIVA pattern".
Methods
We prospectively analyzed BIVA and biochemical data from SIAD patients in two different Endocrinology Divisions in Northern Italy from November 2020 to December 2024. Inclusion criteria were a definitive SIAD diagnosis and concurrent BIVA and biochemical data. Exclusions included patients with hyponatremia from other causes, corrected s-Na after appropriate treatment, or unavailable BIVA data. BIVA confidence analysis allowed for the comparison of vector positions and hydration status across populations. Mean Biavector displacements were compared to the latest Italian reference data (Campa *et al*., 2023) using Hotelling's T^2 test.
Results
Fifty-nine patients (56% female, age 73 [63-78.5]) were analyzed, with 63% diagnosed with senile idiopathic SIAD. In the entire cohort, the s-Na corrected for glycemia was 129 [126-131.8] mmol/l, with a p-Osm of 265 [258-273] mOsm/Kg, u-Osm of 441.6 $\pm$ 142 mOsm/Kg, u-Na of 88.5 $\pm$ 42.2 mmol/l, and copeptin levels of 4.9 [2.9-7.2] pmol/l. BIVA confidence analysis revealed a significant Biavector displacement in both female and male patients ($P < 0.0001$). This was characterized by a lower phase angle (PhA), possibly due to the slightly older age compared to the reference population, and a shorter Biavector, confirming a pathological yet subclinical state of overhydration.
Conclusion
Our data highlight the potential utility of BIVA analysis as an inexpensive and time-efficient tool to support the challenging differential diagnosis of patients with preserved ECF hypotonic hyponatremia due to SIAD.

[1]Amsterdam UMC, University of Amsterdam, Amsterdam Gastroenterology Endocrinology Metabolism, Department of Endocrinology and Metabolism, Amsterdam, Netherlands; [2]Pituitary Centre Amsterdam, Amsterdam, Netherlands; [3]Amsterdam UMC, University of Amsterdam, Department of Ophthalmology, Amsterdam, Netherlands; [4]Amsterdam UMC, University of Amsterdam, Department of Neurosurgery, Amsterdam, Netherlands; [5]Netherlands Institute for Neuroscience (NIN), Department of Sleep and Cognition, Amsterdam, Netherlands; [6]Amsterdam UMC, VU University, Department of Psychiatry, Amsterdam, Netherlands; [7]VU University, Centre for Neurogenomics and Cognitive Research, Integrative Neurophysiology, Amsterdam, Netherlands; [8]Amsterdam UMC, VU University, Amsterdam Gastroenterology Endocrinology Metabolism, Department of Endocrinology and Metabolism, Amsterdam, Netherlands

Objective
Compression of retinal ganglion cell (RGC) axons in the optic chiasm of patients with pituitary adenoma can cause lasting visual impairment. It can also cause retrograde axonal degeneration, leading to significant thinning of the retinal macular ganglion cell complex (mGCC). Retinal thinning due to RGC damage may precede the detection of visual field defects (VFD). The aim of this study was to assess mGCC thickness and the post-illumination pupil response (PIPR) as indicators of structural and functional RGC health in patients with optic chiasm compression with and without VFD, and to determine the effect of transsphenoidal chiasm decompression.
Design
Prospective, observational study with preoperative and postoperative assessments in two predefined groups.
Methods
We studied 16 patients with a pituitary macroadenoma causing chiasm compression: eight with preoperative visual fields defects (VFD+ group) and eight without (VFD-group). Assessments took place preoperatively at baseline, and at 3 and past 12 months postoperatively. Retinal thickness was assessed with spectral domain optical coherence tomography (SD-OCT), and pupillometry was performed to determine the PIPR after blue light.
Results
At this time, we present preliminary data of the preoperative and first postoperative assessment at 3 months. Successful decompressive surgery was achieved in all but one patient. Preoperative mGCC thickness was significantly lower in the VFD+ group vs the VFD-group (nasal mGCC mean difference 40 µm, 95% CI 31–50 µm, $P < 0.001$), and all measurements in VFD+ patients were below the minimum thickness measured in VFD- patients. Postoperative assessment showed stable retinal thickness in both groups, regardless of visual improvement. PIPR results were variable with no significant between-group or pre-postoperative within-group differences, although several patients in both groups showed a PIPR decrease after surgery.
Conclusion
Our preliminary results show that VFD are related to significant mGCC thinning, and that thinning persists 3 months after decompressive surgery, suggesting residual retinal damage. Based on the available evidence, implementation of SD-OCT in the standard diagnostic work-up of patients with optic chiasm compression has the potential to provide valuable information for preoperative counselling and planning of surgical intervention. The role of pupillometry and the PIPR requires further exploration. Comprehensive analysis of follow-up data is pending.

Complete remission of headaches in aggressive pitnets treated with pasireotide. correlation with systemic inflammation biomarkers (SIBs)

Maria Aleksandra Komisarz-Calik[1], Anna Bogusławska[1], Karol Ciszek[1], Alicja Hubalewska-Dydejczyk[1] & Aleksandra Gilis - Januszewska[1]
[1]Jagiellonian University Medical College, Chair and Department of Endocrinology, Kraków, Poland

Introduction
Aggressive PitNets, defined as rapidly growing and resistant to the standard treatment tumors, often present with severe headaches and require individualized multimodal treatment. Pasireotide exhibits antitumor properties and a unique analgesic effect in PitNets.
Objectives
To correlate headaches and SIBs in aggressive PitNets treated with pasireotide.
Methods
We analyzed data regarding the severity of the headaches (according to NRS scale) from 19 patients — 11 men and 8 women with different PitNets: 10 somatotropinomas (38.5%), four corticotropinomas (23.1%), two silent corticotropinomas (7.6%), two gonadotropinomas (7.6%), and one prolactinoma (3.8%) treated with pasireotide in correlation with SIBs.
Results
The average age on diagnosis was 45 years (min -13; max – 86). The maximum tumor diameter was 89 mm. 18/19 (95%) patients were treated pharmacologically before pasireotide implementation. All patients with acromegaly were previously treated with first-generation somatostatin analogs (SA). The patients treated surgically 14/19 were significantly younger than others (40 vs. 66 years), $p = 0.014$. 15/19 patients complained of headaches. The mean value on the NRS scale at baseline was 6,5 (max-10; min-2), while after the pasireotide was 0,7 (max-4; min-0). 100% of patients reported alleviation or disappearance of headaches (OR – 1.34; 95%CI (0.702-1.950), $p<0.001$). Furthermore, a correlation between baseline NRS and WBC was found (rho=0.478, $p=0.05$) Patients with acromegaly (acro) achieved higher PLT/lYMPH ratio values than others (nonacro) (187,2 vs 119,5), $P = 0.006$. Moreover, we observed a strong correlation between higher PLT/lYMPH ratio and higher GH and IGF-1 values (rho=0.736, $P = 0.01$ and rho=0.709, $P = 0.05$). Furthermore, we observed a strong correlation between baseline NRS and NEU/PLT ratio in nonacro group (rho=0.859, $P = 0.01$). In 15/19(79%) patients, the tumor dimensions stabilized or shrank; in 4 patients, the follow-up MRI has not yet been performed. 79% obtained biochemical control of the disease.
Conclusion
Pasireotide is a second-generation SA used in acromegaly and Cushing's disease. Nevertheless, it effectively achieves biochemical control in other PitNET subtypes and relieves headaches.
Keywords
Pasireotide, Aggressive PitNets, Acromegaly, Cushing syndrome, systemic inflammation biomarkers.

Hyponatremia in severe hypothyroidism ("the HYPO2 study")

Evangelia Stasi[1], Julia Beck[1] & Mirjam Christ-Crain[1]
[1]Endocrinology, University Hospital of Basel, Basel, Switzerland

Background
Current guidelines recommend excluding hypothyroidism as a differential diagnosis for euvolemic hyponatremia[1]. However, there is a growing debate on hypothyroidism-induced hyponatremia, with poor evidence on its clinical significance. Especially data in severe hypothyroidism and myxedema is lacking.
Aim
To assess the prevalence of hyponatremia in patients with severe hypothyroidism and identify potential comorbidities associated with its development.
Design and Methods
Retrospective observational study, conducted at the University Hospital of Basel in Switzerland. Data were collected over a 10-year period (01/2014-11/2024) from in-and outpatients, who presented with free thyroxine (fT4) levels $<$8pmol/l with and without the diagnosis of myxedema, as documented in patients' chart.
Results
A total of 820 cases were analyzed, showing a mean sodium level of 138 ± 5 mmol/l, TSH level of 56 ± 62 mU/l and fT4 level of 5 ± 2 pmol/l. The prevalence of hyponatremia in the cohort was 19% ($n = 155$). No significant association was found between fT4 and sodium levels. Within this cohort, severe hypothyroidism, clinically defined by the treating physician, was identified in 45 cases (76% female, mean age of 63 ± 15 years), including 12 cases of myxedema. The prevalence of hyponatremia in this subgroup was 22%, which was comparable to the overall cohort ($P = 0.7$). Further characterization of the hyponatremic population showed a higher frequency of comorbidities compared to the normonatremic group, including malignancy (30% vs 9%), cardiovascular disease (60% vs 43%), heart failure (20% vs.14%), infectious disease (40% vs. 20%) and kidney disease (30% vs. 43%). Presence of malignancy was a significant predictor of lower sodium levels (-5mmol/l, $P = 0.04$), while no significant correlation was found between fT4 levels and sodium levels ($P = 0.6$) or development of hyponatremia ($P = 0.9$). Also, the mortality rate within index hospitalization was higher in the hyponatremic group compared to the normonatremic group (20% vs 6%).
Conclusion
Our analysis suggests that the prevalence of hyponatremia in severe hypothyroidism is comparable to the general hospitalized population, which is estimated to be around 20%[2]. Hyponatremia in our cohort cannot solely be explained by the presence of severe hypothyroidism. Instead, presence of comorbidities such as malignancy seem to play a major role in the development of hyponatremia in severe hypothyroidism.

Effects of dulaglutide on oxytocin plasma levels in healthy men: a secondary analysis of a randomized, double-blind, placebo-controlled crossover study

Vera Reber[1,2], Sophia Lengsfeld[1,2], Nimmy Varghese[3], Yara Emara[1,2], Leila Probst[1,2], Cemile Bathelt[1,2], Laura Werlen[2], Anne Eckert[3] & Bettina Winzeler[1,2,4]
[1]University Hospital Basel, Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University Hospital Basel, University of Basel, Clinical Research, Basel, Switzerland; [3]University Psychiatric Clinics Basel, Neurobiology Laboratory for Brain Aging and Mental Health, Basel, Switzerland; [4]University Hospital Zurich, Department of Endocrinology, Diabetology and Clinical Nutrition, Zurich, Switzerland

Background
In animal studies, systemic and central injections of GLP-1 were found to increase plasma oxytocin concentrations. Additionally, recent rodent research revealed that 70% of GLP-1 receptor-positive neurons in the paraventricular nucleus also expressed oxytocin receptors. When oxytocin and GLP-1 were co-administered systemically, there was a significant increase in action potential firing in oxytocin-receptor-positive neurons in the paraventricular nucleus. Based on these findings, considering the functional and anatomical proximity as well as the synergistic effects, we hypothesized that dulaglutide may modulate and increase oxytocin plasma levels in humans.
Methods
This is a secondary analysis of a randomized, double-blind, placebo-controlled crossover trial of healthy eugonadal men, age 18-50 years with active and satisfactory sex lives that examined the effect of the GLP-1 RA dulaglutide on sexual desire as a primary endpoint. Participants were randomly assigned (1:1) to receive either dulaglutide or placebo for four weeks. Oxytocin plasma levels were measured repetitively in a standardized manner, with three samples taken every 15 minutes at baseline and at the evaluation visit. We used the mean of these three measurements for our analysis. Changes within individuals were then compared after four weeks of treatment with the GLP-1 receptor agonist dulaglutide vs placebo using paired *t*-tests.
Findings
The median [IQR] age of participants at inclusion was 24.5 [21.0, 29.0] years, and the median BMI was 23.85 [22.15, 25.00]. Mean (SD) oxytocin baseline levels were comparable between groups: 50.6 pq/ml (17.0) in the treatment group and 50.5 pq/ml (18.2) in the placebo group. After 4 weeks of treatment with dulaglutide and placebo oxytocin concentrations remained stable and were 53.2 pq/ml (12.7) and 50.5 pq/ml (17.8), respectively. Mean (SD) change from baseline in oxytocin concentrations was + 2.6 pq/ml (21) in the treatment group and 0.0 pq/ml (19.4) in the placebo group. The estimated difference between the two treatment was: 2.58 [95% CI −12.9, 18.4].
Interpretation
Our study found no significant change in oxytocin plasma levels following a four-week treatment with dulaglutide vs placebo. Differences in results compared to animal data may be due to lower dosing, central vs peripheral administration, choice of GLP-1 RA, or acute vs chronic use. In addition, whether the results would be different in women or in people with obesity/diabetes mellitus, where altered GLP-1 metabolism is expected, needs to be investigated in future studies.

Background
Arginine vasopressin is synthesized in the magnocellular neurons of the hypothalamic supraoptic (SON) and paraventricular nuclei (PVN) and stored in the posterior pituitary. It is released into the bloodstream in response to increased osmolality or non-osmotic stimuli such as hypovolemia or stress. During stress, specialized PVN neurons co-release corticotropin-releasing hormone (CRH) and AVP. AVP amplifies CRH-induced adrenocorticotropic hormone (ACTH) secretion. Elevated cortisol or AVP levels exert negative feedback on the hypothalamus and pituitary to regulate CRH and ACTH secretion. However, disruptions in the AVP system can impair this feedback mechanism, resulting in sustained cortisol elevations.
Methods
This is a secondary analysis of a prospective study conducted at seven tertiary medical centers in Europe and Brazil (2018 to 2022), that utilised the hypertonic saline and the arginine infusion for the diagnostic evaluation of patients presenting with polyuria-polydipsia syndrome. ACTH and cortisol were measured at baseline and expected peak for hypertonic saline and arginine stimulation in patients with AVP-Deficiency and primary polydipsia (i.e., clinical controls). The primary objective was to investigate the effect of hypertonic saline and arginine on the HPA axis response between both groups. The ACTH and cortisol differences were compared between groups using a linear mixed effects model and between the stimulation tests using linear regression model.

Findings
This analysis included 20 patients with AVP-Deficiency and 10 clinical controls. Upon arginine (non-osmotic stress), patients with AVP-Deficiency showed a greater increase in plasma ACTH (difference: -9.2 ng/l [95% CI -17 to -1.8]) and plasma cortisol (difference: -141 nmol/l [95% CI -242 to -40]) comparted to clinical controls. Upon hypertonic saline (osmotic stress), the change in plasma ACTH was similar between patients with AVP-Deficiency and clinical controls (difference: -0.31 ng/l [95% CI -11 to 10]), while the increase in plasma cortisol was greater in patients with AVP-Deficiency compared to clinical controls (difference: -78 nmol/l [95% CI -188 to 32]). Independent of the type of stimulation, patients with AVP deficiency exhibited a significantly greater increase in plasma ACTH (-7.0 ng/l [95% CI -13.3 to -0.8], $P = 0.04$) and plasma cortisol (-106 nmol/l [95% CI -188 to -24], $P = 0.02$) compared to clinical controls, with no significant effects between stimulation type and ACTH ($P = 0.36$) or cortisol response ($P = 0.09$).
Interpretation
This study demonstrates an altered sustained ACTH and cortisol response pattern to non-osmotic and osmotic stress in patients with AVP-Deficiency, indicating impaired regulation of the HPA axis.

JOINT2285

Long-term outcomes of gonadotropin-releasing hormone analogue-treated obese girls with central precocious puberty

Natee Sakornyutthadej[1], Jirawat Pruksasri[2], Pat Mahachoklertwattana[2], Sarunyu Pongratanakul[2], Orapan Upakankul[2] & Preamrudee Poomthavorn[2]
[1]Chakri Naruebodindra Medical Institute, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Samut Prakan, Thailand; [2]Department of Pediatrics, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand

Background
Both central precocious puberty (CPP) and obesity cause advanced bone maturation and accelerated growth. Gonadotropin-releasing hormone analogue (GnRHa) is the standard treatment for preserving final height (FH) potential in girls with CPP. It is unclear whether GnRHa-treated obese girls with CPP achieve less favorable FH outcomes as compared with non-obese girls.
Objective
To study long-term outcomes of obese girls with idiopathic CPP (iCPP) who were treated with GnRHa in comparison with those with normal weight.
Methods
Medical records of 233 obese and 334 normal-weight girls with iCPP who had been treated with either monthly or 3-monthly leuprolide or triptorelin acetate, and attained FH at Ramathibodi Hospital, Thailand, between 2007 and 2024 were reviewed. Long-term outcomes of GnRHa treatment, focusing on FH, height gain (FH – pre-treatment predicted adult height), time to menarche after GnRHa discontinuation and body mass index (BMI) were collected and compared between obese and normal-weight iCPP girls.
Results
Medians (IQRs) age at diagnosis of obese and normal-weight iCPP girls were 7.5 (7.0, 7.8) and 7.5 (7.1, 7.8) years, respectively ($p=0.304$). Mid-parental height (MPH) was not different between both groups. At diagnosis, obese girls with iCPP were taller (height SDS: 1.53 (0.70, 2.20) vs. 0.85 (0.18, 1.43), $p<0.001$) and had more bone age (BA) advancement (2.5 (1.8, 3.2) vs. 1.9 (1.1, 2.6) years, $p<0.001$). GnRHa treatment was started and discontinued at 8.3 (7.8, 8.7) and 11.5 (10.7, 12.1), and 8.2 (7.8, 8.8) and 11.7 (11.0, 12.5) years of age in obese and normal-weight girls, respectively. BA at treatment discontinuation was not different between groups. Compared with normal-weight girls, obese girls had greater height gain (8.6 (5.9, 11.8) vs. 7.4 (4.7, 10.4) cm, $p=0.012$), and FH SDS (0.42 (-0.24, 0.99) vs. 0.15 (-0.40, 0.69), $p=0.002$). Duration from GnRHa discontinuation to menarche of obese girls was less than that of normal-weight girls (12.0 (8.4, 18.0) vs. 14.4 (9.6, 20.4) months, $p=0.012$). BMI SDSs at FH were significantly lower than those at diagnosis in both groups (obese: 1.17 (0.53, 2.07) vs. 1.77 (1.31, 2.59), $p<0.001$, normal-weight: -0.32 (-0.96, 0.30) vs. 0.21 (-0.38, 0.61), $p<0.001$).
Conclusions
Despite having greater BA advancement at diagnosis, obese girls achieved greater height gain and FH than normal-weight girls who had comparable MPH, suggesting greater height at diagnosis might compensate for FH attainment. Menstruation began earlier in obese girls following GnRHa discontinuation. BMI SDSs decreased from diagnosis to FH in both groups.

Early prolactin normalization and tumor shrinkage predict the first-year response to cabergoline treatment in invasive macro-giant prolactinomas

Hayri Bostan[1], Bekir Ucan[2], Hakan Duger[3], Sema Hepsen[2], serdar kayıhan[2], Alper Dilli[4], İlknur Ozturk Unsal[2], Erman Cakal[2] & Muhammed Kizilgul[5]
[1]Canakkale Mehmet Akif Ersoy State Hospital, Endocrinology and Metabolism, Canakkale, Türkiye; [2]Ankara Etlik City Hospital, Endocrinology and Metabolism, Ankara, Türkiye; [3]Medical Park Antalya Hospital, Endocrinology and Metabolism, Antalya, Türkiye; [4]Ankara Etlik City Hospital, Radiology, Ankara, Türkiye; [5]University of Minnesota, Ankara Etlik City Hospital, Diabetes, Endocrinology, and Metabolism, Minnesota, United States

Introduction
Invasive macroprolactinomas respond less favorably to dopamine agonist (DA) therapy compared to non-invasive macroadenomas and microadenomas. Understanding the frequency of a good response (GR) —defined as prolactin (PRL) normalization and $\geq$50% tumor volume reduction—and its predictors may aid timely clinical decision-making. Therefore, the current study focused on assessing GR frequency at the first-year follow-up and determining predictive factors of this response in patients with invasive macro-giant prolactinomas.
Methods
This retrospective cohort study included 38 patients (32 males, 6 females; mean age 41.9$\pm$12.8 years) with invasive macro-giant prolactinomas (baseline median PRL: 2530 (1726–5451) ng/mL, mean longest tumor diameter: 36.4$\pm$12.8 mm) who were followed for at least one year under cabergoline therapy. PRL levels and tumor volume changes were analyzed at early and late follow-ups. Patients were classified as good responders (GRs) or poor responders (PRs) based on their first-year outcomes.
Results
At the first-year visit, 17 patients (44.7%) achieved a GR. Baseline parameters such as presenting symptoms and signs, hormonal studies, tumor invasion characteristics, and KNOSP scores were comparable between groups, but GRs had significantly higher normoprolactinemia rates (70.6% vs. 23.8%,$P = 0.004$) and greater tumor shrinkage (57.3$\pm$15.6% vs. 41.9$\pm$21.9%,$P = 0.02$) at 3–6 months evaluations. In the multivariate logistic regression analysis, the best-reduced model to predict GR in the first year included tumor shrinkage percentages (aOR:1.06 (95% CI: 1.01-1.12), $P = 0.023$) and nadir PRL levels (aOR:0.97 (95% CI: 0.94-0.99), $P = 0.019$) at 3-6 months. ROC analyses revealed that an early tumor shrinkage cut-off rate of 44.9% (88% sensitivity, 62% specificity) and an early PRL cut-off level of 30 ng/mL (75% sensitivity, 77% specificity) were identified as effective follow-up parameters to predict GR in the first-year. The median available follow-up duration for the patients was 23.5 (17.0-48.0) months. All GRs maintained PRL normalization and $\geq$50% tumor volume reduction, while 33.3% and 42.9% of PRs failed to meet these goals, respectively, at the last visit ($P = 0.009$, $P = 0.002$). Three of the PRs required surgery during follow-up.
Conclusion
Approximately half of invasive macroprolactinoma patients achieved the composite goal within one year of cabergoline therapy. Early follow-up studies, rather than baseline characteristics, are strong predictors of treatment success. In the early assessments at 3-6 months of these symptomatic invasive tumors under cabergoline treatment, cases with PRL levels of 30 ng/mL or lower, or tumor shrinkage of 45% or more, are highly unlikely to require surgery in the first year or subsequent visits.

Early life exposure to antibiotics and precocious puberty in children: a nationwide population-based cohort study

jinjoo choi[1], Yunsoo Choe[2] & Seung Yang[1]
[1]Hanyang University Hospital, Department of Pediatrics, Seoul, South Korea; [2]Hanyang University Guri Hospital, Department of Pediatrics, Guri, South Korea

Background
Antibiotics exposure in early life may have association with central precocious puberty (CPP), but evidence is limited. This study explored the association of

antibiotics exposure with CPP using nationwide population-based cohort in South Korea.
Methods
Children who had regular health check-up at 4–6 months and 66–71 months of age were included and followed up until 10 years in boys and 9 years in girls. The diagnosis of CPP was based on the ICD-10 code and the prescription of gonadotropin-releasing hormone agonists. Multivariable Cox proportional hazards model was used to estimate adjusted hazard ratios (aHRs) and 95% confidence intervals (Cis) for CPP according to age at first prescription of antibiotics and the number of antibiotic classes, respectively.
Results
Among 322,731 children (135,232 boys and 187,499 girls), 291,703 (90.4%) were prescribed antibiotics before 1 year of age. Compared with those prescribed antibiotics after first year of life, girls who received antibiotics before 3 months of age had an increased risk of CPP (aHR 1.231 [95% CI 1.119–1.355], $P < 0.001$), followed by those prescribed antibiotics at 6–9 months (aHR 1.205 [95% CI 1.098–1.322], $P < 0.001$), 3–6 months (aHR 1.169 [95% CI 1064–1.284], $P = 0.001$), and 9–12 months (aHR 1.146 [95% CI 1.042–1.261], $P = 0.005$) after adjusting for covariates. Furthermore, girls who used 5 or more classes or antibiotics had a higher risk of CPP compared to those who used 2 or less classes. However, in boys, no significant association was observed between age at first prescription or the number of antibiotic classes and CPP.
Conclusions
Exposure to antibiotics in early life and many numbers of antibiotics may be associated with a higher risk of CPP in girls. The effects of long-term antibiotics exposure on pubertal development and underlying should be further investigated.

Exosomal miRNA expression profiles and pathway enrichment analysis in girls with central precocious puberty and premature thelarche

Hye Jin Lee[1,2], Eu Seon Noh[3], Yena Lee[1], Hye Young Jin[4], Young Jun Seo[5], Young Suk Shim[6], Hwalrim Jeong[7] & Il Tae Hwang[3]
[1]Hallym University Sacred Heart Hospital, Pediatrics, Anyang, South Korea; [2]Hallym University Kangman Sacred Heart Hospital, Seoul, South Korea; [3]Kangdong Sacred Heart Hospital, Seoul, South Korea; [4]Kangdong Sacred Heart Hospital, Pediatrics, Seoul, South Korea; [5]Hallym University Chuncheon Sacred Heart Hospital, Pediatrics, Chuncheon, South Korea; [6]Ajou University Hospital, Pediatrics, Suwon, South Korea; [7]Soon-chunhyang University Cheonan Hospital, Pediatrics, Cheonan, South Korea

Context
Central precocious puberty (CPP) is rapidly increasing in prevalence among girls, with most cases being idiopathic. Exaggerated thelarche (ET) and premature thelarche (PT) are variants of early puberty that can be difficult to distinguish from CPP in initial clinical evaluations. Exosomal microRNAs are stable biomarkers capable of crossing the blood-brain barrier. However, human studies on miRNAs in CPP and related conditions remain limited.
Objective
To identify distinct exosomal miRNA profiles in girls with CPP, ET, and PT, and explore the target genes and pathways involved in pubertal development.
Methods
This cross-sectional study included 27 girls aged 6-8 years, categorized into CPP, ET, PT, and control groups. Serum exosomal miRNAs were sequenced, differentially expressed miRNAs (DEmiRNAs) were analyzed, target genes were predicted, and pathway enrichment analysis was performed.
Results
Distinct exosomal miRNA patterns were observed among CPP, ET, and control groups, identifying 307 DEmiRNAs. The PT group showed a distinct miRNA expression from the control group but not show clear separation from the CPP or ET groups. Enriched pathways included AGE-RAGE, MAPK, and mTOR signaling, with group-specific enrichment observed in Hippo and neurotrophin signaling pathways.
Conclusions
This study identifies distinct serum exosomal miRNA patterns in CPP, ET, and PT groups. The enrichment of the AGE-RAGE pathway suggests a potential link to dietary habits. Serum exosomal miRNAs may serve as biomarkers or therapeutic targets, providing insights into environmental factors influencing early puberty.

Optimizing laboratory defined macroprolactin algorithm for follow-up patients

Domagoj Marijančević[1], Adriana Bokulić[1], Sanja Goreta[1] & Ivana Zec[1]
[1]Sestre milosrdnice University Hospital Center, Department of Clinical Chemistry, Zagreb, Croatia

Introduction
Macroprolactinaemia is a well-known analytical problem in the diagnostics of hyperprolactinaemia, usually detected with the polyethylene glycol (PEG) precipitation method. Due to the lack of harmonization in macroprolactin detection and reporting results, this study proposes and evaluates the usefulness of an in-house-developed algorithm. This study aimed to assess whether repeating the PEG precipitation resulted in any difference in recovery and explore the potential for rationalizing the precipitation procedure.
Materials and Method
This is a retrospective study based on extracted data for 547 follow-up patients, of which 453 (83%) were women and 94 (17%) were men. All patients with prolactin concentration above the upper reference limit defined by the manufacturer (women: 23.3 µg/l; men: 15.2 µg/l) were included in the study according to the in-house algorithm. Prolactin concentrations were measured before and after PEG precipitation on the Roche cobas e801 analyser (Roche Diagnostics GmbH, Mannheim, Germany) using the Elecsys Prolactin II sandwich electrochemiluminescence immunoassay. Macroprolactinaemia was defined based on the percentage recovery of prolactin (%Recovery), calculated using the total prolactin (PRL) and the post-PEG prolactin concentration (%Recovery = 100 x PRL/post-PEG prolactin). The normality of data distribution was tested with the D'Agostino-Pearson test. The Wilcoxon rank-sum test was employed to determine the difference between the recoveries of repeated measurements. %Recovery data and the interval between repeated measurements were expressed as median and interquartile range.
Results
%Recovery for the total prolactin concentration was 84 (75-87) %, which was nearly identical to the repeated measurement at 84 (75-88) %. Analysis of the %Recovery data from repeated measurements in follow-up patients ($n = 547$) showed no significant difference ($P = 0.247$). The median interval between repeated measurements was 2.1 (1.2-3.1) years.
Conclusion
Our results demonstrated no statistically significant difference in recovery values between repeated measurements, indicating that the PEG precipitation protocol could be simplified by prolonging the follow-up period. Although the exact pathogenesis of macroprolactinaemia remains unknown, it is regarded as a benign and long-lasting condition consistent with this study's findings.

Discrepancy between central and peripheral ACTH response to desmopressin stimulation: two cases

Aikaterini Themis Vyllioti[1], Artemis Papanikolaou[1], Rodanthi Vamvoukaki[2], Paraskevi Xekouki[2], Constantine Stratakis[3], Athina Markou[1] & Athanasios Fountas[1]
[1]Department of Endocrinology and Diabetes Center, 'Georgios Gennimatas' General Hospital of Athens, Athens, Greece; [2]Endocrinology and Diabetes Clinic, University Hospital of Heraklion, University of Crete, Heraclion, Greece; [3]Astrea Health & Medical Genetics, H. Dunant Hospital Athens; Digenia & Edimo labs and Human Genetics & Precision Medicine, Imbb Forth, Heraclion, Greece

Introduction
Desmopressin stimulation testing (DST) is increasingly used in the differential diagnosis between central and ectopic ACTH-dependent hypercortisolism since CRH became unavailable. Herein, we report two patients with Cushing's disease (CD) and negative DST (10 µg IV) (defined as <50% and <20% increase of ACTH and cortisol levels, respectively) but with positive petrosal sinus ACTH response to desmopressin administration.
Case Presentation
Case 1: A 47-year-old Greek woman, with 1-year history of dyslipidaemia and hypertension, was investigated for Cushingoid phenotype (central obesity, moon face, facial plethora, hirsutism, buffalo hump and supraclavicular fat pads). Hormonal work-up revealed ACTH-dependent hypercortisolism [late night serum cortisol 308 nmol/l (NR <208), 1-mg overnight dexamethasone suppression 286 nmol/l (NR <50), 24h urine free cortisol 724 nmol (NR 11.8-485.6), ACTH 51

pg/ml]. DST led to 45% and 14% rise in peripheral ACTH and cortisol levels, respectively. Pituitary MRI revealed a 3 mm lesion. Due to its size, inferior petrosal sinus sampling (IPSS) was performed. Central-to-peripheral ACTH gradient, before and after IV desmopressin, was indicative of CD. Desmopressin administration led to 593% increase of petrosal sinus ACTH levels compared to 27.4% increase of peripheral ACTH levels. Transsphenoidal adenomectomy resulted in Cushing's remission. Case 2: A 22-year-old Greek woman was investigated for hypercortisolism due to 1-year history of fatigue, muscle weakness, substantial weight gain, hirsutism, easy bruising, round face and abdominal striae. Hormonal evaluation was indicative of ACTH-dependent hypercortisolism [1-mg overnight dexamethasone suppression 13.1 μg/dl (NR < 1.8), 24h urine free cortisol 317 μg (NR 20.9-292.3), ACTH 47 pg/ml]. DST was negative (8.97% and 16.90% increase in peripheral ACTH and cortisol levels, respectively). Pituitary MRI revealed a 4 mm central microadenoma. IPSS with IV desmopressin identified pituitary origin of ACTH excess. Desmopressin administration led to 400% and 46% increase of petrosal sinus and peripheral ACTH levels, respectively. The patient is currently awaiting transsphenoidal surgery.

Discussion

To our knowledge, only four other patients unresponsive to DST but with positive central ACTH response in IPSS after desmopressin administration, as in our cases, have been described. The discrepancy between central and peripheral ACTH levels after desmopressin administration may be attributed to different sampling intervals between DST and IPSS or cyclic hypercortisolism. Short and transient increase in ACTH secretion after desmopressin, detected in the petrosal sinus but not significantly affecting ACTH peripheral levels may also contribute. Our cases highlight that desmopressin administration during IPSS is useful even in patients with negative desmopressin stimulation testing.

Medium-term effects of surgical therapy vs. medical treatment in patients with remission of cushing's disease

Ylenia Alessi[1,2], Luca Balbo[3], Rosalinda Casablanca[3], Angela Alibrandi[4], Filippo Flavio Angileri[1], Francesca Pecori Giraldi[2], Francesco Ferraù[3,5] & Salvatore Cannavò[3,5]

[1]Department of Biomedical, Dental and Morphological and Functional Imaging Sciences, University of Messina, Department of Biomedical, Dental and Morphological and Functional Imaging Sciences, University of Messina, Messina, Italy; [2]Department of Clinical and Community Sciences, University of Milan, Milan, Italy; [3]Endocrine Unit, "Gaetano Martino" University Hospital of Messina, Messina, Italy; [4]Department of Economics, University of Messina, messina, Italy; [5]Department of Human Pathology of Adulthood and Childhood, University of Messina, Messina, Italy

Cushing's disease (CD) is associated with high morbidity and mortality if not adequately treated. The first-line therapy is transsphenoidal surgery (TSS), where indicated, followed by medical therapy and/or radiotherapy and/or bilateral adrenalectomy based on clinical context. The aim of this study was to evaluate any differences in anthropometric, clinical, hormonal, and metabolic parameters, including CD-related comorbidities, between patients who achieve remission after surgical therapy (group S) and those who achieve it through medical therapy (group P), also stratifying them by sex.

Methods

We retrospectively assessed 47 patients with CD (37 women), all treated with TSS except for 2, followed at the Endocrinology Unit of the AOU of Messina from 2014 to 2024; of these, 33 achieved remission after surgery (27 women) and 14 after medical therapy (10 women). Parameters were evaluated before surgery and/or medical therapy (T0) and one year after disease remission achieved through surgery or medical therapy (T1).

Results

At T1, patients in group S compared to T0 showed a significant reduction in waist circumference (WC), transaminase levels, glycated hemoglobin, serum cortisol, urinary free cortisol (UFC), ACTH, DHEAS, an improvement in cardiovascular comorbidities, and a higher incidence of central hypothyroidism. In contrast, patients in group P, compared to T0, showed significant reductions in ACTH, serum cortisol, and DHEAS without significant differences in terms of comorbidities. When comparing the two groups at T1, patients in group S had significantly lower values of WC, triglycerides, and serum cortisol and a significantly reduced prevalence of striae rubrae, easy bruising, hypertension, and cardiomyopathy, compared to patients in group P. After stratification by sex, at T1: males (M) in group S showed lower total and LDL cholesterol values and a higher incidence of hypogonadism and GHD compared to females (F); in group P, males had a higher incidence of cardiomyopathy, hypogonadism, and diabetes compared to females.

Conclusion

One year after remission of CD, patients in surgical remission showed a significant improvement in some typical disease signs and cardiometabolic profile compared to the pharmacological remission group. Additionally, after stratification by sex, in the pharmacological remission group, M showed a poorer cardiometabolic profile than F.

Effect of bone age at GnRH agonist treatment cessation on near adult height in korean girls with central precocious puberty

Minkyu Seo[1], Ji Won Park[1], Eungu Kang[1], Hyo-Kyoung Nam[1], Young-Jun Rhie[1] & Kee-Hyoung Lee[1]

[1]Korea University College of Medicine, Pediatrics, Seoul, South Korea

Introduction

In treatment of central precocious puberty (CPP) girls, existing literatures suggest that stopping treatment around a bone age (BA) of 12 years may result in the most favorable adult height, but there are few real-world studies that compare the effects of BA at the time of treatment cessation on final adult height. Therefore, we investigated whether the differences of BA at treatment cessation significantly influence near adult height (NAH).

Methods

A retrospective study was conducted on 117 CPP girls treated with GnRH agonists. Patients were followed up until their BA was 13 years or older after treatment cessation. Predicted adult height (PAH) at treatment initiation and NAH at the last visit were calculated using the Bayley-Pinneau method. This study compared growth outcomes across three groups classified by BA at treatment cessation ('11.5 year', '12 year', '≥12.5 year') and assessed correlations between several clinical factors and NAH outcomes.

Results

Mean chronological age (CA) at treatment initiation was 8.4 years, and mean BA at treatment initiation was 10.1 years. Differences between BA and CA (BA-CA) at treatment initiation were 1.37 year in the 11.5 year group, 1.78 year in the 12 year group, and 2.05 year in the ≥12.5 year group ($p<0.001$). Predicted adult height (PAH) at treatment initiation were 159.16 cm, 160.03 cm, and 156.82 cm, respectively ($p<0.05$). NAH of each group were 163.89 cm, 164.64 cm, and 163.28 cm, respectively ($p=0.423$), and differences between PAH at treatment initiation and NAH (NAH-PAH) were 4.73 cm, 4.61 cm, and 6.46 cm, respectively ($p<0.05$). Multivariate regression analysis showed significant positive associations of NAH with MPH, height SDS at treatment initiation and cessation, and negative association with the difference between BA and CA at treatment cessation.

Conclusion

Our findings suggest that even patients with markedly advanced BA at the start of treatment could achieve comparable NAH if the treatment duration is sufficiently prolonged. So individualized treatment plans considering BA advancement and height at the end of treatment are essential for the best growth outcomes in CPP patients.

Neurofibromatosis type 1 in the eyes of an endocrinologist - a disease requiring a coordinated care

Marta Burkietowicz[1], Agnieszka Zubkiewicz-Kucharska[1] & Robert Śmigiel[1]

[1]Medical University, Department of Paediatrics, Endocrinology, Diabetology and Metabolic Diseases, Wroclaw, Poland

We performed the retrospective analysis of 66 pediatric patients with NF1 hospitalized at the University Clinical Hospital in Wrocław in 2018-2024. The aim of the study was to assess the scale of endocrine problems in the analyzed group of patients. 22 patients (33.33%) were hospitalized in the Department of Pediatrics, Endocrinology, Diabetology and Metabolic Diseases. These children were referred to the Clinic due to: short stature (8/22 patients - 36.36%), premature puberty (5/22 patients - 22.72%), rapid progression of puberty, primary amenorrhea and body weight deficiency, hyponatremia, hypernatremia, hypothyroidism, hypertension, obesity, as well as due to routine endocrinological assessment due to the underlying disease (2 patients - 9.09%). Hormonal disorders requiring treatment were found in 6/22 children (27.27%). GnRH-

dependent precocious puberty was diagnosed in 5 of them, whereas multi-hormonal hypopituitarism and diabetes insipidus in one patient. In all patients with GnRH-dependent precocious puberty, CNS magnetic resonance imaging revealed pathological NF1 changes, including those affecting the optic pathway and the hypothalamic and pituitary region. Patients were included in the triptorelin treatment program at the average age of 7 years and constituted 4.5% of all patients remaining in the program in the studied years. Two boys came to the Clinic for the first time with advanced puberty (Tanner scale: 3/4 and 4 degrees), considered too progressed to achieve optimal efficacy of triptorelin therapy. Both of them presented clinical symptoms of NF1 from early childhood that allowed for the earlier diagnosis of NF1. Unfortunately, early signs of puberty were missed in both boys, leading to short stature as a consequence of delayed treatment.

Conclusion

1. The analysis confirms the multidisciplinary nature of neurofibromatosis type 1, which requires vigilance and care from many specialists.
2. The most common endocrine disorder in children with NF1 is GnRH-dependent precocious puberty caused by nodular lesions affecting the optic pathway and the hypothalamus. Therefore, a group of patients with CNS lesions in these areas should also remain under constant care of an endocrinologist.
3. The basic, underestimated and often overlooked tools for monitoring the proper development of each patient (including a patient with NF1) are: the Tanner scale (for assessing the puberty status) and percentile charts (for observing the growth pattern).

Galactorrhea and headache in an 18-year-old transfeminine youth: a case report

Chansuda Bongsebandhu-phubhakdi[1,2], Ketsuda Jakchairoongruang[1,2] & Sathida Poonmaksatit[1,2]
[1]Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [2]King Chulalongkorn Memorial Hospital, The Thai Red Cross Society, Bangkok, Thailand

An 18-year-old transfeminine youth presented with galactorrhea for two months, accompanied by intermittent headaches but no other neurological symptoms.

Medical History

The patient was diagnosed with HIV at 15 years of age and has been on antiretroviral therapy (atazanavir, ritonavir, abacavir/lamivudine). Laboratory results revealed a CD4 count of 654 cells/μL, CD4 percentage of 27%, and undetectable HIV viral load. She has a history of PTSD due to sexual assault and MDD, managed with escitalopram (10 mg/day) and trazodone (50 mg/day as needed).

Gender-Affirming Hormone History

At age 11, the patient began self-prescribing oral contraceptives (ethinyl estradiol 0.035 mg and cyproterone acetate 2 mg) based on a friend's suggestion, using them inconsistently due to breast pain and financial limitations. Later, she purchased 17β-estradiol and cyproterone acetate online, following advice from a senior acquaintance, and intermittently used intramuscular hormones advertised online, including estradiol benzoate (3 mg) and progesterone (50 mg). She also performed regular self-breast massages for augmentation.

Clinical Findings

Physical examination showed bilateral breast engorgement and galactorrhea, with normal neurological findings. Laboratory results indicated elevated prolactin (261.5 ng/mL), estradiol (167.8 pg/mL), and low testosterone (0.429 nmol/l), with normal thyroid function. MRI revealed a pituitary microadenoma (3.5 × 2.7 × 2.6 mm) with a small cystic component.

Clinical Course

The patient was advised to discontinue injectable hormones, reduce estrogen doses, and stop breast massage. Despite this, she attended follow-ups irregularly and continued self-prescribed gender-affirming hormone therapy and breast massage against medical advice. Over time, her galactorrhea improved, with prolactin levels decreasing to 83.8 ng/mL at six months and normalizing after two years. Her headaches also resolved.

Conclusion

This case highlights the risks of self-prescribed hormone use in transfeminine youth, emphasizing the need for medical supervision to prevent endocrine complications. Accessible care and regular follow-up are crucial for safer outcomes.

Temperament, character, and quality of life in patients with acromegaly: factors affecting psychosocial processes

Banu Betul Kocaman[1], Yusuf Cicek[2], Cem Sulu[1], Ahmet Dogan[3], Serdar Sahin[1], Senol Turan[2] & Pinar Kadioglu[1]
[1]Division of Endocrinology, Metabolism, and Diabetes, Department of Internal Medicine, Cerrahpasa Faculty of Medicine, Istanbul University-Cerrahpasa, Istanbul, Türkiye; [2]Department of Psychiatry, Cerrahpasa Faculty of Medicine, Istanbul University-Cerrahpasa, Istanbul, Türkiye; [3]Department of Internal Medicine, Cerrahpasa Faculty of Medicine, Istanbul University-Cerrahpasa, Istanbul, Türkiye

Objective

This study aimed to evaluate the character and temperament dimensions in acromegaly patients, and to examine the effects of the disease and the treatments on depression, anxiety, and quality of life (QOL).

Methods

77 acromegaly patients (41 women, 36 men) who were followed up in pituitary center and came for a check-up between 2023-2024 were included in the study. The patients filled out the Acroqol, Temperament and character inventory-revised (TCI-R), Hospital Anxiety and Depression scale. The patients' age, gender, IGF-1 values, comorbidities and treatments were recorded.

Results

There was a positive correlation between age and anxiety scores ($r = +0.228$, $P = 0.046$), and in addition, higher anxiety levels were shown in female patients compared to male patients (7.8 ± 4.3 vs. 5.4 ± 3.6, $P = 0.01$) and in patients who underwent surgery compared to those who did not (7.1 ± 4.2 vs. 3.8 ± 3.1, $P = 0.023$). Depression scores were higher in patients who underwent pituitary surgery compared to those who did not (7.3 ± 4.3 vs. 3.7 ± 3.4, $P = 0.017$). We also showed that QOL was negatively affected in female patients (53.3 ± 22.3 vs. 66.4 ± 22.8, $P = 0.013$), and in those underwent transsphenoidal surgery (56.2 ± 22.5 vs. 81.4 ± 17.9, $P = 0.002$), or radiotherapy (32.9 [30.1–63.1] vs. 65.9 [42.1–80.6], $P = 0.021$). Furthermore, QoL was also decreased with increasing disease duration ($r = -0.248$, $P = 0.030$). Personality dimensions based on TCI scores showed differences according the size of pituitary adenoma at initial presentation and presence of hypopituitarism. Patients with macroadenoma ($n = 50$) had higher novelty seeking (NS) (112 [103.5–120.2] vs. 104.5 [96–112.2], $P = 0.049$) and perseverance (PS) (118 [105.7–126.2] vs. 107 [97.2–118.2], $P = 0.031$). Patients with hypopituitarism of any type ($n = 16$) had lower PS scores (114 [103–123] vs. 116 [98–123.5], $P = 0.013$) compared to those who had not.

Conclusions

The results revealed gender and pituitary-directed therapies might influence general psychological health and QoL of patients with acromegaly. It was also found that disease-related features such as adenoma size and hypopituitarism migh affect personality profile.

Septo-optic dysplasia: clinical phenotype and impact on the child and family

David Cullingford[1,2,3], Mary Abraham[1,2,3], Aris Siafarikas[1,2,3], Marie Blackmore[2], Jenny Downs[2,4] & Catherine Choong[1,2,3]
[1]Perth Children's Hospital, Endocrinology and Diabetes, Perth, Australia; [2]The Kids Research Institute Australia, The Centre for Child Health Research, Perth, Australia; [3]University of Western Australia, Perth, Australia; [4]Curtin University, Perth, Australia

Objectives

To describe the clinical phenotype and impacts on child quality of life (QOL) and family function in children with septo-optic dysplasia (SOD).

Methods

Children with SOD, aged 0-17 years, who attended a single tertiary centre and their parents/carers, participated. A combination of parental surveys describing antenatal history, child medical history, health system utilisation, and validated questionnaires to assess impact on the child and family—KIDSCREEN-27, McMaster family assessment device (FAD), Fatigue Severity Score (FSS) and PedsEyeQ—were completed, with child responses to the KIDSCREEN-27 and PedsEyeQ where appropriate. Comparison for maternal findings was with data from the Western Australian (WA) Midwives Notification System (MNS), and for validated questionnaires with other studies.

Comparisons of cohort maternal features to the general population.

	SOD	Comparison	*P*-value	Reference
Mean BMI	23.2 ± 3.9 (n = 26)	26.3 ± 5.7 (n = 392,306)	0.005	MNS
Low or normal BMI	20/26 (76.9%)	191,568/392,306 (48.8%)	0.004	MNS
Inadequate pregnancy weight gain	14/27 (51.8%)	141/664 (21.2%)	<0.001	Queensland 2011

MNS data from 2006-2023.

Results

Consent was received for 47 children, and 45 surveys (16 females, mean age 10.3 years) were available for analysis. Approximately half (24/45) had pituitary dysfunction or developmental delay (22/45) and 14/45 had neither. Speech and language, social/emotional delay, learning delay and intellectual disability were seen more frequently in those with hypopituitarism than those without ($P < 0.05$). Feeding difficulties were reported in 8/25 term neonates, 5 requiring nasogastric feeding. Mean maternal BMI was lower than the WA population (23.2 vs 26.3, $P = 0.005$). 51.8% of mothers had less antenatal weight gain than recommended, more than double the general population (21.2%, $P < 0.001$). Children saw a mean of 3.4 medical specialties and 2.0 allied health disciplines, with 31/37 travelling at least 20km to attend. KIDSCREEN-27, McMasters FAD and FSS scores were similar to comparison groups in other studies while PedsEyeQ functional vision quality of life scores were lower.

Conclusion

SOD is a heterogenous condition, and mothers may have suboptimal antenatal weight gain and lower maternal BMI compared to the general population. Neonatal feeding difficulties were common, with nasogastric feeding often required. As expected, vision related QOL was reduced in individuals with SOD. Despite the complexity of symptoms, this study did not discern a difference in health-related quality of life scores using KIDSCREEN compared with general population norms. Additional studies assessing maternal weight status, neonatal feeding challenges and quality of life are required to further delineate their involvement in SOD.

Impact of gender-affirming hormone therapy on cardiovascular function: a cross-sectional study

Silvia Ciancia[1], Simon D'hulst[2], Jeroen Vervalcke[3], Daniel Klink[1], Guy T'Sjoen[3], Katya De Groote[2], Laura Muino Mosquera[2] & Martine Cools[1]
[1]Ghent University Hospital, Department of Internal Medicine and Pediatrics, Service of Pediatric Endocrinology, Ghent, Belgium; [2]Ghent University Hospital, Pediatric Cardiology Service, Department of Pediatrics, Ghent, Belgium; [3]Ghent University Hospital, Endocrinology Service, Department of Internal Medicine, Ghent, Belgium

Background

Cardiac parameters and cardiovascular risk (CVR) differ between sexes. Numerous studies have reported an increased CVR among adult transgender individuals, attributed to the metabolic changes associated with gender-affirming hormone therapy (GAHT) and lifestyle factors. However, the impact of GAHT on CV function remains poorly understood, especially if started during adolescence.

Methods

Echocardiographic evaluation was performed in 47 trans men (TM) and 6 trans women (TW), undergoing GAHT since 5-10 years. Assessments included diastolic and systolic cardiac function, cardiac and aortic diameters, and aortic stiffness index (SI). Additionally, CVR factors (such as glucose and lipid profiles, obesity, smoking and drinking habits, and hypertension) were analysed.

Results

Mean GAHT duration was 6.5 (±1.6SD) years in TM and 7.6 (±1.7SD) years in TW, median age was 23.4 (IQR 2.2) and 25.3 (IQR 2.7) years, respectively. Gonadal hormone suppression was obtained with progestins (TM) and cyproterone acetate (TW) in all but one individual per group (who received gonadotropin-releasing hormone agonist). Diastolic dysfunction grade 2 was diagnosed in one TM, while systolic function was normal in all individuals. A mildly dilated left ventricle (LV), after correction for body surface area (BSA), was observed in 6 TM when categorized by the experienced gender (EG), but only in 3 when categorized by the sex registered at birth (SRAB). LV mass/BSA mildly increased in 7 TM when categorized by SRAB, in none when categorized by EG. No correlation between LV mass/BSA and GAHT duration was found. Aortic diameters Z-scores where aligned more with EG than with SRAB in both groups. SI was 5.2 ± 2.3 SD in TM and 5.9 ± 1.9 SD in TW, (reference values 2.65 ± 0.55). Multiple regression analysis was conducted in TM, but not in TW due the small sample size, and showed a positive association only between SI and BMI (P-value = 0.02).

Conclusions

GAHT for more than 5 years induces a shift in cardiac parameters towards the EG. SI is significantly increased in both TM and TW undergoing GAHT, representing an independent risk factor for CV disease and highlighting the need for careful long-term follow-up.

Key-words

GAHT, cardiovascular, aortic stiffness, echocardiography.

CAm^{2}029 octreotide subcutaneous depot provides stable control of IGF-I and improves key symptoms throughout a 4-week post-dose interval: analysis from the ACROINNOVA 1 trial

Monica R. Gadelha[1], Beverly M.K. Biller[2], Maria Fleseriu[3], Joanna L. Spencer-Segal[4], Julie M. Silverstein[5], Irina Bancos[6], Jacob Råstam[7], Alberto M. Pedroncelli[7], Fredrik Tiberg[7] & Diego Ferone[8]
[1]Neuroendocrinology Research Center/Endocrinology Division, Medical School and Hospital Universitario Clementino Fraga Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [2]Neuroendocrine and Pituitary Tumor Clinical Center, Massachusetts General Hospital, Boston, MA, United States; [3]Pituitary Center, Departments of Medicine and Neurological Surgery, Oregon Health and Science University, Portland, OR, United States; [4]Department of Internal Medicine and Michigan Neuroscience Institute, University of Michigan, Ann Arbor, MI, United States; [5]Division of Endocrinology, Metabolism and Lipid Research, Department of Neurosurgery, Washington University School of Medicine, St. Louis, MO, United States; [6]Division of Endocrinology, Mayo Clinic, Rochester, MN, United States; [7]Camurus AB, Lund, Sweden; [8]Endocrinology Unit, Department of Internal Medicine, IRCCS Ospedale Policlinico San Martino, Genova, Italy

Background

Standard-of-care medical therapies (injectable somatostatin receptor ligands) aim to control the excess insulin-like growth factor-I (IGF-I) levels characteristic of acromegaly. Symptom control is also key. However, increased symptoms towards the end of dosing intervals are reported by some patients, possibly indicating waning biochemical control. Designed for self-administration by injection, CAm^{2}029 is a novel subcutaneous octreotide depot with a prolonged-release, long-acting formula developed using FluidCrystal® technology. The efficacy of CAm^{2}029 was evaluated in ACROINNOVA 1, a 24-week, Phase 3 trial (NCT04076462). Superior IGF-I control (IGF-I ≤upper limit of normal [ULN]) vs placebo (72.2% vs 37.5%; $P = 0.0018$) and symptom control were demonstrated in patients previously controlled. We report further analyses in patients receiving CAm^{2}029, evaluating IGF-I and symptom control over a 4-week interval from administration of the final CAm^{2}029 dose.

Table Patients with symptoms of acromegaly.

Symptom	W20*	W22	W24/EOT
		n/N$_{all}$ † (%)	
Fatigue	30/42 (71.4)	28/41 (68.3)	28/42 (66.7)
Headache	19/42 (45.2)	16/41 (39.0)	13/42 (31.0)
JOINT pain	30/42 (71.4)	27/41 (65.9)	34/42 (81.0)
Paraesthesia	14/42 (33.3)	12/41 (29.3)	13/42 (31.0)
Soft tissue swelling	16/42 (38.1)	13/41 (31.7)	13/42 (31.0)
Sweating	19/42 (45.2)	21/41 (51.2)	21/42 (50.0)

*Prior to final CAM2029 administration; †Patients completing treatment with CAM2029 and attending assessment.

Methods
Over a 24-week treatment phase, patients randomised to CAm^{2}029 received 20 mg every 4 weeks ($\pm$1 week); the final dose was administered at week (W) 20. Assessments of IGF-I levels and symptom severity (via the Acromegaly Index of Severity [AIS]; JOINT clinician and patient evaluation of key symptoms) took place at least every 4 weeks throughout the treatment phase, including at W20 prior to CAm^{2}029 administration, W22 and W24/end of trial (EOT).
Results
Forty-eight patients were randomised to CAM2029 and 42 (87.5%) completed treatment. Mean IGF-I/ULN values remained stable over W20, W22 and W24/EOT (0.82, 0.81 and 0.79, respectively). A slight reduction (improvement) in mean AIS overall scores was observed from W20 (4.5) to W22 (4.3) and W24/EOT (4.2). The proportions of patients affected by symptoms of acromegaly across the dose-to-assessment interval are shown in the Table.
Conclusions
Patients established on CAM2029 maintained stable control of IGF-I at all timepoints across the 4 weeks, post-dose. Symptoms were also well controlled throughout the dosing interval, with patients experiencing improvements in some key symptoms such as headache and fatigue. These data indicate that CAm^{2}029 continuously and consistently reduces the burden of disease for patients across the 4-week dosing interval.

BMI trajectories during childhood in girls with precocious puberty: a national register-based study

Grith Laerkholm[1], Rasmus Wibaek[2], Pernille Roenn[2] & Rikke Jensen[1,2,3]
[1]Copenhagen University Hospital, Herlev Hospital, Herlev, Denmark; [2]Steno Diabetes Center Copenhagen, Herlev, Denmark; [3]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark

Background
Childhood obesity is increasing globally and has been linked to early puberty in several epidemiological studies. Low birth weight and subsequent rapid weight gain during infancy and early childhood have been suggested to play a role in this association.
Objectives
We aimed to identify distinct body mass index (BMI) trajectories from birth until 10 years among girls diagnosed with precocious puberty, hypothesizing that specific BMI patterns throughout childhood correlate with pubertal timing.
Methods
We included girls diagnosed with precocious puberty (ICD-10 diagnosis: DE30.1) or central precocious puberty (DE22.8A) as recorded in the Danish National Patient Registry. Data on height and weight for BMI were retrieved from birth and until 10 years, utilizing the Danish Medical Birth Registry and the Children's Database. Only girls diagnosed between ages 4-9 years and with a minimum of three BMI measurements at ages 0-0.5 years, 0.5-3 years and 3-8 years were included (n = 1874). Data-driven latent class trajectory (LCT) modeling was employed to define distinct BMI trajectories for girls experiencing early puberty.
Results
We identified four distinct BMI trajectories. Class 1 (24.1%) or the "very early accelerating" class experienced a marked infancy peak within normal BMI ranges but an early adiposity rebound from 2.5 years. Class 2 (37.4%) had a BMI trajectory within the normal range. Class 3 (30.4%), or the "early accelerating" class, had an initial BMI trajectory within normal limits but then an early adiposity rebound from four years. Class 4 (8.2%) or the "early peak" class had a low BMI at birth but a steep increase during the first year of life (high infancy peak) and remained overweight according to the World Health Organization's classification until 10 years of age. Three out of four classes (62.7%) were at risk of overweight from 7 years of age.
Conclusions
The majority of girls with precocious puberty followed a trajectory characterized by early adiposity rebound and overweight from 7 years of age. This study may facilitate the identification of children at risk of precocious puberty.

JOINT3036

The intra-individual periodicity of serum GH patterns in acromegaly is very high and independent of disease control: analysis of 650 GH time series from 106 patients

Mai C. Arlien-Søborg[1,2], Zoé-Natascha Reynaud Sørensen[1], Kirstine Stochholm[4], Claus Højbjerg Gravholt[1], Aparna Udupi[3], Bo Martin Bibby[3] & Jens Otto Lunde Jørgensen[2,3]
[1]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus, Denmark; [2]Aarhus University Hospital, Medical Research Laboratory, Department of Clinical Medicine, Aarhus, Denmark; [3]University of Aarhus, Department of Biostatistics, Aarhus, Denmark

Background
Growth hormone (GH) is secreted in a pulsatile manner from the anterior pituitary in healthy individuals. In acromegaly, most commonly caused by a GH-secreting pituitary adenoma, the ensuing GH patterns are traditionally described as erratic and irregular due to a substantial shift toward non-pulsatile release. Given the clinical reliance on serum GH and insulin-like growth factor I (IGF-I) as diagnostic and therapeutic biomarkers, it is crucial to establish evidence-based data on GH secretion dynamics in acromegaly. Further investigation into the temporal patterns of GH release may refine diagnostic criteria and improve treatment monitoring in affected individuals.
Aim
The aim of the study is to investigate the day-to-day reproducibility and variability of GH secretion.
Methods
We analyzed medical records of acromegaly patients who received standard treatment and care between 2012 – 2021, including those with a minimum of 3 three GH profiles in conjunction with an oral glucose tolerance test (OGTT) composed of 11 measurements over 3 hours following an overnight fast. To quantify variability in GH secretion patterns, cross correlation analysis and dynamic time warping (DTW), a non-linear alignment algorithm, were applied. DTW distances were computed to assess intra-individual stability across repeated measurements and inter-individual variability among each patient.
Results
We obtained and analyzed 650 GH profiles from 106 patients, of whom the diagnostic GH profile was available in 21 patients. 33 patients were controlled by surgery alone and 72 patients were treated medically with a somatostatin analogue (SA) alone (n = 54) or in combination with a GH antagonist (n = 18). The inter-individual DTW distance was 0.136 with 95%Cl (0.135; 0.138) whereas the intra-individual DTW distance was 0.050 (95%Cl 0.046; 0.055), yielding a ratio of the intra-/inter-individual DTW distance of 0.367 (95%Cl 0.335; 0.403), p $<$0.0001. The intra-/inter-individual DTW distance was independent of treatment modality. Also, the intra-individual cross-correlation coefficients were significantly higher (0.166 (95%Cl 0.137; 0.195)) than inter-individual correlations (0.003 (95%Cl -0.001; 0.007)), P $<$ 0.0001, indicating greater consistency in GH secretion patterns within individuals over time.
Conclusions
1. The unique and highly conserved GH pattern in serum from individual patients challenges the dogma of disorderly GH secretion in acromegaly.
2. This periodicity is independent of disease control and treatment modality suggesting an intrinsic clock within the pituitary somatotrope that is preserved after tumorous transformation.
3. It remains to be studied if our findings depend on the oral glucose load.

Background
Previous research on acromegaly has demonstrated increased morbidity and mortality that are mainly attributable to early cardiovascular diseases (CVD). The aim of our study was to define more comprehensively the risk of CVDs in acromegaly.
Methods
This nation-wide registry study included all Finnish acromegaly patients diagnosed in 1980–2015 at the age of over 16 years. Ten controls matched for age, sex and the area of residence were assigned to each patient. National registries were used to obtain cardiovascular diagnoses given to patients and controls in specialised medical care. CVD-related follow-up started at the acromegaly diagnosis and ended on the date of the CVD of interest, death, or emigration, or the common closing date 31.12.2019. In addition, CVD-related morbidity was analysed for a 10-year period before the acromegaly diagnosis. Clinical data of the acromegaly patients were collected from the Finnish University Hospitals. Morbidity due to different CVDs in patients vs controls was assessed with Kaplan-Meier and Cox regression analyses.
Results
We identified 571 acromegaly patients, of which 565 had sufficient data to be included in the analyses. The incidence of acromegaly was 4.0 [IQR 2.9–4.7] cases/million /year. Mean age at diagnosis was 48.9 (SD 13.3) years. 75% of the tumours were macroadenomas (diameter$\geq$ 10 mm). The median follow-up time was 17.2 [IQR 8.7–26.5] years for the patients and 17.5 [9.4–27.5] years for the controls. Morbidity due to any CVD was found to increase up to 10 years before the acromegaly diagnosis and remained elevated for the whole study period, compared to the controls [HR 2.26 (95% CI 2.04–2.51]. The greatest increase was noted for valvular heart diseases and cardiomyopathies [HR 2.88 (2.24–3.70)], followed by diseases of pulmonary arteries [HR 2.88 (1.96–4.22)] and hypertension [HR 2.30 (2.01–2.64)]. Morbidity was also increased due to arrhythmias [HR 1.77 (1.49–2.11)], heart failure [HR 1.72 (1.35–2.19)], cerebrovascular disease [HR 1.46 (1.16–1.85)], coronary artery disease [HR 1.41(1.16–1.71)] and other diseases of arteries and veins [HR 1.89 (1.60–1.71)].
Conclusion
Acromegaly patients suffered from increased morbidity across all subgroups of CVDs. Morbidity due to any CVD increased years before the acromegaly diagnosis, probably reflecting a long diagnostic delay. We are currently analysing the cardiovascular risk factors and the effect of biochemical control of acromegaly on the cardiovascular prognosis of the patients, to be presented at the meeting.

Soluble alpha Klotho concentrations in patients with pituitary adenomas

Júnia R.O.L. Schweizer[1], Katharina Schilbach[1], Frederick Vogel[1], Isabel Stüfchen[1], Friederike Völter[2], Elisabeth Nowak[1], Anica Pauline Gagliardo[1], Stephanie Zopp[1], Michael Haenelt[1], Sylvère Störmann[1], Jochen Schopohl[1], Antonio Ribeiro de Oliveira Jr[3], Juliana Drummond[4], Martin Reincke[1] & Martin Bidlingmaier[1]
[1]LMU Klinikum; Med. Klinik und Poliklinik IV/Endokrinologie, Munich, Germany; [2]LMU Klinikum; Med. Klinik und Poliklinik IV/Nukelarmedizin/Endokrinologie, Munich, Germany; [3]Crinetics Pharmaceuticals, Boston, United States; [4]Federal Institution of Minas Gerais (UFMG), Endocrinology, Belo Horizonte, Brazil

Background
Alpha klotho is mainly expressed in the kidney but also in other organs, such as the pituitary gland. Soluble alpha klotho (sαKL) is a circulating protein that has been linked to endocrine functions. We previously showed high sαKL concentrations in active acromegaly. However, little is known about sαKL in pituitary adenomas beyond acromegaly.
Objective
To evaluate sαKL concentrations in patients with different types of pituitary adenomas.
Methods
We used an ELISA (IBL, Hamburg, Germany) to measure sαKL in patients prior to surgery for Cushinǵs disease (n = 21, 6 males), prolactinoma (n = 44, 13 males), or non-functioning pituitary adenomas (NFPA, n = 9, 3 males), and compared concentrations to those seen in patients with active acromegaly (n = 29, 9 males). We also compared concentrations (mean [interquartile]) of sαKL to the classical biomarkers in acromegaly (IGF-I and IGFBP3).
Results
SαKL concentrations (pg/ml) were significantly higher in patients with acromegaly (Acro.: 5109 [2859-10232]) compared to all other groups (Cushing (Cush.: 728 [593-982], Prolactinoma (Prol.: 922 [786-1298], NFPA (922 [782-1111]; (Acro. vs. Cush. and Prol., $P < 0.0001$ for both comparisons and Acro. vs. NFPA, $P = 0.0003$). As expected, IGF-I and IGFBP3 were significantly higher in patients with acromegaly (753.9 [485.3-938.3], 6388 [5506-7354]) compared to patients with other pituitary adenomas (Cush.: 175.3 [110.4-228.8), 3212 [2501-3835], Prol.: 163.0 [134.0-201.5], 3896 [3433-4279], NFPA: 120.0 [104.5-174.0]), 3426 (3013-3759), Acro. vs. Cush., Prol. and NFPA, $P < 0.0001$ for all comparisons). Concentrations of sαKL, IGF-I and IGFBP3 did not differ significantly between patients with Cushing's disease, prolactinoma and NFPA ($P > 0.05$ for all comparisons). SαKL significantly correlated with IGF-I and IGFBP3 concentrations in patients with acromegaly ($r_s = 0.66$, $P = 0.0001$ and $r_s = 0.43$, $P = 0.02$, respectively), while there was no correlation with IGF-I or IGFBP3 in patients with other pituitary adenomas ($P > 0.05$ for all).
Discussion
Our study shows that in contrast to patients with acromegaly, sαKL is not grossly elevated in other pituitary adenomas. This supports the idea that sαKL concentrations are associated with high GH and/or IGF-I concentrations whereas influences of other hormone active or inactive pituitary adenomas itself might have, if any, a minor influence on sαKL concentrations.

Endocrine challenges in hypothalamic-pituitary region tumors in pediatric population: a greek children's hospital perspective

Danai Barlampa[1], Maria Dolianiti[1], Ioannis Anargyros Vasilakis[1], Ioanna Farakla[1], Michaela Nikolaou[1], Danai Georgakopoulou[1], Alexandra Tsigkri[1], Sophia Sakka[1] & Christina Kanaka Gantenbein[1]
[1]Division of Endocrinology, Diabetes and Metabolism 'Aghia Sophia' Children's Hospital ENDO-ERN center for Rare Paediatric Endocrine Diseases, First Department of Pediatrics Medical School, National and Kapodistrian University of Athens, "Aghia Sophia" Children's Hospital, Athens, Greece, Athens, Greece

Background
Intracranial tumors affecting the hypothalamic-pituitary (HP) region, including adjacent structures such as the optic pathway, often disrupt the hypothalamic-pituitary axis due to local tissue damage, neurosurgical intervention, tumor progression, or cranial radiation therapy. Tumors located in the suprasellar and intrasellar regions account for approximately 10% of all central nervous system (CNS) tumors in children, with endocrine abnormalities frequently present at diagnosis.
Aim
Of this monocentric study is to evaluate the endocrine profile of children with HP region tumors who have been managed in our hospital and referred to our Endocrine Department, emphasizing pre- treatment and post- treatment complications and outcomes.
Methods
A retrospective analysis was conducted on pediatric HP tumor cases managed between 2013 and 2023. Endocrine data, including pre- and post-treatment deficiencies, BMI changes, and rGH therapy requirements, were extracted from patient records.

Results
• **Demographics**: Among 41 children (56% girls, 44% boys), the mean age at diagnosis was 8.95 years (SD = 4.8).
• **Tumor Diagnosis**: Craniopharyngiomas were most common (36.6%), followed by pituitary adenomas (20%) and prolactinomas (12%). Other tumor types included germinoma/dysgerminoma, glioma, ependymoma, astrocytoma, hamartoma, Rathke cyst.
• **Pre-treatment Endocrine Status**: Hormonal deficiencies included GH (12.8%), TSH (15.38%), ACTH (7.69%), LH/FSH (5.26%), and ADH (12.5%).
• **Post-treatment Endocrine Complications**: Increased endocrine deficiencies were observed post-treatment, including GH (34.88%), LH/FSH (25.58%), ACTH (51.16%), TSH (67.64%), and ADH (41.86%).
• **Body Mass Index (BMI)**: The mean BMI z-score increased significantly from 1.2 (± 1.54) at diagnosis to 1.7 (± 1.17) at 1-year post-treatment ($P < 0.05$). This significant difference persisted at 2 years, but by 5 years, although a difference was noted, it almost missed statistical significance at the 95% CI.
• **Recombinant Growth Hormone (rGH) Therapy**: rGH therapy was initiated in 32% of patients during follow-up.

Conclusion
Early identification and management of endocrine disorders are essential to improve the quality of life and long-term outcomes in pediatric survivors of hypothalamic-pituitary region tumors. Regular monitoring and a multidisciplinary approach are strongly recommended to address the complex health challenges these patients face. However, the results of this study are limited in their generalizability, as the sample was derived specifically from patients referred to the Endocrine Unit. To obtain more comprehensive insights, further studies are needed that include a broader population of patients with all types of brain tumors, regardless of referral pathways or clinical settings.

A case of severe ACTH-dependent cushing syndrome

Georgios Kostopoulos[1], Efstathios Divaris[1], Athanasia Michou[1], Charilaos Kostoulas[2], Ioanna Bouba[2], Ioannis Georgiou[2] & Zoe Efstathiadou[1]
[1]Endocrinology Department, Hippokration General Hospital of Thessaloniki, Thessaloniki, Greece; [2]Laboratory of Medical Genetics in Clinical Practice, Faculty of Medicine, University of Ioannina, Ioannina, Greece

Background
ACTH-dependent Cushing Syndrome is associated with increased morbidity and mortality. Diagnostic evaluation may be challenging, especially in the acute setting. We present a case of severe ACTH-dependent Cushing Syndrome attributed to a corticotroph pituitary adenoma (Cushing's Disease, CD) coexisting with an unspecified syndromic cause of GH deficiency and potential hypopituitarism.

Case Presentation
A 39-year-old woman with decompensated heart failure with reduced ejection fraction was admitted to hospital with severe hypertension, hypokalaemia, and hyperglycaemia. The patient reported generalised weakness, oedema and appearance of wide purple striae, starting two months before her admission. On physical examination, she presented with short stature (1.35m), clinodactyly, low-set ears and micrognathia. Upon questioning, she reported primary amenorrhea and short-term treatment with rGH at the time of adolescence, but no medical records could be retrieved. Of note, she had normal breast development. During her hospitalisation she was admitted to the ICU twice due to acute respiratory failure in the presence of ARDS and later due to acute hemorrhagic pancreatitis. Upon imaging, multiple prevalent spinal fractures were noted. Due to the high clinical suspicion of CS, she was referred for endocrine consultation. After full recovery from acute illness, ACTH-dependent Cushing's Syndrome was confirmed, and pituitary MRI revealed a macroadenoma (max diameter 2 cm) with cavernous sinus invasion. She was started on the novel steroidogenesis inhibitor osilodrostat and teriparatide for osteoporosis, while awaiting neurosurgery. After 4 months of treatment, she had clinical and biochemical remission of hypercortisolism with significant improvement of the related comorbidities. Evaluation of hypothalamus-pituitary axes revealed low gonadotropin, GH and IGF-1 levels. Further testing for the presence of concurrent genetic syndrome was performed. Pelvic ultrasound revealed hypoplastic uterus and ovaries; standard karyotype analysis and array comparative genomic hybridization excluded the diagnosis of Turner Syndrome. Subsequent whole exome sequencing analysis revealed a mutation of VUS in the CDH23 gene (c.1339A>G CDH23 gene), which is implicated in both familiar and sporadic pituitary tumours occurrence. Additionally, further trio-exome sequencing analysis detected a likely pathogenic variant in PAX6 (c.728_731delAAAA) and VUS in SOX2 (c.382C>T), genes encoding transcription factors implicated in pituitary development.

Conclusion
Pituitary insufficiency co-existing with a corticotroph macroadenoma is a rare finding. Whether there is an association between the two entities remains an unresolved issue. Despite recent advances, a genetic cause remains unidentified in many cases of hypopituitarism. Future research to discover additional implicated genes will provide better understanding on the molecular pathways implicated in pituitary development.

Diagnostic delay in children with intracranial germ cell tumour and high burden of endocrinopathies among survivors

Sarah Poon[1], Joanna Tung[1], Gloria Pang[1], Evelyn Lu[1], Dennis Ku[1], Queenie See[2], Ho-Chung Yau[3] & Matthew M.K. Shing[1]
[1]Hong Kong Children's Hospital, Hong Kong, Hong Kong; [2]Queen Mary Hospital, Hong Kong, Hong Kong; [3]Prince of Wales Hospital, Hong Kong, Hong Kong

Objective
Compared to the Western population, incidence of intracranial germ cell tumour (IC-GCT) is significantly higher among Chinese children. These children often present with neurological symptoms or endocrine dysfunction. Endocrine deficits may present with insidious symptoms that precede neurological findings for years, often leading to delay in diagnosis especially among primary care or general pediatricians. This study reviewed clinical features of a cohort of Chinese children with IC-GCT, focusing on initial endocrine manifestations, time lag in diagnosis and long-term disease burden.

Methods
This is a retrospective, cohort study. We identified children with IC-GCT diagnosed ≤ 18 years managed at the Hong Kong Children's Hospital from 2008-2023. Demographics, presentation and tumour-related outcomes were analyzed.

Results
74 children (73% males) diagnosed with IC-GCT at median age of 12.6 years (IQR 10.5-16.5) with median follow-up of 4.4 years (IQR 2.2-11.1) were included. The majority (63.5%) had germinoma and 17.6% were metastatic at diagnosis. IC-GCTs were suprasellar (40.5%), pineal (18.9%), bifocal (17.6%), or at the basal ganglia/thalamus (16.2%). Endocrine deficits were already present in 68.9% of children at diagnosis (diabetes insipidus 59.5%, adrenal insufficiency 55.4%, central hypothyroidism 52.7%, growth hormone deficiency 43.2%, hypogonadotropic hypogonadism 29.7%, precocious puberty 10.8%), and all children with suprasellar tumour exhibited at least one endocrinopathy. Interval between onset of endocrine symptoms and definitive diagnosis of IC-GCT ranged between 0.9 to 71.8 months (median 11.9 months) with more than half (70.3%) being symptomatic for over 6 months. Those with unfavourable oncological outcomes (distant metastasis/relapse/death) had longer symptom interval, though the difference was not statistically significant. At last follow-up, 68.9% required at least one medication for endocrine sequelae. Additionally, there was significant rise in BMI from 17.8 kg/m^2 at diagnosis to 21.6 kg/m^2 at last follow-up, with more of those with endocrinopathies showing ≥ 10% increase in BMI. Low bone mineral density was also common, with 63.2 % having either TBLH/lS z score ≤ -2 on DXA measurements.

Conclusion
Substantial proportion of children with IC-GCT experienced delay in time to diagnosis, which was associated with worse disease outcome. This highlighted the importance of raising both patient and clinician awareness, as well as the need for early neuroimaging in children displaying pituitary hormone deficiencies. For survivors, attention has to be drawn to weight status and bone health in order to optimize long-term well-being.

DISCERN: delta copeptin in the investigation of SIAD and CSW: evaluating the role of a novel biomarker

Sayan Banerjee[1], Arun George[1], Anju Bala[1], Naveen Sankhyan[1], Rakesh Kumar[1], Nidhi Panda[1], Naresh Sachdeva[1] & Jaivinder Yadav[1]
[1]Post Graduate Institute of Medical Education and Research, Endocrinology, Chandigarh, India

Background
The current diagnostic methods for syndrome of inappropriate antidiuresis (SIAD) and cerebral salt wasting (CSW), relying on clinical and biochemical indicators are imprecise. As existing gold standard techniques using radioisotope methodologies are confined to research settings due to high costs and limited accessibility, there is an urgent need for novel biomarkers to enhance diagnostic accuracy.
Objective
To evaluate the change in serum copeptin levels, as an early diagnostic tool in children to differentiate SIAD and CSW.
Methods
A prospective observational study was conducted on hyponatremic children (serum sodium $\leq$ 130 meq/l). Subjects with endocrine disorders, chronic systemic diseases, diarrhea, hypovolemic shock, or those using diuretics were excluded. At baseline, copeptin, NT-proBNP, and fractional excretion of uric acid (FEUA) levels were measured. Subsequently, each subject received 0.9% NS according to their maintenance requirements for six hours. During this period, fluid deficits and polyuria, if present, were managed with fluid replacement. Symptomatic hyponatremia was treated with 3% NS. After six hours, samples were again collected for copeptin and NT-proBNP. The subjects were followed until serum sodium levels normalized to differentiate CSW from SIAD based on FEUA levels.
Results
We studied 15 subjects (73.3% male), of whom 11 were diagnosed with SIAD and four with CSW. The cohort predominantly consisted of patients with tuberculous meningitis (66.67%). Baseline copeptin levels showed no correlation with the degree of hyponatremia ($r = 0.126$). However, delta copeptin was significantly different between the two cohorts and showed a decrease in the SIAD group [-16.43 (-39.07, -4.57) vs 7.94 (-2.30, 29.80) pmol/l, $P = 0.024$]. A cutoff value for delta copeptin of -9.62 pmol/l, yielded a sensitivity of 100% and a specificity of 63.6% for CSW (AUC [95% CI], 0.864 [0.665–1.00]). Chronic hyponatremia developed in 2 SIAD subjects (18.18%), and these subjects had lower weight-for-age z-score [-4.48 (0.33) vs. -2.03 (1.34), $P = 0.037$], lower baseline sodium levels [122 (0.00) vs. 128.31 (2.06), $P = 0.001$] and higher FEUA [32.78(3.19) vs 14.66(5.11), $P = 0.000$]. The utility of other biomarkers (delta NT pro-BNP, copeptin/urine sodium and serum uric acid) in this diagnostic algorithm could not be established.
Conclusion
Our study demonstrates the role of delta copeptin as a potential diagnostic biomarker in the evaluation of SIAD vs CSW, although its validity needs to be ascertained in larger studies.

Background
Patients with acromegaly have an unmet need for therapies with a lower treatment burden that do not require healthcare-professional administration. CAm^{2}029 utilises FluidCrystal® technology and provides a long-acting octreotide subcutaneous depot, self-administered via an autoinjector pen. ACROINNOVA 1 (NCT04076462) was a Phase 3, 24-week, randomised, double-blind trial of CAm^{2}029 in patients who are biochemically controlled (insulin-like growth factor-I [IGF-I] $\leq$ upper limit of normal [ULN] on standard-of-care [SoC] somatostatin receptor ligands at baseline [octreotide long-acting repeatable/lanreotide Autogel]). The primary endpoint was met, demonstrating superior biochemical control with CAm^{2}029 vs placebo. Long-term safety, efficacy and patient-reported outcomes (PROs) with CAm^{2}029 were further evaluated in ACROINNOVA 2 (NCT04125836), a 52-week, open-label Phase 3 trial.
Methods
Patients enrolled into ACROINNOVA 2 directly or after completing ACROINNOVA 1. Directly enrolled patients had IGF-I $\leq 2\times$ULN on SoC. Patients received CAm^{2}029 20 mg every 4 weeks (± 1 week) for 52 weeks (ACROINNOVA 1 prior-placebo: 28 weeks). The primary endpoint characterised safety. PROs included Acromegaly Quality of Life Questionnaire (AcroQoL), Treatment Satisfaction Questionnaire for Medication (TSQM) and severity of signs and symptoms over time (assessed using Acromegaly Index of Severity [AIS]). Data are shown for the overall population for the core 52 weeks.
Results
Of 135 patients enrolled (directly enrolled, $n = 81$; prior-placebo; $n = 18$, prior-CAm^{2}029, $n = 36$), 127 completed treatment. PROs and symptom burden continuously improved from baseline to week 52; results also indicated improvement from week 24 to 52 (Table). CAm^{2}029 was well tolerated, with no new safety signals identified.
Conclusions
Long-term treatment with CAm^{2}029 reduced the symptom burden of patients over 52 weeks, providing continuous improvements in QoL and treatment satisfaction scores vs SoC baseline. ACROINNOVA 2 demonstrates the combined patient benefits of convenient administration, improved QoL, treatment satisfaction and symptom control provided by CAm^{2}029.

JOINT3912

Metformin administration improves treatment response in non-diabetic patients with acromegaly

Maria Tichomirowa[1] & Marily Theodoropoulou[2]
[1]Centre Hospitalier du Nord, Endocrinology, Ettelbrück, Luxembourg; [2]LMU Munich, LMU University Hospital, Department of Medicine IV, Munich, Germany

background
Acromegaly, a condition caused by excess growth hormone (GH) secretion, often requires lifelong pharmacological treatment. Current therapies, including somatostatin receptor ligands (SRLs) and GH receptor antagonists (pegvisomant), are associated with high costs and accessibility challenges. Metformin, a widely used antidiabetic drug, was suggested to have potential benefits in endocrine disorders.

Objective
To evaluate metformin as an adjunctive therapy in non-diabetic patients with acromegaly.
Methods
we analyzed a case series of four male patients with acromegaly treated with SRL ($n = 4$) and/or pegvisomant ($n = 2$). Metformin (500mg-850mg) was added to their existing treatment regimens, and we monitored biochemical response (insulin-like growth factor I; IGF-I), glycemic control (HbA1C), and treatment costs for 3-6 months. Additionally, we assessed *in vitro* the action of metformin on pituitary GH, using a rat Gh promoter reporter vector and determining GH secretion from human GH-secreting pituitary tumors in primary cell culture ($n = 11$).
Results
All four patients were previously treated with SRLs (octreotide LAR or lanreotide) and two received in addition pegvisomant. Addition of metformin reduced IGF-I in all patients, and enabled dose adjustments of SRLs and pegvisomant that resulted in cost savings (EUR/month 482.80 ± 289.88), while maintaining biochemical control. Glycemic control was maintained in all patients. One patient experienced improved gastrointestinal symptoms and weight loss (5kg). *in vitro*, metformin significantly reduced rGh promoter activity, and suppressed GH secretion beyond 20% in 6/11 primary cultures (% suppression 23 ± 2.45). Addition of metformin to octreotide suppressed GH secretion in all cases (% GH suppression 36 ± 6.49). In the *in vitro*-octreotide responder tumors, addition of metformin potentiated octreotide's antisecretory action (% suppression 37 ± 5.18 vs. 25 ± 4.26).
Conclusion
This small case series study suggests that metformin addition to the currently standard SRL/pegvisomant treatment may be useful at improving biochemical control and reducing treatment costs in patients with acromegaly. Our *in vitro* data indicate a direct pituitary action for metformin on GH synthesis. Further large-scale studies are needed to evaluate the efficacy and safety of metformin as adjuvant treatment in non-diabetic patients with acromegaly.

Medical treatment in acromegaly: imunohistochemical features of responder patients

Iulia Florentina Burcea[1], Valeria Nicoleta Nastase[2], Dobre Ramona[1], Dumitriu Roxana Ioana[1], Amalia Raluca Ceausu[2], Anca Maria Cimpean[2], Marius Raica[2] & Catalina Poiana[1]
[1]"Carol Davila" University of Medicine and Pharmacy, "C. I. Parhon" National Institute of Endocrinology, Pituitary and Neuroendocrinology, Bucharest, Romania; [2]"Victor Babes" University of Medicine and Pharmacy, Histology and Angiogenesis Research Center, Timisoara, Romania

Introduction
Identifying acromegaly patients most likely to benefit from long-acting somatostatin receptor ligands (SRLs) and/or growth hormone receptor antagonist is important, as these are the primary medical therapies for active disease.
Material and Methods
The retrospective analysis included 38 naive acromegaly patients (without preoperative medical treatment), with active disease following transsphenoidal (TS) surgery, treated with octreotide / lanreotide ($n = 38$) or pasireotide ($n = 9$) and/or pegvisomant ($n = 8$) if uncontrolled under first generation SRLs (fgSRLs). Key immunohistochemical (IHC) markers, including hormone expression, proliferation index (Ki-67), tumor granulation pattern (sparsely/densely, based on cytokeratin granulation), and somatostatin receptor 2 and 5 (SSTR2, SSTR5) status were evaluated.
Results
Mean age at diagnosis was 45 years (±11). Eight patients (21%) also underwent postoperative radiotherapy. All tumors were acidophilic, had positive IHC expression for growth hormone (GH) and pituitary specific transcription factor 1 (PIT-1), with a Ki-67 proliferation index of <3%. Knosp grade >1 was observed in 84.2% of cases, with a maximum tumor diameter at diagnosis of 22.2 mm (± 10.47). The granulation pattern (densely) correlated with the response to fgSRLs ($P < 0.01$). SSTR2 expression did not correlate with the fgSRLs responder status, although densely granulated tumors had higher SSTR2 expression. Also, the patients resistant to fgSRLs expressed higher SSTR5 levels ($P = 0.003$). The response to pasireotide correlated with the sparsely granulated pattern ($P = 0.002$) and SSTR5 expression ($P < 0.0001$). Sparsely granulated tumors expressed greater levels of SSTR5 ($P = 0.002$). No IHC markers were found to correlate with pegvisomant response (sample size limitation may have played a role).
Conclusion
Pituitary neuroendocrine tumor granularity represents a good predictor for the response to first and second generation SRLs in active acromegaly. Besides this, SSTR5 expression is predictive for the response to pasireotide. There are distinct IHC profiles that may help predict response to targeted medical therapy in acromegaly, and treatment should be initiated and individualized based on postoperative IHC features.

Defining the clinical value of MYD88, a component of the inflammasome machinery, as a diagnosis, prognosis and therapeutic tool in brain endocrine cancers

Natalio Leiva-Hidalgo[1,2], Ignacio Gil-Duque[1,2], Miguel E. G-García[1,2], María Ortega-Bellido[1,2], Miguel A. Núñez-Santos[1,2], Juan Solivera[1], Manuel D. Gahete[1,2,3], Antonio C. Fuentes-Fayos[1,2] & Raúl M. Luque[1,2,3]
[1]Maimónides Biomedical Research Institute of Córdoba (IMIBIC) / Reina Sofía University Hospital, Córdoba, Spain; [2]Department of Cell Biology, Physiology, and Immunology, University of Córdoba, Córdoba, Spain; [3]Biomedical Research Networking Center for Physiopathology of Obesity and Nutrition (CIBERobn)), Madrid, Spain

Glioblastoma (GBM) stands as the most prevalent and lethal primary brain endocrine cancer (ECR) due to the late-stage diagnosis and the resistance to gold standard therapy, which results in a low survival rate after diagnosis (8-9 months) and poor prognosis of patients. Consequently, the identification of novel diagnosis/prognosis biomarkers and therapeutic targets becomes critical to improve the clinical management of this devastating endocrine-related cancer. Here, we focus on the study of the inflammasome, a molecular machinery activated by cellular stress and damage which triggers the maturation and release of proinflammatory cytokines, being closely associated to the modulation of immune responses and cell death, as well as with tumor microenvironment (TME), a well-known hallmark of cancer. Specifically, we initially characterized the expression levels of the inflammasome components in a well-characterized cohort of GBM patients ($n = 63$) and compared with non-tumor brain (NTB; $n = 19$) samples by using a validated qPCR array based on microfluidic technology. Our results revealed a profound dysregulation of the expression pattern of the inflammasome machinery in our cohort of GBM samples, which was later validated in different external cohorts using RNA-seq and microarray data. Remarkably, the expression of key inflammasome components, especially *MYD88*, was associated to several clinical parameters of aggressiveness/poor-prognosis (e.g. survival rate, recurrence, EGFR amplification and MGMT methylation status). Of note, MYD88 expression was also found to be associated with diverse pathways of relevance in GBM pathophysiology (e.g. epithelial to mesenchymal transition, hypoxia, angiogenesis or NFkB-signaling). Moreover, the modulation of the expression of *MYD88 (*through transitory silencing by siRNA or pharmacological inhibition) significantly reduced several key tumor functional parameters in GBM cell models *in vitro*, including cell-proliferation, tumorspheres or colonies formation and migration rate. Taken together, this study demonstrates the critical role of inflammasome machinery in GBM pathophysiology, highlighting the importance of *MYD88* alteration as a potential driver of GBM aggressiveness. Consequently, *MYD88* could serve as a novel diagnostic and/or prognostic biomarker, and potential therapeutic target that might be useful to improve the quality of life of GBM patients.

Menstrual health: schoolgirls' knowledge and hygiene practices

Altaf Garbaa[1], Asma Marzouk[1], Hind Bouguerra[2], Leila Ourir[3], Rahma Thabti[1], Leila Jallouli[1], Ahlem Elkefi[1], Farida Friha[1] & Asma Bouaziz[1]
[1]Ben Arous Regional Hospital, Paediatric Department, Ben Arous, Tunisia; [2]Faculty of Medecine of Tunisia, Tunis, Tunisia; [3]Ben Arous School and University Health Centre, Ben Arous, Tunisia

In order to fight against menstrual ignorance, as highlighted by the WHO over the last few years, we carried out a cross-sectional, descriptive and quantitative observational study using anonymous questionnaire. We surveyed schoolgirls' knowledge of puberty and menstrual management. Our study was conducted in

public and private educational institutions (schools and colleges) in the governorate of Ben Arous (**Tunisia**) and included 720 schoolgirls aged 8 to 14 years old. Results figured that 393 girls had already experienced their **first period** with a median age at menarche for these girls of **12.63 years** (minimum age 8 years; maximum age 14 years). Our serie assessed girls' knowledge of the characteristics of menstruation during normal puberty. Schoolgirls' main source of information about menstrual health was family for 443 girls (61.6%), but also Internet in 23.3% ans schoolmates in 15.1%. Outcomes showed that only 474 girls (65%) knew that menstruation occurs following a monthly **cycle**. We also noticed that 252 participants (35%) knew that menstrual cycle becomes mostly **regular** after 2 years of menarche. Similarly, our research uncovered that 246 of our schoolgirls (34%) knew the normal **duration** of menstruation whereas 452 (63%) knew the normal **length** of menstrual cycle. Moreover, In terms of identifying abnormalities, the data revealed that only 343 of the girls surveyed (48%) recognised that the absence of menstruation after 04 years from the onset of puberty should be considered as pathological. Wheareas, only 337 girls (46.8%) recognised secondary amenorrhoea as requiring medical care. As far as menstrual hygiene is concerned, only 169 of all girls included in our study (less than 25%), admitted that the menstrual period required **extra hygiene precautions**. According to our study, 343 of he girls assessed (47.6%) adhere to **changing** their menstrual pads four to six times a day during period in order to maintain adequate hygiene. On the other hand, almost all of the girls we questionned (696 or 96.7%) claimed that their schools **lack the sanitary facilities** they need (or could need) in order to manage their menstrual period. This study revealed deficiencies in the menstrual hygiene knowledge and practices of schoolgirls in Ben Arous. These results highlight the need to integrate appropriate menstrual education and to improve sanitary facilities in schools.

From CRH to the desmopressin era: a comparative study of stimulation tests in cushing's disease

Ekin Yiğit Köroğlu[1], Şefika Burçak Polat[2], Abbas Ali Tam[2], Ahmet Eren Seçen[3], Fatma Dilek Dellal Kahramanca[1], Cevdet Aydin[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism Diseases, Ankara, Türkiye; [2]Ankara Yıldırım Beyazıt University Faculty of Medicine, Endocrinology and Metabolism Diseases, Ankara, Türkiye; [3]Ankara Bilkent City Hospital, Neurosurgery, Ankara, Türkiye

Purpose
CRH-based dynamic tests can be used in the differential diagnosis of ACTH-dependent Cushing's syndrome(CS) and the differentiation of CS from non-neoplastic hypercortisolism. However, after the worldwide cessation of CRH production as of December 2022, desmopressin-mediated dynamic tests are recommended as an alternative. In this study, we aimed to compare the responses of ACTH-secreting pituitary adenomas to desmopressin and CRH stimuli.
Methods
Patients who underwent a CRH or desmopressin-stimulation test for CS between December 2019 and September 2024 and who were histopathologically diagnosed with CD postoperatively were included in the study. Patients' age, sex, screening test results for CS, baseline ACTH and cortisol levels, peak ACTH and cortisol levels during the tests, the test minute at which peak values were reached, and the rates of peak increase in ACTH(%ΔACTH) and cortisol(%ΔCort) after stimulation were recorded.
Results
A total of 30 CD patients were included in the study. Of these, 18 had a CRH-stimulation test, and 12 had a desmopressin-stimulation test. 27 patients were female(90%), and three were male(10%). The mean age was 44.70±14.44 years. The results of the patients' baseline and screening tests for CS are shown in Table 1. The basal and peak ACTH and cortisol levels of the patients during the stimulation tests and the comparison between groups are shown in Table 2. No statistically significant difference was found when comparing the distributions of peak ACTH minutes and peak cortisol minutes of the tests($P = 0.580$ and $P = 0.518$, respectively).
Conclusion
CRH and desmopressin stimulate ACTH and subsequent cortisol secretion to different degrees. Diagnostic criteria for CRH stimulation are well established, whereas this experience is not yet available for desmopressin. However, using similar diagnostic criteria for these two tests seems doubtful regarding diagnostic adequacy. To use the desmopressin stimulation test more effectively, prospective studies with large patient groups should be performed.

Table 1: The results of the patients' baseline and screening tests for Cushing's Syndrome.

Test	n	Value
ACTH(pg/mL)	30	38.42±30.63
Cortisol(μg/dl)	30	20.60(12.50-28.20)
Serum Cortisol after 1 mg DST(μg/dl)	29	14.45±9.67
Serum Cortisol after 2 mg DST(μg/dl)	29	12.14±7.93
24-hours-urinary free cortisol(μg/day)	30	61.20(6.42-939.00)
Late-night salivary cortisol(μg/dl)	23	0.60±0.36
Late-night serum cortisol(μg/dl)	28	16.01±5.12

Table 2: Basal and peak ACTH and cortisol levels of both stimulation tests and comparison between groups.

Parameter	CRH-stimulation	Desmopressin-stimulation	p
Basal ACTH pg/mL(n)	36.13±22.22(18)	42.15±41.99(11)	0.617
Basal Cortisol μg/dl(n)	18.80(12.50-128.20)(18)	21.10(13.10-24.70)(12)	0.692
Peak ACTH pg/mL(n)	159.51±167.73(18)	103.06±115.20(11)	0.336
Peak Cortisol μg/dl(n)	35.05(21.50-43.10)(18)	30.70(19.90-46.50)(12)	0.095
%ΔACTH(n)	340.63±271.44(18)	159.85±175.28(11)	**0.038**

The effect of GNRHA therapy initiation age on final height in girls with central precocious puberty

Agâh Akın[1], Aylin Kılınç Uğurlu[1], Esra Doger[1], Mahmut Camurdan[1] & Aysun Bideci[1]
[1]Gazi University Faculty of Medicine Hospital, Ankara, Türkiye

Introduction
Precocious puberty is defined as puberty onset before 8 years in girls and 9 years in boys. Elevated estradiol accelerates growth but leads to premature epiphyseal closure, potentially resulting in short final height. In central precocious puberty (CPP), gonadotropin-releasing hormone agonists (GnRHa) mitigate psychosocial effects—such as early menarche—and improve final height. However, the effect of hormone initiation time on final height is controversial in the literature.
Aim
This study aims to determine the effect of GnRHa treatment initiation age on final height. We are analyzing CPP patients treated in our clinic from 2000 to 2024. Of the targeted 300 patients, 150 girls have been evaluated. This interim report presents our findings.
Methods
Patients were categorized into four groups based on treatment initiation age (Group 1: ≤7.99 years, $n = 30$; Group 2: 8–8.99 years, $n = 55$; Group 3: 9–9.99 years, $n = 52$; Group 4: ≥10 years, $n = 13$). Parameters were compared using one-way ANOVA and Bonferroni post-hoc tests.
Results

Table Baseline Characteristics and Final Heights of the Four Groups.

	Group 1 ($n = 30$)	Group 2 ($n = 55$)	Group 3 ($n = 52$)	Group 4 ($n = 13$)	All ($n = 150$)	*P* values
Age (years)	7.07±0.63	8.42±0.29	9.43±0.29	10.37±0.38	8.67±1.07	<0.001
HSDS	1.13±1.02	0.92±1.05	0.95±0.90	0.18±1.17	0.91±1.02	0.043
BMI SDS	0.89±1.03	0.86±0.86	0.79±0.79	0.53±1.04	0.81±0.89	0.644
MPH SDS	-0.81±0.95	-0.70±0.96	-0.67±0.84	-0.90±0.91	-0.73±0.91	0.810
BA (years)	8.58±1.23	10.01±0.87	11.05±0.79	11.52±0.62	10.21±1.33	<0.001
PFH SDS	-1.08±1.03	-1.34±0.82	-1.02±0.98	-1.31±1.13	-1.17±0.95	0.321
FH (cm)	162.08± 6.44	160.18± 5.84	159.61± 4.83	156.42± 5.15	160.04± 5.71	0.023Φ
FH SDS	-0.18±1.10	-0.50±1.00	-0.59±0.82	-1.14±0.88	-0.52±0.97	0.024Ψ
FH SDS – MPH SDS*	0.63±0.86	0.20±0.81	0.07±0.77	-0.23±0.51	0.20±0.82	0.003♣

Values are presented as mean ± standard deviation. HSDS: height standard deviation score, BMI: body mass index, SDS: standard deviation score, MPH: mid-parental height, BA: bone age, PFH: predicted final height, FH: final height *This parameter indicates the difference between the FH SDS and the MPH SDS. Φ **Group 1 vs. Group 4** showed a significant difference in final height. Ψ **Group 1 vs. Group 4** showed a significant difference in final height. ♣ Significant differences were found for **Group 1 vs. Group 3** and **Group 1 vs. Group 4**.

Conclusion
Earlier treatment led to significantly greater final height and superior FH SDS and FH SDS–MPH SDS values. These findings emphasize the importance of early diagnosis and intervention. Once finalized, our study will contribute valuable data to the literature.

A rare cause of isolated hypogonadotrophic hypogonadism: spry4 gene mutation

Ganimet Öner[1] & Microgen Genetic Diseases Diagnostic Center[2]
[1]Tekirdağ Dr. İsmail Fehmi Cumalıoğlu City Hospital, Department of Pediatric Endocrinology, Tekirdag, Türkiye; [2]Microgen Genetic Diseases Diagnostic Center, Ankara, Türkiye

Introduction
Congenital hypogonadotrophic hypogonadism (CHH) is a rare condition with heterogeneous clinical findings resulting from inadequate secretion of normal pulsatile gonadotropin-releasing hormone (GnRH). More than 50 genes have been reported to cause delayed puberty or infertility. Isolated HH/Kallman syndrome cases reported with SPRY4 gene mutation are quite rare in the literature. Here, a case of short stature complaint and heterozygous variant detected in SPRY4 gene is presented.
Case Presentation
A 14.3-year-old male patient applied to the pediatric endocrinology clinic with a complaint of short stature. The patient, who was born at term with a birth weight of 3400 grams, had hypospadias surgery at the age of 7. The patient's neuromotor developmental stages were normal and there was a history of distant consanguinity between the parents. In his physical examination, body weight: 54 kg (-0.42 SDS), height: 150 cm (-2.23 SDS), bone age: 12.7-year-old; testicular volumes 2ml/2ml, penis length: 3.5 cm ($<$10p), coronal hypospadias, pubis stage 2, no axillary hair. The patient, whose basal FSH and LH values were low, underwent LHRH stimulation test and was observed to have pih FSH: 2.51 mIU/mL, peak LH: 0.58 mIU/mL T. testosterone: $<$0.025 ng/mL. The patient's other anterior pituitary hormone levels were within normal range, Inhibin B: 87.1 pg/mL (169-216), IGF1: 121 ng/mL (177-507), IGFBP3: 3.30 mg/l (3.5-10). The patient had no findings of synkinesis and anosmia, and bilateral sensorineural hearing loss was detected in the hearing test. Renal ultrasonography showed double collecting systems in both kidneys, and pituitary MRI showed partially empty sella. Lumbar BMD Z score (corrected for height): -1.95. Karyotype: 46, XY, and WES analysis revealed c.203G$>$A heterozygous variant in the SPRY4 gene. It was found to be compatible with hypogonadotropic hypogonadism with/without anosmia 17 (OMIM: 615266). The patient was started on physiological induction hormone replacement therapy with hCG + FSH protocol.
Conclusion
SPRY4 gene, which encodes a member of SPRY family, is located in 5q31.3 location region. In addition to being in the FGF8 synexpression group, it is also an inhibitor of the RAS-MAPK pathway. Hypogonadotrophic hypogonadism (with/without anosmia), craniofacial defects, dental anomalies, hearing disorders, bone mineral disorders have been reported in this rare SPRY4 gene mutations.

A scoping review to explore eating behaviour and psychological mechanisms associated with obesity in patients with craniopharyngioma

Danielle Eddy[1], Rebecca Elsworth[2], Toby Candler[1,2], Nimra Naeem[2], Sophie Szymkowiak[2], Rachel Perry[2], Blandine Gatta-Cherifi[3], Elizabeth Crowne[1] & Elanor Hinton[2]
[1]Bristol Royal Hospital for Children, University Hospitals Bristol and Weston Foundation Trust, UK, Bristol, United Kingdom; [2]NIHR Bristol Biomedical Research Centre, Diet and Physical Activity theme, University of Bristol, Bristol, United Kingdom; [3]Endocrinology department, CHU of Bordeaux, Bordeaux, France; Neurocentre Magendie, University of Bordeaux, Bordeaux, France

Introduction
Craniopharyngiomas are low-grade suprasellar intracranial tumours commonly associated with obesity. This scoping review explored the potential impact of hyperphagic eating behaviour on the development of obesity in craniopharyngioma patients and to help identify areas for future intervention.
Methods
PRISMA-ScR and JBI methodology was followed. Five databases and two trial registries were searched. All published studies with all study designs were included for both adult onset and childhood craniopharyngioma, including those with or without obesity. The following categories were also included if they demonstrated their impact on eating behaviours: neuroimaging, endocrine response, energy expenditure, sleep, and neuropsychology.
Results
Evidence surrounding eating behaviours in craniopharyngioma patients was sparse with only 18 of the 54 included papers using validated eating behaviour assessments. Eating behaviour was included as a primary outcome (n = 7), secondary outcome (n = 12), or commented on without formal measurement (n = 35). Few studies included patients with adult-onset craniopharyngioma (n = 8), or compared patients with craniopharyngioma with and without obesity (n = 2), and no papers were identified assessing eating behaviours as an intervention for craniopharyngioma-related obesity. Six papers identified more pathological eating behaviour in the craniopharyngioma population whilst two papers found evidence to the contrary. Twelve papers commented on the impact of GLP1 analogues on eating behaviour, demonstrating limited impact on eating behaviours but long-term data on this is lacking. Four case-control studies examined endocrine response and eating behaviours, demonstrating a possible connection between salvia oxytocin levels, fasting ghrelin and adverse eating behaviours in those with craniopharyngioma associated obesity, albeit not consistently. Four studies identified a decrease in resting energy expenditure or basal metabolic rate in those with craniopharyngioma, whilst two further papers reported no difference. Structural imaging studies have correlated increased adverse eating behaviours with extensive intracranial lesions. A variable neural response was noted in craniopharyngioma such as an increase in the activation of the insula and cerebellum when viewing high calorific food. No studies commented on sleep.
Discussion
The quality of evidence on eating behaviours in those with craniopharyngioma and their impact on obesity is poor with mixed findings. Further understanding of eating behaviour following craniopharyngioma is needed, through longer-term research using validated measures. Clinical practice may benefit from exploration of eating behaviour to enhance patient-centred care by informing treatments tailored to patient needs.

An assesment of data completeness in GloBE-Reg, an international registry for studying saftey & effectiveness of novel therapies

Jessica Anderson[1], Malika Alimussina[1,2], Jillian Bryce[1], Minglu Chen[1], Sanhita Koley[1], Suet Ching Chen[1,2] & Faisal Ahmed[1,2]
[1]Office for Rare Conditions, University of Glasgow, Glasgow, United Kingdom; [2]Developmental Endocrinology Research Group, Royal Hospital for Children, Glasgow, United Kingdom

Introduction
The completeness of data within a registry can be directly linked to the quality and reliability of data within a registry and this can directly impact the accuracy of research findings generated from data within that registry. The project focus is to evaluate the completeness of the dataset within the GloBE-Reg registry (https://globe-reg.net/).
Methods
Core data variables were categorised into 'mandatory' (n = 15), and 'non-mandatory' fields (n = 12). Completeness was assessed as a median score of completeness per patient and an overall median percentage completeness for that category. To accurately identify whether or not a variable had been completed, any field left blank or 'unknown' was taken as incomplete.
Results
The analysis examined 2,435 cases that were enrolled in GloBE-Reg registry between October 2022 and December 2024. These cases were from 28 centres in 18 countries with a median number of cases per centre of 28 (10th and 90th centile, 5, 145). All core data fields that were mandatory had a median completeness of 100% (100,100). When the completeness rate for non-mandatory data were categorised, of the 12 non-mandatory fields, 7 (58%) had a completion rate of $>$ 75% with a median completeness of 100% (0,100) and the remaining 5 (42%) had a completion rate of $<$25% with a median completeness of 0% (0,100). The fields which fell into the highest quartile were, Patient follow-up status, Country of birth, Country of usual residence, Data shared for research purposes, Participation in other registries, Name of other registries and registry ID(s). The fields which fell into the lowest quartile were, Can be contacted for patient reported outcomes (PRO), Consent for newsletters, Biobank sample availability, Biobank details,

Biobank patient ID. Of the 28 centres, 26 (92%) achieved a median completeness of 100% (0,100) for the non-mandatory data. The median number of cases at these 26 centres was 28 (5, 147). The remaining 2 centres had a median completeness of 50% (0,100), with 34 and 20 cases in these two centres. There was no association between the number of cases and percentage completeness at the centre.
Conclusions
Despite some variability there is generally a high level of completeness of mandatory and non-mandatory fields within GloBE-Reg core data. Future analysis will extend to all variables in the minimum data set within the registry, to provide a comprehensive assessment of registry completeness.

Case series and review of the literature on the surgical management of hypophysitis: the endocrine outcome seems to be worsened by surgery

Miquel Léa[1], Testud Benoit[2], Nicolas Sahakian[3], Cecilia Piazzola[3], Frederique Albarel[3], Thomas Cuny[3], Thierry Brue[3], Henri Dufour[4], Frederic Castinetti[3] & Thomas Graillon[4]
[1]Service de médecine interne et immunologie clinique, Hôpital de La Conception, Assistance Publique Hôpitaux de Marseille (AP-HM), 13, Marseille, France; [2]Aix Marseille Université, Service de radiologie, Hôpital de la Conception, Assistance Publique Hôpitaux de Marseille (AP-HM), 13, Marseille, France; [3]Aix Marseille Université, MMG, INSERM U125, Marmara Institute, Assistance Publique Hôpitaux de Marseille (AP-HM), Hôpital de la Conception, CRMR HYPO, 13, Marseille, France; [4]Aix Marseille Université, Service de neurochirurgie, Hôpital de La Timone, Assistance Publique-Hôpitaux de Marseille (AP-HM), 13, Marseille, France

Aims
Hypophysitis is an inflammation of the pituitary gland or stalk, lacking standardized diagnostic and treatment guidelines. This study aims to explore the role of surgery in the diagnosis and treatment of hypophysitis.
Patient and Methods
We conducted a monocentric retrospective observational study in a university tertiary hospital. Patients over 15 years of age diagnosed with hypophysitis thanks to histological documentation between January, 1st, 1994 and October, 31st, 2023 were included. A literature review was also performed on cases involving surgical and medical management, collecting data on characteristics, endocrine function, surgery, and complications.
Results
Nine patients were included in our cohort, with surgery primarily performed due to visual disturbances (75%). Almost half were initially suspected of having an pituitary adenoma. All patients recovered their visual function after surgery. The literature review regarding surgical management covered 289 operated patients from 21 articles, among which 204 had partial or complete surgical resection.

	Observation $n = 263$		Glucocorticoids $n = 137$		Resection $n = 219$		p
New deficiency AVP-D	0/159	0%	0/94	0%	16/108	14.8%	**<0.0001[BC]**
Corticotroph deficiency	10/100	10%	0/94	0%	14/141	9.9%	**0.0065[AB]**
Thyrotroph deficiency	4/100	4%	0/94	0%	12/108	11.1%	**0.0016[B]**
Panhypopiutarism	0/100	0%	0/94	0%	9/86	10.4%	**<0.0001[BC]**
≥ 1 deficiency	21/151	13.9%	2/94	2.1%	52/211	24.6%	**<0.0001[ABC]**
Recovery of deficiency Gonadotroph deficiency	9/152	5.9%	17/90	18.9%	10/152	6.6%	**0.0012[AB]**
≥ 1 deficiency	38/204	18.6%	37/116	31.9%	29/219	13.2%	**0.0002[AB]**

[A]$P < 0.05$ between observation and glucocorticoids [B]$P < 0.05$ between glucocorticoids and resection [C]$P < 0.05$ between observation and resection.

Endocrine impairment was observed in 66.5% patients. Forty percent underwent surgery due to a misdiagnosis of adenoma, and 40% for visual impairment. After surgery, 20% developed new endocrine deficiency, while 13% showed hormonal improvement. Surgery resulted in visual improvement in about 80% cases. Non-endocrine complications remains rare but could be severe (5%). Neuropathology was contributive in 98.3% cases. The literature review of all management covered 661 patients. Glucocorticoids prevent the occurrence of new deficiency (2.1%) compared with surgery (25%) or observation alone (14%) ($P < 0.001$). Glucocorticoids improve endocrine function and leading to the recovery of at least one deficiency in 32% cases, better than surgery (13.2%) or observation alone (19%) ($P = 0.002$).
Conclusion
Surgical management in hypophysitis has clear diagnostic value and is part of the therapeutic armamentarium. It should be discussed as a first-line treatment for visual impairment. The risk of worsening endocrine function should be balance with the value of surgery when indicated.

"Long-term hormonal and clinical outcomes in empty sella syndrome: a retrospective cohort analysis"

Stylianos Kopanos[1] & Joachim Feldkamp[1]
[1]Klinikum Bielefeld, Medical School and University Medical Centre East Westphalia-Lippe Bielefeld University, Academic Department of Internal Medicine, Endocrinology, Diabetes and Infectiology, Bielefeld, Germany

Introduction
In most cases, empty sella is an incidental neuroradiological finding associated with varying degrees of pituitary gland flattening, often without clinical significance. However, empty sella syndrome (ESS) involves pituitary hormonal dysfunction, typically hypopituitarism, presenting with heterogeneous clinical manifestations and hormonal alterations that can occasionally be severe. Significant variability in data and underestimation of findings have left much of this condition underexplored. This study evaluates pituitary function in patients with ESS over an extended follow-up period, providing insights into its pathogenesis and management.
Design
A single-centre, retrospective cohort study conducted from 2003 to 2024, including patients from our endocrinology outpatient clinic with neuroradiologically confirmed ES and comprehensive hormonal assessments.
Methods
Hormonal (including basal and dynamic stimulation tests), biochemical, clinical, and neuroradiological data were analyzed at diagnosis and follow-up (minimum of three months).
Results
A total of 101 patients (77% female, mean age 54.5 $\pm$ 15 years) were included. ESS was categorized functionally as partial (63.4%), total (6.9%), or without pituitary deficiency (29.7%). Hypopituitarism was observed in 66.3%, with hypogonadism (5.9%), secondary adrenal insufficiency (30.7%), growth hormone deficiency (3.9%), hypothyroidism (3%), diabetes insipidus (4%), hyperprolactinemia (12.9%), and multiple deficiencies (5.9%). Post hoc pairwise analysis revealed that partial ES was associated with a higher likelihood of pituitary insufficiency compared to total ES in both females ($P = 0.0030$) and males ($P = 0.0226$). Among females, total ES showed a significant association with pituitary deficiency absence compared to partial ES ($P = 0.0344$). Multinomial regression indicated men had a lower but marginally non-significant odds of secondary adrenal insufficiency ($P = 0.052$), while women exhibited a greater likelihood of hypoadrenalism compared to hypogonadism, diabetes insipidus, or hyperprolactinemia. MRI findings were marginally significant for hypogonadism ($P = 0.042$) but not for other hormonal alterations. A significant association was observed between MRI findings and PES type ($P = 0.047$).
Conclusions
This cohort study identifies novel epidemiological features of ES, revealing that nearly two-thirds develop hypopituitarism and over 30% experience secondary adrenal insufficiency. These findings emphasize the necessity for further research into its pathogenesis, tailored management approaches, and vigilant monitoring for early identification and treatment of hormonal deficiencies.

Clinical manifestations and health care utilisation in septo-optic dysplasia, with particular focus on overweight and obesity

David Cullingford[1,2,3], Mary Abraham[1,2,3], Aris Siafarikas[1,2,3], Marie Blackmore[2], Jenny Downs[2,4] & Catherine Choong[1,2,3]
[1]Perth Children's Hospital, Endocrinology and Diabetes, Perth, Australia; [2]The Kids Research Institute Australia, The Centre for Child Health Research, Perth, Australia; [3]University of Western Australia, Perth, Australia; [4]Curtin University, Perth, Australia

Purpose
To describe the clinical phenotype, and burden of health care utilisation in children with septo-optic dysplasia (SOD).
Methods
A single-centre retrospective chart review of patients with SOD seen at a single tertiary centre between 2003 and 2023 was performed. Data were obtained from the clinical record, electronic patient administration system and medical imaging reports, with comparison to local paediatric population data reported by the Australian Bureau of Statistics. An elevated BMI was defined as >1 SDS, and obesity as >1.65. Health care utilisation was assessed by reporting the number of medical and allied health specialties involved, and annual frequency of inpatient, outpatient and emergency department presentations.
Results
Eighty-one children were enrolled (median age 11.6 years, 32 females), 62/81 with bilateral optic nerve hypoplasia. Of 71 children with pituitary and anthropometric data, 41 had hypopituitarism and 31 had an elevated BMI. 37/51 children with pituitary structural defects had hypopituitarism compared to 3/20 without ($P < 0.001$). Children with SOD had higher rates of elevated BMI than the general population (42.5% vs 26.2%, $P = 0.001$) and obesity was more prevalent in those with (33%) and without (24.1%) hormonal deficiencies than the general population (6%, $P < 0.001$). Children with BMI elevation had greater median height SDS scores than those with a normal BMI (0.45 vs -0.78, $P = 0.001$). This was seen in those with and without hypopituitarism, but not demonstrated in those with GH deficiency ($P = 0.103$). Children with hypopituitarism who had an elevated BMI, developed this at a younger age than those without hypopituitarism (median 2.4 years [interquartile range 2.0-5.0] vs 5.9 years [4.1-10.5], $P = 0.038$). 12/31 with elevated BMI and 6/19 with obesity met criteria for these at 2 years of age. Approximately two thirds (55/81) were diagnosed in infancy. The median age at diagnosis of first endocrinopathy was 0.6 years (0.2-3.8). The median number of medical and allied health specialties seen was 9, with 70/81 seeing 5 or more specialties. Children with hypopituitarism had more frequent emergency department presentation, inpatient admission, and outpatient appointments than those without pituitary dysfunction.
Main Conclusions
SOD is a complex multisystem disorder. Regarding BMI elevation, although those with hormonal deficiencies have greater prevalence and develop BMI elevation earlier, prevalence is higher in children with SOD irrespective of pituitary function. The high rates of healthcare attendance in multiple specialties support the importance of treatment in a multidisciplinary clinic to ensure comprehensive care and minimise burden on families.

Clinicopathological characteristics associated with the prognosis of recurrent gonadotroph tumors

Chrysi Kaparounaki[1], Alexandre Vasiljevic[1,2], Emmanuel Jouanneau[1,2], Camille Sergeant[1], Gérald Raverot[1,2] & Mirela-Diana Ilie[2,3]
[1]Reference Center for Rare Pituitary Diseases HYPO, "Groupement Hospitalier Est" Hospices Civils de Lyon, Bron, France; [2]Inserm U1052, CNRS UMR5286, Claude Bernard Lyon 1 University, Cancer Research Center of Lyon, Lyon, France; [3]"C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania

Background
Although gonadotroph tumor regrowth is frequent after pituitary surgery, the systematic use of adjuvant radiotherapy is limited by its long-term complications. In this context, it is important to predict which tumors are most likely to regrow after surgery, and especially, which tumors are most likely to regrow rapidly, and thus which patients might benefit the most from adjuvant radiotherapy vs active surveillance. Clinicopathological characteristics associated with the prognosis of radiotherapy-naïve, recurrent pituitary tumors are currently unknown.
Methods
Here, we performed a longitudinal, observational, retrospective, monocentric cohort study, with the aim of analyzing the clinicopathological characteristics associated with the prognosis of recurrent, radiotherapy-naïve gonadotroph tumors, specifically with the progression-free survival after a second pituitary surgery.
Results
Forty-four patients with recurrent gonadotroph tumors met the inclusion criteria. Ten of these patients had received adjuvant radiotherapy after the second surgery and were excluded from the study cohort. Of note, none of these 10 patients with adjuvant radiotherapy after the second surgery has progressed during the available follow-up ($P = 0.009$). In addition, we found that the Ki67 index of radiotherapy-naïve, recurrent gonadotroph tumors was the only parameter statistically associated with the progression-free survival after the second surgery, $P = 0.02$. Specifically, radiotherapy-naïve gonadotroph tumors with a positive Ki67 index had lower progression-free survival after the second surgery (median 31 months) compared to radiotherapy-naïve gonadotroph tumors with a negative Ki67 index (median 75 months).
Conclusion
Our study confirms the good efficacy of adjuvant radiotherapy for gonadotroph tumors. In addition, our study pinpoints that the Ki67 index could be used to guide the management strategy for recurrent gonadotroph tumors that are still radiotherapy-naïve by the time of the second pituitary surgery. Specifically, a positive Ki67 index should tilt the balance towards adjuvant radiotherapy instead of active surveillance.

Glucagon stimulation test and insulin tolerance test provide equally strong stimulus for growth hormone and cortisol secretion: a cross-over study

Krzysztof Lewandowski[1], Wojciech Horzelski[2], Paulina Lewandowska[3] & Joanna Kawalec[4]
[1]Faculty of Medicine - Collegium Medicum, Mazovian University of Plock, Plock, Poland; [2]The University of Lodz, Faculty of Mathematics and Computer Science, Lodz, Poland; [3]The Medical University of Warsaw, Faculty of Medicine, Warsaw, Poland; [4]"Polish Mother's" Memorial Hospital Research Institute, Department of Endocrinology & Metabolic Diseases, Lodz, Poland

Background
Insulin Tolerance Test (ITT) and Glucagon Stimulation Test (GST) constitute two most commonly used tests in assessment of anterior pituitary function in terms of both growth hormone (GH) and cortisol secretion. We compared concentrations of glucose, cortisol and GH during ITT and GST in 19 subjects (five males), mean age 33.8 years (range 19-60), mean BMI 27.8 kg/m^2 (range 16.5-47.6). Patients were investigated for amenorrhoea ($n = 8$), had history of pituitary macro- ($n = 2$), or microadenomas ($n = 5$), isolated diabetes insipidus ($n = 1$), iatrogenic glucocorticoid-induced adrenal suppression ($n = 1$), hypopituitarism after congenital CMV infection ($n = 1$), or history of cranial irradiation (astrocytoma), $n = 1$. Both Insulin Tolerance Test and standard fixed-dose GST (0, 30, 60, 90, 120, 150 and 180 minutes) were performed in all subjects.
Results
As expected, minimal glucose concentrations were lower during ITT (29.7 ± 7.67 mg/dl, at 30 minutes of ITT) than during GST (73.6 ± 9.67 mg/dl, at 180 minutes of GST, $P < 0.001$) though glucose fluctuations (ΔGlucose) were higher during GST (77.8 ± 22.6 mg/dl vs 56.7 ± 10.9 mg/dl, $P = 0.002$, for GST and ITT, respectively). There was, however, no difference in either cortisol (ΔCortisol 9.28 ± 3.79 µg/dl vs 8.49 ± 3.46 µg/dl, $P = 0.4$), or growth hormone fluctuations during both tests (ΔGH 10.23 ± 10.36 ng/ml vs 10.52 ± 9.67 ng/ml, $P = 1.0$, for GST and ITT, respectively).
Conclusion
Despite the absence of frank hypoglycaemia during GST, in contrast to ITT, both tests lead to similar increments in cortisol and growth hormone in adult individuals. Hence, Glucagon Stimulation Test should not be considered as an "inferior" option in comparison to Insulin Tolerance Test for assessment of an anterior pituitary function.

[1]Medical Faculty, University of Belgrade, Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, University Clinical Center of Serbia, Department of Neuroendocrinology, Belgrade, Serbia; [3]Mother and Child Health Care Institute of Serbia "Dr Vukan Cupic", Belgrade, Serbia; [4]University Children's Clinic, Belgrade, Serbia; [5]Institute of Pathology, Belgrade, Serbia; [6]Clinic for Neurosurgery, University Clinical Center of Serbia, Belgrade, Serbia

Background

Recognizing sellar and parasellar lesions (S&PL) during childhood, adolescence, and transition age can be challenging and is often delayed due to the rarity of these diseases.

Objective

To investigate the clinical characteristics and types of pediatric S&PL:pituitary adenomas (PAs), and nonpituitary lesions (neoplastic, inflammatory).

Methods

A total of 195 patients (11.7%) with PAs diagnosed before the age of 25 were identified from the Department of Neuroendocrinologýs PA database ($n = 1668$) spanning the past 20 years and compared with 47 pediatric patients with nonpituitary S&PL. We analysed gender, age at diagnosis, size and type of S&PL.

Results

A total of 242 patients S&PL were included in the study (189 females,78.1%), with a mean age of 19.6±0.3years (range,3-25). Among these,195 patients had PA, with a mean age of 20.5±0.2years (range,10-25;161 females,82.6%). Of the PA patients,56 (28.7%) were younger than 18 years at the time of diagnosis. Functional PAs were significantly more common ($n = 151$;77.4%) compared to non-functioning PAs ($n = 44$;22.6%). Prolactinomas were the most prevalent type of functional PAs ($n = 133$;68.2%), with 89 microadenomas (86 in females). Thirteen patients (6.2%) had somatotropinomas, most of which were macroadenomas ($n = 12$), with male predominance ($n = 9$). Five patients (2.6%) had corticotropinomas, including three microadenomas (2 in males). Non-functioning PAs accounted for 44 cases (22.6%), with 18 microadenomas (17 in females). Patients with corticotropinomas were younger than those with prolactinomas or non-functioning PAs (17.4±1.4 vs. 20.6± 3.2 and 20.4±3.3years, respectively; $P < 0.05$). Microadenomas ($n = 111$;56.9%) were significantly more prevalent than macroadenomas ($n = 63$;32.3%;$P < 0.05$;tumor size unknown in 21). In conrast,47 patients with nonpituitary S&PL were significantly younger than the PA group (mean age:16.1±0.9 vs. 20.5± 0.2years,$P < 0.001$) and exhibited a male predominance ($n = 28$,59.6%). Craniopharyngiomas were the most common type of nonpituitary lesion ($n = 22$,46.8%), followed by germinomas ($n = 10$,21.3%). Other neoplastic lesions included three xanthogranulomas, one chordoma, one glioma and one granulosa cell tumor ($n = 6$,12.8%). Additionally, histiocytosis X was identified in five patients (10.6%) and hypophysitis was diagnosed in four (8.5%). Among patients with nonpituitary lesions, almost all ($n = 42$,89.4%) underwent surgery, and 22 patients (46.8%) received radiation therapy. Hypopituitarism was common in this group, with 39 patients (83%) diagnosed with multiple pituitary hormone deficiencies (PHD), five (10.6%) with isolated PHD, and 15 (31.9%) with ADH deficiency. Only three patients maintained normal pituitary function (6.4%).

Conclusion

Sellar and parasellar lesions in pediatric patients are rare. Among PAs, functioning tumors, particularly microprolactinomas, are the most common phenotype, with a notable female predominance. Microadenomas are uncommon in adolescent males. Somatotropinomas are predominantly macroadenomas with a male predominance, contrary to corticotropinomas (microadenoma, no sex difference). Patients with nonpituitary S&PL tends to be younger, predominantly male, and more frequently present with hypopituitarism and ADH deficiency compared to those with PAs. Managing these pediatric patients is particularly challenging due to the risk of late-onset complications (endocrine, metabolic, bone, and cardiovascular disorders).

JOINT1485

A Novel autosomal recessive multiple pituitary hormone deficiency and obesity syndrome associated with the SH2B1 gene

Samim Özen[1], Fulya Mete Kalayci[1], Deniz Özalp Kızılay[1], Ayça Aykut[2], Damla Gökşen[1] & Asude Durmaz[2]

[1]Ege University Faculty of Medicine, Division of Pediatric Endocrinology and Diabetes, İzmir, Türkiye; [2]Ege University Faculty of Medicine, Department of Medical Genetics, İzmir, Türkiye

Introduction

The SH2B1 gene encodes an important adaptor protein that is involved in the leptin-melanocortin pathway. Heterozygous variants of SH2B1 have been linked to various conditions, but homozygous variants have not been documented. This report presents a case of a homozygous SH2B1 variant associated with syndromic obesity and multiple pituitary hormone deficiencies. **Case:**A fifteen-year 7-month-old female, presented with the absence of menstrual bleeding despite having started oral contraceptive therapy for primary amenorrhea. She had delayed neuromotor development. Parents were second degree cousins and were both obese. Mother's and father's body mass index (BMI) were 35.9 kg/m^2, 31.5 kg/m^2, respectively. Her target height was 152.5 cm (-1.8 SDS). On physical examination; weight was 63.65 kg (1.1 SDS), height was 147 cm (-2.57 SDS), and BMI was 29.46 kg/m^2 (2.45 SDS). Pubic hair stage was 4 and breast development was Tanner stage 1. The patient had acanthosis nigricans and central obesity, along with a low hairline, short neck, and micrognathia. Cataract, strabismus, amblyopia, myopia, astigmatism, and mild hearing loss were also detected. The WISC-R test indicated mild intellectual disability. Laborotory findings were as follows; TSH: 1.6 mU/l (0.51-4.17), fT4: 0.94 ng/dl (0.98-1.63), FSH: 8.6 mIU/mL (3.5-12.5), LH: 4.59 mIU/mL (2.4-12.6), estradiol (E2): <25 pg/mL (30.9-90.4), AMH: 0.26 ng/mL (1.9-8.3), ACTH: 28.1 ng/l (7.2-63.3), cortisol: 15.8 mg/dl (4.82-19.5), IGF-1: 147 mg/l (151-485), prolactin (PRL): 2.75 mg/l (4.79-23.3). In the LHRH test performed due to delayed puberty, peak FSH was 29.6 mIU/mL, LH 82.1 mIU/mL, with E2 <25 pg/mL. Puberty was delayed, and hormone levels indicated central hypothyroidism, hypoprolactinemia, and hypothalamic hypogonadotropic hypogonadism. Abdominal and pelvic ultrasound revealed grade 2 hepatosteatosis and a hypoplastic uterus with right ovary 1.8 cc, and left ovary 2.99 cc. Pituitary MRI was normal. Clinical exome panel for syndromic obesity revealed a homozygous c.2083G>A (p.Val695Met) pathogenic variant in *SH2B1* gene. Both parents were heterozygous for the same variant.

Conclusion

The homozygous *SH2B1* variant identified in this patient is associated with a novel syndrome characterized by obesity, short stature, intellectual disability, hearing loss, cataracts, and multiple pituitary hormone deficiencies. These findings have not been reported in heterozygous SH2B1 variants and provide new insights into the gene's role. The SH2B1 gene may be important for defining an autosomal recessive syndrome with these features.

Keywords

Syndromic obesity, hypopituitarism, hypogonadism, SH2B1.

Delayed puberty as the initial presentation of combined oxidative phosphorylation deficiency 55

Mohammad Awad[1,2] & Sarah Ehtisham[3]

[1]Al Jalila Children's Specialty Hospital, Dubai, United Arab Emirates; [2]Al Jalila Children's Specialty Hospital, Pediatric Endocrinology, Dubai, United Arab Emirates; [2]Al Jalila Children's Specialty Hospital, Pediatric Endocrinology, Dubai, United Arab Emirates

Background

Combined Oxidative Phosphorylation Deficiency 55 (COXPD55) is a rare mitochondrial disorder caused by mutations in the POLRMT gene, which encodes the mitochondrial RNA polymerase critical for mitochondrial gene expression and genome replication.

Case Presentation

A 17.3-year-old female presented with primary amenorrhea and a reportedly absent uterus. Anthropometric assessment indicated a height SDS of -5.31, weight SDS of -4.67, BMI SDS of -0.93, occipitofrontal circumference of 48 cm (-6.86 SD), and sitting height of 65.9 cm (-5.64 SD). She also exhibited delayed bone age (10.99 years, SDS -6.5) and minimal pubertal development (Tanner stage B2). Notable phenotypic features included microcephaly, alacrima, corneal scarring, learning difficulties, scant scalp hair, low posterior hairline, hypotelorism, hyperconvex nails, and a high-arched palate with a narrow jaw.

Endocrine Evaluation

The patient exhibited hypogonadotropic hypogonadism with low FSH (0.4 mIU/mL; Ref: 0.9-9.1) and LH (<0.3 mIU/mL; Ref: 0.4 - 25) and profoundly reduced estradiol (<18 pmol/l; Ref: 22.3 - 205.2). Thyroid function tests and cortisol levels were within normal limits. IGF-1 and IGFBP-3 were within

reference ranges, at 303.0 ng/mL (Ref: 156 - 479) and 4,207 ng/mL (Ref: 3,705 - 8,065), respectively. DHEA-Sulfate was 7.79 umol/l (Ref: 1.77 - 9.99). Anti-Müllerian hormone was diminished at 0.45 ng/mL. Magnetic resonance imaging initially suggested an absent uterus, but ultrasound confirmed an infantile uterus.
Genetic Analysis
Whole exome sequencing identified a pathogenic POLRMT mutation (c.910C > T, p.Gln304Ter, NM_005035.4). The patient was heterozygous, with maternal heterozygosity and negative paternal testing. Inheritance involved both autosomal recessive and dominant patterns, with the mutation classified as likely pathogenic.
Discussion
Prior COXPD55 cases highlight developmental delay, renal dysfunction, and neuromuscular abnormalities. Bowden *et al*. (2013) described renal Fanconi syndrome with developmental delay and hypotonia, while Olahova *et al*. (2021) reported heterogeneous presentations among 8 patients, including short stature, developmental delay, and eye abnormalities, suggesting the phenotypic variability of COXPD55. However, delayed puberty as the primary clinical manifestation has not been previously reported.
Conclusion
This case is the first to document COXPD55 presenting primarily with delayed puberty and hypogonadotropic hypogonadism, expanding the clinical spectrum of the disorder. The diverse clinical manifestations underscore the importance of early genetic evaluation to facilitate accurate diagnosis and individualized therapeutic interventions.

Background
Paltusotine is a non-peptide, highly selective SST2 receptor agonist in development as a once-daily, oral treatment for acromegaly and carcinoid syndrome. This long-term analysis of safety and efficacy of paltusotine includes patients with acromegaly who have been followed for up to approximately 4 years.
Methods
ACROBAT Advance is an ongoing, single-arm, open-label extension study of paltusotine in patients with acromegaly. Enrolled patients had completed either ACROBAT Edge or Evolve phase 2 parent studies. In Edge, at enrollment all patients were candidates for combination drug therapy: either sub-optimally controlled on an injected SRL (octreotide or lanreotide) alone or in combination with cabergoline, or required combination therapy or pasireotide to achieve normal IGF-I levels. In Evolve, enrolled patients had normal IGF-I levels on injected SRL monotherapy. When the Advance study was initiated, paltusotine was formulated as a capsule (dose range, 10-40 mg); all patients were switched to the tablet formulation (dose range, 20-60 mg) during year 3 of the study. Adjunctive treatment with cabergoline or pegvisomant was allowed in patients who did not attain normal IGF-I levels on the maximum dose of paltusotine.
Results
Forty-three patients were enrolled in Advance (Edge, $n = 32$; Evolve, $n = 11$; 88% of eligible patients): at baseline, mean ± SD age 53.0 ± 11.6 years, 56% female, 86% previous pituitary surgery, and no prior radiotherapy. IGF-I control in Edge and Evolve subsets remained stable at parent study baseline values. For all patients pooled, median (IQR) IGF-I levels were 1.15× ULN (0.84-1.46; $n = 43$) at parent study baseline; in Advance, 1.14× ULN (0.89-1.29; $n = 40$), 1.07× ULN (0.91-1.30; $n = 37$), 1.02× ULN (0.83-1.21; $n = 33$), and 1.01× ULN (0.83-1.13; $n = 20$) at months 12, 24, 36, and 48, respectively. Acromegaly symptoms, as measured using Acromegaly Symptom Diary (score range, 0-70; higher values indicate greater symptom burden), were stably controlled: median (IQR) score of 8.6 (3.6-20.1; $n = 21$) at parent study baseline; in Advance, 10.5 (5.0-18.5; $n = 40$), 10.0 (5.0-23.5; $n = 36$), 11.0 (4.0-26.0; $n = 33$), and 10.0 (4.0-18.0; $n = 20$) at months 12, 24, 36, and 48, respectively. Two serious drug-related AEs (cholelithiasis) were reported. Of the 8 patients who discontinued study, 2 were due to AEs (mild or moderate).
Conclusion
Long-term results (up to ~4 years) show that once-daily oral paltusotine treatment was well tolerated, with stable biochemical and symptom control relative to that observed with injected SRLs.

Background
Increased neuroimaging for different indications and thus prevalence of non-functioning pituitary adenomas (NFPAs) is set to impose a significant burden on patients, practitioners, and amplify costs due to the need for complex and extensive follow-up.
Objective
To determine the risk of surgical intervention and the risk of developing a new endocrinopathy during follow-up in patients with conservatively treated micro-NFPAs.
Methods
We conducted a bibliographical search on PubMed and EMBASE identifying relevant studies. Authors of eligible studies were invited to share individual participant data (IPD). Eligible studies were cohort studies including patients with conservatively treated micro-NFPAs with at least one follow-up MRI. Fourteen studies met the inclusion criteria. Six authors provided IPD ($n = 588$). Data were reanalyzed for verification. In case of discrepancies the original authors were contacted for authentication. Data was extracted using a pre-piloted form.
Results
Risk estimates were reported as number of events per 100 person-years (PYs). Estimates were pooled using the two-step approach. Overall risk of surgery was 0.2/100PYs (95%CI: 0.0 to 0.5; $I^2 = 31\%$). Risk of surgery due to visual impairment was 0.1/100PYs (95%CI: -0.1 to 0.2; $I^2 = 0\%$). Risk of developing a new endocrinopathy was 1.3/100PYs (95%CI: 0.3 to 2.2; $I^2 = 47\%$). We found no difference in risk relative to baseline tumor size (≥6 mm or <6 mm), sex, or age (all P-values > 0.25). Data for classical meta-analysis were available for 7 studies ($n = 1079$) and supported the IPD Results.
Conclusions
Events relevant to patients such as surgery or development of new endocrinopathies rarely occurs in patients with micro-NFPAs and routine follow-up can safely be reduced in the majority of these patients. Current guidelines may need to be revisited regarding this issue.

Giant cell tumour of the bone mimicking pituitary macroadenoma: a case report

Márk Stempler[1], Judit Tőke[1], Bálint Scheich[2], Hajnalka Rajnai[2], Nóra Nyilas[3], Péter Barsi[3], Miklós Garami[4], Gábor Nagy[5], László Sipos[5] & Miklós Tóth[1]
[1]Semmelweis University, Department of Internal Medicine and Oncology, Budapest, Hungary; [2]Semmelweis University, Pathology and Experimental Cancer Research, Budapest, Hungary; [3]Semmelweis University, Neuroradiology, Medical Imaging Centre, Budapest, Hungary; [4]Semmelweis University, Pediatric Center, Budapest, Hungary; [5]Semmelweis University, Neurosurgery and Neurointervention, Budapest, Hungary

Introduction
Giant cell tumour of the bone (GCTB) is a rare tumour that is usually benign but can be locally aggressive. GCTB accounts for about 15–20% of all benign bone tumours and typically arises from the epiphysis of long bones. Surgical removal of GCTBs remains the gold-standard treatment. However, there have been a few reported cases where the tumour originated from the sphenoid bone, and in these instances, total surgical removal is often not feasible due to the proximity of critical anatomical structures. More than a decade ago, denosumab was approved as an alternative treatment for this condition.
Case Report
In May 2018, a 16-year-old female patient presented with severe headache, dizziness, vomiting, double vision and right-sided retrobulbar pain. A pituitary MRI demonstrated a large sellar mass that occupied the pituitary gland and invaded the right cavernous sinus. In June 2018, she underwent a paraseptal, transsphenoidal adenomectomy. However, the histological evaluation revealed only physiological pituitary hyperplasia. In August 2018, she returned with alarming symptoms. Following a thorough endocrine examination, she was diagnosed with severe panhypopituitarism and appropriate hormone replacement therapy was initiated. In September 2018, a follow-up MRI showed significant tumour progression, prompting a second surgical intervention. At that time, the tumour measured 33 x 28 x 51 mm, invaded the right cavernous sinus and elevated the optic chiasm. No visual disturbances were detected during the ophthalmological examination. The histopathological results from this surgery confirmed the presence of GCTB. Subsequently, she began treatment with denosumab. Five months later, a new MRI indicated a 40% regression in tumour size. Denosumab therapy was continued until December 2021, during which stable disease was observed both clinically and radiologically, leading to the discontinuation of the drug. However, in July 2022, a follow-up MRI revealed significant tumour progression and denosumab therapy was reinstated. To date, the patient receives 120 mg of denosumab every four weeks, and there has been no further progression of the tumour.
Conclusion
To our knowledge, this case report presents the longest use of denosumab therapy with efficacy and safety for GCTB in the sellar region. We have not observed any side effects from denosumab throughout the six-year treatment period. However, further research is necessary to determine this thyrapy's optimal long-term dosage and duration and to identify other treatment targets that could provide similar tumour control.

The systemic effects of hormone replacement therapy for central hypoadrenalism in patients affected by hypothalamic-pituitary diseases: a retrospective and longitudinal study

Alessandra Vicari[1,2], Antonella Giampietro[1,2], Pier Paolo Mattogno[1,2], Liverana Lauretti[1,2], Laura De Marinis[1,2], Francesco Doglietto[1,2], Antonio Bianchi[1,2], Sabrina Chiloiro[1,2] & Alfredo Pontecorvi[1,2]
[1]Università Cattolica del Sacro Cuore, Roma, Italy; [2]Policlinico Universitario Agostino Gemelli IRCCS, Roma, Italy

Glucocorticoid replacement therapy in secondary adrenal insufficiency is lifesaving, but the currently available literature reveals that overtreatment can result in long-term effects on bone, cardiovascular and metabolic systems. We conducted a retrospective, observational, longitudinal study at our hypothalamic-pituitary pathology unit on 140 patients who had undergone neurosurgery in the hypothalamic-pituitary region before 2020 for PIT-NETs, craniopharyngiomas, Rathke cleft cyst, chordomas and meningiomas, to verify the effects of glucocorticoid replacement therapy. Exclusion criteria encompassed the utilization of corticosteroids for unrelated indications and prior bariatric surgery. The patients were divided into two groups: group A, consisting of 70 patients with pituitary disease and hypoadrenalism who had been treated with glucocorticoid replacement therapy for at least 3 years, and group B, consisting of 70 patients with pituitary disease but without hypoadrenalism. Lipid metabolism, carbohydrate metabolism, body weight and blood pressure were analyzed at baseline (at diagnosis or immediately before neurosurgery) and after 3 years of therapy. Comparing the two groups, there was no difference in age, carbohydrate metabolism, dyslipidemia and hypertension at baseline. At follow-up, a worsening of glucose metabolism was observed in 45/140 patients, and univariate analysis showed a higher incidence in patients receiving glucocorticoid replacement therapy (64.4%) compared to untreated patients (35.6%) ($P = 0.019$). This result was confirmed by multivariate analysis, which showed an association with glucocorticoid replacement therapy ($P = 0.014$) and with the presence of impaired glucose tolerance ($P = 0.016$) and impaired fasting glucose ($P = 0.04$) at diagnosis. Regarding lipid metabolism, 92/140 patients worsened, of whom 56.5% were on treatment ($P = 0.033$) and 43.5% were not. However, upon multivariate analysis, the only significant data were treatment for dyslipidemia at baseline ($P = 0.001$) and central hypothyroidism ($P = 0.001$). The data on arterial hypertension demonstrated deterioration in 54/140 patients: 30 were undergoing glucocorticoid replacement therapy, while the remaining 24 were not ($P = 0.298$). Multivariate analysis showed a statistically significant association with older age at diagnosis ($P = 0.007$) and with hypertension at baseline ($P = 0.001$). In conclusion, a glucocorticoid replacement therapy that includes a holistic management of the patient, in association with the replacement of other possibly deficient axes, does not have an impact on the risk of developing hypertension and dyslipidemia. Instead, glucocorticoid replacement therapy resulted associated to worsening of glucose metabolism, particularly in patients already predisposed.

Circulating vitamin D levels predict the occurrence of vertebral fractures in patients with cushing's disease

Sabrina Chiloiro[1], Miriam Veleno[1], Ginevra D'Onofrio[1], Antonella Giampietro[1], Amato Infante[1], Elena Ricciardi[1], Diana Broglia[1], Consolato Gulli[1], Pier Paolo Mattogno[1], Quintino Giorgio De Alessandris[1], Liverana Lauretti[1], Alessandro Olivi[1], Laura De Marinis[1], Antonio Bianchi[1], Alfredo Pontecorvi[1] & Francesco Doglietto[1]
[1]Fondazione Policlinico Universitario A. Gemelli, IRCCS, Università Cattolica del Sacro Cuore, Rome, Italy

Context
Skeletal fragility is a clinically relevant complication of Cushing's disease, occurring in 15%-78% of patients. Limited studies are available on predictors of vertebral fractures. Here, we investigated the correlations between occurrence of incidental VFs (i-VFs) and serum V25OH-D concentrations, before and during cholecalciferol supplementation.
Patients and methods
A longitudinal and retrospective study was performed on patients affected by Cushing's disease, treated and untreated with D3 supplementation. The primary objective of the study was to investigate the correlations between the occurrence of VFs and serum V25OH-D concentrations.
Results
Out of 159 patients diagnosed for Cushing's disease at our center, 26 patients were included. At baseline, the median serum V25OH-D level was 21.1 ng/mL (IQR: 17) in the whole study population. Six patients were affected by osteopenia/osteoporosis (23.1%), and 4 patients carried prevalent VFs (15.4%). The median serum V25OH-D concentration was 20.3 (IQR: 27) ng/mL in patients without osteopenia/osteoporosis and was 24.9 (IQR: 15.7) ng/mL in patients with osteopenia/osteoporosis ($P = 0.648$). The median serum V25OH-D concentration was 22.1 (IQR: 16) ng/mL in patients without prevalent VFs and was 11.3 (IQR: 34) ng/mL in patients with prevalent VFs ($P = 0.166$). Eleven patients were treated with D3 supplementation (42.3%). Serum V25OH-D levels at baseline were slightly but not significantly lower in D3 treated vs untreated patients (20.3 IQR: 27.3 vs. 22 IQR: 18 ng/mL; $P = 0.61$). The median D3 weekly dosage was 12500 IU (IQR: 14500), median duration of D3 supplementation was 37 months (IQR: 26). No adverse events related to D3 supplementation were reported by patients or identified from medical records. At last follow-up, seven patients developed incidental VFs (26.9%): three patients were on D3-supplementation (42.9%), and four were not on D3-supplementation (57.1%; $P = 0.665$). Final serum V25OH-D level was lower in patients with i-VFs (28.6 ng/mL, IQR:4.1) as compared to patients without i-VFs (34.2 ng/mL, IQR:9.6; $P = 0.007$). Patients with i-VFs had lower V25OH-D levels before starting D3 supplementation (11.6 ng/mL IQR:10), then patients without i-VFs

(24.9 ng/mL IQR:25.3, $P = 0.003$). I-VFs occurred more frequently in males (57.1%) then in females (42.9%, $P = 0.047$). The logistic regression confirmed the protective role of V25OH-D levels >12 ng/mL before D3-supplementation (OR: 0.07 95%IC:0.01-0.58 $P = 0.05$), of V25OH-D levels >35 ng/mL during follow-up; and the not-protective role of the male gender (OR: 1.5 95%IC:1.1-2.4 $P = 0.008$).
In Conclusion
Our study proved that D3-supplementation should be consider in patients affected by Cushing's disease to reach circulating V25OH-D levels protective for the occurrence of i-VFs.

JOINT2884

Assessing multiple variables following arginine test enhances the diagnosis of vasopressin deficiency

Alessandro Mondin[1], Giulia Bovo[1], Filippo Ceccato[1] & Mattia Barbot[1]
[1]University Hospital of Padua, Endocrinology Unit, Department of Medicine-DIMED, Padua, Italy

Context
A recent head-to-head multicenter trial established the superiority of hypertonic saline-stimulated copeptin in the diagnosis of vasopressin deficiency (AVP-D), with the arginine test presenting suboptimal performance. Nevertheless, the latter is less costly, better tolerated and easier to perform. We tried to enhance its performance by including other parameters on top of copeptin levels.
Methods
We conducted a retrospective analysis of arginine tests performed at our Unit for suspected AVP-D. Clinical, biochemical and radiological findings were collected. Final diagnosis was defined based on a revision of clinical picture, performed tests and follow-up data.
Results
We considered 19 patients, 8 of them presenting a final diagnosis of AVP-D from different causes (42%). Copeptin response to arginine was flattened in AVP-D patients (AUC 4.48 vs 6.97, $P = 0.11$) but, irrespectively of the indexes and thresholds used, it could not provide good discrimination from primary polydipsia (PP). The best performing index was copeptin level at 90 minutes (cut-off 3.45 pmol/l, sensitivity 87.5%, specificity 63.6%, diagnostic accuracy 73.7%, ROC-AUC 0.773). AVP-D patients at the end of the arginine test presented lower urinary osmolarity (UOsm) and higher plasma osmolarity and sodium (Na) levels. The latter was the best predictor of AVP-D (cut-off 141.5 mmol/l, sensitivity 87.5%, specificity 100%, diagnostic accuracy 94.7%, ROC-AUC 0.989). When combining multiple parameters, we were able to obtain perfect discrimination between AVP-D and PP in our cohort. In a multistep approach, a final Na above 142 or below 140 mmol/l identified alone AVP-D and PP respectively, while in case of intermediate values a copeptin peak <4.1 pmol/l or a final UOsm <428 mOsm/kg correctly diagnosed AVP-D (overall diagnostic accuracy 100%). We also obtained via logistic regression formulas to derive a corrected sodium value providing a diagnostic accuracy of 100% (cut-offs: 138.8 mmol/l based on final Na and peak copeptin; 138 mmol/l based on final Na and UOsm).
Discussion
In our cohort, the use of multiple parameters following arginine stimulation could enhance the test performance up to a complete discrimination between AVP-D and PP. Interestingly, this result could be obtained also without copeptin measurement. Our study has nevertheless various limitations, the most important ones being the small sample analysed and the non-use of hypertonic saline-stimulated copeptin. Larger studies with the use of current gold standard test for comparison are needed to evaluate the replicability of our findings.

Cure from acromegaly after long-term medical treatment: may somatostatin receptor ligands drive complete disease disappearance in patients never treated with surgery and/or radiotherapy?

Rosa Pirchio[1], Renata Simona Auriemma[1], Chiara Altieri[1], Antonella Tropiano[1], Claudia Pivonello[2], Roberta Scairati[1], Guendalina Del Vecchio[1], Rosario Pivonello[1] & Annamaria Colao[1]
[1]Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Diabetologia, Andrologia e Nutrizione, Università Federico II di Napoli, Naples, Italy; [2]Dipartimento di Sanità Pubblica, Università Federico II di Napoli, Naples, Italy

Context
Although pituitary surgery is the first therapeutic option for acromegaly, several patients are not eligible for or refuse it. Somatostatin receptor ligands (SRLs) are the treatment of choice in these patients.
Aim
To investigate prevalence and determinants of acromegaly cure in patients treated only with SRLs medical therapy.
Methods
Monocentric retrospective study evaluating 43 acromegaly patients (22 women, 21 men, mean age 66.5±10.8 years) treated with SRLs as first line treatment (mean duration 14.1±7.1 years), never undergone to pituitary surgery or radiotherapy.
Results
Overall, 16 patients (37.2%) experienced tumour disappearance at MRI, of which 6 (37.5%) achieved also biochemical remission (IGF-I level <1xULN), with a successfully withdrawn of SRLs therapy without relapse (cure) after long-term (mean 19 years) SRLs therapy. Patients with tumour disappearance at MRI were older ($P = 0.01$), mainly women ($P = 0.002$), with smaller tumours at diagnosis ($P = 0.04$) as compared to those with tumour persistence. After 1 year-SRLs treatment GH levels were significantly lower ($P = 0.04$) and prevalence of IGF-I normalization (IGF≤1xULN, 77% *vs* 44%, $P = 0.07$) slightly higher in the former as compared to the latter. Considering cured patients, they were all women ($P = 0.07$), with significantly lower levels of random GH ($P = 0.02$) and nadir GH after OGTT ($P = 0.03$) harbouring smaller pituitary tumours ($P = 0.09$) at diagnosis as compared to patients with biochemical persistence of acromegaly. At ROC analysis, at diagnosis random GH < 6.1μg/l had 82.3% sensitivity and 80% specificity (AUC=0.802, $P = 0.03$) to predict acromegaly cure after long-term SRLs. Similarly, at diagnosis nadir GH < 1.93μg/l had 100% sensitivity and 66.7% specificity (AUC=0.888, $P = 0.03$) to predict cure after long-term SRLs. According to the median SRLs duration (13 years), patients administered with SRLs for more than 13 years had a significantly higher prevalence of tumour disappearance at MRI (47.8% *vs* 22.7%, $P = 0.04$) and a slightly higher prevalence of disease cure (21.7% *vs* 4.5%, $P = 0.07$) as compared to those with a shorter therapy length. According to the median age at the evaluation (65 years), patients >65 years had a significantly higher prevalence of tumour disappearance at MRI (47.8% *vs* 22.7%, $P = 0.04$) and a slightly higher prevalence of cure (21.7% *vs* 4.5%, $P = 0.07$) as compared to younger patients.
Conclusions
First line medical therapy is a valid option for several acromegaly patients. Among them, women and older patients with small pituitary tumours and lower levels GH at diagnosis could benefit more of this choice, being able to obtain the tumour disappearance at MRI and even the d cure.

JOINT1376

Clinical profile of patients with hypopituitarism in a tertiary endocrine center in nepal

Ansumali Joshi[1], Srijana Karmacharya[1], Puspa Dahal[1] & Indu Rana[1]
[1]Kathmandu Diabetes and Thyroid Center, Kathmandu, Nepal

Hypopituitarism is an uncommon condition with limited data from Nepal. We retrospectively reviewed data of 36 patients who attended our endocrine center from April 2013 to March 2024. The mean age was 35.88 ± 7.17 years (range 3-69 years). 6 patients were ≤18 years. There were 18 (50%) males and 18 (50%) females. The mean BMI was 25.52 ± 4.76 kg/m^2 (range 14.9 - 33.3). The most common symptom was nausea/vomiting in 14 patients (38.8%) followed by fatigue in 13 patients (36.1%). Visual abnormalities were detected in 12(33.3%) and headache in 12(33.3%) patients. Out of 18 female patients, 15(83.3%) had menstrual disturbances. Secondary amenorrhea was present in 13 patients (72.2%), infertility in 4 patients and loss of libido was present in 3 patients. 2(5.5%) patients presented with pituitary apoplexy. Surgery was the most common cause for hypopituitarism {14(38.8%) patients}, idiopathic in 13 patients (36.1%), surgery + post radiation in 6 (16.6%) patients, Sheehan's syndrome in 2(5.55%) patients, post radiation in 1 patient (2.77%). Co-morbidities like diabetes were seen in 7 (19.4%) and hypertension in 5(13.8%)

patients. One patient had four components of hypopituitarism (hypogonadism + hypothyroidism +hypocortisolism +AVP-D) while most patients 18(50%) had only 2 components (hypocortisolism + hypothyroidism). Hypothyroidism was present in 34 (94.4%) patients. Pituitary adenoma was detected in MRI in 12 patients (33.3%). Among them, 2 had macroprolactinoma, 2 ACTH dependent Cushing disease, 1 had Thyrotropinoma and rest had Nonfunctioning pituitary adenoma (NFPA). Craniopharyngioma was seen in 6 patients (16.6%), Empty sella in 8(22.2%), Meningioma in 2(5.5%) and Rathke cleft cyst 1(2.7%) patient. 7 (19.4%) patients had normal MRI findings. Management was with steroids + thyroxine + Hormone Replacement Therapy (HRT) +desmopressin in 3 patients, steroids + desmopressin in 1 patient, steroids + thyroxine HRT in 9 patients, steroids + HRT + desmopressin in 1 patient, steroids + thyroxine + desmopressin in 2 patients, steroids + thyroxine in 15 patients, thyroxine + HRT in 4 patients and HRT alone in 1 patient (although he was also GH deficient). Steroids used were prednisolone in 25 patients and hydrocortisone in 6 patients. HRT used was OCP in 7 patients, testosterone in 8 patients, HCG and FSH/HMG in 2 patients, both of them (one male, other female) had successful pregnancies. Desmopressin was nasal in 5 patients and oral in 2 patients.

Pituitary apoplexy: a retrospective study of 48 patients from a tertiary endocrine center

Catarina Isabel Lopes[1], Miguel António Duarte[1], Marta Vaz Lopes[1], Mariana de Griné Severino[1], José Vicente Rocha[1,2], Carolina Peixe[1,2], Mariana Lopes-Pinto[1], Ana Gomes[1,2], Maria Inês Alexandre[1,2] & Ema Lacerda Nobre[1,2]

[1]Serviço de Endocrinologia, Diabetes e Metabolismo, Hospital de Santa Maria, ULS Santa Maria, Lisbon, Portugal; [2]Clínica Universitária de Endocrinologia, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal

Pituitary apoplexy is a rare, potentially life-threatening condition caused by hemorrhage or infarction of the pituitary gland, often involving a pre-existing pituitary adenoma. Prompt diagnosis and intervention are essential to optimize patient outcomes. We conducted a retrospective review of 48 pituitary apoplexy cases diagnosed and managed at our tertiary endocrine center. The cohort was predominantly female (62.5%), with a mean age at diagnosis of 50.9 $\pm$ 17.2 years. Headache was the most frequent presenting symptom (52%), followed by amenorrhea (29%; 93% related to Sheehan syndrome). Other symptoms included visual disturbances (23%), cranial nerve palsies (21%), agalactorrhea (19%; all related to Sheehan syndrome), nausea/vomiting (15%), impaired mental status (11%), and fever (2%). A clear precipitating factor was identified in 15 patients (31%), including 14 due to postpartum hemorrhage (Sheehan syndrome) and 1 to somatostatin analog treatment. Potential associations were noted with intense emotional stress (2 patients) and warfarin therapy (1 patient). Endocrine evaluation at diagnosis revealed multiple pituitary deficits: secondary adrenal insufficiency (83%), secondary hypothyroidism (81%), hypogonadotropic hypogonadism (73%), GH/IGF-1 deficiency (44%), prolactin deficiency (35%), and diabetes insipidus (8%). Patients exhibited an average of 3.1 $\pm$ 1.5 hormonal deficiencies, with only 3 (6%) presenting unremarkable blood test Results Imaging showed macroadenomas in 52% of cases (60% with hemorrhage) with a mean tumor diameter of 21 mm; empty/partially empty sella turcica in 27%; microadenomas with hemorrhage in 4%; and Rathke's cleft cyst with hemorrhage in 2%. Surgery was required in 12 patients (25%), mostly for macroadenomas with significant neurological/visual impairment. Pathology revealed 4 gonadotropinomas, 3 somatotropinomas, 2 corticotropinomas, 2 non-functioning adenomas, and 1 sample without identifiable pituitary tissue. Additionally, 5 patients (10%) underwent radiotherapy. Most patients (92%) required hormone replacement therapy, with 77% on levothyroxine, 77% on corticosteroids (hydrocortisone/prednisone), and 21% on testosterone. Less frequent replacements included estrogen/progesterone (10%), GH (2%), and desmopressin (2%). While pituitary apoplexy is acknowledged as a rare disease, our center has documented a significant number of cases, providing valuable insights into its clinical presentation and management. This highlights the need for increased awareness and prompt diagnosis, essential for improving outcomes in this challenging condition.

Effectiveness of serial prolactin measurement in the subsequent detection of pituitary lesions

Raúl Rodríguez Juárez[1], Elena Martínez Silla[1], Juan Luis Delgado Montoya[1], Laura Cánovas Noguera[1], Yael Giner Esteban[1], Nuria Birruezo Hernández[1], Maria Dolores Aviles Perez[1], Torralbo Martín[1] & Pablo J López- Ibarra Lozano[1]

[1]Hospital Universitario Clínico San Cecilio, Granada, Spain

Introduction

Hyperprolactinemia is a common reason of referral to endocrinology outpatient clinics. This condition may be due to physiological, pharmacological or pathological causes. After ruling out some of them, many studies suggest performing a serial prolactin measurement to eliminate stress hyperprolactinemia, and then continuing to study those who truly present altered prolactin values. Objective: to evaluate the subsequent effectiveness of serial prolactin measurement in the detection of pituitary lesions.

Materials and Methods

Descriptive study of 53 patients who underwent serial prolactin measurements between the years 2023-24 in follow-up in our clinics. Demographic (sex, age), analytical (basal prolactin, at 20 and 40 minutes) and radiological (magnetic resonance imaging (MRI) of the sella turcica and the presence of a lesion there) variables were collected. Regarding the measurement, a peripheral intravenous line was inserted and a baseline, at 20 and at 40 minutes value was taken. It was established that prolactin was elevated above 20 (men) or 25 (women). The statistical analysis was performed with the IBM SPSS v.25 programme (Statistical significance $P < 0.05$).

Results

53 patients were analysed, 83% of whom were women with a mean age of 29.9 $\pm$ 12.6 years. 73.6% and 77.4% of patients showed normal prolactin levels at 20 and 40 minutes, respectively. Basal and 20-minute prolactin, basal and 40-minute prolactin and basal and 20 and 40-minute prolactin means difference were 4.1 $\pm$ 6.3, 6.4 $\pm$ 10.1, and 2.2 $\pm$ 5.7, all of which were statistically significant. All patients with elevated prolactin levels at 40 minutes underwent sella turcica MRI, and lesions were observed in 58.3% of them.

Conclusion

In most cases, normalisation of prolactin levels is observed when serial measurements are performed at 20 and 40 minutes. In addition, a statistically significant difference is identified between the basal prolactin values and those obtained in subsequent measurements. Also, in most patients with an altered prolactin value at 40 minutes, the presence of a pituitary MRI lesion is observed. This supports the usefulness of serial prolactin measurement, not only to rule out stress hyperprolactinemia, but also to focus the diagnostic procedure on those patients with true hyperprolactinemia.

Hyperprolactinemia in children and adolescents: clinical characteristics and etiological spectrum

Fatih Kilci[1], Emre Sarıkaya[1], Nurhan Özcan Murat[2], Adnan Deniz[3], İhsan Kara[4] & Uğur Sarı[4]

[1]Kocaeli City Hospital, Pediatric Endocrinology, Kocaeli, Türkiye; [1]Kocaeli City Hospital, Pediatric Endocrinology, Kocaeli, Türkiye; [3]Kocaeli City Hospital, Pediatric Neurology, Kocaeli, Türkiye; [4]Kocaeli City Hospital, Child and Adolescent Psychiatry, Kocaeli, Türkiye

Objective

This study aims to evaluate the etiological, clinical, and biochemical characteristics of pediatric patients diagnosed with hyperprolactinemia.

Methods

We analyzed 160 pediatric patients diagnosed with hyperprolactinemia between January 2018 and December 2024. Hyperprolactinemia was defined as prolactin levels exceeding 25 ng/mL in girls and 20 ng/mL in boys on at least two separate occasions, with blood samples taken between 8:00 AM and 9:00 AM. Patients were categorized into two groups based on the underlying etiology: Group-1: Pituitary and Hypothalamic Disorders ($n = 38$), including prolactinomas ($n = 18$), non-functioning pituitary adenomas ($n = 8$), craniopharyngiomas ($n = 7$), and empty sella ($n = 5$). Group-2: Non-Pituitary and Hypothalamic Disorders (n

= 122), including polycystic ovary syndrome (PCOS) (n = 40), drug-induced hyperprolactinemia (n = 33), macroprolactinemia (n = 20), and idiopathic hyperprolactinemia (n = 29). Clinical presentations, biochemical findings, imaging results, and treatment responses were assessed.
Results
The median age at diagnosis was 15.2 years, (range: 2–17.9 years) with a female predominance of 73.1%. The median prolactin level was 45.8 ng/mL (range: 38.3–14,350). The median prolactin level in Group-1 was 213 ng/mL, which was significantly higher than the median level of 44 ng/mL observed in Group-2 ($P <$ 0.05). However, there were no significant differences between the two groups in terms of age, weight, height, and BMI SDS. The most common presenting symptoms were menstrual irregularities, galactorrhea, headache, and pubertal delay. Overweight/obesity were evident in 47.5% of the overall study cohort. Patients with PCOS exhibited the highest prevalence of overweight/obesity, with a rate of 70%. Cabergoline treatment achieved a 100% success rate in patients with prolactinomas. Additionally, at the end of the first year of cabergoline treatment, a significant decrease in BMI SDS was observed in the patients with prolactinomas ($P < 0.05$), with a mean BMI SDS of 0.8 $\pm$ 1.6 at baseline and 0.3 $\pm$ 1.1 after one year of treatment. Risperidone was the responsible agent in 82% of patients with drug-induced hyperprolactinemia, and prolactin levels normalized after drug discontinuation or switching to an alternative medication.
Conclusion
Pediatric hyperprolactinemia exhibits a diverse etiological spectrum, with PCOS and drug-induced cases being more common than previously reported. Prolactin levels can help differentiate pituitary adenomas from other causes, guiding management. Given that mild prolactin elevations were frequently observed in PCOS, it may be considered part of the PCOS phenotype rather than a distinct pathology, potentially reducing unnecessary endocrinological or radiological evaluations. Cabergoline was highly effective in prolactinoma patients, also contributing to BMI reduction, while drug-induced hyperprolactinemia, primarily linked to risperidone, resolved with medication adjustment.

Improving tumour localisation in cushing's disease: synergistic use of 11c-methionine pet/ct and osilodrostat

Zin Htut[1], James Macfarlane[2], Nair Ramesh[3], Debbie Papadopoulou[3], Niamh Martin[4], Karim Meeran[4], Daniel Gillett[2], Mark Gurnell[2] & Florian Wernig[3]
[1]Imperial College London, London, United Kingdom; [2]University of Cambridge, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; [3]Imperial College Healthcare NHS Trust, London, United Kingdom; [4]Imperial College London, Imperial College Healthcare NHS Trust, London, United Kingdom

Background
Optimal long-term outcomes in Cushing's disease (CD) rely on precise localisation and complete resection of the ACTH-secreting adenoma while preserving normal pituitary function. However, adenomas can sometimes evade detection on conventional MRI. 11C-methionine PET/CT (11C-MET PET/CT) has emerged as an alternative imaging modality that may improve visualisation of these elusive tumours. We hypothesised that preoperative cortisol-lowering therapy would lead to increased ACTH levels, heightened tumour metabolic activity, and enhanced 11C-MET PET signal intensity. Osilodrostat, a potent 11-β-hydroxylase inhibitor, has demonstrated superior efficacy and tolerability compared to traditional steroidogenesis inhibitors such as metyrapone and ketoconazole.
Case
A 28-year-old man with a history of juvenile arthritis, total hip replacement, and postoperative pulmonary embolism presented with uncontrolled hypertension, centripetal obesity, purple striae, and significant weight gain, consistent with Cushing's syndrome (CS). Laboratory investigations confirmed ACTH-dependent hypercortisolism, with markedly elevated post-1 mg dexamethasone cortisol of 807 nmol/l (<50 nmol/l), ACTH of 56.7 ng/l (10–30 ng/l), and 24-hour urinary free cortisol (UFC) of 774 nmol/24h (0–164 nmol/24h). Salivary cortisol and cortisone levels were 13.5 nmol/l (<2.6 nmol/l) and 42.7 nmol/l (<18 nmol/l), respectively. Inferior petrosal sinus sampling (IPSS) ruled out an ectopic source of ACTH secretion, however, MRI failed to identify a discrete pituitary adenoma. Functional imaging with 11C-MET PET/CT demonstrated equivocal tracer uptake near the left cavernous sinus, but did not provide definitive adenoma localisation. Given persistent hypercortisolism, the patient was initially treated with metyrapone but intolerance, leading to a switch to osilodrostat (2 mg twice daily, titrated to achieve eucortisolaemia). With cortisol normalisation, ACTH levels tripled, suggesting increased tumour metabolic activity. After three months of sustained eucortisolaemia, repeat 11C-MET PET/CT revealed a markedly increased focal tracer avidity near the left cavernous sinus, providing a precise target for transsphenoidal surgery.
Conclusion
This case highlights a novel preoperative strategy for enhancing adenoma detection in CD. Cortisol-lowering therapy may improve the sensitivity of functional imaging, enabling more accurate tumour localisation and optimising surgical outcomes. If validated in larger cohorts, this approach could significantly enhance surgical cure rates while preserving normal pituitary function.

Reproductive hormones in infertile men with Y chromosome microdeletions

Malene Asp Bock Mejdahl[1,2,3], Lise Aksglaede[1,3], Anders Juul[1,3,4], Iben Bache[2] & Kristian Almstrup[1,3,5]
[1]Department of Growth and Reproduction, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark; [2]Department of Clinical Genetics, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark; [3]International Center for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health, Copenhagen, Denmark; [4]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [5]Department of Cellular and Molecular Medicine, University of Copenhagen, Copenhagen, Denmark

Background
Microdeletions in the AZF regions of the Y chromosome are well-recognized as a recurrent genetic cause of male infertility. The reproductive system is tightly regulated by hormones of the hypothalamic–pituitary–gonadal axis but large-scale studies investigating the endocrine effects of Y microdeletions are lacking.
Objective
The objective of this study is to investigate the level of reproductive hormones in infertile men with and without Y microdeletions.
Materials and methods
Results from a PCR based Y microdeletion analysis and hormone analyses (testosterone (n=7429), free testosterone (n=7416), LH (n=7509), SHBG (n=7506), FSH (n=7488), inhibin B (n=7535), and INSL3 (n=924)) were obtained from 7615 infertile men (age 20–60) evaluated from 1997 until 2024 at the Department of Growth and Reproduction, Rigshospitalet, prior to fertility treatment.
Results
Out of 7615 analysed patients, 564 (7.4%) had a Y microdeletion and 7051 had no Y microdeletion detected. Patients were grouped based on the specific type of microdeletions: gr/gr (n=263), b1/b3 (n=3), b2/b3 (n=166), b2/b4 (n=45), AZFabc (n=16), AZFbc (n=21) and complex deletions (n=50). Inhibin B and the inhibin B/FSH ratio were significantly lower in patients with b2/b4, AZFabc, AZFbc, and complex deletions ($P < 0.05$) mirrored by significantly higher FSH levels in the same patients ($P < 0.05$). Testosterone and free testosterone concentrations were significantly lower in patients with a AZFabc deletion ($P <$ 0.001), whereas LH was significantly higher in patients with b2/b4, AZFabc and AZFbc ($P < 0.05$). Reproductive hormones in patients carrying gr/gr and b2/b3 deletions did not differ significantly from patients without Y microdeletions. We did not have enough patients in the b1/b3 group or data on INSL3 to allow subdivision into specific types of microdeletions, however across all patients with Y microdeletions INSL3 did not differ significantly (P=0.71) when compared to patients without Y microdeletions.
Discussion and conclusions
Infertile men with larger and complex Y microdeletions have significantly lower inhibin B and inhibin B/FSH ratio along with significantly higher gonadotropins compared to infertile men without Y microdeletions. Only men with complete AZFabc deletions have significantly lower testosterone and free testosterone concentrations. We cannot deduce whether these differences are a direct or indirect effect of the microdeletions.

Parhon" National Institute of Endocrinology, Endocrinology 4, Bucharest, Romania; [3]UMCG Rijksuniversiteit Groningen., Groningen, Netherlands; [4]"C Davila" University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania

Introduction
In mammalian testes, hormones regulate germ cell survival, with Sertoli cells playing a key role in spermatogenesis. Hormonal imbalances can trigger apoptosis, regulated by BCL-2 family proteins, which either inhibit (BCL-2) or promote (BAD, BAK, BAX) cell death. The study aimed to explore the correlation between hormones and these four markers.
Methods
The study included 58 semen and blood samples from 37 infertile men and 21 control patients. The infertile patients were classified into three subgroups: azoospermia (AZO; $n=7$; median age $=35.17$ years), oligoasthenospermia/severe oligoasthenospermia (OAS/OASS; $n=5$; median age $=31.40$ years), and oligoasthenoteratospermia/severe oligoasthenoteratospermia (OATS/OATSS; $n=25$; median age $=33.84$ years). RNA isolation, cDNA synthesis, and qRT-PCR were performed to assess gene expression. Hormone levels (Cortisol, Dehidroepiandrosteron-sulfat, Estradiol, Testosterone, Free Testosterone, Sex Hormone Binding Globuline (SHBG), Follicle-Stimulating Hormone (FSH), Luteinizing Hormone (LH), Prolactin and Inhibin B) were measured in serum samples using the electrochemiluminescence and ELISA detection method according to the manufacturer's recommendations. Statistical analysis was performed using GraphPad Prism 10.4.1.
Results
The analysis revealed significant correlations between hormone levels and apoptosis markers in male infertility. In the AZO group, E2, FSH, and LH negatively correlated with BCL2 ($r=-0.74$, $r=-0.67$, $r=-0.62$), BAX ($r=-0.78$, $r=-0.69$, $r=-0.82$), and BAK1 ($r=-0.73$, $r=-0.68$, $r=-0.86$), suggesting a role in suppressing both pro-apoptotic and anti-apoptotic pathways. Notably, SHBG showed a strong negative correlation with BAK1 ($r=-0.92$), while inhibin B positively correlated with BCL2 ($r=0.61$), indicating its involvement in promoting apoptosis-related pathways while supporting cell survival mechanisms. In the OAS/OASS group, testosterone, free testosterone, and SHBG demonstrated strong positive correlations with BCL2 ($r=0.87$, $r=0.66$, $r=0.94$), BAK1 ($r=1.00$, $r=0.84$, $r=0.99$), and BAX ($r=0.94$, $r=0.96$, $r=0.91$), emphasizing the role of androgenic regulation in apoptosis. The OATS/OATSS and control group, showed only one negative correlation between cortisol and BAK1 ($r=-0.50$), respectively DHEA-S and BAK1 ($r=-0.53$).
Conclusion
The findings indicate that hormonal regulation significantly influences apoptosis in male infertility, with AZO and OAS/OASS groups displaying distinct patterns compared to the control and OATS/OATSS groups. These differences indicate disrupted apoptosis regulation, potentially contributing to infertility and further research is needed to uncover underlying mechanisms and develop targeted therapies.

Immune protein profiling of polycystic ovary syndrome

Tianze Cao[1], Sara Torstensson[2], Angelica Hirschberg Linden[3,4], Elisabet Stener-Victorin[2] & Camila Consiglio[1]
[1]Lund University, Division of Molecular Hematology, Lund, Sweden; [2]Karolinska Institutet, Department of Physiology and Pharmacology, Stockholm, Sweden; [3]Karolinska University Hospital, Department of Gynecology and Reproductive Medicine, Stockholm, Sweden; [4]Karolinska Institutet, Department of Women's and Children's Health, Stockholm, Sweden

Polycystic ovary syndrome (PCOS) is a common endocrine disorder among females characterized by hyperandrogenism, polycystic ovarian morphology, menstrual irregularities, and metabolic dysfunctions such as hyperinsulinemia and an increased risk of type 2 diabetes. Immune involvement in PCOS is indicated by a higher incidence of asthma, higher prevalence of autoimmune thyroid disease and respiratory infections. Although PCOS presents with chronic inflammation in peripheral blood, it remains poorly understood how metabolic and reproductive abnormalities impacts the inflammatory and immune profile in PCOS. To fill this knowledge gap, we profiled 92 immune and inflammatory serum proteins in 106 PCOS patients and 58 controls using the Olink Target Inflammation panel. In addition, general patient information (e.g., age) and levels of markers related to metabolic (e.g., BMI, insulin resistance) and reproductive function (e.g., sex hormone-binding globulin, testosterone) were measured and accounted for in our analysis. After adjusting for age and batch effects, our statistical model shows that several proteins are differentially expressed between PCOS and controls. We observe higher concentrations of pro-inflammatory (IL18R1, IL18, and IL1A) and immune exhaustion (PDL1) proteins, which confirm with the chronic inflammation state in PCOS. Women with PCOS have a clear different metabolic and reproductive profiles compared to controls, including higher level of HOMA-IR, triglycerides, and circulating androgens. Principal component (PC) analysis reveals metabolic-driven PC1 and reproductive-driven PC2, indicating that the metabolic profile and reproductive profile contribute differently to inter-individual differences. We computed metabolic and reproductive scores based the sum of z-score transformed clinical variable values for each individual. Interestingly, metabolic and reproductive scores are positively correlated in controls while the correlation disappeared in PCOS, which suggests that reproductive and metabolic relation is disrupted in PCOS. Overall, the levels of differentially expressed immune proteins in PCOS positively correlate with metabolic measurements, while only a few proteins were found to correlate with reproductive measurements. Interestingly, although PCOS patients have a skewed inflammatory profile and higher testosterone concentrations, we identified that IL6, S100A12, and IL20 negatively correlate with testosterone levels in PCOS. Finally, k-means clustering of the PCOS immune proteome revealed two immune subgroups of PCOS, with subgroup A showing a more pro-inflammatory immune profile and a more severe metabolic profile compared to subgroup B. Our study uncovers novel immune proteome alterations in PCOS and the metabolic and reproductive regulation of such proteins. This has important implications for understanding PCOS pathogenesis and identifying pathways for immunomodulatory intervention.

The effect of testosterone on gene expression in muscle in klinefelter syndrome – a single nucleus RNA sequencing study

Emma Bruun Johannsen[1,2], Lukas Ridder[2,3], Agnete Schou[1,2], Jakob Wang[4], Jean Farup[4], Lin Lin[4], Jesper Just[1,2] & Claus H. Gravholt[1,2,3]
[1]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark; [2]Department of Molecular Medicine, Aarhus University Hospital, Aarhus, Denmark; [3]Department of Endocrinology, Aarhus University Hospital, Aarhus, Denmark; [4]Department of Biomedicine, Aarhus University, Aarhus, Denmark

Introduction
Klinefelter Syndrome (KS) is a genetic condition characterized by an extra X chromosome in males, resulting in a 47,XXY karyotype. This leads to health issues, including hypogonadism, increased risk of metabolic disorders and altered body composition - characterized by higher fat mass and lower muscle mass compared to 46,XY males. KS males routinely receive testosterone replacement therapy (TRT) to lessen these complications, with documented benefits for metabolism and body composition. However, the cellular-level effects of TRT on skeletal muscle in KS remain unclear.
Methods
This study utilized single-nucleus RNA sequencing (snRNAseq) to investigate muscle tissue changes associated with TRT in KS. Skeletal muscle biopsies were obtained from untreated KS males ($n=4$) before initiating TRT, and after one year of treatment. Age-matched 46,XY males ($n=4$) was served as controls. Muscle samples were processed to isolate nuclei, followed by fluorescence-activated nuclei sorting (FANS), and subsequently subjected to snRNAseq using the 10X Genomics platform. The obtained snRNAseq data was integrated and clustered using the Seurat (v5) workflow. Comparative analyses of untreated KS, TRT-treated KS, and 46,XY control muscle samples were performed, enabling detailed insights into cell-specific

transcriptional changes – including differential expression analysis (MAST) and cell-cell communication patterns (MultiNicheNet).
Results
TRT increased testosterone levels to normal ranges in KS males while reducing FSH/lH levels, though not to normal levels. A total of 81,768 nuclei were sequenced, revealing 11 major cell populations: type I, type IIa, and type IIx myonuclei, neuromuscular junctions, fibro-adipogenic progenitors, endothelial cells, muscle stem cells, T-cells, and macrophages. Differential gene expression (DEG) analysis revealed DEGs across all cell types, with 630 DEGs associated with TRT and 287 DEGs associated with KS. Key processes affected included differentiation, proliferation, growth, vascular remodeling, and steroid/androgen signaling pathways. To contextualize these transcriptional changes, cell-to-cell communication analysis was conducted to assess how these changes affected communication pathways. TRT was found to enhance vascular and extracellular matrix remodeling and muscle stem cell activation, while untreated KS muscle relied on maintenance and repair pathways, potentially favoring fibrosis over active regeneration.
Conclusion
This study provides insights into the cellular effects of TRT on skeletal muscle in KS. The findings suggest that TRT promotes a more regenerative and angiogenic muscle state, enhancing structural adaption and tissue remodeling. By identifying key transcriptional and intercellular signaling changes, these results contribute to understanding TRT's therapeutic impact and may aid in optimizing treatment strategies for KS individuals.

Exploring the relationship between sex hormones and abdominal muscle composition in postmenopausal women: insights from the multi-ethnic study of atherosclerosis

amar osmancevic[1], Matthew Allison[2], Iva Miljkovic[3], Chantal A Vella[4], Pamela Ouyang[5], Penelope Trimpou[6] & Bledar Daka[7]
[1]Institution of Medicine, Sahlgrenska Academy, School of Public Health and Community Medicine, Gothenburg, Sweden; [2]Division of Preventive Medicine, School of Medicine, UC San Diego, San Diego, CA, United States of America., San Diego, United States; [3]Department of Epidemiology, School of Public Health, University of Pittsburgh, Pittsburgh, PA, United States of America., Pittsburgh, United States; [4]Department of Movement Sciences, University of Idaho, Moscow, ID, United States of America., Moscow, United States; [5]Institute for Clinical and Translational Research, Johns Hopkins University School of Medicine, Baltimore, MD, United States of America., Baltimore, United States; [6]Department of Endocrinology, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg and Sahlgrenska University Hospital, Gothenburg, Sweden, Gothenburg, Sweden; [7]Institution of Medicine, Sahlgrenska Academy, Gothenburg, Sweden

The relationship between sex hormone levels and muscle composition in postmenopausal women remains underexplored. To address this gap, we conducted a cross-sectional observational study utilizing data from the Multi-Ethnic Study of Atherosclerosis. Our analysis included 682 postmenopausal women aged 45-84 years with complete data, with a mean age of 63.3 years. Using abdominal computed tomography imaging, we assessed abdominal muscle area (cm^2) and muscle radiodensity (Hounsfield units) in relation to serum levels of testosterone (total and free), estradiol, and sex hormone binding globulin, measured with radioimmunoassay's, in pmol/l or nmol/l. Multivariable linear regression models, adjusting for potential confounders, were employed to investigate these associations. In our fully adjusted models, higher levels of estradiol and free testosterone were found to be positively associated with total abdominal muscle area ($\beta = 1.41$, 95% CI 0.4, 2.4, $P = 0.007$ and $\beta = 18.5$, 95% CI 4.0, 33.1, $P = 0.004$, respectively), but not with muscle radiodensity ($p > 0.05$). Conversely, elevated levels of SHBG were associated with lower total abdominal muscle area and radiodensity ($\beta = -2.1$, 95% CI -3.2, -0.9, $P = 0.001$ and $\beta = -0.32$, 95% CI -0.6, -0.0, $P = 0.07$, respectively). Our study highlights significant associations between sex hormone levels and skeletal muscle area in postmenopausal women. Furthermore, the novel findings regarding SHBG, and muscle composition suggest a potential previously unrecognized role of SHBG in skeletal muscle adipose tissue accumulation. However, further validation in other cohorts is necessary to elucidate the potential role of SHBG in body composition.

High risk of type 2 diabetes in klinefelter syndrome irrespective of hypogonadism and testosterone replacement therapy

Simon Chang[1,2], Lars Pedersen[3,4] & Claus H. Gravholt[1,2,4]
[1]Aarhus University Hospital, Department of Endocrinology, Aarhus, Denmark; [2]Aarhus University Hospital, Department of Molecular Medicine, Aarhus, Denmark; [3]Aarhus University Hospital, Department of Epidemiology, Aarhus, Denmark; [4]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark

Background
Testosterone replacement therapy (TRT) in Klinefelter syndrome (KS) is associated with reduced mortality. A potential mechanism behind this could be overall positive effects of TRT on metabolism in KS.
Aim
We investigated whether TRT in KS was associated with risk of type 2 diabetes (T2DM) as a proxy for metabolism.
Methods
We conducted a cohort study with riskset sampling based time of TRT in KS. Using Danish registry data, we estimated the risk of T2DM in KS. We computed the cumulative incidence and hazard ratios (HR) for incident T2DM in KS at three different life-stages: a) undiagnosed, b) diagnosed with no TRT, and c) diagnosed with TRT. We also included a male population control group. Lastly, we evaluated hemoglobin A1c levels (HbA1c) at diagnosis of T2DM and after two years of living with T2DM.
Results
We studied 895 men with KS and 50,110 controls from January 1994 until December 2022. The incidence of T2DM in KS was not associated with diagnosis- or TRT status ($P > 0.2$). The overall risk of T2DM was increased in KS at all life-stages compared with controls ($P < 0.001$). Similar data was seen for 5 and 10-year risk of T2DM. Compared with TRT treated KS, the incidence of T2DM was almost 75 % lower among controls (HR (95 CI), 0.27 (0.14-0.52). Maximum levels of HbA1c at diagnosis and lowest obtained values after two years of T2DM were not different among KS life-stages or comparing KS and controls ($P > 0.2$).
Conclusion
The risk of T2DM in KS is increased and not alleviated by TRT. These data indicate that the unfavorable metabolic profile in KS is only to a lesser extend explained by hypogonadism, and that specific genetic alterations as a consequence of the 47,XXY karyotype could contribute substantially to metabolic risk in the patients.

Precocious puberty and risk of psychiatric disorders: a nationwide register-based cohort study

Trine Koch Hueg[1], Youn-Hee Lim[2], Nadia Micali[3], Stine Agergaard Holmboe[1] & Anders Juul[1]
[1]Copenhagen University Hospital-Rigshospitalet, Copenhagen, Denmark; [2]University of Copenhagen, Copenhagen, Denmark; [3]Institute of Psychiatry, Ballerup, Denmark

Background
Early menarche within the general population has previously been linked to increased risk of mental health disorders. Therefore, extremely early puberty (precocious puberty (PP)) is likely to influence risk of long-term disease. However, little information about the risk of mental health disorders among individuals with PP exist.
Aim
To investigate the prospective association between PP and psychiatric disorders.
Methods
A register-based cohort study including all individuals with a diagnosis of PP in the National Patient Registry (NPR) from 1995 to 2020 ($n = 9,315$ (girls, $n = 8,289$, 89%)) using International Classification of Disease, tenth revision, including a diagnosis of central precocious puberty, premature puberty, premature

thelarche, and premature adrenarche. We included boys and girls with a diagnosis of PP before 10 years of age and 9 years of age, respectively. All individuals with a diagnosis of PP were matched with 5 randomly selected references from the background population (n = 46,566) according to age, gender, and calendar time (at diagnosis). The study population was followed-up in NPR, the Psychiatric Central Research Registry, the National Prescription Registry, and the National Cause of Death Registry for incident psychiatric disorder (addiction, attention deficit hyperactive disorder (ADHD), anxiety, autism spectrum disorder, bipolar disorder, depression, eating disorder, schizophrenia, and suicide including attempt and completed). The minimum average follow-up time was 7.9 years. The association between PP and psychiatric disorders was analyzed using Cox Proportional Hazard models, with strata for matched PP cases and references.

Results

PP was associated with a statistically significant increased risk of ADHD (Hazard Ratio (HR): 1.55, 95% confidence interval (CI): 1.32-1.82), anxiety (HR: 1.60, 95% CI: 1.46-1.76), autism (HR: 1.85, 95% CI: 1.57-2.19), depression (HR: 1.46, 95% CI: 1.33-1.61), eating disorders (HR: 1.32, 95% CI: 1.08-1.61), and schizophrenia (HR: 1.66, 95% CI: 1.31-2.11) but not addiction, bipolar disorder, and suicide (attempt and completed) when compared to matched references. Similar results were observed when stratifying by sex but generally with a larger effect size for boys than girls. However, the association between PP and eating disorders and schizophrenia was only statistically significant for girls.

Conclusion

Our large register-based cohort study highlights a markedly increased risk of psychiatric disorders amongst individuals (boys and girls) with a diagnosis of PP compared to their matched references from the background population. This has important implications for prevention and early intervention.

Liquid chromatography-tandem mass spectrometry (LC-MS/MS) reliability compared to immunometric assay (IA) for testosterone (T) assay in a clinical laboratory setting for male hypogonadism management

Daniele Renda Livraghi[1], Francesco Costantino[1], Giulia Canu[2], Maria Cristina De Santis[2], Laura Roli[2], Tommaso Trenti[2], Tommaso Fasano[2], Sara De Vincentis[1] & Vincenzo Rochira[1]
[1]University of Modena and Reggio Emilia, Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy; [2]Azienda USL, Unit of Laboratory Medicine, Modena, Italy

Background

Testosterone Replacement Therapy (TRT) in Hypogonadism (Hy) is started when total testosterone (TT) levels fall below 3.5 ng/ml in presence of a suggestive clinic, therefore the technology used to measure serum T levels is relevant. LC-MS/MS is the gold standard for sex steroids measurement, but it is mainly used for research, while IA is routinary used for clinical purpose. The use of LC-MS/MS in clinical labs is increasing, but its impact in the clinics remains unclear. We aimed to investigate the role of LC-MS/MS compared to IA in the diagnosis and management of male Hy.

Methods

A total of 116 Hypogonadotropic (70) or Hypergonadotropic (46) Hypogonadic men were enrolled irrespective of their treatment status, serum TT was assessed by LC-MS/MS and IA, together with SHBG for calculated free testosterone (cfT). Hy was defined according to the Italian Society of Andrology and Sexual Medicine (SIAMS) threshold: serum TT $\leq$3.5 ng/mL and/or cfT $<$6.5 ng/dl. TT was quantified using CMIA DxI800 Beckman Coulter (IA) and Chrosystems MassChrom® Steroids in Serum/Plasma kit on Sciex CitrineTM (LC-MS/MS); cfT was calculated with the Vermeulen formula.

Results

Untreated and those patients under TRT were respectively 48 and 68, with a mean $\pm$ SD age of 45.98 $\pm$ 17.56 years and a mean $\pm$ SD BMI of 28.09 $\pm$ 5.36 kg/m^2. Serum TT and cfT assessed with LC-MS/MS were directly related to serum TT (R^2 = 0.6748, $P < 0.001$) and cfT (R^2 = 0.8787, $P < 0.001$) assessed with IA, but the R^2 did not show a precise concordance. Accordingly, the prevalence of biochemical Hy was significantly higher with IA than LC-MS/MS, for all Hy patients TT (59.5% vs 46.6%, OR 1.69, P = 0.025) and those untreated (87.5% vs 64.58%, OR 3.84, P = 0.011). A similar result was found even for cfT in all Hy (53.4% vs 39.7%, OR 1.75, P = 0.018) and the untreated ones (79.17% vs 58.33%, OR 2.71, P = 0.030). Correlation between serum TT measured by LC-MS/MS and IA was higher in the low ($\leq$3.5 ng/mL) (R^2 = 0.6877, $P < 0.001$) than in the normal to high (R^2 = 0.4396, $P < 0.001$) range of serum TT, suggesting incongruence between the two in patients under T therapy.

Conclusions

IA compared to LC-MS/MS in hypogonadal men overestimates significantly both the prevalence of biochemical Hy and TRT compensation both for TT and cfT. These results highlight the role of LC-MS/MS and SHBG assessments in every day clinical practice in the diagnosis and TRT monitoring of male Hy, avoiding unnecessary medication.

Girls with high hormonal steroids, BMI and stress reach puberty early

Lauren Houghton[1], ying wei[1], Stephan Wudy[2], Michaela hartmann[2], Frank stanczyk[3], Julia Knight[4], Irene andrulis[4], Angela Bradbury[5], Lisa Schwartz[5], Saundra Buys[6], Mary Daly[7], Esther John[8], Wendy Chung[9], regina santella[1], Russell Romeo[10] & Mary Beth Terry[1]
[1]Columbia University, New York, United States; [2]Justus Liebig University, Giessen, Germany; [3]Keck School of Medicine, Los Angeles, United States; [4]Lunenfeld-Tanenbaum Research Institute, Toronto, Canada; [5]University of Pennsylvania, Philadelphia, United States; [6]University of Utah, Utah, United States; [7]Fox Chase Cancer Center, Philadelphia, United States; [8]Stanford University, Stanford, United States; [9]Boston Children's Hospital, Boston, United States; [10]Barnard University, New York, United States

Background

There are ongoing concerns about declining age of puberty in females and what is driving the decline. We aimed to identify patterns in the hormonal steroid metabolome associated with accelerated pubertal development in girls, and to determine if this association was modified by body mass index (BMI), markers of stress, and breast cancer family history.

Methods

In the LEGACY Girls Study, we measured 36 metabolites of glucocorticoids, androgens, progesterone, and estrogens in two urine specimens collected before (pre, n = 327) and during puberty (pubertal, n = 115). Parents assessed the age at breast development (thelarche) through the Pubertal Development Scale. Girls aged $\geq$10 years self-reported age at menarche. Study staff measured participants' height and weight and administered the Internalizing Composite Scale (a parent proxy of child stress). We estimated hazard ratios (HR) and 95% confidence intervals (CI) for the association between a doubling in steroid metabolites (µg/mL per mg of creatinine) and age at thelarche, pubarche and menarche using Weibull survival models, testing for interactions with stress BMI z-scores, and family history using cross-product terms. We also used 12 principal components of pre-pubertal steroid metabolite data as predictors in Weibull models.

Results

Higher pre-pubertal levels of urinary metabolites of glucocorticoids (HR = 1.9, 95% CI 1.5-2.5), androgens (HR = 3.9, 95%CI 2.7-5.6) and progesterone (HR = 6.7, 95%CI 4.1-10.9) were associated with accelerated thelarche. Higher pre-pubertal (HR = 0.2, 95%CI 0.1-0.5) and pubertal (HR = 0.4, 95%CI 0.2-0.9) levels of estrogen metabolites were associated with delayed menarche. Higher levels of pubertal androgen (HR = 0.3, 95%CI 0.1-0.8) and progesterone (HR = 0.2, 95%CI 0.07-0.7) metabolites were associated with longer pubertal tempo. Girls with high glucocorticoid metabolites, BMI ($\geq$15.6 kg/m^2) and stress ($\geq$ 46) reached thelarche 7 months earlier than girls with low glucocorticoid metabolites, BMI ($<$15.6 kg/m^2) and stress ($<$ 46). There were no interactions with family history. There were 12 primary principal components that explained 95% of the variation in the steroid metabolites and 3 of these were significantly associated with earlier age at thelarche including scores either high glucocorticoids, or high in androgen and progesterone metabolites and low levels of glucocorticoid metabolites, or high progesterone metabolites, specifically high 17a-hydroxypregnanolone, pregnenediol, but low 11-oxo-androsterone.

Conclusion

Elevated metabolites of glucocorticoids, androgens and progesterone are associated with accelerated pubertal onset, and BMI and stress modify this

association. Previous studies focus on estrogens, menarche and BMI; our results suggest that androgens and stress impact age at thelarche with implications for our understanding of pubertal development.

Modelling polycystic ovary syndrome *in vitro* with endometrium epithelial organoids and stroma cell culture

Anja Dekanski[1], Gustaw Eriksson[1], Tanja Turunen[1], Annika Vesterinen[1], Congru Li[1], Xu Zheng[2], Tina Gorsek-Sparovec[1], Terhi Piltonen[3], Angelica Lindén Hirschberg[4,5], Nayere Taebnia[1] & Elisabet Stener-Victorin[1]

[1]Karolinska Institutet, Physiology and Pharmacology, Stockholm, Sweden; [2]The Chinese University of Hong Kong, Prince of Wales Hospital, Obsetrics and Gynecology, Hong Kong, China; [3]Oulu University Hospital, University of Oulu, Obstetrics and Gynecology, Oulu, Finland; [4]Karolinska Institutet, Women's and Children's Health, Stockholm, Sweden; [5]Karolinska University Hospital, Gynecology and Reproductive Medicine, Stockholm, Sweden

Objective

Women with polycystic ovary syndrome (PCOS) experience reduced fertility associated with implantation failure, miscarriage and endometrial cancer, all linked to endometrial dysfunction[1]. Recently, we have created a single-nuclei transcriptomic atlas of the endometrium of women with PCOS[2]. Creating *in vitro* endometrial models is essential for studying PCOS-related dysfunction and treatments. This study develops three-dimensional (3D) endometrial epithelial organoids (EEOs) and single-layer stromal cells from endometrial biopsies of PCOS patients and controls to assess phenotype retention. Transcriptome profiling of EEOs and decidualized stromal cells is also included.

Methods

The 3D EEOs and the single-layer endometrial stromal cells are established from fresh endometrial biopsies of women with and without PCOS. Immunofluorescence staining showed that the EEOs consist of an intact proliferative basolateral epithelial membrane integrity. EEOs ($n = 4$ PCOS, $n = 4$ control) were subjected to hormone treatment (estrogen, progesterone and cyclic adenosine monophosphate, cAMP) over six days, with bulk RNA sequencing performed at day 0, day 2 and day 6. Similarly, single-layer endometrial stromal cells ($n = 3$ PCOS, $n = 3$ control) were treated with estrogen, progesterone and cAMP for 14 days and analysed for transcriptomic changes and cellular respiration using Seahorse XFe.

Results

EEOs displayed proliferative basolateral integrity and hormone responsiveness but lacked a strong PCOS signature in a static hormonal environment. To better mimic physiological conditions, a microfluidic system is being developed to simulate normal and anovulatory PCOS cycles. In contrast, stromal cells retained more PCOS-specific traits, exhibiting altered decidualization responses and differences in progesterone receptor expression. Metabolic assays showed lower maximum respiration rates in PCOS stromal cells, and transcriptomic analysis revealed disruptions in progesterone signaling, mitochondrial function, and inflammation—potential contributors to implantation failure and adverse pregnancy outcomes.

Conclusion

These preliminary findings indicate that under a static hormonal environment *in vitro*, EEOs lose their PCOS phenotype, whereas stromal cells retain more PCOS-specific characteristics. This suggests that the *in vitro* conditions do not fully replicate the dynamic hormonal environment of the menstrual cycle. Integrating insights from the altered decidualization response in PCOS will further refine *in vitro* modeling, helping to elucidate the mechanistic underpinnings of endometrial dysfunction in PCOS and identify potential therapeutic targets.

Unveiling the genetic architecture of testicular volume: a population-based GWAS using machine learning-based mri segmentations

Philipp Beeken[1], Jan Ernsting[2,3,4], Lynn Ogoniak[1], Jacqueline Kockwelp[1], Tim Hahn[4], Benjamin Risse[1] & Alexander S. Busch[1]

[1]University of Muenster, Medical Faculty, Münster, Germany; [2]Institute for Geoinformatics, University of Münster, Münster, Germany; [3]Faculty of Mathematics and Computer Science, University of Münster, Münster, Germany; [4]Institute for Translational Psychiatry, University of Münster, Münster, Germany

Background

The genetic basis of male fertility remains poorly understood. Previous studies, including those using ICD-10 codes and small-scale datasets, have failed to identify genetic loci associated with male fertility with consistent reproducibility. Testicular volume, a reliable proxy for quantitative spermatogenesis and male fertility, presents distinct challenges for population-level assessment. Traditional measurement methods are invasive, often introducing selection bias and restricting the scalability of studies. Despite its pivotal role in reproductive health, the genetic architecture of testicular volume has not been systematically explored at population level.

Methods

Using machine learning-based segmentation techniques, we analyzed bi-testicular volume in a total of 22,499 male UK Biobank participants with abdominal DIXON MRI data. A subset of 350 scans was manually segmented by a medical professional to train a fully convolutional network (U-Net model), generating 22,149 segmentations. Of these, 859 were excluded by an algorithm for incomplete segmentations, and 2,182 were excluded after manual review for not meeting quality standards. Additionally, 460 participants with male-specific ICD diagnoses that could potentially affect segmentation were excluded. By adding the manually segmented scans, this resulted in 18,998 participants remaining for population level analysis. The segmented volumes were subsequently used for a genome-wide association study (GWAS) of bi-testicular volume, conducted using linear regression in PLINK and adjusted for age and the first ten genetic principal components.

Results

The U-Net used for MRI segmentation achieved a median Dice score of 0.87, demonstrating human-level performance and ensuring accurate volume quantifications used in the analysis. The mean (SD) bi-testicular volume was 52 (16) mL. Our population-based GWAS identified 14 genome-wide significant loci ($P < 5\times10^{-8}$), revealing key genetic determinants of testicular volume and male fertility. The strongest signal was observed at rs12271187 in the *FSHB* locus on chromosome 11 ($P = 1.33\times10^{-41}$), alongside a significant association at the *FSHR* locus on chromosome 2, highlighting the central role of the follicle-stimulating hormone, including its ligand and receptor, in male reproductive biology. Functional annotation revealed that many significant SNPs are enriched in regulatory regions, such as UTRs and intronic sequences, suggesting their involvement in transcriptional regulation.

Conclusion

Our study demonstrates the potential of machine learning for population-level analysis of testicular volume, addressing key challenges in male reproductive health research. It provides a foundation for future exploration of the genetic determinants of male fertility.

Changes in circulating small non-coding RNAs after castration

Ailsa Maria Main[1,2,3], Nina Mørup[1,3], Louise Sørensen[1,3], Mikkel Mejlgaard Fode[4,5], Jens Sønksen[4,5], Sofia Winge[1,3], Peter Busch Østergren[4,5], Anders Juul[1,3,5] & Kristian Almstrup[1,2,3]

[1]Copenhagen University Hospital - Rigshospitalet, Blegdamsvej 9, DK-2100, Copenhagen, Denmark, Department of Growth & Reproduction, Copenhagen, Denmark; [2]Faculty of Health and Medical Sciences, University of Copenhagen, Department of Cellular and Molecular Medicine, Copenhagen, Denmark; [3]International Center for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health, Denmark, Department of Growth & Reproduction, Copenhagen, Denmark;

[4]Department of Urology, Copenhagen University Hospital – Herlev and Gentofte, Herlev, Denmark; [5]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark

Background
Small non-coding RNAs (sncRNAs) are found in circulation and are effective disease biomarkers. Some sncRNAs are actively secreted into circulation and may carry an endocrine signal to target tissues. Here, we identify circulating sncRNAs originating from the testis by mapping circulating sncRNAs before and after castration.
Methods
A cohort of 57 men with prostate cancer were randomised to either subcapsular orchiectomy (O-arm, $n = 28$) or GnRH-analogue (G-arm, $n = 29$) as part of a previous study. Blood samples were taken at baseline (W0), 12 weeks (W12), and 24 weeks (W24). RNA from 169 longitudinally paired serum samples was isolated and sequenced using the RealSeq-Biofluids Small RNA library preparation kit and sequenced on an Illumina NextSeq 550. Data from samples of suboptimal quality ($n = 5$) were excluded.
Results
JOINT analysis of sncRNA reads at W12 and W24 in contrast to W0 identified 81 and 175 circulating sncRNAs that were present at significantly different levels in the O-arm and G-arm, respectively. Most sncRNAs were found in lower levels (67 and 150 in the O- and G-arm, respectively) and only a few at higher levels (14 and 25 in the O- and G-arm, respectively). The most prevalent type of sncRNA identified to be differentially present after castration was piRNAs contributing to 44% (36 piRNAs) in the O-arm and 58% (101 piRNAs) in the G-arm. We identified 16 sncRNAs that were differentially present in both the O- and G-arm. Of the 16 overlapping sncRNAs, 5 have previously been reported in RNAseq from the testes and 8 (50%) were piRNAs, indicating that a testicular origin is likely.
Discussion
We identified several circulating sncRNAs that were significantly altered in serum from men after castration. The sncRNAs likely originate from the testis and could be novel markers of testicular function that potentially carry an endocrine message. However, the study was based on older men with prostate cancer who likely did not possess optimal testicular function at baseline, and we cannot rule out confounding effects from the treatment of prostate cancer.

Maternal urinary paracetamol is associated with reduced uterine size and breast tissue diameter at infancy: a COPANA cohort study of 302 healthy girls

Margit Bistrup Fischer[1,2], Gylli Mola[1,2], Hanne Frederiksen[1,2], Karin Sundberg[3], Ane Lilleøre Rom[4,5], Hanne Kristine Hegaard[4,6], Anders Juul[1,2,6] & Casper P Hagen[1,2,6]
[1]Department of Growth and Reproduction, Copenhagen University Hospital- Rigshospitalet, Copenhagen, Denmark; [2]International Center for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark; [3]Center of Fetal Medicine and Pregnancy, Department of Obstetrics, Copenhagen University Hospital - Rigshospitalet., Copenhagen, Denmark; [4]Department of Gynaecology, Fertility and Obstetrics, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark; [5]Research Unit of Gynaecology and Obstetrics, Department of Clinical Research, University of Southern Denmark, Odense, Denmark; [6]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark

Background
Maternal self-reported use of paracetamol during early pregnancy is associated with impaired ovarian function and reduced uterine size in female offspring. A single study reported urinary paracetamol (U-paracetamol) levels above 4000 ng/mL post-consumption – remaining over 1000 ng/mL for up to two days. However, no standardized cutoff for recent use exists. An alternative source of paracetamol is Aniline (textiles and pesticides), which is metabolized in the liver to paracetamol. Due to potential recall bias in self-reported data, urinary paracetamol levels may offer a more objective exposure assessment.
Aim
The first study evaluating associations between maternal U-Paracetamol measurements and ovarian activity in offspring.
Design
Prospective, observational pregnancy and birth cohort; The Copenhagen Analgesic Study (COPANA). (ClinicalTrials.gov NCT04369222).
Setting
Copenhagen University Hospital - Rigshospitalet (2020-2022).
Methods
Healthy, singleton pregnant women, enrolled in first trimester of pregnancy ($n = 685$), 589 infants (302 girls) examined. All pregnant women provided a urine sample in gestational week 14.1 (1.8) mean ($\pm$SD). Urinary levels of total paracetamol (free and conjugated) were measured (LC-MS/MS) and adjusted for urinary osmolarity. To ensure sufficient statistical power, girls whose maternal U-paracetamol levels exceeded 1500ng/mL ($n = 21$) were defined as highly exposed. Girls examined (age 3.4 months (0.4) mean ($\pm$SD)): breast tissue diameter ($n = 300$), ovarian volume ($n = 203$), total follicle count, ($n = 203$), uterine length ($n = 257$) and volume ($n = 230$) by transabdominal ultrasound. Blood samples ($n = 269/302 = 89\%$): AMH, FSH, LH, Inhibin B (immunoassays), E2 (LC/MS-MS).
Results
Paracetamol was measurable in all urine samples median (IQR) 64.5ng/mL (34.6-141.8), 14/21 women with U-paracetamol >1500ng/mL reported use of paracetamol in the first trimester. Uterine length and volume as well as breast tissue diameter were reduced in girls highly exposed to paracetamol in early fetal life; maternal U-paracetamol ≥ 1500ng/mL vs. <1500ng/mL, uterine length: 22.5 cm (20.4-26.7) vs. 25.5 cm (23.6-27.4) median (IQR) $P = 0.012$, uterine volume: 9.7 cm^3 (8.0-11.8) vs. 12.2 cm^3 (9.8-15.1), $P = 0.038$, mamma tissue diameter: 8. 0 mm (0-10.6) vs. 9. 6 mm (7.1-11.9), $P = 0.049$. Additionally, there was a trend towards reduced ovarian volume: 2.1 cm^3 (1.39-3.47) vs. 2.8 cm^3 (1.7-4.5), $P = 0.095$.
Conclusions
Including novel, objective assessment of paracetamol exposure in early fetal life, high levels of maternal U-paracetamol was associated with reduced sizes of estradiol-targeted organs, specifically the uterus and breast tissue. A trend of smaller ovarian volume suggests lower estradiol production, though single estradiol measurements showed no clear association, possibly due to individual fluctuations during minipuberty. Despite relying on a single U-paracetamol evaluation, findings align with self-reported data, reinforcing concerns about maternal paracetamol use affecting offspring ovarian function.

JOINT1611

Central precocious puberty in males, whether GnRH analog-treated or untreated, is not associated with fertility or general health problems in mid-adulthood

Liat de Vries[1,2], Michal Yackobovitch-Gavan[1,2], Tal Oron[1,2], Moshe Phillip[1,2], Joseph Meyerovitch[1,2], Ariel Tenenbaum[1,2] & Liora Lazar[1,2]
[1]Faculty of Medical & Health Sciences, Tel Aviv University, Tel Aviv, Israel; [2]Schneider Children's Medical Center of Israel, The Jesse Z and Sara Lea Shafer Institute for Endocrinology and Diabetes, Petach Tikva, Israel

Context
Knowledge is limited about the long-term health implications of idiopathic central precocious puberty (ICPP) in males, treated or untreated.
Objective
To assess the general health status and metabolic outcomes of men who had ICPP in childhood.
Design
A case control study of an historical cohort from a tertiary pediatric care center.
Patient
The study group comprised 118 men with ICPP aged 29-48 years, of whom 68 had been treated with GnRH-analog (GnRHa) and 50 were untreated. The control group comprised 351 men who were matched for age, year of birth and community clinic: 204 for the GnRHa-treated and 147 for the untreated group.

Methods
We extracted from the computerized database of a health management organization, demographic data, medical history, medications dispensed, recorded anthropometric measurements and laboratory data.
Outcome Measures
The prevalences of fertility issues, cardio-metabolic disorders (obesity, hypertension, dyslipidemia, diabetes), osteoporosis, malignancy and emotional problems.
Results
The median (interquartile range) current ages of the GnRHa-treated and untreated ICPP groups were 40 (29,44) and 44 (40,46) years, respectively. The prevalence of fertility issues was not statistically different between the study and control groups (11.8 vs. 16.2%, $P = 0.3$), nor between those with ICPP who were treated and untreated (11.8 vs. 18.4%, $P = 0.3$). For the study and control groups, the rates of obesity, metabolic disorders and cardiovascular diseases were similar. For the study group, both treated and not treated, the rates of osteoporosis and malignancy were less than 10%, and comparable to those of the control group. Emotional problems presented similarly, in less than 20%, of the study and control groups.
Conclusion
ICPP in males, treated or untreated, was not associated with increased fertility problems, cardio-metabolic disorders, malignancy or psychopathology in mid-adulthood. The health status of men who had ICPP was comparable to that of the general population.

Testosterone to estradiol ratio in men with acute coronary syndrome

savi shishkov[1,2], Radina Dimitrova[1,2] & Mira Siderova[1,2]
[1]UMHAT "St. Marina", Clinic of Endocrinology and metabolic diseases, Varna, Bulgaria; [2]Medical University Varna, Second department of internal medicine, Varna, Bulgaria

Introduction
Sex hormones are believed to be responsible for gender difference in cardiovascular disease incidence and morbidity. The ratio between testosterone (T) and estradiol (E2) in men is associated with some health outcomes and behavioral traits.
Aim
We decided to investigate the ratio between T and E2 in the acute period after the onset of the acute coronary syndrome (ACS). It was hypothesized that the T to E2 ratio rather than the separate values alone may better reflect the severity of the cardiovascular event or relate to established risk factors.
Methods
For a period of three years 72 male patients with ACS, mean age 56.75, and 35 controls, mean age 54.22, were recruited. Student t-test, Mann-Whitney U-test and correlation analysis in SPSS v24 were applied.
Results
Lower values of both total and free T were found in the ACS group compared to controls (8.97 vs. 10.98 nmol/l, p=.001 for total T and 0.189 vs. 0.223 nmol/l, p=.006 for free T). Patients with myocardial infarction with ST-elevation (STEMI) had significantly lower T fractions compared to ACS without ST-elevation (NSTEMI). E2 values did not differ in both groups ($P > .05$) The T to E2 ratio on the other hand was significantly lower in the ACS group compared to the control subjects. The patient group had a more estrogenic hormonal environment with a mean value of T to E2 ratio 51.7 compared to 71.7 in the controls. ($P < .001$). The same tendency is valid when comparing ACS with ST-elevation to ACS without ST-elevation with lower value in the STEMI subgroup (T/E2: 46.9 vs. 64.1, p=.014). In the ACS group higher body mass index was associated with higher T/E2 ratio (r=-.277, p=.024). Free T was associated with GRACE risk and mortality risk score after adjusting for age (r=-.25, p=.043) but not T/E2 ratio (p=.97) or total T (p=.49).
Conclusion
Lower T/E2 ratio (more estrogenic environment) is observed in patients with ACS. Decrease in the substrate for E2 production as well as an increase in aromatization are possible mechanisms. Comparable to the decrease of T in ACS this may represent an adaptive response, but the significance of this finding is unclear. Free T on the other hand correlates with the cardiovascular risk even after correction for age. These results are in favor of sex hormones interrelation with the onset of acute cardiovascular events.

Keywords
acute coronary syndrome, testosterone, estradiol, ratio.

Introduction
The Long-Acting Growth Hormone Database in China, a brunch of the international GloBE-Reg (https://globe-reg. net/) project, was launched in 2023. It aims to establish the first database focusing on long-acting growth hormone (LAGH) in China and even globally, providing clinical data on the long-term efficacy and safety of PEGylated recombinant human growth hormone (PEG-rhGH)in the clinical practice for children with short stature.
Method
The GloBE-Reg database of LAGH in China has three layers of datasets. The first dataset is the core dataset applicable to any short stature indication, another dataset that allows the selection of a specific therapy and diagnosis, and the third dataset includes a therapy and diagnosis-specific minimum dataset (MDS) which collects information on diagnosis, therapy, clinician reported outcomes, patient reported outcomes and adverse events.
Results
Up to January 9, 2025, 29 hospitals have completed ethical reviews and 25 have been initiated across 17 provinces and cities in China, successfully recruiting 616 patients(male: female, 368: 248). The median age at the start of treatment was 6.42 years (range 0.68-16.00), baseline height was 109.94 cm (range 60.00-152.00), height Standard Deviation Score(Ht SDS) was -2.64±0.73, and baseline weight was 19.48 kg (range 5.30-54.00), -1.4±0.80 SDS. Currently approved indications for PEG-rhGH in China include growth hormone deficiency (GHD), idiopathic short stature (ISS) and Turner syndrome (TS).A total of 569 cases (92.4%) have been recorded for indications, including GHD 373 cases (60.6%), ISS 147 cases (23.9%) and TS 49 cases (8.0%). There are 47 off-label cases, including 22 cases of (3.6%) small for gestational age (SGA), Noonan syndrome(NS) 8 cases(1.3%), Silver-Russell syndrome (SRS) 8 cases (1.3%) and 9 cases of other rare causes of short stature including mixed gonadal dysplasia, 46 XX ootestis and Wiedemann-Steiner syndrome and so on. The initial dose of PEG-rhGH for GHD/ISS/TS/SGA/NS was 0.18/0.18/0.18/0.18/0.17 mg/kg/w respectively, with a mean duration of 2.39 years (range 0.44-7.40). In the 616 cases, 244 were followed up for >6 months, and the Ht SDS increase was 0.54±0.28,199 were followed up for one year, and the Ht SDS increase was 0.88±0.44.
Conclusion
The GloBE-Reg database of LAGH in China has been active. The analysis of large amount of data will provide treatment recommendations and decision support for long-term safety and efficacy studies of PEG-rhGH.

The Effects of isotretinoin on male reproduction

Fie Thomsen[1], Anne Jørgensen[1,2], Christine Andreassen[1,2], Hanne Frederiksen[1], Lærke Priskorn[1], Niels Jørgensen[1], Anders Juul[1] & Anders Rehfeld[1]

[1]Rigshospitalet, Copenhagen University Hospital, Department of Growth and Reproduction, Copenhagen, Denmark; [2]Copenhagen University Hospital - Herlev and Gentofte., Division of Translational Endocrinology, Department of Endocrinology and Internal Medicine, Copenhagen, Denmark

Introduction

The vitamin A derivative, isotretinoin, is known for its efficacy in the treatment of acne vulgaris. Isotretinoin use among young men is increasing. In 2023, the number of users in Denmark had risen to 10,015 (3.40 per 1,000), with the highest incidence observed among men aged 18–24-years (12.51 per 1,000). Isotretinoin is a stereoisomer of retinoic acid, which has a crucial role in spermatogenesis. Recent studies on isotretinoin exposure and male fertility remain inconclusive, suggesting both positive and negative effects. Therefore, we aimed to further investigate the potential side-effects of isotretinoin on male reproductive health.

Methods

The effects of isotretinoin and retinoic acid were investigated 1) *in vitro* on human sperm cells using a Ca^{2+}-fluorometric assay, and 2) *ex vivo* in hanging drop cultures of human testis tissue (for 96 hours). Germ cell proliferation and apoptosis in cultured testicular tissue were assessed through BrdU incorporation and c-PARP antibody detection with IHC staining. Steroid hormones, secreted by the cultured testis tissue, were measured using isotope-diluted on-line Turbo-Flow-LC-MS/MS, and Inhibin B was detected by ELISA. Additionally, 3) a cross-sectional analysis of the *in vivo* data from the Danish Young Men Study (DYMS) cohort compared reproductive hormones and semen parameters between isotretinoin users and non-users.

Results

Isotretinoin and retinoic acid (in concentrations of 12.5-100μM) induced Ca^{2+} signals and inhibited progesterone- and prostaglandin-initiated signals through the CatSper Ca^{2+} channel in sperm cells. In testicular cultures, neither isotretinoin nor retinoic acid significantly affected germ cell proliferation or apoptosis. However, assessment of hormones in the culture media revealed changes in secreted androgens, progestins and corticoids. Testosterone and androstenedione were significantly increased, while DHEAS decreased, after exposure to the highest isotretinoin concentrations (15-25 μM). Dihydrotestosterone (DHT) and inhibin B were significantly decreased under varying isotretinoin and retinoic acid concentrations (10-25μM). Progesterone and 17-hydroxypregnenolone increased across all isotretinoin and retinoic acid concentrations (10-25 μM), as did the corticoids, 11-deoxycorticosterone (DOC) and 11-deoxycortisol (11-DOC). Analysis of the DYMS cohort revealed significantly higher estradiol in isotretinoin users ($n = 51$) compared to non-users ($n = 6{,}498$), but no differences in semen parameters.

Conclusion

Our preliminary results indicate effects of isotretinoin on several male reproductive parameters. To establish its definitive role, further *in vitro* and *ex vivo* studies are needed, alongside more comprehensive investigations of the *in vivo* DYMS cohort data. These efforts are crucial to determining the potential side-effects of isotretinoin on male reproductive functions.

Childhood gonadectomy in ireland in differences of sex development (DSD)/intersex: clinical characteristics, historical and current practices, and incidence of gonadoblastoma

Claire Reynolds[1], Michael McDermott[2], Michelle O'Connell[3], David Coyle[4], Fergal Quinn[4], salvatore Cascio[4], Nikita Deegan[5] & Susan M O'Connell[1,6]

[1]Children's Health Ireland, Department of Paediatric Diabetes and Endocrinology, Dublin, Ireland; [2]Children's Health Ireland, Department of Pathology, Dublin, Ireland; [3]The Royal Children's Hospital and Murdoch Children's Research Institute, Department of Paediatric Endocrinology and Diabetes, Melbourne, Australia; [4]Children's Health Ireland, Department of Paediatric Urology, Dublin, Ireland; [5]Children's Health Ireland, Department of Paediatric and Adolescent Gynaecology, Dublin, Ireland; [6]Royal College of Surgeons in Ireland (RCSI), Paediatrics, Dublin, Ireland

Background

Differences of sex development(DSD)/Intersex are a heterogeneous group of congenital conditions affecting human sex determination and differentiation, classified based on karyotype and include: sex chromosome DSD, 46XX DSD and 46XY DSD. There is a risk of gonadal tumour development with an estimated prevalence of germ cell cancer (GCC) ranging from 0.8 to 40% depending on age and underlying condition. Gonadoblastoma (GB), is the precursor lesion of GCC in the dysgenetic gonad. Clinical recommendations and practice in DSD gonadectomy have evolved over time. International practice in DSD gonadectomy varies and optimal management of gonads is currently not well established.

Objectives

To determine the frequency and indication for childhood gonadectomy in DSD in Ireland over the last 25 years; and the incidence and clinical features of GB during this period.

Methods

From 1999 to 2024, all paediatric patients with DSD who underwent gonadectomy at the national referral centre for DSD at Children's Health Ireland were included. Patients' demographics, karyotype, sex of rearing, genetic results, and gonadal tissue histopathology were collected; retrospectively between 1999-2022 and prospectively between 2022-2024 as part of the International DSD registry study.

Results

A total of 57 patients with DSD (46 females) underwent gonadectomy. The main indications were risk of gonadal tumour development (41/57; 71%), GB identified on biopsy (5/57; 8%), incongruent hormone production (9/57; 15%) and concordance to sex assignment (2/57; 3%). The mean age at gonadectomy was 7.75 years (2 weeks to 18 years). GB was confirmed in 30% (17/57) of cases on histopathology of gonadal tissue, with 3 cases associated with dysgerminoma. GB was most frequently reported in 46XY complete gonadal dysgenesis (CGD) (8/17; 47%), followed by Turner syndrome Y chromosome material (7/17; 41%), and partial gonadal dysgenesis (2/17; 11%). The mean age of tumour diagnosis was 6.96 years (2 weeks to 17 years). The majority of tumours were unilateral (9/17; 52%) and located intra-abdominally (16/17; 94%). For all cases of dysgenetic gonads, the calculated risk of developing gonadal tumours was 38% (16/42). Patients with 46XY CGD demonstrated the highest risk of developing gonadal tumours (8/11; 72%).

Conclusion

The majority of gonadectomies were performed in dysgenetic gonads, either to mitigate tumour risk or remove gonadal tumours. The high incidence of gonadal tumours in dysgenetic gonads, particularly in 46XY CGD, highlights the importance of early prophylactic gonadectomy which should be performed only after multidisciplinary team discussion, which will be informed by these findings.

Testicular index: a simple, clinically applicable tool to predict pregnancy outcomes in men with idiopathic infertility undergoing follicle-stimulating hormone treatment

Giorgia Spaggiari[1], Raffaele Scafa[2], Giuseppe Grande[3], Marilina Romeo[1,4], Leonardo Dalla Valentina[1,4], Andrea Graziani[2], Antonio Raffaele Michele Granata[1], Andrea Garolla[2,3], Manuela Simoni[1,4], Daniele Santi[1,4] & Alberto Ferlin[2,3]

[1]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy; [2]University of Padova, Department of Medicine, Padova, Italy; [3]University Hospital of Padova, Unit of Andrology and Reproductive Medicine, Padova, Italy; [4]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy

Background

Follicle-stimulating hormone (FSH) therapy has been shown to improve spermatogenesis, sperm quality, and reproductive outcomes. However, variability in patients' response and limited data on pregnancy rate complicate its extensive application in male idiopathic infertility.

Aim of the Study

To identify predictors of FSH efficacy in men with idiopathic infertility in terms of pregnancy obtainment.

Materials and Methods

A multicenter, retrospective, observational study was conducted at two Italian outpatient clinics from June 2019 to October 2024. We enrolled men with idiopathic infertility and FSH serum levels < 8 IU/l treated with FSH. Data from two visits were analyzed: baseline (V0) and the final follow-up visit (V1) when FSH treatment was discontinued. Predictors of pregnancy achievement were

searched among the data collected, such as semen parameters, hormonal levels, and testicular volumes. Different "testicular indexes" were calculated using V0 FSH and testosterone serum levels, bi-testicular volume and semen parameters.
Results
443 men were included, of which 84 achieved pregnancy (19%). One testicular index ((FSH + Total testosterone) / bi-testicular volume) was directly related to V0 semen parameters and entered in subsequent analyses. Significant improvements in sperm concentration, motility, and total sperm count were observed following FSH treatment regardless of whether or not pregnancy was achieved. However, men who achieved pregnancy had higher baseline testicular index, larger testicular volume, and lower FSH levels. Multivariate analysis identified patients' age and testicular index as significant predictors of pregnancy success.
Conclusion
This large, multicenter, real-life study identified a novel testicular index that predicts response to exogenous FSH stimulation, overcoming limitations of conventional semen analysis. The index assesses the interstitial compartment function (indicated by testosterone levels), spermatogenic potential (reflected by FSH levels), and target tissue amount (indicated by testicular volume). We demonstrate that low baseline testicular index correlates with a higher likelihood of achieving pregnancy through exogenous FSH stimulation.

Background
Effective and timely induction of puberty is crucial to ensure optimal physical development, psychosocial well-being, and long-term health outcomes in patients with primary ovarian insufficiency(POI). Turner Syndrome (TS) and chemo or radio-induced damage are the main causes of POI in adolescents. The aim of this study is to evaluate and compare the approaches and outcomes of puberty induction in a cohort of patients affected with POI, secondary to TS or who had undergone hematopoietic stem cell transplantation (HSCT) for oncological or hematological conditions.
Methods
Medical records of patients with POI who received hormonal replacement therapy (HRT) between 2012 and 2021 were retrospectively reviewed. Auxological data and estrogen replacement schedules were recorded from baseline(T0) until the initiation of progestin treatment. Data were collected at intervals of 6(T1), 12(T2), 18(T3), 24(T4) and 36 months(T5). Information on bone age, bone mineral density (BMD) and pelvic ultrasonography findings were gathered.
Results
53 patients (29 TS and 24 HSCT) were included. No significant differences in auxological parameters were observed between the groups, except for stature. The mean duration of puberty induction was similar in both groups (2.68 ± 0.98years in TS vs. 2.53 ± 1.03years in HSCT), with a shorter duration of HRT in patients who were already at a pubertal stage beyond S1 at T0 (2.20 ± 1.1 vs. 2.80 ± 0.90years, $P = 0.04$). All patients received transdermal HRT, except for 8 patients with TS who received oral therapy. Across the entire cohort, a positive correlation was observed between the progression of sexual characteristics and the estrogen dose ($r = 0.515$), which remained significant when analyzing the two groups separately. Growth velocity(GV) mimicked a physiological pubertal spurt in all patients. However, from 18 months onward, TS patients exhibited a more pronounced decline in GV compared to HSCT patients (3.9 ± 1.8 vs 4.7 ± 1.9 cm). At T1, GV showed a weak negative correlation with estrogen dose (r:-0.205), which was more evident in the TS group (r:-0.333). By T2, this association became positive (r:0.293; stronger in TS r:0.388). At other timepoints, no significant associations were observed. Age and estrogen dose at T0 were negatively correlated with final BMD ($r = -0.019$), but they were positively associated with the magnitude of BMD's improvement during therapy ($r = 0.333$).
Conclusions
Our results confirm the importance of starting treatment at a physiological age of puberty, independently of POI origin. Comparable outcomes were observed in the two groups in terms of evolution of puberty, growth velocity, at least in the first year, and bone density.

Risk of advanced chronic kidney disease in transgender individuals undergoing gender-affirming hormone therapy compared with the general population

Mees van Zijverden[1,2], Sarah van Eeghen[1,2], Jeske van Diemen[3], Daniël van Raalte[4], Martin den Heijer[1,2] & Abel Thijs[3]
[1]Amsterdam University Medical Center, Department of Endocrinology, Amsterdam, Netherlands; [2]Amsterdam University Medical Center, Center for Expertise on Gender Dysphoria, Amsterdam, Netherlands; [3]Amsterdam University Medical Center, Department of Internal Medicine, Amsterdam, Netherlands

Background
An increasing number of individuals worldwide identify as transgender, and many undergo gender-affirming hormone therapy (GAHT) to align their physical characteristics with their gender identity. Feminizing GAHT typically involves estradiol, with or without an antiandrogen, while masculinizing GAHT involves testosterone. Simultaneously, the worldwide prevalence of chronic kidney disease (CKD) rises, presenting a significant global health challenge. Men in the general population have a higher risk of advanced CKD than women, potentially due to differences in sex hormone concentrations. Previous studies in transgender individuals confirmed this role for sex hormones, as estimated glomerular filtration rate (eGFR) increases with feminizing GAHT and decreases with masculinizing GAHT. However, these studies were limited to short-term follow-up, leaving long-term effects of GAHT on CKD risk unclear. This current study aimed to fill these knowledge gaps, by investigating the long-term risk of advanced CKD in transgender individuals undergoing GAHT, compared with the general population.
Methods
This retrospective cohort study included individuals who visited the gender identity clinic at Amsterdam University Medical Centre (1972–2018). Their records were linked to a nationwide registry (2012–2022). Advanced CKD was defined as eGFR <30 mL/min per $1.73m^2$ or chronic dialysis. Individuals who did not use GAHT or died before 2012 were excluded. Standardized incidence ratios (SIRs) were calculated for transgender women and -men using general population incidence rates stratified by age and socioeconomic status (based on education, income and employment).
Results
The study included 2,694 transgender women (follow-up: 22,759 person-years) and 1,612 transgender men (follow up: 12,970 person-years). Median age at GAHT initiation was 30 years (IQR 24–41) for transgender women and 24 years (IQR 20–32) for transgender men. Seventeen transgender women developed advanced CKD, with no increased risk compared with men (SIR 1.6; 95% CI, 0.9–2.5), but a significantly higher risk compared with women (SIR 2.5; 95% CI, 1.4–3.9) in the general population. Eight transgender men developed advanced CKD, with significantly higher risks compared with both women (SIR 3.8; 95% CI, 1.5–7.0) and men (SIR 2.6; 95% CI, 1.0–4.9) in the general population.
Conclusion
Transgender women undergoing feminizing GAHT are at higher risk of advanced CKD compared with women, but not with men in the general population. Transgender men undergoing masculinizing GAHT are at higher risk compared with both women and men. These findings underline the need for tailored clinical care to address the unique health risks faced by transgender individuals.

Background
NR5A1/SF-1 variants cause differences of sex development (DSD) and manifest with a broad phenotype. Many individuals with DSD and *NR5A1*/SF-1 variants have anomalies in other organs, predominantly the spleen, rarely the adrenals. Oligogenicity could contribute to the variable phenotype. This study aimed at investigating individuals with *NR5A1*/SF-1 variants presenting with DSD and adrenal anomalies for additional genetic variants that may promote their exclusive adrenal phenotype.
Methods
Within the framework of the SF1next study, we had four patients with a DSD phenotype and adrenal anomalies. These individuals were investigated by whole exome sequencing (WES); after filtering, variants were classified according ACMG guidelines for pathogenicity assessment. Of patient 3 (Table1) and a healthy donor, we differentiated human fibroblasts-derived induced pluripotent stem cells (iPSCs) into adrenal-like cells (iALC) and assessed the model by liquid chromatography–mass spectrometry (LC-MS). Analysis of the transcriptome (RNA-seq) was performed to compare differentially expressed genes (DEG) between *NR5A1*/SF-1 mutant and wild-type (wt) iALC.
Results
Table1 summarizes the phenotypic and genetic characteristics of the four patients. Besides the *NR5A1*/SF-1 variants, we found additional (likely) causative variants in *NNT* and *CDKN1C* genes with established involvement in adrenal disorders in two patients. In the other two patients, filtering revealed one potentially deleterious variant in *ADCY1* and *ABLIM3,* respectively. RNAseq showed that expression levels of 1480 genes were significantly different (up or downregulated) in the mutant *NR5A1*/SF-1 in comparison to wt when investigated within the background context of patient and control-derived iALCs. We observed higher expression levels of NR5A1/SF-1 in mutant than in wt iALC, while ABLIM3 expression levels were similar across samples.
Conclusion
Our study indicates that individuals with DSD and rare adrenal anomalies who have *NR5A1*/SF-1 variants, harbor other deleterious gene variants that may explain their adrenal phenotype. Thus, variants in *NR5A1*/SF-1 may not suffice to cause an adrenal phenotype. Our in-vitro model is a potent tool to study adrenal anomalies and the molecular effects of novel genes proposed to be disease-causing.

Background
The global rise in the use of assisted reproductive technology (ART) reflects the declining fertility rates. Investigation of the long-term health of children born after ART is therefore important. A former registry-based study found a higher risk for early puberty in girls and late puberty in boys conceived after ART.
Methods
Pubertal development and serum concentrations of reproductive hormones were evaluated in 606 singletons (292 boys) aged 7-10 years from the Health in Childhood following Assisted Reproductive Technology (HiCART) cohort. The HiCART cohort included children conceived after ART with frozen embryo transfer (FET) $n=$ 200, fresh embryo transfer (Fresh-ET) n = 203 and natural conception (NC) $n=203$. Concentrations of luteinizing hormone (LH), follicle-stimulating hormone (FSH), and sex hormone-binding globulin (SHBG) were measured by immunoassays, and concentrations of estradiol (E2), testosterone (T), dehydroepiandrosterone sulfate (DHEAS), androstenedione and 17-hydroxyprogesterone (17-OHP) were measured by liquid chromatography-tandem mass spectrometry (LC-MS/MS).
Results
Mean age at examination was 8.53 years (0.55 standard deviation [SD]). BMI (SDS) did not differ significantly between the three groups. Stratification for sex revealed a significantly higher weight (SDS) (adjusted mean differences 0.35, 95% CI (0.03; 0.67)) and height (SDS) (0.43 (0.11; 0.76)) in the girls conceived after FET vs. NC. Among girls, clinical signs of puberty (Tanner $\geq$ B2) were found in 14% (16/107) in the FET-group, in 16% (15/98) in the fresh-ET-group and in 23% (23/98) in the NC-group, with no difference between the three groups (Chi-square P = 0.35). Clinical signs of puberty below the age of 8 years were found in 6/314 girls (median age 7.79 [range 7.46-7.87]), of whom three were in the FET-group and three in the NC-group. The concentration of LH was below 0.3 IU/l in all six girls, while four out of six girls had measurable estradiol. Among boys, clinical signs of puberty (testicular volume >3 ml) were absent in boys in the FET-group (0/86), while present in 2% (2/99) in the fresh-ET group and in 1% (1/101) in the NC-group. No significant difference was found in concentrations of hormones (LH, FSH, SHBG, E2, T, DHEAS, Androstenedione and 17-OHP) when comparing respectively girls and boys born after FET, Fresh-ET and NC, neither in the entire cohort nor after excluding pubertal children.
Conclusion
Pubertal development, reproductive hormones, and the prevalence of precocious puberty was not altered in the children conceived after ART. This is re-assuring on an individual and societal level as there is an increasing need for ART.

Habitual activity and muscle strength in children of mothers with, or without, polycystic ovary syndrome

Camilla Viola Palm[1,2,3], Anders Grøntved[4], Henrik Christesen[3,5], Dorte Glintborg[1,3] & Marianne Andersen[1,3]
[1]Odense University Hospital, Endocrinology and Metabolism, Odense, Denmark; [2]Odense University Hospital, Gynecology and Obstetrics, Odense, Denmark; [3]University of Southern Denmark, Clinical Research, Odense, Denmark; [4]University of Southern Denmark, Sports Science and Clinical Biomechanics, Research Unit for Exercise Epideomiology, Odense, Denmark; [5]Odense University Hospital, H.C. Andersens Children's Hospital, Odense, Denmark

Background
Maternal free testosterone (FT) in 3rd trimester is higher in women with polycystic ovary syndrome (PCOS) compared to women without PCOS. In Odense Child Cohort, maternal FT was inversely associated with handgrip strength in boys and girls at age 5 years. Furthermore, higher maternal FT was associated with more body fat in boys at 7 years of age.

Aim
To investigate associations between 3rd trimester FT in women with and without PCOS and child physical activity engagement and isometric muscle strength at 7 years of age.
Hypothesis
Children exposed to higher maternal FT exhibit less physical activity engagement and reduced isometric muscle strength, with possible sexual dimorphism.
Methods
In the prospective Odense Child Cohort, Denmark, 146 of 976 mothers (9%) had a PCOS diagnosis during pregnancy. Maternal FT was calculated from total testosterone analyzed by mass spectrometry and sex hormone binding glubulin measured at gestational weeks 28-30. In their 7-year-old children, we assessed physical activity engagement by 24-hour/7-days accelerometers (n = 695, counts/min (overall activity volume) and time spent in light/moderate/vigorous physical activity), and isometric muscle strength (n = 976, Newton/kg bodyweight), measured by maximal voluntary contraction of the abdomen. Multiple linear regression models were adjusted for maternal age, parity, educational level and accelerometer non-wear.
Results
In boys, maternal PCOS in pregnancy was associated with less overall physical activity engagement, with 265 fewer counts/min on weekends (p=0.02) and 154 fewer counts/min on all days (weekend and weekdays) (p=0.04), whereas no association was found on weekdays. Maternal PCOS was also associated with less moderate (β=-6.7 min/day, p=0.05), vigorous (β=-6.3 min/day, p=0.03) and moderate-vigorous physical activity (β=-12 min/day, p=0.03) on weekends. Maternal FT was not associated with isometric muscle strength in boys. In girls, maternal PCOS was not associated with physical activity engagement. However, one nmol/l increase in maternal FT was associated with an 8.5 Newton/kg bodyweight decrease in isometric muscle strength (p=0.003).
Conclusion
Boys born of mothers with PCOS had less physical activity in weekends. In girls, prenatal exposure to higher 3rd trimester FT was linked to lower isometric muscle strength.

Childhood body mass index trajectories in women diagnosed with polycystic ovary syndrome

Zindie Rasmussen[1], Grith Laerkholm[1], Pernille Roenn[2], Rasmus Wibaek[2] & Rikke Jensen[1,2,3]
[1]Copenhagen University Hospital, Herlev Hospital, Department of Pediatric and Adolescent Medicine, Herlev, Denmark; [2]Steno Diabetes Center Copenhagen, Clinical and Translational Research, Copenhagen University Hospital, Herlev, Denmark; [3]University of Copenhagen, Department of Clinical Medicine, Herlev, Denmark

Background
Most adolescent girls and young women diagnosed with polycystic ovary syndrome (PCOS) have an increased body mass index (BMI) compared to the general population. However, the detailed BMI trajectories during childhood among women later diagnosed with PCOS remain poorly understood.
Methods
This retrospective register-based study retrieved data on anthropometric measurements during childhood in women diagnosed with PCOS between 2003 and 2022. Data were obtained from the Danish registries; The National Patient Register, The Children's Database and The Danish Medical Birth Register. Latent class analysis (LCA) was used to identify distinct BMI trajectories. Additionally, BMI standard deviation score (SDS) was analyzed at 5-10 years of age and at 13-18 years of age. Birth characteristics were investigated by assessing the mean birth weight, mean birth weight (SDS) and mean gestational age.
Results
We identified 16,322 women diagnosed with PCOS between 2003 and 2022. Of these, 1,143 women had ≥3 measurements of height and weight, including birth weight and length, and they were included in the LCA. The LCA revealed three distinct BMI trajectories, all characterized by an early increase in BMI leading to overweight or obesity already during childhood, which persisted into adolescence. However, the trajectories differed in growth pattern, timing, and intensity of BMI change. Median BMI (SDS) was 1.1 (0.2-2.1 IQR) in the 5-10-year age group (n = 599) and 1.2 (0.2-2.1 IQR) in the 13-18-year age group (n = 1,619), suggesting that women later diagnosed with PCOS are overweight throughout childhood and adolescence. Birth characteristics in 16,123 women with PCOS did not differ from the WHO growth standards.
Conclusion
Women with PCOS experience an early and sustained increase in BMI during childhood, which continues into adolescence. The strong correlation between being overweight early in life and later development of PCOS underlines the need for preventive strategies already early in childhood.

Inflammatory stress in leydig cells: implications for steroidogenesis and mitochondrial dysfunction

Oleksandra Fomichova[1], Sara Pereira[1,2], Marco Alves[3], Pedro Oliveira[4] & Raquel L. Bernardino[1,2]
[1]UMIB - Unit for Multidisciplinary Research in Biomedicine, ICBAS - School of Medicine and Biomedical Sciences, University of Porto, 4050-313 Porto, Portugal, Porto, Portugal; [2]ITR - Laboratory for Integrative and Translational Research in Population Health, 4050-600 Porto, Portugal, Porto, Portugal; [3]Institute of Biomedicine (iBiMED), Department of Medical Sciences, University of Aveiro, 3810-193 Aveiro, Portugal, Aveiro, Portugal; [4]LAQV-REQUIMTE and Department of Chemistry, University of Aveiro, 3810-193 Aveiro, Portugal, Aveiro, Portugal

The global prevalence of infertility and subfertility has increased significantly, affecting both men and women. Growing evidence suggests that inflammation is a common feature of various pathological conditions and plays a critical role in male reproductive dysfunction by disrupting steroidogenesis and spermatogenesis. Leydig cells (LCs) are essential for sustaining testicular steroidogenesis, a process that relies heavily on mitochondrial function. Mitochondria mediate the initial steps of cholesterol processing and provide the energy required for testosterone synthesis. Although inflammation is known to impair LC steroidogenic function, the precise mechanisms underlying this disruption remain unclear. In this study, we investigated the link between inflammation, steroidogenic dysfunction, and mitochondrial impairment in LCs. Using a Mus musculus Leydig cell line (TM3), we exposed the cells to bacterial lipopolysaccharide (LPS) for 24 hours to induce an inflammatory response. Mitochondrial function was assessed by measuring the oxygen consumption rate (OCR) after mitochondrial modulation. The expression of key steroidogenic genes (STAR and CYP17A1) was analyzed by qPCR, and total testosterone levels in the post-treatment culture medium were quantified using electrochemiluminescence immunoassay. Our findings demonstrate that exposure to an inflammatory stimulus significantly reduces mitochondrial respiration and impairs steroidogenic activity, as evidenced by decreased gene expression and testosterone production. These results provide compelling evidence that local inflammation, independent of systemic inflammatory conditions, disrupts both steroidogenesis and mitochondrial energy production in LCs, highlighting a potential mechanism contributing to male reproductive dysfunction.

Introduction
The appropriateness of gonadectomy in people with differences of sex development (DSD) is increasingly contested yet reports of contemporary practices are lacking. This study aimed to determine the frequency of gonadectomy and associated care pathways in individuals with DSD internationally.
Methods
A 2-year prospective study was undertaken through the I-DSD Registry (Dec 2022-Dec 2024). Participating centres reported gonadectomies undertaken in individuals with DSD in response to a monthly automated email survey. Where an individual had given informed consent for inclusion in the I-DSD Registry, a secondary survey captured additional clinical information.
Results
Over the 2-year study period, 30/74 (41%) centres reported no gonadectomy, while 173 individuals from 44 centres had gonads removed; median (range) / centre: 1 (0,18). Secondary survey data are available for 82/174 (47%) cases to date; 80% were female. Median (range) age at gonadectomy was 11.7 (0.1,20.0) years. All had specialist multidisciplinary team involvement prior to gonadectomy: endocrinology (98%), genetics (82%) and psychology (67%) were most frequent. Differences of gonadal development (36/82 [44%]) and chromosomal DSD (including Turner syndrome, 24/82 [29%]) were the most frequent underlying diagnoses. Gonads were intra-abdominal in 65/82 (79%). Pre-gonadectomy investigations included: hormonal testing (77/82 [94%]), imaging (73/82 [89%], direct laparoscopic visualisation (29/82 [35%]) and gonadal biopsy (17/82 [21%]). Bilateral gonadectomy was undertaken in 57/82 (70%). Mitigation of future malignancy risk in the context of gonadal insufficiency was the most common primary indication for gonadectomy (55/82 [67%]). Concerning clinical (3/82 [4%]) changes and/or imaging or biopsy findings (8/82 [10%]) were uncommon. Histopathology confirmed neoplastic change in 24/82 (29%) individuals: age range 0.8- 17.0 years. Nine (11%) had precursor lesions alone; 15/82 (18%) had gonadal tumours, of whom 3 had precursor lesions also present. Two individuals had evidence of extra-gonadal metastases. Surveillance imaging pre gonadectomy raised no suspicion for gonadal neoplasm in 18/23 (78%).
Conclusions
This prospective I-DSD surveillance study offers important contemporary insights into the practice of gonadectomy in individuals with DSD internationally. Overall gonadectomy appears relatively infrequent. Multidisciplinary care provision prior to gonadectomy is standard; however, our data confirm variation in care pathways and significant challenges for decision-making regarding gonadal management. The limitations of imaging for reliable gonadal surveillance and the presence of gonadal neoplasms in young children demonstrated here must be measured alongside considerations to defer gonadectomy to prioritise personal autonomy. These findings should inform future shared decision-making resources and clinical care for gonadal management in individuals with DSD.

Testicular germ cell tumors (TGCTs) are the most common malignancy found in young men. They arise from the precursor cells, germ cell neoplasia *in situ*, which are hypothesized to be present in the testes already at birth. Since reproductive hormone levels are affected in patients with a TGCT, we hypothesized that changes in reproductive hormone levels were detectable even before their primary TGCT diagnosis. We measured the concentrations of reproductive hormones (FSH, LH, inhibin B and AMH) in plasma samples from 72 Danish blood donors and participants in the Danish Blood Donor Study (DBDS), 1-20 samples from each, donated up to 11 years before they were diagnosed with a TGCT. We also measured reproductive hormones in 72 sex- and age-matched controls from DBDS. Within one year prior to the primary diagnosis, we found significantly higher concentrations of FSH ($P = 0.033$) and lower concentrations of inhibin B ($P = 0.009$) and AMH ($P = 0.019$) in patients compared with controls. In patients with the histological subtype seminoma, FSH standard deviation (SD) scores were higher ($P < 0.001$) and inhibin B SD scores lower ($P = 0.001$) compared with controls. In patients with non-seminomas, LH SD scores were significantly lower ($P = 0.021$) compared with controls. Significant differences in FSH, inhibin B and AMH SD scores were evident up to three years before diagnosis of a TGCT compared with controls. Lastly, higher FSH and LH and lower inhibin B SD scores ($P = 0.003$, $P = 0.047$, and $P = 0.032$, respectively) were observed in patients with seminomas compared with patients with non-seminomas. In conclusion, changes in reproductive hormone concentrations and sex- and age-adjusted SD scores are evident in patients several years prior to a primary diagnosis of a TGCT, suggesting a gradual reduction in testicular function prior to diagnosis. The observed changes are dependent on the histological subtype of the TGCT.

Effects of selected pre-treatments prior to denosumab administration on germ cell proliferation in ex vivo cultured testicular tissue from humanized RANKL mice

Nadia Krarup Knudsen[1], Anne Jørgensen[1] & Martin Blomberg Jensen[1,2]

[1]Copenhagen University Hospital - Herlev and Gentofte, Division of Translational Endocrinology, Department of Endocrinology and Internal Medicine, Herlev, Denmark; [2]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark

Novel treatment options for male infertility are highly warranted, as male-factor infertility is involved in up to 50% of all infertile couples. Yet for the vast majority (90%) of affected men no treatment options exist. The RANKL/RANK/OPG signaling pathway, known for its role in bone resorption, is also active in the testis of both men and mice. In previous studies, we have demonstrated that inhibition of RANKL with denosumab in mice resulted in higher sperm count and testis weight. Additionally, increased germ cell proliferation was found in *ex vivo* cultures of adult mouse testis tissue following denosumab treatment and a randomized control trial showed that denosumab treatment enhanced sperm concentration in infertile men with serum AMH levels above 38 pmol/l. These findings suggest that RANKL inhibition may be a potential treatment option for some infertile men. Here, the potential beneficial effects of pre-treatment with selected compounds (e.g. prostaglandins, gonadotropins) prior to denosumab treatment was examined. A humanized RANKL mouse model enables the use of the RANKL inhibitor denosumab in mice, and testicular tissue fragments (1.5 mm^3) from these mice were cultured *ex vivo*. The first 24 hours with agents such as hCG, and Ibuprofen, followed by treatment with 100 ng/mL denosumab for 48 hours. Germ cell proliferation was assessed via quantification of BrdU incorporation. Pre-treatment with vehicle, hCG, ibuprofen, or dexamethasone was

examined, and a significantly increased germ cell proliferation was found after pre-treatment with hCG (82%, $P = 0.0042$) and ibuprofen (92%, $P = 0.0017$) when compared to vehicle treated tissue. No effect on germ cell apoptosis was observed. This study suggests that pre-treatment of adult testicular tissue with hCG and ibuprofen prior to denosumab administration may enhance the stimulatory effect of denosumab on germ cell proliferation. However, further research is needed to understand the effects of RANKL inhibition on the interplay between Sertoli and germ cells and the implications for improvement of spermatogenesis.

Hypophosphatemia is a frequent finding in infertile men and is associated with semen quality

Sam Kafai Yahyavi[1,2], Frederikke Bay Toft[2], Mads Jorsal[2], Lise Aksglaede[1], Niels Joergensen[1], Anders Juul[1] & Martin Blomberg Jensen[2]

[1]Department of Growth and Reproduction - Rigshospitalet, Copenhagen, Denmark; [2]Division of Translational Endocrinology - Herlev Hospital, Herlev, Denmark

Background

Phosphate is available in fluid from all segments of the male reproductive tract in concentrations manyfold higher than in serum. However, the role of phosphate in male fertility is largely unknown. Here, the associations between serum phosphate, semen quality, and reproductive hormones were assessed in infertile men.

Methods

A cross-sectional study of 1,488 men, referred due to infertility. Each man underwent a physical examination, had semen parameters assessed, and had blood analyzed prospectively for concentrations of phosphate, ionized calcium, alkaline phosphatase, PTH, 25OHD, and reproductive hormones. 246 were excluded due to serious comorbidities, leaving 1,242 for the analyses.

Results

Infertile men have a high prevalence of mild (25.5%, 0.66–0.80 mmol/l), and moderate hypophosphatemia (10.9%, 0.32–0.65 mmol/l). The percentages of motile spermatozoa and progressively motile spermatozoa were lower in men with moderate hypophosphatemia than in men with mild hypophosphatemia or normophosphatemia (44%, 49%, 51%, $P = 0.040$, and 32%, 35%, 41%, $P = 0.036$, respectively). The total numbers of motile and progressively motile spermatozoa were also lower (13, 12, 18 million, $P = 0.009$, and 9, 9, 14 million, $P = 0.006$, respectively). Serum concentrations of total and free estradiol were highest in men with moderate hypophosphatemia (97.5 pmol/l, 96.2 pmol/l, 92.1 pmol/l, $P = 0.004$, and 2.4 pmol/l, 2.3 pmol/l, 2.2 pmol/l, $P = 0.034$, respectively).

Conclusion

Hypophosphatemia is frequent in infertile men and is associated with lower number of motile sperm. The precise mechanisms through which hypophosphatemia may impact sperm motility remain to be clarified.

Backgroud

MRKH syndrome is a cataclysmic diagnosis with a heavy psychological burden. In a previous national study (T1, $n = 131$, mean age 26.5y), we reported similar global and sexual quality of life to the general population (GP), except for lower psychosocial health and social relationship scores in younger patients, alongside high sexual distress. In an additional qualitative psychological analysis ($n = 40$), we reported traumatic handicap experience, unexpected eating/addictive disorders, and fertility distress. All self-defined heterosexual (T1).

Objective

To study their psychological evolution ten years later (T2), using the same methodology.

Study design

25 patients were included; 8 lost to follow-up, 7 declined. All completed WhoQol-bref (general QoL), FSFI, and FSDS-R (sexual QoL) scales. Qualitative psychological functioning was assessed using clinical interviews, Rorschach and TAT tests. T2 results were compared to previous data T1, after a median 9.6-year interval [IQR 9.2;10].

Results

Median age was 35.7y [32-38.3], (25-35y:$n = 11$, 35-45y:$n = 14$). All were sexually active, two self-defined bisexual. Quality of life decreased only in the physical dimension (T1:78,6 – T2:75, difference -7.1 [-14.3;0], $P = 0.004$) and remained lower than that of the GP ($P = 0.008$), which was not the case at T1. Eleven patients had new health issues between T1 and T2 (only 2 related to MRKH). Psychological health was much lower than in the other dimensions (scores 66.7 vs 75 to 78.1). Besides, compared to GP, the psychosocial score was significantly lower only in the younger group (62.5 vs 70.8 $P = 0.036$), similarly to T1. Sexual quality of life and sexual distress were not different between T1 and T2 (FSFI score: T1:26.2 – T2:27.7, difference 1.2 [-0.9;4], $P = 0.13$), (FSDS-R score: T1:16 – T2:13, difference -2 [-14;4], $P = 0.14$)). Fourteen (56%) had dyspareunia, which was significantly associated to lower WhoQol psychological scores at T2 (60.4 [58.3;69.8] vs 79.2 [64.6;79.2], $P = 0.044$), 14(56%) had cyclic pelvic pain. All patients expressed at Rorschach tests perseverant and erroneous ideations on internal genitals including ovaries as a missing organ. Eating disorders disappeared in 2/5 patients who had them at T1. Sports addiction disappeared in 4 patients who had them at T1. Five patients (20%) had children (3 adopted, 2 surrogated). Motivation for parentality declined from 88% ($n = 22$) to 44% ($n = 11$) and considering uterine transplantation dropped [T1:36% ($n = 8/22$) T2:18% ($n = 2/11$)].

Conclusions

Quality of life remained good after 10 years, except in the psychological domain, especially among younger individuals. Qualitative assessment revealed a higher complex psychosocial impact of uterovaginal aplasia. Dyspareunia was frequent and associated to poor psychological health.

Inhibin b- an important marker to screen testicular function in CAIS patients?

Isabel Viola Frielitz-Wagner[1,2], Nina Tyutyusheva[3], Ulla Doehnert[1], Fabian Simon Frielitz[4], Silvano Bertelloni[3] & Olaf Hiort[1]

[1]University Hospital Schleswig-Holstein, Campus Lübeck, Department of Paediatrics and Adolescent Medicine, Lübeck, Germany; [2]Klinikum Bremen Nord, Paediatric Endocrinology and Diabetology, Bremen, Germany; [3]Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy; [4]University Hospital Magdeburg, Magdeburg, Germany

Introduction and objective

Gonadectomy was carried out for a long time after the diagnosis of complete androgen insensitivity syndrome (CAIS). It is now recommended to leave the gonads *in situ* in order to guarantee endogenous hormone production. It is unclear how to best clinically monitor testicular function. The aim of the study was to investigate whether inhibin B can be used as a future follow-up parameter to screen for gonadal function in CAIS patients.

Material and Methods

A total of 57 adolescent and adult CAIS patients who presented to two DSD centers (Lübeck and Pisa) were included. Hormonal parameters were retrospectively evaluated. Ideally, we included different time points: during puberty (12-16 years), in early adulthood (17-21 years) and later adulthood (22-50 years). We evaluated the testosterone/lH ratio as a measure of Leydig cell function and the inhibin B/FSH quotient for Sertoli cell function.

Results
Testosterone levels were elevated and within the typical male reference range (6.20 ng/ml +/- 3.08). FSH values increased with age. Inhibin B levels were high and even above the male reference range (383.8 pg/ml+/- 206.5 SD). In adulthood, inhibin B levels decreased by 52.53% ($P = 0.0030$) and the inhibin B/FSH ratio by 75.56% ($P = 0.0103$).
Conclusion
Our data show that inhibin B and the inhibin B/FSH ratio is a suitable functional marker for gonadal function and in particular for Sertoli cell function. In CAIS patients from adolescence onward, these parameters may be useful to examine gonadal function and to possibly detect a loss of function that may necessitate hormone replacement therapy.

Introduction
Polycystic ovary syndrome (PCOS) is one of the most common endocrine disorder affecting women of reproductive age. Insulin resistance and consequent cardiometabolic disorders are the main components of PCOS. The data regarding the presence of clinical or subclinical cardiovascular disease in PCOS, are controversial. Moreover, the impact of potential treatment intervention in markers of hormonal, cardiovascular and endothelial function in PCOS has not yet been fully elucidated.
Objective
The aim of the present study is to investigate a) the association between subclinical markers of cardiovascular and endothelial integrity with insulin resistance and hormonal profil in women with PCOS and b) the impact of potential treatment interventions on these markers.
Methods
In total, 40 women with PCOS recruited in the study and received metformin ($n=20$), GLP1-agonists ($n = 10$), or oral contraceptive pills ($n = 10$). At baseline and six months after treatment, 75g-oral glucose tolerance test (OGTT) was performed in all patients. At 0, 60, and 120 min of glucose load insulin, glucose, and the perfused boundary region of sublingual microvessels (high PBR values represent reduced glycocalyx thickness) were measured. Insulin resistance was evaluated using Matsuda index and HOMA index. At baseline and six months after treatment, androgen levels and matrix metalloproteinase 9 (MMP9) concentration were also assessed.
Results
The mean age of all the participants was 30 ± 3years old. At baseline, the percentage change of PBR was associated with the percentage change of glucose at 120min of OGTT ($r = 0,42$, $P < 0.05$). At baseline, Matsuda Index, Homa Index and Testosterone levels were associated with PBR ($2.91\pm0.1\mu m$) at 120min OGTT ($r = 0.41$, $r = 0.38$ and $r = 0.28$, respectively). Moreover, MMP9 levels were associated with Matsuda and Homa Index ($r = 0.45$, $P < 0.05$ and $r = 0.41$, $P < 0.05$ respectively). Six months after treatment, all the participants presented improvement of Matsuda Index (7 ± 0.31 vs 9.1 ± 0.2), Homa Index (5.3 ± 0.8 vs 2.91 ± 0.1), MMP9 (210 ± 30 vs 178 ± 28ng/ml) and testosterone levels (44.2 ± 5 vs 39.1 ± 2ng/dl) compared to baseline ($P < 0.05$ for all the comparisons). Six months post treatment, no association was observed between markers of insulin resistance and testosterone levels with PBR or its change during OGTT. Six months post-treatment, patients received GLP-1 agonists presented the greatest improvement in MMP9 levels compared to baseline.
Conclusion
Postprandial hyperglycemia, insulin resistance and testosterone levels are associated with impaired glycocalyx thickness in women with PCOS. The different treatment options resulted in the improvement of insulin resistance and biochemical markers of atherosclerosis, with GLP-1 agonists presenting the most prominent Results.

Sex steroids measurement by immunometric assay (IA) compared to liquid chromatography-tandem mass spectrometry (LC-MS/MS) in patients with klinefelter syndrome (KS)

Francesco Costantino[1], Daniele Renda Livraghi[1], Beatrice Fazioli[1], Giulia Canu[2], Maria Cristina De Santis[2], Laura Roli[2], Tommaso Trenti[2], Tommaso Fasano[2], Sara De Vincentis[1] & Vincenzo Rochira[1]
[1]University of Modena and Reggio Emilia, Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy; [2]Azienda USL, Unit of Laboratory Medicine, Modena, Italy

Background
KS is a genetic condition characterized by an extra X chromosome in male individuals associated with an increased risk of primary hypogonadism, which requires testosterone replacement therapy (TRT) when suggestive signs, symptoms and low serum Testosterone (T) are present. While IA remains the standard method for T measurement in the clinic, LC-MS/MS is increasingly being utilized also in clinical laboratory settings.
Aim
The aim of this study is to analyze the accuracy of IA compared to the gold standard LC-MS/MS for the diagnosis and monitoring of hypogonadism in patients with KS.
Materials and Methods
A total of 67 measurements (33 untreated and 34 under TRT) in KS patients were accrued: serum total T (TT) was assessed by both LC-MS/MS and IA, together with SHBG for calculated free testosterone (cfT). Hypogonadism was defined according to the Italian Society of Andrology and Sexual Medicine (SIAMS) threshold: serum TT $\leq$ 3.5 ng/mL and/or cfT $<$ 6.5 ng/dl. TT was quantified using CMIA DxI800 Beckman Coulter (IA)and Chrosystems MassChrom® Steroids in Serum/Plasma kit on Sciex CitrineTM (LC-MS/MS); cfT was calculated with the Vermeulen formula.
Results
The overall cohort and the subgroup not under TRT showed similar results, with only some minor differences. Serum TT measured by IA showed a strong positive correlation with LC-MS/MS measurements (respectively $R^2=0.891$, $P < 0.001$ and $R^2=0.849$, $P < 0.001$) similarly to cfT (respectively $R^2=0.853$, $P < 0.001$ and $R^2=0.638$, $P < 0.001$). However, a higher prevalence of biochemical hypogonadism was observed with IA compared to LC-MS/MS for TT both in all (41.17% vs 23.53%, OR 1.94, $P = 0.059$) and in untreated KS (75.75% vs 60.61%, OR 2.03, $P = 0.190$). A similar but significant result was found for cfT in all (54.69% vs 34.38%, OR 2.16, $P = 0.033$) and in untreated KS (75.75% vs 45.46%, OR 3.75, $P = 0.014$). Finally, in the subgroup of patients not under TRT a higher concordance between the two methods, LC-MS/MS and IA, ($R^2=0.950$, $P < 0.001$) was observed for total testosterone levels $>$ 3.5 than $\leq$ 3.5 ng/ml, highlighting some challenges in discriminating hypogonadal subjects.
Discussion
In accordance with what discovered in the overall population at risk for hypogonadism, even in KS patients IA seems to overestimate significantly both the prevalence of hypotestosteronemia and TRT compensation for TT and cfT when compared to LC-MS/MS. Hence, LC-MS/MS and SHBG assessments in every day clinical practice are probably crucial to detect and to correctly address to treatment KS patients, as well as for monitoring TRT.

[1]inserm U1172, Univ. Lille, Inserm, CHU Lille, Lille Neuroscience & Cognition, UMR-S 1172, Lille, France, Lille, France; [2]Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Cordoba, Spain,

Cordoba, Spain; [3]CIMUS, University of Santiago de Compostela-Instituto de Investigación Sanitaria, Spain, Santiago de compostela, Spain; [4]University of Laval, Laval, Canada

Polycystic Ovary Syndrome (PCOS) is the most common endocrinopathy affecting women worldwide, leading to various long-term cardio-metabolic repercussions. Despite its significant impact, there is currently no cure, emphasizing the urgent need for effective treatments. Gestational excess of androgens and anti-Müllerian hormone (AMH) is common in women with PCOS and preclinical studies have demonstrated that abnormal exposure to these hormones during prenatal development can cause PCOS-like traits in adult female offspring. However, it is unclear if there is also a critical period of susceptibility to PCOS during early postnatal life. Interestingly, AMH levels have been found to be significantly higher during mini-puberty in both daughters and sons of mothers with PCOS compared to infants of non-PCOS women. To elucidate whether elevated AMH levels during infancy in offspring of women with PCOS are a byproduct or a driving force behind the condition, we developed an innovative mouse model by exposing otherwise healthy mice to AMH during mini-puberty. We showed that such treatment induced PCOS-like reproductive and metabolic defects in females and males alike. Additionally, we developed a pharmacological approach that showed beneficial effects on both reproductive and metabolic PCOS-related defects. These findings suggest that exposure to elevated serum AMH levels during mini-puberty plays a causal role in the pathophysiology of PCOS. They also identify a window of opportunity for developing novel therapeutic preventive strategies for PCOS.

Visfatin (Nampt) siRNA induced knockdown effect on blastocyst transcriptome, implantation rate and offspring ovarian function. Studies on normal weight and obese mice

Patrycja Kurowska[1], Shinnosuke Honda[2], Genta Tanaka[2], Naojiro Minami[2], Agnieszka Rak[1] & Shuntaro Ikeda[2]
[1]Laboratory of Physiology and Toxicology of Reproduction, Institute of Zoology and Biomedical Research, Faculty of Biology, Jagiellonian University in Krakow, Krakow, Poland; [2]Laboratory of Reproductive Biology, Graduate School of Agriculture, Kyoto University, Kyoto, Japan

Objectives
Adipokines regulate reproduction in dependence of metabolic conditions. Visfatin, upregulated in obesity, improves oocyte maturation in obese and old individuals. Our previous studies showed that lack of visfatin leads to decrease in blastocyst number in obese mice. The aims of this study were to determine the effect of visfatin on the blastocyst transcriptome in normal weight and high-fat-diet induced obese mice, as well as blastocyst implantation rate and ovarian function of offspring.
Methods
We knockdowned the mRNA expression of *Nampt* at the 1 cell stage embryo (siRNA electroporation) and cultured it until the blastocyst stage, then we isolated RNA and evaluated blastocyst transcriptome (RNASeq, padj <0.05), DEGs ontology and pathways were analyzed in qProfiler and DAVID software. As a next step the blastocyst implantation rate/offspring number were calculated and offsprings (17.5 dpi) ovaries were collected to measure steroidogenesis (*Star, Cyp11a1, Cyp17a1, Hsd3b, Cyp19a1*), folliculogenesis/oogenesis (*Gdf-9, Bmp-15, Figla, Dnmt1*) and proliferation/apoptosis (*Pcna, Bax, Bcl2*) related genes level (real-time PCR, $n = 5$). Statistical analysis was performed in GraphPad Prism software.
Results
Transcriptomic analysis showed 73 upregulated and 24 downregulated genes in the blastocyst from normal weight mice after *Nampt* silencing. Ontology and pathways analysis classified these genes to biological processes (cell death, glycolytic process, metabolic process, anatomical structure development) and cellular components (cytoplasm, cytoskeleton, cell junction). According to KEGG we noted estrogen signaling, p53 and progesterone mediated oocyte maturation pathways. In obese mice group only 2 genes were upregulated (*Gm10052, Tspan7*) and 1 (*Tmem^{2}54c*) downregulated. Visfatin silencing does not affect the implantation rate and offspring number in normal weight mice. However, we observed the changes in the expression of marker genes of proper ovarian function in offspring including stimulation in *Bmp-15 and Cyp17a1* and inhibition in *Hsd3b* transcripts.
Conclusion
Visfatin is an important factor in early embryogenesis, and the effect of its absence in early embryonic life is long-lasting and affects the fertility of female offspring. It also indicates that visfatin may play a compensatory role in reproduction during obesity.
Keywords
visfatin, early embryogenesis, siRNA induced gene knockdown, transcriptome.

Fibrosis is an early marker of subcutaneous adipose tissue dysfunction in polycystic ovary syndrome (PCOS)

Yuan Wang[1], Riada McCredie[1], Mick Rae[2], Aoife Cahill[1], Colin Duncan[1] & Katarzyna Siemienowicz[2]
[1]The University of Edinburgh, Centre for Reproductive Health, Edinburgh, United Kingdom; [2]Edinburgh Napier University, Edinburgh, United Kingdom

Prenatally androgenised female sheep are a clinically realistic model of PCOS. In adolescence (11 months of age) there is reduced subcutaneous adipogenesis and in adulthood (30 months of age) there is increased subcutaneous adipose tissue (SAT) dysfunction with inflammation. We hypothesised that analysis of adipose tissue in young adults (20 months of age), after adipogenesis is complete but before inflammation is manifest, would give insights into the evolution of adipose tissue dysfunction in PCOS. Pregnant Scottish Greyface sheep were treated intramuscularly with testosterone propionate (100 mg) or vehicle control twice weekly from day 62-102 of gestation (147 days) and their female offspring were studied. Two cohorts of weight-matched PCOS-like sheep and contemporaneous controls were investigated. At 20 months of age the SAT of young adult PCOS-like sheep ($n = 10$) and control sheep ($n = 10$) was examined by RNAseq and fixed for histochemical analysis. At 30 months of age PCOS-like sheep SAT ($n = 4$) and control sheep SAT ($n = 4$) underwent histochemical analysis. In addition, SAT was collected from obese adult women with PCOS ($n = 12$) and obese adult women without PCOS ($n = 12$) for histochemical analysis. RNAseq analysis of young adult PCOS-like sheep SAT showed that a total of 792 genes were differentially expressed when compared to control sheep (406 upregulated; 386 downregulated). Ingenuity pathways analysis highlighted upregulation of fibrosis signalling pathways, extracellular organisation pathways and the assembly of collagen fibrils in the SAT of PCOS-like sheep. RT-PCR confirmed that *POSTN*, which is associated with tissue remodelling and fibrosis, was increased ($P < 0.05$) in PCOS-like sheep SAT as were *COL1A1* ($P < 0.05$), *COL1A2* ($P < 0.05$) and *COL3A1* ($P < 0.01$). Masson's Trichrome stain showed an increased area of fibrosis in SAT of PCOS-like sheep ($P < 0.05$) when compared to controls. This increased fibrosis was also seen in both adult PCOS-like sheep ($P < 0.05$) and obese women with PCOS ($P < 0.05$) when compared to controls. Early fibrotic changes in SAT occurs in young adult PCOS-sheep and this change is also seen in adulthood and in adult women with PCOS. In young adult PCOS-like sheep SAT fibrosis is present before SAT inflammation is detected. SAT fibrosis might provide a barrier to healthy adipocyte expansion and have a mechanistic role in the development of the detrimental inflammatory environment in PCOS.

Penchev", Faculty of Medicine, Medical University, Department of Endocrinology, Sofia, Bulgaria; [4]Department of Endocrinology and Diabetes, Hellenic Red Cross Hospital, Athens, Greece; [5]Department of Endocrinology, UMC Bežanijska kosa, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [6]Endocrine Unit, Aretaieion University Hospital, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece; [7]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Introduction
Thyroid function is central to the regulation of human metabolism and reproductive function; abnormal thyroid function tests (TFTs) have been

associated with unfavourable metabolic and hormonal changes in women with PCOS. However, it is not known if slight variations in TSH concentration affect these parameters in euthyroid women with PCOS. If a significant association is present, one may suggest thyroxine treatment in this population, even with TFTs within reference values.
Subjects and Methods
Cross sectional data of 1762 European women of Caucasian origin (age: 24.57 ± 5.54 years, BMI: 26.34 ± 6.88 kg/m^2) diagnosed with PCOS by Rotterdam criteria were analysed. All subjects had both normal TSH values (0.4-4.7 IU/ml) and either T4 or FT4 values. None of the subjects was on treatment with Thyroxine. Anthropometric parameters (age, BMI, WHR, FG Score), metabolic indices (glucose, lipids, liver function, HOMA-IR) and hormonal (gonadotropins, testosterone, SHBG, DHEAS, D4, FAI, estradiol, insulin) values were evaluated. Data were stratified by TSH values (higher or lower of 2.5IU/ml) forming two groups: Group A (TSH $<$ 2.5 IU/ml) and Group B (TSH $<$ 2.5 IU/ml). In addition, data were stratified according to TSH quartiles (Q1, TSH 0.4-1.5, Q2 1.5-2.5, Q3, TSH 2.5-3.5, Q4, TSH$>$ 3.5-4.7 IU/ml).
Results
The comparison between Groups A and B reached significant difference ($P <$ 0.05) in TSH values (1.49 ± 0.58 vs. 3.98 ± 0.56IU/ml) as expected. However, except for SHBG (40.78 ± 19.55 vs.37.96 ± 19.64 nmol/l) and DHEAS values (3.03 ± 1.35 vs. 2.84 ± 1.32 nmol/l), no difference was observed in any other parameter evaluated (Table 1). When data were analysed based on TSH quartiles, statistically significant differences were found between subgroups regarding LH, FSH, SHBG and DHEAS values.
Conclusions
Our findings originating from a large European PCOS cohort suggest that TSH values in euthyroid women with PCOS are not significantly associated with any metabolic and hormonal parameters except for SHBG and DHEAS. The association between TSH and these hormones warrants further evaluation but our findings advocate against thyroxine use in women with PCOS and TSH values within the reference range for metabolic or hormonal purposes.

Objective
Polycystic ovary syndrome (PCOS) is a high prevalence chronic disease. Limited studies have explored the issue of remission PCOS indicated by regular menstrual cycles or natural pregnancies. As 90% of women with PCOS showed polycystic ovary morphology (PCOM) on ultrasound examination, the aim of this study was investigated the rate of achieving remission of in patients with PCOS, which was based on the recovery of ovarian morphology in PCOS patients using three-dimensional (3D) ultrasound techniques after pharmacological approaches.
Methods
This retrospective study included 727 reproductive-aged women with PCOS recruited in the PCOS-specialized outpatient clinics at Shanghai Tenth People's Hospital from May 2020 to August 2024. Since the initiation of medication, anthropometric parameters, biochemical variables, reproductive indicators at baseline and post-treatment period were collected at every three months. During the follow-up period, 3D ultrasonography was used to assess the presence of polycystic morphology.
Results
A total of 296 participants were eligible for the study, and 28 participants (9.46%) achieved remission of PCOS with regularized menstrual cycle, normalized ovarian morphology. The mean time to achieve remission of PCOS was 14.1 ± 13.2 months. The remission group had significantly higher waist circumference (WC), waist-to-hip ratio (WHR), and higher follicle number in both ovaries than the non-remission group ($P <$ 0.05) at baseline. In the remission group, significant reductions were observed post-treatment in body mass index (BMI), waist circumference, alanine aminotransferase (ALT), aspartate aminotransferase (AST), low-density lipoprotein cholesterol (LDL), progesterone, and total testosterone (TT). Meanwhile, there was a significant reduction in ovarian volume and follicle numbers of both ovaries in the patients with PCOS remission. Medication promoting insulin resistance and weight-loss (GLP-1 agonists, metformin, SGLT-2 inhibitors) were widely taken in the remission group.
Conclusion
Our study demonstrated that 9.46% patients with PCOS could achieve remission of PCOS with normalized ovarian morphology after taking medications for improving metabolism and weight loss.

Keywords

Paternal use of paracetamol prior to conception is associated with elevated adrenal steroid levels in female infants - a copana study

Emilie Zeuthen[1,2], Margit Bistrup Fischer[1,2], Gylli Mola[1,2], Anna-Maria Andersson[1,2], Hanne Frederiksen[1,2], Karin Sundberg[3], Ane Lilleøre Rom[4,5], Hanne Heggard[5,6], Anders Juul[1,2,5] & Casper Hagen[1,2,5]
[1]Department of Growth and Reproduction, Copenhagen University Hospital- Rigshospitalet, Copenhagen, Denmark; [2]International Center for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark; [3]Center of Fetal Medicine and Pregnancy, Department of Obstetrics, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark; [4]Research Unit of Gynaecology and Obstetrics, Department of Clinical Research, University of Southern Denmark, Odense, Denmark; [5]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [6]Department of Obstetrics, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark

Background
Growing evidence suggest that maternal paracetamol use impairs fetal ovarian development. In animal studies, paternal preconceptional use of paracetamol has been suggested to affect fetal development, possibly through mechanisms including epigenetic changes, altered non-coding RNAs, oxidative stress, or hormonal disruption in the sperm's paracrine environment. The female HPG and HPA axis is functionally established in early infancy enabling assessment of ovarian and adrenal activity.
Aim
Evaluate associations between paternal use of paracetamol and ovarian and adrenal function in female offspring.
Design
Prospective, observational pregnancy and birth cohort; The Copenhagen Analgesic Study (COPANA) (ClinicalTrials.gov NCT04369222).
Setting
Copenhagen University Hospital – Rigshospitalet, Denmark (2020-2022).
Methods
Healthy, singleton pregnant women enrolled in first trimester of pregnancy (n = 685) and 589 children (302 girls) examined in infancy. Fathers (n = 245) reported their paracetamol use (yes/no) prior to conception and girls were categorized as exposed if their father used paracetamol three months prior to conception (exposed = 133, unexposed = 112). Girls were examined at age 3.4 ± 0.4 months (mean(±SD) including transabdominal ultrasound: ovarian volume (n = 161/245). Infant serum hormones (n = 218/245): FSH, LH, AMH, Inhibin B (immunoassays), 16 steroid metabolites (LC/MS-MS). Age and sex specific SD-scores were calculated. Mothers reported their paracetamol use every two weeks during pregnancy (yes/no), and delivery mode (vaginal/elective section/emergency section) was obtained from medical records.
Statistics
Mann Whitney U-test and linear regression models.
Results
There was a trend towards reduced ovarian volume; median (IQR) 236.3 mm^3 (153.1–419.08) vs 316. 0 mm^3 (204.9–458.5) P = 0.069 in exposed girls at

infancy compared to unexposed. Furthermore, paternal use of paracetamol was associated with increased levels of several steroid metabolites (Table 1). The associations were not affected after adjusting for maternal use of paracetamol in early pregnancy or delivery mode, respectively. Paternal use of paracetamol was not associated with levels of reproductive hormones in infancy.

Conclusion

Paternal paracetamol use before conception appears to affect ovarian development in a manner comparable with effects observed after maternal prenatal use of paracetamol. Furthermore, circulating levels of several adrenal steroids were linked to paternal use of paracetamol. This reinforces concerns about the effects of paracetamol on fetal development, likely involving multiple biological mechanisms.

Table 1

	Median (IQR)		*P*-value

Outcomes and fertility in men with PAIS worldwide: lessons from an I-DSD registry platform cohort

Morgane Carré Lecoindre[1,2], Faisal Ahmed[3,4], Jillian Bryce[3], Minglu Chen[4], Ajay Thankamony[5], Tulay Guran[6], Theo C.J Sas[7], Olaf Hiort[8], Anders Juul[9], Marianna Rita Stancampiano[10], Martine Cools[11], Angela Lucas-Herald[7] & Philippe Touraine[2]

[1]Hôpital Robert Debré, Paediatric endocrinology, Paris, France; [2]Hôpitaux Universitaires Pitié Salpêtrière, GHU APHP Sorbonne Université, Endocrinologie et médecine de la reproduction, Paris, France; [3]Royal Hospital for Children, University of Glasgow, Developmental Endocrinology Research Group, Glasgow, United Kingdom; [4]University of Glasgow, Office for Rare Conditions, Glasgow, United Kingdom; [5]University of Cambridge School of Clinical Medicine, Department of Paediatrics, Cambridge, United Kingdom; [6]Marmara University, Paediatric Endocrinology and Diabetes, Istanbul, Türkiye; [7]Erasmus University Medical Centre - Sophia and DIABETER, Centre for Paediatric and Adult Diabetes Care and Research, Rotterdam, Netherlands; [8]University Medical Centre Schleswig-Holstein of Lubeck, Department for Paediatric Endocrinology and Diabetes, Lubeck, Germany; [9]Copenhagen University Hospital – Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark; [10]Scientific Institute San Raffaele, Department of Paediatrics, Endocrine Unit, Milan, Italy; [11]University hospital of Gent, Endocrinology and Diabetology for children and adolescents, Gent, Belgium

The androgen receptor (AR) sensitivity is an important determinant of male phenotype expression in XY individuals during fetal life and from the onset of puberty. Partial Androgen Insensitivity Syndrome (PAIS) is a spectrum of various genital phenotypes and gonadal impairments affecting approximately 1 birth in 130,000 individuals. However, there is still very little information on fertility in men with PAIS in the medical literature. Fertil'PAIS is an international, retrospective, multi-centre, observational study still in progress, evaluating fertility in PAIS men over sixteen years from the I-DSD Registry platform, as well as their genital phenotype at birth, pubertal development, psychological well-being, gender identity, and hormonal replacement therapy. Currently, 68 patients with PAIS from 11 different countries have been included, with a median age of 20.2 (16,3-69) years. Ninety-seven percent were identified as male gender, and among the 2 patients who were identified as female at birth, 1 underwent gender transition to male at 16, and 1 had a legal sex change facilitated by parents. External Genitalia Score at birth was around 8.5 out of 12: 79% had a genital tubercle beneath 30 mm, 20% no labioscrotal fusion, 55% a scrotal meatus, and 30% inguinal or impalpable gonads. Most patients had not undergone gonadectomy or gonadal biopsy and had testes identified by ultrasound. Additionally, among the 22% for whom we had information, all of them, except one, experienced spontaneous puberty at a median age of 12.7 years and 90% had gynecomastia around 13.4 years. More than 50% had high FSH, LH, AMH and total testosterone at 20 years old and we found low inhibin B in only 2 patients. Finally, we found information about fertility desire in only 39% of the 18 patients who had more than 16 years at last assessment, of whom 71% had desired fertility. Only 6 patients had sperm assessment with count - all abnormal-, none of them had sperm cryoconservation, and only one was able to father twice thanks to medically assisted conception (MAP). In conclusion, the phenotype of PAIS men at birth varies greatly, but they mostly exhibit severe variations in genital development and gynecomastia. While most undergo spontaneous puberty and have normal inhibin B levels, fertility remains poorly monitored, and cryoconservation or MAP is not well considered. Therefore, we need to obtain more information about fertility in these patients to better understand their desires and provide them with follow-up and assistance according to their needs.

Splenic structural and functional abnormalities in individuals with NR5A1/SF-1 variants

Fouatih Khadidja[1] & Morel Bouvattier Claire[1]

[1]Bicêtre Hospital, Paris Saclay University, Department of Pediatric Endocrinology and diabetology, Kremlin Bicêtre, France

Objective

Steroidogenic Factor 1 /Nuclear receptor subfamily 5 group A member 1 (SF-1/NR5A1) is essential for spleen development and function, and *NR5A1* variants have been linked to abnormal spleen development. Hyposplenism exposes individuals to severe complications with potential serious sequelae. This study aimed to determine the prevalence and main features of hyposplenim in a cohort of French patients with *NR5A1* variants.

Methods

Morphology and function of the spleen were assessed in 34 patients carrying a heterozygous *NR5A1* variant. Quantification of pocked-RBCs, the reference marker for splenic function, was performed in all participants along radiological examination.

Results

Functional hyposplenism was observed in 61.7% of patients, with 47% having severe forms. 44.1% of participants had morphological abnormalities of the spleen, including complete absence in 11.7%. All patients with splenic morphological abnormalities on imaging also showed functional hyposplenism. 28% of patients with functional hyposplenism did not have any morphological abnormality on imaging. No association between *NR5A1* genotype or gonadal phenotype and splenic anomalies was identified.

Conclusions

Functional hyposplenism is common in patients with *NR5A1* variants, regardless of genotype and gonadal phenotype. Hence, assessing splenic function becomes mandatory in managing these patients, and preventive measures are critical when hyposplenism is present.

JOINT309

Low detransition rates among 709 gender-affirming therapy recipients and associated risk factors: results from a systematic follow-up study

Gili Goldblat[1,2], Iris Yaish[1,2], Yona Greenman[1,2] & Karen Tordjman[1,2]

[1]Tel Aviv University, Faculty of Health & Medical Sciences, Tel Aviv, Israel; [2]Tel Aviv Sourasky Medical Center, Institute of Endocrinology, Metabolism and Hypertension, Tel Aviv, Israel

Background

The dramatic increase in individuals seeking Gender-Affirming Therapy (GAT) has sparked debates about gender dysphoria, including concerns about detransition rates, irreversible effects, and the contentious issue of access to treatment, particularly for minors. While reported detransition rates vary widely (0.5-30%), prior studies have lacked systematic efforts to track and interview individuals who discontinued attendance at specialized gender clinics.

Aim and Methods

This study evaluated detransition rates among individuals initiating GAT at Tel Aviv Sourasky Transgender Health Center between May 2014 and December 2022. Subjects who discontinued follow-up after $\geq$2 visits were contacted, and those who detransitioned participated in structured interviews to understand the motives and circumstances leading to their decision.

Results

Of 709 adults initiating GAT, 239 (33.8%) discontinued follow-up. All but 15 were successfully contacted, providing 694 subjects for analysis. Among the 224 subjects who discontinued clinic attendance, 13 had detransitioned, representing a detransition rate of 1.87% (CI 0.86-2.88). All other subjects, including the 470 who maintained clinic attendance, continued their gender-affirming process.

Focusing on the group of 224 individuals who had discontinued clinic attendance, we found no differences between the 13 detransitioners and those continuing treatment (usually under family physician care) in demographic (gender, age, ethnicity) or socioeconomic (education, profession, employment) parameters. Detransitioners had received GAT for a shorter duration (median 12 vs 79 months, $P < 0.001$) and had lower rates of surgical procedures (23.1% vs 58.8%, $P < 0.001$), with only one subject having undergone genital surgery. Additionally, detransitioners demonstrated markedly higher rates of complete lack of family support (38.5% vs 8.5%, $P = 0.003$), were less likely to reside in the Tel Aviv-Central area (38.5% vs 61.1%, $P < 0.001$), and more frequently had pre-existing psychiatric diagnoses (84.6% vs 41.7%, $P = 0.01$).
Conclusions
In this first systematic follow-up study of transgender individuals who discontinued clinic attendance, we found a notably low detransition rate of 1.87%. While detransitions occurred across various treatment durations, they rarely followed irreversible surgical interventions. Distance from specialized care centers, lack of family support, and pre-existing psychiatric conditions may influence detransition risk, emphasizing the importance of accessible care and comprehensive support systems.

Prevalence and predictive factors of bleeding disorders in adolescents with abnormal uterine bleeding

Maria Elisa Amodeo[1], Sonia Iavarone[2], Francesco d'Aniello[1], Annalisa Deodati[1,3], Chiara Carducci[1], Danila Benevento[1], Matteo Luciani[2] & Graziamaria Ubertini[1]
[1]Bambino Gesù Pediatric Hospital, IRCCS, Rome, Italy, Endocrinology and Diabetology Unit, Rome, Italy; [2]Bambino Gesù Pediatric Hospital, IRCCS, Rome, Italy, Oncology and Hematology Unit, Rome, Italy; [3]University of Rome Tor Vergata, Rome, Italy, Department of Systems Medicine, Rome, Italy

Background
Abnormal uterine bleeding (AUB) is a frequent and potentially severe condition in adolescents, leading to anemia and impacting quality of life. While AUB is commonly attributed to anovulatory cycles, bleeding disorders may underlie a significant proportion of cases, warranting precise identification to optimize management.
Aim
This study investigated the prevalence and types of coagulation disorders in adolescents with AUB and identified potential clinical and biochemical predictors of these disorders.
Methods
A prospective longitudinal cohort study was conducted on 130 female adolescents (10–17 years) with AUB referred to a Tertiary Pediatric Hospital from 2012 to 2022. Patients with prior coagulopathy or endocrinopathy were excluded. Collected data included medical history, bleeding tendencies, laboratory tests and pelvic ultrasounds. Anemia was categorized as mild (Hb:10–12 g/dl), moderate (8–10 g/dl), or severe (<8 g/dl). A potential clinical risk score of bleeding disorder was identified.
Results
Among 130 female adolescents, 89% experienced AUB within 2 years of menarche (mean age: 11.6 ± 1.4 years). Anemia was found in 56%, with 42.4% of which, severe. Coagulation disorders were identified in 15.4% ($n = 20$), including von Willebrand disease (50%), thrombocytopenia (10%), and coagulation factor deficiencies (40%), predominantly Factor VII deficiency. Ferritin levels were significantly more reduced in the coagulation disorder group (11.8 ± 11.3 ng/dl VS 21.6 ± 18.6 ng/dl; $P < 0.005$). A personal history of bleeding at sites other than menorrhagia (20% vs 0.9%) and a family history of bleeding disorder (20% vs 0.9%) were more frequently reported in the coagulation disorder group compared to adolescents without bleeding disorders. A composite score, called the AUB-BDA-Score (Abnormal Uterine Bleeding - Bleeding Disorders Adolescent Score), was developed based on the statistically significant risk factors found. This score is calculated as the sum of three variables:.
1. Personal history of bleeding at other sites (0 = absent, 1 = present);.
2. Family history of bleeding disorders (0 = absent, 1 = present);.
3. Ferritin levels <12 ng/mL (0 = no, 1 = yes).
A score of 3 suggests the need of investigating a potential bleeding disorder.
Conclusions
In our cohort, the 15.4% of adolescents with AUB had a bleeding disorder, with von Willebrand disease and factor VII deficiency being the most prevalent. Predictors included bleeding history, family history of bleeding and ferritin levels below 12 ng/mL. The proposed AUB-BDA-Score needs to be verified in further studies in order to enhance diagnostic precision and improve patient outcomes.

Reference intervals for serum total testosterone, free testosterone and sex hormone binding globulin in middle-aged men; the impact of overweight and obesity

Theresa Stangl[1,2], Renée de Mutsert[3], Martin den Heijer[1,2] & Annemieke C Heijboer[1,4]
[1]Amsterdam Gastroenterology Endocrinology & Metabolism, Amsterdam, Netherlands; [2]Amsterdam UMC location Vrije Universiteit Amsterdam, Amsterdam UMC location University of Amsterdam, Endocrine Laboratory and Department of Laboratory Medicine, Amsterdam, Netherlands; [3]Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, Netherlands; [4]Amsterdam UMC location Vrije Universiteit Amsterdam and location University of Amsterdam, Endocrine Laboratory, Department of Laboratory Medicine, Amsterdam, Netherlands

Introduction
Reference intervals for serum total testosterone (TT), free testosterone (FT), and sex hormone-binding globulin (SHBG) are essential for diagnosing hypogonadism in men. Obesity influences androgen and SHBG concentrations, complicating the interpretation of hormonal changes. This study aims to establish reference intervals for serum TT, FT, and SHBG in middle aged adults and to calculate expected values for different BMI categories.
Methods
The Netherlands Epidemiology of Obesity study is a population-based prospective cohort study comprising 3156 male participants aged 45–65, with oversampling of individuals with a BMI >25kg/m^2. Fasting blood samples were analysed for testosterone and SHBG concentrations using LC–MS/MS and an automated immunoassay (Architect), respectively. FT was calculated using the Vermeulen formula. The reference population was defined by a BMI <25kg/m^2, no history of cardiovascular or hormone-affecting diseases, non-smokers, and no use of medication. Reference intervals were calculated, based on the 2.5th and 97.5th percentiles, for testosterone, SHBG, and free testosterone. The proportions of individuals of BMI groups falling within the reference intervals were assessed.
Results
Reference intervals for 216 men aged 45-65 years with a BMI <25 kg/m^2 were 8.3 – 28.7 nmol/l for TT, 139 – 422 pmol/l for FT, and 17.7 – 80.8 nmol/l for SHBG. As BMI increases, a greater proportion of men fall below the lower limit of the reference intervals. Specifically, among men with a BMI >35 kg/m^2, 24% fall below the reference interval for TT, 17% for FT and 11% for SHBG.
Conclusion
We present reference intervals for TT, FT and SHBG in middle-aged men. Men with overweight or obesity more often fall outside these reference intervals. Our findings can improve interpretation of abnormal laboratory results in individuals with overweight or obesity.

Sleep disturbances in adolescents with PCOS: does metabolic status have an impact beyond obesity?

Tugce Kandemir[1], Hasan Yanik[1], Asli Derya Kardelen Al[1], Melek Yildiz[1], Sukran Poyrazoglu[1], Feyza Darendeliler[1] & Firdevs Bas[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Department of Pediatric Endocrinology, Istanbul, Türkiye

Background
Polycystic ovary syndrome (PCOS) is a complex endocrine disorder in adolescents, often linked to hyperandrogenemia, obesity, and insulin resistance. While metabolic dysfunction in PCOS is well-documented, the role of sleep disturbances remains underestimated. Emerging evidence suggests that poor sleep quality and increased obstructive sleep apnea (OSA) risk may worsen metabolic outcomes, independent of obesity. This study aims to explore the association between sleep disturbances, metabolic dysfunction, and obesity in adolescents with PCOS, with a particular focus on the independent contributions of hyperandrogenemia and insulin resistance.

Methods
A total of 74 adolescents and young adults diagnosed with PCOS (14-24 years) and 87 age-matched healthy controls were included in this cross-sectional study. Sleep quality was assessed using the Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS), and Berlin Questionnaire for OSA risk. Anthropometric measures included BMI, BMI-SDS. Biochemical analyses covered LH/FSH ratio, testosterone, SHBG, androstenedione, DHEAS, glucose, insulin, HOMA-IR, and lipid profile. Analysis was made between PCOS and control groups, as well as within the PCOS cohort based on obesity status.
Results
PCOS patients had significantly higher BMI ($P < 0.001$) and BMI-SDS ($P < 0.001$) than controls. Moreover, 57% of PCOS patients were obese, compared to only 11% in the control group. Compared to controls, PCOS patients had significantly higher ESS scores ($P = 0.04$) and an increased risk of OSA ($P = 0.031$), while overall sleep quality, as measured by PSQI scores, did not differ significantly. Among PCOS patients, obese individuals had significantly higher levels of testosterone ($P = 0.017$), androstenedione ($P = 0.004$), insulin ($P < 0.001$), HOMA-IR ($P < 0.001$), and LDL cholesterol ($P = 0.018$) compared to non-obese PCOS patients. Poor sleep quality (PSQI >5) was strongly associated with an increased risk of OSA ($P < 0.001$). Correlation analysis revealed a weak but positive association between HOMA-IR and Berlin Questionnaire scores ($r = 0.272$, $P = 0.02$), suggesting a potential link between HOMA-IR and OSA risk. Similarly, the triglyceride/glucose ratio showed a weak positive correlation with Berlin scores ($r = 0.292$, $P = 0.015$).
Conclusions
This study highlights that sleep disturbances in PCOS are not solely driven by obesity but are also influenced by metabolic status. Poor sleep quality is associated with increased OSA risk. Given the potential long-term cardiometabolic consequences, integrating sleep health into PCOS management may be crucial, especially in obese individuals. Further research with objective sleep assessments, like polysomnography, is crucial to gaining deeper insights into the complex relationship between PCOS, sleep disturbances, and metabolic dysfunction.

Background
Estrogen-containing contraceptives (EC) and metformin are leading pharmacotherapies for polycystic ovary syndrome (PCOS), yet the impact of these medications on weight and body mass index (BMI) gains over time in adolescents are unclear. We sought to understand the effect of these treatments on the velocity of changes in weight and BMI over time in teens with PCOS, and if there was a differential effect based on preceding BMI category.
Methods
Participant ($n = 899$) information was extracted from the CALICO Database, a longitudinal chart review with data on adolescents with PCOS diagnosed using the 2018 international guidelines at 17 US sites. For this analysis, the primary outcomes were change in weight and BMI over time. As such, we excluded patients taking weight loss medications, atypical antipsychotics, and daily hormone therapies other than EC. Linear mixed effects models evaluated the differences in weight/BMI change trajectories over time between Ever EC Users (pill, patch, or ring, $n = 458$) vs Never EC Users ($n = 441$) and Ever Metformin Users ($n = 503$) vs Never Metformin Users ($n = 396$). All models were adjusted for age, race, and insurance status. Models were conducted by weight subgroup (BMI 5-84%, BMI 85-94%, BMI $\geq$95%). EC models were adjusted for metformin use, and vice versa. Analyses were performed using R version 4.4.2.
Results
For those with a BMI $<$85%ile, no group had an increase in weight trajectory over time. While taking medications, there was a decrease in both weight and BMI trajectories in those taking EC [-0.146(-0.257,-0.036)kg/mo, $P = 0.010$; -0.0627(-0.1055,-0.0198), kg/m^2/mo, $P = 0.005$] or metformin [-0.211(-0.349,-0.074)kg/mo, $P = 0.003$; -0.2112(-0.3485,-0.0738)kg/m^2/mo, $P = 0.003$]. For the overweight participants, no group demonstrated increases in weight velocities over time. Those taking metformin had a decrease in both weight [-0.382(-0.575,-0.189)kg/mo,$P = 0.0002$] and BMI [-0.113(-0.181,-0.0441)kg/m^2/mo, $P = 0.002$] trajectories while taking the medications. For girls with obesity, BMI increased over time for EC [0.026(0.006,0.049)kg/m^2/mo, $P = 0.013$] and metformin [0.0255(0.0008,0.0441) kg/m^2/mo, $P = 0.042$] groups, but not the non-treatment groups [No EC 0.0256(-0.0086,0.0599) kg/m^2/mo, $P = 0.142$; No metformin 0.0272(-0.0073,0.0617) kg/m^2/mo, $P = 0.122$]. There was no change in the positive weight ($P = 0.503$) and BMI ($P = 0.6840$) trajectories while taking EC, whereas during metformin use, the weight [-0.1453(-0.2506,-0.0401) kg/mo, $P = 0.007$] and BMI [-0.0532(-0.0898,-0.0166)kg/m^2/mo, $P = 0.005$] gain trajectories were significantly less positive.
Conclusion
The impact of EC and metformin on weight and BMI over time differ by baseline BMI category in adolescents with PCOS. Counseling of the weight effects of these medications should be guided by the patients' pretreatment BMI category.

Effects of testosterone treatment on the morphology of female internal genitalia assessed by transabdominal ultrasound (TAUS) in trans boys

Pernille Norup[1,2], Karin Sundberg[3], Lisa Jensen[3], Mette Haahr[4,5], Anna-maria Giraldi[4,5], Anne Katrine Pagsberg[5,6], Anders Juul[1,2,5], Malene Hilden[7] & Katharina M. Main[1,2,5]
[1]Department of Growth and Reproduction, Copenhagen University Hospital- Rigshospitalet, Copenhagen, Denmark; [2]International Centre for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Rigshospitalet and University of Copenhagen, Copenhagen, Denmark; [3]Center of Fetal Medicine, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark; [4]Sexological Clinic, Mental Health Centre, Copenhagen, Copenhagen University Hospital – Mental Health Services CPH, Copenhagen, Denmark; [5]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [6]Child and Adolescent Mental Health Center, Copenhagen University Hospital – Mental Health Services CPH, Copenhagen, Denmark; [7]Center of Gender Identity, Department of Gynecology, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark

Background
International guidelines for the healthcare of transgender youth include the possibility of hormone therapy. Recent concerns have been raised about testosterone treatment in trans men and its effects on their fertility potential as well as the risk of endometrial hyperplasia and cancer. To our knowledge, current studies are conducted in adult transmasculine individuals.
Aim
To investigate the effects of testosterone on the internal female genitalia assessed by transabdominal ultrasound (TAUS) in an unselected population of trans boys who initiated hormone therapy before the age of 18 years.
Methods
Trans boys were referred to a TAUS scan after approximately one year of testosterone treatment ($n = 48$). 2D ovarian and uterine TAUS were conducted by experienced gynecologists using the Voluson E10 Ultrasound System (GE Healthcare Medical Systems, Zipf, Austria) and a multifrequency transabdominal probe (C2-9). All TAUS findings are given as median (10th, 90th percentiles). Hormone serum concentrations are presented as median (IQR).

Results
At the start of testosterone treatment the median age was 16.9 years. Some of the trans boys had prior GnRH analog monotherapy ($n = 31$), and Tanner stage ranged from 3 to 5 before any treatment. Self-reported age at menarche was 12 years (range 9 – 15). The median age at TAUS was 18.0 after a median duration of testosterone treatment corresponding to 15.0 months. Serum concentrations were 0.8 IU/l (0.2 – 3.1) for LH, 3.2 IU/l (1.2 – 6.2) for FSH, 18.3 nmol/l (12.2 – 26.9) for testosterone, and 104.8 pmol/l (76.4 – 134.8) for estradiol. The mean ovarian volume, in trans boys with both ovaries visualized, was 8.9 cm^3 (3.4, 13.8). The median number of small follicles was 3 (1, 5), and the largest follicle measured 6.0 mm (3.3, 11.5). Uterine volume was 77.0 cm^3 (37.9, 104.9), uterine length was 6.7 cm (5.0, 7.8), and endometrial thickness was 4.0 mm (2.2, 6.0).
Conclusion
Our results indicate that testosterone monotherapy may not fully suppress the pituitary-ovarian axis in trans boys, and the aromatization of testosterone to estradiol may be sufficient to stimulate the endometrium. This could result in cyclic pain and breakthrough bleeding. Additionally, this may have implications for contraception in sexually active adolescents.

Long-term cardiovascular risk in women with subfertility: systematic review and meta-analysis

Elena Armeni[1], Nikoletta Mili[1], Christina Polymeropoulou[1], Elina Siliogka[1], Areti Augoulea[1] & Irene Lambrinoudaki[1]
[1]National and Kapodistrian University of Athens, Second Department of Obstetrics and Gynaecology, Aretaieio Hospital, Athens, Greece

Objective
Infertility and cardiovascular disease (CVD) are major global health concerns. While some studies suggest infertility may be an early marker of cardiovascular risk, others report no clear association. This meta-analysis (MA) aims to evaluate the relationship between female infertility and the risk of developing CVD later in life, with a focus on the possible impact of assisted reproductive technology (ART) exposure.
Design and Methods
We followed PRISMA guidelines to conduct a MA of 21 studies examining the link between female infertility and CVD outcomes. A total of 178,828 women with a history of infertility and 3,398,781 controls were included. Data on CVD incidence, coronary heart disease (CHD), and cerebrovascular events were extracted. Sensitivity analyses were performed to assess the impact of study design, participants' age at recruitment and ART exposure on the observed associations.
Results
Women with a history of infertility had a 14% higher risk of developing CVD compared to controls (HR = 1.14; 95% CI: 1.12–1.16; $I^2 = 89\%$). Infertility was also associated with a 17% increased risk of CHD (HR = 1.17; 95% CI: 1.12–1.23; $I^2 = 0\%$) and a 16% higher risk of cerebrovascular events (HR = 1.16; 95% CI: 1.11–1.21; $I^2 = 73\%$). Sensitivity analyses of prospective-only studies confirmed these associations, with a 4% increased risk of CVD (HR = 1.04; 95% CI: 1.01–1.08; $I^2 = 0\%$), a 15% increased risk of CHD (HR = 1.15; 95% CI: 1.07–1.24; $I^2 = 54\%$), and an 11% higher risk of cerebrovascular events (HR = 1.11; 95% CI: 1.05–1.17; $I^2 = 54\%$). Among 392,266 ART-exposed women and 33,630,919 controls, we observed a higher risk of CVD (HR = 1.18; 95% CI: 1.11-1.25; $I^2 = 97\%$), although a woman's prior exposure to ART did not significantly increase the risk of prevalent or incident CHD, cerebrovascular events, or heart failure. Studies evaluating infertile women aged < 40 years, when compared to controls, found a higher risk of CVD (HR = 1.20; $I^2 = 81\%$). On the contrary, studies evaluating infertile women over 40 years showed a comparable incident risk for CVD to controls (HR = 1.04; $I^2 = 29\%$).
Discussion
This study shows an increased risk of CVD, including CHD and cerebrovascular events, among women with a history of infertility. ART exposure was associated with higher CVD risk. However, the true magnitude of the effect of ART remains uncertain due to significant heterogeneity across studies, likely secondary to differences in study methodologies and ART protocols.

Genetic landscape and clinical spectrum of 46,XY differences of sex development: a retrospective study in a major saudi referral center

Afaf Alsagheir[1], Abeer Alabduljabbar[2], Zainab Mohamed[1], Zahra Alrubeh[1], Sara Abid[3], Dania Farooq[3], Sara Aljazaeri[3], Yara Khamag[3] & Raghad Alhuthil[2]
[1]Section of Pediatric Endocrinology, Department of Pediatrics, King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia; [2]Department of Pediatrics, King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia; [3]College of Medicine, Alfaisal University, Riyadh, Saudi Arabia

Introduction
46,XY Disorders of Sex Development (DSD) encompass a spectrum of conditions characterized by atypical gonadal, hormonal, or phenotypic development in individuals with a 46,XY karyotype. The underlying etiologies of 46,XY DSD vary widely and may include genetic mutations affecting gonadal differentiation, steroid biosynthesis defects, or androgen insensitivity syndromes. Understanding the prevalence and diagnostic yield in specific populations is crucial for optimizing clinical management and genetic counseling. This study aims to evaluate the diagnostic outcomes and underlying causes of 46,XY DSD among patients in Saudi Arabia, providing insights into the regional distribution of these conditions.
Methodology
A retrospective review was conducted at King Faces Specialist Hospital Research Centre (KFSHRC), analyzing medical records of patients diagnosed with 46,XY Disorders of Sex Development (DSD) who were seen in the endocrine clinic between 2019 and 2024.Clinical, biochemical, and genetic data were systematically reviewed. The diagnostic yield was assessed based on the ability to establish a definitive diagnosis through genetic investigations. STATA version 18 was used for statistical analysis. Ethical approval was obtained from the ethics committee at KFSHRC (reference: 2231110).
Results
A total of 278 DSD patients were included. At birth, 24.4% were assigned female, while 75.6% were assigned male. Currently, 80.9% identify as male, and 19.1% identify as female. Genetic testing was conducted in 201 patients (72.30%), of which 168 (83.58%) yielded positive results with 42 distinct mutations. The most frequently identified genetic abnormality was SRD5A2 deficiency, found in 43 out of 168 cases (25.50%), Complete Androgen Insensitivity Syndrome (CAIS) in 21 (12.50%), Adrenogenital disorders 17 (10.11%), 17β-HSD deficiency in 15 (8.92%), Gonadal dysgenesis in 12 (7.14%), LHCGR in 7 (4.16%), CHARGE syndrome in 4 (2.38%) and 49 (29.16%) others.
Conclusion
This study highlights the high diagnostic yield (83.58%) of genetic testing in 46,XY DSD in the Saudi population, emphasizing its critical role in establishing definitive diagnoses. SRD5A2 deficiency (25.5%), Complete Androgen Insensitivity Syndrome (12.5%), and adrenogenital disorders (10.1%) were the most frequently identified genetic abnormalities among 42 distinct mutations. The findings underscore the genetic heterogeneity of 46,XY DSD and the importance of early genetic evaluation in guiding clinical management. Additionally, the observed discrepancies between assigned sex at birth and current gender identity reinforce the need for a multidisciplinary approach integrating genetic, endocrine, and psychosocial support to optimize patient outcomes.

Mini-puberty induction in male infants with congenital hypogonadotropic hypogonadism: a case series

Clinton Roddick[1,2], Sarah McMahon[1], Diane Jensen[3], Erin Sharwood[1,2] & Kriti Joshi[1,2]
[1]Queensland Children's Hospital, Endocrinology, Brisbane, Australia; [2]Child Health Research Center, University of Queensland, Brisbane, Australia; [3]Gold Coast University Hospital, Paediatrics, Robina, Australia

The aim of this study was to assess safety and efficacy of minipuberty induction with gonadotropin therapy for congenital hypogonadotropic hypogonadism (CHH). We recruited five male infants with clinical ± biochemical CHH. Treatment goal was penile and testicular growth, testicular descent, and normalisation of testosterone and inhibin B levels. Four cases had multiple pituitary hormone deficiency (MPHD); two each with pituitary stalk interruption syndrome and septo-optic dysplasia on MRI. The fifth case had Trisomy 21 with clinical hypogonadism. All five demonstrated micropenis with cryptorchidism noted in four. Clinical and biochemical picture was consistent with hypogonadotropic hypogonadism in all. Minipuberty induction was performed using subcutaneous injections of choriogonadotropin alfa (10-20μg twice-weekly) and recombinant FSH (25-50 IU thrice-weekly). Serial biochemical and clinical monitoring was performed. Age at induction was 11 ± 4.6 weeks for the MPHD patients and 26 weeks for case 5. Treatment duration was 16 ± 6.3 weeks All patients demonstrated good clinical response (**Table 1**). SPL increased from 1.0 ± 0.3 cm to 3.0 ± 0.4 cm ($P < 0.001$), TV (ultrasound) increased from

Table 1: End of treatment assessments

	Case 1	Case 2	Case 3	Case 4	Case 5
Treatment duration (weeks)	24	22	8	18	8
Testosterone LCMS (6-20nmol/l)	18.0	22	22	25	33
Inhibin B (300-500ng/l)	209	95	387	468	228
SPL (cm)	2.8	3.5	2.8	2.6	3.2

The global landscape of managing hypogonadotropic hypogonadism in male infants: results of an international survey

Elisabeth Laurer[1], Julia Rohayem[2], Wolfgang Högler[1], Sabine Heger[3], Sebastian Castro[4], Rodolfo A Rey[4], Anna Nordenström[5] & Sasha R Howard[6]

[1]Johannes Kepler University Linz, Department of Paediatrics and Adolescent Medicine, Linz, Austria; [2]Ostschweizer Kinderspital St. Gallen, St. Gallen, Switzerland; [3]Kinderkrankenhaus Auf der Bult, Hannover, Germany; [4]Centro de Investigaciones Endocrinológicas "Dr. César Bergadá" (CEDIE), CONICET – FEI – División de Endocrinología, Hospital de Niños Ricardo Gutiérrez, Buenos Aires, Argentina; [5]Karolinska University Hospital, Stockholm, Sweden; [6]William Harvey Research Institute, Queen Mary University of London, London, United Kingdom

Introduction

Congenital hypogonadotropic hypogonadism (CHH) impairs gonadotropic axis activation during mini-puberty, puberty, and adulthood. Severely affected males may present as neonates with micropenis and/or undescended testes, while milder cases exhibit delayed or absent puberty and infertility. Mimicking gonadotropin action using central hormone agents is standard for puberty and fertility treatments. However, no consensus exists on replacement therapy for mini-puberty, with strategies ranging from testosterone application to central agents like GnRH or gonadotropins via subcutaneous injections or pumps. Central agents are thought to not only improve penile size and testicular descent, but potentially also fertility outcomes, though supporting long-term data are lacking. Variability in regimens and drug access further complicates decision-making.

Aim

This survey aimed to identify global barriers in diagnosing and managing CHH during mini-puberty, providing insights for future guidelines.

Methods

An online survey using the Jotform platform was distributed via pediatric society networks, conferences, and email snowballing between June 2024 and January 2025.

Results

A total of 153 responses from 32 countries were analyzed, with Europe (85), South America (32), and North America (24) contributing most. Most respondents were paediatric endocrinologists (94%), also acting as primary patient managers (96.7%). Referrals occurred during mini-puberty for most cases (49.7% within the first 24 weeks), though 39.9% were referred later. Diagnostic testing during weeks 4–24 was considered optimal by 78%. Next-generation sequencing was performed by 60.1%, while 27.5% lacked access, predominantly in low- and middle-income countries. Hormone treatment was offered by 79.7%, with testosterone-only regimens used by 70.5%, central agents by 9%, and both by 20.5%. Limiting factors creating barriers toward hormone prescriptions included insufficient data (64.5%) and paucity of knowledge (25.8%). Two-thirds treated 0-2 patients with either testosterone or central hormone agents in the last 12 months ($n = 339$ receiving testosterone, $n = 111$ receiving central agents). Among testosterone prescribers, intramuscular administration (64.9%) over 3 months (68%) was most common, while the most common central hormone regimen was a hCG + recombinant human FSH combination (35.1%), followed by a hCG-only regimen (24,3%) given via subcutaneous injections (69.4%) for 3 or 6 months (47,2% and 33,3%, respectively). Central agents had lower treatment adherence and were more likely discontinued (16.6%) compared to testosterone (8%).

Conclusion

Despite evidence supporting central hormone agents for fertility outcomes, testosterone remains the more commonly used treatment globally. The findings underscore the need for consensus guidelines and long-term studies, particularly on fertility outcomes.

A novel role of pregnancy-specific glycoprotein 1 in the maintenance of human chorionic gonadotropin secretion in human placental trophoblasts

Gang Sun[1]

[1]Ren Ji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

In pregnancy, the placental trophoblasts secrete a large amount of pregnancy-specific glycoprotein 1 (PSG1) into the maternal circulation. However, the exact role of PSG1 in pregnancy remains elusive. Human chorionic gonadotropin (hCG) is a hormone produced primarily by syncytiotrophoblastic cells of the placenta during pregnancy. The hormone stimulates the corpus luteum to produce progesterone to maintain the pregnancy. By using primary human placental trophoblasts, we demonstrated that like the expression of hCG, the expression of PSG1 was also significantly increased during syncytialization of placental trophoblasts. Knock-down of PSG1 expression did not affect hCG beta subunit mRNA levels, but increased intracellular hCG accumulation in trophoblasts while decreased extracellular hCG abundance, suggesting that PSG1 maintains hCG secretion in human placental trophoblasts. Induction of endoplasmic reticulum (ER) stress with thapsigargin (Tg) reduced PSG1 secretion along with increased intracellular hCG in trophoblasts and decreased extracellular hCG. In conclusion, we have demonstrated a novel of PSG1 in the maintenance of hCG secretion in human placental trophoblasts which may be impaired by ER stress. This novel function of PSG1 indicates that PSG1 participates in pregnancy maintainence by stimulating hCG secretion.

Follicular fluid from women with polycystic ovary syndrome and obesity impairs granulosa cell glycolytic function

Mafalda V. Moreira[1,2,3], Emídio Vale-Fernandes[1,2,4], Raquel L. Bernardino[1,2], Mariana P Monteiro[1,2] & Duarte Pignatelli[3,5,6]

[1]Unit for Multidisciplinary Research in Biomedicine (UMIB), School of Medicine and Biomedical Sciences (ICBAS), University of Porto, Porto, Portugal; [2]Laboratory for Integrative and Translational Research in Population Health (ITR), University of Porto, Porto, Portugal; [3]i3S - Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Porto, Portugal; [4]Centre for Medically Assisted Procreation / Public Gamete Bank, Gynaecology Department, Centro Materno-Infantil do Norte Dr. Albino Aroso (CMIN), Centro Hospitalar Universitário de Santo António (CHUdSA), Porto, Portugal; [5]Department of Endocrinology, Unidade Local de Saúde de São João (ULS São João), Porto, Portugal; [6]Department of Biomedicine, Faculty of Medicine of the University of Porto, Porto, Portugal

Polycystic ovary syndrome (PCOS) is an endocrine disorder characterized by exacerbated ovarian androgen production. When PCOS is accompanied by obesity and insulin resistance, reproductive dysfunction is usually even more pronounced. Granulosa cells (GCs) play a pivotal role in oocyte maturation, as key regulators of ovarian steroidogenesis and physiology. Consequently, GCs metabolic dysfunction can disrupt follicular development and potentially result in anovulation. However, the extent to which GC metabolic function is affected in the presence of PCOS remains

largely unknown. This study aim was to explore whether the follicular fluid (FF) microenvironment is able to influence GC glycolytic function. The study enrolled 24 women undergoing controlled ovarian stimulation for infertility treatment: 12 with PCOS and 12 controls. Each group was further subdivided according to BMI, normal weight ($n = 6$; BMI < 25 kg/m^2) and obesity ($n = 6$; BMI ≥ 30 kg/m^2). Human granulosa cells (HGrC1) were incubated for 24 hours in culture medium supplemented with 20% of FF collected during oocyte retrieval from women with PCOS or controls. Glycolytic function was assessed by measuring the extracellular acidification rate (ECAR). HGrC1 cells when exposed to FF from women with PCOS and obesity depicted a significantly lower glycolytic capacity when compared to those incubated with FF from normal-weight controls. Furthermore, non-glycolytic acidification of HGrC1 cells incubated with FF from women with PCOS irrespective of BMI was significantly lower than of those incubated with FF from normal-weight controls. These findings indicate that the FF from women with PCOS and obesity harbours the potential to impair granulosa cell glycolytic function, while suggesting that GC metabolic disruptions could underlie ovarian dysfunction in women with PCOS, particularly when associated with obesity.

The triglyceride-glucose (TyG) index and its relation to metabolic indices in women with PCOS: a phenotype-based analysis

Lena Radic[1], Sanja Ognjanovic[1,2], Bojana Popovic[1,2], Dusan Ilic[1], Valentina Elezovic Kovacevic[1,2], Milica Opalic Palibrk[1], Katarina Krstic[1], Jelica Bjekic Macut[2,3], Tamara Baltic[3], Danijela Vojnovic Milutinovic[4], Olivera Stanojlovic[5] & Djuro Macut[1,2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center of Serbia, Department for Endocrine Tumors and Hereditary Cancer Syndromes, Belgrade, Serbia; [2]Faculty of Medicine University of Belgrade, Belgrade, Serbia; [3]CHC Bezanijska kosa, Department of Endocrinology, Belgrade, Serbia; [4]Institute for biological research "Sinisa Stankovic", Belgrade, Serbia; [5]Institute of Medical Physiology, Faculty of Medicine University of Belgrade, Belgrade, Serbia

Introduction
Polycystic ovary syndrome (PCOS) is an endocrine disorder linked to insulin resistance (IR), dyslipidemia, and hyperandrogenism. The triglyceride-glucose (TyG) index is a proposed surrogate marker for IR, but its relevance across PCOS phenotypes remains unclear. This study aimed to assess the metabolic significance of TyG in women with PCOS from a Serbian population.
Subjects and Methods
A total of 160 women with PCOS, diagnosed using the ESHRE/ASRM criteria, were divided into four phenotypic groups with 40 patients each: A (oligo/anovulation-OA + clinical/biochemical hyperandrogenism-HA + polycystic ovarian morphology-PCOM), B (OA+HA), C (HA+PCOM), D (OA+PCOM). Fasting glucose, insulin, lipid profile, total testosterone and SHBG were analyzed, while HOMA-IR, FAI and the TyG index were calculated. Patients were stratified by the TyG median calculated from our cohort (7.9).
Results
Our patients had a mean age of 25.98±6.03 years, BMI 24.05±5.64 kg/m^2, and waist circumference (WC) 79.73±13.94 cm. Initial analysis showed significant differences in BMI, WC, fasting glucose, HOMA-IR, and androgens across phenotypes, while insulin, lipid indices, and the TyG index did not differ significantly. Stratification by the TyG median (7.9) revealed significant differences in all metabolic parameters except androgens, with insulin showing borderline significance ($P = 0.056$). Pairwise comparisons showed that the TyG was lower in phenotype D (7.92±0.37 mmol/l) than in A (8.16±0.51, $P = 0.027$) and B (8.19±0.62, $P = 0.030$), though these differences did not remain statistically significant after adjustment. In phenotypes A and B, TyG correlated positively with most metabolic parameters and negatively with HDL. Stratification based on the TyG median confirmed that individuals with higher TyG had significantly higher BMI, WC, impaired glucose homeostasis, and dyslipidemia. In phenotype D, TyG correlated only with triglycerides and HDL, with higher triglycerides in the high TyG group, whereas HDL levels were lower but did not reach statistical significance ($P = 0.051$). ROC curve analysis for TyG in relation to HOMA-IR cut-offs (2.5, 2.0, 1.5) showed AUC values of 0.617 (95% CI: 0.530-0.703), 0.641 (95% CI: 0.553-0.729), and 0.658 (95% CI: 0.552-0.764).
Conclusion
Our analysis confirmed that the TyG index correlates with anthropometric and metabolic parameters, showing phenotype-dependent differences. Larger cohort analyses are needed for the assessment of insulin sensitivity in PCOS phenotypes using this simple non-insulin index.

Morphometric and transcriptomic changes during early testicular development in pigs

Petra Ferjan[1], Nina Batorek Lukač[1], Mette Rosenkilde[2] & Milka Vrecl[1]
[1]University of Ljubljana, Veterinary faculty, Institute of Preclinical Sciences, Ljubljana, Slovenia; [2]University of Copenhagen, Faculty of Health and Medical Sciences, Laboratory for Molecular Pharmacology, Department of Biomedical Sciences, Copenhagen, Denmark

Both pigs and humans exhibit a triphasic pattern of Leydig cell development [1,2]. The second phase, termed "mini-puberty" in humans, is associated with penile growth, changes in body composition and cognitive development during the first six months of life [1]. In pigs, this phase begins around 2.5 weeks prenatally, peaks at 2.5 weeks after birth and ends seven weeks postnatally [2]. In contrast to humans, pigs have a functional gonadotropin-releasing hormone type II (GnRH-II)/GnRH-II receptor (GnRHR-II) system in the testes, the activation of which leads to luteinizing hormone (LH) independent testosterone secretion by Leydig cells [3]. This study aims to characterize the morphometric and transcriptomic changes in the porcine testes from 1 to 12 weeks of age to contribute to a better understanding of early testicular development and provide potential translational relevance. Testis samples were collected from pigs at 1, 3, 6 and 12 weeks of age ($n = 6$-10/group). The samples were fixed in Bouin's solution and prepared for histomorphometric analysis. In addition, a portion of each sample was snap-frozen in liquid nitrogen for subsequent qPCR analysis. Histomorphometric analysis revealed a marked decrease in Leydig cell surface area and a progressive increase in nucleoplasmic index in 6- and 12-week-old animals compared with animals aged 1 and 3 weeks. Distinct age-dependent expression patterns were established for androgen receptor (AR), estrogen receptor 2 (ESR2), follicle-stimulating hormone receptor (FSHR), GnRH-II, GnRHR-II, inhibin subunit alpha (INHA), steroidogenic acute regulatory protein (STAR) and betaine-homocysteine S-methyltransferase (BHMT). Expression levels of transcripts for steroidogenic pathway proteins, i.e., HSD3B1, increased with age, whereas the expression of STAR progressively decreased. Upregulation of FSHR, ESR2, GnRH-II and INHA was observed from week 6 and of GnRHR-II, AR and BHMT from week 12. Expression of the LH/choriogonadotropin receptor was comparable across groups. Observed morphometric changes are consistent with the three-phase developmental pattern of Leydig cells and are associated with a reduced requirement for steroidogenesis at the end of mini-puberty, as shown by the reduced expression of STAR. The expression data also suggests that the GnRH-II/GnRHR-II system is not activated in the porcine testis during mini-puberty. Taken together, these preliminary results emphasize the interplay between structural adaptations and transcriptome changes that control testicular maturation in pigs.

"Variable phenotypic expression of NR5A1 mutation in a family: sex development abnormalities and management challenges"

Muhammad Ahmad[1], Manju Chandwani[1], Sumana Chatterjee[1], Toby Candler[1], Dinesh Giri[1], Mark Woodward[1,2], Julie Alderson[1], Emma Kivuva[1], Tessa Homfray[1], Klaus Mohnike[3] & Elizabeth Crowne[1]

Steroidogenic Factor 1 (*SF-1*/*NR5A1*) is essential for gonadal and adrenal development. Mutations in *NR5A1* are associated with differences in sex development (DSD), presenting a broad phenotypic spectrum from asymptomatic carriers to severe DSD. Despite extensive research, the factors influencing these varied clinical manifestations remain unclear. Oligogenic inheritance may contribute, with multiple genetic variants influencing the phenotype. This case highlights a family with a missense *NR5A1* mutation and marked phenotypic variability. Twin 2, from a dichorionic diamniotic pregnancy, presented with ambiguous genitalia, while Twin 1 had normal male genitalia. At birth, Twin 2 had Cilitorophallic enlargement (1 cm), a perineal urethral opening, posterior labioscrotal fusion, and bilateral labioscrotal gonads. The mother had an older phenotypically normal male child and a history of unilateral ovarian germ cell tumour. The maternal aunt, born with genital ambiguity, underwent feminizing genitoplasty and was diagnosed with 46XX ovo-testicular DSD

Twin 2 's Investigation Results.

QF-PCR	No evidence of SRY
Karyotype	46XX
(Day 30)	
LH	5.1 IU/l
FSH	9.3 IU/l
Testosterone	2.3 nmol/l
AMH	184.1 pmol/l (Reference female range < 25)
Synacthen test	Cortisol 871 nmol/l, ruling out adrenal insufficiency
DSD gene panel	Heterozygous *NR5A1* missense variant (NM_004959.5: c.274C>T, p.R92W) was identified in Twin 2, matching the maternal aunt's and later confirmed in the mother.
Examination Under Anaesthesia	Common channel leading to a normal urethra, bladder, and appropriately sized vagina, but no uterus. The gonads appeared abnormal, with a fallopian tube-like structure on the left and an epididymis on the right. Both were relocated to the pelvis, and bilateral inguinal hernia repair was performed.
Histology	Ovarian tissue with numerous primordial follicles

due to a heterozygous *NR5A1* variant. She underwent gonadectomy at age nine, with histology revealing intratubular neoplasia. A multidisciplinary team, in agreement with the parents, decided to raise the child as female. Gonapeptyl injections were given until nine months of age to prevent further virilisation. Genetic testing is ongoing for the patient's two male siblings and maternal grandparents. Future management will involve balancing the risks of malignancy and fertility preservation. The mother had both fertility and malignancy, while the maternal aunt showed malignancy at nine years. If the gonads are retained, a screening protocol will be necessary, along with monitoring for virilisation at puberty. Periodic adrenal function assessment will be required due to the risk of late-onset adrenal insufficiency. Additionally, splenic function will need to be monitored, with appropriate vaccinations, given *NR5A1*'s role in splenic development.

Evidence for bone marrow adipose tissue dysfunction in polycystic ovary syndrome (PCOS)

Riada McCredie[1], Giovanni Levate[1], Yuan Wang[1], Mick Rae[2], Colin Duncan[1] & Katarzyna Siemienowicz[2]
[1]The University of Edinburgh, Centre for Reproductive Health, Edinburgh, United Kingdom; [2]Edinburgh Napier University, Edinburgh, United Kingdom

There are three main functional fat depots in the body: subcutaneous adipose tissue (SAT), visceral adipose tissue (VAT) and bone marrow adipose tissue (BMAT). In women with PCOS the SAT is dysfunctional with larger adipocytes and increased inflammation. This is recapitulated in the clinically realistic ovine model of PCOS using prenatal androgenisation. As BMAT is difficult to access and has not been studied in PCOS we aimed to use PCOS-like sheep to investigate the structure and function of BMAT. Pregnant Scottish Greyface sheep were treated with testosterone propionate (100 mg) or vehicle control twice weekly from day 62 to day 102 of a 147-day pregnancy. The female offspring exposed to increased prenatal androgens in utero develop the features of PCOS. BMAT was collected from adult offspring at 30 months of age (PCOS-like sheep $n = 4$; Control $n = 6$) and fixed for histological analysis and frozen for assessment of gene expression. The number of adipocytes per 3 mm^3 ($P = 0.78$) and size of the adipocytes ($P = 0.31$) in BMAT was no different in PCOS-like sheep when compared to contemporaneous controls. PCOS-like sheep had increased expression of the inflammatory markers *TNF* ($P = 0.0128$), *IL6* ($P = 0.0013$) and the macrophage marker *CD68* ($P = 0.0206$) in BMAT. We therefore performed an additional unbiased analysis of BMAT gene expression in PCOS-like sheep using RNAseq. There was differential expression of 604 genes when compared to controls (232 down and 373 up) in PCOS-like sheep BMAT. Ingenuity Pathway Analysis highlighted up-regulation of inflammatory pathways with significant increases in activation, recruitment and degranulation of leukocytes, synthesis and metabolism of reactive oxygen species, recruitment and migration of phagocytes and the immunogenic cell death signalling pathway. Interestingly the top two canonical pathways altered were related to bone health linked to osteoclast and chondrocyte function suggesting increased bone resorption and remodelling. These results suggest that in PCOS immune cells may be developing in a more inflammatory environment and they already show functional alterations. Additionally, there may be a local effect on bone health. This suggests a possible mechanistic link to the systemic adverse inflammatory environment in PCOS.
